The countries above Egypt are inhabited by two tribes of people resembling each other in physical characters, but of distinct language and origin. One is, perhaps, the aboriginal or native, the other a foreign tribe. Dr Prichard terms them Eastern Nubians, or Nubians of the Red Sea, and Nubians of the Nile, or Berberines. All these tribes are people of a red-brown complexion, their colour in some instances approaching to black, but still different from the ebony hue of the Eastern negroes. Their hair is often frizzled and thick, and is described as even woolly; yet it is not precisely similar to the hair of the negroes of Guinea. The Eastern Nubians are tribes of roving people who inhabit the country between the Nile and the Red Sea; the northern division of this race are the Ababdeh, who reach northward in the eastern desert as far as Kosseir, and, towards the parallel of Deir, border on the Bishari. The Bishari reach thence towards the confines of Abyssinia. The latter are extremely savage and inhospitable; they are said to drink the warm blood of living animals; they are for the most part nomadic, and live on flesh and milk. They are described as a handsome people, with beautiful features, fine expressive eyes, of slender and elegant forms; their complexion is said to be a dark brown, or a dark chocolate colour. The Barábra or Berberines are a people well known in Egypt, whither they resort as labourers from the higher country of the Nile. They inhabit the valley of that name from the southern limit of Egypt to Sennaar. They are a people distinct from the Arabs and all the surrounding nations. They live on the banks of the Nile; and wherever there is any soil, they plant date-trees, set up wheels for irrigation, and sow durra and some leguminous plants. At Cairo, whither many of this race resort, they are esteemed for their honesty. They profess Islam. The Barábra are divided into three sections by their dialects, which are those of the Nuba, the Kenous, and the Dongolawi. According to Dr Prichard, it is probable that the Berberines may be an offset from the original stock which first peopled Egypt and Nubia.

The country of the Nubians is limited on the west by that of the Tibbus, who are spread over the eastern portions of the Sahara, as far as Fezzan and Lake Chad. Dr Latham considers it probable that their language belongs to the Nubian class. They inhabit the locality of the ancient Libyans or *Libyes*. Their colour is not uniform. In some it is quite black, but many have copper-coloured faces. They are slim and well made, have high cheekbones, the nose sometimes flat like that of the negro, and sometimes aquiline. Their mouth is in general large, but their teeth fine. Their lips are frequently formed like those of Europeans; their eyes are expressive, and their hair, though curled, not woolly. The females are especially distinguished by a light and elegant form, and in their walk and erect manner of carrying themselves are very striking. Their feet and ankles are delicately formed, and not loaded with a mass of brass or iron, as is the practice in other countries of Northern Africa, but have merely a light anklet of polished silver or copper, sufficient to show their jetty skin to more advantage; and they also wear neat red slippers. The Tibbus are chiefly a pastoral people. They keep horses, cattle, sheep, and goats, but camels constitute their principal riches. The villages of the Tibbus are very regularly built in a square, with a space left on the north and south faces of the quadrangle for the use of the cattle. The huts are entirely of mats, which exclude the sun, yet admit both the light and the air. The interior of these habitations is singularly neat: clean wooden bowls for the preservation of milk, each with a cover of basket-work, are hung against their walls. They are greatly exposed to predatory incursions into their country by the enemies who surround them. The Tibbus of Tibesti are described by Dr Nachtigal as of medium stature, well made, of elegant though muscular frame; in colour they vary between a clear bronze and black: the greater number are dark bronze-coloured, yet without the slightest trace of what is generally recognised as the negro physiognomy. They carry on a considerable traffic in slaves between Sudan, Fezzan, and Tripoli.

"All that is not Arabic in the kingdom of Marocco," says Dr Latham, "all that is not Arabic in the French provinces of Algeria, and all that is not Arabic in Tunis, Tripoli, and Fezzan, is Berber. The language, also, of the ancient Cyrenaica, indeed the whole country bordering the Mediterranean, between Tripoli and Egypt, is Berber. The extinct language of the Canary Isles was Berber; and, finally, the language of the Sahara is Berber. The Berber languages, in their present geographical localities, are essentially inland languages. As a general rule, the Arabic is the language for the whole of the sea-coast from the Delta of the Nile to the Straits of Gibraltar, and from the Straits of Gibraltar to the mouth of the Senegal." The Berber nation is one of great antiquity, and from the times of the earliest history has been spread over the same extent of country as at present; the ancient Numidian and Mauritanian names of Sallust, and other writers, have a meaning in the modern Berber. It has affinities with the Semitic languages. In the northern parts of Atlas these people are called Berbers; in the southern tracts they are the Shuluh or Shelhas. In the hilly country belonging to Tunis, the Kabyles; in Mount Auress, the Showiah; and in the Desert, the Tuarick,—all belong to the same group. The mountains of Atlas are said to be inhabited by more than twenty different tribes, carrying on perpetual warfare against each other. They are very poor, and make plundering excursions in quest of the means of supporting life. They are described as an athletic, strong-featured people, accustomed to hardships and fatigue. Their only covering is a woollen garment without sleeves, fastened round the waist by a belt.

The Shuluh, who are the mountaineers of the Northern Atlas, live in villages of houses made of stone and mud, with slate roofs, occasionally in tents, and even in caves. They are chiefly huntsmen, but cultivate the ground and rear bees. They are described as lively, intelligent, well-formed, athletic men, not tall, without marked features, and with light complexions. The Kabyles, or Kabaily, of the Algerian and Tunisian territories, are the most industrious inhabitants of the Barbary States, and, besides tillage, work the mines contained in their mountains, and obtain lead, iron, and copper. They live in huts made of the branches of trees and covered with clay, which resemble the *magulia* of the old Numidians, spread in little groups over the sides of the mountains, and preserve the grain, the legumes, and other fruits, which are the produce of their husbandry, in *mattoures*, or conical excavations in the ground. They are of middle stature; their complexion is brown, and sometimes nearly black.

The Tuarick are a people spread in various tribes through the greater portion of the Sahara. The expedition under Richardson, Barth, and Overweg, who traversed and explored a great portion of the Tuarick territories, has greatly added to our knowledge of these people. The following are the names and localities of the principal tribes:—

1. Tanelkum, located in Fezzan.

2. Azghers, { Ouraghen, family of Shafou, / Emanghasatan, ,, of Hateetah, / Amana, ,, of Jabour, } located at Ghat.

3. Aheethanaran, the tribe of Janet.

4. Hagar (Ahagar), pure Hagars and Maghatah. They occupy the tract between Ghat, Tuat, and Timbuktu.

5. Sagamaram, located on the route from Aisou to Tuat.

6. Kailouees, including the Kailouees proper, the Kaltadak, and the Kalfadaï.

7. Kilgris, including the Kilgris proper, the Iteesan, and the Ashraf. These and the tribes under the preceding head inhabit the kingdom of Ahir.

8. Oulimad, tribes surrounding Timbuktu in great numbers. This, probably identical with the Sorghou, is the largest and most powerful tribe, while the Tanelkums are the smallest and weakest.

The various tribes are very different in their characters, but they are all fine men, tall, straight, and handsome. They exact a tribute from all the caravans traversing their country, which chiefly furnishes them with the means of subsistence. They are most abstemious, their food consisting principally of coarse brown bread, dates, olives, and water. Even on the heated desert, where the thermometer generally is from 90° to 120°, they are clothed from head to foot, and cover the face up to the eyes with a black or coloured handkerchief.

The Moors who inhabit large portions of the empire of Marocco, and are spread all along the Mediterranean coast, are a mixed race, grafted upon the ancient Mauritanian stock; whence their name. After the conquest of Africa by the Arabs they became mixed with Arabs; and having conquered Spain in their turn, they intermarried with the natives of that country, whence, after a possession of seven centuries, they were driven back to Mauritania. They are a handsome race, having much more resemblance to Europeans and western Asiatics than to Arabs or Berbers, although their language is Arabic, that is, the Mogrebin dialect, which differs considerably from the Arabic in

Arabia, and even in Egypt. They are an intellectual people, and not altogether unlettered; but they are cruel, revengeful, and blood-thirsty, exhibiting but very few traces of that nobility of mind and delicacy of feeling and taste which graced their ancestors in Spain. The history of the throne of Marocco, of the dynastic revolutions at Algiers, Tunis, and Tripoli, is written with blood; and among the pirates who infested the Mediterranean they were the worst. Their religion is the Mohammedan. They are temperate in their diet and simple in their dress, except the richer classes in the principal towns, where the ladies literally cover themselves with silk, gold, and jewels, while the men indulge to excess their love of fine horses and splendid arms. They generally lead a settled life as merchants, mechanics, or agriculturists, but there are also many wandering tribes. They exhibit considerable skill and taste in dyeing, and in the manufacture of swords, saddlery, leatherware, gold and silver ornaments. At the Great Exhibition in London in 1851, the Moorish department contained several articles which were greatly admired. The Moors along the coast of Marocco still carry on piracy by means of armed boats.

At two different periods, separated from each other by perhaps a thousand years, Africa was invaded by Arabic tribes, which took a lasting possession of the districts they conquered, and whose descendants form no inconsiderable portion of the population of North and Central Africa, while their language has superseded all others as that of civilisation and religion. Of the first invasion more has been said under the head "Abyssinians." The second was that effected by the first successors of Mahomet, who conquered Egypt, and subsequently the whole north of Africa as far as the shores of the Atlantic, in the course of the first century of the Hegira, or the seventh of the Christian era. As regards language, Egypt is now an entirely Arabic country, although in many other respects the Fellahs are totally different from the peasants in Arabia. But there are also several tribes of true Arabic descent scattered about from the high lands of Abyssinia down over Nubia and Egypt, and westward over the central provinces of Kordofan, Darfur, Waday, and Bornu. Others wander in the Libyan deserts and the Great Sahara, as well as in the states of Tripoli, Tunis, and Algiers, leading a similar life with the Kabyles, but constituting a totally distinct race. Others, again, dwell in the empire of Marocco, among whom those along the shores of the Atlantic are notorious for their predatory habits and ferocious character. In many places Arabic adventurers have succeeded in subduing native tribes of every nationality, over which they rule as sovereign lords; and on the coast of Zanzibar resides an Arabic royal dynasty. Many of the smaller islands to the north of Madagascar are inhabited by Arabs, and traces of them have been discovered in Madagascar itself. The African Arabs are not all alike in features and colour of skin, the differences being attributable to some of them having intermarried with natives, while others preserved the purity of their blood.

The early settlements of the Jews in Egypt are facts universally known. Under the Ptolemies, large numbers of them settled at Alexandria and in Cyrenaica, and after the destruction of Jerusalem they rapidly spread over the whole of the Roman possessions in Africa; many also took refuge in Abyssinia. King Philip II. having driven them out of Spain, many thousands of families took refuge on the opposite coast of Africa. They are now numerous in all the larger towns in the north, where they carry on the occupation of merchants, brokers, &c., the trade with Europe being mostly in their hands. They live in a state of great degradation, except in Algiers, where the French restored them to freedom and independence. They have acquired much wealth, and although compelled to hide their riches from the cupidity of their rulers, they lose no opportunity of showing them whenever they can do so without risk of being plundered, fear and vanity being characteristic features of their character. The Jewesses in Marocco and Algiers are of remarkable beauty.

Turks

Ever since the conquest of Egypt by Sultan Selim, and the establishment of Turkish pashalics in Tripoli, Tunis, and Algiers, Turks have settled in the north of Africa; and as they were the rulers of the country, whose numbers were always on the increase on account of the incessant arrivals of Turkish soldiers and officials, the Turkish became, and still is, the language of the different governments. Properly speaking, however, they are not settled, but only encamped in Africa, and hardly deserve a place among the African nations.

Not all the inhabitants of the country called Abyssinia are Abyssinians; nor are the real Abyssinians all of the same origin, being a mixed race, to the formation of which several distinct nations have contributed. The primitive stock is of Ethiopian origin, but, as their language clearly shows, was at an early period mixed with a tribe of the Himyarites from the opposite coast of Arabia, who, in their turn, were ethnologically much more closely connected with the Hebrews than with the Joctanides, or the Arabs properly speaking. In the age of the Egyptian Ptolemies, and after the destruction of Jerusalem, Jews settled in Abyssinia in such numbers, that not only their religion spread among the inhabitants, but the Hebrew language became mixed with the Abyssinian as it then was. Hence the surprising analogy between the principal Abyssinian languages, viz., the Gheez in Tigré, and the Amharic in Amhara, with the Hebrew. The uninterrupted intercourse with Arabia, and the immigration of several Arabic tribes, also contributed towards the apparently Semitic aspect of the present Abyssinian language. A large portion of Abyssinia having been occupied by Galla and other tribes, we shall here only dwell on the original Abyssinians. They inhabit a large tract, extending from the upper course of the Blue River, north as far as the Red Sea, and some isolated districts in the south and south-east. To the west of them are the Agau Abyssinians, a different tribe, whose idiom, however, is the common language of the lower classes in Tigré and Amhara also. Abyssinia was once a large and powerful kingdom, but the Galla having conquered the whole south of it, it gradually declined until the king or emperor became a mere shadow, in whose name several vassal princes exercise an unlimited power each in his own territory. Owing to their jealousy and mutual fears, war seldom ceases among the inhabitants. The Christian religion was introduced into Abyssinia in the first centuries after Christ; but whatever its condition might have been in former times, it now presents a degraded mixture of Christian dogmas and rites, Jewish observances, and heathenish superstition. Yet of Judaism, which was once so powerful, but feeble traces are extant, while the Mohammedan religion is visibly on the increase. European missionaries have been, and still are very active among them, but their efforts have been crowned only with partial success. The Abyssinians, the Gallas being excluded from that denomination, are a fine strong race, of a copper hue, more or less dark, and altogether different from the Negroes, with whom, however, they have frequently been confounded, because they were called a black people. Their noses are nearly straight, their eyes beautifully clear, yet languishing, and their hair is black and crisp, but not woolly. They are on the whole a barbarous people, addicted to the grossest sensual pleasures; and their priests, among whom marriage is customary, are little better than the common herd of the people. They live in huts, a large assemblage of which forms a so-called town; and although they possess some solid constructions of stone, such as churches and bridges, it appears that these were built by the Portuguese, the ruins at Axum and other places belonging to a much earlier period, when the country undoubtedly enjoyed a higher civilisation than at present. Owing to the influence exercised upon them during the last thirty years by European missionaries and travellers, their conduct towards strangers is less rude than it used to be at the time of Bruce. It is a remarkable fact that, notwithstanding the low state of their religion, the Christians in Abyssinia are not allowed to keep slaves, although they may purchase them for the purpose of selling them again.

This extensive race comprehends by far the greater number of African nations, extending over the whole of Middle and South Africa, except its southernmost projection towards the Cape of Good Hope. A line drawn from the mouth of the Senegal in the west to Cape Jerdaffun in the east, forms its northern limits almost with geometrical accuracy, few Ethiopic tribes being found to the north of it. All the members of this race, however, are not Negroes. The latter are only one of its numerous offshoots; but between the receding forehead, the projecting cheek-bones, the thick lips of the Negro of Guinea, and the more straight configuration of the head of a Galla in Abyssinia, there are till many striking analogies; and modern philology havng traced still greater analogies, denoting a common origin, among the only apparently disconnected languages of so many thousands of tribes, whose colour presents all the hues between the deepest black and the yellow brown, it is no longer doubtful that the Negro, the Galla, the Somali, and the Kaffre, all belong to the same ethnological stock.

The principal Negro nations, as we know them, are the *Mandingoes*, who are numerous, powerful, and not uncivilised, in Senegambia, and farther inland, around the head waters of the Quorra, where they have established a great number of kingdoms and smaller sovereignties. The inland trade is chiefly in their hands. They are black, with a mixture of yellow, and their hair is completely woolly. The *Wolofs* or *Yolofs*, whose language is totally different from those of their neighbours, are the handsomest and blackest of all Negroes, although they live at a greater distance from the equator than most of the other black tribes, their principal dwelling-places being between the Senegal and the Gambia, along the coast of the Atlantic. They are a mild and social people. The *Foulahs* or *Fellatahs* occupy the central parts of Soudan, situated in the crescent formed by the course of the Quorra, and also large tracts to the south-east, as far as the equator west to the Senegal, and east till beyond Lake Chad. Their colour, as a rule, is black, intermixed, however, with a striking copper hue, some of them being hardly more dark than gipsies. They are one of the most remarkable nations in Africa, very industrious, live in commodious and clean habitations, and are mostly Mohammedans. A distinction was formerly made between the Foulahs of Senegambia and the Fellatahs of Central Africa, but it has since been ascertained that they belong to the same stock, and speak the same language. The hair of the Foulahs is much less woolly than that of other Negroes. Of the principal nations in Guinea, among whom the true Negro type is particularly distinct, especially around the Bight of Benin, are the Feloops, near the Casamança, very black, yet handsome; and the Ashanti, of the Amina race, who surpass all their neighbours in civilisation, and the cast of whose features differs so much from the Negro type that they are said to be more like Indians than Africans; although this is perhaps only true of the higher orders. They are still in possession of a powerful kingdom. The country behind the Slave Coast is occupied by tribes akin to the Dahomeh on the coast. In South Guinea we meet three principal races, namely, the Congo, the Abunda, and the Benguela Negroes, who are divided into a variety of smaller tribes, with whom we are much less acquainted than with the northern Negroes, although the Portuguese have occupied this coast for upwards of three centuries. The *Wamasai* and *Wakwavi*, possibly of Abyssinian stock, are a remarkable race of wild nomad hunters, who occupy the high plateau which rises between the coast-land and the Victoria Nyanza, extending from the equator southward to the route which leads from Zanzibar to the Tanganyika Lake. They are the terror of the more settled inhabitants of the surrounding countries, and occasionally make raids down even to the coast-land behind Mombas. The next great branch of the Ethiopic race comprehends the Galla, who occupy an immense tract in Eastern Africa, from Abyssinia as far as the fourth degree of S. latitude, on the coast inward from Mombas. Our knowledge of them is chiefly confined to those Gallas who conquered Abyssinia. With regard to their physical conformation, they stand between the Negro of Guinea and the Arab and Berber. Their countenances are rounder than those of the Arabs, their noses are almost straight, and their hair, though strongly frizzled, is not so woolly as that of the Negro, nor are their lips quite so thick. Their eyes are small (in which they again differ from the Abyssinians), deeply set, but very lively. They are a strong, large, almost bulky people, whose colour varies between black and brownish, some of their women being remarkably fair, considering the race they belong to. An interesting tribe of them has lately been brought to the knowledge of Europeans, the Somali, originally Arabs, who have advanced from the southern shores of the Gulf of Aden since the 15th century, and now occupy the greater portion of the East African promontory wedging into the Galla region, and almost dividing that country into two distinct portions. For the most part they pursue a wandering and pastoral life. Somali.

In the central regions of the continent the negroid tribes, which are classed under the general name of Wanyamwezi, occupying the plateau south of the Victoria and east of the Tanganyika Lakes, have been made known by Burton and subsequent travellers; round the west and north of the Victoria are several distinct kingdoms, the chief being those of Karague and Uganda, traversed by Speke and Grant; in the region west of the Upper Nile the countries of the Jur, Dor, and Bongo tribes have been explored by Dr Schweinfurth, and he has passed beyond the watershed of the Nile into a new basin, where he found the Niamniam and Monbuttu tribes. Dr Livingstone, in his latest journey, has entered the country of the Manyuema tribes, west of Tanganyika, in the heart of the continent; these he describes as a fine, tall handsome race, superior alike to the slaves seen at Zanzibar and the typical negro of the west coast; exceedingly numerous, and living in a primitive condition, utterly ignorant of the outer world. The Balunda race of Negroes occupy a great area of South Central Africa, and have two ancient and powerful kingdoms of Muropua and Lunda, the former ruled over by the hereditary "Muata" or chief Hianvo, who has his capital near the Cassabi tributary of the Congo, and the latter by the Hianvo's vassal, the Cazembe, whose palace is near the Luapula river, south-west of Lake Tanganyika. Kibakoe or Quiboque and Lobal, south-west of the kingdom of Hianvo, are the chief states on the borders of Angola and Benguela; towards the Nyassa lake, south-east from the Cazembe's dominions, the Maravi tribe is perhaps the most powerful, and beyond the Nyassa that of the Wahiao is the chief. The Makololo tribe, occupying the central portion of the Zambeze basin, is of southern origin, and forms an intermediate stage between the Negro and Kaffre. Negroid tribes.

The Kaffres, who, together with the tribes most akin to them, occupy the greater portion of South Africa, especially the eastern portions, have some analogy with Europeans in their features; but they are woolly haired, and while some are almost black, others are comparatively fair, although some of their tribes might have been mixed with the Eastern Negroes. They have been very wrongly classed with the Negroes. They are a strong, muscular, active people, addicted to plunder and warfare. The Eastern Kaffres, among whom the Amakosah and Amazulah are best known to us, on account of their frequent invasions of the Cape Colony, are much more savage than the western and northern, or the Bechuana and Sichuana tribes. All Kaffres are pastoral, keeping large herds of cattle; but the last-named tribes inhabit large towns, well-built houses, cultivate the ground carefully, and exhibit every appearance of being capable of entire civilisation. The word Kaffre, or Kafir, as it ought to be written, is Arabic, and was first applied by the Europeans to the inhabitants of the coast of Mozambique, because they were so called by the Mohammedans, in whose eyes they were *Kafirs*, that is infidels.

We conclude this sketch with the Hottentot race, which is entirely different from all the other races of Africa. Where they originally came from, and how they happened to be hemmed in and confined entirely to this remote corner of the earth, is a problem not likely to be ever satisfactorily solved. The only people to whom the Hottentot has been thought to bear a resemblance, are the Chinese or Malays, or their original stock the Mongols. Like these people they have the broad forehead, the high cheek-bones, the oblique eye, the thin beard, and the dull yellow tint of complexion, resembling the colour of a dried tobacco leaf; but there is a difference with regard to the hair, which grows in small tufts, harsh, and rather wiry, covering the scalp somewhat like the hard pellets of a shoe-brush. The women, too, have a peculiarity in their physical conformation, which, though occasionally to be met with in other nations, is not universal, as among the Hottentots. Their constitutional "bustles" sometimes grow to three times the size of those artificial stuffings with which our fashionable ladies have disfigured themselves. Even the females of the diminutive Bosjesmen Hottentots, who frequently perish of hunger in the barren mountains, and are reduced to skeletons, have the same protuberances as the Hottentots of the plains. It is not known even whence the name of Hottentot proceeds, as it is none of their own. It has been conjectured that *hot* and *tot* frequently occurring in their singular language, in which the monosyllables are enunciated with a palatic clacking with the tongue, like that of a hen, may have given rise to the name, and that the early Dutch settlers named them *hot-en-tot*. They call themselves *quiquæ*, pronounced with a clack. They are a lively, cheerful, good-humoured people, and by no means wanting in intellect; but they have met with nothing but harsh treatment since their first connection with Europeans. Neither Bartholomew Diaz, who first discovered, nor Vasco de Gama, who first doubled, the Cape of Good Hope, nor any of the subsequent Portuguese navigators, down to 1509, had much communication with the natives of this southern angle of Africa; but in the year above mentioned, Francisco d'Almeyda, viceroy of India, having landed on his return at Saldanha (now Table) Bay, was killed, with about twenty of his people, in a scuffle with the natives. To avenge his death, a Portuguese captain, about three years afterwards, is said to have landed a piece of ordnance loaded with grape shot, as a pretended present to the Hottentots. Two ropes were attached to this fatal engine; the Hottentots poured down in swarms. Men, women, and children flocked round the deadly machine, as the Trojans did round the wooden horse, "*funemque manu contingere gaudent.*" The brutal Portuguese fired off the piece, and viewed with savage delight the mangled carcasses of the deluded people. The Dutch effected their ruin by gratifying their propensity for brandy and tobacco, at the expense of their herds of cattle, on which they subsisted. Under the British sway they have received protection, and shown themselves not unworthy of it. They now possess property, and enjoy it in security. One of the most beautiful villages, and the neatest and best-cultivated gardens, belong to a large community of Hottentots, under the instruction and guidance of a few Moravian missionaries.

These forlorn people are of Hottentot origin. Of them also several tribes have been discovered much farther north, and intelligence has lately reached Europe, that between the Portuguese possessions, in the very centre of South Africa, there is a nation of dwarfish appearance who possess large herds, and who seem to belong to the original Bushmen stock.

The island of Madagascar is inhabited by a race of Malay origin, exhibiting traces of Negro and Arabic mixture.

The area and population of Africa and its divisions are thus estimated:—[1]

Divisions.	Area in English square miles.	Population.	Average Density. No. to a sq. mile.
North Africa,	4,003,600	20,420,000	5
Marocco,	259,600	2,750,000	10
Algeria,	258,300	2,921,146	11
Tunis,	45,700	2,000,000	43
Tripoli, with Barca and Fezzan,	344,400	750,000	2
Egyptian territory,	659,100	8,000,000	12
Sahara,	2,436,500	4,000,000	1·6
The Mohammedan States of Central Soudan,	631,000	38,800,000	61
Western Soudan, from the Senegal to the Lower Niger, including Upper Guinea, and	818,600	38,500,000	47
French Senegambia,	96,530	209,162	·2
Liberia,	9,580	718,000	72
Dahomeh,	3,880	180,000	47
British possessions,	17,100	577,313	34
Portuguese possessions,	35,880	8,500	0·2
East Africa,	1,595,000	29,700,000	18
Abyssinia,	158,400	3,000,000	19
South Africa,	1,966,000	16,000,000	8
Portuguese territory, East coast,	382,000	300,000	0·8
Portuguese territory, West coast,	312,500	9,000,000	29
Cape Colony,	221,310	682,600	3
Natal,	17,800	269,362	15
Orange R. Free State,	42,500	37,000	0·8
Transvaal Republic,	114,360	120,000	1
Equatorial Regions,	1,522,200	43,000,000	29
Islands in the Atlantic Ocean,	2,720	99,145	37
C. Verd Islands,	1,650	67,347	42
St Thomas and Principe,	454	19,295	42
Fernando Po & Annobon,	488	5,590	11
Ascension,	38	400	10
St Helena,	47	6,860	145
Tristan da Cunha,	45	53	1
Islands in the Indian Ocean,	233,870	6,000,000	25
Socotra,	1,700	3,000	2
Abd-el-Kuri,	64	100	2
Zanzibar,	616	380,000	616
Madagascar,	228,575	5,000,000	22
Comoro Islands (with Mayotta),	1,062	64,600	61
The Arco Islands, &c.,	150	...	...
Réunion,	970	209,737	216
Mauritius and its dependencies,	708	322,924	456
Desert of Kalahari and the Great Inland Lakes,	783,600	...	...
Africa,	11,556,600	192,520,000	16

[1] Compiled from the Tables in Behm and Wagner's *Bevölkerung der Erde*. Gotha, 1872.

In the central forest regions of Africa, wherever communications with the coast-land have been opened up, hunting the elephant for its tusks to barter with the traders appears to be the characteristic occupation, if any, beyond that of mere attention to the daily wants of life, is engaged in; and here the population may be considered as a settled one, living in villages in the more open spaces of the woods. A rudely agricultural state seems to mark the outer belt of negro land on each side of the equatorial zone, where the population is also more or less stationary. The arid regions of the Sahara and the Kalahari beyond have, on the other hand, a thinly scattered nomadic population, though here also the fertile wadys form lines of more permanent habitation, and contain permanent towns and villages. Excepting in the immediate neighbourhood of the Mediterranean in Abyssinia, on a narrow margin of the coasts of the Atlantic and the Indian Ocean, and in those parts which have been colonised by Europeans, or which came directly under their influence, society has remained in a barbarian state, and there remain great areas the inhabitants of which have as yet no knowledge of the outer world.

Agriculture is conducted with little art. The natural fertility of the soil in the well-watered districts supersedes the need of skill, while the production of the simplest manufactures is alone requisite, where the range of personal wants embraces few objects, and those of the humblest class.

Wars, cruel and incessant, waged not for the sake of territory, but for the capture of slaves, form one of the most marked and deplorable features in the social condition of the African races. This practice, though not of foreign introduction, has been largely promoted by the cupidity of the Europeans and Transatlantic nations; and, unhappily, the efforts of private philanthropy, and the political arrangements of various governments, have not yet availed to terminate the hideous traffic in mankind, or abate the suffering entailed upon its victims.

In *Religion*, Christianity is professed in Abyssinia, and in Egypt by the Copts, but its doctrines and precepts are little understood and obeyed. Mohammedanism prevails in all Northern Africa, excepting Abyssinia, as far as a line passing through the Soudan, from the Gambia on the west to the confluence of the Quorra and Benue, and thence eastward, generally following the 10th parallel of N. lat. to the Nile below the junction of the Ghazal; thence south-east, leaving the coast-land in the Mohammedan region, to Cape Delgado. In Marocco, Algeria, and Egypt, there is an admixture of Jews. Heathen Negroes and Caffre tribes extend southward over the continent from the line described above to the colonies in the southern extremity of the continent; and over this vast area the native mind is surrendered to superstitions of infinite number and character. In the Cape Colony Protestantism again prevails, but with a strong intermixture of heathenism. The labours of Christian missionaries have, however, done much, especially in South Africa, towards turning the benighted Africans from idols to the living God.

In describing the political divisions of Africa, we shall proceed from north to south.

The country included under the general name of Barbary extends from the borders of Egypt on the east to the Atlantic on the west, and is bounded by the Mediterranean on the north, and by the Sahara on the south. It comprises the states of Marocco, Algeria, Tunis, and Tripoli.

Marocco, the most westerly state of Barbary, is thus named by the Europeans, but by the Arabs themselves Mogr'-eb-el-Aksa, or "the extreme west." The eastern boundary was determined in the treaty with the French of 18th March 1845, by a line which, in the south, commences east of the oasis Figueg, intersecting the desert of Angad, and reaching the Mediterranean at a point about 30 miles west of the French port Nemours. In the south Marocco embraces the oasis of Tuat and the Wady Draa. The power of the government of Marocco, which is despotic and cruel, as well as the population of the country, appear to have diminished greatly. Two-thirds of the country are independent of the Sultan's authority, and are held by mountain chiefs who defy his power. The trade of the coast is maintained by European merchants. See MAROCCO.

Algeria extends from Marocco in the west, to Tunis in the east, and closely answers in its limits to the ancient kingdom of Numidia. The southern boundaries are not very definite, falling, as they do, within the boundless plains of the desert. See ALGIERS.

Tunis is the smallest of the Barbary states. The configuration of the surface is similar to that of Algeria, in three divisions, the "Tell," or fertile coast slopes, the steppes on the high lands, and the low-lying Sahara beyond. The highest peaks range between 4000 and 5000 feet. The southern plains comprise the land of dates (Belad-el-Jerid), and several extensive salt lakes. Tunis possesses but few rivers and streams, and springs are plentiful only in the mountainous regions.

The climate is, upon the whole, salubrious, and is not of the same excessive character as that of Algeria; regular sea-breezes exercise an ameliorating influence both in summer and winter; frost is almost unknown, and snow never falls. During summer occasional winds from the south render the atmosphere exceedingly dry and hot.

The natural productions of the country are somewhat similar to those of the other Barbary states, but dates of the finest quality are more largely produced. The horses and dromedaries are of excellent breed, and the former are eagerly sought for the French army in Algeria. Bees are reared in great quantity, and coral fisheries are carried on. Of minerals lead, salt, and saltpetre are the most noticeable.

The population consists chiefly of Mohammedan Moors and Arabs; the number of Jews is estimated at 45,000, and of Roman Catholics 25,000. The former have attained a higher degree of industry and civilisation than their brethren elsewhere; those of the latter who inhabit the central mountainous r[illegible]ons are nearly independent.

The government is vested in a hereditary bey, and has been conducted in peace and security for a number of years. From the year 1575 onwards, Tunis has been under the rule of Turkey; but by a firman of October 1871 the Sultan renounced the ancient tribute. The bey, who is styled "Possessor of the kingdom of Tunis," is confirmed in his position at Constantinople, and may neither enter into a war, nor conclude a treaty of peace, nor cede any part of his territory without the sanction of the Sultan. The Tunisian coinage bears the name of the Sultan, and the troops (3900 infantry and artillery, and 100 cavalry, form the regular army) are at the disposal of the Sublime Porte in time of war. In the interior of the country the bey has absolute power. The slave trade was abolished in 1842.

The commerce of Tunis is considerable, but agriculture is in a backward state. The exports consist chiefly of wool, olive-oil, wax, honey, hides, dates, grain, coral, &c.

The principal town is Tunis, situated on a shallow lake on the north coast. It is the most important commercial place on the southern shores of the Mediterranean after Alexandria, and has a population of about 125,000. The site of the ancient Carthage is 13 miles from Tunis in the direction of Cape Bon.

Tripoli, a regency of the Turkish empire, extends from Tunis along the shores of the Mediterranean to the table-land of Barca, which forms a separate province. Politically, it includes the pashalic of Fezzan, a country which, in a physical point of view, belongs to the Sahara.

Tripoli is the least favoured by nature of the Barbary states, possessing a great extent of sterile surface. Mr Richardson graphically describes the physiognomy of the country between the towns of Tripoli and Murzuk in eight zones:—1. The plain along the sea-shore, with the date-palm plantations and the sandhills; 2. The Gharian mountains, with their olive and fig plantations, more favoured with rains than the other regions; 3. The limestone hills and broad valleys between the town of Kalnbah and Ghareeah, gradually assuming the aridity of the Sahara as yo proceed southward; 4. The Hamadah, an immense desert plateau, separating Tripoli from Fezzan; 5. The sandy valleys and limestone rocks between El-Hessi and Es-Shaty, where herbage and trees are found; 6. The sand between Shiaty and El-Wady, piled in masses or heaps, and extending in undulating plains; 7. The sandy valleys of El-Wady, covered with forests of date-palms; 8. The plateau of Murzuk, consisting of shallow valleys, ridges of low sandstone hills, and naked plains. These zones extend parallel with the Mediterranean shores through the greater portion of the ountry. A summit of the Jebel-es-Soda, or Black Mountains, midway between Tripoli and Murzuk, almost 2800 feet high, is supposed to be the culminating point of the regency. Rivers exist only periodically, and springs are exceedingly scarce.

The climate is somewhat more subject to extremes than that of Tunis, especially in the interior, where burning heat is followed by excessive cold. As far south as Sokna snow occasionally falls. The climate of Murzuk is very unhealthy, and frequently fatal to Europeans.

The natural products are very much like those of Tunis. Oxen and horses are small, but of good quality; the mules are of excellent breed. Locusts and scorpions are among the most noxious animals. Salt and sulphur are the chief minerals.

The population is very thin. Arabs are the prominent race, besides which are Turks, Berbers, Jews, Tibbus, and Negroes. The country is governed by a pasha, subject to the Ottoman empire. The military force by which the Turks hold possession of this vast but thinly-peopled territory amounts to 4500 men.

The commerce is not inconsiderable, and the inhabitants of Tripoli trade with almost every part of the Sahara, as well as the Soudan. At Murzuk there is a large annual market, which lasts from October to January. The exports of Tripoli are wheat, wax, ivory, ostrich feathers, madder, esparto grass, cattle, salt, and dates.

Tripoli is the capital of the regency, and the largest town; it lies on the Mediterranean, surrounded by a fertile plain; the number of inhabitants is about 30,000. Murzuk, the capital of Fezzan, has a mixed population of about 11,000 souls. The town of Ghadamis has about 7000 inhabitants.

In 1869 the maritime plateau of Barca and the depressed region inland from it, which contains the oases of Aujila and Jalo, was formed into a separate government, dependent directly upon Constantinople. This country is the seat of the ancient Greek *Pentapolis* of Bernice, Arsinœ, Barca, Apollonia, and Cyrene. Bengazi, the only place of importance, occupies the site of the first of these on the Mediterranean, and has from 6000 to 7000 inhabitants.

Egypt occupies the north-eastern corner of Africa, and is remarkable for its ancient and sacred associations, and its wonderful monuments of human art.

Egypt is a vast desert, the fertile portions susceptible of cultivation being confined to the Delta of the Nile and its narrow valley, a region celebrated in the most ancient historic documents for its singular fertility, and still pouring an annual surplus of grain into the markets of Europe. By the annual inundation of the Nile this region is laid under water, and upon its retirement the grain crops are sown in the layer of mud left behind it. Barren ranges of hills and elevated tracts occupy the land on both sides of the Nile, which is the only river of the country. The amount of its rise is a matter of extreme solicitude to the people, for should it pass its customary bounds a few feet, cattle are drowned, houses are swept away, and immense injury ensues; a falling short of the ordinary height, on the other hand, causes dearth and famine, according to its extent. The water of the Nile is renowned for its agreeable taste and wholesome quality. In connection with the Nile is the Birket-el-Kerun, a salt lake.

The climate is very hot and dry. Rain falls but seldom along the coasts, but the dews are very copious. The hot and oppressive winds, called khamsin and simooms, are a frequent scourge to the country; but the climate is, upon the whole, more salubrious than that of many other tropical countries.

The natural products are not of great variety. The wild plants are but few and scanty, while those cultivated include all the more important kinds adapted to tropical countries; rice, wheat, sugar, cotton, indigo, are cultivated for export; dates, figs, pomegranates, lemons, and olives, are likewise grown. The doum-palm, which appears in Upper Egypt, is characteristic, as also the papyrus. The fauna is characterised by an immense number of waterfowl, flamingoes, pelicans, &c. The hippopotamus and crocodile, the two primeval inhabitants of the Nile, seem to be banished from the Delta, the latter being still seen in Upper Egypt. The cattle are of excellent breed. Large beasts of prey are wanting; but the ichneumon of the ancients still exists. Bees, silkworms, and corals are noticeable. Minerals are scarce, natron, salt, and sulphur being the principal.

The native Egyptians of Arab descent compose the great bulk of the people, the peasant and labouring class, and are termed Fellahs. Next in number, though comparatively few (145,000), are the Copts, descended from the old inhabitants of the country, the ancient Egyptians, but far from being an unmixed race. The Arabic Bedouin tribes, Negroes, European Christians (Greeks, Italians, French, Austrian, English), the Jews, and the dominant Turks, compose the remainder of the population.

Egypt is formally a Turkish pashalic, but the hereditary pasha, by whom the government is conducted, and whose authority is absolute, is practically an independent prince. The government of Nubia and Kordofan is also conducted by the Pasha of Egypt, and recently the whole of the Nile valley, as far south as the equator, has been annexed by the Egyptian government. An army of about 14,000 men is maintained.

The agriculture of Egypt has always been considerable, there being three harvests in the year. The industry is limited: one peculiar branch is the artificial hatching of eggs in ovens heated to the requisite temperature, a process which has been handed down from antiquity, and is now chiefly carried on by the Copts. Floating bee-hives are also peculiar to the Nile. The commerce is extensive and important: the exports to Europe consist chiefly of cotton, flax, indigo, gum-arabic, ostrich feathers, ivory, senna, and gold. The country forms part of the great highway of traffic between Europe and Southern Asia. Railways, from the ports of Alexandria and Damietta in the Mediterranean, and from Suez on the Red Sea, unite at Cairo; and a railway now extends thence up the bank of the Nile to near the first cataract of the river at Assouan, in lat. 24° N.

The Suez canal, uniting the Red Sea and the Mediterranean, was begun in April 1859, and was opened for traffic ten years later, in November 1869. The cutting runs from the artificial harbour of Port Said on the Mediterranean, through the shallow lagoon of Menzaleh, and through two smaller lakes with low sandhills between; nearer Suez a depressed area, in which several salt lakes formerly existed, has been filled up by water let in by the canal, and now forms a wide expanse of water. In length the canal is nearly 100 miles, and has a depth throughout of 26 feet, with a general width of 200 to 300 feet at the top of the banks and 72 feet at the bottom. Vessels are able to steam or be towed through the canal in sixteen hours from sea to sea. Extensive harbours and docks have been constructed both on the Mediterranean side and at Suez. The number of vessels which entered Port Said in 1871 was 1215, of 928,000 tons, exclusive of 87 war-ships.

Egypt proper is divided into three sub-pashalics—Bahari or Lower Egypt, Vostani or Middle Egypt, and Said or Upper Egypt. Cairo, on the east bank of the Nile, is the capital of Egypt, and is the largest town of Africa, containing 354,000 inhabitants: it has 400 mosques, and upwards of 130 minarets, some of them of rich and graceful architecture, presenting at a distance an appearance singularly imposing. Alexandria, on the coast, is the emporium of the commerce with Europe, and has 220,000 inhabitants, among whom are 54,000 Europeans. Damietta has a population of 37,100; Rosetta of 18,300. Suez, on the northern extremity of the Red Sea, is a small, ill-built town, but has assumed importance as a good port since the establishment of the overland route to India and the completion of the maritime canal. It has now nearly 14,000 inhabitants, of whom about 2500 are Europeans. Port Said has 8800 inhabitants, of whom one-half are foreigners.

Nubia extends along the Red Sea, from Egypt to Abyssinia, comprising the middle course of the Nile.

The natural features of the country are varied; the northern portion consisting of a burning sterile wilderness, while the southern, lying within the range of the tropical rains, and watered by the Abyssinian affluents of the Nile, exhibits vegetation in its tropical glory, forests of arborescent grasses, timber-trees, and parasitical plants largely clothing the country. This latter territory, which may be called Upper Nubia, includes the region of ancient Meroe, situated in the peninsula formed by the Nile proper, the Blue River, and the Atbara, and comprises, further south, the recently extinguished modern kingdom of Sennaar.

Nubia forms the link between the plain of Egypt and the high table-lands of Abyssinia; its general physical character is that of a slightly ascending region. The lowest parts in Upper Nubia scarcely exceed an altitude of 1300 feet; Khartum, at the confluence of the Blue and White Rivers, being 1345 feet above the level of the sea. A chain of mountains and elevated land rises abruptly along the shores of the Red Sea, gradually sloping down to the valley of the Nile; the intermediate region being intersected by smaller ranges, groups of hills, and numerous wadys filled with sand. The spurs of the Abyssinian table-land, extending within the southern confines of Nubia, reach a height of 3000 feet. Besides the Nile, the country is watered by two other large rivers, its tributaries, the Bhar-el-Azrek or Blue River, and the Atbara or Takkazze, both being much alike in magnitude, and having their head-streams in the Abyssinian table-land.

The climate of Nubia is tropical throughout, and the heat in the deserts of its central portions is not exceeded by that of any other part of the globe. The southern half of the country is within the influence of the tropical rains, the northern partakes the character of the almost rainless Sahara; and while the latter is generally very salubrious, the former is a land of dangerous fevers, particularly in the plains subject to inundations. Such is the Kolla, a marshy and swampy region of great extent, situated along the foot of the Abyssinian Mountains, between the Blue River and the Takkazze.

The northern region is poor in natural productions, but in the south the vegetation is most luxuriant; palms form a prominent feature, and the monkey bread-tree attains its most colossal dimensions. The date-tree, dourra, cotton, and indigo are cultivated. The date-palm does not extend beyond the south of Abou-Egli, in lat. 18° 36′.

The elephant occasionally wanders as far as Sennaar; the rhinoceros, lion, giraffe, and buffalo are more common. The waters are inhabited by crocodiles more ferocious than those of Egypt, and by huge hippopotami. The young hippopotamus brought to the Zoological Gardens of London in 1850, was captured in Nubia, in an island of the Nile, about 1800 miles above Cairo: no living specimen had been seen in Europe since the period when they were exhibited by the third Gordian in the Colosseum at Rome. Monkeys and antelopes are found in great numbers. The camel does not extend beyond the twelfth degree of latitude to the south. Ostriches roam over the deserts; and among the reptiles, besides the crocodile, are large serpents of the python species, and tortoises. Of the numerous insects the most remarkable is the scarabæus of the ancient Egyptians, still found in Sennaar. Of minerals Nubia possesses gold, silver, copper, iron, salt.

In the inhabitants two principal varieties are recognised, the pure original population, and their descendants, mixed with other nations. The Berberines inhabit the northern part, and the Bisharis the desert regions; the latter are the genuine Nubians, finely moulded and dark complexioned, supposed by some to agree more closely with the ancient Egyptians than the Copts, usually deemed their representatives. In the south-eastern part the true Negro element appears.

Nubia, now a province under the pashalic of Egypt, consisted formerly of a number of small and independent kingdoms. The Turkish conquest lasted from 1813 to 1822; in the latter years it was invaded and mercilessly ravaged by the army of Mahomet Ali, under his second son Ismayl, whose dreadful atrocities entailed a fearful fate upon himself, having been surprised when attending a nocturnal banquet, at some distance from his camp, and burned to death.

The country is favourable for agriculture, which, however, is only carried on to a limited extent, by the women. Cattle are abundant, and the camels of the Bisharin and Ababde are famous for their enduring powers. Salt is largely exported from the shores of the Red Sea to India, and ivory, with other products of tropical Africa, forms a principal article of trade.

Khartum, the capital of Nubia, the headquarters of the Egyptian government, and the chief seat of commerce, contains a population variously estimated at from 20,000 to 50,000. It is a modern town, having been founded in 1821, and lies in a dry, flat, and unhealthy country, near the confluence of the two main branches of the Nile. It is in telegraphic communication with Cairo.

Kordofan, on the western side of Nubia, lies between the parallels of 12° and 16°, and between the meridians 29° and 32°, containing about 30,000 square miles. It is a flat country, interspersed with a few hills, presenting in the dry season a desert with little appearance of vegetation, and in the rainy season a prairie, covered with luxuriant grass and other plants. The general elevation of the country is 2000 feet, and some of the hills attain a height of 3000. The altitude of El Obeid is 2150 feet. There are no permanent rivers in the country, and the natural products are similar to those of the adjoining regions of Nubia.

The population consists of Negroes. This country was, simultaneously with Nubia, made tributary to Egypt. The commerce consists of gum-arabic, ivory, and gold, and is not inconsiderable. El Obeid, the chief town, is composed of several villages of mud-built houses, thatched with straw, containing about 12,000 inhabitants.

The boundaries of Abyssinia are somewhat uncertain; but confining it to the provinces actually under the government of Christian or Mohammedan princes, it may be described as extending from about 9° to 16° N. lat., and from 35° to 40° E. long. See ABYSSINIA.

The Saharan countries extend from the Atlantic in the west, to the Nilotic countries in the east, from the Barbary States in the north, to the basins of the Rivers Senegal and Kawara, and Lake Chad in the south. The area of this large space amounts to at least 2,000,000 square miles, or upwards of one-half of that of the whole of Europe. It is very scantily populated, but from our present defective knowledge of that region, the number of its inhabitants can be but roughly estimated.

The physical configuration of the Sahara has already been indicated. Notwithstanding the proverbial heat, which is almost insupportable by day, there is often great cold at night, owing to the excessive radiation, promoted by the clearness of the sky. Rain is nearly, though not entirely absent, in this desolate region. It appears that when nature has poured her bounty over the adjoining regions in the south, and has little more left to bestow, she sends a few smart showers of rain to the desert, parched by the long prevalence of the perpendicular rays of the sun. The prevailing winds blow during three months from the west, and nine months from the east. When the wind increases into a storm, it frequently raises the loose sand in such quantities that a layer of nearly equal portions of sand and air, and rising about 20 feet above the surface of the ground, divides the purer atmosphere from the solid earth. This sand, when agitated by whirlwinds, sometimes overwhelms caravans with destruction, and, even when not fatal, involves them in the greatest confusion and danger.

The natural products correspond with the physical features of the country. Vegetation and animal life exist only sparingly in the oases or valleys where springs occur, and where the soil is not utterly unfit to nourish certain plants. Amongst the few trees the most important is the date-palm, which is peculiarly suited to the dryness of the climate. This useful tree flourishes best in the eastern part of the desert, inhabited by the Tibbus. The doum-palm is likewise a native of the same part, and seems entirely absent in the western Sahara; its northernmost limit is on the southern borders of Fezzan and Tegerry, in lat. 24° N. Acacias are found in the extreme west towards Senegambia, furnishing the so-called gum-arabic. In many parts of the desert a thorny evergreen plant occurs, about 18 inches high. It is eagerly eaten by the camels, and is almost the only plant which supplies them with food while thus traversing the desert. The cultivation of grains to a small extent is limited to the western oases of Tuat and others, a little barley, rice, and beans, being there grown. In the kingdom of Aïr there are some fields of maize and other grains; but upon the whole, the population depend for these products on Soudan and other regions. There are but a few specimens of wild animals in these wildernesses; lions and panthers are found only on its borders. Gazelles and antelopes are abundant, hares and foxes but scarce. Ostriches are very numerous, and vultures and ravens are also met with. In approaching Soudan, animal and vegetable life becomes more varied and abundant. Of reptiles, only the smaller kinds are found, mostly harmless lizards and a few species of snakes. Of domestic animals, the most important is the camel, but horses and goats are not wanting, and in the country of the Tuaricks an excellent breed of sheep is found, while in that of the Tibbus a large and fine variety of the ass is valuable to the inhabitants. Of minerals, salt is the chief production, which occurs chiefly near Bilma.

The habitable portions of the Sahara are possessed by three different nations. In the extreme western portion are Moors and Arabs. They live in tents, which they remove from one place to another; and their residences consist of similar encampments, formed of from twenty to a hundred of such tents, where they are governed by a sheik of their own body; each encampment constituting, as it were, a particular tribe. They are a daring set of people, and not restrained by any scruple in plundering, ill-treating, and even killing persons who are not of their own faith; but to such as are, they are hospitable and benevolent. The boldest of these children of the desert are the Tuaricks, who occupy the middle of the wilderness, where it is widest. The form of their bodies, and their language, prove that they belong to the aboriginal inhabitants of Northern Africa, who are known by the name of Berbers. They are a fine race of men, tall, straight, and handsome, with an air of independence which is very imposing. They live chiefly upon the tribute they exact from all caravans traversing their country. They render themselves formidable to all their neighbours, with whom they are nearly always in a state of enmity, making predatory incursions into the neighbouring countries. The third division of Saharan people are the Tibbus, who inhabit the eastern portion, comprising one of the best parts of the desert. In some of their features they resemble the Negroes. They are an agricultural and pastoral nation, live mostly in fixed abodes, and are in this respect greatly different from their western neighbours. Their country is as yet little explored by Europeans. The Tibbus are in part Pagans, while the other inhabitants of the Sahara are Mohammedans.

The commerce of the Sahara consists chiefly of gold, ostrich feathers, slaves, ivory, iron, and salt, exchanged for manufactured goods, and transported across the desert by great caravans, which follow lines uniting the greater cities and oases of the southern and northern borders.

Western Africa comprehends the west coast of Africa, from the borders of the Sahara, in about lat. 17° N. to Nourse River, in about the same latitude south, with a considerable space of inland territory, varying in its extent from the shores, and, in fact, completely undefined in its interior limits.

Senegambia, the country of the Senegal and Gambia, extends from the Sahara in the north to lat. 10° in the south, and may be considered as extending inland to the sources of the waters which flow through it to the Atlantic.

The western portion is very flat, and its contiguity to the great desert is frequently evidenced by dry hot winds, an atmosphere loaded with fine sand, and clouds of locusts. The eastern portion is occupied with hills and elevated land. Under the 10th parallel the hills approach quite close to the coast. The country possesses a great number of rivers, among which the Senegal, Gambia, and Rio Grande are the most important. Senegambia ranges, in point of heat, with the Sahara and Nubia. The atmosphere is most oppressive in the rainy season, which lasts from June to November, when an enormous amount of rain drenches the country. The prevailing winds in that period are south-west, whereas in the dry season they are from the east. The climate is, upon the whole, most unhealthy, and too generally proves fatal to Europeans.

The vegetation is most luxuriant and vigorous. The baobab (monkey bread-tree), the most enormous tree on the face of the globe, is eminently characteristic of Senegambia. It attains to no great height, but the circumference of the trunk is frequently 60 to 75 feet, and has been found to measure 112 feet; its fruit, the monkey bread, is a principal article of food with the natives. Bombaceæ (cotton-trees) are likewise numerous, and they are among the loftiest in the world. Acacias, which furnish the gum-arabic, are most abundant, while the shores are lined with mangrove trees. The flora and fauna are similar to those of Nubia. Gold and iron are the chief metals.

The inhabitants consist of various Negro nations, the chief of which are the Wolof.

The gum trade is the most important traffic on the Senegal; bees-wax, ivory, bark, and hides, forming the chief exports from the Gambia.

Of European settlements are: The French possessions on the Senegal; the capital of which is St Louis, built about the year 1626, on an island at the mouth of the river. The total population of the settlement amounts to about 210,000.

The British settlement on the Gambia has about 7000 inhabitants. Bathurst is the chief town.

The Portuguese settlement consists of small factories south of the Gambia, at the Bissagos Islands, Bissao, Cacheo, and some other points.

The west coast of Africa, from Senegambia to the Nourse River, is commonly comprised by the general denomination Guinea Coast, a term of Portuguese origin.

The coast is generally so very low, as to be visible to navigators only within a very short distance, the trees being their only sailing marks. North of the equator, in the Bight of Benin, the coast forms an exception, being high and bold, with the Cameroon Mountains behind; as also at Sierra Leone, which has received its name (Lion Mountain) in consequence. The coast presents a dead level often for thirty to fifty miles inland. It has numerous rivers, some of which extend to the furthest recesses of Inner Africa.

The climate, notoriously fatal to European life, is rendered pestilential by the muddy creeks and inlets, the putrid swamps, and the mangrove jungles that cover the banks of the rivers. There are two seasons in the year, the rainy and the dry season. The former commences in the southern portion in March, but at Sierra Leone and other northern parts, a month later.

Vegetation is exceedingly luxuriant and varied. One of the most important trees is the *Elais guineensis*, a species of palm, from the covering of whose seed or nut is extracted the palm-oil, so well known to English commerce and manufacture; several thousand tons are annually brought into the ports of Liverpool, London, and Bristol. The palm-oil tree is indigenous and abundant from the river Gambia to the Congo; but the oil is manufactured in large quantities chiefly in the country of the Gold and Slave Coasts. The former comprises nearly all the more remarkable of African animals: particularly abundant are elephants, hippopotami, monkeys, lions, leopards, crocodiles, serpents, parrots. The domestic animals are mostly of an inferior quality. The principal minerals are gold and iron. The population consists, besides a few European colonists, of a vast variety of Negro nations, similar in their physical qualities and prevailing customs, but differing considerably in their dispositions and morals.

The chief articles of commerce are palm-oil, ivory, gold, wax, various kinds of timber, spices, gums, and rice.

The divisions of Northern or Upper Guinea are mostly founded on the productions characteristic of the different parts, and are still popularly retained.

The British colony of Sierra Leone extends from Rokelle river in the north, to Kater river in the south, and about twenty miles inland. The chief portion of the settlement is a rugged peninsula of mountains with a barren soil, but surrounded by a belt of rich coast-land, with a moist and pestilential climate. The colony was founded in 1787, and has been maintained with a view to the suppression of the West African slave trade. The population, consisting chiefly of liberated slaves, amounted, in 1869, to 55,374, of which number 129 were white men. Freetown, the capital is, after St Louis, the most considerable European town on the western coast of Africa.

The Malaghetta or Grain Coast extends from Sierra Leone to Cape Palmas. Malaghetta is a species of pepper yielded by a parasitical plant of this region. It is sometimes styled the Windy or Windward Coast, from the frequency of short but furious tornadoes throughout the year. The republic of Liberia, a settlement of the American Colonisation Society, founded in 1822, for the purpose of removing free people of colour from the United States, occupies a considerable extent of the coast, and has for its capital Monrovia, a town named after the president, Mr Monro.

The Ivory Coast extends from Cape Palmas 3° W. long., and obtained its name from the quantity of the article supplied by its numerous elephants. The French settlements of Grand Bassam, Assinie, and Dabou were abandoned in 1871.

The Gold Coast stretches from west of Cape Three Points to the river Volta, and has long been frequented for gold-dust and other products. By a treaty of February 1871, the whole of the Dutch possessions on the Gold Coast were made over to Britain, and the Danish settlements of Christiansburg and Friedensburg were ceded to the English in 1849; so that the British coast now extends from the mouth of the Tenda river, in long 2° 40′ W., to that of the Ewe, in long. 1° 10′ E. of Greenwich. The protected territory extends inland from this coast strip to an average distance of 50 miles. Cape Coast Castle and Fort James, founded by the British, and Elmina (population about 10,000) the most important of the former Dutch stations, with Accra, are the chief settlements.

The Slave Coast tends from the river Volta to the Calabar river, and is, as its name implies, the chief scene of the most disgraceful traffic that blots the history of mankind. Eko or Lagos, one of the chief towns of the coast, was destroyed by the British in 1852, and was proclaimed a British possession in 1861. Palma and Badagry are also British settlements.

The kingdoms of Ashantee, Dahomey, Yoruba, and others, occupy the interior country of the Guinea coast. Ashantee the most powerful Negro state of Upper Guinea, is an exceedingly fertile and productive country. Its inhabitants, though skilled in some manufactures and of a higher intelligence than is usually found in this region, are of an exceedingly sanguinary disposition, and have frequently been involved in war with the British. The capital city, Kumassi, is believed to have a population of about 100,000.

The coast from the Old Calabar river to the Portuguese possessions is inhabited by various tribes. Duke Town, on the former river, is a town of 4000 inhabitants, with considerable trade in palm-oil, ivory, and timber.

On the Gaboon river, close to the equator, are a French settlement (in 1871 the French retained only a coaling station), and American missionary stations. At the equator Southern or Lower Guinea begins, where the only European settlements are those of the Portuguese.

Loango is reckoned from the equator to the Zaïre or Congo river. Its chief town is Boally, called Loango by the Europeans.

Congo extends south of the Zaïre, comprising a very fertile region, with veins of copper and iron. Banza Congo or St Salvador is the capital.

Angola comprises the districts of Angola proper, Benguela, and Mossamedes. In these regions the Portuguese settlements extend farther inland than the two preceding districts, namely, about 200 miles. The capital, St Paulo de Loando, contains 12,300 inhabitants, and has a fine harbour. St Felipe de Benguela is situated in a picturesque but very marshy and most unhealthy spot.

The coast from Benguela to the Cape Colony may, in a general arrangement like this, be included either within West Africa or South Africa. The whole coast is little visited or known, being of a most barren and desolate description, and possessing few harbours. Ichabo island and Angra Peguena Bay are visited for their guano deposits, and are claimed as British possessions.

Under South Africa the Cape Colony only is generally comprised. It takes its name from the Cape of Good Hope, and extends from thence to the Orange river in the north, and to the Kai river in the east. A large proportion of the territory included within these limits, especially in the north, is either unoccupied, or, excepting missionary stations, entirely in the hands of the aborigines.

Apart from the shores, the country consists of high lands, forming parallel mountainous ridges, with elevated plains or terraces of varying extent between. The loftiest range, styled in different parts of its course Sneuw-bergen, Winter-bergen, Nieuveld-bergen, and Roggenveld-bergen, names originated by the Dutch, is the third and last encountered on proceeding into the interior from the south coast. This and the other chains are deeply cut by the transverse valleys called kloofs, which serve as passes across them, and appear as if produced by some sudden convulsion of nature, subsequently widened by the action of the atmosphere and running water.

The high plains or terraces are remarkable for their extraordinary change of aspect in the succession of the seasons. During the summer heats they are perfect deserts, answering to the term applied to them, karroos, signifying, in the Hottentot language, "dry" or "arid." But the sandy soil being pervaded with the roots and fibres of various plants, is spontaneously clothed with the richest verdure after the rains, and becomes transformed for a time into a vast garden of gorgeous flowers, yielding the most fragrant odours. Adapted thus to the support of graminivorous animals, the karroos are the resort of antelopes, zebras, quaggas, and gnus in countless herds, and of the carnivorous beasts that prey upon them, the lion, hyæna, leopard, and panther. These quadrupeds, however, with the elephant, rhinoceros, hippopotamus, giraffe, buffalo, and ostrich, have been largely banished from their old haunts by the advancing footsteps of civilised man, and are only found in the more secluded parts of the interior. The country has a singular and superb flora, but it comprises few native plants useful to man: many such have been now introduced. Heaths of varied species and great beauty abound; and geraniums are treated as common weeds. Many highly productive districts occur; corn, wines, and fruit being the chief objects of cultivation in the neighbourhood of the Cape, while the more inland settlements are grazing farms. Some fine natural forests clothe the sides of the mountains; but in general the colony is deficient in timber trees, as well as in navigable streams, perennial springs, and regular rain. A great deposit of rich copper ore occurs near the mouth of the Orange; and salt is obtained for consumption and sale from salt lakes.

The climate is exceedingly fine and salubrious. There are two seasons, characterised by the prevalence of certain winds. During the summer, which lasts from September to April, the winds blow from south-east, cold and dry; during the winter, namely from May to September, north-west winds prevail. In the most elevated regions the winters are occasionally severe, and snow and ice occur.

The chief native tribes within the British territory are the Hottentots, Bechuanas, and Kaffres. No manufacture is conducted at the Cape except the making of wine, of which from 10,000 to 40,000 gallons are annually exported to England. Various articles of provision are supplied to ships sailing between Europe and the East Indies.

Cape Town is the capital of the colony, and contains 28,460 inhabitants, of whom 15,120 are Europeans. Its commerce is considerable, and the port is frequented by 500 to 600 vessels every year.

The Orange river sovereignty, added to the British territories in 1848, but subsequently given up and constituted a free republic, extends north of the Orange river as far as the Ky Gariep or Vaal river. In consequence of the discovery of rich diamond fields on the lower Vaal river and in the neighbouring territory of the Griqua chief Waterboer, who also petitioned to have his lands subjected to British rule, a wide country surrounding the diamond-fields was incorporated with the Cape Colony in October 1871, under the name of Griqua Land West, divided into the districts of Pneil, Griqua Town, and Klipdrift. The population of this new territory was estimated at 50,000 in 1872, concentrated in camps round the chief diamond-fields. In 1869, Bassuto Land, a mountainous territory at the head waters of the Nu Gariep branch of the Orange river, and on the inward slope of the Drakenberg range, was incorporated as a British possession.

Griqua Land W

Bassuto Land

Natal or Victoria, a district on the east coast, and separated from the Cape Colony by Kaffraria, is a recently formed British settlement, which was created into a colony in 1856. It is highly favoured in those respects in which the Cape is most deficient, having abundance of wood and water, with coal and various metallic ores, a fine alluvial soil, and a climate adapted to the cultivation of the products for which the home demand is large and constant—cotton, silk, and indigo. Pietermaritzburg, the capital of the settlement, lies 50 miles from the coast. Port Natal, now D'Urban, seated on a fine lake-like bay, is the only harbour.

Natal

The Transvaal Republic is an inland state, between the Vaal on the south and the Limpopo river on the north, having the Drakenberg edge on the east, and the Bechuana tribes, which occupy the region bordering on the Kalahira desert, on the west, founded by the Dutch *boers* emigrating from the Cape Colony. Its surface is an elevated plateau, thinly wooded in some parts, but generally affording excellent pasture. The chief town is Potchefstroom, on a tributary of the Vaal; but the seat of government is at Pretoria, in the region of the head streams of the Limpopo.

East Africa extends from Natal northwards to the Red Sea, comprising Sofala, Mozambique, Zanzibar, and the Somali country. But little is known of that region beyond the shores. The Sofala Coast, extending from Delagoa Bay to the Zambeze river, is flat, sandy, and marshy, gradually ascending towards the interior. It abounds with rivers, which are the source of yearly innndations. The soil is very fertile, and produces chiefly rice. In the interior, gold and other metals, as well as precious stones, are found. The Portuguese have settlements at Sofala, in an unhealthy spot, abounding with salt marshes; it consists of only huts, a church, and a fort in ruins. Inhambane, near the tropic of Capricorn, has an excellent harbour.

Sofala

Mozambique extends from the Zambeze to Cape Delgado, and is similar, in its natural features, to the Sofala Coast. The greatest river is the Zambeze. The principal settlement of the Portuguese is at Quillimane, which is situated in a very unhealthy position on the northern arm of the delta of the Zambeze, surrounded with mangrove trees.

The Zanzibar or Sawahili Coast extends from Cape Delgado to the river Jub, near the equator. The coast is generally low, and has but few bays or harbours: its northern portion is rendered dangerous by a line of coral reefs extending along it. The region possesses a great number of

Zanzibar

rivers, but none of them attain a first-rate magnitude. The principal are the Rovuma, the Lufiji, Ruvu, Pangani, and Dana; the two latter rising in the snowy mountains of Kilima-njaro and Kenia. The climate is similar to that of other tropical coasts of Africa, hot and unhealthy in general: in some portions, however, the elevated ground, and with it a more temperate and healthy climate, approaches the shores to within a short distance. The vegetation is luxuriant, and cocoa-nut, palms, maize, rice, and olives are the chief articles of cultivation. The fauna comprises all the more characteristic African species.

The chief inhabitants are the Sawahili, of mixed Arab and Negro descent, but the coasts are under the Arab dominion of the Imaum of Muscat, by whose efforts commerce with the nations of the interior has greatly increased.

The island of Zanzibar (Unguja of the Sawahili) is the residence of a Sultan, tributary to the Imaum of Muscat, and the seat of extensive commerce. Mombas, on a small island close to the main shore, possesses the finest harbour on that coast, and has recently become famous as the seat of an important missionary station.

The Somali country comprises the eastern horn of Africa, from the equator northward to the Bay of Tadjurra, near the entrance into the Red Sea. The coast is generally bold and rocky, in some places covered with sand; and the extensive region it encloses presents a slightly ascending plain, traversed by large valleys of great fertility, among which the Wady Nogal is prominent. This country is not so well watered as the region to the south, and some of its rivers are periodical.

The Somali country is famous for its aromatic productions and gums of various kinds; and it is supposed that the spices and incense consumed in such large quantities by the ancient peoples of Egypt, Greece, Syria, and Rome, were derived from this part of Africa, and not from Arabia.

Zeila and Berbera, on the northern coast, are the chief trading ports: the permanent population of the former is about 3000, while the latter may be said to exist only during the winter, when no less than 20,000 strangers, at an average, arrive to pitch their tents, and thus create a great market-place. Harrar, in the Galla country, is the chief place in the interior, with 8000 inhabitants, who are Mohammedans. One-third of the population is Somali, one-third Arab.

Central Africa comprises the regions which extend from the southern borders of the Sahara in the north to Cape Colony in the south, and from Senegambia in the west to the territory of the Egyptian pashalic on the east. It comprehends the central basins of the great lakes from Lake Chad to the Nyassa, and the greater part of the basins of the Niger, Congo, Nile, and Zambeze. Even the Sahara may well be included in this general denomination. So little is yet known of this vast region that the general features of some portions only can be indicated. The greater portion seems to be densely peopled with numerous tribes, and to possess inexhaustible natural resources. The portion north of the equator, under the name Soudan or Nigritia, comprises a great number of states, among which the principal are Bambarra, Timbuktu, and Houssa, in the west; Bornu, Baghermi, and Waday, around Lake Chad; Darfur in the east; and Adamaua in the south. The inhabitants are of Negro race, with many Arabs, Moors, and Berbers.

Bambarra occupies part of the basin of the Joliba, or upper source of the Quorra. The dominant inhabitants are the Mandingoes and Foulahs, who have embraced Islamism, and are much more advanced in civilisation than the other Negro tribes. The country comprises extensive and excellent pastures, with abundance of domestic animals, as horned cattle, sheep, goats, and horses of a fine breed. Among the vegetable products the most remarkable is the butter-tree, which furnishes an important article of agricultural industry and trade.

Sego, the capital, is situated on the Joliba, and contains 30,000 inhabitants. It was here that Mungo Park first caught sight of the long-sought river.

Timbuktu, or Jennie, comprises the basin of the Joliba below Bambarra, and lies partly within the Great Sahara. Timbuktu, a few miles from the banks of the Joliba, and situated amid sands and deserts, is a celebrated centre of the North African caravan trade. It contains from 12,000 to 15,000 inhabitants.

Houssa is an extensive country extending to the Sahara in the north, to the Joliba or Kawara on the west, to Bornu on the east, and to about 10° N. lat. on the south. The dominant race are the Foulahs, but the mass of the population are Negroes. It is a very fertile and beautiful country, but the climate is insalubrious, and in many parts fatal to Europeans. The inhabitants are engaged in pastoral, as well as in agricultural and commercial pursuits.

The capital, Sakatu, is one of the largest cities in Negroland; it is situated in a fertile but marshy plain. Kano, another large town, containing 30,000 to 40,000 inhabitants, is the great emporium of trade in Houssa; there the English merchandise coming from the north through the Sahara, meets with American goods coming from the Bight of Benin. The manufactures of Kano consist chiefly of cloth, for the dyeing of which that town is famed all over Central Africa.

Bornu is one of the most powerful states of Negroland; Bornu.
extending on the west to the 10th degree of long., on the east to Lake Chad and the kingdom of Baghermi, and on the south as far as Mandara and Adamaua, in about 11° N. lat. Kanem, on the northern side of Lake Chad, has recently been conquered and brought under Bornuese sovereignty.

The general character of Bornu is that of a plain, subject to inundations, particularly near Lake Chad. It is very fertile, and cotton and indigo attain a high degree of excellence. The original Bornuese are an agricultural people.

Kuka, the capital and residence of the Sheik of Bornu, had in 1866 about 60,000 inhabitants.

Baghermi, another powerful kingdom, is situated east of Baghermi.
Bornu. The boundaries, according to Dr Barth, who first visited this country and penetrated as far as Maseña, the capital, are on the west the river Loggene, a tributary of the Shary or Asu, by which it is divided from Bornu and Adamaua; on the north its limits are in about 12½° N. lat., and on the east 19½° E. long., both lines dividing it from Waday; the southern boundary is in about 8½° N. lat. Baghermi is an extensive plain or valley formed by the river Shary or Asu and its tributaries. The inhabitants are very warlike, and frequently engage in slave marauding expeditions into the neighbouring states to the south.

Maseña, the capital, lies in 11° 40′ N. lat., and 17° 20′ E. long.

Waday, or Dar Saley, lies east of Baghermi, and reaches Waday.
as far as Darfur. It comprises an extensive region, stretching as far as the basin of the Nile. Lake Fittri, situated in the western portion, forms a basin, unconnected with that of Lake Chad, and by which the country as far as Darfur is drained. It has never been explored by Europeans. The population comprises a great variety of tribes and different languages.

Wara, the capital, is placed by Dr Barth in 14° N. lat., and 22° E. long.

Darfur, east of Waday, extends as far as Kordofan. The country rises towards the west into a range of hills called Jebel Marrah. It is drained into the Nile. A great portion of the country is Saharan in its character, while other parts are fertile and diversified. Browne, in 1703, estimated the whole population at 200,000. It has an extensive trade with Egypt.

Cobbeih, the capital, is a merchant town, and contains about 6000 inhabitants.

Fumbina or Adamaua is an extensive country south of Houssa and Bornu, under Foulah dominion. It consists of a large, fertile, and highly-cultivated valley, formed by the River Benue. Near Yola, the capital, the Benue receives the Faro, a large tributary coming from the south west. This country was first visited by Dr Barth in 1851.

Yola, the capital, lies in 8° 50′ N. lat., and 13° 30′ E. longitude.

South of the belt of Negro states of the Soudan lies the great unknown region of Central Africa. On the east the unexplored area is bounded by the numerous states of the lake region made known by Burton, Speke, and Livingstone. Of these the chief are Unyamwesi, occupying the plateau south of the Victoria Lake, and east of Lake Tanganyika, with the capital town of Kaseh or Tabora, frequented by Arab traders from Zanzibar; Karague on the western side of the Victoria Nyanza; and Ugauda, stretching round its north-western shores. In the interior, beyond Lake Tanganyika, Livingstone has recently made known the peoples of Manyuema land, where "there is no political cohesion; not one king or kingdom. Each man is independent of every other." To the south of the unknown region are the powerful Negro kingdoms of the Muata Yanvo and of the Cazembe, occupying the whole of the interior between 6° and 12° S. lat. Kabebe, the capital of the former state, is believed to be in about lat. 8° S., long. 23° 30′ E. of Greenwich; and Lunda, the chief town of the latter potentate, is in the Luapula valley, south-west of the Tanganyika Lake, and was visited by Livingstone in 1867–68. The Makololo kingdom, occupying the central basin of the Zambeze river, with the chief town of Linyanti, west of the Victoria Falls; and that of Mosilikatse in the south-east, between the Zambeze and the Limpopo rivers, are the great remaining divisions of Central Africa. Besides these, however, innumerable petty kingdoms, chiefships, and tribes subdivide the vast populations of Negroland.

To Africa belong a considerable number of islands. The Madeiras, belonging to Portugal, lie off the north-west coast of Africa, at a distance of about 360 miles. Madeira, the chief island, is about 100 miles in circuit, and has long been famed for its picturesque beauty, rich fruits, and fine climate, which renders it a favourite resort of invalids. Wine is the staple produce. Funchal, the chief town, with 18,000 inhabitants, is a regular station for the West India mail steam-packets from Southampton, and the Brazilian sailing-packets from Falmouth.

The Canaries, belonging to Spain, the supposed Fortunate Islands of the ancients, are situated about 300 miles south of Madeira. They are 13 in number, all of volcanic origin, Teneriffe being the largest. The latter is remarkable for its peak, which rises as a vast pyramidal mass to the height of 12,173 feet.

The Cape Verde Islands, subject to Portugal, are a numerous group about 80 miles from Cape Verde. They obtained their name from the profusion of sea-weed found by the discoverers in the neighbouring ocean, giving it the appearance of a green meadow. They are also of volcanic origin.

Fernando Po, a very mountainous forest-covered island, is in the Bight of Biafra. The British settlement of Clarence Town was established in 1827, but afterwards abandoned. The island now belongs to Spain.

St Thomas, immediately under the equator, is a Portuguese settlement; as is also Prince's Island, in 2° N. lat.

Annobon in 2° S. lat., belongs to the Spaniards.

Ascension, a small, arid, volcanic islet, was made a British port on the arrival of Napoleon Bonaparte at St Helena, and since retained as a station, at which ships may touch for stores. Green Hill, the summit of the island, rises to the height of 2840 feet.

St Helena is a huge dark mass of rock, rising abruptly from the ocean to the height of 2692 feet. James' Town is the only town and port.

Madagascar, the largest island of Africa, and one of the largest in the world, is separated from the Mozambique coast by a channel of that name. about 250 miles wide. The area exceeds that of France.

The high interior of the island is generally very fertile, with magnificent forests and fine pastures watered by numerous rivers, but a belt of hot swamp land with a deadly climate surrounds the coast.

The inhabitants are diverse races of Negro, Arab, and Malay origin. The Ovahs, a people of the central provinces, are now dominant. The principal town, Antananarivo, has about 80,000 inhabitants.

The French possess the islands of Sante Marie and Nossibe on the coast of Madagascar, and Mayotta island in the Comoro group.

The Comoro isles, four in number, are in the north part of the Mozambique Channel, and inhabited by Arab tribes.

Réunion or Bourbon, 400 miles east of Madagascar, is a colony of France, producing for export, coffee, sugar, cocoa, spices, and timber.

Mauritius, ceded to the British by the French in 1814, is 90 miles north-east of Bourbon. The sugar-cane is chiefly cultivated. Port Louis, the capital, beautifully situated, has 75,000 inhabitants. Within the jurisdiction of the Governor of the Mauritius are the islands of Rodriguez, the Seychelles, and the Amarante islands.

Socotra, a large island, east of Cape Jerdaffun, with an Arab and Negro population, has been known from early times; it belongs to the Imaum of Muscat. This island was long celebrated as producing the finest aloetic drug; it is found still to produce a fine kind of aloe, though much of what passed as Socotrine aloes really came from India. Gums, tobacco, and dates are also exported. (K. J.)

Note.—The above article was completed before it was known with certainty that the saddest event in the history of African exploration had occurred. Dr Livingstone, to whom the article justly assigns "the first place among African discoverers," died of dysentery near Lake Bangweolo on the 4th of May 1873. The story of his latest discoveries, and of the rare devotion with which his native attendants carried his remains with them during an eight months' march to the coast, belongs to a biographical notice. It is more fitting in this place to note, as some consolation for an almost irreparable loss, that Livingstone's death seems to have given a powerful stimulus to the prosecution of the task he had so nearly completed. The expedition of Lieutenant Cameron, above referred to, is being carried out with a vigour and intelligence that give ample promise of a further limitation of the region of the unknown, if not of the complete solution of all outstanding problems. In the spring of 1874 he had commenced a thorough exploration of Lake Tanganyika, which, from his professional experience as a hydrographical surveyor, is expected to lead to very valuable results. And the complete success of Stanley's first memorable mission in search of Livingstone warrants confident hopes in regard to a second expedition, also admirably organised and equipped, which has started under his direction.

AFRICANUS, Julius, called also Sextus by Suidas, a Christian historian of the 3d century, born, according to some, in Africa, and, according to others, in Palestine, of African parents. Little is known of his personal history, except that he lived at Emmaus, and that he went on an embassy to the emperor Heliogabalus to ask the restoration of that town, which had fallen into ruins. His mission succeeded, and Emmaus was henceforward known as Nicopolis. It is by no means certain that he was a bishop or even a priest, though the latter is probable. He wrote a history of the world (Πενταβιβλίον Χρονολογικόν) from the creation to the year 221 A.D., a period, according to his computation, of 5723 years. He calculated the period between the creation and the birth of Christ as 5499 years, and antedated the latter event by three years. This method of reckoning became known as the Alexandrian era, and was adopted by almost all the eastern churches. The history is no longer extant, but copious extracts from it are to be found in the *Chronicon* of Eusebius, besides fragments in Syncellus, Cedrenus, and the *Paschale Chronicon*. Eusebius has also given some extracts from his letter to Aristides, reconciling the apparent discrepancy between St Matthew and St Luke in the genealogy of Christ by a reference to the Jewish law, which compelled a man to marry the widow of his deceased brother, if the latter died without issue. His letter to Origen, impugning the authority of the apocryphal book of Susanna, and Origen's answer, are both extant, the former having been printed at Basle, 1674. The ascription to Africanus of a work entitled Κεστοί, treating of agriculture, natural history, military science, &c., has been disputed on account of the inconsistency between it and the author's other writings. Neander suggests that it was probably written by Africanus before he had devoted himself to religious subjects.

AFZELIUS, Adam, an eminent Swedish naturalist, born at Larf, West Gothland, in 1750. Having studied at Upsala under Linnæus, he became teacher of oriental literature in that university in 1777, and demonstrator of botany in 1785. For two years (1792-94) he resided on the west coast of Africa as botanist to the Sierra Leone Company. After acting for some time as secretary to the Swedish embassy in London, he returned home, became again a teacher in the university of Upsala, and was appointed professor of materia medica in 1812 He edited the autobiography of Linnæus (Upsala, 1823), a German translation of which appeared at Berlin in 1826. His literary work included also a large number of botanical papers contributed to the Linnæan Society of London and the Royal Academy of Stockholm, as well as treatises on certain plants of Guinea and Sweden. He died at Upsala in 1836, having bequeathed his botanical collection to the university. Several species of plants, known as *Afzelia*, are named after this distinguished botanist.

AFZELIUS, Arwid August, the Swedish historian, poet, and comparative mythologist, was born at Fjellåker in 1785. For a while he was a schoolmaster in Stockholm, but afterwards entered the church, and became parish priest of Enköping, where he worked for just half-a-century, till his death in 1871. His poetical career began in 1811 and closed in 1848, when he wrote his *Farewell to the Swedish Harp*. One great work of his life was to collect and publish, in conjunction with the eminent Geijer, three volumes of Swedish Folk-songs; but he will be best remembered by his *History of the Swedish People*, which has won him a European reputation. He did not live to bring this history lower down than 1709. (E. W. G.)

AGA, or Agha, a word, said to be of Tatar origin, signifying a dignitary or lord. Among the Turks it is applied to the chief of the janissaries, to the commanders of the artillery, cavalry, and infantry, and to the eunuchs in charge of the seraglio. It is also employed generally as a term of respect in addressing wealthy men of leisure, landowners, &c. The word is found with a somewhat similar usage in Tartary, Persia, and Algiers.

AGADES, the capital of the kingdom of Aïr, or Asben, in Central Africa, situated in 17° 2′ N. lat., 8° 5′ E. long. The town is built on the edge of a plateau, 2500 feet above the level of the sea, and is supposed to have been founded by the Berbers to serve as a secure magazine for their extensive trade with the Songhay empire. The language of the people is a dialect of Songhay. In former times Agades was a place of great traffic, and had a population of about 50,000. Its importance may be estimated by the fact that the king of Agades paid a tribute of 150,000 ducats to the king of Songhay. Since the beginning of the 16th century the prosperity of the place has gradually declined. Extensive quarters of the town, which has a circuit of 3½ miles, are deserted and ruinous. The occupied houses number only 600 or 700, and the population does not exceed 7000. The houses, which are built of clay, are low and flat-roofed; and the only building of importance is the chief mosque, which is surmounted by a tower 95 feet high. There is little traffic in the markets; no money is used, and the usual medium of exchange is millet. The chief trade is in grain. Agades derives its main importance from its situation on the direct route from the countries to the north-east to Sokoto and other important towns in the Hansa states. The great salt caravans pass through it, as well as pilgrims on their way to Mecca. From its healthy climate and advantageous position, the place might prove to be a good station for a European agent. (See Barth's *Travels in Central Africa*, vol. i.)

AGAMEMNON. The stern obligations of a king and the majesty of his office, as compared with his humane desires and occasional frailty, give the keynote to the character of Agamemnon. But the kingly office, like the sceptre which was the symbol of it, had come to him from Pelops (*Iliad*, ii. 100) through the stained hands of Atreus and Thyestes, and had brought with it a certain fatality, by which his misfortunes, and especially the catastrophe at the close of his life, were explained. As his title of Atrides implies, Agamemnon was a son of Atreus, his mother being Aërope. In a later account he is a son of Pleisthenes. But, apart from this difference, it is agreed that he succeeded to the sovereignty of Atreus over Argolis, Corinth, Achaia, and many islands, his seat being at Mycenæ, not, as Æschylus for political reasons asserts, at Argos. The succession had been usurped by Thyestes and Ægisthus. During the usurpation Agamemnon and his brother Menelaus visited Tyndareus, the king of Sparta, and obtained in marriage his two daughters—the former Clytæmnestra, the latter Helena: with his help Agamemnon was reinstated in his rights. Menelaus succeeded Tyndareus. The children born by Clytæmnestra were Chrysothemis, Iphigenia, Electra, and one son, Orestes. Elsewhere are mentioned also Iphianassa and Laodice; but the latter was the original name of Electra, it appears, and it has been suggested that Iphianassa stood in the same relation to Iphigenia. Agamemnon was then the most powerful prince in Greece; and to him of right, as well as naturally, his brother Menelaus turned for aid to compel the Trojans to give up his wife Helena, whom Paris had carried off. The various princes of Greece having been brought to unite in an expedition for this purpose, Agamemnon was chosen leader, he himself furnishing 100 ships and lending also 60 more to the Arcadians. It was not perhaps his fault that the Greeks landed by mistake on the coast of Mysia, from which, after plundering it, they took ship and were scattered in a storm; but it was owing to him (and this is the beginning of his ill-fate) that after again assembling in

Aulis, whence they had set out, the fleet was storm-bound. He had slain a deer sacred to Artemis, and boasted himself a better hunter than the goddess. This, as Calchas the seer read the divine will, could only be atoned for by his offering up his daughter Iphigenia in sacrifice. Compelled by his duty to the expedition, he allowed her to be sent for, the pretext given to Clytæmnestra being that she was to be married to Achilles. But when the moment of sacrifice came, the goddess substituted a stag, carried her off to the Tauri, and made her immortal. The fleet now sailed; and except the quarrel between him and Achilles at Tenedus or Lemnus, there was no incident in which Agamemnon figured particularly, until, in one of the raids on the towns round Troy, Briseis and Chryseis were brought captives, and assigned, the former to Achilles, the latter to Agamemnon.—who, having to yield up his captive to appease Apollo, claimed and took the other. Upon this Achilles withdrew from the war, and Agamemnon endeavoured at first to maintain it without him. In the face of disaster he repented, and offered reparation—sending costly presents by the hands of Phœnix, Ajax, and Ulysses. His offer rejected, he took the field himself, and did marvels of bravery, but was wounded and defeated. When Troy was finally taken and the captives distributed, he obtained Cassandra, and with her returned home; but before sailing the shade of Achilles appeared to him, foretold what would happen, and sought to restrain him. In his absence Clytæmnestra had yielded to the temptations of Ægisthus, and, to cover her shame, planned with him the death of her husband. The approach of Agamemnon being announced by a spy, a feast and an affected welcome were prepared for him and his followers. At the feast they were fallen upon by hired murderers, assisted by Ægisthus and Clytæmnestra, the latter herself slaying Cassandra (*Odyssey*, iv. 512-537; xi. 385-461). According to Æschylus, Agamemnon was slain in his bath, his wife first throwing a piece of cloth over him to prevent resistance. For his death vengeance was taken by his son Orestes. In the legends of the Peloponnesus, Agamemnon was regarded as the highest type of a powerful monarch, and in Sparta he was worshipped under the title of Zeus Agamemnon. His tomb was pointed out among the ruins of Mycenæ (Pausanias ii. 16. 5). (A. S. M.)

AGAPE, plur. AGAPÆ, the love-feast, or feast of charity, which among the primitive Christians usually accompanied the Eucharist. The word (ἀγάπη, love) is first employed in this sense in the Epistle of Jude, verse 12. The suggestion of a connection between Christian love-feasts and the ἔρανοι and ἑταιρίαι of Greece and Rome is both improbable and unnecessary. The feelings of love and brotherhood fostered by the new faith, strengthened as these must have been by the complete isolation of the little Christian community, are quite sufficient to account for the existence of the Agapæ, without referring them to other more or less similar institutions. According to Chrysostom, the Agape was a common feast, symbolising the community of goods when it no longer really existed, to which the rich brought provisions, and the poor, who brought nothing, were invited. At first it was observed probably every evening in immediate connection with the celebration of the Lord's Supper, though whether before or after is a point that has been much disputed. It closed with the holy kiss (φίλημα ἅγιον, φίλημα αγάπης). The Corinthian church was the first to pervert the Agape by destroying the community between rich and poor (1 Cor. xi. 21). Partly perhaps on account of such irregularities extending, and partly to escape the notice of persecutors, it became usual about the middle of the 2d century to separate the Lord's Supper from the Agape by celebrating the former at the close of morning service on Sunday, and the latter by itself after a considerable interval. Abuses becoming more frequent, love-feasts were gradually put under greater restrictions. The rich began habitually to absent themselves from the Agapæ, which came thus to be regarded as a provision for the poor alone; and the Council of Gangra (360), to correct the abuse, pronounced an anathema upon any who should despise the Agapæ. A number of synods and councils in succession condemned the holding of these feasts in churches, as well as the participation of the clergy in them, and at length the observance altogether died out. In modern times it has been revived in one form or other by the Moravian Brethren, the Wesleyan Methodists, and, in Scotland, by the followers of Robert Sandeman.

AGAPETUS, deacon of the St Sophia Church at Constantinople, presented to the Emperor Justinian a work entitled *Charta Regia*, composed in 527, which contained advice on the duties of a Christian prince. It is highly valued, and has been several times reprinted. The best edition is that contained in Bandauri's *Imperium Orientale* (Paris, 1711). There is an English translation by Thomas Paynell (1550); and a French translation, executed from a Latin version by Louis XIII., with the assistance of his tutor, David Rivault.

AGARDE, ARTHUR, a learned English antiquary, born at Foston, in Derbyshire, about 1540. He was trained a lawyer; but entering the exchequer as a clerk, he became deputy-chamberlain in 1570. This office, which he held for forty-five years, gave him unrivalled opportunities for carrying on his favourite study. Along with his intimate friends, Sir Robert Cotton and Camden, he was one of the original members of the *Society of Antiquaries*. He made a special study of the *Domesday Book*, and prepared an explanation of its more obscure terms, which is of little worth. Hearne, in his *Collection of Curious Discourses written by Eminent Antiquaries* (Oxford, 1720), includes six by Agarde on such subjects as the origin of parliament, the antiquity of shires, the authority and privileges of heralds, &c. Agarde died in 1615, and was buried in the cloister of Westminster Abbey. He bequeathed to the exchequer all his papers relating to that court, and to his friend Sir Robert Cotton his other manuscripts, amounting to twenty volumes.

AGASIAS, son of Dositheus, a famous sculptor of Ephesus, who is supposed to have lived about the 4th century. His celebrated work, known erroneously as the *Borghese Gladiator*, was discovered at the commencement of the 13th century in the ruins of an imperial palace at Antium, where the *Apollo Belvidere* was also found. It represents a figure in action, with the head uplifted as if to meet the attack of a horseman. According to Winckelmann, the representation of the figure is intensely real, without a touch of imagination. The statue forms part of the Louvre collection.

AGASSIZ, LOUIS JOHN RUDOLPH, was the son of a Swiss Protestant clergyman. His father was the pastor of the parish of Motiers, a small town situated near the north-eastern angle of the Little Murtensee, and not far from the eastern extremity of the Lake of Neuchatel. Agassiz was born at this retired place on May 28, 1807. Educated first at home, then spending four years at the gymnasium of Bienne, he completed his elementary studies at the academy of Lausanne. Whilst at this latter place he already became conspicuous amongst his fellow-students, not only for his love of the natural sciences, but for the manifest talent he displayed in pursuing them. The close alliance between these subjects and the science of medicine led him to adopt the latter as his profession, for which he studied successively at the universities of Zurich, Heidelberg, and Munich; at the same time availing himself of the advantages afforded by these universities for extending his knowledge of natural history, especially of botany. Having completed his academical course, he took his degree of doctor of medicine at Munich.

Up to this time he had no particular inclination for the study of ichthyology, which soon afterwards became the great occupation of his life. Agassiz always declared that he was led into ichthyological pursuits through the following circumstances:—In 1819-20, Spix and Martius were engaged in their celebrated Brazilian tour, and on their return to Europe, amongst other collections of natural objects, they brought home an important one of the fresh-water fishes of Brazil, and especially of the Amazon river. Unfortunately Spix did not live long enough to work out the history of these fishes; hence it became necessary that some other naturalist should undertake the task of describing them. It is no insignificant proof of the reputation which Agassiz had already won, that, though little more than a youth just liberated from his academic studies, he was selected for this purpose. His attention being thus directed to the special subject of ichthyology, he at once threw himself into the work with that earnestness of spirit which characterised him to the end of his busy life. Thus, in 1828 we find him, after describing a new species of Cynocephalus, publishing a description of a new cyprinoid fish. This was followed by a yet more elaborate research into the history of the cyprinoid and other fishes found in the lake of Neuchatel. Rapidly enlarging his plans, the publication of the last-named work was succeeded by the issue, in 1830, of a prospectus of a *History of the Fresh-water Fishes of Central Europe.* It was only in 1839, however, that the first part of this important publication appeared. The task of describing and figuring the Brazilian fishes of Spix and Martius was completed and the work published in 1829.

Acquiring fresh confidence through these labours, he now contemplated a yet greater task. Having become a professed ichthyologist, it was impossible that the fossil fishes with which the stratified rocks of his native mountains abound should fail to attract his attention. The rich stores furnished by the slates of Glarus and the limestones of Monte Bolca were already well known; but very little had been accomplished in the way of the scientific study of them. Agassiz at once threw himself into this new field of labour with his wonted enthusiasm, and began the publication of the work which, more than any other, made him known to foreign naturalists, and laid the foundation of his world-wide fame. Five volumes of his *Recherches sur les Poissons Fossiles* appeared at intervals between the years 1833 and 1844. They were magnificently illustrated, chiefly through the labours of Dinkel, an artist of remarkable power in delineating natural objects.

Agassiz soon found that his palæontological labours rendered a new basis of ichthyological classification absolutely necessary. The fossils rarely exhibited any traces of the soft tissues of fishes. They chiefly consisted of the teeth, scales, and fins, even the bones being perfectly preserved in but comparatively few instances. Hence the classifications of Cuvier and other naturalists were of little use to him in determining the mutual relations of the fossil forms. He therefore adopted his well-known classification, which divided fishes into four groups—viz., Ganoids, Placoids, Cycloids, and Ctenoids. The first of these groups was chiefly represented amongst living fishes by the Lepidosteus or bony pike of the great American rivers; by the Polypterus or Bischir of the Nile; and by the sturgeon. The last fish has a wide geographical range; but the other two, which best display the characters on which Agassiz based his Ganoid class, are limited to the fresh-water rivers of local geographical areas. But in the Palæozoic and Mesozoic ages it was strikingly otherwise. The Ganoids were the most remarkable as well as the most widely diffused of primeval fishes; we find them equally in the fresh-water deposits of the weald, in the marine deposits of the oolites, the chalk, and the magnesian limestone, and in the more mixed and dubious deposits of the coal measures. Agassiz, therefore, was fully justified in attaching very great importance to this hitherto unrecognised class. Indeed, later ichthyologists—*e.g.*, J. Müller and Professor Owen—have found it necessary to retain the class in their recent classifications, though in a modified form. The remaining portions of Agassiz' system have not been adopted by them; but though they do not accept the terms Placoids, Cycloids, and Ctenoids as representing classes, all zoologists employ them as new and convenient adjectives, of the utmost value to students of systematic ichthyology. One reason for the rejection of Agassiz' system by modern ichthyologists is the obvious one that he draws the characteristics of his classes from a single organ—the skin—and that not the most important. At the same time, it must be admitted that the Placoids, like the Ganoids, also constituted a natural group closely corresponding with the *Pisces cartilaginei* of Cuvier and others. The distinction between Cycloids and Ctenoids was a much more trivial one, and needlessly separated closely-allied forms. It is only those who are familiar with the magnitude and difficulties of the task thus undertaken that can appreciate the daring courage of the youth who grappled with it. Under twenty-five years of age, and, as already observed, with limited financial resources, he nevertheless seems to have known no fear. He soon announced to geologists several important generalisations, the correctness of which has been confirmed by all subsequent research. In particular, he pointed out that no examples of Cycloids and Ctenoids, comprehending the bulk of the fishes now seen in our markets, were to be found in rocks of older date than the cretaceous age.

As the work proceeded it became obvious that it would over-tax the resources of the intrepid young zoologist, unless some additional assistance could be afforded to him. The British Association for the Advancement of Science wisely came to his aid, and the late Earl of Ellesmere—better known in his youth as Lord Francis Egerton—gave him yet more efficient help. The original drawings made for the work, chiefly by Dinkel, amounted to 1290 in number. These were purchased by the earl; but, with princely liberality, he left all that were necessary for the further prosecution of his labours in the hands of Agassiz.

It was whilst he was thus engaged that Agassiz paid his first visit to England, for the purpose of studying the rich stores of fossil fishes with which this country abounds. He was then in his youthful prime—a model of manly vigour and scientific enthusiasm; but amongst his many qualities none were more remarkable than the quickness with which he detected the peculiarities of any new fossil, and the retentiveness of his memory, which enabled him to make ready use of his newly-acquired knowledge. The consciousness that he possessed these powers led him occasionally—though, it must be allowed, but rarely—to trust unduly to them, and made him sometimes hasty and off-hand in his conclusions.

But fossil ichthyology, though a very large subject, was insufficient to occupy his energetic mind. In 1837 we find him issuing the "Prodrome" of a monograph on the recent and fossil Echinodermata, the first part of which appeared in 1838; and in 1839-40 he published, in addition, two quarto volumes on the fossil Echinoderms of Switzerland. This division of the invertebrate animals was evidently a favourite one with him, since we find it the subject of numerous memoirs which appeared from time to time during his later life.

It was by these great undertakings that he chiefly won his distinguished position as one of the greatest leaders in scientific research; but his observant faculties were by no means concentrated upon them exclusively. His intellectual *tentacula* expanded in every direction. The history of the Belemnites, the muscular system of recent and fossil shells, the principles of classification of the animal kingdom, the embryology of the salmon, and critical studies of special genera of fossil Mollusca—all engaged his attention. During his travels in England in 1834 he was ever on the alert for new specimens for the museum at Neuchatel. One characteristic incident of this kind may be referred to here. A fine porpoise had been caught by the Scarborough fishermen. Agassiz was weary with travel, and had but a few hours to remain in the town, but the chance could not be allowed to escape; the creature was purchased, and midnight saw Agassiz and the writer of this sketch working by the dim light of two tallow candles dissecting the animal, and shipping off its half-cleaned bones to Neuchatel. before he ventured to take the much-needed rest.

Subsequently to his first visit to England the labours of Hugh Miller, Dr Malcolmson, and other geologists brought to light the marvellous ichthyal fauna of the Devonian beds of the north-east of Scotland. Murchison and Sedgwick had some time previously directed attention to the existence of fishes of this geological age, especially amongst the bituminous shales of Caithness; but the more recent discoveries were of far greater interest than the earlier ones, because of the strange forms of the Pterichthys, the Coccosteus, and other species then made known to geologists for the first time. The supposition of Hugh Miller, that some of these fishes had vertical instead of horizontal mouths, suggestive of a transition from the crustacean to the ichthyal type, added fresh interest to the subject in the eyes of a philosophic inquirer like Agassiz. These fossils were reported upon by him more than once, and were finally made the subjects of a special monograph, which was published in 1844. Miller's interpretation of the structure of the mouth Agassiz soon demonstrated to be erroneous.

The year 1840 witnessed the inauguration of a new movement, which has proved to be of the utmost importance to geological science. Previously to this date De Saussure, Venetz, Charpentier, and others had made the glaciers of the Alps the subjects of special study, and Charpentier had even arrived at the important conclusion that the well-known erratic blocks of alpine rocks scattered so abundantly over the slopes and summits of the Jura mountains, had been conveyed thither by glaciers. The question having attracted the attention of Agassiz, he at once grappled with it in his wontedly enthusiastic manner. He not only made successive journeys to the alpine glaciers in company with Charpentier, but he had a rude hut constructed upon one of the Aar glaciers, which for a time he made his comfortless home, in order that he might the more thoroughly investigate the structure and movements of the ice. These labours resulted in the publication of his magnificent illustrated folio entitled *Etudes sur les Glaciers.* In this important work the movements of the glaciers, their moraines, their influence in grooving and rounding off the rocks over which they travelled, producing the striations and *roches montonnés* with which we are now so familiar, were treated with a comprehensiveness which threw into the shade all the writings of previous labourers in this field. He not only accepted Charpentier's idea that some of the alpine glaciers had extended across the wide plains and valleys drained by the Aar and the Rhone, and thus landed parts of their remains upon the uplands of the Jura, but he went still further in the same direction. He concluded that, at a period geologically recent, Switzerland had been another Greenland; that instead of a few glaciers stretching their restricted lines across the areas referred to, one vast sheet of ice, originating in the higher Alps, had extended over the entire valley of north-western Switzerland until it reached the southern slopes of the Jura, which, though they checked and deflected its further extension, did not prevent the ice from reaching in many places the summit of the range. At a later period we shall find him holding a similar view in the case of the vast plains spread out between the Andes and the eastern coast of South America. The publication of this work gave a fresh impetus to the study of glacial phenomena in all parts of the world. In 1841 Agassiz spent many weeks in his hut on the Lower Aar glacier, where he received as his guest the late Professor James Forbes, who was also engaged upon the study of glacial phenomena. The latter philosopher, in his work on *Norway and its Glaciers*, recognised in the fullest manner his indebtedness to Agassiz for much new light respecting the details of glacial action.

Thus familiarised with the phenomena attendant on the movements of recent glaciers, Agassiz was prepared for a new and most unexpected discovery which he made in 1846, in conjunction with the late Professor Buckland. These two *savants* visited the mountains of Scotland together, and found in six different localities clear evidence of some ancient glacial action. The discovery was announced to the Geological Society of London in a joint communication from the two distinguished observers. Similar discoveries were subsequently made by Buckland, Lyell, Ramsay, and others in various parts of Scotland, Westmoreland, Cumberland, and North Wales. The former existence of glaciers in each of these mountainous districts is a fact that no one now presumes to doubt any more than that these glaciers, either directly, or indirectly in the shape of icebergs, have at least contributed largely to the accumulation of those wide-spread deposits with which geologists are familiar under the name of drift and boulder formations.

But we must now follow Agassiz to a new sphere of labour. In 1838 he was appointed to the professorship of natural history at Neuchatel, with a very limited income. In the autumn of 1846 he crossed the Atlantic, with the two-fold design of investigating the natural history and geology of the United States, and delivering a course of lectures on zoology at the Lowell Institute; and the tempting advantages, pecuniary and scientific, presented to him in the New World, induced him to settle in the United States, where he remained to the end of his life. He was appointed professor of zoology and geology in the university of Cambridge, U.S., in 1847. He left that post in 1851 for a medical professorship of comparative anatomy at Charlestown, but returned in 1853 to Cambridge.

This transfer to a new field, and the association with fresh objects of high interest to him, gave his energies a new stimulus. Volume after volume now proceeded from his pen: some of his writings were popular, and addressed to the multitude, but most of them dealt with the higher departments of scientific research. His work on Lake Superior, and his four volumes of *Contributions to the Natural History of the United States*, were of this latter character. But whilst thus working earnestly at American zoology, he still kept in view more generalised inquiries, the fruits of which appeared in 1854, with the title of *Zoologie Générale et Esquisses Générales de Zoologie contenant la Structure, le Développement, la Classification, &c., de tous les Types d'Animaux vivants et détruits.* Before leaving these literary labours, we must not overlook the valuable service he rendered to science by the formation, for his own use, of a catalogue of scientific memoirs—an extraordinary work for a man whose hands were already so full. This catalogue, edited and materially enlarged by the late Hugh Strickland, was published by the Ray Society under the title of *Bibliographia Zoologiæ et Geologiæ*. Nor must we forget that he was building up another magnificent monument of his industry in the Museum of Natural History, which rose under his fostering care, at Cambridge. But at length the great strain on his physical powers began to tell. He then sought to restore his waning health by a southern voyage. His early labours among the fishes of Brazil had often caused him to cast a longing glance towards that country; and he now resolved to combine the pursuit of health with the gratification of his long-cherished desires. In April 1865 he started for Brazil, along with his admirable wife and an excellent class of assistants. Even on shipboard he could not be idle. In his outward voyage he delivered a course of lectures, open to all his fellow-passengers, but especially addressed to his assistants, and intended to instruct them in the nature and bearings of the great problems upon which they might hope to throw light during their stay in Brazil. An interesting account of this journey, to the success of which the emperor of Brazil contributed in every possible way, was published by Mrs Agassiz when they returned home, laden with the natural treasures of the Brazilian rivers.

In 1871 he made a second excursion, visiting the southern shores of the North American continent, both on its Atlantic and its Pacific seaboards. He had for many years yearned after the establishment of some permanent school where zoological science could be studied, not in class-rooms or museums of dead specimens, but amidst the living haunts of the subjects of study. Like all truly great teachers, he had little faith in any school but that of nature. The last, and possibly the most permanently influential, of the labours of his long and successful life was the establishment of such an institution, which he was enabled to effect through the liberality of Mr John Anderson, a citizen of New York. That gentleman not only handed over to Agassiz the island of Penikese, on the east coast, but also presented him with $50,000 wherewith permanently to endow it as a practical school of natural science, especially devoted to the study of marine zoology. Another American friend gave him a fine yacht, of 80 tons burden, to be employed in marine dredging in the surrounding seas. Had Agassiz lived long enough to bring all this machinery into working order, it is difficult to exaggerate the practical advantages which American science would have reaped from it when guided by such experienced hands. But it was otherwise ordained. The disease with which he had struggled for some years proved fatal on Dec. 14, 1873.

A letter to his old friend, Sir Philip M. de Grey Egerton, Bart., written but a few days before his death, and doubtless one of the last that he penned, showed that his spirit was still as indomitable and his designs as large as ever; and one of his latest expressed wishes was that he might be spared for four more years in order that the work he had contemplated might be completed.

Our available space will not allow us to give a detailed sketch of the opinions of this remarkable man on even the more important of the great subjects which he studied so long. From first to last he steadily rejected the doctrine of evolution, and affirmed his belief in independent creations. In like manner he retained his confidence in the former existence and agency of vast continental ice-sheets, rather than in the combined action of more limited glaciers and icebergs, which nearly all modern geologists recognise as the producers of the drifts and boulder-clays. When studying the superficial deposits of the Brazilian plains in 1865, his vivid imagination covered even that wide tropical area, as it had covered Switzerland before, with one vast glacier, extending from the Andes to the sea. His daring conceptions were only equalled by the unwearied industry and genuine enthusiasm with which he worked them out; and if in details his labours were somewhat defective, it was only because he had the courage to attempt what was too much for any one man to accomplish. (W. C. W.)

AGATE (from *Achates*, a river in Sicily, on the banks of which it is said to have been found), a name applied by mineralogists to a stone of the quartz family, generally occurring in rounded nodules or in veins in trap rocks. The number of agate balls in the rock often give it the character of amygdaloid; and when such a rock is decomposed by the elements, the agates drop out, and are found in the beds of streams that descend from it; or they may be obtained in quarrying. Great quantities are obtained from Oberstein and Idar, in Germany, where there are large manufactories for colouring and polishing the stones; and many are brought from India and Brazil. Agate occurs in considerable quantity in Scotland, whence the stone is familiarly known to lapidaries as *Scotch pebble;* and very large masses of calcedony, a variety of it, are brought from Iceland, the Faroe Islands, and Brazil. Agate chiefly consists of calcedony, with mixtures of common quartz and occasional patches of jasper and opal. The colour markings are often in concentric rings of varying forms and intensity, or in straight parallel layers or bands. The colours are chiefly gray, white, yellow, or brownish-red. The composition of agate is not uniform; but it usually contains from 70 to 96 per cent. of silica, with varying proportions of alumina, coloured by oxide of iron or manganese. The principal varieties are—

1. *Calcedony.* In this the colours are in parallel bands. The porosity of this stone, and the presence of iron in it, have given rise to a beautiful artificial process for heightening its natural colours, which has been long practised at Oberstein, and probably long known in India. The stones best suited for this purpose are such as when recently fractured imbibe moisture most readily. The stones are first dried without heat, then immersed in a mixture of honey and water, and afterwards placed in a heated oven, where they remain for two or three weeks, constantly covered with the liquid. They are then washed, dried, and put into an earthenware vessel containing sufficient sulphuric acid to cover them; this vessel is closed and placed in the oven for a space varying from one to twelve hours, according to the hardness of the stone. The agates are now removed, washed, and thoroughly dried; and after being kept in oil for twenty-four hours, are cleaned, cut, and polished. In the best specimens the gray streaks are increased in intensity; some exhibit brown streaks approaching to black, while white impenetrable parts assume a brighter hue by the contrast. This is the process employed to convert the veined calcedony or agate into *onyx*, especially for the production of *cameos* and *intaglios*, in imitation of the antique sculptured gems, of which admirable specimens are found in the cabinets of the curious, and especially in the Florentine Museum. In those minute but exquisite works the ancient Greeks especially excelled; and remarkable specimens of the art have been found in the tombs of Egypt, Assyria, and Etruria. In such works the figures, whether in relief or intaglio, appear of a different colour from the ground.

2. *Carnelian*, or red calcedony, when found, is almost always brownish or muddy. The following process is employed at Oberstein to convert both this sort and the yellowish-brown varieties into a rich red, so as to rival the Indian carnelian, which probably also has its colour heightened artificially:—After being thoroughly dried, the

stones are dipped in sulphuric acid, and immediately exposed in a covered earthenware crucible to a red heat: the whole is allowed to cool slowly, and when cold the stones are removed and washed.

3. *Mocha stones*, originally brought from the East, are clear grayish calcedonies, with clouds and dashes of rich brown of various shades. They probably owe their colour chiefly to art.

4. *Moss agates* are such as contain arborisations or *dendrites* of oxide of iron, some of which seem to be petrifactions of real vegetable forms.

5. *Bloodstone* is a dark-green agate containing bright red spots like blood-drops.

6. *Plasma*, a grass-green stone, found engraved in ruins at Rome, on the Schwartzwald, and on Mount Olympus, appears to be calcedony coloured by chlorite.

7. *Chrysoprase*, found in Silesia, is an agate coloured apple-green by oxide of nickel.

The agate can be cut or sawed easily, and is used for making cups, rings, seals, handles for knives and forks, sword-hilts, rosary beads, and a great variety of trinkets. Many stones of this kind are marked with representations of men, animals, or inanimate natural objects; but there can be no question that a very large proportion of these are to be regarded as productions of art.

AGATHARCHIDES, a celebrated Greek grammarian and geographer who flourished about 140 years B.C., was born at Cnidos. His works are lost, except those passages quoted by Diodorus Siculus and other authors, in which he describes the gold mines of Upper Egypt, and gives the first philosophical explanation of the inundations of the Nile, which he ascribed to the rains on the mountains of Ethiopia. (Hudson's *Greek Geographers.*)

AGATHARCHUS, a Greek painter, commemorated by Vitruvius for having first applied the laws of perspective to architectural painting, which he used successfully in preparing scenery for the plays of Æschylus. He flourished about 480 years B.C.

AGATHIAS, a Greek historian and poet, born at Myrina in Asia Minor, about 536 A.D. He was educated at Alexandria, and in 554 went to Constantinople, where, after studying Roman law for some years, he practised as an advocate. The title "Scholasticus," generally given to Agathias, was that by which advocates were known in Constantinople. Of the poetry by Agathias but little remains; his *Daphniaca* (Δαφνιακά), a collection of erotic poems, being entirely lost, and only the introduction to his Κύκλος, or anthology from earlier and contemporary writers, being extant. A number of his epigrams may be found in the *Anthologia Græca*. His principal work is his history, which begins, where Procopius ends, with the 26th year of the reign of Justinian (553), and carries on the narrative of events until 558. It is valuable as a chronicle, but the style is turgid, and great ignorance is shown of the history and geography of western Europe. It was printed in Greek, with a Latin translation by Bonaventura Vulcanius, at Leyden in 1594. The best edition is that of Niebuhr (Bonn, 1828). A French translation is included in the second volume of Louis Cousin's *History of Constantinople.*

AGATHO, an Athenian tragic poet, the disciple of Prodicus and Socrates, celebrated by Plato in his *Protagoras* for his virtue and his beauty. A tragedy of his obtained the prize in the fourth year of the 90th Olympiad, and he was crowned, in the presence of upwards of 30,000 persons, when a little over thirty years of age. There are no remains of his works, except a few quotations in Aristotle, Athenæus, and others.

AGATHOCLES, a famous tyrant of Sicily, was the son of a potter at Rhegium. By his singular vigour and abilities he raised himself through various gradations of rank till he finally made himself tyrant of Syracuse, and then of nearly all Sicily. He defeated the armies of the Carthaginians several times, both in Sicily and Africa; but at length he met with a reverse, and his soldiers' pay being in arrears, they mutinied, forced him to fly his camp, and murdered his sons. Recovering himself, he relieved Corcyra, which was besieged by Cassander; burnt the Macedonian fleet; and revenged the death of his children by putting the murderers, with their wives and families, to the sword. After ravaging the sea-coast of Italy he took the city of Hipponium. The last years of his life were greatly harassed with ill-health and the turbulence of his grandson Archagathus. He died in the seventy-second year of his age, B.C. 290, after a reign of twenty-eight year.

AGDE, a town of France, in the department of Hérault, on the left bank of the river of that name, 30 miles S.W. of Montpellier. It is a place of great antiquity, and is said to have been founded, under the name of *Agathe*, by the Greeks. In the neighbourhood there is an extinct volcano, and the town is built of black volcanic basalt, which gives it a grim and forbidding aspect. It has a fine old Gothic cathedral, a college, and a school of navigation. The *Canal du Midi*, or Languedoc canal, uniting the Garonne with the Mediterranean Sea, passes under the walls of the town, and the mouth of the Hérault forms a convenient harbour, which is protected by a fort. Thus advantageously situated, the place commands an extensive coasting trade, more than 400 vessels annually entering the port. Soap and verdigris are manufactured, and the staple productions of southern France are largely exported. Population, 9747.

AGE, a term denoting generally any fixed period of time, is used more definitely in a variety of senses. Classical mythology divided the whole history of the earth into a number of periods. Hesiod, for example, in his poem *Works and Days*, describes minutely five successive ages, during each of which the earth was peopled by an entirely distinct *race*. The first or *golden* race lived in perfect happiness on the fruits of the untilled earth, suffered from no bodily infirmity, passed away in a gentle sleep, and became after death guardian dæmons of this world. The second or *silver* race was degenerate, and refusing to worship the immortal gods, was buried by Jove in the earth. The third or *brazen* race, still more degraded, was warlike and cruel, and perished at last by internal violence. The fourth or *heroic* race was a marked advance upon the preceding, its members being the heroes or demi-gods who fought at Troy and Thebes, and who were rewarded after death by being permitted to reap thrice a-year the free produce of the earth. The fifth or *iron* race, to which the poet supposes himself to belong, is the most degenerate of all, sunk so low in every vice that any new change must be for the better. Ovid, in his *Metamorphoses*, follows Hesiod exactly as to nomenclature and very closely as to substance. He makes the degeneracy continuous, however, by omitting the *heroic* race or age, which, as Grote points out, was probably introduced by Hesiod, not as part of his didactic plan, but from a desire to conciliate popular feeling by including in his poem the chief myths that were already current among the Greeks.

A definite period in history distinguished by some special characteristic, such as great literary activity, is generally styled, with some appropriate epithet, an age. It is usual, for example, to speak of the age of Pericles, the Augustan age, the Elizabethan age; of the age of the crusades, the dark ages, the middle ages, the age of steam. Such isolated periods, with no continuity or necessary connection of any kind, are obviously quite distinct from the ages or organically-related periods into which certain eminent modern philosophers have divided the whole course of human history. According to Fichte's scheme there are five ages, distinguished by the relative predominance which instinct, external authority, and reason have in them respectively, instinct being supreme in the first and reason in the last. Comte's scheme distinguishes three ages according to the state of knowledge in each, and he supposes that we are now entering upon the third of these. In the first age of his scheme knowledge is *supernatural* or fictitious; in the second it is *metaphysical* or abstract; in the third it is *positive* or scientific. Schemes somewhat similar have been proposed by other philosophers, chiefly of France and Germany, and seem to be regarded by them as essential to any complete science of history.

In relation to individual as well as to social life, age is used with a considerable variety of application. It frequently denotes the total duration of life in man, animals, or plants, and in this sense belongs to the subject of LONGEVITY (*q.v.*) It also denotes in man the various periods into which his life may be divided, either from a physiological or from a legal point of view. In the former aspect perhaps the most common division is into the four ages of infancy, youth, manhood, and old age. These again have been increased to six or seven by some physiologists—infancy, childhood, boyhood or girlhood, adolescence, manhood or womanhood, age, and old age or second childhood. While both schemes have a sufficient basis of scientific accuracy, they have also each attracted the fancy of the poet. Ovid in his *Metamorphoses* (xv. 198–213) makes a beautiful comparison between the four ages of a man's life and the four seasons of the year, in a passage which has been frequently imitated; and the sevenfold division has been exquisitely cast into poetic form by Shakespeare in *As You Like It*, act ii. scene 7. The division of human life into periods for legal purposes is naturally more sharp and definite than the foregoing. It would be unscientific in the physiologist to name any precise year for the transition from one of his stages to another, inasmuch as that differs very considerably among different nations, and even to some extent among different individuals of the same nation. But the law must necessarily be fixed and uniform, and even where it professes to proceed according to nature, must be more precise than nature. The Roman law divided human life for its purposes into four chief periods, which had their subdivisions—(1.) *Infantia*, lasting till the close of the seventh year; (2.) The period between *infantia* and *pubertas*, males becoming *puberes* at fourteen and females at twelve; (3.) *Adolescentia*, the period between puberty and majority; and (4.) The period after the twenty-fifth year, when males become *majores*. The first period was one of total legal incapacity; in the second period a person could lawfully do certain specified acts, but only with the sanction of his tutor or guardian; in the third the restrictions were fewer, males being permitted to manage their own property, contract marriage, and make a will; but majority was not reached until the age of twenty-five. By English law there are two great periods into which life is divided—*infancy*, which lasts in both sexes until the twenty-first year, and manhood or womanhood. The period of infancy, again, is divided into several stages, marked by the growing development both of rights and obligations. Thus at twelve years of age a male may take the oath of allegiance; at fourteen both sexes are held to have arrived at years of discretion, and may therefore choose guardians, give evidence, and consent or disagree to a marriage. A female has the last privilege from the twelfth year, but the marriage cannot be celebrated until the majority of the parties without the consent of parents or guardians. At fourteen, too, both sexes are fully responsible to the criminal law. Between seven and fourteen there is responsibility only if the accused be proved *doli capax*, capable of discerning between right and wrong, the principle in that case being that *malitia supplet ætatem*. At twenty-one both males and females obtain their full legal rights, and become liable to all legal obligations. A seat in the British Parliament may be taken at twenty-one. Certain professions, however, demand as a qualification in entrants a more advanced age than that of legal manhood. In the church a candidate for deacon's orders must be twenty-three, and for priest's orders twenty-four years of age; and no clergyman is eligible for a bishopric under thirty. In Scotland infancy is not a legal term. The time previous to majority, which, as in England, is reached by both sexes at twenty-one, is divided into two stages: *pupilage* lasts until the attainment of puberty, which the law fixes at fourteen in males and twelve in females; *minority* lasts from these ages respectively until twenty-one. *Minority* obviously corresponds in some degree to the English *years of discretion*, but a Scotch minor has more personal rights than an English infant in the last stage of his infancy, *e.g.*, he may dispose by will of moveable property, make contracts, carry on trade, and, as a necessary consequence, is liable to be declared a bankrupt. Among foreign nations the law on this matter is somewhat varied. In France the year of majority is twenty-one, and the nubile age, according to the *Code Napoleon*, eighteen for males and fifteen for females, with a restriction as to the consent of guardians. In Germany majority is usually reached at twenty-four, though in some states (Bavaria, Saxony, Würtemburg, and Baden) the age is twenty-one. In the United States the age qualification for a president is thirty-five, for a senator thirty, and for a representative twenty-five.

AGELADAS, an eminent statuary of Argos, and the instructor of the three great sculptors, Phidias, Myron, and Polycletus. There is considerable difference in the statements of the date when he flourished. Thiersch meets the difficulty by supposing that there was another artist of the same name.

AGELNOTH, ÆTHELNOTH, or ETHELNOTH, known also as *Achelnotus*, son of Egelmaer the Earl, Archbishop of Canterbury in the reign of Canute, was trained in the monastery at Glastonbury, for which he afterwards obtained new privileges from the king. According to William of Malmesbury, he exercised a great and salutary influence over Canute in the way both of encouragement and restraint. He was appointed dean of Canterbury and chaplain to the king, and was raised to the archbishopric on the death of Living in 1020. He wisely counselled Canute to that course of policy which ultimately led to the fusion of Danes and Saxons, and their united resistance to the invasion of the Normans; and similar pacific counsels in the church brought about a temporary cessation of the mutual persecution on the part of the Benedictine and secular clergy. It being necessary that the archbishop should visit Rome in person to receive the pall, he repaired thither in 1022, and was received by Pope Benedictine VIII. with every mark of honour. At Pavia, on his way home, he purchased a relic, which was said to be the right arm of St Augustine of Hippo, at the cost of 100 talents of silver and 1 of gold. This he sent as a present to Leofric, the young Earl of Mercia. With his own wealth and liberal grants from Canute he restored and adorned his cathedral. When Canute died, he made the archbishop promise to be faithful to his sons by Emma, and the promise was so truly kept that Harold, the usurper, remained unconsecrated until after the death of Agelnoth (1038).

AGEN, the chief town of the department of Lot-et-Garonne in France, is situated on the right bank of the Garonne, 73 miles S.E. of Bordeaux. Through its excellent water communication it affords an outlet for the agricultural produce of the district, and forms an *entrepôt* of trade between Bordeaux and Toulouse. Its chief manufactures are sail-cloth, cotton, linen, leather, and starch. It has a college and several literary institutions, and is the seat of a bishop and a high court of justice. There is a fine bridge of eleven arches over the Garonne. In 1872 the population was 18,887.

AGENT, in *Diplomacy*, *Commerce*, and *Jurisprudence*, is a name applied generally to any person who acts for another. It has probably been adopted from France, as its function in modern civil law was otherwise expressed in Roman jurisprudence. Ducange (s.v. *Agentes*) tells us that in the later Roman empire the officers who collected the grain in the provinces for the troops and the household, and afterwards extended their functions so as to include those of government postmasters or spies, came to be called *agentes in rebus*, their earlier name having been *frumentarii*.

In *Diplomacy*, a class of semi-ambassadors termed agents have been employed generally between states of unequal power. The small community might send an agent to propitiate some powerful government, and secure its protection. A great power would, on the other hand, distribute its agents among the petty states which it kept in clientage, to see that no counteracting influence was at work among them. In this shape our Indian government keep agencies in the protected and other neighbouring states. Similarly, though this class does not fall within the scope of public international law, the self-governing British colonies now employ agents to attend to their interests and represent them in the mother country. The status of diplomatic agents, not of the classes of ambassadors, envoys, ministers, or *chargés d'affaires*, is extremely ill-defined and uncertain. (Phillimore's *International Law*, ii. 246; Heffter *Europäisches Völkerrecht*, § 222.) See AMBASSADOR; DIPLOMACY.

The law of PRINCIPAL AND AGENT has its origin in the law of mandate among the Romans, and fortunately even in England the spirit of that system of jurisprudence pervades this branch of the law. The law of agency is thus almost alike throughout the whole British empire, and a branch of the British commercial code, in which it is of great importance that different nations should understand each other's system, differs only slightly from the law of the rest of Europe.

In a general view of the law of agency it is necessary to have regard to the rights and duties of the principal, the agent, and the public. The agent should not do what he has no authority for; yet if he be seen to have authority, those with whom he deals should not be injured by secret and unusual conditions. The employer is bound by what his agent does in his name, but the public are not entitled to take advantage of obligations which are known to be unauthorised and unusual. The agent is entitled to demand performance by the principal of the obligations undertaken by him within the bounds of his commission, but he is not entitled to pledge him with a recklessness which he would certainly avoid in the management of his own affairs. It is in the regulation of these powers and corresponding checks in such a manner that the legal principle shall apply to daily practice, that the niceties of this branch of the law consist.

Agents are of different kinds, according to their stipulated r consuetudinary powers. The main restraint in the possible powers of an agent is in the old maxim, *delegatus non potest delegare*, designed to check the complexity that might be created by inquiries into repeatedly-deputed responsibility. The agent cannot delegate his commission or put another in his place; but in practice this principle is sometimes modified, for it so may arise from the nature of his office that he is to employ other persons for the accomplishment of certain objects. Thus, there is nothing to prevent a commercial agent from sending a portion of the goods entrusted by him to his own agent for disposal.

In the general case agency is constituted by the acceptance of the mandate or authority to act for the principal, and the evidence of this may be either verbal or in writing. The English statute of frauds requires an agent to have authority in writing for the purposes of its 1st, 2d, and 3d clauses relating to leases. "And it is a general rule, that an agent who has to execute a deed, or to take or give livery or seisin, must be appointed by deed for that purpose. Moreover, as a corporation aggregate can in general act only by deed, its agent must be so appointed, though it would seem that some trifling agencies, even for corporations, may be appointed without one." (Smith's *Mercantile Law*, B. I. chap. iv.) It is a general rule that those obligations which can only be undertaken by solemn formalities cannot be entered on by a delegate who has not received his authority in writing. But it is often constituted, at the same time that its extent is defined, by mere appointment to some known and recognised function—as where one is appointed agent for a banking establishment, factor for a merchant, broker, supercargo, traveller, or attorney. In these cases, usage defines the powers granted to the agent; and the employer will not readily be subjected to obligations going beyond the usual functions of the office; nor will the public dealing with the agent be bound by private instructions inconsistent with its usual character. While, however, the public, ignorant of such secret limitations, are not bound to respect them, the agent himself is liable for the consequences of transgressing them. Agency may also be either created or enlarged by *implication*. What the agent has done with his principal's consent the public are justified in believing him authorised to continue doing. Thus, as a familiar instance, the servant who has continued to purchase goods for his master at a particular shop on credit is presumed to retain authority and trust, and pledges his master's credit in farther purchases, though he should, without the knowledge of the shopkeeper, apply the articles to his own uses. The law is ever jealous in admitting as accessories of a general appointment to any particular agency the power to borrow money in the principal's name, to give his name to bill transactions, and to pledge him to guaranties; but all these acts may be authorised by implication, or by being the continuation of a series of transactions, of the same kind and in the same line of business, to which the principal has given his sanction. Thus an employer may, by the previous sanction of such operations, be liable for the bills or notes drawn, indorsed, and accepted by his clerk or other mandatary; nay, may be responsible for the obligations thus incurred after the mandatary's dismissal, if the party dealing with him knew that he was countenanced in such transactions, and had no reason to suppose that he was dismissed. In questions of this kind the distinction between a general and a special agent is important. A general agent is employed to transact all his principal's business of a particular kind, at a certain place,—as a factor to buy and sell; a broker to negotiate contracts of a particular kind; an attorney to transact his legal business; a shipmaster to do all things relating to the employment of a ship. Such an agent's power to do everything usual in the line of business in which he is employed is not limited by any private restriction or order unknown to the party with whom he is dealing. On the contrary, it is incumbent on the party dealing with a particular agent, *i.e.*, one specially employed in a single transaction, to ascertain the extent of his authority. The law applicable to a mercantile agent's power to pledge or otherwise dispose of the goods entrusted to him being in an unsatisfactory state, a statutory remedy was applied to it by an Act of 1825 (6 Geo. IV. c. 94), which required amendment in 1842 (5 and 6 Vict. c. 39).

The general object of these measures, which appear to extend to Scotland, is to make transactions with an agent in possession of goods as safe as dealing with the owner, to all who treat with him, as purchasers or otherwise, in good faith, and in ignorance of his want of ownership. Thus, when an agent ships goods in his own name, the consignee is entitled to a lien on them for any advances to the agent, or liabilities on bills or notes, if he has not notice by the bill of lading or otherwise at or before the time of the advance or receipt that such person is not the actual and *bonâ fide* owner. The presumption in such cases is ownership; and the burden of disproving it, as well as of showing that the consignee was aware of the mere agency, falls on the person questioning the validity. By the statutes, the person entrusted with and in possession of a bill of lading, dock warrant, warehouse-keeper's certificate, wharfinger's certificate, or other delivery warrant, is held the owner of the goods it represents, so as to render valid any transaction for their sale or disposition of the goods, or the deposit or pledge thereof, or of any part thereof, to parties ignorant of the limited ownership. Besides their effect in rendering valid, in this more comprehensive manner, operations conducted under the appearance and supposition of absolute ownership, the acts have separate provisions for the security of those who deal with agents, knowing them to be such. The acts, however, must be studied in their very words, which are not remarkable for clearness. The following brief description of their general effect, taken from Chitty's *Collection of Statutes*, may be useful:—"First, where goods or documents for the delivery of goods are pledged as a security for present or future advances, with the knowledge that they are not the property of the factor, but without notice that he is acting without authority, in such a case the pledgee acquires an absolute lien. Secondly, where goods are pledged by a factor without notice to the pledgee that they are the property of another, as a security for a pre-existing debt, in that case the pledgee acquires the same right as the factor had. Thirdly, where a contract to pledge is made in consideration of the delivery of other goods or documents of title, upon which the persou delivering them up had a lien for a previous advance (which is deemed to be a contract for a present advance), in that case the pledgee acquires an absolute lien to the extent of the value of the goods given up." The statutes are applicable only to proper mercantile transactions, and not, for example, to advances upon the security of furniture in a furnished house to the apparent owner. (See Smith's *Leading Cases*, vol. i. p. 759 *sqq.*, 6th ed.)

The obligations of the principal are—to pay the agent's remuneration, or, as it is often called, *commission*, the amount of which is fixed by contract or the usage of trade; to pay all advances made by the agent in the regular course of his employment; and to honour the obligations lawfully undertaken for him. The agent is responsible for the possession of the proper skill and means for carrying out the functions which he undertakes. He must devote to the interests of his employer such care and attention as a man of ordinary prudence bestows on his own—a duty capable of no more certain definition, the application of it as a fixed rule being the function of a jury. He is bound to observe the strictest good faith; and in some instances the law interposes to remove him from temptation to sacrifice his employer's interests to his own: thus, when he is employed to buy, he must not be the seller; and when employed to sell, he must not be the purchaser. He ought only to deal with persons in good credit, but he is not responsible for their absolute solvency unless he guarantee them. A mercantile agent guaranteeing the payments he treats for is said to hold a *del credere* commission.

In Scotland the procurators or solicitors who act in the preparation of cases in the various law-courts, and all who take out the attorney licence, are called agents. See ATTORNEY.

In France, the *Agents de Change* were formerly the class generally licensed for conducting all negotiations, as they were termed, whether in commerce or the money market. Of late the term has been practically limited to those who conduct, like our stockbrokers, transactions in public stock; and it is understood that it is rather as speculators than as agents that the majority of them adopt the profession. The laws and regulations as to *courtiers*, or those whose functions were more distinctly confined to transactions in merchandise, have been mixed up with those applicable to *agents de change*. Down to the year 1572 both functions were free; but at that period, partly for financial reasons, a system of licensing was adopted at the suggestion of the Chancellor l'Hôpital. Among the other revolutionary measures of the year 1791, the professions of agent and *courtier* were again opened to the public. Many of the financial convulsions of the ensuing years, which were due to more serious causes, were attributed to this indiscriminate removal of restrictions, and they were reimposed in 1801. From that period regulations have been made from time to time as to the qualifications of agents, the security to be found by them, and the like. They are now regarded as public officers, appointed, with certain privileges and duties, by the government, to act as intermediaries in negotiating transfers of public funds and commercial stocks, and for dealing in metallic currency.

AGESILAUS, king of the Lacedæmonians, the second of the name, son of Archidamus II., was, through the influence of Lysander, raised to the throne in 398 B.C., in opposition to the superior claim of his nephew Leotychides. Immediately on his accession he advised the Lacedæmonians to anticipate the king of Persia, who was making great preparations for war, and attack him in his own dominions. He was himself chosen for this expedit and gained so many advantages over the enemy that, if the league which the Athenians and the Thebans formed against the Lacedæmonians had not obliged him to return home, it seems probable that he would have carried his victorious arms into the very heart of the Persian empire. But he readily gave up all these triumphs to come to the succour of his country, which he happily relieved by his victory over the allies at Chæronea, in Bœotia, 394 B.C. He obtained another near Corinth; but, to his great mortification, the Thebans afterwards gained several victories over the Lacedæmonians. This at first raised a clamour against him. He had been ill when the course of victory turned in favour of the enemy; but as soon as he was able to act in person his valour and prudence prevented the Thebans from reaping the advantages of their successes; so that it was generally believed that, had he been in health at the beginning, the Lacedæmonians would have sustained no losses, and that without him all would have been lost. It cannot be denied, however, that his fondness for war occasioned many losses to his countrymen, and led them into enterprises which in the end contributed much to weaken their power. He died in the third year of the 103d Olympiad, being the 84th year of his age and 38th of his reign, and was succeeded by his son Archidamus. Agesilaus, though a vigorous ruler and great general, was of small stature, and lame from his birth. His accession to the throne was, indeed, opposed on this ground, an oracle having foretold evils to Sparta under a lame sovereignty. As we have seen, the oracle was so far fulfilled that many troubles befell the state during his reign. Few of these, however, are traceable to the policy of the king, whose public life was illustrated by a series of brilliant victories over the enemies of his country. In character, Agesilaus seems to have possessed the Spartan virtues of courage, temperance, and fortitude, without the Spartan vices of hardness, cupidity, and injustice. His life and merits have been commemorated by Xenophon, Plutarch, Diodorus Siculus, and Cornelius Nepos.

AGGREGATION, STATES OF, the three states—*solid*, *liquid*, and *gaseous*—in which matter occurs, depending on the degree of cohesion that subsists between the molecules or atoms of material bodies. In the solid state, the molecules cohere so firmly that their relative positions cannot be changed without the application of force, and the body retains a definite form; in the liquid state, they move freely and readily on each other, the cohesion that exists being so slight that the body has itself no form; in the gaseous state, they are affected by an elastic force that amounts to repulsion, tending to separate them, and so diffuse them through an increased space. The metals, glass, wood, &c., are solids; water and atmospheric air are the most familiar types of liquid and gaseous bodies. The name *fluid* is sometimes used to denote both gases and liquids, which are designated *elastic* and *non-elastic* fluids respectively. These states of aggregation are not in every case—many now believe they are not in any case—permanent and unchangeable. Metals can be melted and vaporised; the liquid water is convertible into ice and into steam; and a number of what were formerly reckoned fixed or permanent gases have been liquified and solidified. Solids are reduced to liquid, and liquids to gaseous forms, principally by heat; pressure effects changes of the opposite kind.

AGHRIM, or AUGHRIM, a small village in Galway, 4 miles W. of Ballinasloe, is rendered memorable by the decisive victory gained there, on 12th July 1691, by the forces of William III., under General Ginkell, over those of James II., under the French general St Ruth. The Irish, numbering 25,000, and strongly posted behind marshy ground, at first maintained a vigorous resistance; but Ginkell, having penetrated their line of defence, and their general being struck down by a cannon-ball at this critical moment, they were at length overcome and routed with terrible slaughter. The loss of the English did not exceed 700 killed and 1000 wounded; while the Irish, in their disastrous flight, lost about 7000 men, besides the whole material of the army. This defeat rendered the adherents of James in Ireland incapable of farther efforts, and was speedily followed by the complete submission of the country.

AGINCOURT, or AZINCOURT, a French village, in the department of Pas de Calais, situated in 50° 35′ N. lat., 2° 10′ E. long., famous on account of the victory obtained there by Henry V. of England over the French. Following the example of several of his predecessors, the young king crossed over to France in the third year of his reign on a military expedition. Having landed at the mouth of the Seine, he took and sacked Harfleur after a siege of thirty-six days, but the army was so much reduced in strength, especially by disease, that some of Henry's advisers counselled a return home without following up the advantage. The proud spirit of the young king, however, would not submit to this, and he resolved on a march through the country to what was then the English fortified town of Calais, though he knew that a force vastly superior to his own was in the field to oppose him. On the morning of Friday, the 25th of October, 1415 A.D., St Crispin's day, the English and French armies were ranged in order of battle, each in three lines, with bodies of cavalry on both wings. The Constable d'Albert, who commanded the French army, fell into the snare that was laid for him, by drawing up his army in a narrow plain between two woods. This deprived him in a great measure of the advantage he should have derived from the prodigious superiority of his numbers, by obliging him to make his lines unnecessarily deep, and to crowd his troops, particularly his cavalry, so close together that they could hardly move or use their arms. The numbers of the French are differently estimated at from 50,000 to 150,000 men, but the latter number is a gross exaggeration. The first line was commanded by the Constable d'Albert, the dukes of Orleans and Bourbon, and many other nobles; the dukes of Alençon, Brabant, and Barre conducted the second line; and the earls of Marle, Damartine, Fauconberg, &c., were at the head of the third line. The king of England placed 200 of his best archers in ambush in a low meadow on the flank of the first line of the French. His own first line consisted wholly of archers, each of whom, besides his bow and arrows, had a battle-axe, a sword, and a stake pointed with iron at both ends, which he fixed before him in the ground, the point inclining outwards, to protect him from cavalry. This was a new invention, and had a happy effect. That he might not be encumbered, Henry dismissed all his prisoners on their word of honour to surrender themselves at Calais if he obtained the victory, and lodged all his baggage near the village of Maisoncelles, in his rear, under a slender guard. The main body of the English army, consisting of men-at-arms, was commanded by Henry in person; the vanguard, committed to Edward Duke of York at his particular request, was posted as a wing to the right; and the rearguard, commanded by Lord Camois, as a wing on the left. The archers were placed between the wings, in the form of a wedge. The lines being formed, the king, in shining armour, mounted on a fine white horse, rode along them, and addressed each corps with a cheerful countenance and in encouraging language. To inflame their resentment against their enemies, he spoke of the cruelty practised by the French against their prisoners; and to rouse their love of honour, he declared that every soldier in the army who behaved well should thenceforth be deemed a gentleman, and entitled to bear coat armour. The two armies, drawn up in this manner, stood a considerable time gazing at one another in silence. But the English king, dreading that the French would discover the danger of their situation and decline a battle, commanded the charge to be sounded, about ten o'clock in the forenoon. At that instant the first line of the English kneeled down and kissed the ground; and then starting up, discharged a flight of arrows, which did great execution among the crowded ranks of the French. Immediately after, upon a signal being given, the archers in ambush arose, and, discharging their arrows on the flank of the French line, threw it into some disorder. The battle now became general, and raged with great fury. The English archers, having expended all their arrows, threw away their bows, and rushing forward, made dreadful havoc with their swords and battle-axes. The first line of the enemy was by these means defeated, its leaders being either killed or taken prisoners. The second line, commanded by the Duke d'Alençon (who had made a vow either to kill or take the king of England, or to perish in the attempt), now advanced, and was met by the second line of the English, led by the king. The duke forced his way to the king, and assaulted him with great fury; but Henry brought him to the ground, where he was instantly despatched by the surrounding soldiers, receiving innumerable wounds. Discouraged by this disaster, the second line made no more resistance, and the third fled without striking a blow; yielding a complete and glorious victory to the English, after a violent struggle of three hours' duration. In the circumstances, the victory could not be followed up. Henry and his army returned at once by Calais to England, and entered London with a pageant of unprecedented splendour. The number slain in the battle is variously stated. The loss to the conquerors is generally reckoned at 1600 men, and the French are said to have left 10,000 slain on the field, including the constable, three dukes, five counts, and ninety barons. (See the Histories of Britain; and *Battle of Agincourt*, by Sir Harris Nicolas.)

AGIO (Ital. *aggio*, exchange, discount), a term used in commerce to denote the difference between the real and the nominal value of money. In some states the coinage is so debased, owing to the wear of circulation, that the real is greatly reduced below the nominal value. Where this reduction amounts, *e.g.*, to 5 per cent., if 100 sovereigns were offered as payment of a debt in England while such sovereigns were current there at their nominal value, they would be received as just payment; but if they were offered as payment of the same amount of debt in a foreign state, they would be received only at their intrinsic value of £95, the additional £5 constituting the agio. Where the state keeps its coinage up to a standard value, no agio is required. The same principle is applied to the paper currency of a country when reduced below the bullion value which it professes to represent. According as there is more demand for gold or for paper money for the purposes of commerce, it often becomes necessary, in order to procure the one of the higher current value, to pay a premium for it, which is called the agio. In countries where silver coinage is the legal tender, agio is sometimes allowed for payment in the more convenient form of gold.

AGIS. Four kings of this name reigned at different periods in Sparta. The first of the name was the son of Eurysthenes, and is supposed to have reigned about 1032 B.C. The designation of *Helots* is said to have had its rise in his time, from the unsuccessful revolt of the inhabitants of Helos, and their final enthralment by the Spartans.

AGIS II. succeeded his father Archidamus, and reigned from 427 to 399 B.C. He distinguished himself during the Peloponnesian war as an able and successful general, and headed the Spartans at the great and decisive battle of Mantinea.

AGIS III. succeeded his father Archidamus III., 338 B.C. He took an active part in the league of the Grecian states against Alexander the Great, and at the head of their forces defeated a Macedonian army under Corragus. He was slain, about 331 B.C., in a battle with Antipater, under the walls of Megalopolis.

AGIS IV., son of Eudamidas II., and lineally descended from Agesilaus II., succeeded his father 244 B.C., and reigned four years. He was more distinguished for the social reforms he attempted to introduce at Sparta than for his success as a general. The degenerate state of the Spartan commonwealth led him to attempt a reformation by restoring the institutions of Lycurgus, and, in the spirit of a true reformer, he set the example in his own person and household. His excellent intentions were seconded by all the younger and poorer portion of the community; but the rich and luxurious were vehemently opposed to measures which threatened to interfere so seriously with their influence and pleasures. His colleague, Leonidas, headed the opposition, and busily propagated the suspicion that Agis aspired to tyranny, by obliterating the distinctions of society and increasing the power of the multitude. Agis was supported by the influence of his uncle Agesilaus, who, being deeply in debt, was highly favourable to the proposed changes. Lysander and Mandroclides, two of the ephori, were also strenuous promoters of the reform. When the time came for Agis to propose in the senate a general discharge of debts and a new division of lands, the measure was lost by a minority of one. The triumph of Leonidas, however, was short. Being accused by Lysander of having violated the laws, he took refuge in the temple of Minerva, and refusing to appear in his own defence, was degraded from his dignity and banished to Tegæa. His son-in-law, Cleombrotus, was elected in his stead. The next election of ephori proved unfavourable to the party of Agis. Lysander and Mandroclides were tried for innovation, but succeeded in persuading the two kings to eject the new magistrates from office, which was effected in the midst of much tumult. The reformation might now have been established but for the intrigues of Agesilaus, whose selfish schemes counteracted the good intentions of the two kings. At this time the Achæans sent to Sparta for assistance in the war with the Ætolians, which was granted. Agis received the command of the troops, and though he gained no advantage over the cautious Aratus, the Achæan general, he conducted the campaign with considerable credit from the good discipline he maintained in his army. On his return he found that the misconduct of Argesilaus had resulted in a revolution and the recall of Leonidas. He took refuge in the temple of Minerva, Cleombrotus in that of Neptune. Leonidas contented himself with banishing his son-in-law, but resolved on the ruin of Agis. The unfortunate king was accordingly seized and cast into prison, where, after a mock trial, he was sentenced to be strangled. His mother and grandmother in vain entreated to gain him a public hearing: they were insidiously permitted to visit him in prison, where they shared his fate.

AGISTMENT (from the old French *gésir* or *gir*, to lie; see *Edin. Rev.*, vol. cxxviii. p. 79), the profit arising from taking in cattle to lie and pasture in one's lands, applied more particularly, in the first instance, to the proceeds of pasturage in the king's forests. The tithe of agistment, or "tithe of cattle and other produce of grass lands," was formally abolished by the Act of Union, on a motion submitted with a view to defeat that measure. (See *Edin. Rev.*, vol. xxxiv. p. 73.)

AGNANO, LAGO D', a small circular lake near Naples, about two miles in circumference, and evidently situated in the crater of an extinct volcano. On its banks are the *stufe*, or natural vapour-baths of San Germano, beneficial in cases of rheumatic disease; and on its opposite shore is the famous *Grotta del Cane*, from the floor of which carbonic acid is continually evolved, rising to a height of about 18 inches, in such quantity as to kill dogs that enter it, while a man, on account of his erect posture, wholly escapes the effects of the gas. (See Spallanzani's *Travels.*) The grotto is a small artificial excavation, 12 feet long by 4 or 5 wide and 6 feet high, seemingly made for obtaining puzzolano, or earthy volcanic tufa.

AGNATES (*Agnati*), in *Roman Law*, are persons related through males only, as opposed to cognates. Relationship by agnation was founded on the idea of the family held together by the *patria potestas; cognatio* involves simply the modern idea of kindred.

AGNESI, MARIA GAETANA, an Italian lady pre-eminently distinguished for her scientific attainments, was born at Milan on the 16th of May 1718, her father being professor of mathematics in the university of Bologna. When only nine years old, she had such command of Latin as to be able to publish an elaborate address in that language, maintaining that the pursuit of liberal studies was not improper for her sex. By her thirteenth year she had acquired Greek, Hebrew, French, Spanish, German, and other languages. She was in consequence generally known as "the Walking Polyglot." Two years later her father began to assemble in his house at stated intervals a circle of the most learned men in Bologna, before whom she read and maintained a series of theses on the most abstruse philosophical questions. President De Brosses has given an interesting account of one of those meetings, at which he was present, in his *Lettres sur l'Italie* (tom. i. p. 243); and a permanent record of Agnesi's share in them has been preserved in the *Propositiones Philosophicæ*, which her father caused to be published in 1738. These displays, being probably not altogether congenial to Maria, who was of a retiring disposition, ceased in her twentieth year, and it is even said that she had at that age a strong desire to enter a convent. Though the wish was not gratified, she lived from that time in a retirement almost conventual, avoiding all society, and devoting herself entirely to the study of mathematics. The most valuable result of her labours was the *Instituzioni Analitiche ad Uso della Gioventu Italiana*, which was published at Milan in 1748. The first volume treats of the analysis of finite quantities, and the second of the analysis of infinitesimals. A French translation of the second volume, by D'Antelmy, with additions by Bossut, appeared at Paris in 1775; and an English translation of the whole work by Colson, the Lucasian professor of mathematics at Cambridge, was published after his death at the expense of Baron Masères. The great merit of the work was universally recognised at the time of its publication; and though in the long interval that elapsed before the English translation appeared the methods of analysis had been greatly improved, it was recognised by a writer in the *Edinburgh Review* (1803) as still the best introduction to the works of Euler and other mathematicians of the continent. Madame Agnesi also wrote a commentary on the *Conic Sections* of the Marquis de l'Hôpital, which, though highly praised by those who saw it in manuscript, was never published. In 1750, on the illness of her father, she was appointed by Pope Benedict XIV. to occupy the chair of mathematics and natural philosophy at Bologna. After the death of her father, in 1752, she carried out a long-cherished purpose by giving herself to the study of theology, and especially of the fathers. Another purpose, which seems also to have been long cherished, was now also fulfilled. After holding for some years the office of directress of the Hospice Trivulzio for Blue Nuns at Milan, she herself joined the sisterhood, and in this austere order ended her days (1799).

AGNESI, Maria Teresa, sister of the above (died 1780), was well known as a musician, having composed a number of cantatas, besides three operas—*Sophonisbe*, *Ciro in Armenia*, and *Nitocri*.

AGNOETÆ (from ἀγνοέω, to be ignorant of), in *Church History*, a sect of ancient heretics who maintained that Christ's human nature did not become omniscient by its union with His divinity. Its founder was Themistius, a deacon of the Monophysites in Alexandria in the 6th century. The sect was anathematised by Gregory the Great.

AGNOLO, Baccio d', wood-carver, sculptor, and architect, was born at Florence in 1460. The first was his original calling, and he attained considerable distinction in it before he turned his attention to architecture, which he went to Rome to study in 1530. He still carried on wood-carving, and his studio was the resort of the most celebrated artists of the day—Michael Angelo, Sansovius, the brothers Sangallo, and others. On his return to Florence he devoted himself chiefly to architecture, and planned many of the finest palaces and villas of that city, such as the Villa Borghese and the Palais Bartolini. The latter was the first dwelling-house which had what had previously been confined to churches—frontispieces of columns to the doors and windows. For introducing this fashion Agnolo incurred the ridicule of the Florentines; but it nevertheless established itself firmly. Another much-admired work of this architect is the campanile or bell-tower of the church *Di Santo Spirito* in Florence. He was also engaged to complete the drum of the cupola in the metropolitan church *Di Santa Maria del Fiore;* but Michael Angelo found fault with his plans, and the work remains unexecuted to this day. He died in 1543, leaving three sons, architects, one of whom, Giuliano, completed his father's unfinished works.

AGNONE, a town of South Italy, at the foot of Monte Capraro, 20 miles N.W. of Campobasso. It has 10,230 inhabitants, chiefly employed in the manufacture of copper wares, for the excellence of which it is celebrated.

AGNUS DEI, the figure of a lamb bearing a cross, symbolical of the Saviour as the "Lamb of God." The device occurs in mediæval sculptures, but the name is especially given in the Church of Rome to a small cake made of the wax of the Easter candles, and impressed with this figure. Since the 9th century it has been customary for the popes to bless these cakes, and distribute them, on the Sunday after Easter, among the faithful, by whom they are highly prized as having the power to avert evil. In modern times the distribution has been limited to persons of distinction, and is made by the pope on his accession, and every seven years thereafter.

Agnus Dei is also the popular name for the anthem beginning with these words, which is said to have been introduced into the missal by Pope Sergius I. (687–701). Based upon John i. 29, the Latin form is *Agnus Dei, qui tollis peccata mundi, miserere nobis.* In the celebration of the mass it is repeated three times before the communion, and it is also appended to many of the litanies.

AGOBARD, a Frank, born in 779, became coadjutor to Leidrad, archbishop of Lyons, in 813, and on the death of the latter succeeded him in the see (816). He was one of the chief supporters of Lothaire and Pepin in their conspiracy against their father, Louis le Debonnaire, and was in consequence deposed by the council of Thionville (835). On making an apology for his conduct, and becoming reconciled to the emperor, he was reinstated in 837. Agobard's works, which were edited by Baluze in 1665 (2 vols. 8vo), show him to have been a man of clear intellect, strongly opposed to the superstitious notions of the time. He wrote against image-worship, the belief in witchcraft, the ascription of tempests to the influence of sorcerers, and trial by the ordeal of fire and water. In the adoptionist controversy Agobard took a prominent part on the orthodox side. He died at Saintonge in 840.

AGONALIA, in *Roman Antiquity*, festivals celebrated on the 9th January, 21st May, and 11th December in each year, in honour of Janus, whom the Romans invoked before undertaking any affair of importance. Ovid, in his *Fasti*, i. 319–332, mentions various etymologies of the word.

AGONIC LINES (from ἀ privative, and γωνία, an angle), the imaginary lines on the earth's surface where the magnetic needle indicates no declination or deviation from the terrestrial meridian—that is, points to the true north and south. There are two great primary agonic lines, varying from time to time, the courses of which for the epochs 1787 (from Hansteen's *Magnetismus der Erde*) and 1840 (by General Sir E. Sabine) are figured in Keith Johnston's *Physical Atlas*.

AGONOTHETA, or Agonothetes (ἀγών and τίθημι), in *Grecian Antiquity*, was the president or superintendent of the sacred games. At first the person who instituted the games and defrayed the expenses was the Agonothetes; but in the great public games, such as the Olympic, Pythian, &c., these presidents were the representatives of different states, or were chosen from the people in whose country the games were celebrated. They received the several titles of αἰσυμνῆται, βραβευταί, ἀγωνάρχαι, ἀγωνοδίκαι, *ἀθλοθέται*. They were also called *ῥαβδοῦχοι* or *ῥαβδονόμοι*, from the rod or sceptre emblematic of their authority.

AGORA (*ἀγείρω*, to congregate), the place used among the ancient Greeks as a public market, and corresponding in general with the Roman forum. From its convenience as a meeting-place, it became in most of the cities of Greece the general resort for social and political purposes. In Thessaly, however, the market-place was kept apart from "the field of freedom," where the commons met; and at Sparta a similar provision was made by the institutions of Lycurgus, that nothing might distract the attention of the auditors. At Athens, with the increase of commerce and political interest, it was found advisable to call public meetings at the Pnyx or the temple of Bacchus; but the important assemblies there, such as meetings for ostracism, were held in the agora. In the best days of Greece the agora was the place where nearly all public traffic was conducted. To frequent it, therefore, was equivalent to being actively engaged in business; and "he has forsaken the agora," indicated that a man was a suspicious character. The agora was most frequented in the forenoon, and then only by men. Slaves did the greater part of the purchasing, though even the noblest citizens of Athens did not scruple to buy and sell there. The name *ἀγορά* was also given (and this is perhaps the primary use of the word) to the assemblies of the people in the Grecian states. These assemblies were convened by proclamation by order of the sovereign power, a herald inviting all concerned to the agora. The right of speech and of vote in these assemblies appears to have been restricted to the nobles, all that was allowed to the populace being the indication of their sentiments on the topics brought before them by signs of applause or disapproval. At Athens the old agora lay to the west of the citadel. It was adorned with trees planted by Cimon the conqueror of the Persians; and around it numerous public buildings were erected, such as the senate hall and the law courts. The new agora lay to the north of the Acropolis, in the Eretrian quarter. Pausanias is the great architectural authority on the agoræ of Megalopolis, Corinth, Elia, Messina, Sparta, &c. Palladius and Vitruvius also give details. The remains of different agoræ are described in the works of Texier, Newton, Barth, and other travellers.

AGORANOMOI, magistrates in the republics of Greece, whose position and duties were similar to those of the ædiles of Rome. In Athens there were ten, chosen annually by lot, five of whom took charge of the city, and five of the harbour. The former saw to the maintenance of order and decency in the markets, took cognisance of the purity of the articles exposed for sale and of all weights and measures, and collected the dues; the latter received the harbour dues and enforced the shipping regulations.

AGORDO, a town in North Italy, 12 miles N.W. of Belluno. The valley of Imperina, in its vicinity, contains the richest copper mines in Italy. Population, 3000.

AGOSTA, or AUGUSTA, a city of Sicily, 14 miles N. of Syracuse, and in the province of that name. It is built on a peninsula, and is united to the mainland by a narrow causeway. By some writers it is supposed to occupy the site of ancient *Megara Hyblæa*. The modern city, which was founded by the emperor Frederick II. in 1229–33, suffered severely during the wars of succeeding centuries, and was several times sacked. It had, however, attained considerable opulence when, in 1693, it was overthrown by an earthquake, the effects of which were aggravated by the explosion of the powder magazine of the citadel. One-third of the inhabitants perished in this disaster. When the city was rebuilt, the streets were laid out in parallel lines, and the houses were constructed with low roofs, so as to mitigate the results of any recurrence of the calamity. Agosta is fortified towards both sea and land; and the harbour, though rather difficult of access, is commodious and well sheltered. The chief trade of the town is in salt; and the other exports include wine, cheese, oil, honey, and sardines. Near Agosta the Dutch were defeated by the French in a naval engagement in 1676, and their famous admiral, De Ruyter, was mortally wounded. Population (1865), 9735.

AGOSTINI, LEONARDO, an eminent antiquary of the 17th century, born at Siena. After being employed for some time by Cardinal Barberini to collect works of art for the Barberini palace, he was appointed by Pope Alexander VII. superintendent of antiquities in the Roman states. He issued a new edition of Paruta's *Sicilian Medals*, with engravings of 400 additional specimens; but a promised volume of letterpress explanation never appeared. In conjunction with Bellori he also published a work on antique sculptured gems, which was translated into Latin by Gronovius (Amsterdam, 1685).

AGOSTINO and AGNOLO (or ANGELO) DA SIENA, two brothers, architects and sculptors, who flourished in the first half of the 14th century. Della Valle and other commentators deny that they were brothers. They certainly studied together under Giovanni Pisano, and in 1317 were jointly appointed architects of their native town, for which they designed the Porta Romana, the church and convent of St Francis, and other buildings. On the recommendation of the celebrated Giotto, who styled them the best sculptors of the time, they were chosen to execute the tomb of Guido, bishop of Arezzo, which that artist had designed. It was esteemed one of the finest artistic works of the 14th century, but unfortunately was destroyed by the French under the Duke of Anjou.

AGOSTINO, PAOLO, an eminent Italian musician, born at Valerano in 1593. He studied under Nanini, and succeeded Ugolini as conductor of the Pope's orchestra in St Peter's. His musical compositions are numerous and of great merit, an *Agnus Dei* for eight voices being specially admired. He died in 1629.

AGOUTI, a genus of mammals (the *Dasyprocta*) found in South America and in some of the West Indian islands, belonging to the same family as the guinea-pig, viz., that of *Cavidæ* in the order *Rodentia*. The largest and commonest species is the *D. Aguti*, somewhat resembling a rabbit, but about the size of a hare, whence it is sometimes called the rabbit or hare of South America. The feet have large and strong claws, but the animal does not burrow; the hind legs are very long, and when eating it squats on them, feeding itself with its fore-paws; and the tail is, except in one species, a very short naked stump. The agoutis are gregarious, live chiefly in woods, and feed on vegetables exclusively, especially on roots and nuts. They commit great havoc in sugar plantations by gnawing the roots of the canes, and in sugar-growing localities are therefore destroyed as vermin. The flesh, which is tender and well-flavoured, is a common article of diet in Guiana and Brazil. When the Antilles and Bahamas were discovered they are said to have been overrun with these animals, which were the largest quadrupeds then found in the islands.

AGRA, a division, district, and city of British India, under the jurisdiction of the lieutenant-governor of the North-Western Provinces. THE AGRA DIVISION comprises the six districts of Agra, Etáwah, Mainpurí, Farrakhábád, Etah, and Mathurá. It is bounded on the N. by the Alígarh district; on the W. by the Bhartpur, Dholpur, and Gwalior states; on the S. by the Jalaun and Cawnpur districts; and on the E. by the Ganges. Agra division contains, according to the census of 1872, a population of 5,038,136 souls; of whom 4,607,946 are Hindus, 427,834 Mahometans, and 2356 Christians and others.

AGRA DISTRICT lies between 26° 43′ 45″ and 27° 24′ 15″ N. lat., and between 77° 28′ and 78° 53′ E. long.

It is bounded on the N. by the district of Mathurá; on the E. by the Mainpurí and Etáwah districts; on the S. by the Gwalior territory and the Dholpur state; and on the W. by the Bhartpur territory. Its area in 1872 was returned at 1873 square miles, and its population at 1,094,184 souls. The general appearance of the district is that common to the Doab, a level plain intersected by watercourses (nálás) and ravines. The only hills are the sandstone elevations in the west and south-west of the district. The principal rivers are the Jamná, Chambal, Uttangan, and Kharí. The Jamná intersects the district, cutting off the subdivisions of Itmadpur and Firozábád; and a branch of the Alígarh division of the Ganges Canal passes through its northern parts. The general elevation of the district is estimated at from 650 to 700 feet above the level of the sea. The soil is sandy; many of the wells are brackish, and the local water supply is scanty. The failure of the periodical rains during the monsoon suffices to produce great scarcity, sometimes reaching the famine point. Only five towns are returned by the census as containing upwards of 5000 inhabitants, viz., Agra city (the capital of the district), population 149,008; Fathipur Sikrí, the site of Akbar's famous mosque and palace, 6878; Firozábád, 14,255; Pináhát, 6571; and Saimrá, 5704. There are three municipalities, viz., Agra city, Firozábád, and Fathipur Sikrí. These muncipalities derive their local revenue from octroi and from property within the municipal limits. The total municipal income and its incidence per head of the population are as follows:—Agra city, municipal income, £15,441, incidence per head, 2s. 0¾d.; Firozábád, £724—1s. per head; Fathipur Sikrí, £366—1s. per head. The land revenue of the whole district was stated in 1871 at £162,882, and the gross revenue at £660,526. A scheme of rural instruction by means of indigenous schools was introduced in 1848. In 1871-72 there were 431 schools in the district, attended by 10,823 pupils, of whom 8820 were Hindus, 1293 Mahometans, and 710 of other denominations. The educational establishments within the city will be described below. The police force consisted of 1358 regular police in 1871, equal to one man to every 1·37 square miles of area, or one to every 805 inhabitants; and a village watch or rural constabulary of 1921 men, being one man to every 0·97 square miles of area, or one to every 570 inhabitants. The chief crimes of the district, in common with the rest of the Doab, are burglary and theft.

Agra City, situated on the banks of the Jamná river, in 27° 10′ N. lat., and ′ [illegible] ′ E. long., is the head-quarters of the division and capital of the district. Formerly it was the provincial capital also, but since the mutiny the seat of government has been removed from Agra to Allahábád. The city, which is about 4 miles in length by 3 in breadth, sweeps along the banks of the river in a semicircle. The principal thoroughfares are a fine broad street intersecting the town from north to south; and the Strand, which runs along the banks of the river for a distance of 2 miles. This road measures 80 feet in width, and is said to have been constructed by the destitute poor during the famine of 1838. In 1846 the population of the city was estimated at 66,000; in 1872 it was ascertained to be 149,000. The conservancy and improvement of the town are in the hands of a municipal committee, which derives its funds principally from octroi duties. In 1871-72, the municipal income was returned as follows:—Octroi duties, £13,587; miscellaneous receipts, such as rent from land belonging to the municipality, &c., £1854—total, £15,441. The details of municipal expenditure were as follow:—Establishment and cost of collection, £1667, 12s.; police, £4041, 12s.; conservancy, £1749, 12s.; lighting, £672, 14s.; watering, £255, 10s.; original works, £3561, 16s.; repairs, £1429, 2s.; education, £120; vaccination, £36, 6s.; dispensary, £360; charities, £240; grants to cantonments, museum, &c., £1465, 2s.—total, £15,599, 6s. The principal educational establishment in Agra is the Government College, a handsome building, situated in the civil lines a short distance from the town. It was established in 1820; in 1872 it contained 385 pupils. The other chief schools are the St John's College, established by the Church Missionary Society in 1854; the Victoria College, established in 1862; and St Peter's Catholic College. These three colleges in 1872 had 643 pupils on their rolls. There is also a medical college, founded in 1853. The total number of students admitted into it during the sixteen years from 1855 to 1870 inclusive, was 1168, of whom 235 passed the prescribed examination and received appointments in the government medical service. The Agra fort has a very imposing appearance, but is of no great strength. It occupies a large space of ground on the banks of the river, enclosed by high walls and towers of red stone. The fortress was constructed by the Emperor Akbar in the latter part of the 16th century, and exceeds a mile in circuit. In 1803 the place was held by the Marhattás; but being invested by Lord Lake's army, it surrendered after a day's bombardment. During the mutiny of 1857 it formed a place of refuge for the European and Christian community of Agra, and was threatened by the insurgent sepoys. The buildings of most note within the walls of the fort are the palace and hall of audience of Sháh Jahán, and the Motí Masjid, or "Pearl Mosque."

"In the centre of the palace," says Mr Fergusson in his *History of Architecture*, vol. ii., pp. 699-700, "is a great court 500 feet by 370, surrounded by arcades, and approached at the opposite ends through a succession of beautiful courts opening into one another by gateways of great magnificence. On one side of this court is the great hall of the palace, the Díwání-Khás, 208 feet by 76, supported by three ranges of arcades of exquisite beauty. It is open on three sides, and with a niche for the throne at the back. This hall is now used as an arsenal. Behind it are two smaller courts, the one containing the Diwáni-Am or hall of private audience, the other the harem. The hall in the former is one of the most elegant of Sháh Jahán's buildings, being wholly of white marble inlaid with precious stones, and the design of the whole being in the best style of his reign."

The Motí Masjid or Pearl Mosque is the most elegant mosque of Indian-Mahometan architecture. Mr Fergusson describes it as follows:—

"Its dimensions are considerable, being externally 235 feet east and west, by 190 feet north and south, and the courtyard 155 feet square. The mass is also considerable, as the whole is raised on a terrace of artificial construction, by the aid of which it stands well out from the surrounding buildings of the fort. Its chief beauty consists in its courtyard, which is wholly of white marble from the pavement to the summit of its domes. In design it somewhat resembles the great Dehli mosque, except that the minarets are omitted, and the side gateways are only recesses. The western part, or mosque properly so called, is of white marble inside and out; and, except an inscription from the Kurán inlaid with black marble as a frieze, has no ornament whatever beyond the lines of its own graceful architecture."

Agra, however, is even more famous for the Táj-Mahal, a splendid mausoleum built by the Emperor Sháh Jahán for the remains of his favourite wife, Mumtázá Mahal, and where he himself is also buried. The building is of white marble, with four tall minarets of the same material, one at each corner. The whole rises from an elevated marble terrace. The following account is extracted from Mr Fergusson's *History of Architecture*, pp. 692-694:—

The enclosure, including the gardens and outer court, is a parallelogram of 1860 feet by more than 1000 feet. The outer court, surrounded by arcades and adorned by four gateways, forms an oblong, occupying in length the whole breadth of the inclosure, by about 450 feet in depth. The principal gateway, measuring 110 feet by 140, leads from the court to the gardens, which, with their marble canals and fountains and cypress trees, are almost as beautiful as the tomb itself. The tomb stands on a raised platform 18 feet high, faced with white marble, and is exactly 313 feet square

At each corner of this terrace stands a minaret 133 feet in height, and of the most exquisite proportions—more beautiful, perhaps, than any other in India. In the centre of the marble platform stands the mausoleum, a square of 186 feet, with the corners cut off to the extent of 33 feet 9 inches. The centre of this is occupied by the principal dome, 58 feet in diameter and 80 feet in height, under which is an inclosure formed by a screen of trellis-work of white marble, a *chef-d'œuvre* of elegance in Indian art. Within this stand the two tombs. These, however, as is usual in Indian sepulchres, are not the true tombs; the bodies rest in a vault level with the surface of the ground, beneath plainer tombstones placed exactly underneath those in the hall above. In each angle of the building is a smaller dome of two storeys in height, 26 feet 8 inches in diameter, and connected by various passages and halls. The light to the central apartment is admitted only through double screens of white marble trellis-work of the most exquisite design, one on the outer and one on the inner face of the walls. In our climate this would produce nearly complete darkness; but in India, and in a building wholly composed of white marble, this was required to temper the glare, which otherwise would have been intolerable. As it is, no words can express the chastened beauty of that central chamber, seen in the soft gloom of the subdued light which reaches it through the distant and half-closed openings that surround it. When used as a pleasure palace, it must have been the coolest and the loveliest of garden retreats; and now that it is sacred to the dead, it is the most graceful and most impressive of the sepulchres of the world. This building is an early example of that system of inlaying with precious stones which became the great characteristic of the style of the Mughuls after the death of Akbar. All the spandrils of the Táj, all the angles and more important architectural details, are heightened by being inlaid with precious stones, such as agates, bloodstones, jaspers, and the like. These are combined in wreaths, scrolls, and frets, as exquisite in design as they are beautiful in colour; and, relieved by the pure white marble in which they are inlaid, they form the most beautiful and precious style of ornament ever adopted in architecture. It is lavishly bestowed on the tombs themselves and the screens that surround them, but more sparingly introduced on the mosque that forms one wing of the Táj, and on the fountains and surrounding buildings. The judgment, indeed, with which this style of ornament is apportioned to the various parts is almost as remarkable as the ornament itself, and conveys a high idea of the taste and skill of the Indian architects of this age."

Tavernier, in his *Travels* (vol. iii., p. 94), mentions that 20,000 workmen were incessantly employed on this work during a period of twenty-two years. The tomb of the Emperor Akbar is contained in a splendid mausoleum at Sikandrá, a suburb of Agra city.

AGRAM, or ZAGRAB, the capital of the Austrian province of Croatia, is finely situated on a hill near the banks of the Save, in 45° 49′ N. lat. and 16° 1′ E. long., 160 miles south of Vienna. It is the seat of the governor of Slavonia and Croatia, of a bishop, of the courts of justice, and of the meetings of the provincial diet. Agram is divided into three parts, called the upper and lower towns, and the town of the bishop. It has a lyceum, library, museum, gymnasium, an ancient cathedral, and a large library. Some silk and porcelain are manufactured, and a brisk trade is carried on in grain, potash, tobacco, and honey. Population in 1869, 19,857.

AGRARIAN LAWS (*Leges Agrariæ*), when used in the most extended signification of the term, are laws for the distribution and regulation of property in land. The history of these enactments is not only important as explanatory of the constitution of the ancient republics, but is rendered highly interesting by the conflicting opinions which have been entertained respecting their object and operation. It seems to have been a notion generally entertained in the ancient world that every citizen of a country should be a landholder; and that the territory of a state, so far as it was not left uninclosed or reserved for public purposes, should be divided in equal portions among the citizens. Such a distribution of public land seems to have been acted upon as a recognised principle from the earliest period to which existing historical records extend. Hence we find the Almighty giving express instructions to Moses as to the manner in which the land of Canaan was to be portioned out among the Hebrews (Num. xxxiii. 54), and naming the persons to whom the division was to be entrusted (Num. xxxiv. 16-18). A division of the land was accordingly made, and the portion assigned to each man became his inalienable property, and descended in perpetuity to his heirs and successors. By the law of Jubilee, all lands were restored free of encumbrances on the recurrence of the "year of release;" so that, though a man's estate might, in the interval, have been repeatedly sold or alienated, yet on the return of the fiftieth year it reverted to the heirs of the original possessor (Levit. xxv. 10). In the republics of ancient Greece, and also in the Grecian colonies, a similar principle of division of land prevailed (Thuc. v. 4, Herod. iv. 159). Lycurgus is represented by Plutarch (*Lycur.*) as redividing the whole territory of Laconia into 39,000 parcels, of which 9000 were assigned in equal lots to as many Spartan families, and 30,000, also in equal lots, to their free subjects; and although this statement is not borne out by any of the early Greek historians, and is even inconsistent with the assertion of Aristotle (*Polit.* ii. 4), yet it is valuable as recognising the principle of the division of the public lands. (See Thirlwall's *Hist. of Greece*, chap. viii., and Grote's *Hist. of Greece*, part ii. chap. vi., with the authorities there quoted.)

It was long a prevalent and undisputed opinion that the territories of the Hebrews, and of the republics of ancient Greece, were divided into equal portions, and that the object of such a distribution was to maintain a state of equality among all the members of the community. This, however, does not appear to be consistent with the distinctions of rank which we find admitted in Scripture (Josh. ix. 15; xxii. 14; 1 Sam. ix. 21, &c., &c.); and from a remark of Thucydides (i. 6), taken in connection with the statement of Aristotle (*Polit.* ii. 9), it may be legitimately inferred that property did not continue to be equally distributed at Lacedæmon. Distinctions of rank are clearly recognised in the legislation of Solon. Aristotle, in the Second Book of his *Politics* (chap. vi., &c.), explains the constitutions of several of the ancient republics, and endeavours to show how the population is to be accommodated to this equal division of land; but it would be foreign to our object to review his arguments. It may be sufficient to remark that such an attempt to arrest the progress of enterprise is altogether inconsistent with the spirit of liberty which gave life and energy to the ancient republics; and that, though it might have been carried into effect under the despotism of Persia or the predominant rule of the kings of Macedonia, it was entirely at variance with the freedom of opinion which prevailed in Greece, and the stubborn resistance to control which animated the Romans after the expulsion of the kings. But granting that such a policy had been practicable, it would have been highly inexpedient. The ignorant Hindu might remain satisfied with the caste which nature had transmitted to him through successive generations, because his progenitors had been prevented from emerging from their obscurity; but the citizens of Greece and Italy, being themselves constituent members of the body politic, and not ignorant of the power thereby conferred on them, could not have been kept in check by the same principle of fear. Such an attempt, moreover, to prevent the acquisition of property would have obstructed the advancement of the arts of civilised life, would have extinguished those feelings of patriotism which led the Greeks so often to hazard their lives in defence of their country, and, by engendering discontent and exciting internal commotions, would have made them an easy prey to their enemies.

The expression Agrarian Laws, however, is more commonly applied to the enactments among the Romans for the management of the public domains (*ager publicus*); and to an account of these the remainder of our space must be devoted. It is a singular fact that, while almost every other subject connected with the Roman constitution had been successfully investigated and explained, the object and intention of the agrarian laws were entirely misunderstood by scholars for many centuries after the revival of letters. They were invariably represented as intended to prohibit Roman citizens from holding property in land above a certain fixed amount; and as authorising the division among the poorer citizens of the estates of private individuals when these exceeded the prescribed limit; thus legalising a system of plunder which would have been subversive of all social order. No such doctrine had, indeed, been admitted in any well-regulated state, ancient or modern; nor did anything analogous to it appear in the principles or practice of the Roman constitution; yet the expressions used by the ancient authors in reference to these enactments, and the disturbances to which they invariably gave rise, seemed to justify an unfavourable interpretation; and the opinion, when once propounded, was unconditionally received by successive generations of learned men, notwithstanding the many embarrassments and contradictions to which it led.

Romulus is represented as dividing his small territory among the members of his infant community at the rate of two *jugera* (each extending to two-thirds of an English acre) a-piece, as inheritable property. The whole district, however, was not thus assigned; one portion was set apart for the service of the gods and for the royal domains; and another was reserved as common land for pasture. The stock kept on the common land served to eke out a maintenance which two *jugera* could not otherwise have furnished to a family, and an agistment was paid to the commonwealth for the pasturage. It is probable that the same principle prevailed under the regal government, and that successive adjustments of the territory were made. Such a law existed among those of Servius Tullius. The equality of property thus established seems to have been considered as a fundamental principle of the Roman constitution; and the agrarian laws were regarded as the necessary means of wresting from the large proprietors the possessions which they had illegally acquired. Machiavelli and Montesquieu both participate in this mistake, and are far from condemning the agrarian laws, even when taken in the common meaning. The former alleges that the interest of every republic requires that the state should be rich and the citizens poor, and thus justifies the assumed spoliation; while Montesquieu receives it as an historical fact that Romulus adopted the principle of equality in his original distribution of the territory of Rome as the future ground of her strength, and that the tribunitian contests were but attempts to restore the original constitution. Adam Smith (*Wealth of Nations*, b. iv. chap. vii. part i.) assents to the same interpretation, without, however, any expression of approval.

The correct interpretation of the agrarian laws must thus be considered as of modern date. Amidst the violence of the French Revolution a scheme for the equal division of the national property was advocated, with great popular favour, by some of the frantic leaders, who sought a sanction for their extravagances in precedents drawn from the ancient republics, and particularly from the agrarian laws of the Romans. The subject was thus invested with a new interest, and engaged the attention of Professor Heyne of Göttingen, who in 1793 (*Opus. Acad.* iv. 350–373) addressed to the members of his university a paper in which he successfully combated the opinions which, up till that time, had been entertained respecting them, and showed that their object had been entirely misunderstood. Other writers, as Heeren and Hegewisch, embraced and illustrated his views; but it was reserved for the acuteness and learning of Niebuhr fully to develop the theory which had been suggested, and to demonstrate the fact "that the agrarian laws of the Romans were in no case intended to interfere with or affect private property in land, but related exclusively to the public domain." The theory of Niebuhr was too startling to meet with universal approval. It has accordingly been assailed by Rudorff, Dureau de la Malle (*Econ. Polit. des Romaines*), Puchta, and others, who have ingeniously and plausibly supported the opinions formerly maintained; but their arguments fail to produce conviction. (*Class. Mus.*, vol. ii.) The language of Livy *passim*, when referring to the agrarian laws, is inexplicable unless the interpretation of Niebuhr be adopted:—

"If," says Dr Arnold, "amongst Niebuhr's countless services to Roman history, any single one may claim our gratitude beyond the rest, it is his explanation of the true nature and character of the agrarian laws. Twenty-four years have not yet elapsed since he first published it, but it has already overthrown the deeply-rooted false impressions which prevailed universally on the subject; and its truth, like Newton's discoveries in natural science, is not now to be proved, but to be taken as the very corner-stone of all our researches into the internal state of the Roman people" (*Hist. of Rome*, vol. ii.)

In almost all countries the legal property of the land has been originally vested in the sovereign, whether we are to understand under that name a single chief, a particular portion of the nation, or the people at large. In the same manner, the property of all the land in a conquered country was held to be transferred to the sovereign power in the conquering state, and was assumed with more or less rigour as circumstances seemed to require. From the earliest times a portion of the Roman territory was thus regarded as the property of the state, and the profits arising from it were applied to the public service. The public domain (*ager publicus*) was at first small, but was gradually extended by the right of conquest till it embraced a large portion of the whole peninsula. In this process of extension the subjugated communities were frequently mulcted of a proportion of their lands, varying according to the alleged offence or the resistance which they had offered to the arms of the conquerors. Thus the Boii were deprived of one-half of their territory; the Hernici forfeited two-thirds; and the whole of the *ager Campanus*, the richest district in Italy, was taken from the inhabitants of Capua on the capture of their city after its revolt to Hannibal.

The lands thus acquired were disposed of in various ways. A portion of them was frequently sold by auction to meet the immediate necessities of the state, and was thus conveyed in perpetuity to the purchasers. The disposal of the remainder depended on the nature and condition of the land, and its position in reference to the bulk of the community. If in good condition and at no great distance from the city, it was frequently assigned, in small allotments of seven jugera (between 4 and 5 acres), to those of the poorer citizens, whose services in war gave them a claim upon the state; while in hostile districts and on exposed frontiers military colonies were planted, each colonist receiving a fixed quantity of land. In both these cases the land so assigned ceased to form part of the public domain, and became the property of the recipients. In some cases the land, after having been assumed as public property, was allowed to remain in the hands of the former owners, who became the tenants of the state for a fixed period, and paid a certain rent to the Roman exchequer.

The preceding remarks refer only to arable or meadow land, vineyards, or olive-gardens, which could be turned to immediate advantage. It is obvious, however, that in a country the greater part of which was acquired by conquest, large districts must have been laid waste, the inhabitants with their houses destroyed, and neither cultivators nor the means of cultivation left. Arrangements of a different description were therefore necessary for lands in this position. Wide ranges of country, fit only for pasture, had to be disposed of, and were available to those alone who were able to stock them with flocks and herds, and to provide slaves to attend to and protect their property. Hence it was usual for the state to invite persons possessed of the necessary means to enter upon the occupation of such lands on advantageous terms; an invitation with which the patricians, as being the wealthy class, could alone comply. The ordinary conditions were, that after the land was again brought into cultivation, the occupants should pay as rent one-tenth of the produce of the corn-lands, and one-fifth of the vines and fruit-trees, with a moderate rate per head for sheep and cattle grazing on the public pastures. The lands were not assigned for any definite period; the occupants were merely tenants at will, liable to extrusion whenever the state found it necessary to employ the land for any other purpose. It was a fundamental principle of Roman law that prescription could not be pleaded against the state; and consequently, though the right of occupancy might not only be transmitted from heir to heir, but might also be sold, no length of time could alter the precarious nature of the tenure by which the lands were held. The state always reserved to itself the power of resuming possession when it thought fit; and though such resumption might in many cases be attended by individual hardship, it was nevertheless justified by the original contract.

Much of the obscurity connected with the Roman agrarian laws has arisen from a misapprehension of the meaning of the words *possidere*, *possessor*, and *possessio*. These terms, when used in a strictly legal sense, denote merely occupancy by a tenant, and never imply an absolute right of property. The act of occupancy was termed *usus*, and the benefit derived by the state *fructus*.

"The *ager publicus*," says Professor Ramsay, "having been acquired and occupied as explained above, numerous abuses arose in process of time, especially among the tenants belonging to the second class. These being, as we have said, in the earlier ages, exclusively patricians, who at the same time monopolised the administration of public affairs, they were in the habit of defrauding the state, either by neglecting altogether to pay the stipulated proportion of the produce, or by paying less than was due; or, finally, by claiming, what was in reality *ager publicus*, as their own private property; it being easy, of course, in the absence of all strict superintendence and of scientific surveys, to shift the land-marks which separated public from private property. Meanwhile the deficiencies in the public treasury were made up by heavier taxes; and the plebeians complained that they were impoverished by new imposts, while the lands belonging to the community, which they had acquired by their blood, if fairly managed, would yield a sufficient return to meet all demands upon the exchequer; or, if portioned out in allotments among themselves, afford them the means of supporting the increased burdens. These complaints, unquestionably founded in justice, were soon vehemently expressed, and were revived from time to time more or less loudly, and enforced more or less earnestly, according to the state of public feeling and the energy of the popular champions. It is true that the wealthier plebeians soon became tenants of the *ager publicus* as well as the patricians; but although this circumstance materially strengthened the hands of the occupiers, it did not improve the condition of the poor, or make them less keenly alive to the injustice of the system against which they protested." (*Manual of Rom. Antiq.* p. 228.)

Assuming, then, that the agrarian laws had for their sole object the distribution and management of the public lands (*ager publicus*), their effect must have been felt in two ways:—(1.) In enforcing the regular payment of rent from the occupants, preventing them from exceeding the limits assigned to them, and compelling the surrender of portions for division among the poorer citizens; and (2.) In insisting upon the immediate application of newly-acquired territories to the establishment of colonies, or its assignment to individuals. It is obvious that the laws first referred to, as involving long-established interests, would necessarily lead to violent contests.

The first agrarian law, properly so called, was proposed and passed by Sp. Cassius Viscellinus, when consul, 486 B.C. (Liv. ii. 41, Dionys. viii. 76), but respecting the provisions of this we have no precise information. Cassius was himself a patrician, and we may therefore infer that the law did not encroach upon the just rights of the dominant class to which he belonged. It is not the object of this article to trace in detail the various measures which were proposed, and the agitations with which they were severally attended. Three such are recorded during the 4th century B.C. (Liv. iv. 36, 47, 48); but by far the most important measure of this class, and that which served as the model of nearly all subsequent agrarian laws, was that carried by C. Licinius Stolo, when tribune of the people, in 367 B.C. (Liv. vi. 42). The provisions of this law were: (1.) That no one should occupy more than 500 jugera (about 338 acres) of the public land; (2.) That none should have more than 100 large and 500 small cattle grazing on the public pastures; and (3.) That every occupant of the public lands should employ a certain proportion of free labourers in cultivating it. Niebuhr (vol. iii. p. 11, &c. *Eng. transl.*) has endeavoured to supply the other details; but these can be received merely as ingenious, and it may be successful, conjectures. For an able controversy as to this law see *Class. Museum*, vol. ii.

After the excitement occasioned by the passing of the Licinian law had subsided, two centuries were allowed to pass with only a single interference (Valer. Max. v. 4, 5; Polyb. ii. 21) with the occupants of the public lands; and during that time large additions had been made to the possessions of the state by the confiscations consequent upon the second Punic war. In the meantime the wealthier families had extended their possessions greatly beyond the limits prescribed by the Licinian law; while the small proprietors had disappeared, and the poor continued to increase. In 133 B.C., Tiberius Gracchus proposed and carried a modification of the Licinian law (Liv. *Epit.* lviii.; Appian. i. 9), which his premature death prevented from being carried into effect; and a similar result attended the enactment of his brother (Liv. *Epit.* lx.) Both were set aside or eluded after the death of Caius. During the period which preceded the subversion of the republic various other laws were passed for the distribution of the public lands; but these it is not necessary to enumerate. It may be mentioned, in conclusion, as a significant fact, that the prominent advocates of the agrarian laws, Cassius, Licinius, and the Gracchi, all belonged to the class which would have been injured by their operation had they led to an undue interference with private property. (G. F.)

AGREDA, a town of Spain, in the province of Old Castile, 23 miles N.E. of Soria. It is the chief town of the mountainous district of the same name, and is built on the skirts of the Sierra Moncayo. At Agreda the river Queiles is crossed by a fine stone bridge of one arch. Population, 3120.

AGRICOLA, CNÆUS JULIUS, was born at Forum Julii, now *Frejus*, in Provence, 37 A.D., and was in Vespasian's time made lieutenant to Vettius Bolanus in Britain. Upon his return he was ranked by that emperor among the patricians, and made governor of Aquitania. This post he held for three years; he then was recalled to Rome, and chosen consul, Britain being assigned to him as his province (78 A.D.) Here he reformed many abuses created by his predecessors, put a stop to extortion, and caused justice to be impartially administered. In the spring of 79 he marched towards the north, where he made new conquests, and ordered forts to be built for the Romans to winter in. He spent the following winter in concerting schemes to bring the Britons to conform to the Roman customs. He thought the best way of diverting them from their warlike propensities was to soften their rough manners by proposing to them new kinds of pleasure, and inspiring them with a desire of imitating the Roman manners. He encouraged the erection of magnificent temples, porticoes, baths, and other fine buildings. The British nobles at length had their sons educated; and they who before had the utmost aversion to the Roman language now began to study it with great assiduity. They likewise adopted the Roman dress; and, as Tacitus observes, they were brought to consider those things as marks of politeness which were only so many badges of slavery. Agricola, in his third campaign, advanced as far as the Solway; and in his fourth he subdued the nations betwixt the Solway and the friths of Forth and Clyde, into which the rivers Bodotria and Glotta discharged themselves; and here he built a chain of fortresses to check the nations yet unconquered. In his fifth he fixed garrisons along the western coasts, over against Ireland. In his sixth campaign he passed the river Bodotria; ordering his fleet, the first which the Romans ever had in those parts, to row along the coasts and take a view of the northern parts. The fleet sailed round by the northern and western coasts, and first proved Britain to be an island. In the following spring, the Britons raised an army of 30,000 men, under the command of Galgacus, to oppose the invaders. In the engagement that ensued at the foot of the Grampians the Romans gained the victory, and 10,000 of the Britons are said to have been killed. This happened in the reign of the emperor Domitian, who, growing jealous of the glory of Agricola, recalled him, under pretence of making him governor of Syria. Agricola was in Britain fully seven years, from 78 to 85 A.D.; and he died on the 23d August, 93 A.D., when he had attained the age of 55. Agricola was a man of great integrity; he possessed high military talents, together with administrative abilities of the first rank. The Life of Agricola, written by his son-in-law, the historian Tacitus, is a model of simple and dignified biography.

AGRICOLA, CHRISTOPH LUDWIG, landscape-painter, was born at Regensburg on the 5th Nov. 1667, and died at the same place in 1719. He spent a great part of his life in travel, visiting England, Holland, and France, and residing for a considerable period at Naples. His numerous landscapes, chiefly cabinet pictures, are remarkable for fidelity to nature, and especially for their skilful representation of varied phases of climate. In composition his style shows the influence of Caspar Poussin, while in light and colour he imitates Claude Lorraine. His pictures are to be found in Dresden, Brunswick, Vienna, Florence, Naples, and many other towns of both Germany and Italy.

AGRICOLA (originally LANDMANN), GEORG, a famous mineralogist, born at Glauchau in Saxony, on the 24th March 1494. After studying at Leipsic and in Italy, he practised for some time as a physician at Joachimsthal in Bohemia. In 1531 he was enabled to gratify his natural inclination towards the study of geology and mineralogy by removing to the mining district of Chemnitz in Saxony, where he had been appointed professor of chemistry. The results of his laborious investigations are chiefly to be found in his great work *De Re Metallica* (Basle, 1546), which describes minutely the various methods of mining, of raising and dressing the ore, and of smelting, and contains a number of curious woodcuts. It has been several times reprinted, and a German translation by Lehmann appeared at Freyberg in 1806-10. He also wrote *De Ortu et Causis Subterraneorum*, *De Animantibus Subterraneorum*, *De Natura Fossilium*, besides other works. Agricola was the first to raise mineralogy to the dignity of a science, and he developed it to such an extent that no substantial advance was made upon his results until the middle of the 18th century. He died at Chemnitz on the 21st November 1555.

AGRICOLA, JOHANN FRIEDRICH, musician, was born at Dobitschen in Saxe-Altenburg, on the 4th Jan. 1720, and died in 1774. While a student of law at Leipsic he studied music under John Sebastian Bach. In 1741 he went to Berlin, where he placed himself under Quanz for instruction in musical composition. He was soon generally recognised as one of the most skilful organists of his time. In 1759, on the death of Graun, he was appointed kapellmeister to Frederick II. He composed several operas of great merit, as well as instrumental pieces and church music. His reputation chiefly rests, however, on his theoretical and critical writings on musical subjects.

AGRICOLA (originally SCHNITTER or SCHNEIDER), JOHANNES, one of the foremost of the German reformers, was born on the 20th April 1492, at Eisleben, whence he is sometimes called *Magister Islebius*. He studied at Wittenberg, where he soon gained the friendship of Luther. In 1519 he accompanied Luther to the great assembly of German divines at Leipsic, and acted as recording secretary. After teaching for some time in Wittenberg, he went to Frankfort in 1525 to establish the worship according to the reformed religion. He had resided there only a month when he was induced to go to Eisleben, where he remained till 1526 as teacher in the school of St Andrew, and preacher in the Nicolai church, enjoying great popularity in the latter capacity. In 1536 he was recalled to Wittenberg to fill a professorial chair, and was welcomed by Luther. Almost immediately afterwards, however, a controversy, which had been begun ten years before and been temporarily silenced, broke out afresh with greater violence. Agricola was the first to teach the views which Luther was the first to stigmatise by the now well-known name *Antinomian*. He held that while the unregenerate were still under the law, Christians were entirely free from it, being under the gospel alone. He denied that Christians owed subjection to any part of the law, even the Decalogue, as a rule of life. Luther conducted the argument with his usual vehemence, and there was in the heat of controversy probably a good deal of misrepresentation on both sides. In 1540 Agricola left Wittenberg secretly for Berlin, where he published a letter addressed to the elector of Saxony, which was generally interpreted as a recantation of his obnoxious views. Luther, however, seems not to have so accepted it, and Agricola remained at Berlin. The elector Joachim II. of Brandenburg having taken him into his favour, appointed him court preacher and general superintendent. He held both offices until his death in 1566, and his career in Brandenburg was one of great activity and great influence. Along with the Catholic bishops Von Pflug and Michael Halding, he prepared the Augsburg Interim of 1548. Agricola wrote a number of theological works which are now of little interest. He was the first to make a collection of German proverbs, which he illustrated with an appropriate commentary. The most complete edition is that published at Wittenberg in 1592.

AGRICOLA, RODOLPHUS (originally ROELOF HUYSMANN), a distinguished scholar, born at Bafflo, near Gröningen, in 1443. He was educated at Louvain, where he graduated as master of arts. After residing for some time in Paris, he went in 1476 to Ferrara in Italy, and attended the lectures of the celebrated Theodore Gaza on the Greek language. Having visited Pavia and Rome, he returned to his native country about 1479, and was soon afterwards appointed syndic of Gröningen. In 1482, on the invitation of Dalberg, bishop of Worms, whose friendship he had gained in Italy, he accepted a professorship at Heidelberg, and for three years delivered lectures in that university and at Worms on the literature of Greece and Rome. By his personal influence much more than by his writings he did a great deal for the promotion of learning in Germany. Hallam says that "no German wrote so pure a style, or possessed so large a portion of classical learning;" and the praises of Erasmus and other critics of the generation immediately succeeding Agricola's are unstinted. In his opposition to the scholastic philosophy he seems to have in some degree anticipated the coming of that great revolution in which many of his pupils were conspicuous actors. He died at Heidelberg in 1485. His principal work is the *De Inventione Dialectica*, in which he attempts to change the scholastic philosophy of the day. (See *Vita et Merita Rudolphi Agricolæ*, by T. F. Tresling, Gröningen, 1830).

AGRICULTURE

CHAPTER I.

It would be interesting to know how the nations of antiquity tilled, and sowed, and reaped; what crops they cultivated, and by what methods they converted them into food and raiment. But it is to be regretted, that the records which have come down to us are all but silent upon these homely topics.

In Mr Hoskyn's admirable treatise[1] we have an excellent specimen of what may yet be done to recover and construct an authentic history of the Agriculture of the ancients, from the casual allusions and accidental notices of rural affairs which lie thinly scattered through the body of general literature; and, more especially, from those mysterious records of the past, which are now being rescued from their long burial under the ruins of some of the most famous cities of antiquity. Although comparatively little has been found in such records bearing directly upon the subject, we must not despair of the learned industry and masterly skill of an advancing and searching criticism, gathering together these gleams of light, and making them happily converge upon the darkness which has hitherto interposed between us and a circumstantial knowledge of the methods and details of ancient husbandry.

Every reader of the Bible is familiar with its frequent references to Egypt as a land so rich in corn, that it not only produced abundance for its own dense population, but yielded supplies for exportation to neighbouring countries. Profane history corroborates these statements. Diodorus Siculus bears explicit testimony to the skill of the farmers of ancient Egypt. He informs us that they were acquainted with the benefits of a rotation of crops, and were skilful in adapting these to the soil and to the seasons. The ordinary annual supply of corn furnished to Rome has been estimated at 20,000,000 bushels. From the same author we also learn that they fed their cattle with hay during the annual inundation, and at other times tethered them in the meadows on green clover. Their flocks were shorn twice annually (a practice common in several Asiatic countries), and their ewes yeaned twice a year. For religious as well as economical reasons, they were great rearers of poultry, and practised artificial hatching, as at the present day. The abundance or scarcity of the harvests in Egypt depended chiefly upon the height of the annual inundation. If too low, much of the land could not be sown, and scarcity or famine ensued. On the other hand, great calamities befell the country when the Nile rose much above the average level. Cattle were drowned, villages destroyed, and the crops necessarily much diminished, as in such cases many of the fields were still under water at the proper seed time. In 1818 a calamity of this kind took place, when the river rapidly attained a height of 3½ feet above the proper level.

It is from the paintings and inscriptions with which the ancient Egyptians decorated their tombs that we get the fullest insight into the state of agriculture amongst this remarkable people. Many of these paintings, after the lapse of two or three thousand years, retain the distinctness of outline and brilliancy of colour of recent productions. The acquaintance which these give us with their occupations, attainments, and habits is truly marvellous, and fills the reader of such works as Wilkinson's *Egypt* with perfect amazement. Every fresh detail seems to give confirmation to that ancient saying, "There is nothing new under the sun." The pictures referring to rural affairs disclose a state of advancement at that early date which may well lead us to speak modestly of our own attainments An Egyptian villa comprised all the conveniences of a European one of the present day. Besides a mansion with numerous apartments, there were gardens, orchards, fish-ponds, and preserves for game. Attached to it was a farm-yard, with sheds for cattle and stables for carriage horses. A steward directed the tillage operations, superintended the labourers, and kept account of the produce and expenditure. The grain was stored in vaulted chambers furnished with an opening at the top, reached by steps, into which it was emptied from sacks, and with an aperture below for removing it when required. Hand-querns, similar to our own, were used for grinding corn; but they had also a larger kind worked by oxen. In one painting, in which the sowing of the grain is represented, a plough drawn by a pair of oxen goes first; next comes the sower scattering the seed from a basket; he is followed by another plough; whilst a roller, drawn by two horses yoked abreast, completes the operation. The steward stands by superintending the whole. Nothing, however, conveys to us so full an impression of the advanced state of civilisation amongst the ancient Egyptians as the value which they attached to land, and the formalities which they observed in the transfer of it. In the time of the Ptolemies, their written deeds of conveyance began with the mention of the reign in which they were executed, the name of the president of the court, and of the clerk who drew them. The name of the seller, with a description of his personal appearance, his parentage, profession, and residence, was engrossed. The nature of the land, its extent, situation, and boundaries; the name and appearance of the purchaser were also included. A clause of warrandice and an explicit acceptance by the purchaser followed, and finally the deed was attested by numerous witnesses (so many as sixteen occur to a trifling bargain), and by the president of the court.

The nomades of the patriarchal ages, like the Tartar, and perhaps some of the Moorish tribes of our own, whilst mainly dependent upon their flocks and herds, practised also agriculture proper. The vast tracts over which they roamed were in ordinary circumstances common to all shepherds alike. During the summer they frequented the mountainous districts and retired to the valleys to winter. Vast flocks of sheep and of goats constituted the chief wealth of the nomades, although they also possessed animals of the ox kind. When these last were possessed in abundance, it seems to be an indication that tillage was practised. We learn that Job, besides immense possessions in flocks and herds, had 500 yoke of oxen, which he employed in ploughing, and a "very great husbandry." Isaac, too, conjoined tillage with pastoral husbandry, and that with success, for we read that he sowed in the land Gerar, and reaped an hundred-fold —a return which, it would appear, in some favoured regions, occasionally rewarded the labour of the husbandman. In the parable of the sower, our Lord (grafting his instructions upon the habits, scenery, and productions of Palestine), mentions an increase of thirty, sixty and an

[1] *Short Inquiry into the History of Agriculture*, by Chandos Wren Hoskyn, Esq.

hundred fold. Such increase, although far above the average rate, was sometimes even greatly exceeded, if we take the authority of Herodotus, Strabo, and Pliny.

Along with the Babylonians, Egyptians, and Romans, the Israelites are classed as one of the great agricultural nations of antiquity. The sojourn of the Israelites in Egypt trained them for the more purely agricultural life that awaited them on their return to take possession of Canaan. Nearly the whole population were virtually husbandmen, and personally engaged in its pursuits. Upon their entrance into Canaan, they found the country occupied by a dense population possessed of walled cities and innumerable villages, masters of great accumulated wealth, and subsisting on the produce of their highly cultivated soil, which abounded with vineyards and oliveyards. It was so rich in grain, that the invading army, numbering 601,730 able-bodied men, with their wives and children, and a mixed multitude of camp-followers, found "old corn" in the land sufficient to maintain them from the day that they passed the Jordan. The Mosaic Institute contained an agrarian law, based upon an equal division of the soil amongst the adult males, a census of whom was taken just before their entrance into Canaan. Provision was thus made for 600,000 yeomen, assigning (according to different calculations) from sixteen to twenty-five acres of land to each. This land, held in direct tenure from Jehovah, their sovereign, was strictly inalienable. The accumulation of debt upon it was prevented by the prohibition of interest, the release of debts every seventh year, and the reversion of the land to the proprietor, or his heirs, at each return of the year of jubilee. The owners of these small farms cultivated them with much care, and rendered them highly productive. They were favoured with a soil extremely fertile, and one which their skill and diligence kept in good condition. The stones were carefully cleared from the fields, which were also watered from canals and conduits, communicating with the brooks and streams with which the country "was well watered everywhere," and enriched by the application of manures. The seventh year's fallow prevented the exhaustion of the soil, which was further enriched by the burning of the weeds and spontaneous growth of the Sabbatical year. The crops chiefly cultivated were wheat, millet, barley, beans, and lentiles; to which it is supposed, on grounds not improbable, may be added rice and cotton. The ox and the ass were used for labour. The word "oxen," which occurs in our version of the Scriptures, as well as in the Septuagint and Vulgate, denotes the species, rather than the sex. As the Hebrews did not mutilate any of their animals, bulls were in common use. The quantity of land ploughed by a yoke of oxen in one day was called a yoke or acre. Towards the end of October, with which month the rainy season begins, seedtime commenced, and of course does so still. The seedtime, begun in October, extends, for wheat and some other white crops, through November and December; and barley continues to be sown until about the middle of February. The seed appears to have been sometimes ploughed in, and at other times to have been covered by harrowing. The cold winds which prevail in January and February frequently injured the crops in the more exposed and higher districts. The rainy season extends from October to April, during which time refreshing showers fall, chiefly during the night, and generally at intervals of a few days. The harvest was earlier or later as the rains towards the end of the season were more or less copious. It, however, generally commenced in April, and continued through May for the different crops in succession. In the south, and in the plains, the harvest, as might be expected, commenced some weeks earlier than in the northern and mountainous districts. The slopes of the hills were carefully terraced and irrigated wherever practicable, and on these slopes the vine and olive were cultivated with great success. At the same time the hill districts and neighbouring deserts afforded pasturage for numerous flocks and herds, and thus admitted of the benefits of a mixed husbandry. With such political and social arrangements, and under the peculiarly felicitous climate of Judea, the country as a whole, and at the more prosperous periods of the commonwealth, must have exhibited such an example of high cultivation, rich and varied produce, and wide-spread plenty and contentment, as the world has never yet elsewhere produced on an equally extensive scale. Not by a figure of speech but literally, every Israelite sat under the shadow of his own vine and fig-tree; whilst the country as a whole is described (2 Kings xviii. 32) as "a land of corn and wine, a land of bread and vineyards, a land of oil-olive and of honey." An interesting illustration of the advanced state of agriculture in these ancient times is afforded by the fact, that, making allowance for climatic differences, the numerous allusions to it with which the Scriptures abound seem natural and appropriate to the British farmer of the present day.

The unrivalled literature of Greece affords us little information regarding the practical details of her husbandry. The people who by what remains to us of their poetry, philosophy, history, and fine arts, still exert such an influence in guiding our intellectual efforts, in regulating taste, and in moulding our institutions, were originally the invaders and conquerors of the territory which they have rendered so famous. Having reduced the aboriginal tribes to bondage, they imposed upon them the labour of cultivating the soil, and hence both the occupation, and those engaged in it, were regarded contemptuously by the dominant race, who addicted themselves to what they regarded as nobler pursuits. With the exception of certain districts, such as Bœotia, the country was naturally unfavourable to agriculture. When we find, however, that valleys were freed from lakes and morasses by drainage, that rocky surfaces were sometimes covered with transported soil, and that they possessed excellent breeds of the domesticated animals, which were reared in vast numbers, we infer that agriculture was better understood, and more carefully practised, than the allusions to it in their literature would seem to warrant.

Amongst the ancient Romans agriculture was highly esteemed, and pursued with earnest love and devoted attention. "In all their foreign enterprises, even in earliest times," as Schlegel remarks, "they were exceedingly covetous of gain, or rather of land; for it was in land, and in the produce of the soil, that their principal and almost only wealth consisted. They were a thoroughly agricultural people, and it was only at a later period that commerce, trades, and arts, were introduced among them, and even then they occupied but a subordinate place."[1] Their passion for agriculture survived very long; and when at length their boundless conquests introduced an unheard-of luxury and corruption of morals, the noblest minds amongst them were strongly attracted towards the ancient virtue of the purer and simpler agricultural times. Several facts in Roman history afford convincing proof, if it were required, of the devotion of this ancient people to agriculture, in their best and happiest times. Whilst their arts and sciences, and general literature, were borrowed from the Greeks, they created an original literature of their own, of which rural affairs formed the substance and inspiration. Schlegel and Mr Hoskyn notice also the striking fact, that

[1] *The Philosophy of History*, by Frederick Von Schlegel. London, 1846, p. 253.

whilst among the Greeks the names of their illustrious families are borrowed from the heroes and gods of their mythology, the most famous houses amongst the ancient Romans, such as the Pisones, Fabii, Lentuli, &c., have taken their names from their favourite crops and vegetables. Perhaps it is not too much to assert, that many of those qualities which fitted them for conquering the world, and perfecting their so celebrated jurisprudence, were acquired, or at all events nourished and matured, by the skill, foresight, and persevering industry, so needful for the intelligent and successful cultivation of the soil. The words which Cicero puts into the mouth of Cato give a fine picture of the ancient Roman enthusiasm in agriculture. "I come now to the pleasures of husbandry, in which I vastly delight. They are not interrupted by old age, and they seem to me to be pursuits in which a wise man's life should be spent. The earth does not rebel against authority; it never gives back but with usury what it receives. The gains of husbandry are not what exclusively commend it. I am charmed with the nature and productive virtues of the soil. Can those old men be called unhappy who delight in the cultivation of the soil? In my opinion there can be no happier life, not only because the tillage of the earth is salutary to all, but from the pleasure it yields. The whole establishment of a good and assiduous husbandman is stored with wealth; it abounds in pigs, in kids, in lambs, in poultry, in milk, in cheese, in honey. Nothing can be more profitable, nothing more beautiful, than a well-cultivated farm."

In ancient Rome each citizen received, at first, an allotment of about two English acres. After the expulsion of the kings this allotment was increased to about six acres. These small inheritances must, of course, have been cultivated by hard labour. On the increase of the Roman territory the allotment was increased to fifty, and afterwards even to five hundred acres Many glimpses into their methods of cultivation are found in those works of Roman authors which have survived the ravages of time. Cato speaks of irrigation, frequent tillage, and manuring, as means of fertilising the soil. Mr Hoskyn, from whose valuable contribution to the History of Agriculture we have drawn freely in this historic summary, quotes the following interesting passage from Pliny, commenting on Virgil:[1]—"Our poet is of opinion that alternate fallows should be made, and that the land should rest entirely every second year. And this is, indeed, both true and profitable, provided a man have land enough to give the soil this repose. But how, if his extent be not sufficient? Let him, in that case, help himself thus. Let him sow next year's wheat-crop on the field where he has just gathered his beans, vetches, or lupines, or such other crop as enriches the ground. For, indeed, it is worth notice that some crops are sown for no other purpose but as food for others, a poor practice in my estimation." In another place he tells us, "Wheat, the later it is reaped, the better it casts; but the sooner it is reaped, the fairer the sample. The best rule is to cut it down before the grain is got hard, when the ear begins to have a reddish-brown appearance. 'Better two days too soon than as many too late,' is a good old maxim, and might pass for an oracle." The following quotation from the same author is excellent:—"Cato would have this point especially to be considered, that the soil of a farm be good and fertile; also, that near it there be plenty of labourers, and that it be not far from a large town: moreover, that it have sufficient means for transporting its produce, either by water or land. Also, that *the house be well built*, and the land about it as well managed. But I observe a great error and self-deception which many men commit, who hold opinion that the negligence and ill-husbandry of the former owner is good for his successor or after-purchaser. Now, I say, there is nothing more dangerous and disadvantageous to the buyer than land so left waste and out of heart; and therefore Cato counsels well to purchase land of one who has managed it well, and not rashly and hand-over-head to despise and make light of the skill and knowledge of another. He says, too, that as well land as men, which are of great charge and expense, how gainful soever they may seem to be, yield little profit in the end, when all reckonings are made. The same Cato being asked, what was the most assured profit rising out of land? made this answer,—'To feed stock well.' Being asked again, 'What was the next?' he answered, 'To feed *with moderation*.' By which answer he would seem to conclude that the most certain and sure revenue was *a low cost of production*. To the same point is to be referred another speech of his, 'That a good husbandman ought to be a seller rather than a buyer;' also, 'that a man should stock his ground early and well, but take long time and leisure before he be a builder;' for it is the best thing in the world, according to the proverb, 'to make use, and derive profit, from other men's follies.' Still when there is a good and convenient house on the farm, the master will be the closer occupier, and take the more pleasure in it; and truly it is a good saying, that 'the master's eye is better than his heel.'"

"It is curious," says Mr Hoskyn, "to read such passages as these, and to find the very same subjects still handled, week after week, in fresh and eager controversy in the agricultural writings and periodicals of the present day, eighteen centuries after those opinions were written."

In the later ages of the empire agriculture was neglected, and those engaged in it regarded with contempt. Many fair regions once carefully cultivated, and highly productive, were abandoned to nature, and became a scene of desolation, the supplies of overgrown Rome being drawn from Egypt, Sicily, and other provinces, which became notable as the granaries of the empire.

Under the Goths, Vandals, and other barbarian conquerors, agriculture in Europe, during the middle ages, seems to have sunk into the lowest condition of neglect and contempt. We owe its revival, like that of other arts and sciences, to the Saracens of Spain, who devoted themselves to the cultivation of that conquered territory, with hereditary love for the occupation, and with the skilful application of the experience which they had gathered in other lands in which they had established their power. By them, and their successors, the Moors, agriculture was carried in Spain to a height which perhaps has not yet been surpassed in Europe. It is said, that so early as the tenth century the revenue of Saracenic Spain alone amounted to £6,000,000 sterling,—probably as much as that of all the rest of Europe at that time. The ruins of their noble works for the irrigation of the soil still attest their skill and industry, and put to shame the ignorance and indolence of their successors. The same remark applies to the Spanish dominions in South America. In the ancient empire of Peru agriculture seems to have reached a high degree of perfection. The ruins of basins and canals, frequently carried through tunnels, prove their industry and skill in irrigation. One of their aqueducts is said by Mr Prescott[2] to have been traced by its ruins for nearly 500 miles. They cultivated the sides of mountains, by means of terraces, which retained forced soil, and were skilled in the application of manure. That on which they chiefly depended was guano, and their Incas protected the penguins, by which it was deposited, by strict laws, which made it

[2] *History of the Conquest of Mexico.*

highly penal to kill one of these birds, or to set foot on the islands at breeding time. The Spaniards thus obtained possession of two good patrimonies, and have wasted them both.

The influence of the crusades upon the agriculture of this period is not to be overlooked. The dreadful oppression of the feudal system received at that time a shock most favourable to the liberties of man, and, with increasing liberty, more enlightened ideas began to be entertained, and greater attention to be paid to the cultivation of the soil.

But, during this long interval, the population of Europe was divided into two great classes, of which by far the larger one was composed of bondmen, without property, or the power of acquiring it, and small tenants, very little superior to bondmen; and the other class, consisting chiefly of the great barons and their retainers, was more frequently employed in laying waste the fields of their rivals than in improving their own. The superstition of the times, which destined a large portion of the land to the support of the church, and which, in some measure, secured it from predatory incursions, was the principal source of what little skill and industry were then displayed in the cultivation of the soil. "If we consider the ancient state of Europe," says Mr Hume,[1] "we shall find that the far greater part of society were everywhere bereaved of their personal liberty, and lived entirely at the will of their masters. Every one that was not noble was a slave; the peasants were not in a better condition; even the gentry themselves were subjected to a long train of subordination under the greater barons, or chief vassals of the crown, who, though seemingly placed in a high state of splendour, yet, having but a slender protection from law, were exposed to every tempest of the state, and by the precarious condition on which they lived, paid dearly for the power of oppressing and tyrannising over their inferiors."—"The villains were entirely occupied in the cultivation of their master's land, and paid their rents either in corn or cattle, and other produce of the farm, or in servile offices, which they performed about the baron's family, and upon farms which he retained in his own possession. In proportion as agriculture improved and money increased, it was found that these services, though extremely burdensome to the villain, were of little advantage to the master; and that the produce of a large estate could be much more conveniently disposed of by the peasants themselves who raised it, than by the landlord or his bailiff, who were formerly accustomed to receive it. A commutation was therefore made of rents for services, and of money-rents for those in kind; and as men in a subsequent age discovered that farms were better cultivated where the farmer enjoyed security in his possession, the practice of granting leases to the peasant began to prevail, which entirely broke the bonds of servitude, already much relaxed from the former practices. The latest laws which we find in England for enforcing or regulating this species of servitude were enacted in the reign of Henry VII. And though the ancient statutes on this subject remain still unrepealed by Parliament, it appears that before the end of Elizabeth the distinction between villain and freeman was totally, though insensibly, abolished, and that no person remained in the state to whom the former laws could be applied."

But long before the 15th century, it is certain that there was a class of tenants holding on leases for lives, or for a term of years, and paying a rent in land produce, in services, or in money. Whether they gradually sprung up from the class of bondmen, according to Lord Kames,[2] or existed from the earliest period of the feudal constitution, according to other writers,[3] their number cannot be supposed to have been considerable during the middle ages. The stock which these tenants employed in cultivation commonly belonged to the proprietor, who received a proportion of the produce as rent,—a system which still exists in France and in other parts of the Continent, where such tenants are called *metayers*, and some vestiges of which may yet be traced in the *steel-bow* of the law of Scotland. Leases of the 13th century still remain,[4] and both the laws and chartularies[5] clearly prove the existence in Scotland of a class of cultivators distinct from the *serfs* or bondmen. Yet the condition of these tenants seems to have been very different from that of the tenants of the present day; and the lease approached nearer in its form to a feu-charter than to the mutual agreement now in use. It was of the nature of a beneficiary grant by the proprietor, under certain conditions, and for a limited period; the consent of the tenant seems never to have been doubted. In the common expression "granting a lease," we have retained an idea of the original character of the deed, even to the present time.

The corn crops cultivated during this period seem to have been of the same species, though all of them probably much inferior in quality to what they are in the present day. Wheat, the most valuable grain, must have borne a small proportion, at least in Britain, to that of other crops; the remarkable fluctuation of price, its extreme scarcity, indicated by the extravagant rate at which it was sometimes sold, as well as the preparatory cultivation required, may convince us that its consumption was confined to the higher orders, and that its growth was by no means extensive. Rye and oats furnished the bread and drink of the great body of the people of Europe. Cultivated herbage and roots were then unknown in the agriculture of Britain. It was not till the end of the reign of Henry VIII. that any salads, carrots, or other edible roots were produced in England. The little of these vegetables that was used was formerly imported from Holland and Flanders. Queen Catherine, when she wanted a salad, was obliged to despatch a messenger thither on purpose.[6]

The ignorance and insecurity of those ages, which necessarily confined the cultivation of corn to a comparatively small portion of country, left all the rest of it in a state of nature, to be depastured by the inferior animals, then only occasionally subjected to the care and control of man. Cultivators were crowded together in miserable hamlets; the ground contiguous was kept continually under tillage; and beyond this, wastes and woodlands of a much greater extent were appropriated to the maintenance of their flocks and herds, which pastured indiscriminately, with little attention from their owners.

The low price of butcher-meat, though it was then the food of the common people, when compared with the price of corn, has been justly noticed by several writers as a decisive proof of the small progress of civilisation and industry.

One of the earliest and greatest agricultural grievances was the levying of Purveyance. This originally comprehended the necessary provisions, carriages, &c., which the nearest farmers were obliged to furnish at the current prices to the king's armies, houses, and castles, in time of war. It was called the *great purveyance*, and the officers who collected those necessaries were called purveyors. The smaller purveyance included the necessary provisions for the household of the king when travelling through the

kingdom, and these the tenants on the king's demesne lands were obliged to furnish gratis, a practice that came to be adopted by the barons and great men in every tour which they thought proper to make in the country. These exactions were so grievous, and levied in so high-handed a manner, that the farmers, when they heard of the court's approach, often deserted their houses, as if the country had been invaded by an enemy. "Purveyance," says Dirom,[1] "was perhaps for many centuries the chief obstruction to the agriculture and improvement of Great Britain. Many laws were made for the reformation and regulation of purveyance, but without effect; and the practice continued down to so late a period as the reign of James the First."

By statute 1449, the tenant was for the first time secured in possession, during the term of his lease, against a purchaser of the land; and in 1469 he was protected from having his property carried off for the landlord's debts, beyond the amount of rent actually due; an enactment which proves his miserable condition before that time.

Soon after the beginning of the 16th century agriculture partook of the general improvement which followed the invention of printing, the revival of learning, and the more settled authority of government; and instead of the occasional notices of historians, we can now refer to regular treatises, written by men who engaged eagerly in this neglected and hitherto degraded occupation. We shall therefore give a short account of the principal works, as well as of the laws and general policy of Britain, in regard to agriculture, from the early part of the 16th century to the Revolution in 1688, when a new era commenced in the legislation of corn, and soon after in the practice of the cultivator.[2]

Early Works on Agriculture.

The first and by far the best of our early works is the *Book of Husbandry*, printed in 1534, commonly ascribed to Fitzherbert, a judge of the Common Pleas in the reign of Henry VIII. This was followed, in 1539, by the *Book of Surveying and Improvements*, by the same author. In the former treatise we have a clear and minute description of the rural practices of that period, and from the latter may be learned a good deal of the economy of the feudal system in its decline. The *Book of Husbandry* has scarcely been excelled by any later production, in as far as concerns the subjects of which it treats; for at that time cultivated herbage and edible roots were still unknown in England. The author writes from his own experience of more than forty years; and, with the exception of passages denoting his belief in the superstition of the Roman writers, there is very little of this valuable work, in so far as regards the culture of corn, that should be omitted, and not a great deal that need be added, even in a manual of husbandry adapted to the present time. Fitzherbert touches on almost every department of the art, and in about a hundred octavo pages has contrived to condense more practical information than will be found scattered through as many volumes of later times; and yet he is minute even to the extreme on points of real utility. There is no reason to say, with Mr Harte, that he had revived the husbandry of the Romans; he merely describes the practices of the age in which he lived; and from his commentary on the old statute *extenta manerii*, in his *Book of Surveying*, in which he does not allude to any recent improvements, it is probable that the management which he details had been long established. But it may surprise some of the agriculturists of the present day to be told, that, after the lapse of almost three centuries, Fitzherbert's practice, in some material particulars, has not been improved upon; and that in several districts abuses until recently existed, which were as clearly pointed out by him at that early period as by any writer of the present age.

The *Book of Husbandry* begins with the plough and other instruments, which are concisely and yet minutely described; and then about a third part of it is occupied with the several operations as they succeed one another throughout the year. Among other things in this part of the work, the following deserve notice:—

"Somme (ploughs) wyll tourn the sheld bredith at every landsende, and plowe all one way;" the same kind of plough that is now found so useful on hilly grounds. Of wheel-ploughs he observes, that "they be good on even grounde that lyetl lyghte;" and on such lands they are still most commonly employed. Cart-wheels were sometimes bound with iron, of which he greatly approves. On the much agitated question about the employment of horses or oxen in labour, the most important arguments are distinctly stated.

"In some places," he says, "a horse plough is better," and in others an oxen plough, to which, upon the whole, he gives the preference, and to this, considering the practices of that period, they were probably entitled. Beans and peas seem to have been common crops. He mentions the different kinds of wheat, barley, and oats; and after describing the method of harrowing "all maner of cornnes," we find the roller employed. "They used to role their barley grounde after a showr of rayne, to make the grounde even to mowe." Under the article "To falowe," he observes, "the greater clottes (clods) the better wheate, for the clottes kepe the wheat warme all wynter; and at March they will melte and breake and fal in menye small peces, the whiche is a new dongynge and refreshynge of the corne." This is agreeable to the present practice, founded on the very same reasons. "In May, the shepe folde is to be set out;" but Fitzherbert does not much approve of folding, and points out its disadvantages in a very judicious manner. "In the latter end of May and the begynnynge of June, is tyme to wede the corne;" and then we have an accurate description of the different weeds, and the instruments and mode of weeding. Next comes a second ploughing of the fallow; and afterwards, in the latter end of June, the mowing of the meadows begins. Of this operation, and of the forks and rakes, and the haymaking, there is a very good account. The corn harvest naturally follows: rye and wheat were usually *shorn*, and barley and oats cut with the scythe. This intelligent writer does not approve of the practice, which still prevails in some places, of cutting wheat high, and then mowing the stubbles. "In Somersetshire," he says, "they do shere theyr wheat very lowe; and the wheate strawe that they purpose to make *thacke* of, they do not threshe it, but cut off the ears, and bynd it in sheves, and call it *rede*, and therewith they thacke theyr houses." He recommends the practice of setting up corn in shocks, with two sheaves to cover eight, instead of ten sheaves as at present; probably owing to the straw being then shorter. The corn was commonly housed; but if there be a want of room, he advises that the ricks be built on a scaffold, and not upon the ground. Corn-stacks are now beginning to be built on pillars and frames. The fallow received a third ploughing in September, and was sown about Michaelmas. "Wheat is moost commonlye sowne under the forowe, that is to say, cast it uppon the falowe, and then plowe it under;" and this branch of his subject is concluded with directions about threshing, winnowing, and other kinds of barn-work.

Fitzherbert next proceeds to live stock. "An housbande," he says, "can not well thryue by his corne without he haue other cattell, nor by his cattell without corne. And bycause that shepe, in myne opynyon, is the mooste profytablest cattell that any man can haue, therefore I pourpose to speake fyrst of shepe." His remarks on this subject are so accurate, that one might imagine they came from a storemaster of the present day; and the minutiæ which he details are exactly what the writer of this article has seen practised in the hilly parts of this country. In some places at present, "they neuer seuer their lambes from their dammes;" "and the poore of the peeke (high) countreye, and such other places, where, as they vse to mylke theyr ewes, they vse to wayne theyr lambes at 12 weekes olde, and to mylke their ewes fiue or syxe weekes;" but that, he observes, "is greate hurte to the ewes, and wyll cause them that they wyll not take the ramme at the tyme of the yere for pouertye, but goo barreyne." "In June is tyme to shere shepe; and ere they be shorne, they must be verye well washen, the which shall be to the owner greate profyte in the sale of his wool, and also to the clothe-maker." It appears that *hand washing* was then a common practice; and yet in the west and north of Scotland its introduction is of comparatively recent date. His remarks on horses, cattle, &c., are not less interesting; and there is a very good account of the diseases of each species, and some just observations on the advantage of mixing different kinds on the same pasture. Swine and bees conclude this branch of the work.

[1] *Inquiry into the Corn Laws*, &c., p. 9.

[2] The account of the Writers on Agriculture taken from Mr Cleghorn's Treatise in the former edition of the *Encyclopædia Britannica*.

The author then points out the great advantages of inclosure; recommends "quycksettynge, dychynge, and hedgeyng;" and gives particular directions about *settes*, and the method of training a hedge, as well as concerning the planting and management of trees. We have then a short information "for a yonge gentylman that intendeth to thryue," and "a prolonge for the wiues occupation," in some instances rather too homely for the present time. Among other things, she is to "make her husband and herself somme clothes;" and "she maye haue the lockes of the shepe eyther to make blankettes and courlettes, or bothe." This is not so much amiss; but what follows will bring the learned judge into disrepute even with our most industrious housewives. "It is a wyues occupation," he says, "to wynowe all maner of cornes, to make malte, to washe and wrynge, to make heye, shere corne, and, in time of nede, to helpe her husbande to fyll the mucke wayne or dounge carte, dryue the ploughe, to loode heye, corne, and suche other; and to go or ride to the market to sel butter, chese, mylke, egges, chekyns, capons, hennes, pygges, gese, and all maner of cornes." The rest of the book contains some useful advices about diligence and economy; and concludes, after the manner of the age, with many pious exhortations.

Such is Fitzherbert's *Book of Husbandry*, and such was the state of agriculture in England in the early part of the 16th century, and probably for a long time before; for he nowhere speaks of the practices which he describes or recommends as of recent introduction.

The *Book of Surveying* adds considerably to our knowledge of the rural economy of that age. "Four maner of commens" are described; several kinds of mills for corn and other purposes, and also "quernes that goo with hand;" different orders of tenants, down to the "boundmen," who "in some places contynue as yet;" "and many tymes, by colour thereof, there be many freemen taken as boundmen, and their lands and goods is taken from them." Lime and marl are mentioned as common manures; and the former was sometimes spread on the surface to destroy heath. Both draining and irrigation are noticed, though the latter but slightly. And the work concludes with an inquiry "how to make a township that is worth XX. marke a yere, worth XX. li. a year;" from which we shall give a specimen of the author's manner, as well as of the economy of the age.

"It is undoubted, that to every townshyppe that standeth in tyllage in the playne countrey, there be errable landes to plowe and sowe, and leyse to tye or tedder theyr horses and mares upon, and common pasture to kepe and pasture their catell, beestes, and shepe upon; and also they have medowe grounde to get theyr hey upon. Than to let it be known how many acres of errable lande euery man hath in tyllage, and of the same acres in euery felde to chaunge with his neyghbours, and to leye them toguyther, and to make hym one seuerall close in euery felde for his errable lands; and his leyse in euery felde to leve them togyther in one felde, and to make one seuerall close for them all. And also another seuerall close for his portion of his common pasture, and also his porcion of his medowe in a seuerall close by itselfe, and al kept in seuerall both in wynter and somer; and euery cottage shall haue his portion assigned hym accordynge to his rent, and than shall nat the ryche man ouerpresse the poore man with his cattell; and euery man may eate his own close at his pleasure. And vndoubted, that hay and strawe that will find one beest in the house wyll finde two beestes in the close, and better they shall lyke. For those beestis in the house have short heare and thynne, and towards March they will pylle and be bare; and therefore they may nat abyde in the fylde before the heerdmen in winter tyme for colde. And those that lye in a close under a hedge haue longe heare and thyck, and they will neuer pylle nor be bare; and by this reason the husbande maye kepe twyse so many catell as he did before.

"This is the cause of this approwment. Nowe euery husbande hath sixe seuerall closes, whereof iii. be for corne, the fourthe for his leyse, the fyfte for his commen pastures, and the sixte for his haye; and in wynter time there is but one occupied with corne, and than hath the husbande other fyue to occupy tyll lente come, and that he hath his falowe felde, his ley felde, and his pasture felde al sommer. And when he hath mowen his medowe then he hath his medowe grounde, soo that if he hath any weyke catell that wold be amended, or dyvers maner of catell, he may put them in any close he wyll, the which is a great advantage; and if all shulde lye commen, than wolde the edyche of the corne feldes and the aftermath of all the medowes be eaten in X. or XII. dayes. And the rych men that hath moche catell wold have the advantage, and the poore man can have no helpe nor relefe in wynter when he hath moste nede; and if an acre of lande be worthe sixe pens, or it be enclosed, it will be worth VIII. pens, when it is enclosed by reason of the compostyng and dongyng of the catell that shall go and lye upon it both day and nighte; and if any of his thre closes that he hath for his corne be worne or ware bare, than he may breke and plowe up his close that he hadde for his layse, or the close that he hadde for his commen pasture, or bothe, and sowe them with corne, and let the other lye for a time, and so shall he have alway reist grounde, the which will bear moche corne with lytel donge; and also he shall have a great profyte of the wod in the hedges whan it is growen; and not only these profytes and advantages beforesaid, but he shall save moche more than al these, for by reason of these closes he shall save meate, drinke, and wages of a shepherde, the wages of the heerdmen, and the wages of the swine herde, the which may fortune to be as chargeable as all his holle rent; and also his corne shall be better saved from eatinge or destroyeng with catel. For dout ye nat but heerdemen with their catell, shepeherdes with their shepe, and tieng of horses and mares, destroyeth moch corne, the which the hedges wold save. Paraduenture some men would say, that this shuld be against the common weale, bicause the shepeherdes, heerdmen, and swyneherdes, shuld than be put out of wages. To that it may be answered, though these occupations be not used, there be as many newe occupations that were not used before; as getting of quickesettes, diching, hedging, and plashing, the which the same men may use and occupye."

The next author who writes professedly on agriculture is Tusser, whose *Five Hundred Points of Husbandry*, published in 1562, was formerly in such high repute as to be recommended by Lord Molesworth to be taught in schools.[1] The edition of 1604 is the one we make use of here. In it the book of husbandry consists of 118 pages, and then follows the *Points of Housewifrie*, occupying 42 pages more. It is written in verse. Amidst a vast heap of rubbish, there are some useful notices concerning the state of agriculture at the time in different parts of England. Hops, which had been introduced in the early part of the 16th century, and on the culture of which a treatise was published in 1574 by Reynolde Scott, are mentioned as a well-known crop. Buckwheat was sown after barley. Hemp and flax are mentioned as common crops. Inclosures must have been numerous in several counties; and there is a very good comparison between "champion (open fields) country, and several," which Blythe afterwards transcribed into his *Improver Improved*. Carrots, cabbages, turnips, and rape, are mentioned among the herbs and roots for the kitchen. There is nothing to be found in Tusser about serfs or bondmen, as in Fitzherbert's works. This author's division of the crop is rather curious, though probably quite inaccurate, if he means that the whole rent might be paid by a tenth of the corn.

Tusser 1562.

"One part cast forth for rent due out of hand.
One other part for seed to sow thy land.
Another part leave parson for his tith.
Another part for harvest, sickle and sith.
One part for ploughwrite, cartwrite, knacker, and smith.
One part to uphold thy teemes that draw therewith.
Another part for servant and workman's wages laie.
One part likewise for filbellie daie by daie.
One part thy wife for needful things doth crave.
Thyself and thy child the last part would have."

The next writer is Barnaby Googe, whose *Whole Art of Husbandry* was printed in 1578, and again by Markham in 1614. The first edition is merely a translation of a German work; and very little is said of English husbandry in the second, though Markham made some trifling interpolations, in order, as it is alleged, to adapt the German husbandry to the English climate. It is for the most part made up of gleanings from the ancient writers of Greece and Rome, whose errors are faithfully retained, with here and there some description of the practices of the age, in which there is little of novelty or importance. Googe mentions a number of English writers who lived about the time of Fitzherbert, whose works have not been preserved.

[1] *Some Considerations for the promoting of Agriculture and employing the Poor.* Dublin, 1723.

For more than fifty years after this, or till near the middle of the 17th century, there are no systematic works on husbandry, though several treatises on particular departments of it. From these it is evident that all the different operations of the farmer were performed with more care and correctness than formerly; that the fallows were better worked, the fields kept freer from weeds, and much more attention paid to manures of every kind. A few of the writers of this period deserve to be shortly noticed.

Sir Hugh Plat, in his *Jewel House of Art and Nature*, printed in 1594 (which Weston in his catalogue erroneously ascribes to Gabriel Plattes), makes some useful observations on manures, but chiefly collected from other writers. His censure of the practice of leaving farm dung lying scattered about is among the most valuable.

Sir John Norden's *Surveyor's Dialogue*, printed in 1607, and reprinted with additions in 1618, is a work of considerable merit. The first three books of it relate to the rights of the lord of the manor and the various tenures by which landed property was then held, with the obligations which they imposed. Among others, we find the singular custom, so humorously described in the *Spectator*, of the incontinent widow riding upon a ram. In the fifth book there are a good many judicious observations on the "different natures of grounds, how they may be employed, how they may be bettered, reformed, and amended." The famous meadows near Salisbury are mentioned; and when cattle have fed their fill, hogs, it is pretended, "are made fat with the remnant—namely, with the knots and sappe of the grasse." "Clouer grasse, or the grasse honey suckle" (white clover), is directed to be sown with other hay seeds. "Carrot rootes" were then raised in several parts of England, and sometimes by farmers. London street and stable dung was carried to a distance by water, though it appears from later writers to have been got for the trouble of removing. And leases of 21 years are recommended for persons of small capital, as better than employing it in purchasing land,—an opinion that prevails very generally among our present farmers.

Bees seem to have been great favourites with these early writers; and among others, there is a treatise by Butler, a gentleman of Oxford, called the *Feminine Monarchie, or the History of Bees*, printed in 1609, full of all manner of quaintness and pedantry.

We shall pass over Markham, Mascall, Gabriel Plattes, and several other authors of this period, the best part of their writings being preserved by Blythe and Hartlib, of whom we shall say a little immediately. In Sir Richard Weston's *Discourse on the Husbandry of Brabant and Flanders*, published by Hartlib in 1645, we may mark the dawn of the vast improvements which have since been effected in Britain. This gentleman was ambassador from England to the elector palatine and king of Bohemia in 1619, and had the merit of being the first who introduced the *great clover*, as it was then called, into English agriculture, about 1645, and probably turnips also. His directions for the cultivation of clover are better than was to be expected. It thrives best, he says, when you sow it on the worst and barrenest ground, such as our worst heath ground is in England. The ground is to be pared and burnt, and unslacked lime must be added to the ashes. It is next to be well ploughed and harrowed; and about ten pounds of clover seed must be sown on an acre in April or the end of March. If you intend to preserve seed, then the second crop must be let stand till it come to a full and dead ripeness, and you shall have at the least five bushels per acre. Being once sown, it will last five years; and then being ploughed, it will yield, three or four years together, rich crops of wheat, and after that a crop of oats, with which clover seed is to be sown again. It is in itself an excellent manure, Sir Richard adds; and so it should be, to enable land to bear this treatment. In less than ten years after its introduction, that is, before 1655, the culture of clover, exactly according to the present method, seems to have been well known in England, and it had also made its way to Ireland.

A great many works on agriculture appeared during the time of the Commonwealth, of which Blythe's *Improver Improved* and Hartlib's *Legacy* are the most valuable. The first edition of the former was published in 1649, and of the latter in 1650; and both of them were enlarged in subsequent editions. In the first edition of the *Improver Improved*, no mention is made of clover, nor in the second of turnips, but in the third, published in 1662, clover is treated of at some length, and turnips are recommended as an excellent cattle crop, the culture of which should be extended from the kitchen garden to the field Sir Richard Weston must have cultivated turnips before this; for Blythe says, that Sir Richard affirmed to himself he did feed his swine with them. They were first given boiled, but afterwards the swine came to eat them raw, and would run after the carts, and pull them forth as they gathered them,—an expression which conveys an idea of their being cultivated in the fields.

Blythe's book is the first systematic work in which there are some traces of the alternate husbandry so beneficially established since, by interposing clover and turnip between culmiferous crops. He is a great enemy to commons and common fields, and to retaining land in old pasture, unless it be of the best quality. His description of the different kinds of ploughs is interesting; and he justly recommends such as were drawn by two horses (some even by one horse), in preference to the weighty and clumsy machines which required four or more horses or oxen. Almost all the manures now used seem to have been then well known, and he brought lime himself from a distance of 20 miles. He speaks of an instrument which ploughed, sowed, and harrowed at the same time; and the *setting of corn* was then a subject of much discussion. "It was not many years," says Blythe, "since the famous city of London petitioned the Parliament of England against two anusancies or offensive commodities, which were likely to come into great use and esteem; and that was Newcastle coal, in regard of their stench, &c., and hops, in regard they would spoyle the taste of drink, and endanger the people."

Hartlib's *Legacy* is a very heterogeneous performance, containing, among some very judicious directions, a great deal of rash speculation. Several of the deficiencies which the writer complains of in English agriculture must be placed to the account of our climate, and never have been or can be supplied. Some of his recommendations are quite unsuitable to the state of the country, and display more of general knowledge and good intention than of either the theory or practice of agriculture. Among the subjects deserving notice may be mentioned the practice of steeping and liming seed corn as a preventive of smut; changing every year the *species* of grain, and bringing seed corn from a distance; ploughing down green crops as manure; and feeding horses with broken oats and chaff. This writer seems to differ a good deal from Blythe about the advantage of interchanging tillage and pasture. "It were no losse to this island," he says, "if that we should not plough at all, if so be that we could certainly have corn at a reasonable rate, and likewise vent for all our manufactures of wool;" and one reason for this is, that pasture employeth more hands than tillage, instead of depopulating the country, as was commonly imagined. The *grout*, which he mentions "as coming over to us in Holland ships," about which he desires information, was probably the same with our present shelled barley; and mills for manufacturing it were introduced into Scotland from Holland towards the beginning of the last century.

To the third edition, published in 1655, are subjoined Dr Beatie's *Annotations* with the writer of the *Legacy's* answers, both of them ingenious, and sometimes instructive. But this cannot be said of Gabriel Plattes's *Mercurius Lætificans*, also added to this edition, which is a most extravagant production. There are also several communications from Hartlib's different correspondents, of which the most interesting are those on the early cultivation and great value of clover. Hartlib himself does not appear much in this collection; but he seems to have been a very useful person in editing the works of others, and as a collector of miscellaneous information on rural subjects. It is strange that neither Blythe nor Hartlib, nor any of Hartlib's correspondents, seem ever to have heard of Fitzherbert's works.

Among the other writers previous to the Revolution, we shall only mention Ray the botanist, and Evelyn, both men of great talent and research, whose works are still in high estimation. A new edition of Evelyn's *Silva and Terra* was published in 1777 by Dr Hunter, with large notes and elegant engravings, and reprinted in 1812.

The preceding review commences with a period of feudal anarchy and despotism and comes down to the time when the exertions of individual interest were protected and encouraged by the firm administration of equal laws; when the prosperity of Great Britain was no longer retarded by internal commotions, nor endangered by hostile invasion.

Laws.

The laws of this period, in so far as they relate to agriculture and rural economy, display a similar progress in improvement.

From the beginning of the reign of Henry VII. to the end of Elizabeth's, a number of statutes were made for the encouragement of tillage, though probably to little purpose. The great grievance of those days was the practice of laying arable land to pasture, and suffering the farm-houses to fall to ruin. "Where in some towns," says the statute 4th Henry VII. (1488), "two hundred persons were occupied and lived of their lawful labours, now there are occupied two or three herdsmen, and the residue fall into idleness;" therefore it is ordained, that houses which within three years have been let for farms, with twenty acres of land lying in tillage or husbandry, shall be upheld, under the penalty of half the profits, to be forfeited to the king or the lord of the fee. Almost half a century afterwards, the practice had become still more alarming; and in 1534 a new Act was tried, apparently with as little success. "Some have 24,000 sheep, some 20,000 sheep, some 10,000, some 6000, some 4000, and some more and some less;" and yet it is alleged the price of wool had nearly doubled, "sheep being come to a few persons' hands." A penalty was therefore imposed on all who kept above 2000 sheep; and no person was to take in farm more than two tenements of husbandry. By the 39th Elizabeth (1597), arable land made pasture since the 1st Elizabeth shall be again converted into tillage, and what is arable shall not be converted into pasture.

Many laws were enacted during this period against vagabonds, as they were called; and persons who could not find employment seem to have been sometimes confounded with those who really preferred idleness and plunder. The dissolution of the feudal system, and the suppression of the monasteries, deprived a great part of the rural population of the means of support. They could not be employed in cultivating the soil, for there was no middle class of farmers possessed of capital to be vested in improvements; and what little disposable capital was in the hands of great proprietors could not, in those rude times, be so advantageously embarked in the expensive and precarious labours of growing corn, as in pasturage, which required much less skill and superintendence. Besides, there was a constant demand for wool on the Continent; while the corn market was not only confined by laws against exportation, but fettered by restrictions on the internal trade. The laws regarding the wages of labour and the price of provisions are a further proof of the ignorance of the age in regard to the proper subject of legislation.

By the statute 1552 it is declared, that any person that shall buy merchandise, victual, &c., coming to market, or make any bargain for buying the same, before they shall be in the market ready to be sold, or shall make any motion for enhancing the price, or dissuade any person from coming to market, or forbear to bring any of the things to market, &c., shall be deemed a *forestaller*. Any person who buys and sells again in the same market, or within four miles thereof, shall be reputed a *regrater*. Any person buying corn growing in the fields, or any other corn, with intent to sell again, shall be reputed an unlawful *ingrosser*. It was also declared, that no person shall sell cattle within five weeks after he had bought them. Licenses, indeed, were to be granted in certain cases, and particularly when the price of wheat was at or under 6s. 8d. a quarter, and other kinds of grain in that proportion.

Corn trade. The laws regarding the exportation and importation of corn during this period could have had little effect in encouraging agriculture, though towards the latter part of it they gradually approached that system which was finally established at and soon after the Revolution. From the time of the above-mentioned statute against forestallers, which effectually prevented exportation, as well as the freedom of the home trade, when corn was above the price therein specified, down to 1688, there are at least twelve statutes on this subject; and some of them are so nearly the same, that it is probable they were not very carefully observed. The price at which wheat was allowed to be exported was raised from 6s. 8d. a quarter, the price fixed by the 1st and 2d of Philip and Mary (1553), to 10s. in 1562; to 20s. in 1593; to 26s. 8d. in 1604; to 32s. in 1623; to 40s. in 1660; to 48s. in 1663; and at last, in 1670, exportation was virtually permitted without limitation. Certain duties, however, were payable, which in some cases seem to have amounted to a prohibition; and until 1660 importation was not restrained even in years of plenty and cheapness. In permitting exportation, the object appears to have been revenue rather than the encouragement of production.

Tolls, 1662. The first statute for levying tolls at turnpikes, to make or repair roads in England, passed in 1662.

Scotland, 16th and 17th centuries. Of the state of agriculture in Scotland in the 16th and the greater part of the 17th century very little is known; no professed treatise on the subject appeared till after the Revolution. The south-eastern counties were the earliest improved, and yet in 1660 their condition seems to have been very wretched. Ray, who made a tour along the eastern coast in that year, says, "We observed little or *no fallow ground* in Scotland; some ley ground we saw, which they manured with sea wreck. The men seemed to be very lazy, and may be frequently observed to plough in their cloaks. It is the fashion of them to wear cloaks when they go abroad, but especially on Sundays. They have neither good bread, cheese, nor drink. They cannot make them, nor will they learn. Their butter is very indifferent, and one would wonder how they could contrive to make it so bad. They use much pottage made of coalwort, which they call *kail*, sometimes broth of decorticated barley. The ordinary country-houses are pitiful cots, built of stone and covered with turfs, having in them but one room, many of them no chimneys, the windows very small holes, and not glazed. The ground in the valleys and plains bears very good corn, but especially bears barley or bigge, and oats, but rarely wheat and rye."[1]

It is probable that no great change had taken place in Scotland from the end of the 15th century, except that tenants gradually became possessed of a little stock of their own, instead of having their farm stocked by the landlord. "The minority of James V., the reign of Mary Stuart, the infancy of her son, and the civil wars of her grandson Charles I., were all periods of lasting waste. The very laws which were made during successive reigns for protecting the tillers of the soil from spoil, are the best proofs of the deplorable state of the husbandman."[2]

Yet in the 17th century were those laws made which paved the way for the present improved system of agriculture in Scotland. By statute 1633, landholders were enabled to have their tithes valued, and to buy them either at nine or six years' purchase, according to the nature of the property. The statute 1685, conferring on landlords a power to entail their estates, was indeed of a very different tendency in regard to its effects on agriculture. But the two Acts in 1695, for the division of commons, and separation of intermixed properties, have facilitated in an eminent degree the progress of improvement.

Progress of Agriculture from 1688 to 1760.

From the Revolution to the accession of George III. the progress of agriculture was by no means so considerable as we should be led to imagine from the great exportation of corn. It is the opinion of well-informed writers,[3] that very little improvement had taken place, either in the cultivation of the soil or in the management of live stock, from the Restoration down to the middle of last century. Even clover and turnips, the great support of the present improved system of agriculture, were confined to a few districts, and at the latter period were scarcely cultivated at all by common farmers in the northern part of the island. Of the writers of this period, therefore, we shall notice only such as describe some improvement in the modes of culture, or some extension of the practices that were formerly little known.

In Houghton's *Collections on Husbandry and Trade*, a periodical work begun in 1681, we have the first notice of turnips being eaten by sheep:—"Some in Essex have their fallow after turnips, which feed their sheep in winter, by which means the turnips are scooped, and so made capable to hold dews and rain water, which, by corrupting, imbibes the nitre of the air, and when the shell breaks it runs about and fertilises. By feeding the sheep, the land is dunged as if it had been folded; and those turnips, though few or none be carried off for human use, are a very excellent improvement, nay, some reckon it so though they only plough the turnips in without feeding."[4] This was written in February 1694; but ten years before, Worlidge, one of his correspondents, observes, "Sheep fatten very well on turnips, which prove an excellent nourishment for them in hard winters when fodder is scarce; for they will not only eat the greens, but feed on the roots in the ground, and scoop them hollow even to the very skin. Ten acres (he adds) sown with clover, turnips, &c., will feed as many sheep as one hundred acres thereof would before have done."[5]

[5] *Ibid.* vol. iv. pp. 142–144.

At this time potatoes were beginning to attract notice.

"The potato," says Houghton, "is a *bocciferous* herb, with *esculent* roots, bearing winged leaves and a bell flower.

"This, I have been informed, was brought first out of Virginia by Sir Walter Raleigh; and he stopping at Ireland, some was planted there, where it thrived very well, and to good purpose; for in their succeeding wars, when all the corn above the ground was destroyed, this supported them; for the soldiers, unless they had dug up all the ground where they grew, and almost sifted it, could not extirpate them; from whence they were brought to Lancashire, where they are very numerous, and now they begin to spread all the kingdom over. They are a pleasant food boiled or roasted, and eaten with butter and sugar. There is a sort brought from Spain, that are of a longer form, and are more luscious than ours; they are much set by, and sold for sixpence or eightpence the pound."[6]

The next writer is Mortimer, whose *Whole Art of Husbandry* was published in 1706, and has since run through several editions. It is a regular, systematic work, of considerable merit; and will even now repay perusal by the practical agriculturist. From the third edition of Hartlib's *Legacy*, we learn that clover was cut green, and given to cattle; and it appears that this practice of *soiling*, as it is now called, had become very common about the beginning of last century, wherever clover was cultivated. Rye-grass was now sown along with it. Turnips were hand-hoed, and extensively employed in feeding sheep and cattle, in the same manner as at present.

The first considerable improvement in the practice of that period was introduced by Jethro Tull, a gentleman of Berkshire, who began to drill wheat and other crops about the year 1701, and whose *Horse-hoeing Husbandry*, published in 1731, exhibits the first decided step in advance upon the principles and practices of his predecessors. Not contented with a careful attention to details, Tull set himself, with admirable skill and perseverance, to investigate the growth of plants, and thus to arrive at a knowledge of the principles by which the cultivation of field-crops should be regulated. Having arrived at the conclusion that the food of plants consists of minute particles of earth taken up by their rootlets, it followed, that the more thoroughly the soil in which they grew was disintegrated, the more abundant would be the "pasture" (as he called it), to which their fibres would have access. He was thus led to adopt that system of sowing his crops in rows or drills, so wide apart as to admit of tillage of the intervals, both by ploughing and hoeing, being continued until they had well-nigh arrived at maturity.

As the distance between his rows appeared much greater than was necessary for the range of the roots of the plants, he begins by showing that these roots extend much farther than is commonly believed, and then proceeds to inquire into the nature of their food. After examining several hypotheses, he decides this to be fine particles of earth. The chief, and almost the only use of dung, he thinks, is to divide the earth, to dissolve "this terrestrial matter, which affords nutriment to the mouths of vegetable roots;" and this can be done more completely by tillage. It is therefore necessary not only to pulverise the soil by repeated ploughings before it be seeded, but, as it becomes gradually more and more compressed afterwards, recourse must be had to tillage while the plants are growing; and this is *hoeing*, which also destroys the weeds that would deprive the plants of their nourishment.

The leading features of Tull's husbandry are his practice of laying the land into narrow ridges of five or six feet, and upon the middle of these drilling one, two, or three rows, distant from one another about seven inches when there were three, and ten when only two. The distance of the

[6] Houghton's *Collections on Husbandry and Trade*, vol. ii. p. 468.

plants on one ridge from those on the contiguous one he called an *interval;* the distance between the rows on the same ridge, a *space* or *partition;* the former was stirred repeatedly by the horse-hoe, the latter by the hand-hoe.

The extraordinary attention this ingenious person gave to his mode of culture is perhaps without a parallel:—

"I formerly was at much pains," he says, "and at some charge in improving my drills for planting the rows at very near distances, and had brought them to such perfection, that one horse would draw a drill with eleven shares, making the rows at three inches and a half distance from one another; and at the same time sow in them three very different sorts of seeds, which did not mix; and these, too, at different depths. As the barley-rows were seven inches asunder, the barley lay four inches deep. A little more than three inches above that, in the same channels, was clover; betwixt every two of these rows was a row of St Foin, covered half an inch deep.

"I had a good crop of barley the first year; the next year two crops of broad clover, where that was sown; and where hop-clover was sown, a mixed crop of that and St Foin; but I am since, by experience, so fully convinced of the folly of these, or any other mixed crops, and more especially of narrow spaces, that I have demolished these instruments, in their full perfection, as a vain curiosity, the drift and use of them being contrary to the true principles and practice of horse-hoeing."[1]

In the culture of wheat, he began with ridges six feet broad, or eleven on a breadth of 66 feet; but on this he afterwards had fourteen ridges. After trying different numbers of rows on a ridge, he at last preferred two, with an intervening space of about 10 inches. He allowed only three pecks of seed for an acre. The first hoeing was performed by turning a furrow from the row, as soon as the plant had put forth four or five leaves; so that it was done before or at the beginning of winter. The next hoeing was in spring, by which the earth was returned to the plants. The subsequent operations depended upon the circumstances and condition of the land and the state of the weather. The next year's crop of wheat was sown upon the intervals which had been unoccupied the former year; but this he does not seem to think was a matter of much consequence.

"My field," he observes, "whereon is now the thirteenth crop of wheat, has shown that the rows may successfully stand upon any part of the ground. The ridges of this field were, for the twelfth crop, changed from six feet to four feet six inches. In order for this alteration the ridges were ploughed down, and then the next ridges were laid out the same way as the former, but one foot six inches narrower, and the double rows drilled on their tops; whereby, of consequence, there must be some rows standing on every part of the ground, both on the former partitions and on every part of the intervals. Notwithstanding this, there was no manner of difference in the goodness of the rows; and the whole field was in every part of it equal, and the best, I believe, that ever grew on it. It is now the thirteenth crop, likely to be good, though the land was not ploughed crossways."[2]

It follows, from this singular management, that Tull thought a succession of crops of different species altogether unnecessary; and he labours hard to prove against Dr Woodward, that the advantages of such a change under his plan of tillage were quite chimerical, though he seems to admit the benefit of a change of the seed itself.

In cultivating turnips he made the ridges of the same breadth as for wheat, but only one row was drilled on each. His management, while the crop was growing, differs very little from the present practice. When drilled on the level, it is impossible, he observes, to hoe-plough them so well as when they are planted upon ridges. But the seed was deposited at different depths, the half about four inches deep, and the other half exactly over that, at the depth of half an inch.

"Thus planted, let the weather be never so dry, the deepest seed will come up, but if it raineth immediately after planting, the shallow will come up first. We also make it come up at four times, by mixing our seed half new and half old, the new coming up a day quicker than the old. These four comings up give it so many chances for escaping the fly; it being often seen that the seed sown over night will be destroyed by the fly, when that sown the next morning will escape, and *vice versa:* or you may hoe-plough them when the fly is like to devour them; this will bury the greatest part of these enemies: or else you may drill in another row without new-ploughing the land."

Drilling and horse and hand hoeing seem to have been in use before the publication of Tull's book. "Hoeing," he says, "may be divided into deep, which is our horse-hoeing; and shallow, which is the English hand-hoeing; and also the shallow horse-hoeing used in some places betwixt rows, where the intervals are very narrow, as 16 or 18 inches. This is but an imitation of the hand-hoe, or a succedaneum to it, and can neither supply the use of dung nor fallow, and may be properly called scratch-hoeing." But in his mode of forming ridges his practice seems to have been original; his implements display much ingenuity; and his claim to the title of father of the present horse-hoeing husbandry of Great Britain seems indisputable. A translation of Tull's book was undertaken at one and the same time in France, by three different persons of consideration, without the privity of each other. Two of them afterwards put their papers into the hands of the third, M. du Hamel du Monceau, of the Royal Academy of Sciences at Paris, who published a treatise on husbandry, on the principles of Mr Tull, a few years after. But Tull seems to have had very few followers in England for more than thirty years. The present method of drilling and horse-hoeing turnips was not introduced into Northumberland till about the year 1780;[3] and it was then borrowed from Scotland, the farmers of which had the merit of first adopting Tull's management in the culture of this root about 1760. From Scotland it made its way, but slowly, into the southern parts of the island.

Tull's doctrines and practices being quite in advance of his own times, were, as is usual in such cases, vehemently opposed by his contemporaries. He was, in consequence, involved in frequent controversy, in conducting which he occasionally showed an asperity of temper which excites our regret, but which is not to be wondered at, when we consider the trials of patience which he encountered from the unreasonable opposition of the agricultural community to his improvements; the thwarting of his experiments by his own labourers, who, in their ignorant zeal against innovations, wilfully broke his machines, and disregarded his orders; and from acute and protracted bodily disease. The soundness of his views and practice, as regards turnip culture, came by-and-by to be acknowledged, and have since been generally adopted. But it was only some twenty-five years ago that his full merit began to be understood. The Rev. Mr Smith, in his *Word in Season*, about that time recalled attention to Tull's peculiar system of wheat culture in a way that startled the whole community; while Professor Way, in a series of eloquent lectures delivered before the Royal Agricultural Society, showed that his science was true in the main, and even more strikingly ahead of his times than his practice.

Among the English writers of this period may be mentioned Bradley, Lawrence, Hales, Miller, Ellis, Smith, Hill, Hitt, Lisle, and Home. Most of their works went through several editions in a few years,—at once a proof of the estimation in which they were held, and of the direction of the public mind towards investigating the principles and practice of agriculture.

Of the progress of the art in Scotland, till towards the end of the 17th century, we are almost entirely ignorant. The first work, written by Donaldson, was printed in 1697, under the title of *Husbandry Anatomized; or, an Inquiry into the Present Manner of Teiling and Manuring the*

[1] *Horse-hoeing Husbandry*, p. 62. Lond. 1762. [2] *Ibid.* p. 424

[3] *Northumberland Survey*, p. 100.

Ground in Scotland. It appears from this treatise, that the state of the art was not more advanced at that time in North Britain than it had been in England in the time of Fitzherbert. Farms were divided into infield and outfield; corn crops followed one another without the intervention of fallow, cultivated herbage, or turnips, though something is said about fallowing the outfield; inclosures were very rare; the tenantry had not begun to emerge from a state of great poverty and depression; and the wages of labour, compared with the price of corn, were much lower than at present; though that price at least in ordinary years, must appear extremely moderate in our times. Leases for a term of years, however, were not uncommon; but the want of capital rendered it impossible for the tenantry to attempt any spirited improvements.

naldson, 97. Donaldson first points out the common management of that period, which he shows to have been very unproductive, and afterwards recommends what he thinks would be a more profitable course.

"Of the dale ground," he says, "that is, such lands as are partly hills and partly valleys, of which sorts may be comprehended the greatest part of arable ground in this kingdom, I shall suppose a farmer to have a lease or tack of three score acres, at three hundred merks of rent per annum (£16, 13s. 4d. sterling). Perhaps some who are not acquainted with rural affairs may think this cheap; but those who are the possessors thereof think otherwise, and find difficulty enough to get the same paid, according to their present way of manuring thereof. But that I may proceed to the comparison, I shall show how commonly this farm-room is managed. It is commonly divided into two parts, viz., one-third croft, and two-thirds outfield, as it is termed. The croft is usually divided into three parts: to wit, one-third barley, which is always dunged that year barley is sown thereon; another third oats; and the last third peas. The outside field is divided into two parts, to wit, the one half oats, and the other half grass, two years successively. The product which may be supposed to be on each acre of croft, four bolls (three Winchester quarters, and that of the outfield, three (2¼ quarters); the quota is seven score bolls, which we shall also reckon at five pounds (8s. 4d.) per boll, cheap year and dear year one with another. This, in all, is worth £700 (£58, 6s. 8d. sterling).

"Then let us see what profit he can make of his cattle. According to the division of his lands there is 20 acres of grass, which cannot be expected to be very good, because it gets not leave to lie above two years, and therefore cannot be well swarded. However, usually, besides four horses, which are kept for ploughing the said land, ten or twelve nolt are also kept upon a farm-room of the above-mentioned bounds, but, in respect of the badness of the grass, as said is, little profit is had of them. Perhaps two or three stone of butter is the most that can be made of the milk of his kine the whole summer, and not above two heffers brought up each year. As to what profit may be made by bringing up young horses, I shall say nothing, supposing he keeps his stock good, by those of his own upbringing. The whole product, then, of his cattle cannot be reckoned above fifty merks (£2, 15s. 6d.) For, in respect his beasts are in a manner half-starved, they are generally small; so that scarce may a heffer be sold at above twelve pounds (£1 sterling). The whole product of his farm-room, therefore, exceeds not the value of £733 (£61, 1s. 8d. sterling), or thereabout."

The labourers employed on this farm were two men and one woman, besides a herd in summer, and other servants in harvest.

Donaldson then proceeds to point out a different mode of management, which he calculates to be more profitable; but no notice is taken of either clover or turnips as crops to be raised in his new course, though they are incidentally noticed in other parts of the work.

"I also recommend potatoes as a very profitable root for husbandmen and others that have numerous families. And because there is a peculiar way of planting this root, not commonly known in this country, I shall here show what way it is ordinary planted or set. The ground must be dry; and so much the better it is if it have a good soard of grass. The beds or riggs are made about eight foot broad, good store of dung being laid upon your ground; horse or sheep dung is the proper manure for them. Throw each potatoe or sett (for they were sometimes cut into setts) into a knot of dung, and afterwards dig earth out of the furrows, and cover them all over, about some three or four inches deep; the furrows left between your riggs must be about two foot broad, and little less will they be in depth before your potatoes be covered. You need not plant this root in your garden; they are commonly set in the fields, and wildest of ground, for enriching of it." As to their consumption, they were sometimes "boiled and broken, and stirred with butter and new milk; also roasted, and eaten with butter; yea, some make bread of them, by mixing them with oat or barley meal; others parboil them and bake with them apples, after the manner of tarts."

There is a good deal in this little treatise about sheep, and other branches of husbandry; and, if the writer was well informed, as in most instances he appears to have been, his account of prices, of wages, and generally of the practices of that period, is very interesting.

The next work on the husbandry of Scotland is, *The Countryman's Rudiments, or an advice to the Farmers in East Lothian, how to labour and improve their grounds,* said to have been written by Lord Belhaven about the time of the Union, and reprinted in 1723. In this we have a deplorable picture of the state of agriculture in what is now the most highly improved county in Scotland. His lordship begins with a very high encomium on his own performance. "I dare be bold to say, there was never such a good easy method of husbandry as this, so succinct, extensive, and methodical in all its parts, published before." And he bespeaks the favour of those to whom he addresses himself, by adding, "neither shall I affright you with hedging, ditching, marling, chalking, paring, and burning, draining, watering, and such like, which are all very good improvements indeed, and very agreeable with the soil and situation of East Lothian; but I know ye cannot bear as yet a crowd of improvements, this being only intended to initiate you in the true method and principles of husbandry." The farm-rooms in East Lothian, as in other districts, were divided into infield and outfield.

"The infield (where wheat is sown) is generally divided by the tenant into four divisions or breaks, as they call them, viz, one of wheat, one of barley, one of pease, and one of oats, so that the wheat is sowd after the pease, the barley after the wheat, and the oats after the barley. The outfield land is ordinarily made use of promiscuously for feeding of their cows, horse, sheep, and oxen; 'tis also dunged by their sheep who lay in earthen folds; and sometimes, when they have much of it, they fauch or fallow a part of it yearly."

Under this management the produce seems to have been three times the seed; and yet, says his lordship, "if in East Lothian they did not leave a higher stubble than in other places of the kingdom, their grounds would be in a much worse condition than at present they are, though bad enough."—"A good crop of corn makes a good stubble, and a good stubble is the equalest mucking that is." Among the advantages of inclosures, he observes, "you will gain much more labour from your servants, a great part of whose time was taken up in gathering thistles and other garbage for their horses to feed upon in their stables and thereby the great trampling and pulling up, and other destruction of the corns, while they are yet tender, will be prevented." Potatoes and turnips are recommended to be sown in the yard (kitchen-garden). Clover does not seem to have been in use. Rents were paid in corn; and, for the largest farm, which he thinks should employ no more than two ploughs, the rent was about six chalders of victual "when the ground is very good, and four in that which is not so good. But I am most fully convinced they should take long leases or tacks, that they may not be straitened with time in the improvement of their rooms; and this is profitable both for master and tenant."

Such was the state of the husbandry of Scotland in the early part of last century. The first attempts at improvement cannot be traced farther back than 1723, when a number of land-holders formed themselves into a society, under the title of the *Society of Improvers in the Knowledge of Agriculture* *in Scotland.* The Earl of Stair, one of their most active members, is said to have been the first who cultivated turnips in that country. The *Select Transactions* of this society were collected and published in 1743 by Mr Maxwell, who took a large part in its proceedings. It is evident from this book that the society had exerted itself in a very laudable manner, and apparently with considerable success, in introducing cultivated herbage and turnips, as well as in improving the former methods of culture. But there is reason to believe that the influence of the example of its numerous members did not extend to the common tenantry, who are always unwilling to adopt the practices of those who are placed in a higher rank, and supposed to cultivate land for pleasure rather than profit. Though this society, the earliest probably in the United Kingdom, soon counted upwards of 300 members, it existed little more than 20 years. Maxwell delivered lectures on agriculture for one or two sessions at Edinburgh, which, from the specimen he has left, ought to have been encouraged.

In the introductory paper in Maxwell's collection, we are told, that—

"The practice of draining, inclosing, summer fallowing, sowing flax, hemp, rape, turnip and grass seeds, planting cabbages after, and potatoes with, the plough, in fields of great extent, is introduced; and that, according to the general opinion, more corn grows now yearly where it was never known to grow before, these twenty years last past, than perhaps a sixth of all that the kingdom was in use to produce at any time before."

In this work we find the first notice of a threshing-machine: it was invented by Mr Michael Menzies, advocate, who obtained a patent for it. Upon a representation made to the society that it was to be seen working in several places, they appointed two of their number to inspect it; and in their report they say, that one man would be sufficient to manage a machine which would do the work of six. One of the machines was "moved by a great water-wheel and triddles," and another "by a little wheel of three feet diameter, moved by a small quantity of water." This machine the society recommended to all gentlemen and farmers.

The next work is by the same Mr Maxwell, printed in 1757, and entitled the *Practical Husbandman; being a collection of miscellaneous papers on Husbandry,* &c. In this book the greater part of the *Select Transactions* is republished, with a number of new papers, among which, an *Essay on the Husbandry of Scotland,* with a proposal for the improvement of it, is the most valuable. In this he lays it down as a rule, that it is bad husbandry to take two crops of grain successively, which marks a considerable progress in the knowledge of modern husbandry; though he adds, that in Scotland the best husbandmen after a fallow take a crop of wheat; after the wheat, peas; then barley, and then oats; and after that they fallow again. The want of inclosures was still a matter of complaint. The ground continued to be cropped so long as it produced two seeds; the best farmers were contented with four seeds, which was more than the general produce.

The first Act of Parliament for collecting tolls on the highway in Scotland was passed in 1750, for repairing the road from Dunglass bridge to Haddington. In ten years after, several Acts followed for the counties of Edinburgh and Lanark, and for making the roads between Edinburgh and Glasgow. The benefit which agriculture has derived from good roads it would not be easy to estimate. The want of them was one great cause of the slow progress of the art in former times.

The Revolution in 1688 was the epoch of that system of corn laws to which very great influence has been ascribed, both on the practice of agriculture and the general prosperity of the country. But for an account of these and later statutes on the subject, we must refer to the article CORN LAWS.

The exportation of wool was prohibited in 1647, in 1660, and in 1688; and the prohibition strictly enforced by subsequent statutes. The effect of this on its price, and the state of the wool trade, from the earliest period to the middle of last century, are distinctly exhibited by the learned and laborious author of *Memoirs on Wool,* printed in 1747.

CHAPTER II.

RECENT BRITISH AGRICULTURE.

Section 1.—Progress during the Eighteenth Century.

Before entering upon a description of the agriculture of Great Britain at the present day, it may help to set matters in a clearer light if we take just so much of a retrospect as will serve as a back-ground to our picture.

At the beginning of the 18th century the agriculture of our country was still of the rudest kind. With the exception of certain parts of England, the land was still for the most part unenclosed, the live stock of each township grazing together, and the arable land being occupied in common field or run-rig. The practice of fallowing annually a portion of the arable land, and of interposing a crop of peas betwixt the cereal crops, was becoming a common practice, and was a great improvement upon the previous and yet common usage of growing successive corps of white-corn until the land was utterly exhausted, when it was left to recruit itself by resting in a state of nature, while other portions were undergoing the same process. Clover and turnips had been introduced before this date, and were coming gradually into cultivation as field crops in the more advanced parts of England. Potatoes were commonly grown in gardens, but had not yet found their way to the fields.

The gradual advance in the price of farm produce soon after the year 1760, occasioned by the increase of population and of wealth derived from manufactures and commerce, gave a powerful stimulus to rural industry, augmented agricultural capital, and called forth a more skilful and enterprising race of farmers. The arable lands of the country, which, under the operation of the feudal system, had been split up into minute portions, cultivated by the tenants and their families without hired labour, began now to be consolidated into larger holdings, and let to those tenants who possessed most energy and substance. This enlargement of farms, and in Scotland the letting of them under leases for a considerable term of years, continued to be a marked feature in the agricultural progress of the country until the end of the century, and is to be regarded both as a cause and a consequence of that progress. The passing of more than 3000 inclosure bills during the reign of Geo. III., before which the whole number was but 244, shows how rapidly the cultivation of new land now proceeded. The disastrous American war for a time interfered with the national prosperity; but with the return of peace in 1783, the cultivation of the country made more rapid progress. The quarter of a century immediately following 1760, is memorable in our agricultural annals for the introduction of various important improvements. It was during this period that the genius of Bakewell produced such an extraordinary change in the character of our more important breeds of live stock; but especially by the perfecting of a new race of sheep—the well-known Leicesters—which have ever since proved such a boon to the country, and have added so much to its wealth. Bakewell's fame as a breeder was for a time enhanced by the improvement which he effected on the long-horned cattle, then the prevailing breed of the midland counties of England. These, however, were ere long rivalled, and have now been entirely superseded by the shorthorn or Durham breed, which the brothers Colling obtained from the useful race of cattle that had long existed in the valley of the Tees, by applying to them the principle of breeding which Bakewell had already established. A more rational system of cropping now began very generally to supersede the thriftless and barbarous practice just referred to of sowing successive crops of corn until the land was utterly exhausted, and then leaving it foul with weeds, to recover its power by an indefinite period of rest. Green crops, such as turnips, clover, and ryegrass, began to be alternated with grain crops, and hence the name *alternate husbandry*, by which this improved system is generally known. The land was now also generally rendered clean and mellow by a summer fallow before being sown with clover or grasses.

Hitherto the husbandry of England had been very superior in every respect to that of Scotland. Improvements now, however, made rapid progress in the latter. Mr Dawson, at Frogden, in Roxburghshire, is believed to have been the first who grew turnips as a field crop to any extent. This enterprising farmer having heard of the success with which this crop was cultivated in certain parts of England, took the precaution of seeing for himself the most approved mode of doing so before attempting to introduce it on his own farm. He accordingly went to Leicestershire, and presenting himself to the celebrated Bakewell in the garb of a Scotch ploughman, hired himself to him for six months in that capacity. Having in this thoroughly practical way acquired the knowledge he was in quest of, he told his employer (who would fain have retained him longer) that it was full time for him to be home to his own large farm. The season was too advanced to admit of his doing more that year than sow a few experimental drills, but the very next year he is said to have sown 70 acres. We have been unable to ascertain the exact date of this occurrence, but it is on record that as early as 1764 Mr Dawson had 100 acres of drilled turnips on his farm in one year.

A few years after this the Messrs Culley—one of them also a pupil of Bakewell—left their paternal property on the banks of the Tees, and settled on the Northumbrian side of the Tweed, bringing with them the valuable breeds of live stock and improved husbandry of their native district. The improvements introduced by these energetic and skilful farmers spread rapidly, and exerted a most beneficial influence upon the border counties. An Act passed in 1770, which relaxed the rigour of strict entails, and afforded power to landlords to grant leases and otherwise improve their estates, had a beneficial effect on Scottish agriculture. From 1784 to 1795 improvements advanced with steady steps. This period was distinguished for the general adoption and industrious working out of ascertained improvements. Small's swing plough, and Meikle's thrashing-machine, although invented some years before this, were now perfected and brought into general use, to the great furtherance of agriculture. Two important additions were about this time made to the field crops, viz., the Swedish turnip and potato oat. The latter was accidentally discovered in 1788, and both soon came into general cultivation. In the same year Merino sheep were introduced by his Majesty, George III., who was a zealous farmer. For a time this breed attracted much attention, and sanguine expectations were entertained that it would prove of national importance. Its unfitness for the production of mutton, and increasing supplies of fine clothing wool from other countries, soon led to its total rejection.

In Scotland, the opening up of the country by the construction of practicable roads, and the enclosing and subdividing of farms by hedge and ditch, was now in active progress. The former admitted of the general use of wheel-carriages, of the ready conveyance of produce to markets, and in particular, of the extended use of lime, the application of which was immediately followed by a great increase of produce. The latter, besides its more obvious advantages, speedily freed large tracts of country from stagnant water, and their inhabitants from ague, and prepared the way for the under-ground draining which soon after began to be practised.

Section 2.—Remarkable progress from 1795 *to* 1815.

The agriculture of the country was thus steadily improving, when suddenly the whole of Europe became involved in the wars of the French Revolution. In 1795, under the joint operation of a deficient harvest, and the cutting off of foreign supplies of grain by the policy of Napoleon, the price of wheat, which, for the twenty preceding years, had been under 50s. a quarter, suddenly rose to 81s. 6d., and in the following year reached to 96s. In 1797 the fear of foreign invasion led to a panic and run upon the banks, in which emergency the Bank Restriction Act, suspending cash payment, was passed, and ushered in a system of unlimited credit transactions. Under the unnatural stimulus of these extraordinary events, every branch of industry extended with unexampled rapidity. But in nothing was this so apparent as in agriculture; the high prices of produce holding out a great inducement to improve lands then arable, to reclaim others that had previously lain waste, and to bring much pasture-land under the plough. Nor did this increased tillage interfere with the increase of live stock, as the green crops of the alternate husbandry more than compensated for the diminished pasturage. This extraordinary state of matters lasted from 1795 to 1814; the prices of produce even increasing towards the close of that period. The average price of wheat for the whole period was 89s. 7d. per quarter; but for the last five years it was 107s., and in 1812 it reached to 126s. 6d. The agriculture of Great Britain, as a whole, advanced with rapid strides during this period; but nowhere was the change so great as in Scotland. Indeed, its progress there, during these twenty years, is probably without parallel in the history of any other country. This is accounted for by a concurrence of circumstances. Previous to this period, the husbandry of Scotland was still in a backward state as compared with the best districts of England, where many practices, only of recent introduction in the north, had been in general use for generations. This disparity made the subsequent contrast the more striking. The land in Scotland was now, with trifling exceptions, let on leases for terms varying from twenty to thirty years, and in farms of sufficient size to employ at the least two or three ploughs. The unlimited issues of Government paper, and the security afforded by these leases, induced the Scotch banks to afford every facility to landlords and tenants to embark capital in the improvement of the land. The substantial education supplied by the parish schools, of which nearly the whole population could then avail themselves, had diffused through all ranks such a measure of intelligence as enabled them promptly to discern, and skilfully and energetically to take advantage of this spring-tide of prosperity, and to profit by the agricultural information now plentifully furnished by means of the Bath and West of England Society, established in 1777, the Highland Society, instituted in 1784, and the National Board of Agriculture, in 1793—of which, however, more anon. As one proof of the astonishing progress of Scottish husbandry during this period, we may mention that the rental of land, which in 1795 amounted to £2.000,000, had in 1815 risen to

£5,278,685, or considerably more than double in twenty years.

But of the causes which have influenced the agriculture of the period under review, none have been so powerful as the extraordinary increase of our population, which, in round numbers, has twice doubled during the past seventy years. Not only are there four times as many people requiring to be fed and clad now as there were then, but from the increased wealth and altered habits of the people, the individual rate of consumption is greater now than formerly. This is particularly apparent in the case of butcher-meat, the consumption of which has increased out of all proportion to that of bread-corn. To meet this demand, there behoved to be more green crops and more live stock; and from that has resulted more wool, more manure, and more corn. While this ever-growing demand for farm-produce has stimulated agricultural improvement, it has also operated in another way. The productiveness of the soil has been greatly increased, and will no doubt be still more so in future; but the area of the country cannot be increased. Land—the raw material from which food is produced—being thus limited in amount and in increasing demand, has necessarily risen in price. So much is this the case, that whereas the average price of wheat for the five years preceding 1872 was £2, 15s. per quarter, or £2, 7s. 6d. less than during the five years preceding 1815, the rent of land is much higher now than it was then. The raw material of the food-grower having thus risen in price, his only resource has been to fall upon plans for lowering the cost of producing his crops and for increasing their amount. To such an extent has he succeeded, that the produce market has been kept full, and prices have decreased. The business of farming has in the main been a less prosperous one than most other branches of national industry, and yet agriculture, as an art and as a science, has made steady progress. We believe it is only in this way that the contemporaneous existence of two things apparently so incompatible as a steady rise in the rent of land, and a steady decrease in the price of its produce, can be satisfactorily accounted for.

PROGRESS SINCE 1815.

Section 3.—Laws affecting Agriculture.

The abundant crop of 1813, and restored communication with the continent of Europe in the same year, gave the first check to these unnaturally exorbitant prices and rents. The restoration of peace to Europe, and the re-enactment of the Corn Laws in 1815, mark the commencement of another era in the history of our national agriculture. It was ushered in with a time of severe depression and suffering to the agricultural community. The immense fall in the price of farm-produce which then took place was aggravated, first, by the unpropitious weather and deficient harvest of the years 1816, 1817; and still more by the passing in 1819 of the Bill restoring cash payments, which, coming into operation in 1821, caused serious embarrassment to all persons who had entered into engagements at a depreciated currency, which had now to be met with the lower prices of an enhanced one. The much-debated Corn Laws, after undergoing various modifications, and proving the fruitful source of business uncertainty, social discontent, and angry partizanship, were finally abolished in 1846, although the Act was not consummated until three years later. Several other Acts of the Legislature, passed during this period, have exerted an important influence on agriculture. Of these, the first in date and importance is the Tithe Commutation Act of 1836. All writers on agriculture had long concurred in pointing out the injurious effects on agriculture of the tithe system as it then stood. The results of the change have amply verified the anticipations of those who were instrumental in procuring it. Since the removal of this formidable hindrance, improvement has been stimulated by those Acts under which the Government has been empowered to advance money on certain conditions for the draining of estates. An important feature in these advances is, that the 6½ per cent. of interest charged upon them provides a sinking fund by which the debt is extinguished in twenty-two years. Additional facilities have also been granted by the Act passed in 1848 for disentailing estates, and for burdening such as are entailed with a share of the cost of certain specified improvements.

Section 4.—Cattle Murrain and Potato Disease.

Another class of outward events, which has had an important influence upon agriculture, requires our notice. We refer to those mysterious diseases affecting both the animal and vegetable kingdoms, the causes and remedies for which have alike baffled discovery. The murrain, or "vesicular epizootic," appeared first in 1841, having been introduced, as is supposed, by foreign cattle. It spread rapidly over the country, affecting all our domesticated animals, except horses, and causing everywhere great alarm and loss, although seldom attended by fatal results. It has prevailed ever since, in a greater or less degree, and has been more widely diffused as well as more virulent in 1871 and 1872 than ever before. It was soon followed by the more terrible lung-disease, or pleuro-pneumonia, which continues to cause serious mortality among our herds. In 1865 the rinderpest, or steppe murrain, originating amongst the vast herds of the Russian steppes, where it would appear to be never altogether wanting, had spread westward over Europe, until it was brought to London by foreign cattle. Several weeks elapsed before the true character of the disease was known, and in this brief space it had already been carried by animals purchased in Smithfield market to all parts of the country. After causing the most frightful losses, it was at last stamped out by the resolute slaughter of all affected animals and of all that had been in contact with them. In the autumn of 1872 this cattle plague was again detected in several cargoes of foreign cattle brought to our ports. Happily the stringent provisions of the Contagious Diseases (Animals) Act had the effect of preventing its entrance, except in the case of one cargo brought to Hull, from which the plague was conveyed to several herds in the adjacent parts of Yorkshire, and caused considerable losses before it was again stamped out. Severe as have been the losses in our flocks and herds from these imported diseases, they have been as nothing in comparison with the effects of the mysterious potato blight, which, first appearing in 1845, has since pervaded the whole of Europe, and in Ireland especially proved the sad precursor of famine and pestilence. This seemingly insignificant blight for a time well-nigh withdrew from cultivation one of our most esteemed field crops; it influences the business of farming in a way that baffles the shrewdest calculators, and is producing social changes of which no man can predict the issue.

Section 5.—Leading Improvements.

We can here do little more than enumerate some of the more prominent improvements in practical agriculture which have taken place during the period under review. Before the close of the past century, and during the first quarter of the present one, a good deal had been done in the way of draining the land, either by open ditches, or by Elkington's system of deep covered drains. This system has now been superseded by one altogether superior to it both in principle and practice. In 1835, James Smith of Deanston (honour to his memory!) promulgated his now well-known system of thorough draining and deep ploughing. It has been carried out already to such an extent as to alter the very appearance and character of whole districts of our country, and has prepared the way for all other improvements. The words "Portable Manures" indicate at once another prominent feature in the agriculture of the times. Early in the present century, ground bones began to be used as a manure for turnips in the eastern counties of England, whence the practice spread, at first slowly, and then very rapidly, over the whole country. It was about 1825 that bones began to be generally used in Scotland. In 1841 the still more potent guano was introduced into Great Britain; and about the same time, bones, under the new form of superphosphate of lime. By means of these invaluable fertilisers, a stimulus has been given to agriculture which can scarcely be over-rated.

The labour of agriculture has been greatly lightened, and its cost curtailed, by means of improved implements and machines. The steam-engine has taken the place of the jaded horses as a thrashing power. This was first done in East Lothian by Mr Aitchison of Drumore, who about 1803 had his thrashing-machinery, at his distillery and farm of Clement's Wells, attached to a steam-engine, which was erected for him a few years previously by Bolton and Watt, for the works of the distillery. About 1818–20 several steam-engines on the condensing principle were erected in East Lothian, solely for the propelling of thrashing-machinery. One of these, put up by Mr Reid of Drem, at a cost of £600, is still doing its work there, and, strange to say, after the lapse of fifty-five years, looks as well and is as efficient as when first erected. It would be tedious to particularise other instances in this department, as it will be treated of fully in its proper place. It is especially in this department that the influence of the ever-memorable Exhibition of the Industry of all Nations in 1851 has told upon agriculture. Reaping by machinery may virtually be regarded as one of the fruits of that great gathering.

The railways, by which the country is now intersected in all directions, have proved of great service to farmers, by conveying their bulky produce to distant markets cheaply and quickly, and by making lime and other manures available to the occupiers of many inland and remote districts. In nothing has this benefit been more apparent than in the case of fatted live stock, which is now invariably transported by this means, with manifest economy to all concerned.

During the whole of this period there has been going on great improvement in all our breeds of domesticated animals. This has been manifested not so much in the production of individual specimens of high merit—in which respect the Leicesters of Bakewell, or the short-horns of Colling, have perhaps not yet been excelled—as in the diffusion of these and other good breeds over the country, and in the improved quality of our live stock as a whole. The fattening of animals is now conducted on more scientific principles. Increased attention has also been successfully bestowed on the improvement of our field crops. Improved varieties, obtained by cross-impregnation, either naturally or artificially brought about, have been carefully propagated, and generally adopted. Increased attention is now bestowed on the cultivation of the natural grasses. The most important additions to our list of field crops during this period have been Italian rye-grass, winter beans, white Belgian carrot, sugar beet, and alsike clover.

Section 6.—Increase and Diffusion of Agricultural Knowledge.

Let us look now at the means by which, during this period, agricultural knowledge has at once been increased and diffused. Notice has already been taken of the institution of the Highland Society and the National Board of Agriculture. These patriotic societies were the means of collecting a vast amount of statistical and general information connected with agriculture, and by their publications and premiums made known the practices of the best-farmed districts of the country, and encouraged their adoption elsewhere. These national associations were soon aided in their important labours by numerous local societies which sprang up in all parts of the kingdom. After a highly useful career, under the zealous presidency of Sir John Sinclair, the Board of Agriculture was dissolved but has left in its Statistical Account, county surveys, and other documents, much interesting and valuable information regarding the agriculture of that period. In 1800 the original *Farmers' Magazine* entered upon its useful career under the editorship of Robert Brown of Markle, the author of the well-known treatise on *Rural Affairs.* The Highland Society having early extended its operations to the whole of Scotland, by-and-by made a corresponding addition to its title, and as the Highland and Agricultural Society of Scotland continues to occupy its important sphere with a steadily increasing membership, popularity, and usefulness. As its revenue and experience increased, it gradually extended its operations. In 1828, shortly after the discontinuance of the *Farmers' Magazine*, its *Prize Essays and Transactions* began to be issued statedly in connection with the *Quarterly Journal of Agriculture*, a periodical which until recently occupied a prominent place in our professional literature. This society early began to hold a great annual show of live stock, implements, &c., the popularity of which continues unabated. In 1842, Mr John Finnie at Swanstone, near Edinburgh, having suggested to some of his neighbours the desirableness of obtaining the aid of chemistry to guide farmers in many departments of their business, the hint was promptly acted upon, and these Mid-Lothian tenant-farmers had the merit of originating an Agricultural Chemistry Association (the first of its kind), by which funds were raised, and an eminent chemist engaged, for the express purpose of conducting such investigations as the title of the society implies. After a successful trial of a few years this association was dissolved, transferring its functions to the Highland and Agricultural Society, which has ever since devoted much of its attention to this subject. The nature and importance of the services which labourers in this department of science have rendered to agriculture may be gathered from the society's Transactions, and numerous other publications of a similar kind. The Highland Society has of late years established itself on a broader basis, and imparted new energy to its operations by lowering its admission-fee in behalf of tenant-farmers, who have in consequence joined it in great numbers, and now take an important part in the conduct of its business. The practice adopted by it, about the same time, of holding periodical meetings for the discussion of important practical questions, by means of essays, prepared by carefully selected writers, did good service, too, to the cause of agricultural progress.

The adoption by Government of a proposal made by this society, to collect the agricultural statistics of Scotland, showed at once how thoroughly it enjoyed the confidence of the tenantry, and how easily, and by what simple and inexpensive machinery, this most important and interesting inquiry could be conducted. Through an unfortunate misunderstanding between the Government and the society on a mere technical point, this most useful inquiry came to an abrupt termination, after having been conducted for five years. This brief experiment had, however, proved so conclusively the value of such statistics, and the ease with which they could be collected, that the Government soon after took the matter in hand, and has ever since, through the agency of the officers of Inland Revenue, obtained annual returns of cropping and live stock for the whole of Great Britain.

The obvious success of this National Scottish Society has led to the formation of similar ones in England and in Ireland. The former, instituted in 1838, and shortly afterwards incorporated by royal charter, at once entered upon a career of usefulness, the extent of which cannot well be over-rated. Its membership—comprising the most influential persons in the kingdom—and its revenues are now so large as to enable it to conduct its proceedings on a scale befitting its position and objects. These are of a varied character, but its efforts are concentrated upon its journal and annual show. The former, published twice a-year, is chiefly composed of the essays and reports to which the liberal prizes of the society have been awarded, and undoubtedly stands at the head of our present agricultural periodicals. At the annual shows of the society, a prominent place is assigned to implements and machines. Such as admit of it, are subjected to comparative trials, which are conducted with such skill and pains that the awards command the entire confidence of exhibitors and their customers. The extent and rapidity of the improvement in agricultural machinery which the society has been mainly instrumental in effecting are altogether extraordinary.

There are few market towns of any importance that have not their organised club or occasional gathering of the farmers in their neighbourhood, for the discussion of professional topics. We have now also a goodly list of agricultural periodicals, both weekly and monthly, most of them ably conducted, which are extensively read, and are the means of collecting and diffusing much valuable knowledge, which, but for them, would often, as in former times, perish with its authors, or be confined to corners. The facilities now afforded by railways for cheap and expeditious travelling, induce most farmers to take an occasional peep at what is going on beyond their own neighbourhood. This, more than anything, deals death-blows to prejudices, and extends good husbandry.

The literature of agriculture has been enriched by the contributions of many able writers. Some deserve to be particularly mentioned. The volumes of the late David Low, Esq., on *Practical Agriculture, Landed Property and Economy of Landed Estates*, and *Domesticated Animals*, must ever be of standard authority on their respective subjects. Mr Henry Stephens' *Book of the Farm*, and Mr J. C. Morton's *Cyclopædia of Agriculture*, are invaluable to the agricultural student for their fulness, and for the minuteness of their details. Mr Caird's *English Agriculture* supplies the means for a most interesting comparison with the descriptions left to us by Arthur Young. Mr Hoskyn's *History of Agriculture* and *Chronicles of a Clay Farm* are the very gems of our professional literature. In a series of essays on our *Farm Crops* by Professor John Wilson of Edinburgh, the scientific and the practical are most happily combined. Among the more recent publications of value may be mentioned Loudon's *Encyclopædia; How Crops Grow*, by Mr Johnson; M'Combie's *Cattle and Cattle-Breeders;* Mechi's *How to Farm Profitably;* Hozier's *Practical Remarks on Agricultural Drainage;* Todd's *American Wheat Culturist*, &c. Johnston, Anderson, Way, and Voelcker, have done admirable service in expounding the chemistry of agriculture; Youatt, Spooner, and Vasey, its zoology; and Smith, Parkes, Webster, Bailey, Denton, Scott Burn, and Starforth, its engineering, mechanics, and architecture.

In reviewing the history of our national agriculture for the past sixty years, it is pleasing to note the growing intelligence displayed by our agriculturists in the prosecution of their calling. It is curious, also, to observe the analogy between the order of that progress, and that which is usually observed in individual minds. For a long time we see agricultural societies and writers occupying themselves chiefly about the practical details and statistics of husbandry, and attaching much importance to empirical rules. Gradually, however, we observe, along with a zealous collecting of facts, a growing disposition to investigate the *causes* of things, and desire to know the *reason* why one practice is preferable to another. When, therefore, the Royal Agricultural Society adopted as its motto, "Practice with Science," it expressed not more the objects to be aimed at in its own proceedings, than the characteristic feature of our present stage of agricultural progress.

CHAPTER III.

PRACTICE OF BRITISH AGRICULTURE.

We shall now endeavour to present a picture of British agriculture in its present state. In doing this, we shall take much the same course which we should pursue, if we were asked to conduct a visitor over our own farm, and to give him a detailed account of its cultivation and management. In the case supposed, we should, first of all, explain to him that the farm comprises a great diversity of *soils;* that its fields are very variously circumstanced as regards *climate*, altitude, exposure, and distance from the homestead; and that in its *tillage*, cropping, and general management, regard must be had to these diversities, whether natural or artificial. We should then conduct him through the homestead, pointing out the position and uses of the various *farm buildings* and of the *machinery* and *implements* contained in them. From thence we should proceed to the fields to examine their *fences* and the *tillage operations.* With some observations about the *succession of crops*, and the *manures* applied to them, there would follow an examination of the *cultivated crops, pastures*, and *meadows*, of the *live stock* of the farm, and of the measures adopted in reclaiming certain *waste lands* belonging to it. This survey being completed, there would naturally follow some discussion about the *tenure* of land, the *capital* required for its profitable cultivation, the condition of *farm labourers*, the necessity for devoting more attention to the *education* of the agricultural community, and the duty of the Legislature to remove certain *obstructions* to agricultural improvement.

Section I.—Soils.

The soil constituting the subject-matter on which the husbandman operates, its character necessarily regulates to a large extent the nature of his proceedings. The soil or surface covering of the earth in which plants are produced is exceedingly varied in its qualities. Being derived from the disintegration and decomposition of the rocks which constitute the solid crust of the globe, with a mixture of vegetable and animal remains, soils take their character from that of the rocks from which they have chiefly been derived. There is thus a generally prevailing resemblance between the soils of a district and the rocks over which they lie, so that a knowledge of the composition of the one affords a key to the character of the other. But this connection is modified by so many circumstances, that it is altogether impossible by the mere study of geology to acquire an easy and certain rule for determining the agricultural character of the soil of any particular district or field, as it has been the fashion with some writers of late years to assert. "When, indeed, we regard a considerable tract of land, we can for the most part trace a connection between the subjacent deposits and the subsoil, and consequently the soil. Thus, in a country of sandstone and arenaceous beds, we shall find the soil sandy; in one of limestone, more or less calcareous; in one of schistose rocks, more or less clayey. But even in tracts of the same geological formation, there exist great differences in the upper stratum, arising from the prevalence of one or other member of the series, or from the greater or less inclination of the strata, by which the debris of the different beds are more or less mixed together on the surface. The action of water, too, in denuding the surface at one part, and carrying the debris in greater or smaller quantity to another, exercises everywhere an important influence on the character of soils. Thus the fertility of a soil on the higher ground, from which the earthy particles are washed, is found to be very different from that of the valley to which these particles are carried. It is seen accordingly, that within the limits of the same geological formation, soils are greatly varied, and that the mere knowledge of the formation will not enable us to predicate the character of the soil of any given tract, either with respect to its texture, its composition, or its productiveness."[1] Even a very limited acquaintance with the geology of Great Britain serves, however, to account for the exceedingly diversified character of its soils. The popular definitions of soils—and to these it is safest for practical farmers to adhere—have respect to their most obvious qualities. Thus they are designated from their composition, as *clays*, *loams*, *sands*, *gravels*, *chalks*, or *peats;* or from their texture, in which respect those in which clay predominates are called *heavy*, *stiff*, or *impervious;* and the others *light*, *friable*, or *porous*. From the tendency of the former to retain moisture they are often spoken of as *wet* and *cold*, and the latter, for the opposite reason, as *dry* and *warm*. According to their measure of fertility, they are also described as *rich* or *poor*. The particular crops for the production of which they are respectively considered to be best adapted have also led to clays being spoken of as *wheat* or *bean soils*, and the friable ones as *barley* and *turnip soils*. This latter mode of discriminating soils is, however, becoming every day less appropriate; as those of the lighter class, when sufficiently enriched by suitable manuring, are found the most suitable of all for the growth of wheat; while the efforts of agriculturists are now successfully directed to the production of root crops on soils so strong as heretofore to have been reckoned unfit for the purpose. But still, such extreme diversities as we everywhere meet with in our soils must necessarily lead to a corresponding diversity in their agricultural treatment, and hence the necessity for keeping this fact prominently in view in every reference to British agriculture as a whole.

Section 2.—Influence of Climate.

But if diversity of soil necessarily modifies the practice of the husbandman, that of climate does so far more powerfully. The soils of the different parts of the globe do not very materially differ from each other, and yet their vegetable products vary in the extreme. This is chiefly owing to difference of temperature, which decreases more or less regularly as we recede from the equator, or ascend from the sea-level. Places in the same latitude and at the same elevation are found, however, to vary exceedingly in temperature, according to their aspect, the prevailing winds to which they are exposed, their proximity to seas or mountains, and the condition of their surface. The different parts of Great Britain are accordingly found to possess very different climates. In passing from south to north, its mean temperature may be taken to decrease one degree Fahrenheit for every 80 miles of latitude, and the same for every 300 feet of elevation. The temperature of the west side of our island also differs materially from that of the east, being more equal throughout the year. This is owing to the prevalence of mild westerly winds charged with moisture, which, while they equalise the temperature, cause the average fall of rain on the west side of Britain to be in many cases double, and in some nearly three times that on the opposite side. In the central parts of England cultivation is carried on at 1000 feet of elevation, but 800 may be taken as the ordinary limit. In Scotland the various crops are usually from two to three weeks later in coming to maturity than in England. In both divisions of the island the western counties, owing to their mild and humid climate, are chiefly devoted to pasturage, and the eastern, or dry ones, to tillage. As compared with the continent of Europe, our summers are neither so hot, our winters so cold, nor our weather so steady. We want, therefore, many of its rich products, but, on the other hand, our milder winter and moister climate are eminently favourable to the production of pasturage and other cattle crops, and admit of agricultural operations being carried on more regularly throughout the year. Indeed, looking to the immense varieties of the products of our soil, there is probably no other country so favourably circumstanced for a varied and successful agriculture.

Section 3.—Influence of Population, &c.

Besides those variations in the agricultural practice of this country which arise from diversities of soil and climate, there are others which are due to the distribution of the population. The proximity of cities and towns, or of populous villages, inhabited by a manufacturing or mining population, implies a demand for dairy produce and vegetables, as well as for provender and litter, and at the same time affords an ample supply of manure to aid in their reproduction. Such commodities, from their bulk or perishable nature, do not admit of long carriage. The supplies of these must therefore be drawn from comparatively limited areas, and the character of the husbandry pursued there is determined apart from those general influences previously referred to. From these and other causes there is a diversity in the practice of British agriculture which increases the difficulty of describing it accurately. Indeed, it is so well known that there are peculiarities of character attaching to almost every individual field and farm, and still more to every different district or county, which demand corresponding modifications of treatment in order to their successful cultivation, that a prudent man, if required to take the management of a farm in some district greatly inferior in its general system of farming to that which he may have left, will yet be very cautious in innovating upon specific practices of the natives.

To such peculiarities it is obviously impracticable to refer in such a treatise as the present. They are referred to now because they suggest an explanation of some of those discrepancies in the practice and opinions of farmers, equally successful in their respective localities, which we constantly meet with; and because, in proceeding to delineate the practice of Berwickshire, where our personal experience has been gained by upwards of forty years of actual farming, we would deprecate the idea of claiming for its modes a superiority over those of other districts. Its geographical position, and the mixed husbandry pursued in it, would justify, in some measure, its being referred to as a fair sample of the national agriculture. But it is on the specific ground that it is best to speak from actual experience as far as that will serve, that we vindicate this selection.

[1] Low's *Practical Agriculture*, p. 42.

CHAPTER IV.

FARM-BUILDINGS.

Section 1.—General Requisites.

In pursuance of the plan already indicated, let us now refer for a little to *Farm-Buildings.* We have spoken of the soil as the raw material upon which the farmer operates: his homestead may, in like manner, be regarded as his manufactory. That it may serve this purpose in any good measure, it is indispensable that the accommodation afforded by it be adequate to the extent of the farm, and adapted to the kind of husbandry pursued upon it. It should be placed upon a dry, sunny, sheltered site, have a good supply of water, and be as near as possible to the centre of the farm. The buildings should be so arranged as to economise labour to the utmost. It should be constructed of substantial materials, so as to be easily kept in repair, and to diminish, to the utmost, risk from fire.

The most cursory examination of existing homesteads will suffice to show that in their construction these obvious conditions have been sadly neglected. For one farm really well equipped in this respect, hundreds are to be met with in all parts of the kingdom, and more especially in England, most wretchedly deficient. Wherever this is the case, it is impossible that the farmer, however skilful or industrious, can make the most of his materials, or compete on equal terms with his better furnished neighbours. As the agricultural community becomes more generally alive to the importance of economising labour by a judicious arrangement of buildings, and of reducing the cost of the production of beef (and adding to the amount and fertilising power of the home-made manure) by the manner in which the live stock is housed, we may hope that improvement in this department will make rapid progress. Tenants will refuse to embark their capital, and waste their skill and labour, on farms unprovided with suitable apparatus for cultivating them to the best advantage. Landlords and their agents will by-and-by find that until this is done, they must put up with an inferior tenantry, an antiquated husbandry, and with lower and worse-paid rents.

Section 2.—Plans.

In erecting new homesteads, or in making considerable additions to or alterations upon existing ones, it is of much importance to call in the aid of an architect of ascertained experience in this department of his art, and then to have the work performed by contracts founded upon the plans and specifications which he has furnished. A reasonable sum thus expended will be amply returned in the cost, trouble, and disappointment, which it usually saves to both landlord and tenant. It is to be hoped that in future a greater number of thoroughly qualified architects will devote themselves to this department of their profession, and that they will meet with adequate encouragement. It is not, therefore, with the view of superseding their services, but simply to illustrate our references to existing practices, that we subjoin a plan of farm-buildings.

While protesting against the utter rudeness and inadequacy of the great majority of homesteads, we must also deprecate the hurtful expenditure sometimes lavished in erecting buildings of an extent and style altogether disproportionate to the size of the farm, and out of keeping with its homely purposes. When royalty or nobility, with equal benefit to themselves and their country, make agriculture their recreation, it is altogether befitting that in such cases the farm-yard should be of such a style as to adorn the park in which it is situated. And even those intended for plain everyday farming need not be unsightly; for ugliness is sometimes more costly than elegance. Let utility, economy, and comfort, first be secured, and, along with these, as much as possible of that pleasing effect which arises from just proportions, harmonious arrangement, and manifest adaptation to the use the buildings are designed for.

Section 3.—Principles of Arrangement.

The barn, with its thrashing-machinery, and other appurtenances, naturally forms the nucleus of the homestead, and regulates the distribution of the other buildings. The command of water-power will often determine the exact site of the barn, and indeed of the whole buildings. The cheapness and safety of this motive-power render it well worth while to make considerable sacrifices to secure it, when a really sufficient and regular supply of it can be had. But the difficulty of securing this when the adjoining lands are thoroughly drained, and the great efficiency and facility of application of steam-power, are good reasons why precarious supplies of water-power should now be rated very differently than they were when a horse-wheel or windmill were the only alternatives. A very usual and suitable arrangement is to have the whole buildings, forming a lengthened parallelogram, facing south or south-east; the barn being placed in the centre of the north range, with the engine-house behind it, and the straw house at right angles in front, with doors on both sides for the ready conveyance of litter and fodder to the yards, &c. It is always advantageous to have the barn of sufficient height to afford ample accommodation to the thrashing and winnowing machinery. When the disposition of the ground admits, it is a great convenience to have the stackyard on a level with the upper barn, so that the unthrashed corn may be wheeled into it on barrows, or on a low-wheeled truck drawn by a horse. Failing this, the sheaves are usually pitched in at a wide opening from a framed cart. The space on which the cart stands while this is going on is usually paved, that loose ears and scattered grain may be gathered up without being soiled; and it is a further improvement to have it covered by some simple roof, to protect the sheaves from sudden rain.

It is a good arrangement to have the straw-barn fitted up with a loft, on the level of the opening at which the straw is discharged from the thrashing-mill, so as to admit of fodder being stored above and litter below. A sparred trap-door in front of the shaker retains the straw above, or lets it fall to the ground as required. This upper floor of the straw-barn is the most convenient place for fixing a chaff-cutter to be driven by the thrashing-power. The granary should communicate with the upper barn, that the dressed grain may be raised to it by machinery.

A loft over the engine-room, communicating with the upper barn and granary, forms a suitable place for fixing a grinding-mill, bruising rollers, and cake-breakers, as it affords opportunity for having these machines easily connected with the steam-power. It suits well to have the house in which cattle food is cooked attached to and under the same roof as the engine-house. One coal store and chimney thus serves for both. Over this cooking-house, and communicating with the grinding-loft, may advantageously be placed a kiln, to be heated by the waste steam from the engine. An open shed outside the barn, for the accommodation of a circular saw, is also a desideratum. By the aid of the latter machine and a handy labourer, the timber required for ordinary repairs on the farm may be cut out at trifling expense.

The cattle-housing, of whatever description, where there are the largest and most frequent demands for straw, is placed nearest to the straw-house, and in communication with the turnip-stores, and the house (if any) in which food is cooked or otherwise prepared. Where cattle are bred, the cow-house and calf-house are kept together. A roomy

working court is always a great convenience, and it suits well to have the stable opening to it, and the cart-shed and tool-house occupying another side. Costly machines, such as corn-drills and reaping machines, require to be kept in a locked place, to preserve them from the collisions, and the loss or derangement of their minute parts, to which they are exposed in an open cart-shed.

An abundant supply of good water is a most important matter. The best source is from springs, at such an elevation as to admit of its being brought in a pipe, with a continuous flow. Failing this a well and pump is the usual alternative, although it is sometimes necessary to collect the rain-water from the roofs, and preserve it in a capacious and carefully-made tank. In every case it is desirable to have a regulating cistern, from which it is distributed by pipe to every part of the homestead where it is required. It is, in every case, of importance to have the eaves of the whole buildings spouted, and the rain-water carried where it can do no mischief. Where fattening cattle are kept in open yards with sheds, by spouting the eaves, and slightly hollowing the yards towards their centres, the urine to a large extent is absorbed by the litter, and retained in the manure. The effectual way, however, is to have the whole of the yards roofed over. The waste of food and litter, and the damage sustained alike by cattle and manure, from the excessive rainfall of winter 1872–3, has probably done more than any amount of argument could do to convince farmers of this. If stall feeding is practised, a pit is required, into which the solid dung is wheeled and the liquid conveyed by drains. Liquid manure tanks are at present in universal repute, but we shall endeavour to show, when treating of manures, that they are not such an indispensable appendage to a farm-yard as is generally asserted. In Scotland it is customary to carry the dung from the byres into a yard in which young cattle are kept, where it is daily spread about and subjected to further treading, along with such quantities of fresh litter as are deemed necessary. That from the stables is carried into the adjoining feeding-yard, and it is usually remarked that the cattle occupying it make more rapid progress than their neighbours.

An important part of the buildings of a farm are the cottages for its labourers. It is in all cases expedient to have the people required for the ordinary working of a farm resident upon it; and it is always much better to have families, each in its own cottage, than a number of young people boarded in the farm-kitchen, or with the farm-overseer. These cottages are usually a little removed from the other farm-buildings, and it is, on various accounts, better to have them so. There is, however, an advantage in having the cottages of the farm-steward and cattleman either within the courtyard, or close to its entrance, that these responsible functionaries may at all times be near their charge, and especially that they may be at hand when any of the live stock require night attendance. As there are manifold advantages in having but one main entrance to the homestead, and that closed by a gate which can be locked at night, it will be obviously necessary to have the keeper of the key close at hand to open the gate by night if required. Much more attention than formerly is now paid to the construction of cottages. The apartments are better floored, higher in the roof, and so arranged as to secure comfort and decency. Besides a small garden, each cottage is usually provided with a pig-sty and ash-pit, and in some cases with a coal-place and privy besides.

The position and style of the farmer's dwelling also claims a remark here. The approved mode used to be, to place it either directly in front or rear of the farm-yard, on the ground that the farmer would thus have his premises and cattle under his eye even when in his parlour or bed-room. As has been well remarked, "The advantages of this parlour-farming are not very apparent, the attendant evils glaringly so. If the condition of ready communication be obtained, the farm-house should be placed where the amenities of a country residence can be best enjoyed."[1] On all hands we now hear it urged, that it is only by men possessed of capital and intelligence that the business of farming can be rendered remunerative. Those who desire to have such men for tenants will be more likely to succeed by providing a commodious and comfortable farmery, pleasantly placed among trees and shrubs, than by setting it down in the precincts of the dung-heap.

CHAPTER V.

FENCES.

Section 1.—*Benefit of Fences.*

The fences by which farms are generally enclosed and subdivided form another part of what may be termed their fixtures, and may therefore be suitably noticed here. When lands are let to a tenant, the buildings and fences are usually put into sufficient repair, and he is taken bound to keep and leave them so at the issue of his occupancy. Although there are some persons who advocate the total removal of subdivision fences, it is admitted on all hands that the farm as a whole, and the sides of public thoroughfares which may intersect it, should be guarded by sufficient fences of some kind. The general belief has hitherto been, that there is a farther advantage in having the land subdivided by permanent fences into enclosures of moderate size. The use of such partition fences is not only to confine the live stock to particular fields, or restrain them from trespassing on the other crops, but to afford shelter from cutting winds. It is now frequently urged, that the heavier cattle should never be turned to pasture at all, but kept on roots and green forage the whole year round, and that sheep can be managed satisfactorily by means of movable hurdles. It is highly probable that the practice of soiling will become more general, as it undoubtedly deserves to do. Still, this does not necessarily call for the total removal of subdivision fences, which we cannot but regard as an imprudent proceeding. It is probable that those who have adopted it have done so very much owing to the prevalence of the opposite extreme. There are large portions of the finest land in England so encumbered with hedges and hedgerow trees, as to be utterly incapable of profitable cultivation. In many cases the fields are so small and the trees so large that their roots actually meet from the opposite sides, and pervade the entire surface soil of the area enclosed by them. When manure is applied to such fields, it is monopolised by these freebooters from the hedges, and the crops of grain or hay, such as they are, are so screened from the sun and wind that there is great risk of their being spoiled in the harvesting. If drains are made in such fields, they are speedily filled up by the rootlets, and thus rendered useless. It has been computed that not less than one and a quarter million acres are occupied by hedgerows in England and Wales, and that if the land overshaded and plundered by roots be included, the amount is three millions. In Devonshire one-fourth of the enclosures in many parishes are under *two* acres; more than one-third under *three* acres; and nearly two-thirds under *four* acres. Two millions, at least, of these acres might be redeemed, and what a margin is here available for increased production! The land thus wasted would probably yield a sum equal to county and poor rates, and perhaps malt-tax

[1] For further information on Farm Buildings, see also *Morton's Cyclopædia of Agriculture*, article "Farm Buildings," and *The Book of Farm Buildings*, by Henry Stephens and R. Scott Burn. Edinburgh, 1861.

too.[1] In such circumstances, it is no wonder that zealous agricultural improvers should look upon hedgerows much as American settlers do upon their forests, and, like them, be sometimes indiscriminate in their clearings. We believe that there is an advantage in having land, whether for pasture or tillage, subdivided into parallel-sided fields of from ten to forty acres each, according to the size of the farm, by means of permanent fences of a kind adapted to the locality

Section 2.—Varieties of Fences.

When the soil and climate are favourable to the growth of the common *white thorn*, hedges formed of it combine efficiency, economy, and ornament, in a greater degree than any other fence. But to have a really efficient thorn hedge, much attention must be paid to its planting, rearing, and after management. In proceeding to *run* a new line of thorn hedge, care must be taken that the soil is clean and in good heart, and that the subsoil is porous and dry. When these conditions do not obtain, they must be secured by fallowing, manuring, draining, and trenching. The young quicks should be stout and well rooted; not taken indiscriminately as they stand in the nurserymen's beds; but of uniform stoutness. Such selected plants are always to be had for a small additional price, which will be found to be well repaid in the superior progress of such plants, when contrasted with that of others taken as they chance to come to hand. The embryo fence must be kept free of weeds, and secured from the encroachments of cattle by a line of rails on both sides. Some persons advise that the young hedge should from the first be trimmed into line by using the pruning-hook after each year's growth. It is certainly better not to touch it with the knife, or, at least, only to restrain an occasional shoot that unduly overtops its neighbours, until the centre stems are at least a couple of inches in diameter. If the plants are then headed over fence-high, and the lateral shoots pruned to a straight line, a close fence with a substantial backbone in it is secured; whereas by pruning annually from the first, a fence is obtained that pleases the eye, but which, consisting only of a mass of spray, presents no effectual barrier to cattle. When a thorn hedge has reached the stage just referred to, the protecting rails may be removed, and the hedge kept in a neat and efficient state by annual pruning. On good, deep soil, thorns will stand this constant removal of the annual growth of spray for many years without injury, especially if the pruning is delayed until the leaf has fallen. In less favourable circumstances, it is found necessary from time to time to withhold the pruning-knife for a few years together. When the hedge has been reinvigorated by such periods of unrestrained growth, it can again be cut back to the centre stems, and subjected anew to a course of annual pruning. To insure a close fence, the bottom of the hedge must at all times be kept clear of tall weeds. The constant use of the weeding-iron is, however, objectionable; for, besides being expensive, it injures the bark of the thorns and thereby impairs their health. It is quite sufficient to cut the weeds close to the surface twice a year by means of a reaping-hook or short scythe.

In arable lands, by this plan of keeping hedges about four feet high, and cutting down the weeds as required, an efficient and ornamental fence is maintained at comparatively small cost, and with little injury to the adjoining crops from shading, or the harbouring of weeds and vermin.

Although the white thorn forms a better hedge than any shrub yet tried for the purpose in this country, there are many upland situations where the beech and hornbeam grow more freely, and are to be preferred either alone or in mixture with it. These plants, and also crab or sloe, are sometimes useful in filling a gap occasioned by the removal of a hedgerow tree or the death of a portion of thorn hedge.

Stone

In exposed situations, where thorns do not thrive, *drystone walls* are the most usual substitute. When carefully constructed, of stones suitable for the purpose, they last a long time, and form an excellent fence. Their durability is much enhanced by having the cope-stones set in lime-mortar. A layer along the centre of the wall, and an external painting, of lime-mortar will also repay the additional first cost thus incurred. A wall of this kind four feet high, exclusive of the cope, while quite sufficient to restrain cattle and the heavier kinds of sheep, is no barrier to the mountain breeds, which can easily clear a six-foot wall.

Wire

A simple and very effective fence has, however, come much into use of late years. It is composed of iron wire (No. 8 being the size most commonly used), which is attached by small staples to common stakes, such as are used for wooden railings, driven firmly into the ground about five feet apart. The wire is drawn out of the coil, and the ends of the various lengths or *threads* are neatly joined by first heating them, and then twisting the one into the other, until the quantity required for the stretch of fence is run out. It is then attached to every third or fourth stake by a staple, which must not be driven home. The other lines of wire are then treated in the same manner, each being attached to the stakes at such width apart as has been determined upon, and marked upon the stakes. A ready way of doing this is by stretching along the stakes a common gardener's line which has been previously rubbed with chalk, or a charred stick, and striking it against the stakes at the required heights, in the way that sawyers mark a plank. When the requisite number of wires has thus been loosely attached, they are pulled as tight as possible by the hands of the workmen, after which a screw or lever is applied to each in turn until it is made perfectly tight. As the efficiency of this kind of fence is wholly dependent on perfect tightness being obtained, a stout straining-post must be fixed securely in the ground at the end of each line of fence. This serves the double purpose of furnishing a fulcrum for the stretching instrument, and a secure attachment for the ends of the wires. When the straining is accomplished, each wire is stapled to each stake. The gates are usually hung upon these straining-posts. Although wooden straining-posts are commonly used, some persons prefer iron ones, fixed into large blocks of stone. Five wires thus stretched, at an average width of six inches, form an effectual fence for the wildest sheep. They could, indeed, easily clear it so far as height is concerned, but they are afraid to leap at an object which they cannot see until they are close upon it. They may be seen at first walking along the line anxiously looking for an opening, and if one more bold than the others makes a run at it, he is sure to catch such a fall as effectually deters him from repeating the attempt. With these cheap and portable materials, which any labourer of ordinary intelligence can easily put together, a fence admirably adapted for enclosing or subdividing mountain pastures is now quite attainable by every sheep-farmer, and will well repay its cost. It is equally available for protecting young thorn hedges, and generally for all purposes for which wooden railing is used. As a fence for cattle or horses, it is advisable to add a single rail of wood nailed *flat* along the top of the stakes, which must be sawn off evenly for this purpose. As compared with wooden railing, wire is much cheaper and more durable, and more easily kept in repair. It is cheaper also than stone walls, available in many situations where they are not, and a more certain barrier to agile sheep; but it is less durable, and affords no shelter.

The latter defect can in some situations be remedied by

[1] See *Farmer's Magazine* for March 1852, p. 253.

raising a low mound of turf, running the wire-fence along the top of this mound, and sowing on it the seeds of the common whin.

We have already noticed that the fences of a farm are usually erected by the landlord and kept in repair by the tenant. The latter is at least usually taken bound in his lease to keep and leave them in good order; but as this obligation is often very indifferently performed, and much damage and vexation occasioned in consequence, it is always expedient that a person should be appointed by the landlord to attend to the fences, and the half of his wages charged against the tenant. By such a course, dilapidation and disputes are effectually guarded against, and the eyesore of defective, ill-kept fences is wholly removed.

CHAPTER VI.

MACHINES AND IMPLEMENTS OF HUSBANDRY.

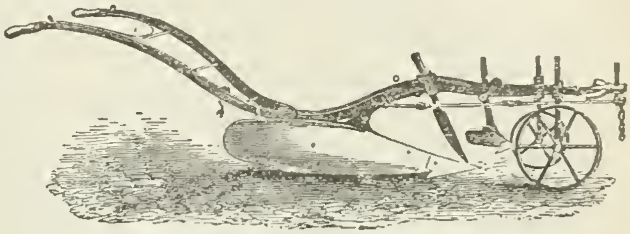
Section 1.—*Recent Improvements.*

That the cultivation of the soil may be carried on to the best advantage, it is necessary that the farmer be provided with a sufficient stock of machines and implements of the best construction. Very great improvement has of late years taken place in this department of mechanics. The great agricultural societies of the kingdom have devoted much of their attention to it; and under their auspices, and stimulated by their premiums, exhibitions, and competitive trials, manufacturers of skill and capital have embarked largely in the business. In many instances the quality of the article has been improved and its cost reduced. There has hitherto been a tendency to produce implements needlessly cumbrous and elaborate, and to introduce variations in form which are not improvements. The inventors of several valuable implements, the exclusive manufacture of which they have secured to themselves by patent, appear to have retarded their sale, and marred their own profits by the exorbitant prices which they have put upon them. Some, however, have become alive to the advantages of looking rather to large sales with a moderate profit on each article, and of lowering prices to secure this. A most salutary practice has now become common of inventors of implements of ascertained usefulness granting licence to other parties to use their patent-right on reasonable terms, and thus removing the temptation to evade it by introducing some alteration which is trumpeted as an improvement, although really the reverse.

The extended use of iron and steel in the construction of agricultural implements is materially adding to their durability, and generally to their efficiency, and is thus a source of considerable saving. While great improvement has taken place in this department, it too commonly happens that the village mechanics, by whom a large portion of this class of implements is made and repaired, are exceedingly unskilled, and lamentably ignorant of the principles of their art. They usually furnish good materials and substantial workmanship, but by their unconscious violation of mechanical laws, enormous waste of motive power is continually incurred, and poor results are attained. This can probably be remedied only by the construction of the more costly and complex machines being carried on in extensive factories, where, under the combined operation of scientific superintendence, ample capital, and skilled labour, aided by steam-power, the work can be so performed as to combine the maximum of excellence with the minimum of cost.

Section 2.—*Ploughs.*

We begin our brief notice of the implements of the farm with those used for the tillage of the soil. Of these the first place is unquestionably due to the plough. A history of this implement, tracing its gradual progress from the ancient *Sarcle* to its most improved form at the present day, is necessarily a history of agriculture. So much is this the case that a tolerably correct estimate of the progress of the art in any country, whether in ancient or modern times, may be formed by ascertaining the structure of the plough. Much attention has been paid to its construction in Britain for the last hundred years, and never more than at the present day. After all that has been done, it is still, however, an unsettled point which is the best plough for different soils and kinds of work; and accordingly, many varying forms of it are in use in those parts of the kingdom which have the reputation of being most skilfully cultivated. Ever since the introduction of Small's improved *swing-plough*, the universal belief in Scotland, and to a considerable extent in England, has been that this is the best form of the implement. Wheel ploughs have accordingly been spoken of by Scottish agriculturists in the most depreciatory terms, and yet it turns out that this has been nothing better than an unfounded prejudice; for when subjected to careful comparative trial, as has been frequently done of late, the



Howard's Champion Plough.

balance of excellence is undoubtedly in favour of the plough with wheels. Its advantages are, that it is easier of draught; that the quality of its work is better and greatly more uniform than can be produced by a swing plough; that in land rendered hard by drought, or other causes, it will enter and turn over even furrows where its rival either cannot work at all, or at best with great irregularity and severe exertion to the ploughman; and, lastly, that its efficiency is independent of skill in the ploughman. This last quality has indeed been usually urged as an objection to wheel-ploughs, as their tendency is said to be to produce an inferior class of workmen. Those who know the difficulty of getting a field ploughed uniformly, and especially of getting the depth of furrow specified by the master adhered to over a field, and by all the ploughmen, can best appreciate the value of an implement that, when once properly adjusted, will cut every furrow of an equal width and depth, and lay them all over at exactly the same angle. The diversity in the quality of the work at those ploughing competitions, to which only the picked men of a neighbourhood are sent, and where each may be supposed to do his very best, shows conclusively how much greater it must be on individual farms, even under the most vigilant superintendence. In every other art the effect of improved machinery is to supersede manual dexterity; and it does seem absurd to count that an objection in agriculture which is an advantage in everything else. There is more force in the objection that wheel-ploughs are inferior to swing ones in ploughing cloddy ground, or in crossing steep ridges, and that they cannot be used for forming drills for turnip or other crops. This objection vanishes when it is known that in the most improved wheel-ploughs, the wheels can be laid aside at pleasure, and that they can then be used in all respects as swing-ploughs. A mould-board, somewhat higher and wider behind than that best adapted for ordinary work, is required for forming turnip-drills. This, however, is easily managed by having two distinct mould-boards for each plough, or, better still, by using only the double mould board or bulking plough for drilling. An important feature in the English ploughs is, that they are fitted with cast-iron shares, which, being case-hardened on their under surface, wear unequally, and so preserve a sharp edge. The necessity for daily recourse to the smithy is thus removed, and along with it that irregularity in the quality of the work and draught of the plough, which so often arises from witting or unwitting alterations being made in the *set* of the share in the course of its unceasing journeys thither. These cast-iron shares are slightly more brittle than those made of malleable iron with steel points; but it is of importance in determining their comparative merits to bear in mind that the prime cost of the former—10d. to 1s. each—is so small as to render them at the year's end the least expensive of the two. When it is desired to turn a very deep furrow, a plough is used differing from the common one only in being somewhat larger and stronger in all its parts, with four horses to draw it.

Ploughs which break and stir the subsoil, without bringing it to the surface, by following in the wake of the common plough, are now much used. The first of the kind—the invention of the late Mr Smith of Deanston—is a ponderous implement, requiring at least four good horses to draw it. It is well adapted for displacing and aiding in the removal of earth-fast stones. The inventor has happily described its operation by terming it a "horse pick." Read's subsoil-plough is a much lighter implement, which can usually be drawn by two horses. Since the introduction of thorough draining, it is found beneficial to loosen the soil to a much greater depth than was formerly practicable, and this class of implements is well fitted for the work. It is always advisable to use this implement, and to mark and dig out the large stones encountered by it, before introducing steam cultivation.

Broadshare or paring-ploughs are much used in various parts of England in the autumn cleaning of stubble. A broad-cutting edge is made to penetrate the soil to the depth of three or four inches, so as to cut up the root-weeds which at that season lie for the most part near the surface. These, as well as the stubble, being thus detached from the firm soil, are removed by harrowing and raking; after which the land is worked by the common plough. An implement of this kind is frequently used in carrying out the operation of paring and burning. Bentall's Broadshare has the reputation of being the best of its class; but we can confidently recommend the common plough, stripped of its mould-board and fitted with a share twelve inches broad, as not only the cheapest, but decidedly the most efficient scarifier that has yet been used.

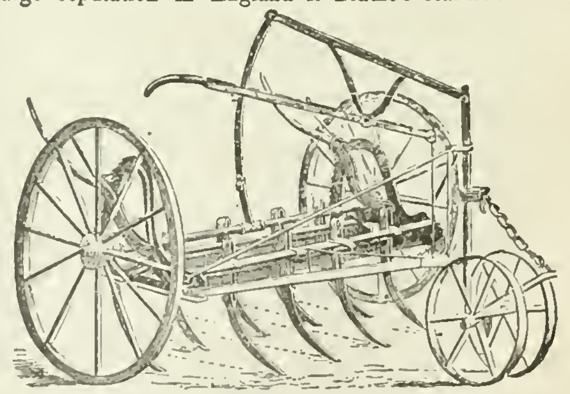
An ingenious Aberdeenshire mechanic, Mr Pirie of Kinmundy, has recently invented a double-furrow plough, on an entirely new principle, which has met with general approval, and has already been adopted by all the great plough makers. By carrying the plough on three wheels, one on the land and two bevelled ones in the angle of the furrow, Mr Pirie dispenses with both soles and side plates, and thereby lessens the friction, and avoids that hurtful glazing and hardening of the bottom of the furrow which attends the use of other ploughs. So much is the draught lessened by this improvement, that *three* horses and one man with this double-plough can perform as much work in a day as *four* horses and two men with two ordinary ploughs. For a seed-furrow or level field of free soil, *two* horses are quite able to work the double-plough.

Various implements of the plough type, so modified as to adapt them for particular processes, have from time to time been offered to public notice, but have failed to meet with general favour. We limit our notice to those of ascertained utility, and refer the reader who desires fuller information to *Ransome's Implements of Agriculture*,[1] and the more recent work by Messrs Stephens and Scott Burn, where he will find descriptions of the most interesting of them.

Section 3.—Grubbers, &c.

Next in importance to the plough is the class of implements variously called grubbers, cultivators, drags, or scarifiers. To prepare the soil for the crops of the husbandman, it is necessary to pulverise it to a sufficient depth, and to rid it of weeds. The appropriate function of the plough is to penetrate, break up, and reverse the firm surface of the field. This, however, is only the first step in the process, and does but prepare for the more thorough disintegration which has usually been accomplished by harrowing, rolling, and repeated ploughings. Now, however excellent in its own place, the plough is a cumbrous and tedious pulveriser, besides needlessly exposing a fresh surface at each operation, and cutting the weeds into minute portions, which renders their removal more difficult. These defects were long felt, and suggested the desirableness of having some implement of intermediate character betwixt the plough and harrow, which should stir the soil deeply and expeditiously without reversing it, and bring the weeds unbroken to the surface. The whole tribe of grubbers, &c., has arisen to meet this demand, and we shall now consider the comparative merits of the more prominent of the group. The first notice is due to Finlayson's harrow, which, as improved by Scoular, was, until recently, the best implement of its kind. Its faults—and they attach equally to Kirkwood's and Wilkie's—are, that it is severe work for two horses, is liable to choke in turfy or foul ground, and that it consolidates the bottom of the furrow, while producing a fine tilth on the surface. Finlayson's grubber, in its improved form, weighs about five cwt., and costs as many pounds.

Another useful implement of this class which enjoys a large reputation in England is Biddle's scarifier. It is



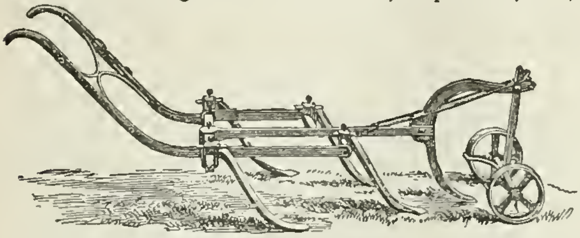
Biddle's Scarifier, as made by Ransome & Co.

mounted on four wheels—two small ones in front and two much larger behind. The frame and tines are of cast-iron, and can be raised and depressed at pleasure by means of two levers which regulate the depth to which the tines shall penetrate. The tines are prepared to receive case-hardened cast-iron points of different widths, or steel hoes of nine inches width, so that the implement can be used for breaking up and paring the surface, or for grubbing out weeds and pulverising the soil, as may be required. An important feature in this scarifier is, that it keeps its hold of a hard surface much better than a plough. It weighs half a ton, is drawn by four or six horses, and costs about £18.

[1] *The Implements of Agriculture*, by J. Allen Ransome, Lond. 1843. *The Book of Farm Implements and Machines*, by Henry Stephens and R. Scott Burn, Edin.

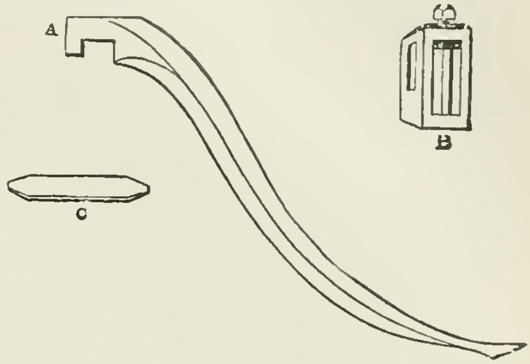
The *Ducie* or Uley cultivator has many features in common with Biddle's, and although brought forward as an improvement upon it, has not established its title to be so regarded. The great weight, high price, and amount of horse-power required to work them, are serious objections to all these implements.

Of more recent notoriety than these, and contrasting with them favourably in these respects, is an implement invented by the late Mr John Tennant, at Shields, near Ayr, and now popularly known as Tennant's grubber. Its construction, as the annexed cut will show, is simple in the extreme. Its weight is about two cwt., its price £4, 10s.,



Tennant's Grubber, as improved by T. Brown, Edington.

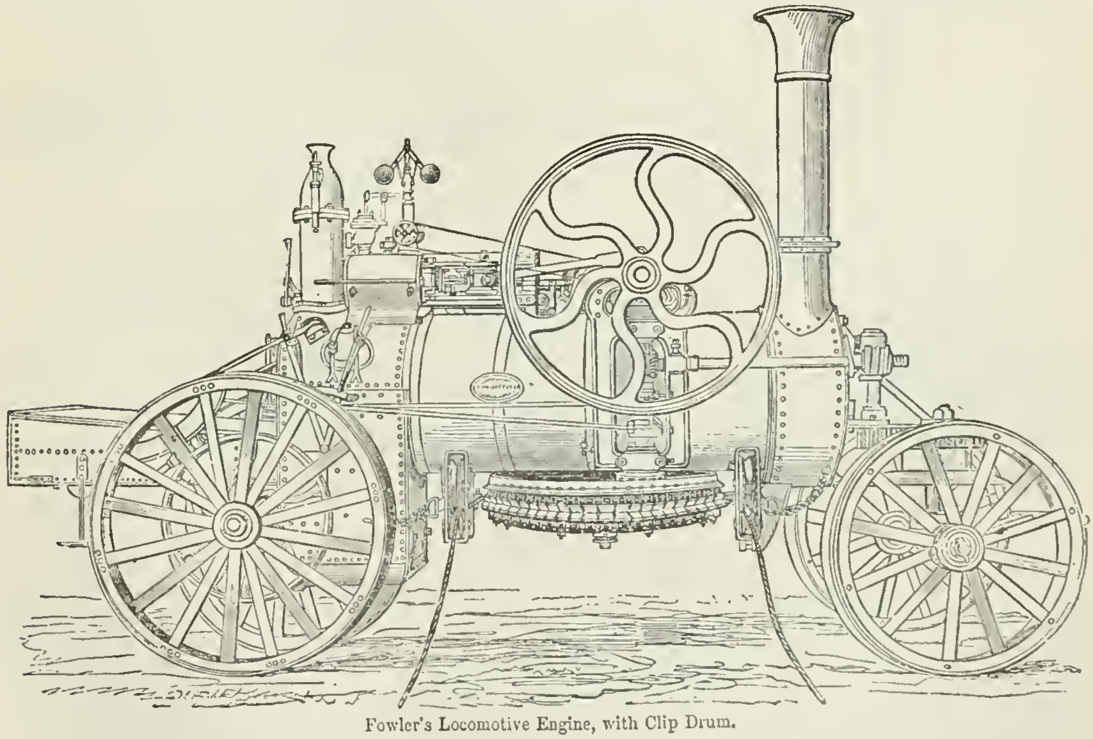
and its draught easily overcome by two horses. The depth at which it works is regulated by raising or lowering the shank which supports its wheels in front. Its tines can be easily moved on their supporting bars, and it may be worked with five or seven as desired. By substituting a shorter hind bar, and setting the tines more closely together, it makes a most efficient drill-grubber. We shall have occasion to refer to this implement frequently in treating of tillage operations. The improvement which Mr T. Brown has made on Tennant's grubber consists mainly in the mode of attaching the tines to the bars. This attachment, which the cut explains, has the merit of being at once very simple and very effectual. The tines when thus fixed are as rigid as if welded to the bars, and yet, by merely slackening the screws and driving out the wedges, they can with ease and rapidity be either adjusted at varying widths apart, or detached for repair.



A, Tine ; B, Keeper; C, Wedge, $\frac{1}{8}$ Actual Size.

Section 4.—Steam-Power Tillage Implements.

Such are the most important of those implements by which the tilling of the soil has hitherto been accomplished, and upon which the farmer must continue to rely so long as he uses the muscular force of animals as his motive power.



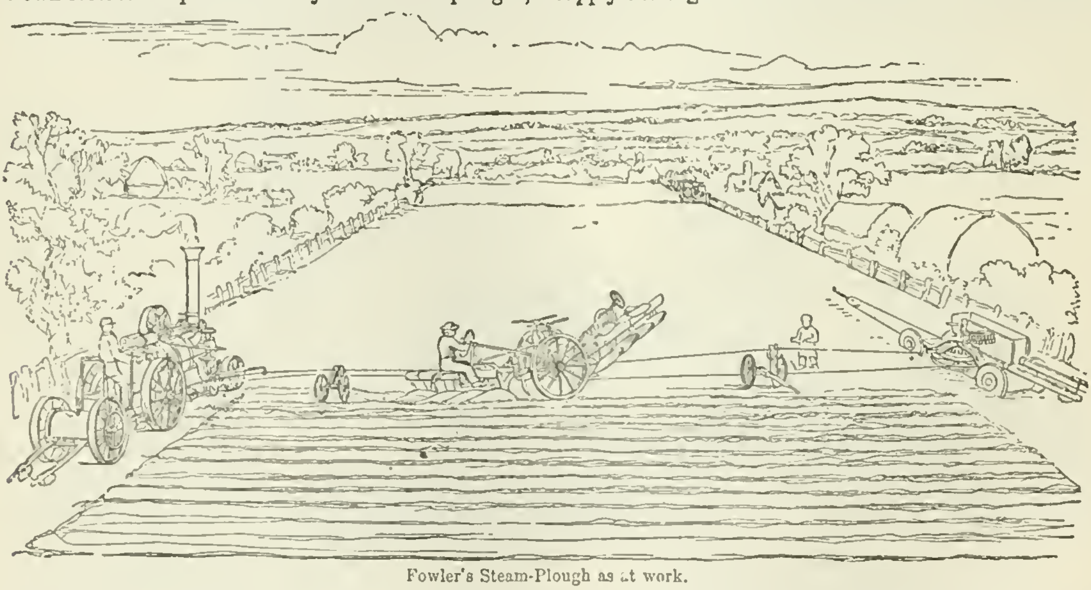
Fowler's Locomotive Engine, with Clip Drum.

But the progress of invention has at last made the steam-engine practically available for this purpose, and accordingly we here introduce some notice of what has now been accomplished, in applying steam power to the cultivation of the soil.

After many abortive attempts to do this by moving the engine itself over the land to be operated upon, it is now admitted on all hands that the only available method is to communicate the power from the engine to the implements by means of steel wire-ropes and windlasses. This is done in a variety of ways, some of the most prominent of which we shall now describe. The systems actually in operation fall under two general classes, which are known severally as the "Direct" and the "Roundabout." The first of these is the system introduced by Messrs John Fowler & Co. of Cornhill, London, and now so well known in connection with their name. The late Mr John Fowler's first efforts were directed to the production of a draining apparatus, and it was after succeeding in this apparently more arduous effort that he adapted his tackle to the hauling of tillage implements. After various tentative changes, Mr Fowler settled on the form which is still in extensive use. It consists of a single locomotive engine, usually of 12 or 14 horse-power, with a windlass attached to it under the boiler. Around this windlass an endless steel wire-rope passes with a single turn in a groove, which, by means of hinged clips, lays hold of nearly the entire circumference of the rope, and that with a force proportioned to the strain upon the rope, which thus obtains sufficient grip to convey the necessary hauling power without risk of slipping upon the drum. This wire-rope, which requires to be just twice as long as the field to be tilled is wide, passes round a sheave upon a self-acting anchor placed at the farther side of the field opposite to the engine. This anchor is a prominent feature in Mr Fowler's apparatus. It consists of a low truck on four wheels, with sharp disc edges, which cut deeply into the soil, and thus obtain a hold sufficient to resist the strain of the wire rope. A box, loaded with stones, is fixed on the outer side of this truck to hinder it from canting over. The sheave mounted upon this truck, besides serving its primary use, gives motion when required to a drum, which winds up a rope, the other end of which is fixed well a-head in the direction in which the truck is required to move. Thus the apparatus warps itself along the headland as the ploughing progresses, and is kept always *vis-à-vis* to the engine, which moves itself forward by its own locomotive power at every bout of the ploughs, and keeps abreast of them. That the rope may not drag upon the ground, friction rollers or rope-porters, as they are called, are placed at suitable intervals. These being mounted on wheels and strung upon the rope, are now in a good measure self-acting, as the tautness of the rope keeps them in its own line. The ploughs are fixed to a balance frame carried on two wheels, and are in duplicate, pointing to each other, so that when the set at one end of the frame is in work, the opposite set is carried aloft in the air. The plough frame is thus hauled to and fro across the field, between the engine and movable anchor, by reversing the action of the windlass; and it is adapted for taking from two to eight furrows at once, according to the power of the engine employed, or the nature of the soil that is operated upon.

Messrs Fowler have made this form of their apparatus more generally available by adapting it for attachment to the ordinary 8-horse power thrashing-engine. When thus used the clip-drum is mounted on a separate frame and connected with the engine, which being stationed in a corner of the field to be ploughed, the rope is carried to two self-acting anchors, one at each side of the field, and thus encloses a triangle. The plough is drawn to and fro betwixt these anchors, and as it gradually approaches the engine at each successive bout, the gearing on the plough-frame tightens up the rope and accommodates it to the diminishing length required.

To work Fowler's apparatus there is required one engine-driver, one ploughman, a stout lad to attend to the anchor, two boys to shift the rope-porters, and a horse and boy to supply the engine with water and fuel.

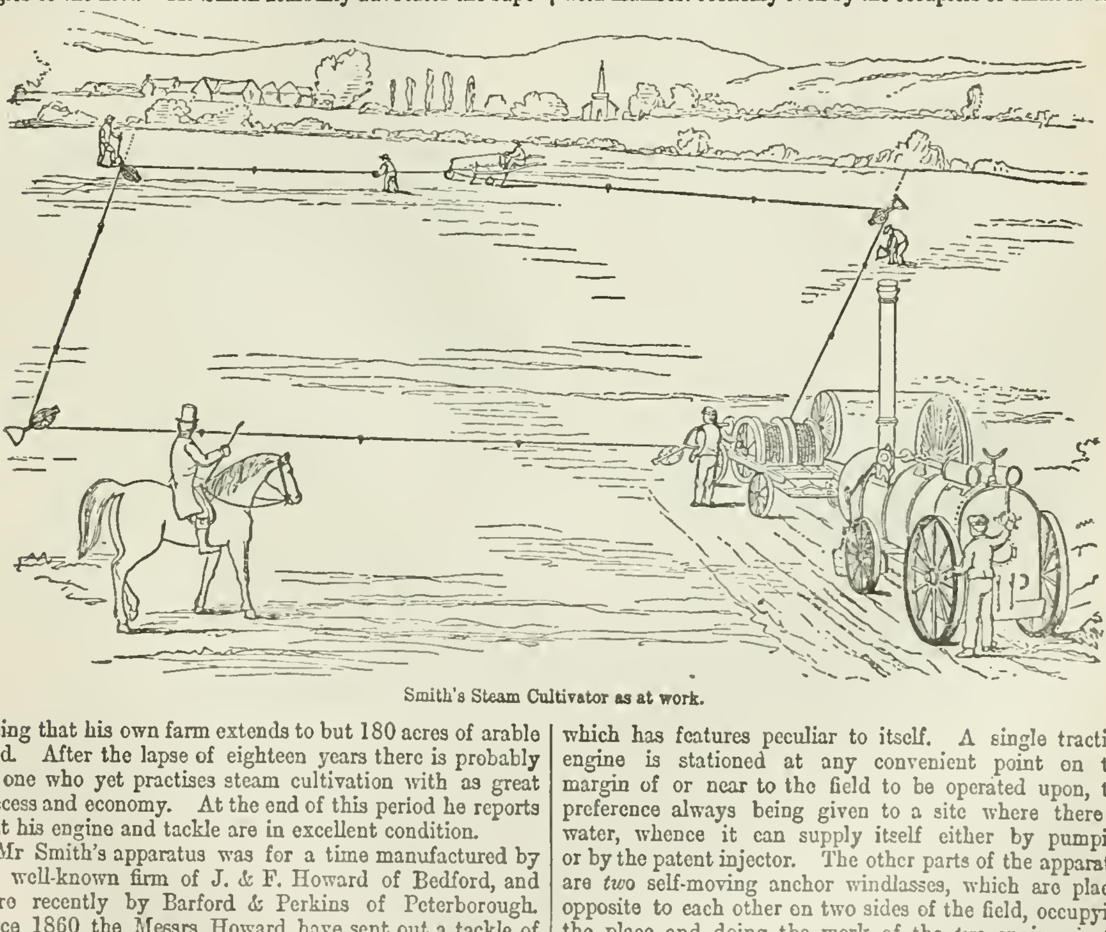


Fowler's Steam-Plough as at work.

About 1865 Messrs Fowler made an important addition to their apparatus by substituting a second engine for their movable anchor. In this arrangement, now well known as the "Double Engine system," a pair of locomotive engines, each having a plain winding drum instead of the clip-drum, are placed opposite to each other at the ends of the field to be operated upon; the rope of each of the engines is attached to the plough, or other tillage implement, which is drawn to and fro betwixt them by each working in turn. While the engine in gear is coiling in its rope and drawing the plough towards itself, the rope of the other engine is paid out with merely so much drag on it as to keep it from kinking or getting ravelled on the drum. The advantages claimed for this system are, economy of power from the direct pull of the engines on the implement; the facility and rapidity with which the engines move themselves and the whole apparatus from field to field, or farm to farm, and take up their positions and get to work without the aid of horses; and the few hands required to work it. Its drawbacks are the large first cost, and corresponding charge for wear and tear, depreciation, and interest; its unsuitableness for working in small and irregularly shaped fields; and the injury done to headlands in wet weather. Its special adaptation is for large farms, and for working for hire; and for these it is undoubtedly without a rival.

Mr William Smith of Woolston, Bedfordshire, may fairly be regarded as the pioneer of cultivation by steam power. At the meeting of the Royal Agricultural Society of England at Carlisle in 1855, he witnessed the performance of the late John Fowler's steam draining-plough, and then contracted with him to construct for him a windlass and other tilling apparatus, with which he got to work on his own farm in the autumn of that year. These two leaders in steam-cultivation did not long work together. They had decided and diverse opinions as to the best road to success, and accordingly each for the future took his own course. Mr Smith's merit is not largely that of an original inventor of machinery, but rather that of a zealous, persevering, and successful applier of the inventions of others. But by his own example and his vigorous writings, he has contributed very largely indeed to the success of steam cultivation. He makes use of the ordinary portable engine, such as is employed as a thrashing power, which gives motion to a detached windlass with two drums, from which a wire-rope is carried round the area to be operated upon, and hence the name "Roundabout" applied to this system. This rope being attached by a turning bow to a powerful grubber, the implement is drawn to and fro across the field by reversing as required the action of the windlass, the slack half of the rope being uncoiled from the one drum as the part in work is wound up upon the other. His mode of working is to break up the ground by using a three-tined grubber, and then to go over it again with a seven-tined one, working at right angles to the first. Mr Smith zealously advocates the superiority of grubbing to ploughing, being of opinion that if the soil is thoroughly broken up to a sufficient depth, it is better not to reverse the surface, as weeds are thus kept on the top, and the removal of them thereby greatly facilitated.

Mr Smith soon made an important addition to his system of tillage by means of an implement which he calls a *Ridger and Subsoiler.* By means of it the soil, after being thoroughly smashed up by the steam-grubber, is thrown into 36-inch ridges, the tine at the same time penetrating and loosening the subsoil in each furrow several inches deeper. His clay soil treated thus immediately after harvest is put into the best possible condition for benefiting by the alternations of wintry weather, for allowing rain-water to pass readily and beneficially to the drains, and for yielding a friable seed-bed in spring. It has enabled him altogether to dispense with dead fallows; to grow abundant crops of wheat and beans alternately for a number of successive years, at an average annual cost of 8s. 6d. per acre for tillage; and to keep his land perfectly clean under this constant cropping. He has the high merit not only of being the first man who successfully used steam power for the cultivation of a farm, but of demonstrating that this can be done with manifest economy even by the occupiers of small farms,



Smith's Steam Cultivator as at work.

seeing that his own farm extends to but 180 acres of arable land. After the lapse of eighteen years there is probably no one who yet practises steam cultivation with as great success and economy. At the end of this period he reports that his engine and tackle are in excellent condition.

Mr Smith's apparatus was for a time manufactured by the well-known firm of J. & F. Howard of Bedford, and more recently by Barford & Perkins of Peterborough. Since 1860 the Messrs Howard have sent out a tackle of their own, in which the main features of Smith's system are retained, but to these they have themselves added from time to time various improvements. By means of a self-acting windlass and self-moving anchors, their tackle can now be worked by one engineman (who also attends to the windlass), one ploughman, and two porter-boys.

Although the earliest in date of invention, the most recent in actual operation is the tackle of Messrs Fisken, which has features peculiar to itself. A single traction engine is stationed at any convenient point on the margin of or near to the field to be operated upon, the preference always being given to a site where there is water, whence it can supply itself either by pumping or by the patent injector. The other parts of the apparatus are *two* self-moving anchor windlasses, which are placed opposite to each other on two sides of the field, occupying the place and doing the work of the *two* engines in the double-engine system. These windlasses are mounted on four disc wheels, and have also a spud which cuts into the soil to give the necessary resistance to the side pull. They each carry a winding-drum with the necessary length of wire-rope, and these windlass-drums wind up and pay out alternately in precisely the same way as in Fowler's double engines. They also have each a winding-forward drum with wire-rope and anchor fixed a-head, by means of which they warp themselves forward and keep abreast as the work progresses. Power is communicated from the engine to these windlasses by means of a light hemp rope, travelling at the speed of the fly-wheel, which is carried all round the field, and takes a double turn round a grooved pulley on each windlass. A set of anchor pulleys on wheels carry this rope round the corners of the field; another set of pulleys, on stakes driven into the ground at suitable points, carry it off the ground; and a tension anchor mounted on four wheels, and having, like the windlasses, an apparatus by which it warps itself forward, and keeps the hemp-rope taut as the length out varies with the progress of the work. The windlasses have each a self-acting clutch, which stops the implement when any obstruction is encountered, and by which the attendants stop it at the turnings, or when otherwise necessary, without in any case requiring to stop the engine. By these arrangements the engine-driver does not require to have the implement in sight, his duty being merely to drive his engine at a uniform speed, as neither stopping nor reversing are required. The advantages claimed for Fisken's tackle are those which it has in common with the other Roundabout systems, and, in addition, the use of a light hemp rope to convey power from engine to implement with less friction and cost than in other systems; great adaptability to fields of any size, or shape, or inequality of surface; and a capacity in certain circumstances of being worked by a fixed steam-engine or water power.

The Royal Agricultural Society of England has from the first devoted much attention and large funds to the promotion of steam cultivation, by the prizes offered at its annual shows, and by the reports published in its *Journal* from year to year. In the prolonged trial of steam-ploughs which took place at Leeds in July 1861 under its auspices, the competition was mainly betwixt Fowler's and the modification, by Howard, of what is popularly known as Smith's system. The award of the judges was as follows:—"The £100 prize offered for the most economical application of steam power to the cultivation of the soil, was awarded to Mr Fowler for his 12-horse power engine, moving anchorage, and plough; and of the £100 offered for the most economical application of the ordinary thrashing-engine of the farm to steam cultivation, £75 was given to Mr Fowler, and £25 to Mr Howard. Besides these a silver medal is given to Mr Hayes, for his clever windlass for the same purpose; and the same to Mr Roby for his combined engine and windlass."

During the summer and autumn of 1861, Mr J. C. Morton, editor of the *Agricultural Gazette*, personally inspected the farms of many of these parties, and published from time to time in that paper detailed accounts of his own observations and of the information supplied to him in regard to each case. In his *New Farmer's Almanac* for 1862, he condensed these reports, and from it we give the following extracts:—

"Little Woodcote Farm lies—a tract of open country and light calcareous soil of various depth—upon the chalk, about a mile from the Carshalton station on the London and Epsom railway. Mr Arnot has had Fowler's 10-horse power steam-engine and ploughing apparatus since the harvest of 1859. His apparatus, rope, and engine cost £700. He works a three-furrow plough. The work done each year by the steam-plough on his 400 acre farm has thus been 393 acres in 1859-60, and 389 acres in 1860-61. It has been done at the rate of six or seven acres a day for ordinary ploughing, and three acres a day (one acre per furrow) when at the 10 and 12-inch deep work. It may average on the whole five acres a day, including all stoppages and removals, and has thus taken close upon eighty days for its accomplishment. Besides this, however, 150 acres have been ploughed during the time for neighbours at a charge, including everything, of 12s. an acre. The engine is also used for thrashing purposes, and 220 acres at home and 250 acres elsewhere are thus thrashed out for hire.

"The cost of repairs has been uncommonly small—including a new cog-wheel, repacking cylinders, and a thorough overhaul and cleaning of the whole apparatus at the end of two years—besides the replacement of shares and sharpening of coulters for the plough, and the gradual wearing of the rope-porters. In all it has not nearly reached £10 a year, at which, nevertheless, we put it. The tear and wear of rope is reported as follows:—A new 400-yard rope, lately bought, costing £35, has made the stock stronger and better than it was at the beginning. This charge may therefore be put against more than two years' work, and is equal to about £15 a year. The weekly cost of labour when at work is as follows:—Engineer, 18s.; ploughman, 14s.; anchor lad, 9s.; two porter lads, 6s. each; horse and water cart, about 24s. weekly—in all, £3, 17s. weekly, or as nearly as possible 12s. a day. The cost for oil is 1s. a day, and for fuel, at nine or ten cwt. a day, it may be put at 10s. daily. The charge for depreciation at 10 per cent is £70 a year, and for interest of capital £35 a year. The whole annual cost may thus be estimated:—

Labour, 80 days	£48
Fuel and oil	44
Repairs and rope . . .	25
Depreciation and interest of capital .	105
Total	£222

"But 500 acres of thrashing, and 70 or 80 acres per annum of steam ploughing for hire, equal in all to at least forty days' work per annum, are also done by this engine. And the profits of this work should be deducted from this sum before Mr Arnot's experience of his investment can be accurately described. The sum of £222, at which, if there had been no other use for engine and apparatus, his cost must have been estimated, is equal to 11s. per acre over the work accomplished, much of which, however, was 12 inches deep. But if the proper share of the interest and depreciation of capital be charged upon its work elsewhere for hire, the cost of steam ploughing will not exceed £190, or 10s. 6d. an acre. But Mr Arnot would contend that the engine is not £30 worse than when he purchased it two years ago; and one-half of this, with interest of capital, will amount to £50, two-thirds only of which should be charged against the plough-work; and £150 would thus appear to be the annual cost of ploughing 400 acres, or 7s. 6d. an acre. In fact, he might very well claim that this sum should be still further reduced by all the profit of his hire elsewhere, which can hardly be put at less than 20s. a day, and this on forty days per annum will amount to £40 or more; so that the net cost to him of his machinery has not been more than £110 a year, or 5s. 6d. an acre over his ploughing.

"What did it use to cost him when he worked thirteen horses on his farm? He now works six horses. His horses get $2\frac{1}{2}$ bushels of oats, and $2\frac{1}{2}$ trusses of hay weekly each, during seven months:—

30 weeks at 11s. amount to .	£16 10 0
22 weeks on clover, &c., at 5s. .	5 10 0
The annual food per horse costs	£22 0 0

"The annual charge for depreciation, farrier, blacksmith, saddler, and implements, is at least £5 per horse, and for interest of capital in horse and implements at least £2 more. This makes the annual cost of each horse £29. The wages paid, in cash and cottage, to ploughmen is at least £32 per pair, or £16 per horse, and the whole cost is thus equal to £45 per horse per annum; which over seven horses amounts to £315 per annum—one-half more than the expenditure, even on the highest estimate, upon the engine which has displaced them, and nearly double what Mr Arnot has actually incurred when he deducts his profits on its hire.

"A clay land farm near Bedford (the Woolston or Bedford apparatus), the Tithe Farm of Stevington, occupied by Mr William Pike, is a tract naturally of poor clay soil. The extent farmed by Mr Pike has till lately been about 475 acres, of which 357 were arable; and fifteen horses were employed in five 3-horse teams upon this extent. Now, about 600 acres are farmed, of which 420 acres are arable; and the whole is managed with ten horses and an 8-horse power engine, working grubbers on the Woolston system. If the additional land requires the same horse-power per 100 acres as was needed on the original farm, then, in place of ten horses, seventeen or eighteen must have been needed, and probably Mr Pike's mere saving by the use of his 8-horse engine and cultivating apparatus does not fall short of £300 a year.

"The present cropping of the land is as follows:—125 acres are in wheat, of which 105 were partly after beans, cross-grubbed by steam-power before sowing, and partly after clover, having been cross-grubbed also by steam-power more than once before the previous harvest time, and then horse scarified and harrowed. The remainder was after horse cultivation. There are 60 acres of beans after wheat, its stubble having been dressed with farm-yard dung, and then ploughed by horse power. There are 60 acres of grass and clover; 20 acres now in vetches have been cross-grubbed after a manuring; 25 acres in mangolds and turnips have been cross-grubbed in autumn, and again steam-scarified and crossed in spring; 50 acres in barley, and 25 acres in oats, make up the extent of the farm, and were got in after steam cultivation. By 'cross-grubbing' it is meant that the operation was repeated.

"More horse cultivation than usual was done in 1860. Clay land was fit only on rare ocasions, and both horse and steam power were then used to the utmost. Mr Pike has had Mr Smith's grubber worked by an ordinary thrashing-engine since July 1858. Since that time 731 acres have been cross-grubbed, *i.e.*, doubly-worked. In addition to this Mr Pike informs me that he has also cross-grubbed for hire 300 acres of land. For this he charges 25s. an acre, the coals being supplied to the employer.

"Excluding this item from our consideration in the meantime, and assuming that 730 acres—double cultivated between July 1858 and June 1861—correspond to 250 acres annually, the average performance of the engine, including all stoppages except removals, has been six acres daily once cultivated. To do 250 acres twice would therefore occupy at least eighty-three days; adding three days for removals, there are eighty-six days' work of the steam-engine to be charged upon the steam cultivation of the farm. The following is the labour and its cost per week:—1 engineer, 16s.; 1 ploughman, 11s.; 2 men shifting anchors, 22s.; 1 man at windlass, 12s.; 1 porter-boy, 6s.; 1 boy and horse with water cart, 24s.: the whole amounts to £3, 19s., or 13s. 2d. daily. In addition to this we add the cost of coals, 10 cwts. at 19s. a ton on the ground. or 9s. 6d. daily. The oil at 5s. a gallon costs about 1s. a day.

"The daily cost thus comes to 23s. 6d., and this over eighty-six days amounts to about £100. Against the engine and apparatus, costing about £510, we must put 10 per cent., or £51, for depreciation, and 5 per cent., or £25, 10s., for interest of capital. The cost of repairs may perhaps be satisfied by an annual charge of £15; and for tear and wear of rope we have the following items: 1400 yards of iron wire-rope originally purchased, £50; steel ropes, 1400 yards, since purchased, £60. Probably the annual charge needed to maintain this may be made on the theory that the rope will last three years, and £25 a year may suffice for this particular. Adding up these items, we have a sum total of £216, 10s. to be charged against the farm for steam cultivation. Putting £216 against 500 acres once grubbed in the course of the year, we have a charge of about 8s. 7d. an acre for the grubbing. Mr Pike informed me that, during the three years of his steam cultivation, on several of the ten fields already specified, he has not used the plough at all. Even the mixing of manure with the soil is done by the grubber. No plough is used to bury it. It is laid upon the land, and grubbed to and fro, and thereby mixed sufficiently. The cleanness of the land, too, is a fair testimony to the quality of cultivation by implements which stir, but do not overturn the soil.

"Mr Pike has till lately used the grubber invented by Mr Smith of Woolston, with the turnbow apparatus for turning the tool at the land's end. Latterly he has used the cultivator of Messrs Howard, each tine of which is double, pointing both fore and aft, so that no turning at all is needed, the claw which follows in the wake of the working tooth as it goes coming into operation in its turn as it comes back again."

Mr Pike thus writes to Messrs Howard, of date December 2, 1861:—

"GENTLEMEN,—I have cultivated my farm by steam-power for the last four years, and therefore feel myself in a position to speak positively of the merits of the system.

"My farm, belonging to the Duke of Bedford, consists principally of poor, strong, hilly, clay land, which, before I entered upon it, was laid up in three yard ridges, with water gutters drawn across the ridges to take off the water. Since I have steam cultivated it, I have done away with ridges and furrows entirely; my fields of 40 and 50 acres each, which are steep in places, are all laid on the flat, and during the wettest season I have never seen any water stand upon them. I am convinced if land is broken up a good depth by the cultivator, and under drained, there is no need of any furrows, if it is ever so strong.

"I am enabled to manage my farm with about half the number of horses. I do it with less trouble to myself. I am always more forward with my work, and the horses I do keep *cost much less* per head than formerly, as all the *hard work* is done by steam.

"The effect of deep stirring this soil is very apparent in the crops; my land is naturally very poor, so that very large yields are out of the question; but I am convinced I can grow much more corn by steam than by horse cultivation, and I can also grow a larger breadth of root crops. I also find that by constant deep tillage my land moves easier every year, consequently it is less expense to cultivate. I seldom use the plough, except my horses have got nothing else to do.

"I break up my clover lays before harvest, and make a *bastard* fallow of them. I am convinced this is the surest way of getting a good wheat crop on strong soil; and, besides cleaning the land, it has this advantage, it does not leave so much work to do at Michaelmas. I also break up my tare land before harvest, so that after harvest I have nothing to do but cultivate my bean and wheat stubbles.

"I put away my tackle as soon as possible after we have heavy rains, the latter part of October or beginning of November, and do not bring it out again until the turnip land is ready to break up for barley. My object is to make the best use of the summer and the early autumn.

"When I commenced cultivating by steam, I used to set down to little pieces, but I found *that* too much trouble, therefore increased the length of my ropes, as I found it made very little difference to my 8-horse engine whether I had out a long or short length of rope. I have now sufficient to do a 50 acre field, without moving either engine or windlass; this is my largest field; I dug a pond at one end, and I do the whole without moving from the pond. When I can, I set my engine and windlass in an adjoining field, so as to finish headlands and all complete, without going into it. Water carting is a great expense, and in a wet season a great nuisance. I therefore have dug some ponds, and sometimes I dam up a ditch or master drain to obtain a supply.

"I am particularly pleased with the new apparatus you made for me last spring. The windlass is much easier moved about, and is very simple to manage. The cultivator takes less time at land's end, there is no danger of overturning, it does not jump so much in work, and the hind shares cause the land to lay looser. No matter how hard the ground, it will break it up, and on sidehills it goes much steadier and better than my old one.

"The first steel rope I had did above 2000 acres, and I have a small portion of it at work yet. If people mean to have their ropes last, they must keep them off the ground, and attend well to the coiling on the windlass drums. I like your new rollers, which carry the rope further from the ground.—I am, Gentlemen, yours very truly,

"Messrs J. & F. Howard, Bedford. WILLIAM PIKE."

It is due to Messrs Howard to state that their numerous other customers concur in testifying to the general efficiency of their tackle, its little liability to breakage or derangement, and to the readiness with which their ordinary farm labourers have learned to work it efficiently.

By this time cultivation by steam-power had been adopted by enterprising individuals in nearly every county in England, and was making steady progress in the face of many hindrances. In every instance the purchaser and his servants had to learn the use of novel and somewhat complicated machinery; much of which, as first sent out, proved to be defective both in structure and in material. The fields also, through lack of preparation, often presented obstacles which, as experience was gained, were seen and remedied. In a few instances, where the purchaser of steam tackle was either unable to give his personal superintendence, or lacked the needed energy and perseverance to cope with the difficulties of a new enterprise, it proved a failure. But with rare exceptions, easily accounted for, it was everywhere demonstrated that by steam-power and appropriate implements, the tillage of the soil can be performed with a rapidity, efficiency, and economy far excelling what is practicable by animal power and the old implements.

In the autumn of 1866, by which date steam tillage had greatly extended, the Royal Agricultural Society of England sent out three sets of commissioners to inspect and report on the position of steam cultivation at that time. The reports obtained were published in the Society's *Journal* for 1867, and present a mass of most interesting and instructive information on the whole subject. The commissioners visited about 150 farms situated in nearly 40 different counties of England, and a few in East Lothian, containing an aggregate area of 66,000 acres, which they estimate to be about a third of the whole area *then* under steam cultivation. They amply confirm what has already been stated as to the success of this new system of tillage, and make it plain that the changes thus brought about are of such importance as really to amount to a revolution in modern agriculture.

At its annual show in 1871, at Wolverhampton, the English Society again provided for a careful competitive trial of steam-tillage machinery, when the following awards were made:—

CLASS I.—For the best combination of machinery for the cultivation of the soil by steam-power—
1st Prize, £100—Awarded to Messrs J. Fowler & Co., Leeds.
2d Prize, £50— do. do. do.

CLASS II.—For the best combination of machinery for the cultivation of the soil by steam-power, the weight of the steam-engine not to exceed 10 tons—
1st Prize, £50—Awarded to Messrs Fowler, Leeds.
2d Prize, £25—Awarded to the Ravensthorpe Engineering Co. (Fisken system).

CLASS III.—For the best combination of machinery for the cultivation of the soil by an ordinary agricultural engine, whether self-propelling or portable.
1st Prize, £50—Awarded to Messrs Fowler, Leeds.
2d Prize, £25—Awarded to Messrs Howard, Bedford.

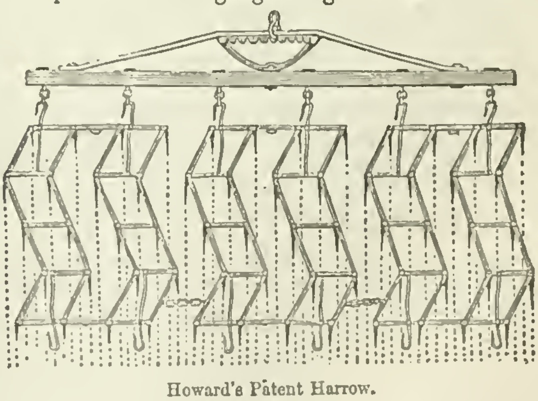
A Silver Cup, value £100, offered by the Right Hon. Lord Vernon, president, for the best combination of machinery for the cultivation of the soil by steam-power, the cost of which shall not exceed £700. The engine to be locomotive, and adapted for threshing and other farm purposes.—Awarded to Messrs Fowler & Co., Leeds.

Steam cultivation has now ceased to be a novelty, and is making rapid progress in all parts of Great Britain and in foreign countries. In March 1873, at an agricultural meeting, it was stated by Messrs Fowler & Co. of Leeds, that they are turning out annually from their works about 100 sets of their tackle for the home market, and from 50 to 60 for foreign countries. Of their home sales about half are to private individuals, and half to persons who work them for hire. In a district around Magdeburgh fifty sets of their tackle are employed in cultivating the soil for the growth of sugar-beet. The other leading makers are also doing a large business, with the certainty of its becoming larger every year. The expiry of several patents applicable to steam cultivating tackle is giving an additional stimulus to the manufacture of such machines. Partly in this way, and also by contrivances of their own, the Messrs Howard of Bedford have recently (1873) made very considerable changes and progress with their tackle. Their self-acting anchors, and their turning cultivator, which is constructed on an entirely new principle, are said to be respectively the best of their kind.

Section 5.—Harrows.

When a field has been broken up by the plough, it is usually next operated upon by the harrow, whether the object be to prepare it for and to cover in seeds, or to bring clods and roots to the surface. This is virtually a rake dragged by horses. In its most ordinary form, the framework is of wood with iron tines, of which each harrow contains twenty. Formerly each horse dragged a single harrow, although two or more were worked abreast. Under this arrangement the harrows had too much independent motion, and were liable to get foul of each other. This has been remedied, first, partially, by coupling them loosely by riders, and then more effectually by a hinge-like joining, which allows a separate vertical motion, but only a combined horizontal one. A rhomboidal form is also given to this *pair* of harrows—usually called *brakes*—so that when properly yoked, no two tines run in the same track. This description of harrow is now frequently made entirely of iron.

Howard's patent harrows are a further improvement on this implement. The zig-zag form given to each section en-

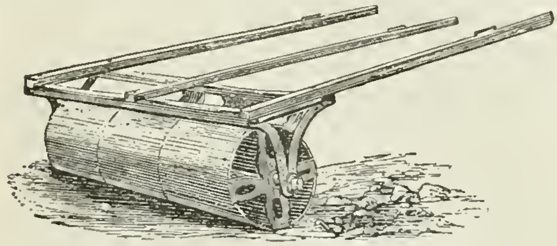


Howard's Patent Harrow.

ables the whole so to fit in, that the working parts are equally distributed over the space operated upon. The number of times is 75, instead of 40, as in the form last noticed, and yet, from the form of frame and manner of coupling, the tines are well apart, and have each a separate line of action. Practical farmers speak very highly of the effective working of this implement. By an exceedingly simple contrivance, the centre part when turned on its back forms a sledge on which its fellows can be piled and drawn along from one field to another. A light description of harrows, with smaller and more numerous tines, is sometimes used for covering in grass-seeds. If a harrow is to be used at all for this purpose, Howard's is a very suitable kind, but a much better implement is Cartwright's chain-harrow, which abrades the surface over which it is drawn to a degree that could not be anticipated from a mere inspection of the implement. It is formed by attaching to a draught-bar pairs of square-linked chains, each 7½ feet long, connecting them by cross links, and keeping the whole expanded by two movable stretchers. The old-fashioned ponderous break harrow is now entirely discarded, and the more efficient cultivator used in its stead. A form of the latter, from its close resemblance to harrows, is noticed now rather than before. It is a very strong iron harrow, with the tines made longer, and very considerably curved forwards. An iron rod with a loop handle is fixed to the hind bar, by means of which the driver can easily hitch it up and get rid of weeds, &c. Two such harrows are coupled together and drawn by four horses. Its pulverising power is very considerable. But when clods have been brought to the surface, they are most effectually reduced by various kinds of rollers.

Section 6.—*Rollers.*

Those formerly used were solid cylinders of timber or stone attached to a frame and shafts, for which hollow ones of cast-iron are now generally substituted. The simplest form of these has a smooth surface, and is cast in sections to admit of more easy turning. They are made of diverse weights, so as to be adapted for the draught of one or two horses as required. Those of the former description, weigh-

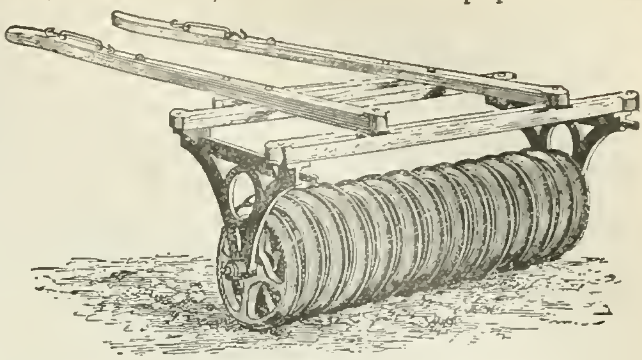


Smooth Cast-Iron Field Roller.

ing in all 6 cwt., and costing as many pounds sterling, are exceedingly useful for all purposes where expedition rather than heavy pressure is wanted. From their greater durability, smoother surface, and less liability to clog, the readiness with which they can be cast of any weight that is required, and their moderate price, it is probable that cast-iron cylinders will speedily supersede all others.

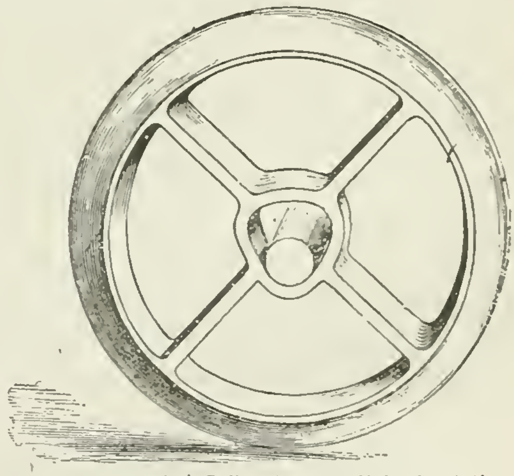
Several important variations on the common smooth roller have been introduced of late years. Of these the first notice is due to Crosskill's clod-crusher, on the ground both of its intrinsic merit and the date of its introduction. It consists of cast-iron discs 2½ feet in diameter, with serrated edge and a series of sideway-projecting teeth. Twenty-three of these discs are strung loosely upon a round axle, so as to revolve independently of each other. The free motion thus given to each disc, and which has latterly been increased by casting each alternate one of greater diameter in the eye, adds at once to the pulverising and self-cleaning power of the roller. Three horses yoked abreast are required to work it. The axle is prolonged at each end sufficiently to receive travelling wheels, on which it is transported from place to place. Although primarily designed and actually much used for breaking clods, it is even more in request for consolidating loose soils, checking the ravages of wire-worm, and covering in clover and grass seeds. For the latter purpose, its action is perfected by attaching a few bushes to it, which fill up the indentations, and leave a surface so beautifully even as to rival the accuracy and neatness of a well-raked border. It is now to be had on a smaller scale adapted to the draught of two horses.

Cambridge's roller possesses several features in common with Crosskill's, and is used for similar purposes. In the



Cambridge's Press-Wheel Roller.

form in which it was first brought out it consisted of discs, fitting close to each other, with fluted instead of serrated edges. In its recently improved form the discs are not made of uniform diameter as formerly, but each alternate one in the set is raised about two inches, and has the centre hole, not circular and close fitting to the axle, but triangular and wide. The result is that while the discs press uniformly on the surface over which they are rolled, the larger ones rise above their fellows with a jerking motion, which gives a most efficient self-cleaning power to the implement, and thus admits of its being used when other rollers would be clogged. The eccentric discs are now made either with serrated or smooth edges as customers prefer. After careful trial we have come to the conclusion that it is the most useful roller for general purposes which we yet possess.



Disc of Cambridge's Roller, showing Self cleaning Action.

Under this head may be noticed press drills, which, by means of a series of narrow cylinders with conical edges, form corresponding grooves in loose soil. Seeds sown broadcast over a surface thus treated come up in rows. The

Land-Presser.

land-presser is a modification of the press-roller. It is made with two or three conical edged cylinders to fit into the seams of as many plough furrows, the other end of the axle on which they are fixed being supported by a plain carriage-wheel. It is drawn by one horse, and follows in the wake of two or three ploughs, according to the number of its cylinders. When wheat is sown after clover lea, this implement is found exceedingly useful in closing the seams and forming a uniform seed-bed.

The Norwegian, or, as it should rather be called, the Swedish harrow is strictly a clod-crushing implement. From its radiating spikes penetrating the surface over which it is drawn, it has been called a harrow; but its revolving motion entitles it rather to be classed with rollers. In its usual form it consists of three rows of cast-iron rowels arranged upon parallel axles fixed in an iron frame, which is supported on three wheels,—one in front and two behind. The outline and arrangements are in fact the same as in Finlayson's grubber, only substituting parallel rows of rowels for tines. There is also the same leverage for raising and depressing the frame. But this implement has recently been constructed on a much simpler and cheaper plan, in which the wheels and lever apparatus are discarded altogether. It thus consists of a simple wrought-iron frame with four rows of rowels. A few boards are laid across the frame, forming a platform over the rowels, on which the driver stands when it is wished to increase the weight and efficiency of the implement. On the upper side at either end is fixed a piece of wheel-tire, on which the implement, when turned on its back, can slide along, sledge-fashion, when it is wished to move it from place to place. As thus constructed it can be made for about £5. This is the best implement yet introduced for breaking *moist* clods.

Section 7.—Breast-Plough and Trenching-Fork.

Before leaving the implements of tillage, it may be proper to notice two, which have been a good deal brought under notice of late years, viz., the breast-plough and trenching-fork. The former is extensively used in carrying out the process of paring and burning. It is the implement known in Scotland as the flaughter (or thin turf) spade. In using it the workman guards his thighs with a piece of board, fastened on apron-wise, and with this presses against the cross-head of the implement, and urges forward its cutting edge. When a thin turf has thus been severed from the surface, he turns it over by a jerk of his arms. The fork is used in giving a deep autumn digging to land in preparation for root crops. Both operations can ordinarily be more economically performed by using horse-power with suitable implements. But for clearing out corners of fields, hedge sides, and similar places, manual labour with these tools can frequently be made to supplement the plough to good purpose.

Section 8.—Implements for Sowing.

A large portion of the grain annually sown in Great Britain is still distributed by hand from the primitive sowing-sheet.

> "The sower stalks
> With measured step, and liberal throws the grain
> Into the faithful bosom of the ground."

In Scotland a decided preference is still given to broadcast sowing, for which purpose a machine is used that covers from 15 to 18 feet, according to the width of ridge adopted. It consists of a long seed-box, carried on a frame mounted on two wheels. From these motion is communicated to a spindle which revolves in the seed-box, and expels the seed by means of cogs or brushes, through openings which can be graduated to suit the required rate of seeding. It is drawn by a single horse, is attended by one man, and can get over 30 acres a day. It is peculiarly adapted for the regular distribution of clover and grass seeds. Now that reaping by machinery has become so general, there is an obvious advantage in having the fields as level and with as few open forms as possible, and hence of having a marker attached to the sowing-machine. In one made by Sheriff at West Barns, by an ingenious apparatus on the principle of the odometer, the machine itself is made to register the space which it travels over, and thus to indicate the rate per acre at which it is distributing the seed. Excellent results have been, and still are, obtained from broadcast sowing. But as tillage becomes more perfect, there arises a demand for greater accuracy in the depth at which seeds are deposited in the soil, for greater precision in the rate and regularity of their distribution, and for greater facilities for removing weeds from amongst the growing crop. These considerations led, at a comparatively early period, to the system of sowing crops in rows or drills, and hence the demand for machines to do this expeditiously and accurately. We accordingly find, in our best cultivated districts, the sowing and after-culture of the crops now conducted with a precision which reminds the spectator of the processes of some well-arranged factory. This is accomplished by means of a variety of drilling-machines, the most prominent of which we shall now notice.

The Suffolk drill is the kind in most general use. It is a complicated and costly machine by which manure and seeds can be simultaneously deposited. That called the "general purpose drill" can sow ten rows of corn, with or without manure, at any width between the rows from 4½ to 10 inches, and at any rate per acre between two pecks and six bushels. It can be arranged also to sow clover and grass seeds,—the heavier seeds of clover being thrown out by minute cups,—and the lighter grass seeds brushed out from a separate compartment. It is further fitted for sowing beans and turnips—the latter either two drills at a time on the ridge, or three on the flat. This drill, as most recently improved by Messrs Hornsby of Grantham and Garrett of Leiston, has an apparatus for preserving the machine in a level position when working on sloping ground. As a main object in drilling crops at all is to admit of the use of the hoe, it becomes an important point to accomplish the drilling with undeviating straightness, and exact parallelism in each successive course of the drill. This is now obtained by means of a fore-carriage, which an assistant walking alongside so controls by a lever as easily to keep the wheel in the same rut down which it had previously passed. Messrs Hornsby have also introduced India-rubber tubes for conducting the seed, in place of the tin funnels hitherto used. These drills cost about £42.

The Woburn drill of the Messrs Hensman is simpler in its construction than those already noticed. "In all other drills, the coulters, which distribute the manure or seed, hang from the carriage. In this drill the carriage rests upon the coulters, which are like the iron of skates; it may be said, indeed, to run on four pairs of skates. Hence this drill's power of penetrating hard ground, and of giving a firm bed to the wheat-seed in soft ground. Each drill coulter, however, preserves its independence as when suspended. This self-adjustment is required by the inequality of tilled ground, and is thus obtained: each pair of coulters is fixed to the end of a balance beam, these again to others, and they to a central one. Thus each coulter, in well-poised rank, gives its independent share of support. It varies from the generality of drills, as it is drawn from the centre by whipple-trees instead of shafts; and the drill-man behind can steer or direct the drill with the greatest nicety. The corn-box of the drill is entirely self-acting, and delivers the seed equally well going either up or down hill. It is also capable of horse-hoeing, by attaching hoes to the levers instead of the coulter-shares

It is drawn by a pair of horses, and the price from £18 to £20."[1]

Turnip drill.—In Scotland, and in the north and west of England, turnips are usually sown on the ridge by a machine which sows two rows at a time. In the south-eastern parts of England, which are hotter and drier, it is found better to sow them on the flat, for which purpose machines are constructed which sow four rows together, depositing manure at the same time. Both kinds are adapted for sowing either turnips or mangold-wurzel seeds as required. With the view of economising seed and manure, what are called drop-drills have recently been introduced, which deposit both—not in continuous streams—but in jets, at such intervals apart in the rows as the farmer wishes the plants to stand. What promises to be a more useful machine is a water-drill invented by a Wiltshire farmer—Mr Chandler of Market Lavington. "His water-drill pours down each manure-coulter the requisite amount of fluid, mixed with powdered manure, and thus brings up the plant from a mere bed of dust. Having used it largely during three years, I may testify to its excellence. Only last July, when my bailiff had ceased turnip sowing on account of the drought, by directing the use of the water-drill, I obtained from this latter sowing an earlier and a better show of young plants than from the former one with the dust-drill. Nor is there any increase of expense if water be within a moderate distance, for we do not use powder-manures alone. They must be mixed with ashes, that they may be diffused in the soil. Now, the expense and labour of supplying these ashes are equal to the cost of fetching mere water; and apart from any want of rain, it is found that this method of moist diffusion, dissolving, instead of mingling only, the superphosphate, quickens its action even upon damp ground, and makes a little of it go further."[2]

Section 9.—*Manure-Distributors.*

The practice of top-dressing wheat, vetches, clover, or meadows, with guano and various light manures, has now so much increased, and the inconvenience of scattering them over the surface by hand is so great, that various machines have recently been invented for distributing them, which can also be used for sowing such manures over turnip drills, covering three at once. Such machines will probably be used in future for distributing lime, which can thus be done much more regularly than by cart and shovel, especially when it is wished to apply small quantities for the destruction of slugs or for other purposes. It seems quite practicable to have this or a similar machine so constructed as that it could be readily hooked on to the tail of a cart containing the lime or other substance which it is desired to distribute by it. The top-dressing material could by such an arrangement be drawn into the hopper of the distributor as it and its tender move along, and the cart when emptied be replaced by a full one with little loss of time.

A cheap and effective machine, capable of being in a similar manner attached to a dung-cart, which could tear asunder fold-yard manure, and distribute it evenly in the bottoms of turnip drills, would be a great boon to farmers, and seems a fitting object to be aimed at by those possessed of the inventive faculty.

Section 10.—*Horse-Hoes.*

It has already been remarked that the great inducement to sow grain and green crops in rows is that hoeing may be resorted to, for the double purpose of ridding them of weeds and stimulating their growth by frequent stirring of the soil. It is now upwards of a century since Jethro Tull demonstrated, in his books and on his fields, the facility with which horse-power could be thus employed. His system was early adopted in regard to turnips, and led, as we have seen, to a complete revolution in the practice of agriculture. The peculiar manner in which he applied his system to grain crops, and the principles on which he grounded his practice, have hitherto been for the most part repudiated by agriculturists, who have thought it indispensable to drill their grain at intervals so narrow as to admit, as was supposed, of the use of the hand-hoe only. But the accuracy with which corn-drills perform their work has been skilfully taken advantage of, and we now have horse-hoes, covering the same breadth as the drill, which can be worked with perfect safety in intervals of but seven inches' width. By such a machine, and the labour of a pair of horses, two men, and a boy, ten acres of corn can be hoed in as many hours. Not only is the work done at a fifth of the expense of hand-hoeing, and far more effectually, but it is practicable in localities and at seasons in which hand-labour cannot be obtained.

Garrett's horse-hoe is admitted to be the best implement of its kind. It can be used for hoeing either beans, turnips, or corn, as the hoes can be adapted to suit any width betwixt rows, and the axle-tree being movable at both ends, the wheels, too, can be shifted so as to be kept between the rows of plants. The shafts can be attached to any part of the frame to avoid injury to the crop by the treading of the horses. Each hoe works on a lever independent of the others, and can be loaded with different weights, on the same principle as the coulters of the corn-drill, to accommodate it to uneven surfaces and varying degrees of hardness in the soil.

A great variety of implements, under the general names of horse-hoes, scufflers, scrapers, or drill-grubbers, fitted for the draught of one horse, and to operate on one drill at a time, is in use in those parts of the country where root crops are chiefly sown on ridgelets from 24 to 30 inches apart. With considerable diversity of form and efficiency, they in general have these features in common, viz., provision for being set so as to work at varying widths and depths, and for being armed either with hoes or tines, according as it is wished to pare the surface or stir the soil more deeply. A miniature Norwegian harrow is sometimes attached to drill-grubbers, by which weeds are detached from the soil, and the surface levelled and pulverised more thoroughly. Tennant's grubber, with its tines set close together, and two horses yoked to it abreast by a tree long enough to allow them to walk in the drills on either side of that operated upon, is the most effective implement for cultivating between the rows of beans, potatoes, turnips, or mangolds, that we have yet seen used for this purpose.

Section 11.—*Turnip-Thinners.*

It sometimes happens, as when drought prevails while the earlier sowings of turnips or mangold are made, and this is followed by copious rains and forcing weather, that the farmer finds it impracticable to get the thinning-out of the seedlings overtaken as fast as is needful. To aid him in such emergencies, a class of machines has been brought out, of which Huckvale's turnip-thinner may be named as a type. They are very favourably reported of by those who have used them. Such machines, drawn by one horse, and made to operate upon either one or two rows of young turnip plants, have first a paring apparatus, which clears off weeds from the sides of the rows, and along with this a set of revolving hoes by which gaps are cut in the rows of turnip plants, and tufts of them are left standing at any

[1] See Mr Pusey's Report on Implements, in the *Journal of the Royal Agricultural Society of England*, vol. xii. p. 604.
[2] Ibid., p. 607.

required distance apart. This does not dispense with the after use of the hand-hoe or fingers to effect a perfect singling of the plants; but as a large space can be gone over in a day at small cost, it enables the farmer to save his crop from getting overgrown and choked until he can overtake the more perfect thinning of it. The next class that claims attention is

Section 12.—Harvesting Implements.

These, till little more than twenty years ago, comprised only the reaping-hook and scythe. An implement by means of which horse-power could be made available for this important operation has long been eagerly desired by farmers. Repeatedly during the first half of the present century their hopes had been excited, only to be disappointed, by the announcement of successful inventions of this kind. These hopes were revived, and raised to a higher pitch than ever, by the appearance, in the Great Exhibition of the Industry of all Nations, of two reaping-machines, known as M'Cormick's and Hussey's, from the United States of America, where for several years they had been used extensively and successfully. These implements were subjected to repeated trials in different parts of England, on crop 1851, but never in circumstances which admitted of their capabilities being tested in a thoroughly satisfactory manner.

At the first of these trials, made under the auspices of the Royal Agricultural Society, the preference was given to M'Cormick's, to which the Exhibition Medal was in consequence awarded. It turned out, however, that at this trial Hussey's machine had not a fair chance, being attended by a person who had never before seen it at work, for, when a further trial took place before the Cleveland Agricultural Society, with Mr Hussey himself superintending his own machine, an all but unanimous decision was given in his favour. Hussey's machine was in consequence adopted by the leading implement makers. such as Messrs Garrett, Crosskill, &c.

Early in 1852, a very important communication from the pen of the late Mr James Slight, curator of the museum of the Highland and Agricultural Society, appeared in the Transactions of the Society, by which the attention of the public was recalled to a reaping-machine of home production, viz., that invented by the Rev. Patrick Bell, minister of the parish of Carmylie in Forfarshire, and for which a premium of £50 had been awarded to him by the Highland Society. This machine attracted much attention at that time. Considerable numbers were made and partially used, but from various causes the invention was lost sight of, until, by the arrival of these American machines, and the notoriety given to them by the Great Exhibition, with concurring causes about to be noticed, an intense interest was again excited regarding reaping by machinery. From Mr Slight's report, the public learned that the identical Bell's machine, to which the prize was awarded, had for the previous fourteen years been statedly employed on the farm of Inch-Michael in the Carse of Gowrie, occupied by Mr George Bell, a brother of the inventor, who, during all that period, had succeeded in reaping, on the average, four-fifths of his crop by means of it every year. Mr Slight further stated, that at least *four* specimens of it had been carried to America, and that from the identity in principle between them and those now brought thence, with other corroborating circumstances, there is little doubt that the so-called American inventions are after all but imitations of this Scottish machine. When it became known that Bell's machine was to be exhibited, and, if possible, subjected to public trial, at the meeting of the Highland and Agricultural Society at Perth, in August 1852, the event was looked forward to by Scottish farmers with eager interest. On that occasion it was accordingly again brought forward, with several important improvements made upon it, by Mr George Bell, already referred to, and was fully tested in competition with Hussey's, as made by Crosskill. To the disappointment of many, Mr M'Cormick did not think fit to enter the lists at this or at some subsequent opportunities.

The success of Bell's machine on this occasion, and at some subsequent public trials, gave it a high place in public estimation, and accordingly many of the implements manufactured by Mr Crosskill of Beverley, were sold to farmers in all parts of Great Britain, and especially in Scotland. After a hopeful start the success of this machine has not been so decided as was at first anticipated. In common with other reaping-machines, it had of course to contend with the disadvantages of unprepared fields and unskilful guides; but in addition to this, it was found to be too heavy in draught, too liable to derangement, and (in the first issues of it) too easily broken in some of its parts to be fitted for general use. These drawbacks were, to a greater or less extent, obviated by subsequent improvements, and the machine continued for a few years to receive a fair measure of public patronage. By-and-by it was in a great measure superseded by other self-delivery machines, such as Burgess & Key's M'Cormick, with its Archimedean screw, which, like Bell's, lays off the reaped grain in a continuous swathe, and by others which, by means of revolving rakes, lay it off in quantities suitable to form a sheaf. In crops of moderate bulk and standing erect, these self-delivery machines make rapid and satisfactory work, but when the crop is lodged and twisted they are nearly useless. The consequence is that for several years, and especially in those districts where reaping by machinery is most practised, the preference is given to manual-delivery machines, on the ground that they are lighter of draught, less liable to derangement, less costly, more easily managed, and thus more to be depended upon for the regular performance of a fair amount of daily work, than their heavier rivals. And, accordingly, light machines on Hussey's principle, but with endless variations, are at present most in demand.

Before leaving this subject, a remark is due in connection with the strange neglect of Bell's machine for twenty-five years, and the enthusiasm with which it was hailed on its reappearance. The first is so far accounted for by the fact noticed by Mr George Bell, that such specimens of his brother's machine as formerly got into the hands of farmers were so imperfectly constructed that they did not work satisfactorily, and thus brought discredit on his invention. The true explanation seems to be. that at that date the country was not ready for such a machine. Not only was manual labour then abundant and cheap, from the number of Irish labourers, who annually, as harvest drew near, flocked into the arable districts of Great Britain, but thorough draining had made little progress, and the land was everywhere laid into high ridges, presenting a surface peculiarly unfavourable for the successful working of a reaping-machine. Now, however, the conditions are reversed. Emigration to the colonies, and the ever-growing demand for labourers in connection with factories, mines, docks, and railways, have to a very great extent withdrawn the class of people that used to be available for harvest work, and have so largely raised the rate of wages to those who still remain as to render reaping-machines indispensable to the farmer. The progress of thorough draining has at the same time enabled him to dispense with the old-fashioned ridges and furrows, and to lay his corn lands in the level state so favourable for reaping and other operations of husbandry. In these altered conditions lies the true explanation of the former apathy and subsequent enthusiasm manifested by our farmers towards this invention.

Section 13.—*Mowing-Machines.*

Another class of labour-saving machines, closely allied to those we have just described, for which we are indebted to our American cousins, is mowing-machines. Several different forms of these were introduced and brought into somewhat general use during the years 1858 and 1859. Having used such machines for the past fourteen years we can testify to their thorough efficiency, and to the very great saving of labour, and still more of time, which can be secured by means of them. In one instance 30 acres of clover—a very full crop, and partially lodged—were mown in 32 hours, and this under all the disadvantages of a first start. This machine being of very light draught, a pair of horses can work it at a smart pace without difficulty. By employing two pairs of horses, and working them by relay, it can, in the long days of June and July, be kept going sixteen hours a day, and will easily mow from 16 to 18 acres of seeds or meadow in that time, making, moreover, better work than can ordinarily be obtained by using the scythe. These mowing-machines, which cost from £16 to £25 each, have proved a most seasonable and truly important addition to our list of agricultural implements. That they may be used to advantage, it is absolutely necessary to have the land well-rolled and carefully freed from stones.

Section 14.—*Haymakers.*

Haymakers are valuable implements, and well deserving of more general use. They do their work thoroughly, and enable the farmer to get through a great amount of it in snatches of favourable weather. Where manual labour is scarce, or when, as in Scotland, haymaking and turnip-thinning usually come on hand together, the mower and haymaker render the horse-power of the farm available for an important process which cannot be done well unless it is done rapidly and in season.

Section 15.—*Horse-Rakes.*

Horse-rakes are in frequent use for gathering together the stalks of corn which are scattered during the process of reaping, for facilitating the process of haymaking, and also for collecting weeds from fallows. By an ingenious contrivance in the most improved form of this implement, the teeth are disengaged from the material which they have gathered without interrupting the progress of the horse.

We seem to be verging on the time when, by means of machines worked by horse-power, farmers will be enabled to cut and carry their grass and grain with little more than the ordinary forces of their farms.

Section 16.—*Wheel-Carriages.*

The cartage of crops, manure, &c., upon an arable farm, is such an important part of the whole labour performed upon it (equal, as shown by a recent estimate, to one-half),[1] that it is a matter of the utmost consequence to have the work performed by carriages of the most suitable kind. It was for a long time keenly debated by agriculturists, whether waggons or carts are most economical. This question is now undoubtedly settled. Mr Pusey says, "It is proved beyond question that the Scotch and Northumbrian farmers, by using one-horse carts, save one-half of the horses which south country farmers still string on to their three-horse waggons and three-horse dung-carts, or dung-pots, as they are called. The said three-horse waggons and dung-pots would also cost nearly three times as much original outlay. Few, I suppose, if any, farmers *buy* these expensive luxuries now, though it is wonderful they should keep them; for last year at Grantham, in a public trial, *five* horses with five carts were matched against five waggons with *ten* horses, and the five horses beat the ten by two loads."[2] The one-horse carts here referred to are usually so constructed as to be easily adapted to the different purposes for which wheel-carriages are needed upon a farm. For each pair of wheels and axle there is provided a close-bodied cart, and another with sparred sides and broad shelvings, called a long-cart, or harvest-cart, either of which can easily be attached to the wheels, according to the nature of the commodities to be carried. Sometimes a simple movable frame is attached to the close-body to fit it for carrying hay or straw; but although one or two such frames are useful for casual purposes throughout the year, they are inferior for harvest work to the regular sparred cart with its own shafts. In some districts the whole of the close-bodied carts used on the farm are made to tip. For many purposes this is a great convenience; but for the conveyance of grain to market, and generally for all road work, a firm frame is much easier for the horse, and less liable to decay and derangement. The Berwickshire practice is to have one pair of tip-carts on each farm, and all the rest firm or dormant-bodied, as they are sometimes called.

Many farms are now provided with a water or tank cart, for conveying and distributing liquid manure.

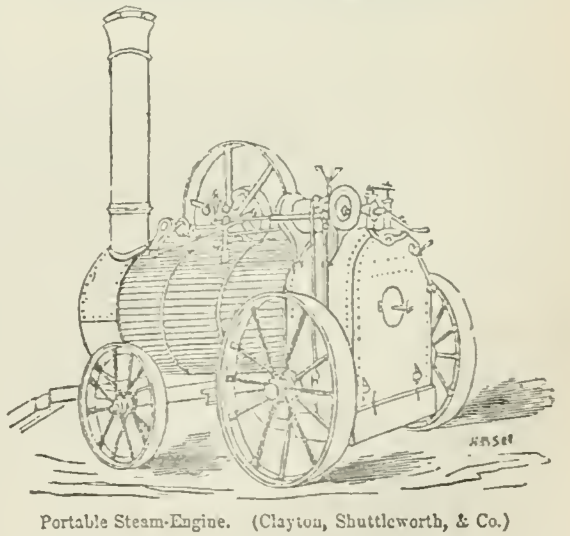
Section 17.—*Road-Engines.*

Although many attempts have been made to adapt the locomotive steam-engine for the conveyance both of passengers and goods on common roads, the results hitherto have not been altogether satisfactory. Progress is, however, undoubtedly being made in this effort; and in not a few instances such engines are actually in use for the carriage of heavy goods. If beet-sugar factories should increase in Great Britain, the carriage of the roots from the farms to the factories will probably be performed by traction engines; for the inexpediency of withdrawing the horse-power of the farm from its other urgent work at the season most suitable for delivering these roots to the sugar-maker presents at present a serious hindrance to the cultivation of this crop.

MACHINES FOR PREPARING CROPS FOR MARKET.
(Sections 18, 19, 20.)

Section 18.—*Steam-Engines.*

The extent to which steam-power is now employed for the purposes of the farm is another marked feature in the recent



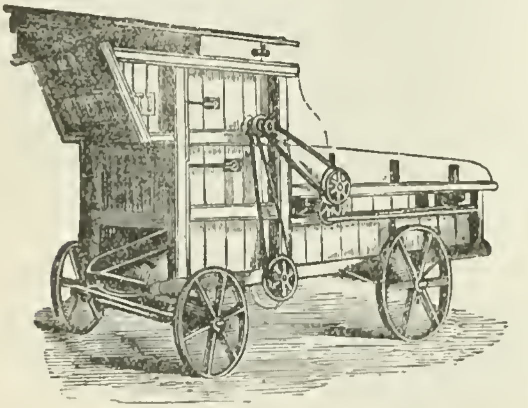
Portable Steam-Engine. (Clayton, Shuttleworth, & Co.)

progress of agriculture. We have already referred to the value of water-power for propelling agricultural machinery

[1] See *Morton's Cyclopædia of Agriculture.* Article "Carriages."

[2] Mr Pusey's Report, in the *Journal of the Royal Agricultural Society of England* vol. xii. p. 617.

when it can be had in sufficient and regular supply. As it is only in exceptional cases that farms are thus favoured, the steam-engine is the power that must generally be reckoned upon, and accordingly its use is now so common that a tall chimney has become, over extended districts, the prominent feature of nearly every homestead. It has been satisfactorily shown that grain can be thrashed and dressed by well-constructed, steam-propelled machinery, at one-fourth the cost of thrashing by horse-power and dressing by hand-fanners. So great, indeed, is the improvement in steam-engines, and so readily can the amount of power be accommodated to the work to be done, that we find them everywhere superseding the one-horse gin, and even manual labour, for pumping, churning, coffee-grinding, &c. Wherever, then, a thrashing-mill is used at all, it may be safely asserted that, next to water, steam is the cheapest power by which it can be propelled. The *portable* engine is the form which has hitherto found most favour in the southern parts of the kingdom. Mr Pusey thus states the reason for which he regards them as preferable to fixed engines:—"If a farm be a large one, and especially if, as is often the case, it be of an irregular shape, there is great waste of labour for horses and men in bringing home all the corn in the straw to one point, and in again carrying out the dung to a distance of perhaps two or three miles. It is therefore common, and should be general, to have a second outlying yard. This accommodation cannot be reconciled with a fixed engine.



Portable Thrashing-Machine. (Clayton, Shuttleworth, & Co.)

"If the farm be of a moderate size, it will hardly—and if small will certainly not—bear the expense of a fixed engine: there would be waste of capital in multiplying fixed engines to be worked but a few days in the year. It is now common, therefore, in some counties for a man to invest a small capital in a movable engine, and earn his livelihood by letting it out to the farmer.

"But there is a further advantage in these movable engines, little, I believe, if at all known. Hitherto corn has been thrashed under cover in barns: but with these engines and the improved thrashing-machines we can thrash the rick in the open air at once as it stands. It will be said, How can you thrash out of doors on a wet day? The answer is simple. Neither can you move your rick into your barn on a wet day; and so rapid is the work of the new thrashing-machines, that it takes no more time to thrash the corn than to move it. Open-air thrashing is also far pleasanter and healthier for the labourers, their lungs not being choked with dust, as under cover they are; and there is, of course, a saving of labour to the tenant not inconsiderable. But when these movable steam-engines have spread generally, there will arise an equally important saving to the landlord in buildings. Instead of three or more barns clustering round the homestead, one or other in constant want of repair, a single building will suffice for dressing corn and for chaff-cutting. The very barn-floors saved will be no insignificant item. Now that buildings are required for new purposes, we must, if we can, retrench those buildings whose objects are obsolete. Open-air thrashing may appear visionary, but it is quite common with the new machinery; nor would any one perform the tedious manœuvre of setting horses and men to pull down a rick, place it on carts, and build it up again in the barn, who had once tried the simple plan of pitching the sheaves at once into the thrashing-machine."[1]

To us these reasons are inconclusive.. A fixed engine can be erected and kept in repair at greatly less cost than a portable one of the same power. It is much easier to keep the steam at working pressure in the common boiler than in the tubular one, which, from its compactness, is generally adopted in portable engines. It is, no doubt, very convenient to draw up engine and machinery alongside a rick and pitch the sheaves at once upon the feeding-board, and very pleasant to do this in the sunshine and "caller air;" but we should think it neither convenient nor pleasant to have engine and thrashing-gear to transport and refix every time of thrashing, to have grain and chaff to cart to the barn, the thrashed straw to convey to the respective places of consumption, and all this in circumstances unfavourable to accurate and cleanly disposal of the products, and excessive exposure to risk of weather. Sudden rain will no doubt interrupt the carrying in of a rick in the one case as the thrashing of it in the other; but there is this vast difference in favour of the former, that the partially carried rick is easily re-covered; machinery, products of thrashing, and work-people, are safely under cover; and the engine is ready by a slight change of gearing for other work, such as bruising, grinding, or chaff-cutting.

It is urged on behalf of the portable engine, that in districts where the farms are generally small, one may serve a good many neighbours. Now, not to dwell on the expense and inconvenience to small occupiers of frequently transporting such heavy carriages, and of having as much of their crop thrashed in a day (there being manifest economy in having at least a day's work when it is employed) as will meet their demands for fodder and litter for weeks to come, we are persuaded that on farms of even 80 or 100 acres, a compact fixed engine of two or three horse-power will thrash, bruise grain, cut chaff, work a churn, and cook cattle food, &c., more economically than such work can be done in any other way. It is very usual to find on such farms, especially in dairy districts, an apparatus for cooking cattle food by steam, or by boiling in a large copper, where as much fuel is used every day, and as much steam generated, as would work such an engine as we have referred to, and do the cooking over and above. Even a small dairy implies a daily demand for boiling water to scrub vessels and cook food for cows. How manifestly economical, then, when the steam is up at any rate, to employ this untiring, obedient agent, so willing to turn the hand of anything, in performing the heavy work of the homestead with a power equal, perhaps, to that of all the men and horses employed upon the farm.

Whenever tillage by steam-power is fairly available, there will undoubtedly be an inducement to use the portable engine as a thrashing-power that has not hitherto existed, as there will be a manifest economy in having both operations performed by the same engine. Even then, however, there is a high probability of its being found impracticable to withdraw the engine even once a week for the needful thrashing during the six or eight weeks immediately after

[1] Mr Pusey's Report on Implements.—*Journal of the Royal Agricultural Society of England*, vol. xii. p. 621.

harvest, when it will be of such consequence to make diligent use of every available hour for pushing on the tillage.

The kind of fixed engine most approved for farm-work in the north of England and south of Scotland is the overhead crank engine, attached by direct action to the spur-wheel, and sometimes even to the drum shaft of the thrashing-machine. Their cheapness, simplicity of construction, easy management, and non-liability to derangement, fit these engines in an eminent degree for farm-work.[1]

Section 19.—Thrashing-Machines.

It is now sixty-five years since an ingenious Scotch mechanist, Andrew Meikle, produced a thrashing-machine so perfect that its essential features are retained unaltered to the present day. Indeed, it is frequently asserted that, after all the modifications and supposed improvements of the thrashing-machine which have been introduced by various parties, the mills made by Meikle himself have not yet been surpassed, so far as thorough and rapid separation of the grain from the straw is concerned. The unthrashed corn is fed evenly into a pair of slowly revolving fluted rollers of cast-iron, by which it is presented to the action of a rapidly revolving cylinder or drum armed with four beaters, which are square spars of wood faced with iron, fixed parallel to its axis, and projecting about four inches from its circumference. The drum is provided with a dome or cover, and the corn being partly held by the fluted rollers as it passes betwixt the drum and its cover, the rapid strokes of the beaters detach the grain from the ears, and throw the straw forward upon slowly revolving rakes, in passing over which the loose grain is shaken out of the straw, and falls through a grating into the hopper of a winnowing and riddling machine, which rids it of dust and chaff, and separates the grain from the unthrashed ears and broken straw, called *roughs* or *shorts*. The grain and roughs are discharged by separate spouts into the apartment below the thrashing-loft, whence the corn is fed into the rollers, and the thrashed straw falls from the rakes into the straw barn beyond. Since Meikle's time further additions have been made to the machinery. In the most improved machines driven by steam or a sufficient water power, the grain is raised by a series of buckets fixed on an endless web into the hopper of a double winnowing-machine, by which it is separated into clean corn, light, whites or capes, and small seeds and sand. The discharging spouts are sufficiently elevated to admit of sacks being hooked on to receive the different products as they fall. When barley is thrashed, it is first carried by a separate set of elevators, which can be detached at pleasure, into a "hummeller," in which it is freed from the awns, and then raised into the second fanners in the same manner as other grain. The hummeller is a hollow cylinder, in which a spindle fitted with transverse blunt knives revolves rapidly. The rough grain is poured in at the top, and, after being acted upon by the knives, is emitted at the bottom through an opening which is enlarged or diminished by a sliding shutter, according to the degree of trimming that is required. A large set of elevators is usually employed to carry up the roughs to the feeding-board, that they may again be subjected to the action of the drum. The roughs are emptied, not directly on the feeding-board, but into a riddle, from which the loose grain passes by a canvas funnel direct to the winnower in the apartment below, and only the unthrashed ears and short straw are allowed to fall upon the board.

The alterations that have been made upon the thrashing-machine since Meikle's time chiefly affect the drum. Meikle himself tried to improve upon his beaters by fixing a projecting ledge of iron on their outer edges, so as to give them a scutching action similar to that of flax-mills. This strips off the grain from oats or barley very well when thinly fed in; but its tendency is to rub off the entire ears, especially of wheat, and also to miss a portion of the ears, whenever there is rapid feeding in. More recent trials of drums on the scutching principle show them to be on the whole inferior to the plain beater.

We have already referred to the general use of portable thrashing-machines in the eastern counties of England. These, for the most part, have drums with six beaters upon a skeleton frame, which revolve with great rapidity (about 800 times per minute, hence often called high-speed drum), within a concave or screen, which encloses the drum for about one-third its circumference. This screen consists alternately of iron ribs and open wire-work, and is so placed that its inner surface can be brought into near contact with the edges of the revolving beaters, and admits of this space being increased or diminished by means of screws. No feeding-rollers are used with this drum, the unthrashed corn being introduced directly to it.

Another form of drum, acting on the same principle as that just referred to, but cased with plate-iron, and having for beaters eight strips of iron projecting about one-fourth of an inch from its surface, and which works within a concave which embraces it for three-fifths of its circumference, is in use when it is desired to preserve the straw as straight and unbroken as possible. These are made of sufficient width to admit of the corn being fed in sideways, and are called *bolting* machines, from the straw being delivered in a fit state for being at once made up into *bolts* or bundles for market. Although the term *beaters* is retained in describing these drums, it is evident that the process by which the grain is separated from the ears is rubbing rather than beating. This necessarily requires that only a narrow space intervene between drum and concave, and that the corn be fed in somewhat thinly. Such machines thrash clean, whether the ears are all at one end of the sheaf or not, and deliver the straw straight and uninjured; but it is objected to these by some that they are slower in their operation than those with the beating drum, are liable to choke if the straw is at all damp, that the grain is sometimes broken by them, and that they require greater power to drive them.

A further and more recent modification is the peg-drum. In this case the drum is fitted with parallel rows of iron pegs, projecting about 2½ inches from its surface, which in its revolutions pass within one-fourth of an inch of similar pegs fixed in the concave in rows running at right angles to the drum. Great things were at first anticipated from this invention, which, however, it has failed to realise. But iron pegs have more recently been added to the common beater-drum with apparent success. The beaters in this case are made one-half narrower than usual, and have stout iron pegs, formed of square rods, driven into their faces, angle foremost, and slightly reflected at the points. These act by a combination of beating and rippling, and are said to thrash clean and to be easily driven.

There is thus a great variety of thrashing-machines to be found in different parts of the country, the comparative merits of which are frequently and keenly discussed by agriculturists. The extraordinary discrepancies in the amount and quality of the work performed by different machines, and in the power required to effect it, are due quite as much to the varying degrees of skill with which their parts are proportioned and put together, as to varying merit in the respective plans of construction.

In the best examples of 6-horse power stationary steam-engines and thrashing-machinery, as found in the Lothians,

[1] See article on "Comparative Advantages of Fixed and Portable Steam Power for the Purposes of a Farm," by Robert Ritchie, Esq., C.E., Edinburgh, in *Transactions of Highland Society* for March 1852, p. 281.

fifty quarters of grain, taking the average of wheat, barley, and oats, are thrashed, dressed, and sacked up ready for market, in a day of ten hours, with a consumption of $7\frac{1}{2}$ cwt. of good coals, and a gross expenditure for wages, value of horse labour fuel, and wear and tear of machinery, of 9d. per quarter.

The exigencies of the labour market are giving a powerful stimulus to the use of labour-saving contrivances of all kinds; and hence the recent introduction of straw elevators, to be worked either by horse-power or by the same steam-engine that is driving the thrashing-machinery. The latter plan finds most favour in England, where it has already been adopted to a considerable extent.

The Royal Agricultural Society of England has done much towards ascertaining the real merits of the various thrashing-machines now in use, by the carefully conducted comparative trials to which it has subjected those which have been presented in competition for its liberal prizes. The accuracy of these trials, and the value of the recorded results, have been much enhanced by the use of an ingenious apparatus invented by Mr C. E. Amos, consulting engineer to the Society, which is figured and described at p. 479 of vol. xi. of the Society's *Journal*. A pencil connected with this apparatus traces a diagram upon a sheet of paper, recording every variation of the power employed during the experiment to work the machine under trial. For reasons already stated, we regard it as unfortunate that the patronage of this great Society has hitherto been so exclusively bestowed upon portable machines.

Section 20.—*Winnowing-Machines.*

We have already referred to the fanners, which, except in portable machines, are almost invariably found in combination with thrashing-machinery, so as to deliver the grain into the corn-chamber in a comparatively clean state; and we have also noticed the further contrivances by which, when there is a sufficient motive power at command, the complete dressing of the grain goes on simultaneously with the thrashing. The winnowers used in such cases do not differ in construction from those worked by hand. Indeed, it is usual to have one at least that can be used in either way at pleasure. In these machines the separation of the clean from the light grain, and of both from dust, sand, and seeds of weeds, or other rubbish, is effected by directing an artificial blast of wind upon a stream of grain as it falls upon a riddle. There is thus a combination of fanning and sifting, which is used in different degrees according to the views of the mechanist. In some forms of this machine the benefit of the artificial blast is in a great measure lost through an injudicious application of it.

Section 21.—*Corn-Bruiser and Grinding-Mill.*

The now frequent use of various kinds of grain in the fattening of live stock creates a necessity for machines to prepare it for this purpose, either by breaking, bruising, or grinding. A profusion of these, to be worked by hand, is everywhere to be met with. Such machines are always most economically worked by steam or water power. When that can be had, a set of rollers for bruising oats or linseed, and millstones to grind the inferior grain of the farm, form a most valuable addition to barn machinery.

Section 22.—*Cake-Crushers.*

Machines for breaking linseed-cake into large pieces for cattle, or smaller ones for sheep, are now in general use. The breaking is performed by passing the cakes between serrated rollers, by which it is nipt into morsels. These are usually driven by hand; but it is always expedient to have a pulley attached to them, and to take advantage of mechanical power when available.

Section 23.—*Chaff-Cutters.*

The use of this class of machines has increased very much of late years. Fodder when cut into lengths of from half-an-inch to an inch is somewhat more easily masticated than when given to animals in its natural state; but the chief advantages of this practice are, that it prevents waste, and admits of different qualities—as of hay and straw, straw and green forage, or chaff and pulped roots—being so mixed that animals cannot pick out the one from amongst the other, but must eat the mixture as it is presented to them. Such cut fodder also forms an excellent vehicle in which to give meal or bruised grain, either cooked or raw, to live stock. This applies particularly to sheep feeding on turnips, as they then require a portion of dry food, but waste it grievously when it is not thus prepared. Chaff-cutters are constructed on a variety of plans; but the principle most frequently adopted is that of radial knives bolted to the arm of a fly-wheel, which work across the end of a feeding-box fitted with rollers, which draw forward the straw or hay and present it in a compressed state to the action of the knives. A machine on this principle, made by Cornes of Barbridge, has gained the first premium in its class at recent meetings of the Royal Agricultural Society of England. Gillets' guillotine chaff-cutter is an exceedingly ingenious and efficient machine, performing its work with great accuracy, and without frequent sharpening of its one double-edged knife. These machines are most economically worked by the power used for thrashing. The most convenient site for them is in the upper loft of the straw-barn, where the straw can be supplied with little labour, and the chaff either shoved aside, or allowed to fall as it is cut through an opening in the floor into the apartment below, and at once conveyed to other parts of the homestead. The practice on some farms where there is a fixed steam-engine, is to thrash a stack of oats in the forenoon, and to cut up the straw, and bruise or grind the grain simultaneously, in the afternoon.

Section 24.—*Turnip-Cutters.*

Cattle and sheep which have arrived at maturity are able to scoop turnips rapidly with their sharp, gouge-like front teeth, and so can be fattened on this kind of food without an absolute necessity of slicing it for them. Even for adult animals there is, however, an advantage in reducing turnips to pieces which they can easily take into their mouths, and at once get between their grinders without any preliminary scooping; but for young stock, during the period of dentition, it is indispensable to their bare subsistence. It is largely through the use of slicing-machines that certain breeds of sheep are fattened on turnips, and got ready for the butcher at fourteen months old. It seems to be admitted on all hands that Gardener's patent turnip-cutter is the best that has yet been produced for slicing roots for sheep. It is now made entirely of iron, and is an exceedingly useful machine.

In cattle feeding it is not usually thought necessary to divide the roots given to them so minutely as for sheep. A simple machine, fashioned much on the principle of nut-crackers, by which, at each depression of the lever handle, one turnip is forced through a set of knives which divide it into slices each an inch thick, is very generally used in Berwickshire for this purpose. Many persons, however, prefer to have the turnips put into the cattle-troughs whole, and then to have them cut by a simple cross-bladed hand-chopper, which at each blow quarters the piece struck by it. The mode of housing fattening cattle largely determines whether roots can be most conveniently sliced before or after being put into the feeding-troughs.

Section 25.—Turnip-Pulpers.

An opinion now obtains, and is on the increase, that it is advantageous to rasp roots into minute fragments and mix them with chaff before giving them to cattle, as this not only facilitates mastication, but in wintry weather prevents the chilling effects of a bellyful of such watery food as turnips are when eaten alone. This system is peculiarly appropriate when it is desired to give a few roots to store cattle which are being fed mainly upon straw or coarse hay. When a few turnips or mangolds are put down in their natural state there is a scramble for the better food, in which the stronger cattle get more than their share, and the weaker are knocked about. But by pulping the roots and mixing them with a full allowance of chaff, every animal gets its fill, and there is nothing to quarrel about.

At the Carlisle meeting of the Royal Agricultural Society a premium was offered for machines to perform this kind of work, under the somewhat inappropriate designation of "pulping-machines." The prize was awarded to Mr Philips for his machine, which reduces roots to minute fragments by means of a series of circular saws. We learn from parties who have made trial of most of the machines of this class yet brought out, that they give the preference to that made by Bentall of Maldon in Sussex.

Section 26.—Steaming Apparatus for Cooking Cattle Food.

We have several times alluded to the cooking of food for cattle. This is performed either by boiling in a common pot, by steaming in a close vessel, or by infusion in boiling water. Varieties of apparatus are in use for these purposes. A convenient one is a close boiler, with a cistern over it, from which it supplies itself with cold water by a self-acting stop-cock. This is alike suitable for cooking either by steaming or infusing.

Section 27.—Weighing-Machines.

It is of course indispensable for every farm to be provided with beam and scales, or other apparatus, for ascertaining the weight of grain, wool, and other commodities, in quantities varying from 1 lb. to 3 cwt. But, besides this, it is very desirable to have a machine by which not only turnips, hay, manures, &c., can be weighed in cart-loads, but by which also the live weight of pigs, sheep, and bullocks can be ascertained. Such a machine, conveniently placed in the homestead, enables the farmer to check the weighing of purchased manure, linseed-cake, coal, and similar commodities, with great facility. It affords the means of conducting various experiments for ascertaining the comparative productiveness of crops, the quantities of food consumed by cattle, and their periodic progress, with readiness and precision. To persons unable to estimate the weight of cattle by the eye readily and accurately, such a machine is invaluable.

Section 28.—Concluding Remarks on Implements.

We have thus enumerated, and briefly described, those machines and implements of agriculture which may be held to be indispensable, if the soil is to be cultivated to the best advantage. The list does not profess to be complete; but enough is given to indicate the progress which has recently taken place in this department. We have already referred to this department of the proceedings of the Royal Agricultural Society of England, and would earnestly recommend to all engaged in agriculture the careful study of the reports on implements contained in the ninth and subsequent volumes of their *Journal*. The care with which they have selected their judges, and the skilful manner in which those entrusted with the difficult and responsible office have discharged their duties, are truly admirable. A few extracts from these reports will serve to show the extent and value of this department of the Society's labours. In the report for 1849, Mr Thomson of Moat-Hall says—"The Society's early shows of implements must be viewed chiefly in the light of bazaars or expositions. Neither stewards nor judges had yet acquired the experience requisite for the adequate discharge of their office, so that such men as Messrs Garrett, Hornsby, Ransome, and a few others, would have laughed in their sleeves had they been told that they could learn anything in the Society's show yard. In spite, however, of a creditable display on the part of a few leading firms, the majority of the implements exhibited at these early shows were of inferior construction and workmanship, and the general appearance of the exhibitions meagre and unsatisfactory.

"The attention of some of the leading members of the Society (especially of the late lamented Mr Handley) was earnestly directed to the improvement of this department, and they soon perceived that little was gained by collecting implements in a show-yard for people to gaze at, unless an adequate trial could be made of their respective merits. To attain this end great exertions were made, and every improvement in the mode of trial was followed by so marked an increase in the number and merit of the implements brought forward at subsequent shows, as to prove the strongest incentive to further effort.

"At the Cambridge and Liverpool meetings, when these trials were in their infancy, their main attraction consisted of ploughing-matches on a large scale, which gratified sight seers, but gave no results that could be depended upon, and therefore disappointed all practical men. It would occupy time unnecessarily to trace the gradual changes which have led to the discontinuance of these showy exhibitions, and the substitution in their place of quiet business-like trials, in the presence of stewards and judges alone. Suffice it to say, that what they have lost in display, they have gained in efficiency, and consequently in favour with those classes for whose benefit they were designed. At the York meeting, the improved mode of trying the thrashing-machines supplied a deficiency which, until that time, had been much felt, viz., the absence of any means of ascertaining the amount of power expended in working the machines under trial; and it may now be asserted, with some confidence, that, with the exception of an occasional error or accident, the best implements are uniformly selected for prizes.

"It now remains to answer the question proposed for consideration, viz., to what extent the great improvement made of late in agricultural implements is due to the exertions of this Society; and with this view a tabular statement is subjoined, which shows the relative extent and importance of the Society's two first and two last shows of implements:—

	No. of Exhibitors.	Awards. Money.	Medals.
1839 Oxford	23	£5	4
1840 Cambridge	36	0	7
1848 York	146	230	21
1849 Norwich	145	364	13

"From this it will be seen that at Cambridge, where the trial of implements was confined to one day, and was, in other respects, so immature as to be of little practical value, the number of exhibitors was only thirty-six, and the judges, in whom a certain discretionary power was vested, awarded no money and but seven medals, in consequence of the scarcity of objects deserving of reward; whilst at York, eight years after, when trials lasted several days, and had attained a considerable degree of perfection, the number of exhibitors had increased four-fold. The additional amount offered in prizes at the later meetings has undoubtedly assisted in creating this great increase of competition, but it cannot be considered the principal cause, since the implement-makers are unanimous in declaring that, even when most successful, the prizes they receive do not reimburse them for their expenses and loss of time. How, then, are the increased exertions of the machine-makers to be accounted for? Simply by the fact that the trials of implements have gradually won the confidence of the farmer, so that, when selecting implements for purchase, he gives the preference to those which have received the Society's mark of approval. This inference is corroborated by the makers themselves, who readily admit that the winner of a prize, for any implement of general utility, is sure to receive an ample amount of orders, and that the award of a medal is worth on an average £50."

In reporting upon the agricultural implement department of the Great Exhibition, Mr Pusey says—"The yearly shows and trials of the Royal Agricultural Society have certainly done more in England for agricultural machines within the last ten years, than had been attempted anywhere in all former time. . . . . It seems proved that since annual country shows were established by Lord Spencer, Mr Handley, and others yet living, old implements have been improved, and new ones devised, whose performances stand the necessary inquiry as to the amount of saving they can effect. To ascertain that amount precisely is difficult; but, looking through the successive stages of management, and seeing that the owner of a stock-farm is enabled, in the preparation of his land, by using lighter ploughs, to cast off one horse in three, and by adopting other simple tools to dispense altogether with a great part of his ploughing,—that in the culture of crops by the various drills, horse labour can be partly reduced, the seed otherwise wanted partly saved, or the use of manures greatly economised, while the horse-hoe replaces the hoe at one-half the expense,—that in harvest the American reapers can effect thirty men's work, whilst the Scotch cart replaces the old English waggon with exactly half the number of horses,—that in preparing corn for man's food, the steam thrashing-machine saves two-thirds of our former expense,—and in preparing food for stock, the turnip-cutter, at an outlay of 1s., adds 8s. a-head in one winter to the value of sheep; lastly, that in the indispensable but costly operation of draining, the materials have been reduced from 80s. to 15s.—to one-fifth, namely, of their former cost,—it seems to be proved that the efforts of agricultural mechanists have been so far successful, *as in all these main branches* of farming labour, taken together, to effect a saving, on outgoings, of little less than one-half."

Since these reports were made, the demand for improved agricultural implements and machinery has increased enormously, so much so that the manufacture of them is now a most important and a rapidly increasing branch of our national industry, and we quite anticipate that in a short time there will be such a general appreciation of the benefits of cultivation by steam power, and such a demand for engines and tackle to carry it out, as the makers and manufacturers will find it difficult to satisfy.

Scottish agriculturists, in reading these reports, will probably note with self-gratulation, that some of the improvements referred to as of recent introduction in England, viz., two-horse ploughs and one-horse carts, have long been established among themselves. Indeed, they will find graceful acknowledgment of the fact in these reports. Unless altogether blinded by prejudice, they will, however, see that our brethren south of the Tweed have already outstripped us in many particulars, and that unless our national Society, our mechanists, and farmers, exert themselves with corresponding judgment and zeal, we must henceforth be fain to follow, where we at least fancy that we have hitherto been leading. But we have more important motives and encouragements to exertion than mere national emulation. The extent to which the cost of production of farm produce has been lessened by recent improvements in the implements of husbandry, and in the details of farm management, is greater than many are aware of. It seems to be in this direction mainly that the farmer must look for a set-off against the steadily increasing cost of land and labour. If by further improvements in his machinery and implements he is enabled to keep fewer horses, to get his deep tillage performed by steam power, and his mowing and reaping accomplished by the ordinary forces which he requires throughout the year, the reduction upon the prime cost of his produce will be really important. A hopeful element in this anticipated progress is that it tends directly to elevate the condition of the rural labourer. Every addition to the steam power and labour-saving machines used upon the farm implies an increased demand for cultured minds to guide them, a lessening of the drudgery heretofore imposed upon human thews and sinews, an equalising of employment throughout the year, and a better and steadier rate of wages. Believing, as we do, that on every farm enormous waste of motive power—mechanical, animal, and manual—is continuously going on through the imperfection of the implements and machines now in use, we would urge upon all concerned to look well to this; for, with all our improvements, there is undoubtedly yet a large margin for retrenchment here.

Besides the bulky and costly implements now enumerated, every farm must be provided with a considerable assortment of hand-implements and tools, all of which it is of consequence to have good of their kind. Although not individually costly, they absorb a considerable capital in the aggregate. When not in use, they require to be kept under lock, and at all times need to be well looked after. Without waiting to describe these in detail, let us now see how the work of the farm is conducted.

CHAPTER VII.

PREPARATION OF THE LAND FOR TILLAGE OPERATIONS.

Section 1.—When Required.

Before those simple tillage operations which are necessary in every instance of committing seeds to the earth can be gone about, there are more costly and elaborate processes of preparation which must be encountered in certain circumstances, in order to fit the soil for bearing cultivated crops. It is now only in exceptional cases that the British agriculturist has to reclaim land from a state of nature. The low-country farmer does occasionally meet with a patch of woodland, or a bank covered with gorse or brushwood, which he sets about converting into arable land. It is in the higher districts that, from the facilities now afforded for readily enriching poor soils by portable manures, the plough still frequently invades new portions of muir and bog, and transforms them into fields. The occupiers of land in these upland districts are accordingly still familiar with the processes of paring and burning, trenching, removing earth-fast stones, and levelling inequalities of surface. In breaking up land that has been for a course of years under pasturage, paring and burning are also frequently resorted to in all parts of the country. The grand improvement of all, thorough underground drainage, is common to every district and class of soils.

Section 2.—Draining.

From the moist climate of Britain, draining is undoubtedly the all-important preliminary operation in setting about the improvement of the soil.

To drain land is to rid it of its superfluous moisture. The rivers of a country with their tributary brooks and rills are the natural provision for removing the rain water which either flows directly from its surface, or which, after percolating through porous strata to an indefinite depth, is again discharged at the surface by springs. The latter may thus be regarded as the outlets of a natural underground drainage. This provision for disposing of the water that falls from the clouds is usually so irregular in its distribution, and so imperfect in its operation, that it leaves much to be accomplished by human labour and ingenuity. The art of the drainer accordingly consists—

1*st*, In improving the natural outfalls by deepening, straightening, or embanking rivers; and by supplementing these, when necessary, by artificial canals and ditches: and,

2*d*, In freeing the soil and subsoil from stagnant water, by means of artificial underground channels.

The first of these operations, called *trunk drainage*, is the most needful; for until it be accomplished there are extensive tracts of land, and that usually of the most valuable kind, to which the secondary process either cannot be applied at all, or only with the most partial and inefficient results. Very many of our British rivers and streams flow with a sluggish and tortuous course through valleys of flat alluvial soil, which, as the coast is approached, expand into extensive plains, but little elevated above the level of the sea. Here the course of the river is obstructed by shifting shoals and sand-banks, and by the periodic influx of the tides. The consequence is, that immense tracts of valuable land are at all times in a water-logged and comparatively worthless state, and on every recurrence of a flood are laid entirely under water. In a subsequent chapter on "Waste Lands" some account shall be given of the extent of this evil, and of the efforts that have been successfully devoted to its remedy. Some of these fen-land and estuary drainage works have been accomplished in the face of natural obstacles of the most formidable character, and constitute trophies of engineering talent of which the country may well be proud. Great as the natural difficulties are which have to be encountered in such cases, there are others of a different kind which have often proved more impracticable. It has been found easier to exclude the sea and restrain land-floods, than to overcome the prejudices and reconcile the conflicting interests of navigation companies, commissioners of sewers, owners of mills, and landed proprietors. Although all these classes suffer the most serious losses and inconveniences from the defective state of many of our rivers, it is found extremely difficult to reconcile their conflicting claims, and to allocate to each his proper share of the cost of improvements by which all are to benefit. A most interesting and instructive illustration of the urgent necessity for improving the state of our rivers, of the difficulties to be encountered in doing so, and of the incalculable benefits thus to be obtained, has been given in an essay on Trunk Drainage, by John Algernon Clarke, Esq., published in vol. xv. (part first) of the *Journal of the Royal Agricultural Society of England.* Mr Clarke, after some most important observations on trunk drainage, describes in detail works projected under powers granted in an Act of Parliament, passed in 1852, "constituting commissioners for the improvement of the river Nene and the navigation thereof."

There is not a district of the kingdom in which works similar in kind are not absolutely indispensable, before extensive tracts of valuable land can be rendered available for profitable cultivation by means of underground drainage. It is interesting to know that the necessity for trunk drainage, and the means of accomplishing it, were distinctly set before the public 200 years ago by a practical draining engineer, to whose writings the attention of the agricultural community has been frequently directed of late by Mr Parkes, Mr Gisborne, and others. From the third edition (1652) of *The Improver Improved*, by Walter Blithe, the author referred to, in which the true principles of land drainage are stated as distinctly, and urged as earnestly, as by any of our modern writers, we here quote the following remarks:—

"A strait water-course, cut a considerable depth, in a thousand parts of this nation, would be more advantageous than we are aware of, or I will task myself here to dispute further. And though many persons are interested therein, and some will agree, and others will oppose; one creek lyeth on one side of the river, in one lord's manor, and another lyeth on the other side, and divers men own the same; why may not one neighbour change with another, when both are gainers? If not, *why may they not be compelled for their own good, and the commonwealth's advantage?* I daresay thousands of acres of very rich land may hereby be gained, and possibly as many more much amended, that are almost destroyed; but a law is wanting herein for the present, which I hope will be supplied if it may appear advancement to the public; for to private interests it is not possible to be the least prejudice, when every man hath benefit, and each man may also have an equall allowance if the least prejudiced.

"But a word or two more, and so shall conclude this chapter—and it is a little to further this improvement through a great destruction (as some may say); it is the removing or the destroying of all such mills, and none else, as drown and corrupt more lands than themselves are worth to the commonwealth, and they are such as are kept up or dammed so high as that they boggyfie all the lands that lye under their mill-head. Such mills as are of little worth, or are by constant great charges maintained, I advise to be pulled down; the advance of the land, when the water is let run his course, and not impounded, will be of far greater value many times. But in case the mills should be so necessary and profitable too, and far more than the lands they spoil, I shall then advise, that under thy mill-dam, so many yards wide from it as may prevent breaking through, thou make a very deep trench all along so far as thy lands are putrefied, and thereinto receive all the issuing, spewing water, and thereby stop or cut off the feeding of it upon thy meadow, and carry it away back into thy back-water or false course, by as deep a trench, cut through the most low and convenient part of thy meads. But put case that thou shouldst have no convenient fall on that side thy mill-dam, then thou must make some course, *or plant some trough under thy mill-dam*, and so carry it under into some lower course that may preserve it from soaking thy meadows or pastures under it; and by this means thou maist in a good measure reduce thy land to good soundness, and probably wholly cure it, and preserve thy mill also."

It is painful to reflect that after the lapse of two centuries, we should still see, as Blithe did, much "gallant land" ruined for want of those draining operations which he so happily describes.

A clear outfall of sufficient depth being secured, the way is open for the application of *underground draining.* And here it may be proper to state, that there is very little of the land of Great Britain naturally so dry as not to be susceptible of improvement by artificial draining; for land is not in a perfect condition with respect to drainage, unless all the rain that falls upon it can sink down to the minimum depth required for the healthy development of the roots of cultivated crops, and thence find vent, either through a naturally porous subsoil or by artificial channels. Much controversy has taken place as to what this minimum depth is. Suffice it to say, that opinion is now decidedly in favour of a greater depth than was considered necessary even a few years ago, and that the best authorities concur in stating it at from three to four feet. There are persons who doubt whether the roots of our ordinary grain or green crops ever penetrate to such a depth as has now been specified. A careful examination will satisfy any one who makes it, that minute filamentary rootlets are sent down to extraordinary depths, wherever they are not arrested by stagnant water. It has also been questioned whether any benefit accrues to crops from this deep descent of their roots. Some persons have even asserted that it is only when they do not find food near at hand that they thus wander. But it must be borne in mind that plants obtain moisture as well as nourishment by means of their roots, and the fact is well known that plants growing in a deep soil resting on a porous subsoil seldom or never suffer from drought. It is instructive, too, on this point, to observe the practice of the most skilful gardeners, and see the importance which they attach to trenching, the great depth at which they often deposit manure, and the stress which they lay upon thorough drainage. On the other hand, it is well known that soils which soonest become saturated, and run from the surface in wet weather, are precisely those which parch and get chapped the soonest in drought. The effectual way to secure our crops at once from drowning and parching, is to put the land in a right condition with respect to drainage.

All soils possess more or less the power of absorbing and retaining water. Pure clays have it in the greatest degree, and gritty siliceous ones in the smallest. In dry weather this power of attracting moisture is constantly operating to supply from below the loss taking place by evaporation at the surface. In heavy rains, as soon as the entire mass has drunk its fill, the excess begins to flow off below; and therefore a deep stratum, through which water can percolate, but in which it can never stagnate—that is, never exceed the point of saturation—is precisely that in which plants are most secure from the extremes of drought and drowning.

If a perfect condition of the soil with respect to drainage is of importance for its influence in preserving it in a right condition as respects moisture, it is still more so for its effects upon its *temperature*. All who are conversant with rural affairs are familiar with that popular classification of soils in virtue of which such as are naturally dry are also invariably spoken of as *warm* and *early;* and conversely, that wet soils are invariably described as being *cold* and *late*. This classification is strictly accurate, and the explanation of it is simple. An excess of water in soil keeps down its temperature in various ways. In passing into the state of vapour it rapidly carries off the heat which the soil has obtained from the sun's rays. Water possesses also a high radiating power; so that, when present in the soil in excess, and in a stagnant state, it is constantly carrying off heat by evaporation and radiation. On the other hand, stagnant water conveys no heat downwards; for although the surface is warmed, the portion of water thus heated being lightest, remains floating on the surface, and will give back its heat to the atmosphere, but conveys none downwards. When the surface of stagnant water becomes colder than the general mass, the very opposite effect immediately ensues; for as water cools its density increases, and thus causes an instant sinking of the portion that has been cooled, and a rising of a warm portion from below to take its place—this movement continuing until the whole has been lowered to 40°, at which point water reaches its maximum density, while, if the temperature be reduced a few degrees more, water will begin to freeze. It is thus that soil surcharged with water is kept at a lower temperature than similar soil that has a sufficient natural or artificial drainage.

But while the presence of stagnant water in a soil has this injurious power of lowering its temperature, a very different effect ensues when rain water can sink freely into it to a depth of several feet, and then find a ready exit by drainage; for in this case the rain water carries down with it the heat which it has acquired from the atmosphere and from the sun-heated surface, and imparts it to the subsoil. There is as yet a lack of published experiments to show the ordinary increase of temperature at various depths and in different soils, as the result of draining wet land. Those conducted by Mr Parkes, in a Lancashire bog in June 1837, showed, as the mean of thirty-five observations, that the drained and cultivated soil at seven inches from the surface was 10° warmer than the adjoining undrained bog in its natural state at the same depth. It is understood that later experiments conducted by the same gentleman on an extended scale fully establish the fact, that an increased temperature of the soil is an unfailing accompaniment of thorough draining. The importance of this result cannot well be over-rated. The temperature and other conditions of the atmosphere, which we call climate, are placed beyond human control; but this power of raising the temperature of all wet, and consequently cold soils, becomes tantamount in some of its results to a power of improving the climate. There are, accordingly, good grounds for stating that in numerous cases grain crops have ripened sooner by ten or twelve days than they would have done but for the draining of the land on which they grew.

The points which we have thus briefly touched upon are so essential to an intelligent appreciation of the subject, that we have felt constrained to notice them, however meagrely. But our space forbids more than a mere enumeration of some of the many evils inseparable from the presence of stagnant water in the soil, and of the benefits that flow from its removal. Wet land, if in grass, produces only the coarser grasses, and many sub-aquatic plants and mosses, which are of little or no value for pasturage; its herbage is late of coming in spring, and fails early in autumn; the animals grazed upon it are unduly liable to disease, and sheep, especially, to the fatal rot. When land is used as arable, tillage operations are easily interrupted by rain, and the period always much limited in which they can be prosecuted at all; the compactness and toughness of such land renders each operation more arduous, and more of them necessary, than in the case of dry land. The surface must necessarily be thrown into ridges, and the furrows and cross-cuts duly cleared out after each process of tillage, on which surface expedients as much labour has probably been expended in each thirty years as would now suffice to make drains enough to lay it permanently dry. With all these precautions the best seed-time is often missed, and this usually proves the prelude to a scanty crop, or to a late and disastrous harvest. The cultivation of the turnip and other root crops, which require the soil to be wrought to a deep and free tilth, either becomes altogether impracticable, and must be abandoned for the safe but costly bare fallow, or is carried out with great labour and hazard; and the crop, when grown, can neither be removed from the ground, nor consumed upon it by sheep without damage by poaching. The dung, lime, and other manure, that is applied to such land is in a great measure wasted; and the breaking of the subsoil and general deep tillage, so beneficial in other circumstances, is here positively mischievous, as it does but increase its power of retaining water. Taking into account the excessive labour, cost, and risk, inseparable from the cultivation of wet land, and the scanty and precarious character of the crops so obtained, it would in many cases be wiser to keep such lands in grass, than to prosecute arable husbandry under such adverse circumstances. These very serious evils can either be entirely removed, or, at the least, very greatly lessened by thorough draining. It often happens that naturally porous soils are so soaked by springs, or so water-logged by resting upon an impervious subsoil, or, it may be, so drowned for want of an outfall in some neighbouring river or stream, that draining at once effects a perfect cure, and places them on a par with the best naturally dry soils. In the case of clay soils, the improvement effected by draining is in some respects greater than in any other class, but still it cannot change the inherent properties of clay. This has sometimes been overlooked by sanguine improvers, who, hastily assuming that their strong land, when drained, would henceforward be as friable and sound as the more porous kinds, have proceeded to treat it on this assumption, and have found to their cost that clay, however well drained, will still get into mortar and clods, if it is tilled or trodden on too soon after rain. It is entirely owing to such rash and unskilful management that an opinion has sometimes got abroad, that clay lands are injured by draining. They merely retain the qualities peculiar to clay, and when they are treated judiciously, show as good a comparative benefit from draining as other soils. The only instances in which even temporary injury arises from draining is in the case of some peaty and fen lands, which are so loose that they suffer from drought in protracted dry weather. As such lands are usually level and have water-courses near them, this inconvenience admits of an easy remedy by shutting up the main outlets, and then admitting water into the ditches. The drains in this way become ready channels for applying the needed moisture by a kind of subterraneous irrigation.

The beneficial effects of thorough draining are of a very decisive and striking kind. The removal of stagnant water from a stratum of 4 feet in depth, and the establishing of a free passage for rain water and air from the surface to the level of the drains, speedily effects most important changes in the condition of the soil and subsoil Ploughing and other tillage operations are performed more easily than before in consequence of a more friable state of the soil. Moderate rains which formerly would have sufficed to arrest these operations do so no longer, and heavy falls of rain cause a much shorter interruption of these labours than they did when the land was in its natural state. Deep tillage, whether by the common or subsoil plough (which formerly did harm), now aids the drainage, and is every way beneficial. Ridges and surface furrows being no longer needed the land can be kept flat, with great benefit to crops and furtherance to field operations. An earlier seed-time and harvest, better crops, a healthier live stock, and an improved style of husbandry, are the usual and well known sequents of judiciously conducted drainage operations. In short, the most experienced and skilful agriculturists now declare with one consent that good drainage is an indispensable preliminary to good cultivation.

Although it has been reserved to the present times to see land draining reduced to a system based on scientific principles, or very great improvement effected in its details, it is by no means a modern discovery. The Romans were careful to keep their arable lands dry by means of open trenches, and there are even some grounds for surmising that they used covered drains for the same purpose. Indubitable proof exists that they constructed underground channels by means of tubes of burned earthenware; but it seems more probable that these were designed to carry water to their dwellings, &c., than that they were used simply as drains. Recent inquiries and discoveries have also shown that it is at least several centuries, since covered channels of various kinds were in use by British husbandmen for drying their land. It is, at all events, two centuries since Captain Walter Blithe wrote as follows :—

"Superfluous and venomous water which lyeth in the earth and much occasioneth bogginesse, mirinesse, rushes, flags, and other filth, is indeed the chief cause of barrenesse in any land of this nature. . . . . Drayning is an excellent and chiefest means for their reducement; and for the depth of such draynes, I cannot possibly bound, because I have not time and opportunity to take in all circumstances. . . . . And for thy drayning trench, it must be made so deepe that it goe to the bottome of the cold, spewing moyst water, that feeds the flagg and the rush; for the widenesse of it, use thine owne liberty, but be sure to make it so wide as thou mayest goe to the bottome of it, which must be so low as any moysture lyeth, which moysture usually lyeth under the over and second swarth of the earth, in some gravel or sand, or else, where some greater stones are mixt with clay, under which thou must goe halfe one spades graft deepe at least; yea, suppose this corruption that feeds and nourisheth the rush or flagg should lie a yard or foure foot deepe, to the bottome of it thou must goe, if ever thou wilt drayne it to purpose. . . . . And for the drayning trench be sure thou indeavour to carry it as neare upon a straight line as possible. . . . . To the bottome where the spewing spring lyeth thou must goe, and one spades depth or graft beneath, how deep so ever it be, if thou wilt drayne thy land to purpose. I am forced to use repetitions of some things, because of the suitableness of the things to which they are applyed; as also because of the slownesse of peoples apprehensions of them, as appears by the non-practice of them, the which wherever you see drayning and trenching you shall rarely find few or none of them wrought to the bottome. . . . . Go to the bottome of the bog, and there make a trench in the sound ground, or else in some old ditch, so low as thou verily conceivest thy selfe assuredly under the level of the spring or spewing water, and then carry up thy trench into thy bogg straight through the middle of it, one foot under that spring; . . . . but for these common and many trenches, oft times crooked too, that men usually make in their boggy grounds, some one foot, some two, never having respect to the cause or matter that maketh the bogg to take that way, I say away with them as a great piece of folly, lost labour and spoyle. . . . . After thou has brought a trench to the bottom of the bog, then cut a good substantial trench about thy bog; and when thou hast so done make one work or two just overthwart it, *upwards and downwards*, all under the matter of the bog. Then thou must take good green faggots, willow, alder, elme, or thorne, and lay in the bottome of thy works, and then take thy turfe thou tookest up in the top of thy trench, and plant upon them with the green sward downwards; *or take great pebbles, stones, or flint stones, and so fill up the bottome of thy trench about fifteen inches high*, and take thy turfe and plant it as aforesaid, being cut very fit for the trench, as it may join close as it is layd downe, and then having covered it all over with earth, and made it even as thy other ground, waite and expect a wonderfull effect through the blessing of God."

These sagacious arguments and instructions were doubtless acted upon by some persons in his own times and since; but still they had never attained to general adoption, and were ultimately forgotten. Towards the close of last century, Mr Elkington, a Warwickshire farmer, discovered and promulgated a plan of laying dry sloping land that is drowned by the outbursting of springs. When the higher lying portion of such land is porous, rain falling upon it sinks down until it is arrested by clay or other impervious matter, which causes it again to issue at the surface and wet the lower-lying ground. Elkington showed that by cutting a deep drain through the clay, aided when necessary by wells or augur holes, the subjacent bed of sand or gravel in which a body of water is pent up by the clay, as in a vessel, might be tapped, and the water conveyed harmlessly in the covered drain to the nearest ditch or stream. In the circumstances to which it is applicable, and in the hands of skilful drainers, Elkington's plan, by bringing into play the natural drainage furnished by porous strata, is often eminently successful. His system was given to the public in a quarto volume, edited by a Mr John Johnston of Edinburgh, who does not seem to have shared the engineering talents of the man whose discoveries he professes to expound. During the thirty or forty years subsequent to the publication of this volume, most of the draining that took place was on this system, and an immense capital was expended in such works with very varying results. Things continued in this position until about the year 1823, when the late James Smith of Deanston, having discovered anew those principles of draining so long before indicated by Blithe, proceeded to exemplify them in his own practice, and to expound them to the public in a way that speedily effected a complete revolution in the art of draining, and marked an era in our agricultural progress. Instead of persisting in fruitless attempts to dry extensive areas by a few dexterous cuts, he insisted on the necessity of providing every field that needed draining at all with a complete system of parallel underground channels, running in the line of the greatest slope of the ground, and so near to each other that the whole rain falling at any time upon the surface should sink down and be carried off by the drains. The distances between drains he showed must be regulated by the greater or less retentiveness of the ground operated upon, and gave 10 feet as the minimum, and 40 feet as the maximum of these distances. The depth which he prescribed for his parallel drains was 30 inches, and these were to be filled with 12 inches of stones small enough to pass through a 3-inch ring—in short, a new edition of Blithe's drain. A main receiving-drain was to be carried along the lowest part of the ground, with sub-mains in every subordinate hollow that the ground presented. These receiving drains were directed to be formed with a culvert of stone work, or of tiles, of waterway sufficient to contain the greatest volume of water at any time requiring to be passed from the area to which they respectively supplied the outlet. The whole cultivated lands of Britain being disposed in ridges which usually lie in the line of greatest ascent, it became customary to form the drains in each furrow, or in each alternate, or third, or fourth one, as the case might require or views of economy dictate, and hence the system soon came to be popularly called *furrow draining*. From the number and arrangement of the drains, the terms *frequent* and *parallel* were also applied to it. Mr Smith himself more appropriately named it, from its effects, *thorough draining*. The sound principles thus promulgated by him were speedily adopted and extensively carried into practice. The great labour and cost incurred in procuring stones in adequate quantities, and the difficulty of carting them in wet seasons, soon led to the substitution of tiles and soles of burned earthenware. The limited supply and high price of these tiles for a time impeded the progress of the new system of draining; but the invention of tile-making machines by the Marquis of Tweeddale and others, removed this impediment, and gave a mighty stimulus to this fundamental agricultural improvement. The substitution of cylindrical pipes for the original horse-shoe tiles has still further lowered the cost and increased the efficiency and permanency of drainage works.

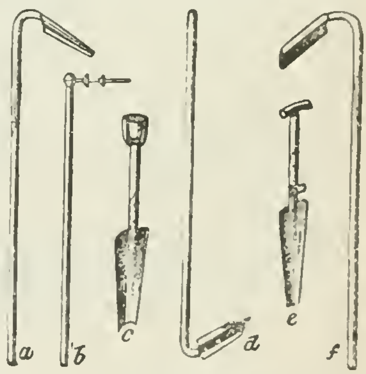
The system introduced and so ably expounded by Smith of Deanston has now been virtually adopted by all drainers. Variations in matters of detail (having respect chiefly to the depth and distance apart of the parallel drains) have indeed been introduced; but the distinctive features of his system are now recognised and acted upon by all scientific drainers.

In setting about the draining of a field, or farm, or estate, the first point is to secure, at whatever cost, a proper outfall. The lines of the receiving drains must next be determined, and then the direction of the parallel drains. The former must occupy the lowest part of the natural hollows, and the latter must run in the line of the greatest ascent of the ground. In the case of flat land, where a fall is obtained chiefly by increasing the depth of the drains at their lower ends, these lines may be disposed in any direction that is found convenient; but in undulating ground a single field may require several distinct sets of drains lying at different angles, so as to suit its several slopes. When a field is ridged in the line of the greatest ascent of the ground, there is an obvious convenience in adopting the furrows as the site of the drains; *but wherever this is not the case the drains must be laid off to suit the contour of the ground, irrespective of the furrows altogether.* When parts of a field are flat, and other parts have a considerable acclivity, it is expedient to cut a receiving drain near to the bottom of the slopes, and to give the flat ground an independent set of drains. In laying off receiving drains it is essential to give hedge-rows and trees a good offing, lest the conduit should be obstructed by roots. When a drain must of necessity pass near to trees, we have found it practicable to exclude their roots from it by the use of coal-tar. In our own practice, a drain carried through the corner of a plantation has by this expedient remained free from obstruction for now fourteen years. In this instance the tar was applied in the following manner:—Sawdust and coal-tar being mixed together to the consistency of ordinary mortar, a layer of this was laid in the bottom of the trench; the drain-pipes were then laid, and completely coated over with the same mixture to the thickness of an inch, and the earth carefully replaced in the ordinary way. When a main drain is so placed that parallel ones empty into it from both sides, care should be taken that the inlets of the latter are not made exactly opposite to each other. Indeed, we have found it expedient in such cases to have two receiving drains parallel to each other, each to receive the subordinate drains from its own side only. As these receiving drains act also as ordinary drains to the land through which they pass, no additional cost is incurred by having two instead of one, provided they are as far apart as the other drains in the field. Much of the success of draining depends on the skilful planning of these main drains, and in making them large enough to discharge the greatest flow of water to which they may be exposed. Very long main drains are to be avoided. Numerous outlets are also objectionable, from their liability to obstruction. An outlet to an area of from ten to fifteen acres is a good arrangement. These outlets should be faced with mason-work, and guarded by iron gratings.

The depths of the parallel drains must next be determined. In order to obtain proper data for doing so, the subsoil must be carefully examined by digging test-holes in various places, and also by taking advantage of any quarries, deep ditches, or other cuttings in the proximity, that afford a good section of the ground. We have already expressed an opinion that the drains should not be less than four feet deep; but it is quite possible that the discovery at a greater depth than four feet of a seam of gravel, or other very porous material charged with water, underlying considerable portions of the ground, may render it expedient to carry the drains so deep as to reach this seam. Such a seam, when furnished with sufficient outlets, supplies a natural drain to the whole area under which it extends. When such exceptional cases are met with, they are precisely those in which deep drains, at wide intervals, can be trusted to dry the whole area. When the subsoil consists of a tenacious clay of considerable depth, it is considered by many persons that a greater depth than three feet is unnecessary. The greater depth is, however, always to be preferred; for a drain of four feet, if it works at all, not only does all that a shallower one can do, but frees from stagnant water a body of subsoil on which the other has no effect at all. It has indeed been alleged that such deep drains may get so closed over by the clay that water will stand above them. If the surface of clay soil is wrought into puddle by improper usage, water can undoubtedly be made to stand for a time over the shallowest drains as easily as over the deepest. But the contraction which takes place in summer in good alluvial clays gradually establishes fissures, by which water reaches the drains. In such soils it is usually a few years before the full effect of draining is attained. This is chiefly due to the contraction and consequent cracking of clay soils in summer just referred to, and partly, as Mr Parkes thinks, to the mining operations of the common earth-worm. Both of these natural aids to drainage operate with greater force with drains four feet deep than when they are shallower. The tardy percolation of water through clay soils seems also a reason why in such cases it should get the benefit of a greater fall, by making the drain deep.

Draining is always a costly operation, and it is therefore peculiarly needful to have it executed in such a way that it shall be effectual and permanent. We advocate a minimum depth of four feet, because of our strong conviction that such drains carefully made will be found to have both these qualities. And this opinion is the result of dear-bought experience, for we have found it necessary in our own case to re-open a very considerable extent of 30-inch drains in consequence of their having totally failed to lay the land dry, and to replace them by four feet ones, which have proved perfectly efficacious. In doing this we have seen a 30-inch drain opened up and found to be perfectly dry, and yet when the same trench was deepened to four feet there was quite a run of water from it. Now also that steam power has become available for the tillage of the soil, and is certain, at no distant day, to be in general requisition for that purpose, it is peculiarly expedient to have the drains laid at such a depth as to admit of that potent agency being used for loosening the subsoil to depths hitherto unattainable, not only without hazard to the drains, but with the certainty of greatly augmenting their efficiency. Therefore we earnestly dissuade all parties who are about to undertake drainage works from giving ear to representations about the sufficiency and economy of shallow drains. These, doubtless, cost somewhat less to begin with, but in thousands of cases they fail to accomplish the desired end, and the unfortunate owners, after all their outlay, are left to the miserable alternative of seeing their land imperfectly drained, or of executing the works anew, and thus losing the whole cost of the first and inefficient ones. The extreme reluctance with which the latter alternative is necessarily regarded will undoubtedly operate for a long time in keeping much land that has been hastily and imperfectly drained from participating in the benefits of *thorough* drainage. The distance apart at which the drains should be cut must be determined by the nature of the subsoil. In the most retentive clays it need not be less than 18 feet. On the other hand, this distance cannot safely be exceeded in the case of any subsoil in which clay predominates, although it should not be of the most retentive kind. In all parts of the country instances abound in which drains cut in such subsoils, from 24 to 30 feet apart, have totally failed to lay the land dry. When ground is once pre-occupied by drains too far apart, there is no remedy but to form a supplementary one betwixt each pair of the first set; and thus, by exceeding the proper width at first, the space betwixt the drains is unavoidably reduced to 12 or 15 feet, although 18 feet would originally have sufficed. It is only with a decided porosity in the subsoil, and in proportion to the degree of that porosity, that the space between drains can safely be increased to 24, or 30, or 36 feet. In those exceptional cases in which drains more than 36 feet apart prove effectual, their success is due to the principle on which Elkington's system is founded. A few years ago an opinion obtained currency, that as the depth of drains was increased their width apart might with safety be increased in a corresponding ratio. And hence it came to be confidently asserted, that with a depth of 5 or 6 feet a width of from 40 to 60 feet might be adopted with a certainty of success, even in the case of retentive soils. We believe that experience has already demonstrated the unsoundness of this opinion. At all events, in recommending a minimum depth of 4 feet, we do so on the ground that (other things being equal) the whole benefits of drainage are more fully and certainly secured by drains of this depth than by those of $2\frac{1}{2}$ or 3 feet. In ordinary cases an increase of depth does not compensate for an increase of the width apart of the drains. Draining can be carried on at all seasons, but is usually best done in summer or autumn. The digging is usually paid for by task work, and the setting of the pipes by day's wages. A thoroughly trustworthy and experienced workman is selected for the latter work, with instructions to set no pipes until he is satisfied that the depth of the drains and level of the bottoms are correct. When the soil is returned into the drains all defects are of course buried, and it therefore behoves the landlord, or his substitute, whether tenant or bailiff, to exercise a vigilant oversight of draining operations. Unless carefully executed they cannot be efficient; and without efficient drainage all other agricultural operations must be carried on under grievous disadvantages. The extent of land in Great Britain naturally so dry as not to need artificial drainage is very much less than even practical farmers, who have not studied the subject, are at all aware of.

Cylindrical pipes with collars are undoubtedly the best draining material that has yet been discovered. The collars referred to are simply short pieces of pipe, just so wide in the bore as to admit of the smaller pipes which form the drain passing freely through them. In use, one of these collars is so placed as to encase the ends of each contiguous pair of tubes, and thus forms a loose fillet around each joining. The ends of these pipes being by this means securely kept in contact, a continuous canal for the free passage of water is infallibly insured, the joinings are guarded against the entrance of mud or vermin, and yet sufficient space is left for the admission of water. Pipes of all diameters, from 1 inch to 16 inches, are now to be had; those from 1 to 2 inches in the bore are used for subordinate drains; the larger sizes for sub-main and main receiving drains. Collars are used with the smaller sizes only, large pipes not being so liable to shift their position as small ones. In constructing a drain, it is of much importance that the bottom be cut out just wide enough to admit the pipes and no more. Pipes, when thus accurately fitted in, are much less liable to derangement than when laid in the bottom of a trench several times their width, and into which a mass of loose earth must necessarily be returned. This accurate fitting is now quite practicable in the case of soils tolerably free from stones, from the excellence of the draining tools that have lately been introduced. The following cut represents the most important of these tools.



Draining Tools.

c and *e* are long tapering spades for digging out the middle and bottom spits. *a*, *d*, and *f* recurved scoops for clearing out the debris, and *b* a pipe-layer, by means of which a workman standing at the margin of a drain hooks up a pipe and collar, and deposits them easily and accurately in the deep narrow trench.

If a quicksand is encountered in constructing a drain, it will be found expedient to put a layer of straw in the bottom of the trench, and then, instead of the ordinary pipe and collar, to use at such a place a double set of pipes—one within the other—taking care that the joinings of the inner set are covered by the centres of the outer ones. By such precautions the water gets vent, and the running sand is excluded from the drain. When a brook has been diverted from its natural course for mill-power or irrigating purposes, it often happens that portions of land are thereby deprived of the outfall required to admit of their being drained to a proper depth. In such cases it is frequently practicable to obtain the needed outlet by carrying a main drain through below the water-course, by using at that point a few yards of cast-iron pipe, and carefully filling up the trench with clay puddle, so that there may be no leakage from the water-course into the drain. While this is being done the water must either be turned off or carried over the temporary gap in a wooden trough.

The cost of draining is so much influenced by the ever-varying price of labour and materials, and by the still more varying character of the land to be operated upon, that it is impossible to give an estimate of the cost that will admit of general application. The following tabular data, taken chiefly from Mr Bailey Denton's valuable treatise, are presented to aid those who wish to form such an estimate:—

TABLE I.—*Showing the number of rods of drain per acre at given distances apart, and the number of pipes of given lengths required per acre.*

Intervals between the drains in feet.	Rods per acre.	12-inch pipes.	13-inch pipes.	14-inch pipes.	15-inch pipes.
18	$146\frac{2}{3}$	2420	2234	2074	1936
21	$125\frac{5}{7}$	2074	1915	1778	1659
24	110	1815	1676	1555	1452
27	$97\frac{7}{9}$	1613	1489	1383	1290
30	88	1452	1340	1244	1161

TABLE II.—*Showing the cost of draining per acre at different intervals between the drains.*

Various attempts have from time to time been made to lower the cost of draining land by the direct application of animal or steam power to the work of excavation.* The

G Small rope.
H Anchor and sheave for small rope.

most successful of these attempts is the steam-draining apparatus invented by Mr John Fowler of Bristol, usually called *Fowler's draining plough.* A six-horse portable steam-engine is anchored in one corner of the field to be drained. It gives motion to two drums, to each of which a rope 500 yards long is attached, the one uncoiling as the other is wound up. These ropes pass round blocks which are anchored at each end of the intended line of drain, and are attached one to the front and the other to the hinder end of the draining apparatus. This consists of a framework, in which is fixed, at any required depth not exceeding $3\frac{1}{2}$ feet, a strong coulter terminating in a short horizontal bar of cylindrical iron, with a piece of rope attached to it, on which a convenient number of drain pipes are strung. This frame being pulled along by the engine, the coulter is forced through the soil at a regulated depth, and deposits its string of pipes with unerring accuracy, thus forming, as it proceeds, a perfect drain. The supply of pipes is kept up by means of holes previously dug in the line of the drain, at distances corresponding to the length of the rope on which they are strung. This machine was subjected to a very thorough trial at the meeting of the Royal Agricultural Society of England at Lincoln in 1854, on which occasion a silver medal and very high commendation were awarded to it. In March 1855 it was publicly stated that five of these implements are now at work in different parts of England, and that already 10,000 acres of land have been drained by means of them. At the Lincoln trial it was satisfactorily proved that this implement could work at a depth of $3\frac{1}{2}$ feet. As it moved along, the soil on each side, to the width of 2 or 3 feet, seemed to be loosened. It is therefore probable that this implement, or at least one propelled on the same principle, may yet be used as a subsoil disintegrator.

A great stimulus has recently been given to the improvement of land by the passing of a series of Acts of Parliament, which have removed certain obstacles that effectually hindered the investment of capital in works of drainage and kindred ameliorations. By the first of these Acts, passed in 1846, a sum of £4,000,000 of the public money was authorised to be advanced to landowners to be expended in draining their lands. The Enclosure Commissioners were charged with the allocation of this money and the superintendence of its outlay. The most important provisions of this Act are that it enables the possessors of entailed estates (equally with others) to share in the benefits of this fund; that it provides, on terms very favourable to the borrower, for the repayment of the money so advanced by twenty-two annual instalments; that before sanctioning the expenditure of these funds on drainage works, the commissioners must have a report from a qualified inspector, to the effect that they are likely to prove remunerative; and, finally, that the works must be performed according to specifications prepared by the inspector, and approved by the commissioners, who have seldom allowed of a less depth of drain than $3\frac{1}{2}$ feet. By the end of the year 1854 the whole of this money was allocated, and more than half of it actually expended. Scottish landowners were so prompt to discern, and so eager to avail themselves of this public fund, that more than half of it fell to their share. The great success of this measure, and the rapid absorption of the fund provided by it, soon led to further legislative Acts, by which *private capital* has been rendered available for the improvement of land, by draining and otherwise, on conditions similar to those just enumerated. These Acts are—

1*st*, The Private Moneys Drainage Act (12 and 13 Vict. c. 100), limited to draining.

2*d*, The West of England, or South-West Land Draining Company's Act (11 and 12 Vict., c. 142), for the purpose of draining, irrigation and warping, embanking, reclaiming and enclosing, and road-making.

3*d*, The General Land-Drainage and Improvement Company's Act (12 and 13 Vict. c. 91), for the purposes of draining, irrigating and warping, embanking, reclaiming and enclosing, road-making and erecting farm-buildings.

4*th*, The Lands Improvement Company's Act (16 and 17 Vict. c. 154), for the same purposes as the above, with the addition of planting for shelter. This company's powers extend to Scotland.

By these Acts ample provision is made for rendering the dormant capital of the country available for the improvement of its soil. To the owners of entailed estates they are peculiarly valuable, from the power which they give to them of charging the cost of draining, &c., upon the inheritance. If such owners apply their own private funds in effecting improvements of this kind, they are enabled, through the medium of these companies, to take a rent-charge on their estates for repayment of the money they so expend, over which they retain personal control, so that they can bequeath as they choose the rent-charge payable by their successor. Besides their direct benefits, these Drainage Acts have already produced some very important indirect fruits. They have led to many improvements in the manner of accomplishing the works to which they relate, to the wide and rapid dissemination of improved modes of draining, &c., and, in particular, they have had the effect of creating, or at least of greatly multiplying and accrediting, a staff of skilful and experienced draining engineers, of whose services all who are about to engage in draining and similar works will do well to avail themselves.

Section 3.—Removal of Earthfast Stones.

Newly reclaimed lands, and even those that have long been under tillage, are frequently much encumbered with earthfast stones. This is particularly the case in many parts of Scotland. Their removal is always desirable, though necessarily accompanied with much trouble and expense. In our personal practice we have proceeded in this way. In giving the autumn furrow preparatory to a fallow crop, each ploughman carries with him a few branches of fir or beech, one of which he sticks in above each stone encountered by his plough. If the stones are numerous, particularly at certain places, two labourers, provided with a pick, a spade, and a long wooden lever shod with iron, attend upon the ploughs, and remove as many of the stones as they can, while yet partially uncovered by the recent furrow. Those thus dug up are rolled aside upon the ploughed land. When the land gets dry enough in spring, those not got out at the time of ploughing are discovered by means of the twigs, and are then dug up. Such as can be lifted by one man are carted off as they are, but those of the larger class must first be reduced by a sledge hammer. They yield to the hammer more easily after a few days' exposure to drought than when attacked as soon as dug up. Before attempting to break very large boulders a brisk fire of dried gorse or brushwood is kept up over them until they are heated, after which a few smart blows from the hammer shiver them completely. Portions of otherwise good land are sometimes so full of these boulders, that to render it available, the stones must be got rid of by trenching the whole to a considerable depth. When ploughing by steam-power becomes general, a preliminary trenching of this kind will in many cases be requisite before tillage instruments thus propelled can be used with safety.

Section 4.—Paring and Burning.

Paring and burning have, from an early period, been resorted to for the more speedy subduing of a rough uncultured surface. This is still the most approved method of dealing with such cases, as well as with any tough old sward which is again to be subjected to tillage. In setting about the operation, which is usually done in March or April, a turf, not exceeding an inch in thickness, is first peeled off in successive stripes by a paring-plough drawn by two horses, or by the breast-plough already described. These turfs are first set on edge and partially dried, after which they are collected into heaps, and burned, or rather charred. The ashes are immediately spread over the surface, and ploughed in with a light furrow. By this process the matted roots of the pasture plants, the seeds of weeds, and the eggs and larvæ of innumerable insects, are at once got rid of, and a highly stimulating top-dressing is supplied to the land. A crop of turnips or rape is then drilled on the flat, and fed off by sheep, after which the land is usually in prime condition for bearing a crop of grain. This practice is unsuitable for sandy soils, which it only renders more sterile; but when clay or peat prevails, its beneficial effects are indisputable. We shall, in the sequel, give an example of its recent successful application.

Section 5.—Levelling.

Land, when subjected to the plough for the first time, abounds not unfrequently with abrupt hollows and protuberances, which impede tillage operations. These can be readily levelled by means of a box shaped like a huge dust-pan, the front part being shod with iron, and a pair of handles attached behind. This levelling-box is drawn by a pair of horses. Being directed against a prominent part, it scoops up its fill of soil, with which it slides along sledge-fashion to the place where it is to discharge its load, which it does by canting over, on the ploughman disengaging the handles.

In all parts of Great Britain, abundance of pasture land, and often tillage land also, is to be met with lying in broad, highly raised, serpentine ridges. These seem to have originated when teams of six or eight bullocks were used in ploughing; and it has been suggested that this curvature of the ridges at first arose from its being easier to turn these long teams at the end of each land by sweeping round in a curve than by driving straight out. The very broad headlands found in connection with these curved ridges point to the same fact. A theory still lingers among our peasantry, that "water runs better in a crooked furrow than in a straight one," and has probably been handed down since the discovered awkwardness of curved ridges was first seen to need some plausible apology. These immense, wave-like ridges are certainly a great annoyance to the modern cultivator; but still the sudden levelling of them is accompanied with so much risk, that it is usually better to cut drains in the intervening hollows, and plough aslant them in straight lines, by which means a gradual approximation to a level surface is made. A field in our own occupation, which was levelled, by cleaving down the old crooked ridges, fifty years ago, still shows, by alternate curving bands of greater and less luxuriance, the exact site of the crowns and furrows of the ancient ridges.

Section 6.—Trenching.

But for its tediousness and costliness, trenching two or three *spits* deep by spade or fork is certainly the most effectual means for at once removing obstructions, levelling the surface, and perfecting the drainage by thoroughly loosening the subsoil. For the reasons mentioned, it is seldom resorted to on a large scale. But it is becoming a common practice, with careful farmers, to have those patches of ground in the corners, and by the fences of fields, which are missed in ploughing, gone over with the trenching-fork. The additional crop thus obtained may fail to compensate for this hand-tillage, but it is vindicated on the ground that these corners and margins are the nurseries of weeds which it is profitable to destroy.

CHAPTER VIII.

TILLAGE OPERATIONS.

Section 1.—*Ploughing.*

When the natural green sward, or ground that has been cleared of a cultivated crop, is to be prepared for the sowing or planting of further crops, the plough leads the way in breaking up the compact surface, by cutting from it successive slices, averaging about ten inches in breadth by seven in depth, which it turns half over upon each other to the right-hand side. This turning of the slices or furrows to one side only renders it necessary to square off the space to be ploughed into parallelograms, half the slices of which are laid the one way and the other half the other, by the going and returning of the plough. These parallel spaces are variously termed *ridges*, *stetches*, *lands*, or *feirings*, which in practice vary in width from a few furrows to 30 yards. When very narrow spaces are used, a waste of labour ensues, from the necessity of opening out and then reclosing an extra number of index or guiding furrows; while very wide ones involve a similar waste from the distance which the plough must go empty in traversing at the ends. The spaces thus formed by equal numbers of furrow-slices turned from opposite sides have necessarily a rounded outline, and are separated by open channels. In a moist climate and impervious soil, this ridging of the surface causes rain-water to pass off more rapidly, and keeps the soil drier than would be the case if it was kept flat. Hence the cultivated lands of Great Britain almost invariably exhibit this ridged form of surface. Until the art of under-ground draining was discovered, this was indeed the only mode of keeping cultivated ground tolerably dry. But it is at best a very defective method, and attended by many disadvantages. When land is naturally dry, or has been made so by thorough drainage, the flatter its surface is kept the better for the crops grown upon it. We are not forgetful that there are, in various parts of Great Britain, clays so impervious that probably no amount of draining or disintegration of the subsoil will render it safe to dispense with ridging. These, however, are exceptional cases, and, as a rule, such a condition of soil and subsoil should be aimed at as will admit of this rude expedient of ridging being altogether dispensed with. Unless land can absorb the whole rain which falls upon it, its full range of fertility cannot be developed; for the same showers which aggravate the coldness and sterility of impervious and already saturated soils carry down with them, and impart to those that are pervious, ever fresh supplies of genial influences. Instead, then, of this perennial source of fertility being encouraged to run off by surface channels, or to stagnate in the soil and become its bane, let provision be made for its free percolation through an open stratum several feet in thickness, and then for its escape by drains of such depth and frequency as each particular case requires. When this is attained, a flat surface will generally be preserved, as alike conducive to the welfare of the crops and to the successful employment of machinery for sowing, weeding, and reaping them.

In all treatises on British agriculture of a date anterior to the first quarter of the present century, we find great stress laid on the proper formation of the ridges, careful cleaning out of the separating channels or water-furrows, and drawing and spading out of cross-cuts in all hollows, so that no water may stagnate on the surface of the field. As thorough under-draining makes progress, such directions are becoming obsolete. But whether ridging or flat work is used, the one-sided action of the plough renders it necessary, in setting about the ploughing of a field, to mark it off into parallel spaces by a series of equi-distant straight lines. Supposing the line of fence, at the side at which he begins, to be straight, the ploughman takes this as his base line; and measuring from it, erects his three or more feiring poles perfectly in line, at a distance from the fence equal to half the width of the ridges or spaces in which it is proposed to plough the field. This operation—called in Scotland *feiring* the land—is usually entrusted to the most skilful ploughman on each farm, and is regarded as a post of honour. Having drawn a furrow in the exact line of his poles, which practice enables him to do with an accuracy truly admirable, he proceeds, using always the last furrow as a fresh base from which to measure the next one, until the field is all marked off. When this is done, it presents the appearance of a neatly ruled sheet of paper. Besides the poles just referred to, the ploughman is frequently furnished with a cross staff, by means of which he first of all marks off two or more lines perpendicular to the straight side at which he commences, and along these he measures with his poles, which are graduated for the purpose, in laying off his parallel lines. This feiring is only required when a process of fallowing, in preparation for green crop, has obliterated the former ridges. In breaking up clover lea or older sward, the ploughman begins at the open furrows, which afford him a sufficient guide.

In ploughing for a seed-bed the furrow-slice is usually cut about five inches deep. In the case of lea, it should be turned over unbroken, of uniform thickness, and laid quite close upon the preceding one, so as to hide all green sward. The improved wheel-plough already referred to does this work very beautifully, cutting out the slice perfectly square from the bottom of the furrow. The perfect uniformity in the width and depth of the slices cut by it permits the harrows to act equally upon the whole surface. When the slice is cut unevenly, they draw the loosened soil from the prominences into the hollows, so that one part is scraped bare, and the other remains untouched and unbroken. This must necessarily yield a poor seed-bed, and contrasts unfavourably with the uniform tilth produced by harrowing after such work as these wheel-ploughs invariably produce. In the Lothians and west of Scotland, a form of plough is much used for ploughing lea, which cuts out the slice with an acute angle at the land side. This, when turned over, stands up with a sharp ridge, which looks particularly well, and offers a good subject for harrows to work upon. But if a few of these furrow-slices are removed, the firm earth below exhibits the same ribbed appearance as the newly ploughed surface, instead of the clear level sole on which the right-angled slice cut by the wheel-plough is laid over so as to rest upon its lower angle. This ribbing of the unstirred subsoil is exceedingly objectionable in all kinds of ploughing.

In the autumn ploughing of stubble-ground in preparation for the root-crops of the following season, a much deeper furrow is turned over than for a seed-furrow. In ordinary cases it should not be less than nine inches, while in very many, if ten or twelve can be attained, so much the better. In all deep soils this bringing up and mixing with the surface of fresh material from below is highly beneficial. It must not, however, be practised indiscriminately. Siliceous and peaty soils need compactness, and to have the soil that has been artificially enriched kept a-top. For such deep work as we have noticed above, three or even four horses are frequently yoked to the plough. When a field slopes considerably one way, it is good practice to work the plough down the slope only, and return without a furrow. A pair of horses working in this way will turn as deep a furrow, and get over as much ground, as three will do taking a furrow both ways, and with less fatigue to themselves and to the ploughman. After bringing a heavy furrow downhill, they get recruited in stepping briskly back with only the plough to draw. This mode of ploughing one furrow *down* the slope tends less to gather the soil toward the bottom than by using a turn-wrest plough *across* the slope. It is while giving this deep autumn furrow that the subsoil plough is used. It follows in the wake of the common plough, and breaks and stirs the subsoil, but without raising it to the surface. This is a laborious operation, and engrosses too much of the horse-power of the farm to admit of large breadths being overtaken in any one season. In all indurated subsoils, however, it repays its cost; for when once thoroughly done, it diminishes the labour of ordinary ploughings for several succeeding rotations, aids the drainage, and adds to the fertility of the soil. It is in the performance of this deep autumn tillage and breaking up of the subsoil, that the steam-engine, with appropriate tackle, has begun to play an important part, and for which it will probably one day supersede all other means.

Section 2.—Harrowing, &c.

The harrow, cultivator, and roller, are all more simple in their action and more easily managed than the plough. Harrowing is most effective when the horses step briskly along. The tines are then not merely drawn through the soil, but, in their combined swinging and forward movement, *strike* into it with considerable force. It is with reference to this that a single application of this implement is called a *stroke* of the harrows. Rollers are used to aid in pulverising and cleaning the soil, by bruising clods and lumps of tangled roots and earth which the other implements have brought a-top; in smoothing the surface for the reception of small seeds, or the better operation of the scythe and other implements; and for consolidating soil that is too loose in its texture. Except for the latter purpose, light rollers are much superior to heavy ones. When it is wanted, for example, to bruise clots of quickens, that the after harrowing may more thoroughly free the roots from the adhering earth, a light cast-iron roller, say of 5 cwt., drawn by one horse, effects this purpose as thoroughly as one double the weight drawn by a pair,—and does it, moreover, in much less time, at less than half the expense, and without injuriously consolidating the free soil. These light rollers are conveniently worked in pairs, the ploughman driving one horse and leading the other. With a pair of active horses, and such rollers, a good deal more than *double* the space can be rolled in a day, than by yoking them both to one heavy one of the same length of cylinder. For mere clod-crushing, provided the clods are moist, the Norwegian harrow is superior to any roller; and for compressing a loose surface or checking wire-worm, serrated or smooth-edged discs, such as Crosskill's or Cambridge's, are better than smooth cylinders of the same weight, so that the heavy smooth roller, requiring two or more horses to draw it, is superseded by better implements for all purposes where rollers are used at all, unless it be for the rolling of the grass-lands.

As a general rule, none of these tillage operations can be performed to advantage when the soil is wet. When rain falls inopportunely there is a strong temptation to push on the field operations, before the soil has recovered the proper state of dryness. When this is done the farmer almost invariably finds in the issue that the more haste he makes the worse he speeds. Soils with a good deal of clay in their composition are peculiarly susceptible of injury in this way. Nice discrimination is needed to handle them aright. They require, moreover, a full stock of well-conditioned horses, that the work may be pushed rapidly through in favourable weather. To manage such soils successfully, especially when root crops are grown, tries the skill of the farmer to the utmost. So at least it has hitherto been; but with steam-power to aid him, there is now a probability that the clay land farmer, by being able to break up his soil without treading it, and to get through with a large extent of tillage when his land is in trim for it, may find it practicable to grow root crops on equal terms with the occupier of freer soil.

Section 3.—Fallowing.

When, by such operations as have now been described, land has been reclaimed from its natural state, and rendered fit for the purposes of the husbandman, it is everywhere so charged with the germs of weeds, most of which possess in a remarkable degree the power of reproduction and multiplication, that it is only by the most incessant and vigorous efforts he can restrain them from encroaching upon his cultivated crops, and regaining entire possession of the soil. He can do much towards this by ordinary tillage, and by sowing his crops in rows, and hoeing in the intervals during the early stages of their growth. But if his efforts are restricted to such measures only, the battle will soon go against him. Besides this, all arable soils in which clay predominates, particularly when undrained, have such a determined tendency to become compact and soured, that under ordinary efforts they fail to yield a genial seed-bed. There is a necessity, therefore, for having recourse, from time to time, to that ameliorating process of lengthened tillage called fallowing. This process begins in autumn, immediately after the removal from the ground of the cereal crop, which had been sown upon the land newly broken up from clover lea or natural sward, and extends either to the time for sowing turnips and analogous crops in the following spring, or is continued during the entire summer in preparation for autumn-sown wheat. We shall first describe that modification of the fallowing process by which the soil is prepared for the sowing of drilled green crops, and then the more prolonged form of it usually called *summer* or *naked* fallow.

Green Crop Fallow.

The object aimed at being the thorough disintegration and cleaning of the soil, the usual practice is to begin by ploughing as deeply as is found practicable. This first or autumn furrow is accordingly turned over to a depth of 8 or 9 inches; or by using a stronger plough drawn by three or four horses, it is carried to 12 inches in depth; and in some cases, by following with a subsoil plough in the wake of the common one, the soil is stirred to the depth of 14 or 16 inches. All cultivators are agreed as to the importance of thus deeply and effectually disintegrating all soils that are naturally dry or thoroughly drained. In the case of undrained lands, and even of very unctuous clays, although well drained, such deep stirring of the soil in autumn does but increase its capacity of retaining the rains of winter, and of being thereby more effectually soured, and is therefore to be avoided. Assuming, however, that we have to do with soil thoroughly drained and moderately friable, it is undoubtedly beneficial to loosen it deeply and thoroughly at this stage. But before this deep ploughing is set about, it will be worth while to consider well its bearing upon the cleaning part of the process. On carefully examining the fields at the time of reaping the grain-crops, and from week to week thereafter, the roots of the couch grass are found at first lying close to the surface; but instantly, on their getting the ground to themselves, they begin to send out fresh fibres, and to push their shoots deeply into the soil. In these circumstances, to proceed at once, according to the customary practice, to plough deeply, allows these weeds much time to increase, while this laborious and tedious operation is going on; and although, when performed, it gives some present check to their progress, by burying them under a mass of loosened soil, it not only increases the difficulty of their after removal, but places them out of the reach of frost, and in the best possible position for pervading the entire soil, on the first recurrence of mild weather. The consequence is, that fallows so treated are invariably found in spring more fully stocked with quickens than they were at the time of the autumn ploughing. The observation of this suggested the practice, now very common in England, of *cleaning fallows in autumn before giving the first deep furrow.* For this purpose, such implements as Biddle's scarifier, the broad-share paring-ploughs, or better still, the common plough, divested of its mould-board and fitted with a share a foot broad, are set to work as fast as the grain-crops are reaped, and the whole surface is rapidly pared at a depth of three or four inches. This completely loosens the yet shallow-lying roots of the couch-grass, which are then freed from the adhering earth by the Norwegian and chain-harrow, raked together and burned, or carted off. This pulverising of the surface soil in early autumn is usually followed by the springing up of an abundant crop of annual weeds and of shaken grain, which are thus got rid of by the subsequent ploughing. So great and manifold are the advantages of this modern practice, that in those districts where it is most in use, other autumn work, even wheat-sowing, is comparatively neglected until it is accomplished. When the weeds have been got rid of in this summary and inexpensive manner, deep ploughing is then resorted to with unalloyed benefit. Whenever steam-power becomes fully available for tillage operations, this autumn cleaning and deep stirring of fallows will be accomplished rapidly and effectually, and the teams will meanwhile be set at liberty for root-storing, wheat-sowing, and other needful work, which can be well done only when accomplished during the brief season of good weather, which usually intervenes betwixt the close of harvest and beginning of winter.

In the case of farms that have for a lengthened period been carefully cultivated, the stubble may be found so clean as not to require the whole area to be scarified in the manner now described. Instead of this, it may suffice to have the ground carefully examined, and such patches or stray plants of couch-grass, or other perennial weeds, as are met with, forked out. By this means the fallows are kept clean at little expense, and when spring arrives, those repeated ploughings, and other tedious and costly operations, are wholly avoided, in performing which the condition of the soil is marred and the best seed-time often missed. When fallows are thus cleaned in autumn, it is highly advantageous to cart on to them at once, and cover in with a deep furrow, all the farm-yard dung that is on hand up to the completion of their first ploughing. From the length of time which must elapse before the land can again be touched, it is quite safe, or rather it is highly advantageous, to apply all the recently made dung, although in a very rough state. In doing this, it is necessary that a person precede each plough, and trim the rank litter into the previous furrow, that it may be properly covered up and regularly distributed. Unless this precaution is observed, the ploughs are constantly choked and impeded, the manure is drawn together into unsightly hassocks, and the whole operation is imperfectly performed. The recommendations to this practice are—*First*, An important saving of labour; for the manure being carted direct from the yards, &c., on to the land, and evenly spread over it, there is no forming, covering up, and turning of dunghills, or refilling and carting in spring. This heavy work is accomplished at a season when time is less pressing than in spring, and the sowing of the crop can be proceeded with more rapidly when the time for it arrives, and while weather favours. *Second*, There is a saving of manure by burying it at once in its rough state, instead of first fermenting it in large heaps; and a large portion of the fallow-break can thus be dressed with home-made manure. *Third*, The rough dung thus ploughed in decomposes slowly, its virtues are absorbed and retained by the soil, with the whole mass of which it is thoroughly incorporated by the spring tillage, and which, in consequence, is found, after such treatment, in a peculiarly mellow and favourable condition for receiving the seed

The advantages of autumn cleaning and manuring of land in preparation for green crops are so great that the utmost exertions should be made to secure them. Over a large portion of England the harvest is usually so early as to leave ample time for accomplishing the cleaning process before being arrested by bad weather. From the later harvest season and more humid climate of Scotland, it is there more difficult to carry it out to the whole extent of the fallow-break; but still, with promptitude and energy, much can be done. One of her shrewd and intelligent sons, Mr Tennant, the inventor of the grubber which bears his name, has, however, introduced a system of autumn tillage, founded upon the same principle, and accomplishing virtually the same end, but less expensive and better adapted to the climate of Scotland than that just described. So soon as the grain crops are harvested, Mr Tennant sets his light grubbers agoing, and by working them over the whole field several times and in opposite directions, stirs the whole surface soil to the depth of six or eight inches, tears up and brings to the surface all root-weeds, where, after being knocked about and freed from adhering soil by repeated harrowings and a final grubbing, they are left for the winter. In our own practice we have latterly improved, as we imagine, on Mr Tennant's plan by broadsharing the land before using the grubbers, and also by employing the Norwegian harrow instead of the common one. The broadsharing ensures that the whole of the couch-grass and other weeds are thoroughly loosened without being buried, and the Norwegian harrow shakes out the roots from the adhering earth better than the common harrow. When it is intended to treat a field in this way, care should be taken at harvest time to reap the crop as close to the ground as possible, as rank stubble seriously encumbers the tillage implements. In setting about the grubbing of a field it is expedient also to begin with the headlands, and to work them thoroughly all round twice over, before they are trodden down by the frequent turning of the horses upon them. If this is omitted it will be found nearly impossible to have the margins of the field as well cultivated as the rest of it. A field thus treated presents for a time a singularly untidy and unpromising appearance; but the ultimate effects of the practice, as well in the cleaning as the disintegrating of the soil, are very remarkable. When roots of couch-grass, &c., are freed from the soil, and fully exposed to the vicissitudes of the weather at a season when their vital force is at the lowest point, they are unable to resist its effects, and gradually die. If placed in similar circumstances in spring, with their vital energy in full play, the merest point of a root embedded in, or even in contact with, pulverised soil, enables them to push down fresh fibres, to re-establish their connection with the soil, and to grow as lustily as ever. But so completely is the destruction of these pests secured by this simple process of winter exposure, that on the return of spring they may be ploughed in with impunity. Mr Tennant assures us, that ever since he adopted this practice he has been enabled to dispense with the removal of these weeds. Having had an opportunity of inspecting his farm, we are enabled to testify to its cleanness and high state of fertility. On this plan, then, the cleaning of fallows is accomplished by tillage operations alone, without any outlay for raking or hand-picking, burning, or carting off. Nor is this done at the expense of the pulverising part of the process. On the contrary, Mr Tennant asserts, and we have so far verified his assertion by actual experiment, that by dis integrating the soil in autumn, as is done by this broadsharing, grubbing, and harrowing, it receives far more benefit from the alternation of frost and thaw, rain and drought, than when merely ploughed and left lying during winter in compact furrow-slices. This plan affords the same facilities as the other for autumn manuring, if the weeds are raked off at once from so much of the fallow-break as it is wished to manure before winter. When the remainder is ploughed in April following, more of it may then have the farm-yard dung applied to it in the same way. Agriculturists owe a large debt of gratitude to Mr Tennant for the invention of his beautifully simple and efficient grubber, and for this scientific application of it to the fallowing process. Those who have been pursuing this system of tillage will be much interested in observing that it has been adopted by Mr Smith of Woolston, who is carrying it out to perfection by means of his steam-drawn implements.

The autumn tillage of the fallows having been accomplished in one or other of the ways described, the land is left untouched till the return of spring. If it is infested by annual weeds, it is expedient, as soon as it is dry enough to bear treading with impunity, to level and stir the surface by a turn of the harrows. This slight moving of the mellowed surface-soil induces the seeds of weeds to germinate more quickly than they would otherwise do, and thus a crop of them is got rid of by the next tilling. This preliminary harrowing is useful also in affording a level course for the tillage implements. By the time that the labour connected with the sowing of spring crops is over, the fallows are usually dry enough to be stirred with safety. This point, must, however, be well seen to, as irreparable mischief is often done by going upon them too soon. And now it is, that, instead of rigidly following any customary routine of so many ploughings, harrowings, and rollings, the skilful cultivator will regulate his procedure by the actual circumstances of his soil, and the object which he has in view. What is needed for the successful growth of drilled green crops is to have the soil free from weeds, thoroughly disintegrated to the depth of six or eight inches, and yet moist enough to ensure the ready germination of seeds deposited in it. Where such autumn cleaning and manuring as we have described have been successfully carried out, all that is needed, in order to obtain a proper tilth, is to go to work with light grubbers, first in the line of the previous furrows and then across them, and then to harrow, roll, and remove any weeds that have been missed in autumn, after which the soil will be in the best possible condition for drilling. On friable soils, this method of performing the spring tillage by means of the grubber instead of the plough is perfectly practicable, and has manifold advantages to recommend it. The saving of labour is very great, as a man and pair of horses will more easily grub four acres than plough one acre. Weeds are more easily removed, as the grubber pulls them out unbroken, whereas the plough cuts them in pieces. The soil that has been all winter subjected to the mellowing influences of the weather, and which, in consequence, is in the best possible condition to yield a genial seed-bed, is retained a-top, whereas ploughing buries it and brings up clods in its stead. And, lastly, the soil being merely stirred, without having its surface reversed, its natural moisture (or *winter sap*) is retained, whereby the germinating of seeds sown in it becomes almost a certainty. The importance of this last point in the cultivation of such crops as the turnip, whose seeds must usually be sown during hot and dry weather, can scarcely be overrated. This practice is peculiarly appropriate for soils of loose texture, which are invariably injured by repeated ploughings. But it is also resorted to successfully on soils of the opposite extreme. Many farmers in the Lothians now grow abundant and extensive crops of turnips on strong clay soils by spreading liberal dressing of dung on the stubble in autumn, ploughing it in with a deep furrow, leaving the land untouched until sowing-time has fully arrived, and then stirring the mellowed surface soil by the grubbers, removing weeds, and drilling and sowing at once without any ploughing. When this system is adopted on tenacious soils, it is prudent to operate upon portions of the field in detail, taking in only so much at a time as can be grubbed and drilled the same day; for if rain should intervene betwixt the grubbing and the drilling, the soil would set like mortar and the tide be lost. When once the ridgelets are made up in good condition, they can withstand a fall of rain with comparative impunity; and hence the occurrence of a course of fine weather, when the season is yet too early for sowing, is sometimes taken advantage of by preparing the land and making it up into ridgelets, although it should require to remain in this state weeks, or even months, before sowing takes place. In such a case, immediately before sowing, the ridgelets are first partially levelled by harrowing length-wise, in order to loosen the soil and destroy annual weeds, and then again made up by using a double-breasted plough. We must here, however, insist upon the importance of having the grubbing thoroughly performed, which it cannot be unless the tines penetrate the soil as deeply as the plough has done at the autumn ploughing. It is owing to the neglect of this that the system has failed in the hands of many farmers, who first mismanage the operation, and then throw the blame upon the grubbers. To ensure success, the implement must be set so as to work at its full depth, sufficient motive power being applied by yoking three horses, if necessary, to each grubber at the first and also at the second going over, and there must be vigilant superintendence exercised lest the ploughman do the work slightly. It is sometimes objected to this system of spring tillage, that it fails to rid the land of thistles and other tap-rooted weeds; but it is surely easier to fork these out as they appear, than to plough a whole field merely to destroy as many thistles as a man, it may be, would dig up in a day. By taking advantage of the tilth obtained by the action of the elements, instead of first ploughing down the mellowed surface, and then attempting laboriously to reduce the obdurate furrows by mechanical means, skilful and energetic farmers now succeed in preparing even tenacious soils for drilled green-crops, at little expense, and with a good measure of certainty.

On these opposite classes of soils, then—the very loose, and the tenacious—spring tillage, in preparation for root-crops, is performed to better purpose by means of the grubber than the plough. Betwixt these extremes, however, lies the most valuable class of soils—the strong fertile loams—on which the heaviest crops and best quality of Swedes are grown. With these it is usually expedient to have recourse to at least one spring ploughing, as soon, but only as soon, as the soil is dry enough to crumble freely to the very bottom of the furrow. As this usually occurs from four to six weeks before the time of sowing the crop, it is advisable to plough the entire field, and leave it so until rain falls, when a moderate use of the grubber, harrows, and light roller, usually suffices to produce a good tilth for ridging. When operations are not thus facilitated by a seasonable fall of rain, it is necessary to proceed somewhat differently. The field is lying as it was left by the plough, with a rough dried surface. If harrowed while in this state, an abundant crop of clods is brought to the surface, which quickly harden when thus fully exposed to drought. To avoid this inconvenience, the field is *first* rolled with a heavy roller, and then grubbed across the direction in which it was last ploughed. By this means the clods, being partially crushed and pressed down amongst the loose earth, resist the grubber, and are crumbled by it, instead of being merely raked out and left entire on the surface, as would happen but for this preliminary rolling. The grubbers are followed closely by harrows and a light roller, and these again by the grubbers; but this time with *seven* tines on instead of five, after which a sufficient tilth is usually obtained. All this is on the supposition that the land is clean when these spring operations are commenced; for should it be otherwise, it is usually better to begin with the grubber on the stale winter furrow, and to get rid of the weeds, before using the plough. If it is found necessary to plough near to the time of sowing, then the harrow and roller must keep pace with the ploughs in order to retain moisture and prevent the formation of clods. The Norwegian harrow is the proper implement to use in such cases. Let it ever be borne in mind that if the soil is cleaned and sufficiently disintegrated, the less working it gets at this stage the better.

It may be well indeed to remind the reader that although the fallowing process can most conveniently be gone about during the period which intervenes betwixt the removal of a grain-crop from the ground and the sowing of the succeeding root-crop, and on this account is often spoken of in a loose way as being performed "in preparation for the root-crop," it is a fallacy to regard this laborious and costly process of tillage and cleaning as undertaken solely or mainly for the benefit of the turnip or other root-crop, then about to be sown. The other crops of the rotation benefit by it in a far greater degree, and it would be required on their account although turnips were not grown at all, as may be seen in the case of clay lands with their periodic naked fallows. It is the overlooking of this fact which has led people to charge the whole cost of this fallowing process, and of all the manure then applied to the land, against the turnip-crop, and then to represent this crop as the most costly one which the farmer grows,—one which often yields him less than it cost to produce it. Undoubtedly the cost of the fallow must be charged equally against all the crops of the rotation.

Summer or *Naked Fallow.*

Having thus described at length that modification of the fallowing process by which the soil is prepared for the sowing of green crops, we shall now, as proposed, speak of that prolonged form of it called a *summer* or *naked* fallow. From the facilities now afforded, by means of tile-draining and portable manures, for an extended culture of green crops, this laborious and costly process, which in its day was justly regarded as the very key to good and profitable farming, is now restricted to the more obdurate clay soils, or to cases where draining and other modern improvements are neglected. The manifold advantages of having abundant crops of turnips, or mangel-wurzel, instead of naked fallow, sometimes tempt the occupiers of clay soils to push the cultivation of these crops beyond due bounds. We know of cases where, after large expenditure in draining, the cultivation of turnips has been carried to such an extent, and conducted so injudiciously, that the land has got foul and soured, and its gross produce has been reduced below what it was while the land was undrained, and under a regular system of all but exclusive naked fallows. However thoroughly drained, clay soils retain their ticklish temper, and are so easily disconcerted by interference during unfavourable weather, that the preparing of them for the cultivation of root-crops, and still more the removing of these crops when grown, is at best a hazardous business, and requires to be conducted with peculiar tact. Judicious farmers, who know by experience the difficulties that have to be overcome in cultivating such soils, are of opinion that all that can yet be ventured upon with safety is to prolong the period of the naked fallow's recurrence, rather than entirely to dispense with it. After a series of alternate grain and cattle crops, it is accordingly still their practice to wind up with a summer fallow, by which they rectify unavoidable defects in the tillage of preceding years, and put their land in good humour for entering again upon a fresh course of cropping.

This process is begun by a deep ploughing in autumn, in performing which the land is gathered into ridges, that it may be kept as dry as possible during winter. When the more urgent labours of the following spring are so far disposed of as to afford leisure for it, a second ploughing is given to the fallow, usually by reversing the furrows of autumn. This is followed at intervals by two cross-ploughings, which are made to reverse each other, in order to keep the land level. As it is the nature of these soils to break into lumps, under the action of the plough, rather than to crumble down, the clods thus produced get so thoroughly parched in dry weather, that root-weeds enclosed in them are killed by sheer desiccation. To further this cheap mode of getting rid of them, the land is not rolled, but stirred by the grubber and harrow as frequently as possible, so as to expose the clods freely to the drought. We know by experience that fallows can be cleaned effectually by thus taking advantage of the tendency in clay soils to bake excessively under exposure to the hot dry weather which usually prevails in June and July. Should the season happen to be a showery one, this line of tactics must needs be abandoned, and recourse had to the judicious use of the grubber, Norwegian and common harrow, in order to free the weeds from the soil, and then clear them off by raking or hand-picking. This is more costly, and, as we believe, less beneficial to the soil than the simple method first noticed, which should therefore be attempted in the first place. As in hay-making, much can here be done in a few favourable days, by keeping grubbers and harrows at work, and turning the clods frequently. When farm-yard dung is to be applied to such fallows, it is desirable that it should be carted on and ploughed in before July expires. In applying it, two methods are followed. That usually adopted is, after marking off the ridges, to put down the dung in small heaps, at regular distances, and forthwith to spread it and plough it in. In the other, the land is formed into ridgelets, running diagonally across the intended line of the ridges, and the dung is enclosed in them in the manner to be hereafter described in treating of turnip culture. In either way, after the lapse of several weeks, the surface is levelled by harrowing, and the land is gathered into ridges by the last of this series of ploughings, hence called the seed-furrow. When lime is to be applied to such land, this is the stage of the rotation which is usually chosen for doing so. It is spread evenly over the surface, immediately before the last ploughing. In finishing off this fallowing process, it is necessary, on undrained lands, to be careful to clean out the ridge-furrows and cross-cuts, in anticipation of winter rains. But if such land is worth cultivating at all, it is surely worth draining, and this operation once thoroughly performed, puts an end to all further solicitude about furrows.

CHAPTER IX.

SUCCESSION OF CROPS.

Section 1.—Rotation necessary.

There are few agricultural facts more fully ascertained than this, that the growth, year after year, on the same soil, of one kind of plants, or family of plants, and the removal from it, either of the entire produce, or at least of the ripened seeds of such plants, rapidly impairs the general fertility of that soil, and, in particular cases, unfits it for bearing further crops of the kind by which it has been exhausted. The explanation of the causes of this phenomenon, belongs to the agricultural chemist or vegetable physiologist, to whom we willingly leave the task. What we have to do with is the fact itself, and its important bearing on agricultural practice. There is no natural tendency in the soil to deterioration. If at any time, therefore, the earth fails to yield its increase for the use of man, it is owing to his own ignorance and cupidity, and not to any defect in the beneficent arrangements of the Creator. The aim, then, of the agriculturist, and the test of his skill, is to obtain from his farm abundant crops at a remunerative cost, and without impairing its future productiveness. In order to this, two conditions are indispensable,—first, that the elements of fertility abstracted from the soil by the crops removed from it be duly and adequately restored; and, second, that it be kept free from weeds. The cereal grains, whose seeds constitute the staple food of the human family, are necessarily the most important and valuable of our ordinary crops. The stated removal from a farm of the grain produced on it, and its consumption elsewhere, is too severe a drain upon its productive powers to admit of these crops being grown every year on the whole, or greater part of it, without speedily impairing its fertility. Supposing, however, that this waste could be at once repaired by the annual return to the soil of manure equivalent in constituent elements to the produce removed, the length of time which grain-crops occupy the soil, and their habit of growth, interpose peculiar difficulties in the way of cleaning it thoroughly, either before they are sown, or while they occupy the ground. Again, although bread-corn is the most important product of our soil, other commodities, such as butcher-meat, dairy produce, vegetables, wool, and flax, are indispensably required. The economical culture of the soil demands the employment of animal power, which, to be profitably used, must be so distributed as to fill up the year. The maintenance of the working cattle, and of other live stock, implies the stated culture of a large amount of herbage and forage. Now, these varied conditions are duly met by cultivating grain and cattle crops alternately, and in about equal proportions. In carrying out these general principles, much discrimination is required in selecting the particular plants best adapted to the soil, climate, and other circumstances, of each farm, and in arranging them in the most profitable sequences; for not only is it necessary duly to alternate grain and green crops, but, in general, there is a necessity, or at least a high expediency, in so varying the species or varieties of the latter class as to prolong, as much as possible, the periodic recurrence of any one of them on the same field. In settling upon a scheme of cropping for any particular farm, regard must be had to its capabilities, to the markets available for the disposal of its products, and to the command of manure. When these things have been maturely considered, it is always beneficial to conduct the cropping of a farm upon a settled scheme. The number of men and horses required to work it is regulated chiefly by the extent of the fallow-break, which it is therefore desirable to keep as near to an average annual breadth as possible. When the lands of a farm vary much—as regards fertility, fitness for particular crops, and proximity to the homestead,—they must be so apportioned as to make the divisions alloted to each class of crops as equal as possible in all respects, taking one year with another. Unless this is done, those fluctuations in the gross produce of farms which arise from varying seasons are needlessly, it may happen ruinously, aggravated; or such an accumulation of labour is thrown on certain years which may prove unfavourable ones as to weather, that the work is neither done well nor in due season.

No better rotation has yet been devised for friable soils of fair quality than the well-known four-field or Norfolk system. By this course half the arable lands are in grain-crops, and half in cattle-crops, annually. It is indeed true that, in the way in which this course has hitherto been usually worked, both turnips and clover have recurred so frequently (every fourth year) on the same fields, that they have become subject to disease, and their produce excessively precarious. But the excellence of this course is, that its main features can be retained, and yet endless variation be introduced in its details. For example, instead of a rigid one-fourth of the land being each year under turnips, barley, clover, and wheat or oats, respectively, half only of the barley division is frequently in practice now sown with clover seeds, and the other half cropped in the following year with beans, peas, potatoes, or vetches. On the same set of fields, coming round again to the same point, the treatment is reversed by the beans, &c., and clover, being made to change places. An interval of *eight* years is thus substituted for one of *four*, so far as these two crops are concerned. Italian rye-grass, unmixed with any other plant, is now frequently taken in lieu of clover on part of the division usually allocated to it, and proves a grateful change both to the land and to the animals which consume it. In like manner, instead of sowing turnips unvaryingly every fourth year on each field, a portion of the annual division allotted to this crop can advantageously be cropped with mangel-wurzel, carrots, or cabbages, care being taken to change the site occupied by each when the same fields again come in turn. The same end is even so far gained by alternating Swedish with yellow or globe turnips. It is also found expedient, either systematically or occasionally, to sow a field with clover and pasture grasses immediately after turnips, without a grain crop, and to allow it to remain in pasture for four years. A corresponding extent of the other land is meanwhile kept in tillage, and two grain crops in succession are taken on a requisite portion to equalise the main divisions, both as respects amount of labour and the different staple products. A closer cover of grasses and a better pasture is obtained in this way than by first taking the customary grain crop after turnips; the land is rested and invigorated for future tillage, the outlay on clover and grass-seeds somewhat diminished, and the land better managed for the interests of all concerned than by a rigid adherence to the customary rotation.

Section 2.—Restrictive Clauses in Leases Hurtful.

It is common enough for landlords, or their agents, to tie down the tenantry over large estates to the rigid observance of some pet rotation of their own. In an unimproved state of agriculture, and for a tenantry deficient both in capital and intelligence, such trammels, kindly enforced, may be as beneficial to them as to their landlord. But when the culture of the soil is undertaken by men of good education, who bring to the business ample capital, and skill to use it to the best advantage, such restrictions are much more likely to do harm than good to both parties. It is to be observed in regard to those restrictive clauses usually inserted in farm-leases,—such as, that two grain-crops shall never be taken in immediate succession; that no hay, straw, or turnips, shall be sold from the farm; that only certain limited quantities of potatoes or flax shall be grown; that land shall be two or more years in grass, &c.,—that they all proceed on the supposition that the farm is to maintain its own fertility. They obviously do not contemplate the stated purchase of large quantities of guano, bones, and similar extraneous manures, or the consumption by live stock of linseed-cake, grain, or other auxiliaries to the green crops produced on the farm. Now, not only are such clauses incompatible with such a system of farming as we have just now indicated, but their direct tendency, if enforced, is to hinder a tenant from adopting it even when disposed to do so. We hear now-a-days of tenants who are annual purchasers of these extraneous fertilising substances to the extent of 20s. to 30s. worth for every acre occupied by them. To enforce the same restriction on such men as on others who buy none at all is obviously neither just nor politic; and we believe that any practical farmer, if he had his choice, would rather be the successor of a liberal manurer, however he may have cropped, than of one who has farmed by rule on the starving system. We are quite aware that, in regard to the first-mentioned of these restrictions (viz., that which forbids taking two grain-crops in immediate succession), the contrary practice is still asserted by agricultural authorities to be necessarily bad farming. Now, we do not concur with this opinion, but believe, on the contrary, that when land is kept clean, and is as highly manured and well tilled as it must be to grow cattle-crops in perfection, the second successive crop of grain will usually be better than the first, its production nowise injurious to the land, and the practice, *in such circumstances*, not only not faulty, but an evidence of the skill and good management of the farmer. A frequent encomium applied to a particularly well-cultivated farm is, that "it is like a garden." The practice of market-gardeners is also frequently referred to as a model for farmers. Now, the point with them is to have every inch of their ground under crop of some kind at all seasons, and to carry everything to market. Under such incessant cropping, the fertility of the soil is maintained only by ample manuring and constant tillage. By these means, however, it is maintained, and the practice is extolled as the perfection of management. Such a system must therefore be as true in farming as in gardening, when the like conditions are observed. Undoubtedly he is a good farmer, who, while keeping his land clean and in good heart, obtains the greatest produce from it at the least proportionate outlay; and it is no valid objection to his practice merely to say that he is violating orthodox rotations.

Section 3.—Experiments at Rothamstead and Lois Weedon.

Some curious information has been obtained regarding the effects of growing successive crops of one kind of plant on the same field, from two examples of it that attracted much attention. We refer to the experiments of Mr Lawes at Rothamstead, and of the Rev. Mr Smith at Lois Weedon. It is well known that Mr Lawes for a number of years devoted a considerable extent of land to the prosecution of a series of interesting experiments, one field being allotted to experiments with wheat, another to turnips, and another to beans. One acre in the wheat-field bore upwards of twenty successive crops of wheat without any manure whatever. The land was annually scarified and thoroughly cleaned as soon as the crop was removed; it was then ploughed and again drilled with wheat, which was duly hoed in spring. Now, with occasional variation, due to the character of particular seasons, Mr Lawes found that the average annual produce of this acre was 16 bushels of grain and 16 cwt. of straw, below which he failed to reduce it by these successive crops. His soil was a strong clay loam, resting at a depth of five or six feet upon chalk. In the case of turnips, he found that, when treated in the same way, they cease after a few years to grow larger than radishes, nor could he, by the application of any amount or variety of manure which he tried, obtain a second successive crop equal to the first. With the wheat, on the contrary, the addition of four cwt. of Peruvian guano at once doubled the produce. Mr Smith's experiments, as is well known, were a revival of Jethro Tull's system of growing wheat continually on the same field, by a plan of alternate strips of wheat and bare fallow, made to change places annually. He improved in so far upon Tull's practice, inasmuch as he thoroughly drained his land, and his fallow spaces were deeply trenched every autumn, as well as ploughed and hoed during the growing season. The result was that his land thus treated yielded an average annual produce of 34 bushels per acre for eleven or twelve successive crops. Now, it is not our intention to offer any opinion on this as a system of wheat growing. We refer to it along with Mr Lawes's, for the purpose of showing that, notwithstanding the prevalent opinion that grain-crops exhaust the fertility of soils more rapidly than green crops, this is true only in a very restricted sense. Green crops judiciously interposed do undoubtedly serve a most important purpose in the means which they furnish for maintaining the fertility of a farm; but it is worthy of note, that whereas, by the addition of suitable manure, thorough tillage, and diligent removal of weeds, clay soil at least will stand an indefinite succession of grain crops, the same means entirely fail to yield the same results with our most popular green crops. Our personal experience quite accords with this; for we suppose it will be admitted that the corn crops of the country are at the present day superior, both in quality and quantity, to those of any preceding period; whereas potatoes, turnips, and clover, which we have so long regarded as our sheet-anchor, have become increasingly precarious, and threaten to fail us altogether. We offer these facts for the consideration of those who out-and-out condemn the practice of sowing two white crops in immediate succession. In stating this opinion, we must, however, guard against misapprehension. Unless the land is highly manured and kept thoroughly clean, we are just as much opposed to the practice as any one can be; but when mischief is done by it, we believe that it is due rather to the presence of weeds than to the second grain-crop. Neither do we plead for the absolute removal of restrictive clauses from farm leases. Human nature being what it is, men who do not see it to be for their own advantage to farm well, will, through ignorance or greed, impoverish their land unless they are restrained. Clauses as to cropping should, however, be prohibitory rather than prescriptive—have reference rather to what is removed from the farm than to what is grown upon it—and they should be contingent upon the other practices of the tenant. So long as he continues, by ample manuring and careful tillage, to maintain the fertility and general good condition of the farm rented by him, it can be no advantage to his landlord to hinder him from cropping it at his own discretion. It will be seen from these remarks, that we attach more importance to those general principles which should regulate the succession of crops, than to the laying down of formulæ to meet supposed cases. The man who cultivates by mere routine is unprepared for emergencies, and is sure to lag in the race of improvement; while he who studies principles is still guided by them, while altering his practice to suit changing circumstances.

CHAPTER X.

MANURES.

Section 1.—Farm-yard Dung.

In our remarks on tillage operations and on the succession of crops, we have seen how much the practice of the husbandman is modified by the kinds and amount of manures at his disposal. In describing the crops of the farm and their culture, frequent reference will also necessarily be made to the use of various fertilising substances; and we shall, therefore, before proceeding to that department of our subject, enumerate and briefly remark on the most important of them. In such an enumeration, the first notice is unquestionably due to farm-yard dung.

This consists of the excrements of cattle, their litter, and the refuse of their fodder; usually first trodden down in successive layers, and partially fermented in the farm-yard, and then removed to some convenient place and thrown together in heaps, where, by further fermentation and decay, it is reduced to a dark-coloured, moist, homogeneous mass, in which state it is usually applied to the land. It is thus the residuum of the whole products of the farm, *minus* the exported grain, and that portion of the other crops which, being first assimilated in the bodies of the live stock, is sold in the form of butcher-meat, dairy-produce, or wool. In applying farm-yard dung to land there is thus a returning to it of what it had previously produced, *less* the above exceptions, and such waste as may occur during the process of decay by gaseous exhalation or liquid drainage. It is obvious that the value of such dung as a fertilising agent must depend much on two circumstances, viz., 1*st*, The nature of the food consumed by the animals whose excrements are mingled with it; and, 2*d*, The success with which waste from drainage and exhalation has been prevented. When cattle used during the winter months to be barely kept alive on straw and water, and were confined in an open yard, which, in addition to its own share of rain, received also the drip from the eaves of the surrounding buildings—which, after percolating the litter, flowed unchecked into the neighbouring ditch—it is needless to say that the dung resulting from such a process was all but worthless. It is much to be regretted that, from the faulty construction of farm-buildings, farmers still find it impossible to guard their dung-stores from injury and waste. When cattle-yards are slightly hollowed towards their centre, and the surrounding eaves are spouted, the litter absorbs the whole of the urine and the rain which falls upon the uncovered area, while the treading of the cattle goes far to prevent undue fermentation and escape of gases. The same remark applies still more strongly to covered boxes, the dung resulting from this mode of housing fattening cattle being of the best quality. In the case of byres and stables it is certainly desirable to have a covered depôt, into which the litter and solid excrements may be wheeled daily, and to have the urine conveyed by proper drains and distributed over this mass of solid matter. As there is usually more liquid than these can at once absorb, it is well to have a tank at the lowest part of this depôt in which to store the surplus, that it may from time to time be returned upon the adjoining mass, or conveyed to heaps in the fields. Advantage is usually taken of frosty weather to cart out to the fallow division of the farm the dung that has accumulated in yards and boxes. It is formed into large square heaps about four feet deep, in situations most convenient for ready application to the land when the season for sowing the crops arrives. It is desirable to prepare a site for these heaps by carting together and spreading down a quantity of earth (or peat, when that can be got), for the purpose of absorbing the ooze from the fermenting mass laid upon it. At the beginning of winter, the loaded dung-carts are driven on to the heaps, and their contents are spread evenly over it, layer above layer, both to equalise the quality of the dung-heap as a whole, and, by the compression thus applied, to prevent a too rapid fermentation. When the heap has attained the requisite bulk, a covering of earth or peat is spread over it to keep it moist and to prevent the escape of its ammonia. When this home-made manure was the only kind statedly at the command of the farmer, it was considered necessary, and we believe truly, to have it in an advanced state of decomposition before applying it to a turnip crop. There was a waste of manure by this practice, but unless it was in a state to supply instant nourishment and stimulus to the young turnip plants, the crop was certain to be a deficient one. The application, along with farm-yard dung, of guano, superphosphate of lime, and other portable manures, quite does away with the necessity of having the former much rotted. These concentrated manures stimulate the growth of the plants during their early stage, and put them in the best condition for making gradual use of the slowly dissolving dung. Excessive decomposition of farm-yard dung is now therefore avoided, and pains rather bestowed to improve its quality by protecting it from the weather, and retaining its ammonia and natural juice. The cheapest, and perhaps also the best, way of doing this is to cart the dung direct from the cattle-yard to the fields, and at once to plough it in.

Section 2.—Liquid Manures.

We have spoken of the importance of carefully retaining the urine of the housed live stock, by having it absorbed in the solid matter of the dung-heap, and of collecting the surplus into a suitable tank, where it may be available for moistening the heap from time to time, and especially when about to be applied to the land. A system has, however, lately attracted much notice, by which pains are taken not only to preserve every drop of urine and ooze from dung-heaps, but, as far as practicable, to apply the whole manure produced on the farm in a liquid form. It is in Ayrshire, and especially on the farm of Myremill, that this system has been carried out most fully. Our reference will be best explained by quoting at length from the *Minutes of Information* issued by the General Board of Health regarding sewage manure.

"The next farm visited was in the immediate vicinity of Glasgow, where the supply of liquid manure is derived from another source, and distributed in a different manner. The supply is from a dairy of 700 cows, attached to a large distillery; the entire drainage from the former flows in a full continuous stream into a tank containing 30,000 or 40,000 gallons, whence it is pumped up immediately by a 12-horse power engine, and forced through 4-inch iron pipes, laid about 18 inches under ground, into large vats or cisterns placed on the highest points of the land to be irrigated. From these it descends by gravitation through another system of pipes laid along the ridges of the hills, finding an outlet through stand-cocks placed at intervals, from which it is distributed through movable iron pipes fitting into each other, and laid along the surface in whatever direction the supply is required. The land thus irrigated consists of three farms lying at some distance apart, the farthest point to which the liquid is conveyed being about two miles, and the highest elevation 80 feet above the site of the tank and engine. The principal use to which the irrigation has been applied has been to preserve the fertility of the pastures, the general appearance of which was at first rather disappointing, but this was explained by the fact that they are fully stocked, and that the cows rush with avidity to those parts that have been last irrigated, and eat them down quite bare. As is the case in other instances, however, by far the most profitable application has been found to be Italian rye-grass, of which 15 (Scotch) acres were under cultivation, some with seed supplied by Mr Dickinson, whose successful cultivation of it by similar means near London has long been known. The first cutting of this had yielded about ten tons the acre, the second nine, and the third, which was ready for cutting, was estimated at eight or nine more. Some crops of turnips and cabbages were pointed out to us in a state of vigorous growth, and with more than common promise of abundance; these were raised by a dressing of ashes and refuse (of little fertilising value, having been purchased at 2s. 6d. a ton), conjoined with four doses of liquid, one after the preceding crop of oats had been carried, one prior to sowing, and two more at different stages of growth. The enterprising gentleman who has carried out these works at his own expense, and in spite of the discouragement arising from partial failure in his earlier attempts, though speaking cautiously, as was natural in a tenant on a nineteen years' lease, of the pecuniary results of this undertaking, imparted some facts which leave little doubt that it must have been largely remunerative. Besides maintaining, if not increasing, the fertility of the pastures, to which the solid manure from the byres was formerly devoted, at a heavy expense of cartage (the whole of which is now saved), he is enabled to sell all this manure, of which we estimated the quantity at about 3000 tons a year, at 6s. a load. For a good deal of the Italian rye-grass not required for his own consumption, he obtained upwards of 13s. a ton, the profit on which, taking into account the yield before stated, may easily be imagined. Thirteen carts, each containing six barrels of ten gallons each, are used to convey the milk to market, where it is sold at 5d. the Scotch pint, equal to six pints imperial measure. The income from milk would, therefore, be not less than £43, 6s. 8d. per day, or £15,816, 13s. 4d. per annum.

"The next place visited was the farm of Myremill, near Maybole, in Ayrshire, the property of Mr Kennedy, who adopted and improved on the method of distribution just described. On this farm, about 400 imperial acres of which are laid down with pipes, some of the solid as well as the liquid manure has been applied by these means, guano and superphosphate of lime having been thus transmitted in solution, whereby their value is considerably enchanced. This is especially the case with guano, the use of which is thus rendered in great measure independent of the uncertainties of climate, and it is made capable of being applied with equal advantage in dry as in wet weather. In some respects the farm labours under peculiar disadvantages, as water for the purpose of diluting the liquid has to be raised from a depth of 70 feet and from a distance of more than 400 yards from the tanks where it is mixed with the drainage from the byres. These tanks are four in number, of the following dimensions respectively :—48 × 14 × 12; 48 × 14 × 15; 72 × 14 × 12; 72 × 17 × 12. They have each a separate communication with the well from which their contents are pumped up; which are used in different degrees of 'ripeness,' a certain amount of fermentation induced by the addition of rape-dust being considered desirable. The liquid is diluted, according to circumstances, with three or four times its bulk of water, and delivered at the rate of about 4000 gallons an hour, that being the usual proportion to an acre. The quantity to be applied is determined by a float-gauge in the tank, which warns the engineer, whose business it is to watch it, when to cut off the supply, and this is a signal to the man distributing it in the field to add another length of hose, and to commence manuring a fresh portion of land. The pumps are worked by a 12-horse power steam-engine, which performs all the usual work on the farm, thrashing, cutting chaff and turnips, crushing oil-cake, grinding, &c., and pumping. The pipes are of iron; mains, submains, and service pipes, five, three, and two inches in diameter respectively, laid eighteen inches or two feet below the surface. At certain points are hydrants to which gutta-percha hose is attached in lengths of twenty yards, at the end of which is a sharp nozzle with an orifice ranging from one to one and a half inch, according to the pressure laid on, from which the liquid makes its exit with a jet of from twelve to fifteen yards. All the labour required is that of a man and a boy to adjust the hose and direct the distribution of the manure, and eight or ten acres may thus be watered in a day. There are now 70 acres of Italian rye-grass and 130 of root crops on the farm. The quantity they would deliver by a jet from a pump worked by a 12-horsepower steam-engine would be 40,000 gallons, or 178 tons, per diem, and the expense per ton about 2d., but a double set of men would reduce the cost. The extreme length of pipe is three quarters of a mile, and with the hose the total extent of delivery is about 1,900,000 yards, or 400 acres. To deliver the same quantity per diem by water-carts, to the same extreme distance, would be impracticable. One field of rye-grass, sown in April, had been cut once, fed off twice with sheep, and was ready (August 20th) to be fed off again. In another, after yielding four cuttings within the year, each estimated at 9 or 10 tons per acre, the value of the aftermath for the keep of sheep was stated at 25s. an acre. Of the turnips, one lot of swedes, dressed with 10 tons of solid farm manure, and about 2000 gallons of the liquid, having six bushels of dissolved bones along with it, was ready for hoeing 10 or 12 days earlier than another lot dressed with double the amount of solid manure without the liquid application, and were fully equal to those in a neighbour's field which had received 30 loads of farm-yard dung, together with 3 cwt. guano and 16 bushels bones per acre; the yield was estimated at 40 tons the Scotch acre, and their great luxuriance seemed to me to justify the expectation. From one field of white globe turnips sown later, and *manured solely with liquid*, from 40 to 50 tons to the Scotch acre was expected. A field of carrots, treated in the same manner as the swedes, to which a second application of liquid was given just before thinning, promise from 20 to 25 tons the acre. Similarly favourable results have been obtained with cabbages; and that the limit of fertility by these means has not yet been reached, was clearly shown in one part of the Italian rye-grass which had accidentally received more than its allowance of liquid, and which showed a marked increase of luxuriance over that around it. The exact increase of produce has not been accurately determined, but the number of cattle on the farm has increased very largely, and by means of the Italian rye-grass at least *four* times as many beasts as before can be kept now on the same extent of land, *the fertility of the land being at the same time increased.* This plant, of all others, appears to receive its nourishment in this form with most gratitude, and to make the most ample returns for it; and great as are the results hitherto obtained, I believe that the maximum of productiveness is not yet reached, and that the present experiment must be carried yet further before we know the full capabilities of this manure. Of one important fact connected with this crop, I am assured, that notwithstanding the rank luxuriance of its growth, animals fed upon it not only are not scoured, but thrive more than on any other kind of grass in cultivation.

"Taking into the irrigation account the whole cost of the engine, and the whole of the fuel and wages—although half of these might have been deducted—the following appears to be the capital account and working expenses for fertilising Myremill farm :—

"Tanks complete	£300 0 0
Steam engine	150 0 0
Pumps	80 0 0
Iron pipes, laying, and hydrants	1000 0 0
Gutta-percha distributing pipes, &c.	56 0 0
	£1586 0 0
"Annual interest on £1586, and wear and tear, at 7½ per cent.	£118 19 0
Annual wages	104 0 0
Fuel	58 10 0
	£281 9 0

This amount, divided by the number of acres, is equal to the annual sum of 14s. per acre.

"I now come to the practical results of so cheap a mode of fertilising land.

"Mr Young informed me that in one of the fields he had himself measured the growth of Italian rye-grass, and had found it to be two inches in twenty-four hours; and that within seven months, Mr Kennedy had cut from a field we were passing at the time 70 tons of grass per acre. Where the whole is cut, four or five heavy crops are thus taken; but upon some of the land during the last two years 20 sheep to the acre have been penned in hurdles, and moved about the same field from time to time; after each remove the fluid has been applied, and immediately followed by an abundant growth of food. There is not the slightest appearance of exhaustion in the land,—its fertility appears to increase. I was informed that, before the liquid manure was used, the land would not keep more than a bullock or five sheep to the acre; now it will maintain, if the crops are cut and carried in, five bullocks or twenty sheep to the acre. Some beans, bran, and oil-cake are bought for the stock; but, on the other hand, one-third or more of the farm is kept in grain, notwithstanding the great number of live stock.

"*Canning Park.*—Mr Telfer's farm, near Ayr. This is a small dairy farm of 40 acres, near the level of the sea, and about a mile and a half west of the town of Ayr. The subsoil is beach gravel with a slight admixture of clay. Water is too abundant. It lies dead within about 20 inches of the surface, and in winter nearer than that.

"No bedding or litter is used here. The cows lie on cocoa-nut mats. The ventilation is perfect; and the air sweeter than in the majority of the dwelling-houses of human beings.

"The following appears to be the cost of carrying out the system of Mr Telfer's farm :—

"Tank	£30 0 0
Engine	60 0 0
Iron pipes and hydrants	100 0 0
Distributing hose-pipe, &c.	20 0 0
	£210 0 0
"Annual interest on £210, and wear and tear, at 7½ per cent.	£15 15 0
Wages and fuel	11 0 0
	£26 15 0

"In summer the cows have a quantity of oil-cake, as well as grass; and in winter they have turnips or mangel-wurzel, bean or barley meal, and cut hay or grass; the whole mess being steamed together. Miss Bell, the cousin of Mr Telfer, manages the dairy, and said that last year the hay bought would amount to from £30 to £40, and she should think the grain to not less than £200. In general terms, the other food is produced upon the farm. As to the produce of grass, which is the chief article, the first cutting during the present year was in the latter end of March about 18 inches thick. The second was from 18 inches to 2 feet thick. The third was from 3 feet to 4 feet 6 inches thick. The fourth nearly the same. The fifth was 2 feet thick; and the sixth, in process of cutting at the time I was there, we measured at 18 inches thick. Taking the mean, where two dimensions are given for the same crop, I find the aggregate depth of grass, grown and cut off this farm within seven months, to be not less than 14 feet 3 inches. All this is, however, eaten upon the premises, and the whole marketable produce of the farm is represented by the milk and butter.

"As to the quantity and value of these, Miss Bell stated that the previous week the butter was 114 lb and 120 lb—together 234 lb, sold at 1s. per pound. This, she stated, was about the average quantity and price. The amount for butter would therefore be £11, 14s. per week, or per annum £608, 8s. She informed me farther, that during about eight months in the year, the cold milk realises about the same amount as the butter. In the summer months, during hot weather, the market value of the milk is only about half that of the butter. From these data, the amount for milk sold per annum is £507.

"The total receipts for the two articles of milk and butter amount to £1115, 8s. per annum.

"I only need to add that, previously to the adoption of the present system of farming, these 40 acres of land were barely sufficient to support eight or nine cows, and would have been well let at a rental of 30s. an acre."

The attention now so generally directed to this subject, and the importance attached to it in many quarters, justify this lengthened quotation, and call for some remarks upon it. We have carefully examined two of the instances referred to in this report, viz., Port-Dundas and Myremill; and some smaller experiments more cursorily. After doing so we are sorry to say that we have arrived at a very different estimate of this system of manuring from that expressed in the above quotations. We at once, and with pleasure, acknowledge that in so far as concerns the storing up and preparing of the liquid manure, its application to the land, and the production, by means of it, of crops of Italian rye-grass almost surpassing belief in their luxuriance and weight of produce, Mr Kennedy's experiments have been crowned with complete success. The excellence of this grass as food for live stock, and their relish for it, is also indisputable. Neither do we dispute the statements of those who tell us that manure, when largely diluted with water, and properly applied in the liquid form, is more beneficial to plants than in any other way in which it can be presented to them. Admitting all this, the question remains, Has it yet been shown that this system can be economically applied to ordinary farms? Data are still wanting from which to answer this question conclusively, but we shall state some of the reasons which constrain us, with our present information, to do so in the negative.

Supposing an adequate motive power already to exist, and to be partly employed for other purposes, the capital that must be invested in providing the tanks and other apparatus necessary for carrying out this system amounts to about £4 per acre over a farm of average extent. If the system be a sound one, the great amount of this outlay cannot fairly be urged as an objection to it. The addition of a permanent rent charge of 5s. per acre to an entire farm, for a benefit which in any one year can be available to but a limited portion of it, is however a serious matter. In each case referred to in the *Minutes of Information*, the whole annual charge, whether arising from interest on capital, wear and tear of machinery, or working expenses, is divided by the whole acreage of the farm. In the first seven cases given in the tabular statement, this mode of calculation is correct, as the whole areas do actually benefit

TABLE III.—*Showing Cost, &c., of the Application of Sewerage Waters and Liquid Manures.*

Name of Place.	No. of English acres.	Mode of Application.	Cost of Works and Apparatus. £ s. d.	Annual Interest, &c., at 7½ per cent. £ s. d.	Annual Working Expenses. £ s. d.	Total Annual Charge per English acre. £ s. d.	Observations.
Edinburgh. Craigentinny Meadows.	63	Steam-engine, pumps, and open gutters and panes,	2000 0 0	150 0 0	117 12 0	4 4 11	Average rental upwards of £16 per English acre.
High-level Sea Meadows.	38	Gravitation, open gutters and panes, . . .	700 0 0	52 10 0	19 17 6	1 18 1	Worth about £20 per English acre; worthless before.
Old Meadows.	228	Do. do.	2700 0 0	202 10 0	119 5 0	1 8 2½	Maximum rental, £25 per English acre.
Nottinghamshire. The Duke of Portland. Clipstone Meadows.	300	Catchmeadow, gravitation, and open gutters, . .	36,000 0 0	2700 0 0	150 0 0	9 10 0	Worth upwards of £12; previously worth from 3s. to 5s. per acre per annum.
Wiltshire. Viley Meadows.	150	Beadwork of ridge and furrow, gravitation and open gutters, . .	3000 0 0	225 0 0	52 10 0	1 17 0	Four heavy crops of grass per annum.
Devonshire. The Duke of Bedford. Tavistock Meadows.	90	Beadwork and catchmeadows, gravitation and open gutters, . .	1183 0 0	88 14 6	67 10 0	1 14 8½	Land more than quadrupled in value after only 4 years irrigation.
Berkshire. Pusey Meadows.	100	Catchmeadow, gravitation, and open gutters. . .	445 0 0	33 7 6	37 18 4	0 14 3	Land not previously worth more than 5s. per acre, yielding six heavy crops of grass per annum.
Glasgow. Mr Harvey's farm.	508	Steam-engine, pumps, underground iron main pipes and iron distributing pipes, . . .	1450 0 0	108 15 0	240 10 0	0 13 9	10 feet thick of grass cut from an acre in six months.
Ayrshire. Myremill farm.	508	Steam-engine, pumps, underground iron mains, gutta-percha hose, and jet pipe, . . .	1586 0 0	118 19 0	162 10 0	0 11 1	70 tons of grass cut from an acre in six months.
Canning Park farm.	50	Do. do.	210 0 0	15 15 0	11 0 0	0 10 8½	14½ feet of grass cut in seven months.
Leg or Dunduff farm.	50	Gravitation, underground iron mains, gutta-percha hose, and jet pipe, . .	191 0 0	14 6 6	3 10 0	0 7 1½	80 stacks per annum; in place of 12, as previously.
Staffordshire. The Duke of Sutherland. Hanchurch farm near Trentham.	83	Steam-engine, pumps, underground iron mains, gutta-percha hose, and jet pipe, . . .	520 13 4	39 1 0	18 6 0	0 13 9¾	Tanks constructed sufficient for 300 acres.
Lancashire. Halewood farm.	120	Do. do.	521 12 0	39 2 5	19 15 2	0 9 9¾	One dressing of liquid equal to 25 or 30 tons of farm-yard manure per acre.
Cheshire. Lescard farm.	150	Do. do.	672 1 10	50 8 0	17 11 0	0 9 8¾	A fourth crop of grass being weighed, was found equal to 10 tons per acre. It was the lightest crop cut off the same land.
Glamorganshire. Porth Kerry Farm.	50	Gravitation, underground iron mains, gutta-percha hose and jet pipe . .	300 0 0	22 10 0	0 10 0	0 13 0	Tanks constructed sufficient for 300 acres. Between 9 and 10 feet of grass cut.

each year by the irrigating process. But when we come to those irrigated by machinery, we find that a half or two-fifths only of the land receives the benefits of it in any one year. If the annual charge in this latter class of cases is divided by the acreage actually irrigated, it becomes evident that the expense is double that of the Pusey meadows, and equal to that of the old meadows near Edinburgh, instead of being less, as it is made to appear. Again, in estimating the profits an opposite course is followed. While the charges are made to appear less by spreading them over the whole area of the farm, the enormous produce of grass from the irrigated parts is put prominently forward, and little is said about its produce as a whole. In the dairy cases, too, we are told of enormous gross profits, without being pointedly reminded that the larger portion of the keep of the cows, such as distillery offal, bean-meal, hay, and even straw and turnips, is actually purchased; that in this way a quantity of extraneous manure becomes available for the associated farm, sufficient (however applied) to maintain it in a state of fertility; and that there would be handsome profits from the dairy, irrespective of the farm altogether. In fact, town dairies usually have no land attached to them. The cows are maintained solely by purchased food, and the sale of manure, liquid and solid, forms one of the stated items of income. In Mr Harvey's and similar cases, two separate businesses are in fact mixed up, and yet the whole is spoken of in such a way as if the profit was mainly due to the use of liquid manure. Indeed, the whole of these *Minutes of Information* issued by the General Board of Health have an air of special pleading about them, which to us seriously detracts from their value.

The entire annual cost of applying manure in this manner is stated to amount to from 10s. to 14s. per acre for the whole extent of the farm. Now this would suffice to provide annually from 1 to 1½ cwt. of Peruvian guano (even at its present high price) for every acre of the farm, or from 2 to 3 cwt. per acre, if applied, as the liquid is, to the portion under green crop only. The stated application of such a dressing of guano, in separate portions, and during showery weather, will be found to yield results little inferior to those obtained by the use of liquid manure. To do this requires no costly apparatus or permanent sinking of capital, and its application can be desisted from at any time when found unremunerative. The adoption of this plan of applying the liquid manure of the farm necessarily demands that the whole system of management be accommodated to it. In order to furnish this liquid manure, the whole green crops must, summer and winter, be conveyed to the homestead, and there consumed in such a manner as that the urine and dung of the animals fed upon it may be scoured into the tanks. It is no such easy matter to replenish these tanks as some persons seem to think. When cattle are housed in boxes or properly protected yards, the whole of the urine is absorbed by the litter, and goes to the field in the dung-cart. This is certainly a more expensive way of conveying it to the fields than by pipes. But then, as in the new system, the urine, &c., is diluted with at least three times its volume of water, there are four tons of manure to convey on the one plan for one on the other. Even where pipes are used, all the litter, and a portion at least of the dung, has still to be carted out, so that no claim of a saving of carriage can validly be put forward on behalf of this system; but its merits must be grounded solely on the superior efficacy of manure, when applied in a liquid instead of a solid form.

In the case of dry and loose soils, the consuming of the turnip crop, by folding sheep upon it, has hitherto been regarded as at once the cheapest way in which it can be converted into wool and mutton, and the land consolidated and enriched, so as to fit it for producing grain and other crops. On tenacious soils, and in a moist climate, which is quite the case at Myremill, it is certainly impracticable to pursue this system in winter. It is perhaps also the case that sheep are healthier, fatten more rapidly, and yield more wool, when fed under cover, than when folded on the open turnip field. Admitting all this, however, we are disposed to think that these benefits are better secured by Mr Randell of Chadbury's plan of littering the pens with burnt clay, which keeps the sheep clean, and their feet in good order, and, when mingled with their urine and dung, forms a most valuable manure for any kind of land. Were this carried out by means of movable covered pens, which could be erected and easily shifted from place to place in the turnip field, the carriage of the turnips and manure would be greatly reduced, especially if accomplished by means of the portable railway.

In the case of dairies near towns, where the cows are largely fed on brewery or distillery offal and other purchased food, the circumstances are totally different from those of ordinary farms, depending solely on their own resources. The liquid manure that would otherwise run to waste, when thus applied, is so much clear gain, in so far as the value of the increased produce exceeds the cost of application. It may form a wholesome caution to some persons to mention here that, notwithstanding all that has been written about the success of the spirited operations at Port-Dundas, we were told by Mr Harvey, that so dubious is he still about it, that if the thing were to do again, he would rather keep his money in his pocket, and let the urine run into the canal as formerly. If there is doubt even in such a case, how much more when the manure must virtually be purchased. And this leads us to remark that we have better hopes of the ultimate success of this plan of manuring, when it is restricted to the application of the surplus liquid manure of the homestead to some piece of meadow near at hand, supplementing this supply, when necessary, by dissolving guano in water, and sending it through the pipes. These remarks apply even more strongly to the sewage from towns. The liquid, in this case, is highly charged with fertilising ingredients of the most valuable kind, seeing that it consists largely of night-soil from a population consuming much animal food. With few exceptions, this valuable liquid, which flows in such quantities from all our towns, is not only utterly lost, but is a grievous nuisance, by polluting our streams and generating disease. In applying it as manure, the expense lies entirely in providing and working the necessary apparatus. In such cases, then, with an unfailing supply of highly fertilising liquid, costing nothing to begin with, there is every inducement to put into operation any plan by which it can be economically applied to field crops. The enhanced value of green forage in the vicinity of towns is an additional motive for attempting this. The profitable disposal of town sewage in a way neither injurious to the health nor offensive to the senses of the community, is, however, a problem yet remaining to be solved.

The ingenuity and enterprise displayed by Mr Kennedy and others, in their endeavours to cheapen by this means the cost of farm produce, and the frankness and untiring patience with which they have shown and explained their proceedings to the unceasing stream of visitors, which the novelty of the operations attracted from all parts of the kingdom, and even from foreign countries, are altogether so admirable and praiseworthy that it requires no slight effort to speak of them otherwise than approvingly. The confidence with which various influential parties have proclaimed the complete success of this scheme of irrigation, and recommended it for general adoption, seems, however, to require that those who have examined it, and arrived at an opposite conclusion, should publicly say so.

It is unreasonable to expect that private parties are to divulge their whole business affairs; and yet, without a full *Dr.* and *Cr.* account for some ordinary arable farm treated on this system, it is impossible to arrive at a sound judgment on its merits. Until this can be done, it would be better to abstain from publishing partial statements, which tend only to mislead the public mind. We offer these remarks in no spirit of hostility to this new system of farming. We shall rejoice unfeignedly to find that our opinion of it is erroneous, and that it really warrants the sanguine expectations which some parties entertain regarding it. We simply maintain that as yet the case is "not proven," and our counsel to those who are disposed to try it is, not to embark in it to an extent that would embarrass them, if, as we fear, it should prove a failure.

Section 3.—Guano.

Next to farm-yard manure, which must ever be looked to as the chief means of maintaining the fertility of a farm, guano claims our notice. This substance is the dung of seafowl, and is found on rocky islets in parts of the world where rain seldom falls. The droppings of the myriads of birds by which such places are frequented have in many cases been permitted to accumulate during untold ages, and are now found in enormous deposits. The principal supply, both for quantity and quality, has hitherto come from the Chincha Islands, on the coast of Peru. The introduction of this powerful and exceedingly portable manure gave a prodigious impetus to agricultural improvement. It is about thirty years since a few casks of this article were brought to Liverpool from Peru, where it has been known and prized as a valuable manure from the remotest periods. No sooner had its value been discovered by our British agriculturists than the demand for it became so keen, that the quantity imported rose from 2881 tons in 1841 to 283,300 tons in 1845. The price at which it was sold at first was £20 per ton, from which, with increased supplies, it fell to £11, when the discovery in 1844 of a considerable deposit on the island of Ichaboe, on the coast of Africa, at once reduced the price to £9.

Discoveries have from time to time been made of other deposits on the African coast and in Australia. The quality of both is much inferior to that from Peru. It is in a more advanced state of decay, and contains more moisture and sand. Great as was the deposit of this valuable fertiliser on the Chincha Islands, it rapidly diminished under the excessive demand for it from Great Britain and other countries. Gradually the quality became very inferior, and in 1871 it was announced that this deposit was entirely exhausted. Considerable supplies are still obtained from other parts of the Peruvian coast; but unfortunately the quality is very inferior to that formerly obtained from the Chinchas. This circumstance would not be of much consequence if the guano was offered for sale on fair terms; but as the agents of the Peruvian Government sell it only at one uniform price per ton, although different cargoes, and even different portions of any one cargo, vary excessively in quality, it is now an unsafe article for farmers to purchase.

We give here, from the Board of Trade returns, a table of the quantities of guano imported yearly, with the computed real value, from 1854 to 1872.

Table showing the Imports of Guano from 1854 *to* 1872.

Year.	Tons.	Value.	Year.	Tons.	Value.
1854	235,111	£2,530,272	1864	131,358	£1,457,088
1855	302,061	3,137,160	1865	237,393	2,675,995
1856	191,501	2,136,431	1866	135,697	1,439,679
1857	288,362	3,613,074	1867	192,308	2,109,506
1858	353,541	4,084,170	1868	182,343	2,039,478
1859	84,122	769,333	1869	210,010	2,640,988
1860	141,435	1,557,895	1870	280,311	3,476,680
1861	178,423	2,022,283	1871	178,678	1,994,145
1862	141,636	1,635,322	1872	118,704	1,201,042
1863	233,574	2,658,856			

The dung of birds, from its including both liquid and solid excrements, is superior as a manure to that of quadrupeds. Pigeons' dung has long been in high repute as an excellent fertiliser, and brought a high price in days when portable manures were scarcely to be had. It is now little heard of, guano, the excrement of fowls which feed upon fish, being superior, weight for weight. The dung of domestic poultry is usually mixed with the general dung-heap, but it could be turned to better account if kept by itself. It has been recommended to strew the floors of poultry-houses daily with sawdust or sand, and to rake this with the droppings into a heap to be kept under cover and used like guano.

Section 4.—Bones.

It is now about sixty years since ground bones began to be used by farmers in the east side of England as a manure for turnips. At first bones were roughly smashed by hammers and applied in great quantities. By and by mills were constructed for grinding them to a coarse powder, in which state they continued to be used as a dressing for turnips, at the rate of sixteen to twenty bushels per acre, in all parts of the kingdom and to a very great extent, until the admirable discovery by Baron Liebig of the mode of preparing superphosphate of lime by dissolving bones in sulphuric acid. We shall not attempt to explain on chemical principles the wonderful superiority of this substance over simple bone-dust in promoting the growth of the turnip plant. What we should do indifferently, by borrowing from others, will be found well done by various accomplished chemists who write specially on these subjects. We can, however, testify from experience to the important fact, that *one* bushel of bone-dust dissolved by a third of its weight of sulphuric acid is as a manure superior in value to *four* bushels of simple bone-dust. It is not merely, or even chiefly, in the lessened cost at which an acre of turnips can be manured that this superiority lies, but especially in this, that from the extraordinary stimulus given by superphosphate of lime to newly germinated turnip plants, they usually arrive at the stage when they are fit for thinning in from ten to fifteen days earlier than when sown over farm-yard dung or simple bone-dust, or both combined. This shortening of the critical period during which the attacks of the insignificant but dreaded turnip-beetle so often baulk the hopes of the husbandman is an advantage not easily estimated, and one well fitted to inspire him with confidence in the science to which he owes the discovery, and with grateful respect for the eminent discoverer. This powerful effect in quickening the growth of the young turnip plants is possessed in nearly as great a degree by Peruvian guano, when it is supplied with sufficient moisture. In climates and seasons which may be characterised as moist and cool, guano will show best results, whereas in those which are rather hot and dry superphosphate has the advantage. Accordingly we find guano the comparative favourite in Scotland, and its rival in the drier counties of England.

Guano is believed to encourage a great expanse of foliage, and to be more especially suited for early sowings; and superphosphate to influence development of bulb, and to deserve the preference for a later seed-time. The obvious inference is that, for the turnip crop at least, these valuable fertilisers should be used in combination; and actual experiment has verified its soundness. The use of them is universal and ever on the increase. They constitute also the standard by which farmers estimate the cost and effects of other purchased manures. The extent to which they are used, their high price, and the facility with which they can be adulterated with comparatively worthless ingredients, have led to almost unparalleled frauds. The adulteration of manures has, in fact, become a regular trade. Had farmers only their bodily senses to aid them, the detection of this fraud would be difficult—perhaps impossible. Here, however, they can call the chemist to their aid, with the certainty of ascertaining the real character of the articles which they are invited to purchase. If purchasers of manures would but insist in every instance on getting from the seller an analysis by some competent chemist, and along with it a written warrandice that the stock is of the quality therein indicated, detection and punishment of fraud would be easy. In regard to superphosphate of lime, the farmer can purchase bone-dust and sulphuric acid and prepare it himself. We conducted this process for several years in the following way:—A trough was provided 7 feet × 3·4 × 2·10, made of 2½-inch deal, strongly jointed, and secured at the corners by wooden pegs, as iron nails would be corroded by the acid. This holds conveniently 48 bushels of bones. The heap of bone-dust is then gone over with a barley riddle, and the small dust which passes through this is laid aside to be used as a drying material for the other portion, after it is subjected to the acid. We find that a third part of the bone-dust passes through the riddle. Three bottles, or carboys as they are called, of concentrated acid, averaging 180 lb. each, are then emptied into the trough and mixed with cold water at the rate of 1½ of water, by measure, to 1 of acid. In practice, the water is poured in first and then the acid. Into this mixture 48 bushels of bones, previously measured and laid close to the trough, are rapidly shovelled by two labourers, who will do well to be attired in clothes and shoes past spoiling. So soon as the bones begin to be thrown in, violent ebullition commences. By the time that the whole of the bones are thrown in, there will be barely liquid enough to moisten the last of them. The labourers therefore dig down at one end of the trough till they reach the bottom, and then carefully turn back and mix the whole quantity until they reach the other end. The surface is then levelled and covered with a layer of the dry riddlings two inches thick. In this state it is allowed to remain for two days, when the trough is emptied, and the same process is repeated until the whole quantity is gone over. When shovelled out of the trough the bones are found to have become a dark-coloured paste, still very warm, and emitting a sweetish smell. While one person throws it out, another adds to it its proportion of dry riddlings, and mixes them carefully. This mass is heaped up in the corner of a shed, and augmented at each emptying of the trough, until the requisite quantity is obtained. After this the mass is carefully turned over several times, at intervals of five or six days, and is then dry enough for sowing either by hand or machine. Some prefer moistening the bones with boiling water, and then adding pure acid as they are shovelled into the trough; but by first mixing the acid and water there is greater certainty of all the bones being equally acted upon. There is also great convenience in using the finest portion of the bone-dust for drying the other, as suitable material for this purpose is sometimes difficult to procure. The homely process now described is quite inferior to, and more costly than, that pursued in factories, and should only be resorted to when a genuine article cannot otherwise be obtained.

We have referred to superphosphate of lime prepared from bones. A new source of supply has, however, been discovered of late years, the extent and importance of which is becoming more apparent as investigation proceeds. We allude to those phosphoric deposits found in such abundance in the crag, and upper and lower green-sand formations in the south of England. The existence of these fossil animal remains was first pointed out by Drs Mantel and Buckland, though it is to Professor Henslow that we are indebted for having called attention to their eminent agricultural value, and described the localities whence they may be most readily obtained. These remains consist of the fractured and rolled bones of sharks, gigantic sea-lizards, and whales, which at one period of our earth's history must have existed in myriads in our oceans and seas. Mixed with these bones are found many fish-teeth and shells of different species, and likewise immense numbers of rolled, water-worn pebbles, which at one period were imagined to be the fossilised excrements of the animals themselves, and were on this account called *coprolites* by Professor Henslow and others. Although this has since been proved a mistake, the name has been adopted, and will probably be continued. These fossil bones, and so-called coprolites of the crag, are found in enormous quantities on the coast of Suffolk, Norfolk, and Essex, whence Mr Lawes of Rothamstead obtained nearly the whole of the material which he employed in the preparation of his well-known "coprolite manure," or "Lawes' superphosphate." Already, it is believed, several thousands of tons of these fossils in one form or other are annually sold for manure, with a rapidly increasing demand. Those found in the crag formation are exceedingly hard, and require to be ground by powerful machinery, and dissolved in sulphuric acid, to render the phosphate of lime available as manure. Fossils, though less abundant in the green-sand, can be reduced to the requisite fineness by simple machinery, and are then fit for agricultural purposes without any chemical preparation. They are found plentifully in the parish of Farnham, so long celebrated for the excellence and abundance of its hops, which are now discovered to be due to the presence in the soil of these fossil remains. The discovery of these *mines* of manure in various parts of our country was made most seasonably, and has proved of immense national importance. When Liebig predicted that, "in the remains of an extinct animal world England is to find the means of increasing her wealth in agricultural produce, as she has already found the great support of her manufacturing industry in fossil fuel," he was regarded by many as merely indulging a fine philosophic fancy; but enough has already been realised to convince the most sceptical of the importance of the data on which he founded his opinion.[1]

On mixing a quantity of bone-dust with its own bulk of mould or sand, and wetting the whole with the liquid which oozes from the dung-heap, violent fermentation immediately ensues, dissolving the bones, and making them more readily available for the nourishment of the turnip crop. Many farmers are so satisfied with this preparation, that they dispense with the acid. This is not judicious, as the superphosphate of lime is a more valuable manure than bones dissolved by simple fermentation.

Bones are sometimes applied as a top-dressing to grass land with singular success. "This Cheshire practice consists in applying an extraordinary dose of bones to pasture-land. 'For pasture land, especially the poorer kind,' says Mr Palin, 'there is nothing equal to bone manure, either as regards the permanency of its effects, or the production of a sweet luxurious herbage, of which all cattle are fond. Many thousand acres of the poor clay soils have been covered with this manure during the last eight or ten years.' The average quantity used is about a ton and a half to the acre; it is therefore a landlord's improvement, on which seven or eight per cent. is generally paid. Boiled bones act as long as unboiled bones, retaining the phosphorus, though not so quickly, having lost the animal matter. Boiled bones (1845) cost £3, 10s. per ton; the outlay then was five guineas per acre, sometimes £7 or £8. 'I have known,' says a correspondent, 'many instances where the annual value of our poorest clay lands has been increased by an outlay of from £7 to £8 an acre, at least 300 per cent.; or, in other words, that the land has been much cheaper after this outlay at 30s., than in its native state at 10s. per acre; with the satisfaction of seeing a miserable covering

[1] *Journal of the Royal Agricultural Society of England*, vol. ix. p. 56, and vol. xii. p. 91.

of pink-grass, rushes, hen-gorse, and other noxious weeds, exchanged for a most luxuriant herbage of wild clover, trefoil, and other succulent grasses.' Though much of the clover and trefoil may disappear in five or ten years (some times they last fifteen years), an excellent herbage remains. 'Draining,' the writer adds, '*may be carried too far* where bones are used, for boned lands suffer by a dry summer. The land should be kept cool.' I have found the same thing on water meadows. The freer the grass is growing, the more it suffers from drought; and this is natural, for a larger supply of sap is required. This writer adds, 'I have known many a poor, honest, but half-broken man, raised from poverty to comparative independence, and many a sinking family saved from inevitable ruin, by the help of this wonderful manure.' Indeed, I believe, land after boning will keep three cows where two fed before. As to this practice, however, caution is necessary. It seems to belong to cold clays for grass in Cheshire, though on such soil it would hardly answer elsewhere, even for turnips. A Cheshire landlord told me that he had tried it vainly for grass in Suffolk. I know no case of its success out of Cheshire, unless in the bordering counties, and have heard some cases of its failure even in those. It will not do, therefore, at all to adopt it hastily. We only know it to have succeeded about Cheshire, which is on the red marls geologically, and on the rainy side of the country, and must remember that it is a costly proceeding, striking in its success, but as yet circumscribed in its practice, and therefore in the proof of its efficacy."[1]

Section 5.—*Rape-Cake, &c.*

Rape-cake reduced to powder forms an excellent manure for wheat and other crops. It is usually applied at the rate of from four to eight cwt. per acre. The cakes resulting after oil has been expressed from camelina, hemp, and cotton seeds, and from pistachio and castor-oil nuts, from beech and other mast, all possess considerable value as manure, and were at one time available for that purpose. Most of them now command a price for cattle feeding that forbids their use as manure unless when in a damaged state.

Section 6.—*Blood, &c.*

All parts of the carcases of animals form valuable manure, and are now carefully used in that way whenever they are unfit for more important uses. The blood and other refuse from shambles and from fish-curers' yards, when mixed with earth and decomposed, make a valuable manure, and are eagerly sought after by farmers to whom such supplies are accessible. In London a company has been formed by whom the blood from the shambles is purchased, and employed instead of water in preparing superphosphate of lime, which, when thus manufactured, contains an amount of ammonia which adds considerably to its efficacy as a manure. In Australia and South America it has long been the practice to slaughter immense numbers of sheep and cattle for the sake of their hides and tallow only, there being no market for them as beef and mutton. To obtain the whole tallow, the carcases are subjected to a process of boiling by steam and afterwards to pressure, and are then thrown aside in great piles. This dried residuum is afterwards used as fuel in the furnaces of the steaming apparatus, and the resulting ashes constitute the bone-ash of commerce, which is now an important raw material in our manure factories.

After many abortive attempts to convey Australian beef and mutton to the British market, the difficulty has at last been overcome by enclosing the meat in a par-boiled state in tin cases, hermetically sealed. This has already grown to a large trade, with every likelihood of its increasing rapidly. As the meat in these cases is sent free from bone, a plan has been found for rendering the bones also a profitable article of export. For this purpose they are crushed into compact cakes 6 inches square by 3 inches thick, in which form they can be stowed in comparatively small space.

The refuse from glue-works; the blubber and dregs from fish-oil; animal charcoal that has been used in the process of sugar-refining; the shavings and filings of horn and bones from various manufactures, and woollen rags, are all made available for manure.

Section 7.—*Night-Soil.*

Night-Soil is a powerful manure; but owing to its offensive odour it has never been systematically used in Britain. Various plans are tried for obviating this objection, that most in repute at present being its mixture with charred peat. From the universal use of water-closets in private dwellings, the great mass of this valuable fertilising matter now passes into sewers, and is carried off by streams and rivers, and is for the most part totally lost as a manure. When sewage water is used for irrigation, as in the neighbourhood of Edinburgh, it is to the night-soil dissolved in it that its astonishing effects in promoting the growth of grass are chiefly due. We have already expressed our views in regard to the use of it in this diluted form of sewage water. That mode of applying it is necessarily restricted to lands in the vicinity of towns. Hitherto the numerous and costly attempts that have been made to separate the fertilising matter from the water in which it is contained have proved utter failures. The most feasible plan for the utilisation of night-soil that we have hitherto heard of is that brought forward by the Rev. Henry Moule, Fordington Vicarage, Devon. In a tract addressed to cottagers he says,—"Now, my discovery is this: The earth of your garden, if dried—or dried and powdered clay—will suck up the liquid part of the privy soil; and, if applied *at once* and *carefully mixed*, will destroy all bad smell and all nasty appearance in the solid part, and will keep all the value of the manure. Three half pints of earth, or even one pint, will be enough for each time. And earth thus mixed *even once* is very good manure. But if, after mixing, you throw it into a shed and dry it, you may use it again and again; and the oftener you use it the stronger the manure will be. I have used some seven and even eight times; and yet, even after being so often mixed, there is no bad smell with the substance; and no one, if not told, would know what it is." To adapt a privy for using dried earth in this way, he says,—"Let the seat be made in the common way, only without any vault beneath. Under the seat place a bucket or box, or, if you have nothing else, an old washing-pan. A bucket is the best, because it is more easily handled; only let it have a good-sized bail or handle. By the side of the seat have a box that will hold (say) a bushel of dried earth, and a scoop or old basin that will take up a pint or a pint and a half, and let that quantity of earth be thrown into the bucket or pan every time it is used. The bucket may be put in or taken out from above by having the whole cover moved with hinges; or else, through a door in front or at the back." He has also invented and patented an *earth-closet*, as a substitute for the ordinary water-closet, which he describes thus:—"The back contains dried and sifted earth, which enters the pan through a hole at the back of it, and covers the bottom. The bottom is moved by the handle and lever; the side of the pan acts as a scraper; and all that is upon the bottom is pushed off, falling into the bucket or shaft below. The earth thus applied at once prevents fermentation, and almost all exhalation and offensive smell. The bottom returns to

[1] Article by Mr Pusey. See *Journal of Royal Society of England*, vol. xi. p. 409.

its place by means of a spring, and a fresh supply of the earth falls upon it from the box."[1]

This scheme has now been tested for a sufficient length of time, and on a wide enough scale, to show that in the case of private houses in rural districts, as well as in prisons, asylums, hospitals, public schools, military camps, and factories, it is entirely successful as regards the sanitary results of its use, and the value of the manure when applied to gardens attached to the premises from which it is obtained. But the cost and annoyance of moving so bulky a substance, and the small percentage of fertilising matter contained in it, forbid the expectation of its being adopted in towns.

Section 8.—Sea-Weed.

Along our sea-board large supplies of useful manure are obtained in the shape of drifted sea-weed. This is either applied as a top-dressing to grass and clover, ploughed in with a light furrow, for various crops, or mixed in dung-heaps. It requires to be used in large quantities per acre—from 40 to 60 loads—and is evanescent in its effects. Grain grown on land manured with sea-weed is generally of fine quality, and is in repute as seed corn.

Section 9.—Manure Crops.

Crops of Buckwheat, Rape, Vetches, and *Mustard* are sometimes ploughed in, while in a green, succulent state, to enrich the land. It is, however, more usual to fold sheep on such crops, and so to get the benefit of them as forage, as well as manure to the land. The leaves of turnips are frequently ploughed in after removing the bulbs, and have a powerful fertilising effect.

Section 10.—Lime.

Besides manures of an animal and vegetable origin, various mineral substances are used for this purpose. The most important and extensively used of these is lime. In the drier parts of England it is not held in much esteem, whereas in the western and northern counties, and in Scotland, its use is considered indispensable to good farming. Experienced farmers in Berwickshire consider it desirable to lime the land every twelve years, at the rate of from 120 to 200 bushels of the unslacked lime per acre. It is found especially beneficial in the reclaiming of moory and boggy lands, on which neither green nor grain crops thrive until it has been applied to them. Its use is found to improve the quality of grain, and to cause it in some cases to ripen earlier. It facilitates the cleaning of land, certain weeds disappearing altogether for a time after a dressing of lime. It is the only known specific for the disease in turnips called "fingers-and-toes," on which account alone it is frequently used in circumstances which would otherwise render such an outlay unwarrantable. The practice, still frequent, of tenants at the beginning of a nineteen years' lease, liming their whole farm at a cost per acre of from £3 to £5, proves conclusively the high estimation in which this manure is held. The belief—in which we fully concur—is however gaining ground, that moderate and frequent applications are preferable to these heavy doses at lengthened intervals.

When bare fallowing was in use, it was commonly towards the close of that process that lime was applied. Having been carted home and laid down in large heaps, it was, when slaked, spread evenly upon the surface and covered in by a light furrow. It is now frequently spread upon the autumn furrow preparatory to root crops, and worked in by harrowing or grubbing, and sometimes by throwing the land into shallow ridgelets. Another method much used is to form it into compost with decayed quickens, parings from road-sides and margins of fields, &c., which, after thorough intermixture by frequent turnings, is spread evenly upon the land when in grass. A cheap and effectual way of getting a dressing of such compost thoroughly comminuted and incorporated with the surface soil, is to fold sheep upon it, and feed them there with turnips for a few days. The value of such compost is much enhanced by mixing common salt with the lime and earth, at the rate of *one part* of salt by measure to *two parts* of lime. A mixture of these two substances in these proportions prepared under cover, and applied in a powdery state, is much approved as a spring top-dressing for corn crops on light soils. In whatever way lime is applied, it is important to remember that the carbonic acid which has been expelled from it by subjecting it in the kiln to a red heat, is quickly regained from the atmosphere, to which therefore it should be as little exposed as possible before applying it to the land. A drenching from heavy rain after it is slaked is also fatal to its usefulness. Careful farmers therefore guard against these evils by laying on lime as soon as it is slaked; or when delay is unavoidable, by coating these heaps with earth, or thatching them with straw. In order to reap the full benefit of a dressing of lime it must be so applied as, while thoroughly incorporated with the soil, to be kept near the surface. This is more particularly to be attended to in laying down land to pasture. This fact is so well illustrated by an example quoted in the article "Agriculture" in the 7th edition of the present work that we here repeat it.

"A few years after 1754," says Mr Dawson, "having a considerable extent of outfield land in fallow, which I wished to lime previous to its being laid down to pasture, and finding that I could not obtain a sufficient quantity of lime for the whole in proper time, I was induced, from observing the effects of fine loam upon the surface of similar soil, even when covered with bent, to try a small quantity of lime on the surface of this fallow, instead of a larger quantity ploughed down in the usual manner. Accordingly, in the autumn, about twenty acres of it were well harrowed in, and then about fifty-six Winchester bushels only, of unslaked lime, were, after being slaked, carefully spread upon each English acre, and immediately well harrowed in. As many pieces of the lime, which had not been fully slaked at first, were gradually reduced to powder by the dews and moisture of the earth,—to mix these with the soil, the land was again well harrowed in three or four days thereafter. This land was sown in the spring with oats, with white and red clover and rye-grass seeds, and well harrowed without being ploughed again. The crop of oats was good, the plants of grass sufficiently numerous and healthy; and they formed a very fine pasture, which continued good until ploughed some years after for corn.

"About twelve years afterwards I took a lease of the hilly farm of Grubbet, many parts of which, though of an earthy mould tolerably deep, were too steep and elevated to be kept in tillage. As these lands had been much exhausted by cropping, and were full of couch-grass, to destroy that and procure a cover of fine grass, I fallowed them, and laid on the same quantity of lime per acre, then harrowed and sowed oats and grass-seeds in the spring, exactly as in the last-mentioned experiment. The oats were a full crop, and the plants of grass abundant. Several of these fields have been now above thirty years in pasture, and are still producing white clover and other fine grasses; no bent or fog has yet appeared upon them. It deserves particular notice, that more than *treble* the quantity of lime was laid upon fields adjoining of a similar soil, but which being fitter for occasional tillage, upon them the lime was ploughed in. These fields were also sown with oats and grass seeds. The latter throve well, and gave a fine pasture the first year; but afterwards the bent spread so fast, that in three years there was more of it than of the finer grasses."

The conclusions which Mr Dawson draws from his extensive practice in the use of lime and dung deserve the attention of all cultivators of similar land:—

"1. That animal dung dropped upon coarse benty pasture produces little or no improvement upon them; and that, even when sheep or cattle are confined to a small space, as in the case of folding, their dung ceases to produce any beneficial effects after a few years, whether the land is continued in pasture or brought under the plough.

[1] *Manure for the Million*, by Rev. Henry Moule, price 1d. Mr Moule has also published a pamphlet on the same subject, entitled *National Health and Wealth.*

"2. That even when land of this description is well fallowed and dunged, but not limed, though the dung augments the produce of the subsequent crop of grain, and of grass also for two or three years, its effects thereafter are no longer discernible either upon the one or the other.

"3. That when this land is limed, if the lime is kept upon the surface of the soil, or well mixed with it, and then laid down to pasture, the finer grasses continue in possession of the soil, even in elevated and exposed situations, for a great many years, to the exclusion of bent and fog. In the case of Grubbet-hills, it was observed, that more than thirty years have now elapsed. Besides this, the dung of the animals pastured upon such land adds every year to the luxuriance, and improves the quality of the pasture, and augments the productive powers of the soil when afterwards ploughed for grain; thus producing upon a benty outfield soil effects similar to what are experienced when rich infield lands have been long in pasture, and which are thereby more and more enriched.

"4. That when a large quantity of lime is laid on such land, and ploughed down deep, the same effects will not be produced, whether in respect to the permanent fineness of the pasture, its gradual amelioration by the dung of the animals depastured on it, or its fertility when afterwards in tillage. On the contrary, unless the surface is fully mixed with lime, the coarse grasses will in a few years regain possession of the soil, and the dung thereafter deposited by cattle will not enrich the land for subsequent tillage.

"*Lastly*, It also appears from what has been stated, that the four-shift husbandry is only proper for very rich land, or in situations where there is a full command of dung; that by far the greatest part of the land of this country requires to be continued in grass two, three, four, or more years, according to its natural poverty; that the objection made to this, viz., that the coarse grasses in a few years usurp possession of the soil, must be owing to the surface soil not being sufficiently mixed with lime, the lime having been covered too deep by the plough."—*Farmers' Magazine*, vol. xiii. p. 69.

Section 11.—*Marl.*

Our remarks hitherto have had reference to carbonate of lime in that form of it to which the term *lime* is exclusively applied by farmers. But there are other substances frequently applied to land which owe their value chiefly to the presence of this mineral. The most important of these is marl, which is a mixture of carbonate of lime with clay, or with clay and sand, and other compounds. When this substance is found in the proximity of, or lying under, sandy or peaty soils, its application in considerable doses is attended with the very best effects. The fen lands of England, the mosses of Lancashire, and sandy soils in Norfolk and elsewhere, have been immensely improved in this way. In Lancashire, marl is carried on the mosses by means of portable railways at the rate of 150 tons, and at a cost of about £3 per acre. In the fens long trenches are dug, and the subjacent marl is thrown out and spread on either side at an expense of 54s. per acre. By this process, often repeated, of *claying* or *marling*, as it is variously called, the appearance and character of the fen lands have been totally changed, excellent wheat being now raised where formerly only very inferior oats were produced. As the composition both of peat and of clay marl varies exceedingly, it is always prudent, either by limited experiment or chemical analysis of both substances, to ascertain the effect of their admixture. Lime is always present in those cases which prove most successful; but an overdose does harm.

Section 12.—*Shell-Marl.*

Under some mosses and fresh-water lakes extensive deposits of shell-marl are frequently found. It contains a larger percentage of lime than clay marl, and must be applied more sparingly.

Section 13.—*Chalk.*

Throughout the extensive chalk districts of England, the practice of spreading this substance over the surface of the land has prevailed from the remotest times. In the case of the Lincolnshire Wolds, once as celebrated for desolate barrenness as they now are for high culture and smiling fertility, chalking was one important means of bringing about this wonderful improvement, as it still is in maintaining it. "The soil being but a few inches in depth, and often containing a large proportion of flints, naturally possesses very little fertility—often being a light sand, not strong enough naturally to grow turnips—so that the farmers were at first obliged to *make* a soil, and must now maintain its new-born productiveness. The three principal means by which this is done are the processes of *chalking*, and *boning*, and *manuring with sheep*. A dressing of 80 or 100 cubic yards per acre of chalk is spread upon the land, and then a crop of barley is obtained if possible, being sown with seeds for grazing. The fields are grazed with sheep two years, the sheep being at the same time fed with oil-cake; and then the land will be capable of producing a fine crop of oats. Bones are also used frequently for the barley crop, and when they first came into use were thrown upon the land in a chopped state, neither broken nor crushed, and as much as 40 or even 50 bushels per acre. The boning and sheep-feeding are in constant operation, but chalking is required only at intervals of a few years. On the western side of the Wold district, wherever the chalk adjoins the white or blue marl, an extensive application of it is made to the surface. Thus immense quantities of earth and stone have been added by manual labour and horse-carriage to the thin covering of original soil; and, besides this, the soil is being continually deepened by deep ploughing, the chalk fragments thus brought to the surface crumbling into mould."[1]

In Dorsetshire "it is usual to chalk the land once in twenty years, the sour description of soil being that to which it is found most advantageous to apply it. The chalk is dug out of pits in the field to which it is applied, and it is laid on sometimes with barrows, but chiefly with the aid of donkeys. The first method costs 40s. an acre, the last 35s. when hire donkeys are used; 20s. to 25s. where the donkeys are the property of the farmer. The chalk is laid on in large lumps, which soon break down by the action of frost and exposure to the weather. Chalk is occasionally burned and applied as lime, in which state it is preferred by many farmers, notwithstanding the additional cost of the burning."[2]

Section 14.—*Shell-Sand and Limestone Gravel.*

On the western shores of Great Britain and Ireland are found great quantities of sand mixed with sea-shells in minute fragments. This calcareous sand is carried inland considerable distances, and applied to the land as lime is elsewhere. Limestone gravel is also found in various places and used in the same way.

Section 15.—*Gypsum.*

Sulphate of lime or gypsum is considered an excellent top-dressing for clover and kindred plants. It is thought by some that the failure of red clover is to be accounted for by the repeated crops of that plant having exhausted the gypsum in the soil. Its application has been followed by favourable results in some cases, but has yet quite failed in others. It is applied in a powdered state at the rate of *two* or *three* cwt. per acre when the plants are moist with rain or dew.

Section 16.—*Burnt Clay.*

About fifty years ago burnt clay was brought much into notice as a manure, and tried in various parts of the country, but again fell into disuse. It is now, however, more extensively and systematically practised than ever. Frequent

[1] "Farming of Lincolnshire," by John Algernon Clarke; *Journal of Royal Agricultural Society*, xii. 331.

[2] See Caird's *English Agriculture*, 1850 and 1851, p. 61.

reference to the practice is to be found in the volumes of the *Journal of the Royal Agricultural Society of England.* This burning of clay is accomplished in several ways. Sometimes it is burned in large heaps or clamps containing from 80 to 100 cart-loads. A fire being kindled with some faggots or brushwood, which is covered up with the clay, taking care not to let the fire break out at any point, more fuel of the kind mentioned, or dross of coals, is added as required, and more clay heaped on. A fierce fire must be avoided, as that would make the clay into brickbats. A low, smothered combustion is what is required; and to maintain this a good deal of skill and close watching on the part of the workman is necessary. A rude kiln is sometimes used for the same purpose. Either of these plans is suitable where the ashes are wanted at a homestead for absorbing liquid manure, &c.; but for merely spreading over the land, that called clod-burning is preferable, and is thus described in volume viii. page 78, of the *Royal Agricultural Society's Journal*:—"Roll and harrow, in dry weather, till the majority of clods are about the size of a large walnut; nothing so good as the clod-crusher to forward this operation: when perfectly dry, collect them into rows about six yards apart, with iron-teethed rakes; take a quarter of a whin faggot, or less, according to size, previously cut into lengths by a man with an axe; place these pieces about four yards apart in the rows, cover them with clods, putting the finest mould upon the top of the heap, to prevent the fire too quickly escaping; observe the wind, and leave an opening accordingly; having set fire to a long branch of whin, run from opening to opening till two or three rows are lighted, secure these, and then put fire to others, keeping a man or two behind to attend to the fires and earthing up till the quantity desired may be burned, which will generally take four or five hours, say from 25 to 35 loads per acre of 30 bushels per load.

"This work is often put out to a gang of men at about 10s. per acre for labour, and the whins cost 4s. 6d. per acre, not including the carting.

"When the heaps are cold, spread and plough in. The great advantage of burning clods in these small heaps, in preference to a large one, is the saving of expense in collecting and spreading; there is much less red brick earth and more black and charred; no horses or carts moving on the land whilst burning; and a large field may be all burned in a day or two, therefore less liable to be delayed by wet weather. In the heavy land part of Suffolk, the farmers purchase whins from the light land occupiers, and often cart them a distance of fourteen or sixteen miles, when there is no work pressing on the farm. These are stacked up and secured by thatching with straw, that they may be dry and fit for use when required. Bean straw is the next best fuel to whins or furze, and it is astonishing to see how small a quantity will burn the clods if they are of the proper size and dry. Observe, if the soil is at all inclined to sand, it will not burn so well. I will here mention, that I often sift and store up a few loads of the best blackened earth to drill with my turnips, instead of buying artificial manure, and find it answers remarkably well, and assists in maintaining the position that a heavy land farm in Suffolk can be farmed in the first-rate style without foreign ingredients."

Burnt clay is an admirable vehicle for absorbing liquid manure. A layer of it in the bottom of cattle-boxes does good service, at once in economising manure, and in yielding to the cattle a drier bed than they would otherwise have until the litter has accumulated to some depth. Valuable results have also been obtained by using it for strewing over the floors of poultry-houses, and especially of pens in which sheep are fed under cover. In the latter case it is mixed with the excrements of the sheep as they patter over it, and forms a substance not unlike guano, nor much inferior to it as a manure. As an application to sandy or chalky soils it is invaluable. It is mainly by this use of burnt clay, in combination with fattening of sheep under cover, that Mr Randell of Chadbury has so astonishingly increased the productiveness of his naturally poor clay soil. A Berwickshire proprietor, himself a practical farmer, who visited Mr Randell's farm in the summer of 1852, thus writes:—"I have visited most of the best managed farms in England, at least those that have so much of late been brought under general notice; but without exception, I never saw land in the splendid condition his is in. The beauty of the system lies in the cheap method by which he has imparted to it this fertility, and in the manner in which he keeps it up. A large part of the farm consisted, fourteen years ago, of poor clay, and was valued to him at his entry at 7s. 6d. per acre. It is now bearing magnificent crops of all kinds, the wheat being estimated to yield from 6 to 7 quarters per acre.

"Mechi has enriched Tiptree-heath, it is true; but then it is effected at a cost that will make it impossible for him to be repaid. Mr Randell, on the other hand, has adopted a course that is nearly self-supporting, his only cost being the preparation of the clay. The great secret of his success lies in his mode of using it; and as I never heard of a similar process, I will briefly explain to you how it is done:—His heavy land not permitting him to consume the turnip and mangold crops on the ground, he carts them home, and feeds his sheep in large sheds. They do not stand on boards or straw, but on the burnt clay, which affords them a beautiful dry bed; and whenever it gets the least damp or dirty, a fresh coating is put under them. The mound rises in height; and in February, when the shearlings are sold (for the sheep are only then twelve months old), the mass is from 7 to 8 feet deep. He was shearing his lambs when I was there, as he considers they thrive much better in the sheds without their fleeces. They are half-bred Shropshire downs; and at the age I mention, attain the great weight of 24 lbs. per quarter.

"I walked through the sheds, but of course they were then empty. I saw the enormous quantity of what he called his 'home-made guano;' the smell from it strongly indicated the ammonia it contained. He had sown his turnips and other green crops with it, and what remained he used for the wheat in autumn. He assured me he had often tested it with other manures, and always found 10 tons of the compound quite outstrip 4 cwt. of guano, when they were applied to an acre of land separately."

Section 17.—*Charred Peat.*

Charred peat has been excessively extolled for its value as a manure, both when applied alone, and still more in combination with night-soil, sewage water, and similar matters, which it dries and deodorises. So great were the expectations of an enormous demand for it, and of the benefits to result to Ireland by thus disposing of her bogs, that a royal charter was granted to a company by whom its manufacture was commenced on an imposing scale. This charcoal is doubtless a useful substance; but, as Dr Anderson has proved, peat, merely dried, is a better absorber and retainer of ammonia than after it is charred.

Section 18.—*Soot.*

Soot has long been in estimation as an excellent top dressing for cereal crops in the early stage of their growth, and for grasses and forage plants. It is applied at the rate of 15 to 30 bushels per acre. On light soils the addition of 8 or 10 bushels of salt to the above quantity of soot is said to increase materially its good effect. This mixture trenched, or deeply ploughed in, is also recommended as one of the most powerful of all manures for carrots.

In *London Labour and the London Poor* we find the following statistics as to metropolitan soot:—

	Bush. of Soot per annum.
"53,840 houses, at a yearly rental above £50, producing six bushels of soot each per annum	323,040
90,002 houses, at a yearly rental above £30 and below £50, producing five bushels of soot each per annum	450,010
163,880 houses, at a yearly rental below £30, producing two bushels of soot each per annum . . .	327,760
Total number of bushels of soot annually produced throughout London . . .	1,100,810

The price of soot per bushel is but 5d., and sometimes 4½d., but 5d. may be taken as an average. Now, 1,000,000 bushels of soot at 5d. will be found to yield £20,833, 6s. 8d. per annum."[1]

Section 19.—*Salt.*

Common salt has often been commended as a valuable manure, but has never been used in this way with such uniform success as to induce a general recourse to it. We have already spoken of it as forming a useful compound with lime and earth. It can also be used beneficially for the destruction of slugs, for which purpose it must be sown over the surface, at the rate of *four* or *five* bushels per acre, early in the morning, or on mild, moist days, when they are seen to be abroad. It is used also to destroy grubs and wireworm, for which purpose it is sown in considerable quantity on grass land some time before it is ploughed up. It can be used safely on light soils, but when clay predominates, it causes a hurtful wetness, and subsequent incrustation of the surface. Its application in its unmixed state as a manure is at best of doubtful benefit; but in combination with lime, soot, nitrate of soda, and perhaps also superphosphate of lime, it appears to exert a beneficial influence.

Section 20.—*Nitrate of Soda.*

Cubic saltpetre, or nitrate of soda, has now become one of our staple manures. The fertilising power of common saltpetre or nitrate of potass has been known from the earliest times, but its high price has hitherto hindered its use as a manure, except in the form in which it is obtained as refuse from the gunpowder mills. The cubic nitre is brought from Peru, where there are inexhaustible supplies of it. The principal deposits of nitrate of soda are in the plain of Tamarugal, at a distance of 18 miles from the coast. The beds are sometimes 7 or 8 feet in thickness, and from these it is quarried with ease It is not found in a perfectly pure state, but contains a mixture of several substances, chiefly common salt. To fit it for certain uses in the arts, it is subjected to a process of purification by boiling and evaporation. But for its use as a manure this is altogether unnecessary, and the cost would be greatly lessened if the nitrate were imported as quarried. As cubic nitre and guano contain very nearly the same percentage of nitrogen (the element to which the fertilising power of all manures is mainly due), it may seem surprising that the former should ever be used in preference to the latter. In practice, however, it is found that when applied as a top-dressing in spring, the former frequently yields a better profit than the latter; and hence the importance to farmers of getting it at a more reasonable price. Nitrate of soda is used as a manure for grain and forage crops. It is now extensively used as a top-dressing for wheat. For this purpose it is applied at the rate of 84 ℔ per acre, in combination with 2 cwt. of salt. The nitre and salt are thoroughly mixed, and carefully sown, by hand, in two or three equal portions, at intervals of several weeks, beginning early in March, and finishing by the third week in April. If nitre alone is used, it has a tendency to produce over-luxuriance, and to render the crop liable to lodging and mildew. But the salt is found to correct this over-luxuriance, and a profitable increase of grain is thus obtained. Mr Pusey[2] informs us that an application of 42 ℔ of nitrate of soda and 84 ℔ of salt per acre, applied by him to ten acres of barley that had been injured by frost, had such an effect upon the crop, that he had *seven* bushels more grain per acre, and of better quality, than on part that was left undressed for comparison. These seven bushels per acre were attained by an outlay of 6s. 4d. only. This nitre is also applied with advantage to forage crops. Mr Hope, Fenton Barns, East Lothian, states that he finds the use of it as a top-dressing to clover, at the rate of one cwt. of nitrate and two of guano per acre, profitable. Its beneficial effects are most apparent when it is applied to light and sterile soils, or to such as have been exhausted by excessive cropping.

Section 21.—*Potash.*

Crude potash, or kainite, has of recent years been largely imported from Germany, and has been somewhat extensively used in combination with other manures for potatoes and other root crops—two cwt. per acre being a common rate for the potash.

Section 22.—*Artificial Manures.*

Besides those substances, the most important of which we have now enumerated, which are available as manure in their natural state, there are various chemical products, such as salts of ammonia, potash, and soda, copperas, sulphuric and muriatic acid, &c., which, in combination with lime, guano, night-soil, and other substances, are employed in the preparation of manures, with a special view to the requirements of particular crops. In some cases these preparations have been eminently successful, in others but doubtfully so. Many failures are probably due to the spuriousness of the article made use of; as it is known that enormous quantities of worthless rubbish have, of late years, been sold to farmers, under high sounding names, and at high prices, as special manures. We would recommend those who desire information regarding the preparation and use of such compounds to study the article on Agricultural Chemistry, by Mr Lawes of Rothamstead, in the *Journal of the Royal Agricultural Society of England* (vol. viii. p. 226); the accounts of experiments with special manures in the *Transactions of the Highland and Agricultural Society of Scotland;* and the articles relating to Agricultural Chemistry in *Morton's Cyclopædia.* Those who purchase manures of this kind ought to be very careful to insist in every instance upon the seller producing an analysis by some chemist of established character, and granting a written warranty that the article sold to them is at least equal to the value indicated by the analysis. Were all farmers to insist upon this mode of buying their manures, they would at once put an end to that wholesale system of fraud by which they have been so enormously cheated of late years.

In applying these concentrated manures, those only of a slowly operating character should be used in autumn or winter, and at that season should invariably be mixed with the soil. Those in which ammonia abounds should in spring also be mixed with the soil when crops to which they are applied are sown. When used for top-dressing growing crops they should be applied only in wet weather.

CHAPTER XI.

CULTIVATED CROPS—GRAIN CROPS.

Pursuing the plan announced at the outset, we have now to speak of field crops, and shall begin with the cereal grasses, or white-corn crops, as they are usually called by farmers.

Section 1.—*Wheat.*

It is unnecessary to dwell upon the value of this grain to the farmer and to the community. It constitutes emphatically our bread-corn—our staff of life. While its increased consumption is, on the one hand, an indication of an improved style of living among the general population, its extended culture points, on the other, to an improving agriculture, as it is only on soils naturally fertile, or that have been made so by good farming, that it can be grown with success. Wheat is sown both in autumn and spring, from which circumstance attempts have been made to classify its varieties by ranging them under these two general heads. This distinction can only serve to mislead; for while it is true that there are varieties best adapted for autumn and for spring sowing respectively, it is also true that a majority of the kinds most esteemed in Britain admit of being sown at either season, and in practice are actually so treated. It is not our intention to present a list of the varieties of wheat cultivated in this country. These are very numerous already, and are constantly being augmented by the accidental discovery of new varieties, or by cross-impregnation artificially brought about for this purpose. The kinds at present in greatest repute in Scotland are the hardier *white wheats*, among which *Hunter's* white still retains the first place. There are many kinds which, in favourable seasons, produce a finer sample; but its hardiness, productiveness, and excellent milling qualities, render it a general favourite both with farmers and millers. Its most marked characteristic is, that in rubbing out a single ear, part of the grains are found to be opaque and white, and others flinty and reddish coloured, as if two kinds of wheat had been mixed together. Selections from Hunter's wheat have been made from time to time, and have obtained a measure of celebrity under various local names. The most esteemed of those is the *Hopeton* wheat. On very rich soils both these varieties have the fault of producing too much straw, and of being thereby liable to lodge. Hence, several new kinds with stiffer straw, and consequent lessened liability to this disaster, are now in request in situations where this evil is apprehended. *Fenton* wheat, possessing this quality in an eminent degree, and being at the same time very productive, and of fair quality, is at present extensively cultivated. It has the peculiarity of producing stems of unequal height from the same root, which gives a crop of it an unpromising appearance, but has perhaps to do with its productiveness. The *red-straw white* and *Piper's thick-set* have properties similar to the Fenton. Piper's had the repute of being the shortest and stiffest strawed wheat in cultivation, but after a brief popularity is now never heard of. The *red-chaff white* is productive, and yields grain of beautiful quality, but it requires good seasons, as it sheds its seeds easily and sprouts quickly in damp weather. The *Chiddam*, *Trump*, *white Kent*, and *Talavera*, have each their admirers, and are all good sorts in favourable seasons; but, in Scotland at least, their culture is attended with greater risk than the kinds previously named; they require frequent change of seed from a sunnier climate, and are only adapted for dry and fertile soils with a good exposure. A new sort, called *square-head*, has quite recently been introduced, and is reported to be so exceedingly prolific as to yield from six to eight bushels more per acre than any wheat previously in cultivation. As red wheats usually sell at from 2s. to 4s. less per quarter than white wheats of similar quality, they are less grown than heretofore. But being more hardy and less liable to mildew and sprouting than the finer white wheats, a recurrence of unfavourable seasons always leads to an increased cultivation of them. Some of these red wheats are, however, so productive that they are preferred in the best cultivated districts of England. *Spalding's prolific* holds a first place among these, being truly prolific, and producing grain of good quality. In Scotland it shows a tendency to produce a rough quality of grain. The *Northumberland red* and the *golden creeping* are there in estimation; the former being well adapted for spring sowing, and the latter for poor soils and exposed situations. Several new varieties of wheat have recently been introduced by Mr Patrick Sheriff of Haddington, formerly of Mungoswells. One is a large-grained red wheat, another somewhat resembles Hunter's in colour, and the third has grain of a pearly whiteness. They have all the peculiarity of being bearded. They are all true autumn wheats; but they seem also well adapted for spring sowing, as they ripen early. A red bearded variety, usually called *April wheat*, from its prospering most when sown in that month, and which indeed is a true summer wheat, is sometimes grown with advantage after turnips, when the season is too advanced for other sorts. But except upon poorish clay soils, it seems only doubtfully entitled to a preference over barley in such circumstances. The list now given could easily be extended; but it comprises the best varieties at present in use, and such as are suited to the most diversified soils, seasons, and situations in which wheat can be grown in this country. In regard to all of them it is reckoned advantageous to have recourse to frequent change of seed, and in doing this to give the preference to that which comes from a soil and climate better and earlier than those of the locality in which it is to be sown. Every farmer will find it worth his while to be at pains to find out from whence he can obtain a change of seed that takes well with his own farm, and having done so, to hold to that, and even to induce his correspondent to grow such sorts as he prefers, although he should have to pay him an extra price for doing so. An experienced farmer once remarked to the writer, that by changing his seed he got it for nothing; that is, his crop was more abundant by *at least* the quantity sown, from the single circumstance of a suitable change of seed. It is proper, however, to state, that this practice of changing the seed is founded more upon mere opinion than upon well-ascertained facts, and that in those instances where it has been followed by beneficial results nothing is known of the causes to which such success is due. It is much to be desired that our agricultural societies should address themselves to the thorough investigation of a question of such vital importance. In fixing upon the kind of wheat which he is to sow, the farmer will do well to look rather to productiveness than to fine quality. For however it may gratify his ambition to show the heaviest and prettiest sample in the market, and to obtain the highest price of the day, no excellence of quality can compensate for a deficiency of even a few bushels per acre in the yield. It is of importance, too, to have seed-corn free from the seeds of weeds and from other grains, and to see that it be true of its kind. Farmers who are systematically careful in these respects frequently obtain an extra price for their produce, by selling it for seed-corn to others; and even millers give a preference to such clean samples.

But there are seeds which no amount of care or accuracy in dressing can remove from seed-corn—viz., those of certain parasitical fungi, which must be got rid of by a different process. The havoc caused to wheat crops by bunt, blackball, or pepper-brand (*Uredo caries* or *Tilletia caries*), before the discovery of the mode of preventing it by steeping the seed-corn in some acrid or caustic bath, was often ruinous. The plan at first most usually adopted was to immerse the seed-wheat in stale chamber-lie, and afterwards to dry it by mixture with quick-lime. This pickle, as it is called, is usually efficacious; but the lime vexes the eyes and excoriates the hands and face of the sower, or clogs the hopper of the sowing-machine, and has therefore been superseded by other substances. Blue vitriol (sulphate of copper) is as good as anything for this purpose, and is used in the following manner. A solution is prepared by dissolving powdered sulphate of copper in water, at the rate of two ounces to a pint for each bushel of wheat. The grain is emptied upon a floor; a little of it is shovelled to one side by one person, while another sprinkles the solution over it, and this process is continued until the whole quantity is gone over. The heap is then turned repeatedly by two persons working with shovels opposite to each other. After lying for a few minutes, the grain absorbs the moisture, and is ready for sowing either by hand or machine.

The season for wheat-sowing extends from September to April, but ordinarily that succeeds best which is committed to the ground during October and November. When summer-fallows exist the first sowings are usually made on them. It is desirable that the land neither be wet nor very dry when this takes place, so that the precise time of sowing is determined by the weather; but it is well to proceed as soon after 1st October, as the land is moist enough to insure a regular germination of the seed.

Over a large portion of England wheat is the crop usually sown after clover or one year's "seeds." In such cases the land is ploughed in the end of September, immediately harrowed, and wheat sown upon it by a drilling machine. On loose soils the land-presser is frequently used to consolidate the soil and to form a channel for the seed, which in such cases comes up in rows, although sown broadcast. It is more usual, however, first to level the pressed furrows by harrowing, and then to use the drill, by means of which various portable manures are frequently deposited along with the seed-corn. The sowing of wheat after clover or "seeds," as now described, is rarely practised in Scotland, where it so invariably fails as to show that it is unsuited to our northern climate. It is here not unusual, however, to plough up such land in July or August, and to prepare it for wheat-sowing by what is called *rag-fallowing.* After the first ploughing the land is harrowed lengthwise, so as to break and level the surface of the furrows and close the interstices without tearing up or exposing any green sward. It is then allowed to lie for ten or fourteen days to allow the herbage to die, which it soon does at this season when light is thus excluded from it. A cross ploughing is next given, followed by repeated grubbings, harrowing, and rollings, after which it is treated in all respects as a summer-fallow.

The fallow and clover leas being disposed of, the land from which potatoes, beans, pease, or vetches have been cleared off will next demand attention. When these crops have been carefully horse and hand hoed, all that is required is to clear off the haulm to plough and sow. If the land is not clean, recourse must be had to a short fallowing process before sowing wheat. For this purpose the surface is loosened by the broadshare and grubber, the weeds harrowed out and raked off, after which the land is ploughed and sown. On soils well adapted for the growth of beans and wheat, viz., those in which clay predominates, any lengthened process of autumn cultivation is necessarily attended with great hazard of being interrupted by rain, to the loss of seed-time altogether. Every pains should therefore be taken to have the land so cleaned before-hand that these unseasonable efforts may be dispensed with; and to have the sowing and harrowing to follow so closely upon the ploughing as to diminish to the utmost the risk of hindrance from wet weather. As the crops of mangolds, carrots, or turnips arrive at maturity, and are either removed to the store-heap or consumed by sheep where they grow, successive sowings of wheat can be made as the ploughing is accomplished and as the weather permits. It is to be noted, however, that it is only on soils naturally dry, or made so by thorough draining, and which are also clean and in a high state of fertility, that wheat-sowing can be continued with advantage during the months of December and January. If the whole of these conditions do not obtain, it is wiser to refrain until February or March. When these late winter sowings are made, it is of especial importance to sow close up to the ploughs daily, as a very slight fall of rain will, at this season, unfit the land for bearing the harrows. This sowing and harrowing, in detail, is the more easily managed, that in the circumstances cross-harrowing is neither necessary nor expedient. Under the most favourable conditions as to weather and drainage, soils with even a slight admixture of clay in their composition will at this season plough up somewhat clammy, so that cross-harrowing pulls the furrows too much about, and exposes the seed, instead of covering it more perfectly. Two double turns of the harrows *lengthwise* is as much as should be attempted at this season.

The sowing of *spring-wheat* is only expedient on dry and fertile soils with a good exposure. Unless the whole conditions are favourable, there is much risk of spring-sown wheat being too late to be properly ripened or well harvested. On the dry and fertile soils in the valley of the Tweed, where the entire fallow-break is sown with turnips, and where consequently it is difficult to get a large breadth cleared in time for sowing wheat in autumn, it is the practice to sow it largely in February and March, and frequently with good success. Many judicious farmers are, however, of opinion that, taking the average of a twenty years' lease, barley is a more remunerative crop than spring-sown wheat, even under circumstances most favourable to the latter. When it is resolved to try it, a very full allowance of seed should be given—not less than three bushels per acre, and 3½ will often be better. If the plants have room they will tiller; and thus the ripening of the crop is retarded, the risk of mildew increased, and the quality of the grain deteriorated. As much seed should therefore be sown as will yield plants enough to occupy the ground fully from the first, and thus remove the tendency to tillering. By such full seeding a fortnight is frequently gained in the ripening of the crop, and this frequently makes all the difference between a remunerative crop and a losing one.

Much controversy has taken place about the quantities of seed-wheat which should be used per acre. The advocates of thin seeding have been so unguarded and extravagant in their encomiums of their favourite method,—some of them insisting that anything more than a few quarts per acre does but waste seed and lessen the produce,—that many persons have been induced to depart from their usual practice to their serious cost. It is true that with land in a high state of fertility, and kept scrupulously clean by frequent hoeings, a full crop of wheat may be obtained from half a bushel of seed per acre, provided that it is sown in September, and deposited regularly over the surface. But what beyond a trifling saving of seed is gained by this practice? And at what cost and hazard is even this secured? It is a mere fallacy to tell us, as the advocates of excessively thin seeding so often do, that they obtain an increase of so many hundred-fold, whereas thick seeders cannot exceed from twelve to twenty fold, when after all the gross produce of the latter may exceed that of the former by more than the quantity of seed saved, with less expense in culture, less risk from accidents and disease, an earlier harvest, and a better quality of grain. Such a crowding of the ground with plants as prevents the proper development of the ear is of course to be avoided; but the most experienced growers of wheat are convinced of the benefit of having the ground fully occupied at the time when active spring growth begins. This is secured by using two bushels per acre for the sowing made early in October, and by increasing this quantity at the rate of half a peck per week until three bushels is reached, which may be held as the maximum. Less than this should not be used from the middle of November to the end of the season. These are the quantities to be used in broad-cast sowing; when drilling or dibbling is resorted to, two-fifths less seed will suffice. In Scotland, at least, often repeated trials have shown that larger crops are obtained by broadcasting than by drilling. The latter mode is, however, to be preferred wherever the land is infested by annual weeds, which can then be got rid of by hoeing. When clover and grass-seeds are sown with the grain crop, it is believed also that they thrive better from the grain being sown in rows, probably because in this case light and air are less excluded from them. It is believed also that in highly-manured soils of a loose texture, grain deposited somewhat deeply in rows is less liable to lodge than when sown broad-cast and shallower. When drilling and hoeing are resorted to, the latter is effected most cheaply and effectively by using Garret's horse-hoe. The mere stirring of the soil is considered by many farmers to be so beneficial to the wheat crop that they use the horse-hoe irrespective of the presence of weeds. Others are of opinion that, apart from the destruction of weeds, hoeing is injurious to grain crops, alleging that the cutting of their surface roots weakens the stems and increases their liability to fall over. Carefully conducted experiments are required to settle this point. We have no personal experience bearing upon it beyond this, that we have repeatedly seen a wheat crop much benefited by mere harrowing in spring. It is always useful to roll wheat, and indeed all cereal crops, in order to facilitate the reaping process, although no other benefit should result from it. When the plants have been loosened by severe frosts, or are suffering from the attacks of the wire-worm, the use of Crosskill's roller is usually of great benefit to the crop.

A plan of growing wheat year after year on the same field without the use of manure was practised for a number of years by the late Rev. Mr Smith of Lois Weedon, Northamptonshire, and detailed by him in the pages of the *Royal Agricultural Society's Journal*, and in a pamphlet which has passed through many editions and had a very extensive circulation. His plan is to a certain extent a revival of that of Jethro Tull, but with this important difference, that whereas Tull occupied his ground with alternate double rows of wheat a foot apart, and vacant spaces, five feet wide, which were carefully cultivated by ploughings and horse-hoeings repeated at intervals from the springing of the wheat until midsummer, Mr Smith introduced two important elements in addition, viz., thorough draining, and trenching the vacant spaces in autumn, so as to bring portions of subsoil to the surface. A field treated on this system consists of alternate strips of wheat and bare fallow, which are made to exchange places year by year, so that each successive crop occupies a different site from its immediate predecessor. It has also the benefit of the fresh soil brought up by the previous autumn's double-digging, which is subsequently mellowed and pulverised by lengthened exposure to the atmosphere, and by frequent stirrings. The produce obtained by Mr Smith from his acre thus treated was very nearly 34 bushels each year for the first five years; but as his crops steadily improved, his average at the end of fourteen years was fully 36 bushels. Writing in July 1861, he said, "The growing crop for 1861, notwithstanding the frost, looks strong and well, with scarcely a gap. Thus year after year gives growing confidence in the scheme." On steam-power being introduced, Mr Smith became convinced of the practicability of carrying out his system with advantage on an entire farm. At first he restricted himself to the employment of manual labour, but he subsequently invented a set of implements for sowing, covering in, rolling, and hoeing his crops by horse labour. We give in his own words his directions for carrying out this system, what he believed to be the advantages of it, and the cost of thus cultivating an acre:—

"I suppose, at the outset, the land intended for wheat to be wheat land; having besides a fair depth of staple, and a subsoil, as will generally, though not universally be the case, of the same chemical composition with the surface. I suppose it dry, or drained three feet deep *at least;* well cleaned of weeds; the lands cast; and the whole tolerably level.

"1. First of all, then, plough the whole land, when dry, one inch deeper than the used staple. If it turn up cloddy, bring the clods down with the roller or the crusher. Let this be done, if possible, in August. Harrow deep, so as to get five or six inches of loose mould to admit the presser. Before sowing wait for rain. After the rain wait for a fine day or two to dry the surface. With this early commencement a week or two is of no material importance compared with that of ploughing dry and sowing wet.

"As early as possible, however, in September, get in your seed with the presser-drill, or with some implement which forms a firm-bedded channel in which to deposit the seed, grain by grain, a few inches apart. Cover over with the crusher or rough roller.

"2. When the lines of wheat appear above ground, guard against the rook, the lark, and the slug—a trite suggestion, but ever needful, especially here. And now, and at spring, and all through summer, watch for the weeds, and wage constant warfare against them. The battle may last for a year or two, or in some foul cases even more; but, in the end, the mastery, and its fruits, without fail, will be yours.

"3. The plant being now distinctly visible, dig the intervals two spits deep, increasing the depth, year after year, till they come to twenty or twenty-four inches. Bring up at first only four, or five, or six inches, according to the nature of the subsoil, whether tenacious, or loamy, or light. To bring up more at the outset would be *a wasteful and injurious expense.*

"The digging is done thus:—Before proceeding with the work, a few cuts are made within three inches of the wheat, the back of the spade being towards the rows. A few double spits, first of all, at the required depth, are then thrown out on the headland, and there left for the present. After this, as the digging proceeds, the staple is cast to the bottom, and the subsoil thrown gently on the top. This process is carried on throughout the whole interval; at the end of which interval, just so much space is left vacant as was occupied by the soil thrown out at the beginning of it. In commencing the second interval at that finished end, the earth is thrown out as at first, not on the headland, however, but into the vacant space of the first interval. And so on all over the acre.

"4. Late in winter, and early in spring, watch your opportunity, in dry weather, before the roots of the plant are laid bare, to press them with the crusher.

"5. In the spring and early summer stir the spaces between the rows as often as the surface becomes crusted over; and move the settled intervals four or five inches deep with the common scarifier, set first of all about twenty-eight inches wide, reducing the width till it come by degrees to twenty-four and eighteen inches. Continue the process, if possible, at the last-named width, up to the time of flowering in June.

"These operations are indispensable to full success, and happily can be carried on at little cost; for, while the intervals of each acre can be scarified in fifty minutes, the horse-hoe implement, covering two lands at once, can stir between the rows in twenty-five.

"6. Immediately the crop is carried, clean the intervals, and move them with the scarifier in order to *sow,* without delay, the shed grains. When these vegetate and come up into plant, move the intervals again five or six inches deep, and so destroy them. After that, level with the harrow implement, and the land is ready for the drill.

"If anything occur to prevent the sowing early in September, and to drive you to the end of October, set the drill for a thicker crop. But, if possible, sow early—for this reason. Tillered wheat has a bad name. But that has reference only to wheat which has tillered late in the spring. And certainly, in that case, there is the fear of danger to the crop, and danger to the sample. For supposing no mildew to fall on it, even then the plant ripens unevenly; the early stems being ready for the sickle, while the late-grown shoots have scarcely lost their verdure. But if mildew come when the stem is soft, and succulent, and porous, instead of being, as it should be at that time, glazed and case-hardened against its attacks, the enemy enters in and checks the circulating sap; and the end is, blackened straw, light ears, and shrivelled grain. Therefore, sow early. Let the plant tiller before winter. Give every stem an equal start at spring; and then, with a strict adherence to rule, there need be no alarm as to the result, subject only to those visitations from which no wheat, on any system, in the same description of soil, and under the same climate, is secure."—(See pamphlet, *Word in Season*, p. 36.)

"The advantages of the system of corn-growing which I have described are principally these:—First, while one crop of wheat is growing, the unsown intervals of the acre are being fallowed and prepared for another. This the farmer well knows to be of infinite moment, meeting, as it does, one of the greatest difficulties he has to contend with. Next, upon this half-portion of the acre, tilled as I describe, there is a yield equal to average crops on a whole acre. Then, for half the portion of an acre, there is, of course, only half the labour and half the expense of an entire acre required for cultivation. And, lastly, the hand-labour required finds constant employment for the poor."—(*Ibid.*, p. 17.)

"After harrowing, and cleaning, and levelling the whole, I marked out the channels for the seed with my *presser implement*, which is drawn with one horse, and presses two lands at once. My scheme of implements, to be complete, embraced a drill, which was to act immediately behind the presser-wheels, and to drop seed by seed into the hard channels. The spindle of the presser was to turn the drill-wheels, and the boxes were to be made removable. Being unable to accomplish this in time for this year's sowing, I had the seed, as heretofore, dropped by hands, and covered over by rollers.

"These rollers form the *roller implement* in the same frame, and are managed thus: the three-wheeled pressers are removed from their sockets, and in their place two rough rollers, formed of several wheels on the self-cleaning principle, are introduced, and cover over two lands at once.

"The portion of the field thus seeded will lie in this firm but rough state till spring time. Then, when the rollers have been applied again to keep the roots of the plant well in their place, they too will be removed from the frame, and light wheels and hoes will be attached, forming the *horse-hoe implement*, for hoeing and stirring between the wheat.

"There is yet one other use for the implement frame. The intervals of the wheat having been trenched in autumn, and well and frequently stirred by the common scarifier at spring, are shut out by the wide-spreading wheat-plant in June from all further processes till the crop is cut and carried. They are then to be moved and levelled by the common one-horse scarifier for seed-time. After this will follow the harrow. The hoes will be removed from the frame, and two small harrows will be attached, to cover two lands at once; and with this implement the horse will walk on the stubble-land, between what before were the intervals · and the cycle of operations is now complete.

"In all these operations (excepting in that of scarifying) the sown lands, and lands about to be made ready for sowing, are untouched by the foot of man or horse.

"The time occupied in scarifying the land is about an hour the acre; in heavily pressing the channels for the seed, half an hour; in the other operations about 20 or 25 minutes."—(Pp. 25, 26.)

"The presser-drill, spoken of in p. 25, is completed, and I now sow the four acres in 90 minutes, timed by watch; being at the rate of 18 or 20 acres a day in a day of 8 hours, with a horse of average power and speed.

"It has been thought advisable to keep the drill in its own frame,—devoting another frame to the roller-wheels or crusher, the hoes, the scarifiers, and harrows, all of which are made removable, and which, with the exception of the spade, the hand-hoe, and the common scarifier for stirring the intervals, perform the whole cycle of operations for cultivating the land for wheat."—(Pp. 33, 34.)

"I have only to show now, by my fresh balance-sheet, how with suitable implements, on wheat-land, the whole scheme I propose is economical, as well as easy and expeditious.

"One double digging in autumn	£1	10	0
Three stirrings with scarifier at spring (6d.)	0	3	0
One ditto with scarifier and harrow implement, before sowing	0	1	0
Two pecks of seed (5s. the bushel)	0	2	6
Pressing and drilling	0	1	0
Rough rolling	0	0	6
Four hoeings between wheat with horse-shoe implement (6d.)	0	2	0
Bird-keeping	0	2	0
Carried forward	£2	2	0
Brought forward	£2	2	0
All the operations from reaping to marketing	1	2	0
Rates, taxes, and interest	0	10	0
Total amount of outlay	£3	14	0

"The produce, supposing it equal to that of former years, in round numbers, would be:—

"Four quarters and two bushels of wheat (at 40s.)	£8	10	0
One ton and 12 cwt. of straw (at £2 the ton)	3	4	0
	£11	14	0
Deduct outlay	3	14	0
Total amount of profit	£8	0	0"

—(*Ibid.*, p. 30.)

Particular attention was directed to this system of wheat culture by a lecture on Tull's husbandry, delivered by Professor Way, at a council meeting of the Royal Agricultural Society of England, and by the animated discussion which followed; when several gentlemen who had visited Mr Smith's farm bore testimony to the continued excellence of his crops, and intimated that they and others had begun to test the system upon their own farms. If such a practice can indeed be pursued on the generality of clay-soils, then the puzzling problem of how to cultivate them with a profit is solved at once. It is not to be thought that practical farmers would regard otherwise than with incredulity a system which so flatly contradicts all existing theory and practice. The facts submitted to them by Mr Smith being beyond challenge, they would naturally imagine there must be some peculiarity in the soil at Lois Weedon which enabled it to sustain such heavy and continued demands on its fertility; and that the issue, there and elsewhere, must eventually be utter sterility. For our own part, believing that we have exceeding much to learn in every department of agriculture, we cannot thus summarily dispose of these facts. We simply accept them as true, and leave the exposition of them to *experience*, whose verdict we await with much interest.

But Mr Smith is not the only person who has furnished us with information regarding the continuous growth of wheat for a series of years on the same soil. Mr Lawes, at Rothamstead, in Herts, so well known by his interesting papers on agricultural chemistry in the *Royal Agricultural Society's Journal*, has furnished some facts in connection with the culture of wheat on clay soils to which farmers were little prepared to give credence. Mr Caird, who visited Rothamstead early in 1851, thus refers to the subject in his valuable work:—

"On a soil of heavy loam, on which sheep cannot be fed on turnips, 4, 5, and 6 feet above the chalk, and therefore uninfluenced by it, except in so far as it is thereby naturally drained, *ten* crops of wheat have been taken in succession, one portion always without any manure whatever, and the rest with a variety of manure, the effects of which have been carefully observed. The seed is of the red cluster variety, drilled uniformly in rows at 8 inches apart, and two bushels to the acre, hand-hoed twice in spring, and kept perfectly free from weeds. When the crop is removed the land is scarified with Bentall's skimmer, all weeds are removed, it is ploughed once, and the seed for the next crop is then drilled in. During the ten years, the land, in a natural state, without manure, has produced a uniform average of 16 bushels of wheat an acre, with 100 lb. of straw per bushel of wheat, the actual quantity varying with the change of seasons between 14 and 20 bushels. The repetition of the crop has made no diminution or change in the uniformity of the average, and the conclusion seems to be established, that if the land is kept clean, and worked at proper seasons, it is impossible to exhaust this soil below the power of producing 16 bushels of wheat every year.

"But this natural produce may be doubled by the application of certain manures. Of these, Mr Lawes's experiments led him to conclude that ammonia is the essential requisite. His conclusions are almost uniform, that no organic matter affects the produce of wheat, except in so far as it yields ammonia; and that the whole of the organic matter of the corn crop is taken from the atmosphere by the medium of ammonia. There is a constant loss of ammonia going on by expiration, so that a larger quantity must be supplied than is contained in the crop. For practical purposes, 5 lb. of ammonia is found to produce a bushel of wheat, and the cheapest form of ammonia at present being Peruvian guano, 1 cwt. of that substance may be calculated to give 4 bushels of wheat. The natural produce of 16 bushels an acre may therefore be doubled by an application of 4 cwt. of Peruvian guano. To this, however, there is a limit—climate. Ammonia gives growth, but it depends on climate whether that produce is straw or corn. In a wet, cold summer a heavy application of ammonia produces an undue development of the circulating condition of the plant, the crop is laid, and the farmer's hopes are disappointed. Seven of corn to ten of straw is usually the most productive crop; five to ten seldom yields well. The prudent farmer will therefore regulate his application of ammonia with a reference to the average character of the climate in which his farm is situated.

"The practical conclusion at which we arrive is this, that in the cultivation of a clay-land farm, of similar quality of soil to that of Mr Lawes, there is no other restriction necessary than to keep the land clean; that while it is very possible to reduce the land by weeds, it is impossible to *exhaust* it (to a certain point it may be *reduced*) by cleanly cultivated corn corps; that it is an ascertained fact that wheat may be taken on soils of this description (provided they are manured) year after year, with no other limit than the necessity for cleaning the land, and that may best be accomplished by an occasional green crop—turnip or mangold, as best suits—at great intervals, the straw being brought to the most rotten state, and applied in the greatest possible quantity to insure a good crop, which will clean the land well. If these conclusions are satisfactorily proved, the present mode of cultivating heavy clays may be greatly changed, and the owners and occupiers of such soils be better compensated in their cultivation than they have of late had reason to anticipate."—(Caird's *English Agriculture*, in 1850 and 1851, pp. 460–462.)[1]

It is certainly curious to observe, that the addition of four cwt. of guano brings up the produce of Mr Lawes's acre from its average annual rate of sixteen bushels, under its reduced normal state, to very nearly the same as Rev. Mr Smith's acre under his system of alternate strips of corn and summer fallow.

From information carefully gathered, Mr Caird gives it as his opinion, that the average produce of wheat per acre in 26 of the 32 counties of England visited by him is $26\frac{2}{3}$ bushels, or 14 per cent. higher than it was estimated at in the same counties by Arthur Young 80 years before. Were the country generally anything like as well cultivated as particular farms that are to be met with in all parts of it, we should have the present average increased by at least eight bushels per acre. 63 lb per bushel is a weight indicating a good quality of grain. A good crop of wheat will yield a ton of grain and about two tons of straw per acre.

Besides its uses on the farm, wheat straw, in certain limited districts in the south of England, is an article of some value, as the raw material of a not unimportant native manufacture, namely, *Straw-Plait*. The first straws used for this purpose in this country were grown in the neighbourhood of Luton in Bedfordshire. This town is still the principal seat of the straw trade and straw bonnet manufacture, and the district around still produces the finest quality of straws; but straw-growing is now also carried on in parts of Hertfordshire, Buckinghamshire, Oxfordshire, and Berkshire. Light, rich soils are best adapted for this purpose. The kinds of wheat grown with this view are the Red Lammas and the Chiddam. A bright, clean, tough straw being required, it is necessary to begin reaping before the flag of the straw falls. If the straw is exposed to rain, it becomes rusted or spotted; if to very hot and dry weather, it gets sunburnt and brittle. The utmost care and energy must, therefore, be used to get the crop dried, carried, and stacked as quickly as possible. In favourable seasons an acre of wheat will yield (besides the grain) from 15 cwt. to a ton of cut straws, of the value of £6 to £8 per ton, clear of all expenses. The farmer sells his straw to a class of men called straw-factors, who draw and cut the straws in his barn. The drawing and cutting-off of the ears being there performed, the factors remove the straw to their own premises. There it undergoes a farther cutting, is exposed to the fumes of sulphur, assorted into proper lengths, and made up into marketable bunches of various sizes and qualities. These bunches are disposed of to the plaiters at the various markets of the district. About 50,000 females and boys are engaged in plaiting. No plait is made in factories, the work being performed by the wives and children of agricultural labourers in their own cottages, where it is carried on all the year except in harvest. The straw trade, in its various departments, is of considerable importance and is steadily increasing. The gross returns are supposed not to fall short of £1,250,000 per annum.

There is now also a small demand for wheat straw for the manufacture of paper.

Section 2.—Barley.

In Great Britain barley is the grain crop which ranks next in importance to wheat, both in an agricultural and commercial point of view. Its use as bread-corn is confined to portions of the lowlands of Scotland, where unleavened cakes, or "bannocks o' barley meal," still constitute the daily bread of the peasantry. It is more largely used in preparing the "barley broth" so much relished by all classes in Scotland. To fit the grain for this purpose, it is prepared by a peculiar kind of mill, originally introduced from Holland by Fletcher of Saltoun, in which a thick cylinder of gritty sandstone is made to revolve rapidly within a case of perforated sheet-iron. The barley is introduced betwixt the stone and its case, and there subjected to violent rubbing, until first its husk and then its outer coatings are removed. It is, however, in the production of malt liquor and ardent spirits, and in the fattening of live-stock, that our barley crops are chiefly consumed. We have no doubt that it would be better for the whole community if this grain were more largely used in the form of butcher-meat and greatly less in that of beer or whisky. It has been customary for farmers to look upon distillation as beneficial to them from the ready market which it affords for barley, and more especially for the lighter qualities of this and other grain crops. But this is a very short-sighted view of the matter; for careful calculation shows that when the labouring man spends a shilling in the dram-shop, not more than a penny of it goes for the agricultural produce (barley) from which the gin or whisky is made; whereas, when he spends the same sum with the butcher or baker, nearly the whole amount goes for the raw material, and only a fraction for the tradesman's profits. And not only so, but the man who spends a part of his wages upon strong drink diminishes, both directly and indirectly, his ability to buy wholesome food and good clothing; so that, apart from the moral and social bearings of this question, it can abundantly be shown that whisky or beer is the very worst form for the farmer in which his grain can be consumed. Were the £50,000,000 at present annually spent in Great Britain upon ardent spirits (not to speak of beer), employed in purchasing bread, meat, dairy produce, vegetables, woollen and linen clothing, farmers would, on the one hand, be relieved from oppressive rates, and, on the other, have such an increased demand for their staple products as would far more than compensate for the closing of what is at present the chief outlet for their barley.

There are many varieties of barley in cultivation, and some of them are known by different names in different districts. Those most esteemed at present in Berwickshire and neighbouring counties are the *Chevalier*, the *Annat*, and the *common-early long-eared*. The chevalier produces the finest and heaviest grain, weighing usually from 54 lb to 56 lb per bushel, and is in high estimation with maltsters.

[1] Mr Lawes continues these experiments of growing successive crops of wheat year after year on the same site, with no material change in the results after a trial of thirty years.

It is also tall and stout in the straw, which is less liable to lodge than that of the common barley; and when this accident does happen, it has the valuable property of not producing aftershoots or greens. It requires about fourteen days longer than the common-early to reach maturity, but as it admits of being sown earlier than the latter sort, this is in practice no drawback to it. The Annat barley resembles the chevalier in its leading features, but is yellower in its complexion, and not quite so round in the grain. It ripens a few days earlier than the chevalier, and in our own experience is more productive. The common-early is more liable than those just noticed to suffer from over-luxuriance. It is generally used for the latest sowings on those portions of land from which the turnip crop has been longest in being removed.

In the elevated or northern parts of the kingdom, four-rowed barley, usually called *bere* or *bigg*, is cultivated, as it is more hardy, and ripens earlier than the two-rowed varieties. A new variety, called Victoria bere, is said to be so productive, and to yield such a heavy sample, as to be worthy of cultivation even in lowland districts.

Barley delights in a warm, friable soil, and thrives best when the seed is deposited rather deeply in a tilthy bed. Being the grain crop best adapted for succeeding turnips that have been consumed by sheep-folding, advantage must be taken of favouring weather to plough up the land in successive portions as the sheep-fold is shifted. So much of it as is ploughed before 1st February will usually get so mellowed by the weather as to be easily brought into suitable condition for receiving the seed. In Scotland the usual practice is to sow broadcast on this stale furrow, and to cover the seed by simple harrowing. A better way is first to level the surface by a stroke of the harrows, and then to form it into ribs *twelve* inches apart by such an implement as has been described when speaking of Tennant's grubber. Over this corrugated surface the seed is sown broadcast, and covered by another turn of the harrows. The ribbing loosens the soil, gives the seed a uniform and sufficient covering, and deposits it in rows. The only advantage of such ribbing over drilling is, that the soil is better stirred, and the seed deposited more deeply, and less crowded than is done by the ordinary drills. It is certainly of great advantage to have the seed-corn deposited in narrow lines, so far as the working of the horse-hoe is concerned; but we are convinced that stiffer stems, larger ears, a more abundant yield, and a brighter sample, are likely to be obtained when the seed is loosely scattered in a channel three or four inches wide than when crowded into a narrow line. This grain is now sown considerably earlier than heretofore. When the soil is enriched by plentiful manuring, its temperature raised by thorough draining, and the climate and exposure favourable, it should be sown as early in March as possible, and will often do remarkably well although sown in February. This early sowing counteracts that tendency to over-luxuriance by which the crop is so often ruined in fertile soils. It is chiefly owing to this early sowing (although aided by the use of hummelling machinery) that the average weight of barley is so much greater now than it was thirty years ago. From 54 ℔ to 56 ℔ per bushel is now about the average weight in well-cultivated districts; while 57 ℔ and 58 ℔ is by no means rare. The produce per acre ranges from 30 to 60 bushels, 36 bushels being about the average. The quantity of seed used per acre is from 2½ to 3 bushels for broadcast sowing, and about a third less when drilled. As already remarked in regard to wheat, it is well, as the season advances, to avoid, by a fuller allowance of seed, the temptation to excessive tillering, and consequent unequal and later ripening. A good crop of barley yields about 1 ton each per acre of grain and straw.

Section 3.—Oats.

Over a large portion of England oats are grown only as provender for horses, for which purpose they are fully ascertained to be superior to all other grains. Except, therefore, on fen-lands and recently-reclaimed muiry soils, the cultivation of oats in South Britain bears a small proportion to the other cereals. It is in Scotland, "the land o' cakes," that this grain is most esteemed and most extensively cultivated. Considerably more than half of the annual grain crops of Scotland consists, in fact, of oats. The important item which oatmeal porridge forms in the diet of her peasantry, and of the children of her other classes, has something to do with this extensive culture of the oat; but it arises mainly from its peculiar adaptation to her humid climate. As with the other cereals, there are very numerous varieties of the oat in cultivation. In Messrs Lawson's *Synopsis of the Vegetable Products of Scotland*, it is said (Div. i. p. 80), "Our collection comprises nearly sixty varieties, about thirty of which are grown in Scotland; but of these not more than twelve are in general cultivation. These twelve varieties, enumerated in the order of their general cultivation, are, the Potato, Hopetoun, Sandy, Early-Angus, Late-Angus, Grey-Angus, Blainslie, Berlie, Dun, Friesland, Black Tartarian, and Barbachlaw." The first four kinds in this list are those chiefly cultivated on the best class of soils. It is to the produce of these that the highest market prices usually have reference. The weight per bushel of these sorts usually runs from 42 ℔ to 46 ℔. From 50 to 60 bushels per acre is a usual yield of oats. The two last named kinds are chiefly esteemed for their large produce, and adaptation to inferior soils; but being of coarse quality, they are chiefly used for provender. A variety which stands the winter is now frequently grown in England, for the double purpose of first yielding a seasonable supply of green food to ewes and lambs in early spring, and afterwards producing a crop of grain. It has already been stated that in Scotland wheat does not prosper when sown after clover or pasture; but with the oat it is quite the reverse, as it never grows better than on land newly broken up from grass. It is, accordingly, almost invariably sown at this stage of the rotation. The land is ploughed in December or January, beginning with the strongest soil, or that which has lain longest in grass, that it may have the longest exposure to the mellowing influences of wintry weather. In March or April the oats are sown broadcast on this first ploughing, and covered in by repeated harrowings. These are given lengthwise until the furrows are well broken down, for if the harrows are worked across the ridges before this is effected, they catch hold of the edges of the slices, and, partially lifting them, permit the seed-corn to fall to the bottom, where it is lost altogether. As it is only when a free tilth is obtained that the crop can be expected to prosper, care must be taken to plough early and somewhat deeply, laying the furrows over with a rectangular shoulder, to sow when the land is in that state of dryness that admits of its crumbling readily when trode upon, and then to use the harrows until they move smoothly and freely in the loose soil, two or three inches deep. The Norwegian harrow is an important auxiliary to the common ones in obtaining this result. When wild mustard and other annual weeds abound, it is advisable to drill the crop and to use the horse-hoe. When the land is clean, the general belief in Scotland is that the largest crops are obtained by sowing broadcast. When the latter plan of sowing is adopted, from 4 to 6 bushels per acre is the quantity of seed used. The latter quantity is required in the case of the Hopetoun and other large-grained varieties. The condition of the soil as to richness and friability must also be taken into account in determining the quantity of seed to be used. When it is in high heart and likely to harrow kindly, a less quantity will suffice than under opposite conditions. In breaking up a tough old sward, even 6 bushels per acre may be too little to sow. The following very interesting experiment bearing on this point was made in the county of Fife:—"Mr Gulland, Wemyss, offered a sweepstakes in 1850, that 4 bushels of oats, sown per Scotch acre, in poor land, would yield a better produce than 8 bushels sown under similar conditions. The late Mr Hill, maintaining the contrary, accepted the sweepstakes, and a number of others took up the same. Experiments were made by Mr Dingwall, Ramornie, and Mr Buist, Hattonhill. . . . .:—

In Mr Buist's experiments,
"4 bush. sown yielded 28 bush. per acre, 34 lb per bush.
8 bush. sown yielded 36 ,, ,, 34¼ lb ,,

"In Mr Dingwall's experiments,
"4 bush. sown yielded 45 bush. per acre, 38½ lb per bush.
8 bush. sown yielded 49 ,, ,, 39 lb ,, "[1]

The advocates for thin seeding will of course regard even the least of these quantities as foolishly redundant. It is quite true, that if the land is in good heart, the crop will ultimately stand close on the ground from a very small seeding; but it will take two or three weeks longer to do this than if the land had been fully stocked with plants from the first, by giving it seed enough. In our precarious climate, where a late harvest and bad crops usually go together, it is of the utmost importance to secure early, uniform, and perfect ripening; and as liberal seeding tends directly to promote such a result, practical farmers will do well to take care how they omit such a simple means of attaining so important an end. We believe that it is on the principle now indicated that the superior result, both as respects quantity and quality of produce, in the double-seeded lots in the experiments now cited, is to be explained.

As with wheat, the vigour and productiveness of the oat is much enhanced by frequent change of seed. Our agricultural authorities usually assert that the change should, if possible, always be from an earlier climate and better soil. This is undoubtedly true as regards high-lying districts; but with a good soil and climate we have always seen the best results with seed from a later district. A homely old couplet tersely expresses the experience of our ancestors in this matter of the changing of seed-corn by directing us to procure—

"Oats from the hills, bere from the sea,
Gude wheat and pease wherever they be."

On poor hard soils it is usually remunerative to apply a cwt. of guano per acre to the oat crop, sowing it broadcast, and harrowing it in along with the seed. As much additional produce is thus ordinarily obtained as more than pays for the manure, and the land is, in all respects, left in better condition for the succeeding green crop. In the case both of very light and strong clay soils, we have obtained excellent results by applying a liberal dressing of farm yard dung in autumn to grass-land about to be broken up for oats. By using in this way the dung produced during the summer months, we have obtained abundant crops of oats from portions of land which, but for this, would have yielded poorly; and, at the same time, by applying the bulky manure at this stage of the rotation, instead of directly for the succeeding green crop, an important saving of time and labour has been effected, as we shall have occasion to notice when treating of turnip-culture.

When the young oat plants have pushed their second leaf, it is always beneficial to use the roller, as it helps to protect the crop from the evil effects of drought, and facilitates the reaping of it. The oat frequently suffers much from a disease called "segging" or "tulip root," which appears to be caused by the presence of a maggot in the pith of the stems close to the ground. On land which is subject to this disease it is advisable not to sow early. A dressing of lime is also believed to be serviceable as a preventative. On muiry soils this crop is also not unfrequently lost by what is called "*slaying*." This seems to result from the occurrence of frosty nights late in spring, when the crop is in its young stage, which, when grown on such soils, it cannot withstand. The application of large dressings of lime to light muiry soils greatly aggravates this tendency to *slaying* in the oat crop. The only effectual remedy is to improve the texture of the soil by a good coating of clay. Oats yield about 1 ton of grain and 1½ ton of straw per acre.

Section 4.—Rye.

The extensive cultivation of this grain in any country being alike indicative of a low state of agriculture, and of a poor style of living among its peasantry, it must be regarded as a happy circumstance that it has become nearly obsolete in Great Britain. It is still occasionally met with in some of our poorest sandy soils, and patches are occasionally grown elsewhere for the sake of the straw, which is in estimation for thatching, for making bee-hives, and for stuffing horse-collars. Its cultivation as a catch crop, to furnish early food for sheep in spring, is on the increase.

Section 5.—LEGUMINOUS CROPS—*Beans.*

The only members of this family statedly cultivated for their grain are beans and pease. Before the introduction of clover and turnips these legumes occupied a more important place in the estimation of the husbandman than they have done since. Indeed, in many districts naturally well adapted for the culture of turnips, that of beans and pease was for a time all but abandoned. Recently, however, increasing precariousness in the growth of clover, and even of turnips, where they have been sown on the same ground every fourth year for a lengthened period, has compelled farmers to return to the culture of beans and pease for the mere purpose of prolonging the intervals in the periodic recurrence of the former crops. But it is found, in regard to the bean itself, in districts where it has long occupied a stated place in rotations of six or seven years, that its average produce gradually diminishes. We have thus an additional illustration of the importance of introducing as great a variety of crops as possible into our field culture. It is on this principle that beans and pease are now again extensively cultivated on dry friable soils. Winter beans, or pease of some early variety, are generally preferred in such cases. The grain of these legumes, though partially used for human food, is chiefly consumed by horses and by fattening cattle and sheep. Being highly nutritious, they are well adapted for this purpose. By growing beans on a limited portion of the land assigned to cattle crops, a larger weight of beef and mutton can be produced from a given number of acres, than by occupying them wholly with roots, forage, and pasturage. Several varieties of field beans are cultivated in Great Britain, such as the *common horse bean*, the *tick*, the *Heligoland*, and the *winter bean*. The latter was introduced into England about the year 1825, and there rises steadily in estimation. It has been tried in many parts of Scotland, and proves quite hardy, but is objected to from the exceeding shortness of its straw. But for this, it is a valuable acquisition, as it ripens so much earlier than the spring-sown varieties. Beans should never be sown on land that is foul. By diligent horse and hand hoeing, land that is clean to begin with can be kept so under beans, and left in fine condition for carrying a white

[1] *Agricultural Gazette*, 20th November 1852.

corn crop; but in opposite circumstances it is sure to get into utter confusion. It is found advisable, therefore, to take beans after the white crop that has succeeded roots or a bare fallow. In Berwickshire, where a five-years' course, consisting of turnips, wheat, or barley, two years' seeds, and oats, has long prevailed, beans are now not unfrequently introduced by substituting them for the second year's grass. A four-years' course with beans instead of a portion of the seeds is certainly preferable. In cultivating this crop the land is ploughed with a deep furrow in autumn, a dressing of dung being first spread over the surface and turned in by the plough. As early in March as the state of the soil admits, it is stirred by the grubber and harrowed. The seeds are then deposited either in narrow rows 14 inches, or in wider rows 27 inches apart. The latter width has long been preferred in Scotland, because of its admitting of the free use of the plough and the drill-grubber, in addition to the hoe, during the early stages of the plant's growth, and also from a belief that the free entrance of light and air, of which the wide rows admits, increases the productiveness of the crop. We shall describe both modes of culture, and then state the grounds upon which, after long sharing in the opinion just noted, and following that practice, we now give a decided preference to sowing in narrow rows. In sowing at the wider intervals, the soil, having been prepared as already stated, is formed, by a single turn of the common plough, into shallow drills 27 inches apart. Ten or twelve such drills being formed to begin with, the seed is scattered broadcast, at the rate of 3 bushels per acre, by a sower who takes in six of these drills at a time, and gives them a double cast, or by a drilling-machine, which sows three rows at once. The beans either roll into the hollows as they fall, or are turned in by the ploughs, which now proceed to open each a fresh drill, in going down the one side of the working interval, and to cover in a seeded one in returning on the other side. If tares are cultivated on the farm, it is usual to sow a small quantity (say a peck per acre) amongst the beans, on which they are borne up, and so ripen their seeds better, and yield more abundantly, than when trailing on the ground. When the crop comes to be thrashed the tares are easily separated from the beans by sifting. Ten days or so after sowing, the drills are partially levelled by a turn of the chain harrow; and if the land is cloddy, it is smoothed by a light roller. If showers occur when the bean plants are appearing above ground, or shortly after, the common harrows may be used again with the best effect in pulverising the soil and destroying newly-sprung weeds. A horse and hand hoeing is then given, and is repeated if weeds again appear. When the plants have got about 6 inches high it is beneficial to stir the soil deeply betwixt the rows by using Tennant's grubber, drawn by a pair of horses. For this purpose the tines are set so close together as to clear the rows of beans, and the horses are yoked to it by a main tree, long enough to allow the horses to work abreast in the rows on either side of the one operated upon. The soil is thus worked thoroughly to the depth of 6 or 8 inches, without reversing the surface and exposing it to drought, or risk of throwing it upon the plants. Just before the blooms appear some farmers pass a bulking-plough betwixt the rows, working it very shallow, and so as merely to move the surface soil towards the plants. This may do good, but a deep earthing up is hurtful. When the blooms open all operations should cease, as otherwise much mischief may be done. Such an amount of culture as has now been described may be thought needlessly costly and laborious, but unless a bean crop is kept clean, it had better not be sown. And it is to be remembered that the benefit of this careful tillage is not confined to it, but will be equally shared in by the wheat crop that follows. The culture of winter beans differs only in this, that they require to be sown as early in autumn as the removal of the preceding grain crop admits of. When it is determined to sow in 14-inch rows, the seeds are deposited by any of the corn drilling-machines in common use, set for the specified width of rows, or (which we prefer) the soil is formed into narrow ribs or drills by means of the one-horse plough, the seeds are scattered broadcast by hand or machine over this corrugated surface, and they are covered by a double turn of the common harrows, and rolled by a light roller. As soon as the bean plants appear, care must be taken to keep down weeds by diligent hoeing. Two good hoeings will usually suffice, for by the time that the second is accomplished, the crop will speedily so close in as to render any further hoeing impracticable and unnecessary. After repeated trials of these two modes of cultivation, made alongside of each other, we have found that the produce from the narrow rows has been at the rate of from 4 to 6 bushels more per acre than that from the wide rows, and that the soil has been left decidedly cleaner after the former than after the latter mode. It is certainly somewhat startling to find results so opposed as these are to preconceived opinion and approved practice. And yet, when the matter is well considered, it becomes obvious enough why it should be so. The wide rows admit of a most effective process of tillage and hoeing up to the time when the beans come into bloom, when, however, it must wholly cease. But when farther culture is precluded, the need for it by no means ceases, seeing that the rows of bean plants usually remain sufficiently apart to admit of the continued growth of weeds during the long period which intervenes betwixt the blooming and the ripening of the crop. And hence it happens—especially if the spring prove cold and parching—that although the wide-rowed beans have been kept scrupulously clean up to the time of blooming, their upright habit of growth renders it impossible that they can so close in upon the wide space betwixt the rows, as to preoccupy and overshadow the ground sufficiently to keep it clean during the long period that the crop must necessarily be left to its own resources. By sowing in narrow rows the crop is soon in a condition to defend itself against weeds and drought, and hence the saving of labour, the more bulky crops, and the cleaner stubble, which result from sowing beans at 14 rather than 27 inch intervals.

In Scotland the haulm of beans is esteemed an excellent fodder for horses and other live stock, whereas in England it is thought unfit for such a use. The reason of this appears to be, that in the southern counties beans are allowed to stand until the leaf is gone and the stems blackened before reaping; whereas in Scotland they are reaped so soon as the eye of the grain gets black. When well got, the juices of the plant are thus, to some extent, retained in the haulm, which in consequence is much relished by live stock, and yields a wholesome and nutritious fodder. A good crop of beans yields about 1 ton of grain and 1½ ton of straw per acre.

Section 6.—*Pease.*

Pease are sown in circumstances similar to those just detailed, but they are better adapted than beans to light soils. They too are best cultivated in rows of such a width as to admit of horse-hoeing. The early stage at which they fall over, and forbid further culture, renders it even more needful than in the case of beans to sow them only on land already clean. If annual weeds can be kept in check until the pease once get a close cover, they then occupy the ground so completely that nothing else can live under them; and the ground, after their removal, is found in the choicest condition. A thin crop of pease should never be allowed to stand, as the land is sure to get perfectly wild. The difficulty of getting this crop well harvested renders it peculiarly advisable to sow only the early varieties

Section 7.—Other Crops.

The cereals and legumes now enumerated constitute the staple grain-crops of Great Britain. Others are grown occasionally, but more for curiosity than profit. Zealous attempts were made by the late William Cobbet to introduce *maize* or *Indian corn* as one of our regular crops. It has been conclusively proved that none of its varieties yet tried can be ripened in the ordinary seasons of this country. It has indeed been suggested that it might form a useful addition to our garden vegetables,—using it, as it is done in America, by cooking the unripe cobs, and also that we might grow it beneficially as a forage crop. *Lentiles* have recently been grown in different parts of the country; but both of these grains can be imported of better quality, and at less cost, than they can be grown at home.

There is great inducement to agriculturists to endeavour more earnestly to obtain improved varieties of grain by cross-impregnation of existing ones. Something has already been accomplished in this direction, but only enough to show what encouragement there is to persevere. Whenever the same skill and perseverance are directed to the improvement of field crops that our gardeners are constantly exerting, with such astonishing results, on fruits, flowers, and vegetables, we may anticipate a great increase of produce, not only from the discovery of more fruitful varieties, but of such as possess a special adaptation to every diversity in the soil and climate of our territory.

Section 8.—Harvesting of Grain Crops, and preparing them for Market.

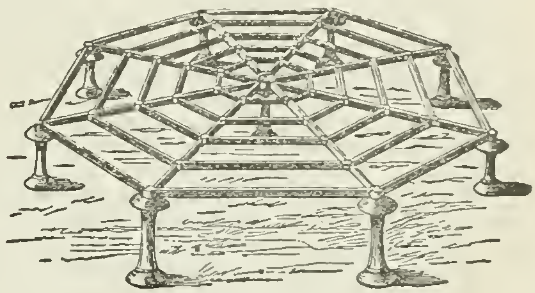
Several distinct modes of reaping grain are in use. The most ancient, and still the most common, is by the sickle or reaping-hook, which is used either with a smooth or serrated edge. The latter was at one time preferred, as by it the work was performed most accurately. The smooth-edged instrument is, however, now the favourite, as it requires less exertion to use it, and the reaper can, in consequence, get through more work in a day; and also because in using it the stalks are less compressed, and consequently dry faster when made into sheaves. In some parts of England the crops are reaped in a method called *fagging* or *bagging*. The cutting instrument used is heavier, straighter, and broader in the blade than the common reaping-hook. The workman uses it with a slashing stroke, and gathers the cut corn as he proceeds by means of a hooked stick held in his left hand. It is a similar process to the mode of reaping with the Hainault scythe—an instrument which has been tried in this country, but never adopted to any extent. The common scythe, especially with that form of handle known as the Aberdeen handle or *sned*, is very extensively used for reaping grain in all parts of the kingdom. Indeed, the practice of mowing grain has been increasing of late years, and would extend more rapidly but for the greater difficulty of finding good mowers than good reapers. A greater amount of dexterity is required to cut grain well by the scythe than by the sickle. The difficulty lies not in making smooth and clean stubble, but in so laying the swathe as to admit of the corn being sheaved accurately. When the mower lays his swathe at right angles to his line of progress, and the gatherer is skilful and careful, corn may be handled as neatly in reaping by the scythe as by the sickle. When the crops are not much laid or twisted, mowing is somewhat the cheapest of these modes of reaping. Its chief recommendation, however, is that mown sheaves dry most quickly, and suffer least from a drenching rain. This arises from the stalks being less handled, and so forming an open sheaf, through which the wind penetrates freely. Tightly bound sheaves are always difficult to dry.

In Berwickshire and adjoining counties the reaping of the crops has hitherto been accomplished by employing, at day's wages, such a number of reapers as suffices to cut down the crops on each farm in from twelve to twenty days. The rate of wages paid to reapers for a number of years has ranged from 2s. 6d. to 3s. 6d. each *per diem*, with victuals in addition, costing about *eightpence* for each person. In marshalling the band, two reapers are placed on each ridge of 15 or 18 feet in breadth, with a binder to each *four* reapers, and a steward, or the farmer in person, to superintend the whole. When the crop is of average bulk, and lies favourably for reaping, each *bandwin*, or set of *four* reapers and a binder, clear *two* acres in a day of ten hours, but $1\frac{1}{4}$ to $1\frac{1}{2}$ acre only, if it is bulky and lodged. The cost of reaping by this method is therefore from 10s. to 15s. per acre. With a reaping-machine cutting say six acres *per diem*, and requiring in all ten persons (five men and five women or stout lads) to attend to and clear up after it, at an average wage, including victuals, of 3s. each, and allowing 3s. *per diem* to cover tear and wear, and interest on its prime cost, there seems a reasonable prospect of a goodly portion of our future crops being reaped for about 6s. per acre. The labour of the horses employed in working the reaper is not included in this estimate, as at this season they would otherwise be idle, and yet eating nearly as much food as when at work. There would thus be a saving in actual outlay of about 5s. per acre. But this is the least important view of the matter. On a Berwickshire farm producing 200 acres of crop, there are usually at least six pairs of horses kept, with a resident population sufficient to yield about thirty persons (including women and youths) available for harvest labour. The stated forces of such a farm will therefore suffice to man *three* reaping-machines, which, if the weather is favourable, and the crops standing erect or lying in one direction, will cut down the crop in about ten days. When portions of the crop are much lodged and twisted, it becomes necessary to employ part of the labourers in clearing out such portions by the scythe or sickle. It is often possible to manage these awkward-lying portions by setting one or more men, each with a stout staff, to raise up the crop and lay it towards the machine. When two or more machines are used on the same farm, it is best to work them together by cutting the whole length or width of the field in whichever direction the general lay of the crop admits of them working to most advantage. As each machine completes its cut, it returns empty to the side from which it started; and they follow each other at such an interval as gives time to the lifters and binders, who are placed equidistant along the whole line, to keep the course clear. In such cases a man is usually employed to sharpen the spare knives, to assist in changing them from time to time, and to attend to the oiling and trimming of the whole machinery. It is good economy to have a spare machine at hand ready to put in the place of one that may be disabled by some breakage, and thus avoid interruption to the urgent work of reaping while the damage is being repaired. Great progress has been made in recent years in working these machines skilfully and systematically; they are in general use in all well-cultivated districts, and the time appears to be at hand when the whole grain crops of the country will be reaped by means of them.

It is now agreed on all hands that grain should be reaped before it becomes what is called *dead* ripe. In the case of wheat and oats, when the grains have ceased to yield a milky fluid on being pressed under the thumb-nail, and when the ears and a few inches of the stem immediately under them have become yellow, the sooner they are reaped the better. Barley requires to be somewhat more matured. Unless the pink stripes on the husk have disappeared, and the grain has acquired a firm substance, it will shrink in drying, and be deficient both in weight and colour. When allowed to stand till it gets curved in the neck, the straw of barley becomes so brittle that many ears break short off in the reaping, and it then suffers even more than other grain crops under a shaking wind.

It is of great consequence to see that corn is dry when it is tied up in sheaves, that these are not too tightly bound, and that every sheaf is kept constantly on foot. From the increased demand for harvest labourers, and the rapidity with which operations must be carried forward, stooking is not now performed with the same accuracy that it was wont to be. There is therefore the greater need for employing a person to review the stooks daily, and keep every sheaf erect. It was formerly the practice in Scotland to set up oats and barley in full stooks of twelve sheaves each, viz., five pairs and two hood-sheaves. These hood-sheaves are an excellent defence when wet weather sets in, but they retard the drying of the corn in fine weather, and there are now few binders who can set them up so as to stand securely. It is better, therefore, to aim at rapid drying, and for this purpose to have the sheaves small individually, and to set but *four* or *six* of them together. Large sheaves are worse to dry than small ones, not only from their greater bulk, but from their being almost inevitably tighter bound. The utmost vigilance is required on the part of farmers to avoid this fault. Beans and pease are reaped by the sickle. The former are usually not bound into sheaves at once, but left prostrate in handfuls for a few days until they have withered a little. But it is on the whole safer to stook them as they are reaped. They are then sheaved and bound with ties of twisted straw, which must be provided beforehand. In stacking beans, the tops of the sheaves are kept outwards, as by this means fewer pods are exposed to the weather, or to the depredations of fowls, &c., than when the butts are to the outside. Pease are rolled into wisps as they are reaped, and afterwards turned daily until they are fit to carry. When stacked, they must instantly be thatched, as they take in wet like a sponge. It requires no little discrimination to know when sheaves are dry enough to keep in a stack. The farmer finds it for his profit to consult his most intelligent and experienced labourers on this point. On thrusting the hand into a sheaf sufficiently dried, there is a lightness and kindliness to the touch not easily mistaken when once understood. Whenever this is ascertained, the crop is carried with the utmost possible dispatch. This is best accomplished by using one-horse carts, and by building the sheaves into round stacks of *ten* or *twelve* loads each. Very large stacks are for ostentation, not for profit. The labour of pitching up the sheaves to them is needlessly great; corn is much sooner in a state to keep in small stacks than in large ones, and sooner gets into condition for market; the crop is more accessible for thrashing in *ten* load quantities than in huge ricks; and the crop of different fields and kinds of grain more easily kept separate. While naming ten or twelve loads as a convenient quantity to put together in each stack, let it be observed that this assumes the sheaves to be in a thoroughly dry condition; for in wet seasons it frequently happens that the sheaves have a sufficient degree of dryness to keep safely in stacks of five or six loads each, although they will certainly heat if double these quantities are put together. Judicious farmers therefore accommodate the size of their stacks to the condition of the sheaves, and are more concerned to get their crops secured rapidly and safely than to have their stacks of uniform size. For the same reasons, it is often expedient to stack portions of the crop either in the field where it grew or at some convenient site nearer than the homestead, but on the way towards it, and where two carts will suffice to keep each stacker in work. An incidental benefit from having the stacks in detached groups is, that it lessens the risk from fire.

It is always desirable to have the stacks built upon frames or stools elevated 18 or 20 inches from the ground. Besides the security from vermin thus attained, there is a free admission of air to every part, particularly when aided by a triangle of rough timber in the centre, which speedily insures thorough dryness in the whole stack. When stacks are built upon the ground with a mere bedding of straw under them, the grain from the basement tiers of sheaves is often lighter by several pounds per bushel than that from the rest of it. A farmer who has his rick-yard fully furnished with these frames can often carry his crop without risk—when, if built on the ground, it would inevitably heat—and have the grain in condition for market earlier by months than in the latter case. As the stacks are built,



Young's Stack-Stool.

they are thatched without delay. For this purpose, careful farmers provide beforehand ample stores of thatch and straw ropes. The thatch is not elaborately drawn, but merely straightened a little as it falls from the thrashing-mill, tied into large bundles, and built up into stacks, where it gets compressed, and so lies more evenly than if used direct from the mill. A good coating of such thatch secured by straw ropes, interlacing each other in chequers, forms a secure and cheap covering, easily put on by ordinary farm labourers, and possesses, with all its roughness, an air of unpretending rustic neatness which harmonises well with surrounding objects, and which we greatly prefer to the elaborate ricks of the southern counties with their shaved sides, combed thatch, and weather-cock a-peak. Apart from its cost, the shaving of stacks is objectionable, as they then suffer more from a beating rain or snow-drift than when the natural roughness is left upon them, on the same principle that a coarse, shaggy topcoat shoots off wet better than a smooth broadcloth. A stout two-ply cord made of cocoa-nut fibre, or coir, is coming into use as a substitute for straw ropes in the thatching of stacks.

With proper machinery propelled by steam or water, the thrashing and dressing of grain is a simple and inexpensive process. As grain is now universally sold with a reference to its weight per bushel, its relative value depends much upon its dryness and thorough freedom from chaff, dust, light grain, and seeds of weeds. Farmers who are systematically careful in the cultivation, harvesting, thrashing, and dressing of their crops, can always command the best prices of the day. In preparing a parcel of grain for market, it is a good plan to measure a few sacks very carefully, ascertain the average weight of these, and then fill every remaining sack to that weight exactly.

CHAPTER XII.

CULTIVATED CROPS—ROOT CROPS.

Section 1.—*Potato.*

The events of late years render it necessary to regard this root somewhat differently than was warranted by its previous history. Its value as an article of food, relished alike by prince and peasant, its easy culture, its adaptation to a very wide diversity of soil and climate, and the largeness of its produce, justly entitled it to the high esteem in which it was universally held. Like many other good gifts, it was, however, grossly abused, and diverted from its legitimate use; and advantage was taken of its amazing productive powers to elevate it from the place of an agreeable, wholesome addition to the daily food of the community to that of "the staff of life." In Ireland and the Highlands of Scotland, the people, already in a painfully degraded condition, and contented with the potato as their sole food all the year round, took occasion, from its very productiveness, under the rudest culture, to subdivide their lands, and marry prematurely, with reckless improvidence, and amid an ever-deepening degradation. We know now, from the utter prostration and helplessness into which this wretched population was at once thrown by the memorable potato disease, the terrible penalty which this abuse of "a good gift" has brought directly on the miserable sufferers, and indirectly on the whole community. It will be well if the stern lesson, enforced by famine and pestilence, have the effect of leading to a better social condition. Viewed in this light, the potato disease may yet prove a blessing to the nation. Its continued prevalence, although in a mitigated form, cannot well be regarded otherwise, when we remember the frantic eagerness with which the Irish peasantry replanted their favourite root on the first indication of its returning vigour, and the desperate energy with which they cling to it under repeated disappointments. Apart from this speciality, the precarious health of this important esculent is much to be regretted. It seems contrary to analogy to suppose that it is likely either to be entirely lost or to manifest a permanent liability to disease. It seems more natural to suppose that by-and-by the disease will disappear, or that some efficient remedy for it will be discovered. Railways afford great facilities for transporting this bulky commodity at little expense to great distances, and thus render the market for it available to a wider district. Apart from disease, this facility of transport would naturally insure its more extended cultivation. This enlarged cultivation of a crop which, to be grown successfully, requires a soil rich in fertilising matters, has moreover been rendered practicable by the facilities which the farmer now has of obtaining guano and other portable manures.

The varieties of the potato, whether for garden or field culture, are exceedingly numerous, and admit of endless increase by propagating from seeds. It would serve no useful purpose to enumerate here even a selection from the sorts in use in different parts of the country. In Messrs Lawson's *Synopsis of the Vegetable Products of Scotland* a description of 175 kinds is given, to which the reader is referred for particulars. When the crop is grown for cattle food, bulk of produce will be the primary consideration; but for sale or family use, flavour, keeping quality, and handsome appearance, will be particularly attended to. Exemption from disease is now a momentous consideration, whatever the use for which it is grown. There is this difficulty, however, connected with selections on the score of healthiness, that while in each season since the disease broke out certain varieties have escaped, it is observed from year to year that the exempted list varies, certain kinds that had been previously healthy becoming as obnoxious to disease as any, and others in a great measure escaping that had suffered much before. Indeed, certain parties, from observing that diseased tubers left in the ground have produced healthy plants in the following season, have been induced purposely to plant diseased potatoes, and with good results. This, however, is probably due to the mere fact of their being kept in the earth.

In field culture the potato is frequently grown on a portion of the fallow break; but its appropriate place in the rotation is that usually assigned to beans, with which, in an agricultural point of view, it has many features in common, and in lieu of which it may with advantage be cultivated. As the potato requires to be planted as early in spring as the weather will admit of, thus leaving little opportunity for cleaning the land, and as its mode of growth forbids any effective removal of root-weeds by after culture, it is peculiarly necessary to have the land devoted to this crop cleaned in autumn. Winter dunging facilitates the planting, and is otherwise beneficial to the crop by producing that loose and mellow condition of the soil in which the potato delights. The quality of the crop is also believed to be better when the dung is thoroughly incorporated with the soil, than when it is applied in the drill at the time of planting. A liberal application of manure is necessary if a full crop is expected. The rank growth thus induced renders it, however, more obnoxious to the blight, and hence at present it is more prudent to aim rather at a sound crop than an abundant one, and for this purpose to stint the manure. When it is applied at the time of planting, the mode of procedure is the same as that which will presently be described in the section on turnip culture. The potato sets are prepared a few days before they are expected to be needed. Tubers about the size of an egg do well to be planted whole; and it is a good plan to select these when harvesting the crop, and to store them by themselves, that they may be ready for use without further labour. The larger tubers are cut into pieces having at least one sound eye in each, although two are better. It is of great consequence to have seed-potatoes stored in a cool and dry pit, so that if possible they may be prepared for planting before they have begun to shoot. If there has been any heating in the pit, the potatoes are found to be covered by a rank crop of shoots, which are necessarily rubbed off, and thus the most vigorous eyes are lost, and much of the substance which should have nourished the young plant is utterly wasted. A sufficient number of dormant eyes are no doubt left, but from the comparatively exhausted state of the tubers, these produce stems of a weaker and more watery character, and more liable to disease than those first protruded. To avoid these evils, gardeners are at pains to invigorate their seed potatoes and husband their whole powers for early and vigorous growth by *greening* them in autumn, storing them in a cool place with a current of air passing through it, and then in early spring exposing them to light on a floor, whence they are carefully removed and planted with their short *green* shoots unbroken. Neither the *greening* nor the sprouting under cover and in the light can ordinarily be practised on the scale on which the field culture of the potato is conducted. But the important feature in it, viz., so treating potatoes intended for seed that the crop shall be produced from the first and most vigorous shoots, and that these shall obtain the full benefit of the natural pabulum stored up for their use in the parent tuber, should be carefully considered and imitated if possible in field culture.

The report of the meeting of the Edinburgh Botanical Society, on 8th January 1852, bears that "Professor Simpson communicated the results of some experiments made by himself and Mr Stewart relative to the growth of alpine plants after having been kept artificially covered with snow in an ice-house for many months. Seeds and plants when kept in this way during winter, and then brought into the warm air of summer, germinate and grow with great rapidity. Mr Stewart had also made experiments with animals, and he found that the chrysalis so treated produced a moth in eleven days after being brought into the atmosphere, while another chrysalis of the same moth did not do so for three or four months after. In arctic regions the rapid growth of plants during the short summer was well known. Professor Simpson alluded to the importance of similar experiments being made on the different kinds of grain. He referred to the rapidity of harvest in Canada and other countries where the cold lasted for many months, and he was disposed to think that if grain was kept in ice-houses during the winter, and sown in spring, there might be an acceleration of the harvest."

The suggestion for the treatment of seed corn is certainly deserving of trial; but the known difficulty of hindering the premature germination of potato sets in the ordinary method of storing them seems to point to them as the peculiarly appropriate subjects of such an experiment.

Potato drills should not be less than 30 inches wide, nor the sets less than 10 or 12 inches apart in the rows. The usual practice is to take the sets to the field in sacks, which are set down at convenient distances for replenishing the baskets or aprons of the planters. When a large breadth is to be planted, a better way is to have the sets in carts, one of which is moved slowly along in front of the planters A person is seated in the cart, who has by him several spare baskets which he keeps ready filled, and which are handed to the planters in exchange for empty ones as often as required. This greatly economises the time of the planters, and admits of a greater amount of work being accomplished by them in a day. Single-bout drills are quite sufficient, so far as the success of the crop is concerned. So soon as the young potato plants are fairly above ground, the drill-grubber should be set to work and followed up without delay by hand-hoeing. Mr Wallace, North Berwick Mains, a most successful cultivator of potatoes, has for many years taken off all the shoots, save one, from the potato sets as they appear above ground, and the prunings are used in filling up blanks; the result has been that the produce of the solitary stem is both larger and of more equal size and quality than when the shoots are all left. A turn of the horse-hoe and another hand-hoeing after a short interval are usually required, after which the common practice is to earth up the rows by the double mould-board ploughs. There is reason to believe that this latter practice usually does harm rather than good. It no doubt prevents the uppermost tubers from getting greened by exposure to the light, but it is believed that the injury inflicted on the roots which spread into the intervals betwixt the rows far more than counterbalances any benefits that result, or have been supposed to result, from this earthing up. After the plants are a foot high, a slight stirring of the surface to keep down weeds is all the culture that is admissible consistently with the well-doing of the crop

When the crop is matured, which is known by the decay of the tops and the firmness of the epidermis when the tubers are forcibly rubbed by the thumb, advantage is taken of every dry day in harvesting the crop. With small plots, the fork is certainly the most efficient implement for raising the tubers; but on the large scale, when expedition is of great consequence, they are always unearthed by the double mould-board plough. Alternate rows are split open in the first instance, and then the intervening ones, as the produce of the first is gathered. When a convenient breadth has thus been cleared, a turn of the harrows is given to uncover such tubers as have been hid from the gleaners at the first going over. This work is now very generally accomplished by means of a bulking-plough divested of its wings, and having attached to its sole a piece of iron terminating in radiating prongs. This being worked directly under the row of potato plants, unearths the tubers, and spreads them on the surface by one operation. The potatoes are gathered into baskets, from which they are emptied into carts and conveyed at once to some dry piece of ground, where they are piled up in long narrow heaps and immediately thatched with straw. The base of the heaps should not exceed a yard in width, and should be raised above the surface level rather than sunk below it, as is very usually done. As the dangers to be guarded against are *heating* and *frost*, measures must be taken with an eye to both. The crop being put together in as dry and clean a state as possible, a good covering of straw is put on, and coated over two or three inches thick with earth, care being taken to leave a chimney every two yards along the ridge. By thus keeping the heaps dry and secure from frost, it is usually possible, even yet, to preserve potatoes in good condition till spring. Such diseased ones as have been picked out at the gathering of the crop can be used for feeding cattle or pigs. The fact that pigs fatten apparently as well on diseased potatoes when cooked by steaming or boiling, as on sound ones, is certainly a very important mitigation of this dreaded calamity. There are several varieties of the potato, such as "yams," "lumpers," "mangel-wurzel potato," &c., which, although unfit for human food, are much relished by cattle, and which, from their abundant produce, healthiness, and great fattening quality, are well deserving of being more generally cultivated for the purpose of being used in combination with turnips and other substances in the fattening of cattle. The turnip crop of recent years has been nearly as much diseased as the potato crop, and as one remedy against "fingers-and-toes" in the former is to let longer intervals of time intervene before their recurrence in the same field, and as it has been ascertained that an acre each of beans, potatoes, and turnips will produce more beef than three acres of turnips alone, it is worthy the consideration of those concerned whether it would not be prudent to substitute a crop of these coarser potatoes for a portion of their turnip crop on fields or parts of fields that have borne diseased turnips in previous rotations. Eight tons per acre is a good crop of potatoes.

Section 2.—Turnips.

The introduction of turnips as a field crop constitutes one of the most marked epochs in British agriculture. To the present day no better criterion exists by which to estimate its state in any district, or the skill of individual farmers, than the measure of success with which this or other root crops are cultivated. We have already, in our section upon fallowing, described in detail the process of preparing the soil for drilled green crops. Referring the reader to what is there said, we now proceed with our description of turnip culture.

Previous to the introduction of bone-dust and guano, farm-yard dung formed, in the majority of cases, the only available manure for the turnip crop. It was almost invariably formed into heaps in the field to which it was to be applied, and repeatedly turned, as great stress was laid on having it well rotted. The introduction of these invaluable portable manures has, however, not only immensely extended the culture of the turnip, but has materially modified the course of procedure. On the first introduction of bone-dust the practice was to use the fold-yard dung as far as it would go, and to apply bone-dust alone, in quantities of from sixteen to twenty bushels per acre, to the remainder of the crop. Guano, too, for a time was used to some extent on the same principle; but now it is most satisfactorily proved that whereas very good crops of turnips can be obtained by manuring either with dung alone, at the rate of from fifteen to twenty tons per acre, or bones alone, at the rate of sixteen to twenty bushels, or guano alone, at the rate of three or four cwt., much *better* crops can be obtained by applying to each acre its proportion of each of these kinds and quantities of manures. A portion of the bones is now usually applied in the form of superphosphate of lime; and as this substance, and also guano, have a remarkable power of stimulating the growth of the turnip in its earliest stage, forcing it to the state fit for thinning from ten to fourteen days earlier than heretofore, there is now no occasion for the dung being in the advanced state of decomposition that was formerly found necessary. When farm-yard dung alone was used, it behoved to be in a soluble state, ready to furnish nourishment to the plant from the beginning. But in bringing it to that state a considerable loss is sustained by fermentation, and its bulk is so much reduced that it becomes difficult to distribute evenly the allowance which would be available for each acre, in order to give the whole crop a share of it. This, however, it is most desirable to do, as good farm-yard manure contains in itself the whole elements required by the crop; and hence an additional reason for the plans of applying farm-yard dung which have already been noticed. If that made during the previous summer has been applied in autumn to the lea before ploughing for oats, as far as it will go, and another portion of the contemplated turnip break dunged before the winter furrow, with all that has been made up to that time, and the future accumulations up to April formed into heaps, to be applied in the drills for the latest sowings, the manures produced on the farm may be made to go over nearly the whole breadth under root crops.

In proceeding to sow those portions that were dunged before the oat crop and on the stubble, all that is required is to form the drills, and apply the guano or bones, or mixture of both, by hand. In doing this, ten or twelve drills are set out the evening before, that all may be ready for a good start. The light manure is taken to the field in carts, which are unyoked at convenient distances for replenishing the aprons of the young persons (one for each plough) or the machine by which it is distributed along the drills. The sowers of the manure being started on the outside drills, the ploughmen proceed to open fresh ones inside in going, and to cover in the manure by reversing the first formed ridgelets as they return. The seed machine, sowing two rows at a time, follows close up to the ploughs, and thus the work goes rapidly on, each plough getting over from 2½ to 3 acres a-day. When farm-yard dung is applied at the time of sowing, the process is the same, except that the drills must be opened somewhat deeper, and that the dung-carts, followed by an adequate number of spreaders, precede the sowers of the light manures. In filling the dung-carts, one able-bodied labourer is required for each plough employed in drilling; and where these amount to three, six spreaders are required to distribute it evenly along the drills. In some districts the double-breasted plough is used in forming the drills and covering in the dung. In the hands of a skilful ploughman that implement does certainly make neater work to look at; but so far as the success of the crop is concerned, the common swing-plough is preferable, for in covering in with it the earth is made to run over the top of the ridgelet, by which means the clods fall into the hollow, and the finest of the mould is left on the top, where the seed is to be deposited. With the double mould-board this cannot so well be done, and the consequence is, that a groove is formed on the top of the ridgelet, in which the small dry clods, carried up by the tail of the mould-board, are left, forming the worst possible bed for the seed. In parching weather it is usual to pass a light roller over the drills immediately after sowing, to retain the moisture and insure germination. The seed is deposited near the surface, half an inch of mould being a sufficient covering. The quantity sown is 2 lb per acre of globe or yellow turnip seeds, and 3 to 4 lb of swedes. Care must be taken that the seed is fresh, so as to have a vigorous and thick plant. Thick sowing increases the difficulty of thinning out the plants, but it hastens their growth, and diminishes the risk of failure from the depredations of the turnip beetle. The time of sowing in the south of Scotland extends from the beginning to the end of May for swedes, and thence to the middle of June for yellows and globes. A partial sowing of yellow or globe is, however, made by careful stock-masters before sowing the swedes, to be ready for use by the end of August or beginning of September, when pasturage fails. Sowings of early varieties, such as the stubble turnip and certain yellow kinds, are also made after winter tares or other catch crops, until the middle of July; but in Scotland they cannot be sown later than this with advantage, unless for the production of a crop of seed. The average weight per acre of swedes may be stated at 18 tons, and of turnips at 22 tons, but double these rates have occasionally been obtained. Recent experiments go to show that with liberal manuring and early sowing, the weight of the crop is considerably increased by thinning out the plants at wider intervals than has hitherto been customary. The usual practice in Scotland has been to sow in ridgelets 27 inches apart, with 9 or 10 inches betwixt the plants. Recent experiments establish the fact that, with 15 inches from plant to plant, much larger bulbs and a greater acreable produce are obtained. As it is ascertained that in the case of swedes the largest bulbs are also the best in quality, it is of the greater consequence to allow them ample room.

The thinning is commenced as soon as the rough leaf is fairly developed. Previous to this operation the horse-hoe is worked betwixt the rows for the double purpose of destroying weeds and facilitating the operation of thinning. This operation is sometimes still farther facilitated by using Huckvale's machine, which slaps out the rows so as to leave tufts of plants at regular distances apart. The *singling* of the plants is performed by the hand-hoe. The young persons by whom this work is usually performed advance in *echelon* with their backs to the untouched work, the steadiest and most expert worker leading the band. This arrangement insures a uniform rate of progress, saves the finished work from being trodden upon, and keeps the workers closely under the eye of the steward. This thinning of the rows, so as to leave single plants at regular intervals of 12 to 15 inches apart, is accomplished by an alternate thrusting and drawing motion of the hoe, which a little practice enables the workers to perform with such precision that very rarely do they either make a gap or leave double plants, and still more rarely do they require to stoop down to disentangle them with their fingers. Three of these workers can usually thin an acre in a day. With ordinary care on the part of the overseer, there is no great difficulty in getting the plants left single at proper intervals; but it is very difficult to get the hoers trained to select and leave only the stoutest plants. And yet so important is this, that, all other things being equal, a difference of two to three tons per acre in the rate of produce has been ascertained to result on comparing rows that had been thinned by a person who took pains to select and leave the best plants, with others on which they had been left indiscriminately. When the plants have rallied after the thinning, and begun to grow rapidly, the usual practice has been to turn a furrow from either side of them into the middle of the interval by a one-horse plough, and then to level this down by a turn of the horse-hoe. A great improvement on this practice is to use Tennant's grubber instead, adjusted for drill work in the manner already described. By thus using a strong implement drawn by two horses, the soil in the intervals betwixt the rows can be stirred a foot deep if required, without any risk of hurting the young plants, and this, too, is accomplished by a single operation. A second hand-hoeing is then given, which usually completes the after culture.

The nature of the soil will generally determine the mode of consuming the crop. On all loose, dry soils, feeding off by sheep is the most profitable plan; whereas on deep, strong loams, it is advisable to withdraw the whole produce, and have it eaten by cattle, as, unless in very favourable weather, when even a fourth is fed off by sheep, the extra manuring does not compensate to the after crops for the injury which they usually sustain from the treading and poaching. On the poorest class of light soils the whole crop should, if possible, be consumed where it grows by sheep; but on those of a better description, a third, a half, or two-thirds may be withdrawn for the feeding of cattle, according to circumstances. Whatever the proportion left on the ground, care is to be taken to regulate the intervals so as to distribute the treading and droppings of the sheep as equally as possible over the field.

The management of the turnip crop so as that it may be supplied to the live stock in the best possible condition during the entire season, is a point of the greatest importance. The portion that is to be used as cattle food is removed from the ground as soon as the crop is sufficiently matured, and before the time when drenching rains and severe frosts may ordinarily be looked for. The best way of preserving turnips is by storing in broad flat heaps, not exceeding 20 inches deep, on some dry and sheltered situation, open to the sun, and covering them with a good coating of straw. It takes less labour to put them together in this way, and less straw to cover them; and being less exposed to frost and parching winds, they retain their juices much better than when stored in long narrow heaps. The pulling of swedes preparatory to storing is much facilitated by passing under them a sharp share, and so cutting across the tap-roots without displacing the bulbs. The thatch of the corn-stacks that are thrashed in autumn is usually reserved for covering turnip heaps. After 1st November it is well to make diligent use of every favourable hour in thus securing the turnip crop.

The portion to be fed off by sheep must necessarily be treated in a different manner. What is to be used after Christmas can be very readily defended against frost by earthing up in the drills with the common plough. But as what is to be consumed by the young sheep must be pulled and trimmed at any rate, in order to be sliced, the best way is to throw the turnips into heaps at regular distances, and cover them with a thin coating of earth. By this means the turnips are kept from running to stems, and the sheep get them clean and fresh, whatever the state of the weather.[1] The same end is secured by opening a trench by a bout of the common plough, into which the turnips from two drills on either side are laid in regular order with their tops uppermost, and the earth turned over upon them by reversing the course of the plough. When wanted for use they are again unearthed by means of the plough. The feeding qualities of turnips are so seriously impaired by exposure to frost, even when they escape actual destruction, that the expense of securing them by one or other of these methods is always amply repaid. In very mild winters, again, storing is equally effective in preventing the virtues both of the turnips and the soil from being wasted by the pushing of the seed stems.

The turnip is liable in the early stages of its growth to the attacks of various insects. The most formidable of these enemies is the *turnip beetle*, which frequently settles upon the plants as soon as they appear above ground in such numbers as totally to destroy the whole of them. The best way of guarding against these nimble adversaries is to endeavour, by careful preparation of the soil, liberal manuring, and thick seeding, to secure a thick plant and rapid growth; for whenever the rough leaf is expanded the risk from this quarter is over. From time to time the young turnip plants are assailed by the larvæ of certain butterflies and moths, which sometimes appear in such numbers as to cause serious alarm, but ordinarily their attacks occasion but a slight check to the growth of the crop.

A far more formidable evil is the disease called "fingers and toes," which, although long known, seems to be steadily extending, and has been wider spread and more virulent since 1851 than in previous years. This truly formidable disease sometimes shows itself by the time that the plants are ready for thinning, but more usually it is about the stage when the second hoeing is given that unmistakable indications of its presence are observed. The crop appears in high health, and is making rapid growth, when suddenly, under hot sunshine, numbers of the plants are seen to droop with flaccid leaves; and examination being made, it is found that the disease has already made serious progress. In some cases it is chiefly confined to the tap-root, which is distorted with knobby excrescences. In others, the roots present a thickened, palmated appearance, giving rise to the popular name for the disease, "fingers and toes;" while in others the lateral roots expand into glandular-looking tubers, which frequently appear partially above ground at distances of several inches from the central stem. For a time all these forms of the excrescences present a smooth healthy looking skin, yielding no trace of the presence of insects of any kind, either externally or internally. By-and-by the skin cracks over the excrescences, which speedily assume a gangrenous appearance. Indeed, the whole symptoms present a striking analogy to cancer in the animal system. By the time that the healthy plants are approaching near to maturity, the most diseased ones have usually lost all resemblance to turnips, and there remains on the land a substance like rotten fungus. In very bad cases whole acres together are found in this state, with here and there a sickly distorted turnip still showing a few green leaves. At other times a few only of the plants are wholly destroyed; the field, to a casual observer, looking not much amiss, though a closer inspection proves that the general crop is of stunted growth, with few plants entirely free from the disease. Such partially diseased roots are not absolutely rejected by sheep, but they are evidently unpalatable and innutritious, while the crop as a whole is more speedily consumed than its general appearance would lead one to expect. When this disease appears on farms that have previously been exempt from it, it is usually confined for a year or two to small patches, which, however, in the absence of remedial measures, steadily and rapidly extend, not only on the recurrence of a turnip crop on the same fields, but over the other parts of the farm. Indeed, there are not wanting indications of its being propagated by contagion; as, for instance, when tainted roots are carted into pastures, and the disease shows itself most in those places where they have been consumed, when, in course of rotation, the field comes afterwards to bear a turnip crop. When they are consumed by cattle in fold-yards, the dung

[1] During the unusually wet winter of 1852–53 a large quantity of turnips and swedes intended for cattle food was stored in this way. The trimming and storing was carried on every dry day, and the carting postponed until the occurrence of frost or drought admitted of its being done without injury to the land.

may be the medium of contamination, on the supposition that this conjecture is well-founded. Ploughing land in a wet state evidently aggravates the disease. We know of one instance where a strip down the middle of a field was ploughed in autumn while soaked by rain, on which wet ploughed portion the turnips were evidently more diseased than over the rest of the field. In another instance which came under our personal observation, a ditch running along part of the top of a field of upwards of 50 acres, was scoured in spring, and the mud spread back over the headland. The whole field was, in the same season, sown with turnips, which proved an excellent crop, entirely free from "fingers and toes," with the exception of that portion of headland on which the mud was spread, where every plant was diseased. Although wholly in the dark as to the nature and propagation of this disease, it is well to know that the judicious application of lime is a certain remedy. In order, however, to its efficacy, it must be applied in a *powdery state* after the autumn ploughing, and immediately incorporated with the soil by harrowing; or else, as a compost with earth, spread on the lea before breaking up for oats. We know from experience that a very moderate dose (say four tons of unslaked shells to the acre) applied in this way will suffice to prevent the disease. It is on light soils that its ravages are most frequently experienced, and to these heavy doses of lime are unsuitable. Indeed, whether for promoting the general fertility of soils, or for warding off the attacks of this disease, moderate applications of lime every *twelve* years or so seem preferable to heavier dressings at longer intervals. The name "fingers and toes" is not unfrequently applied to a distinct disease to which the turnip, in common with the cabbage and other coleworts, is liable—namely *anbury* or club root. When the knobby excrescence which is found on plants affected by anbury is broken up, it is found to encase a white maggot, whose presence is the obvious cause of the mischief. We have seen young cabbages which had begun to droop from clubbing, when pulled up, freed from the parasite, and replanted, regain healthy growth and come to prosperous maturity. In the case of the "finger and toe," the most careful investigation, aided by the microscope, has hitherto failed to detect any insect cause for this disastrous malady.

Section 3.—Mangel-Wurzel.

This root has been steadily rising in estimation of late years. It is peculiarly adapted for those southern parts of England where the climate is too hot and dry for the successful cultivation of the turnip. A competent authority declares that it is there easier to obtain 30 tons of mangold than 20 tons of swedes, and that it is not at all unusual to find individual roots upwards of 20 ℔ in weight. In Scotland it is just the reverse, it being comparatively easy to grow a good crop of swedes, but very difficult to obtain 20 tons of mangold. This plant is very susceptible of injury from frost, and hence in the short summer of Scotland it can neither be sown so early nor left in the ground so late as would be requisite for its mature growth. These difficulties may possibly be got over either by the selection of hardier varieties or by more skilful cultivation. Its feeding quality is said to be nearly equal to that of the swede; it is much relished by live stock—pigs especially doing remarkably well upon it; and it has the very important property of keeping in good condition till midsummer if required. Indeed, it is only after it has been some months in the store heap that it becomes a palatable and safe food for cattle. It is, moreover, exempt from the attacks of the turnip beetle. On all these accounts, therefore, it is peculiarly valuable in those parts of Great Britain where the summer is usually hot and dry—conditions of climate which are favourable to the mangold and peculiarly unfavourable to the turnip.

Up to the act of depositing the seed, the processes of preparation for mangold are identical with those described for the turnip; winter dunging being even more appropriate for the former than for the latter. The ridgelets being formed 28 inches apart, and charged with a liberal allowance of dung and guano, the seeds are deposited along the top, at the rate of about 4 ℔ per acre. The common drilling machines are easily fitted for sowing its large rough seeds, which should be sown from the 10th to the 25th April. The after culture is also identical with that of the turnip. The plants are thinned out at distances of not less than 15 inches apart. Transplanting can be used for filling up of gaps with more certainty of success than in the case of swedes. But we find it much more economical to avoid such gaps by sowing a little swede seed along with the mangold. Several varieties of the plant are cultivated—those in best repute being the *orange globe*, the *long yellow*, and the *long red*. This crop requires a heavier dressing of manure than the turnip to grow it in perfection, and is much benefited by having salt mixed with the manure at the rate of 2 or 3 cwt. per acre. The crop requires to be secured in store heaps as early in autumn as possible, as it is easily injured by frost. The following graphic description of this process is by Mr Morton of Whitfield:—

"The mode of harvesting our root crop which we have adopted for several years is this: We let the lifting, cutting off the leaves and the roots, and putting the roots into the cart—at so much per acre, according to the weight of the crop—to one man, who gets other men to join with him in the work and share in the profits; and the arrangement I require to be adopted is, that the one-horse carts, which I employ to haul the roots, shall be constantly employed, and I require from 16 to 20 loads or tons of roots to be filled hourly. The number of carts required is according to the distance of the field from the store; thus the distance from the middle of the field to the store being 15 chains, four carts are required; 22 chains require five carts; and 30 chains require seven carts.

"*The mode of lifting the roots.*—Five men are employed to pull up the roots; each man pulls up two rows; standing between the rows, he takes with his left hand a root from the row on his left side, and with his right hand a root from the row on his right side, and pulling both up at the same time, places them side by side, across the row where he pulled up the roots with his right hand, so as to have the tops lying in the space between the two rows he has pulled up; the next man takes the two rows at the right hand of the last two rows we have just described, and he, with each of his hands, pulls up a row, and places them on the line of the row which he has pulled up with his left hand, with the root end lying towards the root end of the first row, so that we have now four rows of roots lying close together in two rows, side by side, with their leaves on the outside of each of these rows, and the roots of each row nearly touching each other; and every four rows, when growing, are thus, when pulled, laid in two rows, root to root, occupying not more than 27 inches. Now, as the next four rows are lifted in the same way, and placed in like manner, we have a space unoccupied of three times 27 inches, or 6 feet 9 inches between each double row of roots, for the cart to go between them (viz., this double row of bulbs after they have had the leaves and roots cut off), to carry off the bulbs to the store. After the five men who are pulling the roots there follow ten women or boys, with knives made of pieces of old scythes, who, with repeated blows, cut off the leaves and roots without ever moving one of them with their hands; this is constant but not hard work, and it requires ten active women or boys to keep up with the five men pulling.

"Immediately on the heels of the cutters follow the carts between the two double rows of bulbs as they lie, having their leaves and roots cut off; and a man, one of the principals of the gang, and nine young active boys and girls, throw up the bulbs as fast as they can into the cart, the man speaking to the horse to move forward or stop as they clear the ground; when one cart is full, an empty one has been brought by one of the boys who drive the carts, and placed immediately behind the full one; so that, as he moves off with the full cart, the man calls the horse with the empty cart to move forward, and they proceed to throw the roots into the cart as fast as they did into the one that has just gone off the field.

"The pulling of the roots and the filling of the carts being the principal work, one of the leaders is in each of these departments of the work; so that, by his example, he shows those with him how he wishes them to work, and thus the work proceeds with the utmost regularity and despatch; 20 cart-loads are hourly filled in the fields and delivered in the store; 180 to 182 loads of 22 cwt. and 23 cwt. each in a day of nine hours; thus a cart-load is filled every three minutes by 10 pairs of hands, which are pulled by five pairs of hands, and the leaves and roots cut off by 10 pairs of hands —in all 25 pairs of hands, men, women, and boys. This has been repeatedly done in a day.

"The stores are made of posts and rails, enclosing a space 9 feet apart and 4½ feet high, and of any length, if the space will admit, and as near to where they are to be consumed as possible. The posts are 5 feet apart, let into the ground 18 inches, and 4½ feet above, with five rails above, 4 or 5 inches wide, nailed to the inside of the posts; and each of these stores is 3 feet apart. I have 14 of them, about 70 feet long each, which is sufficient to store from 1000 to 1200 tons of bulbs."

The heaps are carefully thatched, and the spaces betwixt them filled with straw to keep out frost.

It is believed that in many cases crops of turnip and mangold could be more cheaply stored by means of the portable railway than by carts, and with less injury to the land. This is especially the case with clay soils and in wet seasons. In using it, eight drills of roots are trimmed and laid in two rows, as Mr Morton describes; the rails are shifted between the pairs of rows in succession; and the roots are pitched into light trucks, which a man pushes before him to the headland, where the contents are discharged by tipping. Being there heaped up and thatched, the roots are carted to the homestead as required.

Section 4.—Carrot.

This root, though so deservedly esteemed and universally grown in gardens, has not hitherto attained to general cultivation as a field crop. This is owing chiefly to certain practical difficulties attending its culture on a larger scale. Its light feathery seeds cannot easily be sown so as to secure their regular germination; the tardy growth of the young plants, and the difficulty of discriminating between them and weeds makes the thinning a troublesome affair; the harvesting of the crop is comparatively expensive; and it is only on sandy and light loamy soils, or those of a peaty character, that it can be grown successfully. The increasing precariousness in the growth of potatoes, turnips, and clover, and the consequent necessity for a greater variety of green crops, entitle the carrot to increased attention as a field crop. Its intrinsic qualities are, however, very valuable, especially since the introduction of the white Belgian variety. On light soils it is alleged that larger crops of carrots can be obtained than of turnips, and with less exhaustion of their fertility, which is explained as arising from the greater depth to which the carrots descend for their nourishment. This root is eaten with avidity by all kinds of farm stock. Horses, in particular, are very fond of it, and can be kept in working condition with a considerably smaller ration of oats when 20 lb of carrots are given to them daily. It can also be readily kept to an advanced period of spring when stored with ordinary care.

The mode of culture is very similar to that already described for mangel-wurzel. A usual practice is to prepare the seed for sowing by mixing it with moist sand, and turning the mass repeatedly for several days until germination begins, when it is sown by hand at the rate of 6 lb per acre of the dry seeds, in a seam opened by the coulters of the corn or turnip drill, according as it is wished to have it on the flat or on ridgelets. Some prefer merely to rub the mixture of seeds and sand or mould betwixt the palms, until the seeds are thoroughly separated from each other, and so divested of their hairs as, when mixed with sand, to run from a drilling machine. It is of the utmost importance to secure seeds of the previous year's growth, as if older their germination cannot be depended upon. Much care is also needed in saving the seed only from selected roots, as carrots have a decided tendency to degenerate. The white Belgian variety is certainly the best for farm use, not only from the weight of crop, but from its growing more rapidly in its earliest stage than other approved sorts, and showing a broader and deeper coloured leaf, which can more easily be discriminated from weeds, and thus admitting of the earlier use of the hoe. When the sowing and first hoeing and thinning of the crop are got over successfully, the after culture of the crop is very simple; all that is needed being the occasional use of the horse and hand hoe to keep down weeds. The fork must be used in lifting the crop. The greens are then cut off and given to young stock or cows, and the roots stored in long narrow heaps, exactly as mangold. Fifteen tons per acre is an average crop, although on suitable soils, with liberal manuring and skilful cultivation, double the weight is sometimes obtained. Those who intend to cultivate this crop statedly will do well to raise their own seeds from carefully-selected roots. Unless genuine and fresh seed is sown, failure and disappointment can scarcely be avoided.

Section 5.—Parsnip.

This plant bears so close a resemblance to the carrot, and its culture and uses are so similar, that they need not be repeated. It can, however, be cultivated successfully over a much wider range of soils than the carrot, and, unlike it, rather prefers those in which clay predominates. It is grown extensively and with great success in the Channel Islands. The cows there, fed on parsnips and hay, yield butter little inferior, either in colour or flavour, to that produced from pasture. About 10 lb of seed are required per acre. It requires, like that of the carrot, to be steeped before sowing, to hasten germination, and the same care is needed to have it fresh and genuine. It should be sown in April. The roots, when matured, are stored like carrots.

Section 6.—Jerusalem Artichoke.

This root, although decidedly inferior to the potato in flavour, is yet deserving of cultivation. It grows freely in inferior soils, is easily propagated from the tubers, and requires little attention in its cultivation. When once established in the soil, it will produce abundant crops for successive years on the same spot. It is sometimes planted in woods to yield shelter for game, for which purpose it is admirably fitted, as it grows freely under the shade of trees, and yields both food and covert. In properly-fenced woods it might yield abundant and suitable food for hogs, which could there root it at their pleasure, without damage to anything. Where they had mast along with these juicy tubers, they would undoubtedly thrive apace. After they had grubbed up what they could get, enough would be left to reproduce a crop for successive seasons. Such a use of this esculent seems well deserving of careful trial.

CROPS ANALOGOUS TO DRILLED ROOT CROPS.

(*Sections* 7, 8, 9.)

There are several crops which, under a strict classification, should be noticed among forage crops rather than here, but which, in an agricultural point of view, are so closely analogous to drilled root crops that we regard this as the suitable place in which to notice them.

Section 7.—Cabbage.

On strong rich soils large crops of very nutritious food for sheep or cattle, and of a kind very acceptable to them, are obtained from the field culture of the Drumhead cabbage. A seed-bed is prepared in a garden, orchard, or other sheltered situation, about the second week in August, either by sowing in rows 12 inches apart, and thinning the plants about 3 inches in the rows, or broadcast in beds. As early in spring as the land on which the crop is to be grown is dry enough for being worked, let it be thoroughly and deeply stirred by one or more turns of the grubber. Assuming that a liberal dressing of dung has been put into it at the autumn ploughing, 3 or 4 cwt. of guano are now scattered evenly over the surface and ploughed in by a deep square furrow. A lot of plants being brought from the seed-bed, a band of planters, each provided with a dibble and a piece of rod 27 inches long, proceed to insert a row of plants the length of the rods apart in each third plough-seam, the result of which is that the plants stand in regular rows 27 inches apart every way, and can afterwards be kept clean by horse and hand hoeing like any other drilled green crop. Cabbages are much in repute with breeders of rams and prize sheep, which fatten rapidly on this food. Cabbages are usually drawn off and given to sheep on their pastures, or to cattle in byres and yards; but they are also fed off, where they grow, by sheep, in the same way as turnips. It is an exhausting crop when wholly drawn off, and on this account is sometimes grown with advantage on spots greatly enriched by irrigation with sewage or otherwise, and where the succeeding grain crop is expected to suffer from over-luxuriance, the cabbages being grown, as the phrase goes, to "take the shine out of it." In favourable circumstances, from 30 to 40 tons per acre of this nutritious crop may be obtained. From what has been said it is evidently not adapted for extensive field culture; but on most farms a few acres might be grown annually with great advantage. It is a peculiarly suitable food for either sheep or cattle during the autumnal transition from grass to turnips.

Section 8.—Rape.

This plant is peculiarly adapted for peaty soils, and is accordingly a favourite crop in the fen lands of England, and on recently reclaimed mosses and moors elsewhere. Its growth is greatly stimulated by the ashes resulting from the practice of paring and burning. In these cases it is sown broadcast; but when such soils are brought into a regular course of tillage, it is drilled, and otherwise treated in the same manner as turnips. As we shall consider its culture under the head of "Oil-producing Plants" (chap. xiv. sec. 5), we shall only say further here, that its highly nutritious leaves and stems are usually consumed by folding sheep upon it where it grows, and that there is no green food upon which they fatten faster. Occasionally it is carried to the homestead, and used with other forage in carrying out the system of soiling cattle.

Section 9.—Kohl-Rabi.

This plant has been frequently recommended to the notice of farmers of late years. Like mangold, it is better adapted than the turnip for strong soils and dry and warm climates. It may be either sown on drills in the same manner as the turnip, or sown in a seed-bed and afterwards transplanted. The latter plan is expensive, if it is desired to cultivate the crops to any extent; but is commendable for providing a supply of plants to make good deficiencies in the rows of other crops, or when a small quantity only is wanted. By sowing a plot of ground in March in some sheltered corner, and transplanting the crop early in May, it is more likely to prosper than in any other way. Cattle and sheep are fond of it, and it is said not to impart any unpleasant flavour to milk. We have seen a few trials of it in Scotland as a field crop; but, from whatever cause, the weight of food produced per acre was greatly less than from the mangolds and swedes growing alongside of it. For further information about this plant, the reader is referred to the *Book of the Farm*, vol. ii. p. 87; Hewlett Davis's *Farming Essays*, p. 90; Lawson's *Synopsis of the Vegetable Products of Scotland*, div. ii. p. 109. Lawson says that the pulp or flesh of kohl has the same taste as the leaves of the cabbage, and hence its adaptation as food for milch cows.

CHAPTER XIII.

CULTIVATED CROPS.—HERBAGE AND FORAGE CROPS

Section 1.—Grasses, &c.

Under this general heading we propose to include what we have to say concerning the grasses, whether natural or cultivated, and those other crops which are grown expressly for the sake of the cattle food yielded by their leaves and stems. This kind of farm produce is either consumed where it grows by depasturing with live stock, or mown and given to them in a green state under cover, or dried and stored for after use. It thus embraces the cultivation of these crops, and their disposal, whether by grazing, soiling, or haymaking. Following this method, we shall first of all briefly describe the cultivation of those pasture and forage crops which are of best repute in British husbandry.

Tillage lands are now everywhere cropped according to some settled rotation, in which the well-recognised principles of the alternate husbandry are carried out according to the actual circumstances of each locality. With rare exceptions, such lands at stated intervals bear a crop of the clovers or cultivated grasses. As these are usually sown in mixture, especially when intended for pasturage, the resulting crop is technically called "seeds." As it is of importance to have the land clean and in good heart when such crops are sown, they usually follow the grain crop which immediately succeeds the fallowing process. Being for the most part of a lower habit of growth, these can be sown and grown along with white corn crops without injury to either. When the latter are harvested, the former, being already established in the soil, at once occupy it, and grow apace. By this arrangement there is therefore secured an important saving both of time and tillage. Barley being the crop amongst which the seeds of the clovers and grasses are most frequently sown, and amongst which, upon the whole, they thrive best, it is customary to sow these small seeds at the same time as the barley, and to cover them in with a single stroke of the common harrows. This is erroneous practice, both as regards the time and manner of sowing these small seeds. We have already mentioned, in the proper place, that barley should be sown as early in March as possible. Now, if the clovers, &c., are sown as early as this, they are almost certain to get so forward as both to rob the barley of its due share of nourishment, and, when it is reaped, to bulk so largely in the sheaves as to retard their drying, and aggravate the risk of their being ill harvested. It is found, too, that if there be plants enough, the clovers stand the winter better, and ultimately yield a better crop, when, at the reaping of the grain crop, they are puny-looking than when they are very strong. It is better, therefore, to delay the sowing of the small seeds till the end of April or beginning of May. As to the manner of covering them in, we have to remark that the smallness of these seeds and their mode of germinating alike require that they receive only the very slightest covering of soil. This important fact is so well illustrated in the following table, which exhibits the results of some carefully-conducted experiments, reported to the Highland Society by Mr Stirling of Glenbervie, that we shall here quote it:—

"Column I. contains the scientific names.
Column II. contains the average weight of the seeds per bushel in pounds.

Column III. contains the average number of seeds in one ounce.
Column IV. shows, in inches, the depth of cover at which the greatest number of seeds brairded.
Column V. shows, in inches, the depth of cover at which only about half the number of seeds brairded.
Column VI. shows, in inches, the least depth of cover at which none of the seeds brairded.

"The results in the three last columns of the preceding table were obtained by sowing the seed in finely-sifted dark loam, which was kept moist throughout the process of germination, to which is attributable the circumstance of so many of the sorts vegetating best (as shown in Column IV.) without covering, and under full exposure to the light. The combination of such favourable circumstances of soil and moisture can, however, seldom be calculated upon in field sowing, therefore a covering of mould for the seeds, however slight, is always advisable. But it will be seen, by the results in Column VI., that a great number of seeds must be inevitably lost from over-depth of covering, unless the ground be in all cases carefully prepared and pulverised before sowing either the *natural* or *artificial* grasses."[1]

From this it is evident that to scatter these tiny seeds over a cloddy surface, and then to harrow it, may more aptly be called burying than sowing them. The following is a more rational mode of proceeding:—When these seeds are to be sown among winter wheat, it is expedient to begin by using the horse-hoe (supposing the wheat to have been drilled), as well to loosen the surface and produce a kindly bed for the seeds as to destroy weeds. In the case of broadcasted wheat, a turn of the harrows secures the same end. In the case of the more recently sown barley all that is needed is to smooth the surface with the one-horse roller. Over the ground thus prepared the small seeds are distributed by a broadcast sowing-machine, which covers at once a space of 15 or 18 feet in width. The covering is then effected by simply rolling with the smooth roller, or by dragging over the surface the chain-harrow, which may either be attached to the sowing-machine or to a separate frame; or by using Cambridge's or Crosskill's roller, with a very light chain harrow attached to it. On clay soils the chain-web is to be preferred; but on loose soils Crosskill's roller imparts a beneficial firmness, and, with its tail-piece of chain-web to fill up the indentations, gives an accuracy of finish which rivals the neatness of a newly-raked garden plot. We have long regarded this covering in of grass seeds as the most important use to which Crosskill's valuable implement is put. The only drawback to it is, that it makes a heavy demand on the horse-power of the farm at a pressing season. As it can only be worked in dry weather, it is advisable, when the land is in trim, to work it double tides by means of a relay of horses. This mode of procedure is alike applicable to the sowing of mixed clovers and grasses, and to that of the clovers alone, and is the course usually pursued in sowing for one or two years' "seeds."

When it is intended to lay down arable land to grass for several years, or to restore it to permanent pasture or meadow, it is always advisable to sow the seeds without a corn crop. This doubtless involves an additional cost at the outset, but it is usually more than repaid by the enhanced value of the pasture thus obtained. To grow the grasses well, the soil should be pulverised to the depth of 3 or 4 inches only, and be full of manure near the surface. There is no better way of securing these conditions than by first consuming a crop of turnips on the ground by sheep folding, and then pulverising the surface by means of the grubber, harrow, and roller, *without ploughing it.*

Much diversity of practice exists in regard to the kinds and quantities of seeds used in sowing down with a grain crop. In Scotland from 2 to 4 pecks of ryegrass seeds, with from 10 to 14 lb of those of red, white, alsike, and yellow clovers, in about equal proportions, is a common allowance for an acre. A pound or two of field parsley is occasionally added, or rather is substituted for an equal weight of clover seeds. The natural grasses are seldom sown, and only when the land is to be laid to permanent pasture. In England ryegrass is in much less repute than in Scotland, the clovers being there very generally sown unmixed, and always in larger quantities than we have just named—20 lb per acre being a common allowance. There can be little doubt that both these plans are faulty.

When a good natural pasture is carefully examined, it is found to consist of an amazing number of different grasses and other plants. Not only does a natural pasture contain a great variety of herbage at any one time, but it has its plants which replace each other at different seasons; and some also which are prominent only in wet years and others in dry ones. The provision thus made for affording at all times such a variety of food as is at once grateful and wholesome to the animals which browse on it, and for keeping the ground fully occupied under every diversity of seasons and weather, is truly admirable, and the study of it well

[1] *Morton's Cyclopædia of Agriculture*—article "Grasses," vol. i. p. 999.

fitted to interest and instruct the husbandman. The importance of this subject is beginning to be appreciated by agriculturists; as one proof of which we now see our leading seedsmen regularly advertising for sale an extensive list of grasses and other pasture plants. Most of them also, for the guidance of their customers, point out the kinds and quantities per acre which are appropriate for diversity of soils and other circumstances. We refer, as an example of this, to the manual of Messrs Lawson of Edinburgh, who have devoted much attention to this subject.

The following Tables will be found useful:—

"I.—For Alternate Husbandry.

	For 1 year's Hay.	For 1 year's Hay and 1 year's Pasture.	For 1 year's Hay and 2 years' Pasture.
	lb	lb	lb
Lolium italicum	9	9	9
perenne	18	18	18
Dactylis glomerata	—	2	2
Phleum pratense	1	2	2
Medicago lupulina	—	1	1
Trifolium hybridum	1	2	2
pratense	8	4	2
pratense perenne	—	2	4
repens	2	4	4
	39	44	44

"For sheep pastures it will often be found advantageous to add from 2 to 4 lb per acre of *parsley* seed to the above mixtures; and for pastures in certain upland districts established practice will justify the introduction of an additional pound or two of yellow clover (*Medicago lupulina*), together with from 2 to 3 lb of ribgrass (*Plantago lanceolata*). And for very heavy as well as for peaty soils, 1 to 1½ lb of *Phleum pratense* may be added advantageously, both for hay and pasture.

"II.—For Permanent Pasture. No. I.

	lb
Alopecurus pratensis	2
Dactylis glomerata	6
Festuca duriuscula	2
elatior	2
pratensis	2
Lolium italicum	6
perenne	8
Phleum pratense	2
Poa nemoralis sempervirens	2
trivialis	3
Medicago lupulina	1
Trifolium pratense	1
perenne	3
repens	6
	46

"In certain cases the following additions to Table II. may be made—namely, 1 to 2 lb each of *Festuca rubra* and *Poa pratensis* on dry sandy soils; 1 lb of *Achillea Millefolium*, and 1 to 2 lb of *Petrosalinum sativum* in sheep pastures; 2 lb chicory (*Cichorium Intybus*) in cattle pastures, 6 or 10 lb of *Onobrychis sativa* and 4 to 6 lb of *Poterium Sanguisorba* (burnet) in dry calcareous soils. When a crop of hay is taken the first year, both the ryegrasses (*Lolium*) may be increased by a third; and 2 lb of *Trifolium pratense* added. Also ½ to 1 lb per acre of *Anthoxanthum odoratum* when occasional crops of hay are to be taken."[1]

When land has been thus sown for a permanent pasture, care should be taken not to allow a sheep to set foot upon it for the first two years, for if these industrious nibblers are allowed to crop the tender clover seedlings before they are fully established in the soil, they are certain to remove the crown from most of them, and thus ruin the pasture at the very outset. Innumerable instances of failure in the attempt to obtain good permanent pastures are entirely owing to this premature grazing by sheep. The first growth should therefore be mown, care being taken to do so before any of the grasses have flowered. Then roll repeatedly, and stock with young cattle only until the second season is over.

Having described the means to be used for obtaining good pastures, let us now consider how to use them profitably. The art of grazing embraces the practical solution of two important problems, viz., 1*st*, How to obtain the greatest amount and best quality of herbage from any given pasture; and 2*d*, How to consume this herbage by live stock so as to make the most of it. The grazier has ever to keep in view what is best for his land and what is best for his stock; and must take his measures throughout the entire season with an eye to both these objects. As regards the first of them, experience yields the following maxims for his guidance:—

Never to stock his pastures in spring until genial weather is fairly established.

Never to allow the grasses to run to seed, nor parts of a field to be eaten bare, and others to get rank and coarse.

Duly to spread about the droppings of the cattle, to remove stagnant water, and to extirpate tall weeds.

Some time about midsummer to make a point of having the pasture eaten so close that no dead herbage or "foggage" shall be left on any part of it.

In what more immediately concerns the welfare of the live stock he is in like manner taught in stocking his pastures—

To adapt the stock, as regards breed, size, condition, and numbers, to the actual capabilities of the pasturage.

To secure to the stock at all times a full bite of clean, fresh-grown, succulent herbage.

In moving stock from field to field to take care that it be a change to better fare—not to worse.

Pasturage consists either of natural herbage or of "seeds." In the south-eastern counties of Scotland there is little good old grass; all the really fertile soils being employed in arable husbandry, with the exception of small portions around the mansions of landowners. The pasturage consists, therefore, for the most part of the cultivated clovers and grasses. Comparatively few cattle are there fattened on grass; the object of graziers being rather to stock their pastures with young and growing animals, and to get them into forward condition for being afterwards fattened upon turnips. The grazing season is there also much shorter than in England, old grass seldom affording a full bite for a well-conditioned bullock before the middle of May, or later than the middle of September. It is quite otherwise in England, various parts of which abound with old grass lands of the very richest description, on which oxen of the largest size can be fattened rapidly. These, in many cases, admit of being stocked towards the end of April, and under judicious management continue to yield excellent pasturage for half the year. When stocked with cattle in fresh condition, two sets or "runs" are not unfrequently fattened in such pastures in the same season. These grass-fed cattle begin to come to market early in July, and for four or five months thereafter constitute the chief supplies of beef in our markets.

Cattle already well-fleshed are alone suitable for turning into these rich old pastures. When this is attended to, and care taken not to over-stock the pastures until they yield a full bite, the progress of the oxen will usually be very rapid. It is now customary to hasten this progress by giving about 4 lb of oilcake to each beast daily. The dust and crumbs being sifted out, the bits of cake are strewn upon the clean sward, from whence they are quickly and carefully gleaned by the cattle. This is usually a profitable practice. It brings the beasts forward rapidly, improves their appearance and handling, and, besides enriching the land, admits of about *twelve* per cent. more numbers being fed upon a given acreage. These choice old pastures are usually occupied in combination with others of inferior quality. The most forward lot of cattle having been fattened and sold off from the former,

[1] Morton's *Cyclopædia of Agriculture*—article "Grasses," vol. i. p. 1000.

they are ready to receive a fresh stock. If it is contemplated to get them also fattened before the expiry of the season, they are not put on the best land instantly on the first lot being sold; but a crowd of sheep or store-beasts being turned upon it for a few days, the existing herbage is cleared off, and the pasture (*Anglice*) "laid in" or (*Scottice*) "hained," until a fresh clean growth fits it for receiving a suitable number of the best cattle from the other pastures. It is inexpedient to graze sheep promiscuously with cattle on these best lands, as they pick out the sweetest of the herbage, and so retard the fattening of the oxen. Neither do we approve of having horses among such cattle; not so much from their interfering with their pasturage as from the disturbance which they usually cause by galloping about. This does not apply to the draught-horses of a farm, which are usually too tired and hungry when turned out from the yoke to mind anything but food and rest, but it is better thrift to soil *them*; and frolicsome, mischievous colts are unsuitable companions for sedate, portly oxen. In favourable seasons, the grass often grows more rapidly than an ordinary stocking of cattle can consume it, in which case they select the best places, and allow the herbage on some parts to get rank and coarse. If these rank places are neglected until the herbage gets dry and withered, the finer plants die out, the coarser-growing grasses usurp the ground, and the pasturage is injured for future years. To check this evil in time, these neglected places should be mown, and the grass either brought to the homestead for soiling, or left to dry where it grew; in which state the cattle will eat up most of it, and be the better for it, especially if their bowels are unduly relaxed by the succulence of the growing herbage. The remarks now made apply equally to all old pastures employed for the fattening of cattle, although not of the first quality. All that is required is, to observe a due proportion between the capabilities of the pasturage and the breed and size of the cattle. A pasture that will fatten a fifty-stone ox may be quite inadequate for one of seventy, and the hardy Galloway or West Highlander will thrive apace where the heavier and daintier shorthorn could barely subsist.

With the exception of the best class of rich old pastures, grass is usually consumed to greater profit by a mixed stock of sheep and store cattle than by one kind of animals only. This holds true both as regards the natural herbage of pastures or water meadows, and cultivated grasses, clovers, or sainfoin. When old pastures and mixed "seeds" are grazed chiefly by sheep, the same rules apply that have already been noticed in connection with cattle. The herbage should if possible be fully established in a growing state, and so far advanced as to afford a full bite, before the pasture is stocked in spring. If the sheep are turned into it prematurely, their close nibbling hinders the plants from ever getting into a state of rapid growth and productiveness, and the necessity imposed upon the stock of roaming over the whole field, and keeping long afoot before they can glean enough to appease their appetite, is prejudicial alike to them and to their pasture. The prudent grazier endeavours to avoid these evils by having stores of swedes or mangolds to last until the full time at which he may reckon on having good pasturage. In distributing the flocks to different fields, the best pasturage is allotted to those that are in most forward condition. It is advantageous to have the pastures so subdivided that one portion may be double stocked while another is rested. By frequently removing the stock from the one portion to the other the herbage of each by turns gets time to grow and freshen, and is more relished by the sheep, and more wholesome than when the whole is tainted by their uninterrupted occupation of it. In the case of clover, trefoil, sainfoin, and water-meadows, this principle is yet more fully carried out by folding the flock and giving them a fresh piece daily. The crop is thus eaten close off at once in daily portions, and the plants being immediately thereafter left undisturbed, and receiving over the whole area their due share of the excrements of the flock, grow again more rapidly than when subjected to constant browsing under a system of promiscuous grazing. This plan of folding sheep upon such crops has the same advantages to recommend it as soiling, only that it is cheaper to shift the fold daily than to mow and cart home the forage and carry back the manure. In the case of water-meadows it is the practice to irrigate them afresh as each crop of grass is fed off. This is attended with considerable risk of the sheep getting tainted with rot, which must be guarded against as much as possible. In the first place, it is well to give them a daily allowance of bran, beans, or cake, and salt; and besides this, to put on this land only such sheep as are nearly ready for the butcher. They will thus fatten very rapidly, and be slaughtered before there is time for harm to ensue.

The modes of grazing which we have now described are appropriate for sheep in forward condition. The poorer pastures are usually stocked with nursing ewes and lean sheep bought in from higher grazings. Lambs, both before and after weaning, require clean pastures, and of course frequent changes. If kept on tainted pastures, they are certain to become subject to diarrhœa, to be stinted in their growth, and to have their constitution so weakened that many of them will die when afterwards put upon turnips. To avoid these evils, they must be frequently moved from field to field. A sufficient number of store cattle must be grazed along with them, to eat up the tall herbage and rank patches avoided by the sheep. After the lambs are weaned, the ewes require to fare rather poorly for a time, and can thus be made use of to eat up the worst pasturage, and the leavings of the young and fattening sheep. When the latter, with the approach of autumn, are put upon aftermath, clover stubbles, rape, cabbages, or turnips, their previous pastures should in succession be thickly stocked by the ewes and other store stock, so as to be eaten bare and then left to freshen and get ready for the ewes by rutting-time, when they require better food. In depasturing sheep on poor soils it is usually highly advantageous to give them a daily allowance of grain or cake in troughs, which must be shifted daily, so as to distribute the manure regularly over the land. By means of this auxiliary food sheep can be fattened on land the herbage of which would not alone suffice for the purpose. It admits also of a larger number of sheep being kept per acre, and of the pasturage being fed off more closely than could otherwise be done. The produce of poor siliceous soils, both in grass and after crops, is much increased by the additional manuring and treading which the consumption of such extraneous food upon them occasions.

It is always advantageous to have pastures provided with a shed, under which the stock can find shelter from sudden storms, or from the attacks of insects and the scorching rays of the summer's sun. When such sheds are regularly strewed with dried peat or burnt clay, much valuable compost for top-dressing the pasture can be obtained. The dung of the cattle, thus secured and applied, benefits the pastures more than that which is dropped upon it by the animals. Such clots require to be spread about from time to time.

The temperate climate of Britain is so peculiarly favourable to the growth of the grasses and other pasture plants, and to the keeping of live stock with safety in the open fields for a large part of the year, that the practice of consuming these crops by depasturing, as already described, has hitherto been decidedly preferred to soiling. One consequence of this is, that forage crops have been comparatively neglected. There is now, however, a growing conviction among agriculturists that it is more convenient to keep neat cattle and horses, during summer, in yards or loose boxes, and to feed them with succulent forage, mown and brought to them daily as it is needed, than to turn them adrift to browse in the fields. The pasturing plan is preferred by many because it involves the least labour, and is alleged to be more healthful to the animals. In behalf of the soiling plan it is urged that a given space of ground under green crop keeps nearly twice as much stock, when its produce is mown and consumed elsewhere, than when it is constantly nibbled and trodden upon; that housed cattle being exempted from the vicissitudes of the weather, the attacks of insects, mutual disturbance, and the labour of gathering their food, eat less and yet fatten more rapidly than they do at pasture; that more good is gotten of their excrements when mixed with litter and trodden down under cover, than when dropped about in the open fields; and that land from which a green crop has been mown, when ploughed up, is freer of weeds and (other things being equal) bears a better corn-crop than that which has been pastured. It is a further recommendation to the soiling plan that it admits of oilcake or meal being administered along with green food with a precision and economy that is unattainable in the pasture fields. There being so many and such cogent reasons in favour of the practice of soiling, we may warrantably anticipate that it will in future be much more generally adopted. It is proper, however, to notice that the success of this system is absolutely dependent on the following conditions:—The green food must be mown and brought home at least *twice* a-day, owing to the rapidity with which it ferments when put together; it must be given to the stock not less than *four* times daily, and only in such quantity at each feed as they can eat clean up in the interval betwixt meals; they must have constant and ample supplies of pure water and of fresh litter; and, in particular, matters must be so arranged that there shall be an unfailing supply of green forage of the best quality through the entire season. This is accomplished either by successive cuttings of one kind of crop from the same ground—as of irrigated meadow or Italian ryegrass—or by a combination of such crops as naturally come to maturity in succession, or are made to do so by a sequence of sowings. From what has been said it is obvious that soiling can only be carried out successfully with a moderately good soil and climate, a liberal use of manure, and skill and foresight on the part of the farmer. With these, however, its results will usually be highly satisfactory. It is peculiarly adapted for clay soils, on which the culture of root crops is attended with much difficulty, and where there is, therefore, abundance of litter for use in summer, and much need for the soiling system to get it converted into good manure.

Section 2.—Natural Meadow Grass.

In proceeding to notice the crops most usually cultivated in Britain for green forage we shall begin with *natural meadow grass.* In the south-western parts of England abundant crops of grass are obtained by irrigation with water alone. Our remarks will here, however, be restricted to those situations where sewage from towns or villages is available. Wherever a few scores of human families are congregated together, and have their dwellings properly drained and supplied with water, there is an opportunity for manuring a considerable extent of meadow with the sewage-water accruing from them throughout the year. The celebrated meadows in the environs of Edinburgh are interesting illustrations of the value of such water for irrigating purposes, and of the astonishing bulk of rich herbage which can be obtained in the course of a year from an acre of land thus treated. From the thickness of the crop in these meadows, and the rank luxuriance of its growth, the grass must be cut before it exceeds *ten* inches in height, as otherwise the bottom gets blanched and the grass rots out. The mowing begins usually in April and continues till November, so that by fitly proportioning the head of stock to the extent of meadow, and having the latter arranged in plots to be mown in regular succession, soiling can be practised throughout the season by the produce of the meadow alone. This practice is necessarily limited to situations where sewage-water is available. The following excerpts from a paper read before the Royal Scottish Society of Arts in January 1867 *On the Collection, Removal, and Disposal of the Refuse of the City of Edinburgh*, by Charles Macpherson, C.E., burgh engineer, to which the society's silver medal was awarded, will explain this system and exhibit its results:—

"The waters of the Craigentinny Burn, the Lochrin Burn, the Jordan Burn, and the Broughton Burn, are used in irrigating part of the lands adjoining the course of the respective streams. The waters of the Craigentinny Burn are used for irrigating about 250 acres; Lochrin Burn, about 70 acres; Jordan Burn, about 11 acres; and Broughton Burn, about 5 acres—being 336 acres in all irrigated by the water flowing in these four natural outlets for the drainage of Edinburgh.

"The area within the city draining towards the Craigentinny Burn—to the meadows irrigated by the waters of which I shall confine these remarks—is about one square mile and a half in extent. From this district there flows about 20 cubic feet of spring-water per minute; the surplus rainfall being the non-absorbed portion of 24 inches per annum; and the sewage from a population of 95,589 persons, according to the census of 1861, with a water supply of say 25 gallons per head. Of this population about 60,000 have the use of water-closets; and excrementitious matter from about 15,000 or 20,000 of the remainder finds its way to the sewers connected with the burn at the rate of about 265 feet per minute of sewage.

"Various kinds of soil are irrigated. The subsoil of the part of the meadows nearest the city is peat, with loam over it near the course of the burn; while to the northward it is naturally sand, but the sand has been taken away, and the ground made up with rubbish of buildings, &c., dressed off with soil. Further down the course of the stream the soil is reddish clay, or loamy clay, or sandy clay; while at the part of the Figgate Whins adjoining the sea-shore it is pure sand, with a coating of rich loam, varying from 1 inch to 4 or 5 inches deep, entirely derived from repeated applications of the sewage, no soil having been ever spread over the sand. The deeper soil is nearest the channels for conveying the sewage to the land. The meadows on the farm of Lochend, at Restalrig, and at Craigentinny, have a slope transversely to the course of the stream, varying from the steepest part, 1 in 25, which is of small extent, to about 1 in 50, which is the slope of the greatest part of these meadows. The Figgate Whins were artificially levelled to allow of irrigation.

"It is important to remark that the land (except the sand at the Figgate Whins) has been drained thoroughly to a depth of 4 feet below the surface. It was found that with shallower drains the sewage was drawn off by the drain, leaving the lower part of the ground without irrigation. At the Figgate Whins the sewage soaks into the sand, and oozes out upon the sea-shore.

"The kinds of grasses grown are Italian ryegrass and meadow grass. The ryegrass requires to be resown every third year; but the meadow grass has not required resowing, not even on the Figgate Whins, which were sown about forty years ago, when the ground was first irrigated. Opinions differ as to which grass is best adapted for the purpose; but ryegrass seems to produce the heavier crops. The irrigated ground is let off in small plots or squares for the season to the highest bidder. The grass is cut by the tenant as required, so that the annual yield of any particular plot has never been accurately ascertained; but an average crop is considered to be from 30 to 40 tons per acre, in four cuttings. The first cutting takes place at the beginning of April, and the last at the end of September, the let of the ground expiring at 1st October. The time of cutting the intermediate crops depends upon the wants of the tenant.

"The whole grass is eaten by about 3100 cows—the number previous to the cattle plague—in Edinburgh, Newhaven, Leith, and Portobello; but after the fourth crop is cut, sheep are turned on some parts of the ground about the beginning of November, and remain for about a fortnight, should the weather be favourable. The sheep do not seem to thrive, however, although the food is plentiful. The grass has been found most suitable for feeding cows—the attempts to use it for feeding other animals having been found not to answer, and the cost of converting it into hay being proved to be such as to render the process unprofitable.

"The price paid for the plots varies considerably, the best being known to bring £40 per acre, while others are as low as £15 or £20. Last season, owing to the cattle plague, the former high prices could not be obtained. The best land produces the heaviest crop; but on the Figgate Whins, mere irrigated sand, the first crop is earlier in the season—a matter of such consequence that, although the annual yield is less, the rent paid for these plots is about as high as for the plots producing the heavier crop. The rental of the Figgate Whins previous to the irrigation was, I have been informed, about 20s. per acre; while, when irrigated, parts have been let for some years at £40 per acre. The only works having been the levelling of the sandy hillocks and formation of channels for the sewage—neither of them very costly operations—and the annual outlay being small, the increased annual value of that land may be stated at not much less than the difference between the two sums.

"It might be an interesting speculation to consider how far the cost of the works necessary for collecting and removing the sewage from the district of the city draining towards Craigentinny might have been defrayed by the advance of rent obtained by the disposal of the sewage in irrigating the land along the course of the stream. The cost of the whole sewerage works (including many of the branch drains) constructed within the district in the city which is drained to the Craigentinny Burn, may be stated at £96,000. Assuming that the annual rent of the 250 acres irrigated was £5 per acre on an average previous to being laid out for irrigation, while the rent was raised to £25, then the difference, £20 per acre, is the annual value of the irrigation. There being 250 acres, gives £5000 as the return, or upwards of 5 per cent. on the cost of the sewers.

"The produce of the various irrigated meadows round Edinburgh is sufficient to supply the present demand for grass; necessitating any further application of the sewage to some other kind of crop, unless a more extensive market is obtained for the grass produced."

Section 3.—Italian Ryegrass.

Italian ryegrass can be cultivated over as wide a range of soils and climate as any forage crop which we possess, and its value for soiling is every day getting to be more generally appreciated. When first introduced, and indeed until very recently, it was chiefly sown in mixture with other grasses and clovers for pasturage, a purpose to which it is well adapted from its early and rapid growth in spring. Its true function, however, is to produce green food for soiling, for which purpose it is probably unrivalled. It is in connection with the system of irrigation with liquid manure that its astonishing powers have been most fully developed. When grown for this purpose it is sown in April, on land that has borne a grain crop after turnips or summer fallow. If sown *with* a grain crop as thickly as is requisite, it grows to nearly the height of the grain, and both are injured. A liberal dressing of farm-yard dung is spread upon the stubble in autumn, and immediately ploughed in. In the end of March or beginning of April the land is prepared for the seed by being stirred with the grubber and then well harrowed. The seed, at the rate of 4 bushels per acre, is then sown in the way already described for clover and grass seeds. When the liquid manure system is practised, the crop is watered as soon as the young plants are about an inch high, and so rapid is its growth in favourable circumstances that a cutting of 10 tons per acre has in some cases been obtained six weeks after sowing. When there is no provision for supplying liquid manure, a top-dressing of guano, nitrate of soda, soot, or the first two articles mixed, is applied by hand-sowing, care being taken to give this dressing when rain seems at hand or has just fallen. A similar top-dressing is repeated after each cutting, by which means three cuttings are ordinarily obtained from the same space in one season. A very great quantity of stock can thus be supported from a very limited extent of ground. This grass is also found to be very grateful to the palates of horses, cattle, and sheep, which all thrive upon it. Though so very succulent, it does not produce purging in the animals fed upon it. It is peculiarly suitable feeding for milch cows, as appears from the published account at Canning Park. Such results as those obtained by Mr Kennedy and others are not to be expected unless under similar conditions; but on good loams, clean and in good heart, and under such treatment as is described at the beginning of this section, as large crops of this grass as of red clover may be reckoned on, with at least equal feeding powers, and with a degree of certainty which the farmer cannot now entertain in regard to the latter crop. If it is regularly mown when the ear begins to show, and care taken never to allow the seed to form, it is fully ascertained that this grass will grow abundantly for a second year, with the advantage of being ready for use very much earlier than in its first season. It is sometimes sown in autumn, but those who have had the fullest experience in its cultivation give a decided preference to spring sowing, either after a grain crop which has followed a green crop or fallow, or at once after turnips. It is of great importance to get fresh and genuine seed. That directly imported from Italy yields the best crop when otherwise good. As a proof of the fondness of sheep for this grass, it has been observed that when it had been sown in mixture with red clover and cut for hay, sheep, on being turned into the aftermath, eat down the Italian ryegrass in preference to the clover.

Section 4.—Crimson Clover.

Crimson clover, though not hardy enough to withstand the climate of Scotland in ordinary winters, is a most valuable forage crop in England. It is sown as quickly as possible after the removal of a grain crop at the rate of 18 ℔ to 20 ℔ per acre. It is found to succeed better when only the surface of the soil is stirred by the scarifier and harrow than when a ploughing is given. It grows rapidly in spring, and yields an abundant crop of green food, peculiarly palatable to live stock. It is also suitable for making into hay. Only one cutting, however, can be obtained, as it does not shoot again after being mown.

Section 5.—Red Clover.

This plant, either sown alone or in mixture with ryegrass, has for a long time formed the staple crop for soiling; and so long as it grew freely, its power of shooting up again after repeated mowings, the bulk of crop thus obtained, its palatableness to stock and feeding qualities, the great range of soils and climate in which it grows, and its fitness either for pasturage or soiling, well entitled it to this preference. Except on certain rich calcareous clay soils, it has now, however, become an exceedingly precarious crop. The seed, when genuine, which unfortunately is very often not the case, germinates as freely as ever, and no greater difficulty than heretofore is experienced in having a full plant during autumn and the greater part of winter; but over most part of the country, the farmer, after having his hopes raised by seeing a thick cover of vigorous-looking clover plants over his field, finds to his dismay, by March or April, that they have either entirely disappeared, or are found only in capricious patches here and there over the field. No satisfactory explanation of this clover failure has yet been given, nor any certain remedy, of a kind to be applied to the soil, discovered. One important fact is, however, now well established, viz., that when the cropping of the land is so managed that clover does not recur at shorter intervals than eight years, it grows with much of its pristine vigour The knowledge of this fact now determines many farmers in varying their rotation so as to secure this important end. At one time there was a somewhat prevalent belief that the introduction of beans into the rotation had a specific influence of a beneficial kind on the clover when it came next to be sown; but the true explanation seems to be, that the beans operate favourably only by the incidental circumstance of almost necessarily lengthening the interval betwixt the recurrences of clover.

When the four-course rotation is followed, no better plan of managing this process has been yet suggested than to sow beans, pease, potatoes, or tares, instead of clover, for one round, making the rotation one of eight years instead of four. The mechanical condition of the soil seems to have something to do with the success or failure of the clover crop. We have often noticed that head-lands, or the converging line of wheel tracks near a gateway at which the preceding root crop had been carted from a field, have had a good take of clover, when on the field generally it had failed. In the same way a field that has been much poached by sheep while consuming turnips upon it, and which has afterwards been ploughed up in an unkindly state, will have the clover prosper upon it, when it fails in other cases where the soil appears in far better condition. If red clover can be again made a safe crop, it will be a boon indeed to agriculture. Its seeds are usually sown along with a grain crop, any time from 1st February to May, at the rate of 12 lb to 20 lb per acre when not combined with other clovers or grasses.

Italian ryegrass and red clover are now frequently sown in mixture for soiling, and succeed admirably. It is, however, a wiser course to sow them separately, as by substituting the Italian ryegrass for clover, for a single rotation, the farmer not only gets a crop of forage as valuable in all respects, but is enabled, if he choose, to prolong the interval betwixt the sowings of clover to twelve years, by sowing, as already recommended, pulse the first round, Italian ryegrass the second, and clover the third.

These two crops, then, are those on which the arable-land farmer mainly relies for green forage. To have them good, he must be prepared to make a liberal application of manure. Good farm-yard dung may be applied with advantage either in autumn or spring, taking care to cart it upon the land only when it is dry enough to admit of this being done without injury. It must also be spread very evenly so soon as emptied from the carts. But it is usually more expedient to use either guano, nitrate of soda, or soot, for this purpose, at the rates respectively of 2 cwt., 1 cwt., and 20 bushels. If two or more of these substances are used, the quantities of each will be altered in proportion. They are best also to be applied in two or three portions at intervals of fourteen to twenty days, beginning towards the end of December, and only when rain seems imminent or has just fallen.

When manure is broadcast over a young clover field, and presently after washed in by rain, the effect is identical with that of first dissolving it in water, and then distributing the dilution over the surface, with this difference, namely, that the first plan costs only the price of the guano, &c., and is available at any time and to every one, whereas the latter implies the construction of tanks and costly machinery.

Section 6.—Vetches.

Vetches are another very valuable forage crop. Being indigenous to Britain, and not fastidious in regard to soil, they can be cultivated successfully under a great diversity of circumstances, and are well adapted for poor soils. By combining the winter and spring varieties, and making several sowings of each in its season at intervals of two or three weeks, it is practicable to have them fit for use from May till October, and thus to carry out a system of soiling by means of vetches alone. But it is usually more expedient to use them in combination with grass and clover, beginning with the first cutting of the latter in May, taking the winter vetches in June, recurring to the Italian ryegrass or clover as the second cutting is ready, and afterwards bringing the spring vetches into use. Each crop can thus be used when in its best state for cattle food, and so as gratefully to vary their dietary.

Winter Vetches.—There is no botanical difference between winter and spring vetches, and the seeds being identical in appearance, caution is required in purchasing seed to get it of the right sort. Seed grown in England is found the most suitable for sowing in Scotland, as it vegetates more quickly, and produces a more vigorous plant than that which is home-grown. As the great inducement to cultivate this crop is the obtaining of a supply of nutritious green food which shall be ready for use about the 1st May, and so as to fill up the gap which is apt to occur betwixt the root crops of the previous autumn and the ordinary summer food, whether for grazing or soiling, it is of the utmost importance to treat it in such a way that it may be ready for use by the time mentioned. To secure this, winter tares should be sown in August if possible, but always as soon as the land can be cleared of the preceding crop. They may yield a good crop though sown in October, but in this case will probably be very little in advance of early-sown spring vetches, and possess little, if any, advantage over them in any respect. The land on which they are sown should be dry and well sheltered, clean, and in good heart, and be further enriched by ploughing into it from 12 to 15 loads of farm-yard manure. Not less than 3½ bushels of seed per acre should be sown, to which some think it beneficial to add half a bushel of wheat. Rye is frequently used for this purpose, but it gets reedy in the stems, and is rejected by the stock. Winter beans are better than either. The land having been ploughed rather deeply, and well harrowed, it is found advantageous to deposit the seed in rows, either by a drilling-machine or by ribbing. The latter is the best practice, and the ribs should be at least a foot apart and rather deep, that the roots may be well developed before top-growth takes place. As soon in spring as the state of the land and weather admits of it, the crop should be hoed betwixt the drills, a top-dressing at the rate of 40 bushels of soot or 2 cwt. of guano per acre applied by sowing broadcast, and the roller then used for the double purpose of smoothing the surface so as to admit of the free use of the scythe, and of pressing down the plants which may have been loosened by frost. It is thus by early sowing, thick seeding, and liberal manuring, that this crop is to be forced to an early and abundant maturity. May and June are the months in which winter vetches are used to advantage. A second growth will be produced from the roots if the crop is allowed to stand; but it is much better practice to plough up the land as the crop is cleared, and to sow turnips upon it. After a full crop of vetches, land is usually in a good state for a succeeding crop. When the whole process has been well managed, the gross amount of cattle food yielded by a crop of winter vetches, and the turnip crop by which it is followed in the same summer, will be found considerably to exceed what could be obtained from the fullest crop of turnips alone, grown on similar soil, and with the same quantity of manure. It is vain to sow this crop where game abounds.

Spring Vetches, if sown about the 1st of March, will be ready for use by 1st July, when the winter vetches are just cleared off. To obtain the full benefit of this crop, the land on which it is sown must be clean, and to keep it so a much fuller allowance of seed is required than is usually given in Scotland. When the crop is as thick set as it should be, the tendrils interwine, and the ground is covered by a solid mass of herbage, under which no weed can live. To secure this, not less than 4 bushels of seed per acre should be used if sown broadcast, or 3 bushels if in drills. The latter plan, if followed by hoeing, is certainly the best; for if the weeds are kept in check until the crop is fairly established, they have no chance of getting up afterwards. With a thin crop of vetches, on the other hand, the land is so certain to get foul, that they should at once be ploughed down, and something else put in their place. As vetches are in the best state for use when the seeds begin to form in the pods, repeated sowings are made at intervals of three weeks, beginning by the end of February, or as early in March as the season admits, and continuing till May. The usual practice in Scotland has been to sow vetches on part of the oat break, once ploughed from lea. Sometimes this does very well, but a far better plan is to omit sowing clover and grass seeds on part of the land occupied by wheat or barley after turnips, and having ploughed that portion in the autumn to occupy it with vetches, putting them *instead of "seeds"* for one revolution of the course.

When vetches are grown on poor soils, the most profitable way of using them is by folding sheep upon them, a practice very suitable also for clays, upon which a root crop cannot safely be consumed in this way. A different course must, however, be adopted from that followed when turnips are so disposed of. When sheep are turned in upon a piece of tares, a large portion of the food is trodden down and wasted. Cutting the vetches and putting them into racks does not much mend the matter, as much is still pulled out and wasted, and the manure unequally distributed over the land. To avoid those evils, hurdles with vertical spars, betwixt which the sheep can reach with head and neck, are now used. These are set close up to the growing crop along a considerable stretch, and shifted forward as the sheep eat up what is within their reach. This requires the constant attention of the shepherd, but the labour is repaid by the saving of the food, which being always fresh and clean, does the sheep more good. A modification of this plan is to use the same kind of hurdles, but instead of shifting them as just described, to mow a swathe parallel to them, and fork this forward within reach of the sheep as required, repeating this as often during the day as is found necessary, and at night moving the sheep close up to the growing crop, so that they may lie for the next twenty-four hours on the space which has yielded food for the past day. During the night they have such pickings as have been left on the recently-mown space, and so much of the growing crop as they can get at through the spars. There is less labour by this last mode than the other, and having practised it for many years we know that it answers well. This folding upon vetches is suitable either for finishing off for market sheep that are in forward condition, or for recently-weaned lambs, which, after five or six weeks' folding on this clean, nutritious herbage, are found to take on more readily to eat turnips, and to thrive better upon them, than if they had been kept upon the pastures all the autumn. Sheep folded upon vetches must have water always at command, otherwise they will not prosper.

As spring-sown vetches are in perfection at the season when pastures usually get dry and scanty, a common practice is to cart them on to grass land and spread them out in wisps, to be eaten by the sheep or cattle. It is, however, much better either to have them eaten by sheep where they grow, or to cart them to the homestead.

Section 7.—Beans.

The common field bean has not hitherto been recognised as an available *forage* plant. Mr Mechi has, we believe, the merit of first showing its great value for this purpose. In the hot dry summer of 1868, when pastures utterly failed, and men were at their wits' end how to keep their stock in life, he had recourse to his bean crop, then at its full growth, and its green pods filled with soft pulse. His plan of using it was, to mow the needed quantity daily, pass it through a chaff-cutter, and then send it out in troughs to his sheep in their pastures, and to his cattle in their stalls. The quantity of green food per acre yielded by a full crop of beans when used in this way is very great, and probably exceeds that of any other crop we grow. As Mr Mechi observed, on first announcing his practice, "no farmer need to be at a loss for food for his live stock who has a crop of beans at command." We know that many farmers availed themselves of this seasonable hint with the very best results. That pre-eminently successful grazier, Mr William M'Combie, M.P., Tillyfour, has, in his instructive pamphlet, shown how useful it is to have a few acres of mixed beans, peas, and tares ready to give to cattle in forward condition in the month of August, by laying down to them daily on their pastures a supply of this very palatable and nourishing forage. By this expedient they make rapid progress at a season when they would lose the condition they had already gained if left dependent on the then failing pasturage. We can testify from experience that we never have our cattle make such rapid progress on any kind of food as when thus supplied with green pulse on autumn pastures.

Section 8.—Mustard.

After a crop of vetches has been consumed, if the season is too far advanced to admit of turnips being sown, it is not unusual to take a crop of white mustard or crimson clover.

By means of the crops now enumerated, the practice of soiling can be carried out in all cases where it is practicable.

There are other valuable crops of this kind, several of which we shall now describe; but their culture is either limited by their requirements in regard to soil and climate, or attended with too great expense to admit of their competing with those already described.

Section 9.—Sainfoin.

This very important forage plant would be well entitled to a more prominent place in our list but for the circumstance that it is only on dry calcareous soils that its excellences are fully developed; and to these, accordingly, its culture may be said to be confined. In all the chalk districts of England sainfoin occupies an important place in the rotation of crops. Referring to the chalky downs round Ilsley in Berks, Mr Caird says:—"About a tenth part of the land is kept under sainfoin, in which it remains for four years, being each year cut for hay, of which it gives an excellent crop. A farmer having 40 acres of sainfoin sows out 10 acres and breaks up 10 acres annually. This goes regularly over the whole farm, the sainfoin not returning on the same field for considerable intervals, and when its turn comes round the field receives a rest of four years from the routine of cultivation. It is then ploughed up in spring, and sown with oats on one furrow, the crop of which is generally excellent, as much as 80 bushels an acre not being uncommon."[1] The seed, at the rate of 4 bushels per acre, is drilled in immediately after barley or oats has been sown, working the drill at right angles to its course when it deposited the grain. It is frequently pastured for one or more years before being mown either for green forage or for hay. It is sometimes allowed to stand for eight or ten years, but the plan described in the above quotation is the more approved one. A variety called *giant sainfoin* has been introduced by Mr Hart of Ashwell, Herts. As compared with the common sort it is more rapid in its growth in

[1] Caird's *English Agriculture*, p. 114.

spring, and still more so after the first and second cuttings. Three cuttings for hay, and one of these ripening the seed, have been yielded by it in one year, and a good eddish after all. The yield from it in the first year after sowing is large in comparison with the common sainfoin, from its attaining maturity much sooner; but for the same reason it is thought judicious to break it up after three years, while still in vigour.

Section 10.—*Lucerne.*

Lucerne is much cultivated as a forage crop in France and other parts of the continent of Europe, but has never come into general use in Britain. It is, however, frequently met with in small patches in districts where the soil is very light, with *a dry subsoil.* Its thick tap-roots penetrate very deeply into the soil; and if a good cover is once obtained, the plants will continue to yield abundant cuttings of herbage for eight or ten years, provided they are statedly top-dressed and kept free from perennial weeds. In cultivating lucerne, the ground must first be thoroughly cleaned, and put into good heart by consuming a turnip crop upon it with sheep. In March or April, the surface-soil having first been brought to a fine tilth, the seed, at the rate of 10 lb per acre, is sown in rows 15 to 18 inches apart. As soon as the plants appear they must be freed from weeds by careful hoeing and hand-weeding, repeated as occasion requires. Little produce is obtained from them the first season, and not a very heavy cutting the second; but by the third year two or more abundant crops of herbage will be produced, peculiarly suitable for horse-feed. It is the slow growth of the plants at first, and the difficulty of keeping them free from weeds on those dry soils which alone are adapted for growing lucerne, that have deterred farmers from growing it more extensively than has hitherto been done. We have grown it successfully in Berwickshire on a muiry soil resting on sandstone rock, in an exposed situation, at an elevation of 400 feet. The time to cut it is, as with clover and sainfoin, when it is in full flower.

Section 11.—*Chicory, &c.*

Chicory, burnet, cow-parsnip, and *prickly comfrey,* all known to be palatable to cattle and yielding a large bulk of produce, have probably been less carefully experimented with than their merits deserve. Although they have long figured in such notices as the present, or in occasional paragraphs in agricultural periodicals, they have never yet, that we are aware of, been subjected to such a trial as either conclusively to establish their claim to more extended culture, or to justify the neglect which they have hitherto experienced.

Section 12.—*Gorse or Whin.*

Notwithstanding its formidable spines, the young shoots of this hardy evergreen yield a palatable and nutritious winter forage for horses and cattle. To fit it for this purpose it must be chopped and bruised to destroy the spines. This is sometimes done in a primitive and laborious way by laying the gorse upon a block of wood and beating it with a mallet, flat at one end and armed with crossed knife-edges at the other, by the alternate use of which it is bruised and chopped. There are now a variety of machines by which this is done rapidly and efficiently, and which are in use where this kind of forage is used to any extent. The agricultural value of this plant has often been over-rated by theoretical writers. In the case of very poor, dry soils, it does, however, yield much valuable food at a season when green forage is not otherwise to be had. It is on this account of importance to dairymen; and to them it has this further recommendation, that cows fed upon it give much rich milk, which is free from any unpleasant flavour. To turn it to good account, it must be sown in drills, kept clean by hoeing, and treated as a regular green crop. If sown in March, on land fitly prepared and afterwards duly cared for, it is ready for use in the autumn of the following year. A succession of cuttings of proper age is obtained for several years from the same field. It is cut by a short stout scythe, and must be brought from the field daily; for when put in a heap after being chopped and bruised it heats rapidly. It is given to horses and cows in combination with chopped hay or straw. An acre will produce about 2000 faggots of green two-year-old gorse, weighing 20 lb each.

This plant is invaluable in mountain sheep-walks. The rounded form of the furze bushes that are met with in such situations shows how diligently the annual growth, as far as it is accessible, is nibbled by the sheep. The food and shelter afforded to them in snow-storms by clusters of such bushes is of such importance that the wonder is our sheep farmers do not bestow more pains to have it in adequate quantity. Young plants of whin are so kept down by the sheep that they can seldom attain to a profitable size unless protected by a fence for a few years.

Section 13.—*Tussac Grass.*

The tussac grass of the Falkland Islands has of late years attracted considerable attention as a forage plant. From its gigantic growth, even in those ungenial regions, and the extraordinary relish manifested for it by horses and cattle, sanguine hopes were entertained that it was to prove a truly valuable addition to our present list of forage plants; but the attempts hitherto made to introduce it in Britain have not been of a very encouraging kind. The only successful cases have been in the Orkneys and in Lewis. Messrs Lawson of Edinburgh, who have given much attention to it, say—"Our own experience leads to the conclusion, that localities within influence of the sea spray, the soil being of a peaty nature, are without doubt the best adapted for the growth of the tussac; and in such places it is likely to be of great service, as few other nutritive grasses will exist there. In our own experimental grounds it does not thrive well; which may perhaps be accounted for by the nature of the soil, which is light and dry. Regarding its value as a forage plant, we have before us an analysis made, at our request, by Professor Johnston, the results of which show that 'the tussac grass ought to be very nutritive.' Propagation, in the absence of seed, is easily effected, under favourable circumstances, by subdivision of the roots."

We have thus noticed all the more important of our forage crops of ascertained value. Additions will probably be made to them from time to time, especially from the increased attention now bestowed on green crops of all kinds. It has lately been suggested that maize and also lupins, although unfit for our climate as grain crops, might with advantage be tried as forage plants. Both are successfully grown for this purpose in Germany. Being unable to withstand frost, they should be sown not earlier than May. The maize requires a deep rich soil; the lupins again are said to do best on light siliceous soils. Both should be sown in rows 15 to 18 inches apart, and seeded at the rate of 2 bushels per acre. A trial which we made with lupins (both the blue and the yellow sorts) in 1858, on a light moorland, proved a total failure.

Section 14.—*Haymaking.*

Having spoken of the cultivation and use in a green state of herbage and forage crops, it remains to describe the process by which they are preserved for use in a dry state, or *made into hay.* On every farm a supply of good hay, adequate to the wants of its own live stock, is, or at least ought to be, statedly provided. This is no doubt an expensive kind of food, but on the other hand it is highly nutritious, and conduces much to the healthfulness of the animals fed upon it. Many a valuable farm horse is annually sacrificed to a false economy in feeding him solely on innutritious straw or ill-gotten hay. The owners of such stock would do well to consider that the death of a horse yearly, and the impaired health and condition of the whole stud, more than counterbalance any saving that can be effected by using bad fodder instead of good. But the great consumption of hay is by the numerous horses constantly required in this country for other purposes than farm labour. In the vicinity of towns hay is therefore a staple agricultural product, and haymaking an important branch of rural economy. It is one in the practice of which English farmers generally excel their brethren north of the Tweed. In the counties near the metropolis, in particular, this process is conducted with admirable skill.

In converting the grasses and forage plants into hay, the object is to get quit of the water which they contain, amounting to nearly *two-thirds* of their weight, with the least possible loss of their nutritive qualities. In order to this the crops must be mown at that stage of their growth when the greatest weight of produce with the maximum of nutritive value can be obtained; and then it is necessary so to conduct the drying process that the inspissated juices shall not be washed out and lost by external wetting. A simple and sufficiently accurate rule for determining the first point is to mow when the plants are in full flower. If this stage is exceeded, both the quality of the hay and the amount of the foggage or aftermath are seriously impaired. It follows from this that mowing should be commenced somewhat earlier than the stage indicated, otherwise, before the whole can be cut the last portion will have exceeded the proper degree of ripeness. By cutting a part too soon a slight loss of weight is incurred, which, however, is compensated for by a better aftermath; whereas if part is allowed to mature the seeds, there is a loss of weight, quality, and aftermath. Haymaking, to be done well, must be done quickly, and in order to this a full supply of labourers is indispensable. As a good mower can cut on an average an acre in a day, as many must be engaged as can overtake the extent of crop while it is in the best state for cutting. It is of great importance, too, to have the grass cut close to the ground. A loss of from 5 to 10 per cent. on the gross produce is frequently incurred by unskilful or careless mowers leaving the sward too high. Now that efficient mowing-machines can be had, this work can be performed with a celerity and accuracy hitherto unattainable. To admit of accurate and expeditious mowing, whether by scythe or machine, care must be taken, at the proper season, to remove all stones and other obstructions, and to make the surface smooth by rolling.

Confining our attention, in the first place, to natural meadow grass, let us glance at the process as conducted by those who are most proficient in it. The mowers having commenced their work at sunrise, the haymakers, in the proportion of two men and three women to each mower, so soon as the dew is off, shake out the swathes evenly over the whole ground, until they have overtaken as much as they can get into cocks the same day. This quantity they now turn and toss about as frequently as possible, getting it, before evening, either into a compact windrow, or forming it into very small cocks. Next day these cocks are again opened out, and as much more of the grass in swathe as can be overtaken, all of which is anew subjected to the same repeated turnings, and again, as evening approaches, secured from dew and rain by windrowing and cocking; that which is driest being put into larger cocks than on the previous day. If the weather is hot and parching, that which was first cut is by the fourth day ready for the stack, and is immediately carried. A large rick-cloth is drawn over the incipient stack until more hay is in condition to be added to it, and then, if weather favour, the whole process, from mowing to stacking, for a time goes on simultaneously, and is speedily completed. As the building of the stack proceeds, its sides are, by pulling, freed from loose hay, and straightened; and when completed it is thatched with the least possible delay. If the weather prove showery, the grass is left untouched in the swathe until it begins to get yellow on the under side, in which case it is usually turned over without opening out until weather again favour. To produce fine hay, care must be taken to secure from dew or rain by cocking before nightfall all that has been spread out during the day—never to touch it until dew or wet is off—to shake all out so thoroughly as that the whole may be dried alike—and never to suffer it, after being tedded out, to lie so long as to get scorched on one side. When these operations are conducted successfully, the hay is of a fine light-green colour, delightfully fragrant, and retains its nutritious matter unimpaired. To accomplish this in our variable climate much skill and energy, and an ample command of labour, are necessary

The cost and labour of this process are now, indeed, much reduced by the use of machinery, consisting of mower, tedder, and rake, by means of which a man and pair of horses can do the work of ten scythemen, and another man and horse can toss, turn, and draw into windrows as much grass as could be overtaken in the same time by fifteen people. The hay-tedder, moreover, shakes out the grass more thoroughly than it can be done by hand. After the hay is gathered into rows, horse labour is also sometimes employed to collect it into heaps by means of a sweep, that is, a piece of plank with a rope attached to each end of it, by which a horse draws it along *on edge*, while two lads hold it down, and the hay is thus pushed forward in successive portions, which are then by hand labour made into orderly cocks. The yield of meadow hay ranges from 1 to 2 tons per acre, and the cost of making it is about 10s. per ton. In London hay is brought to market in trusses, each weighing 56 ℔, 36 of which are called a load. In cutting up a stack these trusses are removed from it in compact cubes, which are then neatly secured by bands of twisted hay.

In converting the cultivated forage crops, such as clover (either pure or mixed with ryegrass), sainfoin, lucerne, or vetches, into hay, the procedure varies considerably from that pursued with the natural grasses. A considerable part of these plants consists of broad tender leaves, which, when scorched by the sun, become so dry and brittle that, on the least rough handling, they fly into dust, and are totally lost. These crops, therefore, do not admit of being shaken asunder and tossed about like the natural grasses, a circumstance which unfortunately forbids the use of the tedding-machine in getting them. The swathes are accordingly left untouched until they have got slightly withered on the upper side, after which they are turned several times with as little breaking up as possible; made up first into small cocks, opened out again, gently turned, and made into larger cocks, which as speedily as possible are carried and stacked. These crops can be stacked with safety in a very green state by mixing with them frequent layers of clean dry straw, by which the redundant juices are absorbed, and injurious heating prevented. The straw thus impregnated acquires a flavour which renders it palatable to cattle; but it is advisable, when this practice is adopted, to cut the whole into chaff before using it as fodder.

When it is desired to save the seeds of Italian or common ryegrass, the crop, after being mown, is allowed to lie for a day or two in swathe, and is then neatly gathered into sheaves, bound, and stooked, precisely like a crop of oats. When sufficiently dried, the seed is either thrashed out in the field, the straw stacked like other hay, and the seed spread thinly over a granary floor, and turned several times daily until it is dry enough to keep in a bin or in sacks; or the sheaves are built into small round stacks, which stand until the seed is wanted, when it is thrashed out by machinery like grain.

Of late years we have frequently secured considerable quantities of useful hay by mowing seeds that had been pastured by sheep in the early part of the season. In July we run the mowing-machines over such fields, taking care to set the cutting-bar high enough to leave the fresh-grown herbage untouched, and to remove only that of older and taller growth. The mown stuff is left untouched for two or three days; is then drawn together by the horse rake, and put into cocks for a short time, or carted at once to the rick-yard as weather permits. In this way much herbage that would otherwise go to waste is converted into useful winter fodder, and a fresh-grown clean pasture secured for lambs or other stock.

CHAPTER XIV.

CULTIVATED CROPS—CROPS OF LIMITED CULTIVATION.

Under this head we shall notice a variety of crops which, however valuable in themselves, and important to the farmers of particular localities, are, from one cause or other, not adapted for general cultivation.

Section 1.—*Flax.*

Flax is probably the most important of these crops. Indeed, from the rapid growth of our linen trade, the growing demand for linseed and its products, and the fitness of the soil and climate for the successful growth of flax, it is not without cause that its more extended cultivation has been so strenuously urged upon our farmers, and that influential societies have been organised for the express purpose of promoting this object. Viewed merely as an agricultural crop, the cultivation of flax is exceedingly simple, and could be practised as readily and extensively as that of the cereal crops. The difficulty is, that before it can be disposed of to any advantage, it must undergo a process of partial manufacture; thus there is required not only an abundant supply of cheap labour, but such an amount of skill and personal superintendence on the part of the farmer as is incompatible with due attention to corn and cattle husbandry. If a ready and remunerative market were available for the fibre in its simple form of flax straw, this, in combination with the value of the seed for cattle feeding, would at once hold out sufficient motive to our farmers to grow it statedly and to any required extent. Until this is the case, its culture cannot extend in the corn-growing districts of Great Britain. In Ireland and parts of the Highlands of Scotland, where there is a redundant population much in want of such employment as the flax crop furnishes, and where the climate is suited for its growth, it is highly desirable that its culture should extend, and probable that it will do so. Flax prospers most when grown upon land of firm texture resting upon a moist subsoil. It does well to succeed oats or potatoes, as it requires the soil to be in fresh condition without being too rich. Lands newly broken up from pasture suit it well, as these are generally freer from weeds than those that have been long under tillage. It is usually inexpedient to apply manure directly to the flax crop, as the tendency of this is to produce over-luxuriance, and thereby to mar the quality of the fibre, on which its value chiefly depends. For the same reason it must be thickly seeded, the effect of this being to produce tall slender stems, free from branches. The land having been ploughed in autumn, is prepared for sowing by working it with the grubber, harrow, and roller, until a fine tilth is obtained. On the smooth surface the seed is sown broadcast by hand or machine, at the rate of 3 bushels per acre, and covered in the same manner as clover seeds. It is advisable immediately to hand-rake it with common hay-rakes, and thus to remove all stones and clods, and to secure a uniform close cover of plants. When these are about 3 inches long the crop must be carefully hand-weeded. This is a tedious and expensive process, and hence the importance of sowing the crop on land as free as possible from weeds of all kinds. To obtain flax of the very finest quality the crop must be pulled as soon as the flowers fall, but in the improved modes of steeping, whether by Schenck's or Watt's patent, the value of the fibre is not diminished by allowing the seeds to mature. It must not, however, be allowed to become dead ripe, but should be pulled whenever the seeds appear, on opening the capsule, to be slightly brown-coloured. The pulling requires to be managed with much care. It is performed by men or women, who seize a small quantity with both hands and pull it by a slight jerking effort. The important point to be attended to is to keep the butts even as successive quantities are seized and twitched from the ground. When a convenient handful has been pulled it is laid on the ground, and the next parallel to it at a foot or so apart. The next handfuls are laid across these, and so on until a small pile is made, after which another is begun. After lying in this position for a few days, the seed-vessels or bolls are separated from the flax by lifting each handful separately and pulling the top through a ripple or iron comb fixed upon a piece of plank. As many of these handfuls as will make a small sheaf are then laid very evenly together, and bound near both ends with bands formed of a few stems of flax. These sheaves are set up in stooks, and when dry enough to keep without heating are stacked and thatched until an opportunity occurs of disposing of the flax straw. Sometimes the flax is bound into sheaves and stooked as it is pulled, and treated exactly like a grain crop. In this case the seed is separated from the straw by passing the head of each sheaf between iron rollers. The only objection to this plan is that the bolls of separate sheaves get so entangled in each other as to render it exceedingly difficult to handle them in carrying the crop, and in building and taking down the stacks, without disarranging the sheaves and wasting much straw and seed.

It would be tedious to enter here into a minute detail of the ordinary method of separating the flax fibre from the woody part of the stem. Suffice it to say that in the ordinary practice the sheaves or beets of flax straw are immersed in a pit or pool filled with clear soft water. The sheaves are kept under water by laying boards upon them loaded with stones to keep them down. Here the flax undergoes a process of fermentation by which the parts are separated. About nine or ten days are usually required for this purpose, but this is much influenced by the temperature. A good deal of skill and close watching is required to know exactly when it has been watered enough. The flax is now taken from the pit and evenly spread upon a smooth, clean, recently-mown meadow, where it lies for about ten days more, receiving several turnings the while. When the *retting*, as this is called, is perfected, the flax is carefully gathered up when perfectly dry, and again tied into sheaves, in which state it is stored under cover until the breaking and scutching can be overtaken.

All this necessarily requires much skilful watching and nice manipulation,—more, as we have already said, than is compatible with the other avocations of an extensive farmer. There are, however, improved modes of accomplishing this preliminary manufacture of flax which, wherever established, pave the way for the growth of flax as an ordinary field crop. For these see article FLAX.

The extent of flax cultivation in Ireland is considerable, but the acreage has been gradually diminishing during late years. In 1864 it reached the maximum, 301,693 acres; next year it fell to 251,433. Since 1869 it has steadily declined, there being 229,252 acres in flax crop that year, and only 122,003 in 1872.

Hemp, although at one time very generally grown in Great Britain, is now so rarely met with that it is unnecessary to enter into details of its cultivation.

Section 2.—Hops.

The hop is an important crop in several of the southern counties of England. Although an indigenous plant, it was originally brought into England for cultivation from Flanders in 1525. It is cultivated to a considerable extent in Belgium, Bavaria, in the United States of America, and more recently in Australia. Hops, as is well known, are chiefly used for preserving and imparting a peculiar flavour to beer. Probably the only parts of the hop flower which enter into the composition of the beer are the seeds, and the yellow glutinous matter which surrounds the outer integuments of the seed, and lies at the bottom of the petals. This yellow matter (technically termed the *condition* of the hop) has an intensely bitter taste, and emits a peculiar and very agreeable aroma, which, however, is extremely volatile; and hence the necessity for close packing as soon as possible after the hops are dried. When kept over a year, much of this aroma flies off, and hence *new* hops are indispensable in brewing the first kinds of beer. Several varieties of the hop are cultivated in England. Of these, the Farnham and Canterbury *whitebines* and *goldings* are esteemed the finest. These are tall varieties, requiring poles of from 14 to 20 feet. The *grapes*, so called from growing in clusters, and of which there are several varieties of various quality, require poles from 10 to 14 feet long. *Jones's*, adapted for lighter and inferior land, requires these but 8 to 10 feet. The *colegates* are a hardy and late-ripening variety, which grow best on stiff soils; and the *Flemish redbine*, only cultivated from its less liability than the other to be attacked by the aphis or black blight.

The hop is a very exhausting crop for the land, requiring to be planted only on the most fertile soils, and to have them sustained by frequent and large dressings of manure rich in nitrogen. Hops are principally cultivated in the counties of Kent, Sussex, Surrey, Hants, Worcester, and Hereford, and to a more limited extent in Essex, Suffolk, and Nottingham. The best quality of hops are grown at Farnham in Kent, upon the outcrop of the upper greensand formation, from whence the phosphatic nodules or coprolites now so well known in the manure market are obtained. In 1871 the land under hop cultivation in Great Britain measured 60,030 acres; in 1872 it amounted to 61,927 acres, of which there were in Kent 37,927, in Sussex 9738, and in Hereford 6106 acres.

In forming a new plantation, the ground soon after Michaelmas is trenched to the depth of 18 inches, if it has previously been in meadow or old pasture, taking care not to bury the surface-soil above half that depth. Subsoil-ploughing will suffice with land that is in tillage. If the land is wet, drains are made from 4 to 5 feet deep, laid with pipes, and a foot of broken stones over them, to prevent the roots of the hops from obstructing the pipes. The distance between the drains is determined by the necessities of each case. Perfect draining is essential to the success of the crop; and the hops are planted in squares or triangles at equal distances, varying from 6 to 7 feet, according to the fertility of the soil and the greater or less luxuriant habit of growth of the variety selected. The plants are raised by cutting off the layers or shoots of the preceding year, which are bedded out during the month of March in ground previously prepared; and in the succeeding autumn become what are called nursery plants or bedded sets. Early in November these are planted, one, two, or three being used for a hill according to the strength of the plants. Care must be taken to introduce a sufficient number of *male* plants, six hills to the acre being deemed sufficient. The presence of these is found to induce earlier maturity, and to improve both the quality and weight of the crops. The ground must at all times be kept free from weeds and have a good depth of pulverised soil. From the first, a stick, 6 feet high or so, is placed to each hill, to which *all* the young bines, as they shoot out during summer, must be tied. A liberal dressing of superphosphate of lime and guano is in June hoed in around each hill, which is repeated in July, under which treatment 2 or 3 cwt. of hops is obtained the first year, in addition to a crop of mangolds, turnips, or potatoes, grown in the intervals between the hills. On newly broken up ground lime is applied the following spring. When a plantation has been established, the annual routine of culture begins in autumn, as soon as the crop has been gathered, when the haulm is stripped from the poles, and stored away as a substitute for straw. The poles are stacked or piled in quantities of 400 or 500, at regular distances on the ground. During winter they are sorted and repointed when required, and new ones substituted for those that are broken or decayed; this work and the carrying on of manure being accomplished in frosty weather. The ground is dug over by the fork at this season. In March the earth is removed from the plants by a beck or pronged hoe till the crown is exposed, that the plant may be pruned. Immediately after this the poles are set, the length and number of these for each hill depending upon the kind of hops and amount of growth anticipated. They are fixed into holes made for them by a hop-bar. As the season advances, the ground is hoed and again dug or stirred by a nidget or scarifier drawn by a horse. Early in May the bines or young shoots, as soon as long enough, are tied to the poles with rushes or bast. This tying is repeated several times as the bines get higher, and has even to be done by step-ladders. In June the hops are earthed up or *hilled*, at which time weak plants get a dressing of guano. Throughout the summer weeds are destroyed as they appear, and the soil kept loose by the nidget or the hand-hoe. If poles are blown over by high winds, they are immediately replaced.

The picking of the hops usually begins about the second week in September, and furnishes ample employment for several weeks to the entire population of the districts, and to a large influx of strangers; men, women, and children all engaging in it. The hop-pickers are arranged into companies, and are supplied with baskets or bins, holding 7 or 8 bushels each, which are gauged with black lines inside to save the trouble of measuring. Each company is under the superintendence of a hop-bailiff, who keeps an account of the earnings, &c. Under him are several men called pole-pullers, whose duty it is to supply the pickers with poles of hops, and to assist in carrying the picked hops to the carts. They use an iron lever called a hop-dog in pulling up the poles. The hops are picked, one by one, into the bins, care being taken that no bunches, nor leaves, nor mouldy hops, are included. The hops are dried in kilns or oast-houses, on floors of haircloth. Great improvements have been made of late years in the construction of these oasts. Much nice discrimination is required in managing the drying so as to produce the best quality of hops. As soon as they are removed from the kiln they are packed into pockets, which during the process are suspended from a hole in the floor, and the hops trodden into them by a man. This is now done more accurately by machines, in which a piston presses the hops into the pockets. Hop-growing is a hazardous speculative business, the return at times being very great, and at other times not covering expenses. This arises from the liability of the hop to the attacks of insects, but more especially to blight and mould. The blight is caused by innumerable hordes of the *Aphis humuli*, which sometimes destroy the plants altogether. The mould is a parasitical fungus. It is believed that a means has at last been discovered of checking the ravages of these assailants, by enveloping each plant separately in a light covering, and subjecting it to the fumes of tobacco in the case of blight, and to a cloud of powdered brimstone in the case of mildew. In blight years it usually happens that some grounds altogether escape, in which case the returns from them are enormous, owing to the enhanced price.

Section 3.—Sugar-Beet.

The Silesian white beet has long been cultivated in various states of continental Europe for the production of sugar, and in several of them is now a staple product of very great value and importance. After several abortive attempts to introduce this industry into our own country, it seems at last to have obtained a firm footing in England, through the enterprise and perseverance of Mr James

Duncan, sugar-refiner, of Mincing Lane, London, who five years ago erected the necessary buildings and machinery at Lavenham, in Suffolk. Through the kindness of Mr Duncan we are enabled to submit to our readers the following details regarding this most interesting enterprise.

The sugar factory at Lavenham was erected in 1868, although not completed until February 1869. Mr Duncan had first of all contracted with various farmers in that neighbourhood to grow beet for him at the price of 20s. per ton of clean roots, delivered at his factory, with the option to the growers of receiving back the resulting pulp at 12s. per ton, if removed as made. Mr Duncan also procured from the continent the necessary supplies of seed of the best sort, and furnished the growers with instructions as to the proper mode of cultivation. In growing mangolds farmers try to grow the largest possible weight per acre, and for this purpose they manure heavily, and give the individual plants ample space. This will not do in the case of sugar-beet, as it is found that small roots are richest in sugar, and that $2\frac{1}{2}$ ℔ each is the best size to aim at. The endeavour, therefore, must be to have the roots small individually, and yet to secure a good weight per acre. As the part of the bulb that grows above ground contains very little sugar, a further object is to have as little of it exposed to light as possible. All this is accomplished by sowing the crop in rows about 16 inches apart, and leaving the plants close to each other. If all is well managed, the crop should yield from 15 to 20 tons of cleaned roots per acre. The delivery of the roots at the factory begins about the end of September, when they are carted direct from the field as they are pulled. The exigences of wheat-sowing and other field labour at that season induce the growers to store a considerable part of their beet crop at home, and to deliver it at the factory from time to time as they can overtake this heavy cartage. The roots lose weight rapidly when kept in clamps, to cover which a little extra price is given as the season advances. The convenience of the growers is much furthered by this arrangement; but it sometimes results in irregular supplies, and consequent loss to the manufacturer.

Owing to the extreme drought of 1868 the beet was late in being sown, and the crop was small, amounting only to 1200 tons; but it was exceedingly rich in sugar. The following season was moist, and the yield per acre good, but the area under crop was small, and the total quantity delivered at the factory about 3000 tons. The year 1870 was again an extremely hot and dry one, with a gross produce of 4500 tons, which yielded 12 per cent. of syrup. The produce in 1871 was 6000 tons, yielding 10 per cent. of syrup, and that of 1872 exceeded 7000 tons of very good roots; but the wetness of the season and strikes among the labourers so protracted the factory work, that instead of being completed in December it was prolonged until March, and the percentage of sugar was smaller than it ought to have been. The particulars of this last crop are as follows. The total weight of clean roots from 571 acres was—

Delivered fresh from the fields,	2370 tons.
Clamped by growers at their farms,	5485 ,,
	7855 ,,

Of the 571 acres,	89	by 2	growers	averaged	17 tons per acre.
,,	115	by 2	,,	,,	16 ,,
,,	61	by 2	,,	,,	15 ,,
,,	21			,,	14 ,,
,,	147			,,	13 ,,
,,	10			,,	12 ,,
,,	33	by 26	,,	,,	11 ,,
,,	18			,,	10 ,,
,,	15			,,	9 ,,
,,	62			,,	8 ,,

So that with a total average of $13\frac{3}{4}$ tons per acre, two-thirds of the crop averaged 15 tons, and the remaining third only $9\frac{1}{2}$ tons. The proportion of feeding pulp has been large in 1871 and 1872,—both having been moist seasons,—and has been 22 per cent. of the weight of the roots. In 1870 it was only 19 per cent. The details of the disposal of the pulp from crop 1872 are also interesting. Of 1235 tons of pulp purchased by nine farmers—

597	tons were taken	by one,
326	,,	by another,
116	,,	by another,
95	,,	by another, not a grower of beet.

In addition to these quantities sold, about 500 tons were stored at the factory, where at the same time about 100 tons of crop 1871 were still on hand, and in excellent condition. To this latter fact we can add our own testimony, having been favoured by Mr Duncan with a sample of it after it had been eighteen months in store, when we found it perfectly sweet and good, retaining unimpaired the taste and smell of fresh beet-root. The mode of storing the pulp is very simple. On a piece of dry ground a trench is dug out about 7 feet wide and 1 foot deep. Into this trench the pulp is firmly trodden by the feet of the labourers, and gradually drawn to a point, precisely as is done in storing roots. The whole is then covered with earth to the depth of 12 inches; and thus stored, the pulp keeps well for two or three years. In using it, a thin crust from the outsides is rejected. In Germany and Austria tanks of brick-work are used to economise space, but not in France or Belgium. Three tons of this pulp are estimated to be equal in feeding value to one ton of good hay. Hitherto farmers give the preference to fresh-made pulp; but Mr Duncan regards this as quite a mistake, as in his own practice he finds that pulp a year old is a better feeding material than when newly made. In 1872 he fattened 50 cattle on pulp *three* years old, and in the summer of 1873 he had 60 cattle consuming the surplus of the previous season. These cattle (27 yearlings and 33 two-year-olds) consumed daily 35 cwt. of pulp and 4 cwt. of cut chaff (of hay and barley straw) mixed together. The older beasts received daily in addition 7 ℔ each of bean-meal, on which ration they made good progress. To meet the cartage difficulty, Mr Duncan contracted that year (1873) with one grower to perform the haulage of 2000 tons of beet roots a distance of 5 miles by a traction engine.

Several joint-stock companies have been formed for prosecuting this industry, but Mr Duncan's is the only factory as yet in actual operation. It is known also that Mr Lawes and Dr Gilbert have for several years been engaged in extensive experiments on sugar-beet, and with most successful results.

The manufacture of sugar from beet-root has attained to very great dimensions on the continent of Europe. It is known that from the crop of 1872 there has been produced 1,025,000 tons of sugar, worth £24 per ton, and 250,000 tons of molasses, worth £3 per ton, and that new factories, some of them on a gigantic scale, are now in course of erection. A most important fact connected with this rapidly-extending industry is that the erection of a sugar factory is immediately accompanied by an improvement in the agriculture, and an increase in the value of the land, of the surrounding district. In many places farmers gladly contract to supply beet-root at 18s. per ton for ten years, on condition that they receive back pulp in fair proportion to the quantity of root supplied by them. Russia produces the finest quality of beet, instances being known in which the roots yielded 10 per cent. of loaf-sugar. There are good grounds for concluding that Russia will at no very distant date take a prominent place as a sugar-producing country.

There seems at present a reasonable prospect that the cultivation of sugar-beet will be adopted in various parts of our own country. It has already been proved that the beet grown in the south-eastern counties of England is richer in sugar than that produced in the north of France. And it seems well worth while to ascertain, by careful experiment, whether in certain parts of Scotland, such as the Lothians, Fife, and the carses, sugar-beet could not with advantage be substituted for the precarious and exhausting potato crop. The repeal of the sugar-duty would give a great stimulus to this enterprise, and should be pressed for in the interest of our native agriculture.

Section 4.—Chicory (for its Roots).

The very extensive and constantly increasing consumption of the roots of chicory as a substitute for coffee, renders it now an agricultural crop of some importance. The soils best adapted for its growth are deep friable loams. The process of cultivation is very similar to that required for the carrot, excepting only that it is not sown earlier than the first week of May, lest the plants should run to seed. When this happens, such plants must be thrown aside when the crop is dug, else the quality of the whole will be injured. About 4 lb of seed is the quantity to sow per acre, either broadcast or in rows. The latter is undoubtedly the best mode, as it admits of the land being kept clean, and yields roots of greater weight. The crop is ready for digging up in November. A long stout fork is the best implement for this purpose. In using it, care must be taken to get out the roots entire, not only for the sake of the roots, but to lessen an inconvenience attendant on the culture of this plant, namely, that the fragments left in the soil grow amongst the after crops, and are as troublesome as weeds. The roots, when dry, are carefully washed, cut into thin slices, and kiln-dried, when they are fit for the coffee-grinder. From 1 to 1½ tons per acre of the dried root is an average produce.

Section 5.—Oil-yielding Plants.

Various plants are occasionally cultivated in Britain for the sake of the oil which is expressed from their ripened seeds. We have already noticed the value of flax-seed for this purpose, although the fibre is the product which is chiefly had in view in cultivating it. The plants most commonly sown expressly as oil-yielding crops are—rape (*Brassica Napus*), colza (*Brassica campestris oleifera*), gold of pleasure (*Camelina sativa*), and the poppy (*Papaver somniferum*). Rape is the plant most frequently and extensively grown for the production of oil. The colza is said to yield better crops of seed than the other species. This plant is much cultivated in Flanders for this purpose. In Great Britain it seems rather on the decline. It is chiefly on rich alluvial soils that this crop is grown. For a seed-crop rape is sown in June or July, precisely in the manner already described for turnips. The young plants are thinned out to a width of 6 or 8 inches apart, and afterwards kept clean by hoeing. The foliage may be eaten down by sheep early in autumn, without injuring it for the production of a crop of seed. In spring the horse and hand hoe must be used, and the previous application of 1 or 2 cwt. of guano will add to the productiveness of the crop. It suits well to lay down land to clover or grass after a crop of rape or turnip seed, and for this purpose the seeds are sown at the time of giving this spring culture. The crop must be reaped as soon as the seeds are observed to acquire a light brown colour. The reaping is managed precisely as we have described in the case of beans. As the crop, after being reaped and deposited in separate handfuls on the ground, very soon gets dry enough for thrashing, and as the seed is very easily shed after this is the case, this process must be performed as rapidly as possible. Sometimes it is conveyed to the thrashing-mill on harvest carts, on which a cloth is stretched to save the seeds knocked out in the loading and unloading, but more usually the flail is used on temporary thrashing-floors provided in the field by spreading down large cloths. The crop is gently lifted from the ground and placed, heads innermost, on a blanket which two persons grasp by the corners, and carry to the thrashing-floors. A large number of people are required to push this process through rapidly, for unless the crop is quickly handled, a great loss of seed ensues. The seed is immediately spread thinly upon a granary floor, and frequently turned until dry enough to keep in sacks, when it is cleaned and disposed of. On good soil and in favourable seasons the yield sometimes reaches to 40 bushels per acre. The haulm and husks are either used for litter or burned, and the ashes spread upon the land. It makes good fuel for clay-burning.

Section 6.—Seeds of Agricultural Crops.

In the case of seed-corn it is customary for farmers either to select from the best of their own growth, to exchange with or purchase from neighbours, or, if they wish a change from a different locality, to employ a commission-agent to buy for them. In all districts there are careful farmers who, by occupying land that produces grain of good appearance, and being at pains to have good and pure sorts, are stated sellers of seed-corn, and manage in this way to get a few shillings more per quarter for a part of their produce. It is therefore only in the case of new and rare varieties that professional seedsmen ordinarily deal in seed-corn. There are, however, other field crops, such as clovers, grasses, turnip, mangold, carrots, winter vetches, &c., the seeds of which, to a large extent, pass through the hands of seedsmen, and the growing of which is restricted to particular districts, and is in the hands of a limited number of farmers. These seed crops are sometimes very remunerative to the grower; but are hazardous ones for farmers to attempt at their own risk. The only safe course is to grow them at a stipulated price, to the order of some thoroughly respectable seedsman, and to hold to the production of the particular kind or kinds which he requires. This applies in a less degree to the clovers, and to the more commonly cultivated grasses, than to the other seeds just referred to. Such an arrangement is beneficial to all concerned.

We have already described (chap. xiii. sec. 13) the mode of saving the seeds of Italian or common ryegrass; and as other grasses are managed in the same way, it is unnecessary to say more regarding them.

It is only in the southern parts of England that *clover* is grown for the sake of its seeds. When it is meant to take a crop of seed, the clover is fed off with sheep, or mown early in the season, and then allowed to produce its flowers and ripen its seeds. This preliminary eating or cutting over causes the plants to throw up a greater number of seed-stems, and to yield a fuller and more equally ripening crop. The crop is mown when the seeds are seen to be matured. In the case of white clover the cutting takes place while the dew is upon the crop, as working amongst it when dry would cause a loss of seed. After mowing and turning the crop, the ground is raked with close-toothed iron rakes, to catch up loose heads. The thrashing is a twofold process—first the separation of the heads or cobs from the stem, called "cobbing," and then of the seeds from the husks, called "drawing." This was formerly accomplished by a laborious and tedious process of thrashing with flails, but it is now done by machinery. In favourable seasons the yield is about 5 or 6 bushels (of 70 lb each) per acre.

Turnip seed is the next most important crop of this kind.

From the strong tendency in the best varieties of turnips and swedes to degenerate, and the readiness with which they hybridise with each other, or with any member of the family *Brassica*, no small skill and pains are needed to raise seed that can be depended upon to yield roots of the best quality. Turnip seed is saved either from selected and transplanted roots, or from such as have been sown for the express purpose, and allowed to stand as they grow. The first plan, if the selection is made by a competent judge, is undoubtedly that by which seed of the purest quality is obtained. But it is an expensive way, not only from the labour required in carrying it out, but from the yield of seed being generally much less than from plants that have not been disturbed. Professional seed-growers usually resort to a compromise by which the benefit of both plans is secured, viz., by selecting with great care and transplanting a limited number of bulbs, and saving the seed obtained from them to raise the plants which are to stand for their main seed crop. The latter are carefully examined when they come into bloom, and all plants destroyed the colour of whose flower varies from the proper shade. Turnips that are to bear seed are purposely sown much later in the season than when intended to produce cattle food, as it is found that bulbs about 1 lb weight are less liable to be injured by frost or to rot before the seed is matured, than those of larger size. The management of a turnip-seed crop, both as regards culture and harvesting, is identical with that of rape for its seeds, which has already been described.

Mustard.—Both the white and brown mustard is cultivated to some extent in various parts of England. The former is to be found in every garden as a salad plant; but it has of late been coming into increasing favour as a forage crop for sheep, and as a green manure, for which purpose it is ploughed down when about to come into flower. The brown mustard is grown solely for its seeds, which yield the well-known condiment. When white mustard is cultivated for its herbage, it is sown usually in July or August, after some early crop has been removed. The land being brought into a fine tilth, the seed, at the rate of 12 lb per acre, is sown broadcast, and covered in the way recommended for clover seeds. In about six weeks it is ready either for feeding off by sheep or for ploughing down as a preparative for wheat or barley. White mustard is not fastidious in regard to soil. When grown for a seed crop it is treated in the way about to be described for the other variety. For this purpose either kind requires a fertile soil, as it is an exhausting crop The seed is sown in April, is once hoed in May, and requires no further culture. As soon as the pods have assumed a brown colour the crop is reaped and laid down in handfuls, which lie until dry enough for thrashing or stacking. In removing it from the ground it must be handled with great care, and carried to the thrashing-floor or stack on cloths, to avoid the loss of seed. The price depends much on its being saved in dry weather, as the quality suffers much from wet. The yield varies from 20 to 30 bushels per acre, and the price from 10s. to 20s. per bushel. It is chiefly grown on rich alluvial soils in the south-eastern counties of England. This great evil attends its growth, that the seeds which are unavoidably shed in harvesting the crop remain in the soil, and stock it permanently with what proves a pestilent weed amongst future crops.

Market Gardening.—In Essex and Kent no inconsiderable extent of land is annually occupied in growing the seeds of the staple crops of our kitchen and flower gardens. Wholesale seedsmen contract with farmers to grow these seeds for them at a stipulated price.

The growth of fruits and of culinary vegetables is in various parts of Great Britain an important department of farming—for the scale on which it is conducted allies it quite as much to agriculture as to horticulture. In the counties contiguous to London thousands of acres are occupied in growing vegetables and in producing fruit. Very large numbers of persons find employment in these market gardens. The system of cultivation pursued in them is admirable. The soil is trenched two spits deep for nearly every crop; it is heavily manured and kept scrupulously clean by incessant hoeing. Whenever a crop is removed, some other suited to the season is instantly put in its place, and not an inch of ground is suffered to be unproductive. A young farmer, bent on knowing his business thoroughly, could not occupy a few months to better purpose than by placing himself under one of these clever market gardeners.

Kent has long been peculiarly celebrated for its orchards. The best of them are on the borders of the greensand formation, or ragstone as it is provincially called. Apples, pears, plums, cherries, and nuts are produced in immense quantities. The filbert plantations alone are said to occupy 5000 acres. An abundant and cheap supply of fruit and vegetables for the inhabitants of our towns is undoubtedly an important object, and is likely to occupy increased attention wherever a suitable soil and exposure, with facility of carriage by railway, are combined. In Cornwall and in the Channel Islands the cultivation of brocoli and early potatoes is an important and growing industry.

CHAPTER XV.

LIVE STOCK—HORSES.

The breeding and rearing of domesticated animals has ever been a favourite pursuit in Great Britain, and has been carried to greater perfection than any other department of rural affairs. In no other country of similar extent can so many distinct breeds of each class of these animals be found—most of them excellent of their kind, and admirably adapted to the particular use for which they are designed. Observing the usual order, we notice first *Horses.*

Section 1.—*Breeds.*

Here we shall confine our attention to those breeds which are cultivated expressly for the labours of the farm; for although the breeding of saddle-horses is chiefly carried on by farmers, and forms in some districts an important part of their business, it does not seem advisable to treat of it here. It is a department of husbandry requiring such a combination of fitness in the soil, climate, and enclosures of the farm, of access to first-class stallions, and of taste and judgment on the part of the farmer, that few indeed of the many who try it are really successful. The *morale* too of the society into which the breeding of this class of horses almost necessarily brings a man is so unwholesome, that none can mingle in it freely without experiencing to their cost that "evil communications corrupt good manners." We have noted it as a fact of peculiar significance, in this connection, that of the few men who really make money by this business, scarcely one desires to see it prosecuted by his sons.

The immense size and portly presence of the *English black horse* entitle him to priority of notice. This breed is widely diffused throughout England, though found chiefly in the midland counties. It is in the fens and rich pastures of these counties that the celebrated dray horses of London are bred and reared. These horses are too slow and heavy for ordinary farm-work, and would not be bred but for the high prices obtained for them from the great London brewers, who pride themselves on the great size, majestic bearing, and fine condition of their team horses. The breeders of these horses employ brood mares and young colts exclusively for their farm-work. The colts are highly fed, and worked very gently until four years old, when they are sold to the London brewers, often at very great prices. The same breed is largely used in England for ordinary farm labour, although not found of such gigantic proportions as in those districts where they are bred for the special destination just referred to. Although very docile, their short step, sluggish gait, large consumption of food, and liability to foot lameness, render them less profitable for ordinary farm-work than the breeds about to be mentioned.

The Suffolk Punch is a well-marked breed which has long been cultivated in the county from which it takes its name. These horses are, for the most part, of a sorrel, bay, or chestnut colour, and are probably of Scandinavian origin. They are compact, as their name imports, hardy, very active, and exceedingly honest pullers. These horses at one time were very coarse in their form and rather slow; but they have now been so much improved in form and action that we find them the chief prize-takers at recent exhibitions of the Royal Agricultural Society.

The Cleveland Bays are properly carriage-horses; but still in their native districts they are largely employed for field work. Mr Milburn says—"The Cleveland, as a pure breed, is losing something of its distinctiveness. It is running into a proverb, that 'a Cleveland horse is too stiff for a hunter, and too light for a coacher;' but there are still remnants of the breed, though less carefully kept distinctive than may be wished by advocates of purity. Still, the contour of the farm-horses of Cleveland has the lightness, and hardiness, and steadiness of the breed; and it is singular that while the lighter soils have horses more calculated for drays, the strong-land farmer has the compact and smaller, but comparatively more powerful animal."

In the north-eastern counties of England, and the adjacent Scottish borders, compact, clean-legged, active horses, of medium size, with a remote dash of blood in them, are generally preferred to those of a heavier and slower kind. One needs only to see how such horses get along at turnip-sowing, or with a heavy load in a one-horse cart, to be convinced of their fitness for the general work of a farm.

The Clydesdale Horses are not excelled by any cart breed in the kingdom for general usefulness. They belong to the larger class of cart-horses, sixteen hands being an average height. Brown and bay are now the prevailing colours. In the district whose name they bear the breeding of them for sale is extensively prosecuted, and is conducted with much care and success. Liberal premiums are offered by the local agricultural societies for good stallions. Horses of this breed are peculiarly distinguished for the free step with which they move along when exerting their strength in cart or plough. Their merits are now so generally appreciated that they are getting rapidly diffused over the country. Many small farmers in Clydesdale make a business of raising entire colts, which they either sell for stallions or send into distant counties to serve for hire in that capacity.

In the Highlands of Scotland, a breed of hardy and very serviceable ponies, or "garrons," as the natives call them, are found in great numbers. In their native glens they are employed in tillage, and although unfit for stated farm-work in the low country, are even there often used in light carts for work requiring despatch rather than great power. Similar ponies abound in Wales.

Section 2.—Breeding of Cart-Horses.

In breeding cart-horses regard must be had to the purpose for which they are designed. If the farmer contemplates the raising of colts for sale, he must aim at a larger frame than if he simply wishes to keep up his own stock of working cattle. These considerations will so far guide him as to the size of the mares and stallions which he selects to breed from; but vigorous constitutions, perfect freedom from organic disease, symmetrical form, and good temper are qualities always indispensable. Nothing is more common than to see mares used for breeding merely because, from lameness or age, they have ceased to be valuable for labour. Lameness from external injury is, of course, no disqualification: but it is mere folly to expect valuable progeny from unsound, mis-shapen, ill-tempered, or delicate dams, or even from really good ones, when their vigour has declined from age. A farmer may grudge to lose the labour of a first-rate mare for two or three months at his busiest season; but if he cannot make arrangements for doing this, he had better let breeding alone altogether; for it is only by producing horses of the best quality that it can be worth his while to breed them at all. It is always desirable that both sire and dam should have arrived at maturity before being put to breed.

The head of the cart-horse should not be large, at least not heavy in the bones of the face and jaws, nor loaded with flesh. Full development of brain is, indeed, of great importance, and hence a horse somewhat wide between the ears is to be preferred. Prick ears and narrow forehead have by some been reckoned excellences, but we have so invariably noticed such horses to be easily startled, given to shying, and wanting in courage and intelligence, that we regard such a form of head as a defect to be avoided. The eye should be bright, full, and somewhat prominent, the neck inclining to thickness, of medium length, and slightly arched, and the shoulders oblique. Upright shoulders have been commended as an advantage in a horse for draught, it being alleged that such a form enables him to throw his weight better into his collar. It should be remembered, however, that the horses which display the greatest power in drawing heavy loads are characterised by muscular vigour and nervous energy rather than mere weight of carcase; and these qualities are more usually found in connection with the oblique shoulder than the upright one—not to mention that this form is indispensable to that free and full step so necessary in a really useful farm-horse.

"The back should be straight and broad, the ribs well arched, and the false ribs of due length, so as to give the abdomen capacity and roundness. The tail should be well set out, not too drooping, and the quarters should be full and muscular. The horse should girth well, and have his height in his body rather than in his legs, so as to look less than measurement proves him to be. The forelegs should be strong, and flat below the knee, and by no means round and gummy either before or behind, neither should they have white hair about them, nor much hair of any colour. The hocks should be broad in front, and neither too straight nor too crooked, nor yet cat-hammed. All diseases of this joint, whether curbs, spavins, or thoroughpins, are sufficient grounds for rejecting a horse. The feet are a matter of very much importance. The tendency of many heavy horses is to have thin horn and flat feet. A stallion possessing such feet is exceedingly objectionable. Plenty of horn is a recommendation, and the feet had better be too large than too small. The brood mare should possess as many of the points now enumerated as possible. If the mare is small but symmetrical, we may very properly select a large stallion, provided he has good action. If, on the other hand, the mare is large and has a tendency to coarseness, we should select a middle-sized horse of symmetrical appearance."[1]

Sixteen hands is a good height for a farm-horse. Except for very heavy land, we have always had more satisfaction from horses slightly below this standard than above it.

We have repeatedly put a well-bred saddle mare to a cart-horse, and have invariably found the produce to prove excellent farm-horses. The opposite cross, betwixt a cart-mare and blood stallion, is nearly as certain to prove ungainly, vicious, and worthless. These horses are generally

[1] Morton's *Cyclopædia of Agriculture*—article "Horse."

much stronger than their appearance indicates, have great powers of endurance, and can be kept in prime working condition at much less cost than bulkier animals. It is on muscular power and nervous energy that the strength of animals depends, and this, therefore, should be sought after in the farm-horse rather than mere bulk.

Cart-mares should not foal earlier than May Provided they are not unduly pushed or put to draw heavy loads, they may be kept at work almost up to their time of foaling, and are thus available for the pressing labours of spring. It is of importance, too, that the pasture should be fresh and the weather mild ere their nursing duties begin. Mares seldom require assistance in bringing forth their young, and although it is well to keep an eye upon them when this event is expected, they should be kept as quiet as possible, as they are impatient of intrusion, and easily disturbed in such circumstances. A sheltered paddock with good grass, and where there are no other horses, is the most suitable quarters for a mare that has newly foaled. There must be no ditch or pond in it, as young foals have a peculiar fatality for getting drowned in such places. A mare, in ordinary condition, receives the stallion on the ninth or tenth day after foaling, and with a greater certainty of conceiving than when it is delayed until she is again in heat. If the mare's labour can at all be dispensed with, it is desirable to have her with her foal for two months at least. She may then be put to easy work with perfect safety, so that she is not kept away from the foal longer than two or three hours at a time. When the foal has got strong enough, it may even be allowed to follow its dam at her work, and to get suck as often as it desires it. Towards the end of September foals are usually weaned, and are then put under cover at night, and receive a little corn, along with succulent food. Good hay, bran, carrots, or swedes, and a few oats, must be given regularly during the first winter, with a warm shed to lie in, and an open court for exercise. At weaning it is highly expedient to put a cavasin on colts, and lead them about for a few times. A few lessons at this early age, when they are easily controlled, saves a world of trouble afterwards. Before being turned to grass in spring, they should, on the same principle, be tied up in stalls for a week or so. It is customary to castrate colts at a year old. Some, indeed, advise its being done a few weeks after birth, when, of course, the pain to the animal and risk of death are less. It must, however, be borne in mind that this early emasculation will probably ensure a skranky neck, whereas a natural tendency to this defect can in good measure be remedied by deferring the operation. We have seen a puny colt much improved in figure by being left entire until he was two years old. By giving good pasture in summer, and a liberal allowance of hay, roots, and oats in winter, colts may with safety, and even benefit, be put to moderate work in their third spring. Some time before this is done they should be put through a short course of training, to use them to the bit, and make them quiet and handy. Many good cart-horses are ruined for want of a little timely attention in this way. When they have got familiar with the harness, they should be yoked to a log of wood, and made to draw that up and down the furrows of a fallow field, until they become accustomed to the restraint and exertion, after which they may with safety be put to plough alongside a steady and good-tempered horse, and, what is of equal consequence, under the charge of a steady, good-tempered ploughman. As they should not have more than five hours' work a-day for the first summer, it is always an advantage to have a pair of them to yoke at the same time, in which case they take half-day about, and do a full horse's work betwixt them. With such moderate work and generous feeding their growth will be promoted. By midsummer, the press of field labour being over, it is advisable to turn the striplings adrift, and let them enjoy themselves in a good pasture until after harvest, when they can again be put to plough. Horses should not be required to draw heavy loaded carts until they are five years old. When put into the shafts earlier than this they frequently get strained and stiffened in their joints. On every farm requiring four or five pairs of horses it is highly expedient to have a pair of young ones coming in annually. This enables the farmer to be provided against contingencies, and to have his stable occupied at all times with horses in their full vigour, which go through their work with spirit, and never falter for a little extra pushing in emergencies.

Section 3.—Feeding and General Management of Farm-Horses.

As there is true economy in employing only the best quality of horses, and these in their prime, so also is there in feeding them uniformly well, and looking to their comfort in all respects. The following quotation from the *Transactions* (for October 1850) of the Highland and Agricultural Society of Scotland, describes the practice of some of our most experienced farmers in this particular :—

"The system of feeding I adopt is as follows :—From the middle of October till the end of May my horses get one feed of steamed food and two feeds of oats daily, with the best oat or wheat straw for fodder. I never give bean straw unless it has been secured in fine condition, having often seen the bad effects of it, partly owing, I think, to its long exposure to the weather. In our variable climate, and from the quantity of sand which adheres to it, I use it generally for litter. The steamed food used is well washed Swedish turnips and potatoes in equal proportions, mixed with sifted wheat-chaff. In those years when we had a total loss of potatoes Swedish turnip alone was used, but not with the same good effect as when mixed with potatoes. This year, having plenty of diseased potatoes in a firm state, I give a larger proportion of potatoes than turnip, and never upon any occasion give oat husks, commonly called meal-seeds, having often seen their injurious effects. At five o'clock in the morning each horse gets 6 lb weight of bruised oats, at noon the same quantity of oats, and at half-past seven P.M. 47 lb weight of steamed food. I find that it takes 62 lb weight of unsteamed potatoes and turnip to produce 47 lb steamed ; to each feed of steamed food, 4 oz. of common salt are added, and mixed up with one-fourth part of a bushel of wheat-chaff, weighing about 1¼ lb, a greater quantity of wheat-chaff than this having generally too laxative an effect. Each horse eats from 14 lb to 18 lb of fodder during the twenty-four hours, besides what is required for litter. In spring I sometimes give a mixture of bruised beans and oats, instead of oats alone , from June to the middle of October those horses that are required for the working of the green crop, driving manure, and harvest work, are fed with cut grass and tares in the house ; and about 7 lb of oats each day, given at twice, increasing or decreasing the quantity according to the work they have to do ; and I turn out to pasture only those horses that are not required until the busy season. I disapprove of horses that are regularly worked being turned out to grass, and exposed to all the changes of our variable climate, as I believe it to be the origin of many diseases. By this mode of feeding the horses are always in fine sleek condition, and able for their work. I have acted upon this system for the last fifteen years, have always had from 16 to 20 horses, and during that period I have only lost 7 horses, 3 of them from accidental causes ; and I attribute this, in a great measure, to the mode of feeding, and in particular to the steamed food."

The treatment of horses differs somewhat in other places from that now detailed. In Berwickshire, for example, they are usually turned to pasture as soon as the mildness of the weather and the forwardness of the pasture admit of it. While employed in carrying the crop, their fodder consists largely of tares, and afterwards till Martinmas they are fed on hay. From this date oat and bean straw, with 8 or 10 lb of raw swedes to each per diem, is substituted till the 1st of March, when, with the recurrence of harder labour, hay is again given till the return of the grazing season. During three-fourths of the year they receive about 16 lb of oats per diem, in three separate feeds. From the close of turnip-sowing until harvest, oats are either withheld or given only when a harder day's work occurs. The practice

of bruising the whole of the oats given to horses, and also of chopping their hay, is now very prevalent. By giving a few pounds of chopped hay with each feed of bruised oats, and oat-straw in the racks, during the whole of the winter half-year, horses are kept in better condition and at no more expense than by giving them straw alone for half the period, and hay alone the other half. We are persuaded, also, that unless horses are stripped of their shoes and turned adrift altogether for a summer's run, soiling in boxes or sheds, with an open yard, is preferable to grazing. Hay and oats ought undoubtedly to constitute the staple fare of farm-horses. Without a liberal allowance of suitable and nourishing food, it is impossible that they can perform the full amount of work of which they are capable, or be sustained for any length of time in robust health. When *alleged* very cheap plans of feeding horses are inquired into, it is usually found that the amount and quality of the work performed by them is in fitting proportion. In this, as in so many other things, cheapness and economy are not convertible terms. The true way to economise the horse-labour of a farm is to have only good and well-fed animals, and to get the greatest possible amount of work out of them.

CHAPTER XVI.

LIVE STOCK—CATTLE.

Section 1.—*Breeds*—1*st*, *Heavy Breeds.*

As our limits do not admit of even a brief notice of all those breeds of cattle for which Great Britain is so famous, we shall restrict our remarks to some of the most important of them. Without entering upon curious speculations as to the origin of these breeds, we proceed to notice them in the order suggested by their relative importance in practical agriculture. The large lowland cattle thus claim our first attention, and amongst them we cannot hesitate in assigning the first place to the

Short-horns.—It appears that from an early date the valley of the Tees possessed a breed of cattle which, in appearance and general qualities, were probably not unlike those *quasi* short-horns which abound in various parts of the country at the present day. By the time that the Messrs Colling came upon the field it is evident that there were many herds around them in which considerable improvement had already been effected, and that they commenced their memorable efforts in cattle-breeding with exceedingly hopeful materials to work upon. But in their masterly hands these materials seemed at once to acquire an unwonted plasticity; for in an incredibly short time their cattle exhibited, in a degree that has not yet been excelled, that combination of rapid and large growth with aptness to fatten, of which their symmetry, good temper, mellow handling, and gay colours are such pleasing indices and accompaniments, and for which they have now acquired a world-wide celebrity. It was by judicious selection in the first instance, and then by coupling animals of near affinity in blood, that they so developed and stereotyped these qualities in their cattle as to entitle them at once to take rank as the progenitors of a new and well-marked breed. These *Durham*, *Teeswater*, or *Short-horn* cattle, as they were variously called, were soon eagerly sought after, and spread over the whole country with amazing rapidity. For a time their merits were disputed by the eager advocates of other and older breeds, some of which (such as the long-horns, once the most numerous breed in the kingdom) they have utterly supplanted, while others, such as the Herefords, Devons, and Scotch polled cattle, have each their zealous admirers, who still maintain their superiority to the younger race. But this controversy is meanwhile getting practically decided in favour of the short-horns, which constantly encroach upon their rivals even in their headquarters, and seldom lose ground which they once gain. Paradoxical as the statement appears, it is yet true that the very excellence of the short-horns has in many cases led to their discredit. For many persons desiring to possess these valuable cattle, and yet grudging the cost of pure-bred bulls, or being ignorant of the principles of breeding, have used worthless cross-bred males, and so have filled the country with an inferior race of cattle, bearing indeed a general resemblance in colour, and partaking in some measure of the good qualities of short-horns, but utterly wanting in their peculiar excellences. By ignorant or prejudiced persons the genuine race is nevertheless held answerable for the defects of the mongrels which usurp their name, and for the damaging comparisons which are made betwixt them and choice specimens of other breeds. That the short-horn breed should spread as it does, in spite of this hinderance, is no small proof of its inherent excellence, and warrants the inference that whenever justice is done to it, it will take its place as the one appropriate breed of the fertile and sheltered parts of Great Britain. This desirable consummation has hitherto been retarded by the scarcity and high price of pure-bred bulls. We are quite aware that bull-breeding, as hitherto conducted, is a hazardous and unremunerative business, notwithstanding the great prices sometimes obtained for first-class animals. We are of opinion, however, that it might be conducted in such a way as to be safer and more profitable to the breeder, and more beneficial to the country at large, than it has hitherto been. There is at present a large and growing demand for good yearling short-horn bulls, at prices ranging from £25 to £50. With a better supply both as to quality and numbers, this demand would steadily increase, for we have long observed that there is no want of customers for really good animals at such prices as we have named. When higher prices than these are demanded, farmers who breed only for the production of beef feel that they are beyond their reach, and are fain to content themselves with lower-priced and inferior animals. We are glad, therefore, that it is a steadily increasing practice for breeders of short-horns to dispose of their young bulls by an annual auction sale on their own premises; or for a number of breeders to concur in offering their lots for sale on the same day at some central auction mart. The good effects of this increasing supply of well-bred bulls are becoming apparent in the improved quality of the cattle now brought to our markets.

A great stimulus has been given to the breeding of high-class short-horns by the extraordinary prices which of late have been obtained for animals of certain favourite and fashionable strains. To illustrate this we give the following particulars of the four principal sales of the year 1872:—

The late Mr Pawlet's	herd of 60	animals averaged	£195	18	7
Mr G. Bowly's	,, 80	,,	158	1	9
Earl of Dunmore's	,, 54	,,	242	18	9
Messrs Harward & Downay's	,, 61	,,	253	8	2

It is said that the operations of one enterprising Canadian breeder—Mr Cochran of Hillhurst—have had a powerful effect in determining these extraordinary market rates for short-horns of the choicest type. One cargo, including forty short-horn bulls and heifers, and choice specimens of Cotswold sheep and Berkshire pigs, taken out by this gentleman in 1870, is said to have cost him £15,000. American breeders of short-horn cattle have now established a herd-book of their own, and have been so successful in their efforts that already they have made numerous sales to English breeders at long prices. While we write, accounts have come of the sale by auction, on 10th September 1873, of the herd of Mr Campbell of New York Mills, near

Utica, when 108 animals realised $380,000. Of these 10 were bought by British breeders, 6 of which, of the Duchess family, averaged $24,517, and one of them, "Eighth Duchess of Geneva," was bought for Mr Pavin Davies of Gloucestershire at the unprecedented price of £8120. Choice specimens of these cattle are now also being sent in large numbers to our Australian colonies and to various parts of the continent of Europe. Indeed, it may be said of them, that, like our people, they are rapidly spreading over the world.

As already hinted, the *Hereford* is the breed which in England contests most closely with the short-horns for the palm of excellence. They are admirable grazier's cattle, and when of mature age and fully fattened, present exceedingly level, compact, and massive carcases of excellent beef. But the cows are poor milkers, and the oxen require to be at least two years old before being put up to fatten—defects which, in our view, are fatal to the claims which are put forward on their behalf. To the grazier who purchases them when their growth is somewhat matured they usually yield a good profit, and will generally excel short-horns of the same age. But the distinguishing characteristic of the latter is that, when properly treated, they get sufficiently fat and attain to remunerative weights at, or even under, two years old. If they are kept lean until they have reached that age their peculiar excellence is lost. From the largeness of their frame they then cost more money, consume more food, and yet do not fatten more rapidly than bullocks of slower growing and more compactly formed breeds. It is thus that the grazier frequently gives his verdict in favour of Herefords as compared with short-horns. Even under this mode of management short-horns will usually yield at least as good a return as their rivals *to the breeder and grazier conjointly.* But if fully fed from their birth so as to bring into play their peculiar property of growing and fattening simultaneously, we feel warranted in saying that they will yield a quicker and better return for the food consumed by them than cattle of any other breed. Unless, therefore, similar qualities are developed in the Herefords, we may expect to see them more and more giving place to the short-horns. These remarks apply equally to another breed closely allied to the Herefords, viz., the

North Devons, so much admired for their pleasing colour, elegant form, sprightly gait, and gentle temper, qualities which fit them beyond all other cattle for the labour of the field, in which they are still partially employed in various parts of England. If it could be proved that ox-power is really more economical than horse-power for any stated part of the work of the farm, then the Devons, which form such admirable draught oxen, would be deserving of general cultivation. It is found, however, that when agriculture reaches a certain stage of progress, ox-labour is inadequate to the more rapid and varied operations that are called for, and has to be superseded by that of horses.

Scotland possesses several indigenous breeds of heavy cattle, which for the most part are *black* and *hornless*, such as those of Aberdeen, Angus, and Galloway. These are all valuable breeds, being characterised by good milking and grazing qualities, and by a hardiness which peculiarly adapts them for a bleak climate. Cattle of these breeds, when they have attained to three years old, fatten very rapidly, attain to great size and weight of carcase, and yield beef which is not surpassed in quality by that of any cattle in the kingdom.

The cows of these breeds, when coupled with a short-horn bull, produce an admirable cross-breed, which combines largely the good qualities of both parents. The great saving of time and food which is effected by the earlier maturity of the cross-breed has induced a very extensive adoption of this practice in all the north-eastern counties of Scotland. Such a system is necessarily inimical to the improvement of the pure native breeds; but when cows of the cross-breed are continuously coupled with pure short-horn bulls, the progeny in a few generations become assimilated to the male parent, and are characterised by a peculiar vigour of constitution and excellent milking power in the cows. With such native breeds to work upon, and this aptitude to blend thoroughly with the short-horn breed, it is much more profitable to introduce the latter in this gradual way of continuous crossing than at once to substitute the one pure breed for the other. The cost of the former plan is much less, as there needs but the purchase from time to time of a good bull; and the risk is incomparably less, as the stock is acclimatised from the first, and there is no danger from a wrong selection. The greatest risk of miscarriage in this mode of changing the breed is from the temptation to which, from mistaken economy, the breeder is exposed of rearing a cross-bred bull himself, or purchasing a merely nominal short-horn bull from others.

From this hurried review of our heavy breeds of cattle it will be seen that we regard the short-horn as incomparably the best of them all, and that we anticipate its ultimate recognition as the breed which most fully meets the requirements of all those parts of the country where grain and green crops are successfully cultivated.

2d.—*Dairy Breeds.*

The *dairy breeds* of cattle next claim our attention, for although cattle of all breeds are used for this purpose, there are several which are cultivated chiefly, if not exclusively, because of their fitness for it. Dairy husbandry is prosecuted under two very different and well-defined classes of circumstances. In or near towns, and in populous mining and manufacturing districts, it is carried on for the purpose of supplying families with new milk. In the western half of Great Britain, and in many upland districts, where the soil and climate are more favourable to the production of grass and other green crops than of corn, butter and cheese constitute the staple products of the husbandman. The town dairyman looks to quantity rather than quality of milk, and seeks for cows which are large milkers, which are long in going dry, and which can be readily fattened when their daily yield of milk falls below the remunerative measure. Large cows, such as short-horns and their crosses, are accordingly his favourites. In the rural dairy, again, the merits of a cow are estimated by the weight and quality of the cheese or butter which she yields, rather than by the mere quantity of her milk. The breeds that are cultivated expressly for this purpose are accordingly characterised by a less fleshy and robust build than is requisite in grazier's cattle. Of these we select for special notice the Ayrshire, the Suffolk dun, and the Jersey breeds.

The Ayrshires, by common consent, now occupy the very first rank as profitable dairy cattle. From the pains which have been taken to develop their milk-yielding power it is now of the highest order. Persons who have been conversant only with grazing cattle cannot but be surprised at the strange contrast between an Ayrshire cow in full milk and the forms of cattle which they have been used to regard as most perfect. Her wide pelvis, deep flank, and enormous udder, with its small wide-set teats, seem out of all proportion to her fine bone and slender forequarters. As might be expected, the breed possesses little merit for grazing purposes. Very useful animals are, however, obtained by crossing these cows with a short-horn bull, and this practice is now rather extensively pursued in the west of Scotland by farmers who combine dairy husbandry with the fattening of cattle. The function of the Ayrshire cattle is, however, the dairy. For this they are unsurpassed, either as respects the amount of produce yielded by them in proportion to the food which they consume, or the faculty which they possess of converting the herbage of poor exposed soils, such as abound in their native district, into butter and cheese of the best quality.

BULL, HEREFORD BREED

Bred by the Right Hon^{ble} the Earl of Talbot.

EWE & LAMB, SOUTH DOWN BREED

Bred by Thomas Ellman Esq^{r}. Beddingham.

Copied by permission from Professor Low's description of breeds of Domesticated Animals.

The county of Suffolk has for centuries been celebrated for its dairy produce, which is chiefly obtained from a polled breed of cattle, the prevailing colour of which is dun or pale red, from which they are known as the *Suffolk Duns.* They have a strong general resemblance to the Scotch polled cattle, but nevertheless seem to be indigenous to Suffolk. They are ungainly in their form and of little repute with the grazier, but possess an undoubted capacity of yielding a large quantity of milk in proportion to the food which they consume. They are now encroached upon by, and will probably give place to, the short-horns, by which they are decidedly excelled for the combined purposes of the dairy and the fattening stall.

The breeds already referred to are those to which professional dairymen give the preference, but the cattle of the Channel Islands, of which the *Jersey* may be regarded as the type, are so remarkable for the choice quality of the cream and butter obtained from their rather scanty yield of milk, that they are eagerly sought after for private dairies, in which quality of produce is more regarded than quantity. The rearing of heifers for the English market is of such importance to these islands that very stringent regulations have been adopted for insuring the purity of their peculiar breed. These cattle in general are utterly worthless for the purposes of the grazier. The choicer specimens of the Jerseys have a certain deer-like form which gives them a pleasing aspect. The race, as a whole, bears a striking resemblance to the Ayrshires, which are alleged to owe their peculiar excellences to an early admixture of Jersey blood.

3d.—*Mountain Breeds.*

The mountainous parts of Great Britain are not less favoured than the lowlands in possessing breeds of cattle peculiarly adapted to the exigencies of the climate.

The *Kyloes* or *West Highland cattle* are the most prominent of this group. They are widely diffused over the Highlands of Scotland, but are found in the greatest perfection in the larger Hebrides. Well-bred oxen of this breed, when of mature growth and in good condition, exhibit a symmetry of form and noble bearing which is unequalled by any cattle in the kingdom. Although somewhat slow in arriving at maturity, they are contented with the coarsest fare, and ultimately get fat where the daintier short-horns could barely exist. Their hardy constitution, thick mellow hide, and shaggy coat, peculiarly adapt them for a cold humid climate and coarse pasturage. Fewer of these cattle are now reared in the Highlands than formerly, owing to the lessened number of cottars and small tenants, the extension of sheep husbandry, and latterly from the excessive multiplication of deer forests. Large herds of cows are, however, kept on such portions of farms as are unsuited for sheep walks. The milk of these cows is very rich, but as they yield it in small quantity, and go soon dry, they are unsuited for the dairy, and are kept almost solely for the purpose of suckling each her own calf. The calves are generally housed during their first winter, but after that they shift for themselves out of doors all the year round. Vast droves of these cattle are annually transferred to the lowlands, where they are in request for their serviceableness in consuming profitably the produce of coarse pastures and the leavings of daintier stock. Those of a dun or tawny colour are often selected for grazing in the parks of the aristocracy, where they look quite as picturesque as the deer with which they are associated. Indeed, they strikingly resemble the so-called wild cattle that are carefully preserved in the parks of several of our nobility, and like them are probably the descendants of the cattle of the ancient Britons. This view is confirmed by the strong family likeness borne to them by the

Welsh cattle, which is quite what might be expected from the many features, physical and historical, which the two provinces have in common. Although the cattle of Wales, as a whole, are obviously of common origin, they are yet ranged into several groups, which owe their distinctive features either to peculiarities of soil and climate or to intermixture with other breeds. The *Pembrokes* may be taken as the type of the mountain groups. These are hardy cattle, which thrive on scanty pasturage and in a humid climate. They excel the West Highlanders in this respect, that they make good dairy cattle, the cows being peculiarly adapted for cottagers' purposes. When fattened they yield beef of excellent quality. Their prevailing and most esteemed colour is black, with deep orange on the naked parts. The *Anglesea* cattle are larger and coarser than the Pembrokes, and those of *Merioneth* and the higher districts are smaller, and inferior to them in every respect. The county of *Glamorgan* possesses a peculiar breed, bearing its name, which has long been in estimation for combined grazing and dairy purposes. It has latterly been so much encroached upon by Herefords and short-horns that there seems some likelihood of its becoming extinct, which will be cause for regret, unless pains are taken to occupy its place with cattle not inferior to it in dairy qualities. We conclude this rapid review of our native breeds by noticing the most singular of them all, viz.,

The *Shetland cattle*, which are the most diminutive in the world. The carcase of a Shetland cow, when fully fattened, scarcely exceeds in weight that of a long-woolled wether. These little creatures are, however, excellent milkers in proportion to their size; they are very hardy, are contented with the scantiest pasturage, come early to maturity, are easily fattened, and their beef surpasses that of all other breeds for tenderness and delicacy of flavour. The diminutive cows of this breed are not unfrequently coupled with short-horn bulls, and the progeny from such apparently preposterous unions not only possess admirable fattening qualities, but approximate in bulk to their sires. These curious and handsome little creatures, apparently of Scandinavian origin, are so peculiarly fitted to the circumstances of their bleak and stormy habitat, that the utmost pains ought to be taken to preserve the breed in purity, and to improve it by judicious treatment.

Section 2.—Farm Management of Cattle.

We shall now endeavour to describe the farm management of this valuable class of animals, under the heads of *breeding, rearing, fattening,* and *dairy management.* The proceedings of those engaged in the breeding and rearing of cattle for the production of beef are, however, largely determined by the character of the soil and climate of particular districts and farms. The occupiers of all comparatively fertile soils carry forward to maturity such animals as they breed, and dispose of them directly to the butcher. Those who are less fortunately circumstanced in this respect advance their young cattle to such a stage as the capabilities of their farms admit of, and then transfer them to others, by whom the fattening process is conducted. It cannot be too strongly impressed upon those who engage in this business that it never can be profitable to breed inferior cattle; or (however good their quality) to suffer their growth to be arrested by cold or hunger; or to sell them in a lean state. In selecting a breeding stock of cattle, the qualities to be aimed at are a sound constitution and a symmetrical form, aptitude to fatten, quiet temper, and large milk-yielding power in the cows. As all these qualities are hereditary, cattle are valuable for breeding purposes not merely in proportion as they are developed in the individuals, but according to the measure in which they are known to have been possessed by their progenitors. A really good pedigree adds therefore greatly to the value of breeding-stock. It is doubtless important to have both parents good; but in the case of ruminants, the predominating influence of the male in determining the qualities of the progeny is so well ascertained, that the selection of the bull is a matter of prime importance. We are able to state, from ample personal experience, that by using a bull that is at once good himself and of good descent, a level and valuable lot of calves can be obtained from very indifferent cows. It is indeed miserable economy to grudge the price of a good bull. Coarse, mis-shapen, unthrifty cattle cost just as much for rearing and fattening as those of the best quality, and yet may not be worth so much by £3 or £4 a-head when they come ultimately to market. The loss which is annually sustained from breeding inferior cattle is far greater than those concerned seem to be aware of. It is impossible to estimate this loss accurately, but from careful observation and inquiry we are confident that it amounts to not less than 50s. a-head on one-half of the fat cattle annually slaughtered in Great Britain. If this be so, it follows that without expending a farthing more than is done at present on food, housing, and attendance, the profit which would accrue from using only the best class of bulls would be equivalent to an advance of 1s. per stone in the price of beef as regards half of the fat bullocks brought to market. This profit could, moreover, be secured by a very moderate outlay; for if properly gone about, the best class of bulls might be employed without adding more than 3s. or 4s. a-head to the price of each calf reared. We may surely anticipate that such a palpable source of profit will not continue to be neglected by the breeders of cattle. There are many instances in which landlords would find it much for their interest to aid their tenantry in at once procuring really good bulls. Cattle shows and prizes are useful in their way as a means of improving the cattle of a district, but the introduction of an adequate number of bulls from herds already highly improved is the way to accomplish the desired end cheaply, certainly, and speedily. We must here protest against a practice by which short-horn bulls are very often prematurely unfitted for breeding. Their tendency to obesity is so remarkable that unless they are kept on short commons they become unwieldy and unserviceable by their third or fourth year. Instead, however, of counteracting this tendency, the best animals are usually "made up," as it is called, for exhibition at cattle shows or for ostentatious display to visitors at home, and the consequence is, that they are ruined for breeding purposes. We rejoice to see that the directors of our national agricultural societies are resolutely setting their faces against this pernicious practice. It is needful certainly that all young animals, although intended for breeding stock, should be well fed, for without this they cannot attain to their full size and development of form. But when this is secured, care should be taken, in the case of all *breeding* animals, never to exceed that degree of flesh which is indispensable to perfect health and vigour. The frequent occurrence of abortion or barrenness in high-pedigreed herds seems chiefly attributable to overfeeding. The farmer who engages in cattle-breeding with the view of turning out a profitable lot of fat beasts annually, will take pains first of all to provide a useful lot of cows, such as will produce good calves, and if well fed while *giving milk* will yield enough of it to keep two or three calves a-piece. That he may be able to obtain a sufficient supply of good calves he will keep a really good bull, and allow the cottagers residing on the farm or in its neighbourhood to send their cows to him free of charge, stipulating only that when they have a calf for sale he shall have the first offer of it.

Cows are an expensive stock to keep, and it is therefore of importance to turn their milk to the best account. It is poor economy, however, to attempt to rear a greater number of calves than can be done justice to. Seeing that they are to be reared for the production of beef, the only profitable course is to feed them well from birth to maturity. During the first weeks of calf-hood the only suitable diet is unadultered milk, warm from the cow, given three times a-day, and not less than two quarts of it at each meal. By three weeks old they may be taught to eat good hay, linseed cake, and sliced swedes. As the latter items of diet are relished and freely eaten, the allowance of milk is gradually diminished until about the twelfth week, when it may be finally withdrawn. The linseed cake is then given more freely, and water put within their reach. For the first six weeks calves should be kept each in a separate crib; but after this they are the better of having room to frisk about. Their quarters, however, should be well sheltered, as a comfortable degree of warmth greatly promotes their growth. During their first summer they do best to be soiled on vetches, clover, or Italian ryegrass, with from 1 ℔ to 2 ℔ of cake to each calf daily. When the green forage fails, white or yellow turnips are substituted for it. A full allowance of these, with abundance of oat straw, and not less than 2 ℔ of cake daily, is the appropriate fare for them during their first winter. Swedes will be substituted for turnips during the months of spring, and these again will give place in due time to green forage or the best pasturage. The daily ration of cake should never be withdrawn. It greatly promotes growth, fattening, and general good health, and in particular is a specific against the disease called blackleg, which often proves so fatal to young cattle. Young cattle that have been skilfully managed upon the system which we have now sketched, are at 18 months old already of great size, with open horns, mellow hide, and all those other features which indicate to the experienced grazier that they will grow and fatten rapidly. This style of management is not only the best for those who fatten as well as rear, but is also the most profitable for those who rear only.

We have already stated that in Scotland comparatively few cattle are fattened on pasturage. An increasing number of fat beasts are now prepared for market during the summer months by soiling on green forage; but it is by means of the turnip crop, and during the winter months, that this branch of husbandry is all but exclusively conducted in the northern half of Great Britain. But a few years ago the fattening of cattle on Tweedside and in the Lothians was conducted almost exclusively in open courts, with sheds on one or more sides, in which from two to twenty animals were confined together, and fed on turnips and straw alone. Important changes have now been introduced, both as regards housing and feeding, by means of which a great saving of food has been effected. Under the former practice the cattle received as many turnips as they could eat, which, for an average-sized two-year-old bullock, was not less than 220 ℔ daily. The consequence of this enormous consumption of watery food was, that for the first month or two after being thus fed the animals were kept in a state of habitual diarrhœa. Dry fodder was, indeed, always placed within their reach; but as long as they had the opportunity of taking their fill of turnips, the dry straw was all but neglected. By stinting them to about 100 ℔ of turnips daily, they can be compelled to eat a large quantity of straw, and on this diet they thrive faster than on turnips at will. A better plan, however, is to render the fodder so palatable as to induce them to eat it of choice. This can be done by grating down the turnips by one or other of the pulping-machines now getting into common use, and then mixing the grated turnip with an equal quantity, by measure, of cut straw. Some persons allow the food after being thus mixed to lie in a heap for two days, so that fermentation may ensue before it is given to the cattle. There is, however, a preponderance of evidence in favour of using it fresh To this mess can conveniently be added an allowance of ground cake, whether of linseed, rape, or cotton seed, and of meal of any kind of grain which the farmer finds it most economical at the time to use. The ground cake and meal are, in this case, to be thoroughly mixed with the pulped turnip and cut straw. The same end can be accomplished by giving a moderate feed (say 50 ℔) of sliced roots twice a-day, and four hours after each of these meals, another, consisting of cut straw, cake, and meal. In this case the chaff and farinaceous ingredients should be mixed and cooked by steam in a close vessel; or the meal can be boiled in an open kettle, with water enough to make it of the consistency of gruel, and then poured over the chaff, mixed thoroughly with it, and allowed to lie in a heap for two or three hours before it is served out to the cattle. From 2 to 4 ℔ of meal, &c., a-head per diem is enough to begin with. But as the fattening process goes on it is gradually increased, and may rise to 7 or 8 ℔ during the last month before sending to market. It is advisable to mix with the cooked mess about 2 ounces of salt per diem for each bullock. An important recommendation to this mode of preparing cattle food is, that it enables the farmer to use rape-cake freely; for when this article is reduced to a coarse powder, and heated to the boiling point, it not only loses its acrid qualities, but acquires a smell and flavour which induce cattle to eat it greedily. Moreover, if the rape-seeds should have been adulterated with those of wild mustard before going to the crushing-mill (as not unfrequently happens), and a cake is thus produced which in its raw state is poisonous to cattle, it has been ascertained that boiling deprives such spurious cake of its hurtful qualities and renders it safe and wholesome. As rape-cake possesses fattening elements equal to those of linseed-cake, and can usually be bought at half the price, it is well worth while to have recourse to a process by which it can so easily be rendered a palatable and nourishing food for cattle.

Fattening cattle are usually allowed to remain in the pastures to a later date in autumn than is profitable. The pressure of harvest work, or the immature state of his turnip crop, often induces the farmer to delay housing his bullocks until long after they have ceased to make progress on grass. They may still have a full bite on their pastures; but the lengthening nights and lowering temperature lessen the nutritive quality of the herbage, and arrest the further accumulation of fat and flesh. The hair of the cattle begins also to grow rapidly as the nights get chilly, and causes them to be housed with rougher coats than are then expedient. To avoid these evils the farmer should early in August begin to spread on the pasture a daily feed of green forage, consisting of vetches, peas, and beans grown in mixture in about equal proportions, which if well podded and full of soft pulse, supplies exactly the kind of food required to compensate for the deteriorating pasturage. Early in September cabbages and white globe turnips should be given on the pasture in lieu of the green forage. After ten days or so of this treatment they should be transferred to their winter quarters. For the first two months after they go into winter quarters they make as good progress on yellow turnips as on any kind of roots; for the three following months well stored swedes are the best food for them; and from the beginning of March until the end of the season, mangolds and potatoes, in the proportion of four parts of the former to one of the latter. The chaff of wheat, oats, or beans, if tolerably free from dust, is quite as suitable as cut straw for mixing with the pulped roots and cooked food. The addition of a small quantity of chopped hay, or of the husks of kiln-dried oats, to the other food, usually induces cattle to feed more eagerly. In short, the animals must be closely watched, and occasional variations made in the quantity and quality of the food given to particular individuals or of the general lot as their circumstances may require. Besides the food given in the manger it is desirable that each animal should receive a daily allowance of fresh oat straw in a rack to which he has access at pleasure.

A better appreciation of the effects of temperature on the animal economy has of late years exerted a beneficial influence upon the treatment of fattening cattle. Observant farmers have long been aware that their cattle, when kept dry and moderately warm, eat less and thrive faster than under opposite conditions. They accounted for this in a vague way by attributing it to their greater comfort in such circumstances. Scientific men have now, however, showed us that a considerable portion of the food consumed by warm-blooded animals is expended in maintaining the natural heat of their bodies, and that the portion of food thus disposed of is dissipated by a process so closely analogous to combustion that it may fitly be regarded as so much fuel. The fat which, in favourable circumstances, is accumulated in their bodies, may in like manner be regarded as a store of this fuel laid up for future emergencies. The knowledge of this fact enables us to understand how largely the profit to be derived from the fattening of cattle is dependent upon the manner in which they are housed, and necessarily forms an important element in determining the question whether *yards*, *stalls*, or *boxes* are best adapted for this purpose. A really good system of housing must combine the following conditions :—

1st, Facilities for supplying food and litter, and for removing dung with the utmost economy of time and labour;

2d, Complete freedom from disturbance;

3d, A moderate and unvarying degree of warmth;

4th, A constant supply of pure air;

5th, Opportunity for the cattle having a slight degree of exercise; and

6th, The production of manure of the best quality.

We have no hesitation in expressing our opinion that the whole of these conditions are attained most fully by means of well-arranged and well-ventilated boxes. Stalls are to be preferred where the saving of litter is an object, and yards for the rearing of young cattle, which require more exercise than is suitable for fattening stock. These yards are now, however, in the most improved modern homesteads, wholly roofed over, and thus combine the good qualities of both yard and box.

CHAPTER XVII.

LIVE STOCK—SHEEP.

When Fitzherbert so long ago said, "Sheep is the most profitablest cattle that a man can have," he expressed an opinion in which agriculturists of the present day fully concur. But if this was true of the flocks of his time, how much more of the many admirable breeds which now cover the rich pastures, the grassy downs, and the heath-clad mountains of our country. Their flesh is in high estimation with all classes of the community, and constitutes at least one-half of all the butcher meat consumed by them. Their fleeces supply the raw material for one of our most flourishing manufactures. They furnish to the farmer an important source of revenue, and the readiest means of maintaining the fertility of his fields.

Section 1.—Breeds.

The distinct breeds and sub-varieties of sheep found in Great Britain are very numerous. We have no intention of describing them in detail, but shall confine our observations to those breeds which by common consent are the most valuable for their respective appropriate habitats. They may be fitly classed under three heads—viz., the heavy breeds of the plains, those adapted for downs and similar localities, and the mountain breeds.

1*st.—Heavy Breeds.*

Of the first class, the improved *Leicesters* are still the most important to the country. They are more widely diffused in the kingdom than any of their congeners. Although, from the altered taste of the community, their mutton is less esteemed than formerly, they still constitute the staple breed of the midland counties of England. Leicester rams are also more in demand than ever for crossing with other breeds. It is now about a century since this breed was produced by the genius and perseverence of Bakewell, in whose hands they attained a degree of excellence that has probably not yet been exceeded by the many who have cultivated them since his day. The characteristics of this breed are extreme docility, extraordinary aptitude to fatten, and the early age at which they come to maturity. The most marked feature in their structure is the smallness of their heads, and of their bones generally, as contrasted with their weight of carcase. They are clean in the jaws, with a full eye, thin ears, and placid countenance. Their backs are straight, broad, and flat, the ribs arched, the belly carried very light, so that they present nearly as straight a line below as above; the chest is wide, the skin very mellow, and covered with a beautiful fleece of long, soft wool, which weighs on the average from 6 to 7 lb. On good soils and under careful treatment these sheep are currently brought to weigh from 18 to 20 ℔ per quarter at 14 months old, at which age they are now usually slaughtered. At this age their flesh is tender and juicy; but when feeding is carried on till they are older and heavier, fat accumulates so unduly as to detract from the palatableness and market value of the mutton.

Lincolns.—These were at one time very large, ungainly animals, with an immense fleece of very long wool. By crossing them with the Leicesters the character of the breed has been entirely changed, and very greatly for the better. It is now, in fact, a sub-variety of the Leicester, with larger frame and heavier fleece than the pure breed. Their wool, however, retains its distinctive characteristics—viz., great length of staple, an unctuous feeling, and, in particular, a brightness or *lustre* which adds largely to its value. Sheep of this kind are reared in immense numbers on the wolds and heaths of Lincolnshire, and are sold when about a year old in the wool, and in very forward condition, to the graziers of the fens and marshes, who ultimately bring them to very great weights.

Cotswolds, sometimes called Glo'sters or New Oxfords, are also large and long-woolled sheep, with good figure and portly gait. Great improvement has been effected in this breed during the last 30 years, in consequence of which they are rising rapidly in public estimation. The qualities for which they are prized are their hardiness, docility, rapid growth, aptitude to fatten, and the great weight to which they attain. Their chief defect is that they yield mutton somewhat coarse in the grain and with an undue preponderance of fat. But in addition to their great merits as a pure breed they are especially valuable for the purpose of crossing with Downs and other short-woolled sheep. Of this we shall speak more particularly when we come to notice the *Cross-breeds.*

Teeswaters.—This breed, found formerly in the vale of the Tees, used to have the reputation of being one of the largest and heaviest of our native breeds. They had lighter fleeces than the old Lincolns, but greater aptitude to fatten. Like them, however, they have been so blended with Leicester blood as to have lost their former characteristics. As now met with, they constitute simply a sub-variety of the latter breed.

The *Kents* or *Romney Marsh Sheep*, are another distinct long-woolled breed which have much in common with the old Lincolns, although they never equalled them either in the weight or quality of their fleece. They too have been much modified by a large infusion of Leicester blood; but as their distinctive qualities fit them well for a bleak and humid habitat, there is now an aversion to risk these by further crossing. As they now exist they are a great improvement upon the old breed of the Kentish marshes; and this, in the first instance at least, was the result of crossing rather than selection.

2d.—*Down and Forest Breeds.*

The breeds peculiar to our chalky downs and other pastures of medium elevation next claim our notice.

Southdowns.—Not long after Robert Bakewell had begun, with admirable skill and perseverance, to bring to perfection his celebrated Leicesters, which, as we have seen, have either superseded or totally altered the character of all the heavy breeds of the country, another breeder, Mr John Ellman of Glynde, in Sussex, equal to Bakewell in judgment, perseverance, and zeal, and wholly devoid of his illiberal prejudice and narrow selfishness, addressed himself to the task of improving the native sheep of the downs, and succeeded in bringing them to as great perfection, with respect to early maturity and fattening power, as they are perhaps susceptible of. Like Bakewell, he early began the practice of letting out rams for hire. These were soon eagerly sought after, and the qualities of his improved flock being rapidly communicated to others, the whole race of down sheep has more or less become assimilated to their standard. These improved Southdowns have, in fact, been to all the old *forest* and other fine-woolled breeds what the Leicesters have been to their congeners. Many of them have entirely disappeared, and others only survive in those modifications of the improved Southdown type which are to be found in particular localities. These down sheep possess certain well-marked features which distinguish them from all other breeds. They have a close-set fleece of fine wool, weighing, when the animals are well fed, about 4 lb.; their faces and legs are of a dusky brown colour, their neck slightly arched, their limbs short, their carcase broad and compact, their offal light, and their buttocks very thick and square behind. They are less impatient of folding, and suffer less from a pasture being thickly stocked with them than any other breed. It is in connection with this breed that the practice of folding as a means of manuring the soil is so largely carried out in the chalk districts of England. It is well ascertained that the injury done to a flock by this practice exceeds the benefit conferred on the crops. Now that portable manures are so abundant, it is to be hoped that this pernicious practice of using sheep as mere muck machines will be everywhere abandoned.

These sheep are now usually classed as *Sussex Downs* and *Hampshire Downs*, the former being the most refined type of the class, both as regards wool and carcase, and the latter, as compared with them, having a heavier fleece, stronger bone, and somewhat coarser and larger frame.

The *Shropshire* sheep, while partaking of the general characteristics of the Southdown, is so much heavier both in fleece and carcase, and is altogether so much more robust an animal, that it now claims to be ranked as a separate breed. The qualities just referred to as distinguishing it from other downs seem, however, to be the result of selection rather than of crossing with other breeds, and thus the Shropshire sheep, while a pure down, is yet of so distinct a type from the high-bred "Southdown," that it is well entitled to be recognised as a distinct and very valuable breed, as has been done by the Royal Society, which now assigns it a separate class at its annual meetings. Shropshire rams are eagerly sought after, and many breeders of eminence in that county have now their annual sales of these animals.

These breeds are peculiarly adapted for all those parts of England where low grassy hills occur, interspersed with, or in proximity to, arable land. In such situations they are prolific, hardy, and easily fattened at an early age. It is to their peculiar adaptation for crossing with the long-woolled breeds that they are indebted for their recent and rapid extension to other districts.

Dorsets.—This breed has from time immemorial been naturalised in the county of Dorset and adjacent parts. They are a white-faced, horned breed, with fine wool, weighing about 4 ℔ per fleece. They are a hardy and docile race of sheep, of good size, and fair quality of mutton. But the property which distinguishes them from every other breed in Great Britain is the fecundity of the ewes, and their readiness to receive the male at an early season. They have even been known to yean twice in the same year. Being, in addition to this, excellent nurses, they have long been in use for rearing house lamb for the London market. For this purpose the rams are put to them early in June, so that the lambs are brought forth in October, and are ready for market by Christmas. But for this peculiarity, they would ere now have shared the fate of so many other native breeds, which have given place either to the Leicesters or Southdowns, according to the nature of the pastures. So long, however, as the rearing of early house lamb is found profitable, there is a sufficient inducement to preserve the Dorset breed in their purity, as they are unique in their property of early yeaning.

3d.—*Mountain Breeds.*

Cheviots.—As we approach and cross the Scottish border we find a range of hills covered with coarser herbage than the chalky downs of the south, and with a climate considerably more rigorous. Here the Southdown sheep have been tried with but indifferent success. This, however, is not to be regretted, seeing that the native Cheviot breed rivals them in most of their good qualities, and possesses in addition a hardihood equal to the necessities of the climate. This breed, besides occupying the grassy hills of the border counties, is now found in great force in the north and west Highlands of Scotland. In the counties of Sutherland and Caithness, where they were introduced by the late Sir John Sinclair, they have thriven amazingly, and in the hands of some spirited breeders have attained to as great perfection as in their native district. During the last 30 years this breed has undergone very great improvement in size, figure, weight of fleece, and aptitude to fatten. In proof of this, it is enough to mention that Cheviot wether lambs are now in the border counties brought to market when weaned, and are transferred to the low country graziers, by whom they are sent fat to the butcher at sixteen months old, weighing then from 16 to 18 ℔ per quarter. This is particularly the case in Cumberland, where Cheviot lambs are preferred to all other breeds by the low-country farmers, by whom they are managed with great skill and success. It is not at all unusual with them to realise an increase of from 20s. to 25s. per head on the purchase price of these lambs, after a twelvemonth's keep. This fact is peculiarly interesting from the proof which it affords of a hitherto unsuspected capacity in Cheviots, and probably in other upland breeds, to attain to a profitable degree of fatness and weight of carcase at almost as early an age as the lowland breeds when the same attention and liberal feeding is bestowed upon them. There is no breed equally well adapted for elevated pastures, consisting of the coarser grasses with a mixture of heath; but whenever, from the nature of the soil or greater elevation, the heaths unmistakably predominate, a still hardier race is to be preferred, viz.—

The *Blackfaced* or *Heath Breed.*—They are accordingly found on the mountainous parts of Yorkshire, Lancashire, Cumberland, and Westmoreland; over the whole of the Lammermuir range, the upper part of Lanarkshire, and generally over the Highlands of Scotland. Both male and female of this breed have horns, which in the former are very large and spirally twisted. The face and legs are black or specked with black, with an occasional tendency to this colour on the fleece; but there is nothing of the brown or russet colour which distinguishes the down breeds. The choicest flocks of these sheep

LEICESTER EWE

Bred by and the Property of Mr George Thomson, Haymount Roxburghshire are found in Lanarkshire and in the Lammermuirs, where considerable pains are now bestowed on their improvement. Their chief defects are coarseness of fleece and slowness of fattening until their growth is matured. In most flocks the wool, besides being open and coarse in the staple, is mixed with *kemps* or hairs, which detract from its value. Rams with this defect are now carefully avoided by the best breeders, who prefer those with black faces, a mealy mouth, a slight tuft of fine wool on the forehead, horns flat, not very large, and growing well out from the head, with a thickset fleece of long, wavy, white wool. Greater attention is now also being paid to their improvement in regard to fattening tendency; in which respect we do not despair of seeing them brought nearer to a par with other improved breeds. Whenever this is accomplished we shall possess in the breeds now enumerated, and their crosses, the means of converting the produce of our fertile plains, grassy downs, tough upland pastures, and heath-clad mountains, into wool and mutton of the best quality, and with the utmost economy of which the circumstances admit.

In the higher grounds of Cumberland, and also in Westmoreland, Lancashire, and parts of Yorkshire, two varieties of the heath breed of sheep are found, viz., Herdwicks and Lonks—which, with a general resemblance to the blackfaced Highland breed, differ from it in having a close-set fleece of fine soft wool. They are sometimes described by saying that they have "the fleece of a Cheviot on the carcase of a Highlander;" but the Herdwicks are so small, and both breeds are so inferior to the blackfaced in aptitude to fatten, that they are losing ground in their native districts, where the blackfaces are spreading rapidly, being in great repute for breeding crosses to long-woolled rams.

4*th.—Cross-Breeds.*

We have thus enumerated the most important of our pure breeds of sheep, but our list would be defective were we to omit those cross-breeds which are acquiring increased importance every day. With the extended cultivation of turnips and other green crops there has arisen an increased demand for sheep to consume them. Flockmasters in upland districts, stimulated by this demand, happily bethought them of putting rams of the improved low-country breeds to their Cheviot ewes, when it was discovered that the lambs produced from this cross, if taken to the low country as soon as weaned, could be fattened nearly as quickly, and brought to nearly as good weights, as the pure low-country breeds. The comparatively low prime cost of these cross-bred lambs is a farther recommendation to the grazier, who finds also that their mutton, partaking at once of the fatness of the one parent and of the juiciness, high flavour, and larger proportion of lean flesh of the other, is more generally acceptable to consumers than any other kind, and can always be sold at the best price of the day. The wool, moreover, of these crosses, being at once long and fine in the staple, is peculiarly adapted for the manufacture of a class of fabrics now much in demand, and brings in consequence the best price of any British-grown wool. The individual fleeces, from being close set in the pile, weigh nearly as much as those of the pure Leicesters. On all these accounts, therefore, these sheep of mixed blood have risen rapidly in public estimation, and are produced in ever-increasing numbers. This is accomplished in several ways. The occupiers of uplying grazings in some cases keep part of their ewe flock pure, and breed crosses from another part. They sell the whole of their cross-bred lambs, and get as many females from the other portion as keeps up the number of their breeding flock. This system of crossing cannot be pursued on the most elevated farms, as ewes bearing these heavier crossed lambs require better fare than when coupled with rams of their own race. The surplus ewe lambs from such high-lying grazings are an available source of supply to those of a lower range, and are eagerly sought after for this purpose. Others, however, take a bolder course. Selecting a few of the choicest pure Cheviot ewes which they can find, and putting these to a first-rate Leicester ram, they thus obtain a supply of rams of the first cross, and putting these to ewes, also of the first cross, manage in this way to have their entire flock *half-bred*, and to go on continuously with their own stock without advancing beyond a first cross. They, however, never keep rams from such crossed parentage, but always select them from the issue of parents each genuine of their respective races. We know several large farms on which flocks of crosses betwixt the Cheviot ewe and Leicester ram have been maintained in this way for many years with entire success; and one at least in which a similar cross with Southdown ewes has equally prospered. Many, however, prefer buying in females of this first cross, and coupling them again with pure Leicester rams. In one or other of these ways cross-bred flocks are increasing on every side. So much has the system spread in Berwickshire, that whereas, in our memory, pure Leicesters were the prevailing breed of the county, they are now confined to a few ram-breeding flocks. The cross-breed in best estimation in England is that betwixt the Cotswold and Southdown, which is in such high repute that it is virtually established as a separate breed under the name of Oxford Downs. In Scotland the cross betwixt the Leicester ram and Cheviot ewe is that which seems best adapted to the climate and other conditions of the country, and is that accordingly which is most resorted to on farms a portion of which is in tillage. On higher grounds a cross betwixt the Cheviot ram and blackfaced ewe is in good estimation, and has been extending considerably in recent years. This cross-breed seems to equal the pure blackfaced in hardiness, and is of considerably greater value both in fleece and carcase. This cross-breed is known by the name of *Halflangs.* As in the case of the Leicester-Cheviot ewes, flocks are maintained by using rams of the cross-breed.

Section 2.—Management of Lowland Sheep.

As the management of sheep is influenced mainly by the nature of the lands upon which they are kept, we shall first describe the practice of Lowland flockmasters, and afterwards that pursued on Highland sheep-walks.

On arable farms, where turnips are grown and a breeding stock of sheep regularly kept, it is usual to wean the lambs about the middle of July. When this has been done, the aged and faulty ewes are drafted out, and put upon good aftermath or other succulent food, that they may be got ready for market as soon as possible. In many districts it is the practice to take but three crops of lambs from each ewe. A third part of the breeding flock—viz., the four-year-old ewes—is thus drafted off every autumn, and their places supplied by the introduction of a corresponding number of the best of the ewe-lambs of the preceding year's crop. These cast or draft ewes are then sold to the occupiers of richer soils in populous districts, who keep them for another season to feed fat lambs. Such parties buy in a fresh stock of ewes every autumn, and, as they phrase it, "feed lamb and dam." In other cases the ewes are kept as long as their teeth continue sound, and after that they are fattened and sold to the butcher directly from the farm on which they have been reared. When the ewes that are retained for breeding stock have been thus overhauled, they are put to the worst pasture on the farm, and run rather thickly upon it. Attention is necessary, for some days after weaning, to see that none of them suffer from gorging of the udder. When it appears very turgid in any of them, they are caught and partially milked by hand; but usually the change to poorer pasturage, aided by their restlessness and bleating for want of their lambs, at once arrests the flow of milk. The time of admitting the ram is regulated by the purpose for which the flock is kept, and by the date at which fresh green food can be reckoned upon in spring. When the produce is to be disposed of as fat lambs, it is of course an object to have them early; but for a holding stock, to be reared and fattened at fourteen to sixteen months old, from 20th September to 20th October, according to the climate of the particular locality, is a usual time for admitting rams to ewes. A few weeks before this takes place the ewes are removed from bare pasture, and put on the freshest that the farm affords, or, better still, on rape; failing which one good feed of white turnips per diem is carted and spread on their pastures, or the ewes are folded for part of the day on growing turnips. The rams are turned in amongst them just when this better fare has begun to tell in their improving appearance, as it is found that in such circumstances they come in heat more rapidly, and with a greatly increased likelihood of conceiving twins. On level ground, and with moderate-sized enclosures, one ram suffices for sixty ewes; but it is bad economy to overtask the rams, and one to forty ewes is better practice. Sometimes a large lot of ewes are kept in one flock, and several rams, at the above proportion, turned among them promiscuously. It is better, however, when they can be placed in separate lots. The breasts of the rams are rubbed with ruddle, that the shepherd may know what they are about. Those who themselves breed rams, or others who hire in what they use at high prices, have recourse to a different plan for the purpose of getting more service from each male, and of knowing exactly when each ewe may be expected to lamb; and also of putting each ewe to the ram most suitable to her in point of size, figure, and quality of flesh and fleece. The rams in this case are kept in pens in a small enclosure. What is technically called a *teaser* is turned among the general flock of ewes, which, on being seen to be in heat, are brought up and put to the ram that is selected for them. They are then numbered, and a note kept of the date, or otherwise a common mark, varied for each successive week, is put on all as they come up. The more usual practice is to mark the breast of the ram with ruddle, as already described, for the first seventeen days that they are among the ewes—that being the time of the periodic recurrence of the heat—and then to use soot instead. When lambing-time draws near, the red-rumped ewes, or those that conceived from the first copulation, are brought into the fold, and the remainder after the lapse of the proper interval. If all goes on well, six weeks is long enough for the rams to remain with the flock. The ewes are then put to more moderate fare, taking care, however, not to pinch them, but to preserve the due medium betwixt fatness and poverty. Under the first-mentioned extreme there is great risk of losing both ewe and lamb at the time of parturition; and under the second, of the ewe shedding her wool, and being unable to nourish her lamb properly either before its birth or after. When there is a considerable breadth of grass-land, the *grit* or in-lamb ewes are run thinly upon it so long as the weather continues moderate. As the pasturage fails or winter weather sets in, they receive a daily feed of turnips or hay, or part of both. In districts where the four-course rotation is pursued, and wheat sown after seeds, there is a necessity for keeping the ewes wholly on turnips and chopped hay or straw. In this case they are made to follow the fattening sheep, and to eat up their scraps, an arrangement which is suitable for both lots. A recently-introduced practice is better still—namely, to feed the ewes at this season on a mixture of one part by measure of pulped turnips or mangel-wurzel to two of chopped straw, which is served out to them in troughs set down in their pastures. From the large quantity of straw which ewes are thus induced to eat, they can be allowed to take their fill of this mixture, and be kept in a satisfied and thriving state with a very moderate allowance of roots. As their time to lamb draws near, the mess should be made more nourishing by adding to it ground rape-cake, bean-meal, and bran, at the rate of from ¼th to ⅓d of a pound of each of these articles to each ewe daily.

The period of gestation in the ewe is twenty-one weeks. No lambs that are born more than twelve days short of this period survive. Before any lambs are expected to arrive a comfortable fold is provided, into which either the entire flock of ewes, or those that by their markings are known to lamb first, are brought every night. This fold, which may either be a permanent erection or fitted up annually for the occasion, is provided all round with separate pens or cribs of size enough to accommodate a single ewe with her lamb or pair. The pasture or turnip fold to which the flock is turned by day is also furnished with several temporary but well-sheltered cribs, for the reception of such ewes as lamb during the day. It is of especial consequence that ewes producing twins be at once consigned to a separate apartment, as, if left in the crowd, they frequently lose sight of one lamb, and may refuse to own it when restored to them, even after a very short separation. Some ewes will make a favourite of one lamb, and wholly repudiate the other, even when due care has been taken to keep them together from the first. In this case the favourite must either be separated from her or be muzzled with a piece of network, to prevent it from getting more than its share of the milk in the shepherd's absence. Indeed the maternal affection seems much dependent on the flow of milk, as ewes with a well-filled udder seldom trouble the shepherd by such capricious partialities. As soon as the lambs have got fairly afoot, their dams are turned with them into the most forward piece of seeds, or to rape, rye, winter-oats, or water-meadow, the great point being to have abundance of succulent green food for the ewes as soon as they lamb. Without this they cannot yield milk abundantly, and without plenty of milk it is impossible to have good lambs. It is sometimes necessary to aid a lamb that has a poor nurse with cow's milk. This is at best a poor alternative; but if it must be resorted to, it is only the milk of a farrow cow, or at least of one that has been calved six months, that is at all fit for this purpose. To give the milk of a recently-calved cow to a young lamb is usually equivalent to knocking it on the head. Ewe milk is poor in butter, but very rich in curd, which is known to be also in a measure the character of that of cows that have been long calved and are not again pregnant. We have found the Aberdeen yellow bullock turnip the best for pregnant and nursing ewes. Mangel-wurzel is much approved of by the flockmasters of the southern counties for the same purpose. It is of importance at this season to remove at once from the fold and pens all dead lambs, and filth of every kind, the presence of putrefying matter being most hurtful to the flock. Should a case of puerperal fever occur, the shepherd must scrupulously avoid touching the ewe so affected; or if he has done so, some one should take his accoucheur duties for a few days, as this deadly malady is highly contagious, and is often unconsciously communicated to numbers of the flock by the shepherd's hands. Unnecessary interference with ewes during parturition is much to be deprecated. When the presentation is all right, it is best to leave them as much as possible to their natural efforts. When a false presentation does occur, the shepherd must endeavour to rectify it by gently introducing his hand after first lubricating it with fresh lard or olive-oil. The less dogging or disturbance of any kind that ewes receive during pregnancy the less risk is there of unnatural presentations. As soon as lambs are brought forth the shepherd must give them suck. When they have once got a bellyful, and are protected from wet or excessive cold for two or three days, there is no fear of their taking harm from ordinary weather, provided only that the ewes have plenty of suitable food. Lambs are castrated, docked, and ear-marked, with least risk when about ten days old. Ewes with lambs must have good and clean pasturage throughout the summer. For this purpose they must either be run thinly among cattle or have two or more enclosures, one of which may always be getting clean and fresh for their reception as the other gets bare and soiled. We have not found any advantage in allowing lambs yeaned in March to run with their dams beyond 20th July. A clover eddish or other perfectly clean pasture is the most suitable for newly-weaned lambs. Such as abound in *tath*, as it is called in Scotland—that is, rank herbage growing above the droppings of sheep or other animals—are peculiarly noxious to them. Folding upon rape or vetches suits them admirably, so that fresh supplies are given regularly as required. Sheep, when folded on green rye or vetches, require a good deal of water, and will not thrive unless this is supplied to them.

All sheep are liable to be infested with certain vermin, especially "fags" or "kaids" (*Melophagus ovinus*) and lice. To rid them of these parasites various means are resorted to. Some farmers use mercurial ointment, which is applied by parting the wool, and then with the finger rubbing the ointment on the skin, in three or four longitudinal seams on each side, and a few shorter ones on the neck, belly, legs, &c. Those who use this salve dress their lambs with it immediately after shearing their ewes, and again just before putting them on turnips. More frequently the sheep are immersed, all but their heads, in a bath in which arsenic and other ingredients are dissolved. On being lifted out of the bath, the animal is laid on spars, over a shallow vessel so placed that the superfluous liquor, as it is wrung out of the fleece, flows back into the bath. If this is done when the ewes are newly shorn, the liquor goes farther than when the process is deferred until the lambs are larger and their wool longer. It is a good practice to souse the newly-shorn ewes, and indeed the whole flock at the same time, in a similar bath, so as to rid them all of vermin.[1]

As turnips constitute the staple winter fare of sheep, it is necessary to have a portion of these sown in time to be fit for use in September. Young sheep always show a reluctance to take to this very succulent food, and should therefore be put upon it so early in autumn that they may get thoroughly reconciled to it while the weather is yet temperate. Rape or cabbage suits admirably as transitionary food from grass to turnips. When this transference from summer to winter fare is well managed, they usually make rapid progress during October and November. Some farmers recommend giving the *hoggets*, as they are now called, a daily run off from the turnip-fold to a neighbouring pasture for the first few weeks after their being put to this diet. We have found it decidedly better to keep them steadily in the turnip-fold from the very first. When they are once taught to look for this daily enlargement, they become impatient for it, and do not settle quietly to their food. If possible, not more than 200 should be kept in one lot. The youngest and weakest sheep should also have a separate berth and more generous treatment. Turnips being a more watery food than sheep naturally feed upon, there is great advantage in giving them from the first, along with turnips, a liberal allowance of clover hay cut into half-inch chaff. When given in this form, in suitable troughs and in regular feeds, they will eat up the whole without waste, and be greatly the better for it. To economise the hay, equal parts of good oat straw may be cut up with it, and will be readily eaten by the flock. A liberal supply of this dry food corrects the injurious effects which are so often produced by feeding sheep on turnips alone, and at the same time lessens the consumption of the green food. We believe also that there is true economy in early beginning to give them a small daily allowance, say ¼ ℔ each, of cake or corn. This is more especially desirable when sheep are folded on poor soil. The extraneous food both supplies the lack of nutrition in the turnips and fertilises the soil for bearing succeeding crops. An immense improvement has been effected in the winter feeding of sheep by the introduction of machines for slicing turnips. Some careful farmers slice the whole of the turnips used by their fattening sheep, of whatever age; but usually the practice is restricted to hoggets, and only resorted to for them when their milk-teeth begin to fail. In the latter case the economy of the practice does not admit of debate. When Mr Pusey states the difference in value between hoggets that have had their turnips sliced and others that have not, at 8s. per head in favour of the former from this cause alone, we do not think that he over-estimates the benefit. Those who slice turnips for older sheep, and for hoggets also as soon as ever they have taken to them, are, we suspect, acting upon a sound principle, and their example is therefore likely to be generally followed. There is no doubt of this at least, that hoggets frequently lose part of the flesh which they had already gained from the slicing of the turnips being unduly delayed. By 1st December their first teeth, although not actually gone have become so inefficient that they require longer time and greater exertion to feed their fill than before; and this, concurring with shorter days and colder weather, operates much to their prejudice. When the slicing is begun, it is well to leave a portion of growing turnips in each day's fold, as there are always some timid sheep in a lot that never come freely to the troughs; and they serve, moreover, to occupy the lot during moonlight nights, and at other times when the troughs cannot be instantly replenished. As the sheep have access to both sides of the troughs, each will accommodate nearly as many as it is feet in length. There should therefore be provided at least as many foot-lengths of trough as there are sheep in the fold. The troughs should be perpendicular at their outer edges, as the sheep are less apt to scatter the sliced turnips on the ground with this form than when they slope outwards. It is expedient to have a separate set of similar troughs for the cake or grain and chopped fodder, which it is best to use mixed together.

As the season when frost and snow may be expected approaches it is necessary to provide in time for the flock having clean unfrozen turnips to eat in the hardest weather. To secure this, care must be taken to have always several weeks' supply put together in heaps and covered with earth to a sufficient thickness to exclude frost. The covering with earth is the only extra cost incurred from using this precaution, for if slicing the roots is practised at all, it necessarily implies that the roots must be pulled, trimmed, and thrown together, and this again should be done in such a way as to insure that the dung and urine of the sheep shall be equally distributed over the whole field. This is secured by throwing together the produce of 18 or 20 drills into small heaps, of about a ton each, in a straight row and at equal distances apart. For a time it will suffice to cover these heaps with a few of the turnip leaves and a spadeful of earth here and there to prevent the leaves from being blown off. This arrangement necessitates the regular moving of the troughs over the whole ground. As the heaps are stript of their covering special care must be taken to scatter the tops well about, otherwise there

[1] The mercurial and arsenical salves and washes commonly in use are believed often to have a hurtful effect on the health of the flocks to which they are applied, and have sometimes caused very serious losses. Having used Macdougall's dip (a preparation of carbolic acid) for many years, we can testify to its efficacy and safety.

will be corresponding rank spots in the grain crop that follows.

On light dry soils it is usually most profitable to consume the whole turnip crop where it grows by sheep, and to convert the straw of the farm into dung by store cattle kept in suitable yards, to which a daily allowance of rape or cotton cake is given, with wholesome water constantly at their command. But it may at times be more profitable to use young sheep instead of cattle for this purpose, and it is quite practicable to do so. In the winter of 1865–66, in consequence of the prevalence of rinderpest, we had recourse to this expedient with entire success. A lot of 200 hoggets was put into two contiguous yards, of a size which ordinarily had accommodated 15 cattle each; the hoggets were fed on hay cut into chaff, which was served to them in troughs so placed as to be protected from rain. Along with this chaff they received 2 ℔ each daily of mixed cakes and grain, and a constant supply of water. A covered passage by which the yards communicated was coated with quicklime, which was stirred up daily and added to twice a-week. Care was taken to drive the whole lot of sheep over this limed passage once every day, with liberty to them to pass and repass as much as they liked at all times. The yards were kept clean by being thinly covered over with fresh straw every day. By this means, and by an occasional paring of the hoofs when seen to be necessary, their feet were kept perfectly sound. In other respects they throve well, and the death-rate was unusually small.

To clear the ground in time for the succeeding grain crop a portion of the turnip crop is usually stored on some piece of grass or fallow, where the flock is folded until the pastures are ready to receive them. As the date of this varies exceedingly, it is well to lay in turnips for a late season, and rather to have some to spare than to be obliged to stock the pastures prematurely. If corn or cake has been given in the turnip field, it must be continued in the pasture. Hoggets that have been well managed will be ready for market as soon as they can be shorn, and may not require grass at all. They usually, however, grow very rapidly on the first flush of clovers and sown grasses, especially when aided by cake or corn. When the soil is of poor quality, it is expedient to continue the use of such extra food during summer. The best sheep are generally sent to market first, and the others as they attain to a proper degree of fatness. Store sheep or cattle are then purchased to occupy their places until the next crop of lambs is weaned.

Lowland flocks are for the most part shorn in May, although many fat sheep are sent to market out of their wool at a much earlier date. Indeed railway transit has made it practicable to forward newly-shorn sheep to market so quickly that there is now little risk of their suffering from exposure to bad weather, and accordingly few fat sheep are now sent to market *rough* after the 1st of April. But in the case of nursing ewes and store sheep of all kinds it is highly inexpedient to deprive them of their fleeces until summer weather has fairly set in. Accordingly, the latter half of May and the first half of June are, in average seasons, the best shearing time, beginning with the hoggets and ending with the ewes.

This practice of shearing a portion of the flock so early as April renders it necessary to make a change on that mode of sheep-washing so well described by the author of the *Seasons*. Artificial washing-pools are accordingly now provided by damming up some small stream of clean water. The bottom is paved and three sides faced with bricks set in cement, with a sluice to let off the foul water when necessary. The most accessible side of the pool is formed of strong planks, securely jointed, behind which the men engaged in washing the sheep stand dry, and accomplish their work much in the way that a washerwoman does hers at her tub. A sloping passage at the upper end of the pool allows the sheep to walk out, one by one, as they are washed. One such pool is often made to accommodate several neighbouring farms.

Section 3.—Management of Mountain Sheep.

We have already taken notice of the extent to which Cheviot sheep have of late years been introduced in the Highlands of Scotland. Many of the immense grazings there are rented by farmers resident in the south of Scotland, who only visit their Highland farms from time to time, and intrust the management of their flocks and shepherds, which rival in numbers those of the ancient patriarchs, to an overseer, whose duty it is to be constantly on the grounds, to attend in all respects to the interests of his employer, see his orders carried into effect, and give him stated information of how it fares with his charge.

The following pertinent remarks we quote from an extensive and experienced Highland sheep-farmer:—

"The management of flocks in the Highlands is much the same as on high and exposed farms in the higher districts of Roxburghshire, Dumfriesshire, and Selkirkshire, as regards the ewe hirsels; the ewe lambs either not being weaned, or that only for eight or ten days, so that they may continue to follow their mothers. The wether lambs are sent to the wether ground about the beginning of August, and herded on the part of it considered most adapted for their keep till about the middle of October, when they are sent to turnips mostly in Ross-shire, where they remain till the middle of March or beginning of April. This is one of the heaviest items of expense in Highland farming, amounting to fully 4s. per head; and thus, upon a farm equally stocked with ewes and wethers, adds just about one-third to the rental of the farm. On the return of the wether hogs they are put to particular parts of the wether ground, at large amongst the other ages of wether stock, where they remain until drawn out when three years old at the usual season to send to market; with this exception, that the year following (when they are dinmonts), the smallest of them, those that are not considered capable of wintering at home, say to the extent of two or three to the score, are again drawn out and sent with the hogs to turnips.

"Mr Sellar, in his Report of the County of Sutherland, gives a very minute and detailed account of the mode of management as practised on his farms. This, however, does not apply to extensive West Highland farms, which have no arable farms attached, no fields to bring in the diseased or falling-off part of the stock to, nor is it ever practicable to shift any part of the stock to different parts of the farm from that on which they have been reared."

Sheep Farming on the hills drained by the Tweed.

Until quite a recent date the grassy hills enclosing the upper valley of the Tweed and its numerous tributaries were stocked almost entirely with Cheviot sheep, and the highest and most heathery portions of the Lammermuir hills with the blackfaced breed. Since about the year 1850, under the stimulus of a growing demand and rapidly advancing price for cross-bred lambs, a great change of practice has been going steadily on. Formerly, on such hill-country farms, cultivation of the soil was restricted to a very small scale indeed, but latterly it has been extending up the valleys and hill-sides at a rapid rate. Large areas of rough natural pasture are yearly being converted into fields, which are well enclosed by substantial stone walls, and by draining, liming, and the liberal application of portable manures, are made to produce luxuriant crops of turnips, oats, and the cultivated clovers and grasses. As this process of reclamation goes on, *half-bred sheep* (Leicester-Cheviots) are substituted for pure Cheviots, the lambs of this cross breed being at weaning-time worth from 10s. to 15s. more per head than Cheviots, their fleeces heavier by 2 ℔ each as well as more valuable per ℔, and the draft ewes also more valuable in about the same proportion as the lambs. These half-bred sheep must be kept almost exclusively on the reclaimed lands, which, however, will keep about double the number of this more valuable breed of sheep than they did of the less valuable when in their natural unreclaimed state. When the lowest-lying and kindliest soils of such farms have thus been improved and devoted to the keeping of half-bred sheep, the higher and poorer parts are often unfit for keeping Cheviot sheep, and are stocked with the hardier blackfaced breed. Cheviots are in consequence rather at a discount at present as compared with a period still recent.

The general management of these hill-country half-bred flocks does not differ materially from those of the plains. They require generous feeding, and being prolific and good nurses, they pay well for it. The oats grown on such farms are disposed of most profitably when consumed by the flock.

We begin our description of the management of strictly hill flocks with autumn, and assume that the yearly cast of lambs and aged ewes has been disposed of, and only as many of the ewe lambs retained as are required to keep up the breeding stock. A former practice was to keep these ewe lambs or hoggets by themselves on the best portions of the respective walks, or *rakes* as they are called on the Borders. Now, however, they are kept apart from their dams only as long (eight or ten days) as suffices to let the milk dry up; whereupon they are returned to the flock or *hirsel* to which they belong, and at once associate again each with its own dam. The hoggets, under the guidance of the ewes, are thus led about over the ground, according to varying seasons, and under the promptings of an instinct which far surpasses the skill and care of the best shepherd. The latter, indeed, restricts his interference chiefly to keeping his flock upon their own beat, and allows them to distribute themselves over it according to their own choice. When thus left to themselves each little squad usually selects its own ground, and may be found, the same individuals about the same neighbourhood day after day. This plan of grazing the hoggets and ewes together has been attended with the best results. There are far fewer deaths among the former than when kept separate, and being from the first used to the pasturage and acquainted with the ground, they get inured to its peculiarities, and grow up a healthy and shifty stock, more easily managed and better able to cope with trying seasons than if nursed elsewhere, and brought on to the ground at a more advanced age. Each hogget and its dam may be seen in couples all through the winter and spring, and with the return of summer it is a pretty sight to see these family groups grown into triplets by the addition to each of a little lamb.

As the autumn advances, the flockmaster makes his preparations for smearing or bathing. The smearing material is a salve composed of tar and butter, which is prepared in the following manner:—Six gallons of Archangel tar and 50 ℔ of grease-butter are thoroughly incorporated, and as much milk added as makes the salve work freely. This quantity suffices for 100 sheep. This salve destroys vermin, and by matting the fleece is supposed to add to the comfort and healthiness of the sheep. It adds considerably to the weight of the fleece, but imparts to it an irremediable stain, which detracts seriously from its value per ℔. A white salve introduced by Mr Ballantyne of Holylee is now in repute on the borders. It is prepared as follows:—30 ℔ butter, 14 ℔ rough turpentine, and 3 ℔ soft soap are melted and mingled in a large pot; 2 ℔ soda and ½ ℔ arsenic are then dissolved in a gallon of boiling water, and this, along with 12 gallons more of cold water, is intimately mixed with the other ingredients, and yields enough for dressing 100 sheep at the rate of a quart to each. Some persons, believing the arsenic an unsafe application, substitute for it half-a-gallon of tobacco juice. Instead of the rough turpentine, some also use half-a-gill of spirit of tar for each sheep; this ingredient being mixed in each quart-potful at the time of application.

In applying these salves, the sheep are brought to the homestead in daily detachments, according to the number of men employed, each man getting over about sixty in a day. A sheep being caught and laid upon a stool, the wool is parted in lines running from head to tail, and the tar salve spread upon the skin by taking a little upon the fingers and drawing them along. In using the white salve each shepherd has a boy assistant who pours the liquid salve from a tin pot with a spout, while he holds the wool apart. This white salve destroys vermin, and is believed to nourish the wool and to promote its growth. Of late years the practice of dipping has largely been substituted for salving or pouring. It is practised as already described in the case of low-country flocks, save only that with large flocks it is expedient to have it performed at some central and otherwise convenient part of the grounds. Instead of a movable tub and dripping board of wood, it is better to have a fixed one built of concrete, or bricks set in cement, with a paved dripping pen large enough to hold 50 sheep in each of its two divisions. The other requisites are a boiler to supply hot water for dissolving the dipping stuff, a pipe to convey cold water to the bath, and a waste pipe to empty it for cleansing. This salving or dipping must all be accomplished before the 20th November, about which time the rams are admitted to the flock. Before this is done another preliminary is required. As the ewe hoggets graze with the flock, it is necessary to guard them from receiving the male, for which purpose a piece of cloth is sewed firmly over their tails, and remains until the rams are withdrawn. This is called *breeking* them. On open hilly grounds about forty ewes are sufficient for each ram. To insure the vigour and good quality of the flock, it is necessary to have a frequent change of blood. To secure this by purchasing the whole rams required would be very costly, and therefore each flockmaster endeavours to rear a home supply. For this purpose he purchases every autumn, often at a high price, one or two choice rams from some flock of known excellence, and to these he puts a lot of his best ewes, carefully selected from his whole flock. These are kept in an enclosed field until the rutting season is over, and after receiving a distinctive mark are then returned to their respective hirsels. From the progeny of these selected ewes a sufficient number of the best male lambs is reserved to keep up the breeding stock of the farm. The rams are withdrawn from the flock about 1st January, and are then kept in an enclosed field, where they receive a daily feed of turnips.

Except in heavy falls of snow and intense frosts, the flocks subsist during the entire season on the natural produce of their pastures. It is necessary, however, to be provided for such emergencies both as regards food and shelter. For this purpose each shepherd has at suitable parts of his beat several *stells* or artificial shelters, such as are described at p. 402, and beside each of them a stack of hay from which to fodder the flock when required. So long as the sheep can get at heather or rushes by scraping away the snow with their feet they will not touch the hay, but when the whole surface gets buried and bound up, they are fain to take to it. The hay is laid out in handfuls over the snow, twice a day, if need be. The hay should, however, be administered with caution, and never to a greater extent than is absolutely necessary. Whenever there is a lull in the storm, the shepherd should use his utmost endeavour to move the flock out from their shelter to the nearest piece of rough heather or ground from which the wind has drifted off the snow, and where the sheep can by scraping with their feet get at their natural food. This should be done not merely to economise hay, but because it is found that sheep invariably come through the hardships of winter in better condition when thus encouraged to shift as much as possible for themselves, than when fed to the full on hay, and allowed to keep to their shelter all the day.

Much vigilance, promptitude, and courage, are required on the part of shepherds in these wild and stormy districts in getting their flocks into places of safety on the breaking out of sudden snow-storms, and tending them skilfully there.

In spring advantage is taken of any dry weather that occurs to set fire to the roughest portions of the old heather and other coarse herbage, and this being thus cleared off, a fresh young growth comes up, which yields a sweeter pasture to the flocks for several succeeding years. Careful shepherds are at pains to manage the muir-burning so as to remove the dry effete herbage in long narrow strips, and thus to secure a regular intermixture of old and young heath.

The lambing season is one of much anxiety to the master; and to his shepherds and their faithful sagacious dogs it is one of incessant toil. They must be a-foot from "dawn till dewy eve," visiting every part of their wide range several times a-day, to see that all is right, and to give assistance when required. The ewes of these hardy mountain breeds seldom require man's assistance in the act of parturition, but still cross presentations and difficult cases occur even with them. Deaths occur also among the newly-dropt lambs, in which case the dam is taken to the nearest stell, and a twin-lamb (of which there are usually enough to serve this purpose) put in the dead one's place. The dead lamb's skin is stript off, and wrapt about the living one, which is then shut up beside the dam in a small crib or *parik*, by which means she is usually induced in a few hours (and always the sooner the more milk she has) to adopt the supposititious lamb. As the lambing season draws to a close, each shepherd collects the unlambed ewes of his flock into an inclosure near his cottage, and examines them one by one to ascertain which are pregnant. To the barren ones he affixes a particular mark, and at once turns them again to the hill, but the others are retained close at hand until they lamb, by which means he can attend to them closely with comparatively little labour. The lambs are castrated and docked at from 10 to 20 days old. For this and for all sorting and drafting purposes an ample fold and suit of pens, formed of stout post and rail, are provided on some dry knoll convenient for each main division of the flock. To this the flock is gently gathered, and penned off in successive lots of 10 or 12, taking care that each lamb has its own dam with it before it is penned, and to do this with as little dogging and running as possible. The male lambs of the pure blackfaced breed, when designed to be kept as wethers, are not castrated until they are eight or ten weeks old, partly because when this is done sooner their horns have a tendency to get so crumpled as to grow into their eyes, and partly because a bold horn is thought to improve the appearance of an aged wether.

On these elevated sheep-walks shearing does not take place until July. It cannot, in fact, be performed until the young wool has begun to grow or *rise*, and so admit of the shears working freely betwixt the skin and the old matted fleece. The sheep are previously washed by causing them to swim repeatedly across a pool with a gentle current flowing through it. They are made to plunge in from a bank raised, either naturally or artificially, several feet above the surface of the water. This sousing and swimming in pure water cleanses the fleece far more effectually than could be supposed by persons accustomed only to the mode pursued in arable districts. Shearing takes place three or four days after washing, and in the interim much vigilance is required on the part of the shepherd to prevent the sheep from rubbing themselves under banks of moss or earth, and so undoing the washing. In the case of blackfaced flocks washing is now not unfrequently altogether dispensed with, because the greater weight of unwashed wool more than counterbalances the difference in price betwixt washed and unwashed fleeces. Each man usually shears about 60 sheep a-day. It is neither practicable nor expedient to shear these mountain sheep so closely as the fat denizens of lowland pastures. For this operation each shearer is provided with a low-legged sparred stool, having a seat at one end, or with a bench built of green turf. These are arranged in a row close in front of a pen, in which the unshorn sheep are placed. The shearers being seated, each astride his stool or bench, with their backs to the pen, a man in it catches and hands over a sheep to each of them. The sheep is first laid on its back upon the stool, and the wool shorn from the under parts, after which its legs are bound together with a soft woollen cord, and the fleece removed, first from the one side and then from the other, by a succession of cuts running from head to tail. The fleeces are thrown upon a cloth and immediately carried to the wool-room, where, after being freed from clots, they are neatly wrapped up and stored away. Before the shorn sheep are released each receives a mark or *buist* by dipping the owner's cypher in melted pitch, and stamping it upon the skin of the animal. To discriminate different ages and hirsels, these marks vary in themselves or are affixed to different parts of the sheep. Once or twice a year all stray sheep found upon the farms of a well-defined district are brought to a fixed rendezvous, where their marks are examined by the assembled shepherds, and each is restored to its proper owner.

Weaning takes place in August or early in September. A sufficient number of the best ewe lambs of the pure breeds are selected for maintaining the flock, and are treated in the way already noticed. With this exception, the whole of the lambs are sold either to low-country graziers or as fat lambs to the butcher. The wether lambs usually go to the former, and the ewe lambs of the cross betwixt blackfaced ewes and Leicester rams to the latter. These ewes being excellent nurses, make their lambs very fat in favourable seasons, in which case they are worth more to kill as lambs than to rear. Immediately after the weaning, the ewes which have attained mature age are disposed of, generally to low-country graziers, who keep them for another year, and fatten lamb and dam. To facilitate the culling out of these full-aged ewes, each successive crop of ewe lambs receives a distinctive earmark, by which all of any one age in the flock can be at once recognised.

Section 4.—Wool.

Wool is such an important part of the produce of our flocks that it seems proper to offer a few remarks upon it before leaving this subject, although it will fall to be considered under its proper heading. We here insert with much pleasure the following communication received from the late John Barff, Esq., of Wakefield :—

"I willingly give you a reply to your various inquiries regarding wool, as far as I am able. As to the kinds grown in the various counties of the United Kingdom, this I cannot fully answer, as there are some counties' wools which have not come much under my inspection ; but generally I may remark that wherever the turnip can be cultivated and has been introduced, the Leicester, Lincolnshire, Cotswold, and the half-breds from Down and Cheviot, are to be found ; and in the same counties, in several instances, you have several kinds, if we except Lincolnshire and Leicestershire, which have entirely the long-wool sheep. The great bulk also of York, Warwick, Oxford, Cambridge, Gloucester, Northampton, and Nottingham shires, have this description of sheep, but they have also Downs and half-breds. Kent has its own sheep, called Kents; the wool being much finer than the real long-wool sheep, running in quality and weight of fleece between the latter and the Down, something like your half-breds from Cheviot ewes by Leicester rams. They have somewhat of a similar sheep in Devon, Cornwall, Hereford, and Shropshire, but the quality in the two former counties scarcely so fine as the two latter, or the Kent wools. Norfolk has the original Down and the half-bred; Surrey, Suffolk, Essex, Sussex, and Hampshire are nearly all Down wools, though in these counties, upon some of their best lands, where they can cultivate the turnip, the half-bred are being introduced; and I need scarcely say to you, the Leicester sheep, as well as half-breds and Cheviots, are to be found in Durham, Northumberland, Berwickshire, Roxburghshire, Lothians, and other parts of Scotland where the turnip is cultivated; and in those parts where it is not, and on the hills, the Cheviot and blackfaced prevail. The blackfaced are used for low padding cloths, carpets, and horse-rugs. The Down wools were formerly all used for cloths and flannels; but now, from the improvement in worsted machinery, one-third is used for worsted yarns and goods; and as the portion suitable for combing purposes is more valuable for this purpose than for cloths or flannels, the grower aims at getting it as deep-stapled as possible; and this has led to a great increase in the weight of the fleece, but at the same time a deterioration in the quality. The Leicester, Lincolnshire, and half-bred, and Cotswolds, as well as the Kents and Devons, are entirely used for worsted yarns and goods; and a very small portion of the wools imported come in competition with them. The nearest approach is a little imported from Holland and Denmark; but they partake more of your cross from a blackfaced ewe by a Leicester ram. The Irish wools are either the long-woolled sheep similar to the Leicester, the mountain sheep similar to your Cheviot, or the small Welsh sheep. The Irish wools are generally open-haired, and have not the richness of the Leicester or our English, and are not so much esteemed or valuable as English wool of apparently the same quality by ½d. to 1d. per lb. Richness of handle is now very desirable, as there is a demand for what are called *glossy* yarns, which wools fed on pasture or good new seeds only can produce, and which cannot be obtained from the wools grown on chalk or hard lands, such as our midland counties—viz., Oxford, Bedford, and Northampton—generally produce.

"In every fleece of wool there are two or three qualities—not more than two or three in the blackfaced, four or five in the long-woolled sheep, five or six in the half-bred, and seven or eight in a Down fleece; and I may say every fleece undergoes this sorting or separation before being put into any process of manufacture. Of course the more there is of the best quality in any fleece the more desirable and valuable the fleece is; in blackfaced, to be free from dead hair or kemps; and we find in all the other wools that the more close the staple and *purly* the wool, the more it yields of the finer qualities, whilst the open-haired makes more of the lower quality. The breeder should therefore, in selecting his tups with a view to good wool, choose them with a close purly staple. A great deal of the excellence, however, of wool depends upon the nature of the soil on which the sheep are fed. Upon the chalk and sandy hard lands we always find the worst qualities of wool of its kind, whilst the best comes from the rich good lands, where there is plenty of old grass or seeds. Thus the wools of Roxburghshire, as a general rule, are better than Berwickshire or Lothian; Leicester, Lincolnshire, Nottingham, and Warwickshire, superior to Oxford, Cambridge, Bedford, or Northampton; and in Downs, Sussex and Surrey, better than Essex and Norfolk, from their downs being more grassy and the land better. The principal quality required in wool is a rich soft handle, as such is always found to improve in every process it is put through in the various stages of its manufacture, whilst the wools grown on chalk or hard lands, and which have a hard bristly handle, get coarser as they progress in the manufacture.

"With regard to the salves or baths used for destroying vermin, we do not know what kinds are used in the different localities, but of those used with you we dislike the spirit of tar and tobacco. Wilson of Coldstream's dip appears to answer, and one called Ballantyne's, used in Selkirkshire; but in all these a great deal depends upon their being properly attended to, and being put on at the proper season. If put on in the autumn, we don't perceive that they have been used, and whenever we have to make a complaint on this head, we find it arises from the baths having been used in spring."

CHAPTER XVIII.

LIVE STOCK—GOATS, &c.

Section 1.—*Goats.*

Goats never occupied an important place among the domesticated animals of the British Islands, and, with the exception of Ireland, their numbers have been constantly diminishing. By the statistical returns it appears that in 1871 there were 232,892 goats in Ireland, which in 1872 had increased to 242,310. The value of goat's milk, as a source of household economy, is much greater than is usually supposed. This is so well shown by Cuthbert W. Johnston, Esq., in an article in the *Farmers' Magazine*, that we shall quote from it at some length.

"The comfort derived by the inmates of a cottage from a regular supply of new milk need hardly be dwelt upon. Every cottager's wife over her tea, every poor parent of a family of children fed almost entirely on a vegetable diet, will agree with me that it is above all things desirable to be able to have new milk as a variation to their daily food of bread and garden vegetables. The inhabitant of towns and of suburban districts, we all know, is at the mercy of the milk dealer; the milk he procures is rarely of the best quality, and under the most favourable circumstances he receives it with suspicion, and his family consume it with sundry misgivings as to its wholesomeness.

"Having personally experienced these difficulties, and having about three years since commenced the attempt to supply my family with goat's milk, and as our experience is cheering, I desire in this paper to advocate the claims of the milch goat to the attention of the cottager, and the other dwellers in the suburban and rural districts.

"Few persons are perhaps aware of the gentleness and playfulness of the female goat—how very cleanly are its habits, how readily it accommodates itself to any situation in which it is placed. Confined in an outhouse, turned on to a common or into a yard, tethered on a grass plat, it seems equally content. I have found it readily accommodate itself to the tethering system, fastened by a leathern collar, rope, and iron swivel, secured by a staple to a heavy log of wood. The log is the best (and this with a smooth even surface at the bottom), because it can be readily moved about from one part of the grass plat to another. The goat, too, uses the log as a resting-place in damp weather. The goat should be furnished with a dry sleeping-place, and this, in case of its inhabiting open yards, can be readily furnished; anything that will serve for a dry dog-kennel will be comfortable enough for a goat.

"The milk of the goat is only distinguishable from that of the cow by its superior richness, approaching, in fact, the thin cream of cow's milk in quality. The cream of goat's milk, it is true, separates from the milk with great tardiness, and never so completely as in the case of cow's milk. This, however, is of little consequence, since the superior richness of goat's milk renders the use of its cream almost needless. The comparative analysis of milk of the cow and goat will show my readers how much richer the latter is than that of the former; 100 parts of each, according to M. Regnault, gave on an average—

	Cow.	Goat.
Water	84·7	82·6
Butter	4·0	4·5
Sugar of milk and soluble salts	5·0	4·5
Caseine (cheese), albumen, and insoluble salts,	3·6	9·0

So that, while the milk of the cow yields 12·6 per cent. of solid matters, that of the goat produces 17 per cent., goat's milk yielding rather more butter, rather less sugar of milk, but considerably more caseine (cheese) than that of the cow.

"It must not be supposed that the *taste* of the milk of the goat differs in any degree from that of the cow; it is, if anything, sweeter, but it is quite devoid of any taste which might very reasonably be supposed to be derivable from the high-flavoured shrubs and herbs upon which the animal delights to browse.

"The amount of the milk yielded by the goat varies from two quarts to one quart per day; it is greatest soon after kidding time, and this gradually decreases to about a pint per day, a quantity which will continue for twelve months. This is not a large supply, it is true; but still it is one which is available for many very useful purposes; and be it remembered that when mixed with more than its own bulk of lukewarm water, it is then in every respect superior to the milk supplied by the London dairymen.

"In regard to the best variety of goat to be kept, I would recommend the smooth-haired kind, which are quite devoid of beards or long hair. In this opinion I am confirmed by an experienced correspondent, Mr W. H. Place of Hound House, near Guildford, who remarked, in a recent obliging communication—'I found that the short-haired goats with very little beards were the best milkers; but from these I seldom had more than four pints a-day at the best (I should say three pints were the average), and this quantity decreases as the time for kidding approaches (the goat carries her young 21 to 22 weeks). They should not be fed too well near the time of kidding, or you will lose the kids. In winter I gave them hay, together with mangel-wurzel, globe and Swedish turnips, carrots, and sometimes a few oats, and these kept up their milk as well as anything, but of course it was most abundant when they could get fresh grass. The milk I always found excellent, but I never had a sufficient quantity to induce me to attempt making butter except once, as an experiment: my cook then made a little, which was easily done in a little box-churn; the butter proved very good. I found the flesh of the kids very tender and delicate.

"I can add little to Mr Place's information as to their food; mine have generally fed out of the same rack as a Shetland pony, with whom they are on excellent terms. The pony throughout the summer is soiled with cut grass, and I notice that the goats pick out the sorrel, sow thistle, and all those weeds which the pony rejects.

"In the garden (if they are, by any chance, allowed to browse), I notice that they select the rose-trees, common laurels, arbutus, laurestinas, and the laburnum. Of culinary vegetables they prefer cabbages and lettuces; they also bite pieces out of the tubers of the potato. They carefully pick up the leaves, whether green or autumnal, of timber trees; of these they prefer those of the oak and elm, and delight in acorns and oak-apples. We are accustomed to collect and store the acorns for them against winter; spreading the acorns thinly on a dry floor, to avoid the mouldiness which follows the sweating of acorns laid in a heap. As I have before remarked, none of these astringent substances affect the taste of their milk; and I may here observe that, with ordinary gentleness, there is no more difficulty, if so much, in milking a goat than a cow.

"The he-goat engenders at a year old. The she-goat can produce when seven months old. She generally yeans two kids. The manure of the goat is perhaps the most powerful of all our domestic animals.

"Such are the chief facts which I have deemed likely to be useful in inducing the extended keeping of the milch goat. It is an animal that, I feel well assured, may be kept with equal advantage by the cottager and the dwellers in larger houses. It is useless to compare it with the cow, or to suppose that the goat can supplant it in situations where the cow can be readily kept; but in the absence of pastures, and in places where there is too little food for cows, I feel well convinced that, with ordinary care and attention, and a moderate firmness in overcoming the prejudices of those unaccustomed to the goat (and unless these are found in the owner, live stock never are profitable), the value and the comfort of a milch goat are much greater than is commonly known.

"The waste produce of a garden is exceedingly useful in the keep of a goat. By them almost every refuse weed, all the cuttings and clearings which are wheeled into the rubbish-yard, are carefully picked over and consumed. To them the trimmings of laurels and other evergreens, pea-haulm, and cabbage stalks, &c., are all grateful variations of their food. In winter a little sainfoin, hay, or a few oats, keeps them in excellent condition. In summer, the mowings of a small grass-plot, watered with either common or sewage water, will, with the aid of the refuse garden produce, keep a goat from the end of April until October."

Section 2.—Hogs.

Although occupying a less prominent place in the estimation of the farmer than the ox and sheep, the hog is nevertheless an animal of great value. He is easily reared, comes rapidly to maturity, is not very nice as to food, consuming offal of all kinds, and yields a larger amount of flesh in proportion to his live weight and to the food which he has consumed, than any other of our domesticated animals whose flesh is used for food. To the peasantry he is invaluable, enabling the labouring man to turn the scraps even from his scanty kitchen, and from his garden or allotment, to the best account. On such fare, aided by a little barley or pollard, he can fatten a good pig, and supply his family with wholesome animal food at the cheapest possible rate.

The breeds of swine in Great Britain are numerous, and so exceedingly blended that it is often impossible to discriminate or classify them properly. The original breeds of the country seem to be two, viz., "*The old English Hog*," tall, gaunt, very long in the body, with pendent ears and a thick covering of bristles. The representatives of this old breed are found chiefly in the western counties of England, especially in Lancashire, Yorkshire, and Cheshire, where hogs of immense size are still reared, but greatly improved as compared with their ancestry. Their bones are smaller, their hair finer and thinner set, their skin thinner and with a pink tint, the ears still pendulous but much thinner, the carcase much thicker, and their propensity to fatten greatly increased. This large breed is exceedingly prolific, and the sows are excellent nurses, it being quite common for them to farrow and rear from 12 to 18 pigs at each litter. They are somewhat tardy in arriving at maturity, and do not fatten readily until that is the case. After sixteen months old they, however, lay on flesh very rapidly, grow to very great weights, and produce hams of excellent quality, with a large proportion of lean flesh in them. The *Berkshire* and *Hampshire hog* seems originally to have been from the same stock, but by some early cross acquired the thicker carcase, prick-ears, shorter limbs, and earlier maturity of growth, by which they are characterised. The other native breed is found in the *Highlands and Islands of Scotland*. They are very small, of a dusky brown colour, with coarse bristles along the spine, and prick-ears. They are exceedingly hardy, and subsist on the poorest fare, being often left to range about without shelter, and support themselves as they best can on the roots of plants, shell-fish, seaweed, and dead fish cast up by the tide.

The improved breeds now so abundant have been obtained by crossing these old races with foreign hogs, and chiefly with the *Chinese* and *Neapolitan*. Our modern *white breeds*, with prick-ears, short limbs, fine bone, delicate white flesh, and remarkable propensity to fatten at an early age, are indebted for these qualities to the Chinese stocks. The improved *black breeds*, of which the Essex may be selected as the type, and which possess the qualities just enumerated in even a greater degree, are a cross from the Neapolitan. They are characterised by their very small muzzle, fine bone, black colour, and soft skin nearly destitute of hair. They can be brought to profitable maturity at from eight to twelve months old, the white breeds at from twelve to sixteen months. Both kinds are peculiarly suitable for producing small pork to be used fresh, or for pickling. The flesh of these smaller breeds produces, however, excellent bacon when used in that manner, and at less cost than that of the larger breeds, for this reason, that it is only from the flesh of a hog that has reached maturity that bacon of the first quality can be produced; and as these have reached that point at an age when the others are but ready for beginning the fattening process, it follows that the carcase of the former, in a state fit for curing, is produced at less cost than that of the latter. Sows of the Neapolitan breed and its crosses are better mothers and nurses than the Chinese. Both kinds require peculiar care to prevent the pregnant sow from becoming hurtfully fat. Unless kept on poor and scanty fare they inevitably become useless for the purpose of breeding. The Berkshire hog combines the good qualities of the larger and smaller breeds already referred to, so happily, that he deservedly enjoys the reputation of being as profitable a sort for the farmer as can be found. With proper treatment he arrives at maturity at about sixteen months old, yields a good weight of carcase for the food which he has consumed, and his flesh is well adapted for being used either as fresh meat, pickled pork, or bacon, according to the age at which he is slaughtered. A very profitable hog is also obtained by coupling sows of the larger breeds with males of some of the smaller races.

It too frequently happens that less care is bestowed on the breeding of pigs than of the other domesticated animals.

From the early age at which they begin to breed there is need for constant change of the male, to prevent the intermingling of blood too near akin. These animals, too, are exceedingly sensitive to cold, and often suffer much from the want of comfortable quarters. Whether for fattening hogs, or sows with young pigs, there is no better plan than to lodge them in a roomy house with a somewhat lofty *thatched* roof, the floor being carefully paved with stone or brick, and the area partitioned off into separate pens, each furnished with a cast-iron feeding-trough at the side next the dividing alley, and with adequate drainage, so that the litter in them may be always dry. The period of gestation with the sow is sixteen weeks, and as her pigs may be weaned with safety at six weeks old, she usually farrows twice in the year. In this climate it is desirable that her accouchement should never occur in the winter months. It is a common arrangement to have a pig-shed so placed that the store pigs lodged in it can have access to the cattle-courts, where they grub amongst the litter, and pick up scattered grains that have escaped the thrashing-mill, and fragments of turnips and other food dropped by the cattle. On such pickings, and the wash and offal from the farm kitchen, aided by a few raw potatoes, Swedes, or mangold, and in summer by green vetches, a moderate number of store pigs can be got into forward condition, and afterwards fattened very quickly, by putting them

into pens and improving their fare. There is no cheaper way of fattening hogs than by feeding them on boiled or steamed potatoes, mashed and mixed with a portion of barley or pease-meal. When barley-meal alone is used, it should be mixed with cold water, and allowed to soak for twelve hours before being given to the hogs. A few morsels of coal should be frequently thrown into their troughs. These are eaten with evident relish, and conduce to the health of the animals.

An interesting account of the most approved methods of cutting up, curing, and disposing of carcases of pork, is given in the *Journal of the Royal Agricultural Society*, vol. xi., p. 585.

Section 3.—Poultry,

is a class of stock deserving more attention than farmers generally give it. There are, indeed, few farm-yards untenanted by fowls of some sort, and few homesteads without a poultry-house. It is rare, however, to meet with an instance where the breeding and management of poultry is conducted with the care and intelligence so frequently bestowed on other kinds of live stock. Now, if poultry is kept at all, whether for pleasure or profit, it is surely worth while to use rational means for securing the object in view. To have good fowls, it is necessary to provide a dry, warm, well-ventilated house, in which they may roost and deposit their eggs. This house must be kept clean, and its tenants regularly supplied with abundance of suitable food. Constant and careful attention is also absolutely indispensable. On farms of the lesser sort, this duty is usually undertaken by the farmer's wife or daughters. It will, however, in most cases be better to entrust the entire charge of the poultry to some elderly female servant, who shall give her undivided attention to it.

The kinds of poultry most suitable for a farm-yard are the common fowls, geese, and ducks. Turkeys and guinea-fowl are difficult to rear, troublesome to manage, and less profitable than the other sorts. Of the common fowl there are now many excellent and distinct breeds. The *Cochin China* or *Shanghae* is the largest breed we have. They are hardy and very docile; their flesh is of good quality when young; their eggs, of a buff colour, are comparatively small but excellent in flavour, and are produced in great abundance. The hens resume laying very soon after hatching a brood; sometimes so soon as three weeks. They are the more valuable from the circumstance that their principal laying season is from October to March, when other fowls are usually unproductive. The *Dorkings*, of which there are several varieties, as the speckled, the silver, and the white, are not excelled by any breed for general usefulness. The hens are peculiarly noted for their fidelity in brooding, and their care of their young. The *Spanish fowls* are very handsome in their plumage and form, have very white and excellent flesh, and lay larger eggs than any other breed. The *Polish* and *Dutch every-day layers* are peculiarly suitable where eggs rather than chickens are desired, as the hens of both these breeds continue to lay for a long time before showing any desire to brood.

It is to be recommended that, except in situations where a good price can be got for chickens, the return should be sought for chiefly in eggs.

A suitable stock of fowls being selected, pains must be taken to preserve their health and other good qualities by breeding only from the best of both sexes, and these not too near akin. A very simple plan for securing this is to select a cock, and not more than six or eight hens, of the best that can be got, to entrust these to the care of some neighbouring cottager, whose dwelling is sufficiently apart to prevent intercourse with other fowls, and then to use only the eggs from these selected fowls for the general hatching. There are many advantages in such a course. The whole stock of fowls can thus be had of uniform character and superior quality. If it suit the fancy or object of the owner, his fowls may be of several distinct breeds without any risk of their intermingling; the select breeding stocks can be kept up by merely changing the cock every second year, and not more than one cock to thirty hens need be kept for the general stock, as it is no consequence whether their eggs are impregnated or not. Besides having the run of the barn-door, cattle-courts, and stack-yard, fowls are greatly benefited by having free access to a pasture or roomy grass-plot. If the latter is interspersed with evergreen shrubs so much the better, as fowls delight to bask under the sunny side of a bush, besides seeking shelter under it from sudden rain. Their court should also be at all times provided with clean water, and a heap of dry sand or coal-ashes, in which they wallow, and free themselves from vermin. To keep them in profitable condition, they require, besides scraps from the kitchen and refuse of garden stuffs, &c., a daily feed of barley or oats at the rate of a fistful to every three or four fowls. In cold weather they are the better of having some warm boiled potatoes thrown down to them, as also chopped liver or scraps of animal food of any kind. There is an advantage in having the poultry-house adjoining to that in which cattle-food is cooked in winter, as, by carrying the flue of the furnace up the partition-wall, the fowls get the benefit of the warmth thus imparted to their roosting-place. Saw-dust, dried peat, or burnt clay, are suitable materials for littering poultry-houses, and are preferable to straw. By strewing the floor with such substances two or three times a week, each time carefully removing the previous application, and storing it with the mingled droppings of the fowls *under cover*, a valuable manure can be secured. When 100 common fowls, a score of geese, and a dozen or two of ducks are kept, the quantity and value of the manure produced by them, if kept by itself and secured from the weather, will surprise those who have not made trial of such a plan.

Of late years the breeding of poultry has in various parts of the kingdom become quite a passion. Not only have many separate treatises been published entirely devoted to this subject, but every agricultural periodical now bears evidence to the popularity of this pursuit.

Section 4.—Treatment of Live Stock under Disease.

Time was when every such treatise as the present was expected to contain a description of the diseases to which the domesticated animals are most subject, and instructions for their treatment under them. But now that farriery is discarded and veterinary medicine is taught in colleges, the handling of such a subject is obviously beyond the province of a practical farmer. A few general observations is all, therefore, that we offer regarding it. The province of the stockmaster obviously is to study how to prevent disease, rather than how to cure it. For this end let him exercise the utmost care, first, in selecting sound and vigorous animals of their respective kinds, and then in avoiding those errors in feeding and general treatment which are the most frequent causes of disease. When cases of serious disease occur, let the best professional aid that is available be instantly resorted to; but in all those cases which farmers usually consider themselves competent to treat we advise that they should trust rather to good nursing, and to the healing power of nature, than to that indiscriminate bleeding and purging which is so commonly resorted to, and which in the majority of cases does harm instead of good.

CHAPTER XIX.

IMPROVEMENT OF WASTE LANDS.

Notwithstanding the great progress which agriculture has made, and the immense amount of capital, energy, and skill which for generations has been brought to bear upon the improvement of our soil, there are still large portions of the surface of our country lying in their natural state, and usually classed under the head of *Waste Lands*, in contradistinction to those which are under tillage, or have at some time been subjected to the plough. Of this (so called) waste land but a limited portion is absolutely unproductive. Much of it is capable of being converted into arable land, and doubtless will in course of time be so dealt with, but in the meantime this class of waste lands, and very much more that will never be tilled, is of great and steadily increasing value as sheep-walks. Even for this purpose most of it is susceptible of great improvement, and would well repay it. These lands are comprised under the following descriptions:—1*st*, Those hilly and mountainous parts of Great Britain which, from their steep and rugged surface and ungenial climate, are unfit for tillage; 2*d*, Those which lie uncultivated owing to natural poverty of soil, its wetness, or the degree to which it is encumbered with stones; 3*d*, Bogs and mosses; 4*th*, Lands so near the sea-level as to be more or less liable to be submerged; and 5*th*, Blowing sands:

Section 1.—*Improvement of High-lying Sheep Pastures.*

The lands referred to under the first of these heads are of very great extent, embracing the whole of the mountainous parts of Scotland and Wales, and much of the high grounds in the north of England and south of Scotland. These high grounds afford pasturage for innumerable flocks of sheep of our valuable mountain breeds. The business of sheep-farming has received a great stimulus of late years from the ever-growing demand for sheep to consume the green crops of arable districts. These upland sheep-walks are accordingly rising in value, and their improvement is becoming every day of increasing importance. The improvement of these hill grazings embraces these leading features, viz., drainage, shelter, and enclosure. Until of late years our hill flocks were peculiarly liable to the rot and other diseases arising from the presence of stagnant and flood water upon their pastures. Many grazings that had at one time an evil reputation on this account now yield sound and healthy sheep, solely from the care with which they have been drained. To guard against the pernicious effects of flooding, the courses of brooks and runnels, which in heavy rains overflow their grassy margins, are straightened, deepened, and widened, to such an extent as is required to carry off all flood water without allowing it to overflow. Some grounds are naturally so dry that this is all that is required to render them safe. But in general the slopes and hollows of hilly grounds abound with springs and deposits of peat, and with flats on which water stagnates after rain. On well-managed grounds such places are covered with a network of open drains or shallow ditches, about 30 inches wide at top and half as many deep, by which superfluous water is rapidly carried off. The cutting of these drains costs from 8s. to 10s. per 100 rods (of six yards each). In pastoral districts there are labourers who are skilled in this kind of work, and to whom the laying out of the lines is frequently entrusted, as well as the execution of the work. On very steep places they are careful to avoid a run directly down the declivity, as a strong current of water in such circumstances gutters the bottom of the drain, and chokes those below with the debris thus produced; but with this exception the drains are always run straight down the greatest slope of the ground. When such drains have been properly made, it is necessary to have them statedly overhauled and kept in good order.

Next in importance to drainage is good and sufficient shelter. This, in the absence of natural coppices of birch or hazel, is provided by means of clumps and belts of fir plantation. These should always be of such extent that the trees may shelter each other as well as the sheep. Trees planted in a mass always shoot up faster than in narrow strips, and restrain the snow-drift which passes through the latter. A shepherd who knows the ground well should always be consulted about the sites of such plantations. The conditions requisite are, that the soil be such as trees will grow in; that it be so far removed from any brook, ravine, or bog, as to be accessible to the flock from all sides; that there be rough herbage, such as heather, gorse, or rushes, near at hand, which the sheep may be able to get at in deep snow; that it be contiguous to the sheep-walk, and placed so as to afford defence against the most prevalent winds. A less costly shelter is formed by building what are called *stells*, which consist of a simple dry-stone wall enclosing a circular space twenty yards or so in diameter, with an opening on one side; or forming a cross, in one angle of which the sheep find shelter from whatever point the wind blows. A haystack is a necessary adjunct to such defences.

It is a further point of importance to have such grazings surrounded with a ring fence, consisting either of dry-stone walls, turf walls with wire a-top, or a simple wire fence. This prevents trespass; and the sheep having freedom to range, without watching, up to the boundary, more of them can be kept on the ground than when they are ever and anon turned back by the shepherd. These needful and inexpensive improvements are now generally attended to over the wide pastoral districts of the Scottish border counties. In the remote Highlands they are still much neglected. There are, however, few agricultural improvements which yield so quick and certain a return.

Section 2.—*Reclaiming of Moor Lands.*

The improvement of the second class of these unreclaimed lands is now much facilitated by the readiness with which portable manures can be obtained for them. Draining and enclosing here necessarily demand the first attention. In some cases the land is so encumbered with stones that careful trenching of the whole surface is the only way of getting rid of them. In the north of Scotland many thousands of acres formerly useless have been converted into valuable arable land by this means.

In nearly all parts of the country there are extensive tracts of this muiry soil, producing only a scanty and coarse herbage, which are susceptible of remunerative improvement. We are happy in being able to submit to the reader the following detailed account of a successful instance of this, kindly furnished to us by George A. Grey, Esq. of Millfield Hill, Northumberland:—

"It is said that necessity is the mother of invention. I was told by some of my friends that I had given too high a price for this estate, and that it would be a dearer farm to me now than when I rented it from Lord Grey. To overcome this opinion or fact, I thought of several plans of making it more remunerative, and decided on that which I am now about to describe.

"On the high part of the farm, at an elevation of from 400 to 500 feet above the sea, I had upwards of 100 acres of moorland of a poor description, which had never been under the plough. This consisted of short heath, bilberry bushes, and dry white bent grass, and a soft dry deep moss, delightful as a Turkey carpet under foot, and excellent excursive ground for old hunters, with a small portion of spratty grass and rushes in the damp hollows. The soil is of a free turnip and barley loam on the rotten whinstone. By planting on the west side, and in some places suitable for shelter, I reduced the quantity to about 100 acres. This I divided into three fields of about 35 acres each.

"My great dread was the length of time which such a rough dry surface would require to decompose sufficiently to allow of cultivation, having seen heathery moors in many parts of Scotland lying for two, three, and four years before crops could be obtained, owing to the great cover of coarse vegetation preventing the furrow from lying over, and keeping the land so open and dry through summer that if a *braird* of corn or green crop was obtained, it would wither away in dry weather.

"I had heard of paring and burning, but knew nothing of the process. I, however, obtained the necessary information very much from Mr Langlands of Bewick, who had practised it to a considerable extent. With what I saw there I was so much pleased that I determined to proceed at once.

"I also saw Mr Langlands's work done by a paring-plough, such as is used in the south of England, with a wide plate to cut a furrow of 10 or 12 inches in width. On the point of this is an upright piece of steel, which cuts and divides the heath,—the mould-board turns the furrow over flat on its back, and from end to end of the landing the furrows lay side by side like planks from a saw-mill, and were about half an inch in thickness.

"I must, however, remark, as a caution to others against falling into the same error as I did, that this land had been in tillage at some former time, and was in ridges with a regular surface, so that when the plough was *set*, it cut the whole furrow at a uniform depth, and was drawn by two horses with ease, and at an expense of about eight shillings per acre.

"I got this plough, and gave it a fair trial, but from my land never having been laid smooth, it cut one part as thin as was wished, and the next yard perhaps six or twelve inches thick, which caused a great extra expense in drying, lifting, and burning, and wasted more soil than was necessary or desirable. Also my land having a great deal of small whinstone below the turf, the steel plate frequently got injured and broken. It was therefore with great reluctance laid aside, and the ordinary method of paring by hand adopted, which is slower and much more expensive, but very perfect. It saves soil and cheapens the burning operation, the paring being so thin when the heath, &c., was divided, that light could be seen through the sod, which was only held together with the roots and fibres.

"I began with No. 1 field in July 1849. I let the paring and burning to a company at 25s. per acre, but they made low wages, and after getting more than their work came to, gave up the job. I then got some experienced hands to pare, and paid them the usual wages, at that time 9s. per week, and gave them their food, say 13s. per week, the work being very hard. The total cost of this averaged me 24s. 9d. per acre. A portion of the top part of No. 1 was left undone owing to the lateness of the season. This was dry benty turf. It was ploughed in the common way, and grew no oats in 1850. It was again ploughed and much harrowed and rolled, and sown with the remainder of the field in 1851 with rape, and has grown only a few plants at wide distances. It is still in such a dry undecomposed state that although it is on the high part of the field where sheep draw to lie, I do not expect that it will grow a crop of corn next year; while a portion which was pared down the middle of it grew good corn and rape.

"A portion of No. 2 field was also ploughed in the ordinary way. This was moist land, growing shorter and sweeter grass than any other. It grew a very thin irregular crop of oats in 1850, not within three-quarters per acre of the pared land, but is now (1851) bearing a good crop of oats, that field being a second time in oat crop. To return:

"I had a fair crop of rape in the autumn of 1849 on a considerable portion of No. 1, where it was sown in tolerable season during all August; after that it appeared to be too late. All was, however, ploughed up at once to secure the ashes, and was well harrowed and sown with oats in the spring of 1850. The pared land turned out to be much too thickly sown at four bushels per acre. Corn tillers so much on such land that in some parts it prevented it from coming to maturity. I have since sown much thinner, say three bushels per acre, and even in some degree I find the same fault, there being from five to eight stems from one root. My crop of 1850 turned out to be 30 bushels per acre, but it was on the point of being cut when the high wind in August devastated this district, and that lying high and fully exposed to the wind suffered most severely. I should say it was not below six quarters per acre, and the quality of the grain good.

"In June and July 1850 I pared No. 3 by the same hands who finished my work the previous year. I let the burning of it to an Irishman at 2s. 6d. per acre, binding him to burn it closely piled up in good-sized heaps like hay-cocks, to prevent the escape of the ashes in the shape of smoke into the atmosphere.

"This, with the paring, cost me on 36 acres 19s. 6d. per acre. I got 20 acres of it ploughed and sown with white turnips, broadcast in July and August. I had a close nice crop, though the roots were small, which kept a large flock of sheep for several weeks. This had the good effect of treading down the land and making it plough better for oats.

"Nos. 1 and 2 were limed at the rate of 7 loads per acre. In June 1851 No. 1 was sown broadcast with rape, by mixing 4 lb. of rape seed with one bushel of oat shellings for an acre, and sowing them out of a grass-seed machine. The crop is very close and fine, and has kept twenty scores of sheep from an early day in August to this date (September 27th).

"No. 2 in 1851 was again sown with oats, which proved a very fine crop, as also did No. 3. The produce was about nine quarters per acre. The oats are very thick and tall, and have very long, large heads, and the grain is plump and good; the stalks being strong, the crop is not lodged so as to injure the yield. I estimate it at certainly 7½ quarters per acre, but shall calculate it at 6 quarters.

"I sow on that land the sandy oat, being early, not liable to lodge nor to shake in moderately high winds, although it was not proof against that of 1850.

"Previously to breaking up I drained with pipes all the land which required drying, of which I shall give a statement, along with the expenses and profits of the whole.

"The result shows that if I had, some years ago, when prices of grain were good, done as *a tenant* what I have done now, I should have been amply repaid by the first or second crops, and have had my farm for the remainder of a twenty-one years' lease worth fully £100 a year more than when I began.

"The result of my experience is, that I neither agree with the generality of Scotsmen nor with many Southerns. The former are of opinion that burning wastes the vegetable matter, which should be kept to decompose and enrich the soil, not considering that at once the land receives a rich dressing of ashes quite equal to two quarters of bones, or 4 or 5 cwt. of the best guano; and that, during the several years which such a slow process would require to take place, the land might be much more enriched by growing and having eaten upon it fine crops of rape and turnip, and by producing heavy corn crops, which would in a much shorter space be returned to it in the shape of manure; and also that by the process of burning the land is freed from the larvæ of insects, such as grubs, slugs, wireworms, &c. &c., which are engendered among the rough grass, and fostered for a length of time under the rough, dry, undecomposed turf; to say nothing of the length of time which the speculator is kept out of a large amount of capital and interest, instead of having the former returned with the latter after the first or at most the second year.

"The latter, again (the Englishmen), are too much in the habit of repeating the operation of burning, even after the land has lain in grass only for a few years, when it might as well be ploughed and cultivated without such expense, thereby unnecessarily reducing the soil, there not being the same difficulties to be overcome nor the same advantage to be gained from it.

"I should certainly burn all land with a rough harsh surface, and should as certainly plough and sow all land with a sweet grassy face upon it.

"In my opinion there are few farms in this country which do not contain certain portions of land capable of remunerative improvement, and I have shown that such improvement is quite within the scope of a tenant with a lease, without which no man can farm well, at least in the Northumbrian system. Would it not be better, then, for landlords, tenants, and the country generally, were tenants to employ labourers on works so speedily remunerative to themselves, rather than run to their landlord whenever they feel the screw, and ask for abatement of rent, or to be allowed to plough out some piece of valuable old grass, or otherwise cross crop their land, with a view of obtaining some temporary advantage, but in the end to the inevitable injury of all concerned? (Signed) "G. A. GREY.

"Millfield Hill, *Dec.* 1, 1851."

From a statement of outlay and returns appended to the above paper it appears that the profits on the three fields were respectively £50, 12s. 5d., £84, 19s. 3d., and £39, 2s. 9d., from which, however, there falls to be deducted the expense of fencing (£35), leaving a gross profit of £139, 14s. 5d.

Section 3.—*Reclaiming of Bogs.*

The reclamation of extensive bogs, or deposits of peat, is a more arduous undertaking, requiring a considerable expenditure of capital and longer time before a return is obtained from it. The extent of land of this description in Great Britain and Ireland is very great. Very exaggerated statements of the profits to be derived from its improvement have often been published, and not a few persons have incurred serious loss by rashly undertaking this kind of work. On the other hand, when bogs are favourably situated with reference to a command of marl or other calcareous matter, to assist in their decomposition and consolidation, and of manure to enrich them, their reclamation has proved a very profitable speculation. The well-known instance of Chat Moss in Lancashire affords so interesting an example of this that we shall here quote a description of it.

"Chat Moss, well known as that black barren swamp between Liverpool and Manchester, contains 6000 acres, one-half of which is in the township of Barton, and the remainder in the townships of Bedford, Astley, and Worsley.

"The principal part of this moss, which lies in Barton township, belongs to the Trafford family, and is entailed, but the ancestor of the present Sir Thomas de Trafford appears to have obtained, at the latter end of the last century, an Act of Parliament to grant a ninety-nine years' lease of 2500 acres to a Mr Wakefield, who about the year 1805 disposed of his interest in it to the late William Roscoe, of literary celebrity, who spent a large sum in a fruitless endeavour to improve it, failing in which, the lease was sold in 1821 to other parties. J. A. Brown, Esq., of Woolden Hall, bought 1300 acres; the late Edward Baines, M.P. for Leeds, purchased the remaining 1200 acres. The most extensive and successful efforts at improving this moss have been made on a part of the 1200 acres bought by Mr Baines, who, besides occupying the part operated upon by Mr Roscoe, improved a considerable breadth himself, and let several portions to other parties, who have made considerable progress in improving small portions. The most extensive operations, however, upon the whole, have been carried out by a company to whom Mr Baines, in 1828, granted a lease of 550 acres for 68 years, the remainder of the original term, at a nominal rent for the first year, increasing gradually till at the end of five years the rent attained its maximum of £165 per annum for the 550 acres. This company, which was formed at the time the Liverpool and Manchester Railway was in progress of being made on the property, consisted, amongst others, of some practical farmers, and originated with William Reed, who for the three first years was the manager, and resided on this farm, which they called Barton Moss farm. During that period I had the pleasure of paying my friend Reed a visit, and of witnessing the skill and success attending his enterprise and various experiments.

"The first operation, that of draining, had been effected by opening side drains at intervals of fifty yards, into which were laid covered ones six yards apart, at right angles with and emptying into the open side drains.

"The moss being in a semi-fluid state, it was necessary to proceed slowly with draining, taking out only one graft or depth at a time, allowing it to remain a week or a month, according to the state of the weather, before taking out the second graft; this admitted of the sides becoming consolidated, and of the second graft being taken out without the moss closing in. It was again allowed to remain as before till sufficiently dry to admit of the third being removed.

"The open drains were made 3 feet wide and 3 feet 6 inches deep, and the covered drains 16 inches wide and 3 feet deep; the last graft of the latter being only about 6 inches wide at the top, tapering to 4 inches at the bottom, and being taken out of the middle of the cut, left a shoulder on each side. The sod or graft first taken out had by this time become tough and dry, and was placed, with the heath side downwards, in the shoulder, thus leaving the narrow spit at the bottom open for a depth of about 14 inches; the other square sod being put on the top, completed the drain."

"The cost of this mode of draining, including the side drains, was about 38s. per acre. The drains first put in required to be renewed in a few years, in consequence of the moss becoming so much consolidated and reduced in height that the plough, as well as the horses' feet, broke through the roof, although the horses were shod with 'pattens,' or boards of about 10 inches square, with the angles taken off. The second draining, however, was more permanent, and would probably not have required renewing for many years but for the moles, which have been very troublesome in working down to the drains, and filling them up in various places; so that the operation of draining has required to be partially renewed in every field, and in many of them entirely so; and thus these little animals have been the cause of a very considerable increase in the cost of labour. It has subsequently been found advisable to put the under drains in at 4 yards, instead of 6 yards asunder, and the advantage in one crop has been quite sufficient to pay the extra cost. A two-horse engine was erected, which drives the thrashing-machine, straw-cutter, and crushing-mill; and the escape-steam from it steams the horses' food.

"The buildings were erected principally of timber, covered with asphalted felt.

"After draining, making roads, and burning off the heath plant, the land was scarified lengthwise of the fields by an implement with knives shaped like coulters, reversed, sharp on the convex side, fixed in two bars, and drawn by three horses yoked abreast.

"The tough surface was by this means cut at every four inches; the land was then ploughed across the scarifying; a roller, surrounded with knives, was next passed across the plough; after this the land was well harrowed till sufficiently reduced.

"From 60 to 100 cubic yards of marl were put on an acre, and in the following summer the land was manured, also by means of the movable railway, at the rate of fifty tons of black Manchester manure per acre, and planted with potatoes, which were followed by wheat, sown with red clover and ryegrass, for mowing for one or two years; then oats and potatoes, &c., as before. These were all flourishing crops; the wheat in particular looked bright and beautiful. The potatoes were sold for £25 and £30 per acre, which more than paid the whole cost of improvement. Mr John Bell, resident bailiff, has made many valuable experiments relative to the improvement of raw moss, one of which has resulted in a discovery likely to be of considerable importance, which is, that a mixture of lime and salt applied a while before seeding, with the addition of a good dressing of guano, in the proportion of four tons of lime and five cwt. of salt per acre, qualifies it to produce a crop of potatoes or oats equal to that after the application of 60 yards of marl per acre. It is essential that the mixture should be spread while it is hot. Mr Evens (one of the proprietors) is convinced that the peat on the surface ought never to be burned; he has always found that, when the heath sod is turned down to decay, much better crops have been obtained than when it has been burnt off, or than when the top has been taken away either for fuel or other purposes. What are termed moss-fallows,—that is, parts which have had the moss taken off for fuel,—will never bear so good a crop as the upper surface, however deep the moss may be underneath."—(*Notes on the Agriculture of Lancashire, with Suggestions for its Improvement*, by Jonathan Binns.)

About a century ago, Lord Kames, on becoming proprietor of the estate of Blair-Drummond, in the county of Perth, began the improvement of a large tract of worthless moss by a totally different process from that now detailed. In this case the moss had accumulated upon a good alluvial clay soil. Instead, therefore, of attempts being made to improve the moss itself, it was floated off piecemeal into the neighbouring Firth of Forth. The supply of water required for this purpose was obtained from the river Teith, from which it was raised to the requisite height by a powerful water-wheel. Being conveyed through the moss in channels, successive layers of peat were dug and thrown into these channels, which were shifted as occasion required, until the whole inert mass was removed. A thin stratum next the clay was burnt, and the ashes used as manure. An immense extent of moss has thus been got rid of on that estate and on others in the neighbourhood, and "an extensive tract of country, where formerly only a few snipes and muir-fowl could find subsistence, has been converted, as if by magic, into a rich and fertile carse of alluvial soil, worth from £3 to £5 per acre."

Section 4.—Reclaiming of Fen Lands.

We next notice the fen lands of England. "In popular language, the word *fen* designates all low wet lands, whether peat-bog, river alluvium, or salt marsh; but in the great Bedford level, which, extending itself in Cambridgeshire and five adjoining counties, is the largest tract of fen land in the kingdom, the farmer always distinguishes, and it is thought conveniently and correctly, between fen land and marsh land. By the former they mean land partly alluvial and formed by river floods, and partly accumulated by the growth of peat. Such lands are almost invariably of a black colour, and contain a great percentage of carbon. By marsh lands they mean low tracts gained from the sea, either by the gradual silting up of estuaries or by artificial embankments." Low-lying peat occurs in small patches in nearly every maritime county of Britain, being usually separated from the sea or from estuaries by salt marsh or alluvium. There is a large extent of such land in Somersetshire yet but partially drained, and a still larger breadth in Lancashire, where its improvement makes steady progress. In Kent, on the seaboard of Norfolk, on both shores of the Humber, and stretching along the sides of its tributaries, there are immense tracts of this description of land. But these are all exceeded in importance by the "great level of the fens, which occupies the south-eastern quarter of Lincolnshire, the northern half of Cambridgeshire, and spreads also into the counties of Norfolk, Suffolk, Huntingdon, and Northampton. Its length is about 70 miles, its breadth from 3 or 4 to 30 or 40 miles, the whole area being upwards of 1060 square miles, or 680,000 acres. On the map the fens appear like an enlargement of the Wash, and in reality have the aspect of a sea of land, lying between that bay and the high lands in each of the above-named counties, which seem to form an irregular coast-line around it." This fen country has for centuries been the scene of drainage operations on a stupendous scale. The whole surface of the great basin of the fens is lower than the sea, the level varying from four to sixteen feet below high-water mark in the German Ocean. The difficulty of draining this flat tract is increased from the circumstance that the ground is highest near the shore, and falls inland towards the foot of the slope. These inland and lowest grounds consist of spongy peat, which has a natural tendency to retain water. The rivers and streams which flow from the higher inlands discharge upon these level grounds, and originally found their way into the broad and shallow estuary of the Wash, obstructed in all directions by bars and shifting sand-banks. These upland waters being now caught at their point of entrance upon the fens, are confined within strong artificial banks, and so guided straight seaward. They are thus restrained from flooding the low grounds, and by their concentration and momentum assist in scouring out the silt from the narrow channel to which they are confined. The tidal waters are at the same time fenced out by sea-banks, which are provided at proper intervals with sluice doors, by which the waters escape at ebb-tide. To show the extent of these operations, it may be mentioned that the whole sea-coast of Lincolnshire and part of Norfolk, a line of at least 130 miles, consists of marsh lands lower than the tides, and is protected by barrier banks, besides which there are hundreds of miles of river embankments. When this does not provide such a drainage as to admit of cultivation, the water is lifted mechanically by wind or steam mills into the main aqueducts.

The first use of steam-engines for the purpose of draining was in Deeping fen, where, in 1824-5, two, of 80 and 60 horse-power respectively, were erected. By means of these two engines upwards of 20,000 acres have now a good drainage, whereas formerly forty-four wind-mills, with an aggregate power of 400 horses, failed to keep them sufficiently dry. The scoop-wheel of the larger engine is 28 feet in diameter, and the float-boards are 5 feet wide. It was intended to have a "dip" of 5 feet, but the land has subsided so much in consequence of the draining that it seldom has a dip of more than 2 feet 9 inches. The water is lifted on an average 7 feet high. When both engines are at work they raise 300 tons weight of water per minute.

The soil of the fens consists for the most part of dark-coloured peat, from 1 to 8 or 10 feet in depth. The surface in general is not pure peat, but is mixed with silt or other soil. Under this there is in general a stratum of brown spongy peat, which sometimes rests upon gravel, but for the most part upon clay, which usually contains a portion of calcareous matter. The removal of the water has of course been the primary improvement; but subsidiary to this the rapid amelioration and great fertility of the fen lands are largely due to this fortunate conjunction of clay and peat. The early practice of the fen farmers was to pare and burn the surface, grow repeated crops of rape, oats, wheat, &c., and burn again. The subsidence of the soil subsequent to the draining and repeated paring and burning, brought the surface nearer to the subjacent clay, which the cultivators by and by began to dig up and spread over the surface. This practice is now universal, and its continued use, together with careful cultivation and liberal manuring, has changed a not very productive peat into one of the most fertile soils in the kingdom. Nowhere in our country has the industry and skill of man effected greater changes than in the fens. What was once a dismal morass, presenting to the view in summer a wilderness of reeds, sedges, and pools of water, among which the cattle waded, and in winter almost an unbroken expanse of water, is now a fertile corn land. The fen men, who formerly lived upon the adjacent high lands, and occupied themselves with fishing, fowling, and attending to their cattle, have now erected homesteads upon the fen lands, divided them by thorn hedges, and brought them into the highest state of cultivation.

We referred at the outset to the distinction betwixt *fen* land and *marsh* land. The following pertinent observations on the reclamation of marsh land are extracted from Mr David Stevenson's paper in the *Highland and Agricultural Society's Transactions*, vol. iii., 1871.

First, In order to insure success, the space to be reclaimed must be within the influence of water containing much alluvial matter, and not on the shores of an open sandy estuary.

Secondly, The spaces to be reclaimed should be allowed to receive the deposit left by the tide for as long a period as possible, and no attempt should be made entirely to exclude the water from them, until they have by gradual accretion attained the level of at least ordinary spring tides.

The first case to which I shall refer is Loch Foyle, a situation where the amount of salt water greatly preponderates over the fresh. Extensive reclamations have been made there, and I have received from Mr G. Henry Wiggins, of Londonderry, some notes regarding them, from which I extract the following interesting information:—

"After the salt water had been excluded, shallow surface drains were made with spades or forks, and in about two years ryegrass grew pretty freely: exceptional spots remained barren for some time. The grass was followed by oats, which improved as the salt left the soil. Deeper draining allowed the cultivation of flax and clover; afterwards, on deeper draining, all ordinary crops began to grow well—wheat, beans, turnips, mangold, and carrots—but all requiring fully as much manure as any old upper land. These sloblands, says Mr Wiggins, yield a great return for manure, but must have manure on the lower and damper portions. Feorin grass grows well without manure.

"Whenever the ditches have so far drained the soil as to allow of its becoming cracked and open to the air, the crops begin to increase in produce, but the full value of the soil is never known until thoroughly under-drained with tile or stone; it then mostly yields excellent crops of almost any produce, clover and ryegrass for hay being perhaps the most profitable. Grazing the land does not answer, except from the beginning of May to the end of September; after this the soil is too cold and damp for the beasts to lie down, and they begin to fail."

The expense of these intakes on the Foyle may be taken at about £20 an acre to get them from the sea; the expense of bringing the land when got into cultivation will come to at least £10 more; making a total of £30 per acre. The best lands are worth 50s. to 40s. the Cunningham or Scotch acre, and the lowest and wettest parts perhaps not more than 10s.—say 30s. round as a fair average. To this has to be added the expense of keeping up the banks and pumping water; so that I believe Mr Wiggins is right when he says that no great profit can be expected, and that these matters are generally undertaken by hopeful and energetic enthusiasts, who seldom realise their expectations, and afterwards fall into the hands of other parties, who are perhaps rather more successful.

The reclamations made by the Ulverston and Lancaster Railway in Morecambe Bay were rapidly formed by the embankment for carrying the railway, which was made in pretty deep water. Like the Foyle, there is also predominance of sea-water. Mr G. Drewry, of Holker in Lancashire, has favoured me with the following information:—"A portion of the land enclosed by the railway in 1856 was grassed over, and the remainder was sand without any vegetation on it. After it was levelled it was divided into fields by open ditches and wire fences; the ditches had to be made very wide at the top, in order to get them to stand. The land was then drained with 3-inch pipes, each drain opening into the ditch at each side of the field. The tiles were all covered round with peat moss, to act as a filter to prevent the sand from running into them. The sand is so fine that without this precaution the drains would have filled up very quickly. The drainage is the great difficulty, as they are very apt to fill up after every precaution has been taken.

"On the portion which was grassed over, two crops of oats were first taken, and then it was green-cropped. It grew for a few years good crops of wheat, beans, and clover, as well as Swedish turnips and mangolds; but though a great quantity of manure was used, the crops fell off, and at present it is nearly all in grass. The portion which was bare sand was treated in the same way, except as to the first two crops of oats. It was green-cropped after it had been enclosed about two years. After the railway was made there was no means of silting the land. The tide was entirely kept out; had it been admitted, this land would have been much more valuable and much higher—we would then have had a better drainage and a richer sand. That portion which was grassed over at the time it was enclosed is still much the best.

"When land is reclaimed from the sea, the first thing to be looked to is a good outfall for the water, and, when it is possible, no doubt it is very desirable that the land should be silted up gradually. In our case this could not be done, as the reclamation of the land was a very secondary affair."

In the district called Marshland, in Norfolk, extending between the Ouse and the Nen; in that called South Holland, in Lincolnshire, stretching between the Nen and the Welland; northward of Spalding, and also north-east of Boston, there is a considerable tract of marine clay soil. In Marshland this is chiefly arable land, producing large crops of wheat and beans; but in Lincolnshire it forms exceedingly fine grazing land. This tract lies within the old Roman embankment by which the district was first defended from the ocean. Outside this barrier are the proper marsh lands, which have been reclaimed in portions at successive periods, and are still intersected in all directions by ranges of banks. The extraordinary feature of this tract is, that the surface outside the Roman bank is 3 or 4 feet higher than that in the inside, and the level of each new enclosure is more elevated than the previous one. The land rises step by step as the coast is approached, so that the most recently reclaimed land is often 12 or even 18 feet higher than the lowest fen land in the interior, the drainage from which must nevertheless be conveyed through these more elevated marshes to the sea.

Lands such as some of those which we have just been describing are often greatly improved, or rather may be said to be *made*, by means of a peculiar mode of irrigation called "warping." It is practicable only in the case of land lying below the level of high tide in muddy rivers. It is little more than a century since it was first practised in England, the first instance of it being near Howden, on the banks of the Humber. But although the practice is comparatively new in Britain, it has long been in use on the continent of Europe, particularly in Italy, and is thus described by Mr Cadell:—"In the Val de Chiana, fields that are too low are raised and fertilised by the process called *colmata*, which is done in the following manner:—The field is surrounded by an embankment to confine the water. The dike of the rivulet is broken down so as to admit the muddy water of the high floods. The Chiana itself is too powerful a body of water to be used for this purpose; it is only the streams that flow into the Chiana that are thus used. This water is allowed to settle and deposit its mud upon the field. The water is then let off into the river at the lower end of the field by a discharging course called *scolo*, and in French *canal d'ecoulement*. The water-course which conducts the water from a river, either to a field for irrigation or to a mill, is called *yora*. In this manner a field will be raised $5\frac{1}{2}$ and sometimes $7\frac{1}{2}$ feet in ten years. If the dike is broken down to the bottom, the field may be raised to the same height in seven years; but then in this case gravel is also carried in along with the mud. In a field of 25 acres, which had been six years under the process of *colmata*, in which the dike was broken down to within 3 feet of the bottom, the process was seen to be so far advanced that only another year was requisite for its completion. The floods in this instance had been much charged with soil. The water which comes off cultivated land completes the process sooner than that which comes off hill and woodland. Almost the whole of the Val di Chiana has been raised by the process of *colmata*."[1]

Section 5.—Blowing Sands.

On many parts of our sea-coasts, and especially in the Hebrides, there occur extensive tracts of blowing sands, which are naturally not only sterile themselves, but a source of danger to better lands adjoining them, which in some instances have been quite ruined by the sand deposited upon them by the winds. This mischief is effectually prevented by a process beautifully simple and useful, namely, planting the sand-banks with sea bent-grass (*Arundo arenaria*), the matting fibres and stems of which not only bind the sand, but clothe it with a herbage which is relished by cattle, and which, being able to resist the severest winter weather, furnishes a valuable winter forage in those bleak situations. The bent-grass can be propagated by seed, but in exposed situations it is found better to transplant it. This operation is performed betwixt October and March, as it succeeds best when the sand is moist and evaporation slow.

CHAPTER XX.

GENERAL OBSERVATIONS.

According to the method proposed at the outset, we now offer a few observations on several topics connected with our subject.

Section 1.—Of the Tenure of Land.

The extent of land in Great Britain occupied by its owners for agricultural purposes bears a very small proportion to the whole area. The yeoman class is still numerous in several parts of England, but must have diminished greatly from that continuous amalgamation of small estates into large ones which has formed a marked feature in our social history during the present century. This change, although to be regretted on public grounds, has had a favourable influence on the cultivation of the soil, for it almost invariably happens that a larger produce is obtained from land when it is occupied by a tenant than when it is cultivated by its proprietor. As a matter of fact, the land of the country is now, with trifling exceptions, let out to professional farmers in quantities varying from the rood-allotment of the village labourer to the square miles of the Highland grazier. Farms of all sizes are usually to be found in any district, and most important it is that this should be the case; but the extent of farms is chiefly determined by the amount of hired labour employed upon them, and the measure of personal superintendence on the part of the tenant which the kind of husbandry pursued upon them calls for. We accordingly find that in very fertile tracts, in the vicinity of towns, and in dairy districts, they seldom exceed 200 acres; where the ordinary alternate husbandry is practised the average ranges from 300 to 400; in more elevated tracts, where a portion of natural sheep-walk is occupied along with arable land, it rises to 800 or 1000; while that of the sheep grazings of our hills and mountains is limited only by the capital of the tenant. About a century ago there occurred in various parts of Great Britain a similar amalgamation of small holdings into farms of the sizes which we have now referred to as is at present in progress in Ireland. This enlargement of farms, with the employment of increased capital in their cultivation, insures a more rapid reclamation of waste lands, and general progress of agriculture up to a certain point, than would otherwise take place. But as every step in advance beyond this point implies an

[1] *Journey in Carniola, Italy, and France*, by W. A. Cadell, Esq. F.R.S.

increase of outlay in proportion to the extent, and the need for closer superintendence, it seems likely that, in future, the size of arable farms will not further increase, but may rather be expected to approximate towards that which at present obtains in suburban districts.

Farms are held either by yearly tenancy or under leases for a specified number of years. The latter plan is that upon which nearly the whole lands of Scotland are let; and it obtains also to a considerable extent in the northern counties of England, in West Norfolk, and in Lancashire. But with these and other exceptions, amounting altogether to about a tenth part, the farms of England are held by yearly tenancy, which can be terminated by either of the contracting parties giving the other six months' notice to that effect. This precarious tenure has been attended by far fewer changes than a stranger might suppose, owing to the highly honourable conduct for which English proprietors as a class have long been noted. On all the large estates it is quite common to find families occupying farms of which their ancestors have been tenants for generations, or even for centuries. The mutual esteem and confidence which usually subsist between such landlords and tenants are undoubtedly much to the credit of both, but not the less has the system, as a whole, operated unfavourably for all concerned; for however numerous and striking the exceptions, it is yet the fact that under this system of tenancy-at-will less capital has been invested in the improvement of farms, less labour has been employed, and less enterprise displayed in their ordinary cultivation, less produce has been obtained from them by the occupiers, and less rent has been received for them by the owners, than in the case of similar lands let on leases for a term of years. These different results ensue, not because tenants with leases are abler men or better farmers than their neighbours who are without them, but solely bcause the one system recognises certain important principles which the other ignores. It is contrary to human nature to expect that any body of men will as freely invest their capital, whether in the shape of money, skill, or labour, in a business yielding such slow returns as agriculture, with no better guarantee that they or their families shall reap the fruits of it than the continued good-will of existing proprietors or those who any day may succeed them, as they will do with the security which a lease for a term of years affords. It does therefore seem strange that a majority of the farmers of Great Britain should be tenants-at-will, and still more strange that they should be so of choice. It is nevertheless true that a considerable portion of the tenantry of England are even less disposed to accept of leases than their landlords are to grant them. The latter cling to the system because of the greater control which they thereby retain over their estates, and the greater political influence with which it invests them: the former do so because low rents are one of its accompaniments. Since the removal of restrictions on the importation of foreign agricultural produce, there are indications that neither landlords nor tenants are so well satisfied with this system of tenancy-at-will as they once were. Not only is the granting of leases becoming more common than it has hitherto been, but there is a growing desire on the part of tenants to obtain the benefit of that guarantee for the realising of their capital which *tenant-right* affords to enterprising farmers who may have unexpectedly to quit their farms. In certain districts of England this claim, called *tenant-right*, has been recognised so long that, apart either from written stipulation or statutory enactment, it has, by mere usage, attained to something like a legal standing. In Lincolnshire an out-going tenant can, by virtue of this usage, claim from his landlord or successor repayment, in certain definite proportions, of the cost of such ameliorations of a specified kind as he may have made during the last years of his occupancy, and the benefits of which his removal hinders him from realising in the natural way.

Tenant-right is certainly a valuable adjunct to tenancy-at-will, but still it does not meet the real exigencies of the case. There are feelings inherent in man's nature which cause him to recoil from exertions the fruits of which are as likely to be enjoyed by a stranger as by himself or his family. This repugnance, and its paralysing influence, is not to be removed by a mere "right" to pecuniary compensation. It is certainty of tenure—so far at least as human arrangements can be certain—which will really induce a farmer to throw his whole heart into his business. It is accordingly to this principle that leases owe their value, and by it also that the only weak point in them is to be accounted for. The first years of a lease are usually characterised by an energetic performance of various improvements, whereas towards its close there is usually such a withdrawing even of ordinary outlay as is unfavourable to the interests of both landlord and tenant. There is at present a very generally entertained opinion that this inconvenience would be obviated by engrafting the system of tenant-right upon that of leases. So strongly has the current of opinion been running in this direction that a bill has been submitted to the legislature for the purpose of conferring on out-going tenants a legal claim to compensation for certain specified investments which may have been made by them, but of which their removal hinders them from reaping the benefit. This bill further provided that in the event of a tenant having erected buildings for his own accommodation without the sanction of his landlord, he should have a right to remove the materials if the landlord or incoming tenant declined to purchase them. Through accidental circumstances this bill was withdrawn without being discussed, but it is certain to be re-introduced, and sooner or later to be passed. It is now admitted on all hands that land cannot be cultivated to its full measure of productiveness without a large investment of capital, and that this outlay, when once incurred, cannot be recouped for several years at the least. It is in vain, therefore, to expect that these so much needed investments will be made until those who should make them are secured against having their property confiscated by a six months' notice to quit.

It seems to be generally admitted that twenty-one years is the proper duration for an agricultural lease. Such a term suffices to give confidence to the tenant in embarking his capital, and secures to the landlord his legitimate control over his property, and due participation in its varying value. It is generally felt by tenants that the lease or document in which their agreement with their landlord is engrossed might with advantage be much shortened, as well as simplified in its terms. When treating of the succession of crops we have already expressed our views regarding those restrictive clauses which usually occupy a prominent place in such writings. Such restrictions are of course introduced with the view of guarding the property of the landlord from deterioration; but when he is so unfortunate as to meet with incompetent or dishonest tenants, they entirely fail to secure this object, and yet are a hindrance and discouragement to enterprising and conscientious tenants. It is probable that the existence of the laws of distraint in England and hypothec in Scotland, which give to landlords a lien over the effects of their tenantry in security for the payment of the current year's rent, has had its influence in adding to the number and stringency of these clauses, and has encouraged the practice of letting lands by tender to the highest offerer. For the law in question, by rendering landlords to a considerable extent independent of the personal character and pecuniary circumstances of the occupiers of their land, has obviously a direct tendency to render them less cautious than they would otherwise be, and to induce them, when tempted by the promise of high rents, to trust more to this legal security than to the moral character, business habits, professional skill, and pecuniary competency of candidates for their farms.

Section 2.—Capital required for working a Farm.

The amount of capital that is required in order that the business of farming may be conducted advantageously, is largely determined by the nature of the soil, &c., of each farm, the system of management appropriate to it, the price of stock and of labour, and the terms at which its rents are payable. In the case of land of fair quality, on which the alternate husbandry is pursued, and when the rents are payable as the produce is realised, £10 per acre may be regarded as an amount of capital which will enable a tenant to prosecute his business with advantage and comfort. In letting a farm, a landlord not only does a just and prudent thing for himself, but acts as a true friend to his proposed tenant, when he insists upon being shown that the latter is possessed of available funds to an amount adequate to its probable requirements.

The importance of the topics to which we have thus referred is happily expressed by Mr Pusey, when, after enumerating various agricultural desiderata, he says, "In some degree none of us carry out all that is in our power; but want of capital and want of confidence in the tenure of farms are, I suppose, the two principal causes of this omission."

Section 3.—Education of Farmers.

But the mere possession of capital does not qualify a man for being a farmer, nor is there any virtue inherent in a lease to insure his success. To these must be added probity, knowledge of his business, and diligence in prosecuting it. These qualifications are the fruits of good *education* (in the fullest sense of that term), and are no more to be looked for without it than good crops without good husbandry. Common school instruction will, of course, form the groundwork of a farmer's education; but to this should be added, if possible, a classical curriculum. It has been the fashion to ask, "Of what use are Greek and Latin to a farmer?" Now, apart from the benefit which it is to him, in common with other men, to know the structure of language, and to read with intelligence the literature of his profession, which more and more abounds in scientific terminology, we believe that no better discipline for the youthful mind has yet been devised than the classical course which is in use in our best public schools. Of this discipline we desire that every future farmer should have the advantage. But the great difficulty at present lies in finding appropriate occupation for such youths between their fifteenth and twentieth years. In many cases the sons of farmers are during that period put to farm labour. If they are kept statedly at it, and are made proficient in every kind of work performed on a farm, it is a good professional training as far as it goes. The more common one—at least as regards the sons of the larger class of farmers—which consists of loitering about without any stated occupation, attending fairs and markets, and probably the race-course and hunting-field, is about the most absurd and pernicious that can well be imagined. Such youths are truly to be pitied, for they are neither inured to bodily labour nor afforded the benefits of a liberal education. It need not surprise any one that such hapless lads often prove incompetent for the struggles of life, and have to yield their places to more vigorous men who have enjoyed the benefit of "bearing the yoke in their youth." Unless young men are kept at labour, either of mind or of body, until continuous exertion during stated hours, confinement to one place, and prompt obedience to their superiors have ceased to be irksome, there is little hope of their either prospering in business or distinguishing themselves in their profession. Owing to the altered habits of society, there is now less likelihood than ever of such young persons as we are referring to being subjected to that arduous training to bodily labour which was once the universal practice; and hence the necessity for an appropriate course of study to take its place. Many Scottish farmers endeavour to supply this want by placing their sons for several years in the chambers of an attorney, estate-agent, or land surveyor, partly in order that they may acquire a knowledge of accounts, but especially for the sake of the wholesome discipline which is implied in continuous application and subjection to superiors. It is also common for such youths to be sent to Edinburgh for a winter or two to attend the class of agriculture in the University, and perhaps also that of chemistry, and the Veterinary College classes. This is well enough in its way; but there is wanting in it an adequate guarantee that there is real study—the actual performance of daily mental work. The agricultural college at Cirencester appears to come more fully up to our notion of what is needed for the professional training of farmers than any other institution which we yet possess. We shall rejoice to see such opportunities of instruction as it affords multiplied in Great Britain. After enjoying the benefits of such a course of training as we have now indicated, young men would be in circumstances to derive real advantage from a residence with some experienced practical farmer, or from a tour through the best-cultivated districts of the country. We are well aware that what we have now recommended will appear sufficiently absurd to the still numerous class of persons who believe that any one has wit enough to be a farmer. But those who are competent to judge in the case can well afford to smile at such ignorance. They know that agriculture is at once an art, a science, and a business; that the researches of naturalists, chemists, geologists, and mechanicians are daily contributing to the elucidation of its principles and the guidance of its practice; and that while its pursuits afford scope for the acutest minds, they are relished by the most cultivated. As a business it shares to the full in the effects of that vehement competition which is experienced in every other branch of industry, and has besides many risks peculiar to itself. The easy routine of the olden time is gone for ever; and without a good measure of tact, energy, and industry, no man can now obtain a livelihood by farming. It is desirable that all this should be known, as nothing has been more common than for parents who have sons too dull to be scholars or too indolent for trade, to put them to farming; or for persons who have earned a competency in some other calling to covet the (supposed) easy life of a farmer, and find it to their sorrow a harassing and ill-requited one.

Section 4.—Farm Labourers.

The agriculture of a country must ever be largely affected by the condition and character of the peasantry by whom its labours are performed. An acute observer has shown that in England a poor style of farming and low wages—that good farming and high wages, usually go together; and that a low rate of wages is significantly associated with a high poor-rate. The worst paid and worst lodged labourers are also the most ignorant, the most prejudiced, the most reckless and insubordinate. The eminence of the agriculture of Scotland is due in large measure, to the moral worth and intelligence of her peasantry. For this she is indebted to the early establishment of her parochial schools, and to the sterling quality of the elementary education which the children of her tenantry and peasantry have for generations received in these schools together. These schools had unfortunately become inadequate to the increased population; but still in the rural districts of the Scottish lowlands it is a rare thing to meet with a farm labourer who cannot both read and write. Apart from higher benefits, the facilities which the services of such a class of labourers have afforded for the introduction and development of improved agricultural practices, the use of intricate machinery, and the keeping of accurate accounts, cannot well be over-rated. It is an interesting testimony to the value of a sound system of national education that our Scottish peasantry should be in such request in other parts of the kingdom as bailiffs, gardeners, and overseers. Recent legislation warrants the expectation that this inestimable blessing will speedily be enjoyed by our entire population.

The pernicious influence of the present law of settlement and removal upon the English labourer is now attracting the attention which it so urgently demands. The proprietors and tenants of particular parishes in various parts of England at present combine to lessen their own share of the burden of the poor-rate by pulling down cottages and compelling their labourers to reside out of their bounds. The folly and cruelty of such short-sighted policy cannot be too strongly reprobated. These poor people are thus driven into towns, where their families are crowded into wretched apartments, for which they must pay exorbitant rents, and where they are constantly exposed to moral and physical contamination of every sort. From these comfortless abodes the wearied and dispirited men must trudge in all weathers to the distant scene of their daily labours. One cannot conceive of a prosperous agriculture co-existing with such a system, nor feel any surprise that thieving, incendiarism, and burdensome rates should be its frequent accompaniments. It is pleasant to contrast with this close-parish policy the conduct of some of our English nobility, who are building comfortable cottages and providing good schools for the whole of the labourers upon their princely estates.

About the middle of the 18th century, when the old township system began to be broken up, and the land to be enclosed and arranged into compact farms of considerable size, it happily became the practice in the south-eastern counties of Scotland, and a portion of the north of England, to provide each farm with its own homestead, set down as near its centre as possible, and with as many cottages as would accommodate all the people statedly required for the work of that farm. These cottages, always placed in convenient proximity to the homestead, are let to the tenant along with the farm as a necessary part of its equipment. The farmer hires his servants by the year at stipulated wages, each family getting the use of a cottage and small garden rent free. The farmer has thus always at hand a staff of labourers on whose services he can depend; and they, again, being engaged for a year, are never thrown out of work at slack seasons, nor are they liable to loss of wages from bad weather or casual sickness. This arrangement has the further advantage of the men being removed from the temptations of the village alehouse. So successfully has this system worked that the counties in which it prevails have long had, and still have, an agricultural population unequalled in Great Britain for intelligence, good conduct, and general well-being.

Over a very large portion of Scotland, and more especially in the counties lying betwixt the Forth and the Moray Frith, while the arrangement of farms and mode of management are substantially the same as those of the border counties, there is this marked difference, that the ploughmen as a rule live by themselves in bothies. They are for the most part unmarried men, although not a few of them have wives and children living under the most unfavourable conditions in distant towns and villages; and so it comes to pass, under this bothy system, that about two-thirds of all the men statedly employed in farm labour are shut out from all the comforts and blessings of family life, and have become in consequence rude, reckless, and immoral. Until a quite recent date this system, because of its supposed economy, was stoutly defended both by landlords and farmers; but its evil effects have become so manifest as to convince them at last that the system is wrong, and there is now in consequence a general demand for more cottages on farms.

The condition of the agricultural labourers in the southern counties of England has long been of a most unsatisfactory character. The discontent that had long existed among them has at last, in the summer of 1873, culminated in wide-spread combinations and strikes for higher wages and better terms. To a large extent the labourers have been able to make good their demands, although at the cost of much unhinging of old relations betwixt them and their employers, and a great deal of mutual grudging and jealousy. The thorough healing of chronic social maladies is always difficult, and usually demands the patient use of a variety of remedial measures. We venture to express the opinion that much benefit would ensue from the adoption in southern England of the essential parts of the border system, viz., cottages on each farm for all its regular labourers, yearly engagements, and a cow's keep as part of the wages of each family.[1]

Section 5.—What the Legislature should do for Agriculture.

The further progress of our national agriculture is undoubtedly to be looked for from the independent exertions of those immediately engaged in it; but important assistance might be, and ought to be, afforded to them by the legislature, chiefly in the way of removing obstructions. What we desiderate in this respect is the repeal, or at least the important modification, of the law of distraint and hypothec; the commutation of the burdens attaching to copyhold lands; the reformation of the law of settlement; the removal of the risk and costs which at present interfere with the transference of land; the endowment of an adequate number of agricultural colleges, with suitable museums, apparatus, and illustrative farms; and the compulsory adoption of a uniform standard of weights and measures. We desire also to see the *arterial* or *trunk drainage* of the country undertaken by government. Until this is done, vast tracts of the most fertile land in the kingdom cannot be cultivated with safety and economy, or attain to the productiveness of which they are capable. It is the opinion of Mr Bailey Denton, the eminent draining engineer, that not more than three millions of acres of the land of Great Britain have yet been drained. Our national interests surely require that its agriculture should be freed from such obstructions as these, and that it should receive the benefit of a fair share of public provision, such as is made for training youths for the learned professions and for the public service; and of such grants as are given in aid of scientific research for the encouragement of the fine arts, and for the furtherance of manufactures and commerce.

We cannot close this section without referring to another grievance which has long had a most depressing effect on the agriculture of particular districts of our country, and is now, we regret to say, spreading rapidly to all parts of it,

[1] For confirmation and full illustration of the statements and opinions in the above section on agricultural labourers, the reader is referred to the reports of, and the evidence collected by, the "Commission on the Employment of Children, Young Persons, and Women in Agriculture." in 1870.

in the excessive preservation of game. This evil has been greatly aggravated since that mode of sporting called the battue has unhappily become the fashion. For this amusement a very large head of game is reckoned to be indispensable, and proprietors who engage in it are naturally enough led to vie with each other as to who shall show the greatest quantity of game, and report the heaviest bag, at their respective shooting parties. All this necessarily implies a grievous waste of farm produce, and frightful loss to farmers whose crops are exposed to the incursions of the privileged vermin. Worst of all, these hordes of game present such irresistible temptation to poaching that the rural population is demoralised by it to an alarming extent. So long as field sports were in a great measure restricted to resident landowners and their personal friends, they were, with rare exceptions, careful not to allow their tenants to be injured by game. Now, however, there are multitudes of men who, having acquired wealth in business, are eager to engage in field sports, and ready to give almost any amount of money for the privilege of doing so. These game tenants are often utterly regardless of the interests of farmers, and cause them both loss and annoyance. All this is occasioning such an amount of heart-burning and alienation of feeling between different classes of society as cannot fail to have disastrous consequences. A few years ago the removal of hares and rabbits from the list of animals protected by the game-laws would, so far at least as landlords and their tenants are concerned, have put an end to all this misery. The refusal of so moderate a concession has in all likelihood sealed the fate of these oppressive laws which have so long embittered society and disgraced our country.

Section 6.—Concluding Remarks.

On carefully comparing the present condition of British agriculture with what it was forty years ago, the change for the better is found to be very great indeed. But on all hands there are many indications warranting the anticipation that the progress of discovery and improvement in future will be more steady, more rapid, and more general than it has hitherto been. There is not only a more general and more earnest spirit of inquiry, but practical men, instead of despising the aids of science, seek more and more to conduct their investigations under its guidance. Experiments are made on an ever-widening scale and upon well-concerted plans. Their results are so recorded and published that they at once become available to all, and each fresh investigator, instead of wasting his energies in re-discovering what (unknown to him) has been discovered before, now makes his start from a well-ascertained and ever-advancing frontier. Formerly the knowledge of the husbandman consisted very much of isolated facts, and his procedure was often little better than a groping in the dark. As the *rationale* of his various processes is more clearly discovered, he will be enabled to conduct them with greater economy and precision than he can do at present. A clearer knowledge of what really constitutes the food of plants, and of the various influences which affect their growth, will necessarily lead to important improvements in all that relates to the collection, preparation, and use of manures.

What may truly be called a revolution in agriculture is now in the act of rapid development, in the application of steam-power to the tillage of the soil, which is spreading on every side. Enough has already been accomplished to show that, under the combined influence of drainage and steam tillage, the clay soils of England will speedily have their latent fertility brought into play in a manner that will mightily augment our supplies of home-grown bread-corn and butcher-meat. It may indeed now be reasonably anticipated that these hitherto impracticable soils will again take their place as our best corn-growing lands, and that those large portions of the country where for a long time our national agriculture presented its poorest aspect, may ere long exhibit its proudest achievements.

In closing this rapid review of British Agriculture, it is gratifying and cheering to reflect that never was this great branch of national industry in a healthier condition, and never were there such solid grounds for anticipating for it a steady and rapid progress. The time has hardly yet gone by when it was much the way with our manufacturing and trading men, and our civic population generally, to regard our farmers as a dull, plodding sort of people, greatly inferior to themselves in intelligence and energy. Many of them seem now, however, to be awakening to the fact that their rural brethren possess a full share of those qualities which so honourably distinguish the British race. Nay, some of them may have experienced no little surprise when they became aware that in a full competition of our whole industrial products with those of other nations, as at Paris in 1855, and at similar and more recent international expositions, the one department in which Britain confessedly outstripped all her rivals was not in any of her great staple manufactures, but in the live stock of her farms, and in her agricultural implements and machinery

List of Plates accompanying this Article.

Plate
No. III. Plan of Covered Homestead for a small Farm, by Mr J. Cowie.
IV. Ground Plan of Steading and Offices on the Home Farm of the Earl of Southesk.
V. Shorthorn Bull and Cow.
VI. Hereford Bull, and South Down Ewe and Lamb.
VII. Cheviot Ewe and Blackfaced Heath Sheep.
VIII. Leicester Ram and Ewe.
IX. Romsey Marsh Ewe, and Sow of the Large English Breed

The following description has been supplied along with the plan given in Plate IV. :—"It represents the ground plan of a steading of offices recently built on the home farm of the Earl of Southesk, planned by Charles Lyall, Esq., his lordship's factor. It contains a powerful thrashing-mill, corn-bruiser, oil-crusher, chaff-cutter, and turnip-slicer, all driven by a portable steam-engine; and is amply supplied with water for the troughs, and is lighted by gas. It may be regarded as a model, containing as it does all the conveniences and appliances necessary for the complete development of the stock and implement departments. It is calculated for an occupancy of 500 acres, and was built, including the steam-engine, at a cost of about £5000."

This plan may very well illustrate the present state of opinion as to whether or not cattle should be kept wholly under cover. It gives an affirmative answer to this question in the case of fattening cattle; but for breeding stock of all ages it provides accommodation in open yards. This we consider the best arrangement; for it is impossible in the case of breeding stock to retain that fine coat of hair which so enhances the good looks and value of high-class cattle without such an amount of exposure to the weather as is afforded by open yards with covered sheds. There is one feature in this plan which we cannot but regret, viz., its bothy. It is indeed one of the best of its kind, having a separate sleeping-place for each of its inmates, and suitable arrangements for their cleanliness and comfort; but the meanest cottage in the country, inasmuch as it admits of family life, is to be preferred to the most perfect bothy. (J. W.)

CHAPTER XXI.

LARGE AND SMALL FARMING.

No treatise on agriculture will in these days be considered complete which does not take note of some of the various modes in which the treatment of the soil may be affected by variations in the cultivating occupier's form of tenure. A farm may be the property of its occupier, or be held by him at will or on lease. According to its extent it will be the subject of *grande* or of *petite culture*, expressions which in the following pages will be Anglicised as large and small culture or farming. If a farm be of small size, and if its occupant be also its owner, peasant proprietorship comes into play. If it be let, its rent may consist of a payment of predetermined amount in money or in kind, or may, instead of a fixed portion, be a predetermined proportion of the annual produce. It may be let to one individual, singly responsible for the rent and for all imposts, fiscal or other, and exclusively entitled to the whole of the remaining net produce; or it may be held in common by any number of coparceners, all co-operating in the cultivation, and jointly and severally responsible for the rent and other dues, and all participating in the net profits.

Each of these systems has its advocates, and of one of them, at least, the admirers are so much enamoured as to be unable to perceive merit in any of the rest. A judgment upon them that would be generally acceptable is therefore impossible, and need not be attempted here. Nothing more will be aimed at than such an impartial estimate of the advantages and disadvantages of each as may help an unbiassed reader to judge for himself.

I. In regard to tenancy at will and to leases, little need be added to the observations made in previous chapters of this article. For the consideration, however, of those who insist on the undoubted fact that in Great Britain, where tenancy at will is still the rule, and leases as yet only the exception, the same families, although liable to be ousted at six months' notice, are nevertheless often found occupying the same land from generation to generation, the following may be suggested as a not improbable explanation of the landlord's non-exercise of the power of eviction. It may perhaps be not so much that the farmers really confound past continuity with future permanency of tenure, as that their want of security for the future prevents their investing liberally in improvements, and thereby bringing the land into a condition calculated to attract higher bidders for its possession. Such increase as does take place in its lettable value is chiefly due to enhancement of the prices of produce; and to a rise of rent proportionate to such enhancement the old tenants readily submit rather than be removed. The principal loser here is the landlord, whose short-sighted policy deters his tenants from a species of enterprise the benefit of which would eventually become principally his own. If the tenants took the trouble to make the comparison, they might, it is true, deliberately prefer the mere chance of a long series of years at a low rent to the certainty of the same low rent for a limited term, coupled with the nearly equal certainty of a rise of rent at the end of the term. Their gains in the former case, they might argue, however meagre, might at least be easily earned; whereas materially to increase them in the latter case, although perhaps possible, would be possible only at the expense of much anxiety of mind as well as of much extra sweat of the brow.

II. Of *grande culture*, or large farming, it may perhaps be thought almost superfluous here to enumerate the recommendations, which indeed on one condition are obvious and incontrovertible. Provided a large farmer be possessed of capital duly proportioned to the extent of his holding, and of intelligence to employ his capital judiciously, his husbandry can scarcely fail to prove abundantly satisfactory. In a territory entirely parcelled out among farmers of this description there would, from a purely agricultural point of view, seem little left to desire. The system certainly approaches towards the realisation of the great object of all agriculture—that of the production of the greatest possible quantity and the best possible quality of raw material for the use of man. The distinguishing characteristic of large culture is the scope it affords for the application to husbandry of the great principle of division of labour. A well-managed large farm is indeed a factory for the production of vegetable and animal substance. The extensive scale on which operations are there carried on necessitates the employment of several persons, to each of whom some special occupation may be assigned, and constant practice naturally increases the labourer's skill. Time, too, is saved which would otherwise be lost in turning frequently from one occupation to another; and there is also a further saving in implements, large and small, and in draught cattle, fewer of which will suffice for the tillage of a given area held entire than would be needed if the same acreage were divided amongst numerous tenants. Some, again, of the more important of agricultural operations, and notably those of drainage and irrigation, are in many situations incapable of being efficiently performed except on a large scale; and though they may be, and often are, most efficiently performed on the very largest scale by a combination of small landholders, still every such combination must necessarily be preceded by negotiations involving indefinitely prolonged delay, with which a single individual, occupying the entire tract, could at his option dispense. And a similar remark applies to the costlier implements and machines, in the adoption of which associations of small farmers may slowly follow the example of individual large farmers, but which they would not, without such example, have themselves adopted—which, indeed, unless previously patronised by large farmers, would never have been offered for their adoption. Probably no inventive genius, however disinterestedly ardent, would have been at the pains to devise a steam thrashing-machine or a steam plough, had there not been wealthy agriculturists, some of whom might readily be persuaded to risk, at their own cost and charges, an immediate trial of any promising invention. Farmers of limited means, even when living in the same neighbourhood, would have to be educated into faith in the novel apparatus before the inventor would get a single specimen taken off his hands.

Besides, wherever large farming prevails, large properties are its invariable concomitants; and wherever it is the fashion for proprietors to reside on their estates, many of them are sure to amuse themselves with farming. Very likely, if they were to count the cost, they might find the amusement an expensive one. Not impossibly they often spend on the land as much as they get back from it, or even more, the expenditure in that case at best producing only its bare equivalent. But the same expenditure, unless so applied, would as likely as not have remained utterly unproductive, being devoted to some other amusement, or to mere parade or luxury, from which no tangible return whatever would be possible; so that its application to agricultural extravagance is virtually a gain, in the sense, at all events, of preventing total loss. Nor in that sense only; for rich men who take to farming as a pastime are precisely those most likely to be forward in putting new inventions and new processes to the test of experiment; while the experience thereby acquired, instead of being jealously concealed, is liberally published far and wide, so becoming the property of the whole body of farmers by profession, and serving them, according to circumstances, as a guide to follow or a beacon to avoid. Every one interested in such matters knows how much has been done in this way by successive Dukes of Bedford and Portland and Marquesses Townshend; by the late Earls of Leicester and Scarborough and Earl Spencer; and by the present Earl of Ducie and Earl Grey; nor are there many ways in which a landed aristocracy can better rebut the reproach of inutility than by thus doing honour to agriculture, and having the honour reflected back on themselves.

As already hinted, however, it is only on condition of being conducted with adequate capital that large farming can succeed. True, with deficient capital small farming could succeed no better, perhaps indeed not so well; but then there is much more danger of the needful capital being wanting to a large farmer than a small one. Whatever, from £5 to £20, be the desirable proportion per acre, the number of persons possessing the £50 or £200 required for stocking a farm of ten acres is likely to be everywhere many times more than fifty-fold that of those possessing the £2500 or the £10,000 which a single farm of 500 acres would require. Besides, in countries abounding with fortunate individuals able to count their pounds sterling by the thousand, promising modes of investing such considerable sums abound proportionally; and even in a country so exceptionally rich as our own, the number of capitalists prepared to invest their thousands in farming is sadly below the number of farms which would be all the better for having the same thousands so invested. We are justified then by experience in saying, that wherever large farming is the rule, there will probably be very many farmers without adequate capital. Now, in agriculture, inadequate capital means, among other things, insufficient live stock and insufficient manure, and, as an inevitable consequence, defective crops. It means, in short, imperfect cultivation.

III. From these premises it would apparently result that small farmers will generally be more nearly provided with the capital required for their business than large ones; and such seems to be actually the fact whereever peculiar circumstances have not been at work as preventives. It is not indeed so in Ireland, where feudal oppression or anarchy, alternating with alien misrule, has in all generations made destitution the heritage of the peasantry. Neither is it so in France, where the swarms of petty landholders had little of either precept or example to teach them that to employ their spare napoleons in thoroughly cultivating the few acres they already possess, would be a much better investment of their money than the purchase with it of an additional acre or two to be as imperfectly cultivated as the rest. In England the system of small cultivation, strictly so called, has probably ceased to exist, now that amateur farming has come so much into fashion, and that the instances have become comparatively so numerous of men of considerable substance turning to farming for a livelihood. It will not, however, help us much, when endeavouring to ascertain the relative merits of two rival agricultural systems, to contrast good specimens of the one and bad specimens of the other. If we would accurately gauge their respective capabilities, we should take them both at their best, and the comparison here of large with small farming will accordingly be of the former as it presents itself in England, and of the latter as developed in Flanders. Now, in the territory first named the average capital of occupants of 100 acres and upwards would certainly not be understated, and would probably be materially overstated, at £6 per acre; yet M. de Laveleye, while giving £8 as the average for Flanders (where the medium size of farms is but 7½ acres in the western, and no more than 5 acres in the eastern province), adds that good farmers, judging of others by themselves, would call that sum much too low even for an average; and further remarks that, although a small tenant may, on entering, have only £8 an acre, the additions he is continually making to his live stock, and his continually increasing purchases of manure, commonly raise the £8 to £16 before the expiration of his lease. He also informs us that in other Belgian districts—in the Hesbayan portions of Brabant and Hainault, whereof one-sixth is occupied by farms of 100 acres and upwards, and in the Condrusian portion of the province of Namur, where farms of 250 acres and upwards are pretty numerous—a farmer's average capital is estimated at between £5, 12s. and £6, 8s., and between £3 and £4 per acre respectively. True, as already intimated, there are certain descriptions of stock on which the small farmer's expenditure must necessarily somewhat exceed his rival's—ten Flemish farmers of 10 acres each being probably obliged to keep ten horses, while an English farmer of 100 acres might not perhaps have occasion for more than a pair, reducing also his number of carts, ploughs, and the like, in similar proportion. But after all reasonable deduction on this account, the balance of capital remaining for the purchase and maintenance of those animals and materials of which no farmer ever has too many or too much, is in general much greater in the Fleming's case than in the Englishman's. "It would startle the English farmer of 400 acres of arable land," said Mr Rham forty years ago, "to be told that he should constantly feed 100 head of cattle, yet this would not be too large a proportion if the Flemish system were strictly followed, a beast for every 3 acres being a common Flemish proportion, and *on very small occupations*, where spade husbandry is used, the proportion being still greater." "That the occupier," he proceeds, "of only 10 or 12 acres of light arable soil should be able to maintain four or five cows may appear astonishing, but the fact is notorious throughout the Waes country." These statements are of somewhat ancient date, but are still as applicable as ever. During a recent tour through Belgium, the present writer visited two farms near St Nicolas, in the Pays de Waes—the first two that came in his way. On one, of 10 acres, he found four cows, two calves, one horse, and two pigs, besides rabbits and poultry. On the other, of 38 acres, one bull, six cows, two heifers, one horse, and seventy-five sheep—these last, however, being allowed, in addition to what they got on their owner's ground, the run of all the stubbles in the commune; the whole commune, on the other hand, being allowed the use of the bull gratis. A few days later the writer went over a farm a few miles from Ypres. On this, of 32 acres in extent, he counted eight cows, six bullocks, a calf eight weeks old, and four pigs. To possess plenty of live stock is to possess in an equal abundance the first requisites of sustained fertility. "No cattle, no dung; no dung, no crop," is a Flemish adage; and the wealthiest of English agriculturists are less prodigal of manure than the Flemish peasantry. Mr Caird, in his instructive and interesting treatise on *English Agriculture*, cites as something extraordinary that, for a farm six miles from Manchester, manure should have been bought at the rate of 12 or 13 tons an acre; but this, which in England passes for lavishness, might seem more like niggardliness in Flanders; for there from 10 to 15 tons of good rotten dung and 10 hogsheads of liquid from the urine tank, per acre, are quite common sacrifices and libations to the Sterculine Saturn, and some 30s. worth of purchased fertilisers—bones, wood-ashes, linseed-cake, and guano—are not unfrequently superadded. Nay, when potatoes are the crop for whose increase the deity is invoked, 60 tons of manure per acre are no unusual quantity to lay on. The holder of the farm of 32 acres near Ypres, just alluded to, assured the writer, in his landlord's presence, that, over and above what his own cattle supply, he purchases manure to the value of no less than £200 annually.

One of the respects in which small culture has been admitted to stand at some disadvantage in comparison with large is that of division of labour; but against whatever loss of time or even inferiority of skill may result from the necessity there is for each of the labourers engaged in the former culture to occupy himself with a variety of operations instead of confining himself to one, are to be set the additions voluntarily made to the labour employed, and also its superior heartiness. The tillage of a small farm is executed often entirely, and always in great measure, by the farmer himself and the members of his family; and when these have adequate security that the entire increase of the soil, over and above a specified quantity, will belong to themselves, they generally do their utmost to make the increase as large as possible. Not, indeed, always. Industry, in common with other virtues, is greatly influenced by example; and small leaseholders, or even small freeholders, thinly interspersed among numerous tenants-at-will, are much more likely to accept as their standard of becoming exertion the habitual listlessness of the latter than to set up an independent standard of their own. Where, however, small farmers are in a decided majority, they are, unless some extraordinary circumstances are in operation to depress their energy, sure to appear as models of diligence. Their activity is not then restricted within set hours of work. Whenever a thing requires to be done is with them the proper time for doing it, and early and late, consequently—long before the hired journeyman comes in the morning and long after he has gone home in the evening—they may be seen afield, doing, too, whatever they do, not only with all their might, but with all the heed which people usually bestow on their own affairs, even though they bestow it on nothing else. In particular, they waste nothing—least of all anything that can be used as manure. Now, there are no crops which would not be the better for such special attention, and there are some to which it is an almost indispensable condition of excellence. Flax, hemp, hops, wine, oil, and tobacco furnish instances of culture in which the individual plants require, or at any rate abundantly repay, separate care. But such minute attention no supervision can ensure—no rate of hire can command. It is habitually rendered by those only who are directly interested in rendering it, or otherwise directly stimulated—by the small farmer and the small farmer's wife and children all working with their own hands for their own behoof, and by his servants, if he have any; for that must be a pitiful creature indeed who, with his employer working by his side, will let his employer work harder than himself. Herein, then—(in the greater quantity and better quality of work which the same number of persons will do in small as compared with large farming)—consisting the distinctive excellence of the former system, how far does this counterbalance the superiority of large farming in regard to the saving of labour and implements? There can be no more conclusive mode of answering this question than by contrasting the substantial results of the two systems, adopting as tests the respective amounts both of gross and of net produce. Now, in England the average yield of wheat per acre was in 1837 only 21 bushels, the highest average for any single county being no more than 26 bushels. The highest average since claimed for the whole of England is 32 bushels; but this is pronounced to be much too high by the best, perhaps, of all authorities, Mr Caird, who gives 26½ bushels as "the average of figures furnished to him by competent judges in all parts of the kingdom," adding, as the result of his own observation, that 32 bushels, as an average produce, is to be met with "only on farms where both soil and management are superior to the present average of England." In Jersey, however, where the average size of farms is only 16 acres, the average produce of wheat for the five years ending with 1833 was, by official investigation, ascertained to be 40 bushels. In Guernsey, where farms are still smaller, 32 bushels per acre was, according to Inglis, considered, about the same time, "a good, but still a common, crop;" and the light soil of the Channel Islands is naturally by no means particularly suitable for the growth of wheat. That of Flanders, originally a coarse silicious sand, is particularly unsuitable, and accordingly little wheat is sown there, but of that little the average yield, at least in the Waes district, is, according to a very minute and careful observer, from 32 to 36 bushels. Of barley, a more congenial cereal, the average is in Flanders 41 bushels, and in good ground 60 bushels; while in England it is probably under 33, and would certainly be overstated at 36 bushels. Of course the English averages are considerably exceeded in particular localities—on such farms, for instance, as those of Mr Paget, near Nottingham, and of Mr Stansfeld, in the West Riding of Yorkshire, wheat crops of 46 bushels per acre being not extraordinary, and of 56 bushels not unknown; but these exceptional cases may be more than matched in Guernsey, where the largest yield of wheat per acre, in each of the three years ending with 1847, was proved to the satisfaction of the local agricultural society to have been not less than 76, 80, and 72 bushels respectively. Of potatoes, 10 tons per acre would anywhere in England, even on the rich "warp lands" bordering the tidal affluents of the Humber, be considered a high average crop; but in Jersey the average is reckoned at 15 tons, and near Tamise, in eastern Flanders, Mr Rham found a cultivator of 8 acres of poor land raising nearly 12 tons from one of them. Clover, again, "the glory of Flemish farming," "is nowhere else found in such perfect luxuriance" as in Flanders, where it exhibits "a vigour and weight of produce truly surprising," especially when it is discovered "that such prodigious crops are raised from 6 lb of seed per acre." Most of the other green crops, and also most of the root crops, grown in Flanders deserve to be spoken of in similar terms; and to the extraordinary number of cattle fed upon these green and root crops reference has already been made. If any reliance may be placed on these statistics, it cannot, however startling at first hearing, be too much to affirm that in the Channel Islands and in Flanders the average of gross produce is greater than in England by fully one-fourth, or say by the equivalent of 9 bushels of wheat per acre.

Gross produce, however, is not the only thing to be considered, for there is no doubt that on equal areas small farming employs more hands than large; and it might be that the entire produce of a small farm was not more than sufficient to feed the extra mouths. This would not necessarily be an evil, unless on the assumption that the condition of agricultural labourers is necessarily so wretched that an increase in their number is tantamount to an increase of wretchedness. Possibly, however, the extra produce might be less than sufficient to feed the extra mouths, so that the quantity of net produce remaining available for sale to the non-agricultural portion of the community would be diminished; and, if this were really the fact, it might be conclusively condemnatory of small farming. Nor, to prove that it is not the fact, will it suffice to urge that land, when divided among numerous occupants, commonly fetches a much higher rent than when united into a few extensive holdings—that whereas, for example, 30s. an acre would in England be considered a fair and even a high rate for middling land, it must be very middling land indeed which in Guernsey will not let for at least £4, while in Switzerland, another territory of *petite culture*, the average rent is £6. For these higher rents might be the results of an incident, not of culture, but of tenure—of that excessive competition for land which is unhappily a too frequent accompaniment of small farming. Neither will it suffice to show that, although the agricultural population of a minutely-divided territory is always far denser than that of one of large farms, certain territories of the former description are nevertheless among those which maintain the largest manufacturing and commercial population—Belgium, for instance, being second to England alone in that respect, and Switzerland and Rhenish Prussia being likewise cases in point. For it may obviously be replied that the non-agricultural classes of a community need not be entirely dependent for food on home produce, but may derive part of their supplies from abroad, and it may generally be impossible to ascertain what is the proportion imported. This objection does not, indeed, apply to the Channel Islands; and Mr W. T. Thornton has, in a new edition of his *Plea for Peasant Proprietors*, been at considerable pains to prove that in Guernsey two, and in Jersey four, non-agricultural inhabitants are maintained on the produce of every acre and a half of cultivated land, whereas in England only one such person is so fed. Be this as it may, a preferable, or at any rate more generally applicable, test is the proportion between the extra production of small farming and the consumption of the extra labourers therein employed. Now, in Flanders and in the two principal Channel Islands the agricultural population is about four times as dense as in England, being at the rate of about one person for every 4 acres, instead of one for every 17; but cause has also been shown for believing that in Flanders and in the same islands the average produce of the soil is greater than in England by the equivalent of 9 bushels of wheat per acre, or of 153 bushels for every 17 acres. But 153 bushels, or say 19 quarters, of wheat is much more than three persons—and these not all adult males, but, more likely, a man, a woman, and a child—would consume, even if it were supplied to them, and there were nothing else for them to eat, and is fully three times as much as three such persons of the farm labourers' class in any part of Europe have the means of procuring. After deduction, therefore, of their consumption, there would still remain available for sale to non-agriculturists from the produce of

17 acres under small culture, the equivalent of nearly 100 bushels of wheat more than could be spared for the same purpose from an equal extent of land under a large farmer. These conclusions are not put forward as more than roughly approximate, nor, indeed, in the present disgracefully defective state of British agricultural statistics, are any but rough approximations on the subject possible. But, unless very wide indeed of the truth, they must be acknowledged to furnish adequate reason why rural magnates should not engross all our praises, and why the honest agricultural muse should reserve a share of commendation for small leaseholding farmers also.

IV. And while so much can be said for small leaseholders, it is obvious that every one of the arguments adduced in favour of that class applies with redoubled force to small freeholders cultivating their own freeholds. A peasant proprietor, whose whole produce belongs to himself, is of course richer than he would be if he had to pay rent—can more easily bear the expenses of cultivation, of procuring proper implements and manure, of drainage and irrigation, and of the keep of live stock. Small leaseholders, as a class, lay out more money on their land, in proportion to its extent, than large occupiers; but a small freeholder has more money to lay out than a leaseholder of the same degree, and has besides stronger motives for laying it out on improvements. "A small proprietor," says Adam Smith, "who knows every part of his little territory, who views it with all the affection which property, especially small property, naturally inspires, and who, upon that account, takes pleasure not only in cultivating but in adorning it, is generally of all improvers the most industrious, the most intelligent, and the most successful." It might have been added, that he is likewise the most enterprising. He need not carefully calculate whether his outlay will be fully recovered by him within a certain term of years; he has only to consider whether the increased value of his land will be equal to fair interest on the sum which the improvements will cost. He does not require that the principal should ever be returned. He is satisfied to sink it for ever in his own land, provided that, in that safest of all investments, it promise to yield a perpetual annuity equal to what would be its annual increase in another employment.

Again, the peasant proprietor has the strongest possible incentives to diligence. A man never works so well as when paid by the piece; but even then, the more he is paid, the better he works. The small leaseholder, not less than the small proprietor, is paid in proportion to his labour; but the latter is paid at a higher rate, for he takes to himself the whole fruit of his labour, while the former must content himself with part. The proprietor, too, knows that, so long as his labour continues equally productive, his remuneration will remain the same; while that of the tenant, though augmented solely by his own exertions, may be diminished at the expiration of his lease. Besides, many rural operations yield no profit until after a long lapse of time; and the annual profit of others is so small that the enjoyment of it in perpetuity is requisite to recompense the labour expended. Such operations are seldom undertaken except by proprietors. No tenant would think of planting an orchard such as Arthur Young saw near Sauve on a tract consisting "seemingly of nothing but bare rocks;" or, as in the mountains of Languedoc, would "carry earth in baskets on the back to form a garden where nature had denied it;" or would enclose and till fields and gardens on a "wretched blowing sand naturally as white as snow." But, as Young exclaims, "give a man the secure possession of a bleak rock, and he will turn it into a garden!" There is "no way so sure of carrying tillage to a mountain-top as by permitting the neighbouring villagers to acquire it in property. The magic of property turns sand to gold." It may perhaps be objected that the gold does not repay the cost of transmutation, and that therefore the labour expended upon it has been wasted; and no doubt a monied speculator, who should engage in such alchemy with hired labour, might never recover the amount of his outlay. But—and here comes a conclusive answer to those who, instead of admiring such achievements, condemn them as mere waste of power—the peasant who performs them on his own account performs them with labour which would otherwise be valueless at that particular time. When the hired journeyman has earned his day's wages, and gives himself up to rest or amusement, the little landowner is content to recreate himself by turning to some lighter work. It is sufficient amusement for him to weed or water his cabbages, or to train or prune his fruit-trees; and, in wet or wintry weather, when outdoor work is scarce worth paying for, and when the day-labourer must often remain idle because no one will employ him, then it is that the independent cottager builds up terraces on the steep hillside, or lays the site of a garden among rocks. It is, in short, one prime excellence of peasant proprietorship that it stirs into activity labour which otherwise would not have been exerted—in other words, would not have existed, and the fruits of which, consequently, however insignificant, are at any rate all pure gain.

The pastoral tribes, by which most civilised countries were originally occupied, have almost invariably been followed, either immediately or after a certain interval, by a race of peasant proprietors. The revolution has taken place at different stages of national progress, but scarcely an instance can be mentioned in which it has not occurred sooner or later. In territories of very small extent, very barren or much intersected by mountains, rivers, or other natural barriers, it has commonly been coeval with the first appropriation of land by individuals. In such situations, the original tribes of nomad herdsmen must necessarily have been small for want of pasture; and the same cause must have prevented any individual from acquiring very great numbers of cattle, and from very greatly surpassing his companions in wealth and power. All must have been nearly equal in rank; and, whenever a partition of their common territory was resolved upon, every one, no doubt, made good his claim to a share. On the other hand, in countries containing abundance of good pasture, separate tribes might expand indefinitely, and the cattle of single proprietors be counted by thousands and tens of thousands. Great wealth would then imply great disparity of rank, and rich herdsmen would have many poor retainers entirely indebted to their bounty, and consequently entirely devoted to their service. Such dependants, when the community passed from a migratory and pastoral to a stationary and agricultural condition, could put forward no pretensions on their own behalf. Their relation to their masters would remain the same as before, or rather would be exchanged for a more stringent form of bondage. From servants they would become serfs, and the duty assigned to them would be that of tilling their masters' fields, as they had previously tended his herds. In the course of ages, however, they would imperceptibly acquire some important privileges. Residing for many successive generations on the lands allotted to them for their own subsistence, and paying to their lord always the same, or nearly the same, portion of the produce, they would come at length to be regarded as conditional proprietors of their respective holdings, or as perpetual lessees at a quit and almost nominal rent. Their proprietary title, although at first merely prescriptive, would be eventually legalised; and thus it is that from villeins and serfs has descended a progeny no less respectable than English copy-holders and German bauers.

V. In one or other of these ways almost every country on the face of the globe which has passed regularly through the various stages that separate barbarism from civilisation, has been at some period, as many are still, occupied in great measure by peasant proprietors. In those countries, however, in which peasant proprietorship has been evolved from serfdom, there must have been, intermingled with the lands held by servile tenure, others, not less extensive, in the immediate occupation of a rural aristocracy. These seignorial domains would long continue to be cultivated by the serfs or slaves of their respective owners, but as feudal and domestic slavery fell into desuetude, the landlords, in order to get their lands tilled, would be reduced to the necessity of holding out inducements to free husbandmen to lend their assistance. In England, where, thanks to the comparative security enjoyed by industry, plebeians of some substance were already not rare, it might suffice to offer tenancies for terms of years or for lives; but, in those continental countries in which feudal misrule had given way, only to be replaced by monarchical tyranny, it was generally necessary for the landowner, who desired that his farms should be tolerably stocked, to stock them himself. Hence arose a system which, having never existed in England, has no English name, but which in certain provinces of Italy and France, where it was once almost universal, and is still very common, is called *mezzeria* and *métayage*, or halving—the halving, that is, of the produce of the soil between landowner and landholder. These expressions are not, however, to be understood in a more precise sense than that in which we sometimes talk of a larger and a smaller half. They merely signify that the produce is divisible in certain definite proportions, which must obviously vary with the varying fertility of the soil and other circumstances, and which do in practice vary so much that the landlord's share is sometimes as much as two-thirds, sometimes as little as one-third. Sometimes the landlord supplies all the stock, sometimes only part—the cattle and seed perhaps, while the farmer provides implements; or perhaps only half the seed and half the cattle, the farmer finding the other halves—taxes too being paid wholly by one or the other, or jointly by both.

Now, with whatever virtue a system like this may be conditionally credited, it plainly can have no virtue at all except on condition of its being believed to be permanent. The *métayer* must have full confidence that the landlord, although authorised by law, will be prevented by respect for custom, from increasing his exactions; but even on this condition the system is open to the serious objection, that the metayer will deem it his interest to lay out on the land as little as possible, if anything, of his own, except labour. If in England, previously to tithe commutation, a farmer was discouraged from spending money on improvements by the knowledge that the parson would claim one out of every ten additional sheaves of corn or pounds of butter produced in consequence, what chance is there of a metayer risking a similar expenditure, while knowing that the landlord's share of the consequent produce would be a moiety or more instead of a tenth? In this particular, metayage closely resembles English tenancies at will, which practically render it almost equally incumbent on the landlord to bear the entire expense of all costly improvements, and over which métayage, in another and nearly allied particular, possesses a marked advantage. Although the métayer may, for one very cogent reason—a reason, however, likely to be somewhat counteracted by belief, whether well or ill founded, in the fixity of his tenure—be reluctant to use in his business any capital of his own, he will, for the converse of that same reason, be anxious to make the most of the capital entrusted to him by his landlord. He is his landlord's partner, entitled to a moiety or thereabout in his landlord's gains. It is his interest, then, to get the most out of the land that can be brought out of it by means of the landlord's stock. Virtually, indeed, he is himself, in a qualified sense, a peasant proprietor, possessing in a minor degree all the stimulants to diligence, heedfulness, and thrift, incidental to that character; and there can scarcely, therefore, be inherent in his constitution any such incurable vice as would warrant his being condemned *a priori*. Equally with other people he is entitled to be judged by his behaviour. As to this the testimony of experience is very conflicting. English writers who see nothing of métayage at home, and may be suspected of looking with not wholly unprejudiced eyes at what they see of it abroad, were, until Mr J. S. Mill adopted a different tone, unanimous in condemning it. They judged it, however, by its appearance in France, where it has never worn a very attractive aspect. In that country every form of agriculture still retains many of the traditions of the ante-Revolutionary period, and métayage, in particular, labours under great difficulties in consequence. Under the *ancien régime* not only were all direct taxes paid by the métayer, the noble landowner being exempt, but these taxes, being assessed according to the visible produce of the soil, operated as penalties upon all endeavours to augment its productiveness. No wonder, then, if the métayer fancied that his interest lay less in exerting himself to augment the total to be divided between himself and his landlord, than in studying how to defraud the latter of part of his rightful share; nor any great wonder either if he has not yet got entirely rid of habits so acquired. Rather would it be strange if he had, especially when it is considered that he still is, as his predecessors were formerly, destitute of the virtual fixity of tenure without which métayage cannot reasonably be expected to prosper. French métayers, in Arthur Young's time, were "removable at pleasure, and obliged to conform in all things to the will of their landlords," and so in general they are still. Yet even in France, according to M. de Lavergne, although "métayage and extreme rural poverty usually coincide," there is one province, Anjou, where the contrary is the fact, as it is also in Italy. Indeed, to every tourist who has passed through the plains of Lombardy with his eyes open, the knowledge that métayage has for ages been there the prevailing form of tenure ought to suffice for the triumphant vindication of métayage in the abstract. Its perfect compatibility with the most flourishing agriculture must be clear to any one who, noting the number and populousness of the cities in the Lombard provinces, is at the same time aware how much of agricultural produce those provinces export and how little they import. An explanation of the contrasts presented by métayage in different regions is not far to seek. Métayage, in order to be in any measure worthy of commendation, must be a genuine partnership, one in which there is no sleeping partner, but in the affairs of which the landlord, as well as the tenant, takes an active part. If he do this, he cannot be an absentee. He must be on the spot to judge when and what advances are required from him, and to watch over their proper application; to that end conferring habitually with the métayer, and taking as well as giving counsel on the subject, as on one in which both are equally concerned. This exhibition of common interest on one side is sure to beget it, if previously wanting, on the other; feelings of mutual attachment insensibly spring up, and the spirit which governs the mutual relations becomes one of friendly and almost affectionate association. Such is, or at any rate used to be, the state of affairs in Piedmont, in Lombardy, and in Tuscany; and wherever the same description applies, the results of métayage appear to be as eminently satisfactory, as they are decidedly the reverse wherever the landlord holds himself aloof, contenting himself, as it were, with putting out his stock to usury, and never intervening except to carp at the smallness of the returns. Instead of community, there is then conflict, of interests. Antagonism takes the place of association. The landlord grudges the scantiest advances, and even of those the farmer does his best to cheat the soil, which, starved by them who ought to feed it, leaves them to starve in return.

On the whole, and according to preponderance of testimony, métayage must perhaps be admitted to be everywhere showing a tendency to degenerate after the above fashion; yet even so, the worst that need be said of it is, that it is becoming an anachronism; this, moreover, being perhaps a reproach less to itself than to the age in which we live. It is the present generation of mankind who are chiefly to blame if the ties which anciently linked together employers and employed in more or less kindly fellowship, are now-a-days, in agriculture as in other departments of industry, visibly decaying, and if each section of the agrarian class, bidding the others keep their distance, prefers to perform its own functions separately, and without more of natural intercourse than business obligations, arranged beforehand, render indispensable. But whenever, from whatever cause, landowners have come to be regarded by landholders as mere receivers of rent, métayage cannot possibly thrive, and it is accordingly dying out, even in the quarters to which it has hitherto appeared most congenial. Even in the Milanese, where the minute and assiduous attention to details which métayers, next after peasant proprietors, can best be depended on for bestowing, is in especial demand for sericulture and viticulture, métayage is undergoing changes which M. de Laveleye (*Economie Rurale de la Lombardie*) describes as follows:—

"The primitive conditions of contract which fixed, according to local and traditional usage, the cultivator's share, are daily more and more departed from. For a considerable time past, in the parts about Como and Milan, to the arrangement for sharing by halves, which now applies only to plantation crops, grasses, and cocoons, has been added a clause providing for the annual payment of a determinate quantity of corn; and, as this quantity is settled no longer by local custom, but by the demands of the proprietors and the offers of intending tenants, it follows that métayage is losing its character of fixity, and falling under the law of increase which governs farming rent. The clause in question is continually becoming more and more of a habit; and, even where it has not yet been adopted, the ancient contract has undergone other and not less regretable modifications. The high price of commodities, particularly of silk, having markedly augmented the profits of the métayers, the landlords have availed themselves of this circumstance to introduce new stipulations—sometimes taking more than half of the cocoons, sometimes claiming a quantity of mulberry leaves to sell for their own profit, sometimes taking tithes first and then halving the residue. All this is done with the same aim and the same result, the aim being to secure to the landlord the whole benefit of continually rising prices, the result that of depriving the métayer of the security which the primitive agreement gave him, and of subjecting him to all the disadvantages of a leaseholder without any of the latter's compensations."

VI. The plan of industrial partnerships, wherever it has had a fair trial, has invariably been attended by the happiest results; but it has hardly yet been fairly tried in farming, where, however, its application would in one respect be comparatively easy. In most other kinds of business, to determine to the satisfaction of both parties concerned how much, if any, of extra profits had been due to extra zeal on the part of the employed, might be an operation of some difficulty; but there need never be any doubt whether the crops of a given acreage were or were not above the average, or what, therefore, if any, was the surplus in which, according to the agreement, the employed were entitled to participate. That farmers would risk but little and only occasional loss, and in the long run would be sure to gain considerably, by permitting their labourers to share with them in a surplus which the labourers would have by voluntary exertion to create before they could share in it, may perhaps to an indifferent bystander seem a self-evident proposition. Farmers in general, however, may long be prevented from recognising its truth by an intervening haze of traditional prejudice, which must first be cleared away, and the removal may occupy so much time that not improbably another and more advanced form of agricultural co-operation, not needing the farmers' concurrence, may in the mean time come into vogue.

Intermingled with the multitudinous peasant proprietary of France are not only a much larger number of well-to-do country gentlemen than is commonly supposed, but also a not inconsiderable sprinkling of rural magnates, who, even beside English dukes, might well pass for extensive landowners. Among these latter are representatives of some of the oldest and noblest French families—men rejoicing in the grand historic names of Rochefoucauld, Noailles, Luynes, Montemart, D'Usez, and the like—who having at the restoration been partially reinstated in the domains of which the first revolution had despoiled them, disappeared, on the second expulsion of the Bourbons, from court and office, and, returning to their country seats, betook themselves, under the Orleanist dynasty and second empire, to the improvement of their estates. A difficulty which here confronted them was that of finding tenants possessed of capital enough for any but very small farms, and this they have latterly endeavoured to obviate by devising, under the name of *métayage par groupes*, an expanded modification of a discredited tenure. This consists in letting a considerable farm, not to one *métayer*, but to an association of several, who work together for the general good, under the supervision either of the landlord himself, or of a manager or bailiff of his appointment. This plan is by no means the novelty it may perhaps appear, its near counterpart having within the present century existed in some singular patriarchal communities —Jaults, Guittards, and Garriotts (see Thornton *On Labour*, 2d edition, pp. 488–90), in Nivernais and Auvergne, and still existing among the *massari* of the subalpine districts of northern Italy. Its merit consists in its tendency to excite among the associates the generous emulation and other healthy stimulating and controlling influences of co-operative fellowship; but as yet it has scarcely been long enough in operation to show very decisively how it is likely to work. In the event of its proving a marked success, it may become the starting-point of much further progress. One easy and important step in advance would be for a body of métayers to persuade their landlord to let them have their farm on lease, and at a fixed rent, thus raising themselves to that higher stage of agricultural co-operation of which an imperfect but encouraging example has been afforded among ourselves by Mr Gurdon's well-known experiment at Assington in Suffolk. Of the two or three scores of labourers who are there parties to the leases by which two farms—one of 130, the other of 212 acres—are held, not more than ten or a dozen have regular work in their own fields, the rest being therefore little more than passive capitalists, sleeping partners in the concern, while the active members receive, in addition to wages at the rates current in the neighbourhood, no larger shares in the profits than the members who do not exert themselves to increase those profits. Nevertheless, to sum up in a single phrase of especial significance for our present purpose the praises of the results achieved, Mr Gurdon declares that "he has no other land so well farmed" as that on which the co-operative principle is even thus partially applied. It would seem, therefore, that the adoption of the same principle in its integrity would result in better farming still, and it may be hoped that the question will, at Assington or elsewhere, be ere long put to the proof. (W. T. T.)

Alphabetical Contents.

AGRIGENTUM, in *Ancient Geography*, a city on the south coast of Sicily, part of the site of which is now occupied by a town called *Girgenti*, from the old name. (See GIRGENTI.) It was founded by a colony from Gela, 582 B.C. An advantageous situation, a free government, and an active commercial spirit raised the city to a degree of wealth and importance unknown to the other Greek settlements, Syracuse alone excepted. The prosperity of Agrigentum was interrupted by the usurpation of Phalaris which lasted about fifteen years. He met with the common fate of tyrants, and after his death the Agrigentines enjoyed their liberty for sixty years; at the expiration of which term Theron usurped the sovereign authority. The moderation, justice, and valour of this prince preserved him from opposition. He joined his son-in-law Gelon, king of Syracuse, in a victorious war against the Carthaginians. Soon after his decease, 472 B.C., his son Thrasydeus was deprived of the diadem, and Agrigentum restored to her old democratical government, which she retained till the Carthaginian invasion in 406 B.C. During this interval of prosperity were executed most of those splendid public works which excited the admiration of succeeding ages, and caused Empedocles to remark "that the Agrigentines built their dwellings as though they were to live for ever, and indulged in luxury as if they were to die on the morrow." The total number of the inhabitants at this period was estimated by Diodorus at 200,000. The power of the Agrigentines now experienced a terrible reverse. They were attacked by the Carthaginians in 406 B.C., their armies routed, their city taken, and their race almost extirpated, scarcely a vestige of their material greatness being left. Although some of the fugitive inhabitants availed themselves of permission to return to the ruined city, and after a few years were even able to shake off the yoke of Carthage, Agrigentum never fully recovered from this fatal disaster. Such was the condition of the city 340 B.C. that Timoleon, after his triumph over the Carthaginians, found it necessary to recolonise it with citizens from Velia in Italy. During the first Punic war Agrigentum was the headquarters of the Carthaginians, and was besieged by the Roman consuls, who, after eight months' blockade, took it by storm. It nevertheless changed masters several times during the contest, and in every instance suffered most cruel outrages. At the close of the war Agrigentum finally fell under the dominion of Rome.

The profuse luxury and display for which the Agrigentines are celebrated in history were supported by a fertile territory and an extensive commerce, by means of which the commonwealth was able to resist many shocks of adversity. It was, however, crushed in the fall of the Eastern Empire, and the Saracens obtained possession of the city.

Agrigentum occupied a hill rising between the small rivers Agragas and Hypsas, and was remarkable for its strength as a fortress. The whole space comprehended within the walls of the ancient city abounds with traces of antiquity. Of its many celebrated edifices, the most magnificent was the temple of Olympian Jupiter. Of this vast structure nothing remains except the basement and a few fragments of the columns and entablature; but these and many other monuments attest the ancient magnificence of the Agrigentines.

AGRIONIA, festivals celebrated annually by the Bœotians in honour of Dionysus, in which the women, after playfully pretending for some time to search for thet god, desisted, saying that he had hidden himself among the Muses. They were solemnised at night by women and the priests only. The tradition is that the daughters of Minyas, having despised the rites of the god, were seized with frenzy and ate the flesh of one of their children, and that the Agrionia were celebrated in expiation of the offence.

AGRIPPA, HEROD, the son of Aristobulus and Berenice, and grandson of Herod the Great, was born about 11 B.C. Josephus informs us that, after the death of his father, Herod, his grandfather, sent him to Rome to the court of Tiberius. The emperor conceived a great affection for Agrippa, and placed him near his son Drusus whose favour he very soon won, as well as that of the empress Antonia. On the death of Drusus, Agrippa, who had been recklessly extravagant, was obliged to leave Rome, overwhelmed with debt, and retired to the castle of Malatha. After a brief seclusion, Herod the tetrarch, his uncle, who had married Herodias, his sister, made him principal magistrate of Tiberias, and presented him with a large sum of money; but his uncle grudging to continue his support, and reproaching him with his bad economy, Agrippa left Judea, and soon after returned to Rome. There he was received with favour by Tiberius, and commanded to attend Tiberius Nero, the son of Drusus. Agrippa, however, chose rather to attach himself to Caius, who at that time was universally beloved, and so far won upon this prince that he kept him continually about him. Agrippa being one day overheard by Eutyches, a slave whom he had made free, to express his wishes for Tiberius's death and the advancement of Caius, was betrayed to the emperor and cast into prison. Tiberius soon after died, and Caius Caligula ascended the throne 37 A.D. The new emperor heaped wealth and favours upon Agrippa, changed his iron fetters into a chain of gold, set a royal diadem upon his head, and gave him the tetrarchy of Batanæa and Trachonitis, which Philip, the son of Herod the Great, had formerly possessed. To this he added that held by Lysanias; and Agrippa returned very soon into Judea to take possession of his new kingdom. On the assassination of Caligula, Agrippa, who was then at Rome, contributed much by his advice to maintain Claudius in possession of the imperial dignity, to which he had been advanced by the army; and while he made a show of being in the interest of the senate, he secretly advised Claudius to maintain his position with firmness. The emperor, as an acknowledgment of his services, gave him the government of Judea; and the kingdom of Chalcis, at his request, was given to his brother Herod. Thus Agrippa became of a sudden one of the greatest princes of the East, the territory he possessed equalling in extent that held by Herod the Great, his grandfather. He returned to Judea, and governed it to the great satisfaction of the Jews. But the desire of pleasing them, and a mistaken zeal for their religion, impelled him to acts of cruelty, the memory of which is preserved in Scripture (Acts xii. 1, 2, &c.) About the feast of the Passover, 44 A.D., James the elder, the son of Zebedee and brother of John the evangelist, was seized by his order and put to death. He proceeded also to lay hands on Peter, and imprisoned him, delaying his execution till the close of the festival. But God having miraculously delivered Peter from prison, the designs of Agrippa were frustrated. After the Passover, he went from Jerusalem to Cæsarea, where he had games performed in honour of Claudius, and the inhabitants of Tyre and Sidon waited on him to sue for peace. Agrippa having come early in the morning to the theatre to give them audience, seated himself on his throne, dressed in a robe of silver tissue, which reflected the rays of the rising sun with such lustre as to dazzle the eyes of the spectators. When the king had delivered his address, the parasites around him shouted out that it was not the voice of a man but of a god. The vain Agrippa received the impious flattery with complacent satisfaction; but in the midst of his elation, looking upwards, he saw, with superstitious alarm, an owl perched over his head. During his confinement by Tiberius he had been startled by a like omen, which had been interpreted as portending his speedy release, with the warning that whenever he should behold the same sight again, his death was to follow within the space of five days. Seized with terror, he was immediately smitten with disease, and after a few days of excruciating torment, died, according to the Scripture expression, "eaten of worms," 44 A.D.

AGRIPPA, HEROD, II., son of the preceding, born about 27 A.D., was made king of Chalcis on the death of his uncle Herod, 48 A.D.; but three or four years after he was deprived of that kingdom by Claudius, who gave him other provinces instead of it. In the war which Vespasian carried on against the Jews Herod sent him a succour of 2000 men, by which it appears that, though a Jew in religion, he was yet entirely devoted to the Romans, whose assistance indeed he required to secure the peace of his own kingdom. He died at Rome in the third year of Trajan, 100 A.D. He was the seventh and last king of the family of Herod the Great. It was before him and Berenice, his sister, that St Paul pleaded his cause at Cæsarea (Acts xxvi.)

AGRIPPA, MARCUS VIPSANIUS, according to Tacitus, was born of humble parents about 63 B.C. At the age of eighteen he was the chosen companion of Octavius (afterwards Octavianus), the nephew and successor of Julius Cæsar, many of whose successes were mainly due to the courage and military talents of Agrippa. On the assassination of Cæsar, 44 B.C., Agrippa accompanied his friend to Italy, and rendered essential service in the conduct of the first war against M. Antonins, which terminated in the capture of Perusia in 40 B.C. Three years after this Agrippa was made consul, and had the command in Gaul, when he defeated the Aquitani, and led the Roman eagles beyond the Rhine to punish the aggressions of the Germans on his province. But Agrippa was soon summoned to Italy by the critical state of the affairs of Octavianus, the whole coast being commanded by the superior fleets of Sex. Pompeius. His first care was the formation of a secure harbour for the ships of Octavianus, and this he accomplished by uniting the Lucrine lake with the sea. He made an inner haven also by joining the lake Avernus to the Lucrine. In these secure ports the fleet was equipped, and 20,000 manumitted slaves were sedulously trained in rowing and naval manœuvres until they were able to cope with the seamen of Pompeius. Agrippa was thus enabled in the following year to defeat Pompeius in the naval action of Mylæ; and soon after won a more signal victory near Naulochus. These victories gave Octavianus the empire of the Mediterranean, and secured to him Sicily, the granary of Rome, after an easy triumph over his feeble colleague Lepidus; and they prepared the way for the overthrow of the power of M. Antonius, the other triumvir. The merit of all these successes was very much due to the skill, resolution, and sagacity of Agrippa.

Agrippa was chosen ædile 33 B.C., and signalised his tenure of office by great improvements in the city of Rome, in the repair and construction of aqueducts and fountains neglected or injured during the civil wars, and in the enlargement and repair of the sewers. He appears also to have introduced an effectual mode of *flushing* the sewers by conducting into them the united waters of several different streams. From these useful labours Agrippa was again called away in 31 B.C. to command the Roman fleet, which, by the victory at Actium, fixed the empire of the world on Octavianus. The services of Agrippa made him a special favourite with Octavianus, who gave him his niece Marcella in marriage, 27 B.C., when he was consul for the third time. In the following year the servile senate bestowed on Octavianus the imperial title of AUGUSTUS. Agrippa, in commemoration of the naval victory of Actium, dedicated to Jupiter and all the other gods the Pantheon, now called *La Rotonda*. The inscription on its portico still remains, M. AGRIPPA L. F. COS. TERTIUM FECIT. In 25 B.C. we find this eminent man employed in Spain, where he reduced the insurgent Cantabri, the ancestors of the present Biscayans.

The friendship of Augustus and Agrippa seems to have been clouded by the jealousy of Marcellus, which was probably fomented by the intrigues of Livia, the second wife of Augustus, in dread of his influence with her husband. The consequence was that Agrippa left Rome; and though, to cloak his retirement, he was appointed proconsul of Syria, he went no farther than Mytilene. Marcellus dying within a year, Agrippa was recalled to Rome, and being divorced from Marcella, became the husband of the widowed Julia, who was no less distinguished by her beauty and abilities than afterwards by her shameless profligacy.

In 19 B.C. Agrippa again led an army into Spain, where he subdued the Cantabri, who had been for two years in insurrection against the Romans. While in Gaul, where he also pacified the insurgent inhabitants, he constructed four great public roads, and the splendid aqueduct at Nemausus (now Nismes), the ruins of which even yet excite admiration. On his return to Rome, 18 B.C., he was invested with the tribunician power, along with the emperor, for five years. After that he was a second time made governor of Syria, 17 B.C., where, by his just and wise administration, he obtained general commendation, especially from the Hebrew population of his province, of which Judea formed a part. This resulted from his having, at the request of Herod the Great, gone up to Jerusalem, and granted special privileges for their religious worship to the Jewish subjects of the empire. In this journey, too, he colonised Berytus (now Beyrout) as a military and commercial settlement.

The last military employment of Agrippa was in Pannonia, 13 B.C., where his character for equity was of itself sufficient to put down insurrection without bloodshed. Returning to Italy, he lived there in retirement, greatly honoured, and died at Campania, 12 B.C., two years before his imperial father-in-law. He was the greatest military commander of Rome since the days of Julius Cæsar, and the most honest of Roman governors in any province.

Under the care of Agrippa, Julius Cæsar's design of having a complete survey of the empire made was carried out. He had a chart of the entire empire drawn up, and projected a great work on the geography of its provinces. His materials were placed in the public archives, where Pliny consulted them (*Nat. Hist.*, iii.) Agrippa also wrote an account, now lost, of the transactions in which he had taken part.

Agrippa left several children: by his first wife he had Pomponia Vipsania, who became the first wife of Tiberius, and was the mother of Drusus; and by Julia he was the father of Caius and Lucius Cæsar, who were adopted by Augustus: of Julia, married to Lepidus; of Agrippina the elder; and of Agrippa Posthumus. (See Dio Cassius; Appianus; Suetonius; Velleius Paterculus; Fergusson's *Rom. Rep.*; Merivale's *Romans under the Empire.*)

AGRIPPA HENRY CORNELIUS (VON NETTESHEIM), knight, doctor, and by common reputation a magician, was born of a noble family at Cologne on the 14th Sept. 1486. Educated at the university of Cologne, he entered when still very young into the service of the Emperor Maximilian, who sent him on a diplomatic mission to Paris in 1506.

During the next three years he was engaged in a military expedition to Catalonia, and then in the formation of a secret society of theosophists, the first of those alternations between the career of the knight and the career of the student in which his whole life was passed. In 1509 he went by invitation to the university of Dôle in Burgundy, and read lectures on Reuchlin's *De Verbo Mirifico*, which gained for him the degree of doctor of divinity and a stipend. It was these lectures that first stirred against him that malignant hatred of the monks which embittered his life and blackened his memory. He was denounced as an impious and heretical cabalist by an obscure monk named Catilinet, in lectures delivered at Ghent (1510) before Margaret of Burgundy, and his hopes of securing the patronage of that princess were thus for the time disappointed. To win her favour, he had composed (1509) and dedicated to her a treatise, *De Nobilitate et Præcellentia Fœminei Sexus*, the publication of which was delayed from motives of prudence until 1532. For the same reason the same course was followed in regard to his treatise *De Occulta Philosophia*, which, though completed in the spring of 1510, did not appear until 1531. In writing it he had the advice and assistance of the abbot Trithemius of Würzburg. Failing to receive encouragement as a man of letters, Agrippa was forced again to enter the diplomatic service. In 1510 the emperor sent him on a mission to London, where he became the guest of Dean Colet at Stepney. Soon after his return home he was summoned to follow his imperial master to the war in Italy, where he won his spurs—probably at the battle of Ravenna. In the autumn of 1511, on the invitation of the Cardinal de Santa Croce, he attended the schismatic council of Pisa as theologian, and by so doing still further provoked the hostility of the papal party. After a period spent in the service of the Marquis of Montferrat, during which he visited Switzerland, Agrippa was invited in 1515 to the university of Pavia, where he delivered lectures on the *Pimander* of Hermes Trismegistus, the first of which is preserved among his published works, and received a doctor's degree in law and medicine. He was still doomed, however, to a harassed, unsettled life. Three years were spent in the service of the Marquis of Montferrat and the Duke of Savoy. In 1518 he became syndic at Metz, where he was involved in disputes with the monks, and especially with the inquisitor Nicolas Savin, before whom he boldly and persistently defended a woman accused of witchcraft. He was, chiefly in consequence of this, compelled to resign his office, and quitted Metz for Cologne in January 1520. After two years spent in seclusion in his native city, he went to Geneva, where he practised medicine for a short time. In 1523 he removed to Friburg, having been appointed town physician. In the following year he was induced to go to Lyons as court physician to the queen-mother, Louisa of Savoy, but the change did not better his condition, since, though he received several empty honours, his salary remained unpaid. It was probably amid the privations of poverty that he composed, in 1526, his *De Incertitudine et Vanitate Scientiarum et Artium atque Excellentia Verbi Dei Declamatio*, which was first published in 1530. The work is remarkable for the keenness of its satire on the existing state of science and the pretensions of the learned, and when published furnished fresh occasion for the malicious misrepresentation of his enemies. A quarrel with the queen compelled Agrippa to leave Lyons and betake himself to the Netherlands. In 1529 he was appointed historiographer to the Emperor Charles V., and in that capacity wrote a history of the emperor's reign. The salary attached to the office was, however, left unpaid, and Agrippa was consequently imprisoned at Brussels, and afterwards banished from Cologne, for debt. He died at Grenoble in 1535.

The character of Agrippa has been very variously represented. The earlier accounts are grossly disfigured by the calumnies of the Dominicans, whose hatred, following him even to the grave, placed over it an inscription that is probably unique in its spiteful malignity. In later times full justice has been done to his memory. A Life of Agrippa by Henry Morley (London 1856) contains a detailed analysis of his more important works. A complete edition of his writings appeared in two volumes at Leyden in 1550, and has been several times republished.

AGRIPPINA (THE ELDER), the virtuous and heroic but unfortunate offspring of M. Agrippa by a very abandoned mother, and herself the parent of a still more profligate and guilty daughter of the same name. She was early married to Germanicus, the son of Drusus and Antonia, the niece of Augustus. On the death of Augustus she joined her husband in his German campaigns, where she had several opportunities of showing her intrepidity, sharing with Germanicus his toils and his triumphs. The love which the army showed for this leader was the cause of his recall from the Rhine by the suspicious Tiberius. He was soon afterwards sent into Syria, where he died at Antioch from the effects, as was believed, of poison administered to him by Piso, the governor of Syria.

On his deathbed Germanicus implored his wife, for the sake of their numerous children, to submit with resignation to the evil times on which they were fallen, and not to provoke the vengeance of the tyrant Tiberius. But, unhappily, this prudent advice was not followed by the high-spirited woman, who, on landing at Brundusium, went straight to Rome, entered the city bearing the urn of her deceased husband in her arms, and was received amid the tears of the citizens and the soldiery, to whom Germanicus was dear. She boldly accused Piso of the murder of her husband; and he, to avoid public infamy, committed suicide. She continued to reside at Rome, watched and suspected by Tiberius, who for some time dreaded to glut his vengeance on the widow and family of so popular a prince as Germanicus. She soon had the temerity to upbraid the tyrant with his hypocrisy in pretending to worship at the tomb of Augustus. He began by putting to death both men and women who had shown attachment to the family of Germanicus; and finally he arrested Agrippina and her two eldest sons, Nero and Drusus, and transported them to the isle of Pandataria, where her mother Julia had perished; and there she was starved, or starved herself, to death in the 33d year of our era. Tiberius also ordered the execution of her two eldest sons; yet it is remarkable that by his will the emperor left her youngest son Caius, better known by the name of *Caligula*, as one of the heirs of the empire.

AGRIPPINA, daughter of Germanicus and Agrippina the elder, sister of Caligula, and mother of Nero, was born about 15 A.D., at Oppidum Ubiorum, which was at that time the headquarters of her father's legions, and which was after her named *Colonia Agrippina Ubiorum* (now Cologne). She wrote memoirs of her times, which Tacitus quotes, and Pliny commends; but her life is notorious for intrigue and perfidy. In 28 A.D. she became the wife of Cn. Dom. Ahenobarbus, who died 40 A.D. Her next husband was Crispus Passienus, whom some years afterwards she was accused of poisoning. For flagitious conduct, Caligula banished her to the isle of Pontia; but on the accession of her uncle Claudius, 41 A.D., she was set free, and began to succeed in her ambitious schemes. After Messalina had been put to death, 48 A.D., Agrippina was raised by Claudius to her place as his imperial consort, 49 A.D. She prevailed upon him to discard Britannicus his own son, and to adopt her son Domitius in his stead. She removed from her path all whom she feared or envied, and in 54 A.D. poisoned Claudius at Sinuessa that she might reign as regent for her son. Nero in a short time grew tired of her interference, and when she first intrigued against and then frowned upon him, he ordered her to be slain at her villa on the Lucrine lake. After having been slightly wounded by Anicetus, she perished by the sword of a centurion, 60 A.D.

AGROTERAS THUSIA, an annual festival at Athens in honour of Artemis or Diana, in fulfilment of a vow made by the city before the battle of Marathon to offer in sacrifice a number of goats equal to that of the Persians slain in the conflict. The number was afterwards restricted to 500.

AGTELEK, a village of Hungary, in the county of Gömör, near the road from Pesth to Kaschau. In the neighbourhood is the celebrated stalactite grotto of Baradla, one of the most remarkable in Europe. The entrance is extremely narrow, but the interior spreads out into a labyrinth of caverns, the largest of which, called the Flower Garden, is 96 feet high and 90 feet wide, and extends nearly 900 feet in a straight line. In these caverns there are numerous stalactite structures, which, from their curious and fantastic shapes, have received such names as the Image of the Virgin, the Mosaic Altar, &c.

AGUA, VOLCANO DE, a huge mountain in Central America, 25 miles S.W. of Guatemala. It is of a conical shape, and rises to a height of 15,000 feet above the level of the sea. At the summit there is a crater, measuring about 140 yards by 120, from which stones and torrents of boiling water are occasionally discharged. In close proximity to Agua are the volcanoes of Pacaya, on the S.E., and Fuego on the W., and the three present together a scene of great magnificence.

AGUADO, ALEXANDER MARIA, one of the most famous bankers of modern times, was born of Jewish parentage at Seville in 1784. He commenced life as a soldier, fighting with distinction in the Spanish war of independence on the side of Joseph. After the battle of Baylen (1808) he entered the French army, in which he had risen to be colonel and aide-de-camp to Marshal Soult, when he took his discharge in 1815. He immediately commenced business as a commission-agent in Paris, and chiefly through his connection with Spain and the Spanish colonies, acquired in a few years wealth enough to enable him to undertake banking. The Spanish government gave him full powers to negotiate the loans of 1823, 1828, 1830, and 1831 ; and Ferdinand VII. rewarded him with the title of Marquis de las Marismas del Guadalquiver, and the decorations of several orders. Aguado also negotiated the Greek loan of 1834. In 1828, having become possessed of large estates in France, including the Chateau Margaux, famous for its wine, he was naturalised as a French citizen. He died in 1842, leaving a fortune computed at 60,000,000 francs. The designs of the leading pictures in an extensive and admirable art collection which he had formed were published by Gavard under the title *Galerie Aguado* (1837–42).

AGUAS CALIENTES, a town in Mexico, capital of the state of the same name, situated 270 miles N.W. of the city of Mexico, in 22° N. lat., and 101° 45′ W. long. It takes its name from the hot springs in its vicinity. The climate is fine, and the extensive and beautiful gardens surrounding the town produce an abundance of olives, figs, grapes, and pears. It has a large manufactory of woollen cloth, and the general trade is considerable. Population, 22,534.

AGUILAR, GRACE (1816–47), an admired English authoress, was the daughter of a Jewish merchant in London. She was educated wholly by her parents, and commenced her literary career at an early age. Her works, written in a pleasing, elegant, and impressive style, consist chiefly of religious fictions, such as *The Martyr* and *Home Influence.* She also wrote, in defence of her faith and its professors, *The Spirit of Judaism*, and other works. Her services in the latter direction were acknowledged gratefully by the "women of Israel," in a testimonial which they presented shortly before her death. In 1835 she had a severe attack of measles, from the effects of which her constitution never wholly recovered. After a long struggle with increasing bodily infirmities, she died at Frankfort, on her way to Schwalbach, in the autumn of 1847.

AGUILAR DE LA FRONTERA, a town of Spain, stands near the river Cabra, 22 miles S.S.E. of Cordova. The houses are well built, and distinguished by their cleanness and regularity. The town has three handsome public squares, and the principal buildings are the parish church, the chapter-house, a new town-hall, the prison, and the markets. Near the church are the ruins of a once magnificent Moorish castle. The district produces excellent wines, which go by the name of Montilla, and there is also some trade in corn and oil. Population, 12,000.

AGUILLON, FRANCOIS D', an eminent mathematician, born at Brussels in 1566. He entered the Society of Jesus in 1586, and was successively professor of philosophy at Douay and rector of the Jesuit College at Antwerp. Eminent for his skill in mathematics, he was the first to introduce the study of that science among the Jesuits in the Low Countries. He wrote a treatise on Optics in six books (Antwerp, 1613), and was employed in finishing another on Catoptrics and Dioptrics when he died, in 1617.

AGUIRRA, JOSEF SAENZ D', a distinguished Spanish ecclesiastic and theological writer, was born at Logrogno on the 24th March 1630. He belonged to the Benedictine order, and was abbot of St Vincent, professor of theology at the university of Salamanca, and afterwards secretary to the Spanish Inquisition. For a work (*Defensio Cathedræ S. Petri adversus Declarationes Cleri Gallici*, 1682), which he wrote in support of the papal authority against the four propositions of the Gallican Church, he was promoted to the rank of cardinal by Pope Innocent XI. in 1686. Of his other works the chief are a *Collection of the Councils of Spain* (1693–4), and a *Treatise on the Theology of Anselm*, only three volumes of which appeared, the fourth and last being still incomplete when the author died, August 19th, 1699. To judge from a warm eulogium of Bossuet, his opponent in controversy, Aguirra had a very high reputation for piety.

AGULHAS, CAPE, the most southern point of Africa, 100 miles E.S.E of the Cape of Good Hope, in 34° 51′ 30″ S. lat., and 19° 56′ 30″ E. long. At a distance of a mile from the sea it rises to a height of 455 feet. In 1849 a lighthouse was opened on it nearer the shore, the light in which stands 128 feet above high-water mark. An immense bank, the *Agulhas Bank*, extends from the Cape of Good Hope along the coast to the great Fish River, a distance of 560 miles, with a breadth, opposite to the Cape, of 200 miles. The great oceanic current from the Indian Ocean to the Atlantic sets along its outward edge, and has sharply defined it. This current has such velocity that ships are often carried far to the westward, and round the Cape of Good Hope, even against a smart breeze. The bank abounds with fish ; and the approach to it is denoted by the appearance of many whales, sharks, and seals, and innumerable sea-birds.

AHAB, king of Israel, was the son and successor of Omri. He ascended the throne in the 38th year of Asa, king of Judah, *i.e.*, 918 B.C., and reigned over Samaria 22 years. Having married Jezebel, daughter of Ethbaal, king of the Sidonians, he was brought into closer conne tion with the neighbouring powers in the north, and strengthened himself considerably, so that he was able to consolidate the disunited kingdom, and render it powerful against Judah. Some notices out of Menander, preserved by Josephus, led to the conclusion that Ethbaal, father of Jezebel, was identical with Ithobal, priest of Astarte, who usurped the throne of Tyre after murdering Pheles the king. It is not improbable that Ahab's marriage with such a princess was the means of procuring him great riches, which brought pomp and luxury in their train, along with the material and social influence that give a certain security to monarchy. We read of his building an ivory palace and founding new cities, the effect perhaps of a share in the flourishing commerce of Phœnicia. But his matrimonial connection with Tyre and Sidon, however fruitful in wealth, was in many respects detrimental. His wife was a strong-minded, passionate devotee of idolatry, who exercised an injurious influence over him. Led by her, he gave a great impulse to the worship of Baal and Astarte in his kingdom. For the former he built a temple with an altar; of the latter he made the well-known image which existed long after. Under the patronage of Jezebel, the Phœnician cultus assumed important dimensions, for Baal is said to have had 450, Astarte 400 priests and prophets. The infatuated queen was especially hostile to the prophets and priests of Jehovah, whom she tried to exterminate; but the former in particular, though sore pressed, were not entirely cut off. They still held their ground; and Elijah, the most conspicuous of them, came off victor in the contest with Baal's ministers. Jehovism triumphed in the person of the intrepid Tishbite, whom the queen was unable to get into her power. Ahab was a public-spirited and courageous monarch. He defeated the Syrians twice, and concluded a peace with Benhadad on favourable terms. Mesha, king of Moab, paid him a large yearly tribute. In conjunction with Jehoshaphat, king of Judah, he went forth to battle a third time against the Syrians, and was slain at Ramoth-Gilead. It speaks favourably for his disposition that he repented of the cruel measures taken against Naboth, and that he humbled himself before the Lord. Though he feared Elijah and Micaiah, he was not insensible to their utterances; nor could he have suffered so many as 400 prophets to live in his kingdom without some little regard for their office. The prophetic voice, held as it was in small esteem, must have had some influence upon his administration, especially when political grounds coincided with it. His evil courses were due much more to the influence of Jezebel than to his own vicious impulses.

As the accounts of Ahab are fragmentary, it is not always easy to make out from them a clear or connected history of his reign. There is room for conjecture and misconception. Thus Ewald represents him as building a splendid temple with an oracle-grove of Astarte near his favourite palace at Jesreel, on the basis of 1 Kings xvi. 32, xviii. 19; but this is imaginary, since the original does not speak of *a grove* but of *Astarte* (xviii. 19); nor is it probable that a second structure of the kind mentioned existed elsewhere in addition to Baal's temple in Samaria. Neither can it be held as likely that a large statue of Baal was set up in front of his temple, and small statues of him in the interior, merely because we read in 2 Kings x. 26, 27, first of bringing forth the *images* of Baal, and then of breaking *the image* of the same sun-god. Rather were the smaller images in the porch and the chief one in the interior, so that the reading or punctuation of verse 26 should be slightly altered. Whether the 450 or 400 prophets were distinct from the priests is doubtful. Identifying them, we believe that the priests acted as prophets, procuring for themselves greater renown among the ignorant people by their arts of necromancy and magic.

For the biography of this monarch we are indebted almost exclusively to the books of Kings, where the writers consider him in a theocratic rather than a political aspect. Viewing him from their later prophetic standpoint, their portrait is somewhat one-sided, though correct in the main. It is observable that the portions of the Kings in which he is spoken of are somewhat different in character and expression, betraying the use of different sources by the compiler. 1 Kings xvi. 29-33, xxii. 39, 2 Kings x. 25-28, are more historical than the rest, which contain almost all that is related of Ahab, and were derived from tradition. It has been conjectured by Hitzig that the 45th psalm owes its origin to Ahab, being the joyous poetical expression of a matrimonial connection with Tyre, which augured unusual prosperity for the distracted kingdom. But the assumption is improbable, because, as De Wette observes, an event belonging to Ephraim was hardly a fitting subject for a poem included in the canon.

Another Ahab, a false prophet in the time of the Babylonian exile, is mentioned by Jeremiah (xxix. 21), and threatened with terrible punishment. (S. D.)

AHALA, a noble Roman family of the gens Servilia, which produced many distinguished men. Of these the most celebrated is C. Servilius Structus Ahala, master of the horse to the dictator Cincinnatus, B. C. 439. He signalised himself by his boldness in slaying in the forum with his own hand the popular agitator Sp. Mælius, for refusing to appear before the dictator on a charge of conspiracy against the state. For this act Ahala was brought to trial. He saved himself from condemnation by retiring into exile.

AHANTA, a territory on the Gold Coast of Africa, lying on the second parallel of W long. It is one of the richest and most fertile districts in that part of the continent. Axim, the chief settlement, was founded by the Dutch, but now belongs to Britain.

AHASUERUS, the Latinised form of the Hebrew *Ahashverosh*, אֲחַשְׁוֵרוֹשׁ (in the LXX. Ἀσσουήρος, once in Tobit Ἀσύηρος), occurs as a royal Persian or Median name in three of the books of the canonical Scriptures, and in one of the books of the Apocrypha. In every case the identification of the person thus named with those found in profane history is matter of controversy. The hypothesis of Fürst and others, that in all the passages one and the same person is meant, viz., the well-known Xerxes, may be set aside as quite inapplicable to the facts; and it becomes necessary to glance at the particular places.

In Dan. ix. 1, Ahasuerus appears as the father of Darius the Mede, who "was made king over the realm of the Chaldeans" after the conquest of Babylon and death of Belshazzar. Who this Darius was is one of the most difficult and disputed questions of ancient history. If, as is very generally supposed, he is Astyages, the grandfather of the great Cyrus, and the last independent king of Media, then Ahasuerus is to be identified with Cyaxares, the father of Astyages. The passage in Tobit where the name occurs (xiv. 15) lends confirmation to this view. It is there stated that Nineveh was captured and destroyed by "Nabuchodonosor and Assuerus." According to Herodotus (i. 106 *cf.* Rawlinson's *Her.*, vol. i. 412), it was the Medes under Cyaxares who took Nineveh.

In Ezra iv. 6, Ahasuerus is mentioned as a king of Persia, to whom the enemies of the Jews sent representations opposing the rebuilding of the temple at Jerusalem. Here the sequence of the reigns in the sacred writer and in the profane historians—in the one, Cyrus, Ahasuerus, Artaxerxes, Darius; in the other, Cyrus, Cambyses, Smerdis, Darius—leads naturally to the identification of Ahasuerus with Cambyses. Other circumstances, especially the known policy of the usurper Smerdis, and its reversal by Darius (see Inscr. of Behistun, col. i. § 14), corroborate this conclusion.

In the Book of Esther, Ahasuerus is the name borne by that king of Persia, certain events of whose court and empire (which will be noticed elsewhere, see ESTHER) form the subject of the whole narrative. (Throughout this book the LXX. render the name by Ἀρταξέρξης.) The hypothesis of certain writers, that this Ahasuerus is the Cyaxares, king of Media, already referred to, may be at once dismissed. That of others, identifying him with Artaxerxes Longimanus, the son and successor of Xerxes, though countenanced by Josephus, deserves scarcely more consideration. Recent inquirers are all but universally of opinion that he must be a monarch of the Achæmenian dynasty, earlier than this Artaxerxes; and opinion is divided between Darius Hystaspis and his son and successor Xerxes. In support of the former view it is alleged, among other things (see Tyrwhitt's *Esther and Ahasuerus*, p. 162), that Darius was the first Persian king of whom it could be said, as in Esther i. 1, that he "reigned from India even unto Ethiopia, over an hundred and seven and twenty provinces;" and that it was also the distinction of Darius that (Esther x. 1) he "laid a tribute upon the land and upon the isles of the sea" (*cf.* Herod. iii. 89). In support of the latter view it is alleged—(1.) That the Hebrew

Ahashverosh is the natural equivalent of the old Persian *Khshayarsha*, the true name of the monarch called by the Greeks Xerxes, as now read in his inscriptions; (2.) That there is a striking similarity of character between the Xerxes of Herodotus and the Ahasuerus of Esther; (3.) That certain coincidences in dates and events corroborate this identity, as, *e.g.*, "In the third year of his reign Ahasuerus gave a grand feast to his nobles, lasting one hundred and eighty days (Esther i. 3); and Xerxes in *his* third year also assembled his chief officers to deliberate on the invasion of Greece (Herod. vii. 8). Again, Ahasuerus married Esther at Shushan in the seventh year of his reign; in the same year of *his* reign Xerxes returned to Susa with the mortification of his defeat, and sought to forget himself in pleasure. Lastly, the tribute imposed on the land and isles of the sea also accords with the state of his revenue, exhausted by his insane attempt against Greece" (Kitto's *Cyclopædia, s.v.* Ahasuerus). To this it may be added that the interval of four years between the divorce of Vashti and the marriage of Esther is well accounted for by the intervention of an important series of events fully occupying the monarch's thoughts, such as the invasion of Greece. It may be added that by the advocates of both views appeal is made, with more or less of confidence, to the names of the queens of the respective sovereigns; Atossa, wife of Darius, answering to Hadassah, and Amestris, wife of Xerxes, to Esther (Esther ii. 7); and also to the number of generations indicated in the genealogy of Mordecai from the deportation of the Jews into Babylon (Esther ii. 5; *cf.* Tyrwhitt, p. 95, with Rawlinson, *Bampton Lect.*, p. 186). If, as seems probable, the name Ahasuerus is the transcription of the Persian *Khshayarsha* (written *Hisiarsa* in Babylonian) which, according to Sir H. Rawlinson, means "venerable king" (see Rawlinson's *Her.* iii. 363), then this name may be reasonably supposed to have been originally an appellative, and its application, especially by foreigners like the Jews, to different royal persons, is explained.

AHAZ (literally *Possessor*), son of Jotham, and the eleventh king of Judah, reigned 16 years, from 741 to 725 B.C. He was the most weak-minded and corrupt of all the kings that had hitherto reigned over Judah. About the time of his accession, Pekah, king of Israel, and Rezin, king of Syria, had formed an alliance with the view of acquiring the kingdom of Judah by conquest. They invaded the country, laid siege to Jerusalem, and carried away an immense number of captives, though they failed to secure their ultimate object. At the same time incursions were made by the Edomites and Philistines, and Ahaz was fain to call in the aid of Tiglath-Pileser, king of Assyria, who destroyed the power of Syria, but took care to exact heavy tribute for the service thus rendered. Ahaz was even compelled to appear as a vassal at Damascus, and so to bring his kingdom to the lowest point of political degradation. In religion Ahaz was a heathen. He broke in pieces the vessels of the temple of God, and at last ventured to close its gates altogether. He sacrificed to Syrian deities, erected altars on which incense was to be offered, and caused his son to pass through the fire to Moloch. He was succeeded by his son Hezekiah. In the inscriptions of Tiglath-Pileser II., king of Assyria, *Yahukhazi Jahudai*, that is, Joahaz or Ahaz of Israel, appears among the names of those who acknowledged his sovereignty and paid tribute. (Schrader's *Die Keilinschriften und das Alte Testament.*)

AHAZIAH (lit. *Whom the Lord sustains*), son and successor of Ahab, and eighth king of Israel, reigned scarcely two years, from 897 to 896 B.C. He continued in the idolatrous practices of his father, worshipping Baal and Astarte. Upon his accession the Moabites revolted, and refused any longer to pay the tribute which had been exacted from them since the establishment of Israel as a separate kingdom. Before Ahaziah could take measures to subdue them, he was seriously injured by a fall from the lattice of an upper chamber in his palace. He immediately sent messengers to the oracle of the god Baalzebub at Ekron to inquire the issue of his illness. While on their way they were met by Elijah the prophet, who bade them return and tell the king that he would surely die.

AHAZIAH, son of Jehoram and Athaliah, daughter of Ahab, and sixth king of Judah, reigned one year, 885 B.C. Under the evil influence of his mother, he walked in the ways of Ahab's house, and was an idolatrous and wicked king. He was slain by Jehu, the son of Nimshi.

AHENOBARBUS, the name of a plebeian Roman family of the gens Domitia, which rose in the course of time to considerable distinction. The name was derived from the red beard and hair by which many of the family were distinguished. The emperor Nero was of this family.

AHITHOPHEL (lit. *Brother of Foolishness*, i.e., *foolish*), the very singular name of one of the sagest politicians in Old Testament history. In regard to his family relationships it is almost beyond doubt that he was the grandfather of Bathsheba, and it has been suggested as probable that he was first introduced at court through this connection. He was one of David's most trusted counsellors, and his defection to the cause of Absalom was a severe blow to the king, who prayed that God would bring his counsel to "foolishness," probably alluding to his name. David's grief at the desertion is expressed in Ps. xli. 9, lv. 12–14. Ahithophel's advice was at first acceptable to Absalom's party, and probably laid down the policy which alone was likely to be successful; but Hushai's counsel of delay, given in the secret interest of David, was ultimately adopted. Ahithophel's political foresight enabled him to see that this resolution would prove fatal to the rebel cause, and he at once returned to his home at Giloh, "put his household in order, and hanged himself." This is the only case of *deliberate* suicide that is mentioned in the Old Testament.

AHMADÁBÁD, a district and city of British India, in the province of Gujrát, within the jurisdiction of the governor of Bombay. The DISTRICT lies between 21°·4 and 23° 5′ N. lat., and between 71° 2′ and 73° 25′ E. long. It is bounded by the province of Kátiwár on the N. and W., by the Mahi Kánta on the N. and E., by the Kaira collectorate on the E. and S., and by the gulf of Cambay on the S. The area of the district is returned at 3844 square miles. The river Sábarmatí and its tributaries, flowing from north-east to south-west into the gulf of Cambay, are the principal streams that water the district. The north-eastern portion is slightly elevated, and dotted with low hills, which gradually sink into a vast plain, subject to inundation on its western extremity. With the exception of this latter portion, the soil is very fertile, and some parts of the district are beautifully wooded. The total population of Ahmadábád is returned at 829,637 souls, the average density, as compared with the area, being 216 to the square mile, and the proportion of females 891 to every 1000 males. About 86 per cent. of the population are returned as Hindus, 10 per cent. as Mahometans, and 4 as Buddhists. The percentage of persons of other denominations is infinitesimal, their total number being only 1237 souls.

The hamlets for the most part consist of substantial houses of bricks and tiles, with only a small proportion of huts. Some of the larger villages contain houses with upper stories, and the general appearance of the inhabitants indicates prosperity. The principal agricultural products are rice, wheat, bajra, and cotton, with a little sugar-cane, tobacco, and oil-seeds. Silk manufacture forms an important industry of the city. The total revenue of the district in 1872 amounted to £152,344, of which £147,283 was derived from the land; the total net expenditure on civil administration in the same year amounted to £21,700. The fiscal system consists for the most part of settlements direct with the husbandman, technically known as rayatwárí; but some villages are "*tálukdárí*," in which the "tálukdár" or landholder collects the revenue, and pays 70 per cent. of it to Government, retaining the remaining 30 per cent. for himself. The excise revenue is generally farmed out, but a government distillery exists in the city. The land settlement is fixed for a period of thirty years, and expires in different parts of the district between the years 1884 and 1888. Seventy-five per cent. of the total area of the district is cultivable, of which 55 per cent. is actually under cultivation, the other 20 per cent. remaining fallow. The principal marts in Ahmadábád are Dhollerá, Gogo, Dholká, and Víramgáon. Municipalities have been established in the towns of Ahmadábád, Dholká, Mandú, Gogo, Dhandúka, Prántej, and Moráshá; the rate of municipal taxation per head of population varies from 2s. 6½d. in Ahmadabád to 4½d. in Moráshá, the average throughout the eight towns being 1s. 7⅝d. per head. The municipal income is chiefly derived from octroi duties, which in some of the towns are farmed. Thirteen towns are returned as containing a population exceeding 5000 souls, namely, Ahmadábád, population 116,873; Dholká, 20,854; Víramgáon, 19,661; Dhollerá, 12,468; Dhandúka, 9782; Gogo, 9571; Prántej, 8341; Moráshá, 7436; Sanand, 7229; Mandú, 6774; Patrí, 6320; Barwálá, 5813; and Ranpur, 5796. The district contains 145 schools, in eight of which English is taught. The police force numbers 1189 men. The Kolís contribute most largely to the criminal population.

Ahmadabad City, the capital of the district, is situated on the east or left bank of the river Sábarmatí, in 23° N. lat., and 72° 36′ E. long. It was formerly one of the largest towns in India, celebrated for its commerce and manufactures of gold and silver, silk and cotton fabrics, articles of gold, silver, steel; enamel, mother of pearl, lacquered ware, and fine wood-work. Excellent paper was also manufactured, and a large trade carried on in indigo, cotton, and opium. With the rise of the Marhattá power, however, Ahmadábád became the scene of repeated struggles between the Marhattás and the Mussulmans, whose power was then on the wane, and from this period its prosperity declined. It was captured by the Marhattás in 1755, and again by the British in 1780. The latter soon afterwards gave the town back to the Marhattás, who held it till it finally came into the hands of the English in 1818. The present state of the city is flourishing. It contains a population of 116,873 souls, and is a large and important station on the Bombay, Baroda, and Central India Railway. It is the seat of important silk manufactures, and has two cotton-mills worked by steam-power.

The principal objects of architectural interest are the Jain temple of Seth Hathisinh and the Juma Masjid or Great Mosque. The Jain temple is a modern edifice, having been erected about twenty-five years ago by Hathi Sinh, a rich Jain merchant, who dedicated it to Dharmnáth. This modern style shows that the Jain style of architecture has hardly degenerated from its ancient excellence. The external porch, between two circular towers, is of great magnificence, most elaborately ornamented, and leads to an outer court, with sixteen cells on either side. In the centre of this court is a domed porch of the usual form, with twenty pillars. The court leads to an inner porch of twenty-two pillars, two stories in height, with a roof of a shape very fashionable in modern Jain temples, though by no means remarkable for beauty. This inner porch conducts to a triple sanctuary. The exterior of the temple expresses the interior more completely than even a Gothic design; and whether looked at from its courts or from the outside, it possesses variety without confusion, and an appropriateness of every part to the purpose for which it was intended. The Juma Masjid or Great Mosque of Ahmadábád, although not remarkable for its size, is one of the most beautiful mosques in the East, the Jain style of architecture being plainly visible in its construction. Its external dimensions are 382 feet by 258 feet.

AHMADNAGAR, a district and city in British India, in the province of Gujrát, within the jurisdiction of the Governor of the Presidency of Bombay. The collectorate extends from 18° 6′ to 19° 50′ N. lat., and from 73° 40′ to 75° 37′ E. long., and contains the following eleven tálukás or sub-districts:—Nagar, Jámkhair, Párnair, Srígonda, Karjat, Newasa, Kopargám, Sangamnair, Rahurí, Siogám, and Ankolá. A natural boundary is formed on the west of the Ankolá táluká by the Western Gháts, and, further south, by the edge of the table-land of Párnair; on the S.W. the district is bounded by the Gor river; on the S. by the Bhímá and Sholápur collectorates; on the E. by the Nizám's dominions; on the N.E. by the Godávarí river; and on the N. by the Násik district. The total area of the district is returned at 4,209,036 acres, or 6576·62 square miles. Of the total area, 3,068,162 acres, or 4794·00 square miles, are cultivated; 121,474 acres, or 189·80 square miles, are cultivable, but not actually under tillage; and 1,019,400 acres, or 1592·81 square miles, are uncultivable. The last portion includes (besides unarable lands) village sites, roads, tanks, rivers, &c. The population of the district, according to the census taken on the night of the 21st February 1872, numbered 773,938 souls, divided into the following five classes:—Hindus, 716,820, or 92·62 per cent. of the total population; Mahometans, 42,435, or 5·49 per cent.; Buddhists, 12,547, or 1·62 per cent.; Christians, 941, or 0·12 per cent.; and other denominations, 1195, or 0·15 per cent. The bulk of the population consists of Marhattás and Kunbís, the latter being the agriculturists. On the north the district is watered by the Godávarí and its tributaries the Prawara and the Múlá; on the north-east by the Dor, another tributary of the Godávarí; on the east by the Séphaní, which flows through the valley below the Bálá Ghát range; and in the extreme south by the Bhímá and its tributary the Gor. The Siná river, another tributary of the Bhímá, flows through the Nagar and Karjat tálukás. The collectorate on the whole is fairly well watered, although in some villages among the hills and spurs of the Western Gháts the supply is insufficient. The district is intersected by the Bombay and Agra road; a second road connects Puná *via* Serur with the town of Ahmadnagar, and is continued thence towards Máligám; a third road leads from Puná to Náráyangám, besides various cross-tracts and minor roads connecting the different towns of the district.

The only important industry is weaving. The principal agricultural products are wheat, gram, bajrá, joár, and tur dál. The early or spring crop is bajrá and tur dál; wheat, gram, and joár being sown later in the season. Several other food grains are also raised; and sugar-cane, betel leaves, a little cotton, and all descriptions of vegetables are sown on suitable soils. The staple food of the people is bajrá and joár (coarse kinds of millet). The total revenue of the district is returned at nearly £170,000; about £140,000 being derived from the land revenue. The total annual expenditure is returned at £50,000. The present land settlement was introduced about 1844–45, and the thirty years' leases are now beginning to fall in. In a few villages which were transferred to Ahmadnagar from the Násik collectorate the leases have already expired, and a revision of the settlement is in progress (1873). The following eight towns are returned as containing a population of upwards of 5000 souls:—Ahmadnagar, population 32,841; Sangamnair, 9978; Páthardí, 7117; Khurdá, 6889; Srigonda, 6175; Bhingar, 5752; Karjat, 5535; and Sonái, 5254. The municipal system has been introduced into the towns of Ahmadnagar, Sangamnair, and Bhingar. In the two first named, the municipal revenue is derived from a house tax and octroi duties on goods and articles imported into the town for consumption. In Bhingar the municipal revenue is raised by the levy of a classified tax on professions and trades carried on within the town. The municipal revenue and expenditure in 1872, together with the incidence of municipal tax per head of the population in each of the three towns, was as follows:—Ahmadnagar, municipal income, £3611, 18s.; municipal expenditure, £3557, 12s.; incidence per head of population, 2s. 2¼d. Sangamnair, municipal income, £275, 4s.,—6½d. per head; expenditure, £217. Bhingar, municipal revenue, £259, 18s.—8⅜d. per head; expenditure, £259, 18s. Ahmadnagar district contains 1 high school, 1 first-grade Anglo-vernacular school, 3 middle-class schools, 164 lower-class schools, and 1 girls' school. Education is making fair progress, and the number of schools is annually increasing as funds become available. For the protection of person and property, a regular police force of 594 men of all grades is maintained, at a cost, during 1872–73, of £9869. A village police, numbering 2042 men, is also kept up, at a cost of £1978 per annum. There are no special criminal classes in the district except a few Bhils, and they are now much less troublesome than formerly.

Ahmadnagar City, the capital of the district of the same name, is situated in 19° 6′ N. lat., and 74° 46′ E. long. It is a town of considerable antiquity, having been founded, in 1494, by Ahmad Nizám Sháh, on the site of a more ancient city, Bhingar. This Ahmad established a new monarchy, which lasted until its overthrow by Sháh Jahán in 1636. In 1759 the Peshwá obtained possession of the place by bribing the Mahometan commander; and in 1797 it was ceded by the Peshwá to the Marhattá chief Daulat Ráo Sindhiá. During our war with the Marhattás in 1803 Ahmadnagar was invested by a British force under General Wellesley, and captured. It was afterwards restored to the Marhattás, but again came into the possession of the British in 1817, according to the terms of the treaty of Puná. The town has rapidly advanced in prosperity under British rule. It now contains a population of 32,841 souls, is an important station on the Great Indian Peninsular Railway, and has been created a municipality, as is mentioned above.

AHMED SHAH, founder of the Duráni dynasty in Afghanistan, born about 1724, was the son of Sammaun-Khan, hereditary chief of the Abdali tribe. While still a boy Ahmed fell into the hands of the hostile tribe of Ghilzais, by whom he was kept prisoner at Kandahar. In March 1738 he was rescued by Nadir Shah, who soon afterwards gave him the command of a body of cavalry composed chiefly of Abdalis. On the assassination of Nadir in 1747, Ahmed, having failed in an attempt to seize the Persian treasures, retreated to Afghanistan, where he easily persuaded the native tribes to assert their independence, and accept him as their sovereign. He was crowned at Kandahar in October 1747, and about the same time he changed the name of his tribe to Duráni. Two things may be said to have contributed greatly to the consolidation of his power. He interfered as little as possible with the independence of the different tribes, demanding from each only its due proportion of tribute and military service; and he kept his army constantly engaged in brilliant schemes of foreign conquest. Being possessed of the Koh-i-noor diamond, and being fortunate enough to intercept a treasure on its way to the Shah of Persia, he had all the advantages which great wealth can give. He first crossed the Indus in 1748, when he took Lahore; and in 1751, after a feeble resistance on the part of the Mahometan viceroy, he became master of the entire Panjáb. In 1750 he had taken Nishapúr, and in 1752 he subdued Kashmir. His great expedition to Dehli was undertaken in 1756 in order to avenge himself on the Great Mogul for the recapture of Lahore. Ahmed entered Dehli with his army in triumph, and for more than a month the city was given over to pillage. The Shah himself added to his wives a princess of the imperial family, and bestowed another upon his son Timur Shah, whom he made governor of the Panjáb and Sirhind. As his viceroy in Dehli he left a Rohilla chief in whom he had all confidence, but scarcely had he crossed the Indus when the Mahometan vizier drove the chief from the city, killed the Great Mogul, and set another prince of the family, a tool of his own, upon the throne. The Mahratta chiefs availed themselves of these circumstances to endeavour to possess themselves of the whole country, and Ahmed was compelled more than once to cross the Indus in order to protect his territory from them and the Sikhs, who were constantly attacking his garrisons. In 1758 the Mahrattas obtained possession of the Panjáb, but on the 6th January 1761 they were totally routed by Ahmed in the great battle of Pánipat. In a later expedition he inflicted a severe defeat upon the Sikhs, but had to hasten westwards immediately afterwards in order to quell an insurrection in Afghanistan. Meanwhile the Sikhs again rose, and Ahmed was now forced to abandon all hope of retaining the command of the Panjáb. After lengthened suffering from a terrible disease, said to have been cancer in the face, he died in 1773, leaving to his son Timur the kingdom he had founded.

AHRIMAN or ARIMANES (*Angra-Mainyus*, Hostile or Destroying Spirit), in the *Zend-Avesta*, the principle of evil, opposed to *Ormuzd*, the principle of good, the one being symbolised by darkness and the other by light. Both were visible manifestations of the *Zervan-Akerene* (Infinite Time), and existed from all eternity, according to the doctrine of the Magians. Zoroaster himself, however, seems to have taught that Ormuzd alone was eternal, while Ahriman was created. In the *Avesta* this world is represented as the theatre of a fierce conflict between the two spirits, which is to last for 12,000 years. In the end Ahriman is to acknowledge the supremacy of Ormuzd. (See ZOROASTER.)

AHWAZ, a town in Persia, on the left bank of the river Karoon, about 100 miles N.E. of Bassorah. Though now an insignificant place, it occupies the site of what was once an extensive and important city. Of this ancient city vast remains are left, extending 12 miles along the bank of the river. Among the most remarkable are the ruins of a bridge and a palace, besides vestiges of canals and water-mills, which tell of former commercial activity. There is also, in a ruined state, a bund or stone dyke of great strength thrown across the river for purposes of irrigation. It extends 100 feet in length, and many single blocks in it measure from 8 to 10 feet in thickness. Ahwaz reached the height of its prosperity in the time of the earliest Mahometan caliphs.

AI (Sept. Ἀγγαί, Ἀγγαί, and Γαΐ; Vulg. *Hai*), a royal city of the Canaanites, east of Bethel. It existed in the time of Abraham, who pitched his tent between the two cities (Gen. xii. 8; xiii. 3); but it is chiefly noted for its capture and destruction by Joshua (vii. 2–5; viii. 1–29), who made it "a heap for ever, even a desolation." At a later period Ai was, however, rebuilt, and is mentioned by Isaiah (x. 28), and also after the captivity. The site was known, and some scanty ruins still existed, in the time of Eusebius and Jerome (*Onomast.*, s.v. Ἀγγαί). Dr Robinson was unable to discover any certain traces of either. He remarks (*Bib. Researches*, ii. 313), however, that its situation with regard to Bethel may be well determined by the facts recorded in Scripture. That Ai lay to the east of Bethel is distinctly stated; and the two cities were not so far distant from each other but that the men of Bethel mingled in the pursuit of the Israelites as they feigned to flee before the king of Ai, and thus both cities were left defenceless (Josh. viii. 17). A little to the south of a village called Deir Diwan, and one hour's journey from Bethel, the site of an ancient place is indicated by reservoirs hewn in the rock, excavated tombs, and foundations of hewn stone. This, Dr Robinson thinks, may mark the site of Ai, as it agrees with all the intimations as to its position. In this view more recent authorities generally coincide. Kiepert's map gives it a place near these ancient ruins. Stanley places it at the head of the *Wady Harith*.

AIDAN, a king of Scottish Dalriada, who reigned about the close of the 6th century. He usurped the succession from the son of Conall, and was crowned by Columba, who personally preferred another, and, it is said, was compelled to perform the ceremony by an interposition of divine power. During Aidan's reign the Scottish Dalriada was completely freed from subjection to the Irish monarchs. (See Adamnan, lib. iii., c. 5; and Bede.)

AIDAN, ST, first bishop of Lindisfarne or Holy Island, embraced a religious life in the monastery of Iona. Oswald, king of Northumbria, having requested a mission of monks from Iona to labour for the conversion of his subjects, Aidan was chosen by the abbot as leader of the expedition, and was consecrated a bishop about 634–5 A.D. Bede speaks of the holiness of his life, of the influence of his preaching as seen in the conversion of multitudes, and also of numerous miracles which he performed. Aidan died on the 31st August 651.

AIDE-DE-CAMP, a confidential officer attached to the "personal" or private staff of a general. In the field he is the bearer of his chief's written or verbal orders, and when employed as the general's mouthpiece, must be implicitly obeyed. In garrison and quarters his duties are more of a social character—he superintends the general's household, writes and answers invitations, &c. To increase their state, colonial governors and the Lord-Lieutenant of Ireland have aides-de-camp with functions analogous to those of equerries to royalty. Officers above the rank of captain are seldom taken as aides, and none of less than two years' service. The sovereign, as head of the army, may have an indefinite number of aides-de-camp. In 1874 there were thirty-three military aides-de-camp; of these, twelve, taken from the militia, were honorary, the remainder, from the regular army and marines, were chosen for distinguished war services. The appointment carries with it promotion to the army rank of "full" colonel. The Queen has also at present (1874) eleven naval aides-de-camp, in compliment to the sister service; but the appointment is more especially of a military character. An admiral's aide-de-camp is his flag-lieutenant.

AIDIN, or Guzel-Hissar, a town of Turkey in Asia, in the pashalic of Anatolia, about 70 miles S.E. of Smyrna. It is beautifully situated near the river Meander, and is the residence of a pasha. Since 1866 it has been connected with Smyrna and Ephesus by rail. On a neighbouring height are to be seen the ruins of the ancient *Tralles*. Aidin is a place of very extensive trade, and is celebrated for its figs, which are grown in great abundance in the beautiful orchards between the town and the river, and form an important article of export. The streets of the town, overshadowed by trees, and having numerous well-frequented bazaars, present a very picturesque appearance. Among the inhabitants are considerable numbers of Greeks, Armenians, and Jews; and there are several churches and synagogues in addition to the fine Turkish mosques. Population, 30,000.

AIDS (*Auxilia*), a pecuniary tribute under the feudal system, paid by a vassal to his lord on particular occasions; originally a voluntary grant which in process of time became exigible as a right. The aids of this kind were chiefly three, viz.:—1*st*, When the lord made his eldest son a knight; 2*d*, To provide a dower when he gave his eldest daughter in marriage; 3*d*, To ransom the person of the lord when taken prisoner. The amount of the first two was definitely fixed by 3 Ed. I., c. 36, but that of the last was of course uncertain. The right of levying aids was abolished by 12 Car. II., c. 24.

AIKIN, John, M.D. (1747–1822), was born at Kibworth-Harcourt, received his elementary education at the dissenting academy of Warrington, where his father was tutor, and prosecuted his medical studies in the university of Edinburgh, and in London under the celebrated Dr William Hunter. He commenced his professional career as a surgeon at Chester; but being unsuccessful, he removed to Warrington. Finally, he went to Leyden, took the degree of M.D. in that university (1780), and attempted to establish himself as a physician in London. His success in this new field does not seem to have been considerable; chiefly, no doubt, because he concerned himself more with the advocacy of liberty of conscience than with his professional duties. He therefore began at an early period to devote himself to literary pursuits. Dr Aikin's reputation chiefly rests on his endeavour to popularise scientific inquiries. In conjunction with his sister, Mrs Barbauld, he commenced the publication of a series of volumes on this principle, entitled *Evenings at Home* (6 vols., 1792–5), a popular and interesting work, chiefly commendable for the purity of the principles it inculcates, and the pleasing views it gives of human nature. It has been translated into almost every European language. His love of nature, and his power in delineating its features, are well illustrated in *The Natural History of the Year*, as well as in his miscellaneous *Essays*. In 1798 Dr Aikin retired from professional life, and devoted himself with great industry to literary undertakings of numerous and varied kinds, among which his valuable *Biographical Dictionary* (10 vols. 1799–1815) holds a conspicuous place. Besides these, he published *Biog. Memoirs of Medicine* (1780); *Lives of John Selden and Archbishop Usher; Memoirs of Huet, Bishop of Avranches; Geographical Delineations of All Nations*, &c. He edited the *Monthly Magazine* from 1796 to 1807, and started the *Athenæum* in 1807. The latter was discontinued, however, in 1809.

AIKIN, Lucy, daughter of the preceding, a well-known historical writer, was born at Warrington on 6th Nov. 1781. After rendering valuable assistance to her father in several of his later works, she commenced her own career as an authoress by the publication of several books for the young, the most important of which were the *Adventures of Rolando*, a translation, and *Lorimer*, a tale. In 1818 she published her *Memoirs of the Court of Queen Elizabeth*, the first and best of the series of historical works on which her reputation rests. It was very popular, and passed through several editions. The *Memoirs of the Court of King James I.* (1822) was highly commended in the *Edinburgh Review*, which pronounced it "a work very nearly as entertaining as a novel, and far more instructive than most histories." Her *Memoirs of the Court of Charles I.* (1833) showed a falling off; and her latest work, the *Life of Addison* (1843), was declared disappointing by Macaulay in the *Edinburgh Review*, vol. lxxviii. Miss Aikin died at Hampstead, where she had resided for forty years, on the 29th Jan. 1864. A Life by P. H. le Breton appeared in a volume entitled *Memoirs, Miscellanies, and Letters of Lucy Aikin* (Lond. 1864).

AIKMAN, William, a celebrated portrait-painter, born at Cairney, Forfarshire, on the 24th Oct. 1682. He was intended by his father for the bar, but followed his natural bent by becoming a pupil under Sir John Medina, the leading painter of the day in Scotland. In 1707 he went to Italy, resided in Rome for three years, afterwards travelled to Constantinople and Smyrna, and in 1712 returned home. In Edinburgh, where he practised as a portrait-painter for some years, he enjoyed the patronage of the Duke of Argyll; and on his removal to London in 1723 he soon obtained many important commissions. Perhaps his most successful work was the portrait of the poet Gay. He also painted portraits of himself, Fletcher of Saltoun, William Carstairs, and Thomson the poet. The likenesses were generally truthful, and the style was modelled very closely upon that of Sir Godfrey Kneller. Aikman held a good position in literary society; and counted among his personal friends Swift, Pope, Thomson, Allan Ramsay, Somerville, and Mallet. He died in June 1731, leaving unfinished a large picture of the royal family.

AILRED, Ealred, Ethelredus, Aluredus, an English ecclesiastic and historian, born at Hexham in 1109. He was educated at the Scotch court with Henry the son of King David. The king is said to have offered him a bishopric, which he refused, preferring to become a monk in the Cistercian abbey of Rievaulx, Yorkshire. In 1146 he was chosen abbot, and he held that position till his death in 1166,—the accounts which state that he was transferred to Revesby in Lincolnshire being probably founded on a confusion of names. Leland says that he had seen his tomb at Rievaulx adorned with gold and silver ornaments

Ailred was the author of a large number of historical and theological works. The former are of little value, owing to his credulity, except for the occasional glimpses they give of contemporary life and manners. His theological works, including a volume of homilies, a treatise on charity, and a treatise on friendship, are somewhat in the style of St Bernard. (For a full account of the historical writings see Sir T. D. Hardy's *Descriptive Catalogue.*)

AILSA CRAIG, a remarkable island-rock at the mouth of the Firth of Clyde, off the coast of Ayrshire, Scotland. It is of a conoidal form, with an irregular elliptic base, and rises abruptly from the sea to the height of 1139 feet. The only side from which the rock can be ascended is the east; the other sides being for the most part perpendicular, and generally presenting lofty columnar forms, though not so regular as those of Staffa. The rock is a greenstone or syenite, with a basis of grayish compact felspar traversed by numerous trap veins. A columnar cave exists towards the north side, and on the eastern are the remains of a tower, with several vaulted rooms. Two springs occur on the island, and some scanty grass affords subsistence to numerous rabbits. The precipitous parts of the rock are frequented by large flocks of solan geese and other aquatic wild fowl. It is situated in 55° 15′ N. lat., 5° 7′ W. long.

AIN, a department on the eastern frontier of France, bounded on the N. by the departments of Jura and Saône-et-Loire, on the W. by Saône-et-Loire and Rhône, on the S. by Isère, and on the E. by the departments of Savoie and Haute Savoie and the Swiss cantons Geneva and Vaud. It extends at the widest points 52 miles from N. to S., and about the same distance from E. to W., with an area of 2241 square miles. The east of the department is very mountainous, being traversed by the southern portion of the Jura range, but in the north-west the surface is comparatively level, and in the south-west flat and marshy. Ain is wholly within the basin of the Rhône, that river itself being the boundary on the east and south, while it receives the Ain, which passes southward through the centre, and the Saône, which forms the western boundary of the department. The climate is usually cold, but on the whole healthy, except in the damp marshy districts on the west. The soil in the valleys and plains of the department is fertile, producing wheat, barley, maize, rye, and fruits of various kinds, as well as wine of excellent quality; the tops of many of the mountains are covered with forests of fir and oak, and the lower slopes yield excellent pasture for sheep and cattle. The chief mineral product is asphalt, besides which potter's clay, iron, building-stone, and the best lithographic stone in France, are produced in the department. There are many corn and saw mills on the mountain streams; and cotton, linen, and silk fabrics, coarse woollen cloth, paper, and clocks, are manufactured to a limited extent. Ain, which formed a part of the ancient province of Burgundy, is divided into five arrondissements—Bourg and Trevoux in the west, and Gex, Nantua, and Belley in the east; containing in all 36 cantons and 452 communes. Bourg is the capital, and Belley is the seat of a bishop. Population of Ain in 1872, 363,290, of whom 185,074 were males, and 178,216 were females. Of the total population, 115,407 could neither read nor write, and 46,450 more could not write.

AINAD, a town of Arabia, in the province of Hadramaut, about 207 miles N.E. of Aden. Near it is the tomb of a Moslem prophet much frequented by pilgrims, at which a great annual fair is also held. The population is said to be about 10,000.

AINMULLER, MAXIMILIAN EMMANUEL, founder of a new school of glass-painting, was born at Munich on the 14th February 1807. He was induced, by the advice of Gärtner, director of the royal porcelain manufactory, to devote himself to the study of glass-painting, both as a mechanical process and as an art, and he made such progress that in 1828 he was appointed director of the newly-founded royal painted-glass manufactory at Munich. The method which he gradually perfected there was a development of the enamel process adopted in the Renaissance, and consisted in actually painting the design upon the glass, which was subjected, as each colour was laid on, to carefully-adjusted heating. The fault of this new style is its production of transparent pictures seen by transmitted and not by reflected light; but the popular verdict in its favour has been, notwithstanding, proved by the extent to which it has been adopted. The earliest specimens of Ainmüller's work are to be found in the cathedral of Ratisbon. With a few exceptions, all the windows in Glasgow cathedral are from his hand. Specimens may also be seen in St Paul's cathedral and St Peter's College, Cambridge. On the Continent it must suffice to mention Cologne cathedral as containing some of his finest productions. Ainmüller had considerable skill as an oil-painter, especially in interiors; and his pictures of the Chapel Royal at Windsor and of Westminster Abbey have been much admired. He died 9th December 1870.

AINOS, the name of a small but remarkable tribe in Japan, found chiefly in the island of Yesso. They are different in race and character from the ordinary Japanese, and seem to have been the earliest inhabitants of the country. Since the invasion of the islands by the Japanese, however, the Ainos have been gradually supplanted by the invaders, and are now completely subject to them, although they still preserve the appearance of internal self-government, living in societies of from ten to twenty families, under a hereditary chief. Their language is quite distinct from the Japanese, and intercourse between the two peoples is carried on by a sort of mongrel dialect. The Ainos are not tall, averaging a little over 5 feet; but they are well-proportioned and strongly-built, with a type of countenance European rather than Asiatic. They are distinguished by an exuberance of hair on the head and body, a circumstance which has given rise to their name of "Hairy Kuriles." The women are ugly, and are much addicted to tattooing. The dress of the Ainos consists of a robe of skin or cotton, reaching to the knees and secured by a girdle; their huts are small and uncomfortable, with little or no furniture; and their food is mostly the produce of fishing and hunting, together with rice got by barter from the Japanese. They are probably less than 50,000 in number.

AINSWORTH, HENRY, divine and scholar, was born "about 1560" at Pleasington, near Blackburn, Lancashire, having been second son of Lawrence Ainsworth of Pleasington Hall. Young Henry Ainsworth is believed to have received his education at Queen Elizabeth's Grammar School in Blackburn, of which his father was an original founder. According to tradition, he was a Roman Catholic, and a younger brother, John, a Protestant; and the two brothers, entering into a written controversy, mutually converted each other—Henry having embraced Protestantism, and John, Popery. The subsequent earlier history of Ainsworth is still obscure. No record survives; but various authorities concur in stating that he passed from Blackburn to Cambridge. He associated with the Puritan party in the Church of England, and eventually adopted the platform of the Independents as represented by the Brownists. He was driven from his native country by the state proscription of the sectaries before the year 1593. He is found resident in "a blind lane at Amsterdam" about 1595–6. His exile must have reduced him to extreme poverty. He is stated to have been a "porter" to a scholarly bookseller in Amsterdam, who, on discovering his skill in the Hebrew language, made him known to his countrymen. Roger

Williams, in one of his fiery tractates, reproaches Ainsworth as "living upon ninepence a week and some boiled roots." When the Brownists erected a church in Amsterdam, Francis Johnson was chosen for their pastor, and Henry Ainsworth for their doctor or teacher. In 1596 these two divines drew up a confession of their faith (in Latin), which was reprinted in 1598, and dedicated to the various universities of Europe (including St Andrews, Scotland). The separations and controversies which ensued at Amsterdam and at Leyden belong to church history. Of Ainsworth it may be said, that while he never put himself forward or sought notoriety, he was beyond comparison the most steadfast and most resolute and most cultured champion of those principles of civil and religious freedom represented by the now large and influential body of Nonconformists in Britain and America called Independents or Congregationalists. The personal squabbles and temporary animosities have long passed away; and it is recognised that in Henry Ainsworth Nonconformity had a man of saintly worth, of intellectual power, and of uncompromising intrepidity. Amid the strifes and clamours of controversy he pursued steadfastly his rabbinical studies. The combination was so unique that Moreri and Zedler, like others, made two Henry Ainsworths—one Dr Henry Ainsworth, a learned biblical commentator; the other H. Ainsworth, an arch-heretic, and "the ringleader of the Separatists at Amsterdam." Kindred mistakes are found regarding his writings in Hornbeck's *Summa Controversiarum*, and more recent bibliographical authorities. In 1608 our Ainsworth defended the Separation against Richard Bernard and William Crashaw (father of the poet). But his ablest and most arduous minor work in controversy was his crushing reply to the notorious Smyth, entitled *A. Defence of the Holy Scriptures, Worship, and Ministry, used in the Christian Church separated from Antichrist, against the Challenges, Cavils, and Contradictions of M. Smyth* (1609). His memory abides through his rabbinical learning. The ripe fruit of many years' diligence appeared in his Notes on Genesis, 1616; Exodus, 1617; Leviticus, 1618; Numbers, 1619; Deuteronomy, 1619; Psalms, 1612, 2d edition 1617; Song of Solomon, 1623. These were collected in folio in 1627, and again in 1639, and later in various forms. From the outset the *Annotations* have taken a commanding place especially among Continental scholars, as witness Clement, Dornius, Voght, Lilienthal, and Simon, the last urging Catholics to study and value them. Perhaps nothing more clearly shows even his home repute than the praiseworthy zeal with which Vice-Chancellor Dr John Worthington endeavoured to recover certain posthumous MSS. of Ainsworth. These, it is to be feared, have irrecoverably disappeared. Moreri mentions a current report that the famous Lightfoot "pillaged the best of his observations" from Ainsworth. A comparison of the *Exercitations* with the *Annotations* shows, however, that the two scholars worked independently. Moreri's groundless remark has been transmuted into an imputation as groundless—that Lightfoot had got into his possession the MSS. of Ainsworth. The character and learning of the great rabbinist ought to have silenced such an unworthy suspicion. There is nothing more striking in the career of Ainsworth than the reported manner of his death, which took place at Amsterdam in 1622–3. It is stated that, having found a diamond of great value, he advertised it; and when the owner, who was a Jew, came to demand it, he offered the finder any gratuity he sought. Ainsworth, though poor, requested only of the Jew that he would procure him a conference with some of his rabbis upon the prophecies of the Old Testament relating to the Messiah, which the Jew promised; but not having interest to obtain such a conference, it is thought that he contrived to get Ainsworth poisoned (Neal, *Puritans*, ii. 47). Another account says that he attended the conference, and so confounded the Jews that, from spite and malice, they in this manner put a period to his life (Brook, *Puritans*, ii. 302). There is an air of improbability about the narrative; but it is certain he was dead in 1623, for in that year was published his *Seasonable Discourse, or a Censure upon a Dialogue of the Anabaptists*, in which the editor speaks of him as a departed worthy. For a pretty complete list of his writings, lesser and larger, see Chalmers, Brook, and Hanbury. Many are now extremely rare and high-priced. (See Worthington's *Diary* [Chetham Society], by Crossley, i. 263–6; Hanbury's *Memorials*, s.v.; Works of Robinson, iii., Appendix, and *supra*.) (A. B. G.)

AINSWORTH, ROBERT (1660–1743), author of a well-known Latin dictionary, was born at Woodvale, near Manchester. After teaching for some time in Bolton, he removed to London, where he conducted a boarding-school, first at Bethnal Green, and then at Hackney. At a comparatively early period of his life he had realised a competency, and was able to retire. Proposals for the preparation of a Latin dictionary were made to him in 1714, but the work was not published till 1736. It was long extensively used in schools, and often reprinted, the later editions being revised and enlarged by other hands. Ainsworth's *Dictionary* was, however, radically imperfect, containing a mere register of words, with no scientific classification or complete and exact definition of their various meanings, and necessarily wanting the results of modern philological research. Later works have now entirely superseded it.

AINTAB, a large garrison town on the northern frontier of Syria, 65 miles N.N.E. of Aleppo, in 36° 58′ N. lat., 37° 13′ E. long. It has a considerable trade, chiefly in hides and leather, and cotton of coarse quality is grown in the district. Population, about 20,000.

AIR was the name formerly given to all gaseous substances. The gas now known as oxygen, for instance, was named by Priestley *dephlogisticated air*, in contradistinction to nitrogen or azote, which was *phlogisticated air*. So hydrogen gas was known to the early chemists as *inflammable air*, carbonic acid gas as *fixed air*, &c. The name is now ordinarily restricted to what is more accurately called atmospheric air—the air we breathe—the invisible elastic fluid which surrounds the earth, extending to an unknown height. The properties of this fluid will be fully considered under such headings as ATMOSPHERE, BAROMETER, CHEMISTRY, VENTILATION, &c. Reference may be made here to the mechanical use of air as a moving power, or rather as a means for transferring power, just as it is transferred by a train of wheelwork. Compressed air can be employed in this way with great advantage in mines, tunnels, and other confined situations, where the discharge of steam would be attended with inconvenience. The work is really done in these cases by a steam-engine or other prime mover in compressing the air. In the construction of the Mont Cenis tunnel the air was first compressed by water-power, and then carried through pipes into the heart of the mountain to work the boring machines. This use of compressed air in such situations is also of indirect advantage in serving not only to ventilate the place in which it is worked, but also to cool it; for it must be remembered that air falls in temperature during expansion, and therefore, as its temperature in the machines was only that of the atmosphere, it must, on being discharged from them, fall far below that temperature. This fall is so great that one of the most serious practical difficulties in working machines by compressed air has been found to be the formation of ice in the pipes by the freezing of the moisture in the air, which frequently chokes them entirely up.

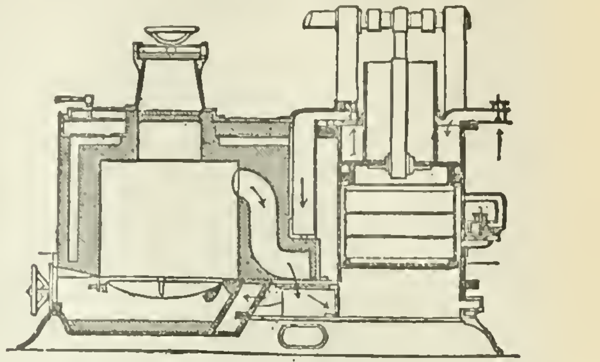
AIR-ENGINE. Engines which have for their working fluid heated air instead of steam are called "air-engines." The name "caloric engine" has also been applied to them, but is not to be commended, for they have no more right to that title than steam-engines—the useful effect of both machines being due to the transformation of heat into mechanical energy, the air in the one case and the steam in the other being merely convenient media through which to effect that transformation.

The utilisation of the expansion of heated air for driving an engine has for many years been a subject which has exercised the ingenuity of inventors. The history of air-engines has, however, been little more hitherto than a history of failures, and they are as far now from superseding steam-engines as they were fifty years ago. This is owing mostly to the fact that the inventors have too often worked empirically, without any real knowledge of the conditions under which, and under which only, the real advantages of the fluid could be attained, and have therefore continually violated these conditions. There are also certain constructive difficulties in the way of making a successful air-engine which have never been fully overcome. It should be distinctly understood that, regarded simply as a medium for transforming heat into work, air possesses *no* advantage over steam or any other fluid. Its advantage is, that it can be used with safety at much higher temperatures than steam (and therefore a larger proportion of the heat given to it can be transformed into work), and that by employing the gases of combustion in the cylinder much heat can be utilised which with steam-engines is necessarily wasted.

Of the air-engines which have actually worked we have—(1.) Those in which the changes of temperature take place at a pair of constant volumes; (2.) those in which the changes of temperature take place at a pair of constant pressures; and (3.) those in which heat is received and rejected at a pair of constant pressures. The first two classes, fitted with "economisers," are in theory "perfect" engines; that is, they are theoretically capable of transforming into work the largest fraction the limits of temperature allow of the heat received from the fuel. The third class are not perfect engines, but possess certain practical advantages which will be afterwards mentioned.

The well-known engine invented by the Rev. Dr Stirling in 1816, and subsequently improved by him, in conjunction with his brother, Mr James Stirling, C.E., of Edinburgh, belongs to the first class. In this engine the same mass of air is used again and again, and is compressed at starting to a pressure of 7 to 10 atmospheres. A cylindrical air-receiver, in which a plunger can be moved up and down, is placed over the flue of the furnace. The annular space between the plunger and the sides of this receiver is occupied by an immense number of thin sheets of metal, which form the "economiser." In the upper part of the receiver, which communicates freely with one end of a working cylinder of the usual construction, is a "refrigerator," consisting of a coil of tubing through which cold water continually circulates. The plunger is alternately raised and lowered by suitable mechanism, and in its motion causes the great body of air in the machine to occupy alternately the bottom or heating end and the top or cooling end of the receiver. It thus undergoes alternate expansion and contraction, and thereby gives motion to the piston of the working cylinner, and thence to a crank shaft in the usual way. The advantages of this engine were, that the air in the cylinder was always cool, and that the great pressure which could be used rendered the size of the machine for a given power very moderate. It was ultimately abandoned because of the failure of the receiver to stand the destructive action of the heat.

The most familiar example of the second class of air-engines is that invented by Captain Ericsson. It differed from Stirling's in many respects, and does not seem in any one particular to have been an improvement on it. Fresh air was drawn from the atmosphere at every stroke, and a very low pressure used, and what was the receiver in Stirling's engine became the working cylinder of Ericsson's. It was thus excessively bulky in proportion to its power, and all the working parts were exposed to the destructive action of intense heat. It is chiefly interesting on account of the enormous scale on which its construction was actually carried out. The engines of the steamship "Ericsson" had four working cylinders, each 14 ft. in diameter, with other parts in proportion. The trials of this vessel were conducted in a manner which did not allow any confidence to be placed in the results said to be obtained, and steam-engines replaced those of Ericsson within two years.



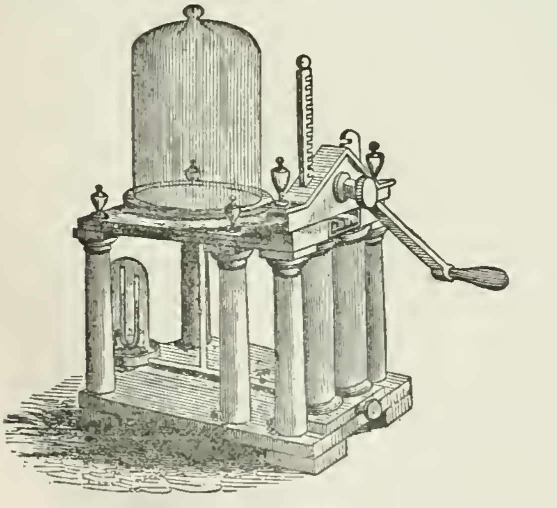
To the third class of air-engines belong those of Sir George Cayley and several of the older inventors. The best known modern example is, however, the engine of Mr Philander Shaw, which is shown in our engraving, and which was exhibited at the Paris Exhibition of 1867. The most important feature of this type of engine is the use of the products of combustion themselves, instead of merely the air heated by them, to drive the piston. The construction of the engine is very simple: the working piston is fitted with a trunk on its upper side, which, thus reduced in area, serves as a compressing pump, and the products of combustion act directly upon its under side, which is protected by a large drum filled with non-conducting material from the heat. The furnace stands beside the cylinder, and is entirely closed up, means being provided for feeding it with fuel without allowing any air to enter. The air compressed by the pump is delivered into the furnace, where it combines with the fuel to form the gases of combustion, and in this way receiving additional heat, expands, and raises the piston of the working cylinder for a portion of its stroke. The admission-valve of the latter is then closed, and the gases expand, without addition of heat, until the piston has completed its stroke, and are then discharged into the atmosphere. By the addition of an "economiser," the efficiency of this type of engine may be very greatly increased; but its principal advantage is that, by actually using the products of combustion inside the engine, much heat is saved which in other engines is unavoidably sent up the chimney and lost.

One of the principal features of all air-engines is the "economiser" (sometimes erroneously called the "regenerator"), an invention of Mr Stirling's. The object of this apparatus is to store up the heat rejected by the fluid when it falls in temperature, and subsequently to raise the temperature of the fluid by re-storing the same heat, so that the only heat which the furnace has to supply is the latent heat of expansion, together with the amount of sensible heat which may be lost through the imperfection of the economiser.

(For a popular explanation of the theory of air-engines, see an admirable paper by the late Professor Rankine in the *Edinburgh Philosophical Journal* for January 1855; and for a complete account of the same, involving the use of the higher mathematics, see the same author's *Steam-Engine*, pp. 345, *et seq.* See also Prof. Clerk Maxwell's *Theory of Heat*, and a series of papers on the subject in *Engineering*, 1874.) (A. B. W. K.)

AIR-GUN, a weapon like a common gun in shape, in which the force employed to propel the bullet is the elasticity of condensed atmospheric air. It has attached to it, or constructed in it, a strong metal chamber, into which air is forced by a condensing syringe (see PNEUMATICS). In this way a pressure may be obtained of several hundred atmospheres. When a trigger is touched, the condensed air rushes into a space behind the bullet with such force as to propel it from the barrel to a considerable distance. If only a little air be allowed to escape each time, a single charge will propel a number of bullets in succession, with a constantly diminishing force. Sometimes the weapon is made in the form of a walking-stick, and is then called an *air-cane.* The air-gun is little else than a scientific toy, and has no practical value. The apparatus is costly, the process of condensation requires considerable labour, and the propulsive force of the air is, at its maximum, less than that of an ordinary charge of gunpowder. The only advantage it can be said to have in any way is the questionable one of its use being unattended by the explosive noise that accompanies the discharge of a common gun.

AIR-PUMP, an apparatus by means of which a closed vessel can have the air it contains removed from it. It consists essentially of two parts—a receiver, from which the air is to be exhausted; and a pump, to perform the work of exhaustion. The receiver is in general made of glass, in order that the condition of objects placed within it for the purpose of experiment may be readily seen by the operator. It is open at the bottom, and has its lower edge accurately ground; when in its place in the air-pump it stands upon a smooth brass plate. The pump itself is a brass cylinder, having a piston in it, which can be moved backwards and forwards by means of a rod, in the usual way. At the end of the cylinder nearest the receiver is placed a small valve, in the piston itself is another (or some mechanism which serves the purpose of a valve), and there is frequently a third in the outer end of the cylinder. All these valves open outwards from the receiver. The action of the pump, when arranged in this way, is exactly similar to the action of an ordinary well-pump, with air as the fluid instead of water. The air-pump was invented about 1654 by Otto von Guericke, a magistrate of Magdeburg, and a man who devoted great attention to various problems in pneumatics.[1] The first description of his pump was published in 1657 in the *Mechanica Hydraulico-pneumatica* of Gaspar Schottus, professor of mathematics at Wurtemberg. He used a spherical glass receiver, with a pumping syringe attached, and kept the whole of the working parts under water to prevent leakage. His pump



was very imperfectly constructed, but he did eventually succeed in getting a very good vacuum with it. The method of producing the Torricellian vacuum, by filling a vessel with liquid and then removing the liquid without permitting ingress of air, was previously known; but a vacuum produced in this way was obviously useless for experiments with any objects but those which could previously be immersed in the liquid used. Guericke was, however, the first to recognise that, by virtue of its perfect elasticity, or tendency to expand indefinitely, air could be pumped out of a closed space as well as water; and this is the principle of his and all succeeding air-pumps. Although the invention of the air-pump is due to a German, almost all the improvements made in it from time to time have come from Englishmen. Dr Boyle contributed so much to its perfection that for a long time the state of the air in an exhausted receiver was called *vacuum Boyleanum*, and the air-pump itself *machina Boyleana.* Dr Hook, Hawkesbee, John Smeaton, and others brought the air-pump externally to very much the same form as that in which it is commonly seen at present, and which is shown in the annexed woodcut. The pump here has two cylinders, which are worked by a winch handle, the pump rods having toothed racks on the upper part of their length. Professor Tate is the inventor of a double-action air-pump, now much used where a very perfect vacuum is required. It has two pistons in one barrel, the air being drawn from the receiver at the centre of the barrel, and discharged into the atmosphere at its extremities. Very complete air-pumps have two or three barrels, arranged as shown in the woodcut, for rapid exhaustion, until the pressure in the receiver is equal to (say) half-an-inch of mercury; and in addition to these a horizontal Tate's barrel, which can then be put into action to bring the vacuum down to $\frac{1}{20}$ inch of mercury (1-600th of the pressure of the atmosphere), or even less at low temperatures. See PNEUMATICS.

AIR-PUMP, in steam-engines, is the pump which draws the condensed steam, along with the air which is always mixed with it, and also the condensing water (except where a surface condenser is used), away from the condenser, and discharges it into the hot well. See STEAM-ENGINE. (A. B. W. K.)

AIR, or ASBEN, a country of central Africa, lying between 15° and 19° N. lat. and 6° and 10° E. long. The northern and best known portion of this region is of a very diversified character. It has numerous mountain ranges, some of which rise to a height of 5000 feet, with richly-wooded hollows and extensive plains interspersed. The mimosa, the dum-palm, and the date are abundant; and the valleys are covered with the exuberant vegetation of the tropics. Some of the plains afford good pasturage for camels, asses, goats, and cattle; others are desert table-lands. In the less frequented districts wild animals abound, notably the lion and the gazelle. The country generally is of sandstone or granite formation, with occasional trachyte and basaltic ranges. There are no permanent rivers; but during the rainy season, from August to October, very heavy floods convert the water-courses in the hollows of the mountains into broad and rapid streams. Numerous wells supply the wants of the people and their cattle. To the south of this variegated region lies a desert plateau, 2000 feet above the level of the sea, destitute of water, and tenanted only by the wild ox, the ostrich, and the giraffe. Still further south is the district of Damerghu, nominally tributary to Air, undulating and fertile, and yielding rich crops. Notwithstanding the fertility of the valleys in the northern portion of the country, there is little of the soil under cultivation except in the neighbourhood of the villages, where slaves are employed in tillage. Millet, dates, indigo, and senna are the principal productions. The great bulk of the food supplies is brought from Damerghu, and the whole materials for clothing are also imported. Were it not for the traffic in salt between Bilma and the Hansa states of Soudan, the country could scarcely maintain its present limited number of inhabitants. A great caravan annually passes through Air, consisting of several thousand camels, carrying salt from Bilma to Sokoto. Air was called Asben by the native tribes until they were conquered by the Berbers. The present inhabitants are for the most

[1] He was also the inventor of the "Magdeburg hemispheres."

part of a mixed race, combining the finer personal traits of the Berbers with the characteristics of the negro. The king or sultan of Air occupies a very precarious position, being to a great extent dependent on the chiefs of the Tawarek tribes inhabiting a vast tract of the Sahara to the north-west, who are continually at war among themselves. A large part of the revenue of the king is derived from tribute exacted from the salt caravan. His authority does not seem to be great in the outlying parts of his dominions. The chief town of Air is AGADES (*q.v.*) (See Dr Barth's *Travels in Central Africa*, vol. i.)

AIRAY, HENRY, D.D. This celebrated Puritan president of Queen's College, Oxford, was born at Kentmere, near Windermere, but no record remains of the date of either birth or baptism. Anthony a Wood names Westmoreland as his birthplace. In the well-known *Life of Bernard Gilpin* it is told that when he was making preparations for martyrdom, he "received the account with great composure; and immediately after called up *William Airay*, a favourite domestic, who had long served him as his almoner and steward." From the great kindness shown to our Airay by Gilpin, and from the vicinity of Kentmere to the Rectory, it does not appear to be hazarding too much to assume that this William Airay was his father, and that the family tradition is right in assigning Kentmere, not Barton or Wilford, as his birthplace. The truly apostolic man's bounty showed itself in sending Henry and a (probable) brother Ewan or Evan to his own endowed school, where they were fully educated "in grammatical learning," and were in attendance at Oxford when Gilpin lay a-dying. From the *Athenæ* we glean the details of Airay's college attendance. He was "sent," says Wood, "to St Edmund's Hall in 1579, aged nineteen or thereabouts." "Soon after," he continues, "our author, Airay, was translated to Queen's College, where he became *pauper puer serviens;* that is, a poor serving child that waits on the fellows in the common hall at meals, and in their chambers, and do other servile work about the college." His transference to Queen's College is explained by its having been Gilpin's own college, and by his Westmoreland origin giving him a claim on Eaglesfield's foundation. He proceeded B.A. on June 19, 1583. On June 15, 1586, he passed M.A.; B.D. in 1594; and D.D. on June 17, 1600—all in Queen's College. "About the time he was master" (1586), "he entered holy orders, and became a frequent and zealous preacher in the university" His Commentary on the Epistle to the Philippians (1618), reprinted 1864, is a specimen of his preaching before his college, and of his fiery denunciation of Popery, and his fearless enunciation of that Calvinism which Oxford, in common with all England, prized then. In 1598 he was chosen provost of his college, and in 1606 was vice-chancellor of the university. In the discharge of his vice-chancellor's duties, he came into conflict with Laud, who even thus early was betraying his Romish tendencies. He was also rector of Otmore (or Otmoor), near Oxford, a living which involved him in a trying litigation, whereof present incumbents reap the benefit. He died on 6th October 1616. His character as a man, preacher, divine, and as an important ruler in the university, will be found portrayed in the Epistle by Potter, prefixed to the *Commentary*. He must have been a fine specimen of the more cultured Puritans—possessed of a robust common-sense in admirable contrast with some of his contemporaries. (*Lectures on the whole Epistle of Paul to the Philippians*, 1618, 1864; Wood's *Athenæ*, by Bliss, ii. 177, 178, &c.; Laud's Works; Wills (Surtees Society.) (A. B. G.)

AIRDRIE, a parliamentary and municipal burgh and market-town of Scotland, in the parish of New Monkland, Lanarkshire, 11 miles E. of Glasgow and 32 W. of Edinburgh. The high road between these cities passes through Airdrie, forming its principal street, from which others diverge at right angles. It is well built, paved, and lighted with gas, but it contains little that is beautiful or attractive. It possesses a fine town-hall and a handsome edifice erected as the county buildings, as well as two places of worship belonging to the Church of Scotland, three to the Free Church, two to the United Presbyterians, and one each to the Reformed Presbyterians, the Congregationalists, the Baptists, the Wesleyan Methodists, and the Roman Catholics; five branch banks, with excellent places of business constructed or in course of construction; a mechanics' institute, and several schools. The extensive coal and iron mines in the vicinity give employment to a large part of the population of Airdrie, and have been the means of raising it, since the commencement of the century, from the insignificance of a village to its present prosperity. In the town itself there are manufactories of cotton goods and iron wares, besides foundries, engineering shops, saw-mills, and other branches of industry. A branch of the North British Railway from Glasgow, passing through Airdrie to Edinburgh, connects it by a direct line with both cities. It is also connected with Glasgow by the Monkland Canal, which comes within a mile of the town. By the Reform Act of 1832 Airdrie was created a parliamentary burgh, uniting with Falkirk, Hamilton, Lanark, and Linlithgow in sending one member to parliament. Its municipal corporation, which dates from 1821, consists of twelve councillors, including a provost and three bailies. There are weekly courts held by the magistrates, and courts are held twice a week by the sheriff-substitute and the justices of the peace respectively. The market-day is Tuesday, but the market is of little importance. By the census of 1871 the population of Airdrie was 13,488, the number of inhabited houses 1167, and the parliamentary constituency 1702, increased in 1873 to 1932. The annual value of real property in the burgh, not including railways, is £26,145; and the corporation revenue for 1873, £3401.

AIRE, an English river which rises in the West Riding of Yorkshire and pursues a south-easterly course through the populous "clothing district" of which Leeds is the capital. At Castleford, below Leeds, it receives a small tributary, the Calder, and it joins the Ouse shortly before that river's expansion into the estuary of the Humber above Hull. It is navigable to Leeds for small craft.

AIRE, a fortified town of France, on the river Lys, in the department of Pas-de-Calais, 10 miles S.E. of St Omer. Although its situation is low and marshy, the town is neat and well built. It possesses extensive barracks; and the Church of St Paul is a handsome Gothic structure. Its manufactures consist of hats, cotton and woollen goods, hardware, yarn, soap, and oil. Population, 8803.

AIRE, a town in the south of France, in the department of Landes, on the left bank of the Adour, 14 miles S.S.E. of St Sever. At one time it was the capital of the Visigoths, and since the fifth century it has been the seat of a bishopric. It has a college and cathedral; and there are manufactories of leather and hats. Population, 5144.

AISLE sometimes written ISLE, YLE, and ALLEY (Lat. and Ital. *Ala*, a wing; Fr. *Aile, Bas côté;* Ger. *Seitenschiff, Seitenchor*), in its primary sense, the wing of a house, but generally used to describe the alleys or passages at the sides of the naves and choirs of churches. In reckoning their number, the nave is usually counted. Thus a nave with an aisle on each side is generally called a three-aisled church; if with two aisles on each side, a five-aisled church. In England there are many churches with one side-aisle only; but there is only one cathedral with five aisles, that at Chichester. There are, however, very many such on the Continent, the most celebrated of which are at Milan and Amiens. Others have three aisles on each side, or seven aisles in all, as the cathedrals at Antwerp and Paris. The most extraordinary, however, is that at Cordova, originally erected for a mosque. It was first built with a nave and five aisles on each side, and eight others afterwards were added, making nineteen aisles in all. Old English writers frequently call the transepts "the cross isle, or yle," and the nave the "middle ile."

AISNE, a frontier department in the north-east of France, bounded on the N. by the department of Nord and the kingdom of Belgium, on the E. by the department of Ardennes, on the S.E. by that of Marne, on the S. by that of Seine-et-Marne, and on the W. by those of Oise and Somme; extending at the widest points 75 miles from N. to S., and 53 from E. to W., with an area of 2838 square miles. The surface of the department consists of fine undulating plains, diversified in the north by hilly ground which forms a part of the mountain system of the Ardennes. The chief rivers are the Somme, the Escaut, and the Sambre in the north; the Oise, traversing the north-west, with its tributaries the Serre and the Aisne, the latter of which joins it beyond the limits of the department; and the Marne and the Ourcq in the south. The soil of Aisne is, as a whole, fertile, and in some parts very rich, yielding wheat, barley, rye, oats, hops, flax, fruit, beetroot, and potatoes; there is good pasturage, and much attention is paid to the rearing of cattle, sheep, and horses. Wine is produced, but, except in the valley of the Marne, its quality is inferior. Large tracts of the department are under wood, the chief forests being those of Nouvion and St Michel in the north, Coucy and St Gobain in the centre, and Villers-Cotterets in the south. There are no minerals of importance in the department, but good building-stone and slates of a fair quality are found. Aisne is an important manufacturing department; its chief industrial products being shawls and muslin—as well as other cotton, linen, and woollen goods—glass, including the famous mirrors of St Gobain, iron wares, beetroot sugar, leather, and pottery. It has a good trade, which is much facilitated by railroads (the most important being those between Paris and Strasbourg, and Paris and Mons), canals, and the navigable portions of the rivers. Aisne, which is composed of parts of the ancient provinces of Picardy and the Isle of France, is divided into five arrondissements—St Quentin and Vervins in the north, Laon in the centre, and Soissons and Chateau Thierry in the south. It contains in all 37 cantons and 837 communes. Laon is the capital, and Soissons the seat of the bishop. The other towns of importance are Chauny, St Quentin, Vervins, Hirson, Suise, Villers-Cotterets, and Chateau Thierry. Population in 1872, 552,439, of whom 183,104 could neither read nor write, and 28,651 could read, but could not write.

AITON, WILLIAM (1731–1793), an eminent botanist and gardener, was born near Hamilton in Scotland. Having been regularly trained to the profession of a gardener, he travelled to England in the year 1754, where he became assistant to Philip Miller, then superintendent of the physic garden at Chelsea. In 1759 he was appointed director of the newly-established botanical garden at Kew, in which office he continued till his death. The garden at Kew, under the auspices of King George III., was destined to be the grand repository of all the vegetable riches which could be accumulated by regal munificence, from researches through every quarter of the globe. Aiton's care and skill in cultivation, and intelligence in arrangement, gained for him high reputation among the lovers of the science, and the particular esteem of his royal patrons. Under his superintendence many improvements took place in the plan and edifices of Kew gardens, which rendered them the principal scene of botanical culture in the kingdom. In 1783 his merit was rewarded with the lucrative office of manager of the pleasure and kitchen gardens of Kew, which he was allowed to hold along with the botanical direction. In 1789 he published his *Hortus Kewensis*, a catalogue of the plants cultivated in the Royal Botanical Garden at Kew, in 3 vols. 8vo, with 13 plates—a work which had been the labour of many years. The *Hortus*, in which the Linnæan system of arrangement, with some modification, was adopted, was very favourably received by students of science, and a second edition was issued (1810–3) by W. T. Aiton, his eldest son and successor. He was for many years honoured with the friendship of Sir Joseph Banks, the president of the Royal Society, and was aided by the Swedish naturalists, Solander and Dryander, in the preparation of his *Hortus Kewensis*.

AITZEMA, LEON VAN, Dutch historian and statesman, was born at Doccum, in Friesland, on the 19th November 1600, and died at the Hague on the 23d February 1669. In his youth he published a volume of Latin poems under the title of *Poemata Juvenilia*. He subsequently devoted himself almost entirely to political life, and held for a lengthened period the position of resident at the Hague for the towns of the Hanseatic League. His most important work was the *Historie oft Verhaal van Saäken van Staet in Oorlogh* (14 vols 4to, 1657–71), embracing the period from 1621 to 1668. It contains a large number of state documents, and is an invaluable authority on one of the most eventful periods of Dutch history.

AIX, an ancient city of France, the chief town of the arrondissement of the same name, in the department of the Bouches-du-Rhone. It was the *Aquæ Sextiæ* of the Romans, and between this and *Arelate* (Arles) is the field on which Marius gained his great victory over the Teutons. Under the counts of Provence, Aix became celebrated as a seat of learning; and it still retains many relics of its former splendour, and is distinguished by the number and excellence of its literary institutions. It has a library of 100,000 volumes, an academy of law, science, and theology, a museum, and a chamber of commerce. The cathedral—the baptistry of which is said to have been constructed from the remains of a Roman temple—the "Palais," the town-hall, and the clock-tower, are fine specimens of ancient architecture. There are numerous public fountains, on one of which is sculptured a figure of King René by David. The hot springs, from which the city derives its name, are not now in much repute. Aix is the seat of a court of justice and an archbishopric. The chief manufactures are cotton, silk, thread, and hardware; and olives and almonds are cultivated on the surrounding hills. There is considerable commerce in corn, wine, and oil. The naturalists Adanson and Tournefort, and the painter Vanloo, were born at Aix. Population (1872), 29,020.

AIX, or AIX-LES-BAINS, a town of France, in the department of Savoie, near Lake Bourget, 8 miles north of Chambéry. It was a celebrated bathing-place in the time of the Romans, and possesses numerous ancient remains. The hot springs, which are of sulphureous quality, and have a temperature of from 109° to 113° Fahr., are still much frequented, attracting annually above 2000 visitors. They are used for drinking as well as for bathing purposes. Population, 4430.

AIX-LA-CHAPELLE, the German AACHEN, the capital of a district of the same name in Rhenish Prussia, situated near the Wurm, a tributary of the Meuse, in a pleasant and fertile valley about 40 miles west of Cologne, with which it is connected by railway. It is well built, and is enclosed by ramparts that have been converted into promenades, and its appearance is rather that of a prosperous modern town than of an ancient city full of historical associations. Its town-house, built in 1353 on the ruins of Charlemagne's palace, contains the magnificent coronation hall of the German emperors, 162 feet long by 60 feet wide. Near the town-house are two ancient towers, one of which, called the *Granusthurm*, is sometimes said to be of Roman origin; and a fountain, with a statue of Charlemagne, which was erected in 1620. The cathedral of Aix-la-Chapelle consists of two parts, distinct both as to the time of their erection and their style of architecture. The older portion may be said to date either from 796 A.D., when it was erected by Charlemagne as the palace chapel, or from 983, when it was rebuilt on the old model by Otho III., after having been almost entirely destroyed by the Normans. It consists of an octagon, planned after that of St Vitale at Ravenna, surrounded by a sixteen-sided gallery, and terminating in a cupola. It contains the tomb of Charlemagne, which was opened in the year 1000, when the body of the emperor was found seated on a marble throne which was afterwards used in the imperial coronation ceremonies. The Gothic choir, which forms the more modern portion of the cathedral, was added during the latter half of the 14th and the beginning of the 15th centuries. The cathedral possesses many relics, the most sacred of which are exhibited only once every seven years, when they attract large crowds of worshippers. Besides these buildings, almost the only other of any antiquity is the corn exchange, probably of the 12th century. Of modern edifices, Aix-la-Chapelle possesses a theatre, a public library, a gymnasium, and several churches and hospitals. The chief manufactures of Aix-la-Chapelle are woollen cloths, stockings, shawls, silks, leather, glass, needles, pins, machines, general ironmongery, carriages, beer, brandy, tobacco, and chemicals. There is a good trade in these articles, not only with Germany and other continental countries, but also, in the case of cloth especially, with the United States of America. The hot sulphur springs of Aix-la-Chapelle are another important source of revenue to the inhabitants. These springs were known to the Romans, and have long been celebrated for the cure of rheumatism and gout. There are six in all, of which the Kaiserquelle is the chief, with a temperature reaching as high as 136° Fahr. There are also two cold chalybeate springs. Aix-la-Chapelle is the *Aquisgranum*, or *Civitas Aquensis*, of the Romans. Charlemagne, who perhaps was born and certainly died in the town, made it the second city of his empire and the capital of his dominions north of the Alps. He conferred numerous privileges upon its citizens, exempting them from military service and from all taxes, even when they were living in other parts of the empire. From 813 to 1531 the emperors of Germany were crowned at Aix-la-Chapelle, which during that period became one of the most important free imperial cities, although it was ravaged by the Normans in 851, and again in 882. By the removal of the coronations to Frankfort, Aix-la-Chapelle lost its leading position in Germany, and its internal prosperity was much injured by a disastrous fire in 1656. During the revolution it for a time belonged to France, but in 1815 it was ceded to Prussia, and has now become one of the chief seats of commerce in that kingdom. Population of Aix-la-Chapelle (1871), 74,238.

AIX-LA-CHAPELLE, *Congresses and Treaties of*. The first congress of Aix-la-Chapelle concerned the succession of Maria Theresa to the empire. It was held in 1748, and resulted in the treaty of Aix-la-Chapelle, signed in the same year, by which Maria Theresa was left in possession of most of her hereditary dominions, the chief exception being Silesia, which was ceded to Prussia. The second congress, held in 1818, resulted in the convention of Aix-la-Chapelle. The object of this congress was the regulation of the affairs of Europe, especially of France, after the war. A treaty of peace between France and Spain was also signed in this city in 1668, whereby Louis XIV. gave up his claim to the Spanish Netherlands, but was left in possession of much that he had already conquered.

AJACCIO, the chief town of Corsica, one of the departments of France. It is a seaport, situated on the west coast of the island, in 41° 54′ N. lat., and 8° 44′ E. long. The harbour is commodious, and sheltered on all sides save the south-west. The town is well built, and its principal buildings are the cathedral, the town-house, and the citadel. It is the seat of a bishop and a court of justice, and has a commercial college, a school of hydrography, a large library, and a botanic garden. Wine, fruits, and olive oil are the chief articles of trade; and anchovy and coral fisheries are extensively prosecuted along the coast. Ajaccio is celebrated as the birthplace of Napoleon Bonaparte. The house where he was born (15th August 1769) is still standing in good preservation. A marble statue was erected to his honour in 1850, and the people still retain strong Bonapartist sympathies. Population (1872), 16,545.

AJAN (the ancient *Azania*), a tract which forms the eastern horn of Africa, with a coast-line of about 10° of latitude, from Cape Gardafui nearly to the equator. It extends inland to the territory of the Gallas, but its limits cannot be strictly defined, as this part of Africa has been little explored. The coast towards the south is low and sandy, but northward, near Cape D'Orfui, it becomes high and mountainous, with some fertile valleys interspersed. Cape Gardafui, the most eastern point of Africa, is a bold promontory backed by lofty hills. There are no considerable rivers in Ajan, and the land for the most part is barren. The inhabitants, a tribe of the Somali, carry on a trade with the Arabs in ivory and gum, and the country possesses an excellent breed of horses.

AJAX (Αἴας), the son of Telamon. In Greek legend Ajax represents throughout only physical qualities, like Hercules, with whom, indeed, a likeness must have been recognised, or there would have been no sufficient basis for the belief that the child Ajax was born at the prayer of Hercules in behalf of his friend Telamon (the name Αἴας —or Αἴ-ας with digamma—being an allusion to the eagle, αἴετος, which appeared to announce the success of the prayer); and again, that Hercules was present at the birth of the infant, and by wrapping it in his lion's skin made it invulnerable, except in the armpit. In respect of being open to a wound in only one small spot Ajax resembles Achilles, with whom in the usual genealogy he claims to be related as cousin. But of this relationship there is no evidence in the *Iliad*, where Ajax appears of colossal frame (πελώριος), in himself a tower of strength (πύργος Ἀχαιῶν), and, as the simile implies, prepared for defence, not to lead assaults, unmoved by the shafts of enemies as is an ass in a corn-field by the pelting of boys (*Iliad*, xi. 556–566), while Achilles is no less clearly drawn as sensitive to finer passions and tastes, if equally bold in war. Unwarranted as it was by the *Iliad*, the identification of Ajax with the family of Æacus was chiefly a matter which concerned the Athenians, and that not until Salamis had come into their possession, on which occasion Solon inserted a line in the *Iliad* (ii. 557) for the purpose of supporting the Athenian claim to the island. Ajax then became an Attic hero, his name being given to one of the tribes. In this way his deeds came to be a favourite subject of the Attic drama, though they are not always represented in a creditable manner—as, for example, when, contrary to his steady character in the *Iliad* of being respectful to the gods, he is charged with insult to Athena, to account for her having influenced the decision against him in his competition with Ulysses for the armour of Achilles. It was Athena, also, who made him insane then, and led him to take his own life. From his blood sprang a flower, as at the death of Hyacinthus, which bore the initial letter of his name. In later times the people of Novum Ilium believed him to have been wronged by the decision, and told how, when Ulysses had been shipwrecked, the armour of Achilles was wafted by the tide upon the shore near the tomb of Ajax. (A. S. M.)

AJAX OILEUS, or the LESSER AJAX, was a son of the King of Locri, whose subjects he led before Troy, contributing a contingent of forty ships. In boldness he was in the first rank among the Greeks there, equal to make a stand against Hector, and swift of foot next to Achilles. But, compared with the other leaders, he is impatient and overbearing. Like the Telamonian Ajax, he appears as an enemy of Ulysses, and as the victim of Athena's vengeance. It was due to her influence that he, known for his speed, lost the race with Ulysses at the games in honour of Patroclus (*Iliad*, xxiii. 754–784); and again it was through her that on his return homeward his ship was wrecked upon the mythical Gyræan rock (*Odyssey*, iv. 499). As it stands in later story, he had drawn down Athena's anger by his assault upon Cassandra at the image of the goddess. Ulysses charged him with this offence, and demanded that he should be stoned. But, according to another version of the legend, he had only carried her off to his tent without any harm, when Agamemnon took her from him, and spread a report that Athena would destroy the whole army unless Ajax were slain; upon which, thinking of the unjust verdict given against his namesake, he went to sea in a frail vessel and perished. The news was received in the camp with grief, a funeral pile was erected on the ship which had conveyed him to Troy, sacrifice was offered, and when the evening wind came on, the burning ship was cut adrift. (A. S. M.)

AJEHO, or A-SHE-HOH, also called ALCHUKU, a considerable and rapidly increasing city of Manchuria, 30 miles south of the river Soongari, and about 120 north of Kirin. It is advantageously situated on the slopes of a gentle descent leading to the river. The country around is very fertile, producing in abundance various kinds of grain, besides pulse and opium. The population of the district consists entirely of Chinese immigrants, who are engaged in the reclamation and cultivation of the soil, which is given to them at a nominal price. A large trade is done in the town; and although the shops are of mean appearance, quantities of porcelain and other ornamental articles exposed for sale indicate its growing wealth. The population is about 40,000, and includes a considerable number of Mahometans.

AJMÍR, a district and town of British India, in Rájputáná. The DISTRICT lies between 25° 43′ and 26° 42′ N. lat., and 74° 22′ and 75° 33′ E. long., measuring 80 miles in length from north to south, by 50 miles in breadth, and comprising an area of 2057 square miles. It is bounded on the E. by the states of Krishnagar and Jaipur, on the S. by Mewár, on the W. by the British district of Mairwárá, and on the N.W. by the state of Jodhpur. The population in 1865 was returned at 426,268; of whom 363,539, or 85 per cent., were Hindus, and the remainder chiefly Mahometans. The eastern portion of the district is generally flat, broken only by gentle undulations, but the north and north-western parts are intersected by the great ARAVALLI range (*q.v.*) Many of the valleys in this region are mere sandy deserts, with an occasional oasis of cultivation, but there are also some very fertile tracts; among these is the plain on which lies the town of Ajmír. This valley, however, is not only fortunate in possessing a noble artificial lake, but is protected by the massive walls of the Nág-páthar range or Serpent rock, which forms a barrier against the sand. The only hills in the district are the Aravalli range and its offshoots. Ajmír is almost totally devoid of rivers, the Banás being the only stream which can be dignified with that name, and it only touches the south-eastern boundary of the district so as to irrigate the Pargana of Samur. Four small streams—the Ságarmatí, Saraswatí, Kharí, and Daí—also intersect the district. In the dry weather they are little more than brooks. The Ságar-matí and Saraswatí unite at Gobindgarh, the united waters flowing on under the name of the Luní (or salt water) river. There are two first-class roads in Ajmír, viz., one from Ajmír city to Gangwana, and thence through the Krishnagarh and Jaipur states to Agra; and another from the city to the cantonment station of Násírábád, a distance of 14 miles. There is also a second-class road from Ajmír to Nayá Nagar, a distance of 36 miles, besides sixteen third-class tracks connecting the principal towns and villages with the city. The principal products of the district are wheat, barley, rice, sugar-cane, peas, bajrá, maize, til (oil-seed), tobacco, and cotton. With the exception of woollen blankets, turbans, &c., manufactures can be scarcely said to exist in Ajmír. Salt is made in a rude method at Rámsur, from the saline exudations of the soil, to the extent of 3000 cwt. per annum. After supplying local wants, the surplus is exported towards Málwa and Ságar. The principal trade is in wool, cotton, opium, printed cloths, and tobacco. A large quantity of cotton is exported to Nayá Nagar, in Mairwárá district, whence it finds its way into the Bombay market. Oil is also a profitable article of trade. The domestic animals are sheep, horses, bullocks, camels, and goats. Cattle, and especially bullocks, are much valued, but are very scarce, owing partly to the want of sufficient pasturage and partly to frequent droughts. When these occur, the cattle are sent away to the neighbouring states, where better pasture can be procured, and very few find their way back. The imperial revenue obtained from the district in 1867 amounted to £61,791, 8s., exclusive of local funds raised by a road, tank, and postal cess.

The tenures of the agricultural village communities in Ajmír are of a very simple and uniform kind. They all belong to the type known as "imperfect patídárí," by which the better descriptions of land are held in severalty by each member of the proprietary body. Each member is responsible for the amount of revenue allotted on his holding; but in event of the default of any shareholder, the whole community is collectively liable for the total sum. The inferior and waste lands remain the property of the whole village, and the income derived from them is credited to the common account. The cultivators are nearly all proprietors of the land they till. A large portion of Ajmír district is parcelled out into estates, varying in size from a single village to a large *parganá* (or fiscal division). These estates are held by Rájput chiefs, some of whom descend from the original ruling families, while others owe their position to force or to the favour of the reigning power. They have all been confirmed in their estates by the British on payment of a fixed annual quit rent. Three towns are returned as containing a population of upwards of 5000 inhabitants in 1867—viz., Ajmír city (the capital and the only municipality in the district), population 34,763; Kekri, 6357; and Pisangun, 5055. There is also a military cantonment at Nasírábád, the garrison of which in 1867 consisted of a battery of European artillery, a European infantry regiment, a squadron of native cavalry, and a regiment of native infantry. In 1867 there were eighteen government schools in the district, attended by 647 pupils, and a government college at Ajmír city attended by 320 students. Besides these there were three mission schools for boys and one for girls in Ajmír city, and eight others in its neighbourhood. The average attendance at the mission schools amounted to 347.

AJMÍR CITY, the capital of Ajmír district, is situated in a picturesque and fertile valley surrounded by mountains, in 26° 29′ N. lat. and 74° 43′ E. long. The town is partly built on the lower slope of the Táragarh hill, and is surrounded by a stone wall with five handsome gates. To the north of the city is a large artificial lake called the Anaságar, whence the water supply of the place is derived. The town is clean, and possesses several handsome streets, the dwellings of the better classes being large and well built. The population in 1867 numbered 34,763, about two-thirds being Hindus, and the remainder Mahometans. The city trade chiefly consists of salt and opium. The former is imported in large quantities from the Sambar lake and Rámsur. Oilmaking is also a profitable branch of trade. Cotton cloths are manufactured to some extent, for the dyeing of which the city has attained a high reputation. A municipal income of about £2000 a-year is derived from octroi duties levied on articles consumed in the town. Out of this the police and conservancy arrangements are paid, the balance being spent on roads and in the support of charitable institutions. The Ajmír college, affiliated to the Calcutta university, had 320 pupils in 1867. The college buildings being inadequate to this number of pupils, the foundation-stone of a new structure was laid on the 17th February 1868. The agent to the governor-general for Rájputáná resides at Ajmír, which is also the headquarters of the commissioner of the Ajmír and Mairwárá division. It is likewise a station of a Scotch Presbyterian mission.

The chief object of interest is the *dargá*, or tomb of a famous Mahometan saint named Mayud-úd-dín. It is situated at the foot of the Táragarh mountain, and consists of a block of white marble buildings, without much pretension to architectural beauty. To this place the emperor Akbar, with his empress, performed a pilgrimage on foot from Agra, in accordance with the terms of a vow he had made when praying for a son. The large pillars erected at intervals of two miles the whole way, to mark the daily halting-place of the imperial pilgrim, are still extant. An ancient Jain temple, now converted into a Mahometan mosque, is situated on the lower slope of the Táragarh hill. With the exception of that part used as a mosque, nearly the whole of the ancient temple has fallen into ruins, but the relics are not excelled in beauty of architecture and sculpture by any remains of Hindu art. Forty columns support the roof, but no two are alike, and great fertility of invention is manifested in the execution of the ornaments. The summit of Táragarh mountain, overhanging Ajmír, is crowned by a fort, the lofty thick battlements of which run along its brow and enclose the table-land. The walls are 2 miles in circumference, and the fort can only be approached by steep and very roughly-paved planes, commanded by the fort and the outworks, and by the hill to the west. On coming into the hands of the English, the fort was dismantled by order of Lord William Bentinck, and is now converted into a sanitarium for the troops at Nasírábád. Ajmír was founded about the year 145 A.D. by Ají, a Chohán, who established the dynasty which continued to rule the country (with many vicissitudes of fortune) while the repeated waves of Mahometan invasion swept over India, until it eventually became an appanage of the crown of Dehli in 1193. Its internal government, however, was handed over to its ancient rulers upon the payment of a heavy tribute to the conquerors. It then remained feudatory to Dehli till 1365, when it was captured by the ruler of Mewár. In 1509 the place became a source of contention between the chiefs of Mewár and Márwár, and was ultimately conquered in 1532 by the latter prince, who in his turn in 1559 had to give way before the emperor Akbar. It continued in the hands of the Mughuls, with occasional revolts, till 1770, when it was ceded to the Marhattás, from which time up to 1818 the unhappy district was the scene of a continual struggle, being seized at different times by the Mewár and Márwár rájás, from whom it was as often retaken by the Marhattás. In 1818 the latter ceded it to the British in return for a payment of 50,000 rupees. Since then the country has enjoyed unbroken peace and a stable government.

AJURUOCA, a town of Brazil, in the province of Minas Geraes, 117 miles N. of Rio de Janeiro. It is situated on the Ajuruoca river, which is here crossed by a bridge. Gold was once found in the vicinity, but the soil has been long exhausted of the precious metals; and the people are chiefly engaged in agriculture, and in rearing animals for the markets of Rio. The land is fertile, and produces millet, mandioca, coffee, sugar-cane, and tobacco. The population of the town and district is 12,000.

AKABAH, THE GULF OF, the *Sinus Elanites* of antiquity, is the eastmost of the two divisions into which the Red Sea bifurcates near its northern extremity. It penetrates into Arabia Petræa in a N.N.E. direction, from 28° to 29° 32′ N. lat., a distance of 100 miles, and its breadth varies from 12 to 17 miles. The entrance is contracted by Tiran and other islands, so that the passage is rendered somewhat difficult; and its navigation is dangerous on account of the numerous coral reefs, and the sudden squalls which sweep down from the adjacent mountains, many of which rise perpendicularly to a height of 2000 feet. The only well-sheltered harbour is that called the Golden Port, situated on its western shore about 33 miles from the entrance, and 29 miles E. of Mount Sinai. About 2½ miles from the head of the gulf is the village of AKABAH, with a fortified castle, garrisoned by a few soldiers for the protection of the Moslem pilgrims on their way to Mecca. In the vicinity of the village there are extensive date groves; and there is abundance of good water, fruit, and vegetables. Akabah, though now of small importance, is not devoid of historical interest. It is supposed to occupy the site of the *Elath* of Scripture, which in remote ages carried on an extensive commerce; and some ruins in the sea a short distance southward are surmised to be the remains of *Eziongeber*.

AKBAR, AKHBAR, or AKBER, JELLALADIN MOHAMMED, one of the greatest and wisest of the Moghul emperors, was born at Amerkote in Sindh on the 14th October 1542, his father, Humayun, having been driven from the throne a short time before by the usurper Sher Khan. After more than twelve years' exile, Humayun regained his sovereignty, which, however, he had held only for a few months when he died. Akbar succeeded his father in 1556 under the regency of Bahram Khan, a Turkoman noble, whose energy in repelling pretenders to the throne, and severity in maintaining the discipline of the army, tended greatly to the consolidation of the newly-recovered empire. Bahram, however, was naturally despotic and cruel; and when order was somewhat restored, Akbar found it necessary to take the reins of government into his own hands, which he did by a proclamation issued in March 1560. The discarded regent lived for some time in rebellion, endeavouring to establish an independent principality in Malwah, but at last he was forced to cast himself on Akbar's mercy. The emperor not only freely pardoned him, but magnanimously offered him the choice of a high place in the army or a suitable escort for a pilgrimage to Mecca, and Bahram preferred the latter alternative. When Akbar ascended the throne, only a small portion of what had formerly been comprised within the Moghul empire owned his authority, and he devoted himself with great determination and marvellous success to the recovery of the revolted provinces. Over each of these, as it was restored, he placed a governor, whom he superintended with great vigilance and wisdom. He tried by every means to develop and encourage commerce; he had the land accurately measured for the purpose of rightly adjusting taxation; he gave the strictest instructions to prevent extortion on the part of the tax-gatherers, and in many other respects displayed an enlightened and equitable policy. Thus it happened that, in the fortieth year of Akbar's reign the empire had more than regained all that it had lost, the recovered provinces being reduced, not to subjection only as before, but to a great degree of peace, order, and contentment. Akbar's method of dealing with what must always be the chief difficulty of one who has to rule widely diverse races, affords perhaps the crowning evidence of his wisdom and moderation. In religion he was at first a Mussulman, but the intolerant exclusiveness of that creed was quite foreign to his character. Scepticism as to the divine origin of the Koran led him to seek the true religion in an eclectic system. He accordingly set himself to obtain information about other religions, sent to Goa, requesting that the Portuguese missionaries there would visit him, and listened to them with intelligent attention when they came. As the result of these inquiries, he adopted the creed of pure deism and a ritual based upon the system of Zoroaster. The religion thus founded, however, having no vital force, never spread beyond the limits of the court, and died with Akbar himself. But though his eclectic system failed, the spirit of toleration which originated it produced in other ways many important results; and, indeed, may be said to have done more to establish Akbar's power on a secure basis than all his economic and social reforms. He conciliated the Hindoos by giving them freedom of worship; while at the same time he strictly prohibited certain barbarous Brahminical practices, such as trial by ordeal and the burning of widows against their will. He also abolished all taxes upon pilgrims as an interference with the liberty of worship, and the capitation tax upon Hindoos, probably upon similar grounds. Measures like these gained for him during his lifetime the title of "Guardian of Mankind," and caused him to be held up as a model to Indian princes of later times, who in the matter of religious toleration have only too seldom followed his example. Akbar was a munificent patron of literature. He established schools throughout his empire for the education of Hindoos as well as Moslems, and he gathered round him many men of literary talent, among whom may be mentioned the brothers Feizi and Abulfazl. The former was commissioned by Akbar to translate a number of Sanscrit scientific works into Persian; and the latter (see ABULFAZL) has left, in the *Akbar-Nameh*, an enduring record of the emperor's reign. It is also said that Akbar employed Jerome Xavier, a Jesuit missionary, to translate the four Gospels into Persian. The closing years of Akbar's reign were rendered very unhappy by the misconduct of his sons. Two of them died in youth, the victims of intemperance; and the third, Selim, afterwards the emperor Jehanghir, was frequently in rebellion against his father. These calamities were keenly felt by Akbar, and may even have tended to hasten his death, which occurred at Agra on the 13th October 1605. His body was deposited in a magnificent mausoleum at Sicandra, near Agra.

AKEN, or ACKEN, a town in Prussian Saxony, situated on the Elbe, 25 miles E.S.E. of Magdeburg, close to the frontiers of Anhalt. It has manufactures of cloth, leather, chemicals, and optical instruments; large quantities of beetroot sugar are produced in the neighbourhood; and there is a considerable transit trade on the Elbe. Population (1871), 5273.

AKENSIDE, MARK. Like young Henry Kirke White, the poet of the *Pleasures of Imagination* was the son of a butcher. He was born at Newcastle-on-Tyne on November 9th, 1721. His school was the free one founded by a former mayor of Newcastle, Thomas Horsley. Later, one of the ministers of the Presbyterians added to his school-acquired knowledge in private. In his sixteenth year he sent to the *Gentleman's Magazine* a copy of verses entitled "The Virtuoso." Sylvanus Urban graciously printed the poem; but the old man was not difficult to please. Other verse contributions succeeded—imitative, yet not without gleams of a true faculty. Some written in the Lake country, while on visits with friends at Morpeth, have Wordsworthian touches. The memories of these visits transfigure the *Pleasures of Imagination*. In his nineteenth year, being intended for the clerical profession, he proceeded to the university of Edinburgh; but within one session, like many others, he changed his purpose, and transferred his name from the theological to the medical classes—although, indeed, then, as still, the opening years were occupied with the same studies for either. On his change he honourably returned certain moneys which his fellow Presbyterians had advanced towards his theological education. He attended the university for only two years. While there, in 1740, a medical society, which combined with it a debating club, gave him a fine field for the exercise of his oratorical powers. Dugald Stewart states that Robertson the historian, then a student of divinity, used to attend the meetings in order to hear Akenside's speeches. Some of his minor poems belong to this period, such as his Ode "for the Winter Solstice," the elegy called "Love," and the verses "to Cordelia." He returned to his native town in 1741, and then his friendship with Jeremiah Dyson had commenced, "a name never to be mentioned by any lover of genius or noble deeds without affection and reverence" (Willmott). In the years 1741 to 1743 he must have been ardent in his wooing of the Muses. In the summer or autumn of 1743 Dodsley carried with him to Pope at Twickenham a MS. for which the writer asked £120. The oracle of Twickenham having read the poem, counselled the publisher to make no niggardly offer, because "this was no every-day writer." It was something for Pope to be thus prescient in the absence of rhyme—albeit Pope's insertions in *The Seasons* remain to attest that, supreme artist as he was in rhyme, he could also manage blank verse with exquisite cunningness. The MS. was the *Pleasures of Imagination*, which Dodsley published in 1744. In his twenty-third year the author, like Byron, awoke to find himself famous. The assaults of Warburton and Hurd were scarcely a deduction from the universal welcome. The poet's "Epistle" to Warburton was effective. He went to Leyden, and there pursued his medical studies with ardour. He obtained the degree of M.D., May 16th, 1744; his inaugural dissertation describing the formation and growth of the human fœtus with original observation and acuteness. He now returned to England, advancing more and more in his friendship with the good and large-hearted Dyson. He chose Northampton as the place wherein he should commence practice. It was an unfortunate selection, as Sir James Stonehouse "possessed the confidence of the town," and it was deemed an intrusion. A not very creditable controversy arose; and we are at a loss whether most to admire the stinging rebuffs in honeyed courtesies or the mutual pretence of ultimate satisfaction and good-will. At Northampton Akenside was on friendly terms with Dr Doddridge. There, too, he wrote his "Epistle to Curio," which Lord Macaulay pronounced his best production, as "indicating powers of elevated satire, which, if diligently cultivated, might have disputed the pre-eminence of Dryden." Willmott traces some of the most nervous lines of the *Pleasures of Hope* to this "Epistle to Curio." Not succeeding in his profession at Northampton, he removed to Hampstead in 1747. The *Odes* had then been published. Dr Akenside came to Hampstead under the ægis of the generous Dyson. Somehow, in Hampstead as at Northampton, he manifested a vanity of self-display and hauteur of manner that made him many enemies. Within three years he had to leave Hampstead for London. He set up in Bloomsbury Square in a "fine house," and with an annuity of £300 from the still ungrudging Dyson. One is pleased to come on these words of a far greater poet a century later, "I am not unfrequently," wrote Wordsworth in 1837, "a visitor on Hampstead Heath, and I seldom pass by the entrance of Mr Dyson's villa at Goulder's Hill, close by, without thinking of the pleasure which Akenside often had there." The generous clerk of the House of Commons and secretary of the Treasury nobly earned his imperishable place in the (revised) *Pleasures of Imagination*. Contemporaneous with his professional duties, the poet became an essayist and reviewer for Dodsley in the now forgotten *Museum*. In 1753 the university of Cambridge bestowed on him the degree of doctor of medicine. In 1754 he was elected a fellow of the College of Physicians. In 1755 he read before the college the Gulstonian Lectures; and in 1756 the Croonian Lectures. In 1759 he was chosen assistant, and two months later chief.

physician of St Thomas's Hospital. In this year he had removed to Craven Street. In 1762 he changed once more to Burlington Street. In 1760 was published the *Harveian Oration* by order of the College of Physicians. In 1761, along with Dyson, he passed from a somewhat noisy Whiggery to the Tories, which added "renegade" to his name. In 1765–6 he was working upon the revised and enlarged copy of the *Pleasures of Imagination.* His fame was widening professionally and poetically, when a putrid fever carried him off suddenly on June 23d, 1770. He was buried at St James's Church on the 28th. As a man, the nearer one gets to Akenside the less is there lovable about him; there seem to have been ineradicable meannesses in his nature. Lavish in his expenditure while practically dependent on Dyson, and remaining dependent after his professional income ought to have released his patron, we cannot think of him as high-minded. His personal vanity was constantly bringing him sorenesses. The "Doctor" in *Peregrine Pickle* was painted from the life, not a mere creation of Smollett's genius. As a poet, the place of Akenside is secure, but it is not very lofty. His imagination is rhetorical rather than subtle, consisting more of pomp of words than greatness of thought. His chief defect is lack of emotion, and especially pathos. The enlarged *Pleasures of Imagination*, notwithstanding some noble additions, was a blunder. Some of his minor pieces have a classical grace and charm of expression. (See the original editions of his writings; Bucke's *Life, Writings, and Genius of Akenside,* 1832; Dyce and Willmott's edition of his *Poems;* Cunningham's Johnson's *Lives of the Poets,* s.v.; *Biog. Brit.; Medical Biog.*, s.v.) (A. B. G.)

AKERBLAD, JAN DAVID (1760–1819), a learned Swede, distinguished for his researches in Runic, Coptic, Phœnician, and ancient Egyptian literature. He entered the diplomatic service as secretary to the Swedish embassy at Constantinople, and utilised the leisure which the situation afforded by visiting Jerusalem (1792) and the Troad (1797). After an interval spent at Göttingen, he was appointed ambassador to Paris. His last years were passed at Rome, where he enjoyed a pension from the Duchess of Devonshire. Akerblad was a diligent student of hieroglyphics; and though he failed to decipher the Rosetta stone, he arrived at certain conjectural conclusions with regard to the true method of interpretation, which were afterwards confirmed by Dr Young. His works include letters on the Coptish cursive writing and on the Rosetta inscription, both addressed to M. de Sacy; and a number of pamphlets on the interpretation of various Runic and Phœnician inscriptions.

AKERMAN (perhaps the ancient *Tyras* or *Julia Alba*), a town of Russia in Europe, in the province of Bessarabia, on a tongue of land projecting into the estuary of the Dniester. Its harbour is too shallow to admit vessels of large size; but the trade of the town is, notwithstanding, very considerable. Large quantities of salt are obtained from the saline lakes in the neighbourhood; and corn, wine, wool, and leather are among the other exports. The town, which is ill-built, contains several mosques and Greek and Armenian churches; it is guarded by ramparts, and is commanded by a citadel placed on an eminence. Akerman derives some historical celebrity from the treaty concluded there in 1826 between Russia and the Porte, securing considerable advantages to the former. It was the non-observance of this treaty by Turkey that led to the war of 1828. Population (1867), 29,609.

AKERMAN, JOHN YONGE, an antiquarian, distinguished chiefly in the department of numismatics, was born in Wiltshire on the 12th June 1806. He became early known in connection with his favourite study, having initiated the *Numismatic Journal* in 1836. In the following year he became the secretary of the newly-established Numismatic Society. In 1848 he was elected secretary to the Society of Antiquaries, an office which he was compelled to resign in 1860 on account of failing health. He died on 18th November 1873. Akerman published a considerable number of works on his special subject, the more important being a *Catalogue of Roman Coins* (1839); a *Numismatic Manual* (1840); *Roman Coins relating to Britain* (1844), for which he received the medal of the French Institute; *Ancient Coins—Hispania, Gallia, Britannia* (1846); and *Numismatic Illustrations of the New Testament* (1846). He wrote also a *Glossary of Words used in Wiltshire* (1842); *Wiltshire Tales, illustrative of the Dialect* (1853); and *Remains of Pagan Saxondom* (1855).

AKHALZIKH, a city of Georgia, in Asiatic Russia, on an affluent of the Kur, 110 miles west of Tiflis, in 41° 40′ N. lat., 43° 1′ E. long. It contains a strong castle, a college and library, and a fine mosque, and has a considerable trade in silk, honey, and wax. Population (1867), 15,977.

AKHISSAR, the ancient *Thyatira*, a town of Turkey in Asia, in Anatolia, 58 miles N.E. of Smyrna. The inhabitants are Greeks, Armenians, and Turks. The houses are built of earth or turf dried in the sun, and are very low and ill-constructed; but there are six or seven mosques, which are all of marble. Remarkable inscriptions are to be seen in several parts of the town on portions of the ruins of the ancient city. Cotton of excellent quality is grown in the neighbourhood, and the place is celebrated for its scarlet dyes. Population, about 6000.

AKHTYRKA, a town of Russia in Europe, in the Ukraine, situated on a river of the same name, 45 miles N.W. of Kharkov. It has eight churches, one of which, containing an image of the Virgin, is held in great veneration. The town is enclosed by ditches; and the environs are fertile, the orchards producing excellent fruit. There are some manufactures of light woollen stuffs, and a great market is held annually in May. Population (1867), 17,411.

AKIBA, BEN JOSEPH, a famous rabbi who flourished about the close of the first and the beginning of the second centuries. It is almost impossible to separate the true from the false in the numerous traditions respecting his life. He became the chief teacher in the rabbinical school of Jaffa, where, it is said, he had 24,000 scholars. Whatever their number, it seems certain that among them was the celebrated Rabbi Meir, and that through him and others Akiba exerted a great influence on the development of the doctrines embodied in the Talmud. He sided with Barchochebas in his revolt, recognised him as the Messiah, and acted as his sword-bearer. Being taken prisoner by the Romans under Julius Severus, he was flayed alive with circumstances of great cruelty, and met his fate, according to tradition, with marvellous steadfastness and composure. He is said to have been a hundred and twenty years old at the time of his death. The Jews were long accustomed to pay visits to his tomb, and he is one of the ten Jewish martyrs whose names occur in a penitential prayer still used once a year in the synagogue service. A number of works commonly attributed to Akiba are of later origin; but the one entitled מִשְׁנָה דְּרַבִּי עֲקִיבָא (*Doctrine of Rabbi Akiba*) is probably genuine.

AKOLÁ, a district and city of British India, in the commissionership of West Berar, within the Haidarábád assigned districts. AKOLÁ DISTRICT lies between 20° 23′ and 21° 10′ N. lat., and between 76° 25′ and 77° 19′ E. long.; its greatest length from N. to S. being 72 miles, and its greatest breadth from E. to W. 63 miles. It is bounded on the N. by the Sátpurá range; on the E. by Elichpur district; on the S. by the Sátmál and Ajantá hills; and on the W. by the Buldáná and Khandesh districts. The total area of the district in 1869 was $2697\frac{3}{4}$ square miles.

or 1,726,625 acres, of which 1,326,583 acres, or 2072·78 square miles were under cultivation; 127,003 acres, or 198·45 square miles, cultivable but not actually under tillage; 41,198 acres, or 64·37 square miles, alienated land held rent free; the remaining 231,842 acres, or 362·25 square miles, consisting chiefly of unarable land, but including river-beds, tanks, village sites, pasturage land, or land occupied for public uses, &c. The population of the district in 1869 numbered 487,558—viz., Hindus, 433,238; Mahometans, 39,030; aborigines, 15,157; Christians, 78; Pársís, 45; Jews, 10. The district is square in shape and almost of a dead level, with the exception of two conical-shaped hills which stand out quite apart from any other eminences, and rise straight up from the plain. The principal river of Akolá, which, although not navigable, represents the main line of drainage, and into which the other streams discharge themselves, is the Púrná, flowing east and west. The principal tributaries on its south bank are the Kátá Púrná, Murná, Núm, and Bordí; and on its north bank, the Sháhnúr, Idrúpá, and Wún. None of these streams are navigable, and some of them almost dry up after the rainy season.

The extension line of the Great Indian Peninsular Railway from Bhosáwal to Nágpur intersects the district, with stations at Jalam Shegáon, Páras, Akolá, and Borgáon. Of eight main roads, three have been metalled. The first runs from Akolá to Akot, a rising cotton mart, and is 28 miles in length, running north-north-east. It is metalled, and all the smaller water-courses are bridged. The Púrná and Sháhnúr rivers, however, cross the line, and are not bridged, a circumstance which impairs the usefulness of the road during the rainy season. The second road is known as the Básim road, and runs for 24 miles southwards through the district. The third road is 12 miles long, from Khámgáon to Nándurá railway station, and is metalled throughout. The other five lines of road are neither bridged nor metalled, but only marked out and levelled. The district imports piece goods from Bombay, and food grains from the adjoining districts. Its principal exports are cotton to Bombay, clarified butter, dyes (indigo and kusambá), and cattle. Internal trade is chiefly carried on at weekly markets and by annual fairs. The principal manufacture of the district is the weaving of cotton. Carpets and coarse cloths are woven in almost every village, with turbans at Bálápur, and silk cloths for native women at Akolá and in the larger towns. The principal agricultural products are as follows:—The wet weather or kharíf crop consists of joár (eighteen varieties); bajrá (two kinds); cotton (two kinds); túr, urid, and mug (three kinds of pulse); rice and kulkar (a smaller variety of rice); Indian corn; rálá; ganjá; ajwán; indigo; and til (oil-seeds of two kinds). The cold weather or rabí crop consists of—wheat (three kinds); gram; linseed; lakh (a pulse); peas; músuri; tobacco; and mustard. The principal articles of garden produce are the following:—Sugar-cane (two kinds); Indian corn (two kinds); ground nuts; onions; garlic; coriander; pán leaves; chillies; opium; sweet potatoes; grapes; plantains; saffron; and numerous kinds of vegetables. A tenure peculiar to Akolá is that known as *metkarí* holdings. These consist of certain strips of land extending along the whole breadth of the district at the foot of the frontier range. They are now of considerable value, and were originally held as payment for the maintenance of a chain of outposts or watch-towers on elevated points in the ridge, with a view to giving warning of the approach of the Bhil or Gond banditti, and warding off their attacks. Seven towns are returned as containing a population exceeding 5000—viz., Akolá (the capital of the district), population 12,236; Akot, one of the principal cotton marts of Berar, and also celebrated for its cotton manufacture, 14,006; Khámgáon, now the largest cotton mart in the province, but which has only sprung into importance within recent times, 9432; Bálápur, one of the chief military stations in the Berars during the Mahometan rule, 12,631; Jalgáon, an important cotton market, 8763; Patur, 6011; Shegáon, a station on the Great Indian Peninsular Railway, and a cotton market, 7450. In 1869 there were 1 higher class, 10 middle class, and 63 lower schools for boys in Akolá district; besides 7 female schools and 1 normal school for training Hindustáni and Marhatí masters, making a total of 82 schools in all. For the protection of person and property there were in 1869 13 police stations and 12 outposts, with a regular police force of 536 officers and men, equal to one man to every five miles of the district area, or one man to every 909 of the population.

AKOLÁ TOWN, the headquarters of the district of the same name, and also of the west Berar division of the Haidarábád assigned territory, is situated on the Nágpur extension of the Great Indian Peninsular Railway, in 20° 6′ N. lat., and 76° 2′ E. long. The town contains three or four wealthy merchants; and two markets are held each week—one on Sundays, the other on Wednesdays. The commissioner's and deputy-commissioner's court-houses, the central jail (capable of holding 500 prisoners), the post-office, and barracks or rest-houses for European troops, close to the station, are the principal public buildings. Besides these, there are a civil hospital, a charitable dispensary, an English high school, a town-hall, and an English church. A detachment of infantry is stationed at the town. Population in 1869, 12,236.

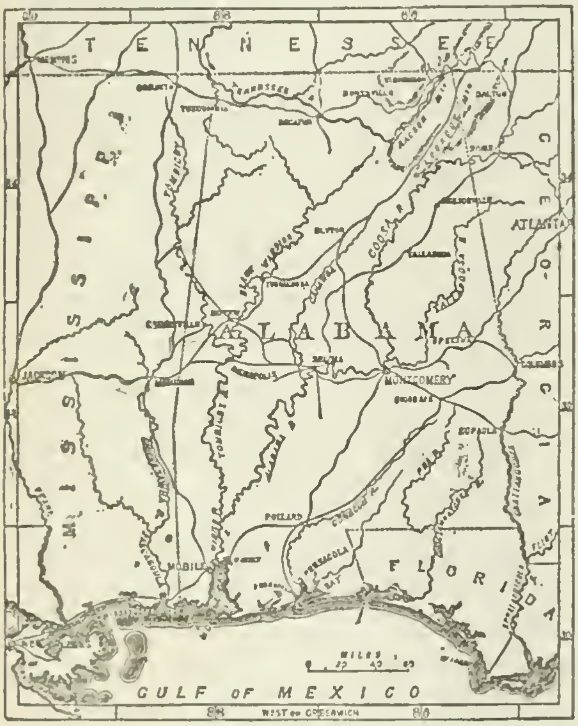
AKRON, a town of the United States, capital of Summit county, Ohio, situated on the Atlantic and Great Western Railway, and on the Ohio and Erie Canal, at its junction with the Pennsylvania and Ohio Canal, 36 miles S. of Cleveland. By means of the canal and the Little Cuyahoga river the town is amply supplied with water-power, which is employed in a variety of manufactures; and its mercantile business is extensive. It has several flour mills, woollen factories, and manufactories of iron goods. Mineral fire-proof paint, immense beds of which are found in the vicinity, and wheat are important articles of export. Akron was founded in 1825, and was made the capital of the county in 1841. Population in 1870, 10,006.

AK-SU, a town of Chinese Turkestan, is situated in 41° 7′ N. lat., 79° E. long., 250 miles N.E. of Yarkand. It has a flourishing trade, and is resorted to for purposes of commerce by caravans from all parts of Central Asia. There are some cotton manufactures; and the place is celebrated for its richly-ornamented saddlery made from deer-skin. A Chinese garrison is stationed here, and copper and iron are wrought in the neighbourhood by exiled Chinese criminals. The district is well cultivated, and sheep and cattle are extensively reared. The population of the town is about 20,000; that of the town and district 100,000.

AKYAB, a district and city within the Arákán division of British Burmah, and under the jurisdiction of the chief commissioner of that province. The DISTRICT lies along the north-eastern shores of the Bay of Bengal, between 20° and $21\frac{1}{2}$° N. lat., and 92° 12′ and 94° E. long. It forms the northernmost district of British Burmah, and the largest of the three districts of the Arákán division. It is bounded on the N. by the Chittagong district of Bengal; on the E. by the Sumadoung ranges, which separate it from Independent Burmah; on the S. by the Arákán districts of Rámri and Sandoway; and on the W. by the Bay of Bengal. In 1871 the frontier or hill tracts of the district were placed under a special administration, with a view to the better government of the wild tribes which inhabit them. The present area is returned at 4858 square miles, of which 521 square miles are cultivated, 913 cultivable but not actually under tillage, and 3424 square miles uncultivable and waste. The population of the district in 1872 amounted to 263,152, of whom 192,885 were Buddhists or Jains, 47,349 Mahometans, 8687 Hindus, 13,928 aborigines, and 303 Christians. The central part of the district consists of three fertile valleys, watered by the Myu, Koladyne, and Lemyu. These rivers approach each other at their mouths, and form a vast network of tidal channels, creeks, and islands. Their alluvial valleys yield inexhaustible supplies of rice, which the abundant water carriage brings down to the port of Akyab at a very cheap rate. The four chief towns are Khúmgchú in the extreme north-east of the district; Koladyne in the centre; Arákán, further down the rivers; and Akyab on the coast, where their mouths converge. This district passed into the hands of the British, together with the rest of Arákán division, at the close of the first Burmese war of 1825.

Akyab, Town and Port, situated at the point of convergence of the three large rivers Myu, Koladyne, and Lemyu, 20° 9′ N. lat., and 92° 56′ E. long., is the chief town of the district of the same name, and the most flourishing city of the Arákán division. The town is regularly built, with broad streets running at right angles to each other. The port is commodious, is the seat of a large export trade in rice, and possesses steam communication direct with Calcutta once a fortnight, except during the south-west monsoon. The population in 1871–72 numbered 15,281. Akyab monopolises almost the whole sea-borne trade of the province of Arákán, amounting in 1871–72 to £1,345,417; to which the export of rice contributed £105,894. During 1871–72, 256 vessels, of a total burden of 129,061 tons, entered the port; and 262 vessels, of a burden of 130,203 tons, cleared.

ALABAMA, one of the Southern States of the North American Union, lies between 30° 13′ and 35° N. lat., and between 85° and 88° 35′ W. long.[1] It is bounded by Florida and the Gulf of Mexico on the S., Mississippi on the W., Tennessee on the N., and Georgia on the E.



Its length is 330 miles, average breadth 154, and area 50,722 square miles. The Alleghany range stretches into the northern portion of the state, but the elevation is nowhere great; the centre is also hilly and broken; on the south, however, for nearly 60 miles inland, the country is very flat, and raised but little above the sea-level. The Alabama is the chief river of the state. It is formed by the junction of the Coosa and the Talapoosa, which unite about 10 miles above the city of Montgomery. Forty-five miles above Mobile the Alabama is joined by the Tombigbee, and from that point is known as the Mobile River. It is navigable from Mobile to Wetumpka, on the Coosa, some 460 miles. The Tombigbee is navigable to Columbus, and the Black Warrior, one of its chief tributaries, to Tuscaloosa. The Tennessee flows through the northern portion of the state, and the Chattahoochee forms part of its eastern boundary. The climate of Alabama is semi-tropical. The temperature ranges from 82° to 18° Fahr. in winter, and in summer from 105° to 60°; the mean temperature for the year being a little over 60°. The average severity of the winter months is considered to have increased—a result due, it is said, mainly to the felling of the forests, which gives more unrestricted scope to the cold north-west winds from the Rocky Mountains. The uplands are healthy, but the inhabitants of the low-lying lands are subject to attacks of intermittent, bilious, and congestive fevers. The stratified rocks of the state belong to the silurian, carboniferous, cretaceous, and tertiary systems. The silurian strata throw up numerous mineral springs along the line of the anticlinal axes, some of which, such as Blount Springs and the St Clair Springs, are much resorted to for their health-giving properties. There are also several noted springs arising from the tertiary beds, such as those of Tallahatta and Bladon. Alabama possesses extensive coal deposits. Mr Tait, the state commissioner for the industrial resources of Alabama, considers that the area of the coal-lands in the state amounts to 5500 square miles, of which 5000 belong to the Warrior, and the remaining 500 to the Cahawba and Coosa fields. Assuming that only one-half of this area can be worked to advantage, Mr Tait further estimates the aggregate possible yield at 52,250,000,000 tons. At present, however, the annual output probably does not exceed 12,000 tons. In regard to iron, the natural wealth of Alabama is also very great. Mr Tait asserts that a ridge of iron, of an average thickness of 15 feet, runs parallel to one of the principal railway lines for a distance of 100 miles; and in other parts of the country there are large deposits of ore, both red hematite and blackband. The ores of Alabama are said to yield from 10 to 20 per cent. more iron than those of Britain. Granite, marble, flagstones, roofing-slate, lime, and porcelain clay, are among the other mineral products. A little gold has also been found in the state.

The soil of Alabama varies greatly in character, but is for the most part productive to a greater or lesser extent, except in the south, where there are considerable tracts of sandy, barren, and almost worthless soil. The forests are mainly in the central and northern parts of the state, and embrace oaks, poplars, cedars, chestnuts, pines, hickories, mulberries, elms, and cypresses. The following table exhibits the chief agricultural statistics of Alabama for 1870, as compared with 1860, the year before the war:—

			1870.	1860.
Land in Farms.	Improved,	acres	5,062,204	6,385,724
	Unimproved,	,,	9,898,974	12,718,821
Live Stock on Farms.	Horses,		80,770	127,063
	Mules and Asses,		76,675	111,687
	Cattle,		487,163	773,396
	Sheep,		241,934	370,156
	Swine,		719,757	1,748,321
Chief Products.	Indian Corn,	bushels	16,977,948	33,226,282
	Wheat,	,,	1,055,068	1,218,444
	Rye,	,,	18,977	72,457
	Oats,	,,	770,866	682,179
	Potatoes,	,,	2,033,872	5,931,563
	Pease and Beans,	,,	156,574	1,482,036
	Butter,	lb	3,213,753	6,028,478
	Cotton,	bales	429,482	989,955
	Wool,	,,	381,253	775,117
	Rice,	lb	222,945	493,465
	Tobacco,	,,	152,742	232,914
	Molasses,	gallons	433,281	140,768

Alabama possesses comparatively few manufactures. It is estimated that in 1870 the capital invested amounted to £1,140,806, and the total products in the same year were valued at £2,608,124. There were in 1870 thirteen establishments for the manufacture of cotton goods, whose products amounted in all to 2,843,000 lb, including 4,518,403 yards of sheetings and shirtings, and 1,039,321

yards of ginghams and checks. In the same year 613 flour mills operated on 3,298,848 bushels of grain. There were 284 lumber mills, producing 1,115,000 laths, 97,192 feet of lumber, and 1,422,000 shingles. In the iron manufactures there has been a marked advance, which is the more noticeable because several other industries have experienced a serious decline. Thus, in 1850 the quantity of ore used for making pig-iron was only 1138 tons, in 1860 it had risen to 3720 tons, and in 1870 to 11,350; the value of the products being respectively £4500, £12,918, and £42,051. Alabama has also manufactories of rolled and cast iron; but the rise in the value of their products is not so marked. There are, besides, tanneries, carriage and waggon works, and machinery factories, in addition to industries of a local nature. Mobile is the chief mercantile city of the state. In the years ending June 30, 1871 and 1872, 688 and 369 vessels (gross burden, 558,525 and 272,853 tons) entered, and 711 and 369 (551,310 and 277,356 tons) cleared the port of Mobile. Cotton was the principal article of export—the amount in 1871 being 287,074 bales, and in 1872, 137,977; of which 240,660 and 123,522 bales went to Great Britain. Mobile is connected with the general network of railways of the United States. A line runs from the city through Montgomery and on to Atlanta in Georgia; another runs from Mobile to Meridian in Mississippi; a line crosses the state from Meridian through Cahawba to Montgomery; a loop-line runs from Montgomery to Troy, and proceeding round by Columbus in Georgia, rejoins the main line at Opelika; from Selma a line proceeds north-easterly, following the valley of the Coosa, and passing through Georgia and Tennessee; and another traverses the valley of the Tennessee, from which a branch strikes off to the north to join the Tennessee group of railways at Nashville. A line also connects Mobile with New Orleans. The part of the line from Mobile to Montgomery between Mobile and Tensas was completed under considerable engineering difficulties. It crosses the Mobile river by a swing drawbridge 1000 feet in length, with a draw of 260 feet; while the Tensas river bridge is built on cylindrical piers, each span measuring 152 feet, and its total length 2084 feet. There are at present 1602 miles of railway and 2135 of telegraph lines in operation in Alabama.

Alabama returns 8 members to Congress. The state government is vested in a governor, Senate, and House of Representatives. The Senate consists of 33 members elected for four years, one half retiring every two years. The House of Representatives consists of not more than 100 members, elected for two years, and apportioned among the counties according to population, each county, however, being entitled to at least one representative. The members of both houses receive 16s. 8d. each per diem, and the governor £520. 16s. 8d. per annum. The taxation in 1870 amounted to $2,982,932, and the public debt to $13,277,154. In 1860 the taxation was only $851,171. The state is divided into 65 counties, and Montgomery is the capital. The other principal towns are Mobile, Tuscaloosa (the former capital), Florence, Huntsville, Selma, and Wetumpka.

Alabama was first penetrated by the Spaniards in quest of gold in 1541, under the celebrated leader De Soto. The natives defended themselves stubbornly, and in their defence inflicted and sustained very severe losses. The present site of Mobile was first occupied by the French in 1711. In 1763 the French possessions east of the Mississippi, including Alabama, were ceded to England. Alabama was originally included in Georgia, but in 1802 became part of the territory of Mississippi. In 1813 the Creek indians made a desperate effort to check the encroachments of the Anglo-Saxons, but were eventually crushed in the battle of Horse Shoe Bend by General Jackson, who compelled them to surrender three-fourths of their territory. In 1819 Alabama was admitted into the Union as an independent member of the confederation. It seceded in the year 1861, but since the close of the war has been again admitted into the Union.

The census of 1870 showed the following results:—Total population of Alabama, 996,992; coloured, 475,510; with 98 Indians. Of these, 987,030 were native born, and 9962 foreign. In 1860 the population was 964,201, of whom 526,271 were whites and 437,770 (435,080 slaves) were coloured; in 1820 (the year after Alabama had been admitted into the Union) the numbers were—total, 127,901; whites, 85,451; coloured, 42,450 (41,879 slaves). Of the total population in 1870, 488,738 were males (255,023 whites, 233,677 coloured, 38 Indians) and 508,254 females (respectively, 266,361, 241,833, 60). In regard to education, there were in the state between 5 and 18 years of age, 173,273 males (91,989 whites, 81,274 coloured, and 10 Indians) and 169,703 females (89,798, 79,882, and 23); of whom 77,139 have attended school (viz., 31,098 white and 7502 coloured males, and 30,226 white and 8313 coloured females). The returns give 2969 schools, with 2372 male and 992 female teachers. Of persons 10 years and upwards, there were 349,771 returned as unable to read, and 383,012 as unable to write.

ALABASTER (said to be derived from the Arabic *al batstraton*, the whitish stone), a name properly restricted to the fine massive variety of gypsum, or sulphate of lime, which is used in the manufacture of ornamental vases, statuettes, clock-frames, &c. When pure, it is of a brilliant pearly-white lustre, so very soft as to be easily scratched by the nail, and is soluble to a slight extent in water. It occurs in large and very pure masses at several localities in Tuscany, and is turned or chiselled into its various ornamental forms in Florence, which is the centre of the alabaster trade. At a time when the taste for alabaster work was more general than now, it was quarried at Lagny, near Paris. In England considerable deposits are found in various localities, but chiefly in Derbyshire and Staffordshire, where it is worked to form the plaster of Paris moulds used by potters; hence it is termed "potters' stone." Fine blocks found in quarrying the potters' stone are reserved for the alabaster turners. A yellow variety of alabaster, found at Sienna, is termed "alabastra agatato." When it presents a fibrous structure, it is known as "satin spar," which when cut has the opalescent appearance of "cat's eyes." Oriental alabaster is the name applied to the stalagmitic variety of carbonate of lime formed on the floors of limestone caves by the percolation of water, an entirely different material from the above. It is usually clouded or banded in an agate-like manner, and hence is sometimes known as onyx marble. The alabaster yielded by celebrated quarries, known to the ancients and now again worked, in the province of Oran, Algeria, is of this kind. It is this oriental alabaster that is referred to in the Bible, the ἀλαβαστρίτης of the Greeks. The stone was held in very high estimation among the civilised nations of antiquity, being then chiefly procured from quarries in the neighbourhood of Thebes, which to this day remain unexhausted. At the present time it is procured from Oran (Algerian onyx), the Pyrenees, Chili, California, &c. In the Soanean Museum there is an Egyptian sarcophagus in oriental alabaster, covered with hieroglyphics, which was purchased by Sir John Soane for 2000 guineas.

ALABASTER, WILLIAM, D.D., poet and scholar. If to have been commemorated with golden words by Edmund Spenser in his *Colin Clouts come Home Againe*, ll. 400 415, and by Herrick in his *Hesperides;* and to have been reckoned "foeman worthy of his steel" by Bishop

Bedell; and to have had his portrait painted by Cornelius Jansen, and engraved by Payne; and to have been pronounced by Fuller "a most rare poet as any our age or nation hath produced;" and to have drawn from Samuel Johnson unequivocal eulogium, may be regarded as entitling to a claim on our interest at this later day, Dr William Alabaster unites in himself all these memorable tributes. Alabaster was his own spelling, as it was Bedell's and Fuller's; but it is found contemporaneously "Arblastier." The name is derived from *arcubalista* (in arms of the family, a cross-bow bent in pale), and the same probably as Arblastier. He was born at Hadleigh, Suffolk, about 1567, was educated at Westminster School, and went thence to Trinity College, Cambridge. He was also incorporated at Oxford in 1592. He became fellow of Trinity. Having been appointed chaplain to Robert, Earl of Essex, he attended him in that expedition, designed to aid Henry IV. against the League in 1591, celebrated by Dr Donne in "The Storm" and "The Calm." While in France (in his twenty-fourth year), he was converted to Roman Catholicism, and a quaint English sonnet, "Of his Conversion," survives, wherein he defies the "frowne and scorne and purblind pittie" of the world, as having a vision of perdition if he yielded thereto. He did not long remain a Roman Catholic. In the preface to his work entitled *Ecce Sponsus Venit* (1633), he relates that certain doctrines of his having become obnoxious to the court of Rome, he was enticed to that city and imprisoned there by authority of the Inquisition; and that on his liberation he was confined within the city walls, but escaped at the peril of his life, and returned to England. On his return he became prebendary of St Paul's and rector of Hatfield. Dr Alabaster was famous as a Hebraist; but his studies of Hebrew took a twist in the direction of the cabalistic learning, by which he luxuriated in discussions on the mystical meanings imagined to be hidden in the words of the Old Testament. The investigation and application of this supposed mystical meaning of Scripture was the main object of his *Apparatus in Revelationem Jesu Christi* (Antwerp, 1607); and, indeed, it runs through all his critical writings, as in his singular *Spiraculum Tubarum, sive Fons Spiritualium Expositionem ex equivocis Pentaglotti Significationibus* (n.d., folio), his *Lexicon Pentaglotton* (1637, folio), and the *Commentarius de Bestia Apocalyptica* (1621). It was of these books Herrick wrote as making Alabaster "the one, one onely glory of a million." A MS. of Alabaster's *Elisæis* is among Emanuel College MSS.; a better one, with additional poems, entitled "Iuuenta Bellica"—recalling Herbert's "Triumphus Mortis," so headed—and "Iuuenta Adespota," is in the Chetham Library, Manchester. The poem is unfinished, but has lines in it which account for Spenser's lofty praise and hopes. It has never been printed. His best known verse is a Latin tragedy called *Roxana*. This is praised by Fuller, stirred Anthony à Wood into enthusiasm, and is regarded by Dr Johnson as the only Latin verse in England worthy to be named previous to Milton. It was prepared for his college (Trinity), and never meant for publication. Having been surreptitiously published in 1632, the author thereupon reprinted it, with this on the title-page, "A plagiariis unguibus vindicata, aucta et agnita." It is a curious composition. The subject is an oriental tale which had previously been dramatised in the *Dalida* of Groto, an Italian. The scenes consist of conversations between real and allegorical personages. The first act is entirely carried on between the ghost of one of the characters and personifications of Death and Suspicion. Hallam charges Alabaster with plagiarism from *Dalida*, but he cannot have really read the two. Alabaster died about 1640. (A. B. G.)

ALACRANES, a group of coral reefs and islands in the Gulf of Mexico, 80 miles off the north coast of Yucatan, and extending 14 miles from north to south, and 11 from east to west. On the 12th February 1847 the mail steamer Tweed was wrecked on the Alacranes; and in January 1849 a similar disaster befell the Forth, belonging to the same company. On the south side, in 22° 23′ 36″ N. lat., and 89° 42′ W. long., there is a secure harbour, well sheltered by dry reefs.

ALAGOAS, a maritime province of Brazil, formerly a district of Pernambuco, is situated between 9° and 10° 30′ S. lat., and extends inland 150 miles. It is bounded on the N. and W. by Pernambuco, and is separated by the river San Francisco from the province of Sergipe on the S. It embraces an area of 12,000 square miles. The country, particularly in the north-west, is very mountainous, but at the same time richly wooded. On the eastern side of the mountains, hilly tracts, well suited for the cultivation of cotton, descend towards the coast, and nearer the sea there is a rich alluvial soil interspersed with swamps (lagoas), whence the province takes its name. The chief articles of produce and export are sugar-cane, rice, cotton, hides, and rosewood. Tropical fruits of all kinds are produced in abundance, and the forests, besides admirable timber, yield various dyes and drugs. The people are chiefly engaged in agriculture, and there are no manufactures of importance. The population of the province is 300,000. The town of ALAGOAS, formerly the capital of the province, is situated on Lake Manguaba. It has declined considerably since the transfer of the local government to Maceio. Population, including district, 12,000.

ALAIN DE LILLE (ALANUS AB INSULIS), theologian and ecclesiastic, born at Lille or Ryssel about the year 1114. The facts of his life are involved in uncertainty, owing to his having been frequently confounded by biographers with others, nearly contemporary, who bore the same name. Some have identified him with Alanus, bishop of Auxerres; others confound him with an elder Alanus, also born at Lille. These, however, were probably three distinct persons. Of the theological writer known as the *doctor universalis*, all that can be said with certainty is that he was a Cistercian monk. It is probable that he passed a great part of his life in England, though he ended his days in the abbey of Citeaux. His works are very numerous, the most important of them being entitled *Anti-Claudianus, sive de Officio Viri Boni et Perfecti*. The title denotes that the work takes for its model Claudian's satire against Rufinus, the minister of Theodosius. It is written in verse, and partakes somewhat of the character of an encyclopædia. Alain's *De Arte Catholicæ Fidei* is remarkable for its endeavour to base dogmatic theology on the exact reasoning of mathematical demonstration, and for its admission that heresy was to be overcome by argument and not by mere authority. His exposition of the prophecies of Merlin, in seven books, is of some importance in its bearing upon English history. A Life of St Bernard and a treatise against heretics, usually included among the works of this author, are, from internal evidence, to be attributed with more probability to the bishop of Auxerres. Alain died about 1202–3.

ALAIS, a flourishing town of France, in the department of the Gard, on the right bank of the Gardon, at the foot of the Cevennes, 25 miles north-north-west of Nîmes, with which it is united by rail. In the 17th century it was a stronghold of the French Protestants, and was besieged and taken by Louis XIII. in 1629. It has a citadel, erected by Louis XIV., a fine Gothic church, and a mining school. The town itself has considerable manufactures of ribands, silk, earthenware, glass, and vitriol; but its prosperity is chiefly derived from the adjacent mineral field, which was opened up in 1819, and yields great quantities of coal and iron, as well as zinc, lead, and manganese. The numerous mines, blast furnaces, and iron foundries, afford employment to many workmen. There are cold mineral springs in the vicinity, which attract large numbers of visitors during the summer months. Population in 1872, 19,230.

ALAJUELA, a city in the state of Costa Rica, Central America, 23 miles W.N.W. from Cartago, and midway between it and the west coast. It is a place of considerable trade, and is connected by a mule road with the port of Puntas Arenas, the only good harbour possessed by Costa Rica on the Pacific Ocean. Some parts of the town are well built and beautifully situated; and the detached houses in the environs are embowered by trees and flowering shrubs. The sugar-cane is cultivated in the neighbourhood. Population, 12,575.

ALAMANNI, or ALEMANNI, LUIGI, an Italian statesman and poet, was born at Florence in 1495. His father was a devoted adherent of the Medici party, but Luigi, smarting under a supposed injustice, joined with others in an unsuccessful conspiracy against Giulio de' Medici, afterwards Pope Clement VII. He was obliged in consequence to take refuge in Venice, and, on the accession of Clement, to flee to France. When Florence shook off the papal yoke, Alamanni returned, and took a prominent part in the management of the affairs of the republic. On the restoration of the Medici (1530), he had again to take refuge in France, where he composed the greater part of his works. He was a favourite with Francis I., who sent him as ambassador to Charles V. after the peace of Crespi in 1544. As an instance of his tact in this capacity, it is related that, when Charles interrupted a complimentary address by quoting from a satirical poem of Alamanni's the words—

> "l'aquila grifagna,
> Che per piu devorar, duoi rostri porta."
> (Two crooked bills the ravenous eagle bears,
> The better to devour,)

the latter at once replied that he spoke then as a poet, who was permitted to use fictions, but that he spoke now as an ambassador, who was obliged to tell the truth. The ready reply pleased Charles, who added some complimentary words. After the death of Francis, Alamanni enjoyed the confidence of his successor Henry II., and in 1551 was sent by him as his ambassador to Genoa. He died at Amboise in 1556. He wrote a large number of poems, distinguished by the purity and excellence of their style. The best is a didactic poem, *La Coltivazione* (1533), written in imitation of Virgil's *Georgics*. His *Opere Toscane* (1532) consists of satirical pieces written in blank verse. An unfinished poem, *Arvarchide*, in imitation of the *Iliad*, was the work of his old age, and has little merit. It has been said by some that Alamanni was the first to use blank verse in Italian poetry, but the distinction belongs rather to his contemporary Trissino.

ALAMOS, Los, a town of Mexico, in the state of Sinaloa, situated on a barren plain 140 miles N.N.W. of Sinaloa. The houses of the town are mostly of stone or brick covered with stucco, and several of the streets are well paved; provisions are dear and water scarce. The surrounding district contains many rich silver mines. Of the population, amounting to about 10,000, a large proportion are employed in the mines.

ALAMOS DE BARRIENTOS, DON BALTHAZAR, a Spanish philologist, born at Medina del Campo, in Castile, about 1550. He was on terms of intimate friendship with Antonio Perez, secretary to Philip II.; and when the latter fell into disgrace, Alamos was cast into prison, where he remained nearly twelve years. During this period he prepared the translation of Tacitus, with a commentary, which gave him his reputation as a classical scholar. On the death of Philip II. Alamos recovered his liberty, and afterwards received various important court appointments through the influence of the Duke de Lerma and the Count d'Olivarez. He died at the age of eighty-five.

ALAN, ALLEN, or ALLYN, WILLIAM (1532–94), cardinal, was born at Rossall in Lancashire. He studied at Oriel College, Oxford, and was appointed principal of St Mary's Hall in 1556. Two years later he was made a canon of York; but being opposed to the Reformation, was forced to flee to Louvain on the accession of Elizabeth. He returned to England after a time, and for some years resided chiefly at Oxford; but his proselytising zeal being discovered, necessitated a second flight. At Douay he received a doctor's degree from the recently-founded university, and he himself established a college there for English Catholics. In 1587 he was made cardinal of St Martin de Montibus, and in 1589 archbishop of Mechlin. The great aim of his life seems to have been to restore the papal supremacy in England. For this purpose he founded the college at Douay, and sent over the Jesuit priests trained there to his native land. He was, of course, a bitter enemy of Elizabeth, who expelled his emissaries, and even caused some of them to be put to death. One of his pamphlets, prepared for circulation among the English people, contained charges against the queen so foul and scurrilous that they can scarcely be repeated. It was only natural that he should be one of the chief intriguers in the Spanish plot which led to the fitting out of the Armada, especially as the pope had promised him the archbishopric of Canterbury in the event of the expedition being successful. His letters to Philip were full of encouragement, and the failure of the enterprise must have been a severe blow to him. When the fact became known, he lost favour at the papal court and was refused permission to return to his diocese.

ALAND ISLANDS, an archipelago at the entrance to the Gulf of Bothnia, about 25 miles from the coast of Sweden, and 15 from that of Finland. The group consists of nearly 300 islands, of which about 80 are inhabited, the remainder being desolate rocks. These islands form a continuation of a dangerous granite reef extending along the south coast of Finland. They formerly belonged to Sweden; and in the neighbourhood the first victory of the Russian fleet over the Swedes was gained by Peter the Great in 1714. They finally passed into the possession of Russia in 1809. The inhabitants, amounting to about 16,000, are mostly of Swedish descent, and are hardy seamen and fishermen. The surface of the islands is generally sandy, the soil is thin, and the climate is keen; yet Scotch fir, spruce, and birch are grown; and rye, barley, flax, and vegetables are produced in sufficient quantity for the wants of the people. Great numbers of cattle are reared; and cheese, butter, and hides, as well as salted meat and fish, are exported. The largest island, which gives its name to the group, is 18 miles long by 14 broad, and contains about two-thirds of the total population. There are several excellent harbours (notably that of Ytternæs), which are of great importance to Russia from the fact that they are frozen up for a much briefer period than those on the coast of Finland. The fortress of Bomarsund, in one of these islands, was attacked and destroyed by an Anglo-French force in 1854.

ALANI, a number of nomadic tribes of eastern origin, who spread themselves over Europe during the decline of the Roman empire. The name was probably at first confined to one tribe of Tatar race, whose original seat was on the northern shores of the Caspian Sea, and was afterwards, as the power of that race extended, applied to other tribes. It is supposed that their first encounter with the Romans was during the Mithridatic war, when Pompey led an expedition into the Caucasus. Isolated statements in contemporary writers show that the Alani were frequently in conflict with the Roman power. In March 276 A.D. they received a decisive check in an attempt to make their way eastward into Persia, being defeated by the emperor Tacitus, who forced them to recross the Phasis. The most complete account of the Alani is to be found in the pages of Ammianus Marcellinus (lib. xxxi.), who describes their manners and customs at considerable length. From him, too, we learn of the advance of the Huns, who signally defeated the Alani in a battle fought on the banks of the Tanais in 375. The race thereupon divided, some retiring to the east, while the great majority joined their conquerors in an invasion of the kingdom of the Goths. Associated with the Vandals and Suevi, they left the settlements they had in Pannonia and entered Gaul in 406, whence three years later they crossed the Pyrenees into Spain, and founded a settlement in Lusitania and Bætica, where they remained in peace for some years. In 418, however, they were attacked and defeated by Wallia, king of the Visigoths, with whom they had quarrelled. Their king, Ataces, was slain in the battle, and they became subject to Gunderic, king of the Vandals, their national independence being lost. Those of the Alani who had remained in Gaul when the others invaded Spain, settled near Valence and Orleans. Though serving under Theodoric, they sympathised with Attila and the Huns, and by deserting at Chalons (451), all but changed the victory of the Romans into a defeat. Soon afterwards their separate national existence in Gaul was merged in that of the Visigoths. The small portion of the Alani that had remained in their original seat in the Caucasus are frequently noticed in history down to the middle ages. In 572 they were allied with the Armenians under King Saroes. They seem to have afterwards regained their independence. In 1221 they were defeated by Gengis Khan, and in 1237 they were so completely subjugated by Batu-Khan that their very name disappears in subsequent history.

ALARCON, Hernando de, a Spanish navigator of the 16th century, known only in connection with the expedition to the coast of California, of which he was leader. He set sail on the 9th May 1540, with orders from the Spanish court to await at a certain point on the coast the arrival of an expedition by land under the command of Vasquez de Coronado. The junction was not effected, though Alarcon reached the appointed place and left letters, which were afterwards found by Diaz, another explorer. Alarcon was the first to determine with certainty that California was a peninsula and not an island, as had been supposed. He made a careful and exact survey of the coast, sailed a considerable distance up the Rio del Tizon (Colorado), and was thus able, on his return to New Spain in 1541, to construct a map of California, which, according to M. Duflot de Mofras, scarcely differs from one of the present day.

ALARCON Y MENDOZA, Juan Ruiz de, one of the most distinguished Spanish dramatists, born at Tasco in Mexico about the close of the 16th century, was descended from a noble family belonging to Alarcon in Cuença. Nothing is known with certainty of his early life, but it is probable that he was educated at one of the Spanish universities. In 1622 he had taken up his residence at Madrid, and in 1628 he was appointed to the office of *relator* (reporter) of the royal council of the Indies, which afforded him a competency. In the same year he published the first volume of his comedies, dedicating it to "the rabble" in a daringly contemptuous address. A second volume of comedies appeared at Barcelona in 1634, in which he brought charges against several poets of appropriating his productions. About the same time he was successful in an open competition for a dramatic libretto to be played at the fêtes in honour of Philip IV. These two facts, combined with his haughty disdain both of the public and of his literary brethren, made Alarcon very unpopular; and he was scurrilously lampooned by most of the poets and dramatists of the day, Calderon honourably distinguishing himself by his silence. A further injustice was done him in the piracy of his works by other and better known authors than himself. To such an extent was this carried that Alarcon's reputation as a dramatist was almost extinct even before the close of his life, and it is only quite recently that it has been revived. The date of his death is given, on doubtful authority, as 1639. Alarcon holds a foremost place among Spanish dramatists, being surpassed only, if at all, by Lope de Vega and Calderon. He is distinguished by the correctness of his language, the harmony of his verse, and the elevation of his sentiment. His *La Verdad Sospechosa* (Suspicious Truth) supplied Corneille with the materials for his *Menteur*, and called forth the highest praise from the great French dramatist. His *Tejedor de Segovia* (Weaver of Segovia) and *Las Paredes Oyen* (Walls have Ears) are acted at the present day. A complete edition of his comedies was published by Hartzenbusch at Madrid (1848–52).

ALARIC (*Al-ric, i.e.*, All rich), a chief, and afterwards king of the Visigoths, was born of the noble family of Balti (*baltha*, bold). He first appears in history (394 A.D.) as a commander in the army of subjugated Goths whom the Emperor Theodosius employed in his war with Eugenius. On the death of Theodosius in 395 the Goths asserted their independence, and under the leadership of Alaric made an incursion from Thrace, where they had been located, into the Morea. Athens yielded to them without resistance, and Alaric enriched himself with the movable treasures of the city, though he did not, as some have asserted, destroy buildings and works of art. Rufinus, the crafty minister of Arcadius, did nothing to check the advance of the barbarians, and it has even been said that he had a secret understanding with Alaric. Opposition came, however, from the Western Empire. Stilicho, the famous general, landed at Corinth, and drove the Goths to Mount Pholoe, on the frontiers of Elis, where he besieged their camp. With proper vigilance, the siege could not have been raised; but the Romans were careless, and Alaric with his army contrived to escape to Epirus. Stilicho was prevented from following him by an order from the Emperor Arcadius, who conferred upon Alaric the prefecture of eastern Illyricum. About the same time the Gothic chief was chosen king by his people. It was natural that Alaric's desire of conquest should increase with the increase of his power, and accordingly about the year 400 A.D. he set out to invade the Empire of the West. His march was exceedingly slow, and it was not until the spring of 403 that he appeared before Milan, from which the Emperor Honorius instantly fled to the fortress of Asta in Liguria. Being besieged there, he was on the point of capitulating when he was relieved by Stilicho, who, in the battle of Pollentia, fought on Easter-day, gained a somewhat doubtful victory over Alaric. Some time after, the contest was renewed at Verona, and Alaric sustained a decisive defeat. He was obliged to accept terms of peace, and to retreat for the time; but his attitude was always threatening, and Honorius found it expedient to buy him off by appointing him prefect of western Illyricum, with a large revenue. In this capacity Stilicho encouraged Alaric to lead his army against Constantinople, probably more with the design of keeping him at a distance from Italy than with any hope of reuniting the divided empire. The final expedition to Constantinople was not undertaken; but for his services during three years in Epirus, Alaric claimed an extravagant reward, and Honorius, on the advice of Stilicho, promised him 4000 pounds of gold. Shortly afterwards the weak-minded emperor procured the assassination of his minister, the only Roman who had proved himself able to cope with the Gothic forces, and broke all the treaties which Stilicho had made with Alaric. The latter at once marched upon Rome (408) by the Via Flaminia, and laid siege to the city. On coming to treat with him, the Romans found his demands so extravagant that they threatened a desperate resistance, to which Alaric made the well-known reply, "The closer hay is pressed, the easier is it mown." At last the barbarian was induced to retire by the promise of 5000 pounds of gold and 30,000 pounds of silver, besides other treasure. The respite, however, was but for a time. Honorius, who had left Rome for Ravenna, refused to ratify by treaty certain conditions, moderate in themselves, on which Alaric firmly insisted, and the capital was again at the mercy of the enemy. With commendable forbearance, Alaric contented himself at first with taking possession of Ostia, from which he summoned the city to surrender, threatening the immediate destruction of the food stores in case of refusal. The terrified people at once opened their gates, and agreed that the conqueror should appoint another emperor in place of Honorius. Alaric's choice fell upon Attalus, the prefect of the city, who, though well received at first, soon proved himself thoroughly incompetent, and Honorius had to be restored. While the conferences as to the restoration were still being carried on at Ravenna, the treachery of Honorius occasioned yet another and more disastrous siege of Rome by the Goths. Sarus, a barbarian and a hereditary enemy of the house of Balti, was permitted by the emperor to attack the camp of the Goths and return in triumph to Ravenna. Alaric was naturally indignant, laid siege to Rome for the third time, and gained an entrance by the Salarian gate on the night of the 24th August 410. For six days the city was given over to the horrors of a pillage, which the humane orders of Alaric did but little to mitigate. On the 29th August Alaric withdrew his troops from Rome, and led them into southern Italy, which he ravaged for several months. Towards the close of the year, while engaged in the siege of Cosentia (*Cosenza*), he was seized with an illness which proved fatal after a very short duration. He was buried with his treasures in the bed of the river Busentinus, which was diverted from its channel for that purpose, and all the prisoners who were engaged in the work were put to death in order that the place of his sepulture might remain unknown. The character of Alaric has been somewhat variously represented by historians. In forming an estimate of it many have been misled by the use of the term barbarian, which, as applied to him, it should be remembered, indicates a national and not a personal distinction. Many proofs may be found of his humanity and moderation in trying circumstances, while, on the other hand, the charges of cruelty brought against him are not borne out by evidence. His marked respect for Christianity is explained by the fact that, if he was not himself a Christian, he had come early under Christian influence, having had frequent intercourse with Arian teachers.

ALARIC II., eighth king of the Goths in Spain, succeeded his father Euric or Evaric about 484. His dominions not only included the greater part of Spain (Hispania Tarraconensis and Bætica), but extended into Gaul as far as the rivers Rhone and Loire. In religion Alaric was an Arian, but that he was tolerant of the orthodox Catholics is shown by the decrees of the Council of Agde, summoned by him in 506. He displayed similar wisdom and liberality in political affairs by appointing a commission to prepare an abstract of the Roman laws and imperial decrees, which should form the authoritative code for his dominions. This is generally known as the *Breviarium Alaricianum*. It contains six books of the code of Theodosius, and is therefore sometimes called the *Corpus Theodosii*. The full text has been given by Savigny. Alaric was of a peaceful disposition, and endeavoured strictly to maintain the treaty which his father had concluded with the Franks. Clovis, however, desiring to obtain the Gothic province in Gaul, found a pretext for war in the Arianism of Alaric. The intervention of Theodoric, king of the Ostrogoths and father-in-law of Alaric, proved unavailing. The two armies met in 507 at Voglade (*Vouillé*), near Poitiers, where the Goths were defeated, and their king, who took to flight, was overtaken and slain by Clovis himself.

ALASCO, JOHN (in Polish, *Lascki*), a Polish nobleman, born in 1499, who travelled extensively in his youth, and during a residence in Zurich imbibed the doctrines of the Reformation from Zwingli. At Basel in 1525 he had frequent intercourse with Erasmus, who held him in great esteem, and bequeathed his library to him. On his return to his native country he was offered more than once ecclesiastical preferment, which the change in his religious opinions prevented him from accepting. With the view of securing more freedom, he quitted Poland, and after travelling for a time, became pastor of a Protestant congregation at Embden, in East Friesland, in 1542. Foreseeing persecution there, he went to London in 1551, on the invitation of Cranmer, and became superintendent of the congregation of foreign Protestants, most of whom were driven into exile like himself in consequence of the Interim. The revenues of the church of Augustin Friars were assigned to support him and four assistant ministers, who had to be approved by the king. On the accession of Mary in 1553, Alasco and all his congregation were banished. In 1556 he returned to Poland, where he died on the 13th January 1560. Alasco wrote a number of theological treatises, chiefly in defence of the doctrine of the sacraments as held by the Swiss Reformers, and he was one of the eighteen divines who prepared the Polish version of the Bible, which was published in 1563.

ALA-SHEHR, a city of Asiatic Turkey, in the pashalic of Anatolia, 83 miles E. of Smyrna. It is dirty and ill-built; but, standing on elevated ground, and commanding the prospect of the extensive and fertile plain of the Hermus, presents at a distance an imposing appearance. It is the seat of a Greek archbishop, and has five Christian churches and fifteen mosques. The city occupies the site of the ancient *Philadelphia*, one of the "seven churches in Asia" of the Apocalypse. The ancient city, founded two centuries B.C., was subject to frequent earthquakes. In more modern times it was celebrated for its prolonged resistance to the Turks, who took it in 1390, after all the other cities of Asia Minor had surrendered. Ala-Shehr has an active trade, and the population is about 18,000.

ALASKA, or ALIASKA, formerly RUSSIAN AMERICA, but now a territory of the United States, is a vast tract of country forming the north-west portion of North America, bounded on the N. by the Arctic Ocean, on the E. by British America, and on the S. and W. by the Pacific Ocean. The name was formerly confined to a long narrow peninsula stretching into the Pacific, but has been extended to the whole territory. Alaska comprises the whole of North America from 141° W. long. to Behring Strait, and also numerous islands along the coast, notably Prince of Wales Islands, King George III. Archipelago, the Kodiak Islands, and the Aleutian Islands, which stretch seaward from the extremity of the peninsula. From the main portion of the territory a narrow strip, with a breadth of about 50 miles, extends south-east along the Pacific coast, and terminates at the confines of British Columbia, in 54° 40′ N. lat. From north to south the extreme length of

Alaska is about 1100 miles, and the greatest breadth from east to west is 800 miles. The area of the whole territory is estimated at 514,700 square miles.

The numerous islands, creeks, and inlets of Alaska lengthen out its coast-line to 7860 miles, an extent greater than that of the eastern coast-line of the United States. Beginning at the south-east, the chief creeks and bays are Cook's Inlet, Bristol Bay, Norton Sound, and Kotzebue Sound; while, following the same order, the principal headlands, in addition to the extremity of the peninsula, are Cape Newenham and Cape Romanzoff in the Pacific, Cape Prince of Wales in Behring Strait, and Cape Lisburne, Icy Cape, and Point Barrow in the Arctic Ocean. Point Barrow is in 71° 23′ N. lat., and is the extreme northern point of the country. The exploration of the northern coast was chiefly the work of the British navigators Cook, Beechy, and Franklin, and of the officers of the Hudson's Bay Company. The principal river of Alaska is the Yukon, or Kwichpak, which rises in British America, and, receiving the Porcupine river at Fort Yukon, flows westward across the territory, and falls into the Pacific Ocean to the south of Norton Sound. At a distance of 600 miles from the sea this magnificent river has a width of more than a mile. Its tributaries would in Europe be reckoned large rivers, and its volume is so great that 10 miles out from its principal mouth the water is fresh. Among the other rivers of Alaska are the Copper river, the Suschitna, the Nuschagak, and the Kuskokwim, falling into the Pacific, and the Colville, flowing northward into the Arctic Ocean. A great mountain range extends from British Columbia, in a north-west direction, along the coast of Alaska, the summit being covered with snow and glaciers. Mount St Elias, an active volcano, in 60° 18′ N. lat., and 140° 30′ W. long., rises to the height of 14,970 feet above the sea. The mountain chain runs out along the peninsula which has given its name to the country, and at the western extremity there are several volcanic cones of great elevation; while in the island of Uminak, separated from the mainland by only a narrow strait, there are enormous volcanoes, one rising to more than 8000 feet in height. In the interior and to the north the country is also mountainous, with great intervening plains.

The north-west coast of this part of America was discovered and explored by a Russian expedition under Behring in 1741; and at subsequent periods settlements were made by the Russians at various places, chiefly for the prosecution of the fur trade. In 1799 the territory was granted to a Russo-American fur company by the Emperor Paul VIII., and in 1839 the charter of the company was renewed. New Archangel, in the island of Sitka, was the principal settlement, but the company had about forty stations. They exported annually 25,000 skins of the seal, sea-otter, beaver, &c., besides about 20,000 sea-horse teeth. The privileges of the company expired in 1863; and in 1867 the whole Russian possessions in America were ceded to the United States for a money payment of $7,200,000. The treaty was signed on 30th March, and ratified on 20th June 1867; and on 9th October following, the possession of the country was formally made over to a military force of the United States at New Archangel. It still remains in the military keeping of the United States, no steps having been taken to organise a territorial government. It has, however, been constituted a revenue district, with New Archangel, or Sitka, as the port of entry. Since Alaska was ceded to the United States considerable information has been collected as to the resources of the less sterile parts of the country; but the central and northern parts of this region are only known as the inhospitable home of some wandering tribes of Indians and Esquimaux. Portions of Alaska have also been recently explored by the employés of the Russo-American Telegraph Company in surveying a route for a line of telegraph which was designed to cross from America to Asia near Behring Strait—a project which was abandoned, after an expenditure of £600,000, on communication with Europe being secured by the Atlantic cable.

The climate of the south-western coast of Alaska is tolerably mild, considering its high latitude. The great warm current of the Pacific, sweeping in a north-easterly circuit from the East India Islands, and corresponding very much in character and effects to the Gulf Stream of the Atlantic, washes its shores; and while it modifies the temperature, also causes an excessive rainfall. At Sitka the mean temperature is 42°·9, and the average rainfall about 80 inches. Alaska will never have any great agricultural value. From the great amount of rain and the want of heat, cereals grow, but will not ripen, and vegetables do not thrive. Native grasses and berries grow plentifully, but the chief wealth of the country is in its vast forests, in the furs of its wild animals, and in the fish with which its rivers and seas abound. The forests, rising from the coast and covering the mountains to a height of 2000 feet, consist of a very durable yellow cedar, spruce, larch, and fir of great size, and also cypress and hemlock. The wild animals include the elk, the deer, and various species of bear, and also many fur-bearing animals, such as the wolf and fox, the beaver, ermine, marten, otter, and squirrel. Near the coast and islands there are innumerable fur-bearing seals, which are caught in great numbers by the settlers; but from the rigour of the climate and the arduous nature of the work, the trapping of the animals of the interior is left to the Indians. The salmon abounds in the rivers, and there are great banks along the shores, the favourite haunt of cod and other fish. About eighty whalers prosecute their fishing off the coast of Alaska. Coal and iron are the most important minerals, but the value of the deposits remains to be ascertained.

The population is very limited, consisting of 8000 whites and 15,000 Indians, with some Esquimaux on the northern coast. The Indians are rapidly decreasing in number, and are described as treacherous and discontented. New Archangel, now called Sitka, in the island of Sitka, in 57° 3′ N. lat., and 135° 18′ W. long., was the seat of the Russian governor, and is the headquarters of the United States authorities. It contains about 1500 inhabitants, is the residence of a Greek bishop, and has fortifications, magazines, and a magnetic observatory. Of the other settlements, Fort Nicholas on Cook's Inlet, and Fort St Michael on Norton Sound, are the more important. The admirable harbours on the coast and the great navigable river Yukon afford facilities for the formation of new settlements and the increase of trade by the Americans. At the junction of the Porcupine river and the Yukon a fort was established by the Hudson's Bay Company in 1847. (See Whymper, *Travels in Alaska and on the Yukon*, 1868; Dall, *Alaska and its Resources*, 1870.)

ALATRI, the ancient *Alatrium*, a town of Italy, 6 miles N. of Frosinone, in the province of that name, which until 1870 formed part of the papal territory. It is the see of a bishop, and has considerable remains of Pelasgian antiquity. Population of commune, 11,370.

ALAVA, one of the Provincias Vascongadas, or Basque Provinces, in the north of Spain. It is of a triangular shape, and is bounded on the N. by Guipuzcoa and Biscay, on the E. by Navarre, on the S.W. by Logrono, and on the W. by Burgos; with an area of about 1200 square miles. The surface of Alava is very mountainous, especially on the north, where a part of the Pyrenees forms its natural boundary. It is separated from Logrono by the

Ebro, and the other rivers are the Zadorra and the Ayuda. The soil in the valleys is fertile, yielding wheat, barley, maize, flax, hemp, and fruits. Oil, and a poor kind of wine called chacoli, are also produced. Many of the mountains are clothed with forests of oak, chestnuts, beeches, and other trees, and contain iron, copper, lead, and marble. Salt is also found in large quantities in the province. The manufactures of Alava are unimportant; coarse cloth, iron ware, earthenware, hats, and shoes being among the chief. The capital of the province is Vitoria. Population in 1870, 102,494.

ALAVA, Don Miguel Ricardo d', a Spanish general and statesman, born at Vitoria in 1771. He served first in the navy, and had risen to be captain of a frigate when he exchanged into the army, receiving corresponding rank. In politics he followed a very devious course. At the assembly of Bayonne, in 1808, he was one of the most prominent of those who accepted the new constitution from Joseph Bonaparte as king of Spain. In 1811, when Joseph's position was becoming insecure, Alava joined the national independent party, who were fighting in alliance with the English. The Spanish Cortes appointed him commissary at the English headquarters, and Wellington, who seems to have regarded him with great favour, made him one of his aides-de-camp. Before the close of the campaign he had risen to the rank of brigadier-general. On the restoration of Ferdinand, Alava was cast into prison, but the influence of his uncle Ethenard, the inquisitor, and of Wellington, secured his speedy release. He soon contrived to gain the favour of the king, who appointed him in 1815 ambassador to the Hague. Four years later he was recalled, owing, it is said, to the marked kindness he had shown to his banished fellow-countrymen. On the breaking out of the revolution of 1820 he was chosen by the province of Alava to represent it in the Cortes, where he became conspicuous in the party of the *Exaltados*, and in 1822 was made president. In the latter year he fought with the militia under Ballasteros and Murillo to maintain the authority of the Cortes against the rebels. When the French invested Cadiz, Alava was commissioned by the Cortes to treat with the Duc d'Angoulême, and the negotiations resulted in the restoration of Ferdinand, who pledged himself to a liberal policy. No sooner had he regained power, however, than he ceased to hold himself bound by his promises, and Alava found it necessary to retire first to Gibraltar and then to England. On the death of Ferdinand, he returned to Spain, and, espousing the cause of Maria Christina against Don Carlos, was appointed ambassador to London in 1834, and to Paris in 1835. After the insurrection of La Granja, he refused to sign the constitution of 1812, declaring himself tired of taking new oaths, and was consequently obliged to retire to France, where he died at Barèges in 1843.

ALAY (lit. a triumphant procession), a Turkish ceremony observed on the assembling of the forces at the outbreak of war. Its essential feature is the public display of the sacred standard of Mahomet, which may be seen only by Moslems and touched only by the emirs. On one occasion, when, owing to a long interval of peace, this rule had been forgotten, the Christians, who had witnessed the spectacle in large numbers, were cruelly massacred. The procession in which the standard is carried is headed by artisans bearing the implements of their respective trades.

ALB, or Albe, a vestment of white linen, hanging down to the feet, worn by priests at all the more solemn services of the church. It corresponds to the surplice of the English clergy, the difference being that the alb is closer in the sleeves, and bound at the waist by a girdle. In the ancient church it was customary for the neophytes who were baptized on Easter-day to wear an alb for the eight days following, and hence the Sunday after Easter was called *Dominica in Albis*.

ALBA, the ancient *Alba Pompeia*, a town of Italy, in the province of Cuneo, situated on the Tanaro, 30 miles S.E. of Turin. It is the seat of a bishop, and contains a cathedral, founded in 1486, as well as other churches and religious establishments. It has a large trade in cattle, and the surrounding district is very fertile, producing silk, wine, oil, grain, and fruits, and also marble and rock-salt. Population of the commune (1865), 9687.

ALBA LONGA, the most ancient town in Latium, was situated 15 miles S.E. from Rome, on a ridge between the mountain and the lake that were both called from it *Albanus*. It derived its name probably from its elevated or *Alpine* situation, the story of the *white* sow discovered by Æneas on landing (Virgil, *Æneid*, iii. 390–392) being of course mythical. Little beyond the bare fact of its existence for a considerable period as the foremost town in Latium can be accepted as strictly historical. According to the legendary accounts, it was founded by Ascanius, the son of Æneas, 300, or, as a later version has it, 360 years before the foundation of Rome. Fourteen kings, whose names are all preserved, are said to have reigned over it in succession. The names, however, are evidently an invention, having probably this substratum of historic truth, that the ruling family belonged to the Silvian *gens*. The city was destroyed by the Romans under Tullus Hostilius, and its inhabitants removed to Rome. Several of the patrician families, such as the *Julii, Curiatii, Servilii, Tullii, Quintii*, ascribed their origin to these immigrants from Alba.

ALBACETE, one of the new provinces of Spain, was formed in 1833 out of districts taken from Murcia and New Castile. It is bounded on the N. by Cuença, on the E. by Valencia and Alicant, on the S. by Murcia, and on the W. by Ciudad Real and Jaen. The area is 5971 square miles. The province is generally hilly, some of the peaks of the sierras rising to a height of 5000 feet; but it contains rich plains and many fertile valleys. The principal rivers are the Mundo in the southern and the Jucar in the northern part of the province; and there are numerous smaller streams. Some parts of the country have a bare appearance, being destitute of wood, but the neighbourhood of Alcarez is covered with fruit trees, and presents the aspect of a garden. Agriculture is in a tolerably prosperous state, more advanced than in the centre of Castile, but less so than in the rich districts of Murcia and Valencia. Cereals, pulse, and fruits of all kinds are produced, as well as wine of fair quality, and excellent honey. Saffron also is produced in large quantities, and some attention is given to the keeping of silk-worms. Many of the inhabitants devote themselves to the rearing of cattle, sheep, and goats. The bulls of Albacete are in request for bull-fights; there is a good breed of mules, and the horses of the province have long mounted the Spanish cavalry. Manufactures are confined to the spinning of hemp, and the making of coarse cloths, porcelain, earthenware, and cutlery. There are several distilleries, and a considerable trade in wood. The district is rich in minerals, including silver, iron, copper, zinc, sulphur, gypsum, and coal; but, excepting stones and marble for building purposes, they are little wrought. In addition to agricultural produce, small quantities of zinc, iron, and sulphur are exported. There are numerous mineral springs, chiefly sulphureous, and hot as well as cold, at various places in the province. Among the chief towns are Albacete, Chinchilla, Bonillo, and Alcarez. The railway from Madrid to Valencia traverses the province, and at Chinchilla a line branches southward to Murcia

The state of education throughout the province is very low. In the town of Albacete, where it is best, little more than half the population can read; while at Yeste, where it is worst, the proportion is only 1 in 15. The graver crimes are of infrequent occurrence; but the inhabitants always wear arms, and offences against the person are numerous. Population in 1867, 221,444.

Albacete, a town of Spain, capital of the above province, is situated about 140 miles S.E. of Madrid, and is a station on the railway between Madrid and Valencia. It is surrounded by a fertile plain, and has considerable trade in saffron and in the agricultural products of the district. A great market, chiefly for the sale of cattle, is held annually in September, and extends over several days. The town is well built, and has several churches, two hospitals, and a normal school. At one time it had an extensive trade in cutlery, from which it received the name of the Sheffield of Spain. This manufacture has been very much reduced by the importation of cutlery from England and Germany, but Albacete is still famous for its daggers, which are held in high repute and much worn by the Spaniards. They are formidable weapons, of coarse manufacture, but with richly-ornamented handles, and frequently bear proverbial inscriptions suitable to their murderous appearance. Population, 15,150.

ALBAN, St, usually styled the protomartyr of Britain, was born at Verulamium, and flourished towards the end of the third century. In his youth he took a journey to Rome in company with Amphibalus, a monk of Caerleon, and served seven years as a soldier under the Emperor Diocletian. On his return home he settled at Verulamium, and, influenced by the example and instructions of Amphibalus, renounced the errors of paganism, in which he had been educated, and became a convert to the Christian religion. It is generally agreed that Alban suffered martyrdom during the great persecution in the reign of Diocletian; but authors differ as to the precise date. Bede, who gives a full account of the event, fixes it in 286; some refer it to the year 296; while Usher reckons it amongst the events of 303. Between 400 and 500 years after St Alban's death, Offa, king of the Mercians, built a large and stately monastery near Verulamium to his memory, and around it the present town of St Albans was gradually erected.

ALBANI, or Albano, Francesco (1578–1660), a celebrated Italian painter, was born at Bologna. His father was a silk merchant, and intended to bring up his son to the same occupation; but Albani was already, at the age of twelve, filled with so strong an inclination for painting, that on the death of his father he devoted himself entirely to art. His first master was Denis Calvart, with whom Guido Reni was at the same time a pupil. He was soon left by Calvart entirely to the care of Guido, and contracted with him a close friendship. He followed Guido to the school of the Caracci; but after this, owing to mutual rivalry, their friendship began gradually to cool. They kept up for a long time a keen competition, and their mutual emulation called forth some of their best productions. Notwithstanding this rivalry, they still spoke of each other with the highest esteem. Albani, after having greatly improved himself in the school of the Caracci, went to Rome, where he opened an academy and resided for many years. Here he painted, after the designs of Annibal Caracci, the whole of the frescoes in the chapel of St Diego in the church of San Giacomo degli Spagnuoli. His best frescoes are those on mythological subjects, of which there is a large number in the Verospi Palace, now Torlonia. On the death of his wife he returned to Bologna, where he married a second time, and resided till his death in the enjoyment of much domestic happiness and general esteem. His wife and children were very beautiful, and served him for models. But while thus studying from nature, his love of artificial refinement and conventional expression was so great, that even his best works are deficient in breadth and vigour, as well as in unaffected grace and natural feeling. The learning displayed in the composition of his pictures, and their minute elaboration and exquisite finish, gave them great celebrity, and entitle them to a distinctive place among the products of the Bolognese school.

"In point of original invention," says Lanzi, "Albani is superior to Domenichino, perhaps to any other of the school; and in his representation of female forms, according to Mengs, he has no equal. By some he is denominated the Anacreon of painting. Like that poet, with his short odes, so Albani, from his small paintings, acquired great reputation; and as the one sings Venus and the Loves, and maids and boys, so does the artist hold up to the eye the same delicate and graceful subjects. Nature, indeed, formed, the perusal of the poets inclined, and fortune encouraged his genius for this kind of painting; and possessing a consort and twelve children, all of surprising beauty, he was at the same time blest with the finest models for the pursuit of his studies. He had a villa most delightfully situated, which further presented him with a variety of objects enabling him to represent the beautiful rural views so familiar to his eye.

A great number of his works are at Bologna. Among the most celebrated of his pictures are the "Four Seasons;" "Diana and Venus," in the Florentine gallery; the "Toilet of Venus," in the Louvre; "Venus landing at Cythera," in the Ghigi palace at Rome, &c. Among the best of his sacred subjects are a "St Sebastian" and an "Assumption of the Virgin," both in the church of St Sebastian at Rome. He was among the first of the Italian painters to devote himself to the painting of cabinet pictures.

ALBANIA, a country of considerable extent, which though frequently ruled by turbulent and nearly independent chiefs, ranks as one of the provinces of the Turkish empire. The tract of land to which this name is now applied extends from 39° to 43° N. lat., and from 18° 24′ to 21° 48′ E. long.; from the Gulf of Cattaro in the north to the Gulf of Arta in the south, and from the coast of the Adriatic Sea and Ionian Sea on the west to an irregular ill-defined line inland towards the east, roughly indicated in its northern part by the Tchar Dagh, the ancient *Scardus*, a part of the Hæmus or Balkan range, and southwards by the Pindus chain, or rather the portions of it now called the mountains of Sagori, Metzovo, and Suli. Within these limits is included the ancient *Epirus*, corresponding to the southern part of the country now comprehended under the general name of Albania, and divided from Albania, properly so called, by the river Voyutza or Viosa, which enters the Adriatic a few miles north of Avlona. Albania, therefore, is bounded on the N. by Dalmatia, Montenegro (from which it is separated by the river Moraka), and Bosnia; on the E. by Servia and the Turkish province of Rum-ili, in which Macedonia, or the greater part of it, is included; and on the S. by Hellas or Northern Greece, which was the Turkish province of Livadia before Greece regained its independence, and from which it is separated by the river Garla or Suli. The superficial area of Albania is estimated at about 18,944 square miles, and it has a coast-line of about 280 miles from north to south, without reckoning indentations, &c. It nowhere extends more than 100 miles from the sea, and in the southern part not more than 30 miles.

According to the most recent division of the Turkish empire into eyalets, sanjaks, and livas, Albania is comprehended in three eyalets, namely, Uskub or Uskup in the north; Roumelia, which also includes part of Macedonia, in the centre; and Yania, corresponding pretty nearly to the ancient *Epirus*, in the south. The chief towns of these eyalets are respectively Scutari, Monastir, and Joannina, sometimes written Janina or Yanina; and these divisions are therefore spoken of by some writers as the pashaliks of Scutari, Monastir, and Joannina. The divisions chiefly recognised by the Albanians themselves are those formed by the varieties of the native tribes. Colonel Leake, who is considered one of the best informed authorities on this head, divides them into the Ngege or Ghegides, whose principal towns are Dulcigno, Scutari, and Durazzo; the Toske or Toskides, who occupy Berat and Elbasan; the Liape, a poor and predatory race, who inhabit the mountains between the Toske and Delvino; and the Tsami, who inhabit the most southerly district, and whose principal towns are Suli and Paramithia. The country is mountainous, the interior being traversed by a range which forms a prolongation of the Dinaric Alps, and which is continued southwards in the Pindus range. These mountains, from which numerous spurs are thrown out to the east and west, run in a direction from north to south, parallel to the course of the Tchar Dagh. Along the southern part of the coast-line, and parallel with it, run the Khimara mountains, known to the ancients as the *Acroceraunian* range, terminating northwards in the bold headland of Cape Glossa. There are three lakes of great size in Albania—Scutari in the north, Okhrida in the centre, and Joannina in the south. The rivers for the most part are short, and run, generally speaking, from east to west, or in a north-westerly direction. The Moroka and Zenta enter the lake of Scutari, which is connected with the sea by the Boyana, that flows into the Adriatic near Dulcigno. The White Drin, flowing in a southerly direction, and the Black Drin, running northwards from Lake Okhrida, form the head streams of the Drin. The principal streams in addition to these are the Skombia, Voyutza, Calamas, Arta, and Gurla (the ancient *Acheron*), with its tributary the Vuvó (the ancient *Cocytus*). The climate is generally healthy, though cold and bleak in the highlands; the warmer regions along the coast are also frequently visited by cold northerly winds.

Albania includes not only the ancient *Epirus*, but also part of the ancient *Macedonia*, *Illyria*, and *Chaonia*. This country was in early times, as now, distinguished by the rude valour of its inhabitants. Its remote situation, and the want of union among its tribes, generally prevented it from acting any conspicuous part in Grecian politics. The only remarkable exception occurs in the reign of Pyrrhus, king of Epirus (296–272 B.C.), who was justly ranked among the greatest captains of antiquity. After his death the country was again split into a number of petty states, which were unable to resist the united strength of Macedon; and to that kingdom Epirus continued subject till both were alike subdued by the Roman arms (167 B.C.)

It was during the time of the Greek empire that the name of Albania was first given to this district. During the decline of the empire the Albanians gradually rose to distinction, and at last to independence. Their valour enabled them to maintain their ground against the Bulgarians, who had occupied all the neighbouring districts of Greece. Nor were they less successful against the Turks, a more formidable enemy. Under the command of the celebrated George Castriot, called by the Turks Scanderbeg, they baffled all the efforts of Mahomet II., the conqueror of Constantinople. That powerful monarch entered Albania only to experience a succession of defeats, and was at length compelled to acknowledge its independence by a formal treaty. On the death of Scanderbeg, the Turks redoubled their efforts against Albania, which was at length reduced to a state of nominal subjection. The siege of Scutari, in 1478, formed the termination of this memorable struggle. The subjection, however, was always the imperfect; revolts were frequent, and the inhabitants of mountainous districts still preserved their independence. It was the motives of pay and plunder, rather than compulsion, that brought these hardy soldiers into the Turkish ranks. In proportion as the Ottoman empire declined in vigour, its hold of Albania became less firm; and the vigorous and enterprising genius of Ali Pasha again converted this dependency into what might almost be called a separate kingdom.

In the grand insurrection of Greece (1821–1829), the Albanians, accustomed to view with disdain the Ottoman yoke, showed a considerable disposition to make common cause with the Greeks, and their co-operation would have almost ensured success. But the Greeks, imprudently and unhappily, could not divest themselves of the feelings of enmity cherished during the long series of wars which Ali had waged against them. At the siege of Tripolizza (October 5, 1821) overtures were made to them by a corps of 3000 Albanians, who formed part of the garrison; but the Greeks, having succeeded in entering the place, began a dreadful and indiscriminate massacre, in which the Albanians were not spared. At the siege of Arta, although the capture was much facilitated by the coming over of a corps of Albanians, the Greeks treated them extremely ill. The Albanian nation was thus forcibly thrown into the arms of the Porte, to which it has since continued nominally subject. The allegiance of the Albanians, however, to Turkey rests on a very precarious basis even at the present day, and, it will be remembered, in the Crimean war many Albanian chiefs fought under the Russian flag against the combined forces of England, France, and Turkey.

The inhabitants of Albania are estimated at 1,200,000, of whom a considerable proportion are Turks and Greeks; but the basis of the population consists of the original race, called Arnauts. About half of the entire population are Mahometans; of the other moiety, about 520,000 belong to the Greek Church, and the remainder to the Latin Church. The conversion of those who profess Mahometanism has been, however, very imperfect, and chiefly induced by political motives. In every family the males usually go to the mosque, the females to church; and some members of a family are seen in the most amicable manner eating from the same table, and even from the same plate, meats forbidden to the others. With the Turks, accordingly, infidel and Albanian are terms nearly synonymous. The native Albanian is of middle stature; his face is oval, with high cheek-bones; his neck long; his chest full and broad. His air is erect and majestic to a degree which never fails to strike the traveller. He holds in utter contempt that dissimulation which is characteristic of the Greek, and, unlike the Turk, he is gay, lively, and active. Averse, however, to regular industry his whole delight is in arms and plunder. He goes constantly armed; and there are few Albanians who have not, in the prime of their life, belonged to some of the numerous bands of robbers who infest the mountains of their native country, of Thessaly, and of Macedonia. This occupation carries with it no disgrace: it is common for the Albanian to mention circumstances which occurred "when he was a robber." In proportion as the trade of robbing becomes overstocked, part of those engaged in it seek employment in the service of the sultan and the different pashas throughout the Turkish empire, by all of whom the Albanians are regarded as the most valuable of their troops.

This fierce and haughty race display a greater degree of contempt for the female sex than is usual even among the most barbarous nations. The females are literally regarded as inferior animals, and treated accordingly; but in the country districts they are not confined or veiled, as is customary in Mahometan countries.

The national costume of the Albanians is handsome in appearance, and bears some resemblance to the Highland dress. It consists of a cotton shirt; a white woollen *fustanella* or kilt, which reaches to the knees; a jacket; a sash round the waist, in which pistols and a yataghan are commonly carried; coloured leggings; sandals; and a red cap, round which some twist a shawl or scarf. The chiefs and wealthy Albanians generally wear a jacket and vest of velvet, richly embroidered with gold, and metal greaves over their leggings, which are usually made of fine scarlet cloth. The poorer classes, though picturesque in appearance, are extremely dirty in their habits, and seldom change their clothes. As a protection from the weather, every Albanian has a *capote*, or rough shaggy mantle with a hood attached, and usually made of horse-hair stuff or coarse woollen cloth. The dress of the females is more various, and often fantastical. A singular custom prevails among the girls of stringing together the pieces of money which they have collected for their portion, and wearing them upon their heads. Some of them have their hair hanging down in braids to a great length, loaded with this species of ornament.

Scutari, on the lake of that name, is now considered the chief town of Albania. It is the centre of a large inland trade, and contains about 40,000 inhabitants. Prisrend, in the north-east, is noted for its manufactures of fire-arms and cutlery, and has a population of 25,000. Monastir, or Bitolia, although the capital of the eyalet of Roumelia, is not, strictly speaking, within the confines of Albania. It has a large transit trade between eastern and western Turkey. Joannina, with 36,000 inhabitants, situated on the south-west shore of a lake of the same name, was the capital of Albania in the time of Ali Pasha, and was his stronghold as well as the seat of his government. The other important towns of the interior are Jacova, Tirana, Okhrida, Elbasan, Delvino, and Metzovo. The principal seaports and river-ports are Dulcigno, Durazzo, Parga, Prevesa, and Arta.

The commerce of Albania is chiefly carried on through Arta and Prevesa, on the north side of the entrance to the Gulf of Arta. The principal merchants, however, are Greeks residing at Joannina, among whom a very active commercial spirit appears to prevail. The exports consist almost entirely of unmanufactured produce, live stock, and provisions, and comprise valonia (the cup of the acorn of the Valonia oak, used in tanning), raw silk, cheese, raw hides, drugs, dye-woods, sheep, horses, and salted meats. Notwithstanding its mountainous character, the fertility of its plains affords a surplus of grain, of which a considerable quantity is sent to Italy, the Ionian Isles, Malta, and other places. The vine, olive, pomegranate, orange, lemon, mulberry, and fig are also cultivated. Wool is exported, chiefly unmanufactured, but partly also wrought into coarse cloth. Other important articles of export are oil, tobacco of good quality, cotton, and cotton yarn. Some cargoes of wood for building and firewood are annually sent to Malta. The chief imports consist of woollen cloths, used for winter coverings. For this purpose the preference is given to a coarser and cheaper kind than any that is usually manufactured in Great Britain. This is supplied from Germany. Fire-arms, cutlery, gunpowder, hardware, coffee, and sugar are also imported. The manufactures of Albania are few and unimportant, being almost entirely confined to *capotes*, embroidery on cloth and velvet, fire-arms and cutlery to a limited extent, and gun and pistol stocks—all for home consumption.

See the *Journey through Albania and Turkey* of Mr J. Cam Hobhouse (Lord Broughton); *Travels in the Ionian Isles, Albania, &c.*, by Sir Henry Holland, who resided for some time in the capacity of physician at the court of Ali Pasha; Rev. T. S. Hughes's *Travels in Sicily, Greece, and Albania;* Leake's *Travels in Northern Greece;* Mrs Mary A. Walker's *Through Macedonia to the Albanian Lakes.*

ALBANIA, in *Ancient Geography*, a country of Asia, bounded, according to Strabo, on the W. by Iberia, on the E. by the Caspian Sea, on the N. by Sarmatia, on the S. by Armenia and the river Cyrus (*Kour*). The country formerly called Albania corresponds with the modern *Daghistan*, *Schirvan*, and *Leghistan*, and is extremely fertile, owing to the alluvial deposits made by the river Cyrus. The ancient historians describe the Albanians as tall, strong-bodied, and, generally speaking, of a very graceful appearance. The Albanians were originally a nomad race, and never devoted themselves to agriculture or commerce. They became known to the Romans during Pompey's expedition in pursuit of Mithridates (65 B.C.), against which they opposed a force of 60,000 infantry and 22,000 cavalry. Though Pompey exacted from them a nominal submission, they continued practically independent.

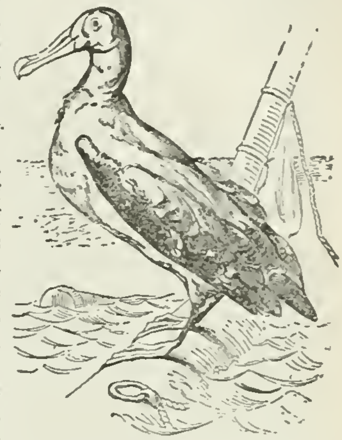
ALBANO, a town and lake in the Campagna di Roma, Italy, about 14 miles S.E. of Rome. The town is much admired for the picturesque scenery around it. It is well built, and the Roman aqueduct and other monuments of antiquity are in tolerable preservation. It contains a cathedral, and there are many handsome villas of the Roman nobles in the vicinity. Population, 6400. The lake of Albano, lying to the N.E. of the town, occupies the crater of an extinct volcano, and is of a beautiful oval form, surrounded with high wooded banks, and about 7 miles in circumference. It has long been an object of attraction to the painter and the traveller. In the fourth century of ancient Rome, during the siege of Veii, there was an extraordinary rise of the waters of this lake, and the oracle declared that there was no hope of success against Veii while the Alban lake was allowed thus to swell. This prompted the Romans to drain it by a tunnel cut through the rock, a mile and a half in length, 4 feet wide, and 6 high, which is still perfect. This outlet keeps the surface of the lake at the height of 920 feet above the level of the sea. Monte Cavo, the ancient *Albanus*, rises on the eastern side of the lake to a height of 3000 feet, and commands a magnificent prospect. On its summit stood the famous temple of Jupiter Latialis.

ALBANY, a city of the United States, capital of the state of New York and of the county of Albany, picturesquely situated in a beautiful and fertile country on the western bank of the Hudson, 145 miles from New York. It is, for an American city, irregularly laid out, and much of its architecture is poor, although it contains several very fine buildings, and many of its more recently made streets are broad and handsome. The Capitol, a brown stone edifice, 115 feet by 90, built in 1807, faces a square called Capitol Park; and opposite it, on the eastern side of the square, are the State Hall and City Hall, both constructed of white marble. There are several beautiful churches, including a large Roman Catholic cathedral. Among the literary and scientific institutions of Albany may be mentioned the university, incorporated in 1852, giving instruction in most branches of education, especially practical science and law; a medical college; an academy, and other schools of various grades; a large observatory; the state library, with about 90,000 volumes; and the Albany Institute for the collection and diffusion of scientific information. Albany is an important centre of trade, being situated at the point where the united Erie and Champlain canals join the Hudson, and possessing good railway communication with most cities of the United States. The chief articles of commerce are timber, wheat, barley, wool, and tobacco, enormous quantities of which, especially of the first-mentioned, pass through the city annually. Besides its transit trade, its numerous foundries, its breweries, carriage and hat manufactories, and tanneries are of importance. In 1873, 536 vessels (83 sailing and 352 unrigged vessels and 101 steamers), of 68,682 tons, belonged to the port. Albany was founded by the Dutch in 1623, and is thus one of the oldest European settlements in the United States, dating sixteen years after that of Jamestown in Virginia. It was captured by the British in 1664, who changed its name from Beaverwyck or Williamstadt in honour of the Duke of York and Albany. It received its charter in 1686, and became the capital of the state of New York in 1797. It is governed by a mayor and twenty aldermen, and is divided into ten wards. Population in 1870, 69,422; number of families, 14,105; and of dwellings, 8748.

ALBANY, Louisa Maria Caroline, Countess of, daughter of Prince Gustavus Adolphus of Stolberg-Gedern, was born at Mons on the 27th Sept. 1753, and assumed the title of Albany in 1772, when she married the Pretender, Charles Edward, grandson of James II. of England. Her husband was much older than herself, and their union proved very unhappy. There were no children, and the Pretender, who was a confirmed drunkard, treated his wife with such brutality that her health and even her life were endangered. In 1780 she obtained a legal separation, and entrusted herself to the care of her husband's brother, the Cardinal of York, who placed her in a convent, and afterwards removed her to his own house at Rome. Here she was frequently visited by the poet Alfieri, who made her the object of what seems to have been the only pure attachment of his life, and who, according to his own avowal, was indebted to her influence for all that was best in his works. (See Alfieri.) In 1788 she was freed from her bonds by the death of the Pretender, and in the same year she is said to have been secretly married to Alfieri. For the remainder of her life she resided at Florence, where she continued to be known as Countess of Albany, and distinguished herself as a patroness of literary men and artists. Alfieri died at her house in 1803, and in 1810 she caused a monument to his memory, by Canova, to be erected in the church of San Croce. With the death of the Cardinal of York in 1807 the Stuart line became extinct, and the countess, who died on the 29th January 1824, was the last who was known by the name of Albany. She was buried beside Alfieri in the church of San Croce.

ALBATEGNI, an Arabian astronomer, whose proper name is *Mohammed Ibn Jábir Ibn Senán Abú Abdillah*, derived this appellation from Batan in Mesopotamia, his native town, of which he is said to have been chief. His astronomical observations extended from 877 A.D. to his death in 929, and were principally conducted at Rakkah or Aracta, on the Euphrates, and at Antioch in Syria. His principal work, *Zidje Sabi*, the original MS. of which is in the Vatican, was published in a Latin translation by Plato Tiburtinus at Nuremberg in 1537, under the title *De Scientia Stellarum*, and reprinted at Bologna in 1645. Among the unpublished works of Albategni are commentaries on the *Almagest* and *Makalát* of Ptolemy, and a *Treatise on Astronomy and Geography*. Instead of the tables of Ptolemy, which were imperfect, he computed new ones; these were adapted to the meridian of Rakkah, and were long used as the best among the Arabs. Albategni gives the motion of the sun's apogee since Ptolemy's time, as well as the motion of the stars, which he estimated at 1° in 70 years. He makes the obliquity of the ecliptic 23° 35′. His determination of the length of the tropical year is more exact than that of Ptolemy, being only 2m. 26s. short. Upon his observations were founded the Alphonsine tables of the moon's motion. He first substituted sines for chords, and also introduced into trigonometry the use of tangents and versed sines. On account of his discoveries, the chief of which is the motion of the sun's apogee, he has been called the Arabian Ptolemy, and has been placed by some at the head of Arabian astronomers.

ALBATROSS, a genus of aquatic birds (*Diomedea*), closely allied to the Petrels and Gulls, belonging to the family of *Longipennatæ*, or long-winged birds, in the order *Natatores*. In the name *Diomedea*, assigned to them by Linnæus, there is a reference to the mythical metamorphosis of the companions of the Greek warrior Diomedes into birds. They have the beak large, strong, and sharp-edged, the upper mandible terminating in a large hook; the wings are narrow and very long; the feet have no hind toe, and the three anterior toes are completely webbed. Of the three species that the genus includes the best known is the Common or Wandering Albatross (*D. exulans*), which occurs in all parts of the Southern Ocean, and in the seas that wash the coast of Asia to the south of Behring Strait. It is the largest and strongest of all sea-birds. The length of the body is stated at 4 feet, and the weight at from 15 to 25 lb. It sometimes measures as much as 17 feet between the tips of the extended wings, averaging probably from 10 to 12 feet. Its strength of wing is very great. It often accompanies a ship for days—not merely following it, but wheeling in wide circles round it—without ever being observed to alight on the water, and continues its flight, apparently untired, in tempestuous as well as in moderate weather. It has even been said to sleep on the wing, and Moore alludes to this fanciful "cloud-rocked slumbering" in his *Fire Worshippers*. It feeds on small fish and on the animal refuse that floats on the sea, eating to such excess at times that it is unable to fly, and rests helplessly on the water. The colour of the bird is a dusky white, the back being streaked transversely with black or brown bands, and the wings darker than the rest of the body. The flesh, though hard, dry, and unsavoury, is eaten by the inhabitants of Kamtchatka, who also capture the bird for its entrails, which they inflate for net-floats, and its long wing-bones, which they manufacture into various articles, particularly tobacco-pipes. The albatross lays one egg; it is white, with a few spots, and is about 4 inches long. In breeding-time the bird resorts to solitary island groups, like the Crozet Islands and the elevated Tristan da Cunha, where it has its nest—a natural hollow or a circle of earth roughly scraped together—on the open ground. The early explorers of the great Southern Sea cheered themselves with the companionship of the albatross in its dreary solitudes; and the evil hap of him who shot with his cross-bow the bird of good omen is familiar to readers of Coleridge's *Rime of the Ancient Mariner*.



ALBAY, a town of Luzon, the chief of the Philippine Islands, in 13° 22′ N. lat. and 123° 52′ E. long. It is the capital of the fertile province of the same name, and the residence of the governor, and has an active trade. Close to the town is an active volcano by which it has been frequently devastated. Population, 13,115.

ALBERONI, Giulio, cardinal and statesman, was born near Piacenza, probably at the village of Fiorenzuola, on the 31st May 1664. His father was a gardener, and he himself became first connected with the church in the humble position of verger in the cathedral of Piacenza. Having gained the favour of Bishop Barni, he took priest's orders, and afterwards accompanied the son of his patron to Rome. During the war of the Spanish succession Alberoni laid the foundation of his political success by the services he rendered to the duke of Vendôme, commander of the French forces in Italy; and when these forces were recalled in 1706, he accompanied the duke to Paris, where he was favourably received by Louis XIV. In 1711 he followed Vendôme into Spain as his secretary. Two years later, the duke having died in the interval, Alberoni was appointed consular agent for Parma at the court of Philip V. of Spain, being raised at the same time to the dignity of count. On his arrival at Madrid he found the Princess des Ursins all but omnipotent with the king, and for a time he judged it expedient to use her influence in carrying out his plans. In concert with her he arranged the king's marriage with Elizabeth Farnese of Parma, whom he represented to be of such a facile disposition that the princess's power over Philip would be in no degree impaired by the union. Alberoni was already in Parma to conclude the negotiation ere the Princess des Ursins discovered that he had entirely deceived her as to the character of Elizabeth. A messenger was at once despatched to prevent, if possible, the ratification of the engagement; but he arrived too late. On reaching Spain Elizabeth's first act, prompted doubtless by Alberoni, was to demand the instant dismissal of the outwitted favourite, who was compelled to leave the Spanish dominions. The influence of the new queen being actively exerted on Alberoni's behalf, he speedily rose to high position. He was made a member of the king's council, bishop of Malaga, and in 1715 prime minister, and was raised to the dignity of cardinal in 1717. His internal policy was exceedingly vigorous, and, though carried out altogether regardless of popular rights and liberties, might have restored the lost greatness of Spain had it not been for his unscrupulous and audacious conduct of foreign affairs. The key to his daring and crafty schemes is probably to be found in the desire of Elizabeth to secure a throne for her son Don Carlos, born in 1716. Seizing the flimsiest pretext for making war upon Austria, he invaded the island of Sardinia, then Austrian territory, and took possession of Sicily In France he pressed the claims of Philip V. to the regency in opposition to the Duke of Orleans; he sought to keep England employed at home by encouraging the Pretender, and he pursued a similar policy towards Austria in connection with Ragotski of Transylvania and the Sultan. An alliance which he formed with Russia and Sweden led to no practical results, and his other schemes similarly failed. England, France, Austria, and Holland united themselves in what is known as the Quadruple Alliance against the aggressions of Spain; and though their first proposals were rejected fearlessly by Alberoni, they were strong enough to succeed when, in a second negotiation, they required of Philip the dismissal of his minister as an indispensable condition of peace. On the 5th December 1719 he was ordered to leave Spain, Elizabeth herself having taken an active part in procuring the decree of banishment. He went to Italy, and there had to take refuge among the Apennines, Pope Clement, who was his bitter enemy, having given strict orders for his arrest. On the death of Clement, Alberoni boldly appeared at the Conclave, and took part in the election of Innocent XIII. (1721), after which he was for a short time imprisoned by the pontiff on the demand of Spain. At the next election he was himself proposed for the papal chair, and secured ten votes at the Conclave which elected Benedict XIII. Benedict's successor, Clement XII., named him legate of Ravenna, in which capacity he incurred the pope's displeasure by the strong and unwarrantable measures he adopted to reduce the little republic of San Marino to subjection to Rome. He was consequently replaced by another legate in 1740, and soon after he retired to Piacenza, where he founded a college which still bears his name. He died on the 16th June 1752, leaving a sum of 600,000 ducats to endow the seminary he had founded, and the residue of the immense wealth he had acquired in Spain to his nephew. Alberoni left a large quantity of manuscripts; but the genuineness of the *Political Testament*, published in his name at Lausanne in 1753, has been questioned.

ALBERT (Albrecht) I., Duke of Austria, and afterwards King of Germany, born in 1248, was the son of Rudolph of Habsburg, the founder of the imperial Austrian dynasty. Rudolph having acquired the duchy of Austria by conquest, vested it in his son, with consent of the electors, in 1282, and thus founded the dynasty which still reigns. He also endeavoured to secure for Albert the succession to the throne of Germany, but was unsuccessful. On the death of his father in 1291, Albert seized the insignia of sovereignty, and with characteristic presumption declared himself king of Germany, without regard to the decision of the electors. Their choice fell (1292) upon Adolphus of Nassau, and Albert, who was called to suppress a revolt among his subjects in Switzerland, found it necessary to acknowledge the superior claims of his rival. The government of Adolphus having become displeasing to the electors, they formally deposed him in 1298, and named Albert his successor. As, however, the former refused to recognise their verdict, the matter had to be referred to the arbitrament of the sword. The forces of the rival kings met at Gölheim, near Worms, where the army of Adolphus was defeated, and he himself slain by Albert's own hand. Upon this, Albert, wishing probably to show his moderation, resigned his claim to the throne; but he was re-elected, and crowned at Aix-la-Chapelle on the 24th August 1298 Pope Boniface VIII., however, denied the right of the electors, and refused to confirm their choice, alleging that the empire belonged to him alone to hold or bestow at his pleasure. In league with Philip the Fair of France, Albert at first openly resisted the pope; but soon finding it advisable to change his policy, he deserted his ally, admitted the papal jurisdiction, and was rewarded with the kingdom of the deposed Philip. It should be noted, however, that he never received from the pope the crown of the Roman empire, though his name is generally included in the list of emperors. His reign as king of Germany was one of continual warfare. With a rapacity which seems to have known no bounds, he endeavoured to subdue Holland, Zealand, Friesland, Hungary, and Bohemia; but was in each case unsuccessful. The attempt to bind his yoke more firmly upon the Swiss cantons caused the revolt of Unterwalden, Schwyz, and Uri, in January 1308, and thus laid the foundation of the Swiss Confederation. It was while endeavouring to check this revolt that Albert met his death at the hand of his nephew, John of Habsburg, whose claim to his father's dominion of Swabia had been refused in the most insulting terms by the king. Incensed at the denial of his rights, John formed a conspiracy with three noblemen of the king's suite. On the 1st May 1308 the four crossed the river Reuss at Windisch with Albert, who was slain immediately on landing, and before the eyes of the other members of the suite, who had been left on the opposite side. He died in the arms of a beggar woman, who happened to be passing.

Albert was married to Elizabeth, daughter of the count of Tyrol, who bore him eleven children.

Four other reigning dukes of Austria bore the name of ALBERT. Of these, Albert II., surnamed the Wise, reigned from 1330 to 1358; Albert III. from 1365 to 1390; and Albert IV., surnamed the Pious, from 1390 to 1402. Albert V., surnamed "The Magnanimous," born in 1397, was elected king of Germany in April 1438, and is therefore sometimes styled Albert II., the higher dignity having been previously borne only by the first of the name. Through his marriage in 1422 with Elizabeth, daughter of Sigismund, king of Bohemia and Hungary, he ultimately added the sovereignty of these dominions to his own, being elected king of Hungary on the death of Sigismund in 1437, and king of Bohemia in May 1438. He died at Langendorf on the 27th October 1439, while engaged in an expedition against the Turks.

ALBERT I., margrave of Brandenburg, surnamed "The Bear," from the heraldic emblem he assumed, born in 1106, was the son of Otto the Rich, count of Ballenstädt, by his marriage with Eilica, eldest daughter of the duke of Saxony. In 1121 he received from the Emperor Lothario the marquisate of Lusatia, to be held in fief, and he served the empire faithfully in the war with Bohemia in 1126. In the following year, from some unknown motive, the emperor conferred the duchy of Saxony, to which Albert, as son of the eldest daughter of Magnus, had the best claim, upon Henry of Bavaria, son of a younger daughter; and in 1131 Albert was deprived of Lusatia. He still remained, however, loyal to the empire, and received as a reward the margravate of Brandenburg in 1134. In 1136–7 he made incursions into the territory of the Wends, his troublesome neighbours on the north, and succeeded in strengthening his position. In 1138 the Emperor Conrad III. conferred upon him the duchy of Saxony; but finding himself unable to maintain his rights against Henry the Lion, he betook himself in 1142 to the emperor, who restored Saxony to his rival, and allotted Swabia to him in compensation. A few years later Albert again attacked the Wends, and secured by conquest large accessions of territory, which he held as a fief of the empire. On the extinction of the house of Staden in 1150, Albert was raised to the dignity of an elector. A third expedition against the Wends, undertaken in 1157, ended in their almost total extinction, and Albert caused the depopulated territory to be colonised by industrious agriculturists from the Rhine and the Netherlands, who greatly improved the face of the country. In 1158 Albert went on a crusade to the Holy Land, in company with his wife, returning the following year. The close of his reign was signalised by another war with Henry of Saxony (1164–8), in which Albert was unsuccessful. Immediately on peace being concluded, he abdicated in favour of his eldest son; and after two years spent in retirement, he died at Ballenstädt on the 18th November 1170.

ALBERT, Margrave of Brandenburg and first Duke of Prussia, third son of the Margrave Friedrich of Anspach, was born on the 17th May 1490. Being intended for the church, he was educated by Archbishop Hermann of Cologne, and became a canon of Cologne cathedral. He seems, however, to have himself preferred a military life, as he accompanied his father in the train of the emperor on an expedition to Venice, and was present at the siege of Pavia. On the 13th Feb. 1511 he joined the Teutonic order; and a few days after, though scarcely twenty-one years old, was chosen grand master, it being expected that, as nephew of Sigismund of Poland, he would be able to secure the privileges and immunities which the order were at the time claiming from that monarch. The refusal of Albert to swear allegiance to Sigismund led, after protracted negotiations, which proved fruitless, to a war with Poland in 1520. A four years' truce being concluded at Thorn in 1521, Albert repaired to the diet at Nuremberg to invoke the aid of his brother German princes on behalf of his order. The diet found itself unable to render him any assistance, and at the same time he received advice from Luther which altogether changed his purpose. Embracing the doctrines of the Reformation, he was declared Duke of Prussia, consented to hold the duchy as a fief from Poland, and took the oath of allegiance at Cracow on the 9th April 1525. At the same time he resigned the grand mastership of the order. In 1527 he married Anne Dorothea, daughter of the king of Denmark. His subsequent reign was marked by zealous efforts, amid many difficulties, to promote the welfare of his duchy. He interested himself especially in the advancement of learning, inviting men of letters to his court, and promoting the publication of their writings. In 1544 he founded the university of Königsberg, in spite of great opposition, chiefly from the pope. Keen theological disputes between the professors of this university were among the many troubles of his later years. He died of the plague on the 20th of March 1568. His second wife, the Princess Anna Maria of Brunswick, who had been attacked by the same disease, survived him only a single day.

ALBERT, Cardinal Archbishop of Magdeburg and Elector of Mentz, born 1489, was the youngest son of John, Elector of Brandenburg. In 1513 he was consecrated archbishop of Magdeburg, and about the same time he was chosen administrator of the diocese of Halberstadt. Next year he was raised to the still higher dignity of archbishop and elector of Mentz, and he continued to hold all three offices simultaneously. For the *pallium* in connection with the latter appointment the pope demanded the exorbitant sum of 30,000 ducats, but enabled the archbishop to recoup himself by granting him the privilege of selling indulgences throughout his diocese. It was his employment of the Dominican Tetzel in this service which, by calling forth Luther's famous ninety-five theses, had so important an influence on the course of the Reformation. In 1518 he was created a cardinal as a reward for his services to the Romish church. His opposition to the doctrines of Luther did not prevent many within his own diocese from accepting the Reformation; and he found it necessary to grant religious liberty to his subjects in 1541, availing himself of the opportunity to extort from them in return for the boon the payment of his debts, which amounted to 500,000 florins. Albert was a patron of learning, and counted Erasmus among his friends. He died at Mentz on the 24th September 1545.

ALBERT (PRINCE), FRANCIS CHARLES AUGUSTUS ALBERT EMMANUEL, Prince Consort of England, born at Rosenau on the 26th Aug. 1819, was the second son of the hereditary Duke of Saxe-Coburg-Gotha, by his first wife the Princess Louise of Saxe-Gotha-Altenburg. He thus belonged to the Ernestine or elder branch of the royal family of Saxony, which, on account of its adherence to the doctrines of the Reformation, had to surrender the kingdom to the Albertine or younger branch, which is still in possession of it. The marriage of his parents proving an unhappy one, they separated in 1824, and the young prince never again saw his mother, who died in 1831. He was educated, along with his elder brother Ernest, under the care of *Consistorial-Rath* Florschütz, who, in a memorandum drawn up after the prince's death, speaks in the highest terms of his pupil's benevolent disposition and studious habits. At the proper age the brothers proceeded to the university of Bonn, where Herr Florschütz still continued to exercise a general superintendence of their studies. Prince Albert devoted himself especially to the natural sciences, political economy, and philosophy, having for teachers men of such world-wide fame as Fichte, Schlegel, and Perthes. He also diligently cultivated at this period the sister arts of music and painting, and thus qualified himself for some of the most valuable services he was afterwards to render to the land of his adoption. His feeling for art in all its forms was very sensitive, and his executive skill, both as a musician and painter, very considerable. In gymnastic exercises he greatly excelled, carrying off the first prize for fencing in a competition with a large number of students.

In 1836 the prince visited England in company with his father, and met his future consort for the first time. The idea of a matrimonial alliance between the cousins had occurred to various members of the family, and had been cherished especially by their grandmother the dowager-duchess of Coburg, and their uncle Leopold, the king of the Belgians. From the time of the queen's accession there seems to have been a family understanding on the subject, though, owing to the youth of the prince and his cousin, no formal engagement was entered into till two years later. In the winter of 1838–9 the prince travelled in Italy, accompanied by Mr Seymour, a young English gentleman, who was selected doubtless out of regard to the probable future of his charge. A year later the hopes of many were realised when, on the 23d Nov. 1839, the queen announced to the Privy Council her intended marriage with her cousin. The circumstances of the engagement have been fully made known since the prince's death, and they show that the union was founded upon mutual choice, springing from mutual affection. On the 10th February 1840 the marriage was celebrated at the chapel-royal, St James's, amid universal rejoicings. A few days before the event two bills had been passed in parliament, one naturalising the prince as a British subject, and the other providing an annuity of £30,000 a year for the maintenance of his establishment. The ministry had proposed that the sum should be £50,000, following the precedent established in the case of Prince Leopold; but the reduction was made on the motion of Colonel Sibthorpe, who received the support of the radicals and the entire opposition. The result of the vote caused the prince considerable vexation and disappointment, which were enhanced when difficulties were raised in parliament as to the precedence to be accorded to him. The latter question was only settled by an exercise of the queen's prerogative. Letters patent were issued on the 5th March, giving the prince precedence next to the queen.

The position in which the prince was placed by his marriage, while it was one of distinguished honour, was also one of peculiar difficulty, and it was only the possession of a rare discretion that enabled him to fill it so irreproachably as he did. Published letters and memoranda show how thoroughly he appreciated the delicate nature of his duties, and how clearly he perceived the limits within which his influence must be confined if it was to be legitimately and usefully exerted. A letter to the Duke of Wellington, declining, after mature consideration, to be designated to the office of commander-in-chief of the army, is especially noteworthy as containing an admirable description of the proper functions of a prince-consort. Generally, his idea was that it was his duty to merge his personality as completely as possible in that of the sovereign, while giving her in all things real but unobtrusive advice and support; and that he acted during his whole life in conformity with this idea those who had the best means of knowing were the readiest to testify. Once, indeed, at the commencement of the Crimean war, it was generally believed that he had overstepped the limits of his position by interfering unwarrantably with the foreign policy of the country and the patronage of the army. The charges were so definite and so widely circulated that it was deemed necessary to take notice of them in parliament. They were met by a complete and emphatic denial on the part of the ministry, and no one now believes that they had any real foundation. It was, of course, both natural and proper that the prince should interest himself deeply in the affairs of the country over which, by an Act passed on the 4th Aug. 1840, he had been named regent in the event of the death of the queen before the heir to the crown had attained the age of eighteen years. He had also a right to interest himself in the administration of the army, as being himself a field-marshal and a colonel of hussars.

It was fortunate for the prince, shut out as he was by the circumstances of his station from any share in party politics, that he found other and more congenial work sufficient to engage all his energies. He was qualified, as few of his rank are, to deal with those social and scientific problems in the solution of which men of all parties are equally interested. He engaged himself especially in endeavours to secure the more perfect application of science and art to manufacturing industry. The Great Exhibition of 1851 originated in a suggestion he threw out at a meeting of the Society of Arts, and owed the greater part of its success to his intelligent and unwearied efforts. Similar institutions, on a smaller scale but with a kindred aim, always found in him warm advocacy and substantial support. It was chiefly at meetings in connection with these that he found occasion for the delivery of addresses characterised by profound thought and comprehensiveness of view, a collection of which was published in 1857. One of the most favourable specimens of his powers as a speaker is the inaugural address which he delivered as President of the British Association for the Advancement of Science when it met at Aberdeen in 1859, printed in an edition of his speeches which appeared in 1862. The education of his family and the management of his domestic affairs furnished the prince with another very important sphere of action, in which he employed himself with conscientious devotedness. The training of the Prince of Wales was carried on under his own superintendence, in accordance with a plan he himself had drawn up; and it may be questioned whether so much wisdom and care was ever bestowed on the upbringing of an heir to the British throne. The estates of the Duchy of Cornwall, the hereditary appanage of the Prince of Wales, were so greatly improved under his father's management that the rent-roll rose from £11,000 to £50,000 a year. Prince Albert, indeed, had a peculiar talent for the management of landed estates. His model farm at Windsor was in every way worthy of the name; and the grounds at Balmoral and Osborne, so universally admired, were laid out entirely in conformity with his designs.

A character so pure, and a life so useful and well-directed in all its aims, could scarcely fail to secure universal respect. As the prince became better known, the mistrust, of which the adverse votes in parliament were undoubtedly to some extent an expression, gave way, and the people vied with their queen in showering deserved honours upon him. After a keen contest with Earl Powis, he was elected chancellor of the university of Cambridge in 1847; and he was afterwards appointed master of the Trinity House. In 1857 the formal title of "Prince-Consort" was conferred upon him by letters patent, in order to settle certain difficulties as to precedence that had been raised at foreign courts. As he had previously possessed no distinctive title, the precedence he had received was only by courtesy.

It was in the prime of manhood and the full career of his usefulness that the prince-consort was removed by death. He had been greatly occupied during the autumn of 1861 with the arrangements for the projected international exhibition, and it was just after returning from one of the meetings in connection with it that he was seized with his last illness. He died of typhoid fever on the 14th of Dec. 1861. Few have ever been more sincerely or more universally mourned. The grief of the queen was deep and lasting, and the whole nation sympathised in the truest sense with her in her sorrow. Perhaps never before, except on the occasion of the death of the Princess Charlotte, had all classes of the people been so closely knit together in the feeling of a common bereavement and a common sorrow. A national memorial, to be erected partly by parliamentary vote and partly by public subscription, was at once resolved upon, and nearly every town of importance throughout the kingdom embodied in a statue or some other form its tribute to the memory of "The Good Prince." The magnificent mausoleum at Frogmore, in which his remains were finally deposited, was erected at the expense of the Queen and the royal family. (See *Early Years of H.R.H. the Prince Consort*, 1867; *Principal Speeches and Addresses of Prince Albert*, with an Introduction, 1862).

ALBERT NYANZA, a large lake in East Central Africa, extending from 2° 45′ N. lat. at least as far as 2° S. Its surface is 2720 feet above the level of the sea: on its western coast are the Blue Mountains, rising 7000 feet higher; and on the east a ridge of steep cliffs, with elevations varying from 1500 to 5000 feet. The White Nile, flowing in a north-westerly direction from Lake Victoria Nyanza, enters Lake Albert Nyanza about 2° 15′ N. lat., and issues from it near its northern extremity. Messrs Speke and Grant were informed of the existence of this lake by the natives, but Sir Samuel (then Mr) Baker and his wife were the first Europeans who explored it in 1864. (See AFRICA and NILE, and also Sir S. W. Baker's *The Albert Nyanza, the Great Basin of the Nile, and Explorations of the Nile Sources*, 2 vols., London, 1866).

ALBERTI, LEON BATTISTA, distinguished as a painter, poet, philosopher, musician, and especially as an architect, was descended from the noble family of the Alberti of Florence. The place and date of his birth are variously given, but it is most probable that he was born at Venice about the year 1404. He was so skilled in Latin verse that a comedy he wrote in his twentieth year, entitled *Philodoxius*, deceived the younger Aldus, who edited and published it as the genuine work of Lepidus. In music he was reputed one of the first organists of the age. He held the appointment of canon in the metropolitan church of Florence, and thus had leisure to devote himself to his favourite art. He is generally regarded as one of the restorers of the ancient style of architecture, and has been called by some writers the Florentine Vitruvius. At Rome he was employed by Pope Nicholas V. in the restoration of the papal palace and of the fountain of Acqua Vergine, and in the ornamentation of the fountain of the Piazza de Trevi. At Rimini he designed the celebrated church of San Francesco, which is generally esteemed his finest work. On a commission from Rucellai, he designed the principal façade of the church of Santa Maria Novella in Florence, as well as the family palace in the Via della Scala, now known as the Palazzo Strozzi. In Mantua he was employed by the Marchese Ludovico Gonzaga to design several buildings, the most important being the church of Sant' Andrea. Alberti wrote works on sculpture, *Della Statua*, and on painting, *De Pictura*, which are highly esteemed; but his most celebrated treatise is that on architecture, *De Re Ædificatoria*, which has been translated into Italian, French, Spanish, and English. A splendid edition of this work in English and Italian, by Leoni, was published at London in 1726, in 3 vols. folio. Alberti, being of an amiable and generous disposition, was highly esteemed by his contemporaries. He died at Rome in 1472, or, according to others, in 1484.

ALBERTRANDY, JAN CHRZCICIEL, or JOHN-CHRISTIAN, historian, was born at Warsaw in 1731, his father being an Italian. Educated in the public school of the Jesuits, he joined their order in his fifteenth year, and gave such proof of his ability that, at the early age of nineteen, he was appointed professor at the college of Pultusk. After having successively filled similar positions in Plock, Nieswiez, and Wilna, he became, in 1766, librarian to Bishop Zaluski, who designed to make his extensive collection of books available to the public. A detailed catalogue of the 200,000 volumes which it contained was accordingly prepared by Albertrandy. In 1764 he was chosen by the primate Lubienski tutor to his grandson, Count Felix Lubienski, afterwards minister of justice. In this capacity he visited Italy in 1770 with his pupil, residing first at Siena and then at Rome. The preference Lubienski showed for numismatics induced Albertrandy to devote himself while in Italy to the special study of that science, and he was soon recognised as an authority on the subject. When he returned to his native country, King Stanislaus Augustus appointed him, at the request of Lubienski, keeper of his medals, and afterwards his reader and librarian. The representations he made to the king as to the extent and value of the materials for Polish history that were scattered throughout the libraries of Rome, induced Stanislaus to send him on a second visit to Italy, in order that he might collect these materials. He arrived at Rome in 1782, and devoted three years to the task. The *Excerpta*, all written with his own hand, filled 110 volumes of manuscript. To complete the collection, he subsequently visited Sweden, where the difficulty of the work was greatly increased by his being forbidden to copy any portions of the books or manuscripts he consulted. An excellent memory, however, enabled him in great measure to overcome the difficulty; and from the libraries of Stockholm and Upsala he made extracts which increased the entire collection to 200 volumes. In recognition of his merit the king bestowed on him the bishopric of Zenopolis. He was the first president of the Royal Society of the Friends of Science in Warsaw, and took a large share in its proceedings up to the time of his death, which occurred on the 10th August 1808.

ALBERTUS MAGNUS, a celebrated scholastic philosopher, was born of the noble family Von Bollstädt at Lauingen in Suabia. The date of his birth is most probably 1193. He was educated principally at Padua, where he received particular instruction in Aristotle's writings. In 1223 he became a member of the Dominican order, and studied theology under its rules at Bologna and elsewhere. Selected to fill the position of lecturer at Cologne, where the order had a house, he taught for several years there, at Regensburg, Freiburg, Strasburg, and Hildesheim. In 1245 he repaired to Paris and received his doctorate, teaching for some time, in accordance with the regulations, and with great success. In 1254 he was made provincial of his order, and fulfilled the arduous duties of the office with great care and effectiveness. During the time he held this office he publicly defended the Dominicans against the university of Paris, commented on St John, and answered the errors of the Arabian philosopher, Averroes. In 1259 the pope made him bishop of Regensburg, which office he resigned after three years. The remainder of his life he spent partly in preaching throughout Bavaria and the adjoining districts, partly in retirement in the various houses of his order; almost the last of his labours was the defence of the orthodoxy of his former pupil, Thomas Aquinas. He died in 1280, aged 87. Albert's works, published in twenty-one folios by the Dominican Peter

Jammy in 1651, sufficiently attest his great activity. He was the most widely read and most learned man of his time. The whole of Aristotle's works, presented in the Latin translations and notes of the Arabian commentators, were by him digested, interpreted, and systematised in accordance with church doctrine. Albert's activity, however, is rather philosophical than theological, for while pressing philosophy in general, and Aristotle in particular, into the service of theology, he excludes from what belongs to the natural reason all that is specially biblical, as, *e.g.*, miracles, the atonement, and the Trinity; though he does not refuse to see with Augustin exemplifications, shadowings, of the latter doctrine even in nature. The philosophical works occupying the first six and the last of the twenty-one volumes are generally divided according to the Aristotelian scheme of the sciences, and consist of interpretations and condensations of Aristotle's relative works, with supplementary discussions depending on the questions then agitated, and occasionally divergences from the opinions of the master. In logic, he attempts to unite the three rival theories of universals, holding that universals exist in three ways—(1.) *Ante res*, as ideas in the mind of God, from which the class is modelled, and which therefore exist before individual things; (2.) *In rebus*, as the common basis in a class of individual objects; (3.) *Post res*, as the mental notion of the class. In the metaphysical and physical treatises he mainly repeats Aristotle, differing from him as regards the eternity of the world and the definition of the soul. His principal theological works are a commentary in three volumes on the *Books of the Sentences* of Peter Lombard (*Magister Sententiarum*), and the *Summa Theologiæ*, in two volumes. This last is in substance a repetition of the first in a more didactic form. Albert's knowledge of physical science was considerable, and for the age accurate. His industry in every department was great, and though we find in his system many of those inner gaps from which no scholastic philosophy was ever free, yet the protracted study of Aristotle gave him a great power of systematic thought and exposition, and the results of that study, as left to us, by no means warrant the contemptuous title sometimes given him—the "Ape of Aristotle." They rather lead us to appreciate the motives which caused his contemporaries to bestow on him the honourable surname "The Great," and the no less honourable title, "Doctor Universalis." For Albert's life the best authorities are Sighart, *Albertus Magnus, sein Leben und seine Wissenschaft*, 1857; and D'Assailly, *Albert le Grand*, 1870. The most comprehensive surveys of his philosophy are those of Stöckl, *Geschichte d. Scholastischen Philosophie*, and, in smaller compass, Erdmann, *Grundriss d. Ges. d. Phil.*, vol. i. Hauréau, Ritter, and Prantl may also be referred to.

ALBI, a city of France, capital of the department of the Tarn, is situated on the river Tarn, 41 miles N.E. of Toulouse. It is a place of great antiquity, and was a stronghold of the early French Protestants, giving its name to the Albigenses. It is the seat of an archbishop, and has a chamber of commerce and a public library of 12,000 volumes. The cathedral, dedicated to St Cecilia, is a magnificent Gothic edifice, in the style of the 13th century, and has one of the finest choirs in France. Here there is a very valuable silver shrine, of exquisite mosaic work, containing the relics of St Clair, the first bishop of the see. The environs are charming, and the promenade of *La Lice*, without the city, is a beautiful terrace bordered with two rows of very fine trees. At one end is the convent of the Dominicans. Albi has woollen and linen manufactures; coal, iron, and copper are wrought in the vicinity; and the surrounding district is very fertile, producing much grain and fruit. Population (1872), 17,469.

ALBIGENSES, a sect opposed to the Church of Rome, which derives its name from Albiga (the modern *Albi*, noticed above), either because its doctrines were expressly condemned at a council held there, or, more probably, because its adherents were to be found in great numbers in that town and its neighbourhood. The Albigenses were kindred in origin and more or less similar in doctrine to the sects known in Italy as Paterins, in Germany as Catharists, and in France as Bulgarians, but they are not to be entirely identified with any of these. Still less ought they to be confounded, as has frequently been the case, with the Waldenses, who first appear at a later period in history, and are materially different in their doctrinal views. The descent of the Albigenses may be traced with tolerable distinctness from the Paulicians, a sect that sprang into existence in the Eastern Church during the 6th century. (See PAULICIANS.) The Paulicians were Gnostics, and were accused by their enemies and persecutors of holding Manichæan doctrines, which, it is said, they vehemently disowned. Their creed, whatever it was precisely, spread gradually westward through Europe. In the 9th century it found many adherents in Bulgaria, and 300 years later it was maintained and defended, though not without important modifications, by the Albigenses in the south of France. The attempt to discover the precise doctrinal opinions held by the Albigenses is attended with a double difficulty. No formal creed or definite doctrinal statement framed by themselves exists, and in default of this it is impossible to depend on the representations of their views given by their opponents in the Church of Rome, who did not scruple to exaggerate and distort the opinions held by those whom they had branded as heretics. It is probably impossible now to determine accurately what is true and what is false in these representations. It seems almost certain, however, that the bond which united the Albigenses was not so much a positive fully-developed religious faith as a determined opposition to the Church of Rome. They inherited indeed, as has been already said, certain doctrines of eastern origin, such as the Manichæan dualism, docetism in relation to the person of Christ, and a theory of metempsychosis. They seem, like the Manichees, to have disowned the authority of the Old Testament; and the division of their adherents into *perfecti* and *credentes* is similar to the Manichæan distinction between *electi* and *auditores*. The statement that they rejected marriage, often made by Roman Catholics, has probably no other foundation in fact than that they denied that marriage was a sacrament; and many other statements as to their doctrine and practice must be received at least with suspicion as coming from prejudiced and implacable opponents. The history of the Albigenses may be said to be written in blood. At first the church was content to condemn their errors at various councils (1165, 1176, 1178, 1179), but as their practical opposition to Rome became stronger, more decided measures were taken. Innocent III. had scarcely ascended the papal throne when he sent legates to Toulouse (1198) to endeavour to suppress the sect. Two Cistercians, Guy and Regnier, were first commissioned, and in 1199 they were joined by Peter of Castelnau and others, who were known throughout the district as inquisitors. Raymond VI., count of Toulouse, took the part of his Albigensian subjects, though not himself belonging to the sect, and for this he was excommunicated in 1207. A year later the pope found a pretext for resorting to the most extreme measures in the assassination of his legate Peter of Castelnau, Jan. 15, 1208. A crusade against the Albigenses was at once ordered, and Raymond, who had meanwhile submitted and done penance, was forced to take the field against his own subjects. The bloody war of extermination which followed has scarcely a parallel in history. As town after town was taken, the inhabitants were put to the sword without distinction of age or sex, and the numerous ecclesiastics who were in the army especially distinguished themselves by a bloodthirsty ferocity. At the taking of Beziers (July 22, 1209), the Abbot Arnold, being asked how the heretics were to be distinguished from the faithful, made the infamous reply, "Slay all; God will know his own." The war was carried on under the command of Simon de Montfort with undiminished cruelty for a number of years. Raymond's nephew, Viscount Raymond Roger, who had espoused the cause of the Albigenses, was taken prisoner at Carcassone, and the sect became fewer in numbers year by year. The establishment of an Inquisition at Languedoc in 1229 accelerated the exterminating process, and a few years later the sect was all but extinct.

ALBINO. The name *Albinism*, or *Leucopathia*, is applied to a remarkable peculiarity in the physical constitution of certain individuals, which consists in the skin and hair being perfectly white. The earliest accounts we have of it refer to its being observed among the negroes of West Africa by the Portuguese, who called the persons so affected *Albinoes*. They have also been called *Leucæthiopes*, *i.e.*, white negroes. Albinism is most common and most marked in the negro and Indian races, but it occurs in all parts of the world and among all the varieties of the human race. The appearance arises from the absence of the minute particles of colouring matter which ordinarily occur in the lowest and last-deposited layers of the epidermis or outer skin, and to the presence of which the skin owes its colour. With very rare exceptions, it affects the entire body, and continues through life. The skin of the albino is of a dull milky or pearly colour, unrelieved by the slightest tint of red or brown, and is generally of rough texture. All the hair on the body is of the same dull hue, and is commonly soft and silky. Another peculiarity that invariably accompanies this whiteness of skin and hair is an affection of the eyes: the pupil is a bright red, and the iris (or *white* of the eye) that surrounds it is of a pale rose colour. This redness is attributable to the absence of a colouring matter, the *pigmentum nigrum* of the membrane of the eye, which serves to protect the retina. In consequence of this defect, the eye of an albino cannot bear a strong light. Albinism is hereditary in the same limited degree as blindness, deafness, &c. See on this Darwin's *Variation of Animals and Plants under Domestication* (chap. xii.), where mention is made that "two brothers married two sisters, their first cousins, none of the four nor any relation being an albino; but the seven children produced from this double marriage were all perfect albinoes." Apart from the peculiarities mentioned above, there is no distinction between albinoes and other men. Albinism is not to be regarded as a diseased condition of body; and the idea, once entertained, that it is accompanied with a want of physical and mental vigour is now completely exploded. Probably this notion arose from some of the albinoes whose condition was first described being unhealthy or imbecile; and even still more (as the interesting account of Saussure, *Voyages dans les Alpes*, 1787, suggests) from the temptation to which, as natural curiosities, they were exposed to live in indolence without exerting their natural powers. In many species of animals albinism occurs, *i.e.*, an abnormal whiteness of the skin, hair, feathers, &c., due to similar causes as in the human albino, but not so uniformly permanent. Of this, white hares, mice, blackbirds, &c., are instances. White elephants are regarded with particular veneration by some eastern nations.

ALBINUS (originally WEISS), BERNARD SIEGFRIED, a celebrated anatomist, born in 1697 at Frankfort-on-the-Oder, where his father was professor of the practice of medicine. In 1702 the latter was transferred to a professorship at Leyden, and it was there that Bernard Siegfried commenced his studies, having for his teachers such men as Boërhaave, Bidloo, and Rau. His great ability, especially in surgery and anatomy, was early recognised, and Rau, so justly celebrated as a lithotomist, is said to have seldom performed an important operation without inviting him to be present. Having finished his studies at Leyden, he went to Paris, where, under the instruction of Vaillant, Winslow, and others, he devoted himself especially to anatomy and botany. After a year's absence, he was, on the recommendation of Boërhaave, recalled in 1719 to Leyden to be a lecturer on anatomy and surgery. Two years later he succeeded his father in the professorship of these subjects, and delivered an address at his installation which was received with universal approbation. Albinus speedily became one of the most famous teachers of anatomy in Europe, his class-room being resorted to not only by students, but by many practising physicians. With little original genius, and no special talent for exposition, he possessed those habits of accurate observation and patient research which are the best qualification for his department of study. The engravings of bones and muscles executed by Wandelaar for the treatise of Albinus on these organs were far superior in clearness and exactness to anything that had previously been produced. In 1745 Albinus was appointed professor of the practice of medicine, being succeeded in the anatomical chair by his brother Frederick Bernard, who, as well as another brother, Christian Bernard, attained considerable distinction. Bernard Siegfried was twice rector of his university, and was an associate of the learned societies of London, St Petersburg, and Haarlem. He died on the 9th September 1770.

ALBINUS, FLACCUS. See ALCUIN.

ALBOIN, a king of the Lombards, who invaded Italy, 568 A.D. He was murdered at Verona on the 8th June 573. See ITALY and LOMBARDS.

ALBORNOZ, GIL ALVAREZ CARILLO DE, a cardinal of Spain, was born at Cuença early in the 14th century, and was related to the royal families of Leon and Arragon. While still young he was appointed archbishop of Toledo by Alfonso XI. of Castile. Uniting, as many in that age did, the exercise of the military with that of the clerical profession, he was able to show his gratitude to his patron by saving the king's life at the battle of Tarifa in 1340. He conducted the siege of Algeciras in 1343, when the king dubbed him a knight. Falling into disfavour with Pedro the Cruel, whose licentious life he had rebuked, he fled to Avignon, then the papal seat, and was soon afterwards made a cardinal by Pope Clement VI. In 1353 Innocent VI. sent him as a legate into Italy, with a view to the restoration of the papal authority in the States of the Church. He was recalled in 1357, but was sent again to Italy after a brief interval; and in 1362 had paved the way for the return of Urban V. to Rome. As a mark of gratitude, the pope appointed him legate at Bologna in 1367, but he died at Viterbo the same year. According to his own desire, his remains were carried to Toledo, where Henry of Castile caused them to be entombed with almost royal honours. A work by Albornoz on the constitution of the Church of Rome, first printed at Jesi in 1473, is now very rare. The college of St Clement at Bologna was founded by Albornoz.

ALBRECHTSBERGER, JOHANN GEORG, a celebrated musician, born at Kloster-Neuburg, near Vienna, on the 3d February 1736. He studied musical composition under the court organist, Mann, and became one of the most learned and skilful contrapuntists of his age. After being employed as organist at Raab and Maria-Taferl, he was appointed in 1772 organist to the court of Vienna, and in 1792 kapellmeister of St Stephen's cathedral. His fame as a theorist attracted to him in the Austrian capital a large number of pupils, some of whom afterwards became eminent musicians. Among these were Beethoven, Hummel, Moschcles, Seyfried, and Weigl. Albrechtsberger died in 1809. His published compositions consist of preludes, fugues, and sonatas for the piano and organ, string quartettes, &c.; but the greater proportion of his works, vocal and instrumental, exist only in manuscript, and are in the possession of Prince Esterhazy. Probably the most valuable service he rendered to music was in his theoretical works, which to a great extent superseded earlier treatises, and are still standard authorities. In 1790 he published at Leipsic a treatise on composition, of which a third edition appeared in 1821. A collection of his writings on harmony, in three volumes, was published under the care of his pupil Seyfried in 1826. The English translation of the latter is from a French version, and not from the original.

ALBUERA, a small village of Spain, in the province of Badajoz, 13 miles S.E. of the town of that name. It is celebrated on account of the victory gained there on the 16th of May 1811 by the English, Portuguese, and Spaniards, under Marshal Beresford, over the French army commanded by Marshal Soult.

ALBUFERA DE VALENCIA, a lagoon, 7 miles south of Valencia in Spain, about 12 miles in length and 4 in breadth, 12 feet being its greatest depth. It communicates with the sea by a narrow outlet, which can be opened or closed at pleasure. The lake is crown property, and is of great value from the fish and wild fowl with which it abounds. In 1812 Marshal Suchet was created duke of Albufera by Napoleon for his conquest of Valencia, and invested with the domain; but the battle of Vitoria soon deprived him of his possession, though he still retained the title. Subsequently the revenues of Albufera were conferred upon the Duke of Wellington, in token of the gratitude of the Spanish nation.

ALBUM (*albus*, white), originally denoted a tablet on which decrees, edicts, and other public notices were inscribed in ancient Rome. It was so called probably because the tablet was made of white or whitened material, though some authorities say that the inscription was in white characters. The Pontifex Maximus wrote his annals (*Annales Maximi*) upon an album. In course of time the term came to be restricted almost exclusively to lists of official names. Such were the *Album Judicum*, *Album Senatorum*, *Album Decurionum*, *Album Centuriæ*. In modern times album denotes a book in which verses, autographs, sketches, photographs, &c., are collected. It is also applied to the official list of matriculated students in a university, and to the roll in which a bishop inscribes the names of his clergy.

ALBUMAZAR (ABU-MAASCHAR), a celebrated Arabian astronomer, born at Balkh, in Turkestan, in 805 A.D., died at Wasid in 885. He had reached the age of forty-seven before he entered on the studies to which he owes his fame. His principal works are *An Introduction to Astronomy* and the *Book of Conjunction*, both published in a Latin translation at Augsburg in 1489, and again at Venice in 1515. A work *On the Revolution of the Years* is also attributed to him, in which it is maintained that the world was created when the seven planets were in conjunction in the first degree of Aries, and that it will come to an end at a like conjunction in the last degree of Pisces.

ALBUMEN, an organic substance of a very complicated structure. It is typical of a group of bodies that have the same chemical composition but very different properties. The principal varieties are named albumen, fibrin, and casein. They are sometimes called the histogenetic bodies, because they are essential to the building up of the animal organism. The vegetable kingdom is the original source of the albumenoid group of substances. In plants the albumen is found in greatest quantity in the seed. The mean average percentage composition of the albumenoids is as follows—

Carbon,	53·8
Hydrogen,	7·0
Nitrogen,	15·7
Sulphur,	1·2
Oxygen,	22·3
	100·0

The true chemical formula of these bodies is unknown, but if we regard the sulphur as replacing oxygen, then the *simplest empirical* formula is $C_{24}H_{38}N_6O_8$.

All the albumenoid bodies are capable of existing in two forms—(*a*) soluble, (*b*) insoluble. They belong to the class of bodies called *colloids*, and easily pass from the one condition into the other. Whether in the soluble or insoluble condition, they are easily dissolved by caustic potash, and may be precipitated by the addition of acetic acid. The soluble varieties are coagulated by alcohol, and precipitated by salts of copper, lead, and mercury. Strong sulphuric acid dissolves them, with the production of leucine, tyrosine, and ammoniacal salts. Strong nitric acid produces in their solutions a coagulum of a bright orange colour, and then gradually dissolves it with effervescence. A solution of nitrate of mercury, when heated with the members of the group, produces a deep red colour, and this is one of the most delicate tests. Some varieties of albumen coagulate when heated. All the albumenoid bodies are amorphous, and may be kept when dry for any length of time, but when moist they rapidly putrefy, and produce a sickening odour. Among the products of putrefaction are found leucine and tyrosine, and carbonate, butyrate, valerate, and sulphide of ammonium. The readiness with which these bodies change in the moist condition produces the digestive and other ferments in the body, and the synaptase, diastase, and emulsin which we find in plants. The special properties of albumen, fibrin, and casein will be described in the article CHEMISTRY. From its property of coagulating when heated, albumen is employed in the arts to remove colouring matters from liquids.

ALBUQUERQUE, a town of Spain, in the province of Badajoz, 9 miles from the frontiers of Portugal. Situated on an eminence, it is defended by an almost impregnable fortress built on a high mountain. It was taken by the allies of Charles, at that time a competitor for the Spanish throne, in 1705, but was restored to the Spanish crown in 1715. It has woollen and linen manufactures, and exports cattle and fruits. Population, 7000.

ALBUQUERQUE, ALPHONSO D' (in Portuguese *Affonso d'Alboquerque*), surnamed "The Great," and "The Portuguese Mars," was born in 1453 at Alexandria, near Lisbon. Through his father, Gonzalvo, who held an important position at court, he was connected by illegitimate descent with the royal family of Portugal, and through his mother, Dona Leonora de Menezes, he could claim kindred with Zarco and other illustrious navigators. He was educated at the court of Alphonso V., and after the death of that monarch seems to have served for some time in Africa. On his return he was appointed *estribeiro-mor* (chief equerry) to João II. In 1503 he set out on his first expedition to the East, which was to be the scene of his future triumphs. In company with his kinsman Francisco he sailed round the Cape of Good Hope to India, and succeeded in establishing the king of Cochin securely on his throne, obtaining in return for this service permission to build a Portuguese fort at Cochin, and thus laying the foundation of his country's empire in the East. He returned home in July 1504, and was well received by King Emmanuel, who entrusted him with the command of a squadron of five vessels in the fleet of sixteen which sailed for India in 1506 under Tristan da Cunha. After a series of successful attacks on the Moorish cities on the east coast of Africa, Albuquerque separated from Da Cunha, and sailed with his squadron against the island of Ormuz, in the Persian Gulf, which was then one of the chief centres of commerce in the East. He arrived on the 25th September 1507, and soon obtained possession of the island, though he was unable long to maintain his position. With his squadron increased by three vessels, he reached the Malabar coast at the close of the year 1508, and immediately made known the commission he had received from the king empowering him to supersede the governor Almeida. The latter, however, refused to recognise Albuquerque's credentials, and cast him into prison, from which he was only released, after three months' confinement, on the arrival of the grand marshal of Portugal with a large fleet. Almeida having returned home, Albuquerque speedily showed the energy and determination of his character. An unsuccessful attack upon Calicut in January 1510, in which the commander-in-chief received a severe wound, was immediately followed by the investment and capture of Goa. Albuquerque, finding himself unable to hold the town on his first occupation, abandoned it in August, to return with reinforcements in November, when he obtained undisputed possession. He next directed his forces against Malacca, which he subdued after a severe struggle. He remained in the town nearly a year in order to strengthen the position of the Portuguese power. In 1512 he sailed for the coast of Malabar. On the voyage a violent storm arose, Albuquerque's vessel, the "Flor de la Mar," which carried the treasure he had amassed in his conquests, was wrecked, and he himself barely escaped with his life. In September of the same year he arrived at Goa, where he quickly suppressed a serious revolt headed by Idalcan, and took such measures for the security and peace of the town that it became the most flourishing of the Portuguese settlements in India. Albuquerque had been for some time under orders from the home government to undertake an expedition to the Red Sea, in order to secure that channel of communication exclusively to Portugal. He accordingly laid siege to Aden in 1513, but was repulsed; and a voyage into the Red Sea, the first ever made by a European fleet, led to no substantial results. In order to destroy the power of Egypt, he is said to have entertained the idea of diverting the course of the Nile, and so rendering the whole country barren. His last warlike undertaking was a second attack upon Ormuz in 1515. The island yielded to him without resistance, and it remained in the possession of the Portuguese until 1622. Albuquerque's great career had a painful and ignominious close. He had several enemies at the Portuguese court who lost no opportunity of stirring up the jealousy of the king against him, and his own injudicious and arbitrary conduct on several occasions served their end only too well. On his return from Ormuz, at the entrance of the harbour of Goa, he met a vessel from Europe bearing despatches announcing that he was superseded by his personal enemy Soarez. The blow was too much for him, and he died at sea on the 16th December 1515. Before his death he wrote a letter to the king in dignified and affecting terms, vindicating his conduct and claiming for his son the honours and rewards that were justly due to himself. His body was buried at Goa in the Church of Our Lady, and it is perhaps the most convincing proof possible of the justice of his administration, that, many years after, Moors and Hindoos used to go to his tomb to invoke protection against the injustice of his successors. The king of Portugal was convinced too late of his fidelity, and endeavoured to atone for the ingratitude with which he had treated him by heaping honours upon his natural son Affonso. The latter published a selection from his father's papers, under the title *Commentarios do Grande Affonso d'Alboquerque.*

ALCÆUS, one of the great lyric poets of Greece, was a native of Mitylene in Lesbos, and flourished about the year 600 B.C. From the fragments of his poems which have come down to us we learn that his life was greatly mixed up with the political disputes and internal feuds of his native city. He sided with the nobles, and took an active part against the tyrants, who at that time set themselves up in Mitylene. He was obliged, in consequence, to quit his native country, and spend the rest of his life in exile. The date of his death is unknown. His poems, which were composed in the Æolian dialect, were collected afterwards, and apparently divided into ten books. The subjects, as we can still see from the fragments, were of the most varied kind: some of his poems were hymns to the gods; others were of a martial or political character; others again breathed an ardent love of liberty and hatred of the tyrants; and lastly, some were of an erotic kind, and appear to have been particularly remarkable for the fervour of the passion they described. Horace looks upon Alcæus as his great model, and has, in one passage (*Od.* ii. 13. 26, *et sqq.*) given a fine picture of the poetical powers of the Æolian bard. The care which Alcæus bestowed upon the construction of his verses was probably the reason why one kind of metre, the Alcaic, was named after him. Not one of his compositions has come down to us entire, but a complete collection of all the extant fragments may be found in Bergk's *Poetæ Lyrici Græci*, Lipsiæ, 1852, 8vo.

ALCAICS, in *Ancient Poetry*, a name given to several kinds of verse, from Alcæus, their reputed inventor. The first kind consists of five feet, viz., a spondee or iambic, an iambic, a long syllable, and two dactyles; the second of two dactyles and two trochees. Besides these, which are called *dactylic Alcaïcs*, there is another, simply styled *Alcaïc*, consisting of an epitrite, two choriambi, and a bacchius; thus—

Cur timet fla|vum Tiberim | tangere, cur | olivum

The Alcaïc ode is composed of several strophes, each consisting of four verses; the first two of which are always alcaïcs of the first kind; the third verse is an iambic diameter hypercatalectic, consisting of four feet and a long syllable; and the fourth verse is an alcaïc of the second kind. The following strophe is of this species, which Horace calls "*Alcæi minaces camenæ*"—

Non possidentem multa vocaveris
Recte beatum; rectius occupat
Nomen beati, qui deorum
Muneribus sapienter uti.

ALCAIDE, or ALCAYDE, a word of Moorish origin, being derived from the Arabic *káda*, to head, which was applied by the Spanish, the Portuguese, and the Moors to the military officer appointed to take charge of a fortress or prison. See ALCALDE.

ALCALA DE GUADAIRA, a town of Spain, in the province of Seville, Andalusia, situated on the Guadaira, 7 miles E. of Seville. It contains an old castle and other Moorish remains; but it is now chiefly remarkable for the excellent quality of its bread, whence the epithet *de los Panaderos*, sometimes applied to it. Nearly the whole of the bread required by the town of Seville is made here. Population, 7000.

ALCALA DE HENARES, an ancient Spanish city on the river Henares, 17 miles E.N.E. of Madrid. It has been identified with the Roman *Complutum*, which was destroyed about the year 1000, and was rebuilt by the Moors in 1083. In later times it was renowned for its richly-endowed university, founded by Cardinal Ximenes in 1510, which, at the height of its prosperity, numbered more than 10,000 students, and was second only to that of Salamanca. Here the famous edition of the Holy Bible known as the *Complutensian Polyglot* was prepared. The college of St Ildefonso contains a magnificent chapel, in which Ximenes is buried, and is distinguished by its splendid architecture, partly Moorish and partly Gothic. Alcala is further celebrated as the birthplace of the German emperor Ferdinand I., the poet Figueroa, the naturalist Bustamente de la Camera, the historian Solis, and last and greatest of all, Cervantes, who was born here in 1547. Since the removal of the university to Madrid in 1836 the town has rapidly declined. It contains a military academy and various public institutions, but is of little commercial importance. Population, 8745.

ALCALA LA REAL, a town of the province of Jaen in Spain, 18 miles S.W. of the town of that name. It stands on a declivity between two mountain ridges, at an elevation of about 3000 feet above the sea. It possesses a fine abbey. Its distinctive name *la Real*, the Royal, is derived from its capture in 1340 by Alphonso XI. of Leon, in person. In 1810 the Spaniards were defeated here by the French under Sebastiani. Some trade is carried on at the place in wine and wool. Population, 11,521.

ALCALDE (from the Arabic *al-cadi*, the judge), an official title given in Spain to various classes of functionaries entrusted with judicial duties. Criminal judges, members of courts of appeal, magistrates, and even parish officers are all known by the name alcalde—secondary descriptive titles distinguishing their different positions and functions. It is to be observed that the word is entirely distinct from Alcaide, the latter being always employed to designate a military officer.

ALCAMENES (Ἀλκαμένης), a famous Athenian sculptor, a pupil of Phidias, who is celebrated for his skill in art by Cicero, Pliny, Pausanias, Lucan, &c. He flourished from about 448 to 400 B.C., and appears as one of the great triumvirate of Greek sculptors, Phidias, Alcamenes, and Polycletus. He is said to have once competed with his master, the subject being a statue of Minerva. In this attempt the style of Alcamenes was exquisite in finish, but he had overlooked the consideration that the statue was to be placed on a high column, and there his work would not bear comparison with that of his great master. His statue of Venus Urania, in the temple of that deity at Athens, was reckoned his masterpiece.

ALCAMO, a city of Sicily, in the Italian province of Trapani, is situated 22 miles E. of Trapani, near the Gulf of Castellamare. It lies in a district of peculiar fertility, which produces some of the best wines in the island. The town is pleasantly situated on elevated ground, but its internal appearance is mean and dirty. It contains a very strong castle, and many churches and monasteries. Near it are the ruins of the ancient *Segesta*, including a Doric temple and a theatre in good preservation; and there are also on the neighbouring hill Moorish towers and other remains, standing as memorials of the Saracen occupation of Sicily. Population (1865), 19,518.

ALCANTARA, the ancient *Norba Cæsarea*, a town of Spain, in the province of Caceres, on a rocky height on the left bank of the Tagus. Alcantara (in Arabic, *the bridge*) derived its name from the magnificent Roman bridge which spanned the Tagus at this point, and which was erected, according to the inscription, A.D. 104, in honour of the emperor Trajan, who was a native of Spain. This remarkable structure is built entirely of blocks of granite without cement, and consisted, until its partial destruction, of six arches of various span, with a total length of 670 feet and a height of 210 feet. The second arch on the right bank was blown up by the English in 1809, and, although temporarily reconstructed, was again destroyed in 1836 to prevent the passage of the Carlist troops. The bridge has never since been repaired; and it is a striking illustration of the want of public spirit in Spain that the river is crossed by means of a ferry-boat in the neighbourhood of this grand engineering work, which it is a national duty to preserve. The population of the town is 4200.

ALCANTARA, a seaport of Brazil, in the province of Maranhão, on the bay of San Marcos. It has a tolerable harbour; and excellent cotton is grown in the vicinity, forming the chief article of commerce. Rice and salt, obtained from the neighbouring lagoons, are also exported. Population, 10,000.

ALCANTARA, KNIGHTS OF (*la Caballeria de Alcantara*), an order of knights of Spain, instituted about 1156 A.D. by the brothers Don Suarez and Don Gomez de Barrientos for protection against the Moors. In 1177 they were confirmed as a religious order of knighthood under Benedictine rule by Pope Alexander III. Until about 1213 they were known as the Knights of San Julian del Pereyro; but when the defence of Alcantara, newly wrested from the Moors by Alphonso IX. of Castile, was entrusted to them, they took their name from that city. For a considerable time they were in some degree subject to the grand master of the kindred order of Calatrava. Ultimately, however, they asserted their independence by electing a grand master of their own, the first holder of the office being Don Diego Sanche. During the rule of thirty-seven successive grand masters, similarly chosen, the influence and wealth of the order gradually increased until the Knights of Alcantara were almost as powerful as the sovereign. In 1494–5 Juan de Zuñiga was prevailed upon to resign the grand mastership to Ferdinand, who thereupon vested it, as he had already done that of two other orders, in his own person as king; and this arrangement was ratified by a bull of Pope Alexander VI., and was declared permanent by Pope Adrian VI. in 1523. The yearly income of Zuñiga at the time of his resignation amounted to 150,000 ducats. In 1540 Pope Paul III. released the knights from the strictness of Benedictine rule by giving them permission to marry, though second marriage was forbidden. The three vows were henceforth *obedientia*, *castitas conjugalis*, and *conversio morum*. In modern times the history of the order has been somewhat chequered. When Joseph Bonaparte became king of Spain in 1808, he deprived the knights of their revenues, which were only partially recovered on the restoration of Ferdinand VII. in 1814. The order ceased to exist as a spiritual body in 1835, though it is still recognised in its civil capacity.

ALCARAZ, a small town in Spain, in the province of Albacete, 34 miles W.S.W. of the town of that name. It stands on very hilly ground near the river Guadarmena, and has the remains of a once strong castle and of a magnificent Roman aqueduct. Weaving, iron-founding, and agriculture are the chief branches of industry. Copper and zinc are found in the vicinity. Population, 7325.

ALCAVALA, a duty formerly charged in Spain and its colonies on all transfers of property, whether public or private. It was originally imposed by Alphonso XI. to secure freedom from the Moors in 1341, as an *ad valorem* tax of 10, increased afterwards to 14 per cent., on the selling price of all commodities, whether raw or manufactured, which was chargeable as often as they were sold or exchanged. It subjected every farmer, every manufacturer, every merchant and shopkeeper, to the continual visits and examination of the tax-gatherers, whose number was necessarily very great. This monstrous impost was permitted to ruin the industry and commerce of the greater part of the kingdom down to the invasion of Napoleon. Catalonia and Aragon purchased from Philip V. an exemption from the alcavala, and, though still burdened with other heavy taxes, were in a comparatively flourishing state, in consequence of their exemption from this oppressive duty. (See M'Culloch *On Taxation.*)

ALCAZAR DE SAN JUAN, a Spanish town, in the province of Ciudad Real, 45 miles N.E. of Ciudad Real, and on the railway between Alicante and Madrid. It is a well-built town, and has manufactures of soap, saltpetre, and gunpowder. This is the *Alce* of the Romans, taken by T. Sempronius Gracchus 180 B.C. Population, 7800.

ALCAZAR KEBIR, a city of Marocco in Africa, 80 miles N.W. of Fez. It was formerly of great note as the magazine and place of rendezvous for the Moorish invasions of Spain. It is now greatly decayed, probably on account of its low and unhealthy situation. Not far from the city is the river Elmahassen, famous for the battle fought in 1578 between Sebastian, king of Portugal, and the Moors, in which the Portuguese were defeated and their king slain. Population, 6000.

ALCESTER, pronounced *Auster*, a market town in the county of Warwick, situated at the junction of the Arrow and Alne, 14 miles W.S.W. of Warwick. Its position on the Roman way known as the Ickenild Street, and the discovery of numerous remains of ancient art, as well as urns and coins, make it sufficiently evident that this was a Roman encampment. A monastery was founded here in 1140; but the building has totally disappeared, though sufficient vestiges remain to indicate its site. The church is a fine building, and contains several interesting monuments, one of which, to the marquis of Hertford, is by Chantrey, and is in the best style of that sculptor. The town possesses a free grammar school and an elegant market-hall. Employment is afforded to about 1200 of the inhabitants in the manufacture of needles, which is the chief branch of industry. Fish-hooks are also manufactured. Population of parish, 2363.

ALCESTIS, or ALCESTE, the daughter of Pelias and Anaxibia, and wife of Admetus, king of Pheræ in Thessaly. She consented to die in place of her husband, and was afterwards restored to life by Hercules. This beautiful instance of conjugal devotion forms the subject of one of the best plays of Euripides, the *Alcestis*, which furnishes the basis for Robert Browning's *Balaustion's Adventure.*

ALCHEMY, CHEMY, or HERMETICS. Considering the present state of the science and the advance of public opinion, the old definition of alchemy as the pretended art of making gold is no longer correct or adequate.

Modern science dates from three discoveries—that of Copernicus, the effect of which (to borrow St Simon's words) was to expel the astrologers from the society of astronomers; that of Torricelli and Pascal, of the weight of the atmosphere, a discovery which was the foundation of physics; lastly, that of Lavoisier, who, by discovering oxygen, destroyed the theory of Stahl, the last alchemist who can be excused for not being a chemist.

Before these three grand stages in the progress of science, the reign of astrology, magic, and alchemy was universal and almost uncontested. Even a genius like Kepler, who by his three great laws laid the foundations for the Copernican system, was guided in his investigations by astrological and cabalistic considerations. Hence it follows that a philosophical history of modern science is certain to fall into the opposite superstition of idolising abstract reason, if it does not do full justice to this long and energetic intellectual struggle which began in India, Greece, and Egypt, and, continuing through the dark ages down to the very dawn of modern enlightenment, preceded and paved the way for the three above-mentioned discoveries, which inaugurated a new era.

It was the alchemists who first stated, however confusedly, the problems which science is still engaged in solving; and to them, in conclusion, we owe the enormous service of removing the endless obstructions which a purely rationalistic method, born before its time and soon degenerating into verbal quibbles and scholastic jargon, had placed in the path of human progress.

Alchemy was, we may say, the sickly but imaginative infancy through which modern chemistry had to pass before it attained its majority, or, in other words, became a positive science. The search for gold was only one crisis in this infancy. This crisis is over, and alchemy is now a thing of the past. There is no longer any need to exhort adventurous spirits, who hope to find Golconda at the bottom of their crucibles, to leave such visions and turn to the safer paths of science or industry. The battle has been fought and won, the problem of the unity of chemical elements or simple bodies belongs rather to the province of metaphysics than to that of experimental science. If here and there an honest student of the black art still survives, he is regarded as a mad but harmless enthusiast; and as for the pretended searchers for the philosopher's stone, they are, if possible, less interesting objects than the dupes they still continue to cheat. Thus the full time is come for applying to the occult sciences the same searching analysis to which the other myths of prehistoric times have been so rigorously subjected. To trace its earliest beginnings, to investigate its development by the aid of modern criticism, is the province of physical science, no less than of the sister science of morals. Nay, more, we shall find that both had a common origin. Those ancient cosmogonies, those poetical systems which the genius of each nation and race has struck out to solve the problem of the universe and of the destiny of mankind, were the germs of science no less than of literature, of philosophy as well as of religion. And as in the infancy of science its various branches were confused and confounded, so in a like stage of society we often find the same person uniting the parts of philosopher, *savant*, and priest. Besides this, it is evident that in the absence of all scientific apparatus or instruments, the ancients, if they had limited themselves to the exercise of their reason, must have remained observers and nothing more. It is true they did observe, and that widely and well; but observation alone, even when aided by the strongest and subtlest reason, can lead to nothing but contradictory theories, irreconcilable, because they cannot be verified. And it is not in human nature to remain a simple spectator. Curiosity was first excited by fancy (and the fancy of primitive man, we must remember, was far more active and vigorous than ours), and when it found itself baffled by a natural reaction, it had recourse to divination.

In a word, the ambition of these earliest philosophers was more intense, because its sphere was narrower. In the first stages of civilisation the magician was the man of science. The mysteries of this magic art being inseparable from those of religion and philosophy, were preserved, as it were, hermetically sealed in the adyta of the temple. Its philosophy was the cabala. We must consequently look on the various cabalas or oral traditions, transmitted from age to age as the oracles of various faiths and creeds, as constituting the elements of that theory which the Jewish cabala promulgated some centuries later in a condensed and mutilated form. Astrology and magic were the efforts made in various ways to verify and apply this theory; magic, indeed, or rather magical power, was at starting purely cosmogonic, *i.e.*, regarded as an attribute of God or nature, before it was counterfeited by the magicians of various countries. But, as St Simon has well observed, chemical phenomena are much more complicated than astronomical—the latter requiring only observation, the former experiment—and hence astrology preceded alchemy. But there was then no hard and fast line between the several branches of science, and hence the most opposite were united, not, as now, by a common philosophical or philanthropical object, but by reason of their common theological origin. Thus alchemy was the daughter of astrology, and it was not till the end of the 16th century A.D. that she passed from a state of tutelage. Just in the same way medicine as a magical or sacred art was prior to alchemy; for, as was natural, before thinking of forming new substances, men employed already existing herbs, stones, drugs, perfumes, and vapours. The medical art was indissolubly bound up with astrology, but, judging from the natural inventiveness of the ancients, we should have expected beforehand that chemical preparations would have played a more important part among the instruments of priestly thaumaturgy

As in the middle ages invention busied itself with instruments of torture, and as in our days it is taken up almost as much with the destructive engines of war as with the productive arts of peace, so in those early ages it applied itself to the fabrication of idols, to the mechanism and theatrical contrivances for mysteries and religious ceremonies. There was then no desire to communicate discoveries; science was a sort of freemasonry, and silence was effectually secured by priestly anathemas; men of science were as jealous of one another as they were of all other classes of society. If we wish to form a clear picture of this earliest stage of civilisation, an age which represents at once the *naïveté* of childhood and the suspicious reticence of senility, we must turn our eyes to the priest, on the one hand, claiming as his own all art and science, and commanding respect by his contemptuous silence; and, on the other hand, to the mechanic plying the loom, extracting the Tyrian dye, practising chemistry, though ignorant of its very name, despised and oppressed, and only tolerated when he furnished Religion with her trappings or War with arms. Thus the growth of chemistry was slow, and by reason of its backwardness it was longer than any other art in ridding itself of the leading-strings of magic and astrology. Practical discoveries must have been made many times without science acquiring thereby any new fact. For to prevent a new discovery from being lost there must be such a combination of favourable circumstances as was rare in that age and for many succeeding ages. There must be publicity, and publicity is of quite recent growth; the application of the discovery must be not only possible but obvious, as satisfying some want. But wants are only felt as civilisation progresses. Nor is this all; for a practical discovery to become a scientific fact, it must serve to demonstrate the error of one hypothesis, and to suggest a new one, better fitted for the synthesis of existing facts. But old beliefs are proverbially obstinate and virulent in their opposition to newer and truer theories which are destined to eject and replace them. To sum up, even in our own day chemistry rests on a less sound basis than either physics, which had the advantage of originating as late as the 17th century, or astronomy, which dates from the time when the Chaldean shepherd had sufficiently provided for his daily wants to find leisure for gazing into the starry heavens.

After this general introduction we may now proceed to consider the subject in detail under the following heads:—First, we will cast a rapid glance at certain cosmologies and philosophical systems, in order to bring prominently before the reader those points which throw light on chemical theories. Secondly, we will consider alchemy at the moment when it ceased to be purely religious and began an independent existence; that is to say, during the 3d and 4th centuries A.D., and in that city which was the battlefield on which the various philosophical and religious creeds of the East met. In the fierce struggles which ensued, in the strange alliances which they there made, we shall find them, by their mutual recriminations, involuntarily revealing to us their hidden secrets. As the darkness of the middle ages approaches, we shall follow our science in its journey to Arabia; from Arabia we shall trace it back to Europe, and hear it taught with stammering lips and feeble tongue by subtile or solemn doctors. We shall attempt to analyse its ambitious aspirations and its barren performances. During the Renaissance we shall see it at its zenith, inspired by a mad enthusiasm which was near akin to genius, an enthusiasm which gave birth to medicine and modern chemistry. Lastly, in the 17th and 18th centuries we shall see it degenerate into pure charlatanism. In conclusion, we shall attempt to recover the few grains of pure ore which may be extracted from its broken alembics.

I. Cosmogonies and Philosophies.

In India, as is well known, the contempt in which the caste of artizans was held was still farther increased by the tendency of religion to consider birth and life, and the actions and desires which are part and parcel of man's life, as an unmixed evil. Consequently, outside the workshop, practical chemistry can have made but little progress. Nevertheless, among the priests of India, as in later times in Europe, we find the ordeal of fire and of serpents commonly practised. It follows that the Brahmins must have possessed some chemical secrets to enable them to kill or save those they thought guilty or innocent. These secrets, too, must from time to time have been divulged by indiscretion or perfidy, and spread beyond the temple; for we read of accused persons escaping unharmed from the ordeal, even when their accuser was a Brahmin. But the Mussulman traveller of the 9th century, who has preserved this curious detail, allows that the trial was in his day becoming more elaborate and complicated, and that it was next to impossible for an accused person to escape. However this may be, it is certain that the meditative genius which distinguishes the race had, even before they conquered the yellow and black races, led these first speculators to certain conceptions which have an important bearing on the present subject. Some had conceived ether as composed of distinct atoms, others imagined an ether decomposing itself into atoms by the free play of its own forces. These two theories, the one dualistic, the other unitarian, strangely foreshadow the discoveries of modern dynamics. We find the speculators of another race indulging the singular fancy that they could observe in atoms what we may call osculations of the play of forces. This, at any rate, is the most natural explanation of the term *nodes* by which the Phœnicians designated atoms. The Persians, who considered the first tree and the first bull as the two ancestors of man, discovered in physics generally two antagonistic principles, one male and one female, primordial fire and primordial water, corresponding to the good and bad principles of their religion. Over all creatures and all things there were presiding genii, *Tzeds* or *Feroners*. They had already formulated the parallelism between the *Sephiroth*, the empyrean, the *primum mobile*, the firmament, Saturn, Jupiter, Mars, Sun, Mercury, Moon, and the parts of the body, the brain, lungs, heart, &c. In this correspondence between the heavenly bodies and the human frame which the ancient Persians laid down, and the Hindu belief in the peregrination of sinful souls through the animal, vegetable, and even the mineral world, till, by these pilgrimages, they at last won absorption into the Deity, or *Moncti*, we have, in their original form, the two fundamental beliefs of alchemy.

The Greeks, unrivalled as they were in poetry, art, and ethics, made little way in occult philosophy. The Greek intellect, precise and anthropomorphic, with no leaning to transcendentalism, was a protest against the boldness of oriental metaphysics. Thus they contented themselves with inventing a strange gamut of deities corresponding to different types of men. This gamut—Jupiter, Saturn, Apollo, Mercury, Mars, and Venus—was afterwards completed in the cabala by the addition of the moon, typifying the phlegmatic character of northern races, and forms a connecting link between astrology and alchemy, by establishing a double correspondence between planets of the same name and metals. The whole was systematised in the works of Paracelsus and Böhme, and called the theory of *signatures*. Whether the Greek philosophers taught that the principle of all things was water, like Thales, or air, like Anaximander, or air and water, as Xenophanes, or the four elements, earth, air, fire, and water, as the school of Hippocrates, the tendency of Greek speculation was to establish those profound distinctions which resulted later in the theory of the four elements, the four humours, &c., which the disciples of Aristotle held. Hippocrates, for example, thought that if man was composed of a single element, he would never be ill; but as he is composed of many elements, complex remedies are required. Thus Hippocrates may be called an anti-alchemist; and though the theory of the four elements reigned supreme throughout the middle ages, it easily lent itself to the search for the philosopher's stone and the universal panacea, because the oriental idea of the transmutation of elements, from the time when the various systems of the East were syncretised at Alexandria and received their final development in Arabia in the writings of Geber Rhasis and Ibn Sina (Avicenna), was a universal article of belief. But even in the palmiest days of Greek anthropomorphism there was a gradual infiltration of Asiatic ideas, partly through the mysteries of Eleusis, partly through the doctrines of certain philosophers, who were by nature susceptive of barbaric influences. For, besides Greece proper, there was a second Greece in Asia Minor and a third in Italy, not to mention the Pelasgic tribes who adhered tenaciously to the primitive ideas of the race.

Among the Greek philosophers, then, who appreciably influenced physics, chemistry, and physiology (the three sciences were then one), we may notice in particular—1. Heraclitus of Ephesus, surnamed the "Obscure." Maintaining that fire alone was the principle of all things, he regarded generation as an ascending road, *i.e.*, a volatilisation; and decomposition as a descending road, *i.e.*, a fixation. Here we have the first idea of Jacob's ladder or "Homer's Chain" of the alchemists. 2. Empedocles, who is indeed the first who mentions the four elements; but he subordinates them as complex products to his primordial indestructible atoms, which were animated by love and hatred. 3. Democritus, who, investing these atoms with a movement of their own, proceeds to construct the universe by shocks and harmonies of shocks or vortices. 4. Anaxagoras, who saw "the all-in-all" (Aristotle, *Met.* 4, 5), the infinitely great universe in the infinitely small atom, and ingeniously applied the principle of analogy to unravel the tangled skein of ancient science. 5. Aristotle, who added to the four elements a fifth, ether, eternal and unchangeable, itself the *primum mobile* (Arist., *De Cœlo*, 1, 2). In the 4th century A.D., Nemesius, bishop of Emesa (the modern *Homs*, on the east bank of the Orontes), is one of the most distinguished representatives of Alexandrian syncretism. A single quotation will suffice to show that the idea of the transmutation of metals, from the time when Platonism, magic, and neo-Christianity were combined in a species of eclectic mysticism, was regarded as an article of orthodox belief:—"To prevent the destruction of elements, or things which are compounded of elements, the Creator has wisely ordained that elements should be capable of transmutation one into the other, or into their component parts, or that their component parts should be resolved again into their original elements. Thus the perpetuity of things is secured by the continual succession of these reciprocal generations." This statement of the pious bishop is all the more weighty, inasmuch as the author of *The Nature of Man* was only treating of psychology and physiology. The study of gnosticism would carry us too far; and one more quotation from this work, which has long fallen into unmerited oblivion, will prove to what an extent the most scientific theories of this day were tinged and vitiated by mysticism:—"Porphyry, in his treatise on sensation, tells us that vision is produced neither by a cone nor an image, nor any other object, but that the mind, being placed *en rapport* with visible objects, only sees itself in these objects, which are nothing else than itself, seeing that the mind embraces everything, and that all that exists is nothing but the mind, which contains bodies of all kinds." Another step, and we are landed in realism. It is not surprising, then, to find that the alchemists, while working in the laboratory, aspired at the same time to find the moral quintessence and verify the doctrines of revealed religion. For mysticism in theory is nothing but a reaction against the positivism of reason and science the mystic, dissatisfied with these, seeks in nature a reflection of his inner feelings. And in practice mysticism rests on confusions or exaggerations, like those of Porphyry, or some such dictum as the one which Nemesius quotes with the following uncritical comment:—"Now, since Porphyry asserts that there is but one reasoning soul for all things, he is right in saying that the soul sees itself in everything."

Such visionaries, though they may to a certain extent have observed, were not likely to experiment. Thus, at Babylon, where similar theories prevailed, the college of philosophers was divided into three classes, the "Hhartumim," or soothsayers; the "Asaphim," who were more agriculturists than zoologists, more zoologists than physicists, more physicists than chemists; the "Mechasphim," or doctors, who were consulted by the great, as often to rid them of their enemies as to cure their families and dependants; lastly, the "Chasedim" or Chaldeans, properly so called; *i.e.*, the astronomers or astrologers. In this classification of sciences as pursued at Babylon by a peculiar caste, chemistry was little regarded. Science was the monopoly of a privileged class before it became the common property of the human race. A class is sure to cling to a monopoly; an individual is obliged by his feebleness to impart his knowledge to others.

In Egypt the doctrine of the Palingenesis was symbolised by the Scarabæus, which suggested to St Augustine the following strange comparison:—"Jesus Christus bonus ille scarabæus meus, non ea tantum de causa quod unigenitus, quod ipsemet sui auctor mortalium speciem induxerit, sed quod in hac fæce nostra sese volutarit et ex ipsa nasci homo voluerit."

These ideas, which St Augustine borrowed from the religious beliefs of Egypt, were adopted by certain alchemists; and Egypt, which saw in the Scarabæus "the Father, Man, a world of trial, a ladder whereby fallen souls may rise," justly claimed to be the birthplace of ancient chemistry, to which it assigned a peculiar rank, calling it the "sacred art." But although certain Egyptian priests may have spread the report that they owed their enormous fortunes to their knowledge of chemical secrets, this veneration produced but few practical results. It was, however, this report which made the emperors Severus and Diocletian issue an edict that all their magical books should be burned.

II. The Sacred Art.

Paganism, at the time when it was engaged in its last struggle with Christianity, had long ceased to be exclusively Greek or Roman. It had assimilated Mithratic, Chaldean, and Egyptian mysteries, and even allied itself to a certain extent with the Helleno-Hebraism of the Cabala. It was not likely, then, to reject what purer times would have regarded as an utter profanation. The narrow ground on which the battle was fought, the intellectual affinities between such men as St Basil and the emperor Julian rendered the struggle as desperate and sanguinary as any struggle can be when the combatants are only rival creeds. The sacred and divine art (τέχνη θεία καὶ ἱερά), the sacred science (ἐπιστήμη ἱερά), was one of the mysteries which paganism derived from the dim religious light of the temple. But we may presume that the sacred art of the Alexandrians was no longer the same as that of the ancient Egyptians, that their Hermes was not the Hermes of Egypt, that the pseudo-Democritus is not the true Democritus, that Pythagoras, as retouched by Iamblicus, is not the original Pythagoras. No epoch was so full of forgeries as the 3d and 4th centuries A.D.; and these forgeries were in one sense fabricated in good faith. An age of eclecticism is as eager for original documents as a *parvenu* is for a coat of arms or a genealogical tree. These forgeries were no obstacle to human progress; but in an age when the learning of Egypt was the fashion, it was natural that Persian, Jewish, and Platonic doctrines should be tricked out in an Egyptian dress. One of the masters of the sacred art, Alexander of Aphrodisias, invented the term *chyics* (χυικόν, from χέω, to pour, χευέω, to fuse or melt), to describe the operations of the laboratory. Hence the word *chemics*, a word unknown in the 4th century, and only popular some centuries later. The reason is, that the true etymology of the word *chemic* is logical, and had therefore no charms for the psychological spirit of the age. Later on, when men began to reflect that the ancient name for Egypt was *Cham* or *Chemia*, because, according to Plutarch, its soil was black like the pupil of the eye (χημεία τοῦ ὀφθάλμου), it flattered the chemists to call chemistry "the art of the ancient Chemi." Hence from a false derivation the art received a fresh impulse.

The discovery of the principal manuscripts of the sacred art we owe to the labour of M. Ferdinand Hoefer. We can take no safer guide than the judicious and profound author of the *History of Chemistry* in investigating the delusions into which a master of the sacred art was most likely to fall.

"Let us forget for an instant the advances which this science has made since the 5th century. Let us fancy ourselves for a moment transported to the laboratory of one of the great masters of the sacred art, and watch as neophytes some of his operations. *1st Experiment.*—Some common water is heated in an open vessel. The water boils and changes to an aeriform body (steam), leaving at the bottom of the vessel a white earth in the form of powder. Conclusion—water changes into air and earth. What objection could we make to this inference, if we were wholly ignorant of the substances which water holds in solution, and which are, after evaporation, deposited at the bottom of the vessel? *2d Experiment.*—A piece of red-hot iron is put under a bell which rests in a basin full of water. The water diminishes in volume, and a candle being introduced into the bell sets fire at once to the gas inside. Conclusion—water changes into fire. Is not this the natural conclusion which would present itself to any one who was ignorant that water is a composite body, consisting of two gases, one of which, oxygen, is absorbed by the iron, while the other, hydrogen, is ignited by contact with the flame? *3d Experiment.*—A piece of lead, or any other metal except gold or silver, is burned (calcined) in contact with the air. It immediately loses its primitive properties, and is transformed into a powder or species of ashes or lime. The ashes, which are the product of the death of the metal, are again taken and heated in a crucible together with some grains of wheat, and the metal is seen rising from its ashes and reassuming its original form and properties. Conclusion—metals are destroyed by fire and revivified by wheat and heat. No objection could be raised against this inference, for the reduction of oxides by means of carbon, such as wheat, was as little known as the phenomenon of the oxidation of metals. It was from this power of resuscitating and reviving dead, *i.e.*, calcined metals, that grains of wheat were made the symbol of the resurrection and life eternal. *4th Experiment.*—Argentiferous lead is burned in cupels composed of ashes or pulverised bones, the lead disappears, and at the end of the operation there remains in the cupel a nugget of pure silver. Nothing was more natural than to conclude that the lead was transformed into silver; and to build on this and analogous facts, the theory of the transmutation of metals, a theory which, later on, led to the search for the philosopher's stone. *5th Experiment.*—A strong acid is poured on copper, the metal is acted upon, and in process of time disappears, or rather is transformed into a green transparent liquid. Then a thin plate of iron is plunged into this liquid, and the copper is seen to reappear in its ordinary aspect, while the iron in its turn is dissolved. What more natural than to conclude that iron is transformed into copper? If instead of the solution of copper, a solution of lead, silver, or gold had been employed, they would have held that iron was transformed into lead, silver, or gold. *6th Experiment.*—Mercury is poured in a gentle shower on melted sulphur, and a substance is produced as black as a raven's wing. This substance, when warmed in a closed vessel, is volatilised without changing, and assumes a brilliant red colour. Must not this curious phenomenon, which even science in the present day is unable to explain, have struck with amazement the worshippers of the sacred art, the more as in their eyes black and red were nothing less than the symbols of light and darkness, the good and evil principles, and that the union of these two principles represented in the moral order of things their God-universe. *7th and last Experiment.*—Organic substances are heated in a still, and from the liquids which are removed by distillation and the essences which escape, there remains a solid residuum. Was it not likely that results such as these would go far to establish the theory which made earth, air, fire, and water the four elements of the world?"

But neither M. F. Hoefer's explanation of the appearances which the first master of the sacred art mistook for fact, nor the metaphysical theory of Nemesius, will enable us to understand how Zosimus the Theban, in the very infancy of the art, succeeded in discovering in sulphuric acid a solvent of metals; in assigning to mercury (which he called "holy water") its proper function, a function which succeeding generations of alchemists so monstrously exaggerated; and finally in disengaging from the red oxide of mercury oxygen gas, that Proteus which so often eluded the grasp of the alchemists, till at last it was held fast by the subtle analysis of Lavoisier. For we must remember that solid metals were considered as living bodies, and gases as souls which they allowed to escape. Of all the ingenious inventions of the Jewess Maria for regulating fusions and distillations, the only one that has survived is the *Balneum Mariæ*. The principle it depends on, viz., that the calcination of violent heat is less powerful as a solvent or component than the liquefaction produced by gentle heat, was afterwards reasserted by the Arabian Geber, and advocated by Francis Bacon. M. Hoefer imagines that Maria the Jewess discovered hydrochloric acid, the formidable rival of sulphuric acid. Succeeding writers on the history of chemistry have remarked that the bandages of Egyptian mummies were not more numerous than the mysteries of the sacred art, and the injunctions not to divulge its secrets, "under pain of the peach tree," or, to translate into modern English the language of an ancient papyrus, under pain of being poisoned by prussic acid. We should be wrong in thinking that all these allegories had no meaning for the initiated, and that this mystical tendency of the sacred art arrested its growth at starting. Rather the truth is, that these myths, which at a later stage prevented the free development of alchemy, at first served to stimulate its nascent powers.

Modern critics have pronounced some traditional sayings of Hermes Trismegistus to be apocryphal, but they have not given sufficient weight to the remarkable circumstance that it is precisely because these sayings are a medley of the cabalistic, gnostic, and Greek ideas with which Alexandria was then seething, that the seven golden chapters, the Emerald Table, and the Pimander obtained their authority—an authority they would never have possessed had they been only a translation of some obscure Egyptian treatise. No Egyptian priest could have written a sentence like that we find so often quoted as an axiom by subsequent alchemists:—"Natura naturam superat; deinde verò natura naturæ congaudet; tandem natura naturam continet." Plato adds (not the disciple of Socrates, but a pseudo-Plato in the famous collection called *Turba Philosophorum*)—"continens autem omnia terra est." For, translated into modern language, this means that there may indeed be in this universe things which pass our intellectual ken; but that all that exists, all that is produced by the strife and changes of the elements, all, in a word, that appears to us supernatural, is really natural. That this is his meaning we may gather from the singularly bold comment which Plato himself adds, and which we may thus translate—"Everything, even heaven and hell, are of this earth." It is true that the alchemists failed to draw any very definite conclusions from this fundamental axiom. But if we consider it carefully, we shall see that this earliest doctrine of the sacred art, which was now rapidly passing into alchemy, by thus excluding the supernatural, was making a great advance in the direction of positive science. This early advance was, however, counterbalanced by an early error (which itself arose from a noble ambition), viz., that art is as powerful as nature. The Emerald Table begins with a sentence no less celebrated than that quoted above:—"This is true, and far distant from a lie; whatsoever is below is like that which is above, and that which is above is like that which is below. By this are acquired and perfected the miracles of the one thing." To understand the importance of this emphatic and categorical exordium, we must forget the sharp distinction we now draw between art, science, and literature; we must think of that foolishness of which St Paul speaks, by which he sought to save those that believe, because of the insufficiency of human reason. The seekers for the philosopher's stone were in the same case. In the absence of clear facts and just notions, reason for them was not sufficient. Thus it was that they and the masters of the sacred art, and after them the Arabs, and in later times the alchemists, one and all listened eagerly to the "foolishness" of Trismegistus's doctrine, which, in a modern form, would run thus: "We go further than the *Zohar*—the sacred book of the cabala—which says that as soon as man appeared, the world above and the world beneath were consummated, seeing that man is the crown of creation and unites all forms. We go further than the *Zohar*, which says in another place that the lower world was created after the similitude of the upper world. We perfect the doctrine of a microcosm and a macrocosm, and declare that there is no such thing as high or low—as heaven or earth, for the earth is a planet, and the planets are earths; we affirm that the chemical processes of our alembics are similar to those of the sidereal laboratories. All is in all. Everywhere analogy infers the same laws." From analogy to identity was an easy step for the theorists; and in the full light of the 19th century we find Hegel a devoted admirer of the mystic Böhme falling into this pitfall. If the *spectrum analysis* had been known, the Alexandrians, the Arabs, and the alchemists would have been able to verify and limit the sweeping generalisation by which they established a vast system of correspondencies between the three worlds, the physical or material, the rational or intermediary, and the psychical or spiritual. Between the heavens and earth and man's nature they were ever seeking to discover affinities, and ignoring differences which would have been fatal to their system. Thus, according to them, even heaven—the abode of spirits—was partly physical; and even in the mineral world there was a spiritual element—viz., colour, brightness, or, in their language, tincture. Neither Linnæus, Berzelius, nor Cuvier had yet classified living beings and things. The distinction between the animal, the vegetable, and the inorganic world was unknown, and indeed it was impossible that it should be known. The alchemists sought for physical conditions in the invisible and spiritual world, and for a spirit even in stocks and stones. This explains the magic which they found in nature, and which they tried to imitate by their art. But to establish this harmony between heaven, man, and nature, they required some fixed standard or scale, for in their eclectic system they were bound to find room for Pythagoras. Where was this scale to be found? In the heavens; for there must be the sphere of true music. Hence arose chemical, medical, and physionomical astrology. (See ASTROLOGY.) Hence the sun, which vivifies all nature, the most active heavenly energy, or rather being—for with them everything had life—in the συνγαμία, or marriage between heaven and earth, represented the male principle, *ita ut cœlum agat et terra patiatur;* and appearing in all terrestrial objects, since everything is penetrated by heat, fire, or sulphur, presided principally over the generation of gold—his image or antitype—in the bowels of the earth. Hence, too, the moon represented silver, Venus copper, Mercury (the planet and the god) the metal of the same name, Mars iron, Jupiter tin; while to Saturn, the most distant and coldest of the planets, lead, the most unsightly of metals, was dedicated. It was an old belief that there was a time when gods and men dwelt together on earth, a belief, moreover, for which they could quote chapter and verse. Was it not written πᾶσιν οὐρανίοις κοινὴν γαῖαν? Further, seeing that there were three worlds, it followed that there were three heavens, three suns, and three golds. For spirits still engrossed with matter the philosopher's stone meant the search for riches—the gold of the third world. For other spirits which belonged to the first world it signified the healing art—the preservation of humanity by means of the universal panacea and a universal theory of morals. Hence two rival systems, the first of which culminated in the great doctor Paracelsus, the second in the great Illuminato Postel. Did not Dante, the bitter foe, not of the science of alchemy, but of that miserable search for gold—for the riches of this world—which, with keen irony, he calls *Peltro* (tin whitened by mercury)—did not Dante himself write his great poem in order to bring back humanity to the right road from which it had strayed (*svia*), misled by those who should have been its true guides, the pope and the emperor? For the symbolism of those ancient masters included an alchemy of morals as well as an alchemy of medicine and metallurgy, though the first was even less known and less appreciated.

Recurring to our former illustration, it was this "foolishness" of St Paul—this divine madness—which inspired the Alexandrians, the Arabs, Roger Bacon, Albertus Magnus, and the host of anonymous alchemists of the middle ages: such was the madness which cast a ray of genius over the daring spirit of even a second-rate author like Raymond Lully, which sustained Robert Fludd, Paracelsus, and Postel, who tried to find the universal panacea in universal peace. The fundamental axiom, the stronghold from which these terribly logical madmen were never wholly dislodged, may perhaps be summarised in a single sentence. The saying of Galen, *in natura nihil planè sincerum*, was adopted by his implacable adversaries:—Nature, they said, is in appearance an illegible scrawl, but when deciphered there will be found a single element, a single force, to separate and reunite, to produce decay and growth—*knowledge is power.* To know the process of generation in this triple universe, wherein one world resembles another; to know by its *signatures* this universe, which is a living organism in the eyes of all alchemists (save indeed Jacob Böhme, who, anticipating Hegel, regarded it as a mighty tree); this is the first step towards counterfeiting nature. Monstrosities are the production of diseased metals (really alloys), which, if properly treated, may be cured, and will turn to gold, or at least silver. The second stage in this imitation of nature is to obtain by tincture or projection solid or liquid gold—the cure of all evils. Finally, to surpass material and rational nature, this is the crowning end. For God delegates his power to the sage.

Alchemy in Arabia.—How the sacred art passed into Moslem lands it is hard, from dearth of evidence, to say. Modern criticism now does more justice to the part which Arabia took in the accumulation of scientific facts, and in the scientific theories which we find in the books of Rhazès and Geber. It is certain that in their treaties with the European Greeks of Constantinople the Arabs always stipulated for the delivery of a fixed number of manuscripts. Their enthusiasm for Aristotle is equally notorious; but it would be unjust to imagine that, in adopting the Aristotelian method, together with the astrology and alchemy of Persia, and of the Jews of Mesopotamia and Arabia, they were wholly devoid of originality. On the other hand, we must not understand Arabia in the ethnological sense of the word, but as signifying an agglomeration of various races united by a common religion. Thus Djafar (who lived in the middle of the 8th century), better known to us as Geber, was a Sabæan. Avicenna, born in 978, was a native of Shiraz. The remarkable geographer and geologist Kazwyny (geology was then a part of alchemy), derived his name from his birthplace, Casbin, in

Persia. Mohammed-ben-Zakaria, so celebrated in mediæval Europe under the name of Rhazès, was also a Persian. In Spain the Jews of the famous school of Saadia and Juda Halevy exercised considerable influence over the academy of Cordova. Lastly, European historians have systematically exaggerated the ignorance of the Arabs before the time of Mahomet and their intolerance after the establishment of Moslemism, either from the zeal which prompted them to carry on a sort of literary crusade in honour of Christianity, or because in the 18th century they directed against Mahomet attacks which were intended for Christianity itself.

Alchemy received from the Arabians many significant titles. It was the *science of the key*, because it opened all the mysteries of creation, physiology, and medicine; it was the science of the letter M (*misam* is the Arabic for balance), because by means of the balance the gain or loss of all bodies could be determined, even while undergoing chemical combinations. Later on, as is well known, it was by a rigorous and obstinate use of the balance in the hands of Priestley, Cavendish, and Lavoisier, that positive chemistry was founded. Lastly, Rhazès gave to the science of the philosopher's stone a name which plunges us again into the mythological ages of chemistry. He called it the *astrology of the lower world*.

The discoveries of Geber as a chemist do not form part of our subject; but we may mention, in passing, the infernal stone, the corrosive sublimate, the exact process of the cupellation of gold and silver, and three sorts of distillation by evaporation, condensation, and simple filtration. In another direction Geber, by re-inventing *aqua fortis*, and by discovering ammoniacal salts for his *aqua regalis*, laid the foundation both of alchemy and chemistry. The salt of ammonia, so easy to volatilise, was the source of many baseless dreams, as is proved by its various names—*anima sensibilis, aqua duorum fratrum ex sorore, cancer, lapis angeli conjungentis*, &c. Geber believed in the parallelism between metals and planets; he thought that metals were all equally composed of mercury, arsenic, and sulphur, and that in the descending scale from gold to lead, mercury, arsenic, and sulphur were each present in a greater or less degree of purity in proportion to the colour and quality of each metal. Later on, the addition of the four elements—heat, cold, dryness, and moisture—complicated still more the reasonings by which the alchemists sought to prove that the transmutation of metals was in the power of any man who imitated nature—*i.e.*, perfected the imperfect metal by correcting its excess of heat or moisture. Geber did not think that an operation of the laboratory could counterfeit the natural work of purification, which demanded a thousand years. But with him moisture played the same part as phlogiston in Stahl's system. In other words, the philosopher to whom all succeeding searchers for the philosopher's stone swore allegiance was contented to formulate his theory without considering the possibility of putting it in practice. He was an alchemist indeed, but no gold-seeker. This forerunner of positive science foresaw the part which the gases would be found to play in the composition of bodies; he called them spirits—a figure which took strong hold on the imagination of Geber, as well as of the masters of the sacred art, and which was formalised by the alchemists of the middle ages. Rhazès, who re-invented sulphuric acid and *aqua vitæ*, was *par excellence* a doctor. The same remark applies to Avicenna, whose works are a methodical, but not very profound, systematisation of the current ideas and science of his day. Artephius was a cabalist, as his theory of the apparent and latent parts of man's nature shows. The author of *The Key of Wisdom* and *A Secret Book on the Philosopher's Stone* was the reputed possessor of an *elixir vitæ*. We do not know whether this was potable gold or a quintessence of all the active elements of the three kingdoms. However this may be, this mysterious alchemist, who lived about 1130, was the inventor of soap, and, what is of more importance for our subject the promoter of a new interpretation of Jacob's ladder or Homer's chain. Minerals, he said, come from the primitive elements, plants from minerals, animals from plants, and as each body is resolved into another body of the order immediately below it, animals become vegetables and vegetables minerals. We see that in this view of the interdependence of the three kingdoms there is as much truth as error. With Calid, the author of the *Book of the Three Words* and of the *Book of the Secrets of Alchemy*, the parallelism between the metals and planets takes a retrograde step towards astrology. This Calid, a *soi-disant* king of Egypt, held that before engaging in any operation of alchemy the stars ought to be consulted. This recommendation was literally followed by the thaumaturgists of the middle ages and the Renaissance. The effect was fatal; if, when Calid or one of his school saw the metals obstinately refuse to be purified in his crucible, he did not wait for a happy conjunction of constellations above in order to try his chance again with the operations of inferior astrology.

The East, when it accepted from Aristotle the theory of form and matter, invested it with a signification of its own never dreamed of by the Stagyrite, and invented, as it were, an Arabian Aristotle—that is, the Aristotle of the middle ages. Not only at Alexandria had the students of the sacred art evolved the theory of the transmutation of the four elements (Cicero assigns the doctrine to the Stoics), but in the East the translators of Aristotle added to the theory a corollary more important than the proposition itself, viz., that every body by its form and natural motions indicates its soul, its natural properties, &c.; that the resemblance between the external appearance of things and beings indicates their natural likenesses, &c. The idea of destiny, which all nations who accepted the doctrine of the Logos expressed by some term or other analogous to the Latin *fatum* (what is spoken), Mahomet translated by his famous phrase *mectoub* (it was written). We find a Turkish writer, the declared enemy of astrology and elixirs, Nabi Effendi, in his remarkable book, *Counsels to my Son, Aboul Khair*, saying that heaven is covered with a writing that only God can read, and seeking what letter the eyes, the eyebrows, the mouth, &c., form to find therein the secret of their better use. Like one of the Talmudists, the obscure Kallir for instance, he decomposes the name Mahomet in order the better to offer the prophet, as it were, the quintessence of praise, more worthy of God, who in that sacred name, as in all terrestrial things, has written at least one letter of the Word which will serve as a key to open all their hidden virtues. By pursuing an analogous direction, mediævalism, and more especially the Renaissance, introduced new subtleties into the astrological branch of alchemy—tetragrams, pentacles, and other mysterious characters and figures.

It is not surprising, then, to find that Nabi Effendi, who lived in the second half of the 17th century, can produce no other reasons for dissuading his son from joining the alchemists than the fact that some were poor, others quacks, and, as the most important ground of all, that God had declared his wrath against those who dare to imitate his works. Indeed, the peculiar symbolism of the various nations of the East had been broken up by revolutions and conquests, and the *disjecta membra* again reunited, so as to form a wonderful phantasmagoria of ideas and images—a sort of scientific Arabian Nights.

III. Alchemy of the Middle Ages.

The care we have taken to note down at the moment of its birth each of the ideas which influenced alchemy, allows us to sketch more rapidly the history of its decline and fall. Albert Groot, commonly known as Albertus Magnus (1193–1280), revived the theory of Geber; and, in spite of the tendencies of the time, entertained the same doubts as his illustrious master on the possibility of transmutation. He is the first to speak of the affinity of bodies, a term he uses in reference to the action of sulphur on metals. He gives the *savans* of the day the sage advice not to take service with princes, who are sure to treat as thieves those who do not succeed. And, indirectly, he warns princes that philosopher's gold is only tinsel. Beginning with nitric acid, which he calls *prime water*, and so on, through a regular series of secondary, tertiary waters, &c., he proposed a method for dissolving all metals. Roger Bacon, while opposing magic, calls oxygen *aer cibus ignis*, and regards the elixir as a substitute for time, that agent of which nature takes no account. Gold is perfect, because nature has consummated her work. But Roger Bacon seems to have turned his genius principally to physics and mechanism. St Thomas Aquinas, in his theological writings, forbids the sale of alchemist's gold, and in his special treatise on the subject unmasks an imposture of the charlatans of the day, who pretended to make silver by projecting a sublimate of white arsenic on copper. Further, Aquinas, by reducing the primitive elements of metals to two, revives and corroborates the theory of Galen and Albertus Magnus. About the same time we find a pope, John XXII., and a king, Alphonso X. of Leon and Castile, occupying themselves with alchemy. But the pope in a well-known bull denounced all those searchers for gold "who promised more than they could perform;" another proof that alchemy and the search for gold, though distinguished by the true alchemist, were confounded by many adepts. It is evident that the science, as far as the seeker for gold was concerned, was approaching the times of king John and Philip the Fair, who found in unscrupulous charlatans abettors in their debasement of the currency, and that for disinterested alchemists those evil days were at hand when, disgusted at attaining no practical result, the most serious of them sought in the physiological mysteries of generation, in the Adam and Eve, the red man and the white woman, of the first chapters of Genesis, what they failed to find in Rhazès, in Geber, and the Arabian Aristotle. The science was still called chemy. It was as a compliment to the Arabian masters, who were still quoted side by side with Genesis, that they added to the word the Arabic article *al.* The popular etymology of the day was likewise Arabic, or, more correctly speaking, Semitic; the Hebrew *chom* or the Arabic *cham* signified heat. Hence their furnaces for heating, the alembics for modifying heat, and the Bains-Marie for imitating the temperature of warm blood; for they could only proceed by analogy. Nevertheless, the great men of the day were the alchemists. The boldness of their actions, the eccentricity of their genius, prove it.

Few novels are as interesting as the story of Raymond Lully (1235-1315). He began life as the passionate lover of the Lady Eleanor of Castello. He was cured of his passion by the lady herself, who discovered to him the ulcer which was eating away her breast. At her desire he consecrated himself to God, to the service of humanity in general, and especially to the conversion of Mussulmans. Christianity, in the mouths of the European disciples of Geber and Rhazès, was better adapted than it now is for converting infidels, whose knowledge it respected while deploring all the more their errors. In his eightieth year Raymond Lully died in sight of the island of Minorca, from the consequences of a stoning he had received at Tunis a few days before while preaching the gospel. This was on his third mission, and he did not hide from his friends that he sought the crown of martyrdom. He had invited the support of all the princes of Europe, and in particular of the kings of France, England, and Castile. Alchemy, indeed, with him seems to have been mainly a means of recommending himself to these kings, and at the same time a search for the panacea. But his trust was placed much more in his rhetoric, which he borrowed from the cabala, in his oriental eloquence, and his Christian faith. By the number of conversions he made at Algiers, at Tunis, and at Bugia, where during his second voyage he was snatched from imminent martyrdom by his friends among the converted Mussulmans—that is to say, in the very strongholds of Islamism—he succeeded in demonstrating that his idea of uniting all worshippers of the true God in a common faith was not chimerical. Lully's principal success was with the disciples of Averroes; and no one who reflects will be surprised at this. As the moral difficulties of missions were less than they are now, so the practical dangers were greater. This too needs no explanation.

Raymond Lully's works on alchemy are hopelessly obscure, notwithstanding elucidations, compendiums, vade-mecums, and a certain *dialogus demogorgon*, which, if the title is to be believed, *Lullianis scriptis nullam præclarè lucem adfert.* Nor need we wonder at this. Eirenæus Philalethes, the pseudonym under which some English adept, whose real name has not been discovered, wrote, states positively that he has learned nothing from Raymond Lully, adding at the same time a curious reason—"Some who are no adepts give more instruction to a beginner than one whom perfect knowledge makes cautious." Eirenæus is fond of quoting Bernard of Trevisa, who, he tells us, has given him, more especially in his letter to Thomas of Bologna, "the main light in the hidden secret." But of all writers he gives the palm to Sir George Ripley. Bernard of Trevisa, whom he mentions, spent a long life and a considerable fortune in romantic travels, in the purchase of books, and in the pursuit of chemical experiments. When depressed and weary with chasing shadows which were ever eluding his grasp, he used, as a pastime and relaxation, to read the *Turba Philosophorum*, or the *Great Rosary*, just as Don Quixote would read the romances of chivalry. At last, when seventy-five years old, the good Bernard, for so the adepts called him, thought he had discovered the secret,—at least the joy of what he considered a real success served for a while to lull his restless energies. His letter to Thomas of Bologna shows no ordinary man. "Dissolutions of this sort," he writes, "by acids or aquafortis, are not the true foundations of the art of transmuting metals; but rather the impostures of sophistical alchemists, who think that in them resides the secret of that sacred art. They affirm that they produce dissolutions (*solutiones*), but what they can never do is to produce the various kinds of metals in their perfection; because metals when dissolved by corrosives do not remain in the same proportion and original form as they do when dissolved by mercury, which may be truly called the water of metals. Bodies dissolved by mercury are not decomposed (*separabuntur*); their nature remains hidden in mercury till they fill up its intervals (*usque ad sui reinspissationem*). Mercury contains interstices (*latentia*), and therefore metals can lie hidden in mercury." He then goes on to compare the part that mercury plays in amalgams to that of water (*simplex aqua*) in vegetable and animal structures. He is well acquainted with what the French now call *l'eau de composition;* but, as usual, he pushes his analogies too far. We may remark in passing that it was his opponents the alchemists who, by the discovery of their *aquæ fortes*, provided modern chemistry with one of its most powerful agents.

In speaking of Bernard, we incidentally hit upon a word which exactly characterises mediæval works on alchemy—they are romances, romances full of interminable allegories; they sometimes begin and always end with an invocation to Christ and the Trinity. From time to time, amid the old abortive attempts to read the riddle of the universe, we find some new idea cropping up. The generation of plants and animals had failed to explain the generation of metals; so they turned to digestion and fermentation for analogies, and though they never reached their goal, they picked up much that was valuable on the way. The road itself was barred, and therefore to profit by their works we must follow them into bypaths and digressions. Thus, for instance, we may study with advantage their dialectics. Whilst refuting their adversaries, they were gradually laying the foundations of the logic of science. True alchemists were generally haughty and contemptuous; the mechanic often grew rich on the scraps which the alchemist was too proud to touch. We cannot always make sure of understanding them, yet from the medley of their writings more fragments of real chemistry may be gathered than is generally supposed. There is rhythm and harmony, a ring of true genius about the best of their works, which charms us if it does not send us to sleep with its sweet but monotonous music. In reading Laurent Ventura's book, *De Ratione Conficiendi Lapidis Philosophici*, we are tempted for a moment to endorse the strange fancy of the Dutch Rabbins, "that even if a man do not understand the language of the *Zohar*, he ought no less to read it; for this language, as the cabalists have written it, is a medicine for the soul."

Often what appeared a work of pure fiction (as the *Roman de la Rose*) concealed a treatise on alchemy; often, on the other hand, what purported to be a work of pure alchemy was a medium for heretical theology, sometimes for the ideas of Spinosa and Goethe. The times, moreover, were sad, and all could appreciate the advantage of a romance. It was not given to every one to follow the terrible logic of Danstin, the contemporary of Raymond Lully, the author of a Rosarius, which has never been published, from which M. F. Höfer gives the following extract:—"All bodies may be divided into three classes—1. Sensible and intellectual beings (animals and men); 2. Vegetables; 3. Minerals. Like always tends to unite with like. Intellectual elements are homogeneous with the Supreme Intelligence; that is why the soul yearns to be absorbed into the Deity. The elements of the body are of the same nature as the surrounding physical world; hence their tendency to unite the one with the other. Death is then for all a moment to be desired." *Dico Amen tibi, reverende mi Doctor*, to borrow Bernard's favourite expression.

After so much mist and fog we need a breath of fresh air. Let us pass at once, then, to the Luther of science, who reproached so bitterly the Luther of theology with only going half-way—to an epoch which witnessed the new birth of intellectual life, and to a man who was carried by the new movement into every sort of extravagance, though his errors were those of a generous and unselfish nature. Let us treat of the Renaissance and Paracelsus.

IV. Paracelsus and his Influence.

Tempting as the subject is, we must not linger either on the philosophical doctrine or the medical system of this extraordinary man, for fear of encroaching on the article Medicine or the article Paracelsus. We only wish to show that he is the pioneer of modern chemists, and the prophet of a revolution in general science. Those who only know Bacon in manuals of philosophy are never tired of repeating that the great English philosopher is the father of experimental science. This is true, indeed, in the sense that Bacon insisted with inexhaustible eloquence on the necessity of experimental science, but it is false if it means that Bacon inaugurated modern science by personal experiments. It was this popular conception of Bacon which Liebig attacked, and he thus found no difficulty in drawing up a long and crushing indictment. Bacon was the prophet of experimentation, and this title is sufficient to secure his fame against the abuse of modern dogmatists, who think that science increases little by little, with here a fact and there an idea, without a single pause, a single relapse or revolution. Few take the trouble to consider how far Bacon's philosophy belongs to the past; most are satisfied with cut and dried phrases about the part he played in modern science. Just in the same way, Paracelsus, the great innovator, who thought himself even more enfranchised from the bondage of Aristotle and Galen than he really was, is dispatched with ready-made phrases, but, unlike Bacon, he gets nothing but ridicule and abuse. Madman, charlatan, impostor—no name is too bad for him with the historians; and yet they are forced to confess that this impudent adventurer brought about a necessary revolution. Thomas Thomson is very severe; he goes so far as to reproach Paracelsus with declining the word *tonitru*. He would have wished, forsooth, the revolutionist of Basle to have delivered before his young and enthusiastic audience "the sober lectures of a professor in a university." Dryasdusts are fond of falling into such anachronisms; a far truer estimate of Paracelsus has been given us by Mr Browning in the drama which bears his name. There are self-deceived visionaries who are always thinking that the problem is solved, who compose elaborate romances with which enthusiasts are enchanted. Raymond Lully was one of this class. There are spirits of light who point out and trace the road along which humanity travels slowly in their wake. Bacon belongs to the first category, but has played the part of a genius of the second order. Thirdly, there are souls of fire always enveloped in clouds, from which ever and anon the lightnings of genius flash forth, who bear humanity towards a goal foreseen rather than seen by themselves, by a rough and rugged road with endless turns and windings. Such a nature was Paracelsus. His pride was more towering than the mountains of his native Switzerland. He believed that through him a new race, the Germans, were destined to succeed to science. The Greeks, the Arabians, and the Italians, their immediate disciples, had had their day with him, and through him the German era was to begin. He studied under Trithema, the abbot of Spanheim, and under his father, a distinguished alchemist: Agrippa was his fellow-student. Afterwards he resorted to strange masters—old wives and workmen, his beloved miners, who confided to him their secrets. He was the greatest traveller in that age of scientific travellers. Lastly, he practised medicine as the doctor of the poor, and inaugurated lectures in the vulgar tongue. Van Helmont, his real successor, who inherited his goodness of nature, established clinical medicine, *i.e.*, lessons at the bedside of the patient. Stahl, who inherited his arrogance and his love of symbolism, developed from one of the ideas of his master the phlogistic theory, the elaboration of which theory was for chemistry a prosperous period of incubation, while from the refutation of this theory the science may be truly said to date its birth. Paracelsus's work, like his genius, oscillates perpetually between magic and science, but what has not been sufficiently observed is, that science invariably ends by carrying the day. If, for instance, he is giving us "the green lion," a recipe for making gold, he ends by breaking a lance with the seekers for gold :— "Away with these false disciples who hold that this divine science, which they dishonour and prostitute, has no other end but that of making gold and silver. True alchemy has but one aim and object, to extract the quintessence of things, and to prepare arcana, tinctures, and elixirs, which may restore to man the health and soundness he has lost." He beards the "white-gloved" disciples of Galen, and, in spite of their juleps and draughts, asserts that alchemy is indispensable, and that without it there is no such thing as medical knowledge. He rejects the easy explanation of the universe by means of an entity, stigmatising it as *paganity*, meaning thereby a necessary consequence of paganism, which as a theosophist he holds in abhorrence. He rejects the favourite instrument of the schoolmen, the syllogism. Nature, as he views it, is not a clear and intelligible system of which the form declares the essence; no, it is mysterious. There is a spirit at work beneath the outside shell. What is written on this shell no one can read but the initiated who have learned to separate the real and the apparent. "At the same time, everything is not active. To separate the active portion (the spirit) of this outside shell from the passive, is the proper province of alchemy." Thus we see that with Paracelsus alchemy ceased to be the search for the first principles of bodies, and made one step in advance towards chemistry. His innate genius for medicine, as he boasted, but more truly his noble heart, urged him to learn a study which better satisfied his pride, but which had not the practical usefulness of medical chemistry to recommend it. The name *iatrochemics* marks this transition from alchemy to chemistry. A remarkable saying of Paracelsus shows us the close connection between his alchemy and his medicine: "*Vita ignis, corpus lignum.*" This notion of the importance of combustion was taken up again by Becker and his disciple Stahl, the inventors of the term phlogiston, which they thought was of an earthy nature, because resin, phosphorus, sulphur, and other combustible bodies are insoluble in water. Paracelsus was too well initiated in the cabalistic theory of astral light, which symbolised the universal agent of light and heat, to have accepted such a gross materialistic theory. A distinguished Frenchman of the present century, who prided himself on being a follower of the cabalists, has in one of his novels, called *La Peau de Chagrin*, reproduced the theory of Paracelsus, *vita ignis, corpus lignum*. Each act, each wish of the possessor of the talisman, causes the skin to shrink; and Mr Huxley, in his remarkable lecture on *The Physical Basis of Life*, has not been ashamed to borrow this illustration from Balzac. What renders Paracelsus's saying so valuable is, that it is neither materialistic nor spiritualistic, but merely dynamical.

Another instance of Paracelsus's oscillating between the modern and the ancient world is seen in the hesitation he shows when discussing the influence of the planets over the internal organs of the body. Sometimes he seems to take the symbol for the thing itself, but he ends by admitting only the parallelism of the macrocosm and the microcosm. When he assigns the brain to the moon and the heart to the sun, he seems to say: "I do not think with Plato that the brain is all; it is but the reflector and guide—the heart is the regulator of the organism. I place my archeus a little above the heart, as a connecting-link between the nervous and sanguine circulation, as Hippocrates has his *enormon*." If he had lived in calmer times, and known the true Aristotle, Paracelsus would have allowed that μορφή does not represent the ἐντελεχεία of the Stagyrite, that ἐνεργέια is the true meaning. But in those times of false Aristotelianism the *Spagirism* of Paracelsus was pitted against the *Stagyrism* of Aristotle. By making the viscera the seat of diseases, Paracelsus claims to be the founder of the organicists; by his chemistry of the blood—mercury which evaporates, sulphur which burns, salt which is constant—he is answerable for the blunderings of Maitre Purgon; by his *archeus*, the grand motor and regulator of the astrology of the body, he is the ancestor in a direct line of animism, and collaterally of modern Hippocratism or vitalism of the Montpellier school. In short, it is hard to name anything that cannot be found in the works of this mad genius, who, in spite of the jars and jolts of his wild career, still manages to keep the road without upsetting either at Paris or Montpellier. What, we may ask, would modern therapeutics be without the opium and mercury of Paracelsus—without the laudanum of his disciple Quercetan, physician to Henry IV, &c? When this charlatan had substituted for astrological influence a simple parallelism, it was easy for Van Helmont to rid modern science of this simple parallelism. Besides all this, Paracelsus was a real doctor. The death of Erasmus's friend, whom he was attending, did him less harm than the cure of another patient, who was dining with him ninety-nine days after he had been pronounced *in extremis;* more fatal still was the case of Cornelius de Liechtenfels, who, when cured by him of the gout, refused to pay his benefactor the stipulated price. Paracelsus would not hold his tongue or submit to the magistrates, and in consequence had to resign his professorship at Basle. A double interest attaches to this story; it hastened Paracelsus's death, and it proves that he would never have accepted the *vis medicatrix naturæ* of Stahl. We have seen that those strange bodies which escaped from the retorts of the masters of the sacred art were called by them souls; their successors, on a closer acquaintance with them, called them spirits. Basil Valentin and Paracelsus, recognising their importance in the transmutation of bodies, gave to them the name of mercury. Van Helmont studied them more minutely, and invented the name gas. He was acquainted with carbonic acid under the name of woody gas. But his ignorance of the action of the oxygen of the atmosphere prevented him from making the fundamental distinctions between experiments performed in a closed vessel and in one open to the air. Priestley, Lavoisier, and Scheele by the use of the test-tube and the balance (both Van Helmont and Stahl had also turned the balance to good account), weighed and tested the results of ancient alchemy. Hence modern chemistry was born. But we must in justice add that the work had already been begun by men of genius, such as Bernard Palissy, Boyle the eminent critic and experimentalist, Homberg, the two Geoffroys, Margraff, Bergmann, Rouelle the master of Lavoisier, who may be called the Diderot of chemistry. Moreover, the most important discoveries in chemistry have been made by men who combined with chemical experiments a marked taste for alchemic theories. We may instance Glauber, ablest of mystics; Kunkel, who thought he had found in the "shining pills" of his *phosphorus mirabilis* as efficacious a remedy as the potable gold in which he also believed; Glaser the alchemist, master of Lemery, who has been called the father of chemistry; Robert Fludd, &c.

It is curious to observe that soon after chemistry was established as a science there was a regular deluge of searchers for the philosopher's stone. The limits of this article prevent us from giving a full list of their names. Suffice it to mention, among Frenchmen, De Lisle, who died in the Bastile of the wounds his guardians inflicted on him to extort his secret; among Englishmen, Dr Price, who committed suicide to escape from a public trial of his pretended discovery. As to the theoretical possibility of making gold, the great French chemist Dumas considered that a solution might be found in the doctrine of isomerism; and the great English chemist Sir Humphrey Davy refused to pronounce that the alchemists must be wrong. Before concluding this short sketch of a vast subject, we must give a brief list of titles of the most important authorities on the subject, and enumerate the principal words which alchemy has bequeathed to scientific terminology, or which have passed into the language of common life:—

AUTHORITIES.—Roger Bacon, Thesaurus Chimicus, 8vo, Francof., 1603; Francis Bacon Lord Verulam, History of Metals, fol., London, 1670; J. J. Becher, Opera Omnia, Francof., 1680; Chymia Philosophica, 8vo, Nuremberg, 1639; John Espagnet, Enchiridion Philosophiæ Hermeticæ, Paris, 1638; Robert Fludd, Clavis Alchimiæ, 2 vols., Francof.; T. R. Glauber, Works, Chimistry, fol., London, 1689; Hermis Trismegisti, Traduction par J. Mesnard, 8vo, Paris (edited by Didier); J. Kunkel, Experiments, 8vo, London, 1705; Paracelsi Opera Omnia (with a remarkable preface by Fred. Bitiski), 2 vols. fol.; J. B. Porta, De Æris Transmutationibus, 4to, Romæ, 1610; Quercetan, Hermetical Physic, 4to, London, 1605; Georgii Ripley, Opera Omnia, 8vo, Cassel, 1649; J. Trithemius, De Lapide Philosophico, 8vo, Par. 1611; Basil Valentin, Last Will, &c., 8vo, London, 1671. Of compilations we may mention—Artis Auriferæ quam Chemiam vocant Duo Volumina (this work includes the Turba Philosophorum), Basileæ, 1610, J. J. Manget, Bibliotheca Chemica Curiosa, 2 vols, fol., 1702; Theatrum Chimicum, 6 vols. 8vo, Argent., 1662; The Lives of the Adepts in Alchemystical Philosophy, with a critical catalogue of the books in this science, and a selection of the most celebrated treatises, &c., 8vo, London, 1814; Essai sur la Conservation de la Vie par le Vcte. Le Lapasse, 8vo, Paris. Among the best historical and critical works with which we are acquainted we will mention—Petr. Gregor. Tholozanus Syntaxeōn Artis Mirabilis, 2 vols., Lugduni, 1576; O. Borrichius de Ortu et Progressu Chemiæ, 4to, 1668; The History of Chemistry, by Thomas Thomson, 2 vols. 8vo, London, 1830; Eusebe Salverte, Les Sciences Occultes, 8vo, Paris, 1829; Ferd. Hoefer, Histoire de la Chimie, 2 vols. 8vo, Paris, and an abridgment by the same author; Histoire de la Physique et de la Chimie, 8vo, Paris, 1872; Louis Cruveilhier, Philosophie des Sciences Médicales, Œuvres Choisies, 8vo, Paris, 1862; Fred. Morin, Genèse de la Science (an important work, which we only know from quotations in French reviews and encyclopædias); Dumas, Philosophie Chimique. Lastly, if we wish to trace the transition of alchemy to chemistry we shall find valuable information in Le Dictionnaire de Physique, dedicated to Mons. le Duc de Berry, 3 vols. 4to, Avignon, 1761, under the words Alkali, Alum, Chimie, Pierre Philosophale, Homberg. The reader will observe that in this encyclopædia, written with the express purpose of propagating the Newtonian theory in France, the classical science could bring no real arguments against alchemy. He may also consult the remarkable work of La Metherie, which has been undeservedly forgotten—Essai Analytique sur l'Air pur et les Differentes Espèces d'Air, 3 vols. Paris, 1785; and The Birth of Chemistry, by G. F. Rodwell, London, 1874.

ETYMOLOGY.—The idea that nature must be tortured to make her reveal her secrets is preserved in the word *crucible:* Fr. *creuset*, Ital. *cruciolo*, Span. *crisol*—all from the Latin *crux*, a cross. The word *matrass*, Fr. *matras*, is probably from the Celtic *matara*, an arrow, through the old French verb *matrasser*, to harass. *Bain-Marie* and *amalgam* (μάλαγμα) are a legacy of the sacred art. We can trace the two principles, male and female, of the alchemists in the word *arsenic* (ἀρσενικόν, male). From the Arabs we get *alcohol* (*al kohl*), properly anything burnt, then a powder of antimony to darken the eyelids, and lastly, spirits of wine; *alkali*, ashes; *borax*, the white substance; *lacker*, from *lac*, resin; *elixir*, from *el ksir*, essence; *alembic*, Arab. *alanbiq*. *Potash* is obviously the ash of the pot, Germ. *potasch*; *laudanum* is a corruption of *laudandum*. The derivation of *tartar*, Fr. *tartre*, is strange. Paracelsus considered tartar to be the cause of the gout, and borrowed the name from the infernal regions (Tartarus). The Spaniards have borrowed from the Arabs, *azogue*, mercury; *azogar*, to overlay with quicksilver; *azoguero*, a worker in mercury; *azogamiento*, agitation; *azogadamente*, with agitation. The same Celtic root which gave to Latin the word *vertragus*, used by Martial for greyhound, and to Greek οὐέρταγος, found in Ælian, from which Dante took the word *veltro*, has also created a large family of words—the Ital. *peltro*, tin and mercury; Span. *peltre*, lead and tin; old Fr. *peautre* = *peltro*; Eng. *pewter*, *pewterer*, &c. The Place *Maubert* at Paris derives its name from the fact that Magister Albertus lived there (Maubert = Ma' Albert). From the alchemists we get both the ideas and the words *affinity* (Albertus Magnus), *precipitate* (B. Valentin), *reduce* (Paracelsus), *saturation* (Van Helmont), *distillation*, *calcination*, *quintessence*, *aqua vitæ* (brandy was originally only employed as a medicine), *aqua regalis*, *aqua secunda*, *gas*, *cobalt*, from Kobolds, the genii of mines, &c. (J. A.)

ALCIATI, ANDREA, an eminent Italian jurist, born at Alzano, near Milan, on the 12th January 1492, died 1550. He displayed great literary skill in his exposition of the laws, for which De Thou highly praises him. He published many legal works, and some annotations on Tacitus. His *Emblems*, a collection of moral sayings in Latin verse, has been greatly admired, and translated into French, Italian, and Spanish. Alciati's history of Milan, under the title *Rerum Patriæ, seu Historiæ Mediolanensis, libri IV.*, was published posthumously at Milan in 1625.

ALCIBIADES was born at Athens about 450 B.C. Through his father, Cleinias, he traced his descent from Eurysaces, the son of Ajax, and through his mother, Deinomache, from Megacles, the head of the Alcmæonidæ. He was thus related to Pericles, who, after the death of Cleinias at the battle of Coronea (447 B.C.), became his guardian. A youth early deprived of his father's control, possessed of great personal beauty, and the heir to great wealth — a youth consequently universally honoured, courted, and caressed—was not in a position to acquire a knowledge of the virtue of self-restraint in any shape or form. Spoilt accordingly by flatteries and blandishments, the boy showed himself self-willed, capricious, and passionate, and indulged in the wildest freaks and most insolent, tyrannical behaviour. Nor did the instructors of his early manhood supply the corrective which his boyhood lacked. The collection of moral, political, and religious beliefs which the earlier Greeks, from custom, convenience, or the promptings of common sense, had accepted as a standard by which to regulate their own conduct and judge that of others, had been exposed by the sophists to the keenest scrutiny and the widest scepticism. Negative criticism, accompanied with showy novel paradoxes, are always attractive to a young man of intellectual vigour; and thus Alcibiades learnt from Protagoras, Prodicus, and others, to laugh at the common opinions about justice, temperance, holiness, patriotism, &c. The long, patient, laborious thought, the self-sufficing and comparatively ascetic life of his master Socrates, he was able to admire, but not to imitate or practise. On the contrary, his ostentatious vanity, his amours, his debaucheries, and his impious revels, became notorious throughout Athens. But great as were Alcibiades's moral vices, his intellectual abilities were still more conspicuous. He proved his courage at the battle of Potidea (432 B.C.), where, wounded, he was rescued by Socrates; at the battle of Delium (424 B.C.), where he protected his former deliverer; and on many subsequent occasions. Though he was not a very fluent speaker, he always kept to the point. His energy was immense, his ambition unbounded but selfish, and provided he could gratify this passion, he never scrupled at the means or the price. He could read the character of others, and adapt himself to it with a versatility, adroitness, and flexibility which if any even of his shifty fellow-countrymen equalled they never surpassed. Nor were his personal qualities his only recommendation to popular favour. His ancestors and relatives had been for generations the recognised leaders of the people; he had many admirers and followers among the clubs of young nobles; he had numerous dependants who partook of his wealth; and he gratified the populace by the lavish expenditure with which he performed his various liturgical duties. On his first entering prominently into public life, he succeeded by a clever but unscrupulous trick in duping the Spartan ambassadors, and persuading the Athenians to conclude an alliance with Argos, Elis, and Mantinea (420 B.C.) Next year he was appointed general, and for three years busily traversed the Peloponnesus, endeavouring to advance the objects of the alliance. But to be the first man in Athens was far too limited an object to satisfy the ambition of Alcibiades: all Greece must be dazzled by his greatness. As the first step towards the accomplishment of this scheme he fixed upon the conquest of Sicily, which would necessarily be followed by that of the Peloponnesus and probably by that of Carthage. With this view, he warmly advocated the adoption of measures for the relief of Segesta. The Sicilian expedition being resolved on with great enthusiasm, he, Nicias, and Lamachus, were appointed generals. But shortly before the day appointed for the armaments setting sail there took place a mysterious crime, which was destined to alter the whole complexion of Alcibiades's future, and with it that of the Athenian state. In the course of one night (May, 415 B.C.) all the busts of Hermes in Athens were sacrilegiously mutilated. The enemies of Alcibiades (many of them probably the actual perpetrators) endeavoured to connect him with the sacrilege; and his well-known impieties gave plausibility to a charge which could never have had any real foundation. Recalled to stand his trial almost as soon as he reached Sicily, he escaped, and made his way to Sparta, where he revealed all the plans of the Athenians, and induced the Spartans to send Gylippus to Sicily and an army to fortify Decelea. He then passed over to Asia Minor, and prevailed upon many of the Ionic allies of Athens to revolt. But in a few months he had lost the confidence of the Spartans; and at the instigation of Agis II., whose personal hostility he had excited, an order was sent from Lacedæmon for his execution. Receiving timely information of this order, he crossed over to Tissaphernes (412 B.C.), and quickly worming himself into the satrap's confidence, he persuaded him to cease giving active assistance to Sparta, so that the two Grecian parties, after wearing themselves out by their mutual struggles, might both be easily expelled from Asia. But Alcibiades was now bent on returning to Athens, and he used his supposed influence with Tissaphernes to effect his purpose. In his negotiation with Peisander, though he failed in his immediate object, he succeeded in producing the impression that, whatever side he joined, he could make Tissaphernes help. Under this impression, he was recalled by Thrasybulus and the armament at Samos, and appointed one of the generals. His appointment was followed by the victories at Cynossema, Abydos, and Cyzicus, and by the recovery of Chalcedon and Byzantium. On his return to Athens after these successes he was welcomed with every demonstration of joy (407 B.C.); all the proceedings against him were cancelled, and he was appointed general with full powers. His ill success, however, at Andros, and the defeat of his lieutenant at Notium, led the Athenians to dismiss him from his command. He thereupon retired to the Thracian Chersonesus; but after the battle of Ægospotami, and the establishment of the Spartan supremacy throughout Greece, he crossed the Hellespont, and took refuge with Pharnabazus in Phrygia. There an attack was made upon him, but by whom or for what cause historians are not agreed; his residence was set on fire, and on rushing out on his cowardly assassins, dagger in hand, he was killed by a shower of arrows, 404 B.C. By his wife Hipparete, Alcibiades left one son, who was named after himself.

ALCINOUS, a Platonic philosopher of uncertain date, author of a work entitled Ἐπιτομὴ τῶν Πλάτωνος δογμάτων, which has been translated into English by Stanley in his *History of Philosophy*. The best edition of the Greek original is that by Fischer, Lips. 1783, 8vo.

ALCINOUS, a mythical king of the Phæacians, in the island of Scheria, was son of Nausithous, and grandson of Neptune and Peribœa. He has been immortalised in the *Odyssey*, the description of his reception and entertainment of Ulysses, who when cast by a storm on the shore of the island was relieved by the king's daughter, Nausicaa, forming the main subject of books vi. to xiii. of that poem. The subjects of Alcinous loved pleasure and good cheer, yet were skilful seamen; and he himself is described as a good prince.

ALCIPHRON, the most eminent of the Greek epistolary writers, was probably a contemporary of Lucian. His letters, of which 116 have been published, are written in the purest Attic dialect, and are considered models of style. The imaginary authors of them are country people, fishermen, courtesans, and parasites, who express their sentiments and opinions on familiar subjects in refined and elegant language, yet without any very apparent inconsistency. The new Attic comedy being the principal source from which Alciphron derived his information, these letters are valuable as delineating the private life of the Athenians at that period. The best editions are by Bergler, Lips. 1715, and Wagner, Lips. 1798.

ALCIRA, probably the *Sætabicula* of the Romans, a Spanish town, on an island in the river Xucar, 25 miles S.W. of Valencia, in the province of that name. It is surrounded by walls, and has two fine bridges. There is a remarkable stalactite grotto in the vicinity. The principal productions are silk, rice, and oranges, which are largely exported. Population, 15,400.

ALCMAN, sometimes also called ALCMÆON, one of the most ancient, and, in the opinion of the Alexandrian critics, the most distinguished of the lyric poets of Greece. According to one account he was by birth a Lydian, while others state that he was a native of Sparta, where, at any rate, he lived from a very early age. The time at which he flourished is uncertain, but it is generally assumed that it embraced the period between the years 670 and 630 B.C. Alcman may in some respects be regarded as the father of lyric poetry among the Greeks, and it was probably for this reason that the Alexandrian critics put him at the head of their lyric canon. His poems, which seem to have formed a collection of six books, are known to us only from a number of small fragments. Many of them were of an erotic character, but others were hymns and didactic pieces. All were written in the vigorous broad dialect of the Dorians. The best collection of these fragments was published by F. G. Welcker, Giesen, 1815, 4to; they are also contained in Bergk's *Poetæ Lyrici Græci*, 1852, 8vo.

ALCMENE, the daughter of Electryon, king of Mycenæ, and wife of Amphitryon. She was the mother of Hercules by Jupiter, who assumed the likeness of her husband during his absence, and of Iphicles by Amphitryon.

ALCOCK, JOHN, doctor of laws, and bishop of Ely in the reign of Henry VII., was born at Beverley in Yorkshire before 1440, and educated at Cambridge. He was made dean of Westminster and master of the rolls in 1462. In 1470 he was appointed ambassador to the court of Castile, and in 1471 was consecrated bishop of Rochester. In 1477 he was translated to the see of Worcester; and in 1486 to that of Ely. He was a prelate of great learning and piety, and so highly esteemed by King Henry that he appointed him lord president of Wales, and afterwards lord keeper of the Great Seal. Alcock founded schools at Kingston-upon-Hull and Beverley, and built the spacious hall belonging to the episcopal palace at Ely. He was also the founder of Jesus College in Cambridge, for a master, six fellows, and as many scholars. This house was formerly a nunnery, dedicated to St Radigund; and Godwin says that the building being greatly decayed, and the revenues reduced almost to nothing, the nuns had all forsaken it, except two; whereupon Bishop Alcock procured a grant from the crown, and converted it into a college. But Camden and others tell us that the nuns of that house were so notorious for their incontinence, that King Henry VII. and Pope Julius II. consented to its dissolution. Bishop Alcock wrote several pieces, among which are the following:—1. *Mons Perfectionis*; 2. *In Psalmos Pœnitentiales*; 3. *Homiliæ Vulgares*; 4. *Meditationes Piæ*. He died at Wisbeach, October 1, 1500, and was buried in the chapel built by himself in Ely cathedral.

ALCOHOL, a volatile organic body, constantly formed during the fermentation of vegetable juices containing sugar in solution. It is extracted from spirituous liquors of different kinds by successive distillations or rectifications; the alcohol being more volatile than water, gradually accumulates in the first portion of each distillate. After a few operations the spirit obtained is as strong as it can be made by this process, and further repetition does not enable us to separate more water from it. In commerce the strongest spirit is known as spirit of wine, and contains about 90 per cent. of alcohol. The remaining 10 per cent. of water must be removed by some chemical agent that will combine with water and retain it at the boiling-point of the spirit, and be without any specific action on the alcohol. The dehydrating substances in general use are certain anhydrous salts, such as carbonate of potash, acetate of potash, or sulphate of copper. These rapidly absorb water at low temperature, and part with it at a red heat; so that they may be used over and over again. The most efficient dehydrating agent is caustic lime or caustic baryta. Lime is generally used in making the absolute alcohol of commerce. For this purpose the caustic lime is broken into small pieces about the size of a walnut, and placed in a retort; spirits of wine is now poured into the vessel, just sufficient to cover the lime, and the whole is left to digest for a night. During this time the lime gradually slakes from the absorption of water, and the anhydrous alcohol is left, ready to distill off at the temperature of the water-bath. Absolute alcohol is a very mobile colourless liquid, having a high refractive power, and possessing a feeble agreeable smell and an acid burning taste, which, however, diminishes as it is diluted with water. The caustic taste is in great part due to the rapidity with which it takes water from any living tissue with which it comes in contact, producing coagulation if the fluids are albuminous. Alcohol has a specific gravity of 0·794 at a temperature of 60° Fahr., and boils at 173°·1 Fahr., barometer being at 30 inches. It does not conduct electricity, and has never been obtained in the solid state, although at very low temperatures it becomes viscid. For this reason alcohol is always used to fill thermometers for registering low temperatures, as mercury freezes, and cannot be employed as an index of temperature below − 39° Fahr. Its high co-efficient of expansion makes alcohol a very sensitive fluid for thermometric purposes. Alcohol has a great tendency to absorb water from the atmosphere, and must be kept in thoroughly sound vessels. It mixes with water in all proportions, and during the dilution there is a considerable amount of heat evolved. When alcohol and water are mixed, a contraction of volume occurs, which augments until 100 parts of alcohol are mixed with 116·23 parts of water; 103·775 volumes of alcohol and water mixed in that ratio contracting to 100. Addition of water beyond the proportion given above causes less and less contraction, and finally no diminution of volume can be observed. As alcohol is diluted with water its volatility and its power of dilatation diminish, whereas the specific gravity increases, continually approaching that of water. Next to water, alcohol is the substance most generally employed as a solvent. It dissolves many organic substances, and is especially used in the arts for the manufacture of varnishes. In medicine it is invaluable as a solvent of the active principle of many substances that are insoluble in water, and would soon decompose in aqueous solution. These alcoholic solutions are generally called tinctures.

Alcohol is an excellent antiseptic agent. As a preservative of animal structures it is generally used in the impure state—known in commerce as methylated spirit. This is spirits of wine mixed with 10 per cent. of commercial wood spirits, which does not interfere with its preservative or solvent powers, although it renders it unfit for use as a beverage.

Alcohol has the following chemical composition:—

Carbon	52·67	per cent.
Hydrogen	12·90	,,
Oxygen	34·43	,,
	100·00	,,

Its formula in chemical symbols is C_2H_6O. During the fermentation of sugar the change that takes place is represented as follows:—

$$\underset{\text{Grape sugar.}}{C_6H_{12}O_6} = \underset{\text{Alcohol.}}{2\,C_2H_6O} + \underset{\text{Carbonic acid.}}{2\,CO_2}$$

The complex body, grape-sugar, breaks up by the action of the ferment or yeast into alcohol or carbonic acid, without anything being added. This kind of chemical change is sometimes called an action of presence, or catalytic action, because the substance inducing it does not enter into the composition of the products of the reaction. The alcohol ferment or yeast is a minute cellular plant that grows rapidly in sugar solution, especially if albumenoid matter is also present, and during the continuance of its vital functions causes a rearrangement of the atoms of the sugar. In order that fermentation may proceed regularly, a temperature of about 60° Fahr. is required, and an amount of sugar in solution not exceeding 10 per cent. The sugar is principally obtained from malt, which is barley that has been allowed to germinate for a certain time, and is then arrested in its growth by heating to a high temperature. During this process of germination there is a peculiar ferment produced called diastase; this has the remarkable property of changing starch into grape-sugar. When the malt is treated with water, the ferment causes all the starch originally present in the grain to appear in solution as grape-sugar. All kinds of starch may be changed into grape-sugar by boiling with dilute sulphuric acid, which in this case acts somewhat like a ferment, because it is not decomposed during the action. The sulphuric acid is afterwards separated by treating with lime, which produces insoluble sulphate of lime (gypsum), and leaves the sugar in solution. In this way sugar for the alcohol manufacture is now largely made from the potato and other starch-yielding plants. Cane-sugar is too expensive to be employed in the distillery. Molasses, or the uncrystallisable portion of the cane-sugar, is, however, largely used.

Alcohol, when acted on by other chemical substances, produces a great variety of new compounds. With acids a remarkable class of bodies are produced called ethers, of which ordinary ether is the type. The majority of them are very volatile fluids, that in many cases have a very agreeable odour, and are not readily soluble in water. Many ethers are obtained by simply heating a mixture of the acid and alcohol in a closed vessel to a temperature of 212° Fahr., and subsequently treating with water. The water dissolves the alcohol not acted upon, and leaves the ether floating on the surface.

When alcohol is treated with chlorine, absorption occurs, and hydrochloric acid is continuously evolved for many hours, the temperature rising considerably during the action. Many substances are formed in succession, but the principal product, after long-continued action, is the substance chloral, now largely used as an anæsthetic. Bromine produces a similar body called bromal. Iodine does not act on alcohol at ordinary temperatures, further than to pass into solution. When treated with a solution of chloride of lime, alcohol is violently attacked, and the result of the action is the well-known substance chloroform. Acted on by oxidising agents, alcohol gives two new substances—aldehyde and acetic acid. The ease with which acetic acid is produced by heating with a mixture of bichromate of potash and sulphuric acid gives a delicate method of detecting and estimating very small quantities of alcohol. When the vapour of alcohol is passed through a red-hot tube filled with fragments of pumice-stone, complete decomposition takes place. Among the products are found naphthalin, benzol, hydrogen, marsh gas, ethylene, and other bodies.

The synthesis of alcohol has been effected by means of the hydro-carbon called olefiant gas, which may be made directly from carbon and hydrogen. When this gas is shaken with strong sulphuric acid it gradually combines with it; and if it is afterwards diluted with water and distilled, alcohol passes over. As olefiant gas is one of the constituents of common coal-gas, this substance may be used to make alcohol by the above method. The action that takes place is represented thus:—

$$\underset{\text{Olefiant Gas.}}{C_2H_4} + \underset{\text{Water.}}{H_2O} = \underset{\text{Alcohol.}}{C_2H_6O}$$

As the value of spirituous liquors depends mainly on the quantity of alcohol they contain, it is essential to find some simple and rapid means of ascertaining the percentage amount of the substance present. For this purpose three methods may be employed, viz., specific gravity determination, temperature of ebullition, or rate of expansion. The easiest plan, and the most generally used, is the density method. Very accurate tables are published of the specific gravity of mixtures of alcohol and water in all proportions, so that it is only necessary to refer to these tables to get the percentage composition. In the case of liquors, like wines or beers, that contain many other substances in solution in addition to alcohol, it is necessary to separate the alcohol from the extractive matters—sugar, salts, &c.—by distillation, and to take the density of the volatile portion. As wines contain many volatile ethers that would pass over with the alcohol in the above process, and interfere with accurate results being obtained, they are generally decomposed by heating with an alkali before the distillation commences.

The physiological action of alcohol is a subject to which considerable attention has been directed of late years, and many investigators have attacked the problem. The most important contribution to our knowledge of the subject is due to Dr Parkes, who has made a long series of observations on soldiers living on a constant diet with and without the use of alcohol. In these experiments the weight of the body, the amount of nitrogen in the urine and fæces, the amount of urea, the pulse, and the temperature of the body were all determined daily. The following are the principal conclusions deduced from the investigation:—

The elimination of nitrogen during exercise was unaffected by brandy; and since a similar result occurred in a series of experiments made during rest, it seems certain that in healthy men on uniform good diet alcohol does not interfere with the disintegration of nitrogenous tissues.

The heat of the body, as judged of by the axilla and rectum temperature, was unaffected by the amount given. The apparent heat after alcohol must therefore be owing to subjective feelings connected with the quickened circulation, rather than to an actual rise of temperature.

The pulse was increased in frequency by 4 ounces of brandy, and palpitation and breathlessness were brought on by larger doses to such an extent as greatly to lessen the amount of work the man could do, and to render quick movements impossible. As the effect of labour alone is to augment the strength and frequency of the heart's action, it would appear obviously improper to act on the heart still more by alcohol. Whether on a heart exhausted by exertion alcohol would produce good or bad effects is not shown by these experiments.

Neither exercise nor alcohol produced any effect on the phosphoric acid of the urine, or the free acidity, or the chlorine.

As the action of alcohol in dietetic doses on the elimination of nitrogen and on the bodily temperature is so entirely negative, it seems reasonable to doubt if alcohol can have the depressing effect on the excretion of pulmonary carbon which is commonly attributed to it. It can hardly depress, one would think, the metamorphosis of tissues or substances furnishing carbon, without affecting either the changes of the nitrogenous structures or bodily heat.

The elimination of alcohol from the body has been a matter of dispute between different observers. Previous to the year 1860 it was the generally-received opinion that the greater portion of any alcohol taken was oxidised in the system, and only a small fraction eliminated unaltered. In that year Messrs Perrin and Lallemand published an elaborate memoir on the subject, in which they maintained that all, or at least nearly all, the alcohol taken is eliminated unaltered. This subject has been recently reinvestigated by Dr Austin, Dr Thudichum, and especially by Dr A. Dupré. The main results of Dr Dupré's series of observations may be summed up as follows:—

The amount of alcohol eliminated per day does not increase with the continuance of the alcohol diet; and therefore all the alcohol consumed daily must of necessity be disposed of daily; and as it certainly is not eliminated within that time, it must be destroyed in the system.

The elimination of alcohol following the ingestion of a dose or doses of alcohol ceases in from nine to twenty-four hours after the last dose has been taken.

The amount of alcohol eliminated in both breath and urine is a minute fraction only of the amount of alcohol taken.

In the course of these experiments the author found that, after six weeks of total abstinence, and even in the case of a teetotaller, a substance is eliminated in the urine, and perhaps also in the breath, which, though apparently not alcohol, gives all the reactions ordinarily used for the detection of traces of alcohol. The quantity present in urine is, however, so small that the precise nature of the substance has not as yet been determined. The author points out an apparent connection between this substance and alcohol. It was found that, after the elimination due to the ingestion of alcohol had ceased, the amount of this substance eliminated in a given time at first remained below the quantity normally excreted, and only gradually rose again to the normal standard. A careful study of this connection may perhaps serve to throw some light upon the physiological action of alcohol.

ALCOY, one of the most thriving manufacturing cities of Spain, on the river Alcoy, in the province of Alicante, 24 miles N.N.W. of the town of that name. It is built on an elevated site at the foot of a gorge of the *Sierra de Mariola*, and presents a picturesque appearance. There are several handsome buildings and a number of public fountains, but the industry of the place is its chief characteristic. The principal employment is papermaking. About 200,000 reams are produced annually, the extraordinary quantity of 180,000 reams being a paper of light texture used for making cigarettes. Coarse woollen stuffs are also manufactured. A very curious festival is held annually in April in honour of St George, the patron saint of the town. Population, 27,000.

ALCUDIA, MANUEL DE GODOY, DUKE OF, "Prince of the Peace," Spanish statesman, was born of poor but noble parentage at Badajoz on the 12th May 1767 (died 1851). In 1784 he came to Madrid to join the royal bodyguard, and by his handsome presence and agreeable manners soon attracted notice. The queen regarded him with great favour, and the weak-minded Charles IV. raised him rapidly from dignity to dignity, until in 1792, on the disgrace of Aranda, he became prime minister. One of the first steps he took on his accession to power was to declare war against the French convention. Though success at first attended the Spanish arms, the position of matters was reversed in a second campaign, and the war was concluded by the treaty of Basle, signed on the 22d July 1795, for negotiating which Godoy received his title of Prince of the Peace and a large landed estate. He was also made at the same time a grandee of Spain of the first class. In 1796 he formed an offensive and defensive alliance with the French republic, which involved Spain in a war with England. Next year he was married to Maria Theresa de Bourbon, niece of the king by a morganatic marriage of his brother Luis. As it was understood that Godoy had already married Dona Josef a Tudo, this second alliance, though it brought him nearer to the king, did much to increase his unpopularity with the nation. On the 28th March 1798 he found himself forced to resign his position in the ministry, but he never lost the favour of the king, who appointed him grand admiral in 1799. About the same time he was restored to power, and entered into an alliance with Napoleon, having for its object the partition of Portugal. The war, in which Godoy himself commanded, was of short duration, the treaty of Badajoz, signed on the 6th June 1801, securing from Portugal a subsidy to France and a cession of territory to Spain. Godoy was rewarded for his service with the title of Count of Everamente, and an annual income of 100,000 piastres. In 1804 he became generalissimo of the land and sea forces of Spain; but the honours thus heaped upon him by the king were accompanied by growing dislike on the part of the nobility and the people. The higher classes regarded him with jealousy as a *parvenu*, and he was necessarily unpopular with a nation that attributed to him the defeat of Trafalgar, and the stoppage of its commerce through the blockade of the ports. A change of policy, by which he endeavoured to break off his alliance with France and enter into friendly relations with England, came too late to save his position. Napoleon determined to remove the Bourbons from the throne of Spain, and the invasion of the French troops gave Godoy's enemies the wished-for opportunity to secure his downfall. The prime minister had retired from Madrid, and was making arrangements for the removal of the king and queen to Mexico, when the project was discovered by the Prince of Asturias, the leader of the party opposed to him. On the 18th March 1808 Godoy was seized at Aranjuez by the mob, who were only restrained from executing summary vengeance upon him by the promise given them that he should undergo a fair trial. Napoleon, however, wishing to avail himself of his influence over Charles, sent Prince Murat to effect his release. He was removed in April to Bayonne, where on the 5th May he signed the deed by which Charles IV. abdicated in favour of the Prince of Asturias. He continued to enjoy the undiminished favour of Charles, whom he accompanied to Rome, his possessions in Spain having been confiscated. On the death of his royal master he removed to Paris, where he received a pension of 5000 francs from Louis Philippe. In 1836–8 he published memoirs of his life, in which he defends his policy. In 1847 his titles and the greater part of his estates were restored to him, and he received permission to return to Spain. He continued, however, to reside in Paris, where he died on the 4th October 1851.

ALCUIN, in Latin *Albinus*, surnamed *Flaccus*, an eminent ecclesiastic and a reviver of learning in the 8th century, was born in Yorkshire about 735 (died 804). He was educated at York under the direction of Archbishop Egbert, as we learn from his own letters, in which he frequently calls that prelate his beloved master, and the clergy of York the companions of his youthful studies. He succeeded Elbert as director of the seminary, and in later life modelled after it his famous school at Tours. He survived Bede about seventy years; it is therefore hardly possible that he could have received any part of his education under him, as some writers of literary history have affirmed; and it is worthy of observation that he never calls Bede his master, though he speaks of him with the highest veneration. It is not well known to what preferments he had attained in the church before he left England, though some say he was abbot of Canterbury. He was sent to Rome by Eanbald, the successor of Ethelbert, to procure the *pallium*, and, in returning, at Parma he met Charlemagne, who, as Alcuin had already visited the French court, was no stranger to his extraordinary merit. The emperor contracted so great an esteem and friendship for him that he earnestly urged and at length induced him to take up his residence at court and become his preceptor in the sciences. Alcuin accordingly instructed Charlemagne and his family in rhetoric, logic, mathematics, and divinity. He particularly distinguished himself by his writings in defence of the orthodox faith against the adoptionists, Felix, bishop of Urgel, and Elipandus, archbishop of Toledo, convincing the former of his error after a six days' debate at Aix-la-Chapelle (799), and treating the latter in the most conciliatory manner; and on more than one occasion he was employed in important missions between Charlemagne and Offa, king of Mercia. "France," says one of our best writers of literary history, with some degree of truth, "is indebted to Alcuin for all the polite learning it boasted of in that and the following ages. The universities of Paris, Tours, Fulden, Soissons, and many others, owe to him their origin and increase, those of which he was not the superior and founder being at least enlightened by his doctrine and example, and enriched by the benefits he procured for them from Charlemagne." Alcuin, it is alleged, however, forbade the reading of the classical poets. In 790 he went to England in the capacity of ambassador, and returned to France in 792, never again to visit his native land. After Alcuin had spent many years in the most intimate familiarity with the greatest prince of his age, he at length, in 801, with great difficulty, obtained leave to retire from court to the abbey of St Martin at Tours, of which he had been appointed the head by Charlemagne in 796. Here he remained and taught till his death in 804. In his retirement he kept up a constant correspondence with Charlemagne, which displays, on the part of both, an ardent love of learning and religion, and great zeal and earnestness in contriving and executing noble designs for their advancement. Alcuin composed many treatises on a great variety of subjects, in a style much superior in purity and elegance to that of most writers of the age in which he flourished. His works were collected and published by Duchesne, in 1 vol. folio, Paris, 1617: a better edition is that of Froben, 2 vols. folio, Ratisbon, 1777. They consist of (1) Tracts upon Scripture; (2) Tracts upon doctrine, discipline, and morality; (3) Historical treatises, letters, and poems. It is not improbable that Alcuin was the writer of the famous *Caroline Books*, issued under the name of Charlemagne, which denounced as idolatrous every form of image-worship. A Life of Alcuin, by Lorenz, was published at Halle in 1829, and appeared in an English translation, by Slee, in 1837.

ALCYONIUS, or ALCIONIUS, PETRUS, a learned Italian, born at Venice in 1487 (died 1527). Distinguished as a classical scholar, he was employed for some time by Aldus Manutius as a corrector of the press, and in 1522 was appointed professor of Greek at Florence through the influence of Giulio de Medici. When the latter became pope, under the title of Clement VII., in 1523, Alcyonius followed him to Rome, and remained there until his death. Alcyonius published at Venice, in 1521, a Latin translation of several of the works of Aristotle, which was shown by the Spaniard Sepulveda to be very incorrect. He wrote a dialogue entitled *Medices Legatus, sive de Exilio*, in connection with which he was charged with plagiarism by his personal enemy, Paulus Manutius. The accusation, which Tiraboschi has shown to be groundless, bore that he had taken the finest passages in the work from Cicero's *De Gloria*, and that he had then destroyed the only existing copy of the original in order to escape detection. Two orations on the taking of Rome by Charles V., and another on the knights who perished at the siege of Rhodes, are also ascribed to Alcyonius.

ALDAN, a river of Siberia, in the government of Yakutsk, which rises about 55° N. lat., and 125° E. long., and after flowing more than 300 miles in a north-east direction, turns to the north-west, joining the Lena about 100 miles below Yakutsk. It has a total length of over 500 miles, for a considerable part of which it is navigable.

ALDAN MOUNTAINS, the name usually applied to a branch of the Stanovoi mountains, which strikes off from the main chain in the direction of the Aldan river, or to a part of this range. According to some geographers, however, the continuation of the Stanovoi range to Behring Strait, or even the whole mountain system of eastern Siberia, ought to receive the name.

ALDBOROUGH, a town of England, in the West Riding of Yorkshire, 16 miles W.N.W. of York. It formerly returned two members to parliament, but was disfranchised by the Reform Act of 1832. The place is remarkable only from its numerous ancient remains. It was the *Isurium* of the Romans, and here and in the neighbourhood the remains of aqueducts, spacious buildings, and tesselated pavements have been found, as well as numerous implements, coins, and urns. Population (1871) of the parish, which extends into the North Riding, 2165; of the town, 502.

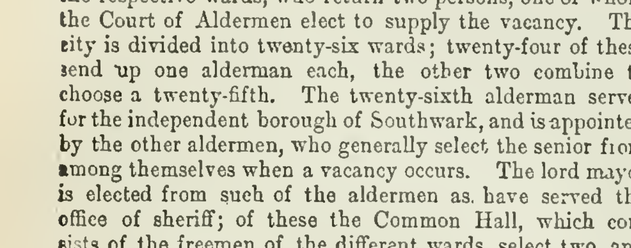
ALDEBURGH, or ALDBOROUGH, a market-town and watering-place in the county of Suffolk, 25 miles E.N.E. of Ipswich. The borough was incorporated by a charter of King Edward VI., and in former times was a place of considerable extent; but the old town was gradually submerged by the encroachments of the sea. Further destruction is now stayed by the accumulated sandbanks, and the place has become a favourite resort of summer visitors. Fishing affords employment to many of the inhabitants. The town is noted as the birthplace of the poet Crabbe, who was born here on 24th December 1754. A marble bust of the poet has been placed in the parish church. Aldeburgh was formerly a parliamentary borough, but was disfranchised by the Reform Act of 1832. Population of the parish in 1871, 1990.

ALDEGREVER, or ALDEGRAF, HEINRICH, a German painter and engraver, born in 1502 at Paderborn, from which he removed in early life to Soest. From the close resemblance of his style to that of his master, Albert Dürer, he has sometimes been called the Albert of Westphalia. His numerous engravings, chiefly from his own designs, are delicate and minute, though somewhat hard in style, and entitle him to a place in the front rank of the so-called "Little Masters." Specimens of his painting are exceedingly rare. The genuineness of the works in the Vienna and Munich collections attributed to him is at least doubtful, the only unchallenged example being a portrait in the gallery at Berlin. Aldegrever died about the year 1562.

ALDER, a genus of plants (*Alnus*) belonging to the order *Betulaceæ*, the best known of which is the common alder (*A. glutinosa*). This tree thrives best in moist soils, has a shrubby appearance, and grows, under favourable circumstances, to a height of 40 or 50 feet. Under water the wood is very durable, and it is therefore used for piles. The supports of the Rialto at Venice, and many buildings at Amsterdam, are of alder-wood. Furniture is sometimes made from the wood, and it supplies excellent charcoal for gunpowder. The bark is astringent; it is used as a gargle, and also in tanning and dyeing.

ALDERMAN, a word derived from the Anglo-Saxon *ealdorman*, compounded of the comparative degree of the adjective *eald* (old) and *man*. The term implies the possession of an office of rank or dignity; and among the Anglo-Saxons, earls, governors of provinces, and other persons of distinction received this title. Thus we read of the *aldermannus totius Angliæ*, who seems to have corresponded to the officer afterwards styled *capitalis justitiarius Angliæ*, or chief justice of England: the *aldermannus regis*, probably an occasional magistrate, answering to our justice of assize, or perhaps an officer whose duty it was to prosecute for the crown; and *aldermannus comitatus*, a magistrate with a middle rank between what was afterwards called the *earl* and the *sheriff*, who sat at the trial of causes with the bishop, and declared the common law, while the bishop proceeded according to ecclesiastical law. Besides these, we meet with the titles of *aldermannus civitatis, burgi, castelli, hundredi sive wapentdchii*, &c. In modern times aldermen are office-bearers in the muncipal corporations of England and Wales, and Ireland. Before the passing of the Municipal Corporation Act their functions varied according to the charters of the different burghs. By the statute 5th and 6th Will. IV. c. 76, and 3d and 4th Vict. c. 118, the aldermen are elected by the councillors from among themselves (in Ireland, by the burgesses), for six years, one-half going out every three years. The number of councillors in each borough varies from 12 to 48, according to its magnitude. One-fourth of the municipal council consists of aldermen, and three-fourths of councillors. In the municipal corporations of Scotland there is no such title as alderman, the office-bearers of corresponding rank there being termed bailies. The corporation of London was not included in the Burgh Reform Act, and the antiquated system remains there in full force. The Court of Aldermen consists of twenty-six, twenty-five of whom are elected for life by the freemen of the respective wards, who return two persons, one of whom the Court of Aldermen elect to supply the vacancy. The city is divided into twenty-six wards; twenty-four of these send up one alderman each, the other two combine to choose a twenty-fifth. The twenty-sixth alderman serves for the independent borough of Southwark, and is appointed by the other aldermen, who generally select the senior from among themselves when a vacancy occurs. The lord mayor is elected from such of the aldermen as have served the office of sheriff; of these the Common Hall, which consists of the freemen of the different wards, select two, and the aldermen elect one of these to the mayoralty. The Court of Aldermen act as magistrates for the city of London, and also possess authority of a judicial nature in the affairs of the corporation. The aldermen are members of the Court of Common Council, the legislative body of the corporation, which consists in all of 232 members, the remainder being elected annually by the freemen. In the United States aldermen form as a rule a legislative rather than a judicial body, although in some cities they hold courts and possess very considerable magisterial powers.

ALDERNEY, one of the Channel Islands, and the most northerly of the four, lies between 49° 41′ and 49° 45′ N. lat., and 2° 9′ and 2° 14′ W. long., 7 miles to the westward



of Cape la Hogue, and is separated from the French coast by a narrow channel called the Race of Alderney. The passage through this strait is rendered very dangerous in stormy weather by its conflicting currents; but through it the scattered remnant of the French fleet under Tourville succeeded in escaping after the defeat of La Hogue in 1692. The harbour of Alderney is 20 miles distant from St Peter Port, Guernsey, 45 miles from St Helen's, Jersey, and 60 miles from Portland Bill, the nearest point of England. There is regular steam communication with Guernsey The length of the island from N.E. to S.W. is $3\frac{1}{2}$ miles; its width about 1 mile; its greatest elevation is 280 feet; and the area is about 4 square miles.

The greater part of Alderney is a level table-land, more or less cultivated. The land continues flat to the edge of the south-eastern and southern cliffs, which present a magnificent succession of broken and perpendicular walls of rock. Towards the north-west, north, and east, the coast is less rocky, and is indented by several bays of tame and naked aspect, of which those of Crabby, Braye, and Longy are the most noticeable. Sandstone, granite, and porphyry are the chief geological formations. From the importance of the island in a military sense, it has been fortified by a chain of defensive works, extending round the northern coast from the Clanque Fort on the west to Fort Essex on the east. The cliffs of the southern shore form a very strong natural bulwark. An extensive granite breakwater has been constructed, protecting the bay of Braye towards the west, intended to form an additional defence, and to convert the bay into a secure harbour of refuge. The works have cost upwards of a million and a quarter sterling; but the new harbour is not much resorted to, and the value of the breakwater as a means of defence has been questioned. Fort Touraille stands on the eastern side of the new harbour, and is a strong fortification, mounting 50 heavy guns, with bomb-proof barracks and powder magazine.

The population of Alderney has increased rapidly of recent years, on account of the extensive public works. In 1841 it was only 1030, in 1871 it was 2738. The inhabitants are Protestants, and Alderney forms part of the diocese of Winchester. Though a French *patois* lingers in the island, English is generally spoken and universally understood. The climate is healthy, and there is abundance of good water. Corn is grown, but much of the sandy soil is in grass, affording excellent pasture to the diminutive but pretty cows for which Alderney is famous. The only exports are cattle and early potatoes. St Anne's, the town of the island, is situated at some distance from the beach, overlooking the new harbour. It is plainly built, but has a fine new church in the early English style, erected as a memorial of the family of Le Mesurier, long the hereditary governors of the island. The only other architectural feature worthy of notice is a Gothic arch built as a memorial of the late Prince Albert of England.

Alderney seems to have been known to the Romans as *Riduna*, and Roman as well as Celtic remains have been discovered. It is subject to the British crown, and is a dependency of Guernsey. For its history and relation to English legislation, see the article on the CHANNEL ISLANDS. The internal government is vested in a judge appointed by the crown, and six *jurats*, chosen for life by the people; and these, with twelve *douzainiers*, who are popular representatives, but have not the power of voting, form the legislature. Justice is administered by the same judge and *jurats*, and several other officers. In civil cases an appeal may be taken to the royal court of Guernsey, while all criminal cases are referred to Guernsey for decision. Two companies of infantry and a battery of artillery compose the local militia.

Off the western coast of Alderney there are many uninhabited rocky islands: and six miles to the westward lie the Casquets, a group of rocks extremely dangerous to ships coming up the English Channel. On these rocks there are three lighthouses, with revolving lights 112 feet above the water.

ALDERSHOTT CAMP, a standing garrison for a large force, situated about 35 miles from London. on the confines of Hampshire and Surrey. It was established in May 1855, and was intended as a military training school, especially for officers of the higher grades. Its germ is to be found in the temporary camp on Chobham Ridges, formed in 1853 by Lord Hardinge, then commander-in-chief, the success of which convinced him of the necessity of giving our troops practical instruction in the field, and affording our generals opportunities of manœuvring large bodies of the three arms. He therefore advised the purchase of a tract of waste land whereon a permanent camp might be established. His choice fell on Aldershott, a spot also recommended by strategic reasons, being so placed that a force holding it covered the capital. Nothing came of Lord Hardinge's proposal till the experience of the Crimean campaign fully endorsed his opinion. The lands at Aldershott—an extensive open heath country, sparsely dotted by fir woods and intersected by the Basingstoke canal—were then acquired by the Crown. The first occupants of the camp were two battalions of the Guards and seven of embodied militia. On the return of the Crimean army, cavalry, artillery, and infantry of the line arrived and took possession of the lines of wooden huts and the permanent barracks, which had by this time been erected. Since then Aldershott has varied little in its principal features. It is separated into two grand divisions, styled the north and south camps. Beyond the latter are the permanent cavalry and infantry barracks and the queen's pavilion. Farnham is the nearest town, being only 4 miles from the south camp; Guildford and Godalming are 10 and 12 respectively, Windsor 18½, and Reading 21 miles. The soil on which the camp stands is a light peat, and a fruitful source of discomfort to its inhabitants. A little wet turns it into tenacious mud, while a little sunshine produces a black dust, not soon forgotten by those who have campaigned in the "Long Valley." The force stationed at Aldershott at the beginning of 1874 was composed of 1 cavalry and 3 infantry brigades; in the former there were 3 full regiments, in the latter a total of 11 battalions, with several depots of regiments abroad. Besides these, there were 2 batteries of horse and 6 of field artillery, 2 companies of Royal Engineers, and 4 troops of Royal Engineers' train (with pontoon, &c.); 7 companies of the Army Service Corps and 2 of the Army Hospital Corps—to provide for transport, and the services of bakehouse and slaughter-house and hospital—made up the total strength of all ranks, as shown in the returns dated 1st January 1874, to 10,601 men, 2198 horses, and 48 guns. It is a lieutenant-general's command, and one highly prized, from its essentially military character and the practical experience it affords in handling a considerable force. Sir William Knollys (afterwards comptroller of the household to the Prince of Wales) was its first chief. He was succeeded by Sir John Pennefather; Sir James Scarlett followed; then Sir Hope Grant, who held the command in 1874. Naturally so large a military colony soon attracted other elements to Aldershott heath. Within a few years a town of Aldershott sprang up close by, and increased rapidly. Here the professions and all trades are well represented; there are respectable solicitors, surgeons, bankers, brewers, many schools, a steam printing press, a weekly military paper, and numerous shops. During the summer months or "drill season" the camp is a scene of incessant activity; field-days and parades follow in rapid succession, and owing to the camp's accessibility from London, the troops are often turned out at a few hours' notice to make a show for royalty or foreign visitors. Yet there is much to beguile vacant hours; many clubs—for cricket, croquet, racquets, and the drama—a gymnasium, and several excellent libraries. Admirable charities also exist for the assistance and relief of the soldiers' wives and children. (A. G.)

ALDHELM, or ADELM, ST, Bishop of Sherborne in the time of the Saxon heptarchy, was born about the middle of the 7th century He is said to have been the son of Kenred, brother to Ina, king of the West Saxons; but, in the opinion of William of Malmesbury, his father was no more than a distant relation to the king. Having received the first part of his education in the school of Meildulf, a learned Irish monk, he travelled in France and Italy for his improvement. On his return home he studied some time under Adrian, abbot of St Augustin's in Canterbury, the most learned professor of the sciences who had ever been in England. The fame of his learning soon spread, not only in England, but in foreign countries. Learned men sent him their writings for his criticism; among others, a son of the king of Scotland is said to have sent his compositions to Aldhelm, "entreating him to give them the last polish by rubbing off their Scotch rust." He was the first Englishman who wrote in the Latin language, both in prose and verse; and he composed a book for the instruction of his countrymen on the prosody of that language. Bede says that Aldhelm "was a man of universal erudition, having an elegant style, and being wonderfully well acquainted with books both on philosophical and religious subjects." His Latin was in later times considered somewhat barbarous and corrupt. From one of his letters to Hedda, bishop of Winchester, concerning the nature of his studies whilst at Canterbury, he appears to have been indefatigable in his endeavours to acquire every species of learning in his power. For a copy of this curious epistle see Henry's *History*, vol. ii. p. 329. King Alfred declared that Aldhelm was the best of all the Saxon poets; and a favourite song, which was universally sung in his time, nearly 200 years after its author's death, was of his composition. He was a musician as well as a poet, and made his own songs the medium of instruction and refinement to his barbarous countrymen. After having governed the monastery of Malmesbury, of which he was the founder, about thirty years, he was made bishop of Sherborne, where he died in May 709.

He wrote—1. *De octo Vitiis Principalibus.* This treatise is extant in the *Bibliotheca Patrum* of Canisius. 2. *Ænigmatum Versus Mille.* This, with several other poems of his, was published by Martin Delrio at Mentz, 1701, 8vo. 3. A book addressed to a certain king of Northumberland named Alfrid, on various subjects. 4. *De Vita Monachorum.* 5. *De Laude Sanctorum.* 6. *De Arithmetica.* 7. *De Astrologia.* 8. A book on the mistake of the Briton. concerning the celebration of Easter; printed by Sonius, 1576. 9. *De Laude Virginitatis;* published among Bede's *Opuscula.* Besides these, he wrote many sonnets, epistles, and homilies in the Saxon language.

ALDINE EDITIONS. See MANUTIUS.

ALDINI, GIOVANNI, a distinguished physicist, born at Bologna on the 10th April 1762 (died 1834), was the nephew of Galvani, and brother of the statesman Count Antonio Aldini. Devoted from his youth to the study of natural science, he was chosen in 1798 to succeed his former teacher Canterzani in the chair of physics at Bologna. His most important service consisted in the numerous experiments by which he sought to secure the better application of science to practical purposes. The subjects of galvanism, the illumination of lighthouses by gas, and an asbestos or fireproof fabric engaged his special attention, and on all of them he published the results of his researches. He was master of the leading European languages; and most of his works were published in Italian, French, and

English. Aldini was one of the founders of the National Institute of Italy, and among his scientific honours he counted the gold medal of the Royal Society of London, and the prize of the Institute of France. In recognition of his merits, the emperor of Austria made him a knight of the Iron Crown and a councillor of state at Milan, where he died on the 17th January 1834. He left by will a considerable sum to found a school of natural science for artisans at Bologna.

ALDRED, EALDRED, or ALRED, a prominent ecclesiastic in the 11th century, was successively abbot of Tavistock, bishop of Worcester, and archbishop of York. He was promoted to the see of Worcester in 1046, and in 1050 was sent on a special mission to Rome by Edward the Confessor. In 1054 he went as ambassador to the court of the Emperor Henry III. with the object of negotiating for the return of Edward the Ætheling from Hungary, and remained a year at Cologne. In 1058 he undertook and accomplished a journey to Jerusalem, a pilgrimage which no English bishop had ventured on before. He was appointed archbishop of York in 1060, and proceeded to Rome to obtain the pallium; but the pope at first refused to confirm the appointment. At length, however, Aldred was duly invested with the robe of office on condition of his resigning his former see, which he had continued to hold till that time. On the death of Edward (1066) Aldred sided with Harold, and officiated at his coronation; but after the battle of Hastings he made submission to William, and poured the sacred oil on the head of the Conqueror ere the year was completed in which he had crowned Harold. There are several traditions, which may be regarded as having some foundation in fact, that represent Aldred as administering rebuke to William in the interests of his countrymen or in defence of his church's rights. At the same time, he remained faithful to William, and when the English rose in the north against the Normans, he counselled submission. He died at York, Sept. 11, 1069, of grief, it is said, because of the threatened attack on his city by the combined forces of the English and Danes.

ALDRICH, Dr HENRY, theologian and philosopher, was born in 1647 at Westminster, and was educated at the collegiate school there, under Dr Busby. In 1662 he entered Christ Church College, Oxford, with which he continued to be intimately connected during his whole life. He took so conspicuous a part in the controversy with the Roman Catholics during the reign of James II., that at the Revolution the deanery of Christ Church was conferred upon him, Massey, the popish dean, having fled to the continent. In 1702 he was appointed rector of Wem in Shropshire, but continued to reside at Oxford, where he died on the 14th Dec. 1710. He was buried in the cathedral without any memorial, at his own desire. Aldrich was a man of unusually varied gifts. He is best known as the author of a *Compendium Artis Logicæ*, a work of almost no value in itself, but historically important as being for upwards of a century the manual in exclusive use at Oxford. His claims to distinction as a musician and an architect, though not so widely recognised, are much better founded than his reputation as a logician. He composed a number of anthems and church services of very considerable merit, which are still frequently sung in cathedrals. He also adapted much of the music of Palestrina and Carissimi to English words with great skill and judgment. The catch "Hark, the bonny Christ Church bells" is one of his most admired compositions in the lighter style. Aldrich wrote a treatise on architecture; and practical evidence of his skill in the art may be seen in the church and campanile of All Saints, Oxford, and in three sides of the so-called Peckwater Quadrangle of Christ Church College, which were erected after his designs.

In classical scholarship Dr Aldrich had some reputation. The *Musæ Anglicanæ* contains two specimens of his Latin verse, the subjects being the accession of King William and the death of the Duke of Gloucester. A humorous Latin version by Aldrich of the popular ballad—

> "A soldier and a sailor,
> A tinker and a tailor," &c.,

has been preserved by Sir John Hawkins. Another specimen of his wit is furnished by the following epigram, entitled "Causæ Bibendi," which some, however, have ascribed to Père Sirmond:—

> *Si bene quid memini, Causæ sunt quinque bibendi;*
> *Hospitis Adventus, præsens Sitis, atque futura,*
> *Aut Vini Bonitas, aut quælibet altera Causa.*

The translation runs—

> If on my theme I rightly think,
> There are five reasons why men drink:—
> Good wine; a friend; because I'm dry;
> Or lest I should be by and by;
> Or—any other reason why.

ALDROVANDI, ULISSE, a celebrated naturalist, born of noble parentage at Bologna on the 11th Sept. 1522 (died 1607). While a boy he was page in the family of a rich bishop, and afterwards apprentice to a merchant in Brescia. Commercial pursuits soon became distasteful to him, and he turned his attention to law and medicine, studying first in his native town and afterwards at Padua. In 1550, having been accused of heresy, he was compelled to proceed to Rome in order to vindicate himself before the Inquisition, which gave him a conditional acquittal. In Rome he published his first work, a treatise on ancient statuary. Here he made the acquaintance of the eminent naturalist Rondelet, from whom it seems not unlikely that he derived the impulse towards what became from that time his exclusive study. On his return to Bologna he devoted himself specially to botany, under the teaching of Lucas Ghino, then professor of that science at the university. In 1553 he took his doctor's degree in medicine, and in the following year he was appointed professor of philosophy and also lecturer on botany at the university. In 1560 he was transferred to the chair of natural history, which he continued to occupy until rendered infirm by age. At his instance the senate of Bologna established in 1568 a botanical garden, of which he was appointed the first director. He was also instrumental in founding the still existing public museum of Bologna, which contains, especially in the natural history department, a large number of specimens collected by Aldrovandi. To procure these it is believed that he visited personally most of the countries of Europe, though the details of his journeys have not been preserved. Some idea of the extent of his labours may be gathered from the fact that his herbarium occupied sixty large folio volumes. To the other offices held by Aldrovandi was added that of inspector of drugs, in which capacity he published in 1574 a work entitled *Antidotarii Bononiensis Epitome*, deserving of notice as furnishing the model according to which nearly all subsequent pharmacopæias have been compiled.

The results of Aldrovandi's various researches were embodied in his *magnum opus*, which was designed on the most complete scale, so as to include everything that was known about natural history. The first three volumes, comprising his ornithology, were published in 1599. Three more, treating of insects and mollusca, appeared during the author's lifetime. The seven volumes which completed the work were compiled from Aldrovandi's manuscript materials, under the editorship of several of his pupils, to whom the task was entrusted by the senate of Bologna. The work was enriched by a large number of pictorial illustrations, prepared at great expense, the author having, it is said, employed several celebrated artists for thirty years. Among these were Lorenzo Benini of Florence and Christopher Coriolanus of Nuremberg. It has been said, indeed, that the cost of the undertaking was so great as to exhaust its author's means, and that he died penniless and blind in the public hospital of Bologna. This, however, is probably incorrect, at least as regards the allegation of poverty. Published records of the senate of Bologna show that it liberally supported Aldrovandi in his undertaking, doubling his salary soon after his appointment as professor and bestowing on him from time to time sums amounting in all to 40,000 crowns. If, therefore, he died in the public hospital, he probably went there for the better treatment of his disease. His death occurred on the 10th Nov. 1607.

Aldrovandi was chiefly remarkable for laborious and patient research. He seems to have been totally destitute of the critical faculty; and hardly any attempt is made in his great work to classify facts or to distinguish between the true and the fabulous, the important and the trivial. Much is thus included that is of no scientific value, but it also contains much information of very great interest to the naturalist.

ALDSTONE, or ALSTON MOOR, a market-town of England, in the county of Cumberland, situated on an eminence near the South Tyne, 19 miles E.S.E. from Carlisle, with which it is connected by railway. The surrounding country, which is bleak and desolate, contains lead mines, mostly belonging to Greenwich Hospital, formerly very valuable, but now almost exhausted. Thread, flannel, and shot are manufactured in the town. Population (1871) of parish, 5680; of town, 2627.

ALE, a fermented liquor obtained from an infusion of malt, and differing from beer chiefly in having a less proportion of hops. Before the introduction of hops into England from Flanders, about 1524, ale was the name exclusively applied to malt liquor, the term beer being gradually introduced at a later period to describe liquor brewed with an infusion of hops. The two words, however, are now used with little distinction of meaning. Ale, the wine of barley, is said to have originally been made in Egypt. The natives alike of Spain, France, and Britain all use an infusion of barley for their ordinary liquor, which was called *cœlia* and *ceria* in the first country, *cerevisia* in the second, and *curmi* in the third—all literally importing *the strong water.*

"All the several nations," says Pliny, "who inhabit the west of Europe have a liquor with which they intoxicate themselves, made of corn and water. The manner of making this liquor is sometimes different in Gaul, Spain, and other countries, and is called by many various names; but its nature and properties are everywhere the same. The people of Spain, in particular, brew the liquor so well that it will keep good a long time. So exquisite is the cunning of mankind in gratifying their vicious appetites that they have thus invented a method to make water itself intoxicate."

The method in which the ancient Britons and other Celtic nations made their ale is thus described by Isidorus and Orosius:—

"The grain is steeped in water, and made to germinate, by which its spirits are excited and set at liberty; it is then dried and ground; after which it is infused in a certain quantity of water, which, being fermented, becomes a pleasant, warming, strengthening, and intoxicating liquor."

This ale was most commonly made of barley, but sometimes of wheat, oats, and millet. Ale was the favourite liquor of the Anglo-Saxons and Danes. Before their conversion to Christianity, they believed that drinking large and frequent draughts of ale was one of the chief felicities which those heroes enjoyed who were admitted into the hall of Odin. Anciently the Welsh and Scots had two kinds of ale, called *common ale* and *spiced ale*, the relative values of which were thus appraised by law: "If a farmer had no mead, he shall pay two casks of spiced ale, or four casks of common ale, for one cask of mead." By this law a cask of spiced ale, nine palms in height and eighteen palms in diameter, was valued at a sum of money equal in value to £7, 10s. of our present money; and a cask of common ale of the same dimensions at a sum equal to £3, 15s. This is a sufficient proof that even common ale at that period was an article of luxury among the Welsh, which could only be obtained by the great and opulent.

For details as to the process of manufacture, statistics, &c., see BREWING.

ALE-CONNER, an officer appointed yearly at the court-leet of ancient manors for the assize of ale and ale-measures. The *gustatores cervisiæ*—called in different localities by the different names, "ale-tasters," "ale-founders," and "ale-conners"—were sworn to examine beer and ale, to take care that they were good and wholesome and were sold at proper prices. In London, four ale-conners are still chosen annually by the liverymen in common hall assembled, on Midsummer Day. Since ale and beer have become excisable commodities the custom of appointing ale-tasters has in most places fallen into disuse. (For the means now employed to test the quality of ales see ADULTERATION, p. 172.)

ALEANDRO, GIROLAMO (HIERONYMUS), cardinal, commonly called "the Elder," to distinguish him from his grand-nephew of the same name, was born at Motta, near Venice, on the 13th of February 1480 (died 1542). He studied at Venice, and while still a youth acquired great reputation for learning. In 1508 he went to Paris, on the invitation of Louis XII., as professor of belles lettres, and he held for a time the position of rector in the university. Entering the service of the prince-bishop of Liege, he was sent by that prelate on a mission to Rome, where Pope Leo X. retained him, giving him (1519) the office of librarian of the Vatican. In the autumn of 1520 he went to Germany to be present as papal nuncio at the coronation of Charles V., and in the following spring he appeared at the diet of Worms, where he headed the opposition to Luther, advocating the most extreme measures to repress the doctrines of the Reformer. His conduct not merely called forth the fiercest denunciations of Luther, but estranged from him Erasmus, who had been his intimate friend at Venice. The edict against the Reformer, which was finally adopted by the emperor and the diet, was drawn up and proposed by Aleandro. After the close of the diet the papal nuncio went to the Netherlands, where he kindled the flames of persecution, two monks of Antwerp, the first martyrs of the Reformation, being burnt to ashes in Brussels at his instigation. In 1523, Clement VII., having appointed him archbishop of Brindisi and Oria, sent him as nuncio to the court of Francis I. He was taken prisoner along with that monarch at the battle of Pavia (1525), and was only released on the payment of a heavy ransom. He was subsequently employed on various papal missions, especially to Germany, but was unsuccessful in preventing the German princes from making a truce with the Reformers, or in checking to any extent the progress of the new doctrines. In 1538 Paul III. conferred upon him the cardinal's hat, when he took the title of St Chrysogonus. He died at Rome on the 31st January or 1st February 1542.

Aleandro compiled a *Lexicon Græco-Latinum*, and wrote Latin verse of considerable merit. The Vatican library contains a volume of manuscript letters and other documents written by him in connection with his various missions against Luther. Its historical value renders this the most important of his works.

ALEMAN, LOUIS, Archbishop of Arles, and Cardinal of St Cecilia, was born at Bugey in 1390. He was one of the presidents of the Council of Basle in 1431, and led the party that maintained the supremacy of councils over popes in opposition to the claims of Eugenius IV. It was on his motion that the latter was deposed by the council, and Felix V. elected in his stead. Eugenius thereupon deposed the arch-pope, and deprived Aleman of all his ecclesiastical dignities, but these were restored by Nicholas V. in 1447, Felix V. having previously resigned, on the advice of the cardinal. In 1527 Aleman was canonised by Pope Clement VII.

ALEMANNI, a large German tribe on the Upper Rhine. They are first mentioned by Dion Cassius, who relates that the Emperor Caracalla gained, in 213 A.D., a victory over them on the banks of the Maine, and thence assumed the surname *Alemannicus.* The origin of this tribe, and the country from which they came, are unknown; but we have a distinct statement, which is apparently confirmed by the very name of the people, that they had flocked together from all parts, and were a mixed race. They proved most formidable enemies to the Romans as well as to the Gauls, their western neighbours, who to this day apply the name Alemanni (Allemands) to all the Germans indiscriminately, though the Alemanni, properly so called, occupied only the country between the Maine and the Danube. In the reign of Aurelian, 270 A.D., they attempted to invade Italy, but were repulsed. After the death of that emperor, however, they renewed their attacks by invading Gaul, and ravaging the country at different times. Several undertakings against them were of little avail, until in 357 A.D. the Emperor Julian completely defeated them in the neighbourhood of Strasburg, where all their forces were assembled under seven chiefs. This and other defeats, however, did not break the power of the Alemanni, who, being pressed on by other barbarians in the north, were forced to advance southward and westward to conquer new countries for themselves. Hence, after the middle of the 5th century, we find them established not only in the country now called Suabia, but also in a part of Switzerland and in Alsace. In these countries the Alemanni have maintained themselves ever since, and the greater part of the modern Suabians and the northern Swiss are descendants of that ancient race.

ALEMBIC (Arab. *alanbiq*, cognate to the Greek ἄμβιξ), an apparatus for distillation, used chiefly by the alchemists, and now almost entirely superseded by the retort and the worm-still. It varied considerably in form and construction, but consisted essentially of three parts—a vessel containing the material to be distilled, and called, from its gourdlike shape, the *cucurbit;* a vessel to receive and condense the vapour, called the *head* or *capital;* and a *receiver* for the spirit, connected by a pipe with the *capital.* The entire apparatus was sometimes constructed of glass, but as this rendered it very expensive and brittle, it was more usual to make the *cucurbit* of copper or earthenware, and the *capital* alone of glass.

ALEMTEJO (Spanish *Alentejo*), a province of Portugal, bounded on the N. by Beira, on the E. by Spanish Estremadura and Andalusia, on the S. by Algarve, and on the W. by the Atlantic and Portuguese Estremadura. It lies between 37° 20′ and 39° 40′ N. lat., and 6° 45′ and 8° 53′ W. long., and has an area of 10,225 square miles. Alemtejo is traversed by several mountain ranges, whose height does not generally rise much above 2000 feet, though one of the peaks of the Sierra de Monchique has an elevation of 4050 feet. The principal rivers are the Guadiana, which, crossing the Spanish frontier, flows southward through the province; and the Sado, which rises in the Sierra de Monchique, and flows to the north. Farther northward are the Soro and the Zatas, tributaries of the Tagus. All these rivers receive numerous affluents. There are several extensive plains, notably that of Alemtejo, the largest in Portugal, lying S.W. from the mountains of Portalegre; and that of Ourique, in the southern part of the province. Some portions of these plains are fruitful, others marshy, while large tracts are mere desolate wastes. The climate in the lower parts of the country is exceedingly hot, and is rendered unhealthy in summer by the stagnant marshes. Towards the Spanish frontier the soil is fertile, and in the south the country is covered by extensive forests of oak, pine, chestnut, cork, and holm, especially on the sides of the Sierras de Monchique and Caldeiraon. In the more fertile parts of the province, grapes, figs, citrons, pomegranates, and other fruits are produced. Wheat, maize, and rice are grown, and some attention is given to the rearing of mules, asses, goats, cattle, and sheep. Agriculture is, however, in a backward state, the sparse population being mostly concentrated in the towns, leaving extensive districts uncultivated and almost uninhabited. Droves of swine are fed on the waste lands, growing to a great size, and affording excellent hams. Minerals are to be found in the mountains, but they are little wrought. Manufactures scarcely exist, being confined to the preparation of olive oil of particularly good quality, and the making of earthenware, woollen cloths, and leather. For administrative purposes Alemtejo is divided into three districts—Beja, Evora, and Portalegre; and it contains 50 communal divisions and 315 parishes. The chief towns are Evora, Portalegre, Elvas, Beja, Estamoz, and Moura. There are no seaports of importance in the province. Population in 1868, 332,237.

ALENÇON, the chief town of the French department of Orne, situated in a wide and fertile plain, on the Sarthe, close to its confluence with the Briante. It is a clean, regularly-built town, with broad handsome streets. It is the seat of a bishop; and the Gothic church of Notre Dame, called the cathedral, is a fine building of the 16th century. The only remains of the ancient castle of Alençon are three towers that form part of the present town-hall. The lace known as "point d'Alençon" is the most noted manufacture of the town, although of late years its importance has somewhat diminished. Among the other industries are tanning, spinning, bleaching, linen manufacturing, and cider-making. The cutting of quartz crystals, often called Alençon diamonds, is also carried on. Alençon was a place of small importance when it was handed over to the Normans by Charles the Simple in the beginning of the 10th century. In 1025 it became subject to the De Belesmes, counts of Alençon, by whom it was enlarged and fortified. It was ceded to King Philip Augustus in 1221 by Alice, the heiress of the last count. The duchy of Alençon was created about the end of the 14th century, and remained with the original family, a branch of the house of Valois, until the middle of the 16th. The town was repeatedly taken and retaken in wars with Henry V. and Henry VI. of England, and also in the time of the League. In the war between France and Germany, Alençon was taken by the Germans under the Grand Duke of Mecklenburg on the 17th of January 1871. The townspeople did not offer much resistance. The mayor and municipality were, indeed, in favour of yielding without a struggle; but the newly-appointed prefect, an ultra-republican, insisted on a more martial policy. A feeble skirmish took place outside the town on the evening of the 16th of January, and the grand duke entered on the following morning without any further opposition. The Germans, as a punishment for the previous resistance, imposed on the citizens a fine of 300,000 francs, besides a large contribution of cattle, corn, and other provisions. Population (1872), 16,037.

ALENIO, GIULIO, a missionary of the Jesuit order, born at Brescia in 1582, died 1649. He became a member of the order in 1600, and arrived at Macao as a propagandist in 1610. For upwards of thirty years he laboured to spread Christianity in China, adopting, in accordance with the principles of his order, the dress and manners of the country. He was the first who planted the faith in the province of Kiang-Si, and he built several churches in the province of Fo-Kien. He composed a number of works in the Chinese language, of which he was thoroughly master, the most important being a *Life of Christ* and a *Cosmography.*

ALEPPO, or HALEB, a city of Syria, capital of the Turkish vilayet of the same name, in 36° 12′ N. lat., 37° 12′ E. long., 70 miles E. of the Mediterranean, near the N.W. extremity of the great Syrian desert. It occupies the site of the ancient *Beroea*, and is a place of great antiquity. After the destruction of Palmyra it speedily became the great emporium of the trade between the Mediterranean and the countries of the East. It was overwhelmed by the flood of Saracen invasion in 638; and in 1260, and again in 1401, it was plundered and laid waste by the Tartars. It finally came into the possession of the Turks in 1517. To the east of the modern city extensive remains of its ancient grandeur have been discovered.

Aleppo is built on eight low hillocks, and is encircled by limestone hills of greater elevation, while beyond these stretches a fertile plain. The river Koeik, the ancient *Chalus*, flows through the town, and loses itself in a morass 18 miles distant. It is subject to floods in winter, when it overflows its banks, and inundates the neighbouring gardens. The city is surrounded by a stone wall, 40 feet high and 3½ miles in circuit, erected by the Saracens. This wall is flanked by frequent towers, but the ditch is partially choked up; and the city, being commanded by the adjacent heights, is entirely indefensible. The wall is pierced by seven gates, which are known by different names. Outside the city there are large irregular suburbs, erected after the great earthquakes of 1822 and 1830, and increasing the circuit of the place to 7 miles. The city suffered very severely by the earthquake of 1822; two-thirds of the inhabitants were swallowed up, the citadel and many of the mosques were overthrown, and a great part of the town was laid in ruins. Before the occurrence of these disasters Aleppo was the fairest and cleanest of Turkish cities; and although it has only partially recovered from their calamitous effects, it has still an attractive appearance, especially when the white minarets of its numerous mosques, and its houses, picturesquely placed on the terraces of the hills, are viewed from a distance. The houses are built of freestone, with flat roofs, and are generally of two or three storeys. One of the mosques, that of Zacharias, is held in peculiar veneration by the Moslem inhabitants. A new citadel has been erected in the N.W. part of the town; and besides many mosques, warehouses, and bazaars, there are several Christian churches and schools, and also Turkish schools, libraries, and hospitals. Aleppo is the seat of a Greek and Armenian patriarch, and of a Maronite bishop. The Mahometan, the Christian, and the Jewish portions of the population dwell in separate quarters of the town. Water is brought to the city by an aqueduct from a distance of 8 miles, and supplies upwards of 200 fountains, massive structures standing in the streets. Among the chief attractions of Aleppo are its gardens, which extend continuously for about 12 miles S.E. of the city. They are watered by the Koeik, and produce abundance of fruit and culinary vegetables; but their most celebrated production is the pistachio-nut, which is regularly cultivated.

Formerly Aleppo stood in the first rank among the cities of Asia Minor as a place of trade; and it is still the emporium of Northern Syria, and has extensive commercial relations with Diarbekir and the upper parts of Anatolia, and also with Mosul and Baghdad. Large caravans resort to Aleppo from these and other eastern places, and the imported foreign goods are brought by caravans from the ports of Scanderoon or Alexandretta and Latakia. The construction of a carriage-road between Aleppo and Alexandretta has been commenced, but no progress whatever was made with it during 1872. Trade is conducted in Aleppo by more than 100 mercantile houses, several of them British; but no commercial bank has as yet been established in the province. The principal manufacture of the city consists of various kinds of cloth, of silk, cotton, and wool, some flowered and striped, others woven with gold and silver thread. These cloths have long been famous throughout the East, and the manufacture of them employs about 6400 looms. A large amount is invested in the manufacture of carpets, cloaks, and girdles. There are, besides, numerous soap, dyeing, and print works, and also rope-walks. In addition to cloths, the exports include wheat, sesame, wool, cotton, oil, scammony, galls, pistachio-nuts, camels' hair, &c.; while the imports chiefly consist of European manufactured goods and colonial produce. The aggregate value of the trade of the province exceeded £1,500,000 in 1872

The air of Aleppo is dry and piercing, but not insalubrious. The city, however, as well as the environs, is subject to a singular epidemic disorder called the boil of Aleppo. It attacks the inhabitants chiefly in their childhood, and the ulcers, which last for a year, commonly break out on the face. This malady is seldom fatal, and does not leave any hurtful effects except the scars, by which almost all the inhabitants are disfigured. The causes of the disease have not been discovered, though some have supposed it due to the quality of the water. Aleppo is also subject to the ravages of the plague, the recurrence of which is anticipated by the inhabitants every ten years. Its effects are rendered the more deadly by the blind fatalism of the Turks, who cannot be persuaded to take any precautions against the progress of this dreadful disease. In the end of last century about 60,000 of the inhabitants were swept off by one visitation; and that of 1827 was also very severe.

By the visitations of the plague, the earthquakes, the cholera of 1832, and the oppression of the Egyptians while Syria was subject to Mehemet Ali, the population of Aleppo has been much reduced. In the earlier part of the century the inhabitants numbered over 200,000; but the population is now estimated at less than 100,000, of whom 15,500 are Christians, 4000 Jews, and the remainder mostly Mahometans. Although the Christians enjoy toleration at the hands of the Turkish government, they have nevertheless been exposed to frequent persecution through the jealousy of the turbulent Mahometan population. The tumults of 1850 and 1862 occasioned some bloodshed, and could only be suppressed by force of arms. In the former, property to the amount of a million sterling was destroyed.

ALES, or ALESS (ALESIUS), ALEXANDER, a celebrated divine of the school of Augsburg, was born at Edinburgh on the 23d April 1500 (died 1565). His name was originally Alane, and that by which he is more generally known (derived from ἀλεείνω) was assumed by him when he went into exile. He studied at St Andrews in the newly-founded college of St Leonards, where he graduated in 1515. Some time afterwards he was appointed a canon of the collegiate church, and in this office he at first contended vigorously for the scholastic theology as against the doctrines of the Reformers. His views were entirely changed, however, on the occasion of the execution of Patrick Hamilton in 1528. He had been chosen to meet Hamilton in controversy, with a view to convincing him of his errors, but the arguments of the Scottish proto-martyr, and above all the spectacle of his intrepid conduct at the stake, impressed Alesius so powerfully that he was entirely won over to the cause of the Reformers, though for a time he did not make the fact known. A sermon which he preached against the dissoluteness of the clergy gave great offence to Prior Hepburn, who cast him into prison, and might have carried his resentment to the extremest limit had not Alesius contrived to escape to the Continent in 1531. After travelling in various countries of northern Europe, he settled down at Wittenberg, where he made the acquaintance of Melancthon, and signed the Augsburg confession. Meanwhile, he was tried in Scotland for heresy, and condemned without a hearing. In 1533 a decree of the Scottish clergy, prohibiting the reading of the New Testament by the laity, drew from Alesius an ably-argued defence of the right of the people, in the form of a letter to James V. A reply to this by John Cochlæus, also addressed to the Scottish king, occasioned a second letter from Alesius, in which he not only restates and amplifies his argument with great force and beauty of style, but enters at some length into more general questions connected with the Reformation. In 1535, Henry VIII. having broken with the Church of Rome, Alesius was induced to remove to England, where he was very cordially received by the king and his advisers Cranmer and Cromwell. After a short residence at Lambeth he was appointed, through the influence of Cromwell, then chancellor of the university, to lecture on theology at Cambridge; but when he had delivered a few expositions of the Hebrew psalms, he was compelled by the opposition of the papal party to desist. Returning to London, he supported himself for some time by practising as a physician. In 1537 he attended a convocation of the clergy, and at the request of Cromwell, the president, conducted a controversy with Stokesley, bishop of London, on the nature of the sacraments. His argument, which was marked by great ability, was afterwards published at Leipsic. In 1539 Alesius was compelled to flee for the second time to Germany, in consequence of the enactment of the persecuting statute known as the Six Articles. He was immediately chosen to fill a theological chair in the university of Frankfort-on-the-Oder, where he was the first professor who taught the Reformed doctrines. In 1543 he quitted Frankfort for a similar position at Leipsic, his contention that it was the duty of the civil magistrate to punish fornication having given offence to some of the authorities of the former university. At Leipsic Alesius remained until his death, which occurred on the 17th March 1565. He enjoyed the intimate friendship of Melancthon, to whom he rendered valuable assistance in many of his disputations with the Catholic doctors.

Alesius was the author of a large number of exegetical, dogmatic, and polemical works. He displayed his warm interest in his native land by the publication (1544) of a *Cohortatio ad Concordiam Pietatis, missa in Patriam suam*, which had the express approval of Luther. In 1560 appeared his treatise, *De Necessitate et Merito Bonorum Operum*, a valuable contribution to the synergistic side in the controversy on good works.

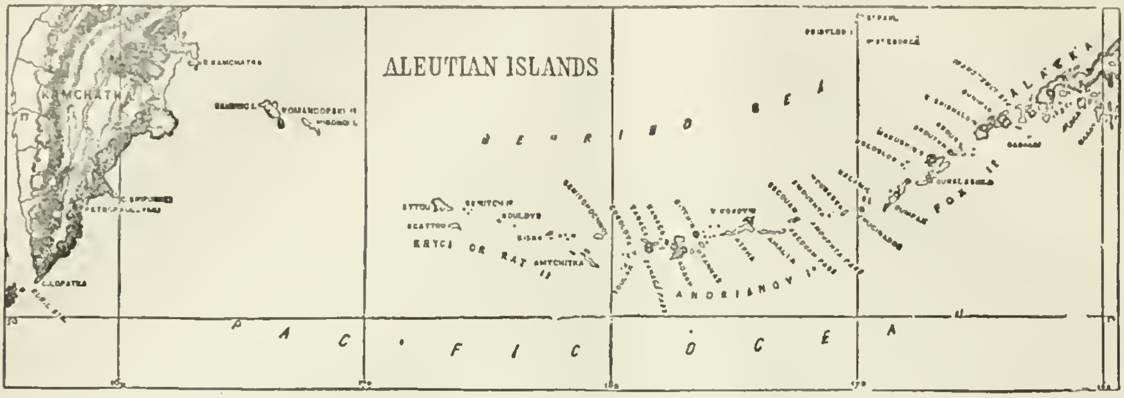
ALESSANDRI, Alessandro (*Alexander ab Alexandro*), a learned jurisconsult, born at Naples about the year 1461 (died 1523). He studied at Naples and Rome, and afterwards practised for a time as advocate in both cities. At Naples he is said to have been royal proto-notary in 1490. Dissatisfied, according to his own account, with the corrupt administration of justice, he at length quitted the bar, and devoted himself entirely to literary pursuits, especially to the study of philology and antiquities. A sinecure appointment, which he owed to the favour of the pope, enabled him to lead a life of learned leisure at Rome, where he died on the 2d October 1523. What is known of his biography has been gathered chiefly from detached statements in his work entitled *Dies Geniales*, which appeared at Rome in 1522, and is constructed after the model of the *Noctes Atticæ* of Aulus Gellius, and the *Saturnalia* of Macrobius. The work consists of a confused mass of heterogeneous materials relating to philology, antiquities, law, dreams, spectres, &c., and shows great credulity and want of judgment on the part of its author.

ALESSANDRIA, a province of Italy, in the former duchy of Piedmont, bounded on the N. by Novara, on the E. by Pavia, on the S. by Genoa, and on the W. by Turin; with an area of 1951 square miles. There are no hills of much elevation in the province, and the surface generally is flat. The chief rivers are the Po, the Tanaro, the Belbo, the Orba, and the Bormida. The soil is fertile, the chief products being wheat, maize, wine, silk, madder, hemp, flax, and fruit. The capital is Alessandria; population of the province in 1871, 683,361.

Alessandria, a city of Italy, the capital of the above province, is situated in a marshy district near the confluence of the Tanaro and the Bormida. It is a strongly fortified place, its citadel, on the left bank of the Tanaro, being one of the most important in Europe. The town itself, which lies chiefly on the right bank of the river, is the seat of a bishop, and contains a cathedral and more than a dozen other churches, besides monasteries and nunneries. The principal manufactures of Alessandria are silk, linen, and woollen goods, stockings, and hats. Large quantities of fruit and flowers are also produced in the neighbourhood. The trade of the city is extensive, and there are two important fairs held every year that are much resorted to by merchants from all parts of Italy. Alessandria was built in 1168 by the Lombard League as a bulwark against Frederick Barbarossa. It received its present name in honour of Pope Alexander III., but it was also called *Cesarea* for a time. In 1174 it was unsuccessfully besieged by Frederick Barbarossa, who nicknamed it in derision *Della Paglia*, *i.e.* "of straw." It was ceded to Savoy by the peace of Utrecht in 1713, after having belonged, at different periods, to the houses of Montferrat and Milan. Its fortifications were greatly enlarged and strengthened by Bonaparte during the French occupation, which lasted from 1800 to 1814. The citadel of Alessandria was taken by the Austrians after the battle of Novara in 1849. Near Alessandria is Marengo, where Napoleon defeated the Austrians in 1800. In consequence of this defeat the Austrians concluded the armistice of Alessandria, ceding all Italy north of the Mincio to the French. Population (1862), 27,027; of commune, 56,545.

ALESSI, Galeazzo (1500–72), a distinguished architect, born at Perugia, was a pupil of Caporali and a friend of Michael Angelo. He was an enthusiastic student of ancient architecture, and his style gained for him a European reputation. Genoa is indebted to him for a number of its most magnificent palaces, and specimens of his skill may be seen in the churches of San-Paolo and San-Vittoria at Milan, in certain parts of the Escurial, and in numerous churches and palaces throughout Sicily, Flanders, and Germany.

ALEUTIAN ISLANDS, so called from the Russian word *aleut*, signifying a bold rock, is the name given by the Russian discoverers to a chain of small islands situated in the Northern Pacific Ocean, and extending in an easterly direction from the peninsula of Kamtchatka, in Asiatic Russia, to the promontory of Alaska, in North America. This archipelago has been sometimes divided into three groups; the islands nearest Kamtchatka being properly called Aleutia, the central group the Andreanov or Andrenovian, and those nearest to the promontory the Fox Islands. They are all included between 52° and 55° N. lat., and 172° E. and 163° W. long. The Aleutian Islands were discovered by the Russian navigator Behring in 1728, and were carefully explored in 1760 by Captain Krenitzin, under a commission from the Empress Catherine. During his third and last voyage, in the year 1778, Captain Cook surveyed the eastern portion of the archipelago, accurately determined the positions of some of the most remarkable islands, and corrected many errors of former navigators. Subsequent expeditions of the Russians, aided by the settlement of fur traders on the islands, as well as on the neighbouring coasts of the American continent, have afforded further information as to this remarkable chain. The whole of the islands are bare and mountainous; and their coasts are rocky and surrounded by breakers, by which the approach is rendered exceedingly dangerous. The land rises immediately from the coasts to steep bald mountains, gradually ascending into lofty ranges running from east to west. Springs take their rise at the bottom of the mountains, and either flow in broad and rapid streams into the neighbouring sea, or, collecting in the rocky vales and glens, form ample lakes, which send off their superfluous waters by natural canals into the adjacent bays. These islands bear evident marks of volcanic formation, and several of them have still active volcanoes, which continually emit smoke and sometimes flames. The most important group of the chain is that called the Fox Islands, of which the largest are Unimak and Ounalaska, both near the western extremity of Alaska. The thin argillaceous soil of the Aleutian Islands produces little vegetation, and agriculture is almost unknown. The climate is subject to sudden changes, and is very unfavourable to any attempts at cultivation. Few trees grow on the islands, but there are some stunted shrubs of birch, willow, and alder. The timber required for building purposes is obtained from the driftwood thrown on the coasts. The principal occupations of the Aleutians are fishing and hunting; and the preparation of the implements necessary for both. Since the end of last century the fur traders have had settlements here for the capture of the seal and the sea-otter, which are found in great numbers on the shores; and of the Arctic fox, which roams over the islands. Fish are abundant; and dogs and reindeer are common. The population of the whole group is about 8000, the natives being a kindred race to the inhabitants of Kamtchatka. They are described as rather low in stature, but plump and well-shaped, with short necks, swarthy faces, black eyes, and long straight black hair. They have nominally been converted to Christianity by the missionaries of the Greek Church, but are said to be unchaste in their habits, and addicted to intemperance whenever they have the opportunity. Until 1867 these islands belonged to Russia, but they were included in the transfer to the United States of the whole Russian possessions in America made in that year. They now form part of the United States territory of Alaska. (See ALASKA.) From the position of the Aleutian Islands, stretching like a broken bridge from Asia to America, some ethnologists have supposed that by means of them America was first peopled.



ALEXANDER THE GREAT

ALEXANDER III., commonly called "The Great," son of Philip II., king of Macedonia, and of Olympias, daughter of the Molossian chief Neoptolemus, was born at Pella, 356 B.C. His father was a man of fearless courage and the soundest judgment; his mother was a woman of savage energy and fierce superstition. Alexander inherited the qualities of both his parents, and the result was the combination of a boundless ambition with the most sober practical wisdom. The child grew up with the consciousness that he was the heir of a king whose power was rapidly growing; and the stories told of him attest at the least the early awakening of a mind formed in the mould of the heroes of mythical Hellas. Nay, the blood of Achilles was flowing, as he believed, in his veins; and the flattery of his Acarnanian tutor Lysimachus, who addressed him as the son of Peleus, may have strengthened his love of the immortal poems which told the story of that fiery warrior. By another tutor, the Molossian Leonidas, his vehement impulses were checked by a wholesome discipline. But the genius of Alexander, the greatest of military conquerors, was moulded in a far greater degree by that of Aristotle, the greatest conqueror in the world of thought. At the age of thirteen he became for three years the pupil of a man who had examined the political constitutions of a crowd of states, and who had brought together a vast mass of facts and observations for the systematic cultivation of physical science. During these three years the boy awoke to the knowledge that a wonderful world lay before him, of which he had seen little, and threw himself eagerly, it is said, into the task of gathering at any cost a collection for the study of natural history. While his mind was thus urged in one direction, he listened to stories which told him of the great quarrel still to be fought out between the East and the West, and learnt to look upon himself as the champion of Hellas against the barbarian despot of Susa.

The future conqueror was sixteen years of age when he was left at home as regent while his father besieged Byzantium and Perinthus. Two years later the alliance of Thebes and Athens was wrecked on the fatal field of Chæronea, where Alexander, now eighteen years of age, encountered and overcame the Sacred Band which had been foremost in the victories of Leuctra and Mantinea (see EPAMINONDAS); but the prospects of Alexander himself became now for a time dark and uncertain. Philip had divorced Olympias and married Cleopatra, the daughter of Attalus. This act roused the wrath not only of Olympias, but of her son, who with her took refuge in Epirus. Cleopatra became the mother of a son. Her father, Attalus, rose higher in the king's favour, and not a few of Alexander's friends were banished. But the feuds in his family were subjects of serious thought for Philip, who sought to counteract their ill effects by a marriage between his daughter and her uncle, the Epirot king Alexander, the brother of Olympias. The marriage feast was celebrated at Ægæ. Clothed in a white robe, and walking purposely apart from his guards, Philip was approaching the theatre when he was struck down by the dagger of Pausanias.

It is certain that Alexander, if he mourned his father's death at all, deplored it only as involving himself in political difficulties; but he took care to act as if he were grieved by it, and he revenged it, we are told, by putting out of the way some whose claims or designs might clash with his own. The Greeks of Thebes and Athens knew little what sort of man had taken the place of Philip. Demosthenes, who, although he was mourning for the death of his own daughter, appeared in festal attire to announce the death of the Macedonian king, held up Alexander to ridicule as a bragging and senseless Margites. But they had to reckon with one who could swoop on his prey with the swiftness of the eagle. Barely two months had passed from the death of his father before the youth of twenty years stood with his army on the plains of Thessaly. The argument of the Macedonian phalanx was not to be resisted. The Thessalians recognised him as the *Hegemôn* or leader of the Greeks; and the young king passed on to Thebes, the citadel of which had been held by a Macedonian garrison since the fight at Chæronea. Thence he took himself across the isthmus to Corinth. Here he was met by Athenian envoys, who brought him apologies more abject and honours more extravagant than any which had been paid to his father. He received them in an assembly, from which he demanded and obtained the title of supreme leader of the Hellenic armies, and to which he guaranteed, at the utmost with a feigned reluctance, the autonomy or independence of every Hellenic city. No one knew better than Alexander that from the whole armoury of weapons which might be employed to reduce Greeks to slavery, none could more effectually do his work than a theory of freedom which meant dissension, and of self-government which meant endless feud, faction, and war.

Alexander was now eager to carry out his great design against Persia; but he could not do so with safety until he had struck a wholesome terror of his power into the mountain tribes which hemmed in his dominions. His blows descended swiftly and surely on the Thracians of Mount Hæmus (*the Balkan*), on the Triballians, and on some clans of Getæ, whom he crossed the Danube to attack. But these expeditions led him away from the world of the Greeks. Silence led to rumours of his defeat, and the rumours of defeat were followed by more confident assertions of his death. At Thebes and at Athens the tidings were received by some with eager belief. The covenant made with Alexander was made only with him personally. The Theban exiles at Athens were anxious to repeat the attempt which half a century earlier had been made against the Spartan garrison of the Cadmea by Pelopidas. With help in arms and money from Demosthenes and other Athenians, they entered Thebes, and summoned the Macedonian garrison to surrender. The answer was a blunt refusal, and a double line of circumvallation was drawn around the citadel, while envoys were sent to call forth aid from every quarter; but these efforts could not affect the issue. The belief in Alexander's death was to be dispelled, by no gradual reports of his escape from the barbarians, but by his own sudden appearance at the Bœotian Onchestus. He had just defeated the Illyrians when he heard of the revolt, and he determined to smite the rebels without turning aside to take even a day's rest at Pella. In little more than a fortnight his army was encamped on the southern side of Thebes, thus cutting off all chances of aid from Athens. It was his wish to avoid an assault, and he contented himself with demanding the surrender of two only of the anti-Macedonian leaders. The citizens generally were anxious to submit, but the exiles felt or feared themselves to be too deeply committed; and the answer took the form of a defiance, accompanied by a demand for the surrender of Antipater and Philotas. They had sealed their own doom. Personal bravery was of no use against the discipline, the numbers, and the engines of the enemy. The defenders were driven back into the city; the invaders burst in with them; and the slaughter which followed was by no means inflicted by the Macedonians alone. The Platæans, Thespians, and Orchomenians felt that they had old scores to settle. To these and to the rest of his Greek allies Alexander submitted the fate of the city. The sentence was promptly pronounced. The measure which the Thebans had dealt to Platææ, and would have dealt to Athens, should now be dealt out to themselves. The whole town was razed to the ground, the house of the poet Pindar being alone spared from demolition, and his descendants alone allowed to retain their freedom. Alexander had gained his end. The spirit of the Greeks was crushed; a great city was blotted out, and the worship of its gods was ended with its ruin. These gods, it was believed, would in due time take vengeance on the conqueror; but for the present the only hindrance to his enterprise was removed from his path. Without turning aside to Athens, he went on to Corinth to receive the adulations of the independent Greeks, and to find, it is said, a less courtly speaker in the cynic Diogenes. From Corinth he returned to Macedonia, having left Greece for the last time.

Six months later he set off from Pella, crossed the Hellespont at Sestus, to appease at Ilium by a costly sacrifice the wrath of the luckless Priam; and then marched on, with not more perhaps than 30,000 infantry and 4000 cavalry, and with a treasure-chest almost empty, to destroy the monarchy of Cyrus. With him went men who were to be linked with the memory of his worst crimes and of his most astonishing triumphs—Clitus, Hephæstion, Eumenes, Seleucus, Ptolemy the son of Lagos, and Parmenion, with his sons Philotas and Nicanor. The effects of Macedonian discipline were to be seen at once on the banks of the Granicus, a little stream flowing to the Propontis from the slopes of Ida. Losing, it is said, only 60 of his cavalry and 30 of his infantry, he annihilated the Persian force, 2000 out of 20,000 foot soldiers being taken prisoners, and nearly all the rest slain. The terror of his name did his work as he marched southwards. The citadel of Sardis might with ease have been held against him: before he came within eight miles of the city, the governor hastened to surrender it with all its treasure. At Ephesus he found the city abandoned by its garrison. Miletus he carried by storm. Before Halicarnassus he encountered a more obstinate resistance from the Athenian Ephialtes; but the generalship of the latter was of no avail. Alexander entered Halicarnassus, and the Rhodian Memnon remained shut up in the citadel. Leaving Ptolemy with 1000 men to blockade it, he spent the winter in conquering Lycia, Pamphylia, and Pisidia, ending his campaign at Gordium, on the river Sangarius. Here was preserved the ancient waggon of Gordius, the mythical Phrygian king. Whoever could untie the knot, curiously twisted with fibres of the cornel tree, which fastened its pole to the yoke, was, so the story ran, to be lord of Asia. Alexander, as much at a loss as others to unloose it, cut it with his sword; but the prophecy was none the less held to be fulfilled. If he was thus favoured by sentiment, he was still more favoured by the infatuation which led Darius to abandon the policy of defence by sea for offensive warfare by land. From all parts of his vast empire was gathered a host, numbering, as some said, 600,000 men; and the despot was as much elated at the sight as Xerxes when he looked down on his motley multitudes at Doriscus. Like Xerxes he had one (the Athenian Charidemus) by his side to warn him that Asiatic myriads were not to be trusted in an encounter with the disciplined thousands of Alexander; but he lacked the generosity which made Xerxes dismiss Demaratus with a smile for his good-will. Darius seized the exile with his own hand, and gave him over to the executioner. "My avenger," said Charidemus, "will soon teach you that I have spoken the truth." The Persian acted as though he wished to bring about the speediest fulfilment of the prediction. The Greek mercenaries were withdrawn from the fleet to be added to the land forces; but although a hundred of these could have effectually barred the passage of Alexander across the range of Taurus, and the passes of the Amanian, Cilician, and Assyrian gates, the invader was suffered to cross these defiles without the loss of a man. Nay, so great was the contempt of Darius for the few thousands of the enemy, that he wished to give them a free path until they reached the plain from which he would sweep them away. But he could not wait patiently for them in his position to the east of the Amanian range. Alexander had been ill, and he had work to do in subjugating western Cilicia. When at length he set out on his march to the southern Amanian pass, Darius, with his unwieldy train, crossed the northern pass, and entered Issus two days after Alexander had left it. He had placed himself in a trap. In a space barely more than a mile and a half in width, hemmed in by the mountains on the one side and the sea on the other, Darius, in his royal chariot, in the midst of multitudes who had scarcely room to move, awaited the attack of Alexander, who fell suddenly on his right wing. The first onset was enough. The Persians broke and fled. Darius, thinking himself in danger, fled among the foremost. The Persian centre behaved well; but it mattered little now what they might do. Even the Greek mercenaries were pushed back and scattered. Four thousand talents filled the treasure-chest of the conqueror, and the wife, mother, and son of Darius, appearing before him as prisoners, were told that they should retain their royal titles, his enterprise being directed, not against Darius personally, but to the issue which was to determine whether he or Alexander should be lord of Asia.

The true value of armed Asiatic hordes was now as clear to all as the sun at noonday. Parmenion advanced to attack Damascus, but he needed not to strike a blow. The governor allowed the treasure in his charge to fall into his hands, and then surrendered the city. Alexander himself marched southward to Phœnicia. At Marathus he replied to a letter in which Darius demanded the restoration of his family and reproached him for his wanton aggression. His answer repeated what he had already said to his wife, adding that, if he wrote again, Darius must address him, not as his equal, but as his lord. "I am now master of Asia," he wrote, "and if you will not own me as such, I shall treat you as an evil-doer. If you wish to debate the point, do so like a man on the battlefield. I shall take care to find you wherever you may be." The island city of Aradus was surrendered on his approach. Sidon opened her gates. From the Tyrians he received a submission which demurred only to his entering their city. A siege of seven months ended in its fall; and Alexander hanged 2000 of the citizens, it is said, on the sea-shore. The survivors, with the women and children, were sold as slaves. Before the catastrophe of the great Phœnician city he had received a second letter, in which Darius offered him his daughter in marriage, together with the cession of all lands to the west of the Euphrates. "Were I Alexander," said Parmenion (if we may believe the story), "I should take these terms, and run no further risk." "So should I," answered Alexander, "if I were Parmenion; but as I am Alexander, I cannot." "You offer me," he wrote accordingly to Darius, "part of your possession, when I am lord of all. If I choose to marry your daughter, I will do so whether you like it or not." Darius sent no more letters. The issue, he saw, must be determined by the sword. For the present he was left to himself. Alexander's face was turned towards Egypt. Gaza dared to resist; but a siege of two months was followed by a ruin as complete as that of Tyre. From Gaza a march of seven days brought him to Pelusium. The Persian governor opened its gates to receive him; and the Egyptians expressed their delight at exchanging a Persian for a Macedonian master. Marching in triumph to Memphis, he offered solemn sacrifice to the calf-god Apis; and then, with the true instinct of the ruler and the statesman, he hastened to found for his new kingdom a new capital, which, after more than two millenniums, remains a highway for the commerce of three continents.

Success thus unparalleled was, it would seem, already producing its effects upon him. Calmly reviewing the course of his march from Sestus and Ilium to Memphis, he could explain it only on the supposition that he was no child of a human father, and he determined to obtain from the oracle of Ammon, in the Libyan Oasis, a solution of this mystery. The response greeted him as the son, not of Philip, but of Zeus; and he returned, it is said, with the conviction that the divine honours paid to Hercules 331 B.C.
and Perseus were his own by indubitable right. Marching back through Phœnicia, he hastened to Thapsacus, and then crossed the Euphrates. Thence turning northwards, he made a sweep which brought him to the Tigris below Nineveh (*Mosul*), and there, without opposition, crossed a stream where the resistance of a few hundreds might have destroyed his army. After a few days' march to the south-east, he received the news that Darius, with all his host, was close at hand. Still convinced that mere numbers must, with ample space, decide the issue of any fight, and attributing his defeat at Issos only to the cramped position of his troops, he had gathered a vast horde, which some represent as more than a million, on the broad plain stretching from Gaugamela eastwards to Arbela. His hopes were further raised by changes made in the weapons of his troops, and more especially in the array of his war-chariots. For the Macedonians it is enough to say that they were led by a man whose consummate generalship had never shone more conspicuously than in the cautious arrangements which preceded the battle of Arbela, or rather of Gaugamela. All went as he had anticipated. As at Issus, Darius fled; and the bravery and even gallantry of the Persians opposed to Parmenion were of no avail when the main body had hurried away after the king. So ended the last of the three great battles (if such they may be termed) which sufficed to destroy the Persian empire, or rather to make Alexander king of Persia; and so ended the first act in the great drama of his life.

The victory of Gaugamela opened for the conqueror the gates of Babylon and Susa. The treasures found in the former furnished an ample donation for all his men: those of Susa amounted, it is said, to nearly twelve millions of pounds sterling. The Persian king had wasted men on the battlefield; he had hoarded coin which, freely spent in getting up a Greek army under Greek generals, might have rendered the enterprise of Alexander impossible. From Susa the conqueror turned his face towards Persepolis, the ancient capital of Cyrus. Before him lay the fortresses of the Uxii, to whom the Persian monarchs had been accustomed to pay tribute when they went from the one capital of their kingdom to the other. The same demand was now made of Alexander, who told them to come to the pass and take it, and then, following a new track which had been pointed out to him, descended on their villages, and taught them that they had now to deal with a sovereign of another kind. With Persepolis, Pasargadæ, the city containing the tomb of Cyrus, opened its gates to receive the avenger of the iniquities of Xerxes. As such, he determined to inflict on Darius a signal punishment. Five thousand camels and a crowd of mules bore away the treasure, amounting, it is said, to nearly thirty millions of pounds sterling, and then the citadel was set on fire. The men in the city were killed, the women made slaves.

For a month Alexander allowed his main army to rest near Persepolis; for himself there could be no repose. With his cavalry he overran, and, in spite of the rigours of winter, subdued, the whole region of Farsistan. Then returning to Persepolis, he set forth on his march to Media, where the fugitive king had hoped to be safe from his pursuit. Darius had left Agbatana (Ecbatana) eight days before his pursuer could reach it. In this ancient fastness of the Median and Persian sovereigns Alexander deposited his treasures, exceeding, we are told, forty millions sterling in amount, under the charge of a strong Macedonian garrison headed by Parmenion. He then hastened on towards the Caspian gates, and learnt, when he had passed them, that Darius had been dethroned, and was now the prisoner of the Bactrian satrap Bessus. The tidings made Alexander still more eager to seize him. His efforts were so far successful that Bessus felt escape to be hopeless unless Darius could be made to leave his chariot and fly on horseback. He refused to obey, and was left behind, mortally wounded. Before Alexander could reach him, he was dead.

The conqueror now regarded, or professed to regard, himself as the legitimate heir and successor of Xerxes. His course of conquest was still unbroken; but successful forays against the Mardians on the northern slopes of Mount Elburz, against the Arians of the modern Herat, and the Drangians of the present Seistan, were followed by an exploit of another sort. He had heard that a conspiracy against himself had been revealed to Philotas, who for two days had kept the secret to himself. On being asked why he had done this, Philotas answered that the information came from a worthless source and deserved no notice. Alexander professed himself satisfied with the explanation; but Philotas, it seems, had spoken freely to his mistress Antigone of the large share which he and his father had had in the conquests of Alexander, and Antigone had in her turn become an informer. Of real evidence against Philotas there was none; and a letter from Parmenion to his sons, found when Philotas was treacherously arrested, could tell against them only in the eyes of one who was resolved that Philotas should die. But Alexander could not rest content with his death alone. There had been nothing yet, even in the way of shadowy slander, to criminate Parmenion, and he resolved that the needful charges should be drawn by tortures from his son. Hidden by a curtain, the conqueror of the world watched the agonies and scoffed at the screams of the friend who had fought by his side in a hundred fights. The issue was, or was said to be, what he desired. Philotas had confessed; and Alexander sent off to Ecbatana a man bearing two despatches, one to cheat Parmenion into a false security, the other carrying to the officers next to him in command the real order for his assassination. The old man was reading the lying letter of the despot when he received a mortal stab in his back. The soldiers, on hearing of what had been done furiously demanded the surrender of the murderers, and were with difficulty withheld from taking summary vengeance on seeing the written orders of Alexander. The command of Philotas, who had been at the head of the companion-cavalry, was shared between Clitus and Hephæstion; and Alexander turned from private murder to public war. The autumn and winter were spent in overrunning parts of the modern Afghanistan and Cabul, in the formation of the Caucasian Alexandria, and in the passage of the Hindu-Kush. He was now in the satrapy of Bessus. The surrender of Aornus and Bactra was followed by the passage of the Oxus and by the betrayal of Bessus, who was sent naked and in chains to the city which had been his capital. His next exploit (there is but slender ground for calling it into question) was the slaughter, in Sogdiana, of the descendants of the Milesian Branchidæ, who, having incurred the hatred of their fellow Greeks by surrendering to Xerxes the treasures of their temple, had followed the despot on his retreat, and by him had been placed in these distant regions. Five generations had passed away since that time, when Alexander gave the order that not one of them, man, woman, or child, should be left alive. From the ruined city, by way of Maracanda (*Samarkand*), he reached the Jaxartes (which he believed to be the Tanais or *Don*), and having laid on its banks the foundation of another Alexandria, he crossed the river to chase some Scythians who had shown themselves on the further side. The end of this chase marked the northernmost point reached in his campaigns.
The winter was spent in the Bactrian city of Zariaspa, 329-328
where Alexander, summoning Bessus before him, had his B.C.
nose and ears cut off, and then sent him to be killed by his countrymen at Ecbatana.

In the following summer his army was gathered again at Maracanda. Repose from field-work left room for the display of the overbearing pride to be expected from one who had convinced himself that he was a god, and for the boundless flattery of those who found their interest in keeping up the delusion. But there were not wanting others to whom this arrogance and servility were intensely disgusting, and whose anger was the more fierce from the necessity of avoiding all open expression of it; and in the banquets of the divine son of Ammon there was always a risk that these pent-up feelings might burst forth like a winter torrent. The catastrophe was not long in coming. In a feast at Maracanda, Alexander, boasting of all that he had done since the death of his father, took credit further for the victories of Philip in the later years of his reign. The patience of Clitus had long been severely taxed, and in the heat of the revel all thought of prudence was cast aside. He spoke his mind plainly, telling Alexander that all his exploits taken together were not equal to those of the man who had found Macedonia a poor and distracted country, and had left it a mighty and coherent state; and that his own greatest victories had been won through the aid of Philip's old soldiers, some of whom he had murdered. Stung to the quick, Alexander gave utterance to his rage; but his retort only led Clitus to remind him of the battlefield of the Granicus, where he had saved him from death by cutting off the arm of the Persian whose sword was raised to smite him, and to warn him that, if he could not bear to listen to the words of truth, he should confine himself to the society of slaves. Alexander felt for his dagger: it had purposely been placed out of his reach. He called to his guards to sound an alarm: they hesitated to obey the orders of a raving drunkard. Some of the more sober and moderate of the party held him in their arms, praying him to do nothing hastily. By way of answer he reviled them for keeping him a prisoner as Bessus had kept Darius, and shaking himself free, snatched a pike from one of the guards, and thrust it through the body of

Clitus, bidding him go to Philip and Parmenion. The rage of the tiger was followed by a furious remorse, in which, with considerable truth, he denounced himself as unfit to live. For three days he would neither eat nor drink; and the army, alarmed at the threatened starvation of their king, voted that Clitus had been justly slain, and that his body should not receive the rites of burial. By reversing this vote, Alexander seemed to feel that he had gone a long way towards acquitting himself; whatever might be yet lacking to restore his self-complacence was supplied by the prophets, who assured him that the disaster had been brought about wholly by the Theban wine-god Dionysus, to whom he had offered no sacrifice on the day of the banquet.

A few weeks after this murder Alexander captured the Sogdian rock, a fastness from which common care would have sent him away baffled. Having next reduced the rock of Chorienes, he returned to Bactra to celebrate his marriage with Roxana, the daughter of Oxyartes, who had been among the captives taken on the Sogdian rock. The feast was seized by Alexander as an opportunity for extracting from his Greek and Macedonian followers a public acknowledgment of his divinity. It was arranged that the sophist Anaxarchus (or, as some said, the Sicilian Cleon) should make a speech, advising all to worship at once the man whom they would certainly have to worship after his death. The speech was delivered. The silence of most of the Macedonian officers showed their disgust: but none ventured to speak until the Olynthian Callisthenes, the nephew of Aristotle, insisted on the impiety of all attempts to confound the distinctions between gods and men. Conceding to the conqueror the highest place amongst military leaders and the first rank amongst statesmen, he rebuked Anaxarchus for making a suggestion which ought to have come from any one rather than from himself. The applause which his words drew from the Macedonians taught Alexander that open opposition would be useless; but he was none the more turned from his purpose, nor was it long before he found a pretext for carrying it out. A conspiracy was discovered amongst his pages. These unfortunate men were tortured (but without extracting from them anything to implicate Callisthenes), and then stoned to death,—as Alexander would have it, not by his orders, but by the loyal impulse of his army. Callisthenes he was resolved, he said, to punish himself, together with those who had sent him,—an insinuation, manifestly, against his uncle Aristotle, possibly also against all other Greeks, for whom freedom of speech and action had not yet altogether lost its value. The philosopher who had extolled Alexander as the greatest of earthly generals and statesmen was first tortured and then hanged; and the conqueror went calmly on to subdue the regions between the Hindu-Kush and the right bank of the Indus, and to storm the impregnable rock of Aornus.

The next river to be crossed was the Indus. The bridge was constructed by Hephæstion and Perdiccas, probably near the present Attock. The surrender of Taxila left Alexander an open path until he reached the Hydaspes (*Jhelum*), where Porus was beaten only after a severe struggle. The Indian prince was taken prisoner, and treated with the courtesy which the family of Darius had received after the battle of Issus. Here died Alexander's horse Boukephalos (Bucephalus), and the loss was commemorated by the founding of Bucephalia. The passage of the Acesines (*Chenab*), running with a full and impetuous stream, was not accomplished without much danger; that of the Hydraotes (*Ravee*) presented less formidable difficulties, but he was encountered on the other side by Indians, who entrenched themselves in their town of Sangala. Their resistance ended, it is said, in the slaughter of 17,000 and the capture of 70,000. About 40 miles further to the south-east flowed the Hyphasis (*Sutlej*). Alexander approached its bank, the limit of the Panjab, in the full confidence that a few days more would bring him to the mighty stream of the Ganges; but he had reached the goal of his conquests. The order for crossing the river called forth murmurs and protests at once from his officers and his soldiers, who expressed plainly their refusal to march they knew not whither. Alexander in vain laid before his officers his schemes of further conquest; and when he offered the sacrifice customary before crossing a river, the signs were pronounced to be unfavourable. The die was cast. Twelve huge altars remained to show that Alexander had advanced thus far on his conquest of the world; and, in the midst of deluges of rain, the army set out on its westward journey. The reinforcements which he found on reaching the Hydaspes might, if they had advanced as far as the Hyphasis, have turned the scale in favour of progress to the east; they enabled Alexander to undertake with greater ease a voyage down the Hydaspes to its junction with the Indus after receiving the waters of the Acesines, Hydraotes, and Hyphasis, and thence onwards to the Indian Ocean. From the mouth of the Indus he ordered his admiral Nearchus to take the fleet along the shores of the ocean and the Persian Gulf to the mouth of the Tigris. The army marched by land through the Gedrosian desert, suffering more from thirst and sickness than they had suffered in all their battles and forced marches. At length he reached Pasargadæ, to find the tomb of Cyrus broken open and plundered, and to avenge the insult offered to the man whom he now regarded as the founder of his own dynasty. Early in the following year he entered Susa, and there, celebrating his marriage with Statira, the daughter of Darius and of Parysatis the daughter of his predecessor Ochus, he offered to pay the debts of those soldiers who would follow his example by taking to themselves Persian wives—a strange mode of inviting sober and steady men who had no debts, but an effectual argument for the spendthrifts and ruffians of his army. His new levies of Persian youths, armed and disciplined after the Macedonian fashion, had now made him independent of his veteran soldiers; and his declared intention of sending home the aged and wounded among them called forth the angry remonstrances of their comrades, who bade him complete his schemes of conquest with the aid of his father Ammon. Alexander rushed into the throng, seized some and had them executed, and then disbanded the whole force. For two days he shut himself up in his palace; on the third he marshalled his Persian levies (*Epigoni*, as he called them) into divisions bearing the Macedonian military titles, under Persian officers. The spirit of the veterans was broken by this ignoring of their existence. They threw down their arms at the palace gates, and begged forgiveness with cries and tears. Alexander accepted their contrition, and the restoration of harmony was celebrated by a sumptuous sacrifice.

But for Alexander past victories were only a stimulus to further exploits. Arabia still remained unsubdued, and for this conquest a large addition was needed to his fleet. Orders were sent to Phœnicia for the construction of ships, which were to be taken to pieces and sent overland to Thapsacus on the Euphrates, while others were to be built at Babylon. His journey to Ecbatana was marked by a violent quarrel between Eumenes and Hephæstion. Their reconciliation was soon followed by the death of the latter from an attack of fever. The grief of the conqueror was as fierce as that of Achilles, if we may not set it down as a manifest imitation of it. For two days he neither ate nor drank; he cut his hair short, and ordered that the horses and mules in his army should have their manes

docked also. Human blood could scarcely be shed with prudence on his pyre; but he was resolved that his friend should begin his life in the unseen world with unstinted wealth, and the precious things destined to be consumed on his funeral pile represented, it is said, a sum of nearly two millions and a half pounds sterling. Messengers were sent to the Egyptian oracle to ask if the dead man might be worshipped as a god, and Eumenes, with many others, took care to anticipate its answer by offering him such honours as might fall in with the humour of the divine mourner. His grief seemed only to render his bursts of passion more fearful. None dared to address him except in language of the most grovelling flattery; and, in the words of Plutarch, his only consolation was found in his old habit of man-hunting. The diversion was this time
23 B.C. furnished by some mountain tribes between Media and Farsistan. His march to Babylon steeped him still more in the intoxication of success. As he advanced on his road he was met by ambassadors not only from Illyrians and Thracians, from Sicily and Sardinia, from Libya and Carthage, but from Lucanians and Etruscans, and, as some said, from Rome itself. The lord of all the earth could scarcely look for wider acknowledgment or more devout submission; but his self-gratulation may have been damped by the warning of the Chaldean priests that it would be safer for him not to enter the gates of Babylon. For a while he hesitated, but he had more to do than to heed their words. The preparations for his Arabian campaign must be hurried on; all that might be needed must be done to improve the navigation of the Euphrates, and a new city must be built to rival, perhaps, the Alexandria which he had founded by the banks of the Nile. More than all, he had to celebrate the obsequies of Hephæstion, whose body had been brought to Babylon from Ecbatana. The feasting which everywhere accompanied the funeral rites of the ancient world was exaggerated by the Macedonians, as by other half rude or savage tribes, into prolonged revelry. Alexander spent the whole night drinking in the house of his friend Medius, and the whole of the next day in sleeping off his drunkenness. Throughout the following night the same orgies were repeated. When he next awoke he was unable to rise. Fever had laid its grasp upon him, and each day its hold became tighter, while he busied himself incessantly with giving orders about his army, his fleet, his generals, until at length the powers of speech began to fail. When asked to name his successor, he said that he left his kingdom to the strongest. His signet-ring he took from his finger and gave to Perdiccas. Throughout the army the tidings of his illness spread consternation; old grudges were all forgotten; his veterans forced themselves into his presence, and with tears bade farewell to their general, who showed by signs that he still knew them. A few hours later Alexander died, after a reign of less than thirteen years, and before he had reached the age of thirty-three.

That the schemes of conquest with which almost to the last moment he had been absorbingly busied would, if he had lived, have been in great part realised, can scarcely be doubted, unless we suppose that causes were at work which at no distant period would have disturbed and upset the balance of his military judgment, and deprived him of that marvellous power of combination and of shaping means to circumstances in which Hannibal and Napoleon are perhaps his only peers. It would be rash to say that such a darkening of his splendid powers might not have been brought about, even before he could reach middle age, by habits which, if we may judge from the history of his later years, were fast becoming confirmed. In truth, except as a general, he had lost the balance of his mind already. The ruling despot who fancied himself a god, who could thrust a pike through the body of one friend and sneer at the cries drawn forth from another by the agonies of torture, was already far removed from the far-sighted prudence of the politic statesman and ruler. His conquests served great ends; and before he set out on his career of victory he may have had a distinct vision of these ends. Desire for knowledge; the wish to see new forms of human and animal life; the curiosity of traversing unknown lands, of laying open their resources, of bringing them all within the limits and the influence of the Macedonian, or, as he preferred to put it, the Greek world; the eagerness to establish over all known, possibly over all unknown, regions a mighty centralised empire, which should avail itself of all their forces, and throw down the barriers which rendered the interchange of their wealth impossible,—may have mingled with his alleged or his real purpose of avenging on the Persian king the misdoings of Xerxes, Darius, and Cyrus. But there is little evidence or none that these motives retained their power undiminished as he advanced further on his path of victory, while there seems to be evidence, only too abundant, that all other motives were gradually and even fast losing strength as the lust of conquest grew with his belief or his fancy of his superhuman power and origin. During his sojourn with Aristotle he must have learnt that real knowledge can be reached and good government insured only where there is freedom of thought and speech, and where the people obey their own laws. A few years later he had come to look on Aristotle as an enemy to be punished with scarcely less severity than Callisthenes. But at the least it must be remembered that his work was left unfinished; possibly he may have regarded it as little more than begun. Looking at it from this point of view, we can neither shut our eyes to the solid benefits accruing from his conquests both for the East and the West, nor, in spite of his awful crimes, can we place him in the rank of those scourges of mankind among whom Alaric and Attila, Genghiz, Timour, and Napoleon stand pre-eminent. Of the several accounts of his career which have come down to us, not one, unhappily, is strictly contemporary; and mere fairness calls upon us to give him the benefit of a doubt, when doubt can be justly entertained, in reference even to deeds which carry with them an unutterable horror and shame. It is impossible to deny that with a higher sense of duty Alexander would better have deserved the title of Great; but the judgment which may be passed on some of his actions cannot affect his transcendent glory as the most consummate general of ancient times, and perhaps even of all ages.

For an examination of the sources of the history of Alexander the Great, see Freeman, *Historical Essays*, second series, essay v. The history itself is presented in various aspects by Thirlwall, *History of Greece*, chaps. xlvii.–lv.; Grote, *History of Greece*, part ii., chaps. xci.–xciv.; Niebuhr's *Lectures on Ancient History*, lectures xxiv.–lxxx.; Williams, *Life of Alexander the Great;* St Croix, *Examen Critique des Anciens Historiens d'Alexandre le Grand;* Droysen, *Geschichte Alexanders der Grossen.* See also Finlay, *Greece under the Romans*, chap. i.; Arnold, *History of Rome*, chap. xxx. For the geography of Alexander's Indian campaigns, see Cunningham's *Ancient Geography of India;* and for the scientific results of his conquests, Humboldt's *Kosmos*, vol. ii., part ii., section 2. (G. W. C.)

ALEXANDER OF APHRODISIAS, the most celebrated of the Greek commentators on the writings of Aristotle, and styled, by way of pre-eminence, ὁ ἐξηγητής, *the Expositor.* He was a native of Aphrodisias in Caria, and taught the Peripatetic philosophy at Athens in the end of the 2d and the beginning of the 3d centuries of the Christian era. Commentaries by Alexander on the following works of Aristotle are still extant:—The *Analytica Priora*, I.; the *Topica;* the *Meteorologica;* the *De Sensu;* and the *Metaphysica*, I.–V., together with an abridgment of what he wrote on the remaining books of the *Metaphysica.* His commentaries were greatly esteemed among the Arabians, who translated many of them. There are also several original writings by Alexander still extant. The most important of these are a work *On Fate*, in which he argues against the Stoic doctrine of necessity; and one *On the Soul*, in which he contends that the undeveloped reason in man is material (νοῦς ὑλικός), and inseparable from the body. He identified the active intellect (νοῦς ποιητικός), through whose agency the potential intellect in man becomes actual, with God. Several of Alexander's works were published in the Aldine edition of Aristotle, Venice, 1495–98; his *De Fato* and *De Anima* were printed along with the works of Themistius at Venice, 1534; the former work, which has been translated into Latin by Grotius and also by Schulthess, was edited by Orelli, Zurich, 1824; and his commentaries on the *Metaphysica* by Bonitz, Berlin, 1847. Nourisson has treated of his doctrine of fate, Paris, 1870.

ALEXANDER OF HALES (ALEXANDER HALENSIS), surnamed *Doctor Irrefragabilis* and *Fons Vitæ*, a celebrated English theologian of the 13th century. Born in Gloucestershire, and trained in the monastery of Hales, from which he takes his name, he was early raised to an archdeaconry. Relinquishing this position, however, he went, like most of the scholars of his day, to study at the university of Paris, where he took the degree of doctor, and became celebrated as a teacher of philosophy and theology. Among his pupils was Bonaventura; but it is evident from a comparison of dates that he did not teach Duns Scotus and Thomas Aquinas, as has been frequently asserted. In 1222, when at the height of his fame, Alexander entered the order of Minorite Friars, and thenceforward lived in strict seclusion. He refused, however, to renounce his degree of doctor, and was the first of his order who continued to bear that title after initiation. He died in 1245, and was buried in the convent of the Cordeliers at Paris, where he had spent the last twenty-three years of his life. The most celebrated work of Alexander was his *Summa Theologiæ* (Nuremberg, 1452; Venice, 1576), undertaken by the orders of Pope Innocent IV., and approved by Alexander IV., after he had submitted it to the examination of seventy learned theologians as a system of instruction for all the schools in Christendom. Based on the *Sentences* of Peter Lombard, it is divided into four parts; the first treating of the nature and attributes of the Deity; the second of the creation and of the various orders of creatures; the third of the scheme of redemption, the incarnation of Christ, the law, and grace; and the fourth of the sacraments. The form is that of question and answer, and the method is rigidly scholastic.

ALEXANDER OF TRALLES (ALEXANDER TRALLIANUS), a medical writer, was a native of Tralles, a city of Lydia, and lived probably about the middle of the 6th century. He is the author of a work, divided into twelve books, in which he treats of bodily distempers. He was the first to open the jugular vein, and to use cantharides as a blister for the gout. Dr Freind, in his *History of Physic*, styles him one of the most valuable authors since the time of Hippocrates.

See also Dr Milward's *Trallianus Reviviscens; or, An Account of Alexander Trallian, one of the Greek Writers that flourished after Galen, being a Supplement to Dr Freind's History of Physic*, London, 1734, 8vo. The Greek text of his principal work was first published by Jac. Goupylus, Lutet. 1548, fol. It was reprinted, and was then accompanied with a Latin version by Jo. Guinterius, Basil, 1556, 8vo. He is likewise the author of an epistle on worms, *De Lumbricis*, which was published, in Greek and Latin, by Mercurialis, in his *Variæ Lectiones*, Venet. 1570, 4to.

ALEXANDER BALAS (a surname that probably means "lord"), a man of low birth who professed to be the son of Antiochus Epiphanes, and eventually became king of Syria. His claims were recognised by the Romans, who desired to revenge themselves on Demetrius Soter; and their example was followed by the king of Egypt and other monarchs. Demetrius was at first victorious, but in 150 B.C. was slain in battle, and Balas obtained possession of the kingdom. The new king soon made himself hateful to his subjects by his voluptuousness and debauchery, and this encouraged Demetrius Nicator, the eldest son of Demetrius Soter, to claim his father's crown. Alexander took the field against him, but was defeated in a pitched battle, and fled to Abæ in Arabia, where he was murdered by the emir, with whom he had sought refuge, 145 B.C.

ALEXANDER JANNÆUS, king of the Jews, succeeded his brother Aristobulus in 104 B.C., and died in 79 B.C. His reign, which he commenced by putting to death one of his brothers who claimed the throne, was disgraced by the cruelties that he perpetrated in order to keep himself in power.

ALEXANDER SEVERUS, Roman emperor. See SEVERUS.

ALEXANDER was the name of eight POPES:—

ALEXANDER I., bishop of Rome, succeeded Evaristus in 108 or 109 A.D., and, according to Eusebius, suffered martyrdom under Hadrian in the year 119. Catholic writers ascribe to him the introduction of holy water, and of the custom of mixing sacramental wine with water.

ALEXANDER II., whose family name was *Anselmo Baggio*, was born at Milan, and occupied the papal chair from 1061 to 1073. He had previously, as bishop of Lucca, been an energetic coadjutor with Hildebrand in endeavouring to suppress simony, and to enforce the celibacy of the clergy; and his efforts to augment the influence of the Roman see prepared the way for the complete ascendancy which was established by his celebrated successor. The imperial sanction being withheld from Alexander's election, a council at Basle chose as anti-pope Cadolaus, bishop of Parma, who assumed the name of Honorius II., and marched to Rome. He was deposed, however, by a council held at Mantua, and Alexander's position remained unchallenged. Alexander was succeeded by his associate Hildebrand, who took the title of Gregory VII.

ALEXANDER III. (*Rolando Ranuci* of Siena), cardinal and chancellor of the Roman church, was elected to the popedom in 1159, and reigned until 1181. His career is of great historical importance on account of the vigour and ultimate success with which he carried out the ideas and policy of Hildebrand in opposition to Frederick Barbarossa and Henry II. of England. Three anti-popes (Victor IV., 1159; Pascal III., 1164; Calixtus III., 1168) were confirmed by the German emperor in succession. Alexander, however, steadfastly maintained his rights, though compelled to take refuge in France between the years 1162 and 1165. The contest between pope and emperor was continued with varying fortune until, on the 29th May 1176, Frederick was decisively defeated at Legnano, when he at once withdrew his support from the anti-pope and submitted to Alexander. On the 1st August 1177 the emperor yielded the customary homage to the pope at Venice by kissing his foot, and was freed from the ban of excommunication under which he had been placed ten years previously. There seems to be no historical authority for the common story that during the ceremony Alexander placed his foot upon the emperor's neck.

In England the papal supremacy was strenuously maintained against Henry II. by Thomas à Becket. Here, as in the case of Germany, the struggle was protracted and severe, but in the end the victory lay with the pope. À Becket was canonised soon after his assassination, and Henry II. was compelled to submit to a humiliating penance. A contest with William the Lion of Scotland, who insisted on instituting his chaplain Hugo, and not the papal nominee, into the see of St Andrews, ended in the excommunication of the king in 1181.

Alexander introduced several important changes in the organisation and administration of the church. Chief among these were the restriction of the right of canonisation to the pope alone, the still-existing law requiring the votes of two-thirds of the cardinals for a valid papal election, and the exemption of the clergy from civil control and of church lands from civil burdens. Several of these measures were ratified by the third general council of the Lateran, summoned by Alexander in 1179.

Alexander IV., *Count Rinaldo de Segni*, cardinal-bishop of Ostia, occupied the papal chair from December 1254 till his death in May 1261. He seems to have been of a weak character, and in the struggle against the house of Hohenstaufen, which he inherited from his predecessors, he did little to strengthen the position of the papacy. The opposition which he offered to Manfred, natural son of Frederick II., proved unavailing, although he obtained the aid of England by promising the disputed sovereignty of the Two Sicilies to the English Prince Edward. Manfred was crowned king at Palermo in 1258, and in 1260 he invaded the States of the Church, and compelled the pope to recognise him as legitimate sovereign. The ecclesiastical administration of Alexander was signalised by his efforts to unite the Greek and Latin churches, by the establishment of the Inquisition in France (1255), and by the support he gave to the orders of Mendicant friars. The last years of his pontificate were passed at Viterbo, where he was compelled to take refuge on account of the violent struggles at Rome between the factions of the Guelphs and the Ghibellines.

Alexander V. (*Pietro Philargi*), a native of Candia, enjoyed the dignity of Pope for only ten months, from the 26th June 1409 to the 3d May 1410. Born of poor parentage, he owed his admission to a religious house to a Franciscan monk, who noticed him begging. He studied at Paris and Oxford, where he acquired such reputation for scholarship, that on his return to Italy he was rapidly promoted from dignity to dignity. In 1402 he was appointed, through the influence of Galeazzo Visconti, to the archbishopric of Milan, and in 1405 he was made a cardinal by Innocent VII. The council of Pisa, after deposing Benedict XIII. and Gregory XII., elected him pope on the understanding that he would set himself to reform the abuses of the church. The weakness of his character and the shortness of his pontificate, however, prevented anything effectual being done. He died, as was generally believed, of poison administered by Balthasar Cossa, who became his successor under the title of John XXIII.

Alexander VI. (*Rodrigo Borgia*), memorable as the most characteristic incarnation of the secular spirit of the papacy of the 15th century, was born at Xativa in Valencia, 1st January 1431. His biographers all but unanimously assert his patronymic to have been Lenzuoli (in its original Valencian form, Llançol), and the name of Borgia (or more properly Borja) to have been assumed on his adoption by his maternal uncle. Francisco Escolano, however, a compatriot, positively affirms (*Cronica*, lib. vi. cap. 33), that Llançol was his mother's name, and that his father was Giofré Borja. It is also disputed whether he originally followed the legal or the military profession; the former appears more probable. In either case, his career was determined by his uncle's elevation to the papacy as Calixtus III., 8th April 1455, and his own immediate summons to Rome, where he was reserved *in petto* as cardinal in the ensuing February, publicly promoted in September, and by an unparalleled act of nepotism elevated to the lucrative and dignified office of vice-chancellor in the following July. He also succeeded his uncle as archbishop of Valencia. An elder brother, Pedro Luis, was made generalissimo of the papal forces by land and sea. The animosity created by so invidious an exaltation prepared Rodrigo's subsequent feud with the Roman patriciate. For the moment he was all-powerful, and the letters of that dexterous courtier Æneas Sylvius attest the importance attached to his good word. We must here notice the ridiculous fiction concerning the parentage of Borgia's natural children, which owes its currency to the uncritical credulity of Gordon, his first formal biographer. An anonymous MS. romance, professing to record the secret history of the Borgia family, exists in many Italian libraries; a copy is in the British Museum. Gordon fell in with this fiction, and whether from lack of judgment or love of marvel, adopted it into his narrative. According to this version, Rodrigo, when summoned to Rome, was living with a beautiful Valencian courtesan, Rosa Vanozza, by whom he had already had several children. Despatching his family to Venice under the care of a major-domo, he entered upon a course of austere hypocrisy, designed to secure his exaltation to the papacy, thus remaining apart from his mistress and children for a period of nearly forty years! This legend, originally circulated as a prime piece of scandal, has been accepted as a vindication by Rodrigo's apologists. Vanozza, they contend, was not his concubine but his wife, and her decease must have preceded his ordination: Cæsar and Lucretia were consequently legitimate. The Abbe Ollivier goes a step further still, and disposes of two scandals at a stroke by identifying Vanozza with Giulia Farnese, whose charms, during Alexander's pontificate forty years afterwards, notoriously procured her brother's elevation to the cardinalate. It is sufficient to reply that in this case the beautiful Lucretia must have espoused the Duke of Ferrara at forty, and have borne him children at sixty. The date of Cæsar's birth, moreover is known to an hour, being fixed by the horoscope preserved in Junctinus (tom. i. p. 171) at 18th September 1475. Nor is the history of Vanozza any longer a secret. It is known that her family name was De' Cattanei; that after bearing five children to Alexander she was twice married, on each occasion to a petty official about the papal court; that she possessed houses and other property in Rome; that she survived Alexander many years, and made use of the name of Borgia (*Reumont*, Bd. 3, pp. 202, 203).

The fortune of the Borgia brothers seemed menaced with eclipse on the death of their uncle, 8th August 1458. Pedro Luis, who had incurred the bitter enmity of the Orsini family, escaped under the escort of Cardinal Barbo to Cività Vecchia, where a fever soon carried him off. Rodrigo remained for the conclave. No papal election is more dramatically narrated in that edifying collection, *Conclavi de' Pontefici Romani*, than the one which resulted in the choice of Æneas Sylvius (Pius II.) Borgia's share in it had earned Pius's gratitude; he was, nevertheless, compelled to submit to some diminution of the authority and emoluments of the vice-chancellorship; and a subsequent indiscretion in the too public indulgence of his taste for female society while discharging a legation at Siena procured him one of the severest reprimands ever addressed to a cardinal by a pope. Pius's reproof is preserved in Raynaldus (Append. ad ann. 1460, num. 31), and alone refutes the fiction of Borgia's religious hypocrisy. Cardinal Barbo, however, who succeeded as Paul II., was the same spirited patrician who had befriended the Borgias in their hour of need, and his ostentatious pontificate ushered in the era of Rodrigo's unbroken prosperity. "He is," writes at this time Gaspar Veronensis (Muratori, tom. iii. pt. 2, p. 1037), "a comely man of cheerful countenance and honeyed discourse, who gains the affections of all the women he admires, and attracts them as the loadstone does iron; it is indeed supposed that he proceeds no further." A supposition rather pious than probable.

On the death of the jovial Paul (1471), Borgia is mentioned, along with Cardinals Orsino and Gonzaga, as one of the three who chiefly contributed to place the tiara on the brows of the then famous preacher and exemplary ascetic Sixtus IV., who immediately (*per fuggire l'ingratitudine*) bestowed on him the opulent abbey of Subiaco, and raised him to the dignity of cardinal-bishop. About the same time must have commenced his intimacy with Vanozza. In 1473 he undertook a legation to Spain, avowedly with the purpose of visiting his diocese and of composing differences between the kings of Castile and Portugal, but in reality to display his magnificence to his countrymen. His demeanour on this occasion is represented in the most unfavourable light by the cardinal of Pavia, who had previously composed for him that elegant oration to his Valencian flock which the Abbé Ollivier has the simplicity to attribute to Borgia himself. The cardinal, however, is too much of a time-server and a rhetorician for his account to be altogether trustworthy. More certain is the occurrence of a tremendous tempest on Borgia's return, in which part of his retinue perished, while he himself narrowly escaped. Innocent VIII., the successor of Sixtus, owed his election to Borgia's coalition with the late pope's nephew, and the fortunes of the former remained unimpaired throughout his tranquil pontificate. The long malady which terminated it afforded scope for the intrigues of aspirants to the succession; and when the cardinals entered into conclave (August 1492), already the rumour ran that a Spaniard would be pope. The simoniacal character of the election is indisputable. We need not believe that the opulent and high-spirited Cardinal Ascanio Sforza was tempted with four mule-loads of silver, but his instant elevation to the vice-chancellorship speaks for itself. Cardinal Orsino was bought with Borgia's palace in Rome; Cardinal Colonna with the abbey of Subiaco; money gained the minor members of the Sacred College; five cardinals alone are recorded as incorruptible. Borgia's uneasiness was betrayed by his hasty assumption of the pontifical vestments, and premature announcement of the election to the expectant crowd. He assumed the name of Alexander VI. His allocution to the cardinals breathed spirit and dignity: an admonitory discourse to his son Cæsar, which may be read in Gordon, is an invention of the anonymous romancer. The pomp of his coronation far surpassed preceding examples, and the compliments of foreign ambassadors on the majesty of his mien and the maturity of his wisdom were echoed by a public accustomed to simony, relieved at their deliverance from a period of anarchy, and sensible of their need of a firmer hand. This hope Alexander justified and surpassed. Ere long he had divided Rome into judicial districts, placed a magistrate at the head of each, and himself established a weekly audience, at which, by the admission of the malcontent Infessura, "he administered justice after a marvellous sort."

Alexander's pontificate might have been less eventful but for a circumstance beyond his control. The political system of Italy was on the eve of dissolution. Ludovico the Moor, anxious to confirm himself in his ill-gotten duchy of Milan, was already tempting the French monarch across the Alps by the bait of the kingdom of Naples. As of old in Greece, so now dissensions and political corruption were about to cast down the civilisation of Italy at the feet of the stranger. The passion for family aggrandisement on this occasion impelled Alexander to a patriotic course. His third son Giofré had espoused the illegitimate daughter of the king of Naples, and received as dower the principality of Squillace. When, therefore, the French envoys demanded the investiture of Naples, they met with a flat refusal. This encouraged Alexander's enemies. Cardinal della Rovere (Julius II.) withdrew from the papal court, seized upon Ostia, and from thence addressed urgent appeals to the French king to march upon Rome, convene a council, and purge Christendom of the simoniacal pope. On this side Alexander felt himself indeed vulnerable. Casting about for alliances, he despatched an envoy to the Sultan; the ambassador was arrested as he returned with a favourable reply; and the publication of his instructions created a fresh scandal. Others still, had Roman manners been less lax, might have arisen from the marriage of the pope's acknowledged daughter Lucretia to the Lord of Pesaro, under the auspices of the whole Sacred College, and from the elevation of his second son Cæsar to the cardinalate at the age of eighteen, unblushing perjury being employed to conceal his illegitimate birth. Yet, at the same period, the successor of Peter appeared for the last time in history as the undisputed bestower of kingdoms and the ultimate tribunal of appeal for Christian nations. Spain and Portugal resorted to him for the adjustment of their claims to the New World; and by tracing a line upon a map he disposed of three-fourths of the human race. Never, according to mediæval ideas, had a pope exerted his prerogative with equal grandeur; but the mediæval conception of the papacy was passing away, and no one's faith in it was feebler than the pope's.

Charles VIII. passed the Alps in the autumn of 1494; city after city fell before him, and by the end of the year Rome was added to the number. Alexander had retired into the castle of St Angelo. His deposition was universally expected, most of all by himself. But Charles's minister, Briçonnet, had been gained by the promise of a cardinal's hat. On 16th January the reconciliation of king and pontiff was officially celebrated: they rode together through the city; but distrust still prevailed between them. With really surprising firmness Alexander continued to refuse the investiture of Naples, with which Charles may have thought himself able to dispense. Nothing, indeed, could have been more rapid than his conquest, except his loss of that kingdom. By March the triumph of the French seemed complete: on 6th July their retreating army cut its way through the Italian hosts at Taro in Upper Italy; on 7th July the King of Naples re-entered his capital. Nothing remained of the French incursion except a fatal contagion, and the more fatal revelation of the weakness of Italy.

The retreat of the French left Alexander at liberty to pursue what must have been the main object of any pope of intelligence and spirit in his place—the extirpation of the petty feudal vassals of the church, and the establishment of the temporal independence of the papacy. This was in truth but a phase of the great struggle of the crown and the people against the aristocracy, universally a characteristic of that age; but the pope's principal motive was unquestionably the insatiable appetite of family aggrandisement. The incurable vice, however, of his policy was imposed upon him by the lack of men and money to carry it into effect. To obtain the former, he was compelled to incline alternately to France and Spain, degrading the majesty of the Holy See, and forfeiting his liberty of action as a member of the Italian body politic. The finances had to be recruited by the sale of offices and spiritual privileges of every kind. Such practices had long been prevalent at Rome, but never had they attained the enormity, the effrontery, or the method imparted to them by Alexander.

His enterprise was at first unfortunate. After some petty successes the papal forces were routed by the Orsini, January 1497. Spanish aid was invoked; the Great Captain checked the Orsini and recovered Ostia. Alexander's spirits rose; on 7th June he alienated Benevento in favour of his eldest son, the Duke of Gandia. That day week the duke disappeared; his body, pierced with wounds, was soon found in the Tiber. The public voice attributed the murder to the pope's second son, the Cardinal Cæsar Borgia, but on no other grounds than his capability of any atrocity, and the gain that accrued to him by this. Some historians know what he said to the pope in confessing his fratricide, and can report the pope's rejoinder; so is history written. Alexander secluded himself in a passion of grief. He talked of abdication, and actually appointed a commission to inquire into the abuses of the Church. While it ineffectually deliberated on reforms, the stake was preparing for a real reformer. The history of Savonarola must be related elsewhere; it can only be said here that Alexander appears to have been most unwilling to proceed against him, and only to have consented to do so when the Dominican's hostile attitude rendered further forbearance impossible.

Cæsar Borgia, meanwhile, was bent on improving the opportunity which he had found or made. Three months after Savonarola's death he propounded to the assembled cardinals his desire to renounce ecclesiastical orders for his soul's health, and was soon at liberty to contract a royal alliance. After encountering a refusal from the daughter of the King of Naples he repaired to France, and there (May 1499) espoused a princess of the house of Navarre, receiving the title of Duke of Valentinois from the French king. Lucretia also benefited by her family's enlarged views; her alliance with the lord of Pesaro was dissolved on a pretext of nullity, and she married the Duke of Bisceglia, a natural son of the King of Naples. This had occurred a year previously, when Alexander still attached weight to the Neapolitan alliance; but the political horizon was now changed. In October 1499 a French army crossed the Alps and conquered Lombardy, almost without resistance. The watchword was thus given for the papal campaign in the Romagna. Caterina Sforza, regent of Imola and Forli, received a summons to discharge certain arrears long owing to her suzerain. Cæsar Borgia followed with an army on the heels of the messenger, and although the intrepid princess defended herself stoutly by sword and poison, she was compelled to succumb to the "Gonfalonier of the Church." The Borgias' enterprise coincided fortunately with the commencement (according to the then method of reckoning) of the new century and the mighty concourse of pilgrims to Rome for the jubilee, each representing some substantial contribution to the papal exchequer. France and Spain, meanwhile, had concerted their secret arrangement for the dispossession of the King of Naples, and Cæsar Borgia prepared to remove the only obstacle to his own participation in it. In July 1500 the Duke of Bisceglia, Lucretia's Neapolitan husband, was attacked by assassins in broad day, and left desperately wounded. The pope placed guards over the prince; Lucretia and her sister-in-law prepared his food to avoid poison; but none the less "quum ex vulneribus sibi datis mori noluisset"—Alphonso of Bisceglia was strangled by men in masks. "All Rome," writes the Venetian ambassador, "trembles before the duke." The worst times of the empire seemed returned, even to the amusements of the amphitheatre, where Cæsar, whose tastes were those of a Spaniard, despatched six bulls successively, severing the head of one from the shoulders at a stroke. The pope looked on helplessly at the Frankenstein of his own creation; "he loves and hugely fears his son," reports the Venetian, who adds that Cæsar had pursued his father's favourite secretary to his arms, and there butchered him, the pope's robe being saturated with the gushing blood. Alexander's easy temper stood him in good stead. "The pope," according to the same authority, "grows younger every day, and is extremely cheerful; his cares and troubles endure only for a night; he thinks continually of aggrandising his children—*ne d'altro ha cura.*" In his conversations with foreign envoys he excused his son's violence as the error of youth. "The duke," he said, "is really a good fellow; it is only a pity that he cannot endure to be offended." Lucretia is extolled by all as "lovely, discreet, and bountiful." Rumour, indeed, imputed to her an incestuous connection with her brother; but this aspersion, like all others upon her, is to this day utterly destitute of proof.

"These devils cannot be cast out by holy water," Cardinal Juan Borgia had formerly reported of the turbulent occupants of the Romagna. The experiment of casting out Satan by Beelzebub remained to be tried. In April 1501 Cæsar entered upon his second campaign, and by perfidy or force quickly added Pesaro, Rimini, and Faenza to his former possessions. Attentive to the maxims of sagacious tyranny, he governed with substantial justice. If his coffers had to be filled by oppression, the odium would be cast on some subordinate agent, whose body, his mission fulfilled, would be found dismembered in the market-place. France and Spain, meanwhile, proceeded to the spoliation of the defenceless king of Naples, and Cæsar (July 1501) shared in the conquest and the booty. In September Alexander himself undertook a campaign against the Colonnas, and humbled those haughty patricians by the capture of all their castles. Lucretia, to the general scandal, represented him in his absence. Worse scandals were in store, could we implicitly credit the contemporary diarist's account of the scenes enacted in the apostolic palace after Alexander's return, but the passage is probably interpolated. At this period the papal court was engrossed with preparations for Lucretia's marriage to Alphonso, son of the Duke of Ferrara, which was celebrated by proxy in December. The pope's daughter, cardinals and prelates in her train, undertook a stately progress through Italy to Ferrara, where she was received with extraordinary splendour. Piombino was reduced at this time, and in July Cæsar treacherously rendered himself master of Urbino. Immediately afterwards his power received a severe shock from the defection of his principal *condottieri.* Cæsar temporised until, to the admiration of Machiavelli, then Florentine envoy at his camp, his adversaries were decoyed into his hands, seized, and executed (31st December 1502). The news gave the signal at Rome for the arrest of the Orsini and the occupation of their castles; thus was the humiliation of the Roman aristocracy completed. Cardinal Orsino was committed to Saint Angelo, where the services of the papal master of the ceremonies were soon required for his interment. "But I," remarks Burcardus with quaint naiveté, "turned the business over to my assistant, for I did not want to know more than was good for me." It must be owned that in that age it would have been impossible to bring a cardinal publicly to the block. This apology does not apply to the charges of secret poisoning which have mainly given the Borgias their sinister celebrity, and which became fearfully rife in Alexander's latter years. They are unproved as yet, but are certainly countenanced by the opulence of the supposed victims, and the avidity with which the pope pounced upon their effects, especially in the case of his rapacious datary, Cardinal Ferrari.

By May 1503 Spain had dispossessed France of her share of ill-gotten Naples. A general war seemed imminent; Alexander and Cæsar leaned to the side of Spain. The Sacred College was already full of Spanish cardinals, docile instruments of their countryman, and Alexander might well deem that he had fettered the Church to the fortune of his house. Men looked for the proclamation of Cæsar as king of Romagna, and the division of the temporal and the spiritual power. The ancient mutual relations of pope and emperor would have been revived, but on the narrow area of Central Italy. But this was not to be. On the morning of 12th August "Pope Alexander felt ill;" so did Cæsar Borgia. Every one knows the story of the supper given to the ten cardinals in the villa, and the fatal exchange of the poisoned flask. This picturesque tale is almost certainly a fiction. An attempt to destroy ten cardinals at once is inconceivable; it would be easier to believe Cardinal Castellesi's assertion that he was to have been the victim, as his sickness at the time is confirmed from an independent source. But his character does not stand high, and the symptoms of his disorder, as described by himself, differ totally from Alexander's, which were those of an ordinary Roman fever. The progress of the pope's malady may be minutely traced in the diary of Burcardus and the despatches of the Ferrarese envoy. He expired on the evening of 18th August, duly provided with all the needful sacraments of the Church. From his own point of view his life probably appeared fortunate and glorious; but the vicissitude of human affairs is ever dramatically illustrated by the death of a pope. Ere the corpse was cold the pontifical apartments were pillaged by the satellites of Cæsar Borgia; at the funeral a brawl between priests and soldiers left it exposed in the body of the church; when placed before the altar, its shocking decomposition confirmed the surmise of poison; finally, stripped of its cerements and wrapped in an old carpet, it was forced, with blows and jeers, into a narrow coffin, and flung into an obscure vault. The remains were subsequently transferred to the Spanish church of St Mary of Montserrat, where they repose at this day.

Alexander has become a myth, and his "acts" are in some respects almost as legendary as those of the primitive saints and martyrs. The peculiar odium attached to his memory rests partly on the charge of incest, of which he must be acquitted; partly on that of secret poisoning, which is at least not established; partly on the confusion between his actions and Cæsar Borgia's. Nearly everything actually criminal in his pontificate is subsequent to the preponderance of the latter. Profligate alike in public and private life, he was no malignant tyrant,—affable, familiar, easy, he justly took credit for his moderation towards notorious malcontents, and his indifference to personal injuries. These virtues, however, as well as his family affection, were merely constitutional with him,—as the many beneficial acts of his administration were rather prompted by a sense of policy than a sense of duty. His ability as a ruler is evinced by the tranquillity he maintained in Rome, his effectual provision against dearth, the regular discharge of financial obligations, the energetic prosecution of useful public works. As a statesman he ranks high in the second class. He was too destitute of morality to have the least insight into the tendencies of his times; but from the point of view of political expediency, his policy was eminently sagacious and adroit. He cannot be accused of preparing the misfortunes of Italy, but he did not disdain to profit by them. His licentiousness and contempt of ecclesiastical decorum are partly palliated by the circumstances of his initiation into the Church. He was untrained to the ecclesiastical profession, never felt himself a priest, and was wholly regardless of the Church's interest as such. In this respect he is almost unique among the successors of St Peter. Were controversies regulated by reason rather than by convenience, the parties to this would change sides,—Alexander's accusers would become his advocates, and his advocates his accusers. The Church in her secret heart must rate him the lowest of her chiefs; the world must feel that he deserves much better of it than many much better popes.

The principal contemporary authority for the reign of Alexander is the diary of the papal master of the ceremonies, Joannes Burcardus, a record replete with trivialities and not exempt from interpolations, but containing indisputable evidence of perfect candour. An excellent edition, commenced in 1855 by the Abbé Gennarelli, was discontinued after the publication of a few parts. The uncritical histories of Gordon and Tomasi are indebted to Burcardus for any value they possess. The paltry productions of modern Roman Catholic apologists (Jorry, Favé, Cerri, &c.) are beneath contempt. The Abbé Ollivier (*Alexandre VI. et les Borgia*, tom. i., Paris, 1870) excites respect by his good faith and amusement by his strange alliance of perverse ingenuity with infantine unsuspiciousness. Of late years the archives of the Italian courts have become accessible, and the transactions of Alexander's reign have been sagaciously investigated from this source by two German scholars, Von Reumont (*Die Stadt Rom*, Bd. 3, Abth. 1, Berlin, 1868) and Gregorovius (*Rom in Mittelalter*, Bd. 7, Stuttgart, 1870). The latter is the more copious, but his general estimate of Alexander is much too low. By far the ablest English contribution to the history of Alexander is a notice of Gregorovius in the *North British Review*, vol. lii., entitled *The Borgias and their Latest Historian.* (R. G.)

ALEXANDER VII. (*Fabio Chigi*), was born at Siena on the 13th February 1599, and occupied the papal chair from the 7th April 1655 to the 22d May 1667. Before his elevation he had filled successively the offices of inquisitor at Malta, vice-legate at Ferrara, and nuncio to Germany at the conference of Munster. The conclave elected him in the belief that he was strongly opposed to the nepotism and other abuses that had characterised the reign of his immediate predecessor, Innocent X., and at the beginning of his pontificate he went so far in this direction as to forbid his relatives even to visit Rome. In a year, however, all was changed, and nepotism prevailed to as great an extent as under any former pontiff. Alexander was a patron of learning, and himself wrote a volume of Latin poems which appeared at Paris in 1656 under the title *Philomathi Labores Juveniles.* He also encouraged architecture, and in particular constructed the beautiful colonnade in the piazza of St Peter's. The most noteworthy events of his pontificate were the reception of the ex-queen Christina of Sweden into the Catholic Church, the promulgation of a bull against the Jansenists, and a protracted dispute with Louis XIV. of France, during which the papal see lost possession of Avignon (1662). Alexander canonised Francis of Sales in 1665.

ALEXANDER VIII. (*Pietro Ottoboni*), born at Venice in 1610, was raised to the pontificate in October 1689 in succession to Innocent XI. He assisted his native state in its wars with the Turks. Although an enemy of the Jansenists, he condemned certain doctrinal errors of the Jesuits as advanced by Professor Bougot of Dijon. He carried nepotism to such an extent that the salaries and gifts bestowed on his relatives during his reign, short though it was, exhausted the papal treasury. He added by purchase the books and manuscripts of Queen Christina to the Vatican library. He died in Feb. 1691.

ALEXANDER I., King of Scotland, son of Malcolm Canmore, succeeded his brother Edgar in 1107, and died in 1124. He was better educated than any of his predecessors, owing to the care of his mother, the amiable Margaret of England. All the qualities of his nature, both good and bad, were strongly marked; from the terror he inspired, he was styled by his subjects *the Fierce*. His reign is distinguished by the determined opposition he offered to any interference on the part of English bishops in the affairs of the Scottish Church. He contrived by energy and valour to subdue the turbulence of his kingdom; specially noticeable are the promptness and vigour he displayed in suppressing the insurrection of Angus, grandson of Lulach, a son of Macbeth's queen. He died at Stirling, and, being childless, was succeeded by his brother David I.

ALEXANDER II., King of Scotland, was born at Haddington in 1198 (died 1249), and succeeded his father, William the Lion, in 1214. Though still young, he exhibited the same prudence and firmness which marked his whole conduct in life. He was excommunicated in 1216 for associating with the English barons in their opposition to King John; but his prudence enabled him to recover the good opinion of the pope, and placed him on the best footing with the English king, Henry III., John's successor. His fidelity to Henry was shown by the assistance he rendered him in protecting, during Henry's absence in France, the northern borders of England, and the friendliness of the kings was strengthened by the marriage of Alexander to Henry's sister Joan (1221). Joan died in 1238, and in May 1239 Alexander married Mary de Coucy. In 1244 Henry marched against Scotland to force from Alexander the homage due to him for the lands he held in the north of England, but in August a peace was concluded at Newcastle. Like Alexander I., he was zealous in defence of the privileges of the Scottish Church; and in 1222 he put to death 400 persons who had been implicated in the murder of the bishop of Caithness. While engaged in quelling an insurrection in Argyleshire, he died of fever in the island of Kerrera in 1249.

ALEXANDER III., King of Scotland, son of Alexander II. by his second wife, Mary de Coucy, was born at Roxburgh on the 4th September 1241 (died 1286), and succeded to the throne on the death of his father in 1249. The fact that in this case the succession of a minor was unopposed is noteworthy, as showing that the hereditary principle had now established itself. By a provision of the treaty of Newcastle Alexander had been betrothed in infancy to the daughter of the king of England, and it suited Henry's policy to insist on an early fulfilment of the contract. Notwithstanding the extreme youth of the parties, the marriage was celebrated at York on the 25th December 1251. On this occasion Alexander is said by Matthew Paris to have done homage for his estates in England, and to have refused homage for his kingdom of Scotland, on the ground that he had not consulted on the matter with his proper advisers. The story, however, seems inconsistent with Henry's policy at the time, and is therefore questionable. With a king so young, in times so unsettled, the hopes and efforts of contending factions were naturally stimulated. At the commencement of his reign Alexander was under the power of the Comyns, the most influential family among the Scottish nobility. A rival party, under the leadership of Durward the justiciar, was supported by England, and in 1254 succeeded in seizing Edinburgh castle, and freeing the king and queen from the domination of the Comyns. Meanwhile Henry had himself marched to Scotland with an army, and in September he met Alexander at Roxburgh. There a regency was arranged, from which the Comyns were entirely excluded. In 1257, however, the latter regained their ascendancy, and obtained possession of the person of the king, whom they kept prisoner at Kinross and Stirling. In the following year a new regency was formed, in which both the opposing parties were represented, and the king was liberated. In 1260 he and his queen paid a visit to the court of England. While at Windsor the queen gave birth to a daughter, Margaret, afterwards married to Eric of Norway. An account of the invasion of Scotland in 1263 by Haco, king of Norway, and of the disastrous defeat at Largs, belongs rather to the history of the country than to the personal biography of the king. Three years after the invasion, Magnus, king of Norway, ceded to Alexander the Isle of Man and the Western Isles, receiving in return a ransom of a thousand marks and an annual rent of a hundred marks. The Orkney and Shetland islands still remained under the dominion of Norway. Alexander was involved in a protracted and on the whole successful struggle with the papal power for the independence of the Scottish Church. The chief matter in dispute was the proper valuation of church lands for the purpose of taxation. In connection with this, Boiamund or Bagimond came from Rome in 1275 with a commission to draw up the valution known as Bagimond's roll, which remained the basis for the taxation of church lands down to the time of the Reformation. The internal condition of the country seems to have improved greatly during the latter years of Alexander's reign. A wise and vigorous administration ensured peace and consequent prosperity. The prospect of Scotland was perhaps never brighter in all her early history than towards the close of his reign, but it was suddenly overcast. A series of calamities, following each other in quick succession, left the nation at the mercy of its foes within and without. In 1275 Alexander's wife died, and a few years later he lost both his children. The succession in the direct line was thus left to the precarious chance of the single life of the infant princess known in history as the "Maid of Norway." In 1285 Alexander married Joletta, daughter of the Count of Dreux. Any hope of strengthening the succession by this union was, however, destroyed by the calamitous event of the following year. On the 12th March 1286 the king was killed by a fall from his horse while riding on the coast of Fife opposite Edinburgh. A spot near Kinghorn, known as the King's Wud End, is pointed out as the scene of the tragical event. The death of Alexander was a turning-point in Scottish history. The national independence, which he maintained so steadfastly against the insidious claims of England, while avoiding an open rupture, was once more placed in jeopardy. The popular estimate of the calamity is well expressed in the following lines, believed to be the earliest specimen of Scotch poetry extant:—

> "Quhen Alysander our kyng was dede,
> That Scotland led in luve and le,
> Awaye was sons of ale and brede,
> Of wyne and wax, of gamyn and glé.
> Our gold was changyd into lede.
> Cryst, born into virgynyte,
> Succour Scotland and remede,
> That stad is in perplexyte."

ALEXANDER, PAULOVICH, Emperor of Russia—born on 28th December 1777, died 1825—was the son of Paul, afterwards emperor, by Maria, daughter of Prince Eugene of Würtemberg. His early education was conducted under his excellent mother, and afterwards was carefully directed by his grandmother, the Empress Catherine II., who confided its general superintendence to Frederick Cæsar de La Harpe. On the assassination of his father Paul in 1801, Alexander succeeded to the Russian throne. He had been married in 1793 to the Princess Louisa Maria of Baden, but the union proved an unhappy one, and had no issue.

The policy of the young emperor was indicated by his concluding a peace with Britain, against which his father had declared war. In 1805 he joined Austria and Sweden in a coalition with Great Britain against the pretensions of France. The war that followed was disastrous to the allies. The armies of Austria were totally defeated in a succession of battles between the 6th and 13th October of that year; and the combined Austrian and Russian armies, under the two emperors, were defeated by Napoleon in the great battle of Austerlitz on the 2d December. Austria concluded a separate treaty of peace, and Alexander led the remains of his army into his own dominions. Prussia, which had injudiciously stood neutral while France was humbling Austria and Russia, rashly engaged in hostilities with Napoleon in 1806, while her allies, the Russians, were still beyond the Vistula; but the defeats at Auerstadt and Jena laid Prussia prostrate; and in the succeeding year the battles of Eylau and Friedland, in which the Russians were fairly beaten, led to the dismemberment of Prussia, and the treaty of Tilsit with Russia. A few days after the last battle, Alexander and Napoleon met on a raft anchored in the river Niemen, and agreed to the treaty, which was signed at Tilsit on July 7. By a secret article of this treaty Alexander was not only to withdraw from his connection with Britain, but to become her enemy; and he declared war against her on the 26th October.

For nearly five years Alexander appeared attached to the alliance of France; but the privations of his subjects by the interruption of the commerce with England, and the intolerable load of Napoleon's "Continental System," at length induced him to return to his old alliance, and to declare war against France on March 19, 1812. On the 24th April he left St Petersburg to join his armies on the west frontier of Lithuania. Napoleon assembled the most numerous and magnificent army that had ever been brought together in modern times, augmented by the unwilling levies of Prussia and Austria, and entered Russia on the 25th June 1812. The first encounter was at Borodino, where there was a well-contested action, in which each army suffered the loss of 25,000 men. The burning of Moscow, and the subsequent retreat of Napoleon, during which his army was all but annihilated, are among the best known events of modern history.

In 1813 the advancing Russians were successively joined by the forces of Prussia, Austria, and Sweden. Alexander continued with the allied armies, and in particular was present at the battles of Dresden and Leipsic. Napoleon had made wonderful exertions to repair his losses in the early part of 1814; but the victories of Wellington in Spain, and his advance into the heart of France, favoured the progress of the allies; and on March 30, 1814, 150,000 men of the allied armies took possession of Paris, which was entered next day by Alexander and the king of Prussia.

After the deposition of Napoleon the allied sovereigns visited England. By the treaty of Vienna, Alexander was acknowledged king of Poland; but before the congress of Vienna broke up, Napoleon had escaped from Elba, and was enthusiastically received at Paris. The two eastern emperors and the king of Prussia remained together until the battle of Waterloo gave peace to Europe. On the advance of the British and Prussians to Paris, the three allied sovereigns again made their entry into that capital, where they concluded, on September 26, the treaty which has been designated *the Holy Alliance.*

Alexander was henceforward chiefly occupied in the internal administration of his vast dominions, which certainly improved more during the twenty-five years of his reign than under any of his predecessors from the time of Peter I. The gradual abolition of the feudal servitude of the peasantry, begun by the most enlightened of his predecessors, was continued under Alexander. Education, agriculture, manufactures, commerce, were also greatly extended; while literature and the fine arts were liberally encouraged. His disposition has been represented by his subjects as mild and merciful; yet his influence in the affairs of Europe was not exerted in the cause of public liberty. But this could hardly be expected from the autocrat of an unmitigated despotism in his own territories. He will, however, bear very favourable comparison with any Russian sovereign, or even with any contemporary monarch.

Early in the winter of 1825 he left St Petersburg for the last time on a tour of inspection of his southern provinces. About the middle of November he was attacked by a violent intermittent fever, which proved fatal at Taganrog on December 1, 1825. In foreign countries his death has been attributed to poison; but this is refuted by the history of his disease, and is very improbable, from his great popularity with his countrymen. He was succeeded, in accordance with a family compact, by his second brother Nicholas.

ALEXANDER JAROSLAWITZ NEVSKI, Saint, Grand Duke of Wladimir, second son of the Grand Duke Jaroslaw II., was born at Wladimir in 1219, and died 14th November 1263. He became prince of Novgorod on the resignation of his father in 1239, his elder brother having died. While Batu Khan was sweeping with his Tatars over the south, the Swedes, Danes, and Livonian knights took advantage of this to oppress the north of Russia; Alexander accordingly directed his arms against them, and gained a brilliant victory with his small army on the 15th July 1240. His surname of *Nevski* was derived from this event, which took place near the Neva, and in the vicinity of the modern St Petersburg. In a second campaign in 1241 he was no less successful, and drove his enemies out of Pleskow in Kiew. In a third campaign he defeated them near lake Peipus (1242), and forced the Livonian knights to sue for peace and retire from the district of Pskow, which they had conquered a short time before. On his father's death in 1247, a younger brother (Andrew) opposed Alexander, and seized the duchy of Wladimir; but in 1251 the latter was established in his rights by the khan of Kaptchak, the district which the Mongolian Batu had taken under his immediate authority. He firmly opposed the proposal of Pope Innocent IV. to unite the Greek with the Roman church. He died at Gorodetz, 14th November 1263, on his return from a visit to Kassimeow. Towards the close of his life he is said to have taken holy orders, but the tradition rests on no sure basis. At his death the people universally spoke of him as their father and protector, and afterwards recorded his deeds in their songs, and honoured him as a saint. Peter the Great, when founding St Petersburg, erected a magnificent monastery to the east of the city in honour of the victory won there by his great predecessor, and created in 1722 one of the eight Russian orders, that of Alexander Nevski. The monastery is now one of the wealthiest in Russia, and has, according to Eckhardt, a yearly revenue of half a million silver roubles.

ALEXANDER, Archibald, D.D., a Presbyterian divine of America, was born of a family, originally Scotch, in Rockbridge county, Virginia, on the 17th April 1772 (died

1851). After completing his preliminary education at Timber Ridge, he came under the influence of the religious movement known as the "great revival," and devoted himself to the study of theology. Licensed to preach in 1791, he was engaged for seven years as an itinerant missionary in his native state, and acquired during this period the facility of extemporaneous speaking for which he was remarkable. For a time president of Hampden Sidney College, he resigned that position in 1807 to become pastor of Pine Street church, Philadelphia. In 1810 the degree of doctor of divinity was conferred upon him by the college of New Jersey, and in the following year he was appointed first professor in the newly-established Presbyterian theological seminary at Princeton. He filled the chair until his death in 1851. Dr Alexander wrote a considerable number of works in theology, which have had a large circulation. Among these may be mentioned his *Outlines of the Evidences of Christianity* (1823), which has passed through several editions, and been translated into various languages; and his *Treatise on the Canon of the Old and New Testament* (1826). He was also a frequent contributor to the *Biblical Repertory*, edited by Professor Hodge.

ALEXANDER, Joseph Addison, D.D., third son of the preceding, one of the most eminent biblical scholars of America, was born in Philadelphia in 1809 (died 1860). He studied at New Jersey, devoting himself specially to Hebrew and other Oriental languages. He graduated in 1826, and from 1830 to 1833 was adjunct professor of ancient languages and literature in his *alma mater*. In 1838 he was appointed professor of biblical criticism and ecclesiastical history in the theological seminary at Princeton. He was transferred in 1852 to the chair of biblical and ecclesiastical history, which he occupied till his death in January 1860. Dr Alexander wrote several valuable works in his own department, the most important being a *Translation of and Commentary on the Psalms*, a *Critical Commentary on the Prophecies of Isaiah*, and a treatise on primitive church government. He also contributed numerous articles to the *Biblical Repertory* and the *Princeton Review*. At the time of his death he was engaged along with Dr Hodge in the preparation of a commentary on the New Testament.

ALEXANDER, Sir William, earl of Stirling, poet. The family of Alexander of Menstrie—*i.e.*, of the poet—is of ancient lineage, "tracing its descent from Somerled, lord of the Isles, in the reign of Malcolm IV., through a misty Highland genealogy, to John, lord of the Isles, who married the Princess Margaret, daughter of King Robert II. Their son, Alexander, was father of Angus, who founded the family of Macalister of Loup, and of Alexander, who obtained from the Argyle family a grant of the lands of Menstrie in Stirlingshire, and settled there—his descendants assuming his christian name of Alexander as their surname. The fifth in descent from this personage was Alexander Alexander, whose successor was his son, William Alexander, the poet" (Works: *Introductory Memoir*, vol. i. p. ix., 1870). From his (rare) engraved portrait, William was, it appears, aged 57 in 1637; so that he must have been born (at Menstrie House, where afterwards was born Sir Ralph Abercromby) in 1580. The grammar school of neighbouring Stirling probably furnished his early education; of his later, it is simply known that he attended the university of Glasgow. On leaving it he proceeded on his travels with Archibald, seventh earl of Argyle. It is supposed that it was during his sojourn on the Continent he composed his series of sonnets, afterwards published under the title of *Avrora* (1604). He was tutor to the young earl. Upon his return he proceeded to court, and won for himself speedily a name as a gentleman of parts and learning. The first of his *Monarchicke Tragedies* had been published at Edinburgh in 1603, viz., *The Tragedie of Darivs*, which, like his *Parenesis to the Prince* (1604), bore on the title-page simply, "By William Alexander of Menstrie." In 1604 he reprinted *Darivs* along with a new tragedy of *Cæsar*, giving the two the afterwards more celebrated title of *Monarchicke Tragedies*—ultimately increased by *The Alexandraen* and *Julius Cæsar* (1607). In 1607 he describes himself as "William Alexander, gentleman of the prince's privy chamber." King James was much taken with him. He held his office with the prince of Wales until his lamented death in 1612, on which he published his *Elegie on the Death of Prince Henrie* (Edinburgh, 1612). In 1612 he was made master of bequests, and knighted; his title-page of the *Elegie* bearing to be by "Sir William Alexander of Menstrie." In 1614 appeared his *Doomesday; or, the Great Day of the Lord's Ivdgement* (Edinburgh). In 1621 (September 21) he received the most prodigious "gift" ever bestowed on a subject, viz., "a gift and grant" of Canada, inclusive of Nova Scotia, or Acadie, and Newfoundland—a fact declarative of royal ignorance of what the gift really was. Yet was it subsequently confirmed by Charles I. In 1624, Alexander, in relation to his grant, published *An Encouragement to Colonies*—twice at least reprinted (1625 and 1630). The gift and grant belong to history rather than biography, and their later results to the romance of the peerage and of law. In 1626 he was appointed Secretary of State for Scotland, and in 1630 created a peer, as Lord Alexander of Tullibody, and Viscount Stirling. In 1631 he was made an extraordinary judge in the Court of Session. In 1632 he built Argyle House, a quaint building, which remains one of the "lions" of Stirling. In 1633 he was advanced a step in the peerage, being created Earl of Stirling and Viscount Canada; and in 1639 Earl of Dovan. In 1637 he collected his poetical works, and issued them as *Recreations with the Muses*, "by William, Earle of Sterline," with his portrait engraved by Marshall. This folio did not include either *Avrora* or the *Psalms of King David* (Oxford, 1631), although there seems little doubt that he, rather than King James, was the main author of the latter. It, however, first gave his second sacred poem (incomplete) of *Jonathan*. He died in London on 12th February 1640, and later his remains were transferred to Stirling. Lauded by Sir Robert Ayton and William Drummond of Hawthornden, the Earl of Stirling, nevertheless, soon fell out of men's memories. The recent careful and beautiful edition of his *Poetical Works* (3 vols.) ought to revive his fame; for while there is too often a wearying wordiness, the student-reader is rewarded with "full many a gem of purest ray serene." His *Doomesday* has some grand things; his *Avrora* suggests comparison with Sidney's *Astrophel and Stella*. (Works as above; Laing's *Baillie's Letters and Journals*, iii. 529; *Drummond MSS.*, by Laing; *Hunter's MSS.*, in Brit. Museum.) (A. B. G.)

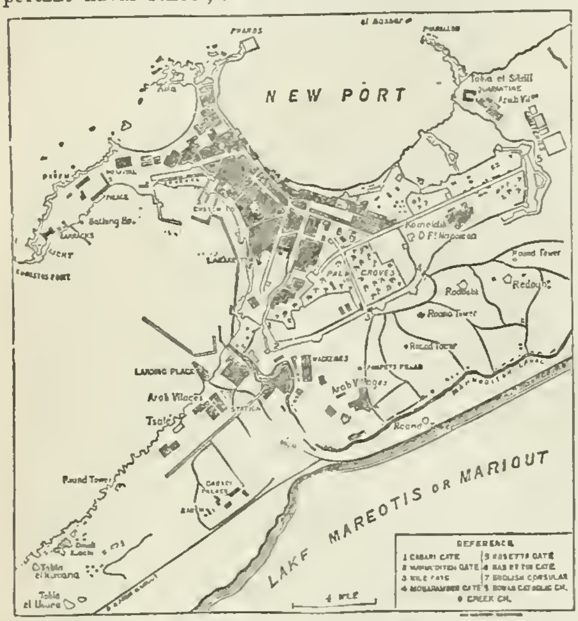
ALEXANDRETTA. See Scanderoon.

ALEXANDRIA, a city of Lower Egypt, and for a long time its capital, was situated on the Mediterranean, 12 miles west of the Canopic mouth of the Nile, in 31° 11′ N. lat., and 29° 52′ E. long. The ancient city was oblong in form, with a length from east to west of 3 to 4, a breadth from north to south of 1, and, according to Pliny, a circumference of 15 miles. Lake Mareotis bathed its walls on the south, and the Mediterranean on the north; on the west was the Necropolis, and on the east the Hippodrome. The city was laid out in straight parallel streets, one of which, about 200 feet wide, ran westward from the Canopic gate to the Necropolis. This street was decorated with magnificent houses, temples, and public buildings, and was intersected by another of the same breadth and magnificence, running from south to north. Ancient Alexandria was divided into three regions: (1.) The *Regio Judæorum*, or the Jews' quarter, forming the north-east portion of the city. (2.) *Rhacotis* on the west, occupied chiefly by Egyptians. Its principal building was the Serapeum, or temple of Serapis, containing an image of the god, brought probably from Pontus. A large part of the famous library of Alexandria was placed in the Serapeum. (3.) *Brucheum*, the Royal or Greek quarter, forming the remaining and most magnificent portion of the city In the Brucheum were the chief public buildings of Alexandria, the most noted of which was the splendid palace of the Ptolemies, on a peninsula called the Lochias, which stretched out into the Mediterranean towards the east of the city; the library proper, and the museum, a sort of college, with a dining-hall and lecture-rooms for the professors (see LIBRARY); the *Cæsarium*, or temple of the Cæsars, where divine honours were paid to the emperors; and the *Dicasterium*, or court of justice. An artificial mole, called the *Heptastadium*, nearly a mile in length, stretched from the continent to the isle of Pharos. Between this mole and the peninsula of Lochias was the greater harbour; on the other side of the mole was the harbour called *Eunostos*, or Safe Return. The two were connected with each other by two breaks in the mole, crossed by two bridges, which could be raised at pleasure. Within the harbour of Eunostos was an artificial basin called *Kibotos, i.e.*, the Chest, communicating with lake Mareotis by a canal, from which a separate arm stretched eastward to the Canopic mouth of the Nile. On the eastern point of the island of Pharos was the famous lighthouse, said to have been 400 feet high. It was begun by Ptolemy Soter, and finished by his successor, Philadelphus. It cost 800 talents, which, if Alexandrian, is equivalent to £218,000. In the time of Diodorus Siculus (50 B.C.), the population of Alexandria was estimated at 300,000 freemen, with probably at least as many slaves.

The city was founded by Alexander the Great 332 B.C.; but the island of Pharos was from an early period a refuge of Greek and Phœnician sea-rovers, a fact commemorated in the name "Pirates' Bay," given to a deep indentation on the north side of the island; and on the mainland was the little town of Rhacotis, subsequently incorporated in the quarter of that name. The architect employed by Alexander was the celebrated Dinocrates, who had acquired a high reputation by rebuilding the temple of Diana at Ephesus. The new city prospered greatly as a centre both of commerce and of learning, particularly during the reigns of the earlier Ptolemies, to whose enlightened liberality, indeed, its literary importance was largely due. But the later monarchs of the house of Lagus were mostly weak and vicious men, under whom the city declined in influence. In 80 B.C. Ptolemy Alexander bequeathed his city to the Romans; but the bequest did not immediately take effect owing to the civil convulsions in Italy, into which Alexandria itself was eventually drawn, and it was not until 30 B.C. that the city submitted to Augustus. It was by him made an imperial city, governed by a prefect appointed by the emperor, while the functions of the Alexandrian senate were suspended, a state of matters which continued until 196 A.D., when Severus restored its municipality.

Alexandria seems from this time to have regained its old prosperity, becoming an important granary of Rome, which, doubtless, was one of the chief reasons that induced Augustus to place it directly under the imperial power. In 215 A.D. the emperor Caracalla visited the city; and, in order to repay some insulting satires that the inhabitants had made upon him, he commanded his troops to put to death all youths capable of bearing arms. This brutal order seems to have been carried out even beyond the letter, for a general massacre was the result. Notwithstanding this terrible disaster, Alexandria soon recovered its former splendour, and for a time was esteemed the first city in the world after Rome. As the power of the Cæsars decreased, however, their hold over Alexandria was weakened, and the city itself suffered from internal commotions and insurrections, which gradually destroyed its importance. In 616 it was taken by Chosroes, king of Persia; and in 640 by the Arabians, under Amru, after a siege that lasted fourteen months, during which Heraclius, the emperor of Constantinople, did not send a single ship to its assistance. Notwithstanding the losses that the city had sustained, Amru was able to write to his master, the caliph Omar, that he had taken a city containing "4000 palaces, 4000 baths, 12,000 dealers in fresh oil, 12,000 gardeners, 40,000 Jews who pay tribute, 400 theatres or places of amusement." The following story, relating to the destruction of the library, is told by Abulfaragius:—John the Grammarian, a famous Peripatetic philosopher, being in Alexandria at the time of its capture, and in high favour with Amru, begged that he would give him the royal library. Amru told him that it was not in his power to grant such a request, but promised to write to the caliph for his consent. Omar, on hearing the request of his general, is said to have replied that if those books contained the same doctrine with the Koran, they could be of no use, since the Koran contained all necessary truths; but if they contained anything contrary to that book, they ought to be destroyed; and therefore, whatever their contents were, he ordered them to be burnt. Pursuant to this order, they were distributed among the public baths, of which there was a large number in the city, where, for six months, they served to supply the fires. Shortly after its capture, Alexandria again fell into the hands of the Greeks, who took advantage of Amru's absence with the greater portion of his army. On hearing what had happened, however, Amru returned, and quickly regained possession of the city. About the year 646 Amru was deprived of his government by the caliph Othman. The Egyptians, by whom Amru was greatly beloved, were so much dissatisfied by this act, and even showed such a tendency to revolt, that Constantine, the Greek emperor, determined to make an effort to reduce Alexandria. The attempt proved perfectly successful, Manuel, Constantine's general, capturing the city with inconsiderable loss. The caliph, perceiving his mistake, immediately restored Amru, who, on his arrival in Egypt, drove the Greeks within the walls of Alexandria, but was only able to capture the city after a most obstinate resistance by the defenders. This so exasperated him that he completely demolished its fortifications, although he seems to have spared the lives of the inhabitants as far as lay in his power. Alexandria now rapidly declined in importance. It was captured by Andalusian adventurers in 823; by the Moghrebins in 924, and again in 928. The building of Cairo in 969, and, above all, the discovery of the route to the East by the Cape of Good Hope in 1497, nearly ruined its commerce; and after this we hear little of the city until the beginning of the present century.

ALEXANDRIA, the modern city, stands partly on what was the island of Pharos, now a peninsula, but mostly on the isthmus by which it is connected with the mainland. This was originally an artificial dyke connecting the island with the land opposite; but, through the constant accumulation of soil and ruins, it has attained its present dimensions. The principal public and government buildings are on the peninsula. The ancient city was situated on the mainland, adjacent to the modern town, and the extent of the ruins that still exist sufficiently attests its greatness. The general appearance of Alexandria is by no means striking; and from its situation its environs are sandy, flat, and sterile. It was formerly surrounded by strong turreted walls, with extensive outworks, but in various parts the walls have lately been destroyed to make way for improvements. In the Turkish quarter the streets are narrow, irregular, and filthy, and the houses mean and ill-built. The Frank quarter, on the other hand, presents the appearance of a European town, having handsome streets and squares, and excellent shops. The streets have been much improved lately by being nearly all paved. The principal hotels, shops, and offices are situated in the Great Square, the centre of which forms a very agreeable promenade, being planted with trees, and well provided with seats. It has also a fountain at each end. In the suburbs are numerous handsome villas, with pleasant gardens. Among the principal public buildings are the palace of the pasha, the naval arsenal, the naval and military hospitals, custom-house, bourse, two theatres, several mosques, churches, convents, &c. There is an important naval school, and a number of other educational



institutions. Among the charities worthy of mention is the hospital of the Deaconesses of Kaisersworth. Formerly the town was supplied with water by means of the ancient reservoirs formed under the old city, which are in many cases as perfect now as when first made, 2000 years ago These were annually filled with water by means of the canal from the Nile, at the time of inundation; but a system of water-works has been formed by a public company, and a constant supply of water is now obtained from the canal at some distance from the town. The principal streets, squares, and railway stations, are lighted with gas.

Few of the remains of the ancient city are now visible. Most of those that were to be seen a few years ago have since disappeared, but frequently in making excavations portions of ancient masonry, broken columns, and fragments of statues are discovered. Among the best known of the ancient relics are the two obelisks commonly called "Cleopatra's Needles." They were originally brought from Heliopolis to Alexandria in the reign of Tiberius, and were set up in front of the temple of Cæsar. They are of red granite, and covered with hieroglyphics. One is still standing, and is 71 feet high and 7 feet 7 inches in diameter at the base. The other, which is fallen and covered with debris, is in a less perfect state, and not quite so long as the former. It was offered to the English government by Mehemet Ali, but after some consideration was declined. Near the obelisks are the ruins of an old round tower, commonly called the "Roman Tower." But the most striking of the ancient monuments is the column styled "Pompey's Pillar." It stands on a mound of earth about 40 feet high, and has a height of 98 feet 9 inches. The shaft consists of a single piece of red granite, and is 73 feet long and 29 feet 8 inches in circumference. The capital is Corinthian, 9 feet high, and the base is a square of about 15 feet on each side. From an inscription it appears to have been erected in honour of the emperor Diocletian, and it was formerly surmounted by a statue of that monarch. To the S.W. of the city are the catacombs, which served for the burial of the dead, and are formed by excavations in the calcareous rock of which the shore is composed. They are of great extent, and one of the chambers is remarkable for its elegance. The climate of Alexandria is mild and salubrious. The heats of summer are modified by the N.W. winds from the sea, which prevail during nine months of the year, the thermometer seldom rising above 85° Fahr. In winter a good deal of rain falls, and throughout the year the atmosphere is generally moist, being saturated with a saline vapour from the sea.

Alexandria has been mainly indebted for its prosperity to the advantages of its position for trade. It was this that first attracted the attention of its far-seeing founder to the site, and its subsequent history in no way belied his penetration. It soon rose to be the most important commercial city in the world, and the great emporium of trade between Europe and the East. Subsequently its fortunes fluctuated with those of its possessors, but the great blow to its prosperity was the discovery of the route to India by the Cape of Good Hope, and under the Turks it sank into insignificance, numbering only about 6000 inhabitants. Soon after Mehemet Ali became ruler of Egypt he turned his attention to the restoration of Alexandria. One of the most important works that he effected with this view was the opening of the Mahmoudieh Canal in 1820. This was accomplished at a cost of about £300,000, and, for want of proper management, at a melancholy loss of human life. It is about 50 miles in length, with an average width of about 100 feet, and communicates with the Rosetta branch of the Nile at the village of Atfeh. Since Alexandria became the centre of the steam communication between Europe and India, and the principal station on the Overland Route, its progress has been rapid. It has now regular communication with England, Marseilles, Brindisi, Constantinople, &c. In 1851 Mr Stephenson was instructed to form a railway between Alexandria and Cairo, which was accomplished, and the line opened for traffic, in 1856. This was shortly afterwards extended to Suez, and several extensions have since been made to the cotton districts of the Delta. A short line of railway (not belonging to the government) connects the town with Ramleh, a sea-bathing village about 7 miles distant.

Alexandria has two ports, an eastern and a western. The latter, called also the Old Port, is by far the larger and better of the two. It extends from the town westward to Marabout, nearly 6 miles, and is about a mile and a-half in width. It has three principal entrances. The first, or that nearest the city, has about 17 feet of water, but is narrow and difficult of access, and only used by small vessels and boats. The second or middle, which is also the principal entrance, is about a quarter of a mile wide, and has, where shallowest, 27 feet of water. The eastern side of this entrance is marked by buoys, and there are landmarks for guiding to the channel. The third or western entrance has its western boundary about three eighths of a mile from Marabout Island, is about half a mile wide, and has from 25 to 27 feet of water where shallowest. Within the harbour ships may anchor close to the town in from 22 to 40 feet of water. Further improvements, in course of construction by a firm of English contractors (at a cost to the Egyptian government of little short of two millions sterling), will eventually render this one of the finest and most capacious harbours on the Mediterranean. Among these are the formation of a breakwater, extending in a south-westerly direction parallel to the shore for 2550 yards south-west of the lighthouse on Cape Eunostos; a mole, springing from the shore, and extending in a northerly direction for 1100 yards, and having a width of about 100 feet; and the construction of nearly 3 miles of quays and wharves, for vessels of the largest size, and with railway connection. The foundation-stone of the breakwater was laid by the viceroy on 15th May 1871. The area of deep water, 30 feet and upwards, enclosed within the outer breakwater, is 1400 acres; the area of 28 feet of water, enclosed by the harbour mole, will be 177 acres. The workshops of the company are at the quarries of Mex, about 3 miles west of the town. In the harbour is a magnificent floating dock, nearly 500 feet long and 100 feet broad. The old lighthouse, on the site of the ancient Pharos, having been found insufficient, a new lighthouse has been erected on Ras-el-teen (1842), bearing a one-minute revolving light, visible at a distance of 20 miles. The eastern or new port, formerly the only port open to Christians, is now little used, being exposed to the northerly gales, and having very limited space for anchorage.

In 1861 the total value of the exports was £2,638,822; and in 1871 this had risen to £10,251,608, of which £7,706,442 was to England. The value of the imports for the latter year was £5,753,020, of which £2,469,026 was from England. The principal articles of export were cotton (£6,402,756), cotton seed (£1,008,278), beans (£753,462), corn (£573,766), sugar (£379,456), gums (£307,932), coffee (£122,110), ivory, wool, linseed, senna, and other drugs. The principal articles of import were manufactured goods (£1,695,870), wool (£307,495), oils (£251,158), wines and liqueurs (£239,944), raw silk, fruits. During that year there entered 1841 sailing vessels and 883 steam vessels with cargoes, and 143 sailing vessels and 54 steam vessels in ballast; and there left 1085 sailing vessels and 843 steam vessels with cargoes, and 797 sailing vessels and 62 steam vessels in ballast. The total tonnage of the vessels that entered was 1,262,602; and that left, 1,267,381. The opening of the Suez Canal will no doubt serve to withdraw a portion of the traffic from Alexandria, but the improvements that are now being made on its harbour, and its direct railway communication with Suez, must still give it certain advantages over the other route, while it must continue to be the great emporium for the rapidly extending trade of Egypt itself.

The population of Alexandria is of a very mixed character, consisting, besides the native Turks and Arabs, of Armenians, Greeks, Syrians, Italians, French, English, Germans, &c. At one time the ancient city is believed to have contained 600,000 inhabitants; but at the beginning of this century the number probably did not exceed 6000. In 1825 this had increased to 16,000, in 1840 to 60,000, and in 1871 to 219,602, of whom 53,829 were foreigners.

ALEXANDRIA, a town of Scotland, in the parish of Bonhill, Dumbartonshire, pleasantly situated on the west bank of the river Leven, about 3 miles from Dumbarton, with which it is connected by a branch railway. It is a place of comparatively recent growth, owing its origin almost entirely to the cotton print and bleaching works of the vicinity, for which there is an abundant supply of excellent water. Population (1871), 4650.

ALEXANDRIA, a town and port of entry of the United States, capital of Alexandria county, Virginia, is beautifully situated on the right bank of the Potomac, 7 miles below Washington. It is neat and well-built, with a good harbour, and exports considerable quantities of grain and flour; but its foreign trade has decreased. The Chesapeake and Ohio canal begins here, and the town is connected with Washington by railway. Population (1870), 13,570.

ALEXANDRIAN MS. (*Codex Alexandrinus*), the name given to a Greek manuscript of the Old and New Testaments, now in the British Museum. This celebrated MS. is known to biblical scholars as Codex A. This abbreviation of Alexandrinus was first employed by Bishop Walton to indicate the various readings of this MS., appended to the text of the Septuagint and of the New Testament in his great Polyglott Bible, and was adopted by Wetstein in conformity with an arrangement, since followed by all editons of the Septuagint and Greek Testament, by which the capital letters of the alphabet are applied to designate the uncial MSS. of the Greek Bible. The MS. was presented in the year 1628 to King Charles I. through his ambassador at the Porte, Sir Thomas Rowe, by Cyrillus Lucaris, patriarch of Constantinople. There seems no good reason to doubt that Cyrillus had brought the document from Alexandria, where he had held the office of patriarch, although Wetstein is of opinion, upon what seems inadequate evidence, that he procured it from the monastery of Mount Athos, where he had resided prior to his coming to Alexandria. It was transferred in 1753 from the king's private library to that of our national museum, where the volume containing the text of the New Testament is now, or was lately, open to public inspection under a glass case. The entire MS. consists of four small folio volumes, three of which contain the text of the Old, and one that of the New Testament. The portion, however, containing the Old Testament is more complete than that which contains the New, the *lacunæ* in the former occurring chiefly in the book of Psalms; while in the New Testament the following portions are wanting—viz., the whole of Matthew's Gospel up to chap. xxv. 6, from John vi. 50 to viii. 52, and from 2 Cor. iv. 13 to xii. 6. Occasionally, also, single letters, as well as the titles of certain divisions, have been destroyed by the operations of the bookbinder. The material of which the MS. is composed is very thin vellum, the page being about 13 inches high by 10 broad, containing from 50 to 52 lines in each page, each line consisting of about 20 letters. The number of pages is 773, of which 640 are occupied with the text of the Old Testament, and 133 with that of the New. The characters are *uncial*, but larger than in the Vatican MS. B. There are no accents or breathings, no spaces between the letters or words save at the end of a paragraph; and the contractions, which are not numerous, are only such as are found in the oldest MSS., and are indicated by a line drawn over the word which is abbreviated, as $\overline{\Theta\Sigma}$ for Θεός. The punctuation consists of a point placed at the end of a sentence, usually on a level with the top of the preceding letter. As regards the date of the MS. very opposite opinions have been held. One critic placed it as low down as the 10th century, but this supposition has been justly characterised by Tregelles as so opposed to all that is known of palæography as not to deserve a serious refutation. From the circumstance that the MS. does not exhibit any traces of *stichometry*—a mode of arranging the text in lines consisting of a larger or smaller number of words, at the end of which the reader was to pause, which was applied to the Pauline epistles by Euthalius of Alexandria in the year 458, and which soon came into general use—it has been inferred that the MS. is not of later date than the middle of the 5th century. Again, the presence, in the text of the Gospels of the Ammonian sections and Eusebian canons, and of the epistle of Athanasius (who died in 373) to Marcellinus, which is prefixed to the Psalms, shows that it could not be older than the end of the 4th century. In addition to this external testimony, palæographic reasons, such as the general style of the writing, and the formation of certain letters, would seem to refer the MS. to about the middle of the 5th century, and this date is now generally acquiesced in by scholars. There is an Arabic inscription, indeed, written on the page which contains the list of the various books of the Old and New Testament, which states that the MS. was written by the hand of the martyr Thecla, while a Latin inscription by Cyril himself gives the tradition that the Thecla who wrote the MS. was a noble Egyptian lady who lived shortly after the Council of Nice. No reliance, however, can be placed on these statements, for, according to Scrivener,

"Tregelles explains the origin of the Arabic inscription on which Cyril's statement appears to rest, by remarking that the New Testament in our MS. at present commences with Matt. xxv. 6, this lesson (Matt. xxv. 1-13) *being that appointed by the Greek Church for the festival of St Thecla.* The Egyptian, therefore, who wrote this Arabic note, observing the name of Thecla in the now mutilated upper margin of the codex, where such rubrical notes are commonly placed by later hands, hastily concluded that she wrote the book, and thus has perplexed our biblical critics. It is hardly too much to say that Tregelles's shrewd conjecture seems to be certain, almost to demonstration."

This MS. contains the last twelve verses of St Mark's Gospel. It is defective in that part of St John's Gospel where the *pericope adulteræ* occurs in the ordinary text, but Scrivener shows by an enumeration of the letters in each page that the two missing leaves did not contain the suspected passage. It is almost unnecessary to say that 1 John v. 7 is not found in this or in any uncial MS. of the New Testament. The reading of the MS. in 1 Tim. iii. 16 has given rise to a good deal of discussion. Woide in his fac-simile edition gave the reading $\overline{\Theta\Sigma}$ for ΘΕΟΣ. The element of uncertainty was whether the cross bar of the theta had not been added by a later hand, so that the original reading may have been ΟΣ. Bishop Ellicott carefully examined the passage with the aid of a strong lens, and the result of his investigation, as given in a note appended to his Critical Commentary on First Timothy, in his edition of the *Pastoral Epistles*, was to satisfy him that the original reading was ὅς, the cross bar of the theta having arisen from the central line of ε in the word εὐσεβεία, which is directly opposite, shining through the leaf, and being mistaken by a scribe for part of the theta, and being touched up accordingly,—a view which was maintained by Wetstein. On the other hand, both Tregelles and Scrivener, who made the same investigation, are of opinion that the stroke of the epsilon cuts the theta much too high to be mistaken by any ordinary scribe for the cross bar of the theta. When critics of such distinguished reputation differ, the question of the original reading will probably remain for ever uncertain.

The first use that was made of the MS. for critical purposes was by Bishop Walton, who had the various readings which it presents inserted in his great Polyglott Bible, under the texts of the Septuagint and New Testament respectively. It was collated by both Mill and Wetstein for their editions of the Greek Testament. In 1786 the New Testament was published in a fac-simile edition by Dr Woide, at that time librarian to the British Museum; the types of this edition were cut so as to represent the general appearance of the letters; and the edition exhibits the MS. page for page, line for line, and letter for letter. The work was accompanied by valuable prolegomena on the history, age, &c., of the MS.; and is allowed to have been executed with remarkable accuracy. In 1828 the Rev. H. H. Baber completed the publication of the Old Testament portion in three large folio volumes (1816–1828) also in fac-simile, with useful prolegomena and notes. Tischendorf considers the editorial accuracy of Baber as inferior to that of Woide, and enumerates a number of instances where the readings of the original have been incorrectly given by Baber (Prolegomena to Tischendorf's 4th ed. of the Septuagint, p. 69, *sq.*) In 1860 the text of the New Testament was published in common type by B. H. Cowper, the defective portions being supplied from Küster's edition of Mill's Greek Testament, and some inaccuracies in Woide's edition corrected from the original. In 1864 there was published at Oxford, under the editorship of Mr Hansell, the text of the *Codex Alexandrinus*, along with that of three of the most ancient MSS., viz., *Codd.* B, C, D, with the Dublin *Cod.* Z, and a collation of the *Cod. Sinaiticus.* The work is arranged in parallel columns, and thus presents, at one view, the readings of four of our earliest authorities for the text of the New Testament. (F. C.)

For more minute information regarding this MS. we refer to the prolegomena of Woide and Baber; to Scrivener's *Introduction to the Criticism of the New Testament*, Cambridge, 1861; to the fourth volume of Horne's *Introduction to the New Testament* by Tregelles, London, 1866; and to Davidson's *Biblical Criticism*, vol. ii., Edinburgh, 1852. We subjoin a list of the books of the Old and New Testament in the order in which they are found in the MS.:—

TOM. I.

Γενεσις Κοσμου	Genesis.
Εξοδας Αιγυπτου	Exodus.
Λευιτικον	Leviticus.
Αριθμοι	Numbers.
Δευτερονομιον	Deuteronomy.
Ιησους Ναυη	Joshua, son of Nun.
Κριται	Judges.
Ρουθ	Ruth.
Βασιλειων α′	Samuel I. (or Kings I.)
Βασιλειων β′	Samuel II. (or Kings II.)
Βασιλειων γ′	Kings I. (or III.)
Βασιλειων δ′	Kings II. (or IV.)
Παραλειπαμενων α′	Chronicles I
Παραλειπουενων β′	Chronicles II

TOM. II.

Ωσηε	Hosea.
Αμως	Amos.
Μιχαιας	Micah.
Ιωηλ	Joel.
Αβδειου	Obadiah.
Ιωνας	Jonah.
Ναουμ	Nahum.
Αμβακουμ	Habakkuk.
Σοφονιας	Zephaniah.
Αγγαιος	Haggai.
Ζαχαριας	Zechariah
Μαλαχιας	Malachi.
Ησαιας	Isaiah.
Ιερεμιας	Jeremiah.
Βαρουχ	Baruch.
Θρηνοι	Lamentations.
Επιστολη Ιερεμιου	Epistle of Jeremiah.
Ιεζεκιηλ	Ezekiel.
Δανιηλ	Daniel.
Εσθηρ.	Esther.
Τωβιτ.	Tobit.
Ιουδειθ	Judith.
Εσδρας α′	Esdras I.
Εσδρας β′	Esdras II., including Νεεμια, and part of the canonical Book of Ezra.
Μακκαβαιων α′	Maccabees I.
Μακκαβαιων β′	Maccabees II.
Μακκαβαιων γ′	Maccabees III
Μακκαβαιων δ′	Maccabees IV.

TOM. III.

Αθανασιου Επιστολη	Epistle of Athanasius to Marcellinus on the Psalms.
Ευσεβιου Υποθεσεις (*sic*)	Hypothesis of Eusebius on the Psalms.
Ψαλτηριον μετ' Ωδων	Psalms 151, Hymns 15.
Ιωβ	Job.
Παροιμιαι	Proverbs.
Εκκλησιαστης	Ecclesiastes.
Ασμα Ασματων	Canticles.
Σοφια Σολομωντος	Wisdom of Solomon.
Σοφια Ιησου υιου Σιραχ	Ecclesiasticus, or Wisdom of Jesus, son of Sirach.

TOM. IV.

Ευαγγελιον κατα Ματθαιον	Matthew.
Ευαγγελιον κατα Μαρκον	Mark.
Ευαγγελιον κατα Λουκαν	Luke.
Ευαγγελιον κατα Ιωαννην	John.
Πραξεις Αποστολων	Acts of the Apostles.
Επιστολαι Καθολικαι ζ′	Seven Catholic Epistles, viz., 1 of James, 2 of Peter, 3 of John, and 1 of Jude.
Επιστολαι Παυλου ιδ′	Fourteen Epistles of Paul.
Αποκαλυψις Ιωαννου	Revelation of John.
Κλημεντος Επιστολη α′	1st Epistle of Clement to the Corinthians.
Κλημεντος Επιστολη β′	2d Epistle of Clement to the Corinthians.
Ψαλμοι Σολομωντος η′	Eight Psalms of Solomon.

ALEXANDRIAN SCHOOL. Under this title are generally included certain strongly-marked tendencies in literature and science which took their rise in the city of Alexandria. That city, founded by Alexander the Great about the time when Greece, in losing her national independence, lost also her intellectual supremacy, was in every way admirably adapted for becoming the new centre of the world's activity and thought. Its situation brought it into commercial relations with all the nations lying around the Mediterranean, and at the same time rendered it the one communicating link with the wealth and civilisation of the East. The great natural advantages it thus enjoyed were artificially increased to an enormous extent by the care of the sovereigns of Egypt. Ptolemy Soter (reigned 306–285 B.C.), to whom, in the general distribution of Alexander's conquests, this kingdom had fallen, began to draw around him from various parts of Greece a circle of men eminent in literature and philosophy. To these he gave every facility for the prosecution of their learned researches. Under the inspiration of his friend Demetrius Phalereus, the Athenian orator, this Ptolemy laid the foundations of the great library, and originated the keen search for all written works, which resulted in the formation of a collection such as the world has seldom seen. He also built, for the convenience of his men of letters, the Museum, in which, maintained by the royal bounty, they resided, studied, and taught. This Museum or academy of science was in many respects not unlike a modern university. The work thus begun by Ptolemy Soter was carried on vigorously by his descendants, in particular by his two immediate successors, Ptolemy Philadelphus and Ptolemy Euergetes. Philadelphus (285–247 B.C.), whose librarian was the celebrated Callimachus, bought up all Aristotle's collection of books, and also introduced a number of Jewish and Egyptian works. Among these appears to have been a portion of the Septuagint. Euergetes (247–222 B.C.) largely increased the library by seizing on the original editions of the dramatists laid up in the Athenian archives, and by compelling all travellers who arrived in Alexandria to leave a copy of any work they possessed.

The intellectual movement so originated extended over a long period of years. If we date its rise from the 4th century B.C., at the time of the fall of Greece and the foundation of the Græco-Macedonian empire, we must look for its final dissolution in the 7th century of the Christian era, at the time of the fall of Alexandria and the rise of the Mahometan power. But this very long period falls into two divisions. The first, extending from about 306 B.C. to about 30 B.C., includes the time from the foundation of the Ptolemaic dynasty to its final subjugation by the Romans; the second extends from 30 B.C. to 640 A.D. The characteristic features of these divisions are very clearly marked, and their difference affords an explanation of the variety and vagueness of meaning attaching to the term Alexandrian School. In the first of the two periods the intellectual activity was of a purely literary and scientific nature. It was an attempt to continue and develop, under new conditions, the old Hellenic culture. This direction of effort was particularly noticeable under the early Ptolemies, Alexandria being then almost the only home in the world for pure literature. During the last century and a half before the Christian era, the school, as it might be called, began to break up and to lose its individuality. This was due partly to the state of government under some of the later Ptolemies, partly to the formation of new literary circles in Rhodes, Syria, &c., whose supporters, though retaining the Alexandrian peculiarities, could scarcely be included in the Alexandrian school. The loss of active life, consequent on this gradual dissolution, was much increased when Alexandria fell under Roman sway. Then the influence of the school was extended over the whole known world, but men of letters began to concentrate at Rome rather than at Alexandria. In that city, however, there were new forces in operation which produced a second grand outburst of intellectual life. The new movement was not in the old direction—had, indeed, nothing in common with it. With its character largely determined by Jewish elements, and even more by contact with the dogmas of Christianity, this second Alexandrian school resulted in the speculative philosophy of the Neo-Platonists and the religious philosophy of the Gnostics and early church fathers.

There appear, therefore, to be at least two definite significations of the title Alexandrian School; or rather, there are two Alexandrian schools, distinct both chronologically and in substance. The one is the Alexandrian school of poetry and science, the other the Alexandrian school of philosophy. As regards the use of the word "school" to denote these movements, it must be observed that the term is misleading. It has not the same meaning as when applied to the Academics or Peripatetics, the Stoics or Epicureans. These consisted of a company united by holding in common certain speculative principles, by having the same theory of things. There was nothing at all corresponding to this among the Alexandrians. In literature their activities were directed to the most diverse objects; they have only in common a certain spirit or form. There was among them no definite system of philosophy. Even in the later schools of philosophy proper there is found a community rather of tendency than of definite result or of fixed principles.

Alexandrian School of Literature.—The general character of the literature of the school appears as the necessary consequence of the state of affairs brought about by the fall of Greek nationality and independence. The great works of the Greek mind had formerly been the products of a fresh life of nature and perfect freedom of thought. All their hymns, epics, and histories were bound up with their individuality as a free people. But the Macedonian conquest at Chæronea brought about a complete dissolution of this Greek life in all its relations, private and political. The full, genial spirit of Greek thought vanished when freedom was lost, with which it was inseparably united. A substitute for this originality was found at Alexandria in learned research, extended and multifarious knowledge. Amply provided with means for acquiring information, and under the watchful care of a great monarch, the Alexandrians readily took this new direction in literature. With all the great objects removed which could excite a true spirit of poetry, they devoted themselves to minute researches in all sciences subordinate to literature proper. They studied criticism, grammar, prosody and metre, antiquities and mythology. The results of this study constantly appear in their productions. Their works are never national, never addressed to a people, but to a circle of learned men. Moreover, the very fact of being under the protection, and, as it were, in the pay of an absolute monarch, was damaging to the character of their literature. There was introduced into it a courtly element, clear traces of which, with all its accompaniments, are found in the extant works of the school. One other fact, not to be forgotten in forming a general estimate of the literary value of their productions, is, that the same writer was frequently or almost always distinguished in several special sciences. The most renowned poets were at the same time men of culture and science, critics, archæologists, astronomers, or physicians. To such writers the poetical form was merely a convenient vehicle for the exposition of science.

The forms of poetical composition chiefly cultivated by the Alexandrians were epic and lyric or elegiac. Grea epics are wanting; but in their place, as might almost have been expected, are found the historical and the didactic or expository epics. The subjects of the historical epics were generally some of the well-known myths, in the exposition of which the writer could exhibit the full extent of his learning and his perfect command of verse. These poems are in a sense valuable as repertories of antiquities; but their style is on the whole bad, and infinite patience is required to clear up their numerous and obscure allusions. The best extant specimen is the *Argonautica* of Apollonius Rhodius; the most characteristic is the *Alexandra* or *Cassandra* of Lycophron, the obscurity of which is almost proverbial.

The subjects of didactic epics were very numerous; they seem to have depended on the special knowledge possessed by the writers, who used verse as a form for unfolding their information. Some, *e.g.*, the lost poem of Callimachus, called Αἴτια, were on the origin of myths and religious observances; others were on special sciences. Thus we have two poems of Aratus, who, though not resident at Alexandria, was so thoroughly imbued with the Alexandrian spirit as to be with reason included in the school; the one is an essay on astronomy, the other an account of the signs of the weather. Nicander of Colophon has also left us two epics, one on remedies for poisons, the other on the bites of venomous beasts. Of many other epic poets only the names are known, as Dicæarchus, Euphorion, Rhianus, Dionysius, Oppianus. The spirit of all their productions is the same, that of learned research. They are distinguished by artistic form, purity of expression, and strict attention to the laws of metre and prosody, qualities which, however good in themselves, do not compensate for want of originality, freshness, and power.

In their lyric and elegiac poetry there is much worthy of admiration. The specimens we possess are not devoid of talent or of a certain happy art of expression. Yet, for the most part they either relate to objects thoroughly incapable of poetic treatment, where the writer's endeavour is rather to expound the matter fully than to render it poetically beautiful, or else expend themselves on short isolated subjects, generally myths, and are erotic in character. The earliest of the elegiac poets was Philetas, the sweet singer of Cos. But the most distinguished was Callimachus, undoubtedly the greatest of the Alexandrian poets. Of his numerous works there remain to us only a few hymns, epigrams, and fragments of elegies. Other lyric poets were Phanocles, Hermesianax, Alexander of Ætolia, and Lycophron.

Some of the best productions of the school were their epigrams. Of these we have several specimens, and the art of composing them seems to have been assiduously cultivated, as might naturally be expected from the court life of the poets, and their constant endeavours after terseness and neatness of expression. Of kindred character were the parodies and satirical poems, of which the best examples were the Σίλλοι of Timon.

Dramatic poetry appears to have flourished to some extent. There are still extant three or four varying lists of the seven great dramatists who composed the Pleiad of Alexandria. Their works, perhaps not unfortunately, have perished. A ruder kind of drama, the amœbæan verse, or bucolic mime, developed into the only pure stream of genial poetry found in the Alexandrian School, the *Idylls* of Theocritus. The name of these poems preserves their original idea; they were *pictures* of fresh country life.

The most interesting fact connected with this Alexandrian poetry is the powerful influence it exercised on Roman literature. That literature, especially in the Augustan age, is not to be thoroughly understood without due appreciation of the character of the Alexandrian School.

Before the Alexandrians had begun to produce original works, their researches were directed towards the masterpieces of ancient Greek literature. If that literature was to be a power in the world, it must be handed down to posterity in a form capable of being understood. This was the task begun and carried out by the Alexandrian critics. These men did not merely collect works, but sought to arrange them, to subject the texts to criticism, and to explain any allusion or reference in them which at a later date might become obscure. The complete philological examination of any work consisted, according to them, of the following processes:—διόρθωσις, arrangement of the text; ἀνάγνωσις, settlement of accents; τέχνη, theory of forms, syntax; ἐξήγησις, explanation either of words or things; and finally, κρίσις, judgment on the author and his work, including all questions as to authenticity and integrity. To perform their task adequately required from the critics a wide circle of knowledge; and from this requirement sprang the sciences of grammar, prosody, lexicography, mythology, and archæology. The service rendered by these critics is invaluable. To them we owe not merely the possession of the greatest works of Greek intellect, but the possession of them in a readable state. The most celebrated critics were Zenodotus; Aristophanes of Byzantium, to whom we owe the theory of Greek accents; and Aristarchus of Samothrace, confessedly the Coryphæus of criticism. Others were Alexander of Ætolia, Lycophron, Callimachus, Eratosthenes, and many of a later age, for the critical school long survived the literary. These philological labours were of great indirect importance, for they led immediately to the study of the natural sciences, and in particular to a more accurate knowledge of geography and history. Considerable attention began to be paid to the ancient history of Greece, and to all the myths relating to the foundation of states and cities. A large collection of such curious information is contained in the *Bibliotheca* of Apollodorus, a pupil of Aristarchus, who flourished in the 2d century B.C. Eratosthenes was the first to write on mathematical and physical geography; he also first attempted to draw up a chronological table of the Egyptian kings, and of the historical events of Greece. His Egyptian chronology, along with that of Manetho, is still of great interest to scholars; and Bunsen speaks with the highest admiration of his researches in Greek history. The sciences of mathematics, astronomy, and medicine were also cultivated with assiduity and success at Alexandria, but they can scarcely be said to have their origin there, or in any strict sense to form a part of the peculiarly Alexandrian literature. The founder of the mathematical school was the celebrated Euclid: among its scholars were Archimedes; Apollonius of Perga, author of a treatise on *Conic Sections;* Eratosthenes, to whom we owe the first measurement of the earth; and Hipparchus, the founder of the epicyclical theory of the heavens, afterwards called the Ptolemaic system, from its most famous expositor, Claudius Ptolemæus. Alexandria continued long after the Christian era to be celebrated as a school of mathematics and science.

Alexandrian School of Philosophy.—Although it is not possible to divide literatures with absolute rigidity by centuries, and although the intellectual life of Alexandria, particularly as applied to science, long survived the Roman conquest, yet at that period the school, which for some time had been gradually breaking up, seems finally to have succumbed. The later productions in the field of pure literature bear the stamp of Rome rather than of Alexandria. But in that city, for some time past, there had been various forces secretly working, and these coming in contact with great spiritual changes occurring in the world around, produced a second outburst of intellectual activity.

Among the natives of foreign countries transplanted to Alexandria by its founder had been a few Jews. These gradually increased in number, until, about the time of the Christian era, they formed an influential part of the populace of Egypt, inhabited two of the five quarters of the capital, and held high offices in the state. They had been well treated by the Ptolemies, and for some time experienced similar treatment from the Romans. The new movement of thought was in great measure due to the presence of this Jewish element. The contact of free Greek speculation with the peculiar Jewish ideas of the transcendence of God, of a special revelation, and of a singular subjective ecstasy, the prophetic state, could not fail to have a strong effect on the mode of thought of the most highly cultured Jews. From many causes they were more than ordinarily open to receive foreign ideas. Their isolated position had been broken in upon by their long residence as a small minority in the midst of an atmosphere of Greek custom and thought, and in the most highly cultivated city in the world. Their separation from their native country had tended to broaden their views by weakening the strong political convictions which united their destiny and their sacred writings with a definite land. It was a necessary consequence that they should endeavour so far as possible to assimilate their principles to Greek ideas. The two systems were not, they found, in total contradiction; they had several points in common. This was specially the case with the Platonic writings. There thus arose among the Jews a constantly increasing tendency to modify or widen their doctrines so as to admit of Greek conceptions, and then, with the aid of these conceptions, to systematise their own somewhat vague religious views. In this way philosophy and religion would be united or identified. There is truth in all philosophy, for philosophy is but a mangled reproduction of the sacred record in which all truth is contained. The Scriptures contain all philosophy, but not explicitly; they require to be interpreted. The system thus developed has a philosophical aspect, yet never ceases to be essentially Jewish, for the ultimate resort is always to a body of doctrine expressly revealed. Progress in this direction was possible in two ways. First, the pure Greek metaphysical thought rejected a body of truth said to have been revealed to a special people, but retained the idea of revelation to the individual thinker. A doctrine was thus evolved which contained most of the oriental or Jewish theosophical ideas, but in logical sequence and based for the most part on the earlier works of Greek thinkers. Religion was retained, but was explained or had a meaning given by philosophy. To this powerful movement of thought the name Neo-Platonism is given; its chief representatives were Ammonius Saccas, Plotinus, Porphyry, Jamblichus, and Proclus. Second, the introduction of the peculiar Christian dogmas could not fail to produce a lively effect on the Alexandrian thinkers. These dogmas had to be reconciled with philosophy, or the one must yield to and be absorbed by the other. The attempt to solve the problem of their mutual relation gave rise to Gnosticism in all its phases, and was the cause of the speculative element in the works of such fathers as Clement of Alexandria and Origen.

To the whole of this great movement the title Alexandrian philosophy must be given, although that term is sometimes identified with Neo-Platonism. Of the exact historical origin of it we have no certain notice. Some thinkers are of opinion that even in the Septuagint traces of rationalism can be discovered. (See Frankel, *Historisch kritische Studien zur Septuaginta*, 1841.) In Aristobulus (160 B.C.) is found a thoroughgoing attempt to show that early Greek speculations were in harmony with the divine record, because they had been borrowed from it. Traces of allegorical interpretation are also found in him, but no conception of a theosophical system. In the peculiar tenets of the *Therapeutæ*, so far as these can be known, may perhaps be traced another stream of influence, the Neo-Pythagorean. The complete representative of the Jewish religious philosophy was Philo, surnamed Judæus, who lived at Alexandria during the Christian era. In him are found a complete and elaborate theosophy fusing together religious and metaphysical ideas, a firm conviction that all truth is to be found in the sacred writings, and a constant application to these writings of the principle of allegorical interpretation. His system is a syncretism of Oriental mysticism and Greek metaphysics, and the effort at such a combination from the Jewish side could go no further. After Philo Judæus there remained as possible courses either Neo-Platonism or Gnosticism.

Of Alexandrian literature there are notices in histories of Greek literature, as Müller and Donaldson, or Bernhardy; of Alexandrian philosophy, in general histories of philosophy and of early Christianity. Special works, which, however, devote most attention to the Neo-Platonists, are—

Matter, *Histoire de l'Ecole d'Alexandrie*, 2d ed. 3 vols. 1840–44; Simon, *Histoire de l'Ecole d'Alexandrie*, 2 vols. 1844–45; Vacherot, *Histoire critique de l'Ecole d'Alexandrie*, 3 vols. 1846–51; Kingsley, *Alexandria and her Schools*, 1854; Gfrörer, *Philo und die Alexandrinische Theosophie*, 1835; Daehne, *Geschicht - Darstellung der Jüdisch-Alexandrinischen Religionsphilosophie*, 2 vols. 1834.

ALEXANDRINE VERSE, a name given to the leading measure in French poetry. It is the heroic French verse, used in epic narrative, in tragedy, and in the higher comedy. There is some doubt as to the origin of the name; but most probably it is derived from a collection of romances, published early in the 13th century, of which Alexander of Macedon was the hero, and in which he was represented, somewhat like our own Arthur, as the pride and crown of chivalry. Before the publication of this work most of the trouvère romances appeared in octo-syllabic verse. The new work, which was henceforth to set the fashion to French literature, was written in lines of twelve syllables, but with a freedom of pause which was afterwards greatly curtailed. The new fashion, however, was not adopted all at once. The metre fell into disuse until the reign of Francis I., when it was revived by Jean Antoine de Bœuf, one of the seven poets known as the Pleiades. It was not he, however, but Ronsard, who made the verse popular, and gave it vogue in France. From his time it became the recognised vehicle for all great poetry, and the regulation of its pauses became more and more strict. The following is an example of the verse as used by Racine—

> "Où suis-je? qu'ai-je fait? || que dois-je faire encore?
> Quel transport me saisit? || quel chagrin me dévore?"

Two inexorable laws came to be established with regard to the pauses. The first is, that each line should be divided into two equal parts, the sixth syllable always ending with a word. In the earlier use of this metre, on the contrary, it frequently happened that the sixth and seventh syllables belonged to the same word. The other is, that, except under the most stringent conditions, there should be none of what the French critics call *enjambement*, that is, the overlapping of the sense from one line on to the next. Ronsard completely ignored this rule, which was after his time settled by the authority of Malherbe. Such verses as the following by Ronsard would be intolerable in modern French poetry—

> "Cette nymphe royale est digne qu'on lui dresse
> Des autels. . . .
> Les Parques se disoient: Charles, qui doit venir
> Au monde. . .

Je veux, s'il est possible, atteindre la louangue
De celle. . . .

Michael Drayton, who was twenty-two years of age when Ronsard died, seemed to think that the Alexandrine might be as pleasing to English as it was to French ears, and in this metre he wrote a long poem in twenty-four books called the *Polyolbion.* The metre, however, failed to catch the English ear. Our principal measure is a line of ten syllables, and we use the Alexandrine only occasionally to give it variety and weight. In our ordinary heroic verse it is but rarely introduced; but in the favourite narrative metre, known as the Spenserian, it comes in regularly as the concluding line of each stanza. In English usage, moreover, it is to be observed that there is no fixed rule as to the position of the pause, though it is true that most commonly the pause occurs at the end of the sixth syllable. Spenser is very free in shifting the pause about; and though the later poets who have used this stanza are not so free, yet, with the exception of Shenstone and of Byron, they do not scruple to obliterate all pause between the sixth and seventh syllables. Thus Thomson (*Castle of Indolence*, i. 42):—

"And music lent new gladness to the morning air."

The danger in the use of the Alexandrine is that, in attempting to give dignity to his line, the poet may only produce heaviness, incurring the sneer of Pope—

"A needless Alexandrine ends the song,
That, like a wounded snake, drags its slow length along."

(E. S. D.)

ALEXIS, an ancient comic poet, born about 394 B.C. at Thurii in Magna Græcia, the uncle and instructor of Menander. Plutarch says that he lived to the age of 106 years, and according to Suidas he wrote 245 plays, of which the titles of 113 are known. The fragments that have been preserved by Athenæus and Stobæus attest the wit and elegance of the author. The plays were frequently translated by the Latin comic writers. (See Meineke, *Fragm. Com. Græc.* vol. i.)

ALEXIUS I., the nephew of Isaac Comnenus, and the most distinguished member of the Comnenus family, was born in 1048, and died in 1118. In early life he signalised himself in the wars against the enemies of his country; but the mean jealousies of the ministers of the emperor Nicephorus (surnamed Botaniates) drove him to take up arms against a sovereign whose cause he had thrice gallantly defended against powerful insurgent leaders; and he ascended the throne of Constantinople in 1081. His character has been too partially drawn by his favourite daughter, Anna Comnena, who has, however, justly remarked that the disorders of the times were both the misfortune and glory of Alexius, and that he paid the penalty for the vices of his predecessors. In his reign the Turks extended their conquests from Persia to the Hellespont; on the north the empire was assailed by hordes of barbarians from the Danube, and on the west by the Normans; while Europe pressed on Asia by way of Constantinople, in the excitement of the first crusade. Amid these disturbances Alexius managed the affairs of the state with a dexterous and courageous hand, though his policy was ascribed by the Latins to cowardice or treachery. He was politic enough to derive solid advantages from the romantic valour of the crusaders. Alexius outlived the love of his subjects, and their patience was all but exhausted in the latter part of his long reign. The nobility were irritated by the extravagance of his relations; the people by his severity and exactions; and the clergy murmured at his appropriation of the church funds to the defence of the state.

ALFANI, DOMENICO, an Italian painter, born at Perugia towards the close of the fifteenth century. The precise date is uncertain, but he was a contemporary of Raphael, with whom he studied in the school of Perugino. The two artists lived on terms of intimate friendship, and the influence of the more distinguished of the two is so clearly traceable in the works of the other, that these have frequently been attributed to Raphael. Towards the close of his life Alfani gradually changed his style, and approximated to that of the later Florentine school. The date of his death, according to some, was 1540, while others say he was alive in 1553. Pictures by Alfani may be seen in collections at Florence, and in several churches in Perugia.

AL-FARABI, ABU NASR MUHAMMAD IBN TARKHAN, one of the earliest Arabian philosophers, flourished during the former half of the 10th century. Philosophy, among the Arabs, was originally an extension of the related sciences of astronomy and medicine, and the first philosophers were physicians. The more eminent of them were court physicians, and to this they doubtless owed their protection against the jealous suspicions of the Mahometan sects. Al-Farabi is supposed (for the detailed accounts of his life are legendary) to have concerned himself more with the theory than the practice of medicine; but he is known to have been a physician at the court of Seif-Eddaula, and died when it was at Damascus in 950. Unlike some of his successors, notably Avicenna, he was an ascetic, and his philosophy, which has a slight Platonic infusion, bears traces of the contrast. He was unsystematic, and the sketches and aphorisms of his which have come down to us (many of his treatises are still in MS.) only partially enable us to reconstruct his philosophy. In his opusculum *De Scientiis* he enumerates six orders of sciences:—(1.) Language, by which he means little more than grammar. (2.) Logic, which he names as an art, conceives generally as a science, and confounds in its details with the corresponding art, with rhetoric, and with criticism. (3.) The mathematical sciences, embracing geometry, arithmetic, optics, the science of the stars, music, and the sciences of weights and of capacities (*ingenia*). Arithmetic is abstract and concrete; geometry is active, passive, and speculative; and the science of the stars includes astronomy, astrology, the science of climates, and of dreams and auguries. (4.) The natural sciences, ten in number. (5.) Civil science, including judicial science and rhetoric. (6.) Divine science, or metaphysics. This hierarchy has striking approximations to the most modern classifications. Logic and mathematics, the most abstract sciences, are near the beginning, if not quite first; what stands for social science follows the physical concrete sciences; and the distinction between abstract and concrete, which Comte made one of the bases of his classification, and which has been more accurately discriminated by Spencer, is on the whole clearly seized. But art is throughout confounded with science; superstitions are mixed up with facts; physical and mental phenomena are not always separated; the subjective and the objective (learning and science) are confused, as they afterwards were by Bacon; and there is no science of man—man was not yet conceived, metaphysically, as an individual. This agrees with Al-Farabi's science of politics as expounded in another work, in which he follows his master, Aristotle, in denying the permanence of the individual soul, and anticipates the Averrhoistic doctrine of the unity of souls. For his metaphysics is Peripatetic, as Peripateticism was interpreted by the Neo-Platonist commentators on Aristotle. Starting with the distinction between the possible and the necessary, he assumes that there must be some supreme necessary existence which accounts for all actual existence. This supreme existence has infinite life, wisdom, power, beauty, goodness, &c., but it is an absolute unity, and is without distinguishable attributes. How does the world, with its infinite multiplicity and diversity, issue from this absolutely one and identical being? Here Al-Farabi neo-platonises. It proceeds by emanation. The absolute Being knows itself, and in virtue of this knowledge the first intelligence exists. He does not explain how self-consciousness comes to be inseparable from necessary existence, but his dynamic, at this and all the lower stages, is self-knowledge; and indeed the act of knowing and the resultant existence appear at this height of abstraction to be all but identical. The first intelligence, intrinsically a unity, contains multiplicity, because it is no longer devoid of attributes. In so far as it necessarily exists, it evolves the second intelligence; in so far as it is merely potential being, and knows itself, it evolves the world-soul and the uppermost world-circle, which is moved by that soul. Similarly descending intelligences, ever-wider world-circles and the corresponding souls, are evolved by the same process of emanation, down to the active reason, which is most nearly related to the earthly elements and human souls. The active reason, by its contact with matter, impresses on it forms, of which the human soul is one, with greater or less permanence according to the degree in which it is immersed in, or rises above, matter. The forms decline in permanence the further we descend below the active reason, and the matter which has least form is the limit of emanation. There is here nothing like what is now called evolution: the conception of the universe is, as in all theories of emanation, really statical, not dynamical, for the ideas of cause and perpetual causation do not yet exist; and of course the process is the reverse of that implied in the modern development theory. (For information on Al-Farabi, see Munk, *Melanges*, pp. 341–52; and Steinschneider, *Memoires de l'Académie de St Petersbourg*, vii. série, tom. xiii. Two of his opuscula have been translated by Schmölders, *Documenta Philosophiæ Arabum*, and two are contained in *Alpharabii Opera Omnia*, Parisiis, 1638.)

ALFIERI, Vittorio, chiefly celebrated as the author who raised the Italian tragic drama from its previous state of degradation, was born on the 17th January 1749, at the town of Asti, in Piedmont. He lost his father in early infancy; but he continued to reside with his mother, who married a second time, till his tenth year, when he was placed at the academy of Turin. After he had passed a twelvemonth at the academy, he went on a short visit to a relation who dwelt at Coni; and during his stay there he made his first poetical attempt, in a sonnet chiefly borrowed from lines in Ariosto and Metastasio, the only poets he had at that time read. When thirteen years of age he was induced to commence the study of civil and canonical law; but the attempt only served to disgust him with every species of application, and to increase his relish for the perusal of French romances. By the death of his uncle, who had hitherto taken some charge of his education and conduct, he was left, at the age of fourteen, to enjoy without control his vast paternal inheritance, augmented by the recent accession of his uncle's fortune. He now began to attend the riding-school, where he acquired that rage for horses and equestrian exercise which continued to be one of his strongest passions till the close of his existence.

After some time spent in alternate fits of extravagant dissipation and ill-directed study, he was seized with a desire of travelling; and having obtained permission from the king, he departed in 1766, under the care of an English preceptor. Restless and unquiet, he posted with the utmost rapidity through the towns of Italy; and his improvement was such as was to be expected from his mode of travelling and his previous habits. Hoping to find in foreign countries some relief from the tedium and *ennui* with which he was oppressed, and being anxious to become acquainted with the French theatre, he proceeded to Paris. But he appears to have been completely dissatisfied with everything he witnessed in France, and contracted a dislike to its people, which his intercourse in future years rather contributed to augment than diminish. In Holland he became deeply enamoured of a married lady, who returned his attachment, but who was soon obliged to accompany her husband to Switzerland. Alfieri, whose feelings were of the most impetuous description, was in despair at this separation, and returned to his own country in the utmost anguish and despondency of mind. While under this depression of spirits he was induced to seek alleviation from works of literature; and the perusal of Plutarch's *Lives*, which he read with profound emotion, inspired him with an enthusiastic passion for freedom and independence. Under the influence of this rage for liberty he recommenced his travels; and his only gratification, in the absence of freedom among the Continental states, appears to have been derived from contemplating the wild and sterile regions of the north of Sweden, where gloomy forests, lakes, and precipices conspired to excite those sublime and melancholy ideas which were congenial to his disposition. Everywhere his soul felt as if confined by the bonds of society; he panted for something more free in government, more elevated in sentiment, more devoted in love, and more perfect in friendship. In search of this ideal world he posted through various countries, more with the rapidity of a courier than of one who travels for amusement or instruction. During a journey to London, he engaged in an intrigue with a married lady of high rank; and having been detected, the publicity of a rencounter with the injured husband, and of a divorce which followed, rendered it expedient and desirable for him to quit England. He then visited Spain and Portugal, where he became acquainted with the Abbé Caluso, who remained through life the most attached and estimable friend he ever possessed. In 1772 Alfieri returned to Turin, where he again became enamoured of a lady, whom he loved with his usual ardour, and who seems to have been as undeserving of a sincere attachment as those he had hitherto adored. In the course of a long attendance on his mistress, during a malady with which she was afflicted, he one day wrote a dialogue or scene of a drama, which he left at her house. On a difference taking place between them, the piece was returned to him, and being retouched and extended to five acts, it was performed at Turin in 1775, under the title of *Cleopatra*.

From this moment Alfieri was seized with an insatiable thirst for theatrical fame, and the remainder of his life was devoted to its attainment. His first two tragedies, *Filippo* and *Polinice*, were originally written in French prose; and when he came to versify them in Italian, he found that, from his Lombard origin, and long intercourse with foreigners, he expressed himself with feebleness and inaccuracy. Accordingly, with the view of improving his Italian style, he went to Tuscany, and, during an alternate residence at Florence and Siena, he completed his *Filippo* and *Polinice*, and conceived the plan of various other dramas. While thus employed, he became acquainted with the Countess of Albany, who then resided with her husband at Florence. For her he formed an attachment which, if less violent than his former loves, appears to have been more permanent. With this motive to remain at Florence, he could not endure the chains by which his vast possessions bound him to Piedmont. He therefore resigned his whole property to his sister, the Countess Cumiana, reserving an annuity which scarcely amounted to a half of his original revenues. At this period the Countess of Albany, urged by the ill-treatment she received from her husband, sought refuge in Rome, where she at length received permission from the pope to live apart from her tormentor.

Alfieri followed the countess to that capital, where he completed fourteen tragedies, four of which were now for the first time printed at Sienna.

At length, however, it was thought proper that, by leaving Rome, he should remove the aspersions which had been thrown on the object of his affections. During the year 1783 he therefore travelled through different states of Italy, and published six additional tragedies. The interests of his love and literary glory had not diminished his rage for horses, which seems to have been at least the third passion of his soul. He came to England solely for the purpose of purchasing a number of these animals, which he carried with him to Italy. On his return he learned that the Countess of Albany had gone to Colmar in Alsace, where he joined her, and resided with her under the same roof during the rest of his life. They chiefly passed their time between Alsace and Paris, but at length took up their abode entirely in that metropolis. While here, Alfieri made arrangements with Didot for an edition of his tragedies; but was soon after forced to quit Paris by the storms of the Revolution. He recrossed the Alps with the countess, and finally settled at Florence. The last ten years of his life, which he spent in that city, seem to have been the happiest of his existence. During that long period his tranquillity was only interrupted by the entrance of the Revolutionary armies into Florence in 1799. Though an enemy of kings, the aristocratic feelings of Alfieri rendered him also a decided foe to the principles and leaders of the French Revolution; and he rejected with the utmost contempt those advances which were made with a view to bring him over to their cause. The concluding years of his life were laudably employed in the study of the Greek literature, and in perfecting a series of comedies. His assiduous labour on this subject, which he pursued with his characteristic impetuosity, exhausted his strength, and brought on a malady for which he would not adopt the prescriptions of his physicians, but obstinately persisted in employing remedies of his own. His disorder rapidly increased, and at length terminated his life on the 8th October 1803, in the fifty-fifth year of his age.

The character of Alfieri may be best appreciated from the portrait which he has drawn of himself in his own *Memoirs of his Life*. He was evidently of an irritable, impetuous, and almost ungovernable temper. Pride, which seems to have been a ruling sentiment, may account for many apparent inconsistencies of his character. But his less amiable qualities were greatly softened by the cultivation of literature. His application to study gradually tranquillised his temper and softened his manners, leaving him at the same time in perfect possession of those good qualities which he had inherited from nature,—a warm and disinterested attachment to his family and friends, united to a generosity, vigour, and elevation of character, which rendered him not unworthy to embody in his dramas the actions and sentiments of Grecian heroes.

It is to his dramas that Alfieri is chiefly indebted for the high reputation he has attained. Before his time the Italian language, so harmonious in the *Sonnets* of Petrarch, and so energetic in the *Commedia* of Dante, had been invariably languid and prosaic in dramatic dialogue. The pedantic and inanimate tragedies of the 16th century were followed, during the iron age of Italian literature, by dramas of which extravagance in the sentiments and improbability in the action were the chief characteristics. The prodigious success of the *Merope* of Maffei, which appeared in the commencement of the last century, may be attributed more to a comparison with such productions than to intrinsic merit. In this degradation of tragic taste the appearance of the tragedies of Alfieri was perhaps the most important literary event that had occurred in Italy during the 18th century. On these tragedies it is difficult to pronounce a judgment, as the taste and system of the author underwent considerable change and modification during the intervals which elapsed between the three periods of their publication. An excessive harshness of style, an asperity of sentiment, and total want of poetical ornament, are the characteristics of his first four tragedies, *Filippo*, *Polinice*, *Antigone*, and *Virginia*. These faults were in some measure corrected in the six tragedies which he gave to the world some years after, and in those which he published along with *Saul*, the drama which enjoyed the greatest success of all his productions; a popularity which may be partly attributed to the severe and unadorned manner of Alfieri being well adapted to the patriarchal simplicity of the age in which the scene of the tragedy is placed. But though there be a considerable difference in his dramas, there are certain observations applicable to them all. None of the plots are of his own invention. They are founded either on mythological fable or history; most of them had been previously treated by the Greek dramatists, or by Seneca. *Rosmunda*, the only one which could be supposed of his own contrivance, and which is certainly the least happy effusion of his genius, is partly founded on the eighteenth novel of the third part of Bandello, and partly on Prevost's *Mémoires d'un Homme de Qualité*. But whatever subject he choose, his dramas are always formed on the Grecian model, and breathe a freedom and independence worthy of an Athenian poet. Indeed, his *Agide* and *Bruto* may rather be considered oratorical declamations and dialogues on liberty than tragedies. The unities of time and place are not so scrupulously observed in his as in the ancient dramas; but he has rigidly adhered to a unity of action and interest. He occupies his scene with one great action and one ruling passion, and removes from it every accessary event or feeling. In this excessive zeal for the observance of unity he seems to have forgotten that its charm consists in producing a common relation between multiplied feelings, and not in the bare exhibition of one, divested of those various accompaniments which give harmony to the whole. Consistently with that austere and simple manner which he considered the chief excellence of dramatic composition, he excluded from his scene all *coups de théâtre*, all philosophical reflections, and that highly ornamented versification which had been so assiduously cultivated by his predecessors. In his anxiety, however, to avoid all superfluous ornament, he has stripped his dramas of the embellishments of imagination; and for the harmony and flow of poetical language he has substituted, even in his best performances, a style which, though correct and pure, is generally harsh, elaborate, and abrupt; often strained into unnatural energy, or condensed into factitious conciseness. The chief excellence of Alfieri consists in powerful delineation of dramatic character. In his *Filippo* he has represented, almost with the masterly touches of Tacitus, the sombre character, the dark mysterious counsels, the *suspensa semper et obscura verba*, of the modern Tiberius. In *Polinice*, the characters of the rival brothers are beautifully contrasted; in *Maria Stuarda*, that unfortunate queen is represented unsuspicious, impatient of contradiction, and violent in her attachments. In *Mirra*, the character of Ciniro is perfect as a father and king, and Cecri is a model of a wife and mother. In the representation of that species of mental alienation where the judgment has perished, but traces of character still remain, he is peculiarly happy. The insanity of Saul is skilfully managed; and the horrid joy of Orestes in killing Ægisthus rises finely and naturally to madness, in finding that, at the same time, he had inadvertently slain his mother.

Whatever may be the merits or defects of Alfieri, he may be considered as the founder of a new school in the Italian drama. His country hailed him as her sole tragic poet; and his successors in the same path of literature have regarded his bold, austere, and rapid manner, as the genuine model of tragic composition.

Besides his tragedies, Alfieri published during his life many sonnets, five odes on American independence, and the poem of *Etruria*, founded on the assassination of Alexander I., duke of Florence. Of his prose works the most distinguished for animation and eloquence is the *Panegyric on Trajan*, composed in a transport of indignation at the supposed feebleness of Pliny's eulogium. The two books entitled *La Tirannide* and the *Essays on Literature and Government*, are remarkable for elegance and vigour of style, but are too evidently imitations of the manner of Machiavel. His *Antigallican*, which was written at the same time with his *Defence of Louis XVI.*, comprehends an historical and satirical view of the French Revolution. The posthumous works of Alfieri consist of satires, six political comedies, and the *Memoirs of his Life*—a work which will always be read with interest, in spite of the cold and languid gravity with which he delineates the most interesting adventures and the strongest passions of his agitated life. See *Mem. di. Vit. Alfieri*; Sismondi *De la Lit. du Midi de l'Europe*; Walker's *Memoir on Italian Tragedy*; *Giorn. de Pisa*. tom. viii.; *Life of Alfieri*, by Centofanti (Florence, 1842); and *Vita, Giornali, Lettere di Alfieri*, by Teza (Florence, 1861).

ALFORD, HENRY, D.D., Dean of Canterbury, one of the most variously-accomplished churchmen of his day—poet, preacher, painter, musician, biblical scholar, critic, and philologist—was born at 25 Alfred Place, Bedford Row, London, October 7th, 1810 (died 1871). He came of a Somersetshire family, five generations of which, in direct succession, contributed clergymen of some distinction to the English Church. The earliest of these, his great-great-grandfather, Thomas Alford, who died in 1708, was for many years the vicar of Curry Rivell, near Taunton—a living that passed from one to another of his descendants. The father of Dean Alford studied for the bar, but after practising for a short time, followed the course of his predecessors by taking holy orders; and, until his death at a venerable age in 1852, had long been familiarly known and revered in his part of the country as the rector of Aston Sandford in Buckinghamshire. His first wife, the dean's mother, whose maiden name was Sarah Eliza Paget, was the younger daughter of a well-to-do banker of Tamworth in Staffordshire. A twelvemonth after their marriage, her husband, then practising as a special pleader, was by her premature death in childbed left a widower. The newly-born infant, who remained to the last the bereaved parent's only child, was confided in the first instance to the affectionate care of the home-circle in the house of his maternal grandfather. Towards the close of 1813 he was taken back to the lonely hearth of his father, who had now entered upon his clerical duties as curate of Steeple Ashton, near Trowbridge in Wiltshire. Being the only son of a secluded scholar, the boy's education was from an unusually early period sedulously cared for; his father being his first instructor, and at the outset his constant companion. So exceptional was his precocity that at six he had already written a little MS. volume entitled (in round hand) the *Travels of St Paul.* Before he was eight he had penned a collection of Latin odes in miniature. When he was scarcely nine he had compiled, in the straggling characters of a schoolboy, a compendious *History of the Jews;* besides drawing out a chronological scheme in which were tabulated the events of the Old Testament. Prior to the completion of his tenth year he actually produced a series of terse sermons or laconically outlined homilies, the significant title of which was *Looking unto Jesus.* During the absence of his father, who had gone abroad as the travelling chaplain of Lord Calthorpe, Henry, at seven years of age, began the round of three academies, at Charmouth and Hammersmith; the happiest time of all for him as a schoolboy being three years and upwards passed in the grammar-school at Ilminster. His character was already displaying a marked individuality. He could repeat not only readily but appreciatively an astonishing number of lines in Greek, Latin, and English, selected from what were then and always afterwards his favourite classic authors. He indulged, too, in those early days, in the luxury of original versification. Then it was also that he first began to manifest that singular capacity for ingenious contrivance and that surprising neatness and dexterity of manipulation for which he was afterwards remarkable. It was said of him later in life, that he could construct an organ and then play upon it; and when his reputation for profound scholarship had been long established, his constructiveness was curiously manifested by his adaptation to the purposes of utility of the seemingly ordinary walking-stick he carried when travelling on the Continent. In its upper joint he secreted his surplus money and his drawing materials; in its lower joint, pens, ink, wax, and pencils. Strangely contrasting with this ineradicable passion for nicety and precision was his delight at all times in giving himself up to the most diversified occupations, and in yielding, often at an instant's notice, as he sometimes notes with regret to the temptation of mere discursiveness.

It was in the October of 1827 that the university life of Alford commenced. At seventeen he went up to Cambridge, having won his scholarship, and had his name entered at Trinity College. During the midsummer of his fourth year at Cambridge, in the June of 1831, he had obtained the second prize essay. As the autumn deepened into winter he was nervously preparing to go in for honours at the examinations. In the possibility of his success he had not the slightest confidence, yet on the 21st January 1832 he appears as thirty-fourth wrangler; while on the 25th February his name comes out eighth on the first-class list of the classical tripos. He now began to take pupils, and within the interval which elapsed between his taking his degree and giving himself up more completely to the great work of his life—the elaboration of his edition of the Greek New Testament—it is believed that he had under his charge at least sixty. These included barristers, clergymen, peers, and members of parliament; many of whom afterwards attained positions of eminence, all of them having their characters moulded more or less under the inspiring influence of his. In his twenty-sixth year he was united in marriage to his cousin Fanny, a daughter of his uncle, the Rev. Samuel Alford, who was then, as his father and his great-grandfather had been before him, vicar of Curry Rivell. Surviving her husband after nearly thirty-five years of wedded life, during which she had seen the development of his intellectual powers and the realisation of some portions at least of his many-sided ambition, she brought out in 1872 his journals and correspondence, carefully edited by herself. A curiously characteristic side-light is thrown upon Alford's inner nature, both moral and intellectual, by the circumstance there recorded—that, with a view to enable his future wife to read the New Testament in Greek, he wrote with his own hand, in the interval between betrothal and marriage, an elementary Greek grammar of sixty folio pages. The incident is all the more interesting as affording the earliest glimpse of what soon proved to be his dominant aspiration. His researches in secular scholarship were at this time becoming every year more and more adventurous. He shrank not from proclaiming even then that he regarded Niebuhr as "one of the greatest men in this ignorant and obstinate world.". Meanwhile, in the midst of his excursive inquiries as a student in the most opposite directions, he was indulging at every available opportunity in the lotos-delight of his own day-dreamings; and in February 1833, he published his maiden work as a lyrist, *Poems and Poetical Fragments.* Simply as an instructor he was working steadily seven hours a-day; but the time came when, in furtherance of his favourite researches, he was known to toil at the desk sometimes twelve or fourteen.

Resolved from childhood to tread the path of life in the footsteps of his forefathers, Alford was ordained deacon on the 26th October 1833, and at once began active professional work as curate of Ampton. So modest was his own estimate of his intellectual capabilities, that it was with unaffected surprise he found his name second on the list of the six Fellows of Trinity who were elected on the 1st of the following October. On the 6th November he was admitted to priest's orders, and four months afterwards, upon the 4th March 1835—scarcely a week before his marriage—entered upon his parochial labours of eighteen years' duration as vicar of Wymeswold in Leicestershire. Twice during the interval of his scholarly seclusion in that quiet vicarage he was vainly tempted with the offer of a colonial bishopric, first in 1841 as bishop of New Zealand, and again in 1844 as bishop of New Brunswick. He contentedly drudged on for years together in comparative obscurity among his pupils and parishioners. Although a ripe scholar, and remarkable for his splendid versatility, it was less by the brilliancy of his achievements than by the sheer force of the most diligent perseverance that he pushed his way eventually into the front rank, and commanded at last the recognition of his contemporaries.

Whatever he put his hand to he carried out with a zeal that at times looked almost like dogged determination. Thrown from his horse in the February of 1847 when going to deliver his first lecture, although very seriously shaken and disfigured, he nevertheless punctually appeared before his audience with his face and head covered with surgical bandages and—resolutely lectured. His reputation as a lecturer of exceptional power was within a few years from that time thoroughly established. Several of his discourses, notably one on Saul of Tarsus, with others on themes as varied as astronomy, music, scenery, and Christianity, acquired in the end a certain amount of celebrity. For two years together, in 1841 and 1842, he held the chair at Cambridge of Hulsean lecturer. As the result of his labours in that capacity, two substantial volumes afterwards made their appearance. Meanwhile, in the midst of his more serious avocations, he was at uncertain intervals making good his claim to be regarded as one of the more subtle and tender of the minor religious poets of England. Adopting an old forgotten title of Quarles's, he brought out, on his arrival at Wymeswold (1835), in two volumes, his *School of the Heart*, coupled with a reissue of his minor poems and sonnets. In 1838, he edited, in six vols., the works of Donne, prefixing a luminous preface, at once critical and biographical. Throughout the year 1839 and part of 1840 he edited a monthly magazine called *Dearden's Miscellany*. In 1841 he published, with other new poems, his *Abbot of Muchelnaye*. A collection of *Psalms and Hymns* appeared from his hand in the spring of 1844. A couple of years before that, in 1842, he had first entered upon his duties at Somerset House, where he acted for many years as examiner in logic and moral and intellectual philosophy in the university of London. So youthful was his appearance at the date of his first receiving this appointment, that on his entering the apartment where he was awaited by the candidates, he was mistaken for one of themselves.

What eventually proved to be the noblest of all his literary undertakings, his new edition, with running commentary, of the *Greek Testament*, engrossed his attention for fully twenty years together, from 1841 to 1861. Originally designed for the use of students in the universities, the work, from its modest first projection, grew in his hands to enormous proportions. He fancied at starting that a single year might witness its completion, and that a couple of thin octavos might embrace both text and commentary. By the time the expanding scheme was actually realised twenty years had elapsed, and the work had swollen into four ponderous tomes, the contents of which were as weighty as they were comprehensive. The idea of the work was suggested to Alford's mind as he listened one day to a sermon at Cambridge. What he proposed to himself at the outset was simply to adopt the main text, and to combine with it the greater part of the readings of Philipp Buttmann and Karl Lachmann. This, however, led to a more extended plan of critical labour and research, including a comprehensive digest of the various readings founded on the latest collations of the principal manuscripts, the Codex Vaticanus, the Codex Sinaiticus, the Codex Alexandrinus, and others. With a view to illustrate more clearly than ever the verbal and idiomatic or constructional usages of the sacred text, an entirely new collection of marginal references was compiled. Added to this there was a copious abundance of English notes, both exegetical and philological. Conscious of the vast stores of learning that had been accumulating in Germany, Alford from an early date determined to render himself as thoroughly as possible a master of the German language and at home in German literature. This intention was fairly carried out at Bonn before the close of the summer of 1847. Then, but hardly till then, he felt himself at last duly qualified to edit the *Greek Testament*. From that time he prepared in earnest to open up systematically to the contemplation of English readers the wealth of German criticism, actually made plain for the first time in our language through his *Prolegomena* and subsequent incidental commentary. In November 1849 (the month the author took his B.D. degree at Cambridge), vol. i. of the *Greek Testament* was published, containing the four Gospels. Through it theological students in this country had placed within their reach in an epitomised form the latest results of the labours of continental critics on the Greek text, including portions even of those of Constantine Tischendorf. Issued from the press volume by volume, the work, as already remarked, was not completed till long afterwards. In January 1861 the fourth or final volume, beginning with the Epistle to the Hebrews and ending with the Book of Revelation, made its appearance. What is chiefly noticeable in regard to the work is its strictly critical character. It is the production of a philologist rather than of a theologian. Abbreviations, punctuations, elisions of orthography, systematic ellipses, the merest turns of the pen in this or that manuscript, are weighed against microscopic scruples in the balance of his judgment. There can be little question that the work appreciably increased the aggregate amount of the biblical knowledge of Alford's immediate contemporaries. So carefully matured were his researches in the regions of exegesis, already crossed and recrossed by the footprints of countless commentators, that the work is regarded as in many respects authoritative even among those who differ from him widely on many important questions.

Early in 1853 Alford first preached in Quebec chapel, London, the building in which his father had been ordained deacon forty years before. Before the year was out, on the 26th September, he had removed from his picturesque church in the wolds of Leicestershire to the plain conventicle in Tyburnia. There he remained for nearly four years, toiling assiduously, preaching twice every Sunday to a large and cultured congregation. Seven volumes, issued from the press at intervals, have, under the title of *The Quebec Chapel Sermons*, preserved 153 of the more remarkable of these discourses—those preached by him in the morning—all of which were carefully prepared beforehand. As a preacher his style was severe and earnest rather than eloquent or impassioned. Perhaps the finest discourse he ever delivered was the one on the text, "A great multitude which no man could number." It was preached from the cathedral pulpit shortly after his advancement by Lord Palmerston, in March 1857, to the deanery of Canterbury. Throughout his life, but especially towards its close, his chief delight intellectually appears to have been the rapid alternation of his pursuits. While he was yet in the midst of his biblical researches he was, simultaneously, at the beginning of 1851, translating the *Odyssey*, arranging his poems, with additions for their American republication, and preparing an article for the *Edinburgh Review* on the *St Paul* of Conybeare and Howson. A series of ingenious lectures, delivered by him in his capacity of philologist, on being compacted into a manual of idiom and usage, entitled *The Queen's English*, attained a high degree of popularity. Nevertheless, in spite of their wholly unpretentious and essentially humorous character, these mere casual notes on spelling and speaking drew down upon their author one of the sharpest criticisms he ever provoked, sarcastically entitled *The Dean's English*. The *Contemporary Review* was inaugurated under his editorship; and from January 1866 to August 1870 was conducted by him as a sort of neutral ground for religious criticism. Under the title of *The Year of Prayer*, Alford in 1866 published a book of family devotion; and in 1867, a collection of original hymns called *The Year of Praise*, works of little pretension, but by which his name was widely popularised. His latest poetic effusion of any considerable length was *The Children of the Lord's Prayer*, which appeared in 1869 as the letterpress accompaniment to designs by F. R. Pickersgill, R.A. The miscellaneous papers he had contributed to periodicals were, the same year, collected under the name of *Essays and Addresses*. He brought out, in 1865, his *Letters from Abroad*, eminently characteristic records of travel, mainly descriptive of Italian cities and scenery; and in 1870, a collection of spirited pen and pencil sketches of *The Riviera*, the latter being reproduced from his water-colour drawings by the aid of chromo-lithography. The artist faculty, it has been observed, and not extravagantly, "would have made him a great landscape painter had he not, either from preference or necessity, become a great Greek scholar and a dean." Such were the pliancy and the resilience of his nature that he would turn with zest, after hours of severe study given to the collation of a Hebrew manuscript or to the examination of the exegetical subtleties of a German commentator on the Greek Testament, to doctoring the hall clock and making it strike the half-hours, to tuning the piano in the drawing-room, or to playing games with his children in the nursery. The wooden front of the organ (which instrument he could play with the hand of a master) was carved according to his own ingenious design and by his own dexterous chiselling. A *Masque of the Seasons*, performed as a holiday pastime on New Year's Day 1861, in the deanery, owed to him both the words and the music—he himself, besides, enacting in it the part of "Father Christmas." A couple of years before his death he appeared as a novelist, conjointly with his niece producing the story of *Netherton on Sea*. The last work of any magnitude upon which he adventured as a biblical scholar was his *Commentary on the Old Testament*. In the diversity of his avocations, and the thoroughness with which they were, one and all, carried to a successful issue, he was his own severest taskmaster. Throughout life, until he was stretched upon his deathbed, he never seemed to indulge in the luxury of inaction. The end came at length to him calmly, on the 12th January 1871, and five days afterwards his remains were interred under a yew tree in St Martin's churchyard, within view of the towers of Canterbury Cathedral. It is significant of the tender poetical quaintness of his whole character, that there is inscribed above his tomb, in obedience to his own directions, "Diversorium Viatoris Hierosolymam Proficiscentis." A statue of the dean, by Pfyffers, was unveiled, before the year of his demise had run out, in a niche on the west front of the most ancient of our cathedrals. Dean Alford was a man as variously accomplished as any of his generation; and he would unquestionably have risen to far greater eminence than he ever achieved in poetry, in oratory, in music, in painting, in theology, or in general literature, if he had aimed at excelling in one or two alone of those arts or sciences, instead of endeavouring to shine in all of them alike. (C. K.)

ALFRED, or ÆLFRED, THE GREAT, the youngest son of Æthelwulf, king of the West Saxons, was born at Wantage in Berkshire in 849 A.D. At an early age he was summoned to the assistance of his brother Æthelred against the Danes. These formidable enemies, whose object hitherto had been mere plunder, were now aiming at a permanent settlement in the country, and after ravaging and subduing Northumbria, East Anglia, and the greater part of Mercia, they fell with their united forces on Wessex itself. A series of encounters took place, in which Alfred greatly distinguished himself, especially at Ashdown, where the Danes were routed with great slaughter, and left several of their most famous leaders dead on the field of battle. Æthelred dying in the midst of the struggle, Alfred was unanimously elected king (871), in the twenty-second year of his age. About a month after his accession he met the enemy at Wilton, where, after a long and doubtful struggle, he was defeated. Both parties were now becoming tired of the war. Immense loss had been suffered on both sides, and although the Danes on the whole had been victorious, their victories had brought them no substantial results. A treaty of peace was concluded, and the Danes withdrew to London.

On the cessation of hostilities, Alfred was enabled to turn his attention to naval affairs. The sea was swarming with pirates, and their descents on the coast kept the country in a state of perpetual alarm. To cope with them successfully Alfred resolved to meet them on their own element, and a naval victory which he gained over seven Danish rovers in 875 is the first on record won by Englishmen. In the following year the peace of 871 was broken. An army of Danes from East Anglia, under their king, Guthrum, sailing along the south coast, landed in Wessex, seized upon Wareham, and afterwards upon Exeter, then the centre of a disaffected Celtic population, and it was not till 877 that the country was once more free from the invader.

The year 878 was the most eventful in the course of Alfred's reign. At mid-winter, without any warning, the Danes came pouring into Wessex from the north, seized Chippenham, and making it the centre of their operations, quickly overran the country. Many of the inhabitants, in despair, fled into foreign lands, and Alfred, totally unprepared to meet the storm, retired to the marshes of Somerset. Never at any other period, either before or after, were his fortunes so low, and the national existence itself was at stake. Had Alfred, like his kinsman Burhed of Mercia, left his people in their hour of need, the heathen Dane in all probability would have acted like the heathen Englishmen before him—a new race would have possessed the land, and the names of England and Englishmen would have disappeared from the page of history. Alfred's misfortunes only roused him to fresh exertions, and his military skill and valour enabled him to carry his people in safety through this momentous crisis. Fortifying himself at Athelney about Easter, he secretly matured his plans for meeting the enemy, and seven weeks after, having collected his forces at Brixton near Selwood, he rapidly advanced in a north-easterly direction, and was close upon the Danes before they had any intelligence of his approach. A fierce conflict ensued at Ethandun, now Edington, in which the Danes were entirely defeated; and about fourteen days after this they were compelled to sue for peace. By the treaty of Wedmore, Watling Street (the old road running across the island from London to Chester and the Irish Channel) was to be the boundary between Alfred and the Danes, the latter were to be vassals to the kings of Wessex, and their chiefs to receive baptism. This treaty was observed by the Danes with much greater fidelity than those of an earlier date had been. Guthrum their king and about thirty of their chiefs were baptised at Wedmore, and Alfred, who stood sponsor for Guthrum, gave him the name of Æthelstan. The Danish army after this slowly withdrew, and eventually settled down peaceably in East Anglia. The acceptance of Christianity by their chiefs seems indeed to have broken for a time the fierce crusading energy which gave a special animus to the piratical expeditions of the heathen Danes.

As soon as peace had been concluded Alfred turned his attention to the internal affairs of his kingdom. He vigorously set to work to put the country in a complete state of defence. Old fortifications were repaired and new ones raised in suitable localities. The fleet was brought into a state of greater efficiency, and it was Alfred indeed that laid the foundation of England's naval greatness. He cleared the land of the bands of robbers that infested it, and took care that justice was impartially administered to all his subjects, severely punishing any wilful perversion of it on the part of the judges. In his code of laws, which is a compilation from those of his predecessors, he wisely abstained from introducing much of his own, giving as his reason that he was afraid it might not be accepted by posterity. He greatly encouraged commerce, and took a lively interest in geographical discovery. We have from his pen a minute account of two voyages of Ohthere, especially of the one round the North Cape into the White Sea, and also of a voyage of Wulfstan to the Baltic. And it is to Alfred that we are indebted for the best account that has reached us of the Germany of the 9th century.

Alfred's devotion to learning, and his exertions in the cause of education are among the most remarkable features of his reign. So deep was the popular ignorance when Alfred ascended the throne that, according to his own testimony, hardly any one south of the Thames could understand the ritual of the church or translate a Latin letter. It was one of the strongest and most cherished of his purposes that this state of matters should be entirely changed, and that every free-born English youth who had the means should qualify himself to read English correctly. In order to accomplish this, he rebuilt the monasteries which had been cast down in the late wars, and which were the great centres of education in those days, invited learned men from all quarters to his court, and by their assistance completed a number of works for the diffusion of knowledge throughout his dominions. These were not original compositions but free translations of Latin authors that were held in much esteem at the time, and the fact that Orosius and Bede are two of the works he selected, shows the high value he set upon an acquaintance with history and geography. A copy of his version of Gregory's *Pastoral Care* was sent to every diocese for the benefit of the clergy. It is in the preface to that work that Alfred gives his touching account of the decay of learning, and expresses his desire for its revival. But the work which seems to have had the greatest attraction for him was *The Consolations of Philosophy* by Boethius. In his translation of this work Alfred gives us more of his own original composition, and a deeper insight into his thoughts and feelings, than in any other of his works. His Manual or Handbook, which is known to have been in existence in the 12th century, is lost, and this is the more to be regretted since, besides the extracts from Latin authors which it contained, it is believed that he had inserted in it not a few compositions of his own.

In occupations such as these fifteen years of comparative tranquillity, disturbed now and then by troubles with the Danes, passed away. A fresh swarm from abroad had landed in Kent in 885 and besieged Rochester, but on the king's approach they raised the siege and returned to their ships. The next eight years were years of uninterrupted peace; but the Danes, suffering a severe defeat at the hands of Arnulf, king of the East Franks, sailed for England in two divisions in 893. One of these divisions was under the command of the terrible Hastings. Their arrival was a signal to the Danes of Northumbria and East Anglia, who rose in great numbers to aid their kinsmen. Alfred, however, was better prepared to meet the danger than he had formerly been. His towns were so strong that the Danes seem studiously to have avoided them. A body of the enemy was routed by Alfred at Farnham in Surrey. Another great host, moving to the west in the line of the Thames, was followed by three of Alfred's aldermen to Buttington in Montgomeryshire and completely defeated. Those who escaped made their way to Essex. Leaving their wives and children there, and receiving considerable additions to their numbers, they crossed the country once more and established themselves within the fortifications of the old Roman town of Chester, which was then uninhabited. There they remained for the winter, when, provisions failing them, they removed to Wales, and with the harvest of plunder they gathered there they retreated into Essex by way of the friendly districts of Northumbria and East Anglia. So rapid had their movements been that Alfred's army was unable to keep up with them. The same year (895), before winter set in, the Danes sailed up the Thames into the Lea, and selecting an advantageous position on the banks of the latter stream, constructed a fortress about 20 miles above London. As this proved a considerable annoyance to the citizens, they attacked it the following summer, but were repulsed with great loss. During harvest the king was obliged to encamp in the neighbourhood of the city to protect the reapers while gathering in their crops. He afterwards raised two forts on each side of the Lea, and so effectually blocked up the passage of the river that the enemy abandoned their vessels and proceeded to Bridgenorth on the Severn. In the summer of 897 the great Danish host broke up, and part of them returned to the continent. The rest dispersed through Northumbria and East Anglia, and for some time gave Alfred no little trouble by their piratical excursions. By means of vessels formed after a model of his own, of unusual length and speed, he succeeded at last in curbing his Danish foes, but not till after a desperate encounter with them on the south coast, in which the advantage was not all on his side. The war was, as usual, accompanied by pestilence, and great numbers perished, many being persons of the highest rank in the state. The rest of Alfred's reign, about which we know almost nothing, seems to have been passed in peace. He died in the year 901, at the age of fifty-two, and was buried at Winchester.

The memory of Alfred has ever been gratefully cherished by his countrymen. There never perhaps was a monarch so highly esteemed; and traditional stories of the most fascinating description cluster around his name, in which he appears almost to as much advantage as in real history. Institutions that existed long before his time, but whose origin it is impossible to trace, have erroneously been attributed to him; and in the times of Norman oppression, when the people were groaning under the burden of slavery, they fondly called to mind the "Darling of the English," to whom they ascribed all those rights and privileges which they so highly valued, and of which they had been unjustly deprived. Time but adds to Alfred's praises. With one consent our historians agree in characterising him as the wisest, best, and greatest king that ever reigned in England.

The following is a list of Alfred's works:—

1. *Manual* or *Handbook*, of which no copy is known to exist. 2. *Laws* (see Wilkin's *Leges Anglo-Saxonicæ*, 1721, and Thorpe's *Ancient Laws and Institutes of England*, London, 1840). Translations into Old English (Anglo-Saxon) of the following:—3. Bede's *Ecclesiastical History*, edited by Wheloc, Cambridge, 1643–4, and by Smith, Cambridge, 1722. 4. *The Universal History of Orosius*, edited by Thorpe, London, 1857. 5. *The Consolations of Philosophy*, by Boethius, edited by Fox, London, 1864. 6. Gregory's *Pastoral Care*, edited by Sweet for the Early English Text Society, London, 1871–2.

For further information about Alfred see Pauli's *Life of Alfred* and Freeman's *Old English History* and *History of the Norman Conquest*.

ALGÆ, or HYDROPHYTA, a large order of cellular, flowerless, cryptogamic plants, found in the sea (seaweeds), in rivers, lakes, marshes, hot springs, and moist places, all over the world. They consist of a brown, red, or green, flattened, cellular, leaf-like expansion, called a *thallus*, sometimes stalked, which bears the organs of reproduction. Some have root-like processes by which they are attached to rocks. These do not act like the nourishing roots of flowering plants; they simply fix the plants and enable them to sway about in the water. This is markedly the case with the Laminarias, or large tangles of our coasts. The leafy appendages of seaweeds are called fronds. They vary in size, colour, and consistence. Some of the red and green delicate fronds form beautiful objects when carefully dried and laid out on drawing-paper. In order to dry seaweeds they must be first washed carefully in fresh water to separate saline matters, and then placed within drying-paper and subjected to pressure. Very delicate seaweeds should be floated out in water, drawing-paper being placed under them, and their fronds being carefully arranged on the paper before they are raised out of the water. They must then be dried partially in the air, and afterwards under pressure between sheets of drying-paper.

Seaweeds are composed entirely of cells, which in some instances become elongated so as to have the appearance of tubes. Some Algæ are uni-cellular, that is, are composed of a single cell, as occurs in some Desmidieæ, as Closterium. At other times they are composed of numerous cells, which are kept together by a gelatinous matter, but separating easily from each other so as to have an independent existence. This is observed in the red snow plant (*Protococcus* or *Palmella nivalis*). The cells of seaweeds are sometimes joined together so as to form a linear series, and to give them a thread-like appearance; and in such a case, when the divisions between the cells are marked, the whole appears like a beaded necklace of cells. When the cells are united both lengthwise and laterally they then form an expanded flat frond. In some instances the frond is gelatinous.

The germinating bodies or spores of seaweeds are cells often contained in cavities (Fig. 2). They vary in colour, and the fronds have frequently the same colour as the spores. In reference to their colour, Algæ have been divided into three sub-orders: 1. Melanospermeæ, brown coloured seaweeds (Fig. 1), with olive-brown spores; 2. Rhodospermeæ, rose-coloured seaweeds, with red spores; 3. Chlorospermeæ, green-coloured seaweeds, with green spores.

Fig. 2.

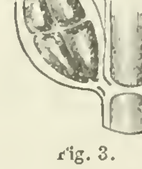

Fig. 3.

Fig. 1.—Thallus, *tt*, of *Fucus vesiculosus*, the common Bladder Seaweed, with air-vesicle, *v*, and masses of conceptacles constituting the fructification, *fr, fr*, which is sometimes called gleba. Fig. 2.—Fructification of a Seaweed, containing spores, which are ultimately discharged at an opening, o. Fig. 3.—Tetraspore of one of the rose-coloured Seaweeds.

Algæ are multiplied by the division of cells and by spores. By cell-division there is a multiplication of cells, and by separation from the parent plant these cells may bear buds. True fertilisation is effected by means of union of cells, or what is called conjugation. In this process two kinds of cells unite by means of a tube, and the contents of the one passes into the other, thus giving rise to germinating spores. This is seen in Confervæ, such as the green matter often seen in ponds, and called *silk-weed*. There are also observed in Algæ two kinds of fertilising bodies, one set called Antheridia, containing moving filaments or spermatozoids; and the other called Archegonia, containing a rudimentary cell, which, after contact with the spermatozoids, becomes a spore forming a new plant. The spores produced by some Algæ move about in water, and have been called Zoospores. Their spontaneous movements are effected by means of vibratile slender threads called cilia. These zoospores are contained in a cell, which ultimately bursts and scatters them. The process is well seen in a green Alga called Vaucheria. The zoospores move about for a certain time, and ultimately the spores get fixed to a rock or the wood of a pier, and then the cilia disappear. Cilia sometimes occur in pairs at one end of a spore, numbering two or three; at other times they are placed round the whole circumference of the spore.

Spores have a tendency to divide into four; such compound spores are called tetraspores (Fig. 3). They are common in the sub-order Rhodospermeæ. They seem to differ from ordinary spores, and to be more of the nature of buds. In some Algæ, such as Corallines, there is a coating of calcareous matter which conceals their tissue. This can be removed by means of hydrochloric acid. Diatoms, a subdivision of Algæ, are so called from two Greek words signifying to cut through, in allusion to the mode of division into two valves. They are microscopic one-celled bodies, covered externally by a siliceous or flinty coat. They are on the confines of the animal and vegetable kingdoms, and have been referred sometimes to the one and sometimes to the other. Their mode of reproduction by conjugation and spores seems to indicate their alliance with Algæ, although some still place them among infusorial animalcules. The siliceous markings of Diatoms are very beautiful microscopic objects. After exposure to the action of fire or nitric acid, the silex remains unaltered, and in that state the streaks of the covering are easily observed.

Many of the Algæ supply nutritious food. *Rhodymenia palmata*, one of the red seaweeds, is the *dulse* of the Scotch, the *dillesk* of the Irish. *Chondrus* (*Sphærococcus*) *crispus* and *C. mammillosus*, two Rhodosperms, receive the name of *carrageen* or Irish moss. Their fronds consist in part of a substance allied to starch, which is extracted by putting them in water, and on cooling it forms a jelly. Species of Ulva, one of the Chlorosperms, supply the green laver. Species of Caulerpa furnish food to turtles. *Laminaria digitata*, and *Laminaria saccharina*, under the name of *tangle*, are eaten in the north of Europe. Dulse and tangle was formerly a common cry in the streets of Edinburgh. *D'Urvillæa utilis* is used as food in Chili. *Alaria esculenta*, a British species, is also edible. *Gigartina speciosa* is used for jelly in the Swan River settlement. *Gracilaria lichenoides*, under the name of Ceylon moss, is used for soups and jellies. *Gracilaria spinosa* supplies the Agar-Agar in China. *Nostoc edule* is a Chinese article of diet. The edible nests of China are supposed to be formed from seaweeds. *Plocaria tenax* is used in China to furnish glue. *Iridæa edulis* is edible. *Laurencia pinnatifida* is called pepper-dulse on account of having pungent qualities. Seaweeds form an excellent manure. They are used on many farms situated near the sea-shore. Seaweeds after burning yield barilla, an impure carbonate of soda. Kelp was for many years prepared from seaweeds in Scotland, more especially in the Western and Northern Islands.

As regards the distribution of seaweeds, some are cosmopolitan or pelagic, as species of Ulva and Enteromorpha, which are equally abundant in high northern and southern latitudes, as they are under the equator and in temperate regions. Many Diatomaceæ are distributed from pole to pole. In general, however, seaweeds are more or less limited in their distribution, so that different marine floras exist in various parts of the ocean. The marine species have been estimated at about 6000, and they are distributed in various regions. The Northern Ocean, from the pole to the 40th degree, the sea of the Antilles, the eastern coasts of South America, those of New Holland, the Indian Archipelago, the Mediterranean, the Red Sea, the Chinese and Japanese seas, all present very large marine regions, each of which possesses a peculiar vegetation. The degree of exposure to light, and the greater or less motion of the waves, are important in the distribution of Algæ. The intervention of great depths of the ocean has an influence on sea plants similar to that of high mountains on land plants. Melanospermeæ increase as we approach the tropics, where the maximum of the species is found. Rhodospermeæ chiefly abound in the temperate zone; while Chlorospermeæ form the chief marine vegetation of the polar zone, and abound in the colder temperate zone. The green colour is characteristic of those Algæ which grow either in fresh water or in the shallower parts of the sea; the olive-coloured Algæ are abundant between the tide-marks; while the red-coloured species occur chiefly in the deeper and the darker parts of the sea.

Some seaweeds are worthy of note on account of the mode of their growth and distribution. *Chorda Filum*, a long cord-like seaweed, lies in beds of 15 to 20 miles in length, and only about 600 feet in breadth, in the North Sea and the British Channel. *Sargassum bacciferum* constitutes the Gulf-weed, which has been noticed by all who have crossed the Atlantic. The Gulf-weed has never been seen attached, but always floating. From the abundance of this seaweed its locality is called the Sargasso Sea. The most remarkable of the seaweeds, as regards size and the extent of range, are *Macrocystis pyrifera* and *Laminaria radiata*. Masses of Macrocystis, like green meadows, are found in every latitude. Many specimens have been seen about 300 feet long; some even extend to 700 feet or upwards. A tree seaweed, *Lessonia fuscescens*, with a stem 10 feet long, 12 inches in circumference, and its fronds 2–3 feet long and 3 inches broad, is found in immense masses off the Patagonian regions. *D'Urvillœa utilis* is another large Antarctic seaweed, which, along with Lessoniæ, occurs at the Falkland Islands, formed by the surf into enormous vegetable cables, several hundred feet long, and thicker than the human body. In Britain we have a marked distribution of seaweeds as regards depth. There is a littoral zone lying between high and low water marks, divided into sub-regions characterised by the following seaweeds:—1. *Fucus canaliculatus;* 2. *Fucus vesiculosus;* 3. *Fucus nodosus;* 4. *Fucus serratus.* Secondly, there is a laminarian zone, commencing at low-water mark, and extending for a depth of 7 to 15 fathoms. Here we meet with the great tangle seaweeds, such as *Laminaria digitata* and *L. saccharina*, along with deep-water Fuci. (J. H. B.)

ALGARDI, Alessandro, one of the most celebrated sculptors of Italy, was born at Bologna in 1602, and died in 1654. While he was attending the school of the Caracci his preference for the plastic art became evident, and he placed himself under the instruction of the sculptor Conventi. At the age of twenty he was brought under the notice of Duke Ferdinand of Mantua, who gave him several commissions. He was also much employed about the same period by jewellers and others in modelling in gold, silver, and ivory. After a short residence in Venice, he went to Rome in 1625 with an introduction from the Duke of Mantua to the pope's nephew, Cardinal Ludovisi, who employed him for a time in the restoration of ancient statues. The death of the Duke of Mantua left him to his own resources, and for several years he earned a precarious maintenance from these restorations and the commissions of goldsmiths and jewellers. In 1640 he executed for Pietro Buoncompagni his first work in marble, a colossal statue of San Filippo Neri, with kneeling angels. Immediately after, he produced a similar group, representing the execution of St Paul, for the church of the Barnabite Fathers in Bologna. These works, displaying great technical skill, though with considerable exaggeration of expression and attitude, at once established Algardi's reputation, and other commissions followed in rapid succession. The turning-point in Algardi's fortune was the accession of Innocent X., of the Bolognese house of Panfili, to the papal throne in 1644. He was employed by Camillo Panfili, nephew of the pontiff, to design the Villa Doria Panfili outside the San Pancrazio gate. The most important of Algardi's other works were the monument of Leo XI., a bronze statue of Innocent X. for the Capitol, and, above all, *La Fuega d'Attila*, the largest alto-rilievo in the world, the two principal figures being about 10 feet high. The great technical excellence of these works is considerably marred by an exaggeration of expression resulting from the vain endeavour to produce in marble effects which can only be legitimately brought out on canvas. From an artistic point of view, he is most successful in his portrait-statues and groups of children, where he is obliged to follow nature most closely. In his later years he became very avaricious, and amassed a great fortune.

ALGAROTTI, Francesco, Count, was born at Venice on the 11th December 1712. He went abroad in his youth, and in 1733 visited Paris, where he issued his Newtonian Philosophy for the Ladies, in the work entitled *The Plurality of Worlds.* He was much honoured by Frederick the Great, who, when crowned at Königsberg in 1740, created him a count of Prussia. He died at Pisa on the 23d of May 1764, and, by his own direction, the following inscription was placed upon his tomb:—*Hic jacet Algarottus, sed non omnis.* He is allowed to have been a great connoisseur in painting, sculpture, and architecture; and he contributed much to the reformation of the Italian opera. His works (6 vols., Leghorn, 1764; 17 vols., Venice, 1791–4) are numerous, and on a variety of subjects, abounding with vivacity, elegance, and wit.

ALGARVE, the most southerly province of Portugal, is bounded on the E. by the Spanish province of Seville, from which it is separated by the river Guadiana; on the N. by Alemtejo; and on the W. and S. by the Atlantic Ocean. Its length from east to west is 85 miles, the average width is 22 miles, and the area, according to the most recent measurement, 1865 square miles. In 1868 the population was 177,342, giving the small proportion of 95 to the square mile.

The Sierra de Caldeiraon and the Sierra de Monchique extend across the northern part of the province, and, sweeping to the south-west, terminate in the lofty promontory of Cape St Vincent, the south-west extremity of Europe. Between the mountainous tracts in the north and the southern coast stretches a narrow plain, watered by numerous rivers flowing southward from the hills. In the hilly districts the roads are bad, the soil unsuited for cultivation, and the inhabitants few. Flocks of goats are reared on the mountain sides. The level country along the southern coast is more fertile, and produces in abundance grapes, figs, oranges, lemons, olives, almonds, and aloes, and even the plantain and the date. The land is, however, not well suited for the production of cereals; little wheat or other corn is grown in the province, and its grain supplies are chiefly derived from Spain. On the coast the people derive their subsistence in great measure from the fisheries, tunny and sardines being caught in considerable quantities. Salt is also made from sea-water. There is no manufacturing or mining industry of any importance. The harbours are bad, and the whole foreign trade is carried on by ships of other nations, although the inhabitants of Algarve are reputed to be the best seamen and fishermen of Portugal. The chief exports are dried fruit, wine, salt, tunny, sardines, and anchovies.

The name of Algarve is derived from the Arabic, and signifies a land lying to the west. The province was taken from the Moors in 1253 by Alphonso III., king of Portugal, who then assumed the additional title of king of Algarve. It is sometimes designated the district of Faro, and is subdivided into fifteen communes and sixty-two parishes. The chief town is Faro, and among the other towns are Castro Marino, Tavira, Portimao, Lagos, and Sagres, all on the coast or on the estuaries of the rivers, and Silves, on the river Portimao, the ancient Moorish capital of Algarve.

ALGAU, or ALLGAU, the name now given to a comparatively small district forming the south-western corner of Bavaria, and belonging to the province of Swabia and Neuburg, but formerly applied to a much larger territory, which extended as far as the Danube on the north, the Inn on the south, and the Lech on the west. The Algau Alps contain several lofty peaks, the highest of which is Mädele-Gabel, 8611 feet above the sea. The district is celebrated for the cattle, milk, butter, and cheese that it produces.

AL-GAZALI, ABU HAMED MUHAMMAD, usually described as an Arabian philosopher, was really a Moslem theologian who met the heretical philosophers on their own ground. He was born in 1058, and belonged to the sect of the Ascharites, or extreme right of the Motecallemin, who (and not the philosophers) were the real Arabian schoolmen. At thirty-three he became the head of a theological college at Baghdad, where his professor's chair was surrounded by eager crowds, including all the imams of the country. It was a time of keen speculation, when philosophic scepticism was encouraged in high places; and the premature convictions of Al-Gazali gave way under a violent reaction against the orthodox creed. Driven by mental inquietude, he escaped from Baghdad on the plea of making a pilgrimage to Mecca, but went to Syria, and (after visiting, though a Mahometan, the Holy Sepulchre at Jerusalem) settled at Damascus, where he spent ten years in seclusion and meditation. Recalled by his private affairs as he was on his way to Egypt, he returned to Baghdad, reluctantly resumed teaching (which he continued for fifteen years), then retired to Tous, his native town, and devoted his remaining years to the contemplative life of the Sufis, who had been his earliest instructors. He died in 1111. His outer life, so restless and unquiet, was the reflex of a mental history disturbed by prolonged agitation. Revolting, in the height of his success, against the current creed, he began to examine the foundations of knowledge. Where could certainty be found? In the perceptions of the senses? But these are contradicted by one another, and disproved by reason. In the notions of reason? Reason, indeed, professes to furnish us with necessary truths; but what assurance have we that the verdicts of reason may not be reversed by some higher authority? Al-Gazali then interrogated all the sects in succession to learn their criterion of truth. He first applied to the theological schoolmen, who grounded their religion on reason; but their aim was only to preserve the faith from heresy. He turned to the philosophers, and examined the accepted Aristotelianism in a treatise which has come down to us—*The Destruction of the Philosophers.* He assails them on twenty points of their mixed physical and metaphysical peripateticism, from the statement of which, in spite of his pretended scepticism, we can deduce some very positive metaphysical opinions of his own. He claims to have shown that the dogmas of the eternity of matter and the permanence of the world are false; that their description of the Deity as the demiurgos is unspiritual; that they fail to prove the existence, the unity, the simplicity, the incorporeality, or the knowledge (both of species and accidents) of God; that their ascription of souls to the celestial spheres is unproved; that their theory of causation, which attributes effects to the very natures of the causes, is false, for that all actions and events are to be ascribed to the Deity; and, finally, that they cannot establish the spirituality of the soul, nor prove its mortality. These criticisms disclose nothing like a sceptical state of mind, but rather a reversion from the metaphysical to the theological stage of thought. He denies the intrinsic tendencies, or souls, by which the Aristotelians explained the motion of the spheres, because he ascribes their motion to God. The sceptic would have denied both. Mr Lewes rightly censures M. Renan for asserting of Al-Gazali's theory of causation—"*Hume n'a rien dit plus.*" It is true that Al-Gazali maintains that the natural law according to which effects proceed inevitably from their causes is only custom, and that there is no *necessary* connection between them. So far the Eastern and the European sceptic are on the same ground. But while Hume absolutely denies the necessity, Al-Gazali merely removes it one stage further back, and plants it in the mind of the Deity. This, of course, is not metaphysics, but theology. Having, as he believed, refuted the opinions of the philosophers, he next investigated the pretensions of the Allegorists, who derived their doctrines from an imam. These Arabian ultramontanes had no word for the doubter. Did he ask for the proof of their doctrine, they could only answer that "thus it was written." They could not, he says, even understand the problems they sought to resolve by the assumption of infallibility, and he turned again, in his despair, to the instructors of his youth—the Sufis. In their mystical intuition of the laws of life, and absorption in the immanent Deity, he at last found peace. This pathetic close of his stormy career negatives the idea that he ever wrote the philosophical work he once contemplated on *The Bases of Belief*, and at the same time shows the true character of the treatise which, alike in mediæval and modern times, has been quoted as containing an exposition of his opinions. The work called *The Tendencies of the Philosophers*, and which was translated in 1506, with the title *Logica et Philosophia Algazelis Arabis*, contains neither the logic nor the philosophy of Al-Gazali. It is a mere abstract or statement of the Peripatetic systems, and was made preliminary to that *Destruction* of which we have already spoken. With this work Arabian philosophy in the East came to an end; but it revived in the new Arabia which had been planted in the West—in Mahometan Spain. If, therefore, Al-Gazali was the Oriental Descartes in being the first destructive sceptic of the old, he was its Descartes no less in being the initiator of the new philosophy.

For direct knowledge of Al-Gazali, see his *Destructio*, &c., in the ninth vol. of Averrhoës's works, but especially his spiritual autobiography, translated by Schmölders in his *Essai sur les Écoles Philosophiques chez les Arabes.* See also Von Hammer, introduction to *O Kind;* Munk, *Mélanges;* and Gosche in *Abhandlungen der König. Akad. der Wissenschaften zu Berlin*, 1858.

ALGEBRA

ALGEBRA is that branch of the mathematical sciences which has for its object the carrying on of operations either in an order different from that which exists in arithmetic, or of a nature not contemplated in fixing the boundaries of that science. The circumstance that algebra has its origin in arithmetic, however widely it may in the end differ from that science, led Sir Isaac Newton to designate it "Universal Arithmetic," a designation which, vague as it is, indicates its character better than any other by which it has been attempted to express its functions—better certainly, to ordinary minds, than the designation which has been applied to it by Sir William Rowan Hamilton, one of the greatest mathematicians the world has seen since the days of Newton—"the Science of Pure Time;" or even than the title by which De Morgan would paraphrase Hamilton's words—"the Calculus of Succession."

To express in few words what it is which effects the transition from the science of arithmetic into a new field is not easy. It will serve, probably, to convey some notion of the position of the boundary line, when it is stated that the operations of arithmetic are all capable of direct interpretation *per se*, whilst those of algebra are in many cases interpretable only by comparison with the assumptions on which they are based. For example, multiplication of fractions—which the older writers on arithmetic, Lucas de Burgo in Italy, and Robert Recorde in England, clearly perceived to be a new application of the term multiplication, scarcely at first sight reconcilable with its original definition as the exponent of equal additions,—multiplication of fractions becomes interpretable by the introduction of the idea of multiplication into the definition of the fraction itself. On the other hand, the independent use of the sign *minus*, on which Diophantus, in the 4th century, laid the foundation of the science of algebra in the West, by placing in the forefront of his treatise, as one of his earliest definitions, the rule of the sign minus, "that *minus* multiplied by *minus* produces *plus*"—this independent use of the sign has no originating operation of the same character as itself, and might, if assumed in all its generality as existing side by side with the laws of arithmetic, more especially with the commutative law, have led to erroneous conclusions. As it is, the unlimited applicability of this definition, in connection with all the laws of arithmetic standing in their integrity, pushes the dominion of algebra into a field on which the oldest of the Greek arithmeticians, Euclid, in his unbending march, could never have advanced a step without doing violence to his convictions.

In asserting that the independent existence of the sign *minus*, side by side with the laws of arithmetic, might have led to anomalous results, had not the operations been subject to some limitation, we are introducing no imaginary hypothesis, but are referring to a fact actually existing. The most recent advance beyond the boundaries of algebra, as it existed fifty years ago, is that beautiful extension to which Sir W. R. Hamilton has given the designation of Quaternions, the very foundation of which requires the removal of one of the ancient axioms of arithmetic, "that operations may be performed in any order."

HISTORY.

At what period and in what country algebra was invented? is a question that has been much discussed. Who were the earliest writers on the subject? What was the progress of its improvement? And lastly, by what means and at what period was the science diffused over Europe? It was a common opinion in the 17th century that the ancient Greek mathematicians must have possessed an analysis of the nature of modern algebra, by which they discovered the theorems and solutions of the problems which we so much admire in their writings; but that they carefully concealed their instruments of investigation, and gave only the results, with synthetic demonstrations.

This opinion is, however, now exploded. A more intimate acquaintance with the writings of the ancient geometers has shown that they had an analysis, but that it was purely geometrical, and essentially different from our algebra.

Although there is no reason to suppose that the great geometers of antiquity derived any aid in their discoveries from the algebraic analysis, yet we find that at a considerably later period it was known to a certain extent among the Greeks.

About the middle of the 4th century of the Christian era, a period when the mathematical sciences were on the decline, and their cultivators, instead of producing original works of genius, contented themselves with commentaries on the works of their more illustrious predecessors, there was a valuable addition made to the fabric of ancient learning.

This was the treatise of Diophantus on arithmetic, consisting originally of thirteen books, of which only the first six, and an incomplete book on polygonal numbers, supposed to be the thirteenth, have descended to our times. Diophantus.

This precious fragment does not exhibit anything like a complete treatise on algebra. It lays, however, an excellent foundation of the science, and the author, after applying his method to the solution of simple and quadratic equations, such as to "find two numbers of which the sum and the sum or difference of the squares are given," proceeds to a peculiar class of arithmetical questions, which belong to what is now called the indeterminate analysis.

Diophantus may have been the inventor of the Greek algebra, but it is more likely that its principles were not unknown before his time; and that, taking the science in the state in which he found it as the basis of his labours, he enriched it with new applications. The elegant solutions of Diophantus show that he possessed great address in the particular branch of which he treated, and that he was able to resolve determinate equations of the second degree. Probably this was the greatest extent to which the science had been carried among the Greeks. Indeed, in no country did it pass this limit, until it had been transplanted into Italy on the revival of learning.

The celebrated Hypatia, the daughter of Theon, composed a commentary on the work of Diophantus. This, however, is now lost, as well as a similar treatise, on the *Conics* of Apollonius, by this illustrious and ill-fated lady, who, as is commonly known, fell a sacrifice to the fury of a fanatical mob about the beginning of the 5th century.

About the middle of the 16th century, the work of Diophantus above referred to, written in the Greek language, was discovered at Rome in the Vatican library, having probably been brought there from Greece when the Turks possessed themselves of Constantinople. A Latin translation, without the original text, was given to the world by Xylander in 1575; and a more complete translation, by Bachet de Mezeriac (one of the earliest members of the French Academy), accompanied by a commentary, appeared in 1621. Bachet was eminently skilful in the indeterminate analysis, and therefore well qualified for the work he had undertaken; but the text of Diophantus was so much injured, that he was frequently obliged to guess the meaning of the author, or supply the deficiency. At a later period, the celebrated French mathematician Fermat supplemented the commentary of Bachet by notes of his own on the writings of the Greek algebraist. These are extremely valuable, on account of Fermat's profound knowledge of this particular branch of analysis. This edition, the best which exists, appeared in 1670.

Although the revival of the writings of Diophantus was an important event in the history of mathematics, yet it was not from them that algebra became first known in Europe. This important invention, as well as the numeral characters and decimal arithmetic, was received from the Arabians. That ingenious people fully appreciated the value of the sciences; for at a period when all Europe was enveloped in the darkness of ignorance, they preserved from extinction the lamp of knowledge. They carefully collected the writings of the Greek mathematicians; they translated them into their language, and illustrated them with commentaries. It was through the medium of the Arabic tongue that the elements of Euclid were first introduced into Europe; and a part of the writings of Apollonius are only known at the present day by a translation from the Arabic, the Greek original being lost.

The Arabians ascribe the invention of their algebra to one of their mathematicians, Mahommed-ben-Musa, or Moses, called also Mahommed of Buziana, who flourished about the middle of the 9th century, in the reign of the Caliph Almamoun.

It is certain that this person composed a treatise on this subject, because an Italian translation was known at one time to have existed in Europe, although it is now lost. Fortunately, however, a copy of the Arabic original is preserved in the Bodleian Library at Oxford, bearing a date of transcription corresponding to the year 1342. The title-page identifies its author with the ancient Arabian. A marginal note concurs in this testimony, and further declares the work to be the first treatise composed on algebra among the faithful; and the preface, besides indicating the author, intimates that he was encouraged by Almamoun, commander of the faithful, to compile a compendious treatise of calculation by algebra.

The circumstance of this treatise professing to be only a compilation, and, moreover, the first Arabian work of the kind, has led to an opinion that it was collected from books in some other language. As the author was intimately acquainted with the astronomy and computations of the Hindoos, he may have derived his knowledge of algebra from the same quarter. The Hindoos, as we shall presently see, had a science of Algebra, and knew how to solve indeterminate problems. Hence we may conclude, with some probability, that the Arabian algebra was originally derived from India.

The algebraic analysis, having been once introduced among the Arabians, was cultivated by their own writers. One of these, Mahommed Abulwafa, who flourished in the last forty years of the 10th century, composed commentaries on the writers who had preceded him. He also translated the writings of Diophantus.

It is remarkable, that although the mathematical sciences were received with avidity, and sedulously cultivated during a long period by the Arabians, yet in their hands they received hardly any improvement. It might have been expected that an acquaintance with the writings of Diophantus would have produced some change in their algebra. This, however, did not happen: their algebra continued nearly in the same state, from their earliest writer on the subject, to one of their latest, Behaudin, who lived between the years 953 and 1031.

Writers on the history of algebra were long under a mistake as to the time and manner of its introduction into Europe. It has now, however, been ascertained that the science was brought into Italy by Leonardo, a merchant of Pisa. This ingenious man resided in his youth in Barbary, and there learned the Indian method of counting by the nine numeral characters. Commercial affairs led him to travel into Egypt, Syria, Greece, and Sicily, where we may suppose he made himself acquainted with everything known respecting numbers. The Indian mode of computation appeared to him to be by far the best. He accordingly studied it carefully; and, with this knowledge, and some additions of his own, and also taking some things from Euclid's Geometry, he composed a treatise on arithmetic. At that period algebra was regarded only as a part of arithmetic. It was indeed the sublime doctrine of that science; and under this view the two branches were handled in Leonardo's treatise, which was originally written in 1202, and again brought forward under a revised form in 1228. When it is considered that this work was composed two centuries before the invention of printing, and that the subject was not such as generally to interest mankind, we need not wonder that it was but little known; hence it has always remained in manuscript, as well as some other works by the same author. Indeed it was not known to exist from an early period until the middle of the last century, when it was discovered in the Magliabecchian library at Florence.

The extent of Leonardo's knowledge was pretty much the same as that of the preceding Arabian writers. He could resolve equations of the first and second degrees, and he was particularly skilful in the Diophantine analysis. He was well acquainted with geometry, and he employed its doctrines in demonstrating his algebraic rules. Like the Arabian writers, his reasoning was expressed in words at length; a mode highly unfavourable to the progress of the art. The use of symbols, and the method of combining them so as to convey to the mind at a single glance a long process of reasoning, was a much later invention.

Considerable attention was given to the cultivation of algebra between the time of Leonardo and the invention of printing. It was publicly taught by professors. Treatises were composed on the subject; and two works of the oriental algebraists were translated from the Arabian language into Italian. One was entitled *the Rule of Algebra*, and the other was the oldest of all the Arabian treatises, that of Mahommed-ben-Musa of Corasan.

The earliest printed book on algebra was composed by Lucas Paciolus, or Lucas de Burgo, a minorite friar. It was first printed in 1494, and again in 1523. The title is *Summa de Arithmetica, Geometria, Proportioni, et Proportionalita.*

This is a very complete treatise on arithmetic, algebra, and geometry, for the time in which it appeared. The author followed close on the steps of Leonardo; and, indeed, it is from this work that one of his lost treatises has been restored.

Lucas de Burgo's work is interesting, inasmuch as it shows the state of algebra in Europe about the year 1500: probably the state of the science was nearly the same in Arabia and Africa, from which it had been received.

The power of algebra as an instrument of research is in a very great degree derived from its notation, by which all the quantities under consideration are kept constantly in view; but in respect of convenience and brevity of expression, the algebraic analysis in the days of Lucas de Burgo was very imperfect: the only symbols employed were a few abbreviations of the words or names which occurred in the processes of calculation, a kind of short-hand, which formed a very imperfect substitute for that compactness of expression which has been attained by the modern notation.

The application of algebra was also at this period very limited; it was confined almost entirely to the resolution of certain questions of no great interest about numbers. No idea was then entertained of that extensive application which it has received in modern times.

The knowledge which the early algebraists had of their science was also circumscribed: it extended only to the resolution of equations of the first and second degrees; and they divided the last into cases, each of which was resolved by its own particular rule. The important analytical fact, that the resolution of all the cases of a problem may be comprehended in a single formula, which may be obtained from the solution of one of its cases, merely by a change of the signs, was not then known: indeed, it was long before this principle was fully comprehended. Dr Halley expresses surprise, that a formula in optics which he had found, should by a mere change of the signs give the focus of both converging and diverging rays, whether reflected or refracted by convex or concave specula or lenses; and Molyneux speaks of the universality of Halley's formula as something that resembled magic.

The rules of algebra may be investigated by its own principles, without any aid from geometry; and although in some cases the two sciences may serve to illustrate each other, there is not now the least necessity in the more elementary parts to call in the aid of the latter in expounding the former. It was otherwise in former times. Lucas de Burgo found it to be convenient, after the example of Leonardo, to employ geometrical constructions to prove the truth of his rules for resolving quadratic equations, the nature of which he did not completely comprehend; and he was induced by the imperfect nature of his notation to express his rules in Latin verses, which will not now be read with the kind of satisfaction we receive from the perusal of the well-known poem, "the Loves of the Triangles."

As Italy was the first European country where algebra became known, it was there that it received its earliest improvements. The science had been nearly stationary from the days of Leonardo to the time of Paciolus, a period of three centuries; but the invention of printing soon excited a spirit of improvement in all the mathematical sciences. Hitherto an imperfect theory of quadratic equations was the limit to which it had been carried. At last this boundary was passed, and about the year 1505 a particular case of equations of the third degree was resolved by Scipio Ferreus, a professor of mathematics in Bononia. This was an important step, because it showed that the difficulty of resolving equations of the higher orders, at least in the case of the third degree, was not insurmountable, and a new field was opened for discovery. It was then the practice among the cultivators of algebra, when they advanced a step, to conceal it carefully from their contemporaries, and to challenge them to resolve arithmetical questions, so framed as to require for their solution a knowledge of their own new-found rules. In this spirit did Ferreus make a secret of his discovery: he communicated it, however, to a favourite scholar, a Venetian named Florido. About the year 1535 this person, having taken up his residence at Venice, challenged Tartalea of Brescia, a man of great ingenuity, to a trial of skill in the resolution of problems by algebra. Florido framed his questions so as to require for their solution a knowledge of the rule which he had learned from his preceptor Ferreus; but Tartalea had, five years before this time, advanced further than Ferreus, and was more than a match for Florido. He therefore accepted the challenge, and a day was appointed when each was to propose to the other thirty questions. Before the time came, Tartalea had resumed the study of cubic equations, and had discovered the solution of two cases in addition to two which he knew before. Florido's questions were such as could be resolved by the single rule of Ferreus; while, on the contrary, those of Tartalea could only be resolved by one or other of three rules, which he himself had found, but which could not be resolved by the remaining rule, which was also that known to Florido. The issue of the contest is easily anticipated; Tartalea resolved all his adversary's questions in two hours, without receiving one answer from him in return.

The celebrated Cardan was a contemporary of Tartalea. This remarkable person was a professor of mathematics at Milan, and a physician. He had studied algebra with great assiduity, and had nearly finished the printing of a book on arithmetic, algebra, and geometry; but being desirous of enriching his work with the discoveries of Tartalea, which at that period must have been the object of considerable attention among literary men in Italy, he endeavoured to draw from him a disclosure of his rules. Tartalea resisted for a time Cardan's entreaties. At last, overcome by his importunity, and his offer to swear on the holy Evangelists, and by the honour of a gentleman, never to publish them, and on his promising on the faith of a Christian to commit them to cypher, so that even after his death they would not be intelligible to any one, he ventured with much hesitation to reveal to him his practical rules, which were expressed by some very bad Italian verses, themselves in no small degree enigmatical. He reserved, however, the demonstrations. Cardan was not long in discovering the reason of the rules, and he even greatly improved them, so as to make them in a manner his own. From the imperfect essays of Tartalea he deduced an ingenious and systematic method of resolving all cubic equations whatsoever; but with a remarkable disregard for the principles of honour, and the oath he had taken, he published in 1545 Tartalea's discoveries, combined with his own, as a supplement to a treatise on arithmetic and algebra, which he had published six years before. This work is remarkable for being the second printed book on algebra known to have existed.

In the following year Tartalea also published a work on algebra, which he dedicated to Henry VIII., king of England.

It is to be regretted that in many instances the authors of important discoveries have been overlooked, while the honours due to them have been transferred to others having only secondary pretensions. The formulæ for the resolution of cubic equations are now called Cardan's rules, notwithstanding the prior claim of Tartalea. It must be confessed, however, that he evinced considerable selfishness in concealing his discovery; and although Cardan cannot be absolved from the charge of bad faith, yet it must be recollected that by his improvements in what Tartalea communicated to him, he made the discovery in some measure his own; and he had moreover the high merit of being the first to publish this important improvement in algebra to the world.

The next step in the progress of algebra was the discovery of a method of resolving equations of the fourth order. An Italian algebraist had proposed a question which could not be resolved by the newly invented rules, because it produced a biquadratic equation. Some supposed that it could not be resolved at all; but Cardan was of a different opinion. He had a pupil named Lewis Ferrari, a young man of great genius, and an ardent student in the algebraic analysis: to him Cardan committed the solution of this difficult question, and he was not disappointed. Ferrari not only resolved the question, but he also found a general method of resolving equations of the fourth degree, by making them depend on the solution of equations of the third degree.

This was another great improvement; and although the precise nature of an equation was not then fully understood, nor was it indeed until half a century later, yet, in the general resolution of equations, a point of progress was then reached which the utmost efforts of modern analysis have never been able to pass.

There was another Italian mathematician of that period who did something for the improvement of algebra. This was Bombelli. He published a valuable work on the subject in 1572, in which he brought into one view what had been done by his predecessors. He explained the nature of the *irreducible case* of cubic equations, which had greatly perplexed Cardan, who could not resolve it by his rule; he showed that the rule would apply sometimes to particular examples, and that all equations of this case admitted of a real solution; and he made the important remark, that the algebraic problem to be resolved in this case corresponds to the ancient problem of the trisection of an angle.
