In a photometric apparatus of the type described in E.P. 112,614, the adjusting appliances for the filters or the screens for the filters are provided with a scale graduated so that by adjusting the colour of the comparison light until it matches that emitted by an incandescent body, more particularly that of an incandescent lamp filament, the temperature of the latter may be read off directly.—J. S. G. T.

Pyrometry; Optical ——. E. A. Keeler, Assr. to Leeds and Northrup Co. U.S.P. 1,379,188, 24.5.21. Appl., 30.10.19.

A current is passed through an incandescent body to bring it to a predetermined temperature, and the current is caused to produce a deflection in a galvanometer. While maintaining the current the potential difference impressed on the galvanometer is reduced and the current through the body is raised until it has the same brightness as the body of which the temperature is to be measured, and the temperature determined from the resultant deflection of the galvanometer.—H. R. D.

Thermo-element. A. Schwartz. G.P. 336,936, 17.6.19.

One electrode is constituted of a compound of silicon and carbon, and the other of a conductor of the first class. Thus, a thermo-element composed of a silicon-carbon electrode and a nickel electrode will withstand a temperature of 1400° C. and furnish a thermo-electric E.M.F. of 0·062 volt.—J. S. G. T.

Gas-analysing apparatus. O. Rohde, Assr. to Svenska Aktiebolaget Mono. U.S.P. 1,380,160, 31.5.21. Appl., 26.1.20.

See E.P. 138,355 of 1920; J., 1921, 417 A.

Moisture; Means for detecting or measuring ——. C. A. Parsons and A. H. Law. U.S.P. 1,383,233, 28.6.21. Appl., 10.7.18.

See E.P. 119,533 of 1917; J., 1918, 720 A.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Anderson. Liquid straining or filtering apparatus. 20,562. Aug. 2.

Boberg, Testrup, and Techno-Chemical Laboratories, Ltd. Evaporation of liquids. 21,264. Aug. 10.

Corsellis and Galbraith. Centrifugal machines and method of manipulating same. 20,211. July 27.

Davis. Filters. 20,414. July 29.

Davis and Twigg. Furnaces. 20,711. Aug. 3.

Ebersbach and Hüttel. Volatilizer. 21,485. Aug. 12.

Fletcher. Means for separating solids of different specific gravities. 20,062. July 26.

Harper and Lamplough. Centrifugal filters. 20,737. Aug. 4.

Kestner. Washing and displacement of gases. 20,158. July 27. (Belgium, 9.9.20.)

Lebeau. Apparatus for refrigeration of liquids, terilisation, carbonisation, oxygenation, and isoarometrical extraction. 20,862. Aug. 5.

Malone. Freezing-machines. 20,854. Aug. 5.

Smeeton. Utilisation of waste heat in furnaces tc. 20,524. Aug. 2.

Stewart. Refrigeration. 21,385. Aug. 11.

Thatcher. 20,147. *See* XI.

West. Furnaces. 20,314. July 28.

Complete Specifications Accepted.

5751–2 (1917). White (Ransome). Mixing achines. (166,566–7). Aug. 4.

2212 (1920). White (By-Products Recovery Co.). *ee* XIXa.

3238 (1920). Wilson. Drying-pans. (167,202.) ug. 17.

5692 (1920). Lunt. Method of recovering lvents. (139,488.) Aug. 10.

7792 (1920). Goldberg. Protecting from fire inammable substances. (146,081.) Aug. 4.

8175 (1920). Brown. Tubular heat-exchangers. (166,930.) Aug. 10.

9504 (1920). Wade (Barrett Co.). Process of catalytic oxidation. (167,219.) Aug. 17.

9989 (1920). Frischer and Drees. Process and apparatus for causing gases and liquids to react with one another. (141,374.) Aug. 4.

11,518 (1920). Weijers. Downdraught kilns, ovens, or the like. (142,803.) Aug. 10.

11,822 (1920). Thornycroft. Apparatus for the extraction of juice from vegetable substances. (166,993.) Aug. 10.

15,617 (1920). Grant. Apparatus for agitating liquids. (167,355.) Aug. 17.

15,876 ((1920). Kennedy. Pulverising-apparatus. (144,723.) Aug. 4.

17,723 (1920). North. Process and apparatus for electrically separating dust from gases and vapours. (145,585.) Aug. 17.

20,536 (1920). Wittemeyer. Air filters. (148,544.) Aug. 10.

20,599 (1920). Marks (Metallatom Ges.). Method of atomising fusible materials. (148,776.) Aug. 17.

20,612 (1920). Metcalfe. Continuous tunnel kilns. (167,070.) Aug. 10.

22,472 (1920). Von Wurstemberger. *See* XI.

22,663 (1920). Duncan. Furnaces. (167,386.) Aug. 17.

25,657 (1920). Nelson. Kilns. (166,834.) Aug. 4.

27,775 (1920). Marks (A.-G. Brown, Boveri & Co.). Horizontal surface condensers. (167,414.) Aug. 17.

29,013 (1920). Koppers Co. Purification of liquids. (152,356.) Aug. 17.

984 (1921). Siemens u. Halske A.-G. Mercury vapour jet pump with arc. (157,118.) Aug. 10.

1018 (1921). Hiorth. Device for effecting gas reactions under high pressure. (157,152.) Aug. 10.

8023 (1921). Fasting. Process of and apparatus for drying material to be ground in revolving drums. (160,423.) Aug. 17.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Bargate and Walkey. Method of extracting oil from shale etc. 20,381. July 29.

Bourcet, Chevalier, and Regnault. Carburant for alcohol. 20,661. Aug. 3. (France, 27.8.20.)

Boving. Method of producing liquid fuel for engines etc. 21,046. Aug. 8.

Colville. Vessels for distilling oil etc. which gives off inflammable vapour. 20,225. July 28.

Curran. Systems for oil storage and refining. 19,963. July 26.

Ehlers. Method of refining mineral oils obtained from earth oil. 20,374. July 29.

Elektrizitätswerk Lonza. Combustion of metaldehyde for cooking, heating, etc. 21,287. Aug. 10. (Switzerland, 4.9.20.)

Evans. Manufacture of producer gas. 21,528. Aug. 13.

Florin. Gas-washers. 21,103. Aug. 9.

Franklin and Pettingall. Fuel. 20,444. July 30.

Harrison. 20,626. *See* VIII.

Harrison. Electric heating. 20,925. Aug. 6.

Helps. Gas manufacture. 20,355. July 29.

Klärding. Purification of gas. 20,317. July 28. (Germany, 28.7.20.)

Laing and Nielsen. Distillation of carbonaceous materials. 21,183. Aug. 9.

Monarch Mantles, Ltd., and Terrell. Light-giving bodies for incandescent lighting. 20,596. Aug. 2.

Plauson's (Patent Co.), Ltd. (Plauson). Extraction of shale etc. 20,968. Aug. 8.

Pritchard. Manufacture of liquid fuel. 20,070. July 26.

Redfern (Stuart). Gas-producers. 20,590. Aug. 2.

Reid. 20,570. *See* X.

Roach-Cumming. Liquid fuels. 21,550. Aug. 13.

Roberts. Carbonisation of coal. 20,191. July 27.

Schattner. Electric incandescent lamps. 20,982. Aug. 8.

Sutcliffe. Treatment of lignite etc. 21,172. Aug. 9.

Tinker. Production of petrol. 20,412. July 29.

Tréfois. Rotary grates for gas producers etc. 20,563. Aug. 1.

Walker. Fractional distillation of crude petroleum. 21,320. Aug. 11.

Walker. Fractional distillation of crude naphtha. 21,321. Aug. 11.

Warden. Coking retort oven heating-flues. 19,994. July 20.

Weller and Young. Incandescent electric lamps. 21,335. Aug. 11.

Young. Manufacture of gas. 20,612. Aug. 2.

Complete Specifications Accepted.

17,125 (1918). Klasson and Kirpotschnikoff. Process for the utilisation of peat as fuel, and apparatus therefor. (166,576.) Aug. 4.

14,771 (1919). Sauer. Process of producing decolorising carbon. (167,195.) Aug. 17.

2317, 2318, and 2321 (1920). American Coke and Chemical Co. Coke ovens and the like. (150,983, 147,531, and 138,127.) Aug. 4 and 10.

10,738 (1920). Brownlee. Lubricating-oils and process of making same. (141,753.) Aug. 4.

11,679 (1920). Engelke. Art of and means for the treating of hydrocarbon oils. (166,989.) Aug. 10.

12,377 (1920). South Metropolitan Gas Co., and Somerville. Glass vessels containing a wire adapted to be heated to incandescence. (167,280.) Aug. 17.

12,471 (1920). Armstrong, Whitworth, and Co., Ltd., Trevelyan, Andrew, and Miller. Furnaces burning powdered fuel. (167,289.) Aug. 17.

12,629 (1920). De Laval Separator Co. Process for cleaning gasoline. (142,859.) Aug. 17.

12,951 (1920). Guignard and Felizat. Destructive distillation of solid combustibles, especially of schists, shales, peat, and similar carbonaceous materials. (143,223.) Aug. 17.

14,294 (1920). Oliensis and Miller, jun. *See* IX.

14,351 (1920). Alexander (Blackstone International Corp.). *See* IX.

17,174 (1920). Fischer. Distillation of coal. (146,287.) Aug. 17.

17,974 (1920). Collin A.-G. zur Verwertung von Brennstoffen und Metallen. *See* VII.

19,743 (1920). Otto und Co. Regenerative coke-ovens. (147,740.) Aug. 4.

23,869 (1920). Hilger. Gas-producers (150,267.) Aug. 10.

36,007 (1920). Otto und Co. Coke-ovens. (155,828.) Aug. 10.

9794 (1921). Brownlee. Synthetically-produced hydrocarbon oils. (161,175.) Aug. 4.

11,289 (1921). Patent-Treuhand Ges. für Elektrische Glühlampen. Tungsten arc lamps. (162,651.) Aug. 10.

III.—TAR AND TAR PRODUCTS.

Applications.

Bodman and Gettings. 20,471. *See* IX.

Colville. 20,225. *See* II.

Soc. Chim. de la Grande Paroisse. Process for preparation of aromatic nitramines. 21,455. Aug. 12. (France, 30.9.20.)

Complete Specifications Accepted.

8804 (1920). Bielouss. Reduction of trinitrotoluol. (166,934.) Aug. 10.

11,515 (1920). Schaefer and Faber. *See* XIX.

IV.—COLOURING MATTERS AND DYES.

Applications.

Dandridge, Thomas, and Scottish Dyes, Ltd. Manufacture of dyestuffs of the anthraquinone series. 20,682. Aug. 3.

Plauson's (Parent Co.), Ltd. (Plauson). Manufacture of insoluble colours, lakes, etc. 20,450. July 30.

Soc. Chim. de la Grande Paroisse. Brown dyestuffs. 21,454. Aug. 12. (France, 30.9.20.)

Soc. Chim. de la Grande Paroisse. 21,455. *See* III.

Complete Specifications Accepted.

17,417 (1914). Ransford (Cassella und Co.). Manufacture of new substances containing sulphur and of new sulphur dyestuffs therefrom. Aug 4.

15,133 (1920). Carpmael (Farbenfabr. vorm. F. Bayer und Co.). Manufacture of new azo dyestuffs. (144,310.) Aug. 17.

15,280 (1920). Soc. Chim. des Usines du Rhône, anc. Gilliard, P. Monnet, et Cartier. Process for the preparation of di-substituted 2.4-diketo-tetrahydro-oxazoles. (159,153.) Aug. 10.

15,457 (1920). Badische Anilin u. Soda Fabrik. Manufacture and production of yellow colouring matters for dyeing animal fibres. (144,658.) Aug. 10.

16,907 (1920). Akt.-Ges. für Anilin-Fabr. Manufacture of new sulphurised dyestuffs. (145,523.) Aug. 10.

25,263 (1920). Ransford (Cassella und Co.). Manufacture of a colour of the anthraquinone series. (150,709.) Aug. 4.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

British Dyestuffs Corp., Ltd., and others. 20,621. *See* VI.

Broadbent. Machines for washing wool etc. 21,222. Aug. 10.

Carpmael (Farbenfabr. vorm. F. Bayer und Co.). Process for protecting wool etc. from moth. 20,214. July 27.

Clemm, Hangleiter, and Zellstoff-fabr. Waldhof. Process for recovery of sulphurous acid and heat from waste gases from pulp-boilers. 19,951 July 25. (Germany, 2.8.20.)

Clemm, and Zellstoff-fabr. Waldhof. Process of filling pulp-boilers with heated sulphite-lye. 19,952. July 25. (Germany, 4.9.20.)

Harris and Kidger. Process of retting, degumming, etc. fibres. 21,529. Aug. 13.

Joiner. Preparing bamboo etc. for paper-making etc. 19,927. July 25.

McGill. Treating fibrous materials. 20,195. July 27.

Parkinson. Machines for drying fabrics. 21,363. Aug. 11.

Sanderson. Means for production of mottled etc. effects on paper etc. 19,923. July 25.

White (Duratex Co.). Coated fabric, and process for making same. 21,300. Aug. 10.

Complete Specifications Accepted.

22,826 (1913). Borzykowski. Method of and apparatus for the production of imitation textile goods from solutions of cellulose or plastic substances. Aug. 10.

1426 (1920). Frood. Fibrous fabrics or compositions for frictional and wearing purposes. (166,916.) Aug. 10.

2056 (1920). Stulemeyer. Processes for the treatment of viscose. (167,199.) Aug. 17.

3116 (1920). Stulemeyer. Processes for making viscose. (167,201.) Aug. 17.

8451 (1920). Bronnert. Manufacture of viscose silk. (166,931.) Aug. 10.

11,658 (1920). Claremont and Beaver. Impregnating paper and the like with insulating-compounds and the like for electrical purposes. (167,232.) Aug. 17.

13,290 (1920). Dreyfus. Manufacture of cellulose derivatives. (166,767.) Aug. 4.

21,634 (1920). Bouillon and Worms. Treatment of viscose filaments, threads, or films. (167,076.) Aug. 10.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Anderson. Process for hardening and finishing fabrics, garments, etc. 20,975. Aug 8.

British Dyestuffs Corp., Ltd., Horsfall, and Jackson. Process for dyeing paper. 20,621. Aug. 2.

Calico Printers' Association, Ltd., and Nelson. Printing of textile fabrics. 21,557. Aug. 13.

Crosland, Dixon, and Hawley. Finishing wool, cotton, silk, artificial silk hose, etc. 21,266. Aug. 10.

Crosland, Dixon, and Hawley. Mercerisation etc. of hose etc. 21,267. Aug. 10.

Crosland, Dixon, and Hawley. Production of a lustre finish on cotton hose etc. 21,268. Aug. 10.

Complete Specifications Accepted.

12,382 (1920). Olig and Kuster. Machine for mercerising hanks of yarn. (146,934.) Aug. 17.

1345 (1921). Krantz. Means for dyeing yarn on bobbins in circulating dye liquor. (157,420.) Aug. 17.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Clemm and others. 19,951. *See* V.

Cumberland Coal Power and Chemicals, Ltd., acques, and West. Production of solid products rom ammonia gas. 20,331. July 28.

Dutt, Godfrey, and Wilson. Extraction of itanium dioxide and alumina from titaniferous auxite. 20,258. July 28.

Priest. 20,708. *See* IX.

Reid. Manufacture of carbonates of soda etc. 0,740. Aug. 4.

Rheinisch-Nassauische Bergwerks- u. Hütten-.-G., and Schüphaus. Method of producing chemially-pure hydrochloric acid. 20,583. Aug. 2. ermany, 16.8.20.)

Riedel. Process for protection of apparatus in e preparation of ammonium chloride. 21,235. ug. 10. (Germany, 13.8.20.)

Stacey. Dynamo-electric machines for producing xides of nitrogen. 21,342. Aug. 11.

Complete Specifications Accepted.

9386 (1920). Schmiedel and Klencke. Process for e production of sulphuric acid. (149,648.) ug. 17.

10,282 (1920). Bird. *See* XVII.

11,116 (1920). Mehner. Manufacture of cyano-n compounds. (142,122.) Aug. 4.

11,343 (1920). Clayton. Sulphur-burning furnaces and the like. (166,961.) Aug. 10.

13,293 (1920). Spence and Sons, Ltd., Spence, and Craig. Purification of sulphur. (167,313.) Aug. 17.

13,702 (1920). Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Process for the production of formate of ammonium from barium cyanide. (143,850.) Aug. 4.

13,810 (1920). Nitrogen Corp. Production of ammonia. (143,550.) Aug. 17.

17,062 (1920). Soc. Electro-Metallurgique Française. Processes for the preparation of aluminate of lime for the manufacture of pure alumina. (146,133.) Aug. 10.

17,974 (1920). Collin A.-G. zur Verwertung von Brennstoffen und Metallen. Process of producing ammonium sulphate from cyanogen compounds produced in the distillation of coal or organic substances. (145,696.) Aug. 4.

1018 (1921). Hiorth. *See* I.

VIII.—GLASS; CERAMICS.

Applications.

Blanc. Gathering of glass. 20,153. July 27.

British Thomson-Houston Co., Ltd. (General Electric Co.). Glass-working machine. 21,564. Aug. 13.

Harrison. Brick kilns, lime kilns, gas retorts, etc. 20,626. Aug. 2.

Jackson (Libbey-Owens Sheet Glass Co.). Drawing sheet glass. 20,298. 20,305. 20,318. July 28.

Jackson (Libbey-Owens Sheet Glass Co.). Apparatus for drawing sheet glass. 20,312. 20,327. July 28.

Marks (Libbey-Owens Sheet Glass Co.). Drawing sheet glass. 20,692. Aug. 3.

Marks (Libbey-Owens Sheet Glass Co.). Sheet glass drawing machine. 20,693–4. 20,697. Aug. 3.

Marks (Libbey-Owens Sheet Glass Co.). Sheet glass drawing and delivery mechanism. 20,695. Aug. 3.

Marks (Libbey-Owens Sheet Glass Co.). Method of working sheet glass. 20,696. Aug. 3.

Complete Specifications Accepted.

11,518 (1920). Weijers. *See* I.

14,763 (1920). Rowart. Apparatus for drawing sheet glass. (167,347.) Aug. 17.

18,755 (1920). Kern. Manufacture of fire-proof heat and sound insulating material from clay or the like. (167,368.) Aug. 17.

20,612 (1920). Metcalfe. *See* I.

IX.—BUILDING MATERIALS.

Applications.

Bodman and Gettings. Manufacture of tar macadam. 20,471. July 30.

Harrison. 20,626. *See* VIII.

Kambach. Heat, cold, and water proof material. 20,944. Aug. 6. (Germany, 14.8.20.)

Priest. Vertical gas-fired kilns for burning limestone etc. 20,708. Aug. 3.

Schlösser. 20,979. *See* XIX.

Soc. de Recherches et de Perfectionnements Industriels. Impregnation of wood. 20,066. 20,198. July 26 and 27. (France, 20.8.20, 19.4.21.)

Complete Specifications Accepted.

14,294 (1920). Oliensis and Miller, jun. Fibred asphalt. (167,334.) Aug. 17.

14,351 (1920). Alexander (Blackstono International Corp.). Method of making bituminous paving. (167,341.) Aug. 17.

33,641 (1920). Stelzer. Method of preparing coloured dental cements. (166,854.) Aug. 4.

35,155 (1920). Graeffe and Haase. Method of preparing building material out of peat. (166,856.) Aug. 4.

X.—METALS; METALLURGY; INCLUDING ELECTRO-METALLURGY.

Applications.

Aitchison. Purification of ferro-alloys. 20,036. July 26.

Aitchison and Dyson. Purification of ores and residues containing oxides of chromium. 20,205. July 27.

Aitchison and Dyson. Purification of tungsten ores and residues containing oxides of tungsten 20,206. July 27.

Aitchison and Dyson. Purification of ores and residues containing metallic oxides. 20,207. July 27.

Ballantine and Wild. Process for production of low-carbon ferro-chrome. 20,914. Aug. 6.

Belais. Production of white gold. 20,873. Aug. 5. (U.S., Apr. 30.)

De Ros. Treating metallic sulphides. 20,706. Aug. 3.

Giboue. Means for utilising waste heat of smelting furnaces. 20,394. July 29.

Girouard and Jones. Reduction or preparation of ores. 20,080. July 26.

Gordon. 20,701. *See* XI.

Greiner. Processes for melting iron containing high percentage of silicon. 20,320. July 28.

Greiner. Process for manufacture of alloys of iron. 20,321. July 28.

Lenegre. Obtaining smelted metal from pulverised materials. 20,533. Aug. 2. (Spain, 3.8.20.)

Milliken. Alloys. 21,147. Aug. 9. (U.S., 18.8.20.)

Perkins, Picard, Sulman, and Taplin. Treatment of ores containing oxidised copper compounds. 20,938. Aug. 6.

Petherick and Taylor. Alloys for soldering. 20.290. July 28.

Reid. Reduction of ore and production of gas. 20.572. Aug. 2.

Rushen (A.-G. B. Felder-Clement). Aluminium-free metals. 21,568. Aug. 13.

Soc. Chim. des Usines du Rhône. Coating wires etc. 21,368. Aug. 11. (Germany, 4.9.20.)

Thorssell. Manufacture of iron sponge. 21,047. Aug. 8.

Vivian. Flotation processes. 20,857. Aug. 5.

Complete Specifications Accepted.

1152 and 21,745 (1920). Longbottom and Greenhalgh. Electric welding. (166,914.) Aug. 10.

5561 and 35,632 (1920). Collins. Separation and recovery or winning of metals. (166,929.) Aug. 10.

8967 (1920). Evans. Manufacture of tin plates. (166.935.) Aug. 10.

10,959 (1920). Collins. Purification of tin. (166,695.) Aug. 4.

11,106 (1920). Rustproofing Synd., Ltd., and Newman. Rust-proofing of ferrous metals. (166,711.) Aug. 4.

11,107 (1920). Rustproofing Synd., Ltd., and Newman. Coating of ferrous metals with a non-rusting alloy. (166.712). Aug. 4.

11,108 (1920). Rustproofing Synd., Ltd., and Newman. Process for the prevention of black oxide of iron on ferrous metal forgings and the like. (166,949.) Aug. 10.

12,214 (1920). Stalhane and Kring. Coating metal objects with a layer of another metal or an alloy and soldering. (167,262.) Aug. 17.

12,486 (1920). Walter. Alloys of silicon with metals of the iron and chromium groups. (142,847.) Aug. 17.

13,661 (1920). Harris. Galvanising-plant. (167,325.) Aug. 17.

13,958 (1920). Mining and Metallurgical Processes Proprietary, Ltd. Blast roasting operations and the like. (146,936.) Aug. 17.

17,901 (1920). Boorne. *See* XI.

21,079 (1920). Bansen, and Façoneisen-Walzwerk, L. Mannstaedt & Co. A.-G. Hearth smelting or annealing furnace. (152,319.) Aug. 4.

21,387 (1920). Kosugi. Alloys. (166,817.) Aug. 4.

I.—GENERAL; PLANT; MACHINERY.

Volatile solvents; Recovery of —— by the Bayer process. H. Carstens. Z. angew. Chem., 1921, 34, 389—392.

In the Bayer process of solvent recovery (G.P. 310,092; J., 1921, 204 A), the vapours are adsorbed by activated charcoal, from which they are then recovered by treatment with steam and condensation. The process is effective even with solvents of low boiling point, such as methyl chloride, and is the only one capable of effecting the complete extraction of benzene hydrocarbons from coal gas. The cost of working is low, and depreciation of plant is slight.—W. J. W.

Patents.

Gas purifiers and coolers. H. E. Theisen. E.P. 108,163, 20.7.17. Conv., 18.5.16.

In a wet gas cleaner, arranged somewhat like a disintegrator with alternate rings of fixed and moving blades which atomise the washing liquid, either the fixed or the rotary supporting ring for the blades is inclined to the shaft so as to make the area swept out by any one ring of blades approximately constant. The rotary ring is provided with a gutter at its periphery with several outlets directly opposite (radially) another gutter on the fixed disc or casing of the machine, in which washing liquid thrown off the blades may be collected and largely prevented from passing out with the current of gas.—B. M. V.

Drying, purification, and cooling of gases, vapours, and the like; Apparatus for the ——. H. E. Theisen. E.P. 108,319, 24.7.17. Conv., 28.2.16.

A heat exchanger and an atomiser or disintegrator are arranged for concentric rotation. The heat-exchanger comprises a cylindrical arrangement or a number of concentric cylindrical arrangements of longitudinal conduits jointed in series, and the atomiser comprises a cylindrical arrangement or a number of concentric cylindrical arrangements of longitudinal arms mounted on a common base, each atomiser arm working between two heat-exchanging cylinders. Heating or cooling fluid is circulated through the conduits, preferably in a direction opposed to the rotation.—H. H.

Gases or vapours and liquids; Device for bringing —— into intimate contact. T. Schmiedel. E.P. 149,647, 31.3.20.

ROLLER running at high speed dips slightly into liquid which is thereby sprayed, whilst at the ame time gas is drawn into the liquid in a finely-livided state by means of adhesion alone. The gas nay pass above (through the spray) and below he roller, or a baffle may be provided nearly ouching the roller to cause nearly all the gas to ass under the roller. The roller may have its urface roughened.—B. M. V.

ases; Separating suspended particles from ——. E. R. Wolcott. U.S.P. 1,383,586, 5.7.21. Appl., 27.8.17.

N electrical precipitator comprises a discharge ectrode and a series of superposed receiving ectrodes, with spaces between them, forming a onduit for the gas to be treated. A series of strong ectric field-zones is provided adjacent to the ceiving electrodes, alternating with a series of eak electrical field zones at the spaces between e receiving electrodes. An outlet for the precipi- ted material communicates with the spaces tween the receiving electrodes.—H. C. R.

Condensers and coolers. R. Rau. E.P. 144,739, 12.6.20. Conv., 12.6.19.

Fluid to be condensed traverses a coil rotating within a fixed casing through which cooling medium is circulated. The hollow rotary axle of the coil is divided into two compartments, of which the larger serves for supplying the fluid to the coil through one end of the axle, and the smaller for discharge of the condensed liquid from the coil through the other end. The condenser may be employed with a compressor and cooler for refrigeration.—H. H.

Bituminous lining for surfaces exposed to corrosive action. The Barber Asphalt Paving Co., Assees. of H. Wiederhold. E.P. 151,639, 27.9.20. Conv., 2.1.15.

A composition for lining tanks etc. is formed by melting together 30—45 pts. of coarse particles of igneous rock larger than 0·1 in., 25—50 pts. of non-carbonaceous mineral matter smaller than 0·1 in., and 15—35 pts. of asphaltum free from calcareous matter.—B. M. V.

Centrifugal drying machines. C. Lumpp. E.P. 159,839, 3.3.21. Conv., 3.3.20.

The wall of the basket is frusto-conical in shape, with the large end downwards, and the bottom of the basket can move vertically, being raised by centrifugal weights at high speeds to form a tight joint with the wall, thus permitting charging and drying to be effected. On lowering the speed the bottom falls, and the solid material is discharged into an appropriate compartment of the outer casing.—B. M. V.

Dryers; Plate —— for granular material. G. Hilgenberg, jun. G.P. 333,200, 18.5.13.

Stretched annular drying surfaces of porous material are attached, one above another, to the periphery of a drum revolving about a vertical axis. The drum is enclosed within a double-walled casing, and the heating gases circulate upwards through one part of the cylindrical chamber, then through the double-walled jacket, and finally pass downwards through the remaining part of the chamber. The device is compact and affords considerable drying space combined with small weight.

—J. S. G. T.

Drying or vaporising atomised liquids and effecting chemical reactions; Continuous process for ——. A. Welter. G.P. 336,612, 26.11.19.

The liquid or solution is atomised at the top of a tower and finely-divided solid material is injected into the resulting mist by means of pressure or suction air; or a counter-current of pressure or suction air is directed against the atomised solution in its course down the tower.—J. S. G. T.

Drying drum. E. Danneberg. G.P. 336,929, 19.10.18.

The drying machine consists of two or more rotating conical drums, with axes inclined to the common axis of rotation of the machine. The drums open at one end into a chamber for the supply of heating medium which flows in counter-current to the material to be dried in the drums effecting the preliminary drying, but in the same direction as the material in those drums in which the drying process is completed.—J. S. G. T.

Grinding or crushing of substances of various kinds; Process and device for ——. F. W. Hildesheim. E.P. 160,142, 12.3.21. Conv., 13.3.20.

One or more double-faced grinding discs are mounted to slide axially upon the driving shaft, and the enclosing casing which provides the other grinding surfaces is mounted to rotate upon another axis perpendicular or inclined to the axis of the discs. As the casing is rotated the opposite sides of the discs will alternately come into use. Dust may be removed by a draught through the trunnions of the casing if they are made hollow. —B. M. V.

Grinding and mixing and agitating machines. P. B. Jagger. E.P. 165,912, 5.3.20.

A machine, *e.g.* for mixing concrete, is formed of two or more rotating drums arranged in tandem with a slope towards the outlet end, each drum revolving in the opposite direction to its neighbour, and the passage of material from drum to drum and the final discharge being regulated by gates in fixed partitions. The gates may be provided with screens to retain grinding balls or pebbles if such are used.—B. M. V.

Evaporation of liquids; Method of and apparatus for ——. F. Merz. E.P. 166,004, 5.5.20.

A liquid is evaporated by contact with a gas, which is then brought in contact with another liquid which will absorb the vapour of the first liquid. Transfer of the latent heat back to the first liquid is effected by distributing the two liquids over opposite sides of tubes, plates, etc., the air or gas circulating through both compartments, but the liquids being kept apart. Three forms of suitable apparatus are described having fixed tubes, moving tubes, and plate surfaces respectively.—B. M. V.

Heat accumulators with two heat-accumulating substances of different boiling points. W. Schmidt. E.P. 166,039, 22.6.20.

A heat accumulator with two heat-accumulating substances of different boiling points (*e.g.*, water and oil or solid material) is charged by superheated steam, which is first led through the oil accumulator in a pipe coil and then into (not through) the water. The oil accumulator is then supercharged either by means of superheated steam or by gases of combustion. If superheated steam is used, it may, after passing through the oil and losing part of its superheat, be led to a place of consumption; or part only may be led to the place of consumption, the other part being returned to the same or another superheater, reheated, and used again. The oil may be in greater mass than the water and subdivided by baffles designed to prevent convection currents, charging and supercharging being effected by the hot gases (steam or combustion products) passing downwards through a pipe coil and discharging effected by steam (from the water accumulator) passing upwards through the same coil and thereby becoming superheated. The water accumulator, being used under high pressure, is best made cylindrical and may be placed within the oil accumulator. In order to bring up the steam pressure in the water accumulator just before and during discharging, oil may be drawn from about the middle of the oil accumulator, passed through a coil in the water accumulator, and returned to the bottom of the oil accumulator. Radiation losses may be minimised by enclosing the whole in a vacuum chamber provided with a false inner wall formed by spaced plates with asbestos or similar material between them. —B. M. V.

Subdivision and treatment of fluids for various purposes. E. L. Pease. E.P. 166,049, 14.4.19.

Apparatus for subdivision and mixing of streams of fluid, for example for mixing air and gas, or coal dust with air, or for heat exchange between fluids, comprises sets of flat plates arranged closely together so that one set makes contact in part with another set, and so shaped as to provide narrow spaces communicating with one another by one or more passages which are disposed transversely to the plates and are formed by juxtaposed edges of the plates.—H. H.

Copper catalysts. D. A. Legg and M. A. Adam. E.P. 166,249, 3.9.19.

Copper oxide which before fusion possesses slight activity becomes after fusion extremely active as a catalyst. Cupric oxide or a salt capable of producing cupric oxide on heating, is fused by heating to about 1100° C., cooled, and broken into lumps. The product is of the nature of a hard brick both as regards density and porosity, and acts as a dehydrogenating or oxidising catalyst. When tested on the dehydrogenation of secondary butyl alcohol it showed many times the efficiency of other catalysts.—F. M. R.

Filter. E. J. Sweetland, Assr. to United Filters Corp. U.S.P. 1,381,944, 21.6.21. Appl., 2.2.17.

A filter leaf is provided with a flattened tube extending downwards inside nearly to the bottom of the drainage area and projecting from the leaf at the top to form both an outlet and means of support. When the cake is discharged by reverse fluid pressure the cloth may be prevented from bulging by hollow shank rivets provided with both soft and metallic washers.—B. M. V.

Filter [; Sand ——]. C. A. Brown, Assr. to G. G. Earl and A. B. Wood. U.S.P. 1,383,384, 5.7.21. Appl., 25.8.16.

A sand filter, which operates downwards when filtering, is provided, for the purpose of reverse current washing, with conduits at the bottom, and with a wash trough above the sand for decanting dirty wash water. Between the wash trough and the normal level of the sand are a number of plates inclined alternately in opposite directions, thus forming passages alternately convergent and divergent. The passages that are divergent in the upward direction converge to narrow slits at the bottom, so that they will not pass much wash water but will serve to collect any sand that has been carried up through the convergent passages in the washing process.—B. M. V.

Centrifugal apparatus. C. P. Landreth. U.S.P. 1,383,313, 5.7.21. Appl., 24.6.20.

The material to be treated is fed to the space between two drums arranged concentrically about a horizontal shaft. The drums rotate in the same direction, but at different speeds, and are provided with a spiral blade fitted to one of them or with other means of pushing the material into the space between conical extensions of the drums, which converge towards the shaft. The pitch of the spiral increases in the direction of movement of the material.—B. M. V.

Superheated steam; Utilisation of —— for heating purposes. R. Kaesbohrer. G.P. 336,611, 28.10.10.

The steam is saturated by bringing it into contact with, or mixing it with a solution to be evaporated, *e.g.*, by atomising the solution, the latter being thereby concentrated. The operation is effected in a closed space without access of air or other gas, and is so regulated that the saturated steam produced has a sufficiently high pressure (temperature) for the purpose for which it is to be subsequently utilised. The mixed steam and solution are then separated and the steam utilised as desired. An increased efficiency of heat utilisation exceeding 13% is claimed.—J. S. G. T.

Gas mixtures; Continuous separating process for —— and apparatus therefor. W. Lachmann. E.P. 100,085, 10.2.16. Conv., 15.2.15.

See U.S.P. 1,363,659 of 1920; J., 1921, 471 A.

Gases and liquids; Process and apparatus for causing —— to react with one another. H. Frischer and M. Drees. E.P. 141,374, 9.4.20. Conv., 29.10.17.

See G.P. 323,474 of 1917; J., 1920, 774 a.

Lixiviation; Process and apparatus for continuous and systematic ——. Soc. Gén. d'Evaporation Proc. Prache et Bouillon (formerly Soc. Anon. d'Exploit. de Proc. Evaporatoires, Systeme Prache et Bouillon). E.P. 144,721, 11.6.20. Conv., 7.4.14.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Use of oil in cleaning ——. G. St. J. Perrott and S. P. Kinney. Chem. and Met. Eng., 1921, 25, 182—188.

The results of laboratory-scale experiments on the Trent process for cleaning coal suggest a new commercial application for low-grade coal or coal refuse. The process consists in agitating a mixture of pulverised coal (to pass 200-mesh), oil, and water. Granules composed of oil and coal substance, together with entrapped water, are formed and can be separated from the mineral matter of the coal which settles to the bottom. Any oil, provided that the viscosity is not too great, may be used, and certain commercial emulsions (*e.g.*, water-gas tar) have been successfully employed. The best conditions for a rapid separation are those in which a low surface tension exists between coal and oil, and a high surface tension between coal and water and between oil and water. The quantity of oil used is about 30% of the weight of coal, varying with the proportion of removable mineral matter in the coal, and it is best to use as small an amount of oil as possible, because better washing of the coal-oil "amalgam" is possible under these conditions. In a large number of laboratory separations by this process the recovery of combustible matter averaged more than 95%, and a considerable reduction in the sulphur content was effected when using anthracite coals. Separation of sulphur from bituminous coals was not satisfactory owing to the readiness with which pyrite was "wetted" and floated by the oil. The oil was almost entirely retained by the coal and may be regarded subsequently as fuel, or may be recovered partially by distillation. Water occluded in the "amalgam" varies in quantity according to the nature of the granules, and may be reduced to about 5% by passing the concentrate through a kneading machine.—C. A. K.

Coals; New method for determining the volatile matter yielded by —— up to various temperatures. W. A. Bone and L. Silver. Chem. Soc. Trans., 1921, **119**, 1145—1152.

The method consists essentially in carbonising a weighed quantity of dried finely divided coal at a definite temperature in a silica tube, heated in an electric resistance furnace, and provided with a delivery tube and a water seal for the exclusion of air during the operation. About 5 g. of coal is weighed into a smaller silica tube closed at one end, which is pushed, open end first, into the retort tube, and kept in position at the far end by means of a silica rod. The retort tube is inclined downwards so as to retain the coal in the smaller tube and prevent tarry matter draining back into it. According to the nature of the coal the heating may either be gradual or, as in most cases, may be applied from the commencement at the desired temperature (usually 900° C.). The time taken for the complete expulsion of volatile matter is usually about 40 min. The loss in weight in duplicate determinations shows close agreement, the values obtained being usually intermediate between those yielded by the "American" method (J., 1900, 174) and the "crucible" method, and of much greater precision owing to the temperature and rate of heating being under perfect control, and risk of oxidation being eliminated.—G. F. M.

Oxide of iron for gas purification; Conditions affecting the usefulness of ——. W. A. Dunkley. Univ. of Illinois Eng. Expt. Stat., Bull. 119, 21.2.21. Gas J., 1921, 150, 382—383, 436—439, 491—493.

Precipitated oxides, natural ores, and oxides obtained by the rusting of iron were examined with special reference to their activity and to their "primary capacity," *i.e.*, the ratio of the weight of hydrogen sulphide which a given weight of the material is capable of decomposing, without any revivification, to the weight theoretically equivalent to the same weight of ferric oxide. For the activity test 6 g. of the material, containing added sawdust if necessary, was moistened with 2 c.c. of water and submitted to the action of an excess of dry hydrogen sulphide for 1 min., and the weight of hydrogen sulphide decomposed per unit of ferric oxide present was noted. The primary capacities noted varied between 18·2% and 78·3%, and the activities between 8·3% and 58·6%. In studying the influence of various water contents of the oxides it was not found possible to prepare stable compounds having the exact compositions usually assigned to hydrated iron oxides (*cf.* Posnjak and Merwin, J., 1919, 412 a). When dried *in vacuo* over sulphuric acid different oxides retain different proportions of water and each has a particular water content corresponding to its maximum activity; the capacity, however, is little affected by water content. The water which affects the behaviour of oxides is probably adsorbed on the surface, and in general those oxides which retain the most water are the most active. Yellow oxides, which probably contain the monohydrate, are more active than red or reddish-brown oxides; they are more porous, of lower density, and retain more water. The more porous oxides retain their activity over a wider range of water content. The decrease in activity with a deficiency of water is ascribed to contraction of the surface, while an excess of water excludes hydrogen sulphide from the surface. Activity due to the presence of adsorbed water can, if lost by drying, be slowly restored by re-moistening, but the activity possessed by monohydrate due to combined water cannot be restored if lost by drying at a high temperature. When a hydrated or non-hydrated oxide is sulphided and revivified in the presence of sufficient water, it tends to return to the same physical state and water content as it possessed before sulphiding, but its activity and capacity are less, due to deposition of sulphur and the formation of sulphides which do not revivify. Oxides precipitated from solutions of ferric or ferrous sulphates by calcium carbonate, or oxides obtained by the hydrolysis and oxidation of dilute solutions of ferrous salts, or by the slow rusting of iron, are more active than oxides precipitated from concentrated solutions by ammonia, and more closely resemble the natural hydrated oxides. In the manufacture of oxides by rusting, soft iron borings or cast iron chips or turnings, free from steel, are spread upon wood shavings, sprinkled with water or a dilute salt solution, and well mixed; overheating should be avoided by frequent turning of the mass and oxidation assisted by prolonged exposure before use. In practice oxides with the highest activity are usually found to have a high capacity and to retain a higher activity after repeated sulphidings.—H. Hg.

Gas meters; Life of ——. Report of the Joint Committee of the Institution of Gas Engineers and the Society of British Gas Industries. Gas World, 1921, 75, 128—129.

The corrosion of meters is caused by hydrocyanic acid, ammonia, carbon bisulphide, oxygen, carbon dioxide, or sulphur dioxide in the presence of moisture. Blue water-gas should not be allowed to go forward until the sulphur dioxide has been removed by means of oxide of iron containing excess alkali, chalk placed on the first tier of the oxide purifiers, or an alkaline solution. Carburetted water-gas contains ammonia, derived from the nitrogenous compounds in the oil, which neutralises the sulphur dioxide when oil is used to the extent of 1½ to 2 galls. per 1000 cub. ft. Meters should not be located in cold places because of the influence of condensation upon corrosion. The water in wet meters should be periodically changed to remove dissolved salts. Ordinary tin-plate was corroded by water saturated with carbon dioxide or by a solution of the salts produced by the interaction of carbon bisulphide and ammonia. Plate coated with lead or with a zinc-tin alloy, or pure iron coated with a lead-tin alloy showed better results; aluminium was unaffected. When meters are sprayed for lubrication of the slide valves and for protection of the diaphragm and case, a heavy paraffin oil with a sp. gr. above 0·85 and which will not polymerise and leave a gummy residue, should be used.
—H. Hg.

Water in oils for transformers; Determination of ——. E. Rengade and J. Clostré. Comptes rend., 1921, 173, 311—313.

A current of perfectly dry air at the rate of 20 l. per hour is passed through 200 c.c. of the oil heated at 80° C. The issuing air is passed through a U-tube cooled in liquid air or solid carbon dioxide. The U-tube is changed each quarter of an hour and is weighed. The condensed liquid is examined for water by its freezing at 0° C., action on anhydrous copper sulphate or on lead potassium iodide, and for oil by its inability to freeze and its inflammability.—W. G.

Analysis of gases. Andoyer. *See* XXIII.

Patents.

Coal: Method of cleaning ——. W. E. Trent. E.P. 146,931, 15.4.20. Conv., 9.7.19.

The coal is crushed, mixed with water, and ground to an impalpable powder in a tube mill. The water and suspended powder are discharged on to a hydraulic classifier in which any particles not sufficiently reduced in size are removed and returned for further treatment. The coal is then separated from impurities by flotation and settling.—H. Hg.

Fuel. L. W. Bates. E.P. 165,418—23 and 165,425, 22.12.19. Conv., 5.8.19.

(a) A mobile fuel, heavier than water, may contain from 10% to 75% of particles of solid carbonaceous matter, *e.g.* coal or coke, added to a liquid hydrocarbon or fuel oil and stabilised, mostly as a coarse suspension, by the aid of a protective agent, *e.g.* a resinous or other soap or a lime rosin grease (*cf.* E.P. 165,424, *infra*). The mixture is produced without intensive grinding. Heat treatment is employed, and the solid material is ground so that approximately 85% of the particles will pass a 200-mesh screen. (b) The stability of the fuel may be promoted by the addition of a peptiser, *e.g.*, one or more of the middle fractions of coal tar distillation. The materials are subjected to heat treatment, preferably at 65°—95° C. (c) Two or more immiscible or only slightly miscible oils are blended, and finely divided carbonaceous solid matter is added, with the aid of heat. Agitation may also be employed. (d) The liquid carrier contains buoyant solid combustible particles of lower specific gravity than the liquid, or of lower apparent specific gravity, due to the solid matter containing occluded air. (e) A suspension of solid matter in a fuel oil in the form of a gel, produced by the addition of more protective agent than is required to ensure stability in liquid form. (f) The fuel may be obtained in the form of a mobile paste by raising the viscosity of the liquid carrier by the addition of a viscous substance, *e.g.* pitch. (g) The natural asphaltum or free carbon particles in the fuel oil may be stabilised by the addition of not more than 2% of lime resin soap.—A. G.

Grease [for the preparation of colloidal fuel]; Process for producing a ——. L. W. Bates. E.P. 165,424, 22.12.19. Conv., 5.8.19.

Slaked lime is mixed with a hydrocarbon oil, the mixture is agitated and heated, resin is added, and the product is saponified. A suitable oil has a flash point (open cup) of at least 120° C., and a viscosity of 20° Engler at 20° C. and 10° Engler at 30° C.
—A. G.

Peat as fuel; Utilisation of —— and apparatus therefor. R. Klasson and V. Kirpotschnikoff. E.P. 166,576, 19.10.18.

Peat is washed down from the moor to some low point by means of a water jet, and the mixture of peat and water is elevated to a drying field by means of a multi-stage turbine pump which also acts as a crushing and mixing machine. Each stage of the pump consists of an upwardly enlarged annular delivery portion and an upwardly contracted guide portion. The inlet to the lowest turbine wheel is enlarged and cutting edges are fixed immediately under it. A stirring wheel is fitted to the shaft extending below the pump. A centrifugal pump may be mounted in conjunction with, and above the turbine pump in order to avoid excessive crushing of the peat. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 1725 of 1875, 13.391 of 1910, and 12,101 of 1913; J., 1911, 1200.)—H. Hg.

Peat and the like; Process and apparatus for treating —— under pressure. H. Tzitschke. G.P. 335,759, 6.3.20.

During the heating of peat in an autoclave, the water which separates is continuously removed, and the pressure restored by further heating. The external heating of the autoclave may be supplemented by internal heating coils, and the water-outlet is provided with a sieve.—W. J. W.

Coke-ovens; Regenerative ——. C. Otto und Co., G.m.b.H. E.P. 147,740, 8.7.20. Conv., 31.3.17.

Under a sub-heated regenerative coke-oven, such as is described in E.P. 147,231 (J., 1921, 501 a), a separate chequerwork chamber is provided for preheating the gas supplied to each burner. The extent of the preheating depends upon the quality of the gas and is controlled by dampers in the waste heat flues leading from the gas and air chambers respectively.—H. Hg.

Coke-ovens and the like. American Coke and Chemical Co., Assees. of A. Roberts. E.P. 150,983, 24.1.20. Conv., 8.9.19.

Each heating wall of a coke-oven is formed of a series of passages connected together in pairs at their upper ends. Each passage is built up on the notched block principle described in E.P. 1570 of 1915 (J., 1916, 299; 1915, 482) so that it forms a meshwork of inter-connected passages. The whole of the air and half the gas to be burnt in each pair of passages are admitted to a number of burners at the base of one passage; the remaining gas is admitted within an enlarged combustion chamber at the top of the other passage, so as to maintain a more uniform temperature over the heating wall. Means are provided for periodically reversing the direction of flow of gas through the passages, the burners being duplicated for this purpose. The flow of gas between the two passages is regulated by means of dampers within the connecting flue. A pair of regenerators is built under the oven in connexion with each pair of heating passages. The gas is admitted to the lower burners from ducts built within the partition wall between two ovens, and is controlled from the top of the oven.—H. Hg.

[*Coke*] *oven-heating system.* E. Piron. U.S.P. 1,384,149, 12.7.21. Appl., 8.5.20.

Vertical combustion chambers having burners at their upper ends are placed between vertical air ducts adjacent to the side wall of a horizontal oven. There is a horizontal waste gas flue under the oven, communicating with the combustion chambers and with the alternate vertical ducts of a recuperator placed below it. The remaining ducts of the recuperator communicate with a horizontal air duct which is under the vertical air ducts and in communication therewith.—H. Hg.

Ammonia and gas; Manufacture of —— by distillation of fuel in vertical retorts of rectangular cross-section. L. J. Terneden and P. J. Kummel. E.P. 140,090, 9.3.20. Conv., 10.3.19.

Vertical flues are embedded and insulated in the walls between the narrow sides of adjacent rectangu-ar vertical gas retorts, and communicate with the etorts on either side through a series of openings. When no steam is to be admitted to the retort all he flues may be used for the rapid withdrawal of gas; alternate flues may be used for the admission f steam when desired.—H. Hg.

uel [*gas*]; *Manufacture, utilisation, and combustion of* ——. G. Helps. E.P. 166,212, 20.3.19.

as having a calorific value between 240 and 150 .Th.U. per cub. ft. is made by dilution of a richer as, or by complete gasification of solid fuel, or as escribed in E.P. 111,495 and 156,812 (J., 1918, 3 a; 1921, 139 a), and is burnt at low pressure in ose contact with the object to be heated.
—H. Hg.

as manufacture. G. Helps. E.P. 166,497, 30.3.18.

he steam required in a gas generator is produced admitting water to vertical tubes heated by the s being generated, and is then superheated. Air ay also be admitted at the open end of each be.—H. Hg.

Water-gas; Apparatus for the production of —— in gas-producing ovens and more especially in retorts. A.-G. für Gas-, Wasser- u Elektrizitäts-Anlagen. G.P. 337,464, 10.4.20.

A tubular steam boiler is built into the flue of the retort bed and the end projecting therefrom is provided with a pipe furnished with a throttle arrangement for drawing off steam and with a pipe for supplying water to the boiler. The pipe leading to the device for injecting steam into the retorts etc. branches off from the boiler at a point before that at which the throttle device is installed.
—J. S. G. T.

Fuels; Process and apparatus for gasification of bituminous ——. A.-G. für Brennstoffvergasung. G.P. 333,789, 27.10.18.

In a gas-making plant a portion of the residual coke is discharged into an adjoining producer chamber, and the gases evolved during its combustion are utilised for effecting the carbonisation of the raw fuel.—W. J. W.

Volatile hydrocarbons; Process of recovering —— from gases. Allgemeine Vergasungs-Ges.m.b.H. G.P. 337,054, 8.2.16.

For the continuous recovery of hydrocarbons from gases, *e.g.*, of gasoline from natural gas, the gases are cooled and passed through a " disintegrator " of which the interior surface may also be cooled.
—W. J. W.

Paraffin wax; Production of —— from high-boiling fractions of producer-gas and low-temperature tars. Allgem. Ges. für Chem. Ind. G.P. 337,512, 30.10.18. Addn. to 310,653 (J., 1920, 327 a).

After treatment of the tar fractions with liquid sulphur dioxide, as described in the original patent, liquid sulphur dioxide is caused to flow over the surface of the solid paraffin obtained, in order to free it from adherent oily particles, without resorting to filtration.—W. J. W.

Lubricating oils and process of making same. R. H. Brownlee. E.P. 141,753, 17.4.20. Conv., 13.5.18.

See U.S.P. 1,309,432 of 1919; J., 1919, 621 a. The catalyst used, *e.g.*, aluminium chloride, has the effect of accelerating the polymerisation of unsaturated hydrocarbons. The product is " reduced " *i.e.*, in volume, by distilling the lighter components.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Patents.

Destructive distillation of carbonaceous substances. E. R. Sutcliffe, and Pure Coal Briquettes, Ltd. E.P. 166,161, 20.4.17.

Two regenerators or blast stoves are built in conjunction with an internally heated vertical retort, and each stove is alternately heated by the combustion of gas within it and used for preheating the gas passed through the retort. The gas to be passed through the retort enters the stove through a nozzle so disposed that some of the gas leaving the retort is injected into the stove and a circulation of gas thereby maintained. On each side of the nozzle is a valve controlling communication between the stove and the retort or the waste outlet.—H. Hg.

Distilling and briquetting carbonaceous material; Apparatus for ——. W. P. Perry. E.P. 166,398, 8.5.20.

A mixture of powdered coal and peat is fed into trays on an endless belt within a closed retort. An endless band of weights above the trays so operates that a weight rests in each tray during its passage through the preliminary distillation zone, the tray being free of the weight during final carbonisation. The carbonised briquettes are discharged on to a transverse endless belt and the volatile distillates are separately withdrawn. The retort is internally heated by hot gas or by producer gas.—H. Hg.

Retort. S. Schieffelin, Assr. to H. L. Brown. U.S.P. 1,381,936, 21.6.21. Appl., 19.6.20.

A still is formed of a rotating spiral tube, one end of which scoops up solid material and the other end discharges it. Distillation products may be withdrawn from the tube at intermediate points by means of a tube arranged axially in the spiral. The pressure of the atmosphere in the heating chamber which surrounds the spiral is kept sufficiently high to prevent escape of vapours from the open ends of the spiral.—B. M. V.

Peat and the like; Process of dry distillation and coking of raw —— in dry pressure-vessels. Torfverwertungsges. Pohl u. von Dewitz. G.P. 337,097, 23.1.20.

The material is heated alternately under pressure and under vacuum by means of heating devices penetrating the mass, so that the temperature of any zone can be regulated independently of the temperature of any other zone. The gases and vapours evolved during the process may be withdrawn through hotter or colder zones as desired.
—J. S. G. T.

Rotating drum for the distillation of bituminous combustible material. G. Cantieny. G.P. 337,793, 5.10.20.

The drum is heated by a flame, and overheating in the immediate neighbourhood of the flame is prevented by surrounding this part of the drum by a jacket and filling the intervening space with a substance, such as sulphur, having a suitable boiling point.—J. S. G. T.

Activated carbonaceous substances; Method of producing ——, and the product. E. R. Sutcliffe. E.P. 166,202, 1.2.19.

Finely divided coal mixed with a proportion of the activated product from a previous operation is briquetted and coked, and the product is activated by the admission of steam at 1000° C. or by any other method used for the activation of charcoal.
—H. Hg.

Decolorising carbon; Process of producing ——. M. B. Punnett and R. A. Whitaker, Assrs. to Eastman Kodak Co. U.S.P. 1,383,755, 5.7.21. Appl., 12.5.19.

The uncarbonised material is mixed with a solution of a sulphate, dried, and charred while exposed to the air.—H. Hg.

Electric light carbons. Gebr. Siemens und Co. E.P. 134,225, 23.10.19. Conv., 5.8.16.

Negative carbon electrodes for projectors are graphitised at such a high temperature and to such a degree that their specific resistance is reduced to less than 10 ohms per m. of 1 sq. mm. cross-section.

Volatile products from distillation of wood; Process and apparatus for treating ——. E. Barbet et Fils et Cie. E.P. 120,560, 11.10.18. Conv., 11.10.17.

See U.S.P. 1,371,461 of 1921; J., 1921, 292 A.

Carbonising wood and other carbonaceous material; Process and apparatus for ——. J. F. Wells. U.S.P. 1,383,888, 5.7.21. Appl., 16.12.19.

See E.P. 149,773 of 1919; J., 1920, 685 A.

Decolorising carbons. E.P. 166,229. *See* XVII.

III.—TAR AND TAR PRODUCTS.

Sulphonations in the presence of iodine. V. Auger and M. Vary. Comptes rend., 1921, 173, 239—240.

Contrary to the results of Ray and Dey (J., 1921, 40 A), the authors find that the suphonation of benzoic acid, either with or without the presence of iodine, only yields 1% of *o*-sulphobenzoic acid. In the sulphonation of catechol in the presence of iodine, the sulphonic acid group enters position 3 and not position 4 as indicated by Ray and Dey (*loc. cit.*).—W. G.

Patents.

Tar; Process of producing purified oils from ——. G. Krickhuhn. G.P. 335,307, 6.5.19.

The oils distilled from tar are condensed and passed into one or more stills, heated by the waste gases from the tar still furnace, and connected with the tar still, by which means a continuous purification of the oils is secured.—W. J. W.

Lignites; Process for the separation of hydrocarbons suitable for conversion into products to be used as lubricating oils, from tars derived from ——. Badische Anilin- u. Soda-Fabrik. G.P. 301,252, 29.10.16.

The hydrocarbons in question are separated from paraffins contained in the tar, by distillation of the lignite tar under high vacuum until paraffins appear in the distillate.—J. S. G. T.

Tar lubricating oils; Process of purifying ——. Rütgerswerke A.-G., and H. Mallison. G.P. 337,091, 20.12.19.

The filtered oils are treated with superheated steam at a temperature below their boiling point, until their acridine-like odour is no longer perceptible.
—W. J. W.

Benzol and the like; Process for recovering —— from washing oils. Kohlendestillations-Apparatebau G.m.b.H. G.P. 333,056, 8.4.15.

In the recovery of benzol from washing oil, the vapours leaving the distillation column are caused to enter a dephlegmating column, where they meet a current of washing oil of lower temperature, whereby separation of any washing oil carried along by the vapour is effected.—W. J. W.

Reduction of nitro-compounds. D. A. Legg and M. A. Adam. E.P. 166,283, 24.12.19.

Nitro-compounds in the vapour state and a reducing agent, such as hydrogen or water-gas, are passed over heated fused copper oxide. Thus, a practically theoretical yield of aniline is obtained from nitrobenzene in this manner when an excess of hydrogen is used and the reaction temperature is 230° C. An alcohol which is capable of being dehydrogenated under the conditions of the reaction may be used in place of hydrogen; for example, a mixture of 3 pts. of secondary butyl alcohol and 1 pt. of nitrobenzene passed over the copper catalyst at 270° C., yields a mixture of aniline and methyl ethyl ketone. The catalyst (*cf.* E.P. 166,249, p. 614 A) does not readily become inactivated, and when after extended use it does become inactivated, its activity can be restored by superficial re-oxidation by heating in air at a high temperature.—F. M. R.

Paraffin wax from tars. G.P. 337,512. *See* IIA.

IV.—COLOURING MATTERS AND DYES.

Patents.

Sulphur-containing products and sulphur dyes therefrom; Manufacture of ——. L. Cassella und Co. E.P. 17,417, 22.7.14.

Aromatic substances containing nitrogen, sulphur, and chlorine are formed by the action of sulphur monochloride on the dry salts of aromatic amines in which one *o*-position to the amino-group is free, or on the free bases or their acyl derivatives, but in the latter cases the reaction is restrained by the addition of a diluent, such as benzene or naphtha, which takes no part in the reaction. The most favourable temperature of reaction is 20°—80° C., but if the reaction is slow the temperature may be raised slightly above 100° C. The products have the general constitution  $\mathrm{Aryl}\left\langle\begin{matrix}\mathrm{N}\\ \mathrm{S}\end{matrix}\right\rangle\mathrm{S.Cl}$, and chlorination also occurs at the *p*-position to the amino-group when that position is free or substituted by an atom or group which is easily replaced by chlorine. When treated with aromatic bases most of these products yield red, violet to blue basic dyes containing sulphur. With bases of the type of *p*-toluidine and *m*-xylidine, which contain an alkyl group in the *p*-position to the amino-group, the reaction with sulphur monochloride takes a somewhat different course and sulphide dyes are formed which dye cotton direct yellow to brown shades fast to chlorine. These products still contain an active chlorine atom and condense with aromatic bases to form yellow to orange sulphide dyes. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 24,938 of 1897; J., 1898, 916.)—F. M. R.

Vat dyestuffs; Manufacture of new substances containing sulphur and of —— *therefrom.* L. Cassella und Co. E.P. 18,292, 7.8.14.

The new substances obtained by the action of di-ulphur dichloride upon aromatic amino-compounds E.P. 17,417; *supra*), when treated with water, are ransformed into ring compounds of the general ormula  $\mathrm{Aryl}\left\langle\begin{matrix}\mathrm{N}\\ \mathrm{S}\end{matrix}\right\rangle\mathrm{S.OH}$ and hydrochloric acid s liberated. When these compounds are treated vith alkalis, preferably with addition of a suitable educing agent, such as sodium hydrosulphite, the ing is opened and compounds are formed which condense with monochloroacetic acid in alkaline solution to yield products which possess the properties of aromatic *o*-aminocarboxylic acids. These aminocarboxylic acids may be diazotised and the diazo-group replaced by cyanogen whereby nitriles are formed, which by treatment with alkalis, alkali sulphides, or acids, are saponified and transformed into new ring compounds. The latter substances, when warmed with dilute acids, evolve carbon dioxide and ammonia, yielding leuco-compounds, which by subsequent oxidation are converted into vat dyestuffs. These vat colours possess a great variety of shades, according to the aromatic amino-compound used, and are distinguished from the known thioindigo dyestuffs by the brilliancy of their shade, their greater affinity for the fibre, and by their increased fastness to washing, scouring, acid cross-dyeing, and bowking. Aniline yields a crimson vat colour, *o*-toluidine a pink, *o*- and *p*-anisidine orange to red, α- and β-naphthylamine brown, acetyl-*p*-phenylenediamine, *p*-phenylenediamine, and benzidine violet, blue, and grey to black colours.—F. M. R.

Vat dyestuffs; Manufacture of ——. F. W. Atack and J. Anderson. E.P. 166,297, 11.2.20.

β-Aminoanthraquinone and caustic potash are heated with a non-hydroxylic diluent or solvent such as aniline, naphthalene or other hydrocarbons at or near the boiling point. When aniline is used and the mixture is boiled under a reflux condenser, the product is impure anthraquinone-1.2.2′.1′-NN′-dihydroazine and dyes cotton green from a hydrosulphite vat, but when naphthalene is used, in presence of an oxidising agent, such as potassium nitrate, and the mixture is boiled under a reflux, pure anthraquinone-1.2.2′.1′-NN′-dihydroazine is obtained.—F. M. R.

Ortho-[hydr]oxy-azo dyestuffs; Manufacture of ——. Act.-Ges. für Anilin-Fabr. E.P. 145,053, 15.6.20. Conv., 18.1.18.

An o-hydroxy-diazo-arylsulphonic acid is coupled with 5.8-dichloro-1-hydroxynaphthalene. The products dye wool from an acid bath, and when after-chromed or dyed and chromed in a single bath, produce reddish-blue, blue, or black shades fast to light and milling.—F. M. R.

Ortho-[hydr]oxy-azo dyestuffs; Manufacture of ——. Act.-Ges. für Anilin-Fabr. E.P. 145,057, 15.6.20. Conv., 31.7.15.

An o-hydroxy-diazo- compound which is not sulphonated, such as diazotised 4-nitro-2-aminophenol, is coupled with 1-*o*-carboxybenzoylamino-7-naphthol. The products are intense dyestuffs, particularly adapted for dyeing wool in the presence of mordants in the same bath. They dye wool in the presence of chromium mordants dark greenish shades of excellent fastness to milling. 1-*o*-Carboxybenzoylamino-7-naphthol is formed when 7-hydroxynaphthylphthalimide, the condensation product of 1-amino-7-naphthol and phthalic anhydride, is treated with an alkali hydroxide.—F. M. R.

Azo dyes for wool; Manufacture of ——. Act.-Ges. für Anilin-Fabr. E.P. 166,033, 9.6.20.

A diazo-aryl-sulphonic or carboxylic acid, which may or may not contain a hydroxyl group, or a substitution derivative thereof, is coupled with 8-hydroxyquinoline or 8-hydroxyquinoline-5-sulphonic acid. The products dye wool in orange to bordeaux shades, and chromed wool in yellow to bordeaux shades.—F. M. R.

[Disazo pigment] dyestuff and process of making the same. A. J. Field. U.S.P. 1,383,710, 5.7.21. Appl., 27.9.17.

Tetrazotised tolidine is coupled with β-naphthol-6-sulphonic acid and β-naphthol-8-sulphonic acid.

The product, which is probably a mixture, is a pigment colour and forms a dyestuff when mixed with dextrin.—F. M. R.

Monoazo dyestuff. A. J. Field. U.S.P. 1,383,711, 5.7.21. Appl., 23.7.18.

Diazotised β-naphthylamine-1-sulphonic acid is coupled with H-acid in alkaline solution. The product dissolves in concentrated sulphuric acid with a deep violet-blue colour and dyes wool and silk bluish-red shades.—F. M. R.

Azo dyestuffs; Manufacture of —— from resin products. R. Arnot. G.P. 337,954, 21.4.16. Conv., 12.5.15.

Dyestuffs are produced by coupling diazotised amino, aminosulpho, or amino-hydroxy substitution derivatives of resins with suitable azo dyestuff components. The amino-resin obtained from resin by nitration and reduction can be diazotised and coupled with α-naphthol in alkaline solution to give a purple-red dyestuff.—A. J. H.

Sulphur-black; Method of preparing ——. Sulphur-black. A. C. Burrage, jun., and G. Meisel, Assrs. to Atlantic Dyestuff Co. U.S.P. (a) 1,383,071 and (b) 1,383,072, 28.6.21. Appl., 17.8. and 4.12.20.

(a) An aqueous suspension of the colouring matter is filtered, and the residual paste is converted into a moist powder by partial evaporation of the water therein. (b) Claim is made to Sulphur Black containing water and a solid soluble comminuted modifier, *e.g.*, a salt, distributed uniformly through the solid colour.—F. M. R.

Nitro-derivatives of β-azides of the anthraquinone series; Process for the production of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 337,734, 19.4.18.

When β-azides of the anthraquinone series are treated with concentrated nitric acid or mixed acid, the nitro-group enters the α-position adjacent to the β-azido-group without elimination of nitrogen. 1-Nitro-2-azidoanthraquinone crystallises from pyridine in faintly yellowish-green crystals, which acquire a faint orange-red colour by the action of air and light; m.p. 210° C. with decomp. An aqueous suspension heated with sodium sulphide is coloured first green and then violet, and on further heating 1.2-diaminoanthraquinone is formed with evolution of nitrogen. 1.5-Dinitro-2.6-diazidoanthraquinone crystallises from hot nitrobenzene in yellow needles, which melt at 200° C. and decompose suddenly at 202° C. It is reduced by sodium sulphide to 1.2.5.6-tetraminoanthraquinone, violet needles. These compounds are to be used for the production of dyes.—F. M. R.

Ortho-[hydr]oxy-disazo dyestuffs; Manufacture of ——. Act.-Ges. f. Anilin-Fabr. E.P. 145,056, 15.6.20. Conv., 28.7.15.

See G.P. 293,657 of 1915; J., 1916, 1150.

Azo dyestuffs; Manufacture of substantive ——. Farbw. vorm. Meister, Lucius und Brüning. E.P. 146,872, 5.7.20. Conv., 23.4.14.

See G.P. 290,398 of 1914; J., 1916, 531.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Fluorescence of cellulose and its derivatives. S. J. Lewis. J. Soc. Dyers and Col., 1921, 37, 201—204.

The method of observation adopted consists in focussing an ultra-violet spectrum on the specimen of paper or fabric placed in the position usually occupied by a photographic plate in a large quartz spectrograph. A fluorescent glow is emitted from the surface of the material and is photographed by means of a special camera of the ordinary type, the glass lens of which is inserted in the back of the camera of the spectrograph. The general fluorescent properties of cellulose and its derivatives have been established, and it is shown that specimens differ not only in their fluorescent power but also in their selective properties for light of various wavelengths. Materials regarded as the same by manufacturer and expert are by no means the same from the standpoint of their fluorescent properties. Two No 30 Whatman filter papers, for example, taken from different batches were widely different, but repeated experiments show that the same specimen gives approximately constant results from time to time. (*Cf.* J., 1918, 542a.).—F. M. R.

Lignin; Investigation of ——. K. H. A. Melander. Cellulosechem., 1921, 2, 69—73.

α-Lignin-S-acid, as obtained from sulphite-cellulose waste lyes (J., 1921, 465 a), forms compounds of widely-varying solubility in water with aromatic amines, such as o- and *p*-toluidine, phenylhydrazine, α- and β-naphthylamine, and quinoline. Analyses of the o-toluidine, aniline, and α-naphthylamine compounds show that there is one N atom for each atom of sulphur, the acidic nature of α-lignin-S-acid is wholly due to the S-grouping, and the formula for the corresponding sulphur-free α-lignin varies from $C_{28}H_{34}O_9$ to $C_{34}H_{44}O_{11}$. On treating a solution of α-lignin-S-acid with increasing quantities of concentrated hydrochloric acid, the quantity of lignin-S-acid precipitated increased rapidly at first, then more slowly, and finally diminished slightly. This behaviour indicates that α-lignin-S-acid is a single acid or a mixture of similar acids. When α-lignin-S-acid is heated with alkalis, acetic acid is liberated, so that the S-free α-lignin is probably a mixture of substances derived by splitting-off of one or more formyl and acetyl groups from a substance present in wood. —A. J. H.

Sulphurous acid. Froboese. *See* XXIII.

Patents.

Bast; Production of —— from fibrous plants. Nessel-Anbau Ges.m.b.H. G.P. 333,588, 10.9.18. Addn. to 331,896 (J., 1921, 343 a).

The plants may be treated with steam instead of water or aqueous solutions, and may be impregnated with substances to make them supple. —A. J. H.

Vegetable fibres; Method and means for disintegrating raw ——. G. Bonwitt and O. Goldschmidt. G.P. 337,640, 9.10.17.

Raw fibres are treated with oxidising agents (*e.g.*, perborates etc.), before or during treatment with boiling solutions containing soap, neutral or feebly alkaline substances, and preferably a colloidal substance.—A. J. H.

Fibrous substances; Process for treating ——. Anhydat-Leder-Werke A.-G. G.P. 337,841, 14.12.16. Addn. to 276,619 (J., 1914, 1006).

Paper fabrics are impregnated by the process described in the principal patent.—J. H. L.

Viscose silk; Manufacture of ——. E. Bronnert. E.P. 166,291, 5.2.20.

Viscose thread of about 6·2 deniers is obtained by feeding viscose to spinning nozzles having an aperture of 0·1 mm., in uniform and exactly measured quantities adjusted to the weight of the thread produced, which is wound-off at a rate of 45 m. per min. A suitable precipitating bath contains

40 kg. of sodium bisulphate, 60 kg. of water, and so much monohydrate sulphuric acid that the liquid contains 28 kg. of free sulphuric acid per 100 kg. Instead of sodium bisulphate, the bath may contain 50% of anhydrous sodium or magnesium sulphate or 20% of the former and 30% of the latter. Excellent results are obtained with viscose which has ripened for 90 hrs. at 18° C. —A. J. H.

Threads, ribbons, films and the like from viscose; Manufacture of ——. J. C. Hartogs. G.P. 337,642, 24.12.19.

Viscose threads are precipitated in the usual way, and an electric current is passed in a longitudinal direction through part or all of the threads by means of electrodes so disposed that the spinning nozzles are outside the current circuit. The threads thereby obtain a better appearance, a greater lustre, and a better "handle."—A. J. H.

Viscose; Process for recovering sulphur liberated in the coagulation and fixing of ——. H. Voss. G.P. 338,291, 22.11.19.

After coagulation of viscose by sulphite solutions, the subsequent fixing by means of acids or acid salts is carried out in closed vessels, whilst the bath is kept in motion, the evolved sulphur dioxide being conducted away and the precipitated sulphur separated from the fixing liquid. By this means the greater part of the sulphur may be recovered and a regenerated cellulose product almost free from sulphur may be obtained.—J. H. L.

Cellulose for artificial silk; Manufacture of ——. G. A. Krause. G.P. 337,725, 9.8.18.

The moist cellulose mass is atomised by means of jets, centrifugal devices or the like, and is then exposed to a current of warm air. The dried cellulose, with or without admixture of other fibres, may be used for spinning.—A. J. H.

Wool substitute; Process for manufacturing —— *from cellulose and similar solutions.* P. H. Minck, Assr. to The Chemical Foundation Inc. U.S.P. 1,383,742, 5.7.21. Appl., 16.5.19.

A wool substitute is produced by dissolving cellulose, squirting the cellulose solution through a spinning nozzle into a precipitating bath, and removing the chemicals from the formed thread by passing it through a "dripping bath" under a tension produced by the kinetic energy of the falling drops of liquid.—A. J. H.

Paper; [Resin] sizing of ——. K. Kieser. G.P. 337,656, 12.5.20.

Paper which has been sized with a resin soap made from partially or completely hydrogenated resin acids is not subject to after-yellowing. If partially hydrogenated acids are used the iodine value hould not be more than about one-third of the usual value for unsaturated resins.—A. J. H.

nvisible designs on banknotes, documents and the like; Production of ——. Veifa-Werke Verein. Elektrotech. Inst. Frankfurt-Aschaffenburg m.b.H., und A. Stirm. G.P. 337,818, 5.4.19.

ALTS of heavy metals or mixtures of such salts, which strongly absorb Röntgen rays, are printed n banknotes etc., so as to form a distinctive esign.—A. J. H.

attick effects on paper; Method for producing ——. Farbw. vorm. Meister, Lucius, und Brüning. G.P. 338,105, 2.9.19.

OLOURED paper is pressed against fabric (under he influence of heat if necessary) which has been moistened with water or other solvents, and the urface of which has been broken into cracks or is covered with a raised "veined" pattern. Battick effects are thereby produced on the paper without it becoming crinkled.—A. J. H.

Vegetable fibres; Process for the treatment of ——. C. Schwartz, Assr. to Gillet et Fils. U.S.P. 1,384,677, 12.7.21. Appl., 9.12.19.

See E.P. 136,569 of 1919; J., 1920, 654 A.

Cellulose ester compositions. British Cellulose and Chemical Manuf. Co., Ltd., Assees. of G. W. Miles. E.P. 146,212, 26.6.20. Conv., 30.6.19.

See U.S.P. 1,357,335 of 1920; J., 1921, 7 A.

Waste liquor from sulphite-cellulose factories; Process of treating ——. R. W. Strehlenert, Assr. to A. H. Kiaer & Co., Ltd. U.S.P. 1,384,219, 12.7.21. Appl., 7.2.18.

See G.P. 310,819 of 1918; J., 1919, 625 A.

Papermaking machinery. A. A. Richards. E.P. 166,716, 22.4.20.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Rapid Fast Red G L (Griesheim Elektron). F. M. Rowe and E. Levin. J. Soc. Dyers and Col., 1921, 37, 204—205.

Rapid Fast Red G L is a yellow-brown paste which, when printed on the fibre and steamed, produces a fast red azo-dye. It is a faintly alkaline aqueous paste of β-hydroxynaphthoic acid anilide (Naphthol AS) and the nitrosamine derived from diazotised *m*-nitro-*p*-toluidine. The nitrosamine is much more soluble than the corresponding compound derived from diazotised *p*-nitroaniline, and crystallises in colourless needles.—F. M. R.

Patents.

Discharge and resist effects on pile fabrics; Production of ——. O. Drey. E.P. 166,271, 4.10.19.

The fabric is passed with the pile surface uppermost over a perforated steam pipe, over a roller by which a dye solution is applied to the back of the foundation of the fabric, over a "doctor" to remove excess of dye solution, and then over a perforated steam pipe, the steam from which forces the dye through the foundation and into the pile of the fabric. After these or a succession of such operations, the fabric is treated to fix the dyestuff. Compressed air may be used instead of steam for forcing the dyestuff through the foundation. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 13,000 of 1890 and 5400 of 1893.)—A. J. H.

Printing of cotton fabrics. The Calico Printers' Assoc., Ltd., and W. Rouse. E.P. 166,337, 12.4.20.

If fabric which has been mordanted with aluminium, iron, tin, chromium, or other metallic oxides, is treated with tannic acid, its affinity for mordant dyestuffs is considerably modified. For example, a chrome-mordanted fabric containing 2·3% Cr_2O_3 (on weight of fibre) and capable of fixing 3·5% of alizarin, was able to fix only 1·3% or 0·610% of alizarin after treatment whereby it absorbed 1·8% or 4·8% of tannic acid, respectively. By the use of sufficient tannic acid, the dyeing of Chromazurin G on a chrome mordant can be completely inhibited. In the case of Modern Violet, a heavily tanned chrome mordant can fix slightly more of the dyestuff than the same mordant untanned, but if the mordant is only slightly tanned, the dyeing is partially inhibited. The shades obtained on tanned mordants are generally less bright but faster than those on the untanned mordant, but when dyeings of Modern Violet on chrome-mordanted fabric are treated with tannic acid, the shades obtained are bright and fast. In printing, varied effects are obtained by suitably tanning cotton fabric which has been mordanted with a metallic oxide (or by mordanting tanned fabric) and then dyeing it in one bath or in separate baths with various mordant dyestuffs selected from those which dye untanned metallic mordants but have little affinity for the tannate of the same mordant, those which dye the tanned metallic mordant but have little affinity for the untanned mordant, and those which dye both the metallic mordant and its tannate but not to the same extent or yield different shades.—A. J. H.

Patterns or ornamental effects upon fabrics; Production of ——. The Calico Printers' Assoc., Ltd., and W. Warr. E.P. 166,346, 13.4.20.

FABRIC which has been subjected, while in the moist state, to combined friction and pressure has an increased affinity for dyestuffs. Ornamental patterns are produced by passing the moist fabric between two friction rollers under pressure, one of which may be suitably engraved in relief or in intaglio, and then dyeing it, when the rubbed portions appear darker than the other parts of the fabric. The pattern produced may appear on one or both sides of the fabric according to the degree of pressure applied. Moist mercerised fabrics can be treated by this process provided that they have been washed and dried after mercerisation (compression of unwashed mercerised fabric decreases its affinity for dyestuffs), but the parts which have been subjected to friction lose some or all of their lustre. The warp threads may be subjected to friction before being woven into fabric.—A. J. H.

Coloured reserves under Aniline Black; Fixation of —— *by means of chromium salts.* C. Pilz. G.P. 337,888, 4.5.15.

THE reserves are printed with a paste containing only thickening, a dyestuff, and a resist such as sodium acetate or zinc oxide, and the correct quantity of a suitable chromium compound is added to the Aniline Black padding mixture. In this way very fast and large coloured patterns can be obtained. For multi-coloured effects, basic dyestuffs (*e.g.*, Rhodamine B) which are fixed with chrome-mordant dyestuffs or form lakes with chromium acetate, can be used. Conversion effects are produced by printing fabric with a reserve containing a reducing agent such as formaldehyde-sulphoxylate and a dyestuff, *e.g.*, the leuco compound of Gallocyanine DF, or Rhodamine B, which is not destroyed by reduction, and then printing a second reserve which contains besides sodium acetate, zinc oxide, etc., a dyestuff, *e.g.*, a chrome-mordant dyestuff, which is destroyed by the reducing action of the first reserve.—A. J. H.

Affinity of dyes for animal fibres; Process for reducing or destroying the ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 337,887, 30.10.15.

THE fibre is treated with aldehydes or their condensation products and with tin salts, with or without the addition of other salts The condensation products of formaldehyde and cresol, naphthalene, or benzidine disulphonic acids, or of acetaldehyde and resorcinol are used, and the treated fibre remains soft and resilient. Piece goods produced from treated and untreated wool and dyed, yield coloured or white effects on the dyed ground.

—F. M. R.

VII.—ACIDS ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Thiosulphate; New method for the determination of —— *in the presence of sulphite and tetrathionate.* A. Kurtenacker and A. Fritsch. Z. anorg. Chem., 1921, 117, 262—266.

THIOSULPHATE may be estimated in the presence of sulphite by the following method: The mixture is titrated with $N/10$ iodine solution whereby the sulphite is converted into sulphate and the thiosulphate to tetrathionate. The solution is then diluted to 200 c.c., treated with phenolphthalein and neutralised with 5% ammonia solution. The neutral solution is treated with about 7 c.c. of 10% potassium cyanide solution, and after 10—15 min. the following reaction will have completed itself: $3KCN+Na_2S_4O_6+H_2O=Na_2S_2O_3+K_2SO_4+KCNS+2HCN$. The solution is then acidified with 25—50 c.c. of sulphuric acid (1:3) and titrated with $N/10$—$N/20$ iodine solution until a permanent blue colour is obtained. From the two titration values the amount of sulphite and thiosulphate may be calculated. The method gives trustworthy results if the conditions mentioned are strictly maintained.—J. F. S.

Potash; Quantitative determination of —— *by the spectrum.* D. P. Rogers. Chem. and Met. Eng., 1921, 25, 161.

TEN g. of flue dust or other material containing water-soluble potash is boiled with 30 c.c. of water for ½ hr., and the filtered solution evaporated to 10 c.c. Material containing insoluble potash is sintered with 0·5 g. of ammonium chloride and 5 g. of calcium carbonate as in the Lawrence Smith method and the filtered aqueous extract of the mass evaporated to 10 c.c. A loop of platinum wire is dipped in the solution and then held in the Bunsen flame. The duration of the potassium flame observed through blue glass against a white background in a dark room is noted in seconds; the test is repeated twenty times and the mean value is compared with the values obtained from similar standard solutions containing 5, 7·5, 10, 12·5, and 15% of potash.—A. R. P.

Calcium phosphate; Reaction of —— *with sodium carbonate and bicarbonate.* J. Pinnow. Z. Elektrochem., 1921, 27, 309—319.

THE reaction between calcium phosphate and sodium carbonate or sodium bicarbonate at 100° C. in the presence of a sufficient excess of base proceeds up to the formation of normal sodium phosphate when carbon dioxide is removed by passing a brisk stream of steam through the mixture. A quaternary phosphate appears in the solid phase under these conditions. It is impossible to separate phosphoric acid from calcium by boiling with saturated sodium carbonate solution. (*Cf.* J.C.S., Sept.)—J. F. S.

Catalytic power of electrosols of platinum; Variations produced by stabilisers in the ——. A. de G. Rocasolano. Comptes rend., 1921, 173, 234—236. (*Cf.* J., 1920, 543 A.)

THE presence of any one of the stabilisers examined (sodium lysalbinate and protalbinate, gum arabic, and gelatin) caused a diminution in the catalytic power of electrosols of platinum, in the decomposition of hydrogen peroxide, the diminution increasing with the amount of stabiliser added. With sodium protalbinate as stabiliser, as the amount added was increased a point was reached at which the catalytic power again increased, but this was really a secondary effect due to the strongly alkaline reaction of this stabiliser.—W. G.

Palladium; Sorption of hydrogen by amorphous ——. J. B. Firth. Chem. Soc. Trans., 1921, **119**, 1120—1126.

The sorptive capacity of palladium black varies according to the method of preparation, the most active sample being that obtained by the reduction of palladous chloride with a weak solution of sodium formate. The difference is due to the varying proportions of amorphous and crystalline palladium in the samples. The sorptive capacity at low temperatures depends on the temperature at which sorption begins, being greater when hydrogen is admitted to the palladium initially at 100° C., than when the metal is cooled to the required temperature in a vacuum before admission of the hydrogen. In the first case the crystalline palladium takes up an appreciable amount of hydrogen prior to being cooled, this hydrogen being retained; in the second case the amount of hydrogen sorbed by the crystalline variety is small below 20° C. On comparing the results of the two series of experiments it was observed that the volumes sorbed increase continuously in the first series from 100° to −190° C., the rate of increase being greater below 20° C., and a maximum sorption of 1132 vols. being attained at −190° C., whilst in the second series the volumes diminish slightly from 100° to 20° C., and then increase to −190° C., at which point 1044 vols. was sorbed. When palladium black is heated the proportion of the crystalline variety increases.

—G. F. M.

Sulphurous acid. Froboese. *See* XXIII.

Patents.

Nitric acid; Process of concentrating ——. H. Frischer. G.P. (a) 307,613, 13.1.18, (b) 303,271, 20.5.17.

(a) A mixture of nitric acid and a dehydrating agent is introduced as a continuous stream into a heated vessel, the outlet being at such a height that the acid mixture becomes denitrated during its passage through the vessel. (b) Sulphuric acid (82—86%) is used as dehydrating agent in the concentration of nitric acid. After distilling off concentrated nitric acid, dilute nitric acid may be distilled off from the residue, leaving sulphuric acid of the original concentration for use again in the process.—W. J. W.

Ammonia oxidation; Process of ——. A. R. Frank and N. Caro. G.P. (a) 303,824, 4.12.14, (b) 304,269, 8.12.14.

(a) In an ammonia oxidation process, the contact agent forms a resistance in an electric circuit and is thereby heated uniformly. (b) The contact agent may suitably consist of metallic gauze.—W. J. W.

Hydrocyanic acid; Process for the production of ——. C. Beindl. E.P. 10,321, 15.7.15. Conv., 17.7.14.

Gaseous or volatile carbon compounds are combined with gaseous or volatile nitrogen compounds, using a catalyst in the form of a mixture of a metal which may be nickel, cobalt, copper, chromium, magnesium, manganese, or titanium) with its nitride, and with or without its oxide. To produce the catalyst the metal may be superficially oxidised by heating in air or oxygen, followed by a partial conversion into nitride by subjection to the reaction gases at a temperature not exceeding 700° C.—H. H.

Cyanogen compounds; Manufacture of ——. H. Mehner. E.P. 142,122, 21.4.20. Conv., 9.10.14.

Alkali metal vapour produced by interaction of molten cast iron and soda, and carrying in suspension about 20% of its weight of pulverised soda, is introduced into a reaction chamber containing glowing coke. A current of producer gas containing 60% N_2 and 30% CO is also led into the reaction chamber in the proportion of about 150 pts. for each 100 pts. of vaporised alkali metal and 20 pts. of soda. A reaction takes place setting free a quantity of heat which allows the soda to form sodium cyanide.—H. R. D.

Formate of ammonium; Production of —— *from barium cyanide.* Norsk Hydro-Elektrisk Kvaelstofaktieselskab. E.P. 143,850, 18.5.20. Conv., 26.5.19.

Barium cyanide is decomposed by reaction with carbonic acid under pressure in an autoclave. The barium is precipitated as carbonate, and the formic acid produced is obtained in solution as ammonium formate.—H. R. D.

Chromic oxide and sodium sulphide; Process for the manufacture of —— *from sodium chromate.* C. J. Head. E.P. 166,289, 15.1.20.

A mixture of sodium chromate, sulphur, and carbon in the proportions corresponding to the equation,

$$2Na_2CrO_4+2S+5C=Cr_2O_3+2Na_2S+5CO,$$

is heated in a closed chamber to dull redness until the reaction is completed, and the residue is treated with water. The insoluble chromic oxide is separated, washed, dried, and calcined, and the solution of sodium sulphide is evaporated.—H. H.

Potassium salts; Recovery of —— *from waste products in the cane sugar and rum distilling industry.* M. Bird. E.P. 166,657, 13.4.20.

The waste liquor previously neutralised with lime is poured into metal pots and evaporated by the aid of hot chimney gases, until complete incineration of the mass takes place. Potassium salts are recovered by leaching, a solution composed mainly of potassium sulphate and potassium chloride being obtained. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 2524 of 1876.)

—H. R. D.

Phosphorus oxychloride; Process of making ——. T. L. Bartleson, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,381,783, 14.6.21. Appl., 21.10.20.

Phosgene is allowed to act upon molten metaphosphoric acid.—J. H. L.

Ammonia-soda process. J. H. McMahon, Assr. to The Mathieson Alkali Works, Inc. U.S.P. 1,384,141, 12.7.21. Appl., 18.8.20.

Water-gas is separated into hydrogen and carbon monoxide. The hydrogen is used for the production of synthetic ammonia, which is absorbed in a solution of common salt, whilst the carbon monoxide is burned to dioxide, and the resulting gas used in carbonating towers.—H. R. D.

Nitrous oxide; Method of stabilising ——. H. Bart. G.P. 337,795, 21.12.17.

Gaseous or liquid nitrous oxide, in presence of water or carbon dioxide, or both, may be stored in metal vessels without risk of explosion.—W. J. W.

Sodium bisulphate; Apparatus for manufacture of ——. V. Zieren. G.P. 337,844, 17.8.19.

For the manufacture of sodium bisulphate, for example, by decomposition of sodium nitrate or sodium chloride with sulphuric acid, cast-iron pans are employed, which are divided into compartments by means of baffle plates suspended from the walls. The pans are heated in a furnace, and the melted material is drawn off from the last compartment; the acid fumes are conducted to a condensing apparatus.—W. J. W.

Hydrofluoric acid; Recovery of fluorine as ——. E. C. R. Marks. From Catlin Shale Products Co. E.P. 166,228, 18.6.19.

SEE U.S.P. 1,293,703 of 1919; J., 1919, 322A.

Perborates; Process for the manufacture of —— by electrolysis. H. G. C. Fairweather. From Frederiksstad Elektrokemiske Fabrikes A./S. E.P. 166,396, 7.5.20.

SEE U.S.P. 1,375,596 of 1921; J., 1921, 432 A.

Sodium pyrophosphate; Manufacture of acid ——. A. Kelly. U.S.P. 1,383,990, 5.7.21. Appl., 22.1.21.

SEE E.P. 161,273 of 1920; J., 1921, 389 A.

Nitrogen and hydrogen mixtures or nitrogen; Process for generating from air and hydrogen either ——. L. Casale. U.S.P. 1,384,428, 12.7.21. Appl., 7.7.20.

SEE E.P. 148,885 of 1920; J., 1921, 584 A.

Sulphur dioxide and cement. G.P. 310,070. *See* IX.

Silicic acid. G.P. 337,796. *See* XX.

VIII.—GLASS; CERAMICS.

Refractories; Jointing materials for ——. L. Bradshaw and W. Emery. Report of Refractory Materials Research Committee to the Inst. of Gas Eng. Gas J., 1921, 155, 157—159.

FINELY-GROUND fireclay and silica brick were mixed together in varying proportions, made into cones, and the refractoriness determined in an electrically-heated furnace. The addition of a small amount of fireclay to silica brick produced a greater effect than a corresponding amount of silica brick added to fireclay brick. The eutectic mixture softened at cone 19—20 and had the composition 15·01% Al_2O_3, 80·3% SiO_2, corresponding to $Al_2O_3,9SiO_2$. For pure kaolin and silica mixtures Seger obtained an eutectic of composition $Al_2O_3,17SiO_2$. Determinations of the refractoriness under load gave similar results, but the differences between the softening temperatures with and without load were less for silicious mixtures than for mixtures rich in fireclay. With coarser-grained materials the effect of mixing fireclay and silica brick upon the softening points was less marked, but probably these would be further reduced in actual use owing to the gradual disintegration of the silica grains. Suitably graded raw fireclay and grog were mixed and the wet mixtures spread between a pair of fireclay bricks keyed together. After drying and firing to cone 8, cracks developed which were invariably across the joints. The contraction, crushing strength, and slag penetration of briquettes were determined. The contraction, the mechanical strength, and the resistance to slag penetration of the clay increased with the fineness of grinding. The addition of grog reduced the contraction but allowed a greater slag penetration. Fine clay with coarse grog had a much greater contraction and crushing strength and suffered less slag penetration in the mass than a mixture of coarse clay with fine grog. The mixtures composed of mixed grades of clay and grog gave the best results. The addition of sand instead of grog rendered the mixture friable.—H. S. H.

Refractory materials; Influence of oxidising and reducing atmospheres on ——. L. Bradshaw and W. Emery. Report of Refractory Materials Research Committee to Inst. of Gas Eng. Gas J., 1921, 155, 159—160.

PYROMETRIC cones were heated electrically in a tube furnace and exposed to a current of coal gas. The cones remained erect at temperatures far above their normal softening points. On examination they were found to consist merely of a hollow shell with a quantity of slag discharged at the base, or of a semi-vitrified mass covered with an infusible skin. The outer shell was extremely refractory, and this appeared to be due to the formation of a thin film of hard carbon in intimate contact with the surface of the cone by the decomposition of methane. Methane decomposed slowly between 800° and 1000° C. and more rapidly above 1000° C. when in contact with hot surfaces; a firm refractory shell could be produced with certainty down to about 950° C. The softening points of the cones corresponding to lower temperatures were raised slightly above the normal, and the residues were impregnated with carbon. The surface deposition of hard carbon was also observed with a fireclay brick, but the temperature of the furnace was not sufficiently high to reduce the clay material to a mobile slag. Fireclay mixed with a little ferruginous marl, by which the softening point was lowered, behaved similarly to cones, the slag bursting through the coating of carbon.—H. S. H.

PATENTS.

Abrasive and refractory material [and an iron alloy]; Manufacture of ——. E. Assié. E.P. 141,351, 6.4.20. Conv., 9.8.17.

BAUXITE, carbon, and chromium oxide are melted together in such proportions that all the oxides other than alumina and a portion of the chromium oxide which remains in the melted mixture as a cement are reduced by the carbon. The melted mixture comprises an iron alloy, which is subsequently separated, and a slag which, when suitably treated and cooled, constitutes an abrasive and refractory product.—H. S. H.

Silicon carbide and method of making same. H. E. Schabacker, Assr. to The Exolon Co. U.S.P. 1,381,316, 14.6.21. Appl., 25.5.20.

A STEP in the process of making a silicon carbide consists in combining sand and pitch coke.
—H. S. H.

Dental cements; Manufacture of ——. S. Schiff. E.P. 145,052, 15.6.20. Conv., 5.5.17.

IN the manufacture of dental cements of the kind in which phosphoric acid or an acid phosphate is used, colloidal silicic acid is added in the form of a hydrogel, acetogel, or alcogel.—H. S. H.

Dental cements; Preparation of ——. M. Andresen. G.P. 337,856, 1.3.14. Addn. to 336,473.

ALUMINIUM silicophosphates of the type xR_2O,Al_2O, $(ySiO_2,zP_2O_5)$, where R is sodium or potassium, $x=0{\cdot}25—0{\cdot}75$, $y=1—3$, and $z/x=1—3$, are mixed with solutions of phosphorous acid or its acid salts, or mixtures of both, or with mixtures of these solutions with other suitable materials, to form a plastic mass, which eventually hardens. An example is given of the preparation of a cement from a potassium aluminium silicophosphate of the composition, $0{\cdot}37K_2O,Al_2O_3,2SiO_2,0{\cdot}71P_2O_5$, and acid aluminium phosphite. The cements are stable towards weak organic acids, and give a material of good transparency.—G. F. M.

Brick-kilns. W. Jones. E.P. 165,673, 12.7.20.

ORDINARY separate round brick kilns are connected by flues so that the waste heat remaining in one kiln, after burning, is conveyed into another kiln for the preliminary heating of the " green " bricks. (Reference is directed, in pursuance of Sect. 7, Subsect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 24,247 of 1901 and 16,258 of 1896; J., 1902, 1396.)—H. S. H.

Tunnel furnaces, kilns, ovens, and the like. H. Francart. E.P. (A) 166,198, and (B) 166,199, 19.12.18.

(A) The tunnel, or any desired section of it, is divided longitudinally by cross-partitions into spaces which intercommunicate in such a way as to cause a helical circulation of the gaseous medium through the tunnel. The tunnel is also divided by transverse vertical partitions, each containing an opening just large enough to allow the passage of the truck carrying the goods. The longitudinal walls have inclined flues communicating with the top of one space and the bottom of an adjacent space. (B) The high-temperature zone of the tunnel is surrounded by a second tunnel, and gases which have previously served for cooling the heated goods circulate in the space between the two tunnels, and then pass to the preheating zone, the flow of the gas being regulated by dampers. Heat-insulating material, *e.g.*, sand, may be delivered on to the top of the inner tunnel, thus increasing the thickness of its roof and diminishing the loss of heat.
—H. S. H.

Tunnel kiln. Tunnel kiln with sectional combustion chambers. P. d'H. Dressler, Assr. to American Dressler Tunnel Kilns, Inc. U.S.P. (A) 1,384,434, and (B) 1,384,435, 12.7.21. Appl., 22.1.19, 27.3.20.

(A) In a tunnel kiln of the Dressler type, gas burners extend into the combustion chambers, through the sides of the latter, so as to project a supply of gas in a horizontal direction through the combustion chambers. Valves are provided to regulate the supply of gas to the burners. (B) A kiln chamber having an elongated hot zone is connected with a series of combustion chambers arranged end to end along the hot zone. The combustion chambers have air and gas inlets at one end and an outlet for products of combustion at the other, the distance between the inlet and outlet of each chamber being several times the maximum transverse dimension of the chamber.—A. B. S.

Stoneware; Continuous chamber kiln, or group of kilns worked like a ring kiln, for burning ——. F. K. Meiser. G.P. 337,384, 12.8.20.

A continuous chamber kiln, or group of kilns arranged to work continuously, with chambers which can be cut out of the circuit, and with connecting flues which may be heated or fitted with chequerwork. On shutting off a chamber, the air passes through a highly heated connecting flue, and can then raise the succeeding chamber rapidly to the sintering temperature required for salt-glazing.
—A. B. S.

Casts; Production of —— from ferrous sulphide. H. Renck. E.P. 166,425, 29.5.20.

The original from which the cast is to be made is first coated with oil, soap, or the like. Ferrous sulphide is heated to its melting point, then cooled to 80°—70° C. and the cast taken.—H. S. H.

Crucible and method of manufacture. W. A. Darrah. U.S.P. 1,381,171, 14.6.21. Appl., 3.1.18.

A process of making crucibles consists in mixing both finely ground and coarsely ground inert refractory material with a colloidal binder, adding fluid until the mixture is liquid, pouring into a porous mould capable of absorbing the fluid, and, after removing the mould, baking the product.
—H. S. H.

Meerschaum; Preparation of artificial ——. P. Deussing. G.P. 334,749, 8.6.20.

An intimate mixture is made of very finely ground Halle earth and Meissner clay, or the latter alone, with elutriated chalk or quartz flour. All gritty constituents are removed by grinding in presence of water, the mixture worked up into a viscous slip, and cast in plaster moulds. After removal from the moulds the ware is baked in a kiln.
—H. S. H.

Magnesite stone; Preparation of synthetic ——. L. Altmann. G.P. 335,349, 17.5.19.

The material is prepared from burnt dolomite from which the lime has been removed by means of magnesium chloride liquor. A dolomite with good sintering power is employed as raw material, and thus the sintering ingredients in their natural state of combination are utilised as binder.—H. S. H.

Soluble constituents of mixtures [clay]; Process for separating the ——. H. Fleissner. G.P. 336,610, 13.6.19. Conv., 21.11. and 15.12.18.

To remove any desired constituents from a mixture, the latter is treated with the requisite solvent and then dried, by which means the constituent accumulates on the outside of the mixture and can be separated, the process being then repeated. Between the respective dryings, the mixture may be moistened, which causes the soluble constituent to permeate the mixture again and assists removal of the last traces. The process is especially applicable to the removal of iron from clay by means of hydrochloric acid.—W. J. W.

IX.—BUILDING MATERIALS.

Patents.

Wood; Process of treating ——. Soc. La Transformation des Bois. E.P. 111,842, 9.11.17. Conv., 4.12.16.

Potassium carbonate is added to a bath of tarry and like material and Sucher's pectic liquor (E.P. 15,713 of 1910; J., 1911, 364) in order to avoid separation of the pectic liquor in the impregnating bath. The wood is immersed in the bath for 3 to 7 hrs., the temperature being maintained at 80°—120° C. according to the nature and degree of dryness of the wood. A suitable bath is made from pine pitch (100—900 pts.); bitumens, heavy tars, heavy coal-oils, raw resins, creosotes, phenol, dephenolated oils, Bordeaux turpentine, and the like (100—900 pts.); potassium carbonate (20 pts.); sodium carbonate (5 pts.); Sucher's pectic liquor or fixing agent (5 pts.).—H. S. H.

Wood; Process for the manufacture of non-explosive preparations, more especially adapted for use in preserving ——. W. Lichty. E.P. 147,608, 8.7.20. Conv., 7.2.14.

A non-explosive preparation for preserving wood is obtained by mixing the metal salts of the mono-, di-, and poly-nitro compounds of phenol and its homologues with metal salts of sulphonic acids of aromatic hydrocarbons or their substitution products.—H. S. H.

Thermally insulating bodies; Process for manufacturing —— from peat. Ges. für Torf-Isolation. G. Huhn. E.P. 148,190, 9.7.20. Conv., 31.8.15.

Peat and fusible binding materials (*e.g.*, pitch, tar, rosin, etc.) are mixed together in a cold state and subjected to pressure and heat, applied simultaneously. The pressure (3—20 atm.) is gradually increased as the temperature is raised.—H. S. H.

Heat-insulating materials. F. J. Phillips. E.P. 166,327, 9.4.20.

An alkali silicate or hydrated silicate and a fibrous or granular material (*e.g.*, cork dust, sawdust, asbestos, etc.) are mixed in a rotary cylinder mixing machine, and the mixture is extruded direct from the cylinder through a die or nozzle by the pressure of the steam inside the cylinder. The material may be ejected through a flexible pipe and nozzle and applied directly to large surfaces such as tanks, floors, walls, etc.—H. S. H.

Stone; Production of artificial coloured ——. A. J. Sanders. E.P. 166,307, 12.3.20.

Freshly formed artificial stone made from Portland cement mortar or asbestos cement mortar is coloured by applying in succession two or more coloured or colour-producing metallic salts (*e.g.*, a concentrated solution of lead acetate and a concentrated solution of sodium chromate in caustic soda or concentrated solutions of potassium ferrocyanide and copper chloride), and allowing them to react with one another and with the soluble component of the stone so as to form an insoluble precipitate within the pores of the stone. A permanent coloured surface capable of taking a high polish is thus obtained.—H. S. H.

Peat; Method of preparing building material of —— R. Graeffe and O. Haase. E.P. 166,856, 14.12.20.

Peat is boiled with water and with 4 pts. of coal tar pitch, which has previously been heated to about 200° C., to every 10 pts. of dry peat, until the peat is macerated and the pitch incorporated. A clay mash, with or without the addition of kieselguhr, may be added during the boiling. The boiled mass may then be pressed in perforated forms, or it may be dried, re-moistened, and then pressed while heated at 100° C. Alternatively, the peat may be mixed directly with pitch heated to about 100° C. and the mixture boiled in water, or the peat-pitch mixture may be dried and roasted at a temperature of at least 150° C., with exclusion of air, until carbonised, and then compressed in heated forms to the desired shape, or the roasting and pressing may be effected simultaneously.—A. B. S.

Concrete or the like; Process of treating ——. R. G. Osborne. U.S.P. 1,383,749, 5.7.21. Appl., 26.12.19.

Concrete is rendered impervious to fluids, by heating it at a temperature sufficient to drive off part of its water of combination and then filling the voids with a fluid-proofing material.— A. J. H.

Cement; Manufacture of sulphur dioxide and ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 310,070, 11.11.17.

Calcium sulphate is heated with mixtures of silica, alumina, and ferric oxide, in which the proportion of ferric oxide exceeds that of the alumina, until fusion takes place. The ferric oxide serves as a flux and appreciably lowers the fusion point.—W. J. W.

Cement; Burning —— *in a divided rotary kiln.* H. Kuhl. G.P. 337,312, 27.5.19.

A rotary kiln is divided into sections, the sintering zone rotating more slowly than the other parts of the kiln. The upper part of the kiln, which preheats the cement-mix, rotates rapidly, so that the mix is lifted to the shoulder of the kiln and then falls freely into the next section, whilst the part of the kiln below the sintering zone rotates at the normal speed. By this means the mix, as long as it can usefully absorb heat, is brought into intimate contact with the hot gases, but the sintering material—which cannot absorb much heat—is prevented from "hanging" in the kiln. The arrangement specified enables a much shorter kiln to produce the same output as a larger one of the customary pattern, as the waste gases are used to better effect in preheating the contents.—A. B. S.

[Cement] kilns. J. Nelson. E.P. 166,834, 6.9.20. See U.S.P. 1,366,586 of 1921; J., 1921, 180 A.

Concrete mixers. Ransome Concrete Machinery Co., Inc., Assees. of A. W. Ransome. E.P 105,235, 26.3.17. Conv., 2.3.16.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron ores; Electric reduction of ——. H. A. de Fries. Chem. and Met. Eng., 1921, 25, 193—194.

A comparison of the costs of producing pig iron in electric shaft and pit furnaces shows that the running costs of the two types are approximately the same, the cost per ton of pig-iron from a 3000 kv.-a. shaft furnace being given as $32·42. The capital cost of the shaft furnace plant is $150,000, whereas a pit furnace plant of similar capacity would cost only $50,000. The chief advantage of the pit furnace over the shaft type is its adaptability to all kinds of ores, whether lump or concentrate, but a large single-phase load is not usually acceptable to the power-producing plant.—C. A. K.

Iron; Electro-deposition of ——. W. E. Hughes. Trans. Amer. Electrochem. Soc., 1921, 15—53. [Advance copy.]

The author reviews the methods employed in the electro-deposition of iron particularly from sulphate, chloride, and sulphate-chloride solutions. The purpose for which the deposit is required determines the nature of the solution employed, as, for example, a solution used to give a thin layer of hard iron would not be suitable if a much thicker deposit was desired, owing to the tendency to crack and peel. The chloride bath allows of greater current density and is a better conductor than the sulphate solution, but has the disadvantage that a higher temperature of working is necessary and the deposited metal oxidises quickly. Mixed solution baths give greater complexity at the anode with increased difficulty of regulation, without a much superior deposit. A slight acidity, especially when using sulphate solutions, improves the conductivity and hinders oxidation of the bath. A greater degree of acidity impedes cathode efficiency and causes diminution in the grain size of the deposit, accompanied by increased hardness and brittleness. The use of organic salts is unnecessary, and however fine the deposit may appear macroscopically, impurities are introduced by "addition agents." (*Cf.* J., 1920, 451 A; 1921, 392 A.)—C. A. K.

Cupola [iron] furnace; Working of the ——. F. Braun and G. Hollender. Stahl u. Eisen, 1921. 41, 1021—1027.

Experiments were carried out working with two cupolas of different throat diameters and tuyère areas. From the curve of the blast pressures and the analysis of the waste gases it is possible to regulate the melting process in the cupola. The experiments also show that direct measurement of the blast capacity is a good means of judging the physical processes occurring in the furnace. A graphic method is explained for determining the maximum carbon dioxide content of the waste gas for a given quantity of coke and a given volume of excess air.—J. W. D.

Open-hearth [steel] furnace; Heating of the —— *with a mixture of lignite briquette producer-gas and blast-furnace gas.* F. Boettcher. Stahl u. Eisen, 1921, 41, 1027—1030.

Melting in an open-hearth furnace heated by means of a mixture of producer gas from lignite briquettes and blast-furnace gas is possible provided the right proportions of each are used. The producer should be worked as slowly and as cold as possible so as to obtain a large amount of tar vapour from the lignite briquettes. The furnace used must be designed so that a large volume of gas can be led with a high velocity across the hearth area.—J. W. D.

Carbon tool-steel; Oxidation of —— on heating in air. H. Scott. Chem. and Met. Eng., 1921, 25, 72—74.

THE rate of scaling (oxidation) and depth of decarbonisation of samples of iron (0·03% C) and steel (0·86% C) were determined by heating specimens of the metals at temperatures up to 1060° C. for 1—5 hrs. Below 850° C. and for periods up to 5 hrs. the rate of scaling was at least equal to the rate of decarbonisation. At all temperatures the iron scaled more rapidly than the steel specimen, and in both cases the rate of scaling was independent of the size of the test-piece. The same depth of decarbonisation did not imply the loss of the same amount of carbon for, while heating for ½ hr. at 1060° C. gave the same depth of decarbonisation as heating for 1 hr. at 970° C., the microstructure showed less free ferrite in the latter case. —A. R. P.

Steels; Artificial seasoning of ——. H. J. French. Chem. and Met. Eng., 1921, 25, 155—158.

THE effect of various seasoning treatments on the length and planeness of hardened steel gauges was determined and the following results were arrived at. Neither short (⅛ in.) nor long (2 in.) gauges showed any appreciable chango in length with or without artificial seasoning, or, except in the case of some plain carbon steels, in planeness, during a period of seven months. None of the seasoning treatments applied prevented dimensional changes in the five steels tested, but these changes were exceedingly minute. The most effective treatment for bringing the steels to a state of permanence was found to consist in dips for 5 mins. alternately in oil at 200° C. and ice-water at 0° to −5° C. The general effect of seasoning was to produce elongation, but in the case of a steel containing 0·87% C, 1·10% Mn, 0·46% Cr, 0·43% W, and 0·12% V shrinkage extending over an extended period was noticed. Microscopical examination showed this steel to consist of martensite-troostite throughout, while the other steels showed troostite and sorbite at the surface and sorbite at the interior.—A. R. P.

Steels; Retarded solution and premature precipitation of cementite in eutectic and hypereutectic carbon ——. Sauvageot. Comptes rend., 1921, 173, 297—300.

FROM a micrographic study of tool steels under certain conditions the author confirms the observations of Portevin and Chevenard (J., 1921, 514 A). In steels which are totally or locally hypereutecoid the influence of the initial state of the ementite on the temperature at which it disappears s very important.—W. G.

ron-carbon alloys. R. Ruer. Z. anorg. Chem., 1921, 117, 249—261. (*Cf.* J., 1921, 150 A.)

CEMENTITE exists undecomposed in the molten ystem iron-carbon, but isolated cementite commences to decompose with the separation of graphite t temperatures slightly above 1100° C.; pure ementite cannot, therefore, be melted undecomosed. The amount of decomposition is 6·0% at 112° and 63% at 1132° C., whilst at 1164° C. the hole mass melts. The pearlite transition occurs t 721° C. (*Cf.* J.C.S., Sept.)—J. F. S.

hromium in steels; Determination of small amounts of ——. B. S. Evans. Analyst, 1921, 46, 285—286.

HE red coloration produced when chromic acid is reated with diphenylsemicarbazide solution affords means of determining very small quantities of romium, *e.g.*, 0·001%, or less, in steel. The reagent is prepared by dissolving 1 g. of diphenylsemicarbazide in 10 c.c. of glacial acetic acid and diluting the solution to 1 l.; 5 c.c. of the reagent and 10 c.c. of sulphuric acid (1:1) are used for each test. The chromium must be separated and oxidised to chromic acid before the test is applied.—W. P. S.

Lead; So-called action of water on ——. [Colorimetric determination of lead.] J. C. Thresh. Analyst, 1921, 46, 270—279.

THE experiments recorded prove that water itself has no action on lead and that it serves simply as an inert medium by means of which foreign substances are enabled to act on the metal. Of the latter substances, dissolved oxygen combines with the lead to form a soluble oxide or hydroxide which remains in solution (to the point of saturation) in the absence of other substances capable of combining with it; this solution is of a colloidal nature and of such a coarse degree of dispersion or so liable to adsorption that it will not pass through a Pasteur filter and may not even pass through a fine filter paper. In the presence of acids forming soluble lead salts, such salts form and pass through any filter; if the acids form insoluble salts, these are precipitated and may be deposited on the metal in such a way as to prevent any further action. Soluble salts in the water may likewise act on the lead hydroxide. To determine small quantities of lead colorimetrically by means of hydrogen sulphide, it is recommended that the test be made in acetic acid solution (1% of N/1 acetic acid) and that this acid should contain 0·1% of gelatin to act as stabiliser.—W. P. S.

Aluminium; Electrolytic behaviour of ——. A. Günther-Schulze. Z. Elektrochem., 1921, 27, 293—295.

THE assertions of Smits (J., 1920, 630 A) that commercial aluminium is not coated with a film of oxide and that anodically polarised aluminium has no primary oxide layer, are both opposed to all known facts. (*Cf.* J.C.S., Sept.)—J. F. S.

Nickel-silver; Physical tests on sheet ——. W. B. Price and P. Davidson. Chem. and Met. Eng., 1921, 25, 141—147.

FOUR series of tests were carried out on alloys containing approximately (a) 65·5% Cu, 6·5% Ni, remainder zinc, (b) 65·5% Cu, 18% Ni, remainder zinc, and (c), (d), each of these with 1% Pb. The bars were annealed and then cold rolled from about 0·155 in. down to 0·038 in., and the tensile strength, hardness, and microstructure examined at each stage of the rolling. All four alloys behaved very similarly, the yield point, ultimate stress, and hardness being increased very considerably, while the elongation and percentage reduction of area were greatly decreased. Neither the presence of lead nor the increase in the proportion of nickel had any marked effect on the values obtained for the various properties or on the behaviour of the metal on rolling. Samples taken at the various stages of rolling were then annealed at temperatures up to 800° C. and the physical properties again determined and the microstructure examined. As the temperature of annealing was increased the tensile strength and hardness fell first rapidly, then more slowly, while the percentage elongation increased extremely rapidly between 350° C. and 425° C. for samples (a) and (c), and between 500° C. and 575° C. for samples (b) and (d). The great differences in the physical properties found for samples reduced different amounts by rolling were approximately equalised by annealing (a) and (c) at 425° C., and (b) and (d) at 575° C., at which temperatures recrystallisation, which commenced after an anneal at 350° C. and 500° C. respectively, was complete. The large number of photomicrographs given show that to obtain a given grain size the alloys with 18% Ni must be annealed at a temperature 100°—150° C. higher than that necessary for alloys containing only 6—7% Ni.—A. R. P.

Metals; Formation of twins in the surface layers of —— during cold working. R. Vogel. Z. anorg. Chem., 1921, 117, 271—280.

During the polishing or shearing of plastic metals and alloys the surface is changed to a definite depth, a fact which must not be overlooked when investigating the characteristic structure of metals. On etching a section, the appearance of a twin-hatching is not a characteristic of the unworked metal, but the property of a thin surface layer which has been subjected to a cold local working, and which on warming the material undergoes recrystallisation and disappears. The formation of the twins is explained as follows: the particles of the polishing material cut furrows in the surface of the metal, and the material thus removed is pushed to either side where it is not in equilibrium with the general orientation of the mass, and therefore a recrystallisation occurs.—J. F. S.

Explosives; Action of —— in cartridges on some metals and alloys. M. Dreifuss. Z. Elektrochem., 1921, 27, 320—323.

In the case of metals of varying hardness the ratio of the depth and breadth respectively of the crater produced by explosion on lead to that produced on other metals increases parallel with the Brinell hardness.—J. F. S.

Patents.

Cast iron; Manufacture of ——. C. A. Keller. E.P. 126,971, 15.5.19. Conv., 20.3.18.

A mixture of steel turnings, powdered carbon, and basic slag is melted in an electric furnace. The quantity of carbon is regulated so as to give a product containing as high a proportion of carbon as is consistent with subsequent dephosphorisation. (*Cf.* E.P. 22,692 of 1913; J., 1914, 868.)—C. A. K.

Iron; Production by the cold way of glaze-like mineral coatings for ——. K. Friedrich. E.P. 152,651, 18.10.20. Conv., 18.10.19.

A coating of ordinary cement mortar is applied to a clean surface of iron, and while this is still moist a glaze coating is applied by spraying. The second coating consists of a thin mixture of finely-sifted cement and water, together with a small addition of substances which do not absorb water (*e.g.*, bituminous substances free from volatile oils), and have been oxidised previously in the presence of alkalis. —C. A. K.

[Steel] piano wire; Rustproof ——. Spring. Edged tool. M. J. Udy and F. C. Nicholson, Assrs. to The Udylite Process Co. U.S.P. (A) 1,383,174, (B) 1,383,175, and (C) 1,383,176, 28.6.21. Appl., (A) 13.6.19, (B, C) 23.10.19.

Iron or steel articles (piano wire, springs, or edged tools) are coated with a film of cadmium by an electroplating process, and then heated to alloy the cadmium with the iron. The piano wire is finally polished.—C. A. K.

Iron alloys; Non-rusting —— for the manufacture of bullet sheathing and small forgings. Plausons Forschungsinstitut, G.m.b.H. G.P. 337,847, 21.7.18.

Alloys prepared from electrolytic, carbon-free iron with 3—10% of copper or a copper alloy resist corrosion by air and moisture; they cast, roll, and draw easily, are essentially stronger and more tenacious than electrolytic iron, and possess a well-developed, uniform structure.—J. W. D.

Electrolytic separation of metals. C. Langer. E.P. 166,409, 19.5.20.

The simultaneous deposition of two or more metals is effected in the same electrolytic cell by the interposition of one or more secondary pervious cathodes between the anode and solid cathode. A mixture of the metals to be separated (*e.g.*, nickel and copper) is employed as anode. The secondary cathodes are arranged and perforated, or otherwise made pervious, to allow of a free passage of ions, and the difference of potential of the cathodes is dependent on the metals to be separated. From a mixture of nickel and copper, the copper is deposited on the intermediate cathode, which is kept at a potential not sufficiently high to decompose the nickel salt. The two electric currents are preferably independent and are regulated so that the density of each is proportionate to the respective metal content in the anode used. It is necessary to remove deposited metal at intervals from the perforated cathode to maintain its porosity, and a slow circulation of the electrolyte is maintained to displace the weakened electrolyte from near the solid cathode.—C. A. K.

Copper-nickel matte; Refining ——. N. V. Hybinette and R. L. Peek. U.S.P. 1,382,361, 21.6.21. Appl., 25.2.20.

Copper is precipitated from nickel-copper solutions by treatment with an excess of finely-divided nickel "at a temperature below that of exhaustion of the nickel."—C. A. K.

Casting and process of treating castings and the like. F. K. Bezzenberger and M. N. Rich, Assrs. to The Aluminium Castings Co. U.S.P. 1,383,517, 5.7.21. Appl., 24.11.19.

Metallic articles (castings) are rendered nonporous by forming silica within the pores, and then partly dehydrating the silica.—C. A. K.

Castings; Process of treating ——. A. B. Norton, Assr. to The Aluminium Castings Co. U.S.P. 1,384,033, 5.7.21. Appl., 5.8.18. Renewed 11.4.21.

A solid compound of sufficient volume to fill the pores of a metal is formed by the chemical action of liquid reagents forced into the pores. The nature of the solid compound is then changed by heating the metal article.—C. A. K.

Wrought iron; Manufacture of ——. H. Wade. From A. M. Byers Co. E.P. 166,452, 22.7.20.

See U.S.P. 1,370,622 of 1921; J., 1921, 307 A.

Lead alloys; Hard ——. United Lead Co., Assecs. of T. F. Wettstein. E.P. 140,824, 26.3.20. Conv., 2.10.18.

See U.S.P. 1,360,339 of 1920; J., 1921, 49 A.

Alloys. T. Kosugi. E.P. 166,817, 15.7.20.

See U.S.P. 1,369,818 of 1921; J., 1921, 308 A.

Electroplating; Compound anode for —— and methods of making same. C. R. Dean, Assee. of B. Bart. E.P. 141,073, 1.4.20. Conv., 12.12.17.

See U.S.P. 1,295,100 of 1919; J., 1919, 374 A.

Open-hearth furnaces. F. B. McKune. E.P. 164,052, 5.12.19.

See U.S.P. 1,339,855 of 1920; J., 1920, 493 A.

Metallurgical furnace. B. Talbot. U.S.P. 1,383,441, 5.7.21. Appl., 29.3.20.

See E.P. 164,901 of 1920; J., 1921, 590 A.

Gases derived from roasting ores; Mechanical device for removal of dust from ——. L. Geschwind, Assr. to Manuf. de Prod. Chim. du Nord, Etabl. Kuhlmann. U.S.P. 1,383,715, 5.7.21. Appl., 20.7.20.

See E.P. 147,020 of 1920; J., 1921, 435 A.

Slag; Means for granulating ——. J. E. Torbock. E.P. 166,370, 23.4.20.

Iron alloy. E.P. 141,351. *See* VIII.

Carbon in ferrous metal. U.S.P. 1,382,072. *See* XXIII.

Property of feeble conductors of electricity. Amaduzzi. *See* XXI.

Patents.

Electric resistance heaters and furnaces for high temperatures. Soc. Anon. des Ateliers de Sécheron, Assees. of B. Bauer and A. von Zeerleder. E.P. 133,706, 10.10.19. Conv., 10.10.18.

Pole rods penetrate into the resistance material for a sufficient distance to ensure efficient transmission of current, the pole rods and the resistance mass being made of similar material, chemically inert and stable and non-fusible at the high temperatures (above 1000° C.) employed, *e.g.*, silundum, carborundum, kryptol, etc. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 12,681 of 1902, 8998 of 1911, 8790 of 1912, and 115,866; J., 1902, 1031; 1911, 1395; 1912, 995; 1918, 428 a.)

Electric resistance heater for melting furnaces. Soc. Anon. des Ateliers de Sécheron, Assees. of A. von Zeerleder. E.P. 137,276, 5.12.19. Conv., 28.12.18. Addn. to 133,706.

In furnaces of the type described in the chief patent (*cf. supra*) the mass of resistance material around the crucible or the like is divided into segments separated by electrically insulating partitions and connected at the end by an annular part formed of the same resistance material. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 13,690 of 1905; J., 1906, 187.)

Electric furnaces. Soc. Anon. des Ateliers de Sécheron, Assees. of A. von Zeerleder. E.P. 138,858, 19.11.19. Conv., 12.2.19. Addn. to 133,706 (*cf. supra*).

A layer of heat-insulating material (firebrick, quartz sand, asbestos) is interposed between the resistance mass and the current supply poles from which the pole rods extend into the resistance material. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 15,920 of 1900, 7004 of 1905, and 8790 of 1912; J., 1901, 977; 1906, 433; 1912, 995.)

Electric resistance heaters and furnaces for high temperatures. Soc. Anon. des Ateliers de Sécheron, Assees. of A. von Zeerleder. E.P. 138,859, 19.11.19. Conv., 12.2.19. Addn. to 133,706 (*cf. supra*).

Besides the pole rods, additional thin rods of the same material are embedded in the resistance mass, in order that the latter may be heated quickly at the start and its electrical conductivity thereby improved. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to 15,920 of 1900, 7004 of 1905, and 8790 of 1912.)

Muffle furnace; Electric ——. Automatic and Electric Furnaces, Ltd., L. W. Wild, and E. P. Barfield. E.P. 166,659, 13.4.20.

The top and bottom of an electric muffle furnace are made flat and parallel, while the ends (sides) are curved. This construction eliminates the tendency of the heating wires to sag and to draw away from the muffle during winding. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 13,951 of 1900; J., 1901, 697.)—J. S. G. T.

Ozone; Apparatus for the production of ——. J. R. Quain. E.P. 166,197, 18.10.18 and 2.4.19.

An apparatus for the production of ozone by the silent discharge comprises a silica tube or plate as dielectric between electrodes, of which one or both are in contact with the silica tube or plate at a number of points or areas, while permitting air or oxygen to pass in contact therewith and with one or both of the electrodes. A tubular silica envelope enclosing one of the electrodes and evacuated or filled with an inert gas, may be used, and the inner electrode may be a tube or a wire helix extending the length of the envelope. The outer electrode may be in the form of a helix of metal wire or ribbon which may be corrugated; or perforated metallic tube of stainless steel may be employed as electrodes. The silica tubes and electrodes are enclosed within an outer casing through which air or oxygen is driven.—J. S. G. T.

Storage batteries [*; Filling for* ——]. J. A. Law. From A. P. Smith. E.P. 166,707, 21.4.20.

An electrolytic filling for storage batteries is made by adding a small quantity of one or more organic liquids such as methyl salicylate, turpentine, creolin, West's disinfectant fluid or similar product containing a phenolic compound, and a medium such as soap for producing an emulsion with water, to an aqueous solution of an alkali silicate. An aqueous solution of sulphuric acid is then added and the resulting jelly-like mass poured while still fluid into the battery.—J. S. G. T.

Separating particles from gases. U.S.P. 1,383,586. *See* I.

Electrolytic separation of metals. E.P. 166,409. *See* X.

Vaccines. E.P. 150,328 and 150,334. *See* XX.

XII.—FATS; OILS; WAXES.

Fatty substances; Oiliness of ——. P. Woog. Comptes rend., 1921, **173**, 303—306.

The author has determined cryoscopically the mean molecular volume of a number of lubricants, measurements being made at different concentrations, and from these results the molecular weight in an infinitely dilute solution has been determined. The mean molecular volume of a fatty oil is much greater than that of a mineral oil of the same viscosity.—W. G.

Hydrogenation of some marine animal oils. H. Marcelet. Comptes rend., 1921, **173**, 104—107.

Hydrogenation was effected by passing hydrogen for periods up to 16 hours, through the oil at 250° C. in presence of 2% of basic nickel carbonate. During the first hour the oils lost their disagreeable odour and their iodine value dropped rapidly. In all cases the iodine value had dropped by about 40—50% at the stage when the oil began to solidify at the ordinary temperature.—W. G.

Linseed oil. Coffey. *See* XIII.

Patents.

Oleic acid-like fatty acids or their soaps; Conversion of fatty acids with several double-linkages or of their glycerides into ——. E. Bennecke, Legal representative of C. Bennecke. E.P. 141,720, 13.4.20. Conv., 6.5.14.

The substance is saponified, and the soap heated without material excess of alkali or alkaline-earth and without evaporation to dryness, to 210°—250° C. The fatty acids may then be recovered from the products of reaction by means of a mineral acid.—H. C. R.

Fatty acids; Polymerisation of unsaturated ——. De Nordiske Fabriker De-no-fa Aktieselskap. E.P. 166,236, 25.7.19. Addn. to 127,814 (J., 1920, 697 A).

The fatty acids are transformed into their alkali salts and refined by boiling with caustic lye (10°—12° B., sp. gr. 1·07—1·09) and precipitating with common salt. The soap is heated for at least 3 hrs. to 180°—214° C. in an autoclave. Part of the water is then distilled off at constant pressure until the soap mass contains about 75% or more of fatty matter, when heating is continued under the same conditions until the desired polymerisation is complete.—H. C. R.

Wool-fat solutions; Process for recovering naphtha or other hydrocarbons from ——. C. N. Wilson. U.S.P. 1,383,585, 5.7.21. Appl., 24.11.19.

The solution is first subjected to cold and the substances congealed are allowed to settle. The solvent is then volatilised from the liquid.—H. C. R.

Oil-hardening process. A. A. Wells. U.S.P. 1,383,887, 5.7.21. Appl., 11.1.18.

A stream of hydrogen is passed from beneath into a body of oil containing finely divided nickel, the oil being violently stirred at the point of entry of the hydrogen stream. The hydrogen is thus disseminated in the form of fine globules throughout the oil.—H. C. R.

Lard; Process for conferring on edible fats an odour and flavour resembling those of ——. A. Granichstädten. G.P. 337,169, 20.6.16. Conv., 18.6.15.

The fat is heated with yeast, preferably by means of a current of heated indifferent gas, and after cooling the yeast is separated from the clear fat. —J. H. L.

Soap substitutes; Use of sulphonic acids of propylated aromatic hydrocarbons as ——. Badische Anilin- und Soda-Fabrik. G.P. 336,558, 23.10.17.

Propylated aromatic sulphonic acids, especially those of naphthalene and other polynuclear hydrocarbons, are obtained by the action of isopropyl alcohol on aromatic sulphonic acids in presence of sulphuric acid. Their solvent action on oils and fats renders them suitable for use as substitutes for soaps and Turkey-red oil. They form consistent emulsions with oils, benzene, petroleum, etc., which may be diluted with water without separating and may be used as drilling oils.—J. H. L.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Linseed oil and its fatty acids. Mechanism of the oxidation of drying oils as elucidated by a study of the true oxygen absorption. I. S. Coffey. Chem. Soc., Trans., 1921, 119, 1152—1161.

True oxygen absorption curves were obtained by exposing known weights of linseed oil distributed on filter paper to the action of oxygen in a closed vessel, in presence of absorbents (sodium hydroxide and sulphuric acid), to remove the volatile products of oxidation (carbon dioxide, acetic acid, etc.), and determining the weight of oxygen absorbed by manometer readings of the pressure. The whole operation was conducted in a thermostat at 100° C. in order to complete each estimation in 6—7 hrs. The results of numerous experiments were almost constant and gave a mean value for oxygen absorption of 28·7%. The fatty acids of the oil examined in a similar way gave 30·09% oxygen absorption. The curves obtained for the oil showed an initial period of induction lasting about 15 min., then a moderately rapid oxidation gradually slowing down, until after 6 hrs. oxidation was complete. With the fatty acids the induction period is much shorter, otherwise the form of the curve is the same, and it is evident that the glyceryl radicle has no influence on the *modus operandi* of the reaction. The ratio of oxygen absorption to iodine absorption is 0·156, hence the reaction is not simply a molecular autoxidation, as the oxygen absorption is about 25% higher than it would be on this assumption. There is in fact an "excess" oxygen absorption of 6%, which probably gives rise to the volatile acid products, the oxygen content of which amounts to 4% as CO_2 and 4% as $-COOH$.—G. F. M.

Fir tree resin; Constituents of ——. (*Turpentine from Pinus silvestris*). F. Henrich. Z. angew. Chem., 1921, 34, 363—367.

Fir tree resin, on steam distillation, yielded about 25% of oil of turpentine having sp. gr. at 20°/4° C., 0·8464; $[\alpha]_D^{20} = +11{\cdot}32^\circ$; and b.p. 155°—161° C. The turpentine contained small quantities of esters and free acids and consisted essentially of pure terpenes (α- and β-pinene). The non-volatile portion of the resin had m.p. 120°—125° C.; acid value, 165—167; ester value, 3·0—14·1; $[\alpha]_D^{20} = -39{\cdot}7^\circ$ to $-44{\cdot}2^\circ$ (in alcohol solution).—W. P. S.

Varnish testing. Testing elasticity. H. Wolff. Farben-Zeit., 1921, 26, 2587—2590.

The apparatus consists of two strips of wood having each a right-angled edge, fastened together by hinges. Strips of tinned iron, parchment, etc., coated with the material under test, are laid across the wooden strips, and fastened by drawing pins, the portion on one of the strips being slotted to permit the relative movement of strip and board when the latter is rotated about the hinge. Since an angle of 90° represents the smallest angle to which a varnished strip can be bent with such an apparatus, its use is restricted to comparatively "short" varnishes. For the examination of elastic varnishes a modified form of apparatus is used in which the edges of the wooden strips adjacent to the hinges are at an acute and an obtuse angle respectively in order that such edges meet when the two strips are laid in the same plane. Approximations to the angle of bending of the strips about the edges of the board are obtained from the readings on a protractor fastened to one of the strips and simple formulæ, the acute angle of the bevel in the second apparatus described being previously determined. For testing, varnished strips are bent on their support, and readings taken at various points, *e.g.*, local cracking, continuous cracking across the whole breadth, surface cracking only, flaking, etc. In the case of very elastic varnishes permitting bending to the fullest range of the apparatus without any failure, repeated bendings, after allowance of a suitable interval for recovery, furnish numerical data for comparison of different products. Where strips of a varnish of unknown composition were prepared by brushing on in one, three, and six coats, respectively, thinning of the varnish in the latter two cases being adjusted to give approximately equal thicknesses of coating as the former, and strips of the same varnish applied by dipping and spraying were compared, results showed that the highest elasticity was afforded by the six-coat brushing and the spraying, which ranged about equal. The minimum proportion of castor oil necessary to confer the maximum elasticity on a spirit varnish was found to be between 3% and 4%. (*Cf.* J., 1921, 357 A.)—A. de W.

Patents.

Red cadmium pigments; Manufacture of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 337,992, 4.9.19.

Permanent bluish-red to orange-red pigments are obtained by adding a solution containing a mixture of alkali or alkaline-earth sulphides and selenides to a solution of a cadmium salt, and igniting the precipitate so produced. Mixtures of 120—95 pts., 95—60 pts., and less than 60 pts. of cadmium selenide with 100 pts. of cadmium sulphide are dark bluish-red, red, and orange respectively.—A. J. H.

Varnish, lacquer, enamel, paint and similar coatings; Method for the removal of —— *from any objects or materials.* G. H. Mains. U.S.P. 1,381,485, 14.6.21. Appl., 6.12.20.

Furfural is applied to the varnished surface, and the loosened varnish is subsequently removed.
—A. de W.

Linseed oil substitute. M. Darrin, Assr. to Koppers Products Co. U.S.P. 1,382,345, 21.6.21. Appl., 7.2.20.

A mixture including a solution of coumarone resins polymerised by heat in solvent naphtha and a paint is claimed.—A. de W.

Rosin size solution. J. A. De Cew, Assr. to Process Engineers, Inc. U.S.P. 1,382,346, 21.6.21. Appl., 10.4.19. Renewed 13.4.21.

A sizing composition contains a drying oil, soap made from a drying oil, rosin, and rosin soap.
—A. de W.

Resinous products; Manufacture of ——. Badische Anilin- und Soda-Fabrik. G.P. 337,993, 14.6.19.

Monocyclic ketones are heated with alkaline condensing agents so that the reaction proceeds beyond the formation of the known simple condensation products, and resinous products, which are hard at the ordinary temperature, are produced. Cyclohexanone heated with methyl alcoholic caustic potash under pressure for 20 hrs. at 200°—220° C. yields a resin soluble in alcohol, benzene, cyclohexanone, linseed oil, etc., whilst cyclohexylidenecyclohexanone heated with 30% methyl alcoholic caustic potash under a reflux condenser at 120° C. yields a colourless resin. Other cyclic ketones yield similar products.—F. M. R.

Resin oils; Manufacture of ——. M. Melamid and L. Grötzinger. G.P. 338,036, 5.4.17.

In the preparation of refined resin oils from resins or crude resin oils by heating with syrupy phosphoric acid, an inert solvent is also added. When heated with a solvent, such as neutral mineral oil, a lower temperature is required, the duration of the operation is diminished, and the yield of oil is increased. The added mineral oil is not separated from the resin oil, which can be used as a transformer oil owing to the decreased viscosity.—F. M. R.

China wood [tung] oil; Process for solidifying —— *and the product thereof.* B. Scobel. U.S.P. 1,383,864, 5.7.21. Appl., 23.3.18.

See E.P. 153,942 of 1919; J., 1921, 52 A.

Pigment dyestuff. U.S.P. 1,383,710. *See* IV.

Coatings on iron. E.P. 152,651. *See* X.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Ilcken-Down process of rubber preparation. O. de Vries and W. Spoon. Comm. Central Rubber Stat., Buitenzorg, 1921, No. 27, 1—19.

The Ilcken-Down process for the preparation of rubber, involving the spontaneous coagulation of the latex in the presence of a proprietary mixture consisting essentially of alcohol (53 pts.) and fusel oil (34 pts.), with the addition, next morning, of a quantity of a mixture of alcohol (2 pts.) and petrol (1 pt.), and final treatment of the freshly rolled crêpe rubber with a dilute solution of sodium bisulphite and sulphuric acid, has been claimed to give a yield of rubber 5—15% greater than that obtained by the customary methods. In three series of experiments made under various conditions in the presence of one of the inventors of the process, no such increased yield was observable, the mean result being slightly under that obtained with the standard method of the estate. The composition of the Ilcken-Down rubber was approximately the same as that of ordinary crêpe obtained from undiluted latex, and the inner properties were normal although the rate of cure was somewhat low.—D. F. T.

[Rubber] latex; Use of serum to dilute ——. O. de Vries. Comm. Central Rubber Stat., Buitenzorg, 1921, No. 28, 1—17.

In order to effect an economy in the consumption of acetic acid or of clean water, serum from the coagulation of the previous day is sometimes used for the dilution of latex. If this is done uninterruptedly for several weeks, accelerators formed by decomposition of the serum may accumulate and give rise to a rather rapidly vulcanising rubber; when, however, bisulphite is regularly used, there is very little effect. The practice of using old serum may therefore give rise to irregularity in the rate of vulcanisation if it becomes necessary to interrupt the course of work and to recommence with a fresh mixture. As the rate of vulcanisation depends also on the concentration of the liquid from which the rubber is coagulated and the consequent amount of serum substances absorbed, the use of serum for dilution purposes, for this reason also, tends to give rise to a product with a rate of vulcanisation above the normal.—D. F. T.

Patents.

Caoutchouc and caoutchouc-like substances; Filler for ——. A. Nixon. E.P. 166,218, 10.5.19.

A mixture of French chalk, china clay, iron oxide, and magnesium carbonate is used as a rubber-compounding ingredient. The mixture may be calcined before use, in which case zinc oxide or zinc sulphide may be added previously; it may also be bleached by successive treatment with acid and washing, zinc oxide then being introduced subsequently.
—D. F. T.

Indiarubber, gutta percha, and the like; Purification of ——. C. H. Gray. E.P. 166,359, 15.4.20.

Mineral impurities, particularly sand, are removed from washed crude rubber or gutta percha by treatment with aqueous hydrofluoric acid; the material may either be immersed in the form of thin sheet in the reagent or it may be mechanically worked with it in a kneading machine.—D. F. T.

Rubber; Process of devulcanising ——. W. B Pratt, Assr. to Rondout Rubber Co. U.S.P. 1,382,669, 28.6.21. Appl., 23.10.14. Renewed 1.12.20.

Vulcanised rubber is subjected to the action of oxalic acid.—J. H. L.

XV.—LEATHER; BONE; HORN; GLUE.

Tanning of gelatin by formaldehyde. W. Moeller. Kolloid-Zeits., 1921, **29**, 45—55.

The hardening of gelatin by formaldehyde is a two-phase process. The actual hardening is a physical process in which only the coagulable portion of the gelatin takes part. The non-coagulable portion of the gelatin enters into a chemical reaction with the formaldehyde with the formation of methylene-amino-acids. The portion of the gelatin capable of hardening corresponds with the coagulation value of the untreated gelatin. If the coagulable part of the gelatin is decreased by hydrolysis in consequence of the action of hydrogen ions, then the portion capable of hardening also decreases. The constituents of the formaldehyde solution which are capable of hardening are the insoluble colloidal polymers of formaldehyde, which are only formed during the action on the gelatin.—J. F. S.

Glue; Simple method for testing [tensile strength of] ——. D. R. Frazer. Analyst, 1921, **46**, 284—285.

Briquettes of pitch-pine of the same dimensions as those used in testing the tensile strength of cement are made, the grain running lengthways; these are sawn across the middle at right angles to the axis, and the surfaces are smoothed with sand-paper. 25 g. of glue is steeped in 100 c.c. of water for 24 hrs., then heated until all the glue has dissolved, evaporated water is replaced, the solution cooled to 50° C., and exactly 0·3 c.c. of the solution is placed on the flat surface of one of the half-briquettes; the other half is put on the top of it and the two halves are held in position by a 2-in. rubber band. After 24 hrs., the briquette is broken in the usual way in a cement-testing machine. The tensile strength of the glue may be expressed in lb. per sq. in. A series of six tests should be made for each sample of glue. A good glue has a tensile strength of over 300 lb. per sq. in.—W. P. S.

Sulphurous acid. Froboese. *See* XXIII.

Patents.

Tanning leather; Method of and arrangements for ——. Tannage Rationnel Meurant, Soc. Anon., Assees. of J. Meurant. E.P. 140,092, 10.3.20. Conv., 12.3.19.

In order to accelerate the tanning process the hides are placed in a series of tanning pits or autoclaves, each of which is connected with a central filtering pit, and the tanning solution is circulated between each tanning pit and the central pit, together with a current of oxygen or air under a pressure of at least 3 atm.—D. F. T.

Tanning; Preparing hides for ——. A. Manvers. E.P. 166,495, 14.2.20.

The hides are suspended in a cylinder which is evacuated, and air-free water is gradually introduced, the hides being occasionally agitated by admitting air from a series of roses at the bottom of the chamber. In this manner dry hides are restored to a normal state without injury. The previous operation is then repeated with the introduction of lime and water in place of water; the temperature is raised to about 80° F. (27° C.), and air again occasionally admitted for short periods into the evacuated chamber, the lime being thus kept agitated. At the end of about a day the hides are removed, thoroughly washed, cleaned from hair and loose flesh, and delimed, being then ready for tanning.—D. F. T.

Hides; Process of tanning ——. Holzverkohlungs-Ind. A.-G. G.P. 336,895, 6.2.16.

Tar, especially that obtained from beechwood, is extracted with an aqueous alkaline solution, and the extract, after partial neutralisation or even acidifying, is treated with formaldehyde solution; the product constitutes a tanning agent, to which other materials may be added if desired. Alternatively, hides may first be treated with the tar extract and then with the formaldehyde solution.
—W. J. W.

Hides; Process of tanning ——. Chem. Fabr. Worms A.-G. G.P. 337,330, 30.3.19.

Tanning agents are produced by treating lignin-sulphonates or sulphite-cellulose waste liquors with ferrous salts. A preliminary treatment of the hides with the ferrous salts, in presence of a small amount of sodium chloride or sodium sulphate, followed by application of the sulphite-cellulose liquors, may be employed.—W. J. W.

Hides; Process of tanning ——. Deutsch-Koloniale Gerb- u. Farbstoff-Ges.m.b.H. G.P. 337,588, 25.9.15. Addn. to 335,122 (see E.P. 18,174 of 1915; J., 1917, 93).

Hides are treated with formaldehyde solution, after removal of which they are subjected to treatment with solutions of sulphonic acids, or sulphonates derived from naphthylamines, aminonaphthols, or dihydroxynaphthalenes. Treatment with these last solutions may precede the formaldehyde treatment.
—W. J. W.

Hides; Depilation of ——. W. Rautenstrauch. G.P. 338,095, 4.8.18. Addn. to 304,251 (J., 1921, 442 A).

In the use of barium hydroxide solution, as described in the previous patent, the addition of a small amount of alkali carbonate or hydroxide prevents formation of white spots, presumably due to separated barium soaps, during subsequent dyeing of the leather.—W. J. W.

Gelatin or glue; Preparation of ——. C. Greiner, jun. G.P. 337,178, 11.9.19.

The material, which may previously have been exposed to the action of a bleaching liquid, *e.g.*, hydrogen peroxide, is treated with carbon dioxide gas or water containing carbon dioxide, in a closed vessel, with or without the aid of pressure. The product is transparent, odourless, tasteless, and edible, and possesses great tenacity.—J. H. L.

Adhesives. Badische Anilin- und Soda-Fabrik. G.P. 337,956, 4.6.18.

Products of the condensation of formaldehyde with naphthalenesulphonic or phenolsulphonic acids or their derivatives, are used for the preparation of substitutes for gum and glue and plastic masses which harden on drying, *e.g.*, cements for glass.
—J. H. L.

XVI.—SOILS; FERTILISERS.

[Fertilisers;] Citrate-soluble phosphoric acid [of ——]. H. Hackl. Chem.-Zeit., 1921, **45**, 730—731.

In testing phosphatic fertilisers, a determination of their solubility in water containing carbon dioxide in solution is of more value than the usual estimations with citric acid and ammonium citrate, inasmuch as carbon dioxide plays an important part in the soil. From dicalcium phosphate, Rhenania phosphate, and basic slag rain water saturated with carbon dioxide dissolved 100%, 44·4%, and 46·7%, respectively, of the combined phosphoric acid. The physical condition of dicalcium phosphate and its neutral reaction are additional advantages in its use, and it is not regarded as being in any way inferior to superphosphate.—W. J. W.

Manganese; General presence of —— in the vegetable kingdom. G. Bertrand and M. Rosenblatt. Comptes rend., 1921, **173**, 333—336.

Contrary to the findings of Maumené (*cf.* Comptes rend., 1884, **98**, 1416) it is shown that the presence of manganese in all the organs and species of plants is quite general.—W. G.

Patents.

Superphosphate; Apparatus and process for manufacturing acid-phosphate or ——. W. T. Doyle, Assr. to Sturtevant Mill Co. U.S.P. 1,383,911–2, 5.7.21. Appl., 13.3.20 and 10.1.21.

Rock phosphate is mixed with sulphuric acid, stored for a period, removed from the storage den by an enclosed conveyor, pulverised, and treated with more rock phosphate to remove excess acid. Means are provided to draw steam and fumes from the storage den through the conveyor casing and also from the pulveriser.—A. G. P.

Manure; Manufacture of —— from minerals. Chem. Fabr. Rhenania, and A. Messerschmitt. E.P. 22,747, 8.10.13.

See F.P. 462,357 of 1913; J., 1914, 327.

Sewage. G.P. 337,287. *See* XIXb.

XVII.—SUGARS; STARCHES; GUMS.

Honeys; Examination of artificial and genuine ——, beet syrups, etc. G. Bruhns. Chem.-Zeit., 1921, **45**, 661—664, 681—682, 685—687, 711—712.

Artificial honeys prepared from pure sucrose by inversion with small quantities of acid invariably contain dextrinous condensation products which are only partially hydrolysed by the Clerget process. In consequence, the content of total solids (found from the density of a 20% solution) is often 3—5% greater than the sum of the contents of invert sugar and of sucrose found by the Clerget method. The Clerget process is of little use with honeys, except to detect large quantities of sucrose; the small amounts of "sucrose" commonly indicated, even in genuine honeys, are probably due to partial hydrolysis of the honey dextrins by the Clerget process and also to the effect of the acid on the rotation of the lævulose present. The dextrinous substances in artificial honeys may be completely hydrolysed by prolonged heating of a 1% solution of the honey in 0·06 *N* hydrochloric acid in a boiling water bath. The author heats 5 portions of such a solution and withdraws them one by one after different periods until the maximum reducing power is attained. A correction, varying with the duration of heating, which may range from 4 to 11 hrs., is made for the loss of reducing power due to destruction of lævulose. After this method of hydrolysis artificial honeys showed invert sugar contents which agreed, to within 0·5%, with the content of total solids. Applied to edible beet syrups, containing 15—30% of sucrose and about 2% of ash, the method indicated, after hydrolysis, invert sugar contents about 6—7% higher than after hydrolysis by the Clerget method, but still about 8—9% lower than the content of dry substance (found from the sp. gr. of 20% solutions). Starch dextrins were found to be hydrolysed much more slowly than honey dextrins under the prescribed conditions, the reducing power continuing to increase considerably after heating for 4—5 hrs.—J. H. L.

Photocatalysis. I. Synthesis of formaldehyde and carbohydrates from carbon dioxide and water. E. C. C. Baly, I. M. Heilbron, and W. F. Barker. Chem. Soc. Trans., 1921, **119**, 1025—1035.

Formaldehyde is formed when an aqueous solution of carbon dioxide is exposed to ultra-violet light of wave length 200 $\mu\mu$, and is polymerised to reducing sugars in light of wave length 290 $\mu\mu$. In the light of a quartz mercury lamp both processes occur simultaneously, and the intermediate production of formaldehyde can only be rendered evident by removing it rapidly from the sphere of the reaction by a current of carbon dioxide, or better, by adding to the solution substances such as paraldehyde, sodium phenoxide, or certain metallic salts, which absorb light of wave length 290 $\mu\mu$, and so protect the formaldehyde from polymerisation. The photosynthesis of formaldehyde from carbon dioxide can be photocatalysed by certain coloured basic substances, *e.g.*, colloidal uranium and ferric hydroxides, Malachite Green, etc., and the photosynthesis then takes place in visible light. Polymerisation to carbohydrates can similarly be photocatalysed. In the unscreened light of the quartz mercury lamp, carbohydrates, glycerol, acetone, etc., give formaldehyde and reducing sugars, an equilibrium being set up between sugar, formaldehyde, and carbon dioxide which apparently lies far over on the side of carbon dioxide. In the presence of a photocatalyst capable of catalysing both stages of the reaction, such as chlorophyll, this equilibrium will be shifted entirely over to the side of of the reducing sugar, since the system will be screened from those rays which decompose carbohydrates. Sugar formation in the growing leaf from very small concentrations of carbon dioxide without the free existence of formaldehyde as an intermediate product is thus explained.—G. F. M.

Amylopectin; Synthesis of —— by phosphoric esterification of the erythroamyloses. Samec and A. Mayer. Comptes rend., 1921, **173**, 321—322.

Using Neuberg's method of esterification (Biochem. Zeits., 1919, **100**, 3) the authors have obtained from the erythroamyloses a calcium amylophosphate which, when subjected to electrodialysis, loses its calcium and gives a viscous jelly resembling amylopectin in its properties.—W. G.

Patents.

Sugar juices; Process for purifying —— by filtration and decantation. F. Tiemann. E.P. 161,987, 21.4.21. Conv., 21.4.20.

The stationary juice, in a special receptacle, is filtered by forcing downwards through it a piston-like basket or frame packed with filtering material. When the basket is at its lowest position the clear juice above it is drawn off from an outlet just above the level of the basket. The sludge below the basket is exhausted by means of water, which is forced through an opening in the bottom of the receptacle, passes upwards through the basket and escapes through the above-mentioned outlet. Subsequently the opening in the bottom of the receptacle is closed, and the basket is raised rapidly, whereby air (or if necessary, water) is sucked downwards through the basket, the sediment being thus detached from the bottom of the latter, and afterwards discharged from the bottom of the receptacle.—J. H. L.

Filtering, decolorising, or purifying processes, and decolorising carbons therefor. J. N. A. Sauer. E.P. 166,229, 20.6.19.

Wood or peat charcoal, of high adsorptive power, containing at least 90% C and very little impurity soluble in acid or water, is boiled with an aqueous solution of an acid in quantity more than sufficient to remove the acid-soluble impurities, and is washed with water until the washings are neutral. The decolorising carbon so produced is used in the wet state for treating aqueous and alcoholic liquids, *e.g.*, sugar solutions, without the usual addition of acid.—H. H.

Sugar cane mills. F. J. de Bruin. E.P. 149,289, 15.7.20. Conv., 15.7.19.

Activated carbonaceous substances. E.P. 166,202. *See* IIb.

Decolorising carbon. U.S.P. 1,383,755. *See* IIb.

Potassium salts. E.P. 166,657. *See* VII.

XVIII.—FERMENTATION INDUSTRIES.

Proteins in yeast extract; Colloidal condition of the ——: yeast phosphoproteins in the sol condition as colloid enzymes. A. Fodor. Kolloid-Zeits., 1921, **29**, 28—45.

Three phosphoproteins, λ_1, λ_2, and λ_3, were obtained from yeast by digesting it at 37° C. for 2 hrs. with 3 times its weight of water and filtering. The golden yellow filtrate was diluted to five times its volume and fractionally precipitated with $N/1$ hydrochloric acid, yielding the λ_1, λ_2, and λ_3 proteins respectively. The fractions after washing and grinding gave sols or suspensions with water, the degree of dispersion of which was greater the smaller the amount of acid used to precipitate them. The sols were strongly opalescent and transparent, but lost their opalescence on treatment with a drop of alkali and were completely precipitated by concentrated hydrochloric acid. These sols act as enzymes and bring about the hydrolysis of glycyl-*l*-leucine, the activity decreasing with decreasing dispersion. They are acid in reaction and carry a negative charge, wandering toward the anode.—J. F. S.

Beer; Determination of carbon dioxide in —— by precipitation. Macheleidt. Z. ges. Brauw., 1921, 130—131.

The method, as applied to beer in bottles of ⅓ l. capacity, is as follows:—Before opening the bottle is chilled and weighed. Immediately after opening, 10 c.c. of 25% ammonia solution is introduced, and after the bottle has been closed and inverted several times to mix the contents it is emptied into a beaker and weighed empty. The ammoniacal sample is treated with 4 or 6 c.c. (for 8% or 12% beers respectively) of "magnesia mixture," and after the precipitation of phosphate is complete the precipitate is filtered off and washed once with 60 c.c. of 2·5% ammonia. The filtrate and washings are together treated with 15 c.c., or, if necessary, 20 c.c., of calcium chloride solution (containing 550 g. of $CaCl_2,6H_2O$ per l.) and heated, preferably to boiling, for a few minutes. The precipitate is collected, washed with boiling water, ignited, and weighed as lime. Unnecessary excess of reagents (magnesia mixture, ammonia, calcium chloride) should be avoided. In operating on draught beers, about ⅓ l. of the beer is run slowly through a glass tube into 20 c.c. of ammonia solution contained in a bottle, which is weighed before and after the introduction of the beer, and emptied into a beaker as above after the contents have been mixed.—J. H. L.

Tartaric acid; Identification of —— in wines. L. Mathieu. Bull. Assoc. Chim. Sucr., 1921, 38, 352—354.

Twenty c.c. of the wine is shaken with amyl alcohol, the latter is separated and shaken with an equal volume of water, and the aqueous layer is drawn off and evaporated to dryness. The residue obtained is dissolved in 5 c.c. of water and the solution treated with 1 drop of calcium chloride solution ($CaCl_2,6H_2O$, 150 g., NH_4Cl, 40 g. per l.) and 2 c.c. of *l*-ammonium tartrate solution (in dilute alcohol). A precipitate of calcium racemate forms immediately if the wine contained not less than 0·5 g. per l. of free tartaric acid.—W. P. S.

Sulphurous acid. Froboese. *See* XXIII.

Patents.

Cellulose-containing materials; Process for converting —— into soluble carbohydrates [for fermentation]. A. Wohl. E.P. 146,455, 3.7.20. Conv., 14.3.17.

After the solution of cellulose from woody or other materials by the hydrolytic action of concentrated hydrochloric or sulphuric acid in the cold, the acid liquor is separated from the insoluble matter by counter-current lixiviation and freed from acid to the required extent by a diffusion process, *e.g.*, similar to the osmosis process applied to molasses. —J. H. L.

Beer wort; Method of cooling and aerating —— and separating sludge. L. Nathan and A. Gille. E.P. 165,378, 24.12.20.

Wort from the copper is run into a settling vessel containing a number of superposed settling plates with upstanding rims, the vessel being sterilised by the hot wort. The wort is drawn off slowly from the upper part of the settling vessel, and after passing over an enclosed surface cooler on which it is exposed to a current of sterile air, it flows back into the settling vessel, entering near the bottom, whence it ascends and displaces the warmer wort. After the sludge has deposited from the cooled wort, the latter is drawn off from the settling vessel, a special obturating device preventing the entrainment of sludge from the bottom of the vessel; and afterwards the settling plates are tilted to discharge the sludge on to the bottom of the vessel, whence it is drawn off.—J. H. L.

Yeast possessing special racial characters; Preparation of cultures of ——, especially of races adapted to ferment concentrated solutions. V. Stein and H. Reiser. G.P. 337,282, 17.12.18. Conv., 30.11.18.

Pitching yeast is prepared from pressed yeast which has been liquefied by addition of substances capable of causing a copious discharge of proteins from the interior of the living cells. Liquefaction may be effected by addition of suitable substances, especially salts, in such quantities as to prevent auto-fermentation of the liquefied yeast. Bisulphites are specifically claimed as liquefying agents. From yeast thus liquefied cultures can be prepared which ferment abnormally concentrated worts, are very resistant to infection, and possess 2 or 3 times the working power of the original yeast.—J. H. L.

Potassium salts. E.P. 166,657. *See* VII.

Decolorising carbons. E.P. 166,229. *See* XVII.

XIXa.—FOODS.

Egg powder; Composition of ——. F. F. Beach, F. E. Needs, and E. Russell. Analyst, 1921, **46**, 279—283.

Examination of a number of so-called egg powders showed that they consist merely of coloured baking powder. In the case of a sample stated to contain egg, the quantity of the latter present was so small that the increase in the amounts of ether-extract, protein, and organic phosphorus was negligible. —W. P. S.

Sulphurous acid. Froboese. *See* XXIII.

Patents.

Meat powder; Production of ——. W. F. Remus, A. E. Macredie, and C. F. Cork. U.S.P. 1,382,673, 28.6.21. Appl., 10.9.19.

Raw cold meat in blocks is dried for 36—40 hrs. in a chamber at about 135° F. (57° C.), then smoked for about 8 hrs., and finally powdered.—J. H. L.

Jam or pulp; Apparatus for the manufacture of juices and jellies, with simultaneous production of ——. C. and O. Bielmann. G.P. 337,042, 17.2.20.

A cooking vessel built in an independent heating plant has its lower part inclined at an angle to the upper part and fitted with a discharging device at the bottom; or there may be several inclined lower parts, each with a discharging device, communicating with a common upper part. The apparatus has a large output and ensures the retention of the flavour and aroma of the material.—J. H. L.

Preservative; Preparation of a —— from benzoic acid. C. Brunnengräber and O. Elsner. G.P. 337,494, 25.10.18.

Benzoic acid is neutralised in part by a solution of a fixed alkali, *e.g.*, sodium carbonate, and in part by ammonia, and the solution is evaporated to dryness if necessary. The product possesses greater preservative power than sodium benzoate.—J. H. L.

Baking powder. Chem. Fabr. Marienfelde G.m.b.H. G.P. 338,196, 16.1.20. Addn. to 335,474.

The non-hygroscopic starch-phosphoric acid prepared in accordance with the chief patent (J., 1921, 508 a) is employed as the acid constituent, together with a carbonate or bicarbonate.—J. H. L.

Margarine; Method and apparatus for making ——. H. Borgen and G. W. Wadsworth. E.P. 166,648, 8.4.20.

Edible fats. G.P. 337,169. *See* XII.

XIXb.—WATER PURIFICATION; SANITATION.

Cresols and cresol soap substitutes. E. Hailer. Arbb. Reichs-Gesundh.-Amt., 1920, 52, 670—695, 696—726. Chem. Zentr., 1921, 92, IV., 310, 311.

Solutions of cresotin-cresol are found to be as effective as pure aqueous solutions of cresol, and for most disinfecting purposes such a solution containing 1% of cresol is suitable. At higher temperatures lower concentrations, *e.g.*, 0·6% at 30° C., and 0·4% at 50° C., may be employed (*cf.* J., 1920, 278 a; 1921, 486 a). The "germ-carrier" method of testing disinfectants is superior to the "suspension" method, for the reasons that larger numbers of micro-organisms can be exposed to the action of the disinfectant; such a large quantity of disinfectant solution can be used that its concentration is not appreciably altered by combination of the disinfectant with the germs or germ-carrier; the active constituents can be removed from the carrier by washing or other means before the culture medium is inoculated, and any inhibitory action in the culture itself thus eliminated. In the suspension method the results are largely influenced by the conditions of growth in the preliminary culture. —W. J. W.

Cresol; Approximate determination of —— in lysol. C. J. Jordan and F. Southerden. Brit. Pharm. Conf., June, 1921. Pharm. J., 1921, 106, 479—480.

The sample is acidified with sulphuric acid and distilled with steam, and the amount of cresol present is calculated from the respective volumes of the layers which separate.—W. P. S.

Action of water on lead. Thresh. *See* X.

Patents.

Chlorine gas; Method of, and apparatus for controlling or measuring a small flow of ——. W. Paterson. E.P. 166,191, 1.8.17.

A liquid seal (sulphuric acid or chloroethylene) is provided in the delivery pipe, so that a definite volume of liquid must be depressed each time the delivery pipe is unsealed and a definite volume of gas passes. The apparatus is for use in the sterilisation of water etc. by chlorine gas.—A. G. P.

Sewage and other foul waters; Apparatus for aerating and circulating ——. M. W. Mills and J. Bolton. E.P. 166,385, 3.5.20.

An inverted cone fitted with curved radial blades revolves within a circular hopper, from the base of which a pipe extends to within a few inches of the bottom of the containing tank. Sewage, delivered to the hopper from below, is rapidly circulated and thrown into the air as a fine spray, and falls back into the tank thoroughly aerated.—A. G. P.

Sewage; Process for fixation of the nitrogen in liquid ——. Chem. Fabr. Rhenania, A.-G., and G. A. Voerkelius. G.P. 337,287, 27.6.19.

For the production of fertilisers, sewage in aerated beds is exposed to the action of nitrifying bacteria, which may be developed by filling the beds with peat or straw. A neutralising agent such as crude phosphate is added to combine with the liberated nitric acid.—W. J. W.

Absorbents for gases. B. Lambert. E.P. 166,275, 9.10.19.

An absorbent for use in respirators for the absorption of noxious gases consists of 8 pts. of quicklime slaked by addition of 1 pt. of potassium or sodium permanganate dissolved in sufficient water to give the slaked mass the consistency of a thick paste, which is dried at a temperature not above 110° C. and broken down to granules. It is non-deliquescent and absorbs chlorine, sulphur dioxide, sulphur trioxide, phosgene, hydrogen sulphide, hydrogen arsenide, hydrocyanic acid, cyanogen, and lachrymatory gases.—A. G. P.

Sewage and analogous liquids; Purification of ——. W. Jones. Reissue 15,140, 5.7.21, of U.S.P. 1,247,543, 20.11.17. Appl., 11.8.19.

See E.P. 22,736 of 1914; J., 1916, 195.

Sand filters. U.S.P. 1,383,384. *See* I.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Aconite; Assay of ——. A. R. L. Dohme. Amer. J. Pharm., 1921, 93, 426—439.

A physiological method is recommended since the ordinary method of extracting the total alkaloids with a solvent does not give any indication of the proportion of the various alkaloids present. Aconitine is about 300 times more toxic than benzoylaconine and 4000 times more toxic than aconine, and there is no suitable quantitative method available for their separation. In the case of the fluid extract of aconite, 1 c.c. is diluted to 10 c.c. with 50% alcohol and varying portions of this solution, diluted to a volume of 1·5 c.c. with normal saline solution, are injected into the subcutaneous tissues of the abdomens of guinea pigs weighing 300—400 g. The lethal dose is taken as being the smallest quantity which will kill within 24 hrs. For aconitine, 0·1 g. is dissolved in 2% acetic acid, 1 c.c. of this solution is diluted to 10 c.c. with water, and quantities of the latter solution, diluted to a volume of 1·5 c.c. with normal saline solution, are used for injection. About 0·00000005 g of aconitine per g. of animal is usually the lethal dose.—W. P. S.

Laurotetanine, the tetanus-producing alkaloid of various Lauraceæ. K. Gorter. Bull. Jard. botan. Buitenzorg, 1921, 3, 180—198. Chem. Zentr., 1921, **92**, III., 344—346.

The formula $C_{19}H_{23}O_5N$ previously assigned to the alkaloid by Fillippo (J., 1899, 603) is confirmed for the base dried over sulphuric acid, but a further mol. of water is lost in vacuum over phosphorus pentoxide, so the anhydrous alkaloid is $C_{19}H_{21}O_4N$, or $C_{16}H_{10}(OH)(OCH_3)_3.NH$. A constitution for dimethyl-laurotetanine, or isoglaucine, similar to that of glaucine, but with one of the methoxyl groups in a different position, is suggested. Numerous salts and other derivatives of laurotetanine are described.—G. F. M.

Salvarsan; Derivatives of sulphur in commercial —— . I. H. King. Chem. Soc. Trans., 1921, **119**, 1107—1120.

The sulphur compounds occurring in commercial samples of salvarsan, to which the varying toxicity of the compound is largely due, are traceable to subsidiary reactions occurring during the reduction of 3-nitro-4-hydroxyphenylarsinic acid by hydrosulphite. In addition to the main product, 10% of 3-amino-4-hydroxy-5-sulphinophenylarsinic acid and the corresponding disulphinoarsenobenzene are formed under certain conditions. The former is completely reduced to the latter by hypophosphorous acid at 100° C., and the mixed arsenobenzene, 3.3′-diamino-4.4′-dihydroxy-5-sulphinoarsenobenzene hydrochloride, was prepared by reduction of equimolecular proportions of the parent phenylarsinic acid and the above sulphino-derivative. This substance is identical with that isolated by Fargher and Pyman (J., 1920, 465 A) from commercial salvarsan by means of its sparing solubility in methyl alcohol, and designated as a monosulphamic acid. The sulphinophenylarsinic acid on oxidation with hydrogen peroxide passes smoothly into the corresponding sulphophenylarsinic acid, and this on reduction gives the sulphoarsenobenzene. The lethal dose of all these sulphur derivatives is apparently about one-half that of pure salvarsan, and the curative dose in some cases as much as four times that of salvarsan.—G. F. M.

Veronal; Determination of ——. L. van Itallie and A. J. Steenhauer. Pharm. Weekblad, 1921, 58, 1062—1068.

For extracting veronal from urine, ethyl acetate is preferable to ether, as the whole may be extracted by one treatment. Purification by means of charcoal gives low yields, owing to adsorption. Treatment of the urine with lead acetate or basic lead acetate precipitates some of its constituents and prevents emulsification during the subsequent extraction with ethyl acetate. If the extract is then treated with potassium permanganate solution, and re-dissolved, quantitative yields are obtained. (*Cf.* J.C.S., Sept.)—W. J. W.

Benzaldehyde; Danger of spontaneous ignition of —— during transport. O. Gerhardt. Chem.-Zeit., 1921, 45, 664.

Owing to a faulty seam in one of four tin cans of benzaldehyde packed in a case with fine wood shavings, the surrounding packing became impregnated with benzaldehyde which was autoxidised to benzoic acid, whereby the temperature of the packing in the neighbourhood of the leak was raised to 52° C. It is recommended that kieselguhr, powdered fireclay or the like, should be used as packing for the transport of benzaldehyde.—J. H. L.

Gas poisoning in warfare. II. Decomposition of the gases by water. P. Rona. Z. ges. exp. Med., 1921, 13, 16—30. Chem. Zentr., 1921, **92**, III., 374.

The decomposition of most of the gases used in chemical warfare gives rise to acids, so that the course of the reaction can be followed by determinations of the acidity. Phosgene is instantaneously hydrolysed both by water and by artificial blood serum, and dichloro- and dibromo-methyl ether behave similarly. Chloropicrin is not decomposed by water at a measurable rate. Dichloroethyl sulphide is hydrolysed at ordinary temperatures fairly rapidly; the reaction is unimolecular and has a velocity constant, 0·4289. Tetrachlorodiethyl sulphide is more slowly decomposed, and ethylene-*bis*-ω-chloroethyl sulphide very slowly. The saponification velocities of dichloromethyl sulphide, dibromomethyl sulphide, dibromoethyl sulphide, and bromoethylethyl sulphide are great, but measurable. With thiodiglycol acetate and thiodiglycol no decomposition by water could be detected by the conductivity method. Diphenylarsine chloride is instantly decomposed by water. Benzyl iodide is hydrolysed with extreme slowness, if at all, but with benzyl and xylyl bromide decomposition is somewhat more rapid. Iodoacetone and iodoacetic ester are quite stable, the iodine passing into the water from the latter substance originating from an impurity in the technical product.—G. F. M.

Ethylene; Catalytic reduction of —— to ethane. D. M. and W. G. Palmer. Proc. Roy. Soc., 1921, A **99**, 402—412.

The combination of hydrogen and ethylene in the presence of finely-divided nickel at temperatures of 73°—119° C. and at atmospheric pressure is preceded by an induction period, varying between a few seconds and three hours, during which there is very little combination; this is followed by a rapid increase in reaction velocity to a maximum and then a rapid falling off to a steady value. The induction period is reduced in a very marked way either by increase of the ethylene content in the gas mixture or by increase in the temperature, whilst the reaction velocity after the maximum has been passed is only very slightly affected by temperature. (*Cf.* J.C.S., Sept.)—J. F. S.

Copper; Catalytic activity of —— [in dehydrogenation of alcohols]. W. G. Palmer. Proc. Roy. Soc., 1921, A **99**, 412—425. (*Cf.* J., 1920, 674 A.)

The activity of copper as a catalyst in the dehydrogenation of ethyl alcohol and isopropyl alcohol does not necessarily increase continuously as the temperature of reduction from the oxide is lowered. The experimental results indicate that the active catalyst is the metal produced by the reduction of cuprous oxide. (*Cf.* J.C.S., Sept.)—J. F. S.

Alcohol and water; Sorption of —— by animal charcoal. J. Driver and J. B. Firth. Chem. Soc. Trans., 1921, **119**, 1126—1131.

The rate of sorption of water by purified animal charcoal is very slow, and it requires about 70 days to attain equilibrium, when 0·13 c.c. is sorbed per grm. of charcoal. In the case of alcohol, equilibrium is attained in about 37 days at a value of 0·62 c.c. per grm. From alcohol-water mixtures alcohol is preferentially sorbed throughout. The amount of alcohol taken up in a given period depends on the alcohol content of the mixture, increasing quantities of water reducing the rate of alcohol sorption. At the higher concentration, the charcoal finally becomes saturated with respect to alcohol, but where the alcohol content is below 25% the sorption becomes very small.—G. F. M.

Photocatalysis. Baly and others. *See* XVII.

Patents.

Aldehyde fatty acids and aldehydes; Process of making —— from mineral oils and their distillates. C. P. Byrnes, Assignee of J. H. James. E.P. 138,113, 22.1.20. Conv., 22.1.19.

A mixture of mineral oil vapour and air, with or without steam as diluent, is passed through a heated reaction zone, preferably in presence of a catalyst, at a temperature between 230° and 500° C., and the products are condensed. Suitable catalysts are the complex oxides of one or more metals of variable valency, *e.g.*, the "blue oxides of molybdenum" (containing MoO_2,MoO_3), uranyl vanadate UO_2,V_2O_5, and the like. The temperature employed depends on the nature of the mineral oil and catalyst, whether or not steam is used, the speed of the current of vapour mixture, and the proportion of aldehydes to acids required. In a test with a Pennsylvanian petroleum distillate (90% of which distilled between 250° and 340° C.) fed at 2·5 galls. per hr., with blue oxides of molybdenum on asbestos at 310°—320° C. as catalyst, 3·7 galls. of product was obtained in 2 hrs., containing 66% of aldehyde-fatty acids and 27·2% of aldehydes by volume.—J. H. L.

Acrolein; Manufacture of ——. C. Moureu and A. Lepape. E.P. 141,057, 31.3.20. Conv., 31.3.19.

Glycerol is allowed to flow in successive quantities or continuously on to a charge of potassium or other bisulphate preferably containing some normal sulphate, the reaction mass being maintained at about 200° C. and in agitation. The acrolein vapours are cooled to about 60°—90° C. to deposit less volatile matters, and then condensed. The product separates into two layers of which the one rich in acrolein is treated with sodium bicarbonate or the like and may be dried by means of a neutral desiccating agent. From 10 pts. of glycerol and 1 pt. of dehydrating agent, ⅔ of the theoretical yield of acrolein is obtained, the product being of over 90% purity and very stable.—J. H. L.

Vaccines; Manufacture of specific ——. Elektro-Osmose A.-G. (Graf Schwerin Ges.). E.P. (a) 150,328, 20.8.20, and (b) 150,334, 21.8.20. Conv., 23.8.19.

(a) Specific vaccines for active immunisation are prepared by subjecting suspensions of dead bacteria to a continuous electric current of medium current strength and comparatively low voltage, whereby the contents of the bacterial cells are liberated and dissolved. The filtered extracts, concentrated *in vacuo* if necessary, are employed as vaccines, or in some cases the bacterial residues, with or without the extracts, are employed. (b) The activity of vaccines prepared as above is rendered much more lasting by the presence of protective colloids, preferably soluble pseudoglobulins and albumins, and these may be derived from normal serum simultaneously with the production of vaccines in accordance with (a); *e.g.*, a suspension of dead bacteria in normal serum is subjected as above, to the action of a continuous current in an electro-osmotic 3-cell apparatus. By filtering from the bacterial residues and precipitated euglobulins a clear and very stable vaccine is obtained; but in certain cases the bacterial residues and the euglobulin may be employed with or without the extract. By employing a specific immune serum in place of a normal serum, vaccines may be obtained which confer passive as well as active immunity.—J. H. L.

Flavouring and perfumery extract. G. J. Esselen, jun., Assr. to D. and L. Slade Co. U.S.P. 1,378,099, 17.5.21. Appl., 5.6.20.

An essential oil or the like dissolved in an ester of glycerol and acetic acid.—J. H. L.

Acids [e.g., acetic acid]; Process of making substantially anhydrous organic ——. R. L. Andreau, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,381,782, 14.6.21. Appl., 31.10.19.

Sulphuric acid is added to a suspension of an acetate in paraffin oil, and the liberated acetic acid is recovered.—J. H. L.

Formaldehyde; Process of producing ——. G. C. Bailey and A. E. Craver, Assrs. to The Barrett Co. U.S.P. 1,383,059, 28.6.21. Appl., 26.5.20.

The vapour of methyl alcohol and a gas containing oxygen is brought into contact with an oxide of vanadium as catalyst at a temperature between 225° and 400° C.—F. M. R.

Arseno-compounds of the pyrazolone series; Production of ——. Farbw. vorm. Meister, Lucius, und Brüning. G.P. 313,320, 16.12.17.

Acidic groups are introduced into the amino-group of arsenodi-(1-aryl-2.3-dialkyl-4-amino-5-pyrazolone). For example, the sulphoxyl group is introduced by the action of aldehydesulphoxylate on 4-nitroso- or 4-nitro-1-aryl-2.3-dialkyl-5-pyrazolonearsinic acids. The arsenopyrazolone derivatives which contain a salt-forming acidic group, such as $-CH_2.COOH$, $-CH_2O.SOH$, or $-CH_2O.SO_2H$, in the 4-amino-group are only slightly poisonous but possess a powerful spirillocidal action. The products form yellow powders, insoluble in water and ether, soluble in dilute mineral acids and alkalis, and are used in the form of their stable alkali salts.
—F. M. R.

p-Hydroxyphenylurea; Preparation of ethers of ——. J. D. Riedel A.-G. G.P. 335,877, 12.3.19.

The carbamide of *p*-aminophenol is alkylated in the usual manner; for example, for the preparation of *p*-phenetolurea, *p*-hydroxyphenylurea is heated at 100° C. with alcoholic sodium hydroxide and ethyl bromide.—G. F. M.

Barium salts of formic acid and its homologues; Preparation of ——. Elektrochem. Werke G.m.b.H., H. Bosshard, and D. Strauss. G.P. 336,710, 30.5.18.

The barium salts of formic, acetic, propionic, and isobutyric acids are obtained from the corresponding calcium salts by allowing them to react with barium carbonate in the warm, either in presence or absence of carbon dioxide.—G. F. M.

Palmyra palm (Borassus flabelliformis); Preparation of a pharmaceutical product from the fruit of the ——. Schilling-Werk, G.m.b.H. G.P. 337,331, 19.7.19.

The cut, dried, and finely ground fruits, with the kernels, are pressed, and the residue is extracted with alcohol. The alcohol is distilled off, and the volatile oil in the extract is recovered by distillation and mixed with the oily extract and part of the fatty oils obtained from the original pressing of the fruit. The fruit itself may be dried and pulped, mixed with water, and treated with alcohol; the oil in the extract is distilled off, and the residue may be separated by pressing and mixed with the seeds, after which the processes of pressing and further treatment, as above, may be carried out.—W. J. W.

Silicic acid and silicic acid-emylodextrin; Preparation of stable colloidal solutions of ——. Lecinwerk E. Laves. G.P. 337,796, 16.3.19. Addn. to 323,596 (J., 1920, 802 a).

Solutions of colloidal silicic acid or of silicic acid-amylodextrin are stabilised by the addition of extremely small quantities of acids. The resulting solutions can be kept indefinitely. They are not changed by heat and do not gelatinise in presence of soluble salts.—G. F. M.

Thebaine; Preparation of a derivative of ——. E. Speyer and E., W., H., and L. Freund. G.P. 338,147, 22.6.15.

Thebaine in aqueous alcoholic solution, or its acetate in aqueous solution, is hydrogenised in presence of a colloidal metal of the platinum

group as catalyst, as, for example, colloidal palladium (1 c.c. = 0·0025 g. Pd). When absorption is complete the basic product is isolated by extraction with chloroform and remains as an oil after evaporation of the solvent. Purified by means of its hydrochloride it crystallises from alcohol in leaflets melting at 145°—150° C., and having the composition $C_{18}H_{23}O_3N$. It differs essentially in its properties from the tetrahydrothebaine, $C_{19}H_{25}O_3N$, described in the literature. Whilst this compound is precipitated from its salts by alkali hydroxide, the new base gives a precipitate which redissolves in excess of the reagent, and has therefore an acidic group. Further, whilst tetrahydrothebaine is readily decomposed by mineral acids, the new compound is stable. Its hydrochloride melts at 310° C. (with decomp.), is soluble in hot water, and slightly soluble in alcohol. The base contains only one methoxyl group, and has a ketonic character. It possesses medicinal value.
—G. F. M.

Sera; Preparation of innocuous —— from poisonous pathogenic micro-organisms. F. Ditthorn and W. Loewenthal. G.P. 338,166, 16.5.16.

The toxic substances present in the bacilli are absorbed by suspending, or preferably shaking, for 24 hrs., suspensions of the bacilli in 1—5% colloidal silicic acid. Examples are given of the preparation of dysentery, typhus, and cholera sera. The bacilli after treatment still retain to the full extent their immunising properties.—G. F. M.

Mercury compounds of glucosides; Manufacture of ——. O. Imray. From Society of Chem. Ind. in Basle. E.P. 163,874, 6.4.20.

See U.S.P. 1,354,105 of 1920; J., 1921, 163 a.

Ozonising substances [e.g., pinene]; Process of and apparatus for ——. E. W. Pattison. From General Research Laboratories. E.P. 166,211, 18.3.19.

See U.S.P. 1,297,716 of 1919; J., 1919, 437 a.

Copper catalysts. E.P. 166,249. *See* I.

Reduction of nitro-compounds. E.P. 166,283. *See* III.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic emulsions; Relation between sensitiveness and size of grains in ——. T. Svedberg and H. Andersson. Phot. J., 1921, 61, 325—332. F. F. Renwick. *Ibid.*, 333—335.

The methods previously adopted by Svedberg (J., 1920, 705 a) were applied in examining the effect on a photographic plate of α and β rays. A thin film, approximately one grain in thickness, was exposed to the action of a film of polonium, electrolytically deposited on a platinum plate, the number of α particles striking the plate being 50,000 per sq. cm. After development and removal of the silver image, the remaining halide grains were counted and measured in the microscope by the aid of an ocular micrometer. The results obtained are in agreement with the assumption that a grain is rendered developable by impact of one α particle, and the formula $P = 100(1 - e^{-A\nu t})$ expresses the relation between sensitiveness and size of grain in the case of α rays, where P is the percentage of grains of cross-section A made developable by exposure of time t to a bombardment of ν α particles per unit area per second. The effect of β rays, obtained from radium bromide, was examined in a similar way. The results show that impact of one or of two β particles on a grain does not as a rule make it developable, a more complicated relationship existing in this case than in that of α particles. It is suggested that the impact of a minimum number of grains in a maximum area of a grain may be required to render the grain developable, and that a similar law may hold in the case of light, assuming the quantum hypothesis.

Renwick suggests that Svedberg's method of obtaining a thin film, by dissolving the emulsion off a coated plate, diluting it, and re-coating, is liable to produce appreciable chemical fog, and that the possibility of incomplete development of halide grains may affect the accuracy of the percentage figures obtained in the counting. Experiments by other than statistical methods have given results supporting the view, apparently accepted by Svedberg, that there is no direct relation between grain size and sensitiveness. For instance, of two emulsions, of which photomicrographs are given, prepared under apparently identical conditions, one having grains of a large variety of size was only one-ninth the speed of the other, the grains of which were very uniform in size and small. The latter also was not a "process" type of plate, as it should have been if all grains of the same size in one emulsion had the same speed; for comparison a photomicrograph of a process plate is also given.
—B. V. S.

[Photographic] development; Effect of safranine on ——. W. Ermen. Brit. J. Phot., 1921, 68, 445—446.

Curves are given showing quantitatively the activating effect of Desensitol (safranine) treatment on subsequent quinol development, and its retarding action on metol-carbonate development, and still more on metol-sulphite development without carbonate.—B. V. S.

[Photographic] printing process; Suggestions for a ——. K. C. D. Hickman. Phot. J., 1921, 61, 338—345.

A description is given of a long series of experiments made with a view to obtain a print-out process by the aid of a dye which easily forms a colourless leuco-base. Methylene Blue is not sensitive to light, has a strong affinity for colloid substances such as organic fibres, and is easily changed by various reducing substances to a leuco-compound which has not the same affinity. Of light-sensitive substances forming a reducing substance by light-action, only ferric salts seemed promising for combination with the dye, and the most suitable appeared to be the oxalate, with which, however, a further reducing substance must be used to absorb the oxygen, which is one product of the decomposition of ferric oxalate by light. In preliminary experiments with solutions, trying a large number of reducing substances such as oxalic acid, tartaric acid, ammonium formate, etc., the greatest sensitiveness was obtained by use of ferric ammonium oxalate with ammonium oxalate and tartaric acid as reducers, but the results obtained were found to be inapplicable to coated paper owing to crystallisation of the salts on drying; for this purpose a solution containing ferric oxalate, potassium oxalate, oxalic acid, glycerin, gelatin, formaldehyde, and the dye was found to be the most satisfactory. Coated paper was less sensitive than the solutions, and complete bleaching by light action was not obtained until the paper was immersed in water. A satisfactory method of fixing the print was not obtained, no means being found for preventing the oxidation of the leuco-compound during washing, so that although a fairly strong positive could be obtained the whites were very degraded. The best fixing bath contained ammonium oxalate, oxalic acid, and charcoal.—B. V. S.

Sulphide-toning; Experiments on ——. E. R. Bullock. Comm. No. 116, Research Lab. Eastman Kodak Co. Brit. J. Phot., 1921, 68, 447—451.

A tabulated statement is given of the variation in tone produced by modifications in the indirect sulphide-toning process, in which a silver image is first converted to bromide by treatment in a ferricyanide-bromide solution, and then darkened in a sulphide solution, and in the direct toning process in which the silver image is converted to sulphide by treatment with a polysulphide solution. In the indirect process the modifications of the bleaching bath included changes in percentage composition, use of chloride and iodide in place of bromide, of thiocyanate, selenocyanide, and cobalticyanide in place of ferricyanide, and variations in time of treatment and amount of washing; the darkening bath was varied in percentage composition and by addition of other substances such as thiosulphate, potassium iodide, polysulphide, etc.; treatment in sodium carbonate solution before darkening was also tried. It is concluded that it is necessary to avoid either entire absence or excessive concentration of bromide in the bleaching bath, too prolonged washing between bleaching and sulphiding, excessive dilution of the sulphide solution, or the presence of a relatively large proportion of thiosulphate. Similar modifications were made in the polysulphide solution for direct toning, including the addition of thiosinamine and thiourea, the latter and thiocyanate having an accelerating effect on a bath containing 1% of pentasulphide and 0·05% of sulphide. It is concluded generally that both methods of toning are affected by the character of the emulsion on the paper, and by the degree of development; that the polysulphide process gives the same result as the "hypo-alum" process, while the indirect process gives a yellower tone, and that the method, often recommended, of giving a preliminary treatment in sulphide solution in the bleach process may give excellent tones but is apt to vary considerably in its results.—B. V. S.

Feeble conductors of electricity; A new property of ——. L. Amaduzzi. Comptes rend., 1921, 173, 222—224.

A repetition of Reboul's work (*cf.* J., 1921, 62 a, 196 a), in which the photographic plate and the feeble conductor, in this case a sheet of filter paper previously impregnated with a solution of nickel chloride or antimony oxychloride, were kept between the poles of a powerful electromagnet throughout the experiment. This magnetic field exerted a deforming action on the lines of impression somewhat similar to that on equipotential lines. The deformation corresponded to a rotation in the sense of the magnetising current for the antimony oxychloride and in the opposite sense for the nickel hloride.—W. G.

Patents.

[*Light-*] *sensitised metallic films or supports.* M. Werthen. E.P. 14,344, 15.6.14.

n order to prevent stripping of a sensitive film rom a metal support on which it has been coated, preliminary coating is given of gelatin, with otassium or sodium silicate, which may be ardened by treatment with formaldehyde or alum. —B. V. S.

atrices; Producing —— and colour-screens therefrom. I. Kitsee. U.S.P. 1,383,819, 5.7.21. Appl., 6.5.19.

n the production of a colour-screen on kinematoraph film, the film is coated with bichromated elatin, printed with fine lines with the aid of a ne-row templet, the hollows left after development lled in, and the alternate lines selectively coloured. —B. V. S.

Light-sensitive films. Badische Anilin- und Soda-Fabrik. G.P. 337,173, 21.12.19.

The light-sensitive substance is a compound of a *p*-diamine base, such as benzidine, and an acid dye, such as Eosin A, used preferably in the presence of the free base and an oxidising agent such as a nitrate, a chlorate, or picric acid. The picture is fixed by treatment with weak alkali solution, *e.g.*, borax, sodium phosphate, or barium hydroxide. —B. V. S.

[*Photographic*] *print-out paper; Preparation of a self-toning silver-chloride* ——. Kraft und Steudel, Fabr. phot. Papiere G.m.b.H. G.P. 337,820, 17.7.19.

A self-toning emulsion is obtained by the addition of 1 pt. of selenium dioxide dissolved in water and alcohol or of tellurous acid dissolved in a solution of lithium hydroxide in water and alcohol to about 800 pts. of a silver chloride emulsion, *e.g.*, a collodion emulsion. The selenium and tellurium may be used together or with a gold salt. The prints are fixed in an acid bath containing, say, 5% of sodium thiosulphate and 10% of potassium metabisulphite. A preliminary washing to remove the soluble chlorides affects the final tone.—B. V. S.

Selenium toning bath. Mimosa Akt.-Ges., Fabr. phot. Papiere. G.P. 337,869, 8.6.20.

If alkaline selenium-toning baths are partly neutralised with boric acid there is no precipitation of the selenium, and the baths then have no action on the skin or on the gelatin of the paper and do not colour the back of the paper. Addition of ammonia reduces the coloration of the whites of the pictures, which may be cleared by bathing in 10% potassium metabisulphite solution.—B. V. S.

[*Photographic*] *carbon prints; Preparation of permanent* ——. A. Nefgen. G.P. 338,185, 10.6.20.

The prints, before development, are treated with cold water, dilute alcohol, alkalis, or acids, or in some other suitable way in order to remove the chromium salt or to prevent its further action on the gelatin, and are then treated with sugar, glycerin, or soap to assist transfer and development, which are carried out in the usual way. —B. V. S.

Colour photography. W. Friese-Greene, Assr. to Colour Photography, Ltd. U.S.P. 1,383,460, 5.7.21. Appl., 31.1.21.

See E.P. 165,826 of 1919; J., 1921, 602 a.

Sensitising composition; Panchromatic ——. W. Friese-Greene. U.S.P. 1,383,620, 5.7.21. Appl., 8.7.19.

XXII.—EXPLOSIVES; MATCHES.

Patents.

Explosives; Manufacture of ——. W. Rintoul, T. J. Nolan, O. W. Strickland, and Nobel's Explosives Co., Ltd. E.P. (a) 166,277, (b) 166,502, 10.10.19.

(a) The hardening of granular, fibrous nitrocellulose powders may be effected by the use of a liquid or solid, non-volatile gelatiniser, either alone, or in conjunction with the use of a volatile solvent, the latter being in much smaller amount than when employed alone. The gelatiniser may be incorporated with the other ingredients; or may be sprayed over the wet or dry grains; or may be applied in a finely-divided condition to the wet grains; or may be sprayed in aqueous solution. The non-volatile gelatinising agents employed comprise: urethanes or esters of substituted carbaminic acids, substituted ureas, condensation products of glycerol and other polyhydric alcohols with aldehydes, homologues of oxanilic ester, non-volatile esters of organic acids or mixtures of these, and anilides or their homologues or mixtures thereof. (B) The gelatinising agents may consist of either liquid or solid hydrocarbons, *e.g.*, dinitrotoluene, and may be introduced as before, or in solution in an organic solvent. If solid, the gelatiniser may be mixed with a suitable non-volatile ingredient to lower its melting point.—W. J. W.

Explosives; Process for granulating ——. Fürstlich Plessische Miedziankitfabrik. G.P. 298,850, 14.4.16.

To assist the granulation of explosives without altering the physical or chemical properties of their constituents, they are treated at normal temperature with a liquid agent, *e.g.*, albumin, together with a substance, such as formaldehyde, which induces solidification of the liquid.—W. J. W.

Ammonium nitrate explosives; Manufacture of ——. Sprengstoff A.-G. Carbonit. G.P. (A) 305,059, 30.8.17, (B) 307,010, 15.8.17.

(A) Ammonium compounds prepared by interaction of ammonium salts with metallic nitrates, or halogen compounds, or salts containing water of crystallisation, are mixed, whilst in a melted condition, with substances which reduce their hygroscopicity and increase their explosive effect. Thus ammonium or potassium perchlorate is dissolved in fused mixtures of ammonium nitrate and calcium chloride, or sodium nitrate, or sodium chloride. Coal dust or a nitro compound is then added. (B) Ammonium compounds, *e.g.*, ammonium nitrate, are fused with salts containing water of crystallisation, such as sodium sulphate, or ignited salts, such as calcium chloride. Other suitable substances, *e.g.*, nitro compounds, may be added to the mixture.—W. J W.

Nitroglycerin explosives; Process for utilisation of waste ——. Westfälisch-Anhaltische Sprengstoff-A.-G. G.P. 337,382, 6.12.18.

By boiling with 1—10% sulphuric acid, the nitroglycerin in explosives containing it is decomposed, and the nitrocellulose may be recovered for other applications. The acid mixture resulting from the treatment may be used repeatedly, after partial neutralisation if necessary, and may ultimately be separated into its constituents.—W. J. W.

Nitroglycerin; Method of extracting —— from explosives. Westfälisch-Anhaltische Sprengstoff A.-G. G.P. 337,383, 14.4.20.

For nitroglycerin extractions in a Soxhlet apparatus, in addition to the solvent a liquid, *e.g.*, water, is used, which is immiscible with either nitroglycerin or the solvent and has a higher boiling point than the latter. The solvent in the flask forms a layer on the surface of the hot liquid and rapidly distils off; the nitroglycerin settles at the bottom and may be drawn off periodically, thus avoiding any undue accumulation in the apparatus.
—W. J. W.

Nitroglycerin powders; Conversion of military —— into blasting explosives. Zentralstelle f. Wissenschaftl.-techn. Untersuchungen G.m.b.H. G.P. 337,461, 26.9.19.

Nitroglycerin powders are steeped in an aqueous solution or emulsion of furfural, and the mixture is then incorporated with other suitable ingredients.
—W. J. W.

Smokeless propellent powders; Conversion of —— into blasting explosives. Köln-Rottweil A.-G. G.P. 337,495, 18.7.19.

Propellent powders of horny consistency are converted into a gelatinous condition by treatment with mononitro-compounds, *e.g.*, mononitrotoluene, nitrobenzene, or mononitroxylene, and may then be mixed with other suitable ingredients, such as ammonium nitrate.—W. J. W.

Nitric esters of glycol and its homologues; Production of ——. Chem. Fabr. Kalk G.m.b.H., and H. Oehme. G.P. 338,056, 16.7.18.

The product obtained by the nitration of gaseous olefines is treated with hydroxides, carbonates, or bicarbonates of the alkali or alkaline-earth metals in aqueous solution or suspension, by which means stable explosives consisting of glycol nitrates are produced.—W. J. W.

XXIII.—ANALYSIS.

Steam distillation; Apparatus for ——. E. A. Roff. Pharm. J., 1921, **107**, 28—29.

A small round flask containing the liquid to be distilled is closed with a cork through which pass a delivery tube and a steam-inlet tube; the latter reaches just above the cork and extends into the liquid in the flask. The lower end of the steam-inlet has the form of a perforated bulb. The flask is placed in a tin fitted with a lever lid and containing water; the delivery tube from the flask passes through a hole in the lid and is connected with a condenser. When the water in the tin is boiled, the steam enters the flask through the inlet tube and escapes, together with the vapour of the liquid, through the delivery tube and condenser. A safety-tube passes through a second hole in the lid of the tin. —W. P. S.

Analysis of gases; Apparatus for the industrial ——. G Andoyer. Comptes rend., 1921, **173**, 237—238.

A gas-measuring tube, graduated to 0·1 c.c. and water-jacketed, is connected at its bottom with a levelling vessel, and at its top by a capillary tube with a three-way tap, on the far side of which is sealed a small cup funnel, by means of which the absorbing reagent can be completely washed out of the tap after each absorption. This, with a number of simple Orsat absorption pipettes, a sparking pipette, and a combustion pipette, comprises the apparatus.—W. G.

Iron; Determination of small quantities of —— [*e.g.*, *in plant ashes*]. L. Maquenne. Bull. Soc. Chim., 1921, **29**, 585—587.

The plant-ash (0·01—0·05 g.) is moistened with nitric acid and calcined. To the residue 1 c.c. of 10% sulphuric acid is added, and the mixture is heated till white fumes are evolved. The residue is extracted with three drops of hydrochloric acid and two lots of 1 c.c. of water. Any calcium sulphate in the decanted liquid is removed by centrifuging. To the clear liquid are added a few drops of sodium phosphate and a slight excess of ammonia until a permanent precipitate is obtained. 1 c.c. of acetic acid is added, and the ferric phosphate, which remains insoluble, is separated by centrifuging, dissolved in three drops of hydrochloric acid, the solution diluted to 2 c.c. with water, and poured into a tube containing a few drops of potassium ferrocyanide. The iron is then estimated colorimetrically against standards.—W. G.

Mercury; Volumetric determination of ——. E. Biilmann and K. Thaulow. Bull. Soc. Chim., 1921, **29**, 587—592.

Two methods are described. An acid solution of the mercuric salt is treated with allyl alcohol, a few drops of phenolphthalein, and a slight excess of sodium hydroxide; the solution is then exactly neutralised with acid, 5 g. of potassium bromide is added, and the alkali liberated is titrated with standard acid. One atom of mercury is equivalent to 1 mol. of potassium hydroxide. The method is based on the reactions

$$C_3H_5OH+HgX_2=HX+(C_3H_5O)HgX;$$
$$(C_3H_5O)HgX+NaOH=(C_3H_5O)HgOH+NaX;$$
$$(C_3H_5O)HgOH+KBr=(C_3H_5O)HgBr+KOH.$$

For the second method the salt is dissolved in dilute acid, and the solution should be free from halogen ions and carbon dioxide. A few drops of phenolphthalein are added, and then an excess of sodium hydroxide. The solution is treated with dilute sulphuric acid until the red colour of the indicator just disappears, and then 5 g. of potassium iodide is added. The reaction occurring is $HgO+2KI+H_2O=HgI_2+2KOH$. The alkali liberated is titrated with standard acid.—W. G.

Antimony; Detection of —— *in presence of tin.* V. Njegovan. Chem.-Zeit., 1921, **45**, 681.

To detect antimony in presence of stannic chloride, in hydrochloric acid solution, as obtained in the course of group-testing for metals, 1 c.c. of the acid solution is partially neutralised with sodium carbonate, and then boiled for 1 min. with one or two drops of $N/2$ sodium thiosulphate solution. Antimonious chloride gives a red precipitate of oxysulphide and stannic chloride a white precipitate containing stannic sulphide and hydroxide. If the concentration of antimony in the solution is only $N/100$ and that of tin $N/2$, the precipitate will show a perceptible pinkish colour. Excess of thiosulphate should be avoided, since a slight pink colour is masked by the presence of much sulphur.—J. H. L.

Nitrogen in organic compounds; Detection of ——. C. D. Zenghelis. Comptes rend., 1921, **173**, 308—310.

A small amount of the substance is mixed with a mixture of soda-lime and copper powder (2:1) in a crucible, and the mixture is covered with a layer of soda-lime and copper powder. The crucible is covered with a watch-glass carrying on its undersurface a drop of the formalin-silver nitrate reagent for detecting ammonia (*cf.* J., 1921, 581 A) and on its top surface a little cold water. The crucible is heated on a quartz plate until drops of water begin to condense on the watch-glass, when it is put on one side. The formation of a silver mirror indicates the presence of nitrogen in the original substance. The method is very sensitive and rapid, requires only a very small amount of material, and is applicable to all classes of organic nitrogenous compounds.—W. G.

Sulphurous acid in organic substances; Volumetric determination of total —— *by the distillation method.* V. Froboese. Arbb. Reichs-Gesundh.-Amt, 1920, **52**, 657—659. Chem. Zentr., 1921, **92**, IV., 225.

The method of Haas (distillation in a current of carbon dioxide, oxidation to sulphuric acid, and gravimetric determination of the latter; Ber., 1882, **15**, 154) is modified in that the sulphur dioxide is absorbed in a known quantity of sodium bicarbonate solution, then oxidised with hydrogen peroxide to sulphuric acid and determined by titrating the excess of alkali with hydrochloric acid in presence of methyl orange. If necessary the sulphuric acid may afterwards be determined also as barium sulphate. No appreciable loss by oxidation of sulphur dioxide occurs during distillation even without carbon dioxide, but probably some oxidation occurs when the liquid is first heated. With a current of carbon dioxide, distillation of volatile acids may be prevented by using a long (reflux) cooling tube, and this is important in analysing wines. The method is suitable for sulphite-cellulose waste liquors, wines, dried fruits, and gelatin.—J. H. L.

Patents.

Specific gravity of gases; Apparatus for the continuous determination of the ——. L. Ubbelohde. E.P. 148,575, 10.7.20. Conv., 6.7.14.

The gas to be tested is sucked through a gas meter and then through a pipe provided with a nozzle or fine orifice. A standard gas, *e.g.*, air, is likewise drawn by the same suction device through a second gas meter and nozzle. The difference in the rates of passage of gas and air through the respective meters is conditioned by the specific gravity of the gas and is recorded by means of differential gear connecting the two meters.—J. S. G. T.

Specific gravity of gases; Balance for determining the ——. M. Arndt. G.P. 332,556, 25.6.18.

Two gas chambers communicate with one another by way of a tube containing the confining liquid. A tube filled with the gas the density of which is to be determined, is connected with one of the chambers in such manner that any change of density of the gas causes liquid to be displaced from one chamber to the other, owing to the altered pressure in the one chamber. The change in the position of the centre of gravity of the liquid is indicated by rotation of the device about a knife-edge. The apparatus can be used for the continuous indication of the content of carbon dioxide in flue gases.—J. S. G. T.

Gases; Determining the composition of ——. L. D. and A. Williams. E.P. 166,266, 1.10.19.

A combustible gas, more especially methane, in an atmosphere containing the same is determined by compressing the mixture under several atmospheres pressure prior to absorption or combustion of the constituent in question. The resulting pressure is determined by means of a gauge. Alternatively the combustion chamber may be enclosed in another chamber, communicating therewith by means of a differential pressure gauge, both chambers being filled with the gas under examination at the initial working pressure, and the difference in pressure measured after combustion. Any temporary increase in pressure due to heating of the gas in the combustion chamber is compensated by means of a heater disposed within a second similar chamber. Alternatively, the percentage of combustible constituent present may be determined by measurement of the volume change accompanying the combustion.—J. S. G. T.

Gas-analysis apparatus. W. L. De Baufre. U.S.P. 1,384,603, 12.7.21. Appl., 10.10.19.

The gas sample passes through a liquid seal into an extractor bell which rises and falls in a liquid seal. It is then subjected to the action of an absorbent during its passage to a measuring bell which also rises and falls in a liquid seal. The measuring bell is connected with a venting device attached to the extractor bell, and means are provided for adjusting the levels of the liquid seals during each cycle of operations.—H. Hg.

Gas and vapour mixtures; Apparatus for the determination of the components of —— yielding exothermic reactions. Badische Anilin- u. Soda-Fabrik. G.P. 333,498, 26.6.19. Addn. to 303,986 (J., 1920, 86 A).

In an apparatus of the type described in the chief patent the gaseous mixture is caused to flow over two pairs of thermo-junctions disposed in two planes having different temperatures, and arranged so that the resultant thermo-electric force in the circuit is increased.—J. S. G. T.

Carbon in ferrous metal; Process and apparatus for determining the amount of ——. W. E. Finkl. U.S.P. 1,382,072, 21.6.21. Appl., 16.6.19.

Carbon in ferrous metal is converted into carbon dioxide, which is absorbed in a dry mixture of finely divided alkali hydroxide and a fibrous material.
—C. A. K.

Polarisers of polarimeters, saccharimeters, and such like instruments. A. Hilger, Ltd., W. E. Williams, and C. F. Smith. E.P. 166,842, 18.10.20.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Arquint. Method of manufacturing heat insulations, and the insulations produced. 21,843. Aug. 17.

Boberg, Testrup, and Techno-Chemical Laboratories, Ltd. Heat treatment of matter for separating liquid therefrom. 22,161. Aug. 20.

Buch and Greff. Refrigerants and refrigerating. 21,605. Aug. 15.

Duffield and Longbottom. Method for drying divided matter. 21,655. Aug. 15.

Dunsmore and Robertson. Centrifugal machines. 22,561. Aug. 25.

Fahrni. Furnace installations. 22,354. Aug. 23. (Switzerland, May 19.)

Fairest. Grinding-machines. 22,316. Aug. 23.

Fothergill. Utilising exhaust steam for evaporating water. 22,352. Aug. 23.

Girouard and Jones. Pulverising or disintegrating machines. 22,382. Aug. 23.

Hauser and Kainer. Process for generating high temperatures. 22,356. Aug. 23.

Hill. Liquid-fuel furnaces. 22,601. Aug. 25.

Innocent. Furnaces. 22,752. Aug. 27.

Jones. Non-corroding anti-freeze mixtures. 22,329. Aug. 23. (U.S., 13.10.20.)

Kershaw. Apparatus for spraying or atomising liquids. 22,128. Aug. 20.

Lambert. Manufacture of absorbents of condensable gases and vapours. 21,926. Aug. 18.

Lodge Fume Co., Ltd. (International Precipitation Co.). 21,872. *See* XI.

Oehm. Production of high temperatures. 22,785. Aug. 27.

Pickett. Removal of sediment of heavy liquor from reservoirs etc. 21,950. Aug. 18.

Ricardo. Heating liquids. 21,697. Aug. 16.

Rigby. Scale-removing composition for boilers. 21,816. Aug. 17.

Robinson. 22,135. *See* XXIII.

Royal-Dawson. Apparatus for separating liquids of different densities. 21,770. Aug. 16.

Soc. Anon. pour l'Exploit. des Proc. M. Leblanc-Vickers. Refrigerating machines. 21,625. Aug. 15. (France, 16.10.20.)

Stehmann. Rotary calcining-furnaces. 22,703. Aug. 26.

Stein and Atkinson, Ltd. Re-heating furnaces. 21,728. Aug. 16. (France, June 16.)

Stein and Atkinson, Ltd. Heat-exchanging apparatus or recuperators. 22,691. Aug. 26. (France, June 23.)

Wallis. Annealing-kilns. 22,136. Aug. 20.

Complete Specifications Accepted.

3830 (1920). Griscom-Russell Co. Heat-interchangers. (138,870.) Aug. 24.

4320 (1920). Hislop. Drying-chambers. (167,512.) Aug. 24.

6227 (1920). Morison. Apparatus for filtering liquid. (167,519.) Aug. 24.

7912 (1920). MacLeod. Air-cooled or evaporative surface condensers. (167,803.) Aug. 31.

12,650 (1920). Wade-Milton, Hepworth, and Fuessly. *See* XIX.

12,922 (1920). Emerson. Apparatus for distillation or evaporation. (143,217.) Aug. 24.

13,055 (1920). Blom. Process for effecting condensation reactions. (167,582.) Aug. 24.

13,655 (1920). Fischbacher. Refrigerating-machinery. (167,858.) Aug. 31.

13,786 (1920). Sokal (Allis Chalmers Manufacturing Co.). *See* X.

15,023 (1920). Maxwell-Lefroy and Cheesman. Apparatus for spraying liquids. (167,634.) Aug. 24.

17,744 (1920). Mond (International Precipitation Co.). *See* XI.

17,896 (1920). Gibbs. Absorption refrigerating apparatus. (167,660.) Aug. 24.

23,615 (1920). Smits. Method of heating apparatus to any desired local temperature with even and uneven supply of heat. (149,983.) Aug. 24.

31,870 (1920). Velten. Apparatus for separating materials of different specific gravity. (159,163.) Aug. 24.

33,931 (1920). Penkala. Straining filters. (154,612.) Aug. 31.

287 (1921). Tafel. Centrifugal air-operated separating-machine. (156,253.) Aug. 24.

7815 (1921). Mattison, junr. Wet mixers. (168,010.) Aug. 31.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Bastian. Method of operating thermal storage apparatus heated by gas or oil flames. 22,167. Aug. 20.

Beasley, Broadbridge, and Edser. Production of briquettes. 22,507. Aug. 24.

Beasley, Broadbridge, and Edser. Production of coal briquettes. 22,508. Aug. 24.

Beasley, Broadbridge, and Edser. Production of coke. 22,524. Aug. 24.

Boysen. Means for utilisation of energy of exhaust gases of internal-combustion engines 21,631. Aug. 15.

Burke. Process of refining hydrocarbon oils. 22,238. Aug. 22.

Carpmael (Chem. Fabr. auf Aktien vorm. E. Schering). Process for manufacture of active charcoal. 22,514. Aug. 24.

Clarke. 22,522. *See* XXIII.

Dixon and Garton. Briquetting coal etc. 22,422. Aug. 24.

Farrer (Allgem. Ges. für Chem. Ind.). Purifying highly boiling fractions of mineral oils. 22,543. Aug. 24.

Foster. Gasification of coal etc. 21,597. Aug. 15.

Foster. Process of treating hydrocarbon oils. 22,370. Aug. 23.

General Electric Co. (Patent-Treuhand Ges. für Elektrische Glühlampen). 22,614. *See* X.

Goody. Water-vapour supply devices for gas-producers. 22,096. Aug. 20.

Healy and Hill. Device for indicating quality of gas generated in suction-gas plants. 22,673. Aug. 26.

Hearson, Holmes and Co., Shewring and Winstanley. Apparatus for gasification of coal etc. 22,137. Aug. 20.

Hill. 22,601. *See* I.

Jensen (Stone). Oil cracking. 22,803. Aug. 27.

Johnson (Badische Anilin- und Soda-Fabrik). Recovery of valuable products from coal-gases. 21,874. Aug. 17.

Jubany. Fuel for internal-combustion engines etc. 22,596–7. Aug. 25. (Spain, May 14 and 27.)

Marks (Hoover Co.). 22,270. *See* VII.

Marks (Hoover Co.). Process of refining oil. 22,271. Aug. 22.

Matthews and Yates, Ltd., and Yates. 21,957. *See* X.

Naaml. Vennoots. Phillips' Gloeilampen-Fabrieken. Electric incandescent lamps. 22,798. Aug. 27. (Holland, 2.9.20.)

Nishikawa. Process of manufacturing carbon filaments for incandescent electric lamps. 21,855. Aug. 17. (Japan, 12.9.20.)

Plauson's (Parent Co.), Ltd. (Plauson). Process of producing lower-boiling hydrocarbons from high-boiling hydrocarbons. 21,693. Aug. 16.

Wallace. Desulphurising oils and gases. 22,678. Aug. 26.

Complete Specifications Accepted.

4928 (1920). Harger. Lubricating oil and nethods of manufacturing the same. (167,789.) Aug. 31.

10,573 (1920). Trent. Treating carbonaceous naterial. (151,236.) Aug. 31.

12,894 (1920). Perry. Apparatus for distilling arbonaceous material. (167,822.) Aug. 31.

12,961 (1920). Krogh and Pedersen. *See* XXIII.

13,173 (1920). Wilford and Durrant. Motor uel. (167,831.) Aug. 31.

13,207 (1920). Thomas. Smoke-consuming and uel-economising apparatus for furnaces and the ke. (167,590.) Aug. 24.

22,754 (1920). Burckhardt. Means for ensuring omplete combustion of the coal used for heating eam boilers. (149,677.) Aug. 24.

26,789 (1920). Wilputte. Coke ovens. (151,278.) ug. 31.

III.—TAR AND TAR PRODUCTS.

Applications.

Burke. 22,238. *See* II.

Farrer (Allgem. Ges. für Chem. Ind.). 22,453. *e* II.

Foster. 22,370. *See* II.

Jensen (Stone). 22,803. *See* II.

Plauson's (Parent Co.), Ltd. (Plauson). 21,693. *See* II.

Complete Specifications Accepted.

12,650 (1920). Wade-Milton and others. *See* XIX.

18,114 (1920). British Cellulose and Chemical Manufacturing Co., and others. *See* XX.

IV.—COLOURING MATTERS AND DYES.

Applications.

Bate, British Dyestuffs Corp., Green, and Saunders. Manufacture of triarylmethane colouring-matters and intermediate compounds for use therein. 21,852. Aug. 17.

British Dyestuffs Corp., Green, and Saunders. Manufacture of soluble acid colouring-matters and intermediate compounds for manufacture thereof. 21,708. Aug. 16.

Jones and Keith. Disazo dye-stuffs. 21,791. Aug. 17.

Complete Specification Accepted.

19,693 (1920). Ransford (Cassella und Co.). Manufacture of vat dye-stuffs. (147,703.) Aug. 31.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Bray. Apparatus for treating wool etc. 21,800. Aug. 17.

Burland. Method of treating cotton etc. fabrics, paper, etc. 22,022. Aug. 19.

Wade (International Cotton Protecting Co.). Impregnating cotton bales. 22,608. Aug. 25.

Wade (International Cotton Protecting Co.). Impregnated cotton bales. 22,609. Aug. 25.

Complete Specifications Accepted.

13,297 (1920). Drut. Manufacture of artificial textile filaments, artificial films, or the like. (143,253.) Aug. 24.

13,541 (1920). Soc. Chim. Usines du Rhône. *See* VI.

13,842 (1920). Thunert. Manufacture of ornamental paper and composite paper and textile fabric. (153,276.) Aug. 31.

13,869 and 35,551 (1920). Commin. Production of plastic compositions containing fibrous or pulped materials. (167,613.) Aug. 24.

16,770 (1920). Howorth (Ayers). Process of method of cleaning fabrics. (167,929.) Aug. 31.

17,252 (1920). Kaye. Paper-making. (167,935.) Aug. 31.

17,777 (1920). Moeller. Process for the treatment of cellulose and products manufactured therefrom. (145,611.) Aug. 24.

19,521 (1920). Claviez. Manufacture of a textile material. (147,585.) Aug. 24.

20,050 (1920). Haddan (Waitz). *See* XIV.

755 (1921). Landraud. Paper-making machines. (156,711.) Aug. 24.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Deutsche Gold- und Silber-Scheideanstalt vorm. Roessler, and Schaidhauf. Process of bleaching. 22,512. Aug. 24.

International Textile Devices, Inc. Apparatus for dyeing tops, yarns, etc. 22,248. Aug. 22. (U.S., 15.10.20.)

COMPLETE SPECIFICATIONS ACCEPTED.

13,541 (1920). Soc. Chim. des Usines du Rhône, anc. Gilliard, P. Monnet, et Cartier. Dyeing of cellulose acetate, artificial silk, films, and the like. (150,989.) Aug. 24.

13,840 (1920). Pollak (A.-G. Seeriet Bleicherei). Process for producing wool-like or transparent effects on cotton fabrics. (167,864.) Aug. 31.

13,875 (1920). Lord. Apparatus for treating hanks of yarns with liquids. (167,868.) Aug. 31.

14,059 (1920). Denton. Apparatus for use in connexion with bleaching, dyeing, and like machines used in the textile industries. (167,621.) Aug. 24.

15,636 (1920). Bloxam (A.-G. für Anilin-Fabrikation. Process for dyeing skins, hairs, feathers, and the like. (167,910.) Aug. 31.

16,892 (1920). Bennert. Preparation of dyebaths. (145,519.) Aug. 31.

24,823 (1920). Callebaut and De Blicquy. Dye vats and like apparatus. (167,692.) Aug. 24.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Chem. Fabr. Rhenania, and Projahn. Process for manufacture of sulphur from sulphuretted hydrogen. 21,881. Aug. 17.

Deutsche Gold- und Silber-Scheideanstalt vorm. Rössler, and Herzog. Manufacture of sodium peroxide. 22,027. Aug. 19.

Hansford. Manufacture of neutral sulphate of ammonia. 22,645. Aug. 26.

Hart. Production of carbon. 22,460. Aug. 24.

Langheinrich. Purification of graphite. 22,170. Aug. 20.

Marks (Hoover Co.). Process of recovering aluminium chloride from spent or partly-spent catalysing-agent. 22,270. Aug. 22.

Paisseau. Process of manufacturing pearl essence. 21,781. Aug. 16.

Rushen (A.-G. B. Felder-Clement). Process for manufacture of tungsten carbides without free carbon. 21,662. Aug. 15.

Soc. L'Air Liquide, Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude. Synthesis of ammonia. 22,393. Aug. 23. (France, 20.11.20.)

Von Faber. Process for recovering iodine. 22,404. Aug. 23. (Holland, 28.10.20.)

COMPLETE SPECIFICATIONS ACCEPTED.

12,040 (1920). South Metropolitan Gas Co., and Parrish. Manufacture of ammonium sulphides. (167,540.) Aug. 24.

12,628 (1920). Matheson. Manufacture of alum and sulphate of alumina. (167,555.) Aug. 24.

22,595 (1920). Candlot. *See* IX.

22,655 (1920). Pfannenschmidt. Acid chambers, acid towers, acid mains, and similar arrangements. (149,667.) Aug. 24.

515 (1921). Holmes and Co., Boocock, and Wyld. Method and apparatus for recovery of ammonia from ammoniacal liquor. (167,719.) Aug. 24.

6783–4 (1921). Eustis. Method of and apparatus for recovering sulphur dioxide from furnace gases or other gases containing the same. (167,725–6.) Aug. 24.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Atkinson, and Stein and Atkinson, Ltd. Glass furnaces. 22,692. Aug. 26.

Cohen and Kann. Silvering glass. 22,604. Aug. 25.

Graham and Graham. Glass etc. furnaces 22,454. Aug. 24.

Hailwood. Glass-making machines. 22,100. Aug. 20.

Williamson. Ovens for firing pottery, bricks, tiles, etc. 21,787. Aug. 16.

COMPLETE SPECIFICATIONS ACCEPTED.

16,017 (1920). Adair. Drying of china clay and arrangements connected therewith. (167,917.) Aug. 31.

1029 (1921). Hartford-Fairmont Co. Method of and apparatus for feeding molten glass. (157,160.) Aug. 24.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Arquint. 21,843. *See* I.

Holzveredelung-Ges. Methods of treating wood. 21,963. Aug. 18. (Germany, 18.8.20.)

Wake. Rotary apparatus for drying road etc. material, calcining ores, etc. 22,062. Aug. 19.

COMPLETE SPECIFICATIONS ACCEPTED.

13,808 (1920). Crozier. Manufacture of cementitious articles. (167,610.) Aug. 24.

22,595 (1920). Candlot. Lime, cement, and like kilns. (150,994.) Aug. 24.

36,100 (1920). Mellersh-Jackson (Bitoslag Paving Co.). Paving mixtures. (167,997.) Aug. 31.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Atkinson, and Powdered Fuel Plant Co. Magnetic separators. 22,583. Aug. 25.

Dyson (Newton). Separation of gold from auriferous gravel etc. 22,346. Aug. 23.

I.—GENERAL; PLANT; MACHINERY.

Vacuum drying. C. O. Lavett and D. J. Van Marle. J. Ind. Eng. Chem., 1921, 13, 600—605.

Vacuum drying involves greater capital outlay in proportion to material handled than other methods and is therefore not suited to bulky materials of low value. Only the rotary drum type of vacuum dryer can be run continuously. Such advantages as low working temperatures, the complete control obtained, and the possibility of solvent recovery, however, make vacuum drying essential for many materials. Thermal efficiencies are high, as the only losses occurring are due to radiation, and the running costs are low. As high a temperature as can be allowed should be employed. For many materials a great capacity is required for the condenser if the vacuum is to be maintained; this is most easily obtained with the barometric type with injection of cold water. For the recovery of solvents other than water a surface cooling condenser must be used, and in such cases the exhaust of the vacuum pump should pass through a small additional condenser. The shelf vacuum dryer is more laborious to operate than other types, but is necessary for materials which cannot be agitated or which clog on drying. An even contact between the trays and hollow steel heating shelves is essential. Rotary dryers are more economical for materials which can be agitated, as they can be fed from a conveyor. They have also the advantage that the material can be cooled before exposure to the air. The vacuum drum dryer which is supplied with a continuous feed of a liquid suspension or solution, rendering a previous filtration or evaporation unnecessary, is an economic possibility because of the very high rate of heat transference to a film of liquid. Cost analyses for drying rubber in shelf and rotary dryers and sulphite-cellulose waste liquor in a vacuum drum dryer are given.—C. I.

Filtration; Study of the fundamental laws of —— using plant-scale equipment. F. P. Baker. J. Ind. Eng. Chem., 1921, 13, 610—612.

The rate of flow of a liquid through a filter-cake is expressed by the equation, $dV/d\theta = KA^2P^n/V^m$, where A is the area of filtering surface, P the pressure, and V the volume filtered; n is a constant depending on the nature of the cake, being 1 in the case of an incompressible material, and m is always in the neighbourhood of 1. A method by which m and thence n and K may be experimentally determined is given, and in an investigation of the filtration of defecated sugar solution to which kieselguhr had been added it is shown that in this case m=1 and n=about 2. The latter remarkable figure is due to the duplex nature of the material. For simple substances n is always less than 1. Experiments are described to show the advantage of working with constant flow rather than constant pressure, except with incompressible solids.—C. I.

Temperature; [Production of] uniform high —— throughout a large volume. E. F. Northrup. J. Ind. Eng. Chem., 1921, 13, 639.

A cylindrical crucible is made from an Acheson graphite electrode by turning, the wall of the rucible being 0·375 in. thick, the internal diameter in., and the depth 12 in.; a graphite lid fits over he crucible, and the latter is surrounded by a micanite jacket, the space between the two being acked with lampblack. The micanite jacket is urrounded by a water-cooled coil of about fifty urns of flattened copper tubing; a current of water is passed through the coil and maintains it at rdinary temperature. A high-frequency electric urrent of 60—100 amps. is passed through the copper coil. Under these conditions the interior of the crucible reaches 2000° C. within an hour, and this temperature is uniform throughout the interior. A graphite tube fitted into the centre of the lid serves as a sight hole for the optical determination of the temperature.—W. P. S.

Colloids; The Plauson [colloid mill] process for the production of —— and its technical application. A. Chwala. Oesterr. Chem.-Zeit., 1921, 24, 107—109.

The Plauson colloid mill (*cf.* Block, J., 1921, 169 A) is briefly described and its technical applications in various directions detailed. The mill can be applied to the recovery of oil from oil cake, fuller's earth, etc. Ozokerite is recovered from bituminous lignites by treatment of the lignite in the mill with 5—10 pts. of water. The mixture consists of two layers, a layer of crude bitumen and a layer of emulsified ozokerite. This is separated by the addition of a small quantity of strong acid. Other applications of the mill include the regeneration and refining of old rubber, oil refining and recovery of paraffin, the separation of paraffins, anthracene, carbazole, and naphthalene from oils, the production of sugar from sugar beet, the conversion of various hydrocarbons into saponifiable compounds, and the production of soaps. The nitration of cellulose may possibly be effected with an economy of material by the Plauson process. (*Cf.* Plauson, J., 1920, 589 A.)—J. S. G. T.

Patents.

Recovering solvents; Method of ——. G. P. Lunt. E.P. 139,488, 25.2.20. Conv., 7.4.16.

To recover a volatile solvent from a colloidal product, *e.g.* nitrocellulose or rubber, the material is heated in a current of inert gas, and the mixture of gas and solvent vapour is drawn through a cold liquid spray which condenses the vapour. The gas is then passed through a strainer and used again. —H. H.

Mercury vapour jet [vacuum] pump with arc. Siemens und Halske, A.-G. E.P. 157,118, 8.1.21. Conv., 3.10.19.

Mercury is boiled by an arc situated at the bottom of one limb of an inverted U-tube. The other limb converges to a jet at the top and continues as a water-cooled expansion chamber, into which air is drawn by the jet from the space to be exhausted and in which the mercury condenses. The air escapes through a side tube, and the mercury flows down a return pipe to the cathode of the arc, which is disposed in the centre of an annular anode. Since the evolution of mercury and heat from the anode is only small, the cathode will only occasionally overflow into the anode, and the outer wall of the tube will be protected from excessive heat. The rising limb of the U-tube is lagged by a portion of the series resistance for the arc.—B. M. V.

Gas reactions under high pressure; Device for effecting ——. K. A. F. Hiorth. E.P. 157,152, 8.1.21. Conv., 2.7.15.

The pressure is produced by the inertia of a liquid current, and the inlet and outlet pipes of the reaction chamber are covered by the liquid before or during the compression, which is thus effected wholly or partly in a valveless closed chamber. The flow of liquid may operate a turbine to be used for preliminary compression of the gases.—H. H.

Separating suspended bodies from electrical insulating gaseous fluids; Apparatus for ——. E. Möller. E.P. 164,014, 30.7.15. Conv., 31.7.14.

In electrostatic dust separators a liquid flushing agent is used to keep the discharge electrodes clean.

This liquid, if insulating, may be used as described in E.P. 17,840 of 1912 (J., 1913, 495 and 874), but if conducting, it must be supplied and led away by "drip-gaps," *i.e.* the stream of liquid must not be continuous, but must break into drops. The cleansing liquid may also be supplied to the discharge electrode, which if tubular may be enlarged at the bottom and provided with a gutter. The temperature of the separating field may be varied by a liquid supplied either as a flush, or in a jacket, to the non-active side of the collecting electrodes.
—B. M. V.

Moisture eliminators [for treating gases]. Heenan and Froude, Ltd., and G. H. Walker. E.P. 166,677, 17.4.20.

Air from which moisture is to be eliminated is passed in many separate streams through one set of baffles, where its velocity is increased, and its direction is then changed abruptly by another set of baffles, the passages between the second set being larger than those between the first. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 2025 of 1900, 3860 of 1902, 8208 of 1908, 25,821 of 1911, 10,577 of 1912, 493 of 1915, and 134,873; J., 1909, 510; 1920, 1 A.)—B. M. V.

Separation of gases. W. E. Davies. E.P. 165,816, 16.4.19.

A mixture of several gases of different densities is passed into a chamber provided with porous packing (brick, coke, charcoal) and divided into sections, one for each separable constituent.—B. M. V.

Pulverising apparatus. O. A. Kreutzberg. E.P. 166,471, 9.9.20.

A rotating table which is depressed towards the centre supports pulverising rollers upon its upper surface and drives them by friction only. The rollers run on axles radial to the table shaft, which can swing freely in a vertical plane, and are depressed by springs. The circumferential speed of the rollers is arranged not to be the same at all points on the line of contact as that of the table, so that some grinding action must take place, and if this is excessive the rollers may be subdivided, the sections of one roller being in staggered relation to the sections of its neighbours. The material to be ground is supplied to the centre of the table and after grinding is thrown off at the circumference where separation by air may be effected, the current of air being produced either by a separate fan or by vanes underneath the table.—B. M. V.

Cooling-towers or structures for cooling water and other liquids [; Spraying device for ——]. F. E. Gill, and The Davenport Engineering Co., Ltd. E.P. 166,790, 31.5.20.

In cooling-towers where, in order to prevent silting, the liquid is supplied through tubes pointing upwards, as described in E.P. 140,898 (J., 1920, 392 A), the jets of liquid are sprayed by stepped cones with their small ends downwards in the path of the jets, the diameter of the smallest step being preferably smaller than that of the jet.—B. M. V.

Tubular heat exchangers. C. A. Brown. E.P. 166,930, 19.3.20.

Tubes having their ends bulged in flat-sided hexagonal form are connected together. The tubes are arranged in staggered formation so that the stream of fluid passing between two tubes strikes against another tube and is divided. The spacing between the tube bodies in directions normal to the flow of the divided streams of fluid is less than or approximately one half of the spacing in the direction normal to the flow of the full or united half streams.
—H. H.

Dryer. P. G. Garza. U.S.P. 1,384,996, 19.7.21. Appl. 30.4.20.

Each of a series of rotating tapered drums, superposed and oppositely arranged, is provided at its larger end with a stationary head for delivering the material to the smaller end of the drum below it. Means revolving with each drum remove condensed moisture from the heads and direct it into a drain pipe communicating with the shaft of the drum. Saturated material is scattered broadcast within one drum, which is provided with a vapour outlet.
—H. H.

Dry-kiln. J. F. Hirt. U.S.P. 1,385,451, 26.7.21. Appl., 20.4.20.

A kiln has separate drying and air-heating chambers. Fresh air is added to the circulating air at a point where it will pass through the heating chamber first. Means are provided for increasing the humidity of the air before it enters the drying chamber and for varying the humidity of the air supplied to different parts of the kiln.—B. M. V.

Crystallisation of a melted mass of crystals; Method of preventing ——. G. E. Ferguson, Assr. to Pyrene Manufacturing Co. U.S.P. 1,385,075, 19.7.21. Appl., 27.9.17.

A mass of melted crystals and a melted substance of about the same melting point, but of lower specific gravity, are placed whilst hot in a container and then cooled, whereby the lighter substance solidifies and seals the mass of melted crystals, thereby preventing it from movement which might induce crystallisation.—B. M. V.

Retort. E. E. Quinker. U.S.P. 1,385,470, 26.7.21. Appl., 24.5.20.

The retort rests upon, and its middle portion is protected by, a base of refractory material with lateral extensions from which arches extend to the upper part of the retort. These arches cover longitudinal fire passages within which the sides of the retort are fitted with heat-conducting plates.—H. H.

Evaporator. H. G. Schwarz. U.S.P. 1,385,499, 26.7.21. Appl., 25.6.18.

An apparatus for concentrating liquids comprises two closed chambers disposed above and below a horizontal heating flue, the upper chamber having an opening for escape of vapour, and the lower chamber having an opening for discharge of concentrated liquid. The chambers are connected across the flue by circulation tubes and by heating tubes of smaller diameter, the latter being disposed forward of the former to shelter them from the hot gases.—H. H.

Valuable solution; Process of recovering —— from mixtures. L. D. Mills. U.S.P. 1,385,701, 26.7.21. Appl., 10.3.19.

Thick pulp is drawn off from the bottom of a settler, washing liquid is added to a portion of it, and the mixture pumped back into (not on to) the settled thick pulp.—B. M. V.

Condenser [for liquefying gases]. N. H. Hiller. U.S.P. 1,385,827, 26.7.21. Appl., 28.9.20.

An upflow condenser for readily liquefiable gases is constructed of a zigzag pipe, cooled by an external fluid, and having a vent for air at the top, and outlets for liquid at various levels leading to corresponding levels of a receiver from which the liquid is finally drawn off from the top.—B. M. V.

Lixiviating plant; Continuously-operated ——. Fellner u. Ziegler, and M. König. G.P. 334,356, 25.7.19.

A rotary stirring and feeding device provided with gliding planes, capable of adjustment during operation of the plant and serving to control the supply of material, is installed in a stationary housing, provided with a heating device. The leaching chamber proper is divided transversely by partitions into three parts; the material to be lixiviated traverses the middle chamber only, whilst the end chambers are provided with stirring and feeding devices. Leaching fluid is supplied to one of the end chambers, which is connected with a chamber to receive the residuum after draining, and also connected by way of this chamber and an opening for withdrawing the residuum, with the middle chamber, so that the leaching fluid passes through the warm residuum before entering the latter chamber.—J. S. G. T.

Filling material for washing and distilling columns. K. Bube. G.P. 337,284, 6.11.19.

Groups of unperforated metal plates alternately inclined in opposite directions are disposed within the column so that only the edges of the plates disposed in the direction of the stream passing through the column make contact with the walls of the latter. Free passage of the stream between the free ends of the plates and the walls of the column is prevented. The plates are provided with ridges transverse to the direction of the stream, and are disposed so close together that the ridges on any plate penetrate the surface of the liquid on the plate immediately below. Thorough mixing and turbulent motion of the stream are effected by the device. —J. S. G. T.

Filter; Rotary ——. E. Hene and B. Waeser. G.P. 337,843, 4.4.20.

The filter drum is divided into a number of compartments in each of which separation of liquor and sludge is effected. Liquor to be filtered is supplied to the first chamber and washing fluid to the last. The washing fluid is mashed with the sludge deposited in the last chamber but one, filtered off, again mashed with sludge and separated, in the next compartment, and so on, enriched washing liquor being finally recovered from the second compartment of the series, and thoroughly washed sludge deposited in the last compartment. —J. S. G. T.

Electrically separating dust from gases and vapours; Process of and apparatus for ——. W. North. E.P. 145,585, 29.6.20. Conv., 27.8.17.

See G.P. 314,014 of 1917; J., 1919, 887 a.

Cooling materials; Apparatus for ——. M. Mathy. U.S.P. 1,385,636, 26.7.21. Appl., 17.7.19.

See E.P. 139,383 of 1919; J., 1920, 310 a.

Separating substances of different dielectric capacities; Apparatus for ——. H. M. Sutton and W. L. and E. G. Steele. U.S.P. 1,386,287, 2.8.21. Appl., 24.9.04.

See E.P. 17,653 of 1905; J., 1906, 1105.

Filtering apparatus. R. Wüster. U.S.P. 1,386,340, 2.8.21. Appl., 2,8.20.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Lignites; Loss of combustible matter in the briquetting of ——. Berner. Chem.-Zeit., 1921, 45, 333—335.

With the moisture content of the raw fuel at 45% and that of the finished briquettes at 15%, the amounts of lignite necessary for 1 kg. of briquettes will be:—Briquette fuel, 1·546; loss due to dust, 0·046; coal for drying, 0·275; giving a total of 1·867 kg. Of this the fuel consumed in the factory is 0·321 kg. or 17·2%. With raw fuel containing 60% moisture, the fuel in the briquettes is 2·125 kg., loss of dust 0·064, fuel for drying 0·892, total 3·081, of which 0·956 kg. is consumed in the factory, or 31·0% of the total. Figures are given for the loss of heat from the gases of combustion with raw coal and with briquettes, and for the economy in transport, handling, etc., resulting from the conversion of the coal into briquettes. With 45% moisture in the raw fuel, this amounts to 9·3% for a transport distance of 200 km., against 17·2% of fuel used in the factory, whilst with 60% moisture in the raw lignite the economy is 22·7%, as against 31·0% used in the factory. The actual loss of fuel in the two cases is therefore 7·9% and 8·3% respectively.—A. G.

Steaming in vertical gas retorts. Report of Fuel Research Board, 1920—1, First Section. 54 pp.

See J., 1921, 333 r.

Blue water-gas installation at Birmingham. Sixth Report of the Research Sub-Committee of the Gas Investigation Committee of the Inst. of Gas Eng. Gas J., 1921, 154, 619—627, 672—676.

The thermal efficiency of various water-gas plants has been calculated by different investigators, the results varying from 42%, in Stewart's calculation, made from tests by A. G. Glasgow in 1890, to 59% in the case of tests carried out by W. A. Bone on a Kramers and Aarts' plant. No complete tests, including measurements of the power required for raising steam and driving the blower, in plant specially designed for blue gas, appear to have been made. The Committee, therefore, decided to carry out such tests. The results are expressed per ton of coke and also per ton of ash-free, dry coke, and details are given of the pressures, temperatures, etc. on the plant, and of the composition of the coke, ashes, clinker, and dust. Balances are given for the water consumed, for carbon, nitrogen, and sulphur, and also for the heat supplied, expressed as therms per 1000 cub. ft. of water-gas made and as percentages of the total heat. The thermal efficiency of the plant, taking into account the fuel for steam for generator and turbine, is given as 45·8%, 46·7%, and 46·4% in three different tests, whilst the corresponding efficiencies, neglecting the heat required for steam for the generator and turbine, are given as 55·2%, 55·9%, and 56·5%. Particulars are also given of the composition of the water-gas at various stages of the process, and of the proportions of steam decomposed at these stages. The amount of hydrogen sulphide present in the gas at various stages was recorded, together with particulars of the composition of the blow-gas. —A. G.

Gasification of coal dust. K. M. Balley. Chem.-Zeit., 1921, 45, 789—790.

The coal dust is carried by means of a current of superheated steam into contact with surfaces (coke, chequerwork) heated to 1400°—1600° C., whereby the coal dust is carbonised and the residual coke converted into water-gas. 1·65 cub. m. of gas of calorific value 4100 Cals. was obtained from 1 kg.

of coal of calorific value 7650 Cals. per kg. Two forms of apparatus for carrying out the process are described.—W. P.

Lignite; Influence of drying —— on the yield of low-temperature tar produced on subsequent carbonisation. F. Seidenschnur. Brennstoff-Chem., 1921, 2, 241—244.

WITH a lignite containing 37·5% of moisture the effect of drying in the steam oven to 15% moisture content was to reduce the tar yield to 99·2% of that from the raw fuel. After drying in the air oven to 15% moisture content the tar yield was 98·9%, and after complete drying at 105° C. in the air oven 95·0% of that from the raw fuel. With another lignite containing 54·8% of moisture the corresponding figures were:—After air-drying to 24% moisture, 93·5%; after drying to 7·5% moisture in the steam oven, 93·5%; after drying to about 15% moisture in the drying oven, 92·9%; and after complete drying at 105° C., 94·1%. The experiments were carried out in a gas-heated iron tube, through which carbon dioxide was passed, and the amounts of tar are calculated as anhydrous material.—A. G.

Lignite; Importance of the water-soluble ash in the utilisation of ——. T. Limberg. Feuerungstech., 1921, 19, 205—207.

THE water-soluble constituents of lignite ash consist mainly of sodium sulphate with a trace of sodium chloride. On distillation of the lignite the sodium sulphate is dehydrated and some passes on in powder form with the gases, to be deposited on the retort sides and in delivery tubes. The sodium sulphate layer lowers the conductivity of the walls of the retorts and its action is deleterious. Slags are also formed with the insoluble constituents of the ash. For briquetting the lignite must be dried, and subsequent absorption of water by the dehydrated sulphate leads to the disintegration of the briquettes.—W. P.

[Oil] shales; Thermal decomposition of ——. R. H. McKee and E. E. Lyder. J. Ind. Eng. Chem., 1921, 13, 613—617.

SAMPLES of a Colorado oil shale were heated in a bath of molten lead at a series of temperatures between 370° C. and 430° C., and the yields, in a given time, of light products and semi-solid bitumen, soluble in carbon bisulphide, determined. The results obtained tend to show that the latter is the primary product of decomposition of the shale, being formed at 400°—410° C., and that the light products are produced by cracking.—C. I.

Hydrocarbon oil; Preparation of —— from a vegetable oil. A. Mailhe. Comptes rend., 1921, 173, 358—359.

WHEN linseed oil is passed over a mixture of electrolytic copper and magnesia at 550°—650° C. and the more volatile products are hydrogenated a mixture of aromatic and cyclic hydrocarbons is obtained. In the mixture benzene, toluene, xylene, cyclohexane, and methylcyclohexane were identified. The product may be separated into an artificial petroleum spirit of sp. gr. 0·7607 at 23° C. and a burning oil of sp. gr. 0·8644 at 21° C.—W. G.

Gasoline and certain other substances; Calcium chloride method for the determination of water in ——. C. W. Clifford. J. Ind. Eng. Chem., 1921, 13, 628—631.

A CURRENT of dry air is bubbled through the gasoline at the rate of 5—15 l. per hr. for 1—2 hrs., and the air is passed through two calcium chloride tubes; dry air is then passed directly through the calcium chloride tubes at the rate of 5 l. per hr. for at least 1 hr. to displace vapour from the tubes before these are weighed. The method may also be used for the determination of water in benzene, chloroform, carbon tetrachloride, carbon bisulphide, sugar, zinc oxide, flowers of sulphur, and rubber stock, but cannot be applied to acetone, pyridine, alcohol, or glycerol.—W. P. S.

Gasoline; Solubility of water in —— and in certain other organic liquids. C. W. Clifford. J. Ind. Eng. Chem., 1921, 13, 631—632.

AT 25° C., 100 g. of gasoline (sp. gr. 0·70; b.p. 40°—145° C.), saturated with water, contained 0·0085—0·0110 g. of water; at 37·5° C., saturation was reached with 0·0121—0·0175 g. of water. The water was determined by the calcium chloride method (preceding abstract) and all was removed when about one-fourth of the volume of the gasoline had been evaporated by the current of air. The solubility of water in other organic liquids (in g. per 100 g. of solution) was found to be as follows:—Benzene, at 21·0° C., 0·046; 26·6° C., 0·056; 42·0° C., 0·088; 55·0° C., 0·113. Chloroform, at 24·5° C., 0·084; 26·7° C., 0·107; 27·8° C., 0·116. Carbon tetrachloride, at 24·0° C., 0·010; 28·5° C., 0·013. Carbon bisulphide, at 25·0° C., 0·010; 27·0° C., 0·012. —W. P. S.

Lubricating greases; Determination of the composition of ——. J. Marcusson and H. Smelkus. Petroleum, 1921, 17, 818—819.

THE grease is extracted in the cold with acetone, which removes water and the fatty portion. Soaps and inorganic material remain. If viscous mineral oils are present the grease should be extracted in a Soxhlet apparatus, calcium chloride being added to the acetone in the flask. The last traces of fatty matter may be extracted with a mixture of acetone and benzine (2:1). Hot extraction must also be used if montan wax is present. To distinguish between montan wax and animal and vegetable fats, the fatty acids are separated and tested for consistency, m.p., and molecular weight. The acids from montan wax are hard, melt at 73°—77° C., and have a mean molecular weight of 460. Raw montan wax may be distinguished from distilled montan wax by saponifying the acetone-soluble portion, and treating the unsaponifiable matter by Holde's method for the estimation of paraffins. If raw wax was present, wax-alcohols and ketones will be found. Since the war the following substitutes have been found in lubricating greases:—magnesium chloride and hydroxide, calcium chloride and sulphate, sodium chloride, and a yellow organic dyestuff giving the reactions of Metanil Yellow. Another sample consisted of 75% of mineral oil and 25% of concentrated sulphite-cellulose waste lye. —H. C. R.

PATENTS.

Coke ovens. American Coke and Chemical Co., Assees. of A. Roberts. E.P. 138,127, 21.1.20. Conv., 12.8.19.

A SINGLE heating wall is provided between consecutive retorts, and is constructed of notched bricks arranged so as to allow the passage of the heating gases, and at the same time to neutralise the side thrusts exerted on the sides of the retorts.—W. P.

Coke ovens. American Coke and Chemical Co., Assees. of A. Roberts. E.P. 147,531, 21.1.20. Conv., 11.7.19.

THE coke ovens are provided with heating walls and recuperators, so that each oven forms a separate and complete unit. The spent gases from the heating walls are collected in a common passage, and pass through a number of openings into two short passages, and thence through ports into the recuperators.—W. P.

Coke ovens. C. Otto und Co., G.m.b.H. E.P. 155,828, 22.12.20. Conv., 27.12.19.

Heating gases and air for combustion are led separately through horizontal ducts to the vertical flues in the heating walls of the ovens. The heating flues are arranged alternately with flues which return the burnt gases to the lower part of the chamber walls.—W. P.

Distillation furnace. J. N. Wingett, Assr. to American Shale Refining Co. U.S.P. 1,384,878, 19.7.21. Appl., 19.7.17.

The retorts and combustion chambers are superposed alternately. Horizontal plates are placed between adjacent chambers, and between the walls and linings of each chamber, for insulating purposes.—W. P.

Gas producers. E. Hilger. E.P. 150,267, 16.8.20. Conv., 16.8.19.

The gas producer has a grate and shaft which rotate in the same direction at speeds which can be varied relative to one another. To enable the discharge of the slag to be discontinued, the movement of the grate is stopped and the shaft continues to rotate alone, while the grinding and stirring of the fuel continues.—W. P.

Gas producer plant and gas engine plant supplied therefrom. H. J. Read and W. J. Bransom. E.P. 166,969, 24.4.20.

By means of a mechanical feeder and a double valve device the supply of fuel to the producer is regulated automatically in accordance with the consumption of gas by the engine.

Gas for lighting or heating purposes from bituminous fuels; Process of manufacturing ——. C. W. Botsford. U.S.P. 1,385,167, 19.7.21. Appl., 13.6.19.

The ignited coal is blown with a regulated proportion of air for partial combustion, and part of the gas is burnt in a second chamber for heating the retorts, which are steam-blown; the water-gas thus formed is carburetted and mixed with the gas from the air-blown retorts.—W. P.

Gas producers; Production of readily fusible slag in ——. Eisenwerk Jagstfeld G.m.b.H. G.P. 338,037, 11.4.18.

After the slag has been run off it is mixed with a ubstance, such as lime, and returned to the proucer, in which the lime then combines with silicic icid in the coke-ash and thus produces a readily usible slag.—W. J. W.

Hydrogenation of hydrocarbons. R. Tern. G.P. 336,334, 24.12.18.

Metallic iron prepared by electrolysis is used as a atalyst in the hydrogenation of petroleum residues. eavy tar oils, and asphalt. Petroleum residues and ydrogen in presence of the catalyst are subjected o a temperature of 250° C. and a pressure of 20 tm. for 6 hrs. Iron prepared by electrolysis of ron salt solutions with platinum electrodes is more ctive and has a stronger resistance to poisons than hat prepared by reduction of iron compounds. —C. A. C.

ineral oils; Treatment of —— for use in switches and transformers. H. Rebs. G.P. 336,342, 2.5.17.

ne oils are treated with about 20% of a solvent for e contained sediment, *e.g.*, naphthalene, methyl lcohol, pyridine, anthracene, creosote, or oil of urpentine.—W. J. W.

Fuel for explosion engines. Haschko-Werke, Eberhard und Jacob, Chem. Fabr. G.P. 338,201, 3.9.19. Addn. to 319,893 (J., 1920, 565 a).

Instead of coal-tar hydrocarbons petroleum distillates (b.p. up to 300° C.; sp. gr. above 0·75) may be mixed with acetic esters; or distillates from lignite tar (b.p. below 300° C.; sp. gr. 0·8) may be employed.—W. J. W.

Lubricants, especially substitutes for cylinder oil; Manufacture of ——. H. W. Klever. G.P. 301,773, 10.6.16.

The solid residues from the distillation of tar oils (*e.g.*, coal-tar pitch), mineral oils, resin oils, or the bitumens of lignite, coal, or shale (if necessary after purification) are treated with hydrogen under pressure at high temperatures in presence of catalysts, such as the heavy metals, the metals of the alkalis, alkaline-earths, and earths, and their compounds, as well as carbon, graphite, fullers' earth, and the like. The high-boiling fractions of tar oils, resin oils, and artificially thickened tar oils may also be subjected to this treatment. Before hydrogenation such substances as sulphur and the like must be removed by extraction or by distillation under high vacuum and by heating in presence of finely-divided metals, preferably in hydrogen under pressure. After separation from the lower-boiling fractions by distillation or steam distillation the products may be used as lubricants for bearings. —C. A. C.

Lubricating oils; Manufacture of stable, highly viscous ——. H. Klever. G.P. 337,157, 27.1.15.

Solutions of metal salts of fatty and resin acids in mineral oils are rendered stable by admixture of organic substances of high boiling point, *e.g.*, alcohols. To a solution of aluminium oleate in spindle oil 0·5 to 1% of benzyl alcohol, cyclohexanol, hydrogenated crude cresol, terpineol, benzyl acetate, benzyl ethyl ether, acetone oil, cyclohexanones or the like may be added. The high viscosity of the oils obtained falls only slightly with rising temperature and hardly changes on keeping. —C. A. C.

Artificial asphalt; Manufacture of ——. Harburger Chem. Werke, Schön und Co., and W. Daitz. G.P. 336,603, 26.5.18.

The bituminous and resinous residues obtained in the treatment of crude mineral oils and their distillates are neutralised with a mixture of burnt magnesia and water. The salt solution is separated from the resulting soft pitch, which is then blown with compressed air at 130°—170° C. for 20—60 hrs. until it has lost its stickiness, and becomes elastic and flexible, and yet capable of being sprayed. —C. A. C.

Gasoline; Process for cleaning ——. De Laval Separator Co., Assees. of M. Leitch. E.P. 142,859, 6.5.20. Conv., 23.9.18.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Ocotillo and the like; Apparatus for distilling ——. S. M. Darling. U.S.P. 1,384,939, 19.7.21. Appl., 21.2.19.

THE vapours evolved on distillation are passed through a condenser and the uncondensed gases are returned to the heated mass at the hottest part of the retort.—W. P.

Charcoal; Process for producing dense absorbent ——. L. F. Hawley. U.S.P. 1,385,826, 26.7.21. Appl., 3.4.19.

FINELY divided wood is pressed into blocks under a pressure of at least 30,000 lb. per sq. in. and distilled while under a mechanical pressure of at least 100 lb. per sq. in., yielding charcoal of sp. gr. at least 0·95.—B. M. V.

Decolorising carbon; Retort for the manufacture of ——. A. Scholz. G.P. 336,797, 15.6.19.

THE material is contained in the retort in several separate pipes closed at the bottom by perforated conical pieces which can all be opened by a common lever, and which project into the tubes so that the heating gases can pass through the perforations and come in contact with the charge in the lowermost part of the retort.—C. A. C.

Distillation of coal. F. Fischer. E.P. 146,287, 24.6.20. Conv., 13.11.16.

SEE G.P. 299,191 of 1916; J., 1920, 56 A.

III.—TAR AND TAR PRODUCTS.

Tars; Composition of high- and low-temperature ——. H. Tropsch. Brennstoff-Chem., 1921, 2, 251—252.

THE author has examined a low-temperature tar from an Upper Silesian coal, by the method of Marcusson and Picard (J., 1921, 462 A). The tar was thin, dark brown and, in thin films, yellowish brown. Its sp. gr. at 15° C. was 0·964 and its moisture content 0·5%. In 5N caustic soda solution, 34% of the tar was soluble, and a distillation test gave the following results:—Distillation commenced at 72°, 3% to 100°, 6% to 140°, 8% to 160°, 12% to 180°, 18% to 200°, 27% to 220°, 34% to 240°, 41% to 260°, 48% to 280°, 53% to 300°, 59% to 320°, 65% to 340°, and 70% up to 360° C. The residue was yellowish brown and viscous. The fraction up to 280° (48% of the tar) contained 30·4% and the fraction 280°—360° (22% of the tar) contained 32% of alkali-soluble components. 50 c.c. of the crude tar was heated on the water bath with 50 c.c. of 5N NaOH for half an hour, with continuous shaking, then diluted with 200 c.c. of water, and the portion insoluble in alkali separated with ether. After evaporating the ether, the alkaline solution was acidified with hydrochloric acid and a black, viscous oil separated which was almost completely soluble in ether. After filtration there remained only 0·6% by weight of the tar as a solid brown substance, insoluble in ether. The author concludes that the low-temperature tar examined by Marcusson and Picard could not be described as a normal low-temperature tar.—A. G.

Lubricating oils; Preparation of viscous —— from coal tar. F. Schreiber. Z. angew. Chem., 1921, 34, 425—426.

EARLIER attempts to prepare viscous lubricants from crude anthracene oil or mixtures of this with mineral oils led to products which, besides having a comparatively low viscosity, had also a tendency to deposit crystals of anthracene, phenanthrene, etc., particularly in cold weather. These and other drawbacks are overcome by subjecting the anthracene oil lubricant to a dehydrogenising process by means of sulphur (*cf.* G.P. 330,970, J., 1921, 339 A). All the sulphur employed is eliminated as hydrogen sulphide, and the hydrocarbons undergo condensation to non-crystalline products of high viscosity, which have no tendency to separate out from the oil. The product is almost odourless, and is claimed to be superior to mineral oils in lubricating properties. It has the following characters:—Sp. gr. 1·14, flash point about 170° C., viscosity at 50° C. about 4·5° Engler, solidif. pt. about −15° C., distillation to 300° C. 0%, to 340° C. 40%, to 400° C. 80%, to 430° C. 95%.—G. F. M.

Quinone; Electrolytic oxidation of benzene to ——. H. Inoue and M. Shikata. Kōgyō-Kwagaku Kwai Shi (J. Chem. Ind. Japan), 1921, 24, 567—590.

BENZENE is electrolytically oxidised to quinone under the following conditions:—Cathode solution, 10 g. of benzene and 100 c.c. of 4% sodium sulphate; cathode and anode, lead plates; current density, 2—3 amp. per 100 sq. cm.; voltage of cell, 3—5 volts; total sum of the electric current, 30 amp.-hrs.; temperature, 20° C. By agitating the anode solution the yield of the product is increased up to 77% of the benzene used, whilst by using 5% sulphuric acid instead of 2% acid for the cathode solution and addition of 1 g. of sodium acetate to the anode solution the yield is increased to 81·5%.—K. K.

Nitrogen in nitronaphthalenes; Modification of the Dumas method and the application of the Kjeldahl method to the determination of ——. P. H. M.-P. Brinton, F. M. Schertz, W. G. Crockett, and P. P. Merkel. J. Ind. Eng. Chem., 1921, 13, 636—639.

IN the modification of the Dumas method described, the carbon dioxide used is generated in a large container by the action of dilute sulphuric acid on sodium carbonate solution, these being admitted in regulated quantities to the container, which, at the commencement, is filled with water. Before entering the combustion tube, where the substance is heated in the usual way with copper oxide, the carbon dioxide is passed through a measuring device consisting of two bottles of known capacity, one filled with water; by suitable connecting tubes and three-way taps the water is forced alternately from one bottle to the other by the pressure of the carbon dioxide; it is necessary to know the volume of carbon dioxide introduced to the combustion tube in order to make allowance for the small quantity of other gases almost invariably present. The carbon dioxide and nitrogen from the combustion tube are collected in three nitrometers charged with sodium hydroxide solution and interconnected with each other; the gases enter the bottom of the first nitrometer and leave at the top through a tube connected with the next one; the current of gas causes a portion of the sodium hydroxide solution to pass from one nitrometer to the next, and this is collected in the levelling bulbs and returned as required. One of the nitrometers is provided with a water-jacket and serves for the final measurement of the nitrogen. To determine nitrogen in nitronaphthalenes by the Kjeldahl method, 0·5 g. of the substance is heated for 2 hrs. on a water-bath with 30 c.c. of sulphuric acid and 2 g. of salicylic acid; after cooling, the mixture is treated with 2 g. of zinc dust, set aside overnight, then heated for 1 hr. on a water-bath and next over a small flame until all visible action is over. The mixture is cooled. 1 g. of mercury is added, the mixture boiled for 1 hr., 7·5 g. of potassium sulphate is then added and the boiling continued for 1 hr. Sodium sulphide and a small quantity of zinc dust are added in the subsequent distillation of the ammonia. The results obtained are always low, the deficit increasing regularly with the nitrogen content; for example, 13·74% of nitrogen found by the Kjeldahl method corresponds with 14·33% by the Dumas method, 14·14% with 14·93%, and 15·48% with 16·85%. A graph is given for obtaining the true nitrogen content of a nitronaphthalene from the result of the Kjeldahl determination.—W. P. S.

Pikamar. Mauthner. *See* XX.

Patents.

Tar, oils, etc; Process and apparatus for dehydration and distillation of ——. Façoneisen-Walzwerk L. Mannstaedt und Co., A.-G., and H. Bansen. G.P. 336,772, 18.2.19.

For the distillation of tar by means of a current of heated gas the retort is provided with a revolving fan or similar device which atomises the material and brings it into intimate contact with the gas.
—W. J. W.

Tar; Process for distilling lignite producer-gas ——. F. W. Klever. G.P. 337,784, 30.9.16.

The tar is heated in a current of gas or steam to the boiling point of water, under gradually increasing vacuum, whereby the water is separated. The vacuum is then interrupted, the temperature is raised, and the vacuum again increased gradually in order to expel any water formed by decomposition of the tar, after which the actual distillation of the tar is carried out under a high vacuum.
—W. J. W.

Azo-compounds and nitro-compounds; Process for the reduction of aromatic ——. T. S. Moore. E.P. 165,838, 18.7.19.

Aromatic azo-compounds and nitro-compounds are reduced to amines by the action of a relatively large quantity of iron filings or borings in presence of water and a relatively small quantity of sulphur dioxide, considerably less than would be required to generate a quantity of hydrosulphite sufficient to effect the reduction. The reaction may be successfully applied to obtain *p*- and *o*-aminophenols from the corresponding nitrophenols, or the former from sodium *p*-hydroxyazo-benzene-*p*-sulphonate, 2.4-diaminophenol from dinitrophenol, *o*- and *p*-phenylenediamine from the corresponding nitranilines, anthranilic acid from *o*-nitrobenzoic acid, etc. *Example.* *p*-Nitrophenol is reduced by mixing with 4 pts. of iron and 5 pts. of water, and gradually adding during 1 hr. 0·2 pt. of sulphurous acid in aqueous solution. When reduction is complete sodium carbonate and sulphite are added and the boiling solution filtered from the iron sludge. The *p*-aminophenol crystallises out from the filtrate, and a second crop is obtainable by evaporation of the mother liquor, the total yield amounting to about 80% of the theoretical.—G. F. M.

Halogenating hydrocarbons [*toluene etc.*]. C. C. Loomis, Assr. to Semet Solvay Co. U.S.P. 1,384,909, 19.7.21. Appl., 8.11.17.

Toluene, its homologues, and its side-chain substitution products are subjected to the action of a halogen in presence of an alkali carbonate.

IV.—COLOURING MATTERS AND DYES.

Cyanines; Constitution of the ——. W. König and O. Treichel. J. prakt. Chem., 1921, **102**, 63—84.

The absorption curve in the ultra-violet of a solution of *p*-dimethylaminocinnamylidenequinaldine methoperchlorate decolorised by hydrochloric acid is widely different from that of a similar solution of isocyanine; it is therefore impossible that the latter should have the butadiene structure formulated by König (J. prakt. Chem., 1912, **86**, 166). Direct comparison of the corresponding *o*-derivative with cyanine was impossible since the former could not be prepared, but inasmuch as *p*- and *o*-dimethylaminobenzylidenequinaldine methoperchlorates show identical absorption curves (after being decolorised by hydrochloric acid) it appears valid to conclude that cyanine also is not a butadiene compound. The work of Mills and Wishart (J., 1920, 540 a) and Mills and Evans (J., 1920, 685 a) is thus confirmed. (*Cf.* J.C.S., Oct.)
—H. W.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Textile cellulose (rag boiling); Action of alkalis and alkaline earths on ——. H. Grimm. Zellstoff u. Papier, 1921, **1**, 7—10, 33—56. Chem. Zentr., 1921, **92**, IV., 436.

A series of constants has been developed for unbleached cotton, unbleached flax, and hemp in the form of the raw materials for paper manufacture, and the absorptive power of these materials for caustic alkalis and alkaline earths established. The absorption of lime during boiling is without influence on the process. Steaming without pressure is insufficient. Injection of carbon dioxide to loosen the fibre is without effect. Boiling with sodium carbonate after preliminary absorption of calcium hydroxide, whereby sodium hydroxide must be formed actually in the fibre, has no more powerful action than the usual boiling process. The mechanical treatment in the washing and half-stuff hollander exerts a considerable influence on the chemical constituents of the fibre, and cannot be replaced by more stringent boiling. Figures are given for the valuation of rag half-stuff prepared on the large scale. Comparisons between lime and lime-caustic soda boils favour the former.
—F. M. R.

Oxycelluloses; Detection of —— *by their barium compounds.* E. Becker. Zellstoff u. Papier, 1921, **1**, 3—5. Chem. Zentr., 1921, **92**, IV., 439.

Oxycelluloses, owing to their acidity, combine chemically with barium, and this barium content may be used for the detection of oxycelluloses. (*Cf.* J., 1921, 295 a.)—F. M. R.

Wood pulp boiling, particularly by the sulphite process. C. G. Schwalbe. Zellstoff u. Papier, 1921, **1**, 11—15. Chem. Zentr., 1921, **92**, IV., 437—438.

On economic grounds the only hydrolysing agents for lignified fibres at present available are, on the one hand, sulphurous acid and lime, and, on the other hand, sodium hydroxide and sodium sulphide. The action of gaseous chlorine is too mild, whilst solutions of chlorine in carbon tetrachloride, acid chlorides, glycerin and its esters, phenols and amines are too expensive. In the Mitscherlich process a considerable amount of lime enters the wood, and it is only in the last stages of the boiling that the lignin dissolves and is then converted into an insoluble CaO-S-lignin compound. The incrustations which dissolve are mainly hexosans. The primary softening of the wood, followed by a further hardening, is to be attributed to condensation with sugars. Hydrolysis is not assisted by the sugar formed during boiling. Preliminary treatment of the wood with spent lye is advantageous owing to the presence of salts of organic acids in the lye, and swelling by means of hot moist air is proposed.—F. M. R.

Hydrocelluloses; Constitution of ——. H. Ost and R. Bretschneider. Z. angew. Chem., 1921, 34, 422—423.

Results indicating that hydrocelluloses are simple substances and not mixtures of cellulose and cellulose dextrins (*cf.* Hauser and Herzfeld, J., 1915, 1048; Schwalbe and Becker, J., 1920, 512 A) have been obtained by a comparative examination of hydrocellulose and cellulose before and after treatment with boiling lime-water. The hydrocellulose, made by Girard's method, and the cellulose, purified as for nitration purposes, had "copper numbers" 6·69 and 2·05, "cellulose numbers" 0·14 and 0·30, and contained 0·24—0·34% and 0·30% of ash and 3·17—3·94% and 5·39% of moisture respectively. After digestion for 12 hrs. in boiling lime-water (0·5—1·0% CaO), 24·4% of the hydrocellulose and 15·8% of the cellulose had dissolved, and the "copper" and "cellulose" numbers of the final undissolved residues were 0·91 and 0·61, 0·29 and 0·36 respectively. The final residue from the hydrocellulose was similar to the untreated hydrocellulose, and was not cellulose, since the viscosity of its solution in cuprammonium solution (after 24 hrs. at 19° C.) was equal to the viscosity of a similar solution of the original hydrocellulose, but approximately only one-half of that of a similar solution of the purified cellulose. Moreover, the portion of hydrocellulose which remained after digestion for 13 hrs. with lime-water gave, on acetylation under various conditions, a cellulose acetate having a solubility in acetone similar to that of the acetate of the original hydrocellulose, but much greater than that of the corresponding acetate from the purified cellulose (*cf.* Ost and Katayama, J., 1912, 713).—A. J. H.

"Lignin" colour reactions; Significance of ——. E. C. Crocker. J. Ind. Eng. Chem., 1921, 13, 625—627.

The colorations obtained when lignin is treated with phloroglucinol or *p*-nitroaniline are not due to the lignin itself, but to traces of an aldehyde which are always present; this aldehyde is probably coniferyl aldehyde, and it may be accompanied by very small quantities of vanillin or furfural. Certain other substances give reactions similar to those of "lignin," the colorations produced being due to the presence of aldehydes; in the case of clove oil and sassafras oil, the aldehyde appears to be identical with that occurring in wood. Maüle's reaction (successive treatment of the wood with permanganate solution, dilute hydrochloric acid, and ammonia) is essentially a chlorination of some constituent of the wood followed by alkaline treatment, and may serve to distinguish between deciduous woods and coniferous woods, since the former, in general, give a bright red coloration and the latter a faint brown coloration with the test. —W. P. S.

Nitrocellulose and its solutions as applied to the manufacture of artificial leather. W. K. Tucker. J. Ind. Eng. Chem., 1921, 13, 623—624.

In specifications for nitrocellulose a standard solvent and temperature should be mentioned for the viscosity determination. The author uses a solution containing 16 oz. of the material to 1 gal. of a mixture of ethyl acetate, 70, and benzene, 30% : the viscosity is determined by noting the time taken for a steel ball $\frac{5}{16}$ in. diam. to fall through a 10-in. column of the solution at 25° C. The industry uses nitrocellulose of three viscosities: low, 5—20 secs., medium, 40—60 secs., and high, 100-2400 secs. The viscosity is influenced to a great extent by the nature of the solvent mixture; *e.g.*, a nitrocellulose having a viscosity of 20 secs. when dissolved in a mixture of ethyl acetate, 70, and benzene, 30%, has a viscosity of 40 secs. when the solvent is ethyl acetate, 30, and benzene, 70%. It used to be the custom to add a certain proportion of solvent of high b.p., such as amyl acetate, ethyl propionate, etc., but these are now usually omitted. The nitrogen content of the material should lie between 11·5 and 13%; the colour is not of great importance, but a well stabilised material appears to be essential for the production of good artificial leather. —W. P. S.

Vacuum drying. Lavett and Van Marle. *See* I.

Patents.

Glass nozzles for the spinning of artificial fibres, horsehair, straw, etc; Process and apparatus for the manufacture of ——. A. Kämpf, Assee. of R. S. Kopf. E.P. 160,168, 14.3.21. Conv., 12.3.20.

Wires of the required degree of fineness are inserted severally into capillary tubes, the thickness of the wall of the tube determining the distance between the wires. A bundle of these tubes of any desired length is closely packed into a large glass tube sealed at one end, the other end being connected with a vacuum pump. When all the air is exhausted the tube is heated in a revolving cylindrical furnace, until a solid glass rod is obtained, which is cut into discs and treated chemically to remove the wire.—D. J. N.

Cellulose derivatives [ethers]; Manufacture of ——. H. Dreyfus. E.P. 166,767, 13.5.20.

Cellulose derivatives are obtained by the interaction of cellulose or its conversion products with halogen derivatives of glycols or polyhydric alcohols or their ethers in presence of alkali solutions of high concentration, whereby the residue introduced into the cellulose molecule contains one or more hydroxyl groups. The halogen derivatives of polyhydric alcohols may be used in conjunction with the halogen derivatives of alkyl, benzyl, or homologous groups. Details of the process are substantially the same as in E.P. 164,374 (J., 1921, 540 A). These new cellulose derivatives may be used for the production of artificial silk, which is capable of being dyed.—D. J. N.

Viscose silk; Manufacture of ——. E. Bronnert. E.P. 166,931, 22.3.20.

Threads of varying degrees of fineness (1—6 deniers) are spun from the same nozzle used in the production of threads of 8—12 deniers, by spinning the viscose solution into a solution of pure sulphuric acid, the fineness of the thread varying with the concentration of the acid. For example, threads of 2 deniers are obtained by using a bath containing 250 g. of sulphuric acid per l. and of 1 denier with 350 g. per l.—D. J. N.

Viscose filaments, threads, or films; Treatment of ——. E. Bouillon and M. Worms. E.P. 167,076, 19.7.20. Addn. to 162,759 (J., 1921, 466 a).

The aluminium salt used in the coagulating bath described in the original patent may be replaced by manganese sulphate, the temperature of the bath being kept at 45°—50° C.—D. J. N.

Cellulose acetate solution. G. W. Goerner, Assr. to The Roessler and Hasslacher Chemical Co. U.S.P. 1,384,188, 9.7.21. Appl., 9.6.20.

A cellulose ester of a monobasic fatty acid is dissolved in methylene chloride.—D. J. N.

Fibrous fabrics or compositions for frictional and wearing purposes. H. Frood. E.P. 166,916, 16.1.20.

Fibrous compositions for the manufacture of brake blocks, discs for friction drives, stair treads, etc., are obtained by treating one or more layers of asbestos millboard, with which may be incorporated pumice, or similar substances, or casein, with a phenol-formaldehyde condensation product either during manufacture or in the form of a powder, varnish, or plastic mass, and subjecting the material to heat and pressure The millboard may be reinforced with wire netting, expanded metal, or similar devices.—D. J. N.

Fibrous material; Process and apparatus for digesting ——. H. Gevers. U.S.P. 1,385,744, 26.7.21. Appl., 24.4.20.

The digestion liquor is heated before being introluced into the digester, the steam from this operaion being utilised to maintain a digestion already n progress.—D. J. N.

extile fibres; Production of —— from species of Typha. P. Hoering. G.P. (a) 300,744, 1.9.16, and (b) 307,063, 2.11.17.

a) The material (*T. angustifolia, T. latifolia*) is oiled with alkali lye of concentration less than ·3—0·5%, and the fibres are then separated by nechanical treatment. (b) Before boiling with the ery weak lye, the material is boiled with stronger ye, or with concentrated ammonia solution, alkali rbonate or silicate, or a concentrated solution of lkaline-earth hydroxide, which is removed before ontinuing the process as described under (a).

ulp mills; Heat-reclaiming system for ——. G. Witham, jun. U.S.P. 1,384,796, 19.7.21. Appl., 15.7.16.

he gases evolved during digestion are removed om the digesters, and caused to give up their heat a stream of water, which may be regulated so as attain any desired temperature.—D. J. N.

aterproofing; Process of ——. W. Alexander, U.S.P. 1,385,854, 26.7.21. Appl., 4.9.18.

e two components of the waterproofing compund, *e.g.*, a metallic salt and an organic acid, e applied simultaneously in aqueous dispersion, d subsequently made to react by the addition of electrolyte, the waterproofing metallic soap ing thus formed on the material.—D. J. N.

xtile goods; Method of and apparatus for production of imitation —— from solutions of cellulose or plastic substances. B. Borzykowski. E.P. 22,826, 9.10.13.

e F.P. 463,400 of 1913; J., 1914, 417.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Cotton and wool; Behaviour of —— towards substantive dyes. R. Haller. Kolloid-Zeits., 1921, 29, 95—100.

Diamine Blue 3R dyes cotton blue and wool red. The dye consists in solution of small red particles and larger blue particles which are separable by ultrafiltration. The dyeing of wool is shown in general to be effected by small particles, and since the size of the particles can be changed by the addition of a neutral salt in suitable concentration, it follows that every substantive cotton dye is capable of being used as a wool dye. (*Cf.* J.C.S., Oct.) —J. F. S.

Antimony tannate from a colloidal standpoint. C. Sunder. Bull. Soc. Ind. Mulhouse, 1921, 87, 236—239.

Antimony tannate readily forms colloidal solutions, a fact which is important in dyeing mordanted fabrics, particularly after a tannin discharge with sodium hydroxide. The white is usually cleared by soaping followed by chlorination, but, in the case of dyes such as Victoria Blue, the shade is too sensitive to be treated in this manner and it is essential, therefore, that the white should be perfect after dyeing on the tannin discharge. The alkaline discharge is printed, steamed, and the sodium hydroxide neutralised so that there is no partial solution of antimony tannate, which would become fixed on the white. This is effected by treatment with a hot solution of tartar emetic containing 20 g. per l. immediately before dyeing. After cooling, the dye is added to the same bath in such a quantity that the bath is practically colourless after dyeing. Any colour fixed on the white by oxycellulose is removed only by prolonged dyeing at 100° C. Satisfactory results are obtained by using a dye bath containing 1300 l. of water, 6·5 kg. of glue, 13 kg. of aluminium sulphate, 80 g. of Victoria Blue R conc. (Bad.), and 60 g. of Crystal Violet 5BO. The dyed pieces should be dried immediately.—F. M. R.

Anthraquinone as catalyst in discharges on α-Naphthylamine Claret. M. Battegay, A. Lipp, and H. Wagner. Bull. Soc. Ind. Mulhouse, 1921, 87, 233—235.

The inactivity of certain qualities of anthraquinone when used as a catalyst in the customary formaldehyde-sulphoxylate discharge is due to an imperfect state of division. Activation results by solution in sulphuric acid followed by re-precipitation with water, by caustic alkaline reduction and precipitation of the solution with a current of air, or actually in the discharge by the addition of a small quantity of sodium hydroxide. The use of anthraquinone α- and β-monosulphonic acids and of several disulphonic acids in the place of anthraquinone in a neutral discharge led to negative results. This inactivity may be due to the reduction of the anthraquinonesulphonic acid in a neutral or acid medium to an oxanthranol derivative which would possess no catalytic action owing to its resistance to oxidation. This view receives support from the fact that satisfactory results were obtained by the use of anthraquinone-β-sulphonic acid in the discharge in conjunction with sodium hydroxide, as in this case the conditions favour the formation of an autoxidisable anthrahydroquinone derivative. On the other hand, as anthraquinonesulphonic acids are reduced to anthracenesulphonic acids by zinc and ammonia, it is possible that this might also occur in the ordinary discharge.—F. M. R.

Patents.

Proteins; Use of decomposition products of —— [in dyeing]. C. Bennert. G.P. 337,151, 24.2.20. Addn. to 330,133 (J., 1921, 256 A).

Decomposition products of albuminoids (keratin, elastin and the like) of the type of protalbinic and lysalbinic acids or their salts are added to dye-baths of all kinds with the exception of vat dyes. The products named are not precipitated even in strongly acid dye-baths.—C. A. C.

Mercerising hanks of yarn; Machine for ——. J. Olig. E.P. 146,934, 4.5.20. Conv., 10.7.19.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphur dioxide [and sulphur trioxide]; Determination of —— in burner-gases. B. C. Stuer and W. Grob. Chem.-Zeit., 1921, 45, 770. A. Sander. *Ibid.*, 771.

Stuer and Grob point out that if oxidation of sulphur dioxide during absorption in alkali is caused by agitation in presence of air, as contended by Sander (J., 1921, 506 A), it will not be prevented by excluding contact with air, as burner gases contain oxygen. The oxidation can be reduced by addition of certain substances, but probably not sufficiently so to render Sander's method (J., 1921, 256 A) satisfactory. In reply Sander gives a series of comparative analyses by his method and the Reich-Lunge method, the former giving a lower sulphur trioxide content in all cases. He points out that the high percentage of oxidation (31—38%) found by Stuer and Grob is contrary to everyday experience in sulphite manufacture, and repeats that unless the solution is violently agitated the error is inappreciable.—C. I.

Reaction $3HNO_2 \rightleftarrows 2NO+HNO_3+H_2O$; Condition of an unattackable electrode in the ——. H. Pick. Z. Elektrochem., 1921, 27, 369—371.

Although the experimental results of Klemenc (J., 1921, 257 A) are not inconsistent with those of earlier workers, he bases his reasoning on false assumptions and therefore arrives at erroneous conclusions.—E. H. R.

Potash from kelp. Continuous counter-current lixiviation of charred kelp. J. W. Turrentine and P. S. Shoaff. J. Ind. Eng. Chem., 1921, 13, 605—609.

Charred kelp containing 75% of water-soluble constituents is extracted in a horizontal wooden agitator fitted with a steel screw conveyor and thence falls into a continuous rotary vacuum filter. The solid material passes in sequence through three such sets of apparatus and the liquor is forced by means of centrifugal pumps through the plant in the reverse direction. The whole process is thus automatic and continuous, and an extraction efficiency of 97·9% is obtained. As the liquor corrodes steel and cast iron, such parts as the pump shafts are made of monel metal.—C. I.

Calcium carbide; Crystalline structure of ——. C. H. Warren. Amer. J. Sci., 1921, 3, 120—128.

Calcium carbide as made in the electric furnace has a very complex structure. It shows a great number of cleavage surfaces, the cleavages being nearly equal, and parallel to three directions at right angles to one another. Examination of a cleavage fragment shows that the carbide contains thin lamellæ which are either parallel, or inclined at 45°, to the cleavage edges. Calcium carbide is considered to be of orthorhombic symmetry with a polysynthetic twinning parallel to the diagonals at 45° to the pinacoids (pseudo-duodecahedral). The twinning is mimetic, causing the carbide to appear pseudo-cubic geometrically, and pseudo-tetragonal optically. Calcium cyanamide, usually present in commercial carbide, is characterised by exceedingly strong double refraction, at least twice that of calcite.—W. J. W.

Litharge; Complete analysis of impure ——. W. Stahl. Chem.-Zeit., 1921, 45, 781—782.

1—2 g. of the finely ground litharge, dried at 105° C., is evaporated to dryness on the water-bath with 40—50 c.c. of nitric acid (1:1) and the residue is treated with a few c.c. of nitric acid and 100—150 c.c. of water. Insoluble material is filtered off, washed with hot dilute ammonium nitrate solution, dried, removed from the paper, the latter burnt off and the ash and dried precipitate fused with 12 times their weight of caustic soda and a little sodium peroxide in a silver crucible. The contents of the crucible are washed out with hot water, the liquid made just acid and evaporated to dryness on the water-bath. The residue is treated with a little warm dilute hydrochloric acid and the insoluble matter filtered off, washed with dilute ammonium nitrate solution, and digested with dilute hydrochloric and tartaric acids to extract the last traces of antimony. The remaining residue is ignited and weighed as SiO_2. The antimony in the last solution is precipitated by hydrogen sulphide, the precipitate is filtered off, washed with ammonium nitrate solution and added to the remainder of the antimony recovered later. The original nitric acid filtrate is treated with dilute sulphuric acid till no further precipitate forms, the lead sulphate is filtered from the cold solution, washed with dilute sulphuric acid, then with alcohol, dried, ignited in the usual manner and weighed. Silver is removed from the hot filtrate by addition of hydrochloric acid in the usual way, the weight of chloride found being converted into oxide, Ag_2O. The filtrate from the silver chloride is united with that obtained from filtering the fusion residue above, the solution is nearly neutralised with ammonia and saturated with hydrogen sulphide. The filtered and washed precipitate is digested with potassium sulphide solution and the residue of sulphides of copper, cadmium, and bismuth, with a small quantity of lead sulphide filtered off and the metals separated and estimated in the usual way, the lead found being added to that already obtained. The potassium sulphide solution is used for the determination of arsenic antimony, and tin, while iron, alumina, zinc, nickel, lime and magnesia, are tested for in the filtrate from the original hydrogen sulphide treatment. For the estimation of sulphur trioxide 2 g. of the litharge is fused with sodium percarbonate in a nickel crucible, the melt is extracted with water, the liquid saturated with carbon dioxide, filtered, and the filtrate, after removal of silica by evaporation with hydrochloric acid, precipitated with barium chloride as usual. Carbon dioxide is determined by heating 5 g. of the litharge at 500°—600° C. for ½ hour in a dry air current free from carbon dioxide and collecting the evolved carbon dioxide in potash as in a steel analysis.—A. R. P.

Silver solution; Action of alkaline hydrogen peroxide on —— and behaviour of silver towards dilute sulphuric acid. [Detection of silver peroxide.] E. Salkowski. J. prakt. Chem., 1921, **102**, 194—208.

When silver nitrate solution is added gradually to a dilute solution of hydrogen peroxide containing a little potassium or sodium hydroxide, a black precipitate is formed initially which becomes greyer as more of the silver solution is introduced. Analysis shows it to be a mixture of silver and silver oxide in which the proportion of the former increases with increasing quantities of hydrogen peroxide in the solution. Silver peroxide is not present. Analysis is effected by treating the mixture with boiling dilute sulphuric acid (100 g. of acid per l.), which dissolves the oxide almost completely but only attacks the metal to a very slight extent. Silver peroxide may be detected by the formation of a silver mirror when it is boiled for a short time with not too small a quantity of an aqueous solution of an aliphatic amino-acid, preferably glycine or alanine; this reaction is not shown by silver dioxide. Also, silver peroxide gives a dark brown solution with nitric acid (sp. gr. 1·2), which becomes lighter and ultimately colourless when heated but retains its colour for days at the laboratory temperature. The second test appears to be somewhat more sensitive than the first. (*Cf.* J. C. S., Oct.).—H. W.

Hydrogen; Conditions for using Schilling's apparatus for the control of —— for use in aeronautics. F. Bourion and C. Courtois. Ann. Chim., 1921, **16**, 55—76.

The water used in the apparatus should be as pure as possible; water from condensers may be used. The authors have constructed tables giving the necessary corrections to allow for the water vapour entering the hydrogen and air during the measurements, at each 5° from 0° to 30° C. By using these values in conjunction with measurements made with Schilling's apparatus the ascensional force of commercial hydrogen may be determined, providing that the only impurities of the dry hydrogen are air or a mixture of gases having a density near that of air.—W. G.

Oxygen gas; Density of ——. E. Moles and F. Gonzalez. Comptes rend., 1921, **173**, 355—358.

The mean of 45 determinations on samples of oxygen prepared in five different ways gave the value 1·42889 as the density of oxygen at 0° C. and 760 mm.—W. G.

Wood charcoal; Spontaneous explosion of —— used in double-walled (Dewar) vessels for storing liquid oxygen. L. Wöhler. Z. Komprim. flüss. Gase, 1919–20, **20**, 109—112, 121—124, 133—137. Chem.-Zeit., 1921, **45**, Rep., 187.

Explosions are liable to occur owing to contact between liquid oxygen and the wood charcoal conained between the walls of Dewar vessels used for toring liquid oxygen, as a result of defects in the nner wall of the vessel. Such explosions are initited by iron oxide contained as an impurity in the harcoal. The phenomenon occurs only when the harcoal possesses a high absorption coefficient, is ranular and well dried, and when the iron is very nely distributed; no explosion occurs if the iron or ron oxide is merely mechanically distributed mongst the charcoal, while explosions result when he surface of the charcoal is contaminated with nely divided copper oxide, zinc oxide, or other metallic oxide. When the iron oxide is homoeneously distributed throughout the charcoal, at east 3% is necessary before an explosion results on ontact with liquid oxygen, but the average content f iron oxide present in wood charcoal is no riterion of the stability of the charcoal, as the xide may be heterogeneously distributed. Charcoal ee from iron and impurities containing oxygen ust be used in order to avoid the risk of explosion. —J. S. G. T.

raphite; Determination of volatile matter in ——. O. L. Shinn. J. Ind. Eng. Chem., 1921, **13**, 633—634.

Whilst the most accurate method consists in heatg the graphite in a current of pure nitrogen, reults very close to the true values may be obtained by the following rapid method:—1 g. of the sample is placed in a platinum crucible provided with a well-fitting lid; the crucible is supported about 10 mm. above a Méker burner so that it can be heated to 700°—750° C., and the heating is continued for exactly 30 secs. The ordinary method of determining volatile matter in coal and coke is untrustworthy in the case of graphite owing to oxidation of the latter; on the other hand, the method described above is unsatisfactory when applied to coal and coke.—W. P. S.

Carbon; Fusion of ——. S. Münch. Z. Elektrochem., 1921, **27**, 367—368. E. Ryschkewitsch. *Ibid.*, 368—369.

The fusion of carbon was effected by passing a direct current of about 1000 amps. through a stick of graphite 5 cm. long by 50 sq. mm. cross section. Stout graphite electrodes were used, to one of which the small stick was joined whilst it pressed lightly against the other. At a white heat the graphite stick became quite plastic and at a still higher temperature it melted at the point of contact with the free electrode, and fell in molten drops. Münch's criticisms of a recent paper by Ryschkewitsch (J., 1921, 178 A) are replied to by the latter author.—E. H. R.

Basicity of chromium salts. Grasser. *See* XV.

Sulphides. Moser and Schattner. *See* XXIII.

Patents.

Sulphur burning furnaces and the like. T. A. Clayton. E.P. 166,961, 23.4.20.

Air is supplied to the furnace through a tubular element, approximately horseshoe-shaped, with closed ends and provided with two sets of jets. Part of the air is projected downwards through one set of jets on to the burning sulphur, whilst the remainder is directed upwards through the other set of jets so as to mix with the gas produced and oxidise any volatilised sulphur.—H. R. D.

Sulphuric acid; Process of making contact ——. H. F. Merriam, Assr. to General Chemical Co. U.S.P. 1,384,566, 12.7.21. Appl., 26.10.20.

Sulphur dioxide produced from Louisiana sulphur is brought into contact with catalytic material, without cooling it below the temperature required for conversion.—C. I.

Sulphuric acid; Production of —— from neutral sodium or ammonium sulphate. F. A. Weber. G.P. 337,211, 12.11.18. Addn. to 336,560 (J., 1921, 582 A).

Neutral sodium or ammonium sulphate is decomposed with excess of hydrochloric acid in presence of water.—C. I.

Hydrocyanic acid; Production of ——. F. J. Metzger, Assr. to Air Reduction Co. Inc. U.S.P. (A) 1,385,335 and (B) 1,385,336, 19.7.21. Appl., 3.5. and 14.8.19.

(A) Material containing solid cyanide is subjected to the action of carbon dioxide, the temperature of the mass in the reaction zone being regulated to prevent polymerisation of the liberated hydrocyanic acid. (B) Polymerisation of the hydrocyanic acid is prevented by withdrawing the gaseous reaction product as rapidly as possible.—H. R. D.

Alumina; Preparation of aluminate of lime for the manufacture of pure ——. Soc. Electro-Métallurgique Française. E.P. 146,133, 23.6.20. Conv., 7.3.16.

Crushed bauxite and limestone are heated in a rotary furnace by the waste gas from a fusion furnace into which the material from the rotary furnace falls. The charge is completely fused in the second furnace and on its discharge can be cooled or granulated.—H. R. D.

Aluminium hydroxide and the like; Process and apparatus for calcining ——. J. Rudolf. G.P. 338,474, 9.10.17.

The material is calcined by means of a countercurrent of heating agent in a rotary kiln in which successive zones are maintained at the temperatures at which successive molecules of water are removed. The liberated moisture is completely removed in each zone and danger of liquefaction thus avoided.—C. I.

Pickling solutions; Process of reclaiming spent ——. J. A. Shaw. U.S.P. 1,384,974, 19.7.21. Appl., 19.5.20.

Pickle solutions containing iron sulphate are intimately mixed with a gas containing a higher oxide of nitrogen. Nitrogen oxides are recovered from the spent gas by means of a salt capable of reacting with and retaining the oxides.—H. R. D.

Antimony trichloride; Process of making anhydrous ——. O. C. Ralston, Assr. to Hooker Electrochemical Co. U.S.P. 1,384,918, 19.7.21. Appl., 10.8.20.

Chlorine is caused to react with metallic antimony submerged in a bath of molten antimony trichloride. —H. R. D.

Iron compounds; Process of manufacturing ——. F. Ball, Assr. to West Coast Kalsomine Co. U.S.P. 1,385,769, 26.7.21. Appl., 16.3.20.

A stream of an oxidising medium is passed through a vessel in which pieces of metallic iron are supported.—H. R. D.

Liquid chlorine; Preparation of —— from chlorine gas mixtures. Farbw. vorm. Meister, Lucius, u. Brüning. G.P. 305,652, 15.7.17.

The gas is compressed and cooled to its boiling point. It is then passed from below into the liquefaction coil which is connected with a collecting reservoir underneath. Losses of chlorine through re-evaporation are thus avoided.—C. I.

Ozone; Method of neutralising the injurious action ——. J. Stöckly. G.P. 337,112, 24.1.20. Addn. to 334,005 (J., 1921, 480 A).

The destructive action of ozone on substances and its injurious effect on health are neutralised by the admixture of vapours of turpentine oil and the like which form ozonides. This method may be applied in works where formation of ozone takes place, *e.g.*, during the electrolytic manufacture of persalts.—C. A. C.

Hydrogen from carbon monoxide and steam; Catalytic manufacture of ——. Badische Anilin- und Soda-Fabr. G.P. 337,153, 24.12.15.

The gas mixture leaving the contact chamber after being used for preheating the cold gases entering the chamber is treated with cold water, and the hot water so obtained is used for preheating the entering gases and charging them with steam; 50% or even more of the steam required for the reaction can be produced in this way.—C. A. C.

Ammonia; Production of ——. Nitrogen Corp., Assees. of J. C. Clancy. E.P. 143,550, 19.5.20. Conv., 23.3.16.

See U.S.P. 1,352.174 and 1,352,180—1 of 1920; J., 1920, 688 A.

Ammonium sulphate; Process of producing —— from cyanogen compounds produced in the distillation of coal or organic substances. F. J. Collin, A.-G. zur Verwertung von Brennstoffen u. Metallen. E.P. 145,696, 30.6.20. Conv., 17.5.19.

See G.P. 328,829 of 1919; J., 1921, 389 A.

VIII.—GLASS; CERAMICS.

Patents.

Muffle-lehr construction. P. L. Geer, Assr. to Amsler-Morton Co. U.S.P. 1,385,868, 26.7.21. Appl., 25.11.19. Renewed, 7.10.20.

A muffle lehr comprises an outer furnace structure, an elevated muffle mounted therein, a longitudinal crown flue above the muffle, a combustion chamber under the forward portion and a reverberatory chamber under the rear portion of the muffle, with a vertical wall separating the chambers, a baffle wall intersecting the crown flue above the reverberatory chamber, and a series of vertical flues on either side of the muffle connecting the combustion chamber with the crown flue. A second series of vertical flues at either side of the muffle, and in the rear of the first flues, connects the crown flue in front of the baffle wall with the reverberatory chamber, while a third series of flues, in the rear of the second series, connects the reverberatory chamber with the crown flues in the rear of the baffle wall. The products of combustion ascend from the combustion chamber about the muffle to the crown flue, then descend about the muffle to the reverberatory furnace and next ascend about the muffle to the crown flue in the rear of the baffle wall.—H. S. H.

Kilns, ovens, or the like; Downdraught ——. A. W. F. Weiyers. E.P. 142,803, 26.4.20. Conv., 2.5.19.

A downdraught kiln or oven has gas-producers arranged in each wall between the chambers so that air, or the mixture of air and combustible gases, is conducted partly under the producers and partly along the wall. Between the gas-producers ducts are arranged with inclined guides or baffles situated above them so as to guide the air passing along the walls of the producers over the outlet openings for the flames and the gas from the producers. —H. S. H.

Tunnel kilns; Continuous ——. R. C. Metcalfe. E.P. 167,070, 10.7.20.

A continuous tunnel kiln has heating muffles in one section of the elongated kiln chamber at both sides of the goods passage. The kiln atmosphere is caused to circulate upwards past the muffle and downwards through the goods. The heating gases flow longitudinally through the kiln in a direction opposite to that in which the goods move, and pass through the muffles in one section and through the kiln chamber itself in another section. Thus in one section the goods are protected from contact with the burning gases while in the other section the advantage of direct heating is obtained. The muffle and the circulation of the gases lessen the temperature variations at different levels of the kiln chamber.—H. S. H.

Baking material; Apparatus [updraught kiln] for ——. I. M. Justice and G. A. Willigman. U.S.P. 1,385,686, 26.7.21. Appl., 22.11.20.

An open-top kiln has a plate on top of the goods to be burned arranged closer on one side than on the other. Burners supplied with air and fuel are situated adjacent to oppositely located apertures in the bottom of the kiln.—H. S. H.

Clay; Process for treating ——. J. H. Ryan, Assr. to D. R. Seaman. U.S.P. 1,385,716, 26.7.21. Appl., 7.4.21.

Clay is broken into small lumps and dried by heat so as to produce preliminary oxidation. It is then mixed with excess of water and the grit allowed to settle out. Ammonia is added to neutralise any acid in the clay and the pulp ground in a pebble mill. A bleaching agent (0·5% of the water content) is next added and the grinding continued for 2 hrs. The pulp is diluted and transferred to an agitator so as to dissolve and remove the chemical. It is allowed to settle and the water is decanted, and the pulp withdrawn, filtered, and dried.

—H. S. H.

Dental cements; Manufacture of ——. M. Andresen. G.P. 336,473, 12.2.13. (*Cf.* G.P. 337,856; J., 1921, 624 a.)

Solutions of phosphorous acid or its acid salts, or mixtures of the two solutions, or mixtures with solutions of other substances are used. To a solution of crystallised phosphorous acid in water aluminium hydroxide is added. After concentrating a further amount of phosphorous acid is added and the liquor is filtered. For the manufacture of plastic mixtures, suitable for permanent stoppings, aluminium or beryllium phosphates or borates are mixed with the above solutions, containing, besides acid aluminium phosphite, free phosphoric acid, or the aqueous acid, or acid phosphites. Zinc oxide may also be added as a binding material to solutions of acid phosphites or phosphorous acid. The stoppings prepared from the above products resist aqueous liquors (saliva) and are less soluble in dilute organic acids and more transparent than the cements obtained by the use of phosphoric acid alone.—C. A. C.

Glass; Production of reflecting surfaces on —— *by means of metals in the platinum group.* J. Rheinberg. U.S.P. 1,385,229, 19.7.21. Appl., 11.10.20.

See E.P. 156,472 of 1920; J., 1921, 149 a.

Fireproof heat and sound insulating material; Manufacture of —— *from clay or the like.* L. Kern. E.P. 167,368, 5.7.20.

See G.P. 331,026 of 1919; J., 1921, 309 a.

Glass; Apparatus for drawing sheet ——. E. Rowart. E.P. 167,347, 31.5.20.

Glass nozzles for spinning threads. E.P. 160,168. *See* V.

IX.—BUILDING MATERIALS.

Magnesite and oxychloride cements; Plastic calcined ——. M. Y. Seaton. Chem. and Met. Eng., 1921, 25, 233—236.

When testing oxychloride cements sand cannot be sed as the sole aggregate, a finely ground powder eing also required. The author's "standard mixure" consists of calcined magnesite, 1 pt., 120-esh silex, 2 pts., and standard Ottawa sand, 5 pts. he quality of an oxychloride cement may be judged om tests of the strength, change in volume, setng time, and permanence of the product. Tenle and compression tests are of little value, as ychloride cements are used in thin coatings, and ese behave differently from more massive shapes. e author recommends the use of bars, 24×2×½ in., ade in steel moulds and tested, after proper ageg, in a cross-bending machine; such bars should ve a modulus of rupture of at least 550 lb. r sq. in. after one day, and at least 1000 lb. r sq. in. after 7 days. Resistance to abrasion y be tested by measuring the depressions caused rotating a set of steel cubes weighing 5 kg., er the surface of a floor covered with the cement, ilst a slow stream of fine silex is fed on to the rface. The change in volume is best measured noting the movement of reference-points inserted a thin bar of the cement formed on waxed paper d not disturbed during the testing. The change volume during 24 hours after the initial set ould not exceed 0·3%. The setting time may be determined by a Vicat or Gillmore needle or a Hill auto-recorder, though the interpretation of the results is complicated by the unavoidable use of an aggregate. The initial set should occur within 1 hr., and the final set within 8 hrs. The permanence of an oxychloride cement is judged by placing the flat bars previously mentioned, when 14 days old, behind a perforated grid, which protects their backs from contact with water, directing a gentle spray or mist of water on their faces, and determining their transverse strength after various periods of wetting and drying—*e.g.*, three successive 24-hr. periods of spraying, with intervening 24-hr. periods of drying—and finally testing the bars when wet and after two days' additional drying. The sprayed samples should be at least 30% as strong as the unsprayed ones. The results of the tests are influenced by the consistency of the mixture, the concentration of the magnesium chloride solution (about 22° B., sp. gr. 1·18; concentrations above 24° B., sp. gr. 1·20, cause undue expansion effects), and the character of the aggregate, very finely ground magnesia being essential. Provided that sufficient is used, the smaller the proportion of magnesia the better will be the product; about 4—5% should suffice if it is finely ground. The test-pieces should be kept in air at a temperature of 70°±10° F. (21°±5·5° C.) with a humidity of 35—65%. A high temperature with low humidity increases the rate at which the cement gains in strength and accelerates the setting. The quality of the magnesia, especially as regards the proportion of "active lime" (*i.e.*, calcium compounds soluble in magnesium chloride solution—see next abstract) present, the time-temperature history of the calcining of the magnesite, and the fineness of the magnesia (at least 97% should pass a 100-mesh sieve, and at least 75% a 200-mesh sieve) are also of importance.—A. B. S.

Magnesium oxychloride cements; Action of lime on ——. M. Y. Seaton, C. R. Hill, and L. C. Stewart. Chem. and Met. Eng., 1921, 25, 270—274.

The proportion of "total lime" in the calcined magnesite or magnesium chloride used for oxychloride cements is of little value in determining the quality of these materials, as different calcium compounds behave differently in such cements. Marble dust and limestone powder sometimes act as fine, inert aggregates, but sufficiently finely divided calcium carbonate will react with magnesium chloride and form calcium chloride, which, like free calcium oxide and hydroxide, reduces the strength of the cement. The best method of determining the proportion of harmful lime compounds, or "active lime," in the ingredients used for oxychloride cements consists in agitating 2·5 g. of the material (calcined magnesite) with 300 c.c. of a 0·75% solution of magnesium chloride for 24 hrs., making the liquid up to 500 c.c., filtering off an aliquot part, and determining the calcium after precipitation as oxalate. Titration of the free lime obtained by extraction with water (Duschak, J., 1920, 747a) gives low results. Extraction of the finely ground cement with alcohol and determination of the lime in the alcoholic solution gave results intermediate between those obtained by the use of water and of magnesium chloride solution. Whilst any sample of calcined magnesite containing a large proportion of "active lime" should be regarded with suspicion, the percentage of this constituent does not necessarily indicate the quality of a sample, though the average results from a large number of samples indicate a general relation between the proportion of active lime and the physical characters of the cement. At present, physical tests of oxychloride cements are the only safe criteria of quality.—A. B. S.

Wood preservatives; Toxicity of ——. C. J. Humphrey, R. M. Fleming, and E. Bateman. J. Ind. Eng. Chem., 1921, **13**, 619—621.

The toxicity of various fractions of beechwood creosote and of mixtures of cresols or coal-tar creosote with inactive oils was determined with regard to a culture of the fungus *Fomes annosus* in agar mixed with the preservative in different proportions. The toxicity of beechwood creosote lies mainly in its phenolic constituents. The toxicity of good coal-tar creosote is not seriously diminished by dilution up to 50%. A preservative containing 23·8% of dinitrophenol was found to be ten times more toxic than 95% cresol.—C. I.

Coal-tar creosote; Toxicity of —— *to wood-destroying fungi.* H. Schmitz and S. M. Zeller. J. Ind. Eng. Chem., 1921, **13**, 621—623.

The toxicity of different fractions of coal-tar creosote containing 7·5% of tar acids to certain fungi was investigated by dilution of the creosote with alcohol and impregnation of sawdust to which, after drying, the culture was added. The authors criticise the method of Humphrey and Fleming (*v. supra*), and consider that their own procedure alone can effect an even distribution of the preservative and be comparable with practical conditions. The most toxic fraction was that boiling between 270° and 315° C., which was effective in the proportion of 1% of the dried sawdust. The residue above 355° C. is of little value.—C. I.

Patents.

Oil-proofed container and process of making same. C. Ellis, Assr. to Ellis-Foster Co. U.S.P. 1,385,941, 26.7.21. Appl., 19.9.17.

Concrete tanks are oil-proofed by applying an acid solution of sulphite-cellulose waste liquor to react with the alkali of the concrete.—H. S. H.

Bricks; Process for preparing light —— *from kieselguhr and cement.* W. Bünte. G.P. 324,375, 23.4.19.

Finely or coarsely crushed, freshly mined kieselguhr is mixed damp with cement and the mixture formed into shapes, which may be rendered weatherproof by means of Kessler's "fluates."—A. R. P.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Mild steel; Stress figures in —— *produced by a new etching process.* A. Fry. Stahl u. Eisen, 1921, **41**, 1090—1097.

The process described consists in annealing the test piece for about ½ hr. at 200° C. and etching with a strong hydrochloric acid solution of cupric chloride. For micro-sections the reagent consists of 40 c.c. of concentrated hydrochloric acid, 30 c.c. of water, 25 c.c. of ethyl alcohol, and 5 g. of crystalline cupric chloride; for macro-etching, 120 c.c. of hydrochloric acid, 100 c.c. of water, and 90 g. of cupric chloride. In mild steel which has been stressed, *e.g.*, by bending, impact, compression, etc., characteristic dark figures which have not been previously observed are rendered visible, by the deposition of copper and iron hydrides. The figures are secondary breakdown phenomena which are brought out by the effect of the elastic stresses remaining in the iron. The crystal structure in the dark figures is found to have undergone considerable destruction by disintegration of the grains, obliteration of the crystal boundaries, and the formation of a great number of stepped slip lines in the crystals themselves. From consideration of the conditions under which the figures occur, it is thought that the phenomena are intimately connected with the cause of "blue brittleness" of iron.—T. H. Bu.

Boiler plates; Cracking of ——. B. Strauss and A. Fry. Stahl u. Eisen, 1921, **41**, 1133—1137.

Stress figures developed by the Krupp etching process (*cf. supra*) were found in all the old defective boiler plates examined and in new plates which had been through the straightening machine. A series of shock tests was made on boiler plate material from the top and bottom of ingots and variously heat treated. It was found that the following conditions lead to the occurrence of stress figures and concurrent brittleness:—High phosphorus content or segregation in cold bent sheets even if annealed to any temperature below Ac3; low finishing temperature of rolling, especially below visible heat—even if finished at a high temperature, the plates should be annealed above 900° C.; bending the plates at 200° C. Sheets which after cold bending, with or without annealing, are brittle, give good impact results if tested at 200° C. whatever the previous treatment. The occurrence of stress figures and brittleness in bent and annealed mild steel may afford a possible explanation of formation of cracks in boiler plates.—T. H. Bu.

Steels for the chemical industry. F. Rittershausen. Z. angew. Chem., 1921, **34**, 413—420.

The effect on the physical properties of steel of the addition of various elements is described with special reference to chrome-nickel steels. The latter may be divided into two classes according to the character of the internal structure, those containing 10—15% Cr and a small quantity of nickel having a troosto-sorbitic structure and being characterised by a high elastic limit and great toughness, and those containing 18—14% Cr with 5—20% Ni having an austenitic structure and showing great resistance to corrosion by sea-water and nitric and sulphurous acids. Tables are given showing the physical properties of a characteristic steel of each class at different temperatures between 20° C. and 1000° C., and their relative resistance to corrosion is compared with that of iron and plain nickel steels. Steels of the second class show very little loss in weight after heating to 1200° C. for 25 hrs. and none at all when immersed in 10% nitric acid for 14 days. They are, however, attacked by sulphuric and hydrochloric acids, for the handling of which, vessels made of an iron-silicon alloy are recommended.—A. R. P.

Sulphur in cast-iron and steel; Colorimetric determination of ——. G. Misson. Ann. Chim. Analyt., 1921, **3**, 200—201.

One g. of the sample is placed in a conical flask, 10 c.c. of benzene and 50 c.c. of hydrochloric acid are added and the mouth of the flask is covered with a piece of filter-paper moistened with arsenious acid solution; on the paper is placed a sheet of white felt 5 mm. thick and above this a thin ebonite plate and a lead plate weighing about 500 g. Control tests with specimens of iron or steel containing known amounts of sulphur are started at the same time, and after 1 hr., the yellow colorations, produced on the filter-papers by the production of arsenious sulphide, are compared. The arsenious acid solution is prepared by dissolving 10 g. of arsenious acid in a mixture of 30 c.c. of concentrated hydrochloric acid and about 500 c.c. of hot water, and then diluting the solution to 1 litre.
—W. P. S.

Silver in alloys; Rapid determination of —— *by a modification of the silver chloride method.* Sauerland. Chem.-Zeit., 1921, **45**, 735—736.

From 0·5 to 1·0 g. of the alloy is decomposed with 10 c.c. of nitric acid (sp. gr. 1·4—1·5), water is then added slowly, the mixture boiled, diluted to 80 c.c., again boiled, and, after 5 mins., the insoluble matter (gold, tin, antimony) is separated by filtration. Hydrochloric acid, in slight excess, is added to the filtrate, the mixture is boiled, and the silver chloride is collected on a filter and washed. The moist filter is then supported on the mouth of a small crucible, the upper part of the paper is folded round the end of a porcelain tube connected with a supply of coal gas, and the crucible is heated to dull redness by a burner. The silver chloride is reduced, the filter paper chars and falls into the crucible and is incinerated, thereby completing the reduction of the silver chloride. The resulting silver is weighed.—W. P. S.

Copper and some of its important industrial alloys; Thermal expansion of ——. P. Hidnert. U.S. Bureau Standards, Sci. Paper 410; 159 pages.

The thermal expansions of 128 samples of copper and brasses and bronzes of different composition and after different mechanical and heat treatments have been determined for temperatures from 20° C. to 300° C. Definite mathematical relations were found to exist between the instantaneous coefficients of expansion and the copper content of most of the alloys tested. Generally the coefficient decreases with increasing copper content and is strongly affected by the presence of lead or tin, the former tending to decrease and the latter to increase it. In the copper-zinc series (brasses) alloys containing 62% and 90% Cu give the same result whether cast or cold-rolled, while alloys having a copper content between these figures have greater coefficients in the cold-rolled state than when cast, and alloys containing more than 90% Cu the reverse. The coefficients of the inside sections of castings are usually slightly less than those of the outside. From a knowledge of the density of cold-rolled copper-zinc alloys it is possible to determine the copper content and from this the coefficient of expansion by means of the following equations.

$$D_{15}=7{\cdot}3605+0{\cdot}019147\text{Cu}-0{\cdot}00003509\text{Cu}^2$$

$$a_{100}=(24{\cdot}673-0{\cdot}08794\text{Cu}+0{\cdot}0001252\text{Cu}^2)10^{-6}$$

where D_{15} is the density in g. per c.c., Cu is the copper content %, and a_{160} is the instantaneous coefficient of expansion at 100° C. In the copper-tin series the coefficients of the cold-rolled alloys are less than those of the castings. Practically all the available information on the thermal expansion of copper and its alloys is briefly reviewed and a description of the apparatus and method of preparing the specimens is given.—A. R. P.

Brass; Compressibility of —— at different temperatures. F. Doerinckel and J. Trockels. Z. Metallk., 1921, 13, 305—315.

The work required to compress cylinders of brass of different copper content to half their height, the maximum decrease in height possible without fracture and the work required to effect this, have been determined for temperatures between 20° C. and 800° C., and the results are illustrated graphically. With brasses containing 58—85% Cu the work required to reduce the height 50% falls slowly with rise in temperature up to about 300° C., after which it falls rapidly up to 500° C., then more slowly again, the curve becoming convex to the axis of temperature. The curve for pure copper is very nearly a straight line, the work required at 800° C. being about ⅓ that necessary at 20° C. When the work required to reduce the height 50% is plotted against the percentage of copper in the alloy the isothermals for temperatures between 500° C. and 800° C. are in general concave to the axis of copper content, but for temperatures below this they exhibit a pronounced hump concave to the same axis at about 63% Cu with a maximum at 67% Cu corresponding to the change from $\alpha+\beta$-brass to pure α-brass. The maximum reduction in height without breaking is shown by pure copper; increasing proportions of zinc decrease this figure and increase of emperature slowly increases it in alloys containing 72 or 63% Cu, while with those containing 58 or 67% it decreases up to 300° C. slightly, then rapidly increases. The 85% Cu alloy, however, has an entirely different curve, which is convex to the temperature axis and up to 500° C. shows a slight falling-off, but above this a rapid increase in the work required.—A. R. P.

Metals [aluminium, iron, and elektron metal]; Researches for the improvement of ——. Hanszel. Z. Metallk., 1921, 13, 319—329.

Addition of magnesium (up to 10%) to aluminium increases the hardness and tensile strength without having much effect on the ductility. Aluminium alloys containing 7% Zn and less than 0·3% Mg make good substitutes for brass for castings, and also for pressing into rods, which may be effected at 400° C. as long as the reduction in area is small at each pressing. Addition of 2—2·5% Cu to aluminium gives an alloy that may be pressed into rods and has then a tensile strength of 22 kg. per sq. mm., an elongation of 5·5%, and a Brinell hardness number of 62—67. During the war brass was replaced in fuses by soft iron containing approximately 0·06% C, 0·3% Mn, 0·03% P, 0·02% S, and 0·03% Cu, which was protected against rust by a coating of metal or varnish. Tables are given showing the composition and physical properties of cast iron used for fuses and the effect on the physical properties of casting in different kinds of moulds. The physical properties and method of working of elektron metal (magnesium alloyed with a small proportion of zinc) are discussed and the danger of fire from ignition of the fine turnings is emphasised. Elektron metal is very readily pressed into rods and the following figures were obtained for 40 mm. pressed rods: tensile strength 25—28 kg. per sq. mm., elongation 15—20%, reduction in area 8—15%, notched bar test, 0·9—1·0 kg. per sq. mm. Brass screws must not be used owing to the ease with which, in damp air, the metal corrodes at the point of contact, but screws of elektron metal are readily made and are an efficient substitute.
—A. R. P.

Mercury; Purification of ——. P. H. Prausnitz. Z. angew. Chem., 1921, 34, 443.

In a trial of Harries' method of purification (J., 1921, 588 a) on mercury containing 1% Pb, no separation of lead oxide occurred in 8 hrs., a froth containing much mercury being formed. A similar amalgam was readily purified by the known method of allowing drops to fall through a tube 1·7 m. long filled with 25% nitric acid saturated with mercurous nitrate.—C. I.

Titanium. M. Billy. Ann. Chim., 1921, 16, 5—54.

A more detailed account of work already published (J., 1912, 1077; 1914, 317; Comptes rend., 1921, 172, 1411).—W. G.

Passivity [of metals] and photo-electricity. W. Frese. Z. wiss. Phot., 1921, 21, 37—44. (*Cf.* Allen, J., 1913, 1114.)

The photo-electric sensitiveness of iron, aluminium, and zinc is greatly reduced after treatment with water or alcohol, but that of copper, nickel, cobalt, silver, gold, palladium, and platinum is unchanged. Oxidising agents reduce the photo-electric sensitiveness of metals, whilst reducing agents, particularly nascent hydrogen, increase it. (*Cf.* J.C.S., Oct.)
—J. F. S.

Blast-furnace gas; Poisoning by ——. O. Johannsen. Stahl u. Eisen, 1921, 41, 1141—1143.

The few bad cases of gas poisoning which have been investigated by a committee of the Verein deutscher Eisenhüttenleute were found to be in no way connected with the degree of purity or method of purifying the gas, *i.e.*, whether the wet or dry purification process was employed. The phenomena were typical of carbon monoxide poisoning. Although purified furnace gas is more dangerous than crude gas—due it has been suggested to the protective effect of the dust—and the use of blast-furnace gas is being continually increased, an increase in furnace gas poisoning is not to be feared, because cleaning of the mains etc. is less frequently necessary with the purified gas, and better sealing appliances are available than in the case of crude gas.—T. H. Bu.

Litharge. Stahl. *See* VII.

Patents.

Open-hearth metal [*steel*]; *Manufacture of* ——. L. B. Lindemuth. U.S.P. 1,385,562, 26.7.21. Appl., 23.7.20.

A "SYNTHETIC pig metal" is produced from scrap in a melting furnace, desulphurised, and charged into an open-hearth furnace for finishing.—J. W. D.

Ingot iron or steel; Process and apparatus for the production of ——. E. Pohl. G.P. 338,119, 16.11.15, and (B) 338,229, 11.10.16.

(A) Several charges of iron or steel that have been treated for the removal of sulphur, silicon, and phosphorus in a Siemens-Martin converter or other furnace, are collected in a suitable container and, after mixing, allowed to stand until de-gassing and separation of slag are complete. If necessary also, suitable alloying metals may be added at this stage; the purified metal is then cast into ingots. (B) The vessel in which the several charges are mixed has a lining which is capable of reacting with the impurities in the metal, and thereby assists in their separation. If necessary fluxes may be added to the mixture, either in the solid state or after melting. For example, iron or steel prepared on a basic hearth is treated in a container lined with acidic material.—A. R. P.

Ferrosilicon castings; Manufacture of dense, highly acid-resisting ——. J. Römheld. G.P. 337,571, 5.6.19. Addn. to 336,561 (J., 1921, 589 A).

Iron and silicon are alloyed in a cupola, and the alloy is then brought to the desired composition in a second furnace where it does not come into contact with the fuel, which may be, for example, oil. An electric furnace is thereby rendered unnecessary. —A. R. P.

(A) *Rust-proofing of ferrous metals.* (B) *Coating of ferrous metals with a non-rusting alloy.* Rust-proofing Synd., Ltd., and F. Newman. E.P. 166,711—2, 21.4.20.

(A) The metal articles, freed from grease and oxidised scale, are coated with copper by immersion in a solution of copper sulphate with sulphuric acid, then dipped in a solution of lime and water to neutralise the acid, and subsequently coated either with a tin-mercury alloy by immersion in a hot solution of caustic soda in which is a quantity of granulated tin and a smaller quantity of mercury, or with a tin-zinc-mercury alloy by immersion in contact with zinc in a similar solution. (B) The metal articles are immersed for about 5 mins. in a boiling solution prepared from 100 galls. of water, 44 lb. of caustic soda, 56 lb. of granulated tin, and 1½ lb. of mercury.—J. W. D.

Ferrous metal forgings and the like; Prevention of black oxide of iron on ——. Rust-proofing Synd., Ltd., and T. F. Newman. E.P. 166,949, 21.4.20.

The forgings are dipped for an instant whilst at or near red heat in a solution consisting of 100 galls. of water and 100 lb. of iron sulphate so as to decompose the water in order that the oxygen shall unite with the metal to form an easily removable film of oxide which arrests the formation of black oxide of iron. After slow cooling this oxide film is removed by pickling or electrolytic means. —J. W. D.

(A, B) *Iron; Process for coating* —— *with lead.* (C) *Coating metals such as copper and alloys with lead.* J. R. Surmann. G.P. (A) 305,070, 16.10.17, (B) 310,628, 30.5.18, and (C) 305,071, 16.10.17.

(A) Iron articles are first coated with zinc or the like, and then dipped in a bath of molten lead containing 3—10% of tin amalgam (60—80% Sn, rest Hg). (B) Zinc is added to the lead bath. In this case iron articles do not require the preliminary zinc coating. The coatings obtained are dense, non-porous, resistant to corrosion and chemical action and harder than the usual lead coating. (C) Articles of copper or other non-ferrous metals do not require the preliminary zinc treatment, but are dipped directly in the lead.—A. R. P.

Metals; Producing bodies or articles from ——. G. Ising and H. Borofski. E.P. 132,261, 3.9.19.

An added substance, *e.g.*, graphite, is stirred or mechanically mixed with a metal heated to a pasty or plastic consistency and the mixture pressed so that the particles of the added substance remain permanently and uniformly distributed between the particles of the metal. Oxide present is removed by skimming from the molten metal or treating the disintegrated metal with an acid solvent, and fresh oxide is prevented from forming by employing an inert or reducing atmosphere. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 5255 of 1883.)—J. W. D.

Coating wires. Western Electric Co., Assees. of J. D. Hathaway. E.P. 146,518, 5.7.20. Conv., 20.9.16.

Copper wire is first subjected to a fluid bath of tin, then drawn through a die to reduce the tin coating to a degree of thinness and of such adherence that the tin is prevented from running when the wire is coated with insulating enamel at a temperature exceeding the melting point of tin.—J. W. D.

Furnace; Hearth smelting or annealing ——. H. Bansen, and Façoneisen-Walzwerk L. Mannstaedt und Co., A.-G. E.P. 152,319, 12.7.20. Conv., 2.12.18.

In a gas-fired furnace the gas and air are delivered from both sides into the combustion space in a direction transverse to the length, and the outlets of the burners are so arranged that the streams of gas and air are directed to different points or asymmetrically with respect to the combustion chamber, which is distinct from but communicates with the hearth chamber, the heating gases proceeding downward into the hearth in the longitudinal direction of the furnace. Additional fuel is supplied by channels which enter the combustion chamber at right angles to the direction of the main body of flames produced.—J. W. D.

Shaft furnace for roasting or burning fine-grained ores or for drying fine-grained materials such as coal dust. K. Luck. G.P. 337,343, 6.5.20. Conv., 26.9.19.

The shaft is provided with conveyors carrying shovels or bowls which constantly turn the material over. The walls of the shaft carry projecting tongues which deflect the stream of rising gases in such a manner that it passes transversely through the free-falling stream of fine-grained material. In this manner coal-dust passing through the hot zones of the furnace in a moist condition is rapidly dried in the stream of air in the lower part of the furnace, and the rising current of steam prevents the de-gassing or ignition of the coal in the hotter parts of the furnace.—A. R. P.

Tin; Purification of ——. J. J. Collins. E.P. 166,695, 20.4.20.

Impure tin is treated with stannic chloride in the presence of excess of tin, the resulting stannous chloride is dehydrated out of contact with air, fused, and electrolysed with the production of pure metallic tin and stannic chloride.—J. W. D.

Alloy. C. G. Fink, Assr. to Chile Exploration Co. U.S.P. 1,384,056, 12.7.21. Appl., 26.1.20.

An alloy resistant to the corrosive action of acid liquors contains lead and 3·0—65·0% of thallium. —J. W. D.

Alloy; Metal —— *and process of producing the same.* J. B. Grenagle, Assr. to The Rare Metals Reduction Co. U.S.P. 1,385,072, 19.7.21. Appl., 24.12.19.

The alloy contains 60—90% of molybdenum and 40—10% of tantalum.—B. M. V.

Alloy. F. Milliken, Assr. to S. F. Weaver and J. M. Repplier. U.S.P. 1,385,223, 19.7.21. Appl., 24.5.20.

An alloy to withstand pressure and with a high resistance to corrosion contains aluminium, lead, and an oxidising agent, the amount of oxidising agent being 1—2% of the deoxidising agent used for purifying the aluminium and lead.—J. W. D.

Zinc lead ores and the like; Treatment of ——. J. J. Collins. E.P. 166,929, 24.2. and 18.12.20.

Crushed sulphide ore or concentrate mixed with a solution of a lower chloride of a metal is subjected to the action of chlorine gas directly injected into the solution whereby the lead sulphide is converted into lead chloride, which is precipitated on cooling, while the zinc sulphide remains substantially unattacked. The chloride solution is then drawn off and the lead chloride dissolved with a hot saturated solution of sodium chloride from the residue, leaving zinc sulphide and sulphur from which any silver present is subsequently recovered.—J. W. D.

Lead and silver; Recovery of —— *from sulphide ores and metallurgical products.* H. Hey. U.S.P. 1,384,465, 12.7.21. Appl., 6.5.20.

The ore mixed with hydrochloric acid is heated to above 100° C. to effect preferential chloridising of the lead and silver.—J. W. D.

Metals; [Electrolytic] method of and apparatus for refining ——. S. A. Tucker. U.S.P. 1,384,499, 12.7.21. Appl., 7.5.20.

An apparatus for refining metal comprises a con- ainer for the crude metal, a container for the re- ined metal, means for permitting communication etween the containers through an electrolyte and or preventing communication between the metals n the two containers.—J. W. D.

A, B) *Molybdenum and molybdenum compounds; Recovery of* —— *from furnace residues.* (C, D) *Recovery of molybdenum and other rare metals that alloy with iron from the cupriferous Mansfeld schists.* Deutsche Molybdän Werke G.m.b.H. G.P. (A) 301,334, 17.3.17, (B) 310,794, 12.1.18, (C) 302,434, 14.11.16, and (D) 303,225, 2.5.17.

A) The residues (sows) are smelted in a blast- urnace with strongly basic fluxes and an excess of ir, whereby all the molybdenum goes into the slag. his is then sintered with sodium carbonate and licious fluxes or treated with alkali sulphides or olysulphides. Extraction of either mass with ater yields a practically pure solution of sodium molybdate. (B) The residues are ground and then roasted in the presence of an alkali and an oxygen carrier, such as alkali chromate or manganate, or substances which produce these compounds. (C) Material containing tungsten, molybdenum, vanadium, or titanium is smelted to a matte after addition of sufficient iron or materials which will produce iron sufficient to combine with and collect these metals. (D) Other metals of the iron group or alloys of these with iron may replace iron. —A. R. P.

Smelting minerals. F. W. Smith, Assr. to J. J. Glasheen, R. J. Snellberger, and W. J. Lewis. U.S.P. 1,385,723, 26.7.21. Appl., 15.8.19.

Gases from a blast furnace are filtered, the fume is discharged into a chamber and burned, and the residue whilst still hot removed by mechanical conveyors, so that filtering of the gases need not be interrupted to allow time for cooling of the burnt fume.—J. W. D.

Calcium molybdate briquettes; Preparation of —— *for the manufacture of molybdenum metal or its alloys.* Ampère-Ges.m.b.H., F. Rother, and O. Diefenthäler. G.P. 337,961, 13.3.20.

The briquettes are made by mixing molybdenum trioxide (roasted molybdenite) and calcium carbonate (limestone meal) with water, pressing the mixture into shapes and drying. No reaction takes place during the mixing process but only on drying, which is thereby hastened.—A. R. P.

Etching and colouring (damascening) metal surfaces; Process for ——. J. Rieder. G.P. 337,197, 6.12.19.

The surface of the metal to be etched is covered with thin porous paper which is saturated with an electrolyte. An electrode in the form of a metallic stencil is clamped on to the paper, and by passing a current between the stencil and the article, the design of the former is etched on the latter. If the surface of the article is not plane, a negatively printed paper with a coating impermeable to the electrolyte is pressed on to the article by means of an elastic electrode. The metallic stencils are protected from attack by coating the paper carrying the electrolyte with metal on one side. Metals that have been coloured by means of an oxide coating may be decorated with a bright pattern by the use of an electrolyte which does not attack the metal but reduces the oxide in the desired spots.—A. R. P.

Sulphide ores; Process and apparatus for roasting or drying and calcining fine-grained materials, e.g. ——, *and for the evaporation of solutions and saturation of liquids with gases or absorption of vapours by fine-grained or liquid substances.* R. G. M. Liebig. G.P. 337,593, 30.7.18.

The furnace consists of a number of hearths arranged in the shape of a ring and connected together by lateral openings or flues. Several series of hearths are arranged one above the other so as to utilise the heat of combustion of one series for preheating the ore charges in the others. The air necessary for the roasting is admitted to that hearth which contains the charge that has been longest in the furnace, and the gases are led backwards over the other charges, finally emerging from the chamber that contains the freshest charge of ore. —A. R. P.

Roasting ores; Process and apparatus for ——. *Process for calcining and for carrying out exothermic reactions in revolving furnaces.* F. Krupp A.-G. Grusonwerk. G.P. (A) 337,752, 18.4.20, and (B) 336,840, 2.12.19.

(A) A definite quantity of ore is charged into a revolving converter, the lining of which acts as a heat regenerator, capable of starting the ignition of the charge, and a corresponding regulated supply of air is admitted so that, throughout the whole roasting operation, the temperature remains practically constant. (b) The air necessary for the combustion or roasting of the material in the furnace passes through the walls in the same direction as the charge passes through the furnace, then enters the combustion chamber at the discharge end and passes backwards over the charge. By this arrangement the air is at the same temperature as the charge and, therefore, does not cool it, and the hot oxygen-rich air first passes through the nearly finished part of the charge thereby removing the last small quantities of combustible matter. —A. R. P.

Zinc dust; Process and apparatus for the production of ——. R. Seiffert. G.P. 337,906, 13.12.19.

In place of the usual condenser, a connecting piece with a narrow passage is inserted between the retort and the collector for the zinc dust. That part of the connecting piece which is attached to the retort is of the same shape and dimensions as the usual condenser. By this means any zinc furnace may be rapidly and cheaply adapted to the production of large quantities of zinc dust.—A. R. P.

Ferrous surfaces; Oxidation and coloration of ——. T. Rondelli and Q. Sestini, Assrs. to Sestron (Foreign Patents), Ltd. U.S.P. 1,386,076, 2.8.21. Appl., 24.8.20.

See E.P. 164,128 of 1920; J., 1921, 516 a.

Pickling solutions. U.S.P. 1,384,974. *See* VII.

Alloy-steel. U.S.P. 1,385,740. *See* XI.

XI.—ELECTRO-CHEMISTRY.

Selenium; Variation of resistance of —— with temperature. S. Datta. Phil. Mag., 1921, **42**, 463—471.

The resistance of selenium decreases from $66{\cdot}0\times10^5$ ohms at 0° C. to $1{\cdot}7\times10^5$ ohms at 160° C.; from this point it rises to $2{\cdot}0\times10^5$ at 170° C., at which temperature sublimation commences. It is shown that not more than 4% of the "light effect" is attributable to heat produced by light.

Quinone. Inoue and Shikata. *See* III.

Patents.

Graphite electrodes for use in electrolysis; Manufacture of ——. C. L. Higgins, D. A. Pritchard, and The United Alkali Co., Ltd. E.P. 167,041, 7.6.20.

Rapid disintegration of graphite electrodes used in electrolysis is prevented by impregnating the electrodes with a solution of a salt of iron or manganese or a mixture of such salts. The impregnation may be effected under reduced pressure, and after impregnation the salts are preferably converted into hydrated oxides or other insoluble compounds.—J. S. G. T.

Electric batttery and method of preparing manganese material therefor. O. E. Ruhoff, Assr. to French Battery and Carbon Co. U.S.P. 1,385,151, 19.7.21. Appl., 26.2.19.

The manganese material is roasted at or above a red heat, cooled, lixiviated with dilute sulphuric or hydrochloric acid, filtered, and the residue washed.—J. S. G. T.

Electric furnace. C. H. vom Baur. U.S.P. 1,385,411, 26.7.21. Appl., 30.12.18.

An electric furnace the plan of which is an ellipse with axes in the ratio 0·64:1 approximately, is provided with three electrodes adapted to be supplied with three-phase current, and placed one at the centre of the furnace and the others on the major axis of the ellipse, halfway between the centre and ends.—J. S. G. T.

Electrolytic cell. G. Baillio. U.S.P. 1,385,655, 26.7.21. Appl., 25.10.20.

An electrolytic cell comprises a vessel to which are clamped abutting side members each containing a cathode. A sheet of porous material is disposed between each side member and the body of the vessel, and an anode is disposed in the body portion between the cathodes.—J. S. G. T.

Alloy-steel; Electrical heating element of ——. P. A. E. Armstrong. U.S.P. 1,385,740, 26.7.21. Appl., 2.12.19.

An electrical heating element is made of alloy steel containing Cr about 20%, Si about 2%, Co about 2%, C under 1·5%, the remainder being mainly iron. —D. J. N.

Negative plates for electric accumulators. A. Pouchain. U.S.P. 1,366,490-1, 25.1.21. Appl., 22.6.20.

See E.P. 164,432-3 of 1920; J., 1921, 550 a.

Electric furnace. A. M. Erichsen. U.S.P. 1,367,364, 1.2.21. Appl., 28.11.19.

See E.P. 154,444 of 1919; J., 1921, 49 a.

Electric-resistance heater for melting furnaces. A. von Zeerleder, Assr. to Soc. Anon. des Ateliers de Sécheron. U.S.P. 1,367,442, 1.2.21. Appl., 22.12.19.

See E.P. 137,276 of 1919; J., 1921, 629 a.

See also pages (a) 647, *Separating suspended bodies* (E.P. 164,014). 663, *Purifying tin* (E.P. 166,695); *Refining metals* (U.S.P. 1,384,499); *Etching metals* (G.P. 337,197). 666, *Artificial resin*, (E.P. 130,608). 672, *Sterilising liquids* (E.P. 164,274). 673, *Killing micro-organisms* (E.P. 150,318).

XII.—FATS; OILS; WAXES.

Oil-plant; The betrata, a new —— from Madagascar. F. Heim, E. Garrige, and M. Husson. Bull. de l'Agence Gén. Col., 1919, **12**, 679—691; 1920, **13**, 14—21. Bull. Agric. Intell., 1921, **11**, 856.

The seeds of betrata (*Ricinodendron mahafalense*) yield 81·4% of kernels and 18·6% of husks. The oil yield is 44·64% of the entire fruit or 57·68% of the decorticated nuts. The cake from the undecorticated nuts is poisonous. The oil has a pale golden yellow colour, is semi-drying, and consists entirely of triglycerides of stearic and oleic acids with a small quantity of triglycerides of volatile fatty acids and hydroxy-acids. It gives a good hard soap when mixed with copra and lard and is specially valuable for soap-paste for the textile industry. The cake contains N 5·43%, K_2O 1·236%, P_2O_5 1·589%. —H. C. R.

Chrysalis oil. S. Kawase, K. Suda, and A. Fukuzawa. Nippon Kwagaku Kwai Shi (J. Chem. Soc. Japan), 1921, **42**, 181—235.

Chrysalis oil had the following characters (mean value of 3 or 4 samples):—Sp. gr. at 15°/15° C., 0·9253; $n^{20}=1{\cdot}4647$; viscosity 8·14° Engler at 20° C.; 2′ 58″ (Redwood) at 30° C.; flashing point, 201° C.; m.p., 11·8°—16° C.; solidif. pt., 6·1° C.; heat of combustion, 9508·76 cals.; acid value, 7·97—71·76;

saponif. value, 194·02; iodine value, 132·90; Hehner value, 94·32; unsaponifiable matter, 2·48%; hydroxy-fatty acids, 0·33—1·18%; acetyl acid value, 140·27; acetyl value, 3·46; glycerol content, 7·40—9·68%; Reichert-Meissl value, 0·585 c.c. The mixed fatty acids of chrysalis oil are composed of about 25% of solid acids and 75% of liquid acids, the former consisting of a small quantity of palmitic acid and a large quantity of a new isomeric acid, isopalmitic acid, m.p. 57°—59° C., methyl ester, m.p. 28° C.; whilst the latter consist of about 80% of oleic acid, 20% of linolenic acid (containing isolinolenic acid), and a small quantity of linolic acid. For the determination of solid and liquid acids in the mixed fatty acids, the authors propose a new lead-salt alcohol method. (*Cf.* J.C.S., Sept.)
—K. K.

Hollyhock seed and oil; Composition of ——. R. S. Hiltner and L. Feldstein. J. Ind. Eng. Chem., 1921, **13**, 635.

Mature seeds from various varieties of hollyhock contained moisture, 4·4; ash, 6·9; oil (ether extract), 11·9; crude protein, 21·2; crude fibre, 25·6; starch, 9·1%. The greenish-yellow coloured oil had sp. gr. at 15·6° C., 0·9275; $n_{\mathrm{D}}^{25}=1{\cdot}4722$; iodine value, 119·0; it yielded a positive reaction with Bechi's and Halphen's tests, but no colour was obtained with the latter test after the oil had been heated at 250° C. for 10 mins.—W. P. S.

Fat of Caballus equus. A. Heiduschka and A. Steinruck. J. prakt. Chem., 1921, **102**, 241—266.

The material was a mixed product obtained from the various fatty tissues of the horse; it had m.p. 32·3° C., sp. gr. 0·9224 at 15° C., 0·9135 at 25° C., $n_{\mathrm{D}}^{40}=1{\cdot}4617$, acid value 2·62, saponif. value 203·9, Reichert-Meissl value 0·42, Polenske value 0·37, iodine value 75·17, acetyl value 14·12, saponif. value after acetylation 6·93. The mixed fatty acids consist of linolenic acid 1·7%, linolic acid 6·7%, oleic acid 55·2%, stearic acid 6·8%, and palmitic acid 29·5%. In addition, 0·43% of unsaponifiable matter, mainly cholesterol, was present.—H. W.

Cholesterol in tissue fats; Source of error in the colorimetric methods for the estimation of ——. J. A. Gardner and F. W. Fox. Biochem. J., 1921, **15**, 376—379.

Alcoholic potash on being extracted with ether yields some resinous matter which when dissolved in hloroform gives a coloration with acetic anhydride nd sulphuric acid. Such a coloration is sufficient o introduce an error in the estimation of cholsterol.—S. S. Z.

oap-mixtures; Partial salting out of ——. J. Wolff. Z. Deuts. Oel- u. Fettind., 1921, **41**, 289—290. Chem. Zentr., 1921, **92**, IV., 204—205.

N working a batch of fat consisting of 39% of nimal fatty acids and 61% of a mixture of palmernel with about ⅙ of coconut oil fatty acids, ariations were observed in the saponification values f the fatty acids obtained from the curd, from the urd-paste obtained by boiling-out the lye, and from he spent lye. The lyes set to a jelly both in the resence and in the absence of caustic alkali. It as established that the fatty acids of the curd and hose of the curd-paste have different saponification alues, and that the values differ considerably cording to whether a product of the first or of the cond salting-out is taken. The values show that he product obtained by the salting-out of the soaps as to form a curd-paste contains greater quantis of the sodium salts of the animal fatty acids than e curd afterwards produced from the paste. The ent lye beneath the curd-paste consists almost tirely of the sodium salts of palm-kernel and coconut oil fatty acids. A small quantity of hydroxy-fatty acids present gave a comparatively high saponification value. The soda and alkali content of the spent lye perhaps favoured the partial salting out of the sodium soaps of the animal fatty acids.

Hydrocarbon oil from vegetable oil. Mailhe. *See* IIa.

Grape pomace. Rabak and Shrader. *See* XIXa.

Patents.

Splitting of oils and fats; Processes of hydrolysis particularly ——. P. J. Fryer, and Catalpo, Ltd. E.P. 166,971, 24.4.20.

The oil or fat is hydrolysed by the usual agents in the presence of colloidal clay (*cf.* E.P. 106,890 and 121,191; J., 1917, 879; 1919, 41 a), whereby the process is expedited and a high degree of hydrolysis attained. The fatty acids are also of better colour than those obtained without the use of the clay.—H. C. R.

Oils; Deodorisation of ——. J. W. Bodman and T. M. Godfrey, Assrs. to W. Garrigue and Co. U.S.P. 1,385,660, 26.7.21. Appl., 12.8.19.

The oil is brought as a spray into contact with a gas in a vacuum chamber at a temperature sufficient for the evaporation of the odorous constituents. The unevaporated oil is quickly removed to a place of considerably lower temperature.—H. C. R.

Fatty acids from marine animal oils; Solid preparations from ——. Chem. Werke Grenzach A.-G. G.P. 335,911 and 336,945, 6.4.19.

The free fatty acids from liver-oils or their salts are treated with suitable oxidising agents and transformed into difficultly soluble salts, especially those of the alkaline-earths and heavy metals. The fatty acids or salts from other fish-oils can be used instead of those from liver-oils. The fatty acids are obtained by the saponification of medicinal cod-liver-oil, fish-liver-oil, sprat or herring oil with aqueous or alcoholic potassium or sodium hydroxide, acidification of the alkaline solution, and separation of the free fatty acids. To oxidise the fatty acids they are either emulsified with water or dissolved in organic solvents or in dilute alkalis or ammonia, and treated with permanganate, hydrogen peroxide, air, or chlorates, in presence of suitable catalysts, such as manganese acetate or 1% osmium tetroxide solution. The iodine value can be reduced to 0 or the oxidation stopped at an earlier stage. Snow-white, light yellow, or brown powders are obtained which have neither taste nor smell. These can be used as substitutes for cod-liver-oil.—H. C. R.

Oil-cake and like hydraulic presses [; Means for supporting press-plates in ——]. J. E. McCoid. E.P. 167,229, 27.4.20.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Lithopone; Light-resistant ——. Steinau. Chem.-Zeit., 1921, **45**, 741—742.

The tendency of lithopone in sunlight, particularly in the presence of moisture, to blacken, and to recover when withdrawn from exposure, is associated with the presence of chlorine introduced from sodium chloride and bleaching powder during the purification of the original zinc liquor. The change is not due to the presence of radium in the barium, for a mixture of calcium sulphate and zinc sulphide prepared in the same way exhibits the same weakness. Chemically pure lithopone and zinc sulphide are resistant to light, but develop the characteristic behaviour when treated with a little zinc chloride solution. It is not possible to remove the traces of zinc chloride by washing and thus to improve the quality of the pigment. Carefully dried lithopone shows blackening in a much smaller degree, and doubtless the distinctly better behaviour of mixtures of lithopone and linseed oil after being dried in the dark is explained by the exclusion of moisture by the latter substance. Not only does moisture accelerate the darkening of lithopone in sunlight, but it also expedites the reverse change in the dark and with the exclusion of moist air, lithopone will remain permanently discoloured. The change is probably accounted for by a dissociation of the illuminated surface with liberation of metallic zinc of a grey colour. The tendency to discoloration can be avoided by excluding air during the roasting operation in manufacture, this operation being responsible for the reaction between the retained sodium or calcium chloride and the zinc sulphide in the lithopone, with the formation of zinc chloride. It is better, however, to effect the purification of the zinc liquors without the aid of chlorides; under these conditions not only is the resulting lithopone free from the common defect, but the separated ferric hydroxide and manganese dioxide are purer and find a ready sale.—D. F. T.

[*Lithopone*]. *Manufacture of mixtures of barium sulphate and zinc sulphide.* P. Desachy. E.P. 126,626, 5.5.19. Conv., 19.10.17.

Into three tanks, which are capable of being heated and are situated above a fourth tank which serves as a mixer and is also heated, are placed respectively the following solutions: neutral zinc sulphate, a solution of an alkali or of a salt of an alkali that will precipitate zinc, *e.g.*, sodium sulphite, and a solution of barium sulphide from which part of the barium (not exceeding one half) has been removed by treatment of the solution with carbon dioxide followed by filtration. The first two solutions are boiled and discharged slowly into the mixer with continued heating until a slight precipitate of zinc sulphite begins to form, when the barium sulphide solution is run in. The rate of mixing the solutions is so arranged that the solution never gives a reaction for sulphide with lead paper and, at the end of the reaction, the precipitate contains a small quantity of zinc sulphite. The precipitate is filtered off, dried at 100° C. in the absence of air, and then heated to 850°—900° C., at which temperature the zinc sulphite decomposes with the evolution of sulphur dioxide, which assists in the production of a good white product.—A. R. P.

Litharge and red lead; Process of making ——. H. M. Gabel. U.S.P. 1,382,282, 21.6.21. Appl., 6.12.19.

Comminuted lead is brought into contact with an oxidising gas and subjected to abrasion. The gas is intermittently heated to temperatures sufficient first to dross the lead and then to convert the drossed lead into litharge.—A. R. P.

Soot; Production of fine —— suitable for the manufacture of pigments. E. Szarvasy. U.S.P. 1,383,674, 5.7.21. Appl., 3.6.20.

Methane diluted with a neutral gas is decomposed by heat treatment.—D. F. T.

Waterproof paints. Dr. Plönnis und Co. G.P. 336,826, 29.5.18. Addn. to 301,783 (J., 1921, 311 A).

If tar oil be mixed with the paint it adheres better, is less brittle, and protects well against rust.
—C. A. C.

Resin; Manufacture of artificial —— and intermediary products. Resan Kunstharzerzeugungsges. E.P. 130,608, 29.7.19. Conv., 22.3.18.

The condensation of phenolic substances with an aldehyde, *e.g.*, formaldehyde, or an aldehyde-generating compound, with formation of resin-like products, is effected by electrolysis with the addition of an electrolyte such as sodium chloride or sulphate, a diaphragm being used if desired.—D. F. T.

Resin-like substances; Manufacture of ——. M. Melamid. E.P. (A) 143,185, 10.1.20, and (B) 143,187, 14.1.20. Conv., 12.5. and 13.5.19. Addns. to 137,291 (J., 1921, 520 A).

(A) The earlier method for producing resin-like substances by the condensation of phenol-alcohols with sulphochlorides derived from aromatic hydrocarbons is improved by using, instead of the latter, sulphochlorides of aromatic compounds containing also carboxyl or hydroxyl groups or both, *e.g.*, salicylic sulphochloride. For the reaction it is necessary to have sufficient alkali present to neutralise at least one of the hydroxyl or carboxyl groups. (B) The products are improved by heat treatment in a vacuum at a temperature above 100° C.—D. F. T.

Resinous substances; Manufacture of ——. A. G. Bloxam. From A.-G. für Anilin-Fabr. E.P. 165,322, 10.6.20.

ar-Tetrahydronaphthol or a mixture of *ar*-tetrahydronaphthols made by fusion of commercial tetrahydronaphthalenesulphonic acid with alkali, is treated with an aldehyde, *e.g.*, formaldehyde or acetaldehyde, with or without addition of a condensing agent, such as hydrochloric acid, ammonium chloride, or potassium hydroxide. The products obtained are soluble in alcohol, benzene, linseed oil, and turpentine oil, but the lacquers obtained from them darken on exposure to the air. This may be obviated by treating the resins with an acidylating, alkylating, or aralkylating substance, *e.g.*, acetic or benzoic anhydride, or ethyl bromide.—A. R. P.

Artificial resin; Manufacture of ——. C. Böhler. G.P. 335,984, 17.4.17.

Anhydroformaldehyde-aniline alone or together with small amounts of acids or alkalis, and with or without aniline, is heated to 130°—140° C. for some time. The product increases the solubility of natural and artificial resins and may be used in fireworks without impairing the light effect.
—C. A. C.

[*Shellac;*] *Fusible adherent* [*from* ——] *and method of making same.* F. H. Davis, Assr. to F. R. Coughlin. U.S.P. 1,374,492, 12.4.21. Appl., 4.2.19.

By boiling shellac or like resinous product with a solution of ammonia and sodium chloride, a precipitate is formed which is suitable for use as a fusible adhesive for transferring gold leaf from a backing on to another object without causing discoloration.

Rosin; Treating ——. F. M. Rogers and C. P. McNeil, Assrs. to Standard Oil Co. U.S.P. 1,381,504, 14.6.21. Appl., 31.8.20.

In order to increase the grease-setting properties of rosin it is digested under pressure at such a temperature, depending on the pressure, that the abietic acid content of the rosin does not distil, but is converted into its grease-setting form.—A. R. P.

Drying oils; Preparation of ——. E. Bielouss, Assr. to H. A. Gardner. U.S.P. 1,384,423, 12.7.21. Appl., 21.7.20.

Drying oils are prepared by limited chlorination of paraffin hydrocarbons with subsequent dechlorination at moderate temperatures and out of contact with an active catalyst, so as to avoid excessive formation of objectionable by-products.—D. F .T.

Drying oils; Preparation of —— from hydrocarbons. H. A. Gardner and E. Bielouss. U.S.P. 1,384,447, 12.7.21. Appl., 9.12.19.

In the production of drying oils from chlorinated hydrocarbons, the chlorine is removed from the material in the presence of a solvent for the chlorinated compound.—D. F. T.

(A) *Paint-vehicle for anhydrous pigments.* (B) *Paint composition.* (C, D, E) *Mineral [paint] oil.* W. N. Blakeman, jun. U.S.P. 1,385,033—7, 19.7.21. Appl., (A, B) 12.6.17, (C, D, E) 9.2.21.

(A) A paint-vehicle comprises a fatty oil, and a mineral oil of the Texas oil type. (B) A paint composition comprises a mineral oil of the Texas oil type, and an anhydrous pigment. (C) A mixture of a mineral oil of the Texas oil type and tung oil. (D) A mixture of an oxidised mineral oil of the Texas oil type and a fatty oil. (E) A hydrogenated mineral oil of the Texas oil type.—C. A. C.

[Linoleum] floor coverings; Manufacture of ——. A. C. Holzapfel. E.P. 165,008, 21.10.20.

A mixture of residual pitch derived from the treatment of fats and oils, *e.g.*, stearine pitch, a finely divided inert substance, such as kieselguhr, and sawdust, preferably from balsa wood, or coconut fibre, is incorporated with a colouring material and the mixture applied to a flexible backing. For example, 57 pts. of the pitch heated to 250°—400° F. (121°—204° C.) is mixed with 8 pts. of kieselguhr, 16 pts. of sawdust, and 19 pts. of colouring material. —A. R. P.

Linoleum; Process for producing —— and product thereof. Linoleum composition and process of making same. G. W. Priest, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,381,737—8, 14.6.21. Appl., 25.9.18.

(A) An oxidised oil, or (B) an oil, is mixed with a polymerised product of the coumarone or indene group of compounds and the mixture is heated to a temperature not above 100° C.—A. R. P.

Linoxyn solutions; Manufacture of ——. C. Tiedemann und H. Deckert. G.P. 335,905, 6.8.18.

Linoxyn which is only sparingly soluble in the usual varnish solvents is brought into solution by heating under normal pressure with a tetrahydronaphthalene alone or together with other additions. The solution may be diluted with the usual varnish solvents. The solution dries to a sticky film which gradually becomes hard, tough, and elastic. —C. A. C.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

[Rubber;] Mechanical properties of calendered sheets [of ——]. A. van Rossem. Indiarubber J., 1921, 62, 343—345.

When unvulcanised rubber has been passed between two hot rolls of a calender and finally over a third cold roll, it possesses a difference in its transverse and longitudinal mechanical properties; the tensile strength longitudinally is much greater and the extensibility much less than the corresponding properties measured transversely. A similar difference is observed if the rubber sheeted between the two hot rolls, is "frictioned" on to a sheet of cloth passing between the second roll and a third hot roll. Using three hot rolls without a cloth, the properties of the rubber are substantially the same in all directions. The effect arises from the fact that the rubber after calendering tends to contract longitudinally; the use of a third cold roll or of the cloth prevents this, the cooled rubber then exhibiting the described lack of uniformity in its properties in different directions; if such cooled rubber is heated to 70° C. for 2 hrs., it contracts lengthwise and its properties become equalised in all directions. Hot vulcanisation also removes the inequality, but it persists after cold vulcanisation with sulphur dioxide and hydrogen sulphide. Gutta-percha and balata calendered in a similar manner, also show a marked difference in extensibility in the two directions, but little difference is observable in the tensile strength.—D. F. T.

Rubber; Swelling of —— in various liquids. Wo. Ostwald. Kolloid-Zeits., 1921, 29, 100—105.

From an examination of data taken from the literature on the swelling of raw and vulcanised rubber in various liquids, it is concluded that the swelling power of a substance (Q) decreases strongly with increasing dielectric constant of the liquid (D) which effects the swelling. As a first approximation this is expressed by the equation $D.\sqrt[n]{Q}=K$, in which n is a number between 2 and 3 and K a constant. (*Cf.* J.C.S., Oct.)—J. F. S.

Vulcanisation in solution, without and with accelerators. M. Le Blanc and M. Kröger. Z. Elektrochem., 1921, 27, 335—358.

Experiments were made on four qualities of Hevea rubber, I., II., IV., and VI., by the sulphur chloride process, the hot sulphur process, and the Peachey (sulphur dioxide and hydrogen sulphide) process, without and with accelerators. The progress of the vulcanisation was followed, according to the process used, by observations on the syneresis phenomenon, by observing the time taken for gel formation to reach a specified stage, or by viscosity measurements. The syneresis experiments on cold vulcanisation with sulphur chloride in benzene showed that the phenomenon—the separation of liquor from the gel—did not start until sufficient sulphur chloride was present to form Hinrichsen's compound, $C_{20}H_{32}S_2Cl_2$. The analogous phenomenon of flocculation which occurs in more dilute solutions follows the same rule. The concentration limit in benzene, for example, between solutions which will gel and those which merely flocculate depends on the previous treatment which the rubber has had. If it has been heated for some hours at 130° C., a 3% solution is needed for gel formation, whereas before heating, a 1% solution will gel. This limiting concentration appears to have an important connexion with the mechanical properties of the rubber, in the sense that bad mechanical properties are associated with a high limit. Working the raw rubber raises the limit. This limiting concentration also depends on the temperature, and consequently the determination of the effect of temperature on rapidity of gel formation under definite conditions of concentration is complicated. The velocity of gel formation, *i.e.*, of vulcanisation, also depends on the solvent, increasing as the viscosity of the solution decreases and as the dielectric constant of the solvent increases. This is to be accounted for by the depolymerising action of the solvent on the rubber molecules. Comparative experiments with the four varieties of rubber examined in 1% benzene solution at 20° C. with sulphur chloride showed decreasing rate of vulcanisation from Hevea I. to Hevea VI. Experiments on hot sulphur vulcanisation were made in tetralin solution at 140° C. Much higher concentrations of rubber, at least 10%, were needed to get gel formation and, to get results in any way comparable with one another, it was necessary to dedepolymerise the rubber by boiling the solution for some time before adding the sulphur. The course of the vulcanisation process appears to be similar to that when sulphur chloride is used—a fall in viscosity followed by gel formation. Results of experiments on the change of viscosity during cold and hot vulcanisation are recorded. To investigate the Peachey process experiments were made on the rate of precipitation of sulphur from benzene solutions of sulphur dioxide and hydrogen sulphide with and without different accelerators. Such substances as quinoline, nicotine, *p*-nitrosodimethylaniline, and *p*-aminodimethylaniline accelerate the precipitation, but not in the order of their effectiveness as accelerators for vulcanisation. In presence of rubber, however, the reaction $2H_2S+SO_2=3S+2H_2O$ proceeds rapidly in benzene solution, and, from the results of syneresis experiments, the compound formed appears to be $C_{20}H_{32}S$. This explains the relatively small quantity of sulphur needed for vulcanisation by the Peachey process, since, according to Hinrichsen, ordinary hot vulcanisation results in the formation of a compound $C_{20}H_{32}S_4$. The effect of accelerators is generally to lower the viscosity of the rubber solution, and it was found possible to make quantitative comparison of the influence of different accelerators by the syneresis and gel formation methods. By this means it is possible to determine in a simple manner whether a particular substance will be of any value as an accelerator. This applies to vulcanisation with sulphur chloride in the cold or with sulphur in the hot. In the Peachey process the usual accelerators have a retarding effect, since they cause the precipitation of the sulphur in an insoluble form. The influence of accelerators is also less in solvents having a high dielectric constant, probably because the solvent itself has already played a part by depolymerising the complex rubber molecules.—E. H. R.

Vulcanisation; Acceleration of —— by organic accelerators. A. Maximoff. Caoutchouc et Gutta-Percha, 1921, **18**, 10,944—10,947, 10,986—10,988.

In the presence of powerful organic accelerators such as secondary aliphatic amines and thiouram mono- and di-sulphides, satisfactory vulcanisation can be obtained with as little as 1·4% of sulphur calculated on the rubber, and in ordinary technical work using such accelerators, it may be necessary to adjust the proportion of sulphur in the unvulcanised mixture. Of all metallic oxides, zinc oxide is most effective in increasing the activity of the accelerator; lead oxide is less effective, whilst the action of the alkaline-earth oxides and antimony oxide is negligible. Aromatic monoamines and phenol do not aid the accelerator except in the presence of lead oxide. A suitable proportion of accelerator is 0·25% (calculated on the rubber), irrespective of its molecular weight, whilst for effective vulcanisation there should also be at least 0·85—1·5% of zinc oxide or 3·5—7% of litharge. The marked accelerating power of the reaction product of carbon bisulphide and dimethylamine is due to the formation, during vulcanisation, of an exceedingly active zinc or lead compound. The crude reaction product is not a pure substance, but consists of tetramethylthiourea (approx. 20%), dimethylamine dimethyldithiocarbamate (approx. 30%), and tetramethylthiouram disulphide (approx. 50%), the first-named being inactive, whilst the other two, in the presence of zinc oxide or lead oxide, are powerful catalysts. The disulphide, which if used in sufficient quantity can effect vulcanisation without the additional presence of sulphur, by treatment with potassium cyanide can be converted into tetramethylthiouram monosulphide, which exhibits comparable acceleration of vulcanisation. The process by which these substances exert their accelerating power involves the formation of the zinc or lead salt of the dimethyldithiocarbamic acid. It is remarkable that the action of the oxides of the alkaline-earths on the thiouram mono- or di-sulphide gives rise not to the corresponding dimethyldithiocarbamates but to inactive tetramethylthiourea and carbon bisulphide, thus providing an explanation of the ineffectiveness of these oxides relative to zinc oxide. Diphenylthiuram disulphide, zinc diphenyldithiocarbamate, ammonium phenyldithiocarbamate, and ammonium dithiocarbamate also decompose with formation of relatively inactive products, such as diphenylthiourea, and so possess no marked accelerative action. The view as to zinc alkyldithiocarbamates forming essential intermediate products is confirmed by the fact that the isolated zinc dimethyldithiocarbamate in the presence of a little zinc oxide is more than ten times as powerful an accelerator as the corresponding secondary amine or tetramethylthiouram disulphide without zinc oxide; similar results were obtained with other bases and their corresponding derivatives, *e.g.*, piperidine, diethylamine, ethylamine, di-isobutylamine, di-isoamylamine, and benzylethylamine. Tetramethylthiouram disulphide does not appreciably affect the surface tension of molten sulphur, but zinc dimethyldithiocarbamate markedly reduces it. Amongst the technical possibilities with powerful organic accelerators is the production of two "solutions," one containing rubber and sulphur and the other containing rubber, zinc oxide, and the accelerator; by mixing these and evaporating it is possible to obtain films which will vulcanise at 100° C. Indeed, with similar mixtures containing 6—8% of sulphur and 10—20% of zinc oxide, it is possible to observe vulcanisation at the ordinary temperature.—D. F. T.

Rubber; Relative acceleration of different compounds of lead in the vulcanising of ——. J. M. Grove. Indiarubber World, 1921, **64**, 663—664.

Using a mixture of smoked sheet rubber 80, sulphur 2½, zinc oxide 5 pts., and different proportions of various lead accelerators, the total of 100 being completed by the addition of barytes, with vulcanisation in all cases for 1 hour at 280° F. (138° C.), the following proportions were found to be necessary to produce results comparable to those yielded with 1% of litharge:—Sublimed white lead 7, basic lead carbonate 3, sublimed blue lead 3. In a further set of experiments in which 3% of basic lead carbonate, sublimed blue lead, sublimed white lead, pure lead sulphate, and normal lead sulphate were introduced separately into a "technical" mixing containing rubber 65%, sulphur 2¼%, zinc oxide 5%, *blanc fixe* 5%, barytes 22½%, and hexamethylenetetramine ¼%, the combination of lead compound with organic accelerator was equivalent to a considerably larger percentage of the latter alone. The results indicate that the accelerating action of basic lead carbonate may not be entirely dependent on its content of lead hydroxide.—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Hide; Characteristics of fresh steer ——. G. D. McLaughlin. J. Amer. Leather Chem. Assoc., 1921, 16, 295—309.

Experiments to determine the effect of acids, alkalis, and salts on the swelling of pieces of hide within 30 mins. after flaying, showed that organic acids gave most swelling in concentrations greater than *N*/20. Further soaking in lactic acid gave additional swelling. Alkali swelling depended on the character of the alkali and the concentration. Heavy metal salts repressed swelling, and their effect should be noted in salting hides and skins, especially in subsequent soaking and liming. Mercuric chloride must be used with due care in the disinfection of hides, as it considerably repressed the swelling. Salts repressed acid swelling but increased alkali swelling. Urea and pyridine did not swell fresh hide.—D. W.

Hide powder; An "insoluble" ——. H. R. Zeuthen. J. Soc. Leather Trades Chem., 1921, 5, 175—177.

Freiberg chromed hide powder was washed with water, then with alcohol and finally dried. The powder so prepared was found to keep perfectly well for a year. Tannin analyses carried out with this powder showed good agreement with parallel analyses using freshly washed chromed hide powder. —D. W.

Chrome tanning. Mechanism of the neutral salt effect. D. Burton. J. Soc. Leather Trades Chem., 1921, 5, 183—186, 192—198.

It is suggested that the effect of neutral salts on chrome tanning liquors is to decelerate the penetration of the chromium compounds by a blockading action of the neutral salt. Changes in swelling will also occur due to the combined action of the acid and salt. Neutral salts cause more acid to be taken up by the pelt, hence a more basic chromium salt with a lower rate of diffusion will remain in the tanning liquor, and thus the penetration of the chromium into the pelt will be retarded. The increase in the acidity of the pelt will involve a longer time for neutralisation and thus further retard the anning. Experiments have been carried out to determine the effect of neutral salt additions on the precipitation points of violet and green chrome lum solutions (*cf.* J., 1920, 666 a) and a comparable hromium sulphate solution. On account of several isturbing factors the only conclusion arrived at was that sulphates cause a greater increase in the mount of alkali required to initiate precipitation han chlorides. The chlorides form acid sulphates with the free acid, thus removing some of the latter and causing further hydrolysis of the chromium salts in solution. The addition of a neutral sulphate diminishes the amount of hydrolysis. These conclusions are in agreement with the facts determined by Wilson and Gallun (J. Amer. Leather Chem. Assoc., 1920, 273) and Thomas and Baldwin (J., 1918, 434 a, 555 a).—D. W.

Chrome tanning. Influence of neutral salts on the absorption of the acid and chromium from chrome [tanning] solutions by gelatin. D. Burton and A. Glover. J. Soc. Leather Trades Chem., 1921, 5, 187—192.

Neutral salts decrease the diffusion of the chromium into gelatin and the order of retardation is the same as that of the degrees of hydration. Neutral chlorides cause an increase in the amount of acid taken up by the gelatin, while sulphates cause a decrease. Double salt formation seems to have very little influence on the rates of diffusion. The swelling may be greater in chrome tanning solutions than in water, but neutral salts diminish this.—D. W.

[Chrome tanning liquors;] Analytical determination of basicity figures [of ——]. J. E. Pickering. J. Soc. Leather Trades Chem., 1921, 5, 177—183.

The acidity determination is carried out in a 500 c.c. beaker instead of a white basin. The chrome liquor is brought to the boil, titrated with *N*/10 alkali, the beaker placed upon a white tile on the burette stand, immediately behind which is a "half-watt" lamp, covered with an opal lamp shade, so arranged that the rays of light strike upwards through the solution in the beaker. The titration is continued steadily with frequent shaking of the beaker, until the liquid assumes a distinct light blue colour and finally a yellowish-pink shade. This procedure obviates difficulties with the titration arising from dark murky atmospheres, unsuitable artificial illuminants, and basins of defective colour.—D. W.

Chromium salts; Basicity of —— *and its graphical representation.* G. Grasser. Collegium, 1921, 319—325.

The basicity expressed according to Schorlemmer's method (*cf.* J., 1921, 155 a) is plotted against the tanning intensity and a maximum is obtained for the salt $Cr_4(SO_4)_3(OH)_6$. Other graphs are shown in which there is an ordinate at each end of the abscissa, one representing the acidity and the other the basic groups, (OH) and (Cr). In a third the basicity is plotted against the acidity. The chemical properties of different chromium salts can be represented by these graphs and deductions made as to their physical properties.—D. W.

Preparations are described, consisting of mixtures of precipitate derived from neutralised mine-water and a filler of calcareous material, in varying proportions. One preparation contains in addition, iron salts, and in another, calcite is the filling material.—A. G. P.

Spray. U.S.P. 1,384,304. *See* XIXb.

XVII.—SUGARS; STARCHES; GUMS.

Bagasse; Deterioration of —— *on keeping.* G. Loos and A. Schweizer. Arch. Suikerind. Nederl.-Indië, 1921, **29**, 21—24.

If a sample of bagasse from the mill be very finely divided, its sugar content will fall from about 3% to *nil* in about 7 hrs.; whereas when the subdivision is less complete, and much of the rind is separated from the pith by sifting, deterioration is much less rapid. It is concluded that the decomposition of the sugar is effected by an enzyme present only in the rind of the cane.—J. P. O.

Micro-organisms concerned in the deterioration of sugar. W. J. T. Amons. Arch. Suikerind. Nederl.-Indië, 1921, **29**, 1—18.

A number of *Aspergillus* and *Penicillium* moulds causing the deterioration of raw sugar in storage have been identified. Frequently sugars in a rapid state of deterioration showed only a few micro-organisms on plating, whereas others which remained sound gave high counts. On the other hand, the reverse state sometimes obtained, and there appears to be no relationship between the number of organisms and the rate of deterioration (*cf.* Kopeloff, J., 1920, 523 A).—J. P. O.

Cane juice; Clarification of raw —— *by defecation with lime.* M. Bird. La. Planter, 1921, **66**, 184.

All the lime necessary for the defecation of the raw juice is added to the dilute juice leaving the last unit of the milling installation, and the alkaline liquor is returned to the first unit for maceration. Advantages of this method of working are that loss of sugar by fermentation during milling is inhibited; the amount of lime necessary for clarification may be precisely controlled; and precipitated impurities are retained to some extent by the bagasse, the work of the filter-presses thus being relieved.—J. P. O.

Cane juice; Clarification of —— *by the sulphitation process.* I. H. Morse. La. Planter, 1920, **65**, 301—302, 315—317.

If the impurities separated on treating the raw juice with sulphurous acid and lime be separated before passing the treated juice to the heaters, separation being effected preferably in the apparatus described in U.S.P., 1,311,831 (J., 1919, 691 A), a greater amount of *bagacillo* is removed and less scale deposited in the heaters than ordinarily.
—J. P. O.

Sugar and molasses; Production of plantation white granulated —— *in Louisiana.* V. H. Eckard. La. Planter, 1921, **66**, 122—124.

Raw juice from the mills is sulphured to an acidity not exceeding 3·5—4·0 c.c. of $N/10$ KOH per 10 c.c., limed back to about 0·8—1·0 c.c. (a little less than the natural acidity of the juice), heated to 180°—200° F. (82°—93° C.), and run into open defecators with coils, the "blanket" accumulating being removed by sweeping into a gutter leading to the filter-presses. The clarified juice is further treated, either in brush pans, or preferably by filtration through bags, concentrated to 54° Brix, allowed to subside in the syrup tanks and boiled to grain in the pans. A first massecuite is boiled from syrup and wash separated from the run-offs from the second massecuite, and a second massecuite from syrup and all the wash and run-offs from the first massecuite, the molasses from the second massecuite not being further exhausted. A granulated sugar comparing well with refined sugar is obtainable by this procedure.—J. P. O.

Sucrose; Modified Clerget (double polarisation) method for the determination of ——. R. F. Jackson and C. L. Gillis. Int. Sugar J., 1921, 23, 445—448.

Replying further to Browne's criticisms (J., 1921, 271 a, 443 a), two series of experiments are described by the authors in evidence of their statement that the salt effect is constant even for concentrations (with respect to both salt and sugar) far beyond those concerned in the methods proposed in Sci. paper, U.S. Bureau Standards, 375 (J., 1920, 634 a). At each of the concentrations selected, viz., 5, 13, 16, 18, 26, and 52 g. of sucrose per 100 c.c., a practically constant difference between the polarisation in the presence and absence of salt (3·392 g. of ammonium chloride or 2·315 g. of sodium chloride) was established. Solutions containing 5—25 g. of sucrose in 100 c.c. when analysed by methods 2, 3, and 4 (*vide* Sci. Paper 375), gave an average mean error of only −0·01%, or +0·01% when invert sugar was also present.—J. P. O.

Sugar refractometer for the determination of the apparent dry substance of juices; Theory of the ——. O. Schönrock. Z. Ver. deuts. Zuckerind., 1921, 417—440.

Kruss' values (J., 1921, 124 a) for the refractive indices of sugar solutions at 20° C., compiled from the tables of Matthiessen, Main, and the author (and based on a smoothed-out curve), are considered unreliable. At 35% concentration the error is 2 units in the 4th decimal place of the refractive index, at 65% it is 4 units, and beyond that it is even higher. On the other hand, the error in the author's own measurements (established with the aid of the spectrometer) is uniformly less than 2 units in the 5th decimal place. (*Cf.* J., 1921, 596 a.)—J. P. O.

Decolorising carbons; Comparative values of ——. A. B. Bradley. Int. Sugar J., 1921, 23, 455—461.

The author urges that a standard method should be used for comparing the values of decolorising carbons for use in the sugar industry and suggests that it should be based on the following conditions: A 50% solution of raw cane sugar should be used. Colour comparisons should be made in a Hess-Ives tint-photometer. The standard carbon should be that commercial carbon which has the greatest decolorising effect on treatment of a 50% sugar liquor with 3%, the grade known as "Super-filtchar" being the most suitable at the present time. The conditions of heating, filtration, and further treatment of samples and standard should be strictly comparable, from 1 to 6% of carbon (on the weight of sugar in the liquor) being used and results plotted as curves. The rates of filtration after treatment should be compared. The percentage of grain left on 60-, 106-, and 124-mesh sieves, and the proportion of carbon passing through the latter, should be ascertained, as should also the volume per unit weight, which is a measure of porosity and friability (*cf.* J., 1921, 157 a).—J. P. O.

Starch iodide. Lottermoser. *See* XXIII.

XVIII.—FERMENTATION INDUSTRIES.

Yeast; Synthesis of vitamin by ——. A. Harden and S. S. Zilva. Biochem. J., 1921, 15, 438—440.

The yeasts *S. cerevisiæ* and *S. ellipsoideus* when grown on a synthetic medium free from vitamin A are capable of curing polyneuritis in pigeons. —S. S. Z.

Grape pomace. Rabak and Shrader. *See* XIXa.

Patent.

Acetone [and butyl alcohol]; Manufacture of —— [by fermentation]. E. Ricard. U.S.P. 1,385,888, 26.7.21. Appl., 7.6.18.

See E.P. 130,666 of 1918; J., 1919, 787 a.

XIXa.—FOODS.

Wheat; Relation of hardness and other factors to protein content of ——. H. F. Roberts. J. Agric. Res., 1921, 21, 507—522.

The author's own results and those from two other experimental stations in America do not indicate any correlation between hardness and protein content of wheat. Further, no correlation between protein content and specific gravity or volume of the grain could be detected.—W. G.

Cassava and rice flours; Chemical identification of ——. L. Desvergnes. Ann. Chim. Analyt., 1921, 3, 205—206.

When 10 g. of cassava or rice flour is boiled for 5 mins. under a reflux condenser with a mixture of 45 c.c. of 95% alcohol and 5 c.c. of hydrochloric acid, and the solution cooled and filtered, a red filtrate is obtained; in the case of oat, wheat, maize, barley, and rye flours, the filtrate is yellow or yellowish-red. Wheat flour containing 10% of cassava flour gives a red filtrate. Wheat offals yield a brown coloration with the test and this may mask the red coloration due to cassava or rice flour; if, however, the alcoholic solution is shaken with 25 c.c. of benzene and 12·5 c.c. of water, and the mixture allowed to separate, the upper layer is coloured yellowish-brown and the lower layer more or less red according to the quantity of cassava or rice present. —W. P. S.

Grape pomace and stems from the grape-juice industry; Commercial utilisation of ——. F. Rabak and J. H. Shrader. U.S. Dept. of Agric., Bull. No. 952, 4.6.21., 24 pages.

The grape skins are separated from the seeds, preferably after the pomace has been dried, and the skins, when boiled with suitable quantities of water, sugar, and tartaric acid, yield a jelly. The seeds consist of about 44% of shell and 56% of kernel; the shells contain 4·1%, and the kernels 19·9% of oil. When undecorticated ground grape seeds are extracted with a solvent (benzene) the yield of oil is 11—12%; a somewhat lower yield of oil is obtained when the seeds are pressed, but the oil cake obtained is of greater value as a feeding stuff than is that resulting from the extraction method. Grape seed oil is semi-drying and is similar in character to soya bean oil and cottonseed oil; it is suitable for use as an edible oil, or as a soap, paint or varnish oil. The shells separated from the seeds yield an extract containing about 15% of tannin of good quality. —W. P. S.

Antineuritic and antiscorbutic factors; Differential dialysis of the ——. S. S. Zilva and M. Miura. Biochem. J., 1921, 15, 422—427.

The antineuritic factor in autolysed yeast and the antiscorbutic factor in decitrated lemon juice diffuse through a collodion membrane of such permeability as permits the passage of substances such as Methylene Blue, Neutral Red, and Safranine. It is suggested that the active molecules whether simple or associated may be of a semi-colloid nature. —S. S. Z.

Potato juice extracted in the presence of acids; Antiscorbutic principle in ——. Bezssonoff. Comptes rend., 1921, 173, 417—419.

Although crude uncrushed potato exercises a marked antiscorbutic action, its juice extracted by pressure possesses only a feeble action (*cf.* J., 1921, 126 A). If, however, the potato is mixed with 2½% by weight of a mixture of 1 pt. of citric or tartaric acid and 4 pts. of sucrose before being crushed and the juice expressed, such juice possesses a much more marked antiscorbutic action. The loss of antiscorbutic properties of the potato by simple pressure is considered to be due to the action of oxidases during the process, and this action is inhibited by the presence of citric acid or tartaric acid. The juice from fresh potatoes has a stronger antiscorbutic action than that from potatoes stored during the winter.—W. G.

Tryptophan; Stability of —— in baryta hydrolysis. H. Onslow. Biochem. J., 1921, 15, 383—392.

When caseinogen is hydrolysed by barium hydroxide, tryptophan is not destroyed; the protection is due to the presence of other products of hydrolysis, since the destruction of tryptophan can be prevented to a great extent by the addition of crystalline amino-acids. When gelatin or zein is hydrolysed by barium hydroxide there are only traces of nitrogen to be found in the mercuric sulphate fraction, but after the addition of pure tryptophan to gelatin the total nitrogen in this fraction is equivalent to the added tryptophan. Tryptophan is more resistant to acid hydrolysis in a pure condition than when present in combination in caseinogen. The precipitation of free tyrosine by the mercury reagent can be prevented by raising the concentration of the sulphuric acid from 5 to 7%. Histidine is fairly stable when boiled with barium hydroxide and its precipitation in acid solution by mercuric sulphate is helped by the presence of other amino-acids. The total nitrogen of the mercuric sulphate fraction reaches a maximum after the casein has been hydrolysed under specified conditions for 60—70 hours.—S. S. Z.

Caseinogen; Nature of the substances precipitated by mercuric sulphate from hydrolysed —— with reference to the estimation and isolation of tryptophan. H. Onslow. Biochem. J., 1921, 15, 392—399.

The character of the mercuric sulphate fraction in the hydrolysis of caseinogen under different conditions has been studied. The fraction contains a number of amino-acids which are probably in combination with tryptophan. Tyrosine does not separate early in the digestion of caseinogen. Good yields of tryptophan are obtained from caseinogen if the decomposed mercuric sulphate precipitate is re-digested and extracted with butyl alcohol. —S. S. Z.

Carnosine; Method for the colorimetric estimation of ——. W. M. Clifford. Biochem. J., 1921, 15, 400—407.

A modification of Koessler and Hanke's colorimetric method for estimating iminazole derivatives (J., 1919, 962 A). The minced tissue is extracted with a known volume of water at 60°—90° C. The aqueous extract is then treated with metaphosphoric acid and filtered. An aliquot portion of the filtrate is made neutral to litmus and the carnosine estimated colorimetrically in a Duboscq colorimeter. Parallel estimations agree to 0·05 mg.—S. S. Z.

Kaoliang; Constituents and nutritive values of ——. J. Kimura. Nippon Kwagaku Kwai Shi (J. Chem. Soc. Japan), 1921, 42, 163—180.

Air-dried kaoliang (*Andropogon sorghum*, Brot.) gave the following analytical results:—Water 9·23, crude protein 10·19, crude fat 2·08, soluble non-nitrogenous substances 76·12, crude fibre 1·33, ash 1·05, total nitrogen 1·63, protein nitrogen 1·60, non-protein nitrogen 0·04, and protein 11·00%. The proteins of kaoliang and of the portion thereof soluble in warm 70% alcohol gave the following yields of diamino-acid nitrogen (calculated on total nitrogen) by Van Slyke's method:—Arginine nitrogen, 5·02%, 4·26%; histidine nitrogen, 2·39%, 3·67%; lysine nitrogen, 2·96%, 4·53%, respectively. Kaoliang seems to be rich in orizanin (water-soluble vitamin), and with addition of tryptophan and diamino-acids gives satisfactory results in nutrition tests.—K. K.

Yeasts. Harden and Zilva. *See* XVIII.

Choropicrin as insecticide. Wille. *See* XIXb.

Patents.

Liquids, particularly milk; Treatment [concentration] of ——. A. E. White. From The By-Products Recovery Co. E.P. 138,119, 23.1.20.

The milk, preheated to 180°—212° F. (82°—100° C.), is delivered to the inner surface of a steam-jacketed cylinder and is spread in a thin film by pivoted spring blades pressing on the surface by centrifugal action. The concentrated product is continuously discharged to a cooling apparatus. —H. H.

Cream; Process for treating —— and the preparation of butter and the like therefrom. A. Collard-Bovy. E.P. 152,690, 21.10.20. Conv., 22.10.19.

"Acid" cream is mixed with water at 32°—35° C., the mixture is passed through a sieve, and the cream is then separated by centrifugal action, cooled, and churned. The butter obtained is particularly free from casein, lactose, etc., and has good keeping qualities. If the washed cream is treated with a culture of a pure ferment before churning, fresh butter for immediate consumption may be obtained.—W. P. S.

Sterilised milk containing vitamins; Process for preparing —— and sterile condensed or dried milk, sterilised cream, and sterilised butter. E. C. Hort. E.P. 166,984, 27.4.20.

The milk is sterilised in an autoclave, so arranged that the steam from the outer vessel passes through the milk in the inner vessel before escaping. The autoclave is maintained at 20 lb. per sq. in. steam pressure (about 116° C.) and passage of steam for 3—5 mins. is sufficient to sterilise the milk. Taste, odour, vitamin-content, and emulsified condition of the fats are unaltered. Sterilised sugar may be added, to make good any loss brought about by heating. Cream is prepared from unsterilised milk and then sterilised; butter is made from sterilised milk, and condensed milk is sterilised after condensation.—A. G. P.

Sterilising liquids; Apparatus for ——. H. B. Rudd. E.P. 164,274, 22.9.20.

The liquid, *e.g.*, milk, is caused to flow between electrodes within a sterilising chamber, the supply and discharge of the liquid being controlled thermostatically. The electrodes are fitted with cooling jackets.—H. H.

Albumin and fat from bones; Process of extracting ——. A. Faitelowitz. E.P. 148,161, 9.7.20.

To extract albumin and fat remaining in bones which have been autoclaved for fat extraction, the residue from the autoclave is crushed and boiled with soda in amount insufficient to saponify the fat. After standing, the top layer of fat, and the second layer, a solution of albumin in soda, are run off separately. The albumin solution is neutralised and the albumin is precipitated by adding 10% of common salt and passing in a strong current of carbon dioxide.—H. H.

Food from fish, with or without the addition of other substances; Manufacture of ——. W. and C. O. Spear. E.P. 166,698, 20.4.20.

The fish is cleaned by irrigation with warm water which may contain a small proportion of an antiseptic. It is then pulped mechanically, dried, and, if necessary, also smoked whilst passing spirally through closed chambers, and finally ground. —H. H.

Malted food products; Process of preparing ——. J. W. Allen. U.S.P. 1,385,352, 26.7.21. Appl., 6.11.19.

Meat is pickled and, while in the pickle, is treated with a substance containing malt.—A. G. P.

Pectin; Process of extracting ——. T. W. Doell and L. A. F. Maes. U.S.P. 1,385,525, 26.7.21. Appl., 22.12.19.

Substances containing pectin are boiled in water containing a small amount of acid, a bleaching agent is added, and the mass filtered. Pectin is precipitated from the filtrate by the addition of a salt of an alkali or alkaline-earth metal. The precipitate is removed, washed, dried, and powdered. —A. G. P.

Bread making; Process of ——. C. J. Patterson, Assr. to The Campbell Baking Co. U.S.P. 1,385,842, 26.7.21. Appl., 30.3.21.

A non-toxic peroxide is added to the dough batch, in such quantity as to increase the moisture-capacity of the dough above normal, without breaking down the gluten of the flour.—A. G. P.

Cocoa waste; Treatment of ——. E. de Greusseau and A. Vicongne. U.S.P. 1,386,166, 2.8.21. Appl., 8.6.18.

See E.P. 120,178 of 1918; J., 1919, 25 a.

Pectous substances; Production of ——. B. T. P. Barker. U.S.P. 1,386,224, 2.8.21. Appl., 5.11.19.

See E.P. 125,330 of 1918; J., 1919, 436 a.

XIXb.—WATER PURIFICATION; SANITATION.

Chloropicrin as an insecticide, especially for combating the grain-weevil (*Calandra granaria*). I. Wille. Z. angew. Entom., 1921, 7, 296—310. Chem. Zentr., 1921, 92, IV., 465.

Chloropicrin vapour at a concentration of 30 c.c. per cub. m. effectively kills the grain-weevil in 6 hrs. For large stacks a concentration of 40 c.c. per cub. m. for 24 hrs. is necessary. Workers can be protected by a leather gas mask charged with a material of high absorption-capacity. Treated grain loses a little in germinating power, but nutritive value and suitability for baking are not affected. Texture and colour do not suffer. The chloropicrin vapour has completely disappeared 6 hrs. after treatment. Moths, bugs, caterpillars, etc., and also spores of wheat smut can be destroyed by chloropicrin.—A. G. P.

Poisoning by blast-furnace gas. Johannsen. *See* X.

Patents.

Purification of liquids such as water for steam-generators and for other purposes. P. Walter. E.P. 166,682, 17.4.20.

Upper and lower injector nozzles with delivery slots of adjustable width admit the liquid and steam respectively to a tank. The liquid is deflected by an inclined surface into a removable receptacle in which the separated impurities collect. The liquid is delivered from the tank against the inner wall of a vertical tube with open ends, causing a further separation of suspended matter, and finally passes through a filter.—H. H.

Filter and process of filtering [*water*]. J. H. Haerry. U.S.P. 1,384,754, 19.7.21. Appl., 10.1.20.

Water is passed substantially horizontally through vertical filtering walls exposed to the air at one end. The water also passes through oxygen-absorbing material between the walls, into which material oxygen is passed in a direction substantially at right angles to the flow of the water. —H. H.

Micro-organisms; Method of killing ——. Elektro-Osmose A.-G. (Graf Schwerin Ges.). E.P. 150,318, 19.8.20. Conv., 19.8.19.

In the case of a solution, sodium chloride is added in quantity sufficient to make a 1·2% solution and this is placed in the middle compartment of a chamber divided into three parts by means of diaphragms; the two end compartments contain water and serve as anode and cathode compartments respectively. The liquid in the middle compartment is then sterilised by passing a current of 10—12 amps. and 20—30 volts through the chambers for 2 hrs. To sterilise solids, the pieces are immersed in a 1·2% sodium chloride solution contained in the middle compartment, and then treated as described. Sodium chloride must be added from time to time to the solution in order to maintain the concentration, and water is circulated through the end chambers in order to regulate the temperature.—W. P. S.

Disinfectants from sulphurated [*sulphonated*] *shale oils; Manufacture of* ——. H. Schaefer and G. Faber. E.P. 166,727, 26.4.20.

The oil is treated with about an equal weight of chlorosulphonic acid at temperatures not exceeding 120° C., and when the reaction is completed the product is further heated to drive off hydrochloric acid and sulphur dioxide. Salts of the disinfectant, "sulphothalassolic acid," so produced are prepared by adding the corresponding metallic carbonate, hydroxide, or oxide, and subjecting the mixture to dialysis.—H. H.

Dangerous atmospheric conditions produced in gold mines and other underground workings by blasting operations; Composition for eliminating or counteracting the ——. H. Walker. E.P. 167,048, 11.6.20.

The composition, which is put up in waterproof cartridges and used between the explosive and priming charges, consists of potassium permanganate 7 lb., potassium chlorate 1½ drams to 4 oz., and gum arabic 1 dram to 4 oz. The proportion used is ½ lb. to 2½—5 lb. of dynamite or gelignite. (*Cf.* E.P. 24,002 of 1905; J., 1906, 609.)—B. M. V.

Spray. F. C. Cook. U.S.P. 1,384,304, 12.7.21. Appl., 15.12.20.

A horticultural spray is composed of a mixture of a solution of a copper salt, *e.g.*, the sulphate, and a solution of a barium compound, *e.g.*, the hydroxide. —H. H.

[*Waste*] *liquids; Purification of* ——. The Koppers Co., Assees. of E. A. Dieterle and S. D. Semenow. E.P. 152,356, 13.10.20. Conv., 15.2.19.

See U.S.P. 1,323,256 of 1919; J., 1920, 80 a.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Liquorice extract and root; Determination of glycyrrhizin in ——. P. A. Houseman. Amer. J. Pharm., 1921, **93**, 481—495. (*Cf.* J., 1916, 486.)

Liquorice extract.—Two g. of the extract and 15 c.c. of water are placed in a centrifuge tube and, after 18 hrs., the mass is stirred until disintegrated completely; 15 c.c. of 75% (by vol.) alcohol and 53 c.c. of 95% alcohol are then added with stirring and, after 3 hrs., the mixture is centrifuged at 1500 revs. per min. The alcoholic liquid is decanted, and the residue of starch and gums washed twice with 75 c.c. of 75% alcohol, rinsed into a basin, dried, and weighed. The alcoholic extracts are evaporated to dryness, the dry residue is dissolved in 10 c.c. of hot water, the solution filtered through a small filter, and the filtrate and washings are diluted to 30 c.c. in a centrifuge tube. After the addition of 3 c.c. of 10% sulphuric acid, the solution is kept at 0° C. for 18 hrs., centrifuged, the clear liquid decanted, and the residue of glycyrrhizin is washed twice with ice-water saturated with ether. The decanted liquids are neutralised with ammonia, evaporated to 5 c.c., 2 c.c. of 10% sulphuric acid is added, the mixture cooled at 0° C. for 18 hrs., and the precipitate of glycyrrhizin separated and washed as before. The two glycyrrhizin precipitates thus obtained are dissolved in warm 95% alcohol, the solutions filtered into a weighed glass basin, the filter is washed with warm alcohol, the contents of the basin are treated with 2 drops of 5% ammonia, evaporated to dryness, the residue dried for many hrs. at 100° C., and weighed. *Liquorice root.*—Three g. of the dry, powdered root is mixed in a centrifuge tube with 75 c.c. of ether, the mixture centrifuged, and the ethereal solution is decanted; this extraction with ether is twice repeated, the residue in the tube heated slightly to expel residual ether, treated with 75 c.c. of 75% alcohol, and the determination then carried out as described for the extract. Spanish and Grecian roots yielded about 10% of glycyrrhizin, Anatolian, Russian, and Chinese roots about 14%.—W. P. S.

Glucoside hydrolysed by emulsin; Presence of a —— in two species of Melampyrum. M. Bridel and M. Braecke. Comptes rend., 1921, **173**, 414—416.

Melampyrum pratense, L. and *M. arvense*, L., each contain a glucoside which is hydrolysed by emulsin giving reducing sugars and a black insoluble compound.—W. G.

Pikamar; Synthesis of ——. F. Mauthner. J. prakt. Chem., 1921, **102**, 36—40.

Pikamar, isolated in 1833 by Reichenbach from beech wood tar, is shown to be 4-hydroxy-3.5-dimethoxypropylbenzene since it may be synthesised by the reduction of 4-acetoxy-3.5-dimethoxyallylbenzene by hydrogen in the presence of colloidal palladium and subsequent hydrolysis of the 4-acetoxy-3.5-dimethoxypropylbenzene thus produced. (*Cf.* J.C.S., Oct.)—H. W.

Chinosol; Reaction for the microchemical detection of ——. C. Griebel. Pharm. Zentralh., 1921, **62**, 452—456.

A bright green crystalline precipitate forms immediately when a small quantity of 2% solution of chinosol (*o*-hydroxyquinoline sulphate) is treated with a drop of potassium ferrocyanide solution; the colour of the crystals changes within a few minutes to orange-red. More dilute solutions of chinosol yield a red precipitate after the lapse of some hours, but the reaction is not given when the concentration is less than 0·5%. Chinosol solutions give a yellow crystalline precipitate when treated with potassium ferricyanide solution.—W. P. S.

Lecithin sols; Ultrafiltration of ——. H. Bechhold and S. M. Neuschloss. Kolloid-Zeits., 1921, **29**, 81—89.

Lecithin sols contain particles of very varying sizes and of these only the largest give rise to a turbidity which is recognisable by nephelometric methods. In a 0·1% lecithin sol only 4% is recognisable by a nephelometer. A portion of the lecithin is adsorbed by the filter on ultrafiltration, the amount becoming greater the greater the density of the filter. The larger particles are more strongly adsorbed than the more highly disperse particles. The quantity of the sol which passes through an ultra-filter depends on the pressure applied, and by varying the pressure the filtrate can be varied from practically pure water to a solution containing the major portion of the lecithin. The interfacial tension of lecithin and water is very small, less than 16 c.g.s. units.—J. F. S.

Mellitic acid; New method for the preparation of ——. E. Philippi and G. Rie. Monatsh. Chem., 1921, **42**, 5—8.

Diethylmesitylene, b.p. 229°—236° C., is obtained by the reduction of diacetylmesitylene with amalgamated zinc and hydrochloric acid and is transformed by acetyl and aluminium chlorides in the presence of carbon bisulphide into acetyldiethylmesitylene, pale yellow liquid, b.p. 286°—304° C. The latter is reduced to triethylmesitylene, b.p. 238°—247° C., which is oxidised by nitric acid to mellitic acid, m.p. 285°—286° C.—H. W.

Hydrogenation by platinum black; Velocity of reaction in ——. G. Vavon. Comptes rend., 1921, **173**, 360—362.

The nature of the solvent and the rapidity with which the products of reaction are removed from contact with the catalyst have an important influence on the velocity of the reaction.—W. G.

Citronellol; Determination of —— by the formylation method. A. St. O. Pfau. J. prakt. Chem., 1921, **102**, 276—282.

The estimation of geraniol and citronellol by the formic acid method gives inexact results, in part because a portion of the former undergoes esterification. Even with pure citronellol the method gives uncertain data (*cf.* Schimmel und Co., Report, Oct., 1913; Simmons, J., 1913, 840). The author's results were irregular and high when 100% acid was used, low with a weaker acid. The action of the 100% acid yields a mixture of products containing unchanged citronellol, a small amount of volatile liquid which is possibly an aliphatic or cyclic terpene, citronellyl formate, b.p. 99°—100° C. at 7 mm., the compound $C(CH_3)_2(OH).[CH_2]_3.CH(CH_3).CH_2.CH_2.O.CHO$, b.p. 129° C. at 5 mm., sp. gr. 0·9651 at 15° C., $\alpha_D = 1°46'$, $n_D^{15} = 1·4488$, and the corresponding diformate, b.p. 140°—141° C. (corr.) at 7 mm.—H. W.

Essential oil of aburachan; Composition of the ——. Y. Shinozaki. Kôygô-Kwagaku Zasshi (J. Chem. Ind. Japan), 1921, **24**, 444—463.

By distillation of the leaves and twigs of aburachan, *Lindera praecox*, Bl., about 0·3% of light brown coloured oil was obtained, which had a somewhat strongly camphoraceous odour and the following characters:—Sp. gr. at 15°, 0·9094—0·9178; $n^{20} = 1·4850$—$1·4866$; $\alpha = -3° 57'$ to $-5° 1'$; acid value, 0·69—0·92; saponif. value, 45·76—48·69;

saponif. value after acetylation, 90·48—98·62. The following substances were isolated:—2% of α-pinene, 14% of camphene, 8% of cineol, 10% of an aliphatic terpene (b.p. 40°—41° C. at 2 mm., sp. gr. at 15° C. 0·8251, n^{20}=1·4840), borneol present in the oil partly free and partly as ester, geraniol (23% with borneol), 8% of caryophyllene, 21% of *d*-cadinene, 5% of a sesquiterpene alcohol, $C_{15}H_{26}O$, and a tertiary alcohol, b.p. 140°—142° C. at 4 mm., sp. gr. at 15° C. 0·9740, n^{20}=1·5072, $\alpha = -5°$. From the alkaline liquor after saponification of the original oil there were isolated:—acetic acid, a decylenic acid, $C_{10}H_{18}O_2$, b.p. 106°—107° C. at 1·5 mm., sp. gr. at 15° C. 0·9339, n^{20}=1·4552, iodine value 142·24, neutral. value 328—334·9, probably identical with citronellic acid, and a saturated weak acid of higher series having a high b.p.—K. K.

Solubility of water in organic liquids. Clifford. *See* IIa.

Patents.

Hydrocarbons [naphthenes]; Manufacture of ——. C. Weizmann and D. A. Legg. E.P. 165,452, 7.3.16.

A mixture of naphthenes is obtained by polymerising, by means of aluminium chloride, the mixture of butylenes obtained by the dehydration of *n*-butyl alcohol. The vapour of *n*-butyl alcohol is passed through a tube containing pumice coated with aluminium oxide heated to 250°—320° C., when a mixture of Δ_2- and Δ_3-butylene is formed containing about 80% of the former. At higher temperatures, say 360°—390° C., the product is practically all Δ_2-butylene, and the yield nearly theoretical. The liquefied butylene is treated with anhydrous aluminium chloride in the proportion of 28 g. of the former to 0·5 g. of the latter, and the temperature is kept below −10° C. If a pressure vessel is employed, a temperature as high as 15° C. is admissible. Polymerisation is complete in about 2 hrs., and a practically quantitative yield of naphthenes is obtained distilling as follows: 8 g. at 260°—270° C. at 17 mm. pressure; 13 g. at 270°—350° C. at 17 mm.; and 5 g. above 350° C. —G. F. M.

Ether; Production of ——. C. S. Bradley, Assr. to American Cellulose and Chemical Manuf. Co. U.S.P. 1,385,040, 19.7.21. Appl., 20.11.19.

Ethylene is absorbed in sulphuric acid at about 140° C., and superheated steam is introduced into the mixture in a separate vessel at a temperature higher than the boiling point of the acid to keep the strength of the acid constant. The apparatus is arranged for continuous working.—C. A. C.

Acetaldehyde; Process of manufacturing ——. H. W. Matheson. U.S.P. 1,384,842, 19.7.21. Appl., 26.11.17.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic image; Structure of the ——. C. E. K. Mees. J. Franklin Inst., 1921, **191**, 631—650.

The various types of silver halide crystals found in silver gelatinobromide emulsions all belong to the cubic system, but exhibit double refraction due to strain, one cause of which is probably the iodide present, which forms homogeneous mixtures with the bromide. The commonest form of grain is that of a flat plate, having a thickness about 1/15 the diameter and caused to lie approximately parallel to the gelatin surface by the drying down of the film. The first crystals formed when moderately concentrated solutions of silver nitrate are added to bromide solutions of similar concentration are smaller than those found at later stages; their size depends on the amount of free bromide present, the temperature, the concentration, and the rate of addition of the silver solution. The factors which determine the characteristic curve of a plate are discussed on the basis of Ross's, Slade and Higson's, and Svedberg's work. The author's earlier assumption that grain sensitiveness and grain size are directly related is modified. While it is probable that the area of the developed silver grain is substantially the same as that of the parent halide grain, the photometric constant probably varies with the size and depth distribution of the developed grain.

Blackening curves. H. Arens. Z. wiss. Phot., 1921, **21**, 28—36.

In the construction and consideration of blackening curves the optical and photographic opacity or blackening must be differentiated. The curves produced on the different bases present notable differences.—J. F. S.

Resistance of selenium. Datta. *See* XI.

XXII.—EXPLOSIVES; MATCHES.

Chlorate [and perchlorate] explosives. Mühlefeld. Z. ges. Schiess- u. Sprengstoffw., 1921, **16**, 113—115.

The author suggests that objections to the use of chlorate explosives are more imaginary than real. Accidents in storage are usually traceable to the presence of chloride, due to insufficient purification of the chlorate, and consequent lowering of the temperature at which oxygen is evolved. No undue degree of sensitiveness is found with chlorate compositions containing oil, resin, etc., as ingredients, and of which the cartridges are suitably wrapped to prevent surface crystallisation. Deleterious fumes on detonation are not more apparent than with other explosives, and when they arise, may be ascribed to the usual causes: faulty or weak detonators, overloading of the bore-hole, or deterioration of the explosive from prolonged storage. The decomposition of perchlorate explosives during storage may be due to the presence of chlorates together with ammonium nitrate, or to impurity of the nitro-compound ingredients. They offer no advantages over chlorate explosives, and have been largely supplanted by the latter in Germany.—W. J. W.

Nitrogen in nitronaphthalenes. Brinton and others. *See* III.

Patents.

Explosives. A. Wohl. E.P. 145,597, 29.6.20. Conv., 1.3.19. Addn. to 146,258 (J., 1921, 562 a).

The solid polymerisation products of acetylene (carbenes) used as carriers and as combustible substances are mixed with soap solutions, resin soap mixtures, alcohol, mixtures of tar bases, Turkey red oil (0·5%) and similar products, in order to render them capable of absorbing aqueous solutions of substances containing oxygen (saltpetre, chlorates, and the like).—C. A. C.

Detonators; Composition for ——. R. M. Cook and B. Grotta, Assrs. to Atlas Powder Co. U.S.P. 1,385,245, 19.7.21. Appl., 31.3.21.

A blasting cap charge comprises a mixture of lead azide and trinitrophenylmethylnitroamine. —C. A. C.

Detonator compositions containing lead azide. C. Claessen. G.P. 310,049, 19.3.18.

Substitutes for mercury fulminate compositions, which are without action on detonator shells, consist of lead azide and nitrates of the alkalis or alkaline-earths, with or without oxygen-carriers, *e.g.*, potassium chlorate, and other ingredients, such as antimony sulphide, powdered glass, salts of aromatic nitro-compounds, etc.—W. J. W.

Volatile explosives, e.g., nitroglycerin; Process and apparatus for removal of —— *from air and other gases.* K. Heimpel and A. Besler. G.P. 301,400, 3.4.17. Conv., 17.2. and 14.11.16.

The cooled gas containing explosive in the form of fog is passed into a centrifuge comprising a conical vessel with channels, in which the explosive which condenses on the walls is collected and conveyed to an outlet.—W. J. W.

Explosive compound. R. L. Hill and A. J. Strane, Assrs. to Atlas Powder Co. Reissue 15,155, 19.7.21, of U.S.P. 1,307,495, 24.6.19. Appl., 14.5.21.

XXIII.—ANALYSIS.

Simmance recording calorimeter. Fifth report of the Research Sub-Committee of the Gas Investigation Committee of the Inst. of Gas Eng. Gas J., 1921, **154**, 677—684, 741—750, and **155**, 35—40, 101—103.

Extensive and detailed tests have been carried out on the instrument, as a result of which the following conclusions have been drawn. The maximum systematic changes in the gas rate for an instrument adjusted at 60° F. and 30 in. bar., and subjected to temperature changes between 50° and 70° F., and barometric changes of 28·5 to 30·5 in. are (for gas of 0·4 sp.gr., *i.e.*, rich coal gas) ±0·5%, for gas of 0·5 sp. gr., *e.g.*, ordinary town gas, ±1·2%, and for gas of 0·6 sp. gr. (rather abnormal) about ±2·2%. A further change in the gas rate is probable, due mainly to slight mechanical defects, and amounting to ±1%, if the burner receives daily attention, but which is otherwise liable to be progressive. The room temperature should be controlled to within ±5° F. The water supply must be carefully watched, as deposits may be formed which restrict the flow of water and thus interfere with the accuracy of the instrument. The water passages of the instrument are not easily cleaned. The instrument is designed so that no irregularities in the water rate are traceable due to air-locking. There is a change of approximately 0·7% in the water rate per degree C. change of temperature in the inlet water, and a change of 0·3% for each degree C. change in the difference between inlet and outlet water temperatures. The air saturator eliminates errors due to the humidity of the air. The recording mechanism is quite satisfactory. It was found very difficult to obtain a satisfactory source of water for a correct inlet temperature, and errors in the charted calorific value due to fluctuating inlet temperature may be considerable. Given a steady inlet temperature, the outlet temperature is steadier with this instrument than with any other so far examined. The direct results obtained with the non-recording calorimeter agree with those from the Junkers and Boys calorimeters, when the results of the latter are fully corrected for atmospheric humidity, within the limits of experimental error, *i.e.*, the same calorific value to ±0·5% should be obtained whichever of the three instruments is used for the determination. Changes of ±25 B.Th.U. are recorded fully on the chart with a lag of 10—15 min. Generally, where the instrument can have daily skilled attention, the error will lie between ±1—1·5% over 24 hrs. If left unattended, the results would be very doubtful at the end of a week and quite useless at the end of a month. The Beasley recorder has also been examined, although not so completely as the Simmance instrument. It is comparatively simple in construction and operation, there is absence of complication since no water supply is required, it responds readily to changes in gas quality, and the gas rate is not dependent on the quality of gas supplied to the instrument. The record is liable to change, however, with alteration of atmospheric conditions, and there is no convenient means for setting or checking the chart. The instrument is also sensitive to draughts, the water level must be corrected daily, and periodical cleaning of the chimney and cap of the hot limb is essential. The instrument is suitable for the control of gas manufacture, but is not suitable for official records. (*Cf.* J., 1921, 326 A.)—A. G.

Fractionating columns in distillation in a vacuum; Efficiency of certain ——. L. Smith. J. prakt. Chem., 1921, **102**, 295—304.

A preliminary account is given of the use of a large number of fractionating columns in the distillation of a mixture of glycerol-monochlorohydrins under diminished pressure. The viscosity of the mixture inhibits the employment of those types in which beads are used. Bulbous columns (including the Young " evaporator " still-head) are not very effective and are generally markedly inferior to the rod and disc or Vigreux types. The reason is to be found in the incomplete mixing of the vapours in the more capacious apparatus, a defect which must be more apparent in vacuum than in ordinary distillation on account of the much greater velocity of the stream of vapour. The rate of distillation has an unexpectedly great influence on the efficiency of separation, the best results being obtained by working as slowly as possible, but, under these conditions, it is exceedingly difficult to keep the process uniform.—H. W.

Metal sulphides; Determination of —— *by ignition in a current of hydrogen sulphide.* L. Moser and A. Schattner. Chem.-Zeit., 1921, **45**, 758—759.

Zinc, cadmium, manganese, or silver may be estimated as sulphides by precipitation with hydrogen sulphide, followed by drying of the precipitate and ignition in a current of dry hydrogen sulphide. The paper is first ashed separately in a crucible, the dried precipitate is added, the crucible is covered with a lid carrying a glass tube reaching two-thirds of the way down and, while passing a slow current of the gas, the bottom of the crucible is brought to a dull red heat and maintained at that temperature for ½—¾ hr., after which the crucible is allowed to cool in the gas. The latter is generated from ferrous sulphide with hydrochloric acid, and is purified by passing through 3 wash-bottles containing hydrochloric acid and 1 containing water, all at 60° C., then through cold water into a tube containing potassium hydrosulphide, and finally through a U-tube containing calcium chloride. The following compounds may be converted into, and weighed as sulphide, by ignition as described above —zinc carbonate, oxide, sulphide; manganese dioxide and sulphate, and trimanganic tetroxide; silver chloride and nitrate. Precipitated ferrous sulphide or ferric oxide may be brought into a state suitable for weighing (FeS) by ignition in a mixture of 5 pts. of hydrogen to 1 of hydrogen sulphide, followed by cooling in hydrogen. Ignition in pure hydrogen sulphide leads to high results due to the formation of higher sulphides. (*Cf.* J.C.S., Sept.)—A. R. P.

Nitrogen; Micro-determination of ——. H. Lührig. Pharm. Zentralh., 1921, **62**, 435—444.

Methods are described in detail for the estimation of quantities of 1 mg., or less, of nitrogen. Protein nitrogen is determined by a micro-Kjeldahl method, nitric nitrogen by reduction with iron, and in each case the ammonia formed is separated by steam distillation and collected in $N/2000$ sulphuric acid. The excess of the latter is then determined iodometrically (addition of potassium iodate and iodide and titration of the liberated iodine) or it may be titrated in the usual way with alkali solution.

—W. P. S.

Starch iodide; Constitution of ——. A. Lottermoser. Z. angew. Chem., 1921, **34**, 427—428.

From the results of electric potential and other physical measurements the conclusion is drawn that the so-called "iodide of starch" is an adsorption compound of starch and molecular iodine. Neither iodion nor potassium iodide is adsorbed by starch to any appreciable extent, but experiments indicated that in potassium iodide solutions of $N/100$ or lower concentration there is a noticeable adsorption of tri-iodion $[I_3^-]$. In $N/10$ or $N/5$ solutions this is so small as to be negligible. In general the experiments confirmed the statement of Mylius that for the formation of the blue colour the presence of iodions is necessary, since they participate, if only very temporarily, in the adsorption.

22,638 (1920). Tozer. Vertical retorts. (168,229.) Sep. 7.

27,966 (1920). Robinson. Retorts etc. for producing mixed gas. (168,535.) Sep. 14.

2310 (1921). Halbergerhütte Ges. Filtration of blast-furnace and like gases. (168,279.) Sep. 7.

III.—TAR AND TAR PRODUCTS.

Applications.

Baddiley, Bainbridge, Payman, and British Dyestuffs Corp. Manufacture of 1.4-naphtholsulphonic acid. 24,139. Sep. 10.

Harding. Sulphonation of aromatic hydrocarbons. 23,784. Sep. 7.

IV.—COLOURING MATTERS AND DYES.

Applications.

Adams, Green, Saunders, and British Dyestuffs Corp. Manufacture of colouring matters and intermediates. 22,991. Aug. 30.

Ransford (Cassella u. Co.). Manufacture of salts of acridinium compounds. 23,286. Sep. 1.

Complete Specifications Accepted.

13,157 (1920). Poncelet. Production of black colouring-matter. (143,241.) Sep. 7.

16,299 (1920). Johnson (Badische Anilin u. Soda Fabrik). Manufacture of intermediate products and colouring matters, and their application in dyeing and printing. (168,447.) Sep. 14.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Baker, Sons, and Perkins, Ltd., and Thomas. Manufacture of paper for filtering. 23,724. Sep. 6.

Clavel. Treatment of cellulose acetate or products made therewith. 22,980. Aug. 30.

Dreyfus. Manufacture of plastic materials etc. 23,428. Sep. 2.

Steinhilber. Production of cellulose from *Cyperaceæ, Gramineæ, and Typhaceæ.* 23,354. Sep. 2.

Complete Specifications Accepted.

5556 (1920). Verein. Glanzstoff-Fabriken. Manufacture of viscose silk. (139,481.) Sep. 7.

11,458 (1920). Burlin. Manufacture of pulp for making paper etc. (168,355.) Sep. 14.

17,762 (1920). Miles. *See* XIII.

818 (1921). Leysieffer. Production of plastic bodies of cellulose ethers. (156,752.) Sep. 14.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Application.

Brandwood and Brandwood. Bleaching, dyeing, etc. yarns in the form of cheeses. 22,932. Aug. 30.

Complete Specifications Accepted.

15,502 (1920). Butterfield. Preparation for stiffening and proofing textile fabrics etc. (168,174.) Sep. 7.

16,299 (1920). Johnson. *See* IV.

17,762 (1920). Miles. *See* XIII.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Broadbridge, Edser, and Sellers. Treatment of caliche. 23,759. Sep. 6.

Craig, Pearson, and Durelco, Ltd. Production of oxides of tungsten and molybdenum. 23,964. Sep. 8.

Dicker (Casale and Leprestre). Synthetic production of ammonia. 23,741. Sep. 6.

Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Production of ammonia from nitrogen and hydrogen. 23,639. Sep. 5. (Norway, 7.9.20.)

Sim (Smith). 23,531. *See* XIII.

Soc. l'Air Liquide. Synthesis of ammonia. 23,740. Sep. 6. (Fr., 20.11.20.)

Complete Specifications Accepted.

15,121 (1920). American Smelting and Refining Co. Method of making sulphur from sulphur dioxide. (144,306.) Sep. 14.

16,392 (1920). Mond (Metallbank u. Metallurgische Ges.). Treatment of sal-ammoniac skimmings. (145,085.). Sep. 7.

VIII.—GLASS; CERAMICS.

Applications.

Marlow. 23,889. *See* I.

Reynolds, and Silica Syndicate. Manufacture of gas-tight seals between metal and vitreous material. 23,855. Sep. 7.

Complete Specifications Accepted.

20,654 (1920). Sachse. Manufacture of white clouded glasses, enamels, and glazes. (148,816.) Sep. 14.

27,346 (1920). Carborundum Co. (Linbarger). Refractory articles. (168,261.) Sep. 7.

IX.—BUILDING MATERIALS.

Application.

Sparkes. Treatment of wood. 23,936. Sep. 8.

Complete Specifications Accepted.

14,801 (1920). Fujiyama. *See* II.

1687 (1921). Wallin. Production of stone-like material. (157,971.) Sep. 7.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

British Thomson-Houston Co. (General Electric Co.). Aluminium alloys. 22,884. Aug. 29.

Burton. Treatment of metals. 23,280. Sep. 1.

Child, and Vivian and Co. Nickel silver. 23,000. Aug. 30.

Hodgkinson. Treatment of earthy and metalliferous minerals. 23,219. Sep. 1.

Hybinette. Separating metals by electrolysis. 22,881. Aug. 29.

Mond (Metallbank u. Metallurgische Ges.). Continuous leaching of ores, metallurgical products, etc. 24,101. Sep. 10.

Pickett. Recovery of copper and zinc from alloys. 22,877. Aug. 29.

Quick. Treatment of ore. 23,952. Sep. 8.

Complete Specifications Accepted.

10,895 (1920). Naef. Treatment of copper nickel natte. (168,097.) Sep. 7.

10,929 (1920). Wood, and Minerals Separation, Ltd. Concentration of oxidised ores. (168,098.) Sep. 7.

15,519 (1920). Moffat and Sutherland. Reduction of oxide ores. (168,434.) Sep. 14.

18,712 (1920). Metallindustrie Schiele u. Bruchaler. Production of castings of aluminium and its lloys. (146,841.) Sep. 14.

20,007 (1920). Gauschemann. Furnaces for melting readily fusible metals from scrap. 147,952.) Sep. 14.

20,023 (1920). Hackspill and Staehling. Manuacture of alkali metals and alloys thereof. 148,122.) Sep. 14.

20,316 (1920). Bea. Treatment of old brass. 148,388.) Sep. 7.

20,512 (1920). Leiser. Production of metallic lloys. (148,533.) Sep. 14.

20,605 (1920). Riedel. *See* II.

24,524 (1920). Wills. Alloy steel. (150,343.) ep. 14.

27,273 (1920). Naismith. Basic open-hearth rnaces. (151,631.) Sep. 14.

XI.—ELECTRO-CHEMISTRY.

Applications.

Beswick, and Fuller's United Electric Works. Manufacture of storage battery electrodes. 23,241. Sep. 1.

Exley and Handasyde. Electric batteries or accumulators. 23,434. Sep. 2.

Haddan (Meier). Galvanic cells. 23,725. Sep. 6.

Hybinette. 22,881. *See* X.

Juchli. Production of electric insulating-material. 23,232. Sep. 1. (Switz., 1.9.20.)

Reynolds. 23,535. *See* XXI.

Complete Specifications Accepted.

19,159 (1920). Brown. *See* I.

19,942 (1920). Féry. Primary batteries. (147,890.) Sep. 14.

22,973 (1920). Mull. Utilising mica for electrical purposes. (168,508.) Sep. 14.

31,804 (1920). A.-G. Kummler u. Matter. Manufacture of electric resistance material. (153,602.) Sep. 7.

XII.—FATS; OILS; WAXES.

Applications.

Melamid. Manufacture of fatty acid substances from resins. 23,003 and 23,284. Aug. 30 and Sep. 1. (Ger., 2 and 20.10.20.)

Complete Specifications Accepted.

17,231 (1920). Johnston. Manufacture of butter fats. (146,154.) Sep. 7.

19,003 (1920). Soc. Gén. d'Evaporation. Decomposition of soapy waters. (147,045.) Sep. 7.

20,715 (1920). Deutsche Erdöl A.-G. Converting hydrocarbons into fatty acids. (148,892.) Sep. 14.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Applications.

Britton, and Griffiths Bros. and Co. Pigments and preservative compositions. 23,860. Sep. 7.

Fairweather (New Jersey Zinc Co.). Manufacture of lithopone and apparatus therefor. 23,010–2. Aug. 30.

Melamid. 23,003 and 23,284. *See* XII.

Sim (Smith). Manufacture of lead carbonate or white lead. 23,531. Sep. 3.

Complete Specification Accepted.

17,762 (1920). Miles. Resin soaps, particularly for coating or printing paper and textiles. (145,601.) Sep. 14.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Applications.

Orme. Coagulating and curing rubber latex. 23,414 and 23,426. Sep. 2. (Ceylon, 5.11.13 and 8.5.14.)

XV.—LEATHER; BONE; HORN; GLUE.

Applications.

Earp. Treatment of hides etc. 23,467. Sep. 3.

Knoll. Producing coloured ornamentation on leather. 23,266. Sep. 1.

Nance. Manufacture of tanning etc. extracts. 23,923. Sep. 8.

XVI.—SOILS; FERTILISERS.

Application.

Plauson's (Parent Co.), Ltd. (Plauson). Manufacture of phosphatic manure. 23,049. Aug. 31.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATION.

Crawford. Clarifying fermented liquors. 23,897. Sep. 7.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Agopian. Process for obtaining vitamines. 23,763. Sep. 6. (Fr., 7.9.20.)

Beylik and Schwartzlose. Process of making pectin-containing material. 23,583. Sep. 5.

Casebourne and Krause. Preservation of fresh fish etc. 23,866–7. Sep. 7.

King and Threlfall. Manufacture of products useful as food or medicine. 23,530. Sep. 3.

Macleod. Preservation of fish. 23,375. Sep. 2. (S. Africa, 3.9.20.)

Plauson's (Parent Co.), Ltd. (Plauson). Preserving foods etc. 23,329. Sep. 2.

Quick. Preservation of milk etc. 22,959. Aug. 30.

Thermokept Products Corp. Treatment of vegetables in preparation for canning. 23,005. Aug. 30. (U.S., 30.8.20.)

COMPLETE SPECIFICATIONS ACCEPTED.

15,757 (1920). Krizek. Apparatus for obtaining alcohol from baking bread. (168,180.) Sep. 7.

17,231 (1920). Johnston. *See* XII.

35,356 (1920). Hay. Manufacture of artificial cream. (168,276.) Sep. 7.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

King and Threlfall. 23,530. *See* XIX.

Soc. Chim. des Usines du Rhône. Production of organic silver alcosols. 23,391. Sep. 2. (Ger., 5.1.21.)

COMPLETE SPECIFICATIONS ACCEPTED.

31,085 (1919) Hansgirg. Production of perylene. (136,561.) Sep. 7.

11,419 (1920). Berk and Co., and Hood. Purification of organic bodies by distillation. (168,108.) Sep. 7.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Cohen and Kann. Production of natural colour photographs. 24,133. Sep. 10.

Martin and Robb. Colour photography. 23,625. Sep. 5.

Reynolds. Composition for screening X-rays and for electric insulating. 23,535. Sep. 3.

COMPLETE SPECIFICATION ACCEPTED.

10,955 (1920) and 1879 (1921). Gorsky. Three-colour photography. (168,100.) Sep. 7.

XXII.—EXPLOSIVES; MATCHES.

APPLICATIONS.

Friederich. Manufacture of priming compositions. 23,160. Aug. 31.

Rathsburg. Manufacture of homogeneous priming compositions. 24,124. Sep. 10.

COMPLETE SPECIFICATION ACCEPTED.

18,711 (1920). Wohl. Explosives. (157,058.) Sep. 7.

XXIII.—ANALYSIS.

APPLICATION.

Schofield. Optical pyrometers. 23,743. Sep. 6.

I.—GENERAL; PLANT; MACHINERY.

Evaporating apparatus; Working results with some ——. Depasse. Bull. Assoc. Chim. Sucr., 1921, 38, 383—409. (*Cf.* J., 1920, 647 A.)

Data are given relating to the working of 19 evaporators, including double, triple, and quadruple effect apparatus, employed for the evaporation of chestnut tannin extracts. In most cases the apparatus was of the vertical tube type, with upper calandria, and tubes 1·2 to 1·6 m. long, with or without a wide central tube. The results indicate that in triple and quadruple effect apparatus greater efficiency is attained where the heating surface diminishes in the successive effects than in apparatus where the effects are all of the same size or in ascending order of size.—J. H. L.

Ash-disposal apparatus for steam boilers. H. Bernhardt. Z. angew. Chem., 1921, 34, 397.

The ashes from the travelling grate are discharged into hoppers which are emptied periodically into a channel supplied with a current of water; the latter carries the ashes into the well of a bucket elevator fitted with perforated buckets. This elevator raises the ashes to an ash bunker whence they are delivered into wagons etc.—W. P. S.

Patents.

Heat interchangers. The Griscom-Russell Co., Assees. of J. Price. E.P. 138,870, 7.2.20. Conv., 8.2.19.

A shell split longitudinally is provided with an inlet and an outlet for one of the fluids, and with inlet and outlet manifolds for the other fluid which traverses a number of flat double spiral coil units having the convolutions of each spiral lying in the same plane and in staggered relation to the convolutions of the other spiral. Baffles in the shell cause the first fluid to traverse a sinuous path in a general longitudinal direction, and the space at the centre of each coil is obstructed to cause the fluid to pass through the interstices between the turns.—H. H.

Distillation or evaporation; Apparatus for ——. V. L. Emerson. E.P. 143,217, 10.5.20. Appl., 8.5.19.

A fire-heated evaporator or still, for use at high temperatures and pressures with such material as petroleum oil, is in the form of a straight-tubed boiler of the water-tube type with the tubes connected to manifolds, the manifolds connected to ross drums which are rather longer and wider than the width and depth respectively of the manifolds, nd with the cross drums connected together by a ongitudinal return drum having a slope from front o back, *i.e.*, roughly parallel to the tubes. The flow rom or to each vertical rank of tubes is kept eparate by partitions in the manifolds, and the apour space is formed in the front cross drum, the eturn drum and back cross drum being substantilly full of liquid. A propeller is provided in the eturn drum to increase the circulation.—B. M. V.

ractionating apparatus. H. F. Perkins, Assr. to Rosanoff Process Co. U.S.P. 1,386,020, 2.8.21. Appl., 23.12.18.

fractionating chamber, provided with an inlet t one end and an outlet at the other, is surrounded etween its ends by a chamber for the circulation of mperature-controlling fluid. A number of flat ollow plates, open at opposite ends to the fluid amber, extend transversely to the fractionating amber with their closed side walls spaced from the ner walls thereof. The plates are so arranged at the substances under treatment must flow in a rtuous path.—H. H.

Fractional-distillation process and apparatus. V. T. Gilchrist, Assr. to Superior Refining Process Co. U.S.P. 1,386,467, 2.8.21. Appl., 30.3.16.

The vapour under treatment is progressively separated at certain temperatures to obtain condensed fractions, and each successive condensed liquid is fractionally distilled by the heat of the vapour previously separated therefrom, an additional vapour and an additional condensed fraction being thus obtained. Each successively formed condensed fraction is further heated by the heat of the vapour of the next previously formed condensed fraction.—H. H.

Distilling apparatus. C. G. Adsit. U.S.P. 1,386,484, 2.8.21. Appl., 14.9.20.

A vertical metallic retort is surrounded by an insulated primary coil, and is heated by induced current following the flow of alternating current through the primary coil.—H. R. D.

Electrolytic destruction; Process for protecting against —— *certain parts of apparatus* [*e.g., condenser tubes*] *which contain several liquid spaces.* F. von Wurstemberger. E.P. 149,632, 28.7.20. Conv., 2.8.19.

In a heat-exchanging apparatus such as a surface condenser, the tubes which are common to both liquid spaces are prevented from becoming anodes by short-circuiting them to the iron parts (*e.g.*, by soldering). Renewable thickening pieces may be used on the iron parts near the joints, *i.e.*, at the points where corrosion will be greatest.—B. M. V.

Acid chambers, towers, mains, and similar arrangements. P. L. Pfannenschmidt. E.P. 149,667, 30.7.20. Conv., 31.7.19.

The walls of chambers, towers, etc., for acids are constructed of a window-like framework, acid-proof either inherently or rendered so by coatings and preferably constructed of individually detachable cross-shaped units joined by fish plates. The framework is filled in with panes of acid-proof material such as quartz glass.—B. M. V.

Steam boilers; Means for ensuring complete combustion of the coal used for heating ——. R. W. Burckhardt. E.P. 149,677, 30.7.20. Conv., 1.8.19.

The combustion gases leaving the furnace of a boiler are cooled to about 600° C. by contact with a portion of the boiler and are then mixed to promote completion of the combustion before coming into contact with other portions of the boiler. Mixing is preferably effected by the device described in E.P. 149,676. In large furnaces the strata of combustible gas are sandwiched between two strata of secondary air, in quantity just sufficient for complete combustion, before passing to the mixing device.—H. Hg.

Furnaces burning powdered fuel. Sir W. G. Armstrong, Whitworth and Co., Ltd., F. B. Trevelyan, J. H. Andrew, and C. P. Miller. E.P. 167,289, 5.5.20.

A furnace in which powdered fuel and air are projected along a flat roof and deflected by means of a rounded end of the furnace so as to travel backwards over the hearth, is constructed with the furnace chamber tapering towards the front which constitutes a narrow exit for the waste gases. Two such furnaces may be combined to form a single furnace by placing them end to end and removing the lower part of the common rounded ends, or, the hearths being omitted, two units inverted relatively to one another may be superimposed.—H. Hg.

Kiln. H. P. Jenks. U.S.P. 1,386,116, 2.8.21. Appl., 8.7.16.

A kiln is provided with a perforated floor below which is located a chequer-work heat reservoir adapted to receive the hot gases passing through the perforations of the floor. A down-take is situated at one edge of the reservoir forming an outlet for it, and a flue is connected with the lower portion of the down-take extending throughout its length in contact with the bottom wall of the reservoir.—G. F. M.

Drum furnace. F. Meyer. G.P. 335,617, 23.1.20.

The furnace consists of a rotating drum lined with refractory material and containing a stationary wall parallel to the axis of rotation which divides the furnace into two compartments, an upper heating compartment and a lower compartment in which the charge is placed. The gases issuing from each section pass through separate flue systems, those from the heating compartment serving to preheat the fuel gases in a regenerator.—A. R. P.

Filters; Straining ——. L. Penkala. E.P. 154,612, 1.12.20. Conv., 1.12.19.

Trapezoidal bars with milled laterally-projecting ledges in contact with adjacent bars are assembled and secured by keying in a frame formed with collecting channels and discharge openings.—H. H.

Drying pans. R. Wilson. E.P. 167,202, 3.2.20.

Each of the steam-jacket bottoms of a double chamber drying pan (*cf.* E.P. 30,234 of 1909; J., 1911, 149) is formed of two plates, neither of which forms part of the cylindrical shell, and the plates are flanged so that the peripheral joint is made between the flanges. The bottom of the upper chamber is a removable self-contained structure.
—H. H.

Drying material to be ground in revolving drums; Process and apparatus for ——. J. S. Fasting. E.P. 160,423, 14.3.21. Conv., 22.3.20.

Material which is to be ground in a tube- or ball-mill is dried by separating the coarse particles, and passing these and a suitable proportion of the balls or pebbles used for grinding, through a heated drying tower, prior to admitting them to the mill. The smaller particles of material are admitted direct to the mill. The heat accumulated in the coarser material and the balls or pebbles is sufficient to dry the whole of the material to be ground.—A. B. S.

Drying; Process of and apparatus for ——. G. D. Harris. E.P. 161,598, 5.8.19.

In a dryer for material that can be dried on trays or similar supports, the material to be dried is divided among a number of chambers with heaters for the drying gas (air) between the chambers, and a larger heater for the air on admission Each heater is individually controlled (*e.g.*, by a steam valve) so that the rate of drying in each chamber can be adjusted to prevent the formation of an impervious skin on the material.
—B. M. V.

Dryer. W. E. Petty. U.S.P. 1,387,168, 9.8.21. Appl., 12.5.19.

The apparatus consists of inner and outer shells, with cross members between, forming a series of separate intervening flues. There is a central ventilator at the top of the dryer, and the interior is divided by a horizontal deflector into an upper storage and a lower heating compartment communicating at the periphery of the deflector, which is inclined upwards from the centre to the circumference. An entrance door is provided in the wall of the dryer, and each flue is provided in its outer shell near the bottom with screened air inlet openings, and in its inner shell with horizontal slots leading to the storage compartment.—H. R. D.

Drying processes, especially in the manufacture of lignite briquettes; Utilisation of waste heat of ——. W. Gensecke. G.P. 336,303, 13.5.19. Addn. to 334,082.

The heat of the vapours evolved in the drying process is transferred to water introduced into the vapour-exit main as a copious spray, and this water is then utilised as heating medium in an evaporator. Heat exchange in the evaporator may be effected by means of a surface device, or partial evaporation of the water may be effected by reducing the pressure in the evaporator.—J. S. G. T.

Agitating liquids; Apparatus for ——. J. C. Grant. E.P. 167,355, 9.6.20.

An endless chain or the like is suspended in the liquid from a drum which is rotated. Two or more such chains may be arranged with the ascending run of one chain close to the descending run of an adjacent chain. The containing vessel may be fitted with an airtight cover to enable the use of such a pressure as may be necessary to prevent frothing of the liquid.—H. H.

Agitator. T. F. Taylor. U.S.P. 1,386,809, 9.8.21. Appl., 27.11.18.

A leaching tank is provided with means for drawing liquid from the lower part of the tank and discharging it in a spray upon the surface of the liquid.—H. H.

Wet mixers. R. V. Mattison, jun. E.P. 168,010, 18.6.20.

For producing a wet mixture, *e.g.*, of asbestos and cement, a vertical cylindrical mixing tank is provided with means at one, preferably its lower, end for moving the materials outwards, means at its other end for moving the materials inwards, and means for moving the materials centrally from the region of inward to the region of outward movement. These movements are effected by means of an axial shaft which carries arms, having hinged scrapers at their ends bearing on the walls of the tank, and intermediate blades extending axially with their upper and lower portions set at different angles. The mixture is discharged through a central valved aperture in the bottom of the tank.
—H. H.

Surface condensers; Horizontal ——. E. C. R. Marks. From A.-G. Brown, Boveri & Co. E.P. 167,414, 30.9.20.

In a horizontal surface condenser of the type in which the water space can be shut off, part at a time, for cleaning and inspection of tubes, the latter are made with a slight dip in them so that the water retained in them may prevent the mud drying off quickly. Leaky tubes are indicated by the rapid disappearance of the water.—B. M. V.

Surface condensers; Air-cooled or evaporative ——. J. MacLeod. E.P. 167,803, 17.3.20.

The tubular heat-exchanging elements are arranged in sections so pitched that the tubes of any section are disposed opposite the spaces between the tube rows of the preceding section. Liquid is sprayed in front of the tubes and is carried through the condenser by the gaseous cooling medium (air).—H. H.

Refrigerating apparatus; Absorption ——. A. L. Gibbs. E.P. 167,660, 30.6.20.

Two generator (absorber) tanks in an ammonia-absorption refrigerating system have their lower ends connected by a pipe which communicates with an expansion coil and their upper ends connected to the top of a heating coil, and two horizontal pipes above the tanks each communicate at one end with one of the tanks. The pipe leading to the expansion coil is connected through a separator with a condenser coil surrounded by a tube conveying cooling water which passes to a tube extending through the coil of a rectifier and to sleeves surrounding the horizontal pipes.—H. H.

Centrifugal machine. T. A. Bryson, Assr. to Tolhurst Machine Works. U.S.P. 1,385,982, 2.8.21. Appl., 22.3.17.

A scraper is supported on a bracket on the casing of a centrifugal machine in such a manner that it can be raised or lowered, and moved to or from the inner wall of the basket.—B. M. V.

Non-flammable volatile liquid. A. Henning. U.S.P. 1,386,497, 2.8.21. Appl., 5.1.21.

A mixture of methyl chloride and methyl bromide.—H. H.

Catalyst; Method of making a ——. A. L. Davis and K. D. Jacob, Assrs. to The United States of America. U.S.P. 1,386,555, 2.8.21. Appl., 3.1.20.

Solutions of ferric nitrate and ammonium molybdate are mixed, heated to boiling, and filtered. The precipitate is washed, dried, and ignited, and then reduced with a fluid free from catalytic poisons.—H. H.

Strongly absorbent carbon of high catalytic activity; Preparation of a ——. Badische Anilin- und Soda-Fabr. G.P. 338,852, 21.9.19.

Substances containing carbon, such as wood, sugar, tarch, or animal residues, either alone or mixed with a carrier, are heated with volatile chlorides, specially aluminium chloride and ammonium hloride, but not zinc chloride. By the use of uitable carriers, mechanically resistant, strongly ctive carbon bricks of any desired size or shape nay be made.—A. R. P.

ank. H. F. Smith, Assr. to The Gas Research Co. U.S.P. 1,387,080, 9.8.21. Appl., 17.1.18.

he shell of a tank for chemically-active material fitted with a lining inert to the material and ith means between the lining and the shell for ealing any leaks in the lining.—H. H.

urification of gases between electrically charged electrodes; Process and apparatus for ——. Siemens-Schuckertwerke, G.m.b.H. G.P. 338,416, 24.1.18.

roups of electrodes raised to various high working nsions and between which the gas flows in succeson are employed. The ohmic fall of potential in e high-potential electrodes is employed to reduce e electrode tension. A high-tension electrode one d of which is earthed is employed. Means are ovided whereby the electrode tension increases ith increasing purity of the gas, the distance art of the electrodes increasing therewith. This vice increases the efficiency of precipitation of spended particles from gases, above that secured disposing the electrodes closer together, as the rticles become more highly charged.—J. S. G. T.

ectrical precipitation of suspended particles from gases or non-conducting fluids; Apparatus for ——. Siemens-Schuckertwerke G.m.b.H. G.P. 338,560, 22.2.20.

e electrodes employed are composed of grids of dulated wires disposed transversely to the direcn of the electric field, the undulations on the es constituting adjacent electrodes being disced relatively to one another. Means are ovided for varying the lengths of the undulated wires at intervals, for the removal of precipitated matter clinging thereto. The wire grids oppose very little resistance to the gas stream, and the precipitation is very efficient, as each particle comes into the immediate neighbourhood of the electrically charged wires.—J. S. G. T.

Tubing construction for use in water-tube boilers, oil stills, and the like. R. H. Brownlee. E.P. 151,582, 18.6.20. Conv., 22.9.19.

Separating materials of different specific gravity; Apparatus for ——. H. Velten. E.P. 159,163, 11.11.20. Conv., 18.2.20. Addn to 155,570.

Refrigerating machinery. P. Fischbacher. E.P. 167,858, 18.5.20.

Lead alloys. G.P. 307,672. *See* X.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Humic acids and coals. J. Marcusson. Z. angew. Chem., 1921, 34, 437—438. (*Cf.* J., 1919, 98 a, 350 a; 1920, 180 a.)

The conclusions of Fischer and Schrader (J., 1921, 172 a) are criticised (*cf.* Erdmann, J., 1921, 570 a), the author expressing the opinion that both lignin and cellulose have taken part in the formation of coal. (*Cf.* J.C.S., Oct.).—W. P.

Calorific value of coal; Determination of ——. F. S. Sinnatt and M. B. Craven. Lancs. and Cheshire Coal Research Assoc. Bull. 10, 1921, 23 pages.

Formulæ for the calculation of calorific value from the proximate analysis of coal (*cf.* Goutal, J., 1902, 1267) are accurate when dealing with samples from the same seam except when the coal contains calcium or substituted calcium carbonates; the value for one of the samples should be determined in a bomb calorimeter, the manipulation of which is described in detail.—H. Hg.

Coal; Transformation of —— into oils by hydrogenation. II. Hydrogenation of coal by means of carbon monoxide. F. Fischer and H. Schrader. Brennstoff-Chem., 1921, 2, 257—261. (*Cf.* J., 1921, 457 a.)

In order to cheapen the process of hydrogenation a mixture of carbon monoxide and steam was tried instead of using sodium formate. At 400° C. and under atmospheric pressure the coal was not appreciably affected. The yield of oils increased with the temperature and with the pressure of the carbon monoxide, and the highest temperature possible without causing decomposition of the oils formed should be used. The limiting temperature was not greater than 500° C. The yields were much greater than those obtained by heating coal with hydrogen under pressure, but rather less than with the sodium formate method.—W. P

Lignite; Carbonisation of —— in vertical chamber ovens. Müller. Gas- u. Wasserfach, 1921, 64, 585—587.

A lignite from Aussig, having a calorific value of 3655 cals., was carbonised in a bench of six vertical chamber ovens, each oven holding 1108 kg. of lignite. The temperature was noted at different periods, during which the yields of gas were measured, samples being analysed and tested for calorific value. Each 100 kg. of lignite gave a total yield of 30·1 cub. m. of gas of calorific value 3960 cals. The coke obtained was unsuitable for heating the ovens.—W. P.

Anthracoal, a new domestic and metallurgical fuel. D. Markle. Amer. Inst. Min. Met. Eng., Sept., 1921. Min. and Met., 1921, No. 176, 28—29.

Anthracoal is a dense coke formed by distilling a mixture of small anthracite coal and coal-tar pitch or other suitable bitumen (*cf.* U.S.P. 1,287,382; J., 1919, 128 a). It may be made in a coke oven, and when pushed from the oven tends to remain in large masses which are broken under a hammer and show an irregular fracture. Anthracoal is denser and tougher than coke. The proportion of pitch used in the mixture is 16—17%, varying slightly with the character of the coal and the method of grinding and mixing. The amount of by-products in anthracoal gas is ½—⅓ of that in gas from bituminous coal, and it is doubtful whether any form of by-product recovery would be commercially feasible. —C. A. K.

Flame of extremely high temperature; Experiments with a ——. E. Hauser and E. Rie. Sitzungsber. K. Akad. Wiss. Wien, 1920 (II. a), **129**, 539—547. Chem. Zentr., 1921, **92**, III., 588.

A liquid fuel is delivered by means of a tube from a storage vessel to a specially designed burner, where it is atomised into the form of a cone with horizontal axis by means of a gas such as hydrogen chemically indifferent towards it. At the same time the fuel is enveloped within a mantle of oxygen blown from the outer part of the burner. The temperature attained is at least 3000° C. Carbon derived from camphor and wood charcoal were converted in the flame into graphite. Soot deposited upon a porcelain plate held in the flame was likewise converted into graphite in the form of thin, sharp-edged plates with a metallic lustre, peculiar regular hexagonal figures being seen on the faces away from the porcelain plate. Upon the faces directed towards the porcelain plate small, transparent, highly refracting crystals of pure carbon were observed. Tungsten, molybdenum, and chromium were melted in the flame. —J. S. G. T.

Patents.

Carbonaceous material; Treating ——. W. E. Trent. E.P. 151,236, 15.4.20. Conv., 16.9.19.

Coal is pulverised in the presence of water to pass a 200-mesh screen, part of the impurities are removed in a hydraulic separator, and the excess water is eliminated in a settling tank. The remaining water and impurities are then expelled from the carbonaceous material by agitation with about 40% of liquid fuel oil. Air may be blown through the mass to facilitate the separation. The water and impurities are removed by decantation, and the residual mixture of oil and carbonaceous material is washed with water. (*Cf.* Perrott and Kinney, J., 1921, 615 a.)—H. Hg.

Briquette pitch; Process for increasing the binding power of ——. C. Fohr and E. Kleinschmidt. G.P. 338,365, 5.4.17.

Anthracene residues obtained from tar distillation are added to the molten pitch immediately before use, and as soon as solution is effected the still molten mixture is added, by spraying, for example, to the briquette material.—G. F. M.

Fuel; Process for preparing ——. *Fuel.* C. H. Urquhart. U.S.P. 1,386,472—3, 2.8.21. Appl., 23.9.19 and 28.10.20.

Cracks are opened up in low-grade coal by heating, a suitable binder is introduced into the cracks, and the coal and binder are fused together.—H. C. R.

Coke ovens, retorts and the like; Heating walls of ——. American Coke and Chemical Co., Assees. of A. Roberts. E.P. 138,126, 24.1.20. Conv., 9.11.17.

The heating wall is formed with a meshwork of interconnected passages so that after passing through a straight upper zone the gases travel in zig-zag fashion while moving in the same general direction. The whole of the air and 60% of the gas for combustion are admitted to the straight upper portions of the passages. Means are provided for admitting the remaining 40% of gas in one or more increments at points lower down the wall, where there would otherwise be a gradual cooling due to completion of the combustion of the gas initially admitted.—H. Hg.

Gas-generating apparatus. F. D. Moses. U.S.P. 1,378,125, 17.5.21. Appl., 8.8.19.

A boiler-superheater is combined with a gas producer in such a way that steam from the bottom of the boiler-superheater may pass either to the top or bottom of the producer through separate conduits provided with valves. Separate discharge conduits and valves are provided at the top and bottom of the producer.—H. Hg.

Gas; Apparatus for making ——. W. D. Wilcox. U.S.P. 1,386,825, 9.8.21. Appl., 23.2.18.

A coking chamber is heated by a secondary combustion chamber which is in communication with the top of a gas producer; steam may be admitted to the combustion chamber. Gases formed in the combustion chamber may be caused to flow downwards through the producer into the coking chamber with which the bottom of the producer is in communication, and blast gases from the producer may be caused to flow through the combustion chamber. —H. Hg.

Distillation of nitrogenous fuel; Method of producing nitrogen compounds during the dry ——. W. Ostwald, Assr. to The Chemical Foundation. U.S.P. 1,386,723, 9.8.21. Appl., 7.9.16. Renewed, 27.1.20.

The fuel is mixed with a chloride and distilled in a current of steam with exclusion of air whereby ammonium chloride is formed.—H. Hg.

Ammonium chloride; Method of recovering —— [*from coke-oven gas*]. E. Piron. U.S.P. 1,386,278, 2.8.21. Appl., 2.9.20.

Coke-oven gas is cooled to its dew point without addition of water, and then washed with a liquid capable of absorbing ammonium chloride.—C. I.

By-product recovery apparatus. A. Roberts, Assr. to American Coke and Chemical Co. U.S.P. 1,366,494, 25.1.21. Appl., 7.9.15.

Gas is passed through a series of spray condensers and the condensed oil passed through the series in the reverse direction by means of the sprays. —C. I.

Ethyl alcohol and other ethyl derivatives; Method for the production of —— *from coal distillation gases.* I. Bronn. G.P. 338,358, 19.12.16.

The gases, purified by the usual methods, are cooled in stages so as to yield a mixture of liquefied methane and ethylene. The two gases are easily separated by fractional distillation, or the ethylene is converted into compounds which are liquid at normal temperatures by treating the liquid mixture in presence of catalysts with concentrated sulphuric acid or with carbon dioxide. The methane obtained, having a calorific value of 8500 cals. per cb. m., is used for lighting, autogenous welding of metals, and as a fuel for gas engines, whilst the ethylene, which is nearly chemically pure, can be converted into ether or subjected to catalytic oxidation or reduction. In consequence of the absence of benzol and the like resinification is avoided, the catalysts are not poisoned, and no secondary reactions take place.—C. A. C.

Gases; Apparatus for purifying ——. R. Bluhm G.P. 338,827, 14.5.19.

The gas is drawn by suction through a stand-pipe into a vessel which plunges up and down in a liquid suitable for purifying the gas, *e.g.*, thin tar if it is desired to separate tar from the gas, or milk of lime to remove sulphur compounds. The gas finally passes up a tower in which it is scrubbed with the purifying liquid.—L. A. C.

[Catalysts used in the] process for separating sulphur compounds from gases by oxidation with air; [Revivifying spent] ——. Badische Anilin- und Soda-Fabr. G.P. 338,828, 1.8.19.

The catalyst is treated with steam above 100° C. but below the distilling temperature of sulphur before treatment with a solvent or highly heated gas to extract the sulphur, which is thus obtained in a pure state.—L. A. C.

Motor fuel. A. T. Wilford and A. A. M. Durrant. E.P. 167,831, 12.5.20.

In order to obtain the most efficient results from alcohol mixtures used in engines with normal compression, 1 to 2% of ammonium nitrate in aqueous solution is added to the alcohol. Hydrazine mononitrate may be added to neutralise the acids formed on combustion. Hydroxylamine nitrite, hydroxylamine nitrate or other dissociable salt of a nitrogenous base and an oxy-acid of nitrogen yielding gaseous products after explosion in the engine may also be added to the fuel.—H. Hg.

Viscosity of liquids [fuels]; Method of lowering the ——. L. W. Bates. U.S.P. 1,382,456, 21.6.21. Appl., 28.11.19.

Dehydrated tar obtained from the cracking of oil vapour derived from coal and oil or oil and steam is mixed with a liquid hydrocarbon to form a stable liquid fuel.—H. Hg.

Distillation of [mineral] oil; Method of ——. E. A. Rudigier, Assr. to Standard Oil Co. U.S.P. 1,386,077, 2.8.21. Appl., 27.5.18.

The oil is passed on to an extended surface located in the vapour space of a still in which a body of oil is undergoing distillation. The temperature on the surface is high enough to evaporate the water, the dehydrated oil flowing into the main body of oil being distilled.—C. A. C.

Oil-cracking process and apparatus therefor. D. E. Day. U.S.P. 1,386,768, 9.8.21. Appl., 5.4.20.

High-boiling hydrocarbons are heated to cracking temperature in a zone containing "spreading material." The vapours of low-boiling hydrocarbons generated pass into a condenser, and, after topping the supply of high-boiling hydrocarbons, he carbon deposited in the zone is burnt, the heat generated being utilised to heat a second zone imilar to the first in which a further quantity of he hydrocarbons is cracked.—L. A. C.

Lubricating oil and methods of manufacturing the same. J. Harger. E.P. 167,789, 18.2.20.

Hydrocarbon oils are treated with a current of air r oxygen in the presence of a catalyst consisting f compounds of manganese, lead, or mercury, or mixtures of the same, at a temperature below the racking point of the oil, *i.e.*, between 50° and 00° C., until the product contains 0·2—1·0% of atty acids. The product may be used alone for ubricating purposes, or may be blended with other ydrocarbon oils, vegetable or animal oils or fats, alkali, soap, graphite, or the like, in which case the oxidation may be carried further so that the final mixture contains 0·2—1·0% of fatty acids. In the preparation of non-emulsifiable lubricating oils, the residual air is cooled while still in contact with the oil under treatment, so that the volatile portion is condensed and returned to the oil.—L. A. C.

Lubricant; Preparation of a homogeneous, solid ——. Verkaufsvereinigung für Teererzeugnisse, G.m.b.H., and M. Brinkmann. G.P. 336,573, 11.6.19.

A solution of residues from the distillation of coal-tar, *e.g.*, anthracene residues, in coal-tar oil at 100° C. is cooled rapidly by injection into cold water or on to cooled plates or rollers, and the product is worked up into a solid mass.—L. A. C.

Lubricants; Production of viscous ——. Rütgerswerke A.-G., and H. Mallison. G.P. 338,955, 4.1.20.

Mixtures of hydrocarbons with alkali or alkaline-earth compounds of carbolic pitch (residue from distillation of tar acids), or mixtures of the same with petroleum pitch, asphalt, coal-tar pitch, or the like, yield stiff emulsions suitable for use as lubricants. Solid lubricants are prepared by mixing the carbolic pitch with fats, fatty acids, or resin acids, or by mixing the alkali or alkaline-earth compounds of carbolic pitch with the calcium compounds of tar acids.—L. A. C.

Coke for blast furnaces; Manufacture of ——. A. Riedel. E.P. 148,781, 10.7.20. Conv., 3.1.16.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Patents.

Destructive distillation of solid combustibles, especially of schists, shales, peat and the like. G. P. Guignard and G. L. Felizat. E.P. 143,223, 10.5.20. Conv., 12.4.19.

Carbonaceous material is distilled in a current of steam under a reduced pressure (620 mm. of mercury) at 350° C. By this means polymerisation is diminished, the formation of gaseous organic sulphur compounds is prevented, and the yield of ammonia is increased.—H. Hg.

Distilling carbonaceous material; Apparatus for ——. W. P. Perry. E.P. 167,822, 10.5.20.

The gas producer used for supplying hot gas for the distillation of carbonaceous material is placed below the level of the retort, an opening is provided between the retort and the producer, and the hot coked residue is transferred from the base of the retort to the top of the producer by mechanical means, such as horizontal plungers. When the producer is full, the excess coked residue passes over the top thereof into a separate gas-tight chamber, whence it may be removed.—H. Hg.

Decolorising carbon; Process of producing ——. J. N. A. Sauer. E.P. 167,195, 11.6.19.

The several processes by which decolorising carbon is produced from raw or partly carbonised material are performed in a single retort or in a series of connected retorts with zones of different temperatures. In the preliminary zone the material is distilled at about 600° C., and a separate off-take is provided for the by-products. The material then passes to the intermediate zone, where the temperature is raised to 1200° C. for the completion of endothermic reactions. In the final zone the material is heated to 1500° C., all gases which would give rise to endothermic reactions being excluded. The raw material may be treated or mixed with other substances, and steam or other gases may be passed through the preliminary and intermediate zones of the retort; chlorine may be passed through the final zone. The gases evolved in each zone are led away separately to avoid decomposition of the by-products formed in the low-temperature zone, and, after recovery of these products, are used for heating the retort. The retort is vertical and is divided into zones by horizontal slides, or a vertical partition may extend to the top of the final zone, forming a gas conduit. Ports for the admission or withdrawal of gas are provided at suitable points in the retort walls. A separate retort for the preliminary recovery of by-products may be used in association with another retort in which the processes are completed.—H. Hg.

Bituminous fuels; Apparatus for the continuous extraction and distillation of ——. G. Cantieny. G.P. 337,792, 18.6.20.

A thin layer of the material is conveyed on a chain-grate through a retort where it is exposed to superheated steam or heating gases which are admitted from underneath by a row of pipes. Each pipe can be regulated separately, so that the heat can be adjusted along the whole length of the layer of fuel.—C. A. C.

Illuminant. L. Elkan Erben G.m.b.H. G.P. 308,401, 10.10.17.

Furfural, either alone or mixed with other illuminants, burns with a bright, non-smoky, luminous flame.—L. A. C.

Glass vessels containing a wire adapted to be heated to incandescence. E.P. 167,280. *See* VIII.

III.—TAR AND TAR PRODUCTS.

Anthracene oils; Constituents of ——. *Influence of chemical constitution on the thermal properties of binary mixtures.* P. Pascal. Bull. Soc. Chim., 1921, 29, 644—656.

Anthracene, phenanthrene, and carbazole taken two by two or all three together give a continuous series of mixed crystals. Except in mixtures in which anthracene and phenanthrene predominate the crystals deposited during the crystallisation have practically the same composition as the residual liquid. With binary mixtures containing acridine as one component the melting-point curves always show a minimum point, most marked when phenanthrene is the second constituent. The introduction into a binary mixture of a constituent, such as retene or chrysene, having an unsymmetrical molecule, almost always results in isodimorphism, except in some cases when the lack of symmetry is due simply to the structure of the side chains substituted in two symmetrical nuclei.—W. G.

Cresol; Determination of —— *by the phenol reagent of Folin and Denis.* R. M. Chapin. J. Biol. Chem., 1921, 47, 309—314.

Apart from other defects the estimation of phenols by the colorimetric method of Folin and Denis (J., 1915, 1111) suffers from the disadvantage that the reagent gives colours of different intensity with equivalent quantities of different phenols. For the estimation of total cresol in mixtures of cresols of approximately known composition the author therefore introduces the use of empirical factors. The method is applied to the estimation of phenolic preservatives in serums.—E. S.

Reduction of nitro-compounds with iron; Complete and partial ——. H. Pomeranz. Chem.-Zeit., 1921, 45, 866—867.

Although picric acid cannot be reduced directly to triaminophenol with iron and hydrochloric acid, picramic acid is readily reduced by this process. Picramic acid is usually manufactured by reducing picric acid with sodium sulphide, but the process of G.P. 289,454 (J., 1916, 415) is particularly suitable for this purpose. Picric acid is only slightly soluble in water, but when picric acid and iron are covered with water and heated, the picric acid dissolves, probably as an iron salt. When a current of sulphur dioxide is passed into such a solution for some time in presence of iron, the temperature rises and picramic acid separates. The yield is practically theoretical and the product is sufficiently pure for technical purposes. This method of reduction is cheaper than the sodium sulphide process. Picramic acid is reduced by iron and an excess of hydrochloric acid to triaminophenol in a similar manner to that used for the production of 2.4-diaminophenol hydrochloride (G.P. 269,542; J., 1914, 246). The use of triaminophenol for the production of Sulphide Blacks, Nigrosines, and azo dyes is suggested.—F. M. R.

Aromatic amines; Alkylation of —— *by heating with aliphatic alcohols.* A. J. Hill and J. J. Donleavy. J. Ind. Eng. Chem., 1921, 13, 504—509.

In the interaction of ethyl alcohol or *n*-butyl alcohol with the hydrochlorides of aniline and the isomeric toluidines, the formation of tertiary amines is promoted by certain catalysts, *e.g.*, cupric chloride, sodium bromide, and calcium chloride, and by the use of a large excess of the alcohol. *o*-Toluidine is the least reactive, but with the other bases the yields are 80—90% of theory. Two new amines have been prepared by the method, namely, di-*n*-butyl-*o*-toluidine, b.p. 256°—258° C. at 755 mm., and di-*n*-butyl-*m*-toluidine, b.p. 278°—280° C. at 755 mm.—W. P. S.

Aminonaphtholmono- and di-sulphonic acids; Volumetric estimation of ——. G. R. Levi. Giorn. Chim. Ind. Appl., 1921, 3, 297—302.

The conditions have been established under which a number of aminonaphtholsulphonic acids may be estimated by titration with diazo-compounds. M-acid (NH_2:OH:SO_3H=1:5:7), 2S-acid (NH_2:OH:($SO_3H)_2$=1:8:2:4) and 2R-acid (2:8:3:6) are titrated with *p*-nitrodiazobenzene in sodium carbonate solution, J-acid (2:5:7) and R-acid (2:3:6) with the same diazo-compound in acetic acid solution, S-acid (1:8:4), γ-acid (2:8:6), and K-acid (1:8:4:6) with diazobenzene in acetic acid solution, and H-acid (1:8:3:6) with diazobenzene in sodium carbonate solution. (*Cf.* J.C.S., Oct.)—T. H. P.

1.6-Dihydroxy-2-methylanthraquinone; Synthesis of ——. J. L. Simonsen and M. G. Rau. Chem. Soc. Trans., 1921, **119**, 1339—1348.

2-Methoxy-*p*-toluic acid when nitrated with a mixture of nitric acid (sp. gr. 1·5) and acetic anhydride at 30° C., gave 3-nitro-2-methoxy-*p*-toluic acid, which was reduced to the amino-compound, and the latter converted into 2-methoxy-3-cyano-*p*-toluic acid by way of the diazo-compound. The cyano-compound was hydrolysed to 3-methoxy-4-methyl-*o*-phthalic anhydride, and the latter condensed with anisole to form 4′-hydroxy-2-methoxy-3-methylbenzophenone-6-carboxylic acid. This acid on methylation yielded methyl 2.4′-dimethoxy-2-methylbenzophenone-6-carboxylate. The methyl ether was hydrolysed by alcoholic potassium hydroxide, and the resulting 2.4′-dimethoxy-3-methylbenzophenone-6-carboxylic acid yielded 1.6-dimethoxy-2-methylanthraquinone on heating with sulphuric acid and phosphorus pentoxide. Attempts to introduce a third hydroxyl group and so get hydroxymethylanthraquinone (morindone) failed.—P. V. M.

Patents.

Dehydration of tars with high water-content; Method and device for the ——. L. Graven. G.P. 335,705, 26.9.20.

The heated tar is sprayed by pressure into a circulating warm salt solution. The water is absorbed by the salt solution whilst the tar collects at the surface and may be drawn off.—C. A. C.

Tar distillation; Method and apparatus for ——. H. Meyer. G.P. 336,415, 24.6.20.

The tar, which has been pre-heated to 70° C., enters an apparatus where the water and the light oils are removed by means of a heating coil through which the condensed middle and heavy oils from a previous distillation are passed. After this the tar is forced into another vessel in which it is sprinkled on to a pipe through which the pitch at about 400° C. is conveyed on its way from the still to the pitch pans; thereby the tar is heated to 250° C. and the middle oils are distilled off. The residual pitch containing some heavy oils passes to the still proper. There is no continuous working in the various vessels.—C. A. C.

Tars, mineral oils, or the like; Dehydration of ——. Rütgerswerke-A.-G., and E. Theobald. G.P. 338,818, 27.11.20.

The hot tar, or the like, is agitated with about 2% y weight of a finely divided material nearly or ompletely insoluble in water and preferably having n alkaline reaction, *e.g.*, kieselguhr or coal ash, nd after settling is separated mechanically from he aqueous layer and filtered to remove further races of water.—L. A. C.

ydrogenation of benzene and homologous hydrocarbons of the benzene and naphthalene series. Tetralin Ges.m.b.H. G.P. 305,104, 8.12.16.

he hydrocarbon in the liquid or vapour phase is urified by treatment in an atmosphere of hydrogen ith finely divided or readily fusible metals, alloys, ydrides, or metallic compounds which do not conain an acid radicle or in which the metal is only osely combined, alone or in conjunction with orous materials, such as fullers' earth. The puriing material is removed and the hydrocarbon then eated with hydrogen in presence of a catalyst. he preparation of hexahydrobenzene from benzene containing thiophene, and the hydrogenation of methylnaphthalene contained in the crude fraction from tar distillation, are described. The products are of value as burning oils, lubricants or solvents, and particularly for the preparation of dyes and drugs.—F. M. R.

Carboxylic acids and hydrogenated organic compounds; Production of ——. H. W. Klever. G.P. 337,099, 12.9.19.

The spontaneous inflammability of the hydrogenation products prepared by the use of alkali, alkaline-earth or like metals as catalysts is removed by treating them with carbon dioxide, best in the wet state. For example the distillate from pitch is hydrogenated using metallic calcium, magnesium, or sodium as catalyst, and is treated at 50°—100° C. with wet carbon dioxide for about 2 hrs. In addition to the refined oil, amorphous brown salts of acids of the consistency of the asphaltic acids are obtained. They are of high molecular weight and can be used in the form of their metallic salts as components of lubricating greases.—H. C. R.

IV.—COLOURING MATTERS AND DYES.

Phenanthraquinone; Dyes derived from ——. E. R. Watson and S. Dutt. Chem. Soc. Trans., 1921, **119**, 1211—1221.

Phenanthraphenazine dyes with auxochromes in the phenanthrene nucleus are prepared by condensing the corresponding amino derivatives of phenanthraquinone with *o*-phenylenediamine. 2-Amino-, 3-amino-, and 4-amino-phenanthraphenazine are prepared by heating the components in alcoholic solution under a reflux condenser for 3 hrs., the separated yellow solid being precipitated from pyridine by hot water; 2.7-diamino- and 4.5-diaminophenanthraphenazine are obtained in like manner by heating for 2 hrs. under a reflux condenser in glacial acid solution. All are yellow and dye light shades on wool. Reduction of 2.7-dinitrophenanthraphenazine gives the violet base 2.7-diaminodihydrophenanthraphenazine (yellow derivatives), which gives unsatisfactory yellow shades on wool. Dyes with auxochromes on both sides of the molecule were also prepared. 2.7.11-Triaminophenanthraphenazine, obtained by condensing 2.7-diaminophenanthraquinone with 1.2.4-triaminobenzene, is yellow-brown, dyes moderately fast shades on wool, and forms magenta-coloured salts. 2.7-Diamino-15-hydroxyphenanthranaphthazine-13-sulphonic acid from 2.7-diaminophenanthraquinone and 7.8-diamino-1-naphthol-3-sulphonic acid dyes fast yellow shades, and the corresponding 2.7-dinitro-15-hydroxyphenanthranaphthazine-13-sulphonic acid orange-yellow shades on wool. 2.7-Dinitro- and 2.7-diamino-11.4′-dimethylflavindulines are both unstable substances. 2.7-Diaminophenanthraquinol hydrochloride and the corresponding 2-amino and 4-amino compounds give black, dark brown, and light brown shades, rendered fast to rubbing by soap and warm water. The following azo-dyes have been prepared:—phenanthraquinone-2.7-bis-(2′)-azo-7′-amino-1′-hydroxynaphthalene-3′-sulphonic acid, phenanthraquinone-2.7-bisazonaphthionic acid, phenanthraquinone-4.5-bis-(2′)-azo-7′-amino-1′-hydroxynaphthalene-3′-sulphonic acid, dihydrophenanthraphenazine - 2.7 - bisazonaphthionic acid, and 11-aminophenanthraphenazine-2.7-bis-(2′)-azo-7′-amino-1′-hydroxynaphthalene-3′-sulphonic acid. The 2.7-phenanthraquinone derivatives are good direct cotton dyes; the 4.5-derivatives are good wool dyes with little affinity for cotton. —P. V. M.

Fastness of Gambines. Robinson. *See* VI.

Patents.

Azo dyestuffs; Manufacture of ——. W. Carpmael. From Farbenfabr. vorm. F. Bayer und Co. E.P. 144,310, 3.6.20.

The dyes obtained by coupling diazo-compounds with 5.5′-dihydroxy-2.2′-dinaphthylamine-7.7′-disulphonic acid (E.P. 24,296 of 1899; J., 1900, 1102) are not fast to ironing. New disazo dyes are obtained by coupling 1 mol. of 5.5′-dihydroxy-2.2′-dinaphthylamine-7.7′-disulphonic acid with 1 or 2 mols. of diazo-compounds of amines which contain a sulphonic or carboxyl group in the o-position, such as anthranilic acid, 4-chloro-2-aminobenzoic acid, etc., or with 1 mol. of these diazo-compounds and 1 mol. of any desired diazo-compound. The products dye cotton in pure red, bluish-red to blue shades fast to ironing; by after-treatment with copper salts bluish-red to violet shades are obtained fast to ironing and to light.—F. M. R.

Disazo dyestuffs for wool; Manufacture of ——. Badische Anilin- u. Soda-Fabrik. G.P. 338,683, 23.9.19. Addn. to 330,824 (J., 1921, 294 A).

Tetrazotised 4.4′-diaminobenzophenone is coupled with 1 mol. of β-naphthylamine-3.6-disulphonic acid and 1 mol. of β-naphthol. The product dyes wool from an acid bath in vivid scarlet shades fast to light, washing, and fulling.—F. M. R.

Vat dyestuffs; Manufacture of ——. R. B. Ransford. From L. Cassella und Co., G.m.b.H. E.P. 147,703, 8.7.20.

The *m*- and *p*-nitroanilides of benzoquinone when heated with a saturated alcoholic solution of ammonium sulphide in an autoclave yield useful vat dyestuffs of dark shade. Particularly valuable vat dyestuffs with a great affinity for animal fibres result if the *m*- and *p*-nitroanilides of halogenated benzoquinones are treated in a similar manner. The shades obtained vary from bluish-grey to greenish-grey according to the duration and temperature of the reaction.—F. M. R.

Trinitrotoluol; Reduction of ——. E. Bielouss. E.P. 166,931, 25.3.20.

The process of reducing trinitrotoluene to triaminotoluene by means of iron and hydrochloric acid, as described in E.P. 137,529 (J., 1921, 538 A), is improved by using only a small quantity of hydrochloric acid as, for example, in the technical reduction of nitrobenzene. The iron compounds are thus obtained as a sludge, which can be filtered off from the triaminotoluene solution. In the example given 230 kg. of trinitrotoluene, 700 kg. of iron turnings, 800 l. of water, and 20 l. of 35% hydrochloric acid, are used, and the reaction mixture is maintained at 60°—80° C. The triaminotoluene serves as a dye for cotton, wool and silk, as a photographic developer, and as an intermediate.—G. F. M.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Wool refuse; Analysis of ——. A. Demolon. Ann. Chim. Analyt., 1921, 3, 244—246.

To obtain a representative sample of this bulky and non-homogeneous material for the determination of total nitrogen, it is recommended that 10 g. of the sample should be heated gently with about 15 c.c. of concentrated sulphuric acid until a black liquid is obtained; plaster is then added in quantity sufficient to produce a dry powder and make the total weight 80 g., and 8 g. of this powder (= 1 g. of the sample) is taken for the nitrogen determination. In the Kjeldahl method, the boiling should be continued for 1 hr. after the mixture has become colourless.—W. P. S.

Wood cellulose. E. Heuser and E. Boedeker. Z. angew. Chem., 1921, 34, 461—464.

Contrary to the views of Cross and Bevan and others, the authors suggest that all plant celluloses, from whatever source derived, when obtained pure are identical, and that there is only one kind of cellulose, namely, that expressed by the formula $(C_6H_{10}O_5)_n$. It has already been shown that purified straw cellulose is identical with cotton cellulose (J., 1918, 365 A, 650 A), and the identity of wood cellulose with the latter is now demonstrated. A bleached wood cellulose was freed from resin and fat by extraction with benzene-alcohol, and was then extracted three times with boiling 6% sodium hydroxide (or alternatively with cold 17% hydroxide), whereby the pentosan content was reduced from 4·06% to 1·92%. At the same time both the ash and the copper number were reduced, the latter from 4·07 to 0·8—0·9. The pentosan remains therefore the only appreciable impurity, and by sufficiently repeated extraction this can be practically eliminated, though of course with considerable loss of cellulose. The hydrolysis of the wood cellulose, purified as above by triple alkali extraction, was compared with that of cotton cellulose, dextrose being estimated periodically both by copper reduction and polarimetrically. The hydrolysis was carried out in concentrated hydrochloric acid by Willstätter and Zechmeister's method (J., 1913, 822). In each case the maximum dextrose reading was reached in 16·5 hrs. and about 97·5% was obtained. From the wood cellulose hydrolysis 94·2% of dextrose was actually isolated in a pure condition and identified by its osazone etc.—G. F. M.

Ethylcellulose; Depolymerisation of ——. K. Hess, W. Wittelsbach, and E. Messmer. Z. angew. Chem., 1921, 34, 449—454.

Reliable conclusions as to the constitution of cellulose from the products of the acetolysis of alkylated celluloses can only be drawn when alkylation has been conducted in such a way as to exclude the probability of the disruption of glucoside or ether-like linkages. Under these conditions the limit of alkylation is reached when two ethyl groups per $C_6H_{10}O_5$ have been taken up. The resulting diethylcellulose is an individual substance, and when subjected to acetolysis a far-reaching depolymerisation occurs with the absorption of one acetyl group for each $C_6H_8O_3(OC_2H_5)_2$, and without the generation of a free aldehyde group. The acetylated product is easily hydrolysed by methyl alcoholic ammonia and gives a product of the same empirical composition as the starting material and with a molecular weight in dilute solution of 800—900, rapidly increasing with increasing concentration. The substance therefore contains at most four dextrose residues, and since free aldehyde groups are absent it must be assumed that these structural units are held together by another linking system than the "glucoside" linkage in the original ethylcellulose. Although with different preparations, isolated at various stages of the acetolysis, approximately identical molecular weights were found, differences in optical rotation and melting-point indicate that the depolymerisation is accompanied by isomerisation. The further acetolysis of the substance resulted in the formation of acetyl-ethylated hexoses, which on hydrolysis gave a syrup, from which triethylglucose was isolated in crystalline form, and which appeared to be mainly a mixture of this with diethylglucose, the latter predominating. The presence or otherwise of other ethylated glucoses in the syrup, and the proportions of di- and triethylglucose which it contains are still to be determined, but the results so far do not show complete agreement with those of either Denham and Woodhouse (J., 1917, 607), or of Irvine (J., 1921, 76 A). —G. F. M.

Wood pulp preservation tests. J. S. Bates. Pulp and Paper Mag., 1921, 19, 851—853.

Further attempts to find an efficient preservative for mechanical wood pulp in storage confirm the statement that sodium fluoride is the most satisfactory chemical for this purpose (*cf.* J., 1921, 577 A). Zinc chloride and mercuric chloride inhibited the decay which results in the disintegration of wood pulp, but seemed to stimulate a peculiar fungus and mould growth, which caused bad discoloration of the pulp. Sodium fluoride applied in approximately 1% solution and in such quantity as would correspond to 0·581% of chemical on the air-dry pulp, gave excellent results, the pulp remaining intact after storage for 18 months under conditions favourable to decay. The chemical was applied to the wet sheet as it was being made into laps, and was retained to the extent of about 80% of the amount used.—D. J. N.

Microscopical examination of paper; Use of iodine solutions in the ——. G. Wisbar. Mitt. Materialprüf., 1920, 38, 316—318.

The microscopical examination of paper is facilitated by the use of solutions of stannic chloride and iodine, calcium chloride and iodine, and particularly aluminium chloride and iodine. The fibre mass is moistened with dilute glycerin on the object glass, some drops of aluminium chloride-iodine solution are added and then taken up with blotting-paper, followed by a drop of zinc chloride-iodine solution, after which the cover glass is fitted. The yellow colour of the lignified fibres is darker and more stable than when zinc chloride-iodine solution alone is used, the wood cellulose is coloured in red-violet tones, whilst straw cellulose is coloured in pure blue tones. If the red-violet is too pale a second drop of zinc chloride-iodine solution is added, whilst if the blue is too dark zinc chloride-iodine solution somewhat diluted with water should be used. The differentiation of straw cellulose from wood cellulose is well effected with dilute calcium chloride-iodine solution, the former giving a grey-blue colour and the latter yellowish-red. Aluminium chloride-iodine and stannic chloride-iodine solutions are prepared by dissolving 0·1 g. of iodine and 0·5 g. of potassium iodide in the minimum quantity of distilled water, and making up to 10 c.c. by the addition of a saturated aluminium chloride solution or stannic chloride solution of sp. gr. 1·53. Calcium chloride-iodine solution is prepared in a similar manner except that the mixture is filtered through asbestos, and the filtrate diluted with an equal volume of water.—F. M. R.

Celluloid-caoutchouc and cellon-caoutchouc. Ditmar. *See* XIV.

Patents.

Textile fibres; Manufacture of —— from nettle and other plant stems. J. Elster. G.P. (A) 305,049, 10.3.17, and (B) 308,525, 5.5.18.

Plant stems are treated with a boiling solution of sodium carbonate whereby the cortex (comprising that portion of the stem which surrounds the inner woody core) is loosened but not disintegrated. This is separated from the stems by combing, and is then converted into pulp, washed free from colouring matters and gums, freed from woody impurities, and the pure fibres so obtained are pressed and dried. In (A) the stems are immersed, after the treatment with sodium carbonate, in cold liquors whereby a better separation of the cortex is effected. Moreover, after combing and also during the subsequent disintegration of the fibres, the bast is treated with boiling caustic soda solution. By this method, fibres, free from harmful impurities and suitable for spinning, are obtained without loss. In (B) the bast is first treated between layers of cloth with hot water or caustic soda, whereby time is economised and the fibres are less attacked. —A. J. H.

Artificial textile filaments, artificial films, or the like; Manufacture of ——. L. Drut. E.P. 143,253, 13.5.20. Conv., 13.5.19.

Artificial fibres of a woolly nature are obtained from ordinary artificial silk solutions, *e.g.*, viscose, cuprammonium cellulose, collodion, gelatin, cellulose acetate, etc., by emulsifying the solution with air or other inert gas or gaseous mixture, and spinning it into a precipitating medium while in an emulsified condition. The emulsion may be rendered more permanent by the addition of such substances as albumin, gelatin, etc. The process may be also used for the production of films. —D. J. N.

Textile material; Manufacture of ——. E. Claviez. E.P. 147,585, 8.7.20.

Artificial silk at some stage during its manufacture is mixed with fibres of different origin, preferably animal or vegetable fibres, the individual character of the added fibres being maintained in the finished product. The fibres may be added to the cellulose derivative before the latter is brought into solution, or may be added to the cellulose solution before it is spun into a precipitating bath. If desired the mixture of cellulose derivative and fibre may be allowed to solidify in moulds, or in the form of films or strips, which may be reduced to fibres by any known comminuting device.—D. J. N.

Viscose; Process for treatment of ——. Process for making viscose. C. L. Stulemeyer. E.P. (A) 167,199, 22.1.20, (B) 167,201, 2.2.20.

(A) Alkali-cellulose required for subsequent conversion into viscose is prepared by digesting cellulose with alkali of the desired strength *in vacuo.* The time required for digestion is by this means considerably reduced, and a product obtained which yields a clear viscose solution that is easily filtered. (B) The time required for complete digestion is reduced to a minimum by conducting the operation first *in vacuo,* and then under a pressure of 3—4 atm.—D. J. N.

Threads, ribbons, films or plates from viscose; Manufacture of artificial ——. M. Müller. U.S.P. 1,386,521, 2.8.21. Appl., 17.7.20.

Viscose is squirted into a precipitating bath consisting of acidified sulphite-cellulose waste lye. —A. B. S.

Non-inflammable cellulose compound. W. G. Lindsay, Assr. to The Celluloid Co. U.S.P. 1,386,576, 2.8.21. Appl., 1.9.16.

A mixture of a cellulose acetate and tricresyl phosphate with a solvent common to both.—D. J. N.

Cellulose; Preparation of —— for the manufacture of artificial silk and the like. W. R. Roederer. G.P. 338,551, 14.1.20.

Improved artificial fibres are obtained if cellulose is first treated with formaldehyde or its homologues, polymers, or condensation products in the presence of a catalyst consisting of an inorganic or organic acid, base, or salt, whereby the wood-gum present in the cellulose is converted into a compound, of higher molecular weight, which is soluble in alkaline solutions.—A. J. H.

Cellulose; Precipitation of —— from viscose solutions. Deutsche Zellstoff-Textilwerke, G.m.b.H. G.P. 339,050, 12.10.18.

A neutral salt, *e.g.*, 5—10 pts. of anhydrous sodium sulphate or 5—20 pts. of sodium chloride or nitrate, is added to 100 pts. of viscose solution, and after maturing for about 6 days, the cellulose is spun into filaments using 20% sulphuric acid as a precipitating bath.—L. A. C.

Cellulose; Production of —— from wood. R. Müller. G.P. 339,303, 26.10.18.

The wood is hydrolysed by treatment with dilute waste nitrating acid containing nitric acid or a mixture of nitric and sulphuric acids, and the cellulose is subsequently treated with alkali for removal of ligneous and other impurities.—L. A. C.

Plastic compositions containing fibrous or pulped materials; Production of ——. F. J. Commin. E.P. 167,613, 20.5 and 17.12.20.

Finely-ground pitch, suspended in an equal weight of a peptising agent, *e.g.*, casein in alkaline solution or sodium resinate solution, is mixed with well-beaten pulp in the proportion of 3—4 pts. of dry pitch to 1 pt. of dry pulp, fire-resisting materials such as clay, chalk, silica, etc., being added if desired. The pitch and fibre are cemented together by the addition of sodium resinate (if not already present as a peptising agent), and subsequent precipitation with alum. Boards are made in the usual way, dried, cut to shape, and superimposed until a board of the required thickness is obtained. This is cemented together by the combined action of heat and pressure, the moulds or rollers being maintained at 70°—100° C., depending on the type of pitch used.—D. J. N.

Paper and the like; Impregnating —— with insulating compounds and the like for electrical purposes. E. A. Claremont and C. J. Beaver. E.P. 167,232, 27.4.20.

Paper or textile fabric, heat-dried in air or *in vacuo*, is impregnated with a weak solution (20—25%) of an insulating compound in a volatile solvent, *e.g.*, ethylene trichloride, and then passed through a closed chamber into a bath of the insulating compound maintained at a temperature considerably above the boiling point of the volatile solvent. The volatile solvent is recovered in the usual way. This process, by ensuring better penetration, yields a more effective insulating material.—D. J. N.

Paper-making [; Use of rubber etc. in ——]. F. Kaye. E.P. 167,935, 25.6.20.

Rubber, gutta percha, balata and the like, in the form of the naturally occurring latex, diluted until the coagulum content is 1—0·1% or less, is well mixed with pulp (previously beaten to the required degree), and coagulated by adding the minimum effective quantity of a suitable precipitant, *e.g.*, organic or mineral acids, or mineral salts. The pulp is then sized, and run on an ordinary paper-making machine, the finished paper being vulcanised, if desired, by any suitable process (*cf.* E.P. 129,826; J., 1919, 688 A). Papers containing 0·5—5% of rubber (preferably derived from the latex of *Hevea Braziliensis*) are exceptionally strong, and give good results when tested on the Schopper folding test machine, a paper containing 0·5% of rubber having given, after vulcanisation, readings of 5000—6000 double folds. This process enables low-grade fibres to be profitably used for paper-making, and is equally applicable to all kinds of fibres, vegetable, animal, or mineral, either with or without addition of mineral fillers such as china clay etc.—D. J. N.

Paper and paper-like materials; Process for making —— waterproof and impermeable to air, at the same time maintaining their suppleness. L. Heilbronner. U.S.P. 1,387,004, 9.8.21. Appl., 3.5.20.

The paper or fabric is impregnated with a solution containing gelatin and a starch-containing substance, dried, and treated with an oil. Alternatively, the material is treated with gelatin which has been rendered insoluble in water, and agar-agar, maintained flexible by addition of a hygroscopic substance, and oiled.—D. J. N.

Paper, cardboard and textile fabrics which are impervious to air and water and have a high electrical resistance; Manufacture of ——. T. E. Blasweiler. G.P. 338,334, 29.2.20.

Two or more layers of paper, cardboard, or fabric are united when in the finished, dry or moist state by means of a layer of tar or pitch with which is incorporated a small quantity of sulphur, a sulphur-containing substance, naphthalene or naphthalene derivatives such as chlorinated or hydrogenated naphthalenes, aniline and its derivatives, oils, fats, fatty acids, waxes, paraffin, bitumen, saponin or substances which contain saponin, natural and synthetic resins or concentrated sulphite-, soda-, or sulphate-cellulose waste liquors.—A. J. H.

Paper; Manufacture of hard-sized ——. Holzverkohlungs-Ind. A.-G. G.P. 338,395, 8.1.16.

Small quantities of condensation products of formaldehyde with phenols, in alkaline solution, are incorporated with paper-pulp and are then precipitated by the addition of a solution of alum or the like. The phenol-resins may also be precipitated on the paper-web if an alkaline solution containing 10—50 g. of the resin per l. be previously mixed with the paper-pulp. The phenol-resins may be used with other sizing materials, *e.g.*, resin. The process is especially suitable for the manufacture of white writing paper.—A. J. H.

Paper; Process for sizing ——. Holzverkohlungs-Ind. A.-G. G.P. 338,396, 4.5.16.

Paper is sized by means of water-glass and alkaline solutions of condensation products of formaldehyde with phenols, naphthols, etc., condensation products obtained from formaldehyde and alkaline solutions or suspensions of tar (preferably beechwood tar) or tar residues from which acetic acid and other acid constituents have been removed, or other resinous substances which react with water-glass so that it is fixed within the paper. The paper-pulp is mixed with the substances mentioned, and aluminium sulphate or other precipitating substance is added. Satisfactory sizing is obtained even when 50% or more of the synthetic resin is replaced by the silicic acid of the water-glass, and other sizing materials, *e.g.*, resin size, may be used.—A. J. H.

Cellulose; Process of producing ——. C. A. Braun, Assr. to H. M., R. G., and G. H. Lachmann. U.S.P. 1,387,441, 9.8.21. Appl., 1.4.20.

See E.P. 137,831 of 1920; J., 1921, 466 A.

Paper-making machines [; Means for regulating admission of steam to drying cylinders of ——]. M. Landraud. E.P. 156,711, 7.1.21. Conv., 6.7.18.

Fabrics [felts of paper machines and the like]; Method of cleaning ——. F. W. Howorth. From J. T. Ayers. E.P. 167,929, 21.6.20.

Lacquers from cellulose esters. G.P. 338,415. *See* XIII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Persulphates as bleaching agents. W. Kind. Textilber., 1921, 2, 325—326.

The bleaching properties of persulphates and perborates are compared. Samples of unbleached cotton (5 g.) and linen (15 g.) yarns were together treated ten times in 400 c.c. of solutions containing potassium persulphate (1 g. per l.) or sodium perborate (0·6 g. per l.), for 1 hr., during which the temperature was raised to 95° C. In some experiments, sodium carbonate or a mixture of sodium carbonate and water-glass was added. After the 4th and 10th treatment, the strength and colour of the yarns were compared. In most cases yarn was less weakened and better bleached by the perborate than by the persulphate. The addition of sodium carbonate and water-glass to the bleaching liquors preserved the strength of the yarn and improved the colour of the whites, the water-glass having the greater effect. The adverse catalytic effect of traces of copper in the bleaching liquor was greater with a perborate than with a persulphate. The most satisfactory bleaching results were obtained from those solutions of a perborate or a persulphate which, at the end of the bleaching, had the greatest oxidising power. A mixture of a persulphate and a perborate has no special advantages as a bleaching agent, although the acidity which the persulphate develops during its reduction is neutralised by the perborate.—A. J. H.

Hæmatin dyeings; Variations in —— with different methods of chrome mordanting. C. W. Staples. Textile Col., 1921, 43, 463—466, 528—531.

Variations in shade and strength caused by the use of different methods of mordanting may be due to the different assistants used in fixing the chromium, and consequently to the form in which the chromium exists in the fibre, to differences in the temperature of the dye-bath, to the method of dyeing, and to the presence or absence of oxidising agents in the bath. In accordance with these factors, the strength and elasticity of the fibre are changed in varying degrees. The establishment of a recognised standard method of mordanting and dyeing to be used in testing logwood and hæmatin is desirable. The bichromate-tartar method of mordanting appears to be most satisfactory, with a dyeing temperature of about 95° C., and 1% dyeings are most suitable for such a standard, as showing the difference in shade and strength to better advantage than heavier shades.—F. M. R.

Pigment dyestuffs derived from tannic acid and some aromatic amines. A. E. Everest and A. J. Hall. J. Soc. Dyers and Col., 1921, 37, 227—229.

Cotton mordanted with tannic acid, or with tannic acid and tartar emetic, gives brown to yellow-brown hades when treated with diazo-compounds (G.P. 5,837). Similar dyeings are obtained when gallic cid is used in place of tannic acid, and the fastness s not greatly affected by the omission of tartar metic. The dyeings from diamines in the benzine series are the fastest and those from amines in he benzene series the least fast. Diazotised amines ill couple with oxidised cellulose but not with ellulose.—F. M. R.

Gambines; Fastness of ——. H. Robinson. J. Soc. Dyers and Col., 1921, 37, 229—231.

Ferrous sulphate alone gives dull olive-green shades ith the Gambines, but in conjunction with oxalic cid considerably brighter and more useful shades esult. In addition to the use of dyes of this type substance, they are also produced directly on the bre. Thus Resorcin Green is produced by padding the material with a solution of 1 mol. of a ferric salt and 2 mols. of resorcinol, and passing through a bath containing sodium nitrite and acetic acid. The colour is produced at once and is exceedingly fast to milling. Wool, silk, and cotton can be dyed by this process. In general, of the lakes obtained with the Gambines the copper compounds are fastest to all influences, followed by the chromium and iron lakes.—F. M. R.

Patents.

Dye-baths [for animal fibres]; Preparation of ——. C. Bennert. E.P. 146,519, 22.6.20. Conv., 24.12.15.

Animal fibres are dyed with soluble dyestuffs in even, brighter and frequently deeper shades when compounds corresponding to the type of protalbinic and lysalbinic acids are added to the dye-liquor (*cf.* G.P. 331,484 and 332,476; J., 1921, 430 a). Such compounds are produced by heating protein substances with a 2—10% solution of caustic soda for 2—3 hrs. at 80°—85° C. A suitable casein product is prepared by heating 100 pts. of casein (calc. as free from ash and moisture) with 15 pts. of sodium hydroxide and 500 pts. of water, cooling the solution to 60° C., adding 10 pts. of calcium hydroxide containing a little magnesia, stirring for ½ hr., and then filtering. The solution is made neutral to phenolphthalein with formic acid and evaporated to dryness *in vacuo*. A suitable dye-liquor contains 2% of Dianil Brown 5G, 2% of casein product, 5% of ammonium formate, and 10% of sodium sulphate crystals.—A. J. H.

Dyeing yarn on bobbins in circulating dye-liquor; Means for ——. H. Krantz. E.P. 157,420, 10.1.21. Conv., 12.1.14. Addn. to 157,418.

The caulking disc described in E.P. 157,418–9 (J., 1921, 506 a, 542 a) is constructed with an enclosed hollow space so that its buoyancy is approximately equal to its own weight and the weight of the quick-traverse bobbin resting upon it. By this means, the bobbins are uniformly compressed and are held in position, irrespective of their hardness, by the caulking discs.—A. J. H.

Dye vats and like apparatus. C. Callebaut and J. de Blicquy. E.P. 167,692, 27.8.20.

In a rectangular dye-vat, the hanks of yarn are suspended between conveying guide walls so that they are more densely packed at the bottom and press against the sides, whereby formation of liquor channels is avoided. Arrangements are provided for circulating a dye liquor upwards between the guiding walls and the sides of the vat and then uniformly downwards through the hanks of yarn.
—A. J. H.

Wool-like or transparent effects on cotton fabrics; Process for producing ——. J. E. Pollak. From A.-G. Seeriet Bleicherei, Filiale Arbon. E.P. 167,864, 19.5.20.

Wool-like or transparent effects are produced on bleached or mercerised cotton fabric, when it is treated at 0° C. or under, for less than 1 min., with suitable mixtures of 48°—50·5° B. (sp. gr. 1·50—1·54) containing sulphuric and nitric acids. For example, a wool-like effect is obtained when fabric is impregnated for 40 secs. at −10° C., with a mixture containing equal volumes of sulphuric acid of 56·5° B. (sp. gr. 1·643) and nitric acid of 40° B. (sp. gr. 1·383), washed with water, and then dried under longitudinal and transverse tension. Transparent effects are obtained under similar conditions except that the acid mixture contains equal volumes of sulphuric acid of 57° B. (sp. gr. 1·652) and nitric acid of 41° B. (sp. gr. 1·397) and the time of impregnation is 10 secs. The treated

fabrics may be mercerised with caustic soda of 28°—32° B. (sp. gr. 1·24—1·29) whereby their transparency is increased. Resists are obtained by printing fabrics before treatment with a solution containing 300 g. of paraffin wax per l. of benzine.
—A. J. H.

Hanks of yarn; Apparatus for treating —— with liquids. G. S. Lord. E.P. 167,868, 20.5.20.

In a machine in which the hanks are squeezed while passing between rollers, arrangements are provided whereby uneven distribution of yarn in the hanks is avoided.—A. J. H.

Dyeing skins, hairs, feathers, and the like; Process for ——. A. G. Bloxam. From A.-G. für Anilin-Fabr. E.P. 167,910, 9.6.20.

p-Phenylenediamine derivatives containing a hydroxynaphthyl group in one amino group and one or two organic substituents in the other amino group (*cf.* E.P. 18,726 of 1900; J., 1901, 981), give dyeings of very good fastness to light and weather on skins, hairs, feathers, and the like in aqueous solution containing hydrogen peroxide. Mordanted or unmordanted pelts are dyed for 3 hrs. at ordinary temperature in a solution containing 2 g. of the *p*-phenylenediamine derivative and 40 c.c. of a 3% solution of hydrogen peroxide per l., and are then washed and finished as usual. By means of 2-hydroxy-7-naphthyl-4-aminodiphenylamine, di-2-hydroxy-7-naphthyl-4.4′-diaminodiphenylamine, 1-hydroxy-5-naphthyl-4-aminodiphenylamine, di-1-hydroxy-5-naphthyl-4.4′-diaminodiphenylamine, 2-hydroxy-7-naphthyl-4-amino-4′-methoxydiphenylamine, and 2-hydroxy-7-naphthyl-4-aminodimethylaniline, grey, blue, and greenish-blue shades are obtained.—A. J. H.

Azo dyes on the fibre; Production of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 301,672, 2.8.16. Addn. to 301,671 (*cf.* U.S.P. 1,215,359; J., 1917, 382).

The tetrahydro-α-naphthalide of 2.3-hydroxynaphthoic acid is dissolved in sodium hydroxide with addition of sodium ricinoleate, and the sodium salt of a nitrosamine of an unsulphonated amine, such as the nitrosamine derived from *p*-nitroaniline, is added. Cotton is padded in this solution and then treated with an acid developer, such as bichromate, an acid salt, or acetic acid. The shades produced in this manner are clearer than those produced by the two-bath process of the chief patent.—F. M. R.

Dyeing of cellulose acetate artificial silk, films, and the like. Soc. Chim. des Usines du Rhône, anc. Gilliard, P. Monnet et Cartier. E.P. 150,989, 17.5.20. Conv., 5.9.19.

See U.S.P. 1,366,023 of 1921; J., 1921, 145 A.

Bleaching, dyeing and like machines employed in the textile industries. J. Denton. E.P. 167,621, 21.5.20.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric and nitric acids; Action of mixtures of —— on metals. P. Pascal, Garnier, and Labourrasse. Bull. Soc. Chim., 1921, 29, 701—709.

The effects of sulphuric and nitric acids mixed in varying proportions and at different concentrations on aluminium, steel, and lead at temperatures ranging between 16° and 21° C. are tabulated, the results being expressed as loss in weight of the metal in g. per sq. m. in 24 hrs. The addition of sulphuric acid to nitric acid facilitates action on aluminium. With nitric acid alone the presence of ammonium nitrate slightly increases the action on the metal. For all the varying proportions of the two acids there is a dilution corresponding to between 10 and 20% of water at which the resistance of steel is a maximum.—W. G.

Ammonium carbonate; Decomposition of —— with calcium sulphate. B. Neumann and W. Gellendien. Z. angew. Chem., 1921, 34, 441—442, 445—447.

From consideration of the solubility relations and dissociation of calcium sulphate and carbonate, it is calculated that in the reaction between calcium sulphate and ammonium carbonate solution, at 18° C. with $N/4$ ammonium carbonate the yield of ammonium sulphate should be 99·97%. The yield was tested experimentally employing pure compounds, the reaction being carried out in glass flasks on a shaking machine. Samples were taken from time to time. Conversion proceeded rapidly at first but equilibrium was only reached in 15—20 hrs. The maximum yields obtained were for the calcium sulphate dihydrate 85%, for the semihydrate and for gypsum heated to 200°—300° C. 92%, and for anhydrite 90%. The yields increased slightly with the concentration of the ammonium carbonate solution. The yield with the dihydrate increased with the temperature up to 38° C. and then remained constant. Change of temperature had no appreciable effect with the semihydrate. The discrepancy between these results and the calculated yields is shown to be due to the formation of a double salt $(NH_4)_2SO_4,CaSO_4,H_2O$. The best results in practice should be obtained by employing either cheap natural anhydrite or gypsum ignited at 200°—300° C. At this temperature gypsum forms a mixture of soluble anhydrides which on stirring with water readily yield the semihydrate. (*Cf.* J.C.S., Oct.)—C. I.

Calcium sulphate; Reaction of —— with ammoniacal liquor. B. Neumann. Z. angew. Chem., 1921, 34, 457—459.

It has been suggested that gas-liquor might replace ammonium carbonate as an agent for the decomposition of calcium sulphate. While theory indicates a yield rising with the concentration of ammonia up to 88% for a $10N$ solution, a practical test showed the yield to fall with an increase in concentration. For $N/1$ ammonia solution only 3% conversion was obtained and the method is evidently useless in practice. For the reverse reaction yields in excess of the theoretical except in very dilute solution were obtained. These discrepancies, like those found with ammonium carbonate (*cf. supra*), are due to the varying solubility of calcium sulphate in ammonium sulphate solutions. (*Cf.* J.C.S., Oct.)—C. I.

Bromine in brines; Determination of ——. P. Lebeau and M. Picon. Bull. Soc. Chim., 1921, 29, 739—743.

A preliminary approximate determination of the amount of bromine as bromide is made by titrating 1 c.c. of the brine with chlorine water, containing 0·5 g. of chlorine per litre, until decolorisation just commences. This volume of chlorine water divided by two gives the approximate amount of chlorine required to displace the bromine. A volume of the brine under examination containing about 0·1 g. of bromine is placed in a separating funnel and to it is added 5 c.c. of 10% hydrochloric acid and the calculated amount of chlorine water containing 5 g. of chlorine per litre. The liberated bromine is extracted with 15 c.c. of chloroform and the chloroform extract is run into 10 c.c. of 10% potassium iodide solution in a stoppered bottle. The liquid in the separating funnel is again extracted with chloroform after the addition of 0·3—0·5 c.c. of chlorine water. This process is repeated until the chloroform extract is colourless. The iodine liberated by the addition of the chloroform extracts to the potassium iodide is titrated with $N/10$ thiosulphate. To obtain satisfactory results by this method the use of excess of chlorine water must be avoided, and the volume of salt water containing 0·1 g of bromine should not exceed 25 c.c., a preliminary evaporation being conducted if necessary.—W. G.

Borax; Physico-chemical study of the double decomposition, $(NH_4)_2B_4O_7+2NaCl \rightleftarrows Na_2B_4O_7+2NH_4Cl$, for the technical preparation of ——. U. Sborgi and C. Franco. Gaz. Chim. Ital., 1921, **51**, II., 1—57.

The Dresel process for the manufacture of borax, represented by the equation, $(NH_4)_2B_4O_7+2NaCl \rightleftarrows Na_2B_4O_7+2NH_4Cl$, is analogous to the Solvay process for sodium carbonate and consists in subjecting a solution containing sodium chloride (or sulphate) and boric acid to the action of ammonia (*cf.* E.P. 14,905 of 1894; J., 1895, 36). The authors have made a complete investigation at various temperatures of the system represented by the above equation and have calculated the yield of borax for each point of the solubility diagram. There are two invariant points in the system, and it is in the neighbourhood of one of these, corresponding to a solid phase composed of ammonium borate, borax, and ammonium chloride, that the best conditions for the practical working of the process are found. At 10° C. these conditions are obtained with an initial mixture in the proportions NaCl 393 g., H_3BO_3 654 g., NH_3 89·95 g., H_2O 1206 g. The quantity of crystallised borax precipitated is 941 g. and the mother liquor contains 282·3 g. NH_4Cl, 35·35 g. $Na_2B_4O_7$, and 84·36 g. NaCl per 1000 g. of water. The yield of precipitated borax is equivalent to a recovery of 73·3% of the sodium and 93·4% of the boric acid in the initial mixture. (*Cf.* J.C.S., Oct.)—T. H. P.

Boric acid industry; Utilisation of the so-called "salaccio" of the —— of Lardarello. U. Sborgi. Giorn. Chim. Ind. Appl., 1921, **3**, 293—297.

A method is described for utilising the so-called "salaccio," which is obtained by evaporating to dryness the mother-liquor left after removal of the crude boric acid, and which contains ammonium, magnesium, and sodium sulphates, in addition to boric acid. A solution of the "salaccio" is boiled with sodium carbonate, and ammonia and carbon dioxide recovered from the vapours. After filtering, the solution is concentrated, the borax which crystallises out is separated, and the solution containing sodium sulphate treated with ammonia and boric acid by the Dresel process (*cf. supra*).
—T. H. P.

Sodium nitrite; Determination of ——. F. Muhlert. Z. angew. Chem., 1921, **34**, 448.

Nitrite is frequently estimated by the diazotisation of sulphanilic acid. For this reagent o-aminobenzoic acid may be advantageously substituted. The end point is sharp, the diazo-compound is table, and the reagent can be easily obtained in a pure state.—C. I.

Alkali hydroxide and carbonate; Determination of —— in presence of cyanide and ferrocyanide. F. Muhlert. Z. angew. Chem., 1921, **34**, 447—448.

A method for the estimation of alkali in potassium r sodium cyanide consists in titrating the cyanide ith silver solution, removing the turbidity formed t the end point with a drop of cyanide solution nd then titrating with $N/1$ acid until the urbidity reappears. The method is accurate if ost of the alkali is present as hydroxide and is therefore suitable for control tests in cyanide manufacture. In presence of other weak acids, *e.g.*, formic acid, this method cannot be used, neither does Clennell's method (J., 1903, 762) give good results. The procedure is as follows. The cyanide is first titrated with silver solution, and the same quantity of solution added to another sample. The resulting solution after filtration can then be used for alkalimetric determination. If great accuracy it not required the solution need not be filtered. If ferrocyanide is present the solution may be titrated directly with $N/1$ acid and methyl orange. The cyanide having been previously determined, the alkali is obtained by difference.—C. I.

Mercury salts; Zinc purpurate as a reagent for ——. G. Denigès. Bull. Soc. Pharm. Bordeaux, 1921, [1]. Ann. Chim. Analyt., 1921, **3**, 251—252.

The reagent is prepared by heating 2 g. of uric acid with 2 c.c. of nitric acid (40° B., sp. gr. 1·38), diluting the solution with 2 c.c. of water, continuing the heating until a clear liquid is obtained and diluting this to 100 c.c.; if 10 c.c. of this liquid is boiled for 5 mins. with the addition of 2 g. of granulated zinc, a yellow-orange coloration develops due to the formation of zinc purpurate. When a mercuric salt solution is treated with a small quantity of the zinc purpurate solution and a few drops of sodium acetate solution, a peach-blossom-coloured precipitate of mercury purpurate is produced. The reaction may be obtained with as little as 0·4 mg. of mercury per c.c. of solution. Silver salts yield a violet-coloured precipitate with the reagent.—W. P. S.

Sulphide sols. Preparation of sols by means of gaseous hydrogen sulphide. F. V. von Hahn. Kolloid-Zeits., 1921, **29**, 139—143.

The stability of metal sulphide sols is increased by those factors which increase the degree of dispersion. It increases with the time of treatment with the gas up to a maximum; increases with the temperature nearly up to the boiling point, and also increases up to a maximum with the velocity of the current of hydrogen sulphide.—J. F. S.

Potash from cement kilns. Krarup. *See* IX.

Chromium salts. Grasser. *See* XV.

Patents.

Sulphuric acid; Process for the production of ——. T. Schmiedel and H. Klencke. E.P. 149,648, 31.3.20.

Burner gases, after being used for denitrating the day's make of sulphuric acid in a small preliminary chamber, are brought into contact with excess of nitrosylsulphuric acid in one or more pairs of small chambers. Of these chambers the first is a mixing chamber in which a roller dipping beneath the surface of the contained acid throws a spray into the gas. In the second or irrigation chamber the exit gases from the first chamber are washed with nitrosylsulphuric acid as in a Gay-Lussac tower, the necessary moisture and nitric acid being supplied at the same time.—C. I.

Sulphur dioxide; Method of and apparatus for recovering —— from furnace gases or other gases containing the same. A. H. Eustis. E.P. 167,726, 4.5.20.

In a method of recovering sulphur dioxide from smelter smoke and the like by its liquefaction (*cf.* U.S.P. 1,341,114–5; J., 1920, 517 a) the gas is cooled and part of the moisture so removed. Part of the sulphur dioxide is also liquefied and collects in a trap, serving to remove the last traces of moisture. This liquefied gas is also used for the cooling of further entering gas.—C. I.

Hydrocyanic acid; Process of producing ——. R. W. Poindexter, Assr. to Poindexter and Co. U.S.P. 1,387,170, 9.8.21. Appl., 6.7.20.

Ammonia is injected into a heated hydrocarbon.
—H. R. D.

Ammonia; Method for the prevention of nitrogen losses in the oxidation of ——. H. Frischer. G.P. 301,681, 24.11.16.

The gases and vapours from the combustion chamber, before absorption, are passed through acids or acid salts, or alkalis or other substances which decompose ammonium compounds.—C. I.

Ammonium sulphides; Manufacture of ——. South Metropolitan Gas Co., and P. Parrish. E.P. 167,540, 30.4.20.

By maintaining a preliminary still at a temperature and pressure properly related, *e.g.*, 98° C. and 16 lb. per sq. in. absolute, the carbon dioxide can be expelled from ammoniacal liquor without loss of hydrogen sulphide. The distilled liquor is then used for the manufacture of ammonium sulphide or polysulphide by treatment with concentrated hydrogen sulphide prepared by decomposing iron sulphide with sulphuric acid.—C. I.

Ammonia; Method and apparatus for the recovery of —— from ammoniacal liquor. W. C. Holmes and Co., Ltd., M. Boocock, and W. Wyld. E.P. 167,719, 6.1.21.

In that type of process in which the liquor is heated and sprayed successively into a number of chambers, the chambers are heated by jackets through which flue gases are passed, and the liquor is preheated by passing it through tubes which traverse the jackets. Fixed ammonium salts are decomposed with a reagent in a separate intermediate chamber. If liquor ammonia is required the condensed gases are freed from carbon dioxide and hydrogen sulphide in a still, and the purified liquor is passed again through spraying chambers.
—C. I.

Alum and sulphate of alumina; Manufacture of ——. A. Matheson. E.P. 167,555, 6.5.20.

Alunite is heated to 700°—900° C. in a furnace having a series of superposed hearths. The sulphur gases from the furnace pass into a chamber at 400°—500° C. containing a portion of the roasted ore and supplied with sufficient water to form sulphuric acid. After treatment with the gases the product is subjected to wet extraction to recover alum and aluminium sulphate.—H. R. D.

Potassium sulphate and aluminium oxide; Method of producing —— from alunite. J. L. Silsbee. U.S.P. 1,386,031, 2.8.21. Appl., 2.12.19.

Alunite ore is crushed and roasted, treated whilst hot with solvent liquor, and the solution, carrying fine aluminium oxide in suspension, is separated from the undissolved matter. The aluminium oxide is then separated from the liquid, and the latter is cooled and potassium sulphate recovered by crystallisation.—H. R. D.

Brine; Method of treating ——. H. H. Dow, Assr. to The Dow Chemical Co. U.S.P. 1,386,244, 2.8.21. Appl., 26.9.18.

The treatment is carried out in stages, viz., precipitation of iron and manganese; precipitation of magnesium; liberation of any ammonia present; precipitation of alkaline-earth metals. The final product is a pure solution of sodium chloride.
—H. R. D.

Potassium salts; Process for extracting ——. J. Allingham. U.S.P. 1,386,486, 2.8.21. Appl., 17.8.18.

Finely divided rock containing potassium is mixed with common salt and sulphur and heated in a reducing atmosphere in a furnace. The mass is then lixiviated with water, and potassium chloride recovered by crystallisation.—H. R. D.

Potassium magnesium sulphate; Process for the preparation of —— from a mixture of potassium chloride and kieserite. Kali-Forschungsanstalt, G.m.b.H. G.P. 338,088, 5.8.20.

Kieserite mixed with potassum chloride is dehydrated at 160°—200° C. and converted into a soluble form. Without the chloride it is not completely dehydrated even at a red heat. Sodium chloride may be substituted for potassium chloride.
—C. I.

Phosphate rock; Method of treating ——. W. Glaeser, Assr. to Potash Extraction Corp. U.S.P. 1,387,151, 9.8.21. Appl., 1.5.16.

Phosphate rock is ground, heated with sodium carbonate and carbon, the water-soluble phosphate leached out from the product and treated with carbonic acid.—H. R. D.

Lead arsenate; Process of making ——. (A) M. L. Tower. (B) M. L. Tower and F. L. Begtrup, Assrs. to Niagara Sprayer Co. U.S.P. (A) 1,387,212, (B) 1,387,213, 9.8.21. Appl., (A) 3.8.20, (B) 31.8.20.

(A) Litharge is dissolved in dilute acetic acid, arsenic acid is added gradually, and the resulting lead arsenate is filtered off. (B) Litharge is treated with arsenic acid in presence of a neutral nitrate.
—H. R. D.

Cyanide-furnace. R. M. Major, Assr. to Driver Harris Co. U.S.P. 1,387,286, 9.8.21. Appl., 17.2.20.

A cyanide pot, sunk into a furnace chamber, is covered by a hood which has a flue independent of the furnace flue. Cyanide is thereby prevented from entering the interior of the furnace.
—C. A. K.

Metallic hydroxides, especially aluminium hydroxide; Production of —— with the simultaneous recovery of ammonium salts. M. Buchner. G.P. 299,781, 27.4.15.

A solution of a metallic sulphate is treated with a halogen compound of a metal the hydroxide of which is not precipitable by ammonia and the sulphate of which is insoluble or only slightly soluble in water, and the solution, after removal of the latter by filtration or crystallisation, is poured into ammonia or treated with liquid or gaseous ammonia. For example, aluminium sulphate is mixed with potassium chloride, the resulting potassium sulphate removed by crystallisation, and the liquor poured into an excess of ammonia to precipitate aluminium hydroxide. Ammonium chloride is recovered from the filtrate by evaporation and sublimation.—A. R. P.

Metallic hydroxides, especially aluminium hydroxide; Production of —— in an easily filterable and washable form. M. Buchner. G.P. 301,675, 6.6.14.

A saturated solution of a salt of the metal, the hydroxide of which is desired, is treated with an alkali, alkaline-earth, ammonia solution, an organic derivative of ammonia, gaseous ammonia, or waste gases containing ammonia, an excess of the precipitant being preferably used.

Metallic hydroxides, especially aluminium hydroxide; Production of —— in an easily filterable and washable form. M. Buchner. G.P. 302,412, 25.11.14. Addn. to 301,675 (*cf. supra*).

The saturated solution of the metallic salt, or the solid salt, partially dehydrated if necessary, is added to the precipitating liquor, which may consist of ammonia or one of its compounds with a volatile acid, *e.g.*, ammonium carbonate or sulphide.—A. R. P.

Metallic hydroxides; Process for the preparation of granular ——. M. Buchner. G.P. 304,281, 18.7.16.

Metallic salts which can be precipitated by bases are treated under pressure with liquid or gaseous ammonia in excess, in suitable vessels provided with stirring apparatus. Water is added when necessary, the granular precipitate filtered off, and the excess of ammonia recovered.—C. I.

Gases containing sulphur; Producing —— suitable for the manufacture of sulphur and a magnesia sludge from magnesium chloride liquor. Harburger Chem. Werke Schön und Co., and W. Daitz. G.P. 307,082, 9.3.18. Addn. to 306,441 (J., 1920, 570 a).

Magnesia, preferably in the form of a sludge, is added instead of, or as well as, magnesium carbonate, to the mixture of calcium sulphate and lime that is to be reduced as specified in the principal patent.—A. R. P.

Basic magnesium carbonate; Production of ——. Chem. Fabr. Buckau. G.P. 338,887, 23.6.14. Addn. to 311,960 (J., 1919, 765 a).

Ammonia gas and carbon dioxide are passed simultaneously or consecutively through a warm solution of a magnesium salt either alone or mixed with aqueous ammonium carbonate, the proportions of the gases being regulated within the limits specified n the chief patent.—A. R. P.

alcium and magnesium carbonates; Preparation of precipitated —— from dolomitic limestone. W. Esch. G.P. 338,888, 1.5.17.

olomitic limestone is strongly burnt aud leached hile hot with calcium chloride solution. The re- ulting calcium oxychloride solution is filtered hot rom the residue of magnesium hydroxide, the filtrate diluted with calcium chloride wash liquor, and reated with carbon dioxide to precipitate calcium arbonate, the regenerated calcium chloride liquor eing used again in the process. The magnesium ydroxide precipitate is digested with magnesium hloride solution to remove calcium salts, and the esulting magnesia slime is dissolved in carbon di- xide with the help of ammonia. The clear solution heated to precipitate basic magnesium carbonate nd the evolved carbon dioxide used again in the rocess.—A. R. P.

lcium hypochlorite; Process for reducing —— to a form suitable for compression into pastilles, balls, cubes, etc. Chem. Fabr. Griesheim-Elektron. G.P. 338,117, 14.6.17.

he dry powdered hypochlorite is mixed with pure, y, ground sodium chloride. By using the sodium loride specially purified from magnesium chlor- e, known as "Fürstensalz," a stable preparation produced, which has a much wider applicability an the usual form of bleaching powder.—G. F. M.

dium hypochlorite; Preparation of solid ——. B. Wieger. G.P. 338,962, 23.4.19.

lid caustic soda is treated with chlorine diluted h indifferent gases, and the reacting mass is kept ll cooled.—A. R. P.

Thionyl chloride; Preparation of —— from sulphur chloride, chlorosulphonic acid, and chlorine. Farbenfabr. vorm. F Bayer und Co. G.P. 338,851, 25.11.19.

A high yield of thionyl chloride of great purity is obtained by treating a mixture of sulphur mono- and di-chlorides with chlorosulphonic acid and chlorine, in the molecular proportion of 2:1, at 60° C. The evolved gases are passed through an air-cooled column of acid-resisting material and then through a superimposed column packed with broken pieces of sulphur into an absorption tower where they are washed with chlorosulphonic acid. —A. R. P.

Sulphur; Purification of ——. P. Spence and Sons, Ltd., H. Spence, and T. J. I. Craig. E.P. 167,373, 13.5.20.

Spent aluminous material which has been used for purifying sulphur as described in U.S.P. 1,331,645—6 and E.P. 140,844 (J., 1920, 295 a, 365 a) is regenerated after ignition, by soaking in dilute hydrochloric acid (sp. gr. 1·05), or sulphuric acid (sp. gr. 1·08), for several hours, then well washed with water and dried.—H. R. D.

Sulphur; Recovery of —— from lignite ash, clinker, etc. A.-G. für Anilin-Fabr. G.P. 339,491, 27.3.20.

Sulphur is recovered in free or combined form by roasting the ash in a furnace. Light ashes are moistened and moulded, and after drying are treated in a shaft kiln into which air is blown. —J. S. G. T.

Halogens; Method of absorbing ——. C. W. Jones, Assr. to The Dow Chemical Co. U.S.P. 1,386,117, 2.8.21. Appl., 23.7.18.

Bromine is separated from admixture with chlorine by treating with sufficient alkali to absorb the chlorine and 1 mol. of bromine to every 5 mols. of chlorine, whereby the latter is converted into chloride, and the former into bromate. The bromate is separated from the chloride and the residual bromine, purified from chlorine as above, is subsequently absorbed.—G. F. M.

Fractionation of air or other gaseous mixture; Process of ——. R. Mewes. G.P. 339,354, 27.4.18. Addn. to G.P. 317,889.

In the fractionation of air or other gaseous mixture as described in the chief patent (*cf.* U.S.P. 1,215,957; J., 1917, 457) the more volatile liquefied constituent (nitrogen in the case of air) which collects in the uppermost part of the plant, and the less volatile constituent (oxygen in the case of air) which collects below are both strongly supercooled in special receptacles, whereby any argon present is frozen and falls by gravity into a special collecting chamber whence it is periodically drawn off. —J. S. G. T.

Sulphur dioxide; Method of and apparatus for recovering —— from furnace gases or other gases containing the same. A. H. Eustis. E.P. 167,725, 4.5.20.

See U.S.P. 1,341,114—5 of 1920; J., 1920, 517 a.

Ammonia; Process and means relating to the production of ——. C. Bosch, Assr. to The Chemical Foundation, Inc. U.S.P. 1,386,760, 9.8.21. Appl., 14.9.12.

See F.P. 406,943 of 1909; J., 1910, 488.

Nitrogen-containing compounds; Method of producing ——. K. Prinz zu Löwenstein, and F. Hauff. U.S.P. 1,386,941, 9.8.21. Appl., 18.8.16.

See G.P. 318,286 of 1915; J., 1920, 404 a.

VIII.—GLASS; CERAMICS.

Patents.

Glass vessels [gas pipettes] containing a wire adapted to be heated to incandescence. South Metropolitan Gas Co., and J. M. Somerville. E.P. 167,280, 4.5.20.

The cracking of glass vessels at the junction between the glass and the wire to be raised to incandescence, is prevented by forming the glass vessel with internal cavities adapted to contain a suitable liquid or solid and so formed that the wire which will conduct heat from the incandescent wire to the glass seal extends through the liquid or solid before touching the glass at the seal, and touches the glass at no other point than the seal. The device is applied more especially to apparatus for the analysis of gases.—J. S. G. T.

Vacuum vessels; Production of a mirror-surface in ——. Ges. f. Verwertung Chem. Produkte m.b.H. Kommanditges. G.P. 332,770, 14.9.19.

A mirror-surface is produced in vacuum vessels by introducing into the annular space a gaseous metal compound, (*e.g.*, nickel tetracarbonyl), and decomposing it by heating the vessel.—A. B. S.

Quartz-glass and the like; Fusing —— by means of acetylene and oxygen, under pressure. W. C Heraeus G.m.b.H. G.P. 338,250, 28.12.19.

Quartz-glass is fused by means of a mixture of acetylene with hydrogen, coal gas, or other technical gases, containing 2—40% of acetylene. The excessive vaporisation, and the furrows formed on the surface of the ware, when an oxyacetylene flame is used, are avoided to a large extent by the use of the mixed gas.—A. B. S.

Burner for tunnel-kilns. P. d'H. Dressler, Assr. to American Dressler Tunnel Kilns, Inc. U.S.P 1,385,986, 2.8.21. Appl., 1.5.20.

In a tunnel kiln, an elongated combustion chamber within the kiln chamber is supported on a masonry bench, and air and gas for combustion are supplied to an aperture in the bottom of the combustion chamber through channels opening through the top surface of the masonry bench.—B. M. V.

Brick-kiln construction. J. T. Pokorny, Assr. to A. T. Eddingston. U.S.P. 1,386,530, 2.8.21. Appl., 22.3.18.

Drying and firing chambers are arranged in superposed relation above the fire-chamber. Hot air circulating about the exterior of the fire-chamber is admitted to the drying chamber through openings in the floor of the latter. Fuel-conducting pipes connect the firing room with the fire-chamber. —A. B. S.

Ceramic articles; Production of a brilliant, lustrous, red coating on ——. A. Heinecke. G.P. 339,339, 5.9.20.

A coating for ceramic ware is made from a mixture of equal weights of ferruginous clay and wood ashes, powdered glass, or other flux, by adding 2—4 pts. of a 15% solution of a reducing agent (*e.g.*, dextrin, sugar or honey), treating the mixture in a ball mill and passing it through a fine sieve immediately before use. During the burning, the finely divided iron oxide is reduced, but is re-oxidised as the ware cools.—A. B. S.

Flake materials [mica]; Process and apparatus for manufacture of sheets by aggregation of ——. C. F. Peterson, Assr. to General Electric Co. U.S.P. 1,386,896, 9.8.21. Appl., 20.9.17.

See E.P. 153,612 of 1918; J., 1921, 11 A.

Glass; Method of and apparatus for feeding molten ——. Hartford-Fairmont Co., Assees. of K. E Peiler. E.P. 157,160, 8.1.21. Conv., 17.3.14.

Glass; Manufacture of articles of ——. T. C. Moorshead. E.P. 168,272, 15.11.20.

IX.—BUILDING MATERIALS.

Potash as a by-product from cement kilns; Recovery of ——. C. Krarup. Chem. and Met. Eng., 1921, 25, 316—320.

About 2—4 lb. of potash (K_2O) is volatilised in the production of each barrel (380 lb.) of Portland cement, but the proportion varies too much for the dust recovered by simple settling to be used direct as an ingredient in mixed fertilisers sold according to their potash content. The potash and soda are present chiefly in the form of sulphates, but simple leaching with water only removes a portion of potash owing to the presence of gypsum, which forms a sparingly soluble double salt. Hence, a separation of the potassium salt from the dust prior to leaching with water is essential. The greater part of the cement dust particles are much larger than those of the potassium salt, hence much of the latter can be carried forward whilst the dust particles settle out. At the works of the Santa Cruz Portland Cement Co., Davenport, Cal., 10—12 tons of potassium salt is recovered daily from 10 kilns, the product containing about 33% of K_2O, as potassium sulphate. The kiln gases are first passed through a wash-tower, 21×6×10 ft., provided with horizontal baffles, 7 ft. apart, the gases being cooled to 100° C. with water sprays which cause 95% of the cement dust to settle; about 75 galls. of water per minute is used. Gypsum crystallises on the walls of the tower, also in the pump and pipe lines, and must be removed every 6 weeks; it also crystallises in the spray nozzles, which are removed daily and cleaned with a sand blast. The spray system is in duplicate so as to avoid stoppage during cleaning. The slime produced by the action of water on the dust flows to a Dorr thickener and is afterwards filtered; the resulting cake is dried and returned to the kiln along with the regular supply of raw material of which it forms a part. This dust averages 6 tons per kiln per 24 hrs.; it contains about 15% of the total potash. The cooled gases, freed from most of the cement dust, next pass through a settling chamber, 30×13×7 ft., above which is an electrical treating chamber of the same size. The floor separating these chambers is provided with adjustable rectangular openings along the outer walls for the passage of the gas, the gas being distributed uniformly throughout the upper chamber, and flowing at a velocity of less than 1 ft. per second. The remaining cement dust settles in the lower chamber and the salts are precipitated electrically in the upper one. On each side of the latter are shelves above the floor, which prevent the collected salt from dropping through the openings into the dust-chamber below. The electrical precipitating plates are suspended vertically from the roof of the upper chamber; they are 18 in. wide and about 6 in. apart. The electrode wires are suspended horizontally, so that the space beneath the plates is quite clear and has no obstructions on which the precipitated salt can settle. The wires are in two superposed rows and are 8 in. apart, strung from bus-bars rigidly supported by insulators at each end of the chamber. In the middle of the span of the wires, a light grid is suspended to keep the wires steady; no slack-reducing device is used. The wires are vibrated for a few seconds every hour, by a light pneumatic hammer; this is necessary to keep them clean and to prevent distortion of the electric field. No rapping device is applied to the plates. The electric treater operates at a potential difference of 40,000—45,000 volts; the efficiency of collection is 75—80%. The salts which drop on to the floor of the upper chamber are removed by a scraper-conveyor and pass through a pair of slowly moving rolls, which consolidate the material, and deliver it into sacks. The power-consumption is about 40 h.p. per kiln (=40 h.p. per ton) of which half is required for the electrical precipitation. Three men are required per shift to run the ten units, and additional men are needed occasionally to clean the tower.—A. B. S.

PATENTS.

Kilns; Lime, cement and like ——. C. Candlot. E.P. 150,994, 29.7.20. Conv., 10.9.19.

A SHAFT-KILN for lime, cement, or the like is fitted at its lower end with a revolving grate having a planetary movement around the axis of the kiln and provided with teeth of lance-like shape, so as to disaggregate the contents of the kiln just previous to discharging them.—A. B. S.

Fibred asphalt. G. L. Oliensis and J. S Miller, jun. E.P. 167,334, 25.5.20.

FIBRED asphalt is made by disintegrating dry felt or other fibrous material, passing it through a 30-mesh sieve, distributing the separated fibres evenly over the surface of molten asphalt, bitumen, or the like, and incorporating them by stirring the mass. As the fibres are completely separated before use, a great increase in the cohesion of the asphalt is secured with only a small proportion (3—4%) of fibre, so that the product is liquefiable by heat and of greater utility for roofing etc. than ordinary mixtures of fibre and asphalt.—A. B. S.

Bituminous paving; Method of making ——. A. E. Alexander. From Blackstone International Corp. E.P. 167,341, 26.5.20.

A BITUMINOUS cement (such as natural asphalt, coal tar pitch, residues of petroleum distillation) which has been made to foam or froth by adding a small quantity of water or by injecting steam into it, is applied, at a temperature of 300°—350° F. (about 150°—180° C.), to particles of crushed stone or slag, gravel, sand, ashes or other mineral matter at a temperature of 300°—500° F. (about 150°—260° C.), so as to cover the latter with a thin coating of cement, and then bituminous cement is poured over the coated particles. Mineral dust, with or without a volatile solvent or petroleum residuum, may afterwards be incorporated if desired.—A. B. S.

Paving mixtures. W. J. Mellersh-Jackson. From Bitoslag Paving Co. E.P. 167,997, 23.12.20.

ASPHALTIC paving material is made by mixing a portion of a filler (*e.g.*, limestone, Portland cement, or slag dust), with hot mineral aggregate (*e.g.*, air-cooled blast-furnace slag), the remainder of the filler with the molten bituminous binding agent (*e.g.*, "blown" or oxidised asphalt), and then mixing the two products.—A. B. S.

Cement process and product; Dry ——. J. L. Tufts. U.S.P. 1,386,914, 9.8.21. Appl., 2.2.14.

A DRY cement, of composition $5MgO,MgCl_2,5H_2O$, is prepared by agitating calcined magnesite in a closed vessel, whilst introducing sufficient hydrochloric acid gas and water vapour.—A. B. S.

Artificial marble or stone; Manufacture of a weather-resisting, non-efflorescent ——. F. Burkhardt. G.P. 338,351, 5.10.19.

A MIXTURE of cement, colouring matter, and sand, stone meal, slag or the like is made into a thick paste with ammonium chloride, acetic acid, and water, and the mixture allowed to set in the usual way. The product is a glassy, non-porous, weather-resistant stone.—A. R. P.

Lumber; Treatment of ——. F. and H. Pfleumer, Assrs. to The Chemical Foundation, Inc. U.S.P. 1,386,727, 9.8.21. Appl., 5.9.16.

SEE G.P. 291,945 of 1915; J., 1916, 843.

Paving material; Method of making —— *from tarry matter.* C. Honda. U.S.P. 1,386,932, 9.8.21. Appl., 30.10.19.

SEE E.P. 151,852 of 1919; J., 1920, 750 A.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron; Some aspects of electrolytic ——. W. A. Noyes, jun. Trans. Amer. Electrochem. Soc., 1921, 1—7. [Advance copy.]

WITH the object of measuring the minimum potential at which the electrolytic deposition of iron could be carried out and the voltage at which transfer of iron from the anode to the cathode actually commenced, a positive electrode was attached to the common circuit end of the filament, and the negative electrode to the grid of a three-element vacuum tube. The grid-filament current was rendered negligible by giving the grid a negative potential. Values were obtained by plotting current against voltage and observing the sharp break when the current began to increase rapidly with increase in voltage. The potential value fell gradually from 0·66 volt at 20° C. to a minimum (0·13) at 109° C., then increased to 0·23 at 182° C. The voltage of steel electrodes coated with electrolytic iron was balanced against a hydrogen electrode and gave a value of 0·428 in the system $Fe-FeSO_4-H$. Logarithmic curves of the current-potential values of an iron electrode measured against that of a normal zinc electrode at varying temperatures showed that the lower part of the curve in each case was a straight line, the slope of which could be calculated approximately from the formula $S=0{\cdot}0002T/0{\cdot}6$. In acid solution anode polarisation is practically negligible, indicating that the iron is rendered active by a slight liberation of hydrogen. (*Cf.* J., 1920, 70 A.)—C. A. K.

Malleable cast iron; Sulphur in ——. L. C. Crome. Chem. and Met. Eng., 1921, 25, 247—248.

IN duplicate determinations on 40 samples of white iron the sulphur content as determined by the evolution method was in many cases much less than when determined by an oxidation process. Complete volatilisation was proved by the absence of sulphur in the solutions and residues. After annealing the metals giving these discordant results, sulphur values determined by the oxidation and evolution methods checked very closely with each other and also with that obtained by the evolution method before annealing. It is concluded that sulphur exists in iron in at least two forms; that which is obtained by the evolution method is probably in the form of manganese or ferrous sulphide, and the remainder is in some unspecified form. It is thought that only the sulphur in sulphide form is injurious to iron, and that the evolution method therefore indicates the harmful constituent even though it does not always give the total sulphur content.—C. A. K.

Pyrites cinder; Desulphurisation of —— in the electric furnace. G. Ongaro. Giorn. Chim. Ind. Appl., 1921, 3, 288—290. (*Cf.* Guédras, J., 1921, 261 A.)

In the production of iron from pyrites cinder in the electric furnace, desulphurisation may be effected by means of substances capable of generating chlorine: $2FeS+3Cl_2=Fe_2Cl_6+2S$. In presence of carbon, carbon monoxide, and chlorine, the liberated sulphur may yield gaseous carbon oxysulphide or it may unite with oxygen to form volatile compounds. A mixture capable of traversing undecomposed the first heating zone of the electric furnace and of yielding chlorine when it reaches the fused charge is prepared by making a paste of magnesium chloride and oxide with water, adding to it manganese dioxide or oxidised manganese ore, with or without chlorides of the alkali or alkaline-earth metals, and allowing the whole to set. In the first heating zone this mixture merely loses its water of combination. These desulphurising agents also facilitate the reduction of the pyrites cinder by lowering the melting point of the slag and rendering the latter less viscous; substances capable of improving the slag may be introduced into the pasty desulphurising mixture before it is dried.—T. H. P.

Iron-silicon system; Equilibrium diagram of the ——. T. Murakami. Sci. Rep. Tôhoku Imp. Univ., 1921, **10**, 79—92.

As a result of thermal, magnetic, and microscopical tests on iron-silicon alloys containing from 1·76% to 32·60% Si, the equilibrium diagram of Guertler and Tammann (J., 1905, 1236) has been revised. The existence of the compound Fe_2Si is not confirmed, but, in addition to the known compound, FeSi, a new one, Fe_3Si_2, has been found to exist. At room temperature the compound, Fe_3Si_2, dissolves in iron up to 16% Si. The critical point of its solid solution in iron gradually decreases from 790° to 450° C. as the silicon content increases from 0 to 16%. As the temperature rises the solubility increases up to 23% Si at 1020° C. Above 1100° C. the compound, Fe_3Si_2, dissociates into iron and FeSi. In alloys containing more than 23% Si, during cooling FeSi separates primarily, and at 1020° C. Fe_3Si_2 is formed by combination of FeSi with iron.—E. H. R.

Steels; "Characteristic curves" of the heat treatment of ——. A. M. Portevin and P. Chevenard. Iron and Steel Inst., Sept., 1921. [Advance proof.] 19 pp.

The result of a heat treatment of steel appears to be determined by the value of the initial temperature (θc) and the rate of cooling (V). If either of these factors is varied the alteration of the transformation temperatures on cooling is not continuous and the geometrical area of the various characteristic limits of the different phases can be plotted. By this means the "characteristic curves" for a given steel are obtained. The intensity of the transformation is measured by the differential dilatometric method (J., 1917, 881, 882). Characteristic curves for a nickel and high-speed steel are given.—C. A. K.

Steel; Coalescence in ——, and its commercial results. A. Portevin and V. Bernard. Iron and Steel Inst., Sept., 1921. [Advance proof.] 35 pp.

The tendency of similar components in an alloy to unite and agglomerate into granules, usually of rounded contour, is influenced by the variations in the intersolubility of the structural elements of the complex $\alpha Fe+Fe_3C$ at constant or falling temperatures, and by the presence of added elements, more particularly Cr, W, and Mo. Coalescence, and therefore the resultant softening of steel, is a function of the rate of heating particularly in the region immediately below the Ac1 transformation point. Mechanical work on either hot or cold metal assists the breaking up of the lamellæ of pro-eutectic or eutectic cementite, particularly when followed by annealing. Chromium and tungsten in small quantity render the coalescence of 1·0—1·2% C steels more difficult, but when more is present complete coalescence of carbon may be obtained. Ball-bearing steel (1·0% C; 1·0—2·0% Cr) can only be rendered sufficiently soft for machining by causing the cementite to coalesce. The original hardness (Brinell) has been reduced by 50% by heating at 750° C. for 25 hrs., and cooling to 650° C. at an average rate of 5° C. per hr. The metal was later restored to lamellar form by heating for 3 hrs. at 850° C. and cooling in air. Coalescence facilitates the deformation of steel, a result of value in operations such as die-stamping and cold drawing, and it may be stated in general that steels with a globular structure possess a greater interval between the elastic limit and the breaking strain than those with a lamellar structure. The final heat treatment must be defined entirely by the "characteristic curves" of the steel (*cf. supra*). —C. A. K.

Steels; Mechanical properties of —— at high temperatures. E. Dupuy. Rev. Mét., 1921, **18**, 331—365. Iron and Steel Inst., Sept., 1921. [Advance proof.] 22 pp.

Five steels varying in carbon content between 0·15% and 1·23% were tested mechanically at 50° C. intervals up to a temperature of 1250° C. With rising temperature the breaking strain generally fell a little at first, but then increased and attained a slight maximum about 300° C. A steady lowering then occurred until the temperature approached 750° C., above which temperature a slight recovery in the value was followed by a steadily decreasing tensile strength up to the point of incipient fusion. The variation in the curve showing the percentage reduction in area was more marked. A minimum value was shown at 300° C., increasing to 450° C., at which point a depression again occurred, more marked as the metal contained less ferrite. The reduction in area varies in relation to the carbon content of the steel. Soft steel showed a rapid fall to 875° C., and after several undulations in the curve the reduction in area attained a value of 100% at about 1050° C. The nature of the curve for eutectoid steel showed an increased reduction in area from 600° C., attaining 100% value at 760° C. Hypereutectoid steels had a relatively constant value for the reduction in area at temperatures between 760° C. and those of complete fracture (100%). It is concluded that below the A1 point ferrite is deformed by cleavage before rupture occurs, and that a eutectoid steel is fractured almost without deformation. Rupture is due to cementite in a hypereutectoid steel. At higher temperatures the plasticity of steel is entirely dependent on γ-iron.—C. A. K.

Mild steel; Metallographic evidence for determining the previous annealing treatment of ——. P. Oberhoffer. Stahl u. Eisen, 1921, **41**, 1215—1217.

The author shows that micrographic evidence is obtainable as to whether or not mild steel containing about 0·07—0·12% C has been annealed between Ac1 and Ac3. Boiler-plate material containing C 0·09%, Mn 0·53%, P 0·03%, S 0·036%, was examined at a magnification of 900 in the unannealed condition and also annealed at 700°, 800°, and 950° C. respectively for ½ hr. and cooled in air. In the case of the specimen annealed between Ac1 and Ac3 there developed around the pearlite islands ferrite areas, which although not separated from the rest of the ferrite by definite grain boun-

daries, nevertheless stood out in relief. The phenomenon is visible at lower magnifications, *e.g.*, ×100, in which case it is usually shown as a broken or ragged structure. The appearance of the structure is explained in the light of the iron-carbon diagram.
—T. H. Bu.

Steel; Nature of the transformations occurring during the hardening of ——. P. Dejean. Rev. Mét., 1921, **18**, 419—427.

A complete diagram of the critical points of nickel carbon steels is difficult to establish because higher carbon steels heated to a temperature below the Ac1 point throw out varying quantities of graphite which renders the interpretation of the cooling curves uncertain. This feature is not observed in the case of manganese steels in which, however, the affinity for carbon is so great that it is not easy to obtain a manganese steel containing less than 0·2% C. Additions of manganese or nickel lower progressively the temperature of the Ar3 transformation of iron, and any addition of carbon reduces this point still further. The temperature of the Ar1 transformation is lowered to a less extent by the presence of nickel or manganese, and the effect of carbon, at least in manganese steels, is to raise this point. Owing to the opposed action of carbon it is possible in several ways to produce a pearlitic or troostitic steel. From a comparison of the electromotive forces of solution of tempered and annealed steel it is concluded that the region of stability of martensite extends only below the annealing temperature.—C. A. K.

Steel; Hardening of ——. A. Portevin and P. Chevenard. Rev. Mét., 1921, **18**, 428—444.

The authors criticise the hypothesis put forward by Honda (J., 1919, 821 A) that the reversible transformation austenite ⇄ pearlite (or troostite) always takes place through the intermediate stage of martensite, which would necessitate an equilibrium between four phases. The contraction immediately following the dilatation of transformation is entirely thermal and not the indication of a secondary transition point. The retarded solution and premature separation of cementite is discussed. With certain steels (*e.g.*, nickel-chromium steels) quenching from a high temperature tends to retain an excess of austenite and yields a brittle metal. It is better to cool in air to a temperature (350°—400° C.) near to the transformation point Ar, and then to immerse in water. The result of the micrographic examination of natural nickel-iron (meteor- tes) and of similar artificial alloys which have been cooled very slowly indicates that the alloy is not a solid solution but a mixture of two constitu- nts comparable with the ferrite-cementite of arbon steels, but the exact nature of the two constituents, kamacite and tœnite, is not yet determined. (*Cf.* J., 1920, 66 A.)—C. A. K.

ickel-cast-iron alloy; Manufacture of a 5% —— in an electric furnace. D. N. Witman. Amer. Inst. Min. Met. Eng., Sept., 1921. Min. and Met., 1921, No. 176, 29—32.

lectrical resistance grids made of cast iron con- ining 4—5% Ni require careful moulding, as the sistance of the cast grid must be within a 10% mit. The nickel imparts toughness and pliability the metal and enables the smallest castings to ssess an open, grey and highly graphitic structure. ving to the high temperature (1660° C.) necessary obtain fluidity of the metal, the melting is rried out in an electric furnace. Any accumula- on of slag is skimmed off, and adjustment of the tal is made from inspection of a trial cast test r. The average power consumption covering a riod of nine months was 1100 kw. per ton, with electrode consumption of 28 lb. per ton.
—C. A. K.

Nickel steels; Anomalous thermal expansion in hardened irreversible ——. T. Sutoki. Sci. Rep. Tôhoku Imp. Univ., 1921, **10**, 93—99.

Experiments were made with steels containing from 2 to 30% Ni to determine the effect of the nickel on the tempering temperature. The steels contained about 0·9% C, and the properties studied were thermal expansion and magnetisation. The low nickel steels were hardened by quenching in oil from 900° C., the high-nickel steels being quenched in liquid air. The anomalous expansion in the nickel steels is shown to be due to tempering. The effect of adding nickel to a carbon steel is to raise the temperature of tempering, slowly at first, then more rapidly, from 330° to 400° C. The effect of nickel on the transformation of carbon steels during rapid cooling is discussed. In low-nickel steels both α- and β-martensite are present, but in high-nickel steel only β-martensite is found, the transformation from β to α not having taken place to an appreciable extent. The magnetisation experiments showed that, in the case of low-nickel steels, intensity of magnetisation increased with rising temperature to a slight maximum at 180° C., indicating the transformation of α-martensite into pearlite. From 180° to 300° C. the intensity steadily increased to a maximum, due to transformation of β-martensite into sorbite. After this the curves gradually descended. In high-nickel steels the maximum at 180° C. was absent, whilst the change from β-martensite to sorbite was indicated by a break in the direction of the curve at about 400° C.—E. H. R.

Copper; Working and annealing of ——. F. Johnson. Inst. of Metals, Sept., 1921. [Advance copy.] 25 pp.

Annealing for 1 hr. at 200° C. of copper strips which had been reduced in successive rollings 18—98% produced softening in all cases where the reduction had exceeded 40%. The greatest softening effect was shown by the most severely worked metal. Severely worked strips showed a tensile strength equal to, or lower than, that of the original bar when annealed at 250° C. The increase in strength conferred by rolling was almost entirely removed by annealing for 1 hr. at 350° C. or for 30 mins. at 750° C. Copper rods which had been reduced 60% in area by cold drawing varied when annealed according to their composition. "Tough pitch" arsenical copper (0·36—0·52% As; 0·026—0·06% O) retained its strength up to 300° C., whereas "tough pitch" electrolytic rod (0·089% O) lost considerable strength. Arsenical copper containing silver (0·29%) had a slightly higher annealing temperature than metal free from silver. Copper containing 0·69% As and 0·43% Fe commenced to soften at an annealing temperature of 300° C., but did not exhibit rapid crystallisation until a temperature of 420° C. was reached.—C. A. K.

Zinc; Relation between mechanical properties and microstructure in pure rolled ——. D. H. Ingall. Inst. of Metals, Sept., 1921. [Advance copy.] 28 pp.

Rolled zinc possesses no absolute values for mechanical or other properties owing to its inherent variability, particularly in size of grain. With a reduction by rolling of 77%, pure zinc has a tensile strength of about 6 tons per sq. in., which is increased to about 13·5 tons at a 96% reduction. The ductility of zinc annealed at 100°—150° C. is poor across the direction of rolling until a reduction of 88% is reached, from which point it rises rapidly until at 96% reduction the metal is quite ductile in both longitudinal and transverse directions. Pure rolled zinc when reduced 77—96% shows an equiaxial structure. Annealing at 200° C. causes large grain growth and results in a brittle material; the largest grains are found where the most severe work (*e.g.*, shearing) has been done on the metal. The tensile strength curves indicate that an annealing temperature of 150° C. is a critical point for 86—88 % reduction by rolling, though this is not supported by any abnormal increase in the grain size of the metal.—C. A. K.

[*Brass;*] *Extrusion defect* [*in* ——]. R. Genders. Inst. of Metals, Sept., 1921. [Advance copy.] 9 pp.

During the ordinary method of extrusion of copper alloys through a die by means of a hydraulic press, the outer skin of the billet is cooled by contact with the walls of the container, and as the ram descends is bent over inwardly to be carried forward in the flow of metal. The author suggests a method already in use in the treatment of soft lead alloys, by which the die, mounted on a hollow ram, is pushed into the metal billet. By this method the relative movement between the billet and the receiver is avoided, and experiments on a small scale showed that the flow of metal was confined nearer to the die, with the result that a sound rod was produced for 95% of its length.—C. A. K.

Copper-zinc alloys; Density of ——. T. G. Bamford. Inst. of Metals, Sept., 1921. [Advance copy.] 12 pp.

The work of previous authors is reviewed, and their results are reproduced and compared with those obtained by the author for copper-zinc alloys chill and sand cast. The densities of the sand cast specimens are less than those of the chill cast, except for the alloy containing 60·7% Cu, where they are equal, the maximum divergences occurring at 83, 50, and 35% Cu and the minimum at 24 and 40% Cu. From pure copper down to the alloy containing 30% Cu a contraction takes place on alloying, but below this a marked expansion takes place, culminating in a minimum density at 12% Cu. The relation of the density differences in the chill and sand castings at the compositions noted above to the various change-points on the melting-point diagram is discussed.—A. R. P.

Brasses; Corrosion of certain complex —— in sea-water. L. Belladen. Gazz. Chim. Ital., 1921, **51**, II., 144—159.

The author has investigated the corrosion by sea-water of three samples of delta metal, having the following percentage compositions:

	Pb	Mn	Fe	Al	Ni	Cu	Zn
I. ..	0·10	0·40	0·30	0·38	—	59·34	39·29
II. ..	0·58	0·90	0·71	0·15	0·07	57·10	40·39
III. ..	0·38	0·35	0·48	0·27	—	56·62	41·54

The α and β metallographic constituents were present in each case. Metal II. was the most resistant to sea-water, a protective film of brown salts, probably derived from the lead and manganese, forming on the whole surface and preventing sporadic corrosion up to the thirty-fifth day of immersion. The most corrodible was metal III., which contains low proportions of manganese and aluminium, but is the richest in zinc. Apart from the accessory metals present, the compositions of these three brasses would indicate that the first should be the most, and the last the least, resistant to corrosion, since increase in the proportion of zinc corresponds with increase in the β-solution, which is the more readily corrodible; this conclusion actually agrees with the results of experiments on the electrolytic corrosion of the metals in sea-water. Very prolonged electrolytic corrosion does not always give results similar to those obtained in practice, since certain protecting saline layers are destroyed by the action of the current; this method is, however, well adapted to the study of the effects of corrosion, sections cut after deep corrosion indicating the course of the corrosion in the interior of the metal. In this way it was found that for a depth of several tenths of a millimetre the β-solution became completely replaced by copper, confirmation being thus furnished for the view that in the corrosion of αβ-brass true dezincification of the β solution takes place; this process occurred to the greatest extent with metal I. and to the least with metal II. —T. H. P.

Admiralty gun-metal; Effect of increasing proportions of lead upon the properties of ——. R. T. Rolfe. Inst. of Metals, Sept., 1921. [Advance copy.] 19 pp.

Addition of lead up to 1·5% to sand cast Admiralty gun-metal (88% Cu, 10% Sn, 2% Zn) increases the tensile strength and ductility, but slightly decreases the hardness. Above this proportion, lead reduces the figures obtained for the first two properties and increases the hardness. Maximum resistance to impact is obtained with an alloy containing 1% Pb. Castings containing up to 1·68% Pb are sound, but there is a tendency towards segregation of the α-δ eutectoid, and in the microstructure the lead may be seen as soft black spots, scattered through the matrix and associated with the eutectoid. In chill-cast gun-metal lead progressively decreases the ductility and impact figures but has the same effect on the hardness as in the sand-cast alloy and is not so readily detected in the microstructure. From the results obtained it is suggested that the maximum lead permissible in Admiralty gun-metal might be increased from 0·5 to 1%. Similar experiments on a gun-metal containing 85% Cu, 5% Sn, and 10% Zn showed that lead tends to cause a slight falling off in the tensile strength and yield point but that it increases the ductility. In sand-cast bars the minimum hardness is obtained with 1% Pb, whereas with chill-cast this is a point of maximum hardness. The microstructure of the alloy consists of the α-eutectic in which the lead may be observed as separate segregations.—A. R. P.

Bronze; Effect of progressive cold drawing upon some of the physical properties of low tin ——. W. E. Alkins and W. Cartwright. Inst. of Metals, Sept., 1921. [Advance copy.] 23 pp.

The effect of different gradation of drafting in wire drawing of bronzes containing 0·853%, 1·01%, and 0·68% Sn respectively was determined. The increase of the tensile strength is closely connected with the severity of the reduction in area. The curves for the changes in tensile strength, specific volume, and hardness, follow generally the nature of similar curves for copper (*cf.* J., 1920, 368 A), though the location and relative accentuation of the maximum and minimum occur at rather a later stage. —C. A. K.

Monel metal; Notched bar impact tests and toughness of ——. R. G. Waltenberg. Chem. and Met. Eng., 1921, **25**, 322—323.

The mean of five impact tests of monel metal in the Charpy machine on notched bars cut from 1 in. hot rolled rods was 166 ft.-lb. and on bars cut from ¾ in. rods, 153 ft.-lb. The results obtained in the Izod machine were unreliable as in no case did the specimen break. The angle of bend in the Izod test is 60° while in the Charpy test it is 120°. The toughness of monel metal is thus extraordinarily high, the energy absorbed in the Charpy test being twice that with the best heat-treated nickel steel. The quality factor for toughness (ultimate tensile strength × elongation ÷ 2400) of monel metal is 1580, while that of a heat-treated nickel-chromium steel is 1440 and of a heat-treated carbon steel only 920.—A. R. P.

Aluminium [*; Action of acids and bromine on* ——]. E. R. Hodges. Chem. News, 1921, **123**, 141.

Aluminium is not attacked by boiling acetic acid or by hot strong solutions of tartaric or citric acids; oxalic and phosphoric acids, however, dissolve the foil, the former extremely slowly in the cold, readily on warming. In the presence of a few drops of hydrogen peroxide, cold, strong acetic acid dissolves thin aluminium foil in about 30 hrs. Bromine combines with the metal, if slightly warmed, with incandescence, yielding grey vapours of the bromide and a brown deliquescent residue. (*Cf.* J.C.S., Oct.)—A. R. P.

Alloys of aluminium with magnesium and silicon; Constitution and age-hardening of ——. D. Hanson and M. L. V. Gayler. Inst. of Metals, Sept., 1921. [Advance copy.] 35 pp.

The binary systems Al—Mg and Al—Si were investigated, and a portion of the ternary system (alloys containing up to 35% Mg and up to 11% Si). Aluminium and silicon form a simple eutectic series, the eutectic temperature being 570° C. (10·5% Si). The occurence of a definite compound, Mg_2Si, in the alloys suggests that this compound is associated with the hardening properties. At 580° C., 1·6% Mg_2Si is held in solution in aluminium; the solubility falls to 0·9% at 350° C. and to not more than 0·5% at 30° C. Even a slight excess of magnesium causes a rapid reduction in the solubility of Mg_2Si, which is then found in the alloy as a separate constituent. Excess of silicon appears to have little effect on the solubility of Mg_2Si. The hardness due to ageing increases with the quantity of Mg_2Si in the alloy up to the limit of its solubility at the quenching temperature, and it is suggested that the gradual hardening is the result of the tendency for separate crystals of aluminium and Mg_2Si to form in the alloy.—C. A. K.

Magnesium alloy "electron." S. Beckinsale. Inst. of Metals, Sept., 1921. [Advance copy.] 2 pp.

Specimens of the alloy, of German origin, contained about 95% Mg, 4·5% Zn, and 0·5% Cu; the sp. gr. was 1·78. The mechanical properties of the alloy were:—Yield point 12·0, maximum load 16·1—18·4, crushing load 23·0 tons per sq. in., elongation 13—19%. The specimens machined well, and compared favourably with alluminium alloys, allowance being made for the much lower specific gravity. —C. A. K.

Nickel-aluminium-copper alloys; Properties of some ——. A. A. Read and R. H. Greaves. Inst. of Metals, Sept., 1921. [Advance copy.] 24 pp.

Some of the copper-rich nickel-aluminium-copper alloys retain much more nickel and aluminium in the α solid solution at 900° C. than at ordinary temperatures. The physical properties of these alloys containing 90—87% Cu, 4—7% Ni, rest Al, have been determined after various mechanical and heat treatments. They are comparatively soft after quenching from 900° C. (Brinell number 73—91), but may be hardened by slow cooling from 900° C. (Brinell number 120—148) or by reheating for some time at lower temperatures. The increased hardness is due to the separation of a new constituent, probably a nickel-aluminium-copper solid solution, which is accompanied not only by changes in the tensile strength, hardness, and resistance to impact, but also in the density and electrical conductivity. The separation of this constituent takes place slowly so that chill-cast alloys and small, hot-rolled rods consist almost entirely of the α solid solution, in which condition they may be cold-rolled without cracking. Slowly cooled alloys, on the other hand, crack badly on cold rolling, and must be heated to 900° C. and quenched in water. Alloys treated in this manner should be annealed for ½ hr. at 300°—500° C. for complete restoration of elastic limit in tension, which is also generally accompanied by an increase in the maximum tensile strength. With some of the alloys a progressive increase of hardness may be obtained by maintaining them for various periods at 500° C., at which temperature the precipitation of the new constituent begins to take place at an appreciable rate. If this treatment is carried on for sufficient time the previous softening may be counterbalanced and an alloy of high elastic limit and tensile strength (50 tons per sq. in.) and with a 20% elongation may be obtained. The maximum hardness is obtained by reheating the quenched alloy for 2 hrs. at 600° C. or ½ hr. at 700° C. The alloy then has a yield point above 20 tons per sq. in., a tensile strength over 40 tons, and an elongation of 15—25%.—A. R. P.

Mercury; Thornhill's sodium sulphide process for the recovery of —— *as applied to cinnabar ore from Puhipuhi.* W. Donovan. N. Z. J. Sci. Techn., 1921, 4, 129—134.

The mercury ore of Puhipuhi consists of a silicified breccia mixed with clay rock and containing small quantities of cinnabar, metacinnabarite, iron pyrites, and magnetite. It assays 0·75—1·44% Hg and, in consequence of the large amount of fines, cannot be successfully treated by direct furnace methods. The following treatment has been found to give good results. The ore is ground to 100-mesh and treated in an oil flotation plant with 5 lb. of eucalyptus oil, 1 lb. of caustic soda, and 2½ lb. of common salt per ton. The concentrate contains 85—90% of the cinnabar in the ore and assays 30% Hg. It is agitated for 3—4 hrs. with a solution containing 4% of sodium sulphide and 1% of caustic soda, allowing 50 lb. of solution to each 1 lb. of sulphide in the ore. The filtered solution, which contains all the mercury, is electrolysed at 3 volts with a current density at the cathode of 5 amps. per sq. dm., using a graphite anode and a mercury cathode. The recovery of metal is complete, and the solution can be used again for the treatment of concentrates. The cost of working the process on an ore containing 0·75% Hg averages about 2s. 9d.—3s. per lb. of mercury recovered, including standing charges.—A. R. P.

Tin and antimony [in alloys]; Quantitative separation of —— *in the presence of phosphoric acid.* Mouret and J. Barlot. Bull. Soc. Chim., 1921, 29, 743—745.

The tin-antimony alloy is dissolved in *aqua regia*, the solution is evaporated nearly to dryness, and the residue treated with warm concentrated hydrochloric acid. After dilution with an equal volume of water, the solution is treated with at least 50 c.c. of an 8—9% solution of crystalline orthophosphoric acid for every 0·01 g. of tin present. The antimony is precipitated as sulphide at 80°—90° C. by the passage of hydrogen sulphide. The precipitate is filtered off and the antimony is subsequently determined electrolytically. The filtrate is boiled to remove hydrogen sulphide, and the tin is precipitated by the addition of cupferron, and determined in the usual manner.—W. G.

Electric furnaces for non-ferrous alloys. H. W. Gillett. Trans. Amer. Electrochem. Soc., 1921, 277—295. [Advance copy.]

The total number of electric furnaces in operation in U.S.A. in January, 1921, melting non-ferrous metals was 318. The operation of individual types is described in detail. Electric melting is well established on brass and bronze, common on nickel-chromium and similar alloys, but is not used to any great extent for melting aluminium or the lower melting alloys. On the usual aluminium alloys the electric furnace does not show any particular saving in metal, and cannot properly compete with the most suitable fuel-fired furnaces.—C. A. K.

Electrolytic etching of metals [for micrographic examination]. F. Adcock. Inst. of Metals, Sept., 1921. [Advance copy.] 9 pp.

Electrolytic etching in a 10% citric acid solution, using a cathode of platinum wire gauze and the specimen as the anode, gave satisfactory results with copper-nickel alloys, nickel silver, and brass. About 0·05 amp. was sufficient for the first-named, but 0·1 amp. was necessary for copper. Silver can be etched similarly if a few drops of nitric acid are added to the electrolyte. The specimens should be vigorously polished on a damp disc with alumina before etching, in order to obtain good definition of crystal boundaries. Ammoniacal ammonium molybdate solution may be used in place of citric acid but is not so convenient. With a β-γ brass containing 6% Al it reveals a peculiar cell structure in the β regions and it darkens the traces of cementite to be found in Swedish iron. Electrolytic etching of gold may be satisfactorily carried out in an electrolyte of strong hydrochloric acid containing ferric chloride by the use of about 1 amp. for each 2 sq. cm. of area.—A. R. P.

Alloys; Method of determining the quantitative composition of —— of which the constitution is known. K. Schmidt. Chem.-Zeit., 1921, 45, 825—826.

The percentage composition of an alloy of two metals A and B may be found from the equations,

$$x=100a_2(Vs_2-P)/[P(a_1s_2-a_2s_1)/s_1-Vs_2(a_1-a_2)]$$

and $x+y=100$, where a_1 and a_2 are the atomic weights of A and B, and s_1 and s_2 their sp. gr. respectively, and P and V are respectively the weight and volume of the alloy AB. The four constants in the first equation, viz., s_2, a_2, $(a_1s_2-a_2s_1)/s_1$ and $s_2(a_1-a_2)$ are worked out and the results tabulated for the following binary alloys; copper with gold, silver, nickel, zinc, and tin, lead with tin and antimony, tin-antimony, zinc-nickel, and silver-gold. If P and V are determined to 4 places of decimals the results are correct to the first place except in the copper-nickel series, where they are only correct to the nearest whole number. Similar equations may be developed for ternary alloys and the factors for the copper-silver-gold series are worked out.—A. R. P.

Scleroscope; Use of the —— on light specimens of metals. F. S. Tritton. Inst. of Metals, Sept., 1921. [Advance copy.] 10 pp.

The mode of support of light test-pieces is important if a proper rebound of a scleroscope hammer is to be obtained. A layer of pitch less than 0·025 in. in thickness between the test-piece and the base block proved effective. Other substances of high viscosity (*e.g.*, liquid glucose) also gave good results when similarly applied.—C. A. K.

Pyrite; Flotation of ——. W. S. Morley. Amer. Inst. Min. Met. Eng., Sept., 1921. Min. and Met., 1921, No. 176, 32—33.

Mountain copper pyrite (to pass 100-mesh) mixed with three times its weight of sand was subjected to tests with 22 standard flotation agents. Those containing viscous ingredients (*e.g.*, coal tar) failed. "Pentarco," Nos. 350 and 400, and acid sludge gave a recovery of more than 90%. A small addition of sulphuric acid was beneficial probably because it removed the tarnish and gave a cleaner concentrate. Pyrite should be ground to pass at least a 170-mesh screen in order to obtain an efficient flotation. The recovery of copper as chalcopyrite was variable, the best result (93·2%) being obtained by the use of "X cake" and xylidine in alkaline solution; this reagent gave recoveries of 47·9% for copper as pyrite and 71·0% for zinc as sphalerite.—C. A. K.

Patents.

Wrought iron, steel, or the like; Hardening agent for ——. W. Kaiser. E.P. 143,510, 17.5.20. Conv., 18.1.18.

"Pyoktanin" is mixed with the usual hardening salts, such as common salt and saltpetre, as well as carbonaceous substances, such as burnt horn shavings, leather, or bone charcoal, or a solution of "pyoktanin" in ammonia liquor is mixed with solutions of the above hardening salts, containing also lime, and holding the carbonaceous substances in suspension.—J. W. D.

Cast iron; Production of —— from scrap iron and wood charcoal in cupolas. O. Johannsen. G.P. 328,904, 16.3.18.

The air blast for working the cupolas is preheated to a high temperature.—L. A. C.

Cast iron; Increasing the phosphorus content of ——. F. Bardenheuer. G.P. 338,663, 18.11.19.

Material containing phosphorus, such as basic slag, apatite, phosphorite, and the like, is added to molten cast iron contained in a cupola furnace, together with silicious fluxes. A readily fusible gray iron is obtained.—A. R. P.

Steel alloy of great toughness and resistance to wear and of low magnetisability. E. Becker. G.P. 338,664, 5.12.19.

The steel contains 2·5—15% Mn, at least 4% Ni or Co, or both, and 0·2—11·0% W, and may be improved by the addition of up to 2% V. The alloy has the advantage over plain manganese steel that it is non-rusting.—A. R. P.

Iron articles; Process for rendering —— rust-proof by combination with nitrogen. H. Hanemann. G.P. 338,329, 25.5.18. (*Cf.* F.P. 458,283, J., 1913, 1072; G.P. 284,803, J., 1915, 1098.)

The gas employed, *e.g.* ammonia, is brought into contact with the iron articles, heated to the temperature necessary for the reaction, as they are conveyed through an oven. In this process no decomposition of ammonia occurs until the gas comes into contact with the heated articles, whereupon a film of nitride is formed.—J. H. L.

Flux for welding iron and its alloys. Deutsch-Luxemburgische Bergwerks- und Hütten-A.G., and S. Hilpert. G.P. 330,011, 17.12.16.

The flux contains a mixture of phosphates and alkali silicates, such as water-glass. A mixture of 20% of sodium metaphosphate and 80% of water-glass, together with twice its weight of iron filings and some resin, is suitable for welding high-speed tool steel to ordinary steel.—L. A. C.

Ferrotitanium or refined iron or steel; Direct production of ——. H. C. and A. J. Loke. G.P. 338,662, 23.7.19. Conv., 20.3.19.

Oxidised titaniferous iron is melted in an electric-arc furnace, deoxidised, and refined, without admixture of reducing agents or the addition of material to assist the reaction. The process is especially applicable to the volcanic ash of Java, and other material found within recent years to be widely distributed, and containing up to about 95% of titaniferous iron.—J. S. G. T.

Electrolytic apparatus. [Electro-deposition of copper or other metal on steel wires or other elongated cathodes.] M. M. Merritt. E.P. 141,733, 15.4.20. Conv., 15.4.19.

Steel wire or the like is led over rollers into an acid cleansing bath and then passes in succession under a stream of water and through an alkaline electrolytic bath wherein it functions as cathode and receives a slight coating of copper. The wire then passes over sheaves so as to traverse as cathode the depositing apparatus in both directions from end to end in a continuous path, and the depositing troughs are supplied with electrolyte from a tank placed at a lower level. The electrolyte after circulating in the trough is again discharged to the tank, being aerated during its fall through the air. The electrolytic troughs are preferably provided with a steam coil or other heating agent to facilitate the escape of hydrogen bubbles. Means are provided for raising or lowering the electrolytic troughs. (*Cf.* U.S.P. 1,322,494; J., 1920, 32 A.) —J. S. G. T.

Blast roasting operations and the like. Mining and Metallurgical Processes Proprietary, Ltd., Assees. of G. Rigg. E.P. 146,936, 20.5.20. Conv., 9.7.19.

The charge is roasted on a perforated grate situated in a pot. Below the grate is a reciprocating plate with projecting hollow teeth which are periodically caused to pass through the grate perforations and so open up the clinker adjacent thereto, thus permitting the continued uniform passage of the blast. —J. W. D.

Copper and oxide of zinc; Treatment of old brass for the purpose of obtaining ——. R. E. Bea. E.P. 148,388, 9.7.20. Conv., 3.8.17.

The brass is melted in a hooded electric furnace of the arc type, which rests on four rollers, two of which are loosely mounted and two are connected with a driving shaft thereby oscillating the furnace and agitating the metal in a current of air so as to oxidise the zinc. Means are provided for exhausting the vapours of zinc oxide through the hood of the furnace. The residual copper is of 98—99·5% purity.—A. R. P.

Atomising fusible materials [e.g. metals]; Method of ——. E. C. R. Marks. From Metallatom G.m.b.H. E.P. 148,776, 10.7.20.

Material which is to be atomised is supplied in the form of a thin ribbon (several inches in width) to a double nozzle in one zone of which it is fused by, *e.g.*, an oxyhydrogen flame applied evenly over both sides of the ribbon and in the next zone is sprayed by gas under high pressure. The ribbon is fed forward by rollers and guided by flanges on the rollers as well as fixed guides in the jet.—B. M. V.

Coating metal objects with a layer of another metal or an alloy, and soldering. O. Stalhane and O. O. Kring. E. P. 167,262, 3.5.20.

A bath consisting partly of the metal or alloy with which the objects are to be coated and partly of a suitable flux is kept in a molten condition by passing an alternating electric current through the flux. The objects are first dipped in the flux and afterwards, when they have been sufficiently heated, in the metal bath. When the objects are in the form of wire, ribbon, or the like, they are led continuously through the flux bath down into the metal bath, whilst when two or more pieces are to be joined together the surfaces which are to be joined are kept together when the pieces are dipped. —J. W. D.

Coating metal. H. Jones. E.P. 167,646, 16.6.20.

Coating metal, *e.g.*, nickel alloy, treated with a flux is placed in a mould with plaster of Paris between it and the walls of the mould, and the metal to be coated is melted and poured into the mould.—J. W. D.

Arc welding compositions. The British Thomson Houston Co., Ltd. From General Electric Co. E.P. 167,399, 20.8.20.

Titanium and an alkali metal together with other substances are fused, ground, mixed with water with or without suitable fluxing material, then applied to the electrode, and converted into an enamel by baking at a sufficiently high temperature. —J. W. D.

Copper-nickel matte; Treatment of ——. E. E. Naef. E.P. 168,097, 20.4.20.

Finely ground copper-nickel matte is heated to 300°—800° C. with caustic soda, either alone or mixed with all or any of the following, sodium carbonate, chloride, sulphate, sulphide, calcium oxide and hydroxide, with or without the addition of finely divided coal or, if desired, in an atmosphere of hydrogen or gases containing it. Finely divided nickel and copper sink to the bottom of the melt, while the sulphur reacts with the flux to form sulphide and thiosulphate. The melt is leached and the solution filtered, evaporated to dryness, and the salts used again, or the sulphur compounds may be removed by crystallisation and the remaining salts used again. The sludge of finely divided metals is heated with dilute sulphuric acid to dissolve the nickel and leave a residue of metallic copper. (Reference is directed, in pursuance of Sect. 7, Subsect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 499 of 1893; J., 1893, 451.)—A. R. P.

Oxidised ores; Concentration of —— [by flotation]. L. A. Wood, and Minerals Separation, Ltd. E.P. 168,098, 20.4.20.

The finely divided ore, *e.g.*, tin ore or carbonates or silicates of lead or zinc, is treated in a froth flotation machine with a frothing agent consisting of a fatty acid or one of its compounds, such as soap, in the presence of carbon dioxide as a gangue-modifying agent. The gas is introduced into the pulp during agitation and/or aeration. —A. R. P.

Froth flotation process for concentration of ores. K. Schlitzberger. G.P. 338,845, 9.11.19.

Ore pulp is contained in a funnel-shaped container and is fed to the settling device along with a current of air flowing in the same direction and holding oil in suspension, this current being delivered to the narrower end of the funnel-shaped container by means of an injector pump. An intimate mixture of oil, ore, and gas is obtained in this manner. The mixture is delivered to the settling vessel, ascending which the gas bubbles burst, and the gangue particles fall to the bottom. The froth containing ore concentrate overflows into a collecting channel. —J. S. G. T.

Frothing and mineral selective [flotation] agent, and process of using the same. R. Luckenbach, Assr. to Luckenbach Processes, Inc. U.S.P. 1,386,716, 9.8.21. Appl., 5.4.18.

An alkaline solution of resin, lac, and a fatty acid, is added to a pulp of ore and water, and the mixture aerated to form a froth.—C. A. K.

Metallurgical process. J. W. Bass. U.S.P. 1,386,226, 2.8.21. Appl., 3.5.20.

Borings, turnings, or other small metallic pieces are spread in bulk form on the bottom of a furnace, heat is applied to the upper surface of the mass to cause a crust to form, and the products of combustion are made to flow from one end of the mass to the other over its upper side, whilst successive portions of the metal in the direction of flow of the gases are agitated.—J. W. D.

Silicon; Refining crude electric-furnace ——. F. M. Becket, Assr. to Electro Metallurgical Co. U.S.P. 1,386,227, 2.8.21. Appl., 26.9.19.

The crude material is crushed, and the particles then subjected to the solvent action of hydrofluoric acid at a sufficiently low temperature to avoid substantial loss of silicon.—J. W. D.

Lead bullion; Process of treating ——. G. P. Hulst and M. W. Krejci. U.S.P. 1,386,503, 2.8.21. Appl., 16.2.20.

A bath of molten lead is agitated and treated, under conditions precluding oxidation, with a suitable reagent to cause the impurities in it to segregate in the form of dross.—J. W. D.

Aluminium; Process for extracting —— from mixtures or alloys containing aluminium produced by a thermal process. Gebr. Giulini G.m.b.H. G.P. 302,594, 29.2.16.

Material containing aluminium carbide is treated with zinc or cadmium or mixtures, alloys, or the vapours of these metals, the operation being carried out in the presence of an indifferent gas, preferably containing carbon monoxide, *e.g.*, water-gas, whereby not only the metallic aluminium but also a portion of that present as aluminium carbide is dissolved in the zinc and recovered.—J. S. G. T.

Metals and alloys practically free from aluminium; Process for the production of —— from alloys containing aluminium. F. Caspari. G.P. 337,078, 16.4.20.

Aluminium is caused to combine preferentially to form a compound prior to the remaining metals contained in the alloy. For this purpose an oxidising agent and a basic compound are added to the alloy, either alone or together, during the process of fusion, or subsequently. Zinc fluoride or other easily fusible metallic salts, either alone or mixed with fluorides, chlorides, hydroxides, etc. of the alkalis, are likewise added to the alloy during fusion or subsequently. Compounds of heavy metals other than zinc may be added, for the production of zinc alloys, which, however, must not contain more of such heavy metal apart from that present in the original alloy than the equivalent of the aluminium present in the latter.—J. S. G. T.

Lead alloys [; Utilisation of ——]. Metallbank u. Metallurgische Ges. A.-G. G.P. 307,672, 1.11.17. Addn. to 301,380 (*cf.* E.P. 140,790; J., 1921, 15 A).

The bearing-metal alloys of lead and barium described in the principal patent are used where mechanical strength combined with resistance to chemical action are required, more especially in the manufacture of plates for accumulators, acid pumps, and fans for acid gases.—J. S. G. T.

Ferrosilicon; Process for the production of moulded articles of ——. Maschinenfabr. Esslingen. G.P. 315,323, 20.11.17.

Massive ferrosilicon is broken to the size of hazel nuts, if necessary some powdered ferrosilicon is added, and the whole mixed either with cement, preferably quick-setting cement, and water or suitable salt solutions, or with similar binding material, and formed into briquettes, which are air-dried and hardened. These briquettes can be melted in the usual way in a cupola and their use renders possible the production of acid-resisting iron of uniform quality in continued working.

—J. S. G. T.

Cyaniding process. L. D. Mills and T. B. Crowe, Assrs. to The Merrill Co. U.S.P. 1,387,289, 9.8.21. Appl., 21.3.18.

Acid is added to the cyanide solution of a metal and air is drawn through the solution and through an alkaline absorbent to remove the hydrocyanic acid generated.—C. A. K.

Aluminium; Method of soldering ——. M. M. Merritt, Assr. to Merritt Metals Co. U.S.P. 1,387,426, 9.8.21. Appl., 13.10.19.

Aluminium is prepared for soldering by treatment with hydrochloric acid, and then coating it with a deposit of electrolytic copper.—C. A. K.

Zinc or zinc residues; Method of melting —— without loss under organic materials. K. Ochs. G.P. 338,490, 29.4.16.

Small additions of other metals such as aluminium, cadmium, tin, or the like, or alloys of these with zinc, are added to the charge so as to reduce the melting point of the zinc to about the boiling point of the organic material such as paraffin-wax. In this way loss of zinc is avoided and the formation of hard zinc in the presence of iron prevented.

—A. R. P.

Copper, nickel, and similar metals and their alloys; Process for casting ——. Metallhütte Baer und Co., Kommanditges., Abt. der Metallindustrie Schiele und Bruchsaler. G.P. 338,868, 20.9.19. Addn. to 310,404 (J., 1919, 374 A).

The metals are cast in iron or metal moulds that have been coated with aluminium bronze by the method described in the principal patent.—A. R. P.

Iron articles; Production of rust- and heat-resisting coatings of aluminium bronze on ——. Metallhütte Baer und Co., Kommanditges., Abt. der Metallindustrie Schiele und Bruchsaler. G.P. 339,326, 27.6.19.

The cleaned articles are first sherardised or rubbed with zinc bronze, then treated with a coating of aluminium bronze varnish, after which they are heated to 500° C. to burn off the organic matter and cause the coating metals to alloy with each other and the surface of the iron. The zinc coating prevents the iron rusting in the small exposed parts resulting from the burning off of the varnish.—A. R. P.

Printing plates; Manufacture of durable, rust-resisting —— by electrolytic means. M. Schlötter. G.P. 339,127, 13.9.18.

The electrolytic solution contains salts of chromium, nickel, or cobalt in addition to iron.—L. A. C.

Metals; Process for the extraction of precious —— from very dilute solutions, especially from sea water, brines, and aqueous liquors from potash factories. A. Goldberg. G.P. 338,128, 29.5.19.

In the extraction of noble metals by passing the liquids over an adsorbent material, the metals are subsequently re-dissolved from the latter by means of dilute solutions of alkali cyanide or gaseous cyanogen, and finally re-deposited by known methods. Claim is made to the use of peat or peat products as adsorbent agents.—J. H. L.

Gold; Process of extracting —— from sea water. Siemens und Halske A.-G. G.P. 338,129, 17.8.18.

Sea water is treated with carbon monoxide, and the gold thus precipitated from solution is collected by means of materials such as clay, powdered coal, plankton, etc., which subside or rise to the surface. Deposited sludge containing gold may be used repeatedly for the same purpose.—J. H. L.

Briquetting dusty smelter residues and earthy ores. F. Dahl. G.P. 339,408, 12.12.19.

The binder used is the finely-ground discharge from the converter in which the Thomas process is carried out. This material is prepared for use by ignition followed by rapid drying.—A. R. P.

Smelting process and furnace for metals and the like, especially for the direct production of iron from ores. R. Wussow and M. Stephani. G.P. 339,496, 19.7.19.

The process is carried out in a reverberatory furnace provided with a wall designed to keep the furnace gases out of contact with the charge, which is heated by radiation from the crown of the furnace. In this way the charge may be subjected to the action of any desired gas or gases; thus, in the case of iron ore, the charge is treated with preheated producer gas for the production of iron, which may then be refined (puddling process) by passing a stream of heated air over it.—A. R. P.

Roasting furnace with superimposed hearths and passages for the charge; Mechanical ——. R. Scherfenberg. G.P. 339,540, 23.5.20.

THE passages for the transference of the material from one hearth to another are made fast to the edge of the exit flue for the gases by means of a movable arrangement and are provided above the roasting hearth with exchangeable shovels which may be raised or lowered according to the unevenness of the hearth produced by changes of temperature, etc. By this arrangement the issuing gases are prevented from coming into contact with the charge and are therefore not contaminated with particles of impurities.—A. R. P.

Casting metal; Methods of ——. C. McKnight, jun. E.P. 155,798, 29.6.20. Conv., 20.12.19.

SEE U.S.P. 1,331,816 of 1920; J., 1920, 303 A.

Alloys; Production of metallic ——. W. B. Ballantine, Assr. to The Empire (Alloy) Steel Corp., Ltd. U.S.P. 1,386,981, 9.8.21. Appl., 19.8.20.

SEE E.P. 159,568 of 1919; J., 1921, 307 A.

Tin scrap; Method of obtaining iron and tin from ——. P. A. Mackay. U.S.P. 1,387,443, 9.8.21. Appl., 4.4.21.

SEE E.P. 161,654 of 1920; J., 1921, 395 A.

Electrodes for use in depositing molten metal. W. H. Boorne. E.P. 167,063.

Electrodes. E.P. 157,871. *See* XI.

XI.—ELECTRO-CHEMISTRY.

lectric discharge; Chemical action of the ——. I. G. Poma. *II.* G. Poma and G. Bassi. *III.* G. Poma and A. Nesti. Gaz. Chim. Ital., 1921, 51, II., 58—70, 71—79, 80—94.

HE various views which have been advanced to xplain the mechanism of the chemical actions rought about by the electric discharge are criticsed, and analyses are given of the mixtures of roducts formed by the action on the vapours of ertain simple organic compounds of an intense xplosive discharge from an induction coil, and of he gaseous products formed by the action of the ark discharge on the vapours of methyl and ethyl lcohols, formic and acetic acids, acetone and ethyl ethyl ketone. PATENTS.

torage and supply of electrical energy by an electro-chemical process. F. P. Habicht. E.P. 143,532, 17.5.20. Conv., 17.5.19.

LKALI metals or their alloys are produced in ectro-chemical cells and are supplied in liquid rm as electrode material to chemo-electric cells ring their operation, in which cells they are renverted with evolution of electrical energy into bstances of low energy content, *e.g.*, alkali droxides, which are removed during the operation the cell and subsequently re-converted in electrochemical cells into products of high energy content (alkali metals), the cycle of operations being then repeated. The chemo-electric cells may contain electrolytes of fused alkali hydroxide and cathodes of iron or silver to which air or oxygen charged with steam and heated to a suitable temperature is supplied.—J. S. G. T.

Metallic diaphragms of electrolytic cells; Manufacture of ——. R. Pechkranz. E.P. 144,719, 11.6.20. Conv., 12.6.19.

POROUS metal diaphragms, more especially of nickel, are prepared by depositing the metal electrolytically upon a metallic plate the faces of which have been oxidised and the coating of oxide then sprayed or dusted with an insulating varnish so as to provide a number of insulating points, corresponding with the degree of porosity required, on those parts where metal is not to be deposited. The deposited metal is then stripped from the metallic plate. —J. S. G. T.

Electric battery; Method of preventing loss of zinc in an ——. A. Pouchain. E.P. 167,250, 30.4.20.

LOCAL action due to impurities, causing wasting of zinc electrodes in batteries, on open circuit, is prevented by coating the electrodes after amalgamation, with grease, preferably the thick grease commonly used for lubricating gear wheels. The layer of grease may be made adherent by means of a grating or rigid frame, or by enclosing the plate in a greased paper envelope.—J. S. G. T.

Electrode element for galvanic batteries and method of producing same. T. A. Edison, Assr. to T. A. Edison, Inc. U.S.P. 1,386,095, 2.8.21. Appl., 6.11.19.

AN electrode element for galvanic batteries is composed of an agglomerated mass of finely divided copper oxide held together by a binder comprising cupric oxide formed *in situ* in the mass.—J. S. G. T.

Galvanic battery with alkaline electrolyte [; Depolariser for ——.] F. Böcker and A. Eichhoff. G.P. 339,136, 20.11.18.

MERCUROUS oxide is mixed with the compounds of manganese oxide employed as depolariser. Thereby the voltage falls off much more slowly than when mercuric oxide is added to the depolariser. —J. S. G. T.

Electrodes for electric accumulators; Positive ——. A. Pouchain. E.P. (A) 167,568, 8.5.20, (B) 167,577, 10.5.20.

(A) IN order to prolong the retention of their charge in the dry state, formed positive lead peroxide electrodes are subjected, either during first charging or subsequently, to the current in a bath of sulphuric acid containing ammonium sulphate, preferably 5—10%. (B) In positive electrodes consisting of a grating in the open spaces of which active material is supported, some or all of the points of intersection of the grating bars are perforated in order to permit passage of liquid from one side of the electrode to the other. Preferably, at these intersections the grating has a greater thickness than the rest of the bars, to prevent closing of the perforations when the grating has been covered with active material.—J. S. G. T.

Electrodes for use in electrolysis [; Cobalt-silicon ——]. Chile Exploration Co., Assees. of C. G. Fink. E.P. 157,871, 17.5.20. Conv., 21.1.20.

ANODES highly resistant to anodic disintegration, of high electrical conductivity, and possessing a low anode potential are constituted of a cobalt-silicon alloy. A suitable depolarising ingredient, such as manganese, is preferably added to the alloy, also a hardening agent, such as chromium, tungsten,

molybdenum, uranium, or the like, and if desired, a relatively small percentage of carbon. For example the anode may be constituted of 7—20% Si, 3—45% Mn, 4—10% Cr, and the balance cobalt. If desired, the cobalt may be replaced in part by nickel. The anodes are especially applicable to the electrolysis of solutions of copper sulphate derived from the leaching of copper ores, and containing copper sulphate, sulphuric acid, alkali nitrates, sulphates, chlorides, and iron sulphates.
—J. S. G. T.

Cast electrodes; Manufacture of porous ——. "Franklin" Industrie-Ges.m.b.H. G.P. 332,216, 15.5.19.

The core or cores employed are composed of a gauze or plaited structure of metal or alloy, such as zinc, magnesium, aluminium, or alloys thereof. By subsequent removal of the core by chemical or electrochemical treatment, electrodes traversed by fine channels and presenting a very large surface are produced. Removal of active material from the electrode by crumbling is thereby reduced.
—J. S. G. T.

Carbon especially suitable for use in electrodes; Process for manufacturing ——. Rombacher Hüttenwerke Coblenz, and J. I. Bronn. G.P. 336,552, 14.7.18.

An intimate mixture of coal with petroleum pitch or other variety of pitch, and if necessary with graphite and anthracite, is carbonised in coking ovens.—J. S. G. T.

Electrolytic apparatus. H. H. Dow, Assr. to The Dow Chemical Co. U.S.P. 1,386,094, 2.8.21. Appl., 3.9.18.

An anode and a cathode are disposed on the respective sides of a partition depending below the normal level of the solution contained in an electrolytic cell. Between and spaced from the anode and cathode is a diaphragm depending substantially vertically from the partition. The anode side of the cell is provided with a cover, the other side being open.—J. S. G. T.

Electric resistance furnaces. A. Imbery. E.P. 167,537, 30.4.20.

A resistance element is composed of spheres or ovoids of graphite, carbon, or other material arranged between two annular terminal plates, disposed within the furnace body and provided with means for regulating the pressure on the spheres or ovoids between the plates. In order to minimise loss of heat from the furnace, the spheres or ovoids are graduated in size so that the temperature is reduced at the top and bottom of the furnace.
—J. S. G. T.

Electric furnaces [; Induction ——]. The British Thomson-Houston Co., Ltd., and G. J. Ralph. E.P. 167,545, 5.5.20.

An electric furnace of the induction type is provided with means for inserting and withdrawing the charge and is capable of rotation about an approximately horizontal axis. The heating chamber of steel or iron or the contents thereof constitute a short-circuited secondary winding. The primary coil may be wound directly on the chamber and insulated therefrom, and may revolve with the chamber or may be stationary.—J. S. G. T.

Electric furnace. W. S. Burch and W. A. Schell, Assrs. to Rochester Railway and Light Co. U.S.P. 1,386,155, 2.8.21. Appl., 31.7.19.

An electric furnace comprises a refractory body provided with a reaction chamber in which primary electrodes are disposed. Below the primary electrodes are refining electrodes, one of which is adjustable. The material after its descent from the sphere of action of the primary electrodes is subjected to the influence of the discharge between the refining electrodes. Independent sources of current are provided for the primary and refining electrodes.—J. S. G. T.

Insulating material. L. McCulloch, Assr. to Westinghouse Electric and Manuf. Co. U.S.P. 1,386,008, 2.8.21. Appl., 5.1.17.

An insulating material is composed of flake material together with a lead-free binder containing an oxygen compound of boron.—J. S. G. T.

Insulating materials; Electrical ——. Farbenfabriken vorm F. Bayer u Co. G.P. 301,664, 3.10.16.

Substances for use more especially for impregnating paper to be used in the insulation of cables, as transformer oil, as filling material for oil switches etc., are produced by the condensation of halogenated side-chain coal tar hydrocarbons, or the like, *e.g.*, benzyl chloride, xylyl chloride, *p*-xylylene dichloride, on the one hand, with naphthalene and its derivatives, or with tar oils or constituents thereof, such as phenanthrene, anthracene, the xylenes, benzene, toluene, cymene, and solvent naphtha, or their derivatives and substitution products, on the other hand.—J. S. G. T.

Electric rotating furnaces. C. E. Cornelius. E.P. 168,018, 13.4.20.

XII.—FATS; OILS; WAXES.

Oils; Determination of refractive indices of ——. H. S. Simms. J. Ind. Eng. Chem., 1921, 13, 546—547.

The oil is drawn into a bulb, 0·5 in. in diameter, having a capillary above and below it; the lower capillary is then sealed and the bulb full of oil is immersed in an oil of known refractive index contained in a wide test-tube. The bulb is raised up and down while looking through it at a distant object; if the image rises as the bulb is raised and sinks as the bulb is lowered, the refractive index of the oil is less than that of the standard oil in the test-tube. Similarly, if the bulb is filled with an oil having a greater refractive index than that of the standard, the image sinks when the bulb is raised and rises when the bulb is lowered. By testing the bulb in a series of oils of different but known refractive indices, the value for the oil under examination may be found within 0·0005 of the true value.—W. P. S.

Linseed oil; Drying of ——. H. Wolff. Farben-Zeit., 1921, 26, 2851.

The interior and exterior layers of a compact block formed by soaking thin tissue papers in linseed oil, pressing together and allowing to dry, were found to show nearly equal iodine values, although the proportion of oxidised fatty acids in the outer layers was considerably higher. The phenomenon is probably due to rapid oxidation of the oil in the outer, simultaneously with strong polymerisation in the inner layers. More prolonged drying diminished the degree of difference between the layers.

Of two samples of the same linseed oil stored in the dark for 1½ years in a closed glass bottle and in a closed galvanised tin, respectively, the latter took 8 to 14 times as long to dry as the former, in spite of the two samples having practically identical iodine, hexabromide, acid, and saponif. values, which were moreover very slightly different from those of the original oil.—A. de W.

Linolenic and hexabromostearic acids and some derivatives. S. Coffey. Chem. Soc. Trans., 1921, **119**, 1306—1310.

THE mixed liquid fatty acids of linseed oil, isolated by freezing in light petroleum to −18° C., were converted into zinc salts and the latter, m.p. 71°—74° C., repeatedly crystallised from alcohol. The most soluble portion, m.p. 75°—76·5° C., contained 10·5% Zn (basic zinc linolenate requires 14·7%) and gave a mixture of acids, sp. gr. at 17°/4° C. 0·899, yielding 14% of hexabromide. The less soluble portion, m.p. 71°—73° C., contained 10% of linolenate, and 10·5% Zn. The mixed acids obtained from it had sp. gr. at 16°/4° C. 0·900. The isolation of pure zinc linolenate was impossible owing to the similarity of solubility between it and zinc linolate. Hexabromostearic acid prepared from linseed oil (Erdmann and Bedford, J., 1909, 530), and crystallised from benzene or acetic acid, melts at 185° C. and remains unaltered after fractional crystallisation from alcohol, phenol and ether, nitrobenzene, etc. The quinine, strychnine, morphine, and narcotine salts of the acid were prepared.—P. V. M.

Hydrogenation; Relation between occlusive power of palladium for hydrogen and its activity for catalytic ——. E. B. Maxted. Chem. Soc. Trans., 1921, **119**, 1280—1284.

A LINEAR relation is shown to exist between the cclusive power of palladium for hydrogen and the lead content of the system. Lead both depresses the occlusive power (measured by the volume of ydrogen absorbed at 15°, the palladium having een previously evacuated at 100° C.), and de-reases the rate of absorption. The activity of alladium for catalytic hydrogenation, as measured y the rate of hydrogenation of oleic acid in acetic cid at 50° C., is also a linear function of the lead ontent from zero concentration of the poison to a oint at which the activity has been depressed 0%. Higher concentrations of lead produce a ore gradual falling off in the catalytic activity. he slope of the linear graph connecting the occlu-ive power of palladium with its lead content is onsiderably less steep than that showing the fall catalytic activity, which latter varies in gradient ith the fineness of division of the catalyst. It is ggested that this is due to the fact that catalysis mainly a surface phenomenon, whereas occlusion hydrogen is not confined to the surface.
—P. V. M.

atalytic action at solid surfaces. VI. Surface area and specific nature of a catalyst: two independent factors controlling the resultant activity. E. F. Armstrong and T. P. Hilditch. Proc. Roy. Soc., 1921, **A 99**, 490—495. (*Cf.* J., 1920, 663 A.)

ICKEL hydroxide reduced on kieselguhr gives a uch larger apparent volume than when reduced the ordinary way. Nickel catalysts produced on eselguhr are much more active in the hydrogena-n of oils than nickel catalysts not produced on pports. The variations in the catalytic power of duced nickel are to be ascribed to the different rface areas of the exposed free nickel, and do not quire for their interpretation the assumption of e presence of any catalyst (such as an oxide) other an metallic nickel.—J. F. S.

Thistles; Utilisation of Argentine ——. B. Rewald. Chem.-Zeit., 1921, **45**, 805.

THE seeds of Argentine thistles contain 41—44% of oil, 33—36% being obtained by pressing. The oil has the following characters: Sp. gr. at 15° C., 0·9242; sodidif. pt., 13° C.; n_D^{15}=1·4770; acid value, 1·63; iodine value, 119. The pressed cake contains moisture, 0·52; ash, 4·43; oil, 10·96; proteins, 52·50; crude fibre, 17·99%. Large quantities of the seeds may be obtained.—W. P. S.

PATENTS.

Hydrogenation of oils and fatty bodies; Catalytic process and apparatus for use, more particularly in ——. La Soc. Anon. l'Oxhydrique Française. E.P. 143,848, 11.5.20. Conv., 28.5.19.

TUBULAR or hollow filtering elements made of asbestos- or biscuit-porcelain are introduced into the reaction vessel and serve both for the separation of the catalyst from the oil on the completion of hydrogenation, by the withdrawal of the oil through the tubes, and for the introduction of the hydrogen in an extremely finely divided state. The choking of the filter tubes is prevented by using them alternately for the withdrawal of oil and for the introduction of hydrogen. The catalyst may be separated in an adjacent communicating vessel, and means for cleaning the filtering surface may be provided.—H. C. R.

Oil; Process for obtaining —— from the fruit-heads of palm trees. The Pericarp Synd., Ltd., and E. W. J. Trevor. E.P. 167,792, 19.2.20.

THE whole fruit-heads, or the spikes or shoots carrying the fruits, are sterilised by heat, the fruits being thereby loosened and fermentation arrested. The material is then passed through a decorticating machine and a de-pulping or de-pericarping machine in succession, the resulting pulp being pressed or extracted. The expressed or extracted oil is purified by settling in a clarifying tank and, if desired, sterilised.—H. C. R.

Sulpho-aromatic agents for the hydrolysis of fatty acid glycerides; Manufacture of ——. A. Godal. E.P. 138,650, 6.2.20. Conv., 29.4.18.

SULPHONATION is effected in the presence of a solvent in which both the fatty acid and the aromatic substance dissolve, and which is not acted upon by the sulphuric acid used. The reaction can then be carried out at a low temperature. Benzine may be used as a solvent, and aromatic sulphonic acids may be removed after sulphonation is complete by washing with dilute sulphuric acid. The reagent is then extracted with water, leaving excess of fatty acid and aromatic substance dissolved in the benzine. With a reagent prepared as described excessive colouring of the fatty acids liberated from fats by hydrolysis is avoided.—H. C. R.

Cacao-oil; Method of refining ——. J. N. Tuttle and J. W. Phelan, Assrs. to Kalmus, Comstock and Wescott, Inc. U.S.P. 1,386,471, 2.8.21. Appl., 15.7.19.

THE oil is agitated with alkalised fuller's earth, which is afterwards removed by filtration.
—H. C. R.

Cacao-oil; Method of refining ——. E. J. Wall, Assr. to Kalmus, Comstock and Wescott, Inc. U.S.P. 1,386,476, 2.8.21. Appl., 15.7.19.

THE objectionable taste and odour are destroyed by subjecting the oil to the action of ultra-violet rays.
—H. C. R.

Cacao-oil; Method of refining ——. J. W. Phelan and E. J. Wall, Assrs. to Kalmus, Comstock and Wescott, Inc. U.S.P. 1,386,527, 2.8.21. Appl., 15.7.19.

The oil is exposed in thin layers to a current of gas under such conditions that the colour is retained and some of the gustable and odorous substances are removed.—H. C. R.

Soaps; Production of solid toilet and household —— in the form of tablets or powder. Junger und Gebhardt G.m.b.H. G.P. (A) 339,047, 22.8.15, (B) 339,048, and (C) 339,049, 31.3.16.

(A) A mixture of carbohydrates capable of swelling or plant products consisting mainly of these substances (*e.g.*, starch, meal, or cellulose) and adsorbent colloidal matter (*e.g.*, clay, kaolin, talc, silicates) is warmed with dilute sodium hydroxide solution so that the vegetable matter combines with practically the whole of the alkali and is transformed into a gelatinous state. The mass is then worked up with solid soap or soap powder. The vegetable matter may be treated alone with sodium hydroxide solution, and after swelling has taken place, be mixed with the adsorbent colloid and the soap. The cleansing power of the soap is not reduced by these additions. (B) The adsorbent colloid is produced directly in the swollen vegetable material by the precipitation of a soluble silicate with calcium or other alkaline-earth hydroxide; or the vegetable material may be divided into two parts, one being treated with sodium silicate and the other with calcium hydroxide solution mixed with dilute caustic alkali. Both parts are then heated until swelling takes place and the two intimately mixed. The gelatinous precipitate obtained with alkaline-earth silicates has especially strong adsorbent properties. (C) The calculated quantity of caustic alkali is mixed with a weighed quantity of warm liquid soap and incorporated with the mixture of vegetable matter and adsorbent colloid, which may be first made into a paste with water, soap solution, or a suitable salt solution (*e.g.*, alkali carbonate solution).—H. C. R.

Margarine. U.S.P. 1,386,475. *See* XIX A.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Ink spots on paper; Blackness of ——. W. Mecklenburg. Mitt. Materialprüf., 1920, 38, 35—62.

The resistance of ink spots to the action of water and alcohol, and the action of the light from a mercury quartz lamp, was studied and numerically defined by the use of a Tyndallmeter as described previously (J., 1916, 428). Spots of iron gallate ink were fast to the action of water and 50% alcohol; from spots of fancy coloured ink (containing aniline dyestuffs) the colour was extracted by both liquids. Iron gallate ink spots were fairly fast to the light from a mercury quartz lamp, whilst fancy coloured ink spots were quite unstable. Of two logwood inks one behaved in a similar manner to iron gallate ink and the other to the fancy coloured inks.—F. M. R.

Shellac; Bleaching ——. S. T. Gadre. J. Indian Industries and Labour. Chem. News, 1921, **123**, 127—128.

Shellac is bleached by dissolving in sodium carbonate solution and adding sodium hypochlorite solution gradually. The loss of weight on bleaching is about 4%. The product is white and rather brittle. In the form of a dry powder it is used for the preparation of shellac varnish. It gradually deteriorates on exposure to light and air, becoming insoluble in alcohol and alkalis; the change is accelerated at high temperatures. Bleached shellac should be stored under water.—H. C. R.

[*Furfural-aniline resins.*] *Condensation of water solutions of furfural with aniline.* J. P. Montgomery and E. S. Ernst. Met. and Chem. Eng., 1921, 25, 335.

The resin produced by Mains and Phillips (J., 1921, 357 A) by the condensation of furfural and aniline at 200° C. may also be obtained by using aqueous solutions containing as little as 2% of furfural and heating with aniline at 125° C. for 15 mins. in an autoclave. Excess of aniline, which makes the resin oily and non-brittle, may be removed by steam distillation. In the recovery of furfural by fractionation from aqueous solutions in the process of manufacture, the rejected water may contain 8—10% of the aldehyde, and it is suggested that this could be profitably recovered as furfur-aniline by the above process.—A. R. P.

Drying of linseed oil. Wolff. *See* XII.

Patents.

[*Paracoumarone*] *resin; Manufacture of* ——. H. Wade. From The Barrett Co. E.P. 166,818, 15.7.20.

In the production of resin from naphtha, after polymerisation and neutralisation, and before distillation, the naphtha is washed with a solution of a chloride, *e.g.*, about 20% by vol. of a solution of sodium chloride of about 3% strength. The wash liquor separates much more rapidly than when water alone is used.—A. de W.

Resins; Process of making artificial ——. C. Ellis and H. M. Weber, Assrs. to Ellis-Foster Co. U.S.P. 1,381,863, 14.6.21. Appl., 2.10.20.

The products claimed are prepared by the interaction of gum copal, colophony, and glycerol.
—J. H. L.

[*Resinous*] *condensation products of naphthalene and its derivatives; Manufacture of* ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 302,521, 17.6.16. Addn. to 301,713 (J., 1921, 210 A).

Instead of being condensed with acetyl halides, naphthalene and its derivatives are condensed with higher halogenated derivatives of the homologues of benzene in presence of iron and its compounds. Aluminium powder and bronze may also be used as catalysts. Resins are obtained from dichloroxylene and naphthalene or methylnaphthalene, and from technical xylene chlorinated at 130° C., or from cumene chlorinated at 150° C. and naphthalene.—C. A. C.

Lacquers; Production of flexible —— from cellulose esters. A. Hildesheimer. G.P. 338,475, 9.4.18.

Glycol esters of fatty acids of non-drying oils are employed together with cellulose esters, in suitable solvents. The former confer greater flexibility than the corresponding glycerol esters, and also render the lacquer more proof against cold. The glycol esters of the fatty acids from rape oil, prepared by heating for several hours at 150° C., with the aid of catalysts such as Twitchell's reagent, have a saponification value of 167 and viscosities of 6·74° and 10·74° Engler at 20° and 10° C. respectively.
—J. H. L.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber; Variability of crude ——. J. B. Tuttle. J. Ind. Eng. Chem., 1921, 13, 519—522.

The usual method of testing for variability in crude rubber (vulcanisation with sulphur alone) really determines the variability in the amounts and character of certain foreign substances, which, in the absence of pigments producing an alkaline medium for the reaction, tend to obscure the variation which may exist in the rubber. For instance, the presence of as little as 0·1% of a substance which under proper conditions is a strong accelerator (hexamethylenetetramine) is sufficient, in the absence of alkaline fillers, to prevent the vulcanisation almost entirely, whereas in presence of 10% of zinc oxide the accelerating effect of the hexamethylenetetramine becomes evident. It is recommended that all tests should be made on mixtures to which has been added 2—5% of zinc oxide.
—W. P. S.

Celluloid-caoutchouc and cellon-caoutchouc, two new elastic materials. R. Ditmar. Chem.-Zeit., 1921, 45, 819—820.

The difficulty of preparing a celluloid-caoutchouc material which would combine the valuable properties of both these substances has lain hitherto in the absence of a solvent in which they are mutually soluble. The hydrogenation products of naphthalene and phenol are now found to supply this deficiency, and the desired product may be obtained by mixing in any required proportions solutions of caoutchouc and celluloid or cellulose esters in hexalin (cyclohexanol) for example. The new product has many valuable properties, and in the liquid form can be dyed with inorganic colours and used as a lacquer for all purposes. The material itself can be used in the manufacture of photographic and cinematograph films, linoleum, and all similar articles where it is desirable to eliminate the brittle character of the celluloid without introducing the springiness of the caoutchouc.—G. F. M.

Patents.

Rubber; Process for the vulcanisation of ——. G. Bruni, Assr. to Pirelli & Co. U.S.P. 1,386,153, 2.8.21. Appl., 9.3.20.

Rubber is vulcanised by treatment with sulphur and a metallic salt of a dithiocarbamic acid, and heating to a temperature lower than 100° C.—J. S. G. T.

Tyre fillers and method of making same. F. D. Mayer. E.P. 167,235, 28.4.20.

To a mixture of, *e.g.*, sunflowerseed or other oil (152 lb.), calcium hydroxide (5 lb.), soluble dyes 4 oz.), and "soap oil" (8 lb.) is added sulphur chloride (16 lb.). After standing for 24 hrs. a urther 16 lb. of sulphur chloride is added with agitation, and the mass transferred to moulds. "Soap oil" is an intermediate product in the treatment of crude oil consisting largely of a neutral oil of medium viscosity with varying quantities of paraffin wax.—A. de W.

Linoleum, tiling, floorcloth, panelling, furniture construction, etc.; Material for use as ——. W. Baines. E.P. 167,716, 17.12.20.

A mixture of rubber, sulphur, and 50%—90% of wood-flour is vulcanised by heat and pressure.
—A. do W.

XV.—LEATHER; BONE; HORN; GLUE.

Tannin from goran bark; Determination of optimum temperature and state of sub-division for maximum extraction of ——. B. B. Dhavale and S. R. Das. J. Soc. Leather Trades Chem., 1921, 5, 229—239.

The optimum temperature for the extraction of goran bark (*Ceriops Roxburghiana*) varies with the sub-division of the particles; the finer the particles, the lower is the optimum temperature. 60-mesh material yields the greatest quantity and best quality of tannin at the lowest temperature, but it is too fine for practical purposes. The quantity and quality of the tannin extracted improve with increasing fineness of sub-division. The 10-mesh material allows the highest amount of tannin, 28·49%, to be extracted at 55°—60° C. consistently with a high ratio of tans to non-tans (3/1) and seems to be best suited for extract manufacture.—D. W.

Hide powder; An "insoluble" ——. G. Baldracco and S. Camilla. Collegium, 1921, 367—369.

Zeuthen's suggestions (*cf.* J., 1921, 669 a) are criticised. The washing of the hide powder removes the small content of acid which is necessary to ensure the absorption of all the colloidal and difficultly soluble substances (*e.g.* phlobaphenes) and these are very desirable for tanning purposes.—D. W.

Chromium salts; Structure of ——. G. Grasser. Collegium, 1921, 356—367.

Formulæ are assigned to the cyanides, oxides, sulphides, hydroxides, ammonium compounds, sulphates, and chlorides of chromium, utilising Werner's principal and subsidiary valency theory. Hexahydrated chromium chloride contains three ionisable chlorine atoms and is represented as $[Cr(OH_2)_6]Cl_3$. By the loss of 2 mols. of water a green hydrated form, $[CrCl_2(OH_2)_4]Cl$, is obtained in which only one chlorine atom is capable of being ionised. Salts of the type $[(NH_3)_5.Cr.OH.Cr(NH_3)_5]X_5$ are described. Soluble salts of chromium complexes do not tan unless the chromium can pass into the ionised state, *e.g.* $[Cr(OC(NH_2)_2)_6]Cl_3$. The low tanning velocity shown by neutral chromium salts is explained by hydrolysis with the formation of free sulphuric acid and a basic chromium salt. The degree of adsorption is not proportional to the colloidal character. There are two kinds of chromium salts, those which hydrolyse and those which form complex salts. The structure of the different chlorides and sulphates is discussed for the whole range of basicities and the influence of possible structure on the tanning properties is indicated.
—D. W.

Imbibition [by gelatin]; Experiments on ——. A. G. Brotman. J. Soc. Leather Trades Chem., 1921, 5, 226—228.

The imbibition of water by a sample of gelatin can be increased by the dispersion of the gelatin. The capacity for imbibition shown by a gelatin gel depends on the quantity of gelatin it contains and on the distribution of the gelatin in the gel, *i.e.*, on the gel structure. Pure air-dry gelatin imbibes water to a maximum amount, attained in about 24 hrs., and varying according to the variety of gelatin employed. Dispersion of the swollen gelatin in water, and subsequent setting, gives a gel which is capable of taking up more water. Dispersion apparently effects a distribution between the gelatin and water in the gel, which differs from that existing in the original swollen gelatin.—D. W.

Sulphurous acid; Determination of —— *in animal glue.* A. Gutbier, E. Sauer, and H. Brintzinger. Kolloid-Zeits., 1921, 29, 130—139.

Different methods are used in the determination of sulphurous acid in bone glue and in leather glue. Bone glue is generally somewhat acid whilst leather glue reacts neutral or faintly alkaline. The total acid in bone glue is determined by titration with $N/10$ sodium hydroxide solution using phenolphthalein or rosolic acid as indicator. The solution should contain 1—6% of glue, and 1 c.c. of phenolphthalein or 5 drops of rosolic acid solution is used for each titration. The sulphurous acid present, which is generally all free, is titrated with $N/10$ iodine solution. The difference between the total acid and the sulphurous acid is mainly sulphuric acid and this difference can be obtained directly by titrating with $N/10$ sodium hydroxide, using alizarin as indicator. Leather glue contains its sulphurous acid combined and it also may contain formaldehyde. The glue solution is acidified with phosphoric acid and distilled in a current of steam and carbon dioxide, the vapours being passed into iodine solution. The sulphuric acid thus formed is determined as barium sulphate. The presence of formaldehyde is determined by distillation in a current of carbon dioxide into Schiff's reagent. For mixed glues the same method is used as for leather glue. Both the above methods give trustworthy results.—J. F. S.

PATENTS.

Tanning. W. H. Ockleston and T. B. Carmichael. E.P. 167,538, 30.4.20.

STARCH is covered with a 1% solution of commercial hydrochloric or other acid, allowed to stand for 7—14 days, the acid run off, and the starch washed free from acid, mixed with a suitable tanning liquid and boiled with it for 2 hrs. The product is used in suspension pits or in the layers or for drum tanning and finishing.—D. W.

Tanning; Process for ——. A. Manvers. E.P 167,785, 14.2.20.

DEPILATED and dried hides suspended in a cylindrical vessel are exposed to a high vacuum for ½ to 1 hr., whereupon a strong tanning solution from which all air has been removed is pumped into the vessel under a pressure of 20—40 lb. per sq. in. When tanning is complete, the liquor is run off, and the hides are washed and treated with a weak glue or gelatin solution which is subjected alternately to high vacuum and high pressure. The hides are subsequently washed and then dried *in vacuo* by the admission of a small quantity of hot air into the vessel.—L. A. C.

Tanning with unsaturated fatty acids; Process for ——. W. Fahrion. G.P. 338,476, 5.11.14.

THE unsaturated fatty acids from marine animal or vegetable oils are dissolved in alcohol or other solvent, the solutions subjected to cold for eight days to remove the solid acids, and the clear solution employed in tanning, either alone or in combination with other tanning agents. About 5% of fatty acids is necessary to give a good leather.
—D. W.

Leather; Production of flexible, iron-tanned ——. W. Moos and D. Kutsis. G.P. 339,028, 30.11.17.

HIDES are steeped for 1—2 hrs. in a 3—4% sodium chloride solution, and a ferrous salt, *e.g.*, ferrous sulphate, waste liquor from the manufacture of cellulose, and sodium nitrite, are then added to the bath. After 5—8 days tanning is complete.

XVI.—SOILS; FERTILISERS.

Soils; Physico-chemical researches on the absorptive power of —— *and the manner in which plants take up food from the soil.* L. Casale. Staz. Sperim. Agrar. Ital., 1921, **54**, 65—113. Chem. Zentr., 1921, **92**, III., 744—745.

THE soil colloids are in part negatively and in part positively charged. Absorption in soils is due to the reaction of the charged colloids with the anions and cations in the soil solution. The amount of absorption of these ions, and their coagulating effect on the colloids are carefully balanced. Iron and aluminium are the strongest coagulants, followed in order by magnesium, calcium, potassium, ammonium, and sodium. The rate of absorption of cations is greatest for potassium and ammonium, and then follow the series calcium, magnesium, and sodium. The ions are attached to the colloidal membrane in the order in which they are attracted —those toward the exterior being the ones most easily removed or substituted. Absorption and substitution are governed by the potential difference between the colloids and the soil solution. The absorptive power of soil colloids, notably basic silicates and humates, is destroyed by boiling hydrochloric acid. Organic colloids have a slightly smaller negative charge than the inorganic and need strong electrolytes to coagulate them. The ectoplasm of the absorbing plant cells has a slightly smaller negative charge than the soil colloids, so that there exists a difference of potential between plant and soil. The plant obtains its food as a result of the subsequent migration of the ions. The acidity produced in culture solutions during the growth of plants does not occur if colloids are added to absorb H-ions. The action of fertilisers may to a large extent be due to their ability to regulate the difference of potential between the plant and the soil solution.—A. G. P.

Soils; Methods for determining the amount of colloidal material in ——. C. J. Moore, W. H. Fry, and H. E. Middleton. J. Ind. Eng. Chem., 1921, **13**, 527—530.

A COLLOIDAL substance, the presence of which imparts to soil its absorptive properties, was separated by shaking the soil with water, allowing the mixture to settle for 24 hrs., decanting the supernatant liquid, and passing it through a Sharples centrifuge; the opalescent liquid issuing from the machine was then passed through a battery of Pasteur-Chamberland filter tubes, and the slimy sticky mass collecting on the tubes was removed, washed, and dried. It consisted chiefly of hydrated aluminium silicate and has been termed "ultra-clay." After being dried at 110° C., each c.c. of this substance absorbed 93·05 c.c. of dry ammonia gas, but lost its absorbent power when heated at 1130° C. Each c.c. of the soil from which the "ultra-clay" was obtained absorbed 27·7 c.c. of ammonia and 1·4 c.c. after heating at 1130° C. After allowing for the latter small absorption (apparently due to non-colloidal substances), these results show that the soil contained 28·3% of colloidal substance. Exactly the same result was obtained by measuring the comparative absorption of dyestuff by the soil and by the "ultra-clay"; Malachite Green was used in a solution containing an excess of sodium oxalate, and the absorption was determined colorimetrically.—W. P. S.

Leucite; Solubility of —— *in arable soil.* G. de Angelis d'Ossat. Atti R. Accad. Lincei, 1921, **30**, i., 379—383.

VITREOUS fragments of leucite weighing 96·853 g. and having a total surface of 31·485 sq. dm. were kept in distilled water for six months, the water being changed each month and the total volume used being 1·5 litres; the mineral lost 0·124% of its weight, but underwent no visible alteration. The non-soluble dissociated part assumed the form of a gel, the water clearing immediately after mixing. Another quantity of 69·345 g. of leucite with a surface of 4·3859 sq. dm., when treated for six months with 800 c.c. of 2% citric acid solution, lost 0·677% of its weight, corresponding with 0·145 g. K_2O; in this case also no superficial alteration was evident.—T. H. P.

Carbon dioxide and plant growth. Bornemann. Mitt. deuts. Landw. Ges., 1920. Biedermann's Zentr., 1921, **50**, 296—299.

The increased fertility of dunged soil may, in part, be due to the resulting increase in the carbon dioxide content of the soil atmosphere. Plants grown in frames were treated with carbon dioxide for 10 hrs. daily, each plant having a separate delivery of carbon dioxide round its roots. Relative increases of 40% and upwards were obtained with peas, potatoes, oats, and onions. Smaller increases were obtained with barley and kohlrabi.—A. G. P.

Carbon dioxide as a plant food. O. Lemmermann. Mitt. deuts. Landw. Ges., 1921, **51**, 696. Biedermann's Zentr., 1921, **50**, 299—304.

Experiments undertaken to test the theory that plants are benefited by the carbon dioxide produced by the decomposition of dung and of green manures in the soil are described. Plants grown in soil heavily manured with artificial fertilisers were not improved by treatment with green manures, with dung (ploughed in or as top-dressing), or with carbon dioxide. Plants grown in pots standing over recently dunged land showed no improvement over those in similar pots standing on unmanured and. Analysis of air drawn through a sample of oil mixed with decomposing organic manures showed that the rate of production of carbon dioxide n the case of dung averaged 0·008 g. CO_2 per 100 g. of dung per day. The air immediately in contact with the surface of a dunged soil showed no inreased content of carbon dioxide.—A. G. P.

asic slag and ammonium sulphate (Thomas-ammonium-phosphatkalk); Experiments with a mixture of ——. E. Haselhoff. Fühlings Landw. Zeit., 1920, **69**, 401. Biedermann's Zentr., 1921, **50**, 286—288.

he mixed fertiliser is now on the market, in much etter condition than formerly. Experiments show hat the moistened product, alone, or mixed with oil, loses no ammonia. No loss of nitrogen occurs uring long storage. The citric-solubility of the asic slag is slightly increased by the admixture, nd as a compound fertiliser the mixture is uperior to equivalent quantities of the two conituents.—A. G. P.

ool refuse. Demolon. *See* V.

XVII.—SUGARS; STARCHES; GUMS.

Sucrose; Optical rotation of a normal weight solution of ——. V. Stanek. Z. Zuckerind. Czechoslov., 1921, **45**, 417—423, 425—431.

Working with a Bates-Fric saccharimeter, and verifying the accuracy of the scale calibration by means of quartz plates based on the Herzfeld-Schönrock standard (34·657 circular degrees = 100 sugar scale degrees for spectrally purified sodium light), it was found that the polarisation of a normal solution (26 g. in 100 metric c.c.) of carefully purified samples of sucrose averaged only 99·81° instead of 100°, which work confirms the statement of Bates and Jackson (J., 1916, 1126) that a revision of the present standard is necessary. —J. P. O.

Patents.

[Sugar beet;] Apparatus for the extraction of juice from vegetable substances [——]. J. I. Thornycroft. E.P. 166,993, 28.4.20.

Certain modifications are made in the apparatus claimed in E.P. 120,448 (J., 1919, 49 a). A vertical screw conveyor, preferably perforated, is provided within the diffuser to support the weight of the slices and prevent the lower part of the charge from becoming too compact. This conveyor is rotated at intervals, concurrently with the introduction of fresh slices into the bottom of the diffuser. A portion of the wall of the feed cylinder is movable vertically so as to form a feed valve through which fresh slices may enter the cylinder, under gravity, from an inclined lateral shoot. The lower part of the wall of the shoot may communicate, by perforations, with a receptacle containing juice, so that the slices are surrounded by juice when they enter the feed cylinder, and air is thus excluded. The periodic movements of the various parts of the apparatus may be suitably co-ordinated by hydraulic means. Two forms of apparatus are described in detail. —J. H. L.

[Sugar] syrup; Process of improving the flavour and brilliance of edible ——. W. Meyer. G.P. 338,415, 13.7.19.

In the preparation of syrups from unrefined sugar solutions by inversion, neutralisation, filtration, and evaporation, the juice, after neutralisation, is treated with 0·05—0·2% of phosphoric, oxalic, tartaric, or silicic acid or salts thereof. Silicic acid is used in the form of water-glass. The process is not applicable to starch-glucose syrups.—J. H. L.

XVIII.—FERMENTATION INDUSTRIES.

Wines; Possible improvements in the ebulliometric determination of alcohol in ——. U. Pratolongo. Giorn. Chim. Ind. Appl., 1921, **3**, 290—293. (*Cf.* J., 1921, 484 a.)

The construction of the scale, and the construction, control, and use of the apparatus are considered. The adoption of the conventional ebulliometric scale, based on aqueous solutions of alcohol, is recommended, as this scale is easily controllable at every point, corresponds sufficiently closely with the real scale over the necessary range, and satisfies industrial requirements. A table of corrections for measurements made at various barometric pressures should be supplied; for wines of medium alcoholic strength and for variations of 10 mm. in the pressure, these corrections lie within the experimental error, which is about 0·05% of alcohol. The apparatus should be tested at different pressures, as its indications at one pressure may be accurate and those at another pressure inaccurate. During one determination or a series of determinations, the barometric pressure should not vary by more than about 0·1 mm. of mercury, since, with a wine containing 15% of alcohol, variation of the pressure by 1 mm. without corresponding adjustment of the position of the scale, introduces an error of 0·1% of alcohol; by the use of duplex apparatus, with simultaneous determination of the zero and of the alcoholic content of the wine, such errors are avoided. The source of heat used should be as constant as possible, electric heating giving the best results.—T. H. P.

Methyl alcohol; Improved Denigès test for the detection and determination of —— in the presence of ethyl alcohol. R. M. Chapin. J. Ind. Eng. Chem., 1921, **13**, 543—545.

The solution is diluted so as to contain 1% of total alcohols (solution *A*); 10 c.c. of this solution is mixed with 10 c.c. of 4% (by vol.) ethyl alcohol and diluted to 50 c.c. (solution *B*); 10 c.c. of the latter solution is in turn mixed with 10 c.c. of 4% ethyl alcohol and diluted to 50 c.c. (solution *C*). Portions (4 c.c.) of each of these solutions are placed respectively in three Nessler cylinders, and a series of standards is prepared in other cylinders, using 1, 2 and 3 c.c., respectively, of a 0·04% methyl alcohol solution, adding to each 1 c.c. of 4% ethyl alcohol and diluting to a volume of 4 c.c. To each cylinder are then added 1 c.c. of phosphoric acid solution (1:5) and 2 c.c. of 3% potassium permanganate solution; after 30 mins. 1 c.c. of 10% oxalic acid solution is added, followed after 2 mins. by 1 c.c. of concentrated sulphuric acid and 5 c.c. of Schiff-Elvove reagent (J., 1917, 468). The colorations obtained are compared after the lapse of 1 hr. The procedure may be repeated with more closely set standards if desired. The above method may be used qualitatively; in this case, 10 mins. contact with the permanganate solution is sufficient, and the coloration is observed 10 mins. after the Schiff-Elvove reagent has been added. The transitory coloration due to ethyl alcohol (acetaldehyde) will then have disappeared, and a pale green colour remains if less than 2% of methyl alcohol was present in the total alcohols. The presence of acetone and of higher alcohols does not interfere, but carbohydrates, glycerol, acetic acid, and formic acid must be removed previously by distilling the alcohol sample after neutralisation; formaldehyde, terpenes, etc. are eliminated by treatment with sodium hydroxide and silver nitrate, followed by distillation, and phenols by distillation with an excess of sodium hydroxide.—W. P. S.

Alcoholic fermentation liquids; Concentration and purification of ——. I. Distillation in steam of certain alcohols. J. Reilly and W. J. Hickinbottom. Sci. Proc. Roy. Dublin Soc., 1921, **16**, 233—247.

Employing apparatus similar to that used in their recent work on fatty acids (J., 1919, 913 A) the authors investigated the distillation constants of the lower fatty alcohols (up to isoamyl alcohol) in dilute aqueous solutions. In all cases the volume of liquid in the distillation flask was maintained constant throughout the distillation by introduction of water. The results indicate that the rate of distillation of the various alcohols from dilute solutions increases with their molecular weights. For any given alcohol the distillation constant was found to increase appreciably as the concentration of the alcohol diminished. Sorel (J., 1893, 782) and Gröning made similar observations, and the authors discuss several possible explanations thereof.
—J. H. L.

Alcoholometry; Application of the determination of miscibility temperatures to ——. H. Rosset. Ann. Chim. Analyt., 1921, 3, 235—239.

The miscibility temperature of a mixture of definite volumes of acetone, petroleum spirit, and alcohol varies with the alcoholic strength of the latter. With 30 c.c. of pure acetone, 5 c.c. of petroleum spirit (b.p. 216°—225° C.), and 5 c.c. of alcohol, the point varies from −5·5° C. for 90% alcohol to +27·6° C. for 65% alcohol. A different mixture is recommended for use with weaker alcohols, namely, 50 c.c. of acetone, 5 c.c. of petroleum spirit, and 5 c.c. of alcohol; in this case the miscibility temperature is −1·0° C. for 65% alcohol and +23·0° C. for 28% alcohol. The method is unsuitable for use with still weaker alcohol.—W. P. S.

Yeast test for vitamin B. Eddy and others. *See* XIXA.

Patents.

Yeast; Process of improving the odour, flavour and digestibility of crude —— with a view to its use as nutrient yeast. H. Otto Traun's Forschungslaboratorium G.m.b.H. G.P. 331,348, 16.3.19.

Yeast freed from bitter substances and, if necessary, treated in a high-speed beating mill to rupture the cells, is heated and exposed, in the moist or dried state, to hydrogen under pressure in an autoclave. The process is improved and accelerated by addition of small quantities of sodium chloride, organic acids and the like, and catalysts.—J. H. L.

Vinegar-making; Methods of ——. E. Klein. E.P. 144,693, 10.6.20. Conv., 12.1.16.

See U.S.P. 1,272,276—7 of 1918; J., 1918, 601 A.

XIXA.—FOODS.

Casein; Precipitation of grain-curd —— from pasteurised milk, including sweet cream buttermilk. H. F. Zoller. J. Ind. Eng. Chem., 1921, **13**, 510—514.

The milk is heated to a temperature which depends on the pasteurising conditions to which the milk has been subjected; if these conditions are not known, the optimum temperature must be determined by experiment. Dilute hydrochloric acid (1:8) is then added slowly with constant stirring until the curd first separates from the whey; the addition of acid is stopped when 10 c.c. of the milk or whey shows a bright red coloration with 5 drops of 0·04% methyl-red solution. The curd is then drained, washed with water at 30°—35° C. containing hydrochloric acid to make p_H=4·8, and dried. Rennin is not a suitable precipitant for use with pasteurised milk.—W. P. S.

Vegetables; Relation of moisture content to the deterioration of dried raw —— upon storage. H. C. Gore and C. E. Mangels. J. Ind. Eng. Chem., 1921, **13**, 523—524.

When raw vegetables (*e.g.*, carrots, onions, turnips, tomatoes, celery, cabbages, etc.) are cut into small pieces, dried in a current of air, and stored in airtight containers, they will not retain their original colour and flavour unless the moisture content is reduced to or below a certain limit; this limit for various vegetables is as follows:—carrots, 5·0—7·4; turnips, 5·0; onions, 5·7—6·6; spinach, 3·8—5·4; cabbage, 3·0—3·3%.—W. P. S.

Vegetables; Effect of heat on different dehydrated ——. C. E. Mangels and H. C. Gore. J. Ind. Eng. Chem., 1921, **13**, 525—526.

Dried onions, turnips, celery, tomatoes, and cabbages are readily injured (darkened) by heat (about 50° C.); potatoes, carrots, beans, and maize are fairly resistant (about 60° C.), whilst sweet potatoes may be heated at 80° C. for many hours without injury. A dry atmosphere is less injurious than a relatively moist atmosphere at the same temperature.—W. P. S.

Vitamins, A, B, and C; Methods of extracting and concentrating —— together with an apparatus for reducing milk, fruit juices, and other fluids to a powder without destruction of vitamins. J. F. McClendon. J. Biol. Chem., 1921, 47, 411—420.

The essential features of the methods are: the use of high pressure in the extraction of vitamin A from dried green leaves or fruit skins moistened with 95% alcohol; the similar extraction, using 80% alcohol, of vitamin B from wheat germ or yeast, followed by the separation of resinous and lipoid material by acidification up to the isoelectric point of these colloids; and the removal of sugar from the vitamin B extract and also from fruit juices containing vitamin C by fermentation with yeast. The extracts so obtained are concentrated by a spray process in which hot flue gases meet a descending spray of the extract. Oxygen is excluded from the flue gases by regulation of the combustion of the furnace.—E. S.

Fat-soluble vitamin. VIII. Fat-soluble vitamin content of peas in relation to their pigmentation. H. Steenbock, M. T. Sell, and P. W. Boutwell. J. Biol. Chem., 1921, 47, 303—308.

Of the ripe peas tested, those of a green colour were richer in vitamin A than those of a yellow colour. The former also contained more yellow pigment than the latter.—E. S.

Vitamin content. II. The yeast test as a measure of vitamin B. W. H. Eddy, H. L. Heft, H. C. Stevenson, and R. Johnson. J. Biol. Chem., 1921, 47, 249—275.

Confirmatory evidence is produced showing that the yeast test is not a quantitative measure of vitamin B content. It is possible, however, that the presence of vitamin B is one of the factors causing the stimulation of the growth of yeast by vegetable extracts.—E. S.

Tyrosinase reaction; Colloid chemical phenomena in the ——. H. Haehn. Kolloid-Zeits., 1921, 29, 125—130.

The enzyme tyrosinase consists of two parts, the enzyme α-tyrosinase and an inorganic salt, both of which are necessary for the formation of melanin from tyrosine. The essential difference between red ind black melanin is one of degree of dispersion. The tyrosine reaction is composed of two parts, a biochemical and a colloid-chemical reaction. In the ormer the α-tyrosinase decomposes the tyrosine, with formation of the red melanin molecule; this is ollowed by the second reaction in which coagulaion occurs and the finely disperse red phase is conerted into the coarsely disperse black phase, after which precipitation occurs.—J. F. S.

ævulinic acid in foods; Detection and determination of ——. L. Grünhut. Z. Unters. Nahr. Genussm., 1921, 41, 261—279.

ÆVULINIC acid may occur in soup extracts, gravy lts, and "artificial meat extracts" prepared from egetable matter. It results from the treatment of rbohydrates with mineral acids, and may be entified by the red coloration it yields with dium nitroprusside in alkaline or acetic acid lution. It is usually accompanied in foods by rmic acid, and sometimes by acetic and lactic ids. To determine the quantity of these acids esent, the food is acidified with phosphoric acid d extracted with ether, a quantity of sodium droxide being placed in the extraction flask prevent volatilisation of the formic acid with e ether vapour; the ethereal layer is then washed with sodium hydroxide solution, the united alkaline solutions evaporated to dryness and the residue dissolved in a definite volume of water. Formic acid is determined in a portion of this solution by the mercuric chloride method; another portion is oxidised by boiling with potassium bichromate solution and sulphuric acid under a reflux condenser, the formic acid being thus converted into carbon dioxide, and the lævulinic acid into acetic acid and carbon dioxide; the mixture is then distilled and the acetic acid is titrated in the distillate. If formic and lævulinic acids alone are present, the amount of acetic acid found will correspond with that calculated from the amount of bichromate reduced after allowance has been made for the formic acid. If more than this quantity of acetic acid is found, the sample itself contained free acetic acid. Lactic acid is also oxidised by chromic acid and yields a corresponding amount of acetic acid; if this acid is present, it is advisable to submit the solution containing the four acids to a preliminary distillation; all of the acetic acid, most of the formic acid, a very small portion of the lævulinic acid and practically none of the lactic acid pass over into the distillate, whilst the distillation residue contains all the lactic acid, the remainder of the formic acid, and most of the lævulinic acid. The two solutions thus obtained are analysed separately as described. —W. P. S.

Patents.

Fish and other articles of food; Freezing of ——. N. Dahl. E.P. 167,862, 19.5.20.

Fish, in packages, is subjected to a preliminary freezing by a liquid (at −5° C.) supplied under pressure to the interior of the package. The fish are thus stiffened and prevented from coalescing and the liquid is thoroughly spread through the mass. The final freezing is carried out by downward percolation, through a number of packages, of a freezing liquid at −10° to −15° C.—A. G. P.

Food products and process of making same. S. Luft. E.P. 167,994, 2.12.20.

Starchy material, preferably powdered, is heated to a temperature just below the point at which the flavour is impaired by the formation of "caramel" substances. While still dry it is impregnated with fat. Seasoning material, desiccated vegetables, meat extracts, etc., may be added. The product keeps well and may be used for soups after treating with boiling water.—A. G. P.

Beverage extract; Manufacture of solid soluble ——. O. Roewade, Assr. to Postum Cereal Co. U.S.P. 1,366,495, 25.1.21. Appl., 8.3.18.

Roasted cereal is cooked in water, mixed with roasted bran and caramelised saccharine matter, and digested with more water. The fluid extract is drained off and evaporated.—C. I.

Food product [from cereal grains]. J. D. Bourdeau and W. B. Fink, Assrs. to The Quaker Oats Co. U.S.P. 1,381,858, 14.6.21. Appl., 25.4.19. Renewed 9.8.20.

Cereal grains containing oily constituents liable to become rancid are treated with an alkaline solution so as to retain sufficient alkali in loose combination with carbohydrate constituents to neutralise any acid formed subsequently from the oil.—J. H. L.

Margarine and method of making the same. E. J. Wall and J. W. Phelan, Assrs. to Kalmus, Comstock, and Wescott, Inc. U.S.P. 1,386,475, 2.8.21. Appl., 15.7.19.

Milk or cream is churned to the point of incipient butter formation. Melted cacao oil is then added and the churning continued until the formation of

butter is complete. The cacao oil forms the disperse phase and the butter fat the continuous phase.
—H. C. R.

Feeding stuff; Process for preparing a dry flaked —— from straw and hay. H. Oexmann. G.P. 301,207, 14.3.15, and 304,331, 11.8.15.

The plant material, after digestion, is mixed with starchy substances, *e.g.*, potatoes, broken up and moistened, and the mixture flaked in a potato-flaking machine or similar appliance. The product can be easily crumbled and masticated. A modification consists of raising the moisture content of the straw pulp to 65—75%, kneading it and then drying as usual. Straw which has been pressed may be moistened by the addition of yeast, molasses, etc.
—A. G. P.

Feeding stuff; Process for preparation of —— from straw. J. Paechtner. G.P. 338,920, 22.8.18.

Straw is thoroughly disintegrated, mixed with small quantities of electrolytes, *e.g.*, sodium or calcium chlorides, and submitted to a brief electrolysis. The product is a palatable fodder of high nutritive value.—A. G. P.

Milk or the like; Process for drying —— in vacuo. L. Wischnewetzky. G.P. 337,452, 23.2.18, and 338,908, 18.7.18.

Milk is dried by forcing it as a fine sheet of spray round a heating appliance in the interior of a vacuum vessel. Filter-cloth is interposed between the milk spray and the heated surfaces to prevent actual contact.—A. G. P.

Lupin seeds: Process for the removal of the bitter and poisonous constituents of ——. Veredelungsges. für Nahrungs- u. Futtermittel. G.P. 339,029, 24.4.18.

After removal of husks, the seeds are coarsely ground and soaked in water at 40°—70° C. The temperature used and time of soaking are varied according to the nature of the material. By this treatment the seeds are freed from bitter and toxic constituents with the least possible loss of protein.
—A. G. P.

Butter fats; Manufacture of ——. A. W. Johnston, Assee. of E. B. Phelps, A. F. Stevenson, and J. C. Baker. E.P. 146,154, 24.6.20. Conv., 26.6.19.

Base-exchanging; Process of ——. W. C. Foster. U.S.P. 1,385,124, 19.7.21. Appl., 18.1.17.

Base-exchanging materials used in water-softening are regenerated by passing regenerating material through the mass in the opposite direction to the flow of water, which is temporarily stopped. After washing this process is repeated.—A. G. P.

Water purification and softening by means of membrane filters; Process for ——. R. Zsigmondy and W. Bachmann. G.P. 338,087, 24.6.17.

A precipitate is produced in the water by ordinary methods, to induce adsorption of colloidal matter and bacteria. The combined precipitate is removed by filtration through a membrane filter. The latter consists of cellulose esters dissolved in a suitable solvent, *e.g.*, acetone with glacial acetic acid, and dried in a damp atmosphere at room temperature. All turbidity and bacteria can be thus removed. By the addition of suitable reagents the water may be softened and iron and manganese removed.
—A. G. P.

Water containing tarry matters; Method of treating and filtering ——. E. Wade-Wilton, W. Hepworth, and C. H. Fuessly. E.P. 167,556, 7.5.20.

The effluent water from wood refuse producer plants is passed into a circular tank provided with a funnel-shaped receiver, the upper end of which is at about the water level in the tank, and with baffle plates having their upper ends above the water level. The effluent flows in a circular direction around the outer periphery of the receiver, and the tarry matter separates, floats on the surface, and is directed by the baffles into the funnel, whence it is withdrawn. The separated water passes into and flows upwards through a filter tank, filled with wood wool, and then through a second filter tank filled with charcoal or sand. It is discharged from the bottom of the second filter, and if the mechanical separation is not sufficient, a chemical agent may be added from a separate tank fixed on the side of the second filter.—C. A. C.

Residual waters containing fatty and soapy matters; Process for treating ——. Soc. Gén. d'Evaporation Proc. Prache et Bouillon. E.P. 147,044, 6.7.20. Conv., 9.3.14.

See F.P. 475,639 of 1914; J., 1916, 67.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Ouabain and strophanthin; Identification of ——, and a new test to distinguish between the two glucosides. A. Richaud. J. Pharm. Chim., 1921, 24, 161—166.

Ouabain is soluble in 150 pts. of water at 15° C., whilst strophanthin dissolves in 40—43 pts. at that temperature. The solution of the former is perfectly clear and colourless, and does not give a persistent froth on shaking. Strophanthin solutions, on the other hand, are inclined to be yellowish and are not perfectly transparent. They have a very pronounced bitter taste, and give a persistent froth on agitation. Under the microscope ouabain appears as a pure white powder or small rectangular tabular crystals, whilst strophanthin is usually a dirty or yellowish white amorphous powder or crystallised in leaflets often grouped round a centre. On warming in a water bath to 60°—70° C. in a test tube, 5 c.c. of concentrated hydrochloric acid, a trace of resorcinol, and a few crystals of the glucoside, ouabain gives no coloration, and strophanthin a rose colour. the test depending on the difference in the sugars generated by the hydrolysis of the two glucosides.—G. F. M.

Aminoacylcholine esters. I. Glycylcholine. H. W. Dudley. Chem. Soc. Trans., 1921, **119**, 1256—1260.

Glycylcholine is prepared by heating at 100° C. *in* *vacuo* a mixture of finely powdered glycyl chloride hydrochloride and choline chloride. It is isolated after digestion with alcohol, as the platinum salt, m.p. 236°—238° C., from which the hydrochloride is obtained by removing the platinum with hydrogen sulphide, extracting with alcohol, and evaporating to dryness. Crystalline choline is obtained from the chloride by treatment with fresh silver oxide. Successive evaporations with absolute alcohol and dry ether, and standing over phosphoric oxide are necessary in order to obtain the material crystalline.—P. V. M.

β-Aminoethyl alcohol; Separation of —— from admixture with choline. E. Fourneau and A. González. Ann. Soc. Espan. Fis. Quim., 1921, **19**, 151—155. Chem. Zentr., 1921, **92**, IV., 454—455.

The hydrochlorides of the bases are dissolved in methyl alcohol and the bases liberated by the addition of the theoretical quantity of sodium methoxide. The solution, after filtering, is evaporated *in vacuo*, the residue dissolved in absolute ether, and a solution of 0·5 mol. of β-naphthalenesulphonic chloride added with cooling. After ½ hr. 1 mol. of soda solution is added, the ether layer separated, and the aqueous layer, after washing with ether, is acidified with dilute hydrochloric acid. The precipitated amide is washed and crystallised from toluene.—G. F. M.

Salicylates and phenol; Determination of ——. W. O. Emery. J. Ind. Eng. Chem., 1921, **13**, 538—539.

The method proposed depends on the formation of diiodophenylene oxide when phenol or salicylic acid is treated with iodine in the presence of sodium carbonate. $2C_6H_5OH+6I_2+4Na_2CO_3=2C_6H_2I_2O+8NaI+4CO_2+4H_2O$ and $2C_6H_4(OH)CO_2H+6I_2+4Na_2CO_3=2C_6H_2I_2O+8NaI+6CO_2+4H_2O$. To determine salol in pills or tablets, a portion of the sample containing about 0·1 g. of salol is extracted with chloroform, the extract is evaporated to dryness, the residue obtained is treated with 10 c.c. of 1% sodium hydroxide and heated under a reflux condenser so that boiling commences in about 2 mins.; further quantities (10, 30, and 50 c.c.) of water are then added, the mixture being boiled after each addition, and 1 g. of sodium carbonate is added with the last portion of water. The boiling solution is then treated with 60 c.c. (an excess) of iodine solution, the flask is removed from the condenser, 1 g. of sodium carbonate is added, the mixture boiled gently for 20 mins., the precipitate then collected on a weighed filter, washed with not less than 200 c.c. of hot water, dried at 100° C., and weighed. The weight found multiplied by 0·3113 gives the quantity of salol. Caffeine, acetanilide, and phenacetin do not affect the results, but if the last-named substance is present, the quantity of iodine solution mentioned should be increased by 5 c.c. for each 0·1 g. of phenacetin assumed to be present. —W. P. S.

Toluene; Sulphonation of —— with chlorosulphonic acid. L. Harding. Chem. Soc. Trans., 1921, **119**, 1261—1266.

N the interaction between toluene and chlorosulphonic acid, *o*- and *p*-toluenesulphonic acids are the main products below —35° C., even with excess of chlorosulphonic acid; at 0° C. and higher temperaures *o*- and *p*-toluenesulphonic chlorides predomiate. Excess of chlorosulphonic acid tends to increase the proportion of acid chloride in the prouct and favours the formation of the *o*-isomer; ncrease of temperature favours the formation of he *p*-isomer. Maximum yields of *o*-toluenesulhonic chloride were obtained by dissolving the oluene (10 g.) in the chlorosulphonic acid (40 g.) at temperature below —40° C., pouring the mixture gradually into tubes surrounded by ice, and allowing the reaction to proceed at 5°—10° C. The reaction may be represented by the equations:—

$$C_6H_5.CH_3+SO_3HCl=CH_3.C_6H_4.SO_3H+HCl,$$

and

$$CH_3.C_6H_4.SO_3H+SO_3HCl=CH_3.C_6H_4.SO_2Cl+H_2SO_4.$$

As the second reaction is retarded by dilution of the chlorosulphonic acid sufficient time must be allowed for completion of the reaction before separation of the products.—P. V. M.

Urea; Colour reaction for ——. V. Arreguine and E. D. García. Anal. Asoc. Quim. Argentina, 1921, **9**, 183—191.

The reaction consists in adding hydrochloric acid and resorcinol to an aqueous solution of the substance and boiling for about a minute. On cooling, diluting with water, and shaking out with ether, the ethereal layer is coloured pink to red according to the amount of urea present. (*Cf.* J.C.S., Oct.) —G. W. R.

Odoriferous substances and smell. A. Tschirch. Schweiz. Apoth. Zeit., 1921, **59**, 229—232, 241—246, 254—258, 265—272. Chem. Zentr., 1921, **92**, III., 190—191.

Odour cannot be entirely ascribed to a constitutional characteristic of the substance exhibiting it, although certain groups such as –CHO, –CO–, –OH, –OCH₃, –O.CH₂.O–, –COOR, –CN, etc., can be recognised under certain circumstances, though not always, as smell-producing groups. The partition coefficient between air-odoriferous substance and the lipoid plasm of the olfactory cells must be favourable for the latter, and the above-mentioned characteristic groups only function as smell-producing groups if they can react with the colloidal contents of the olfactory cells, the general chemical constitution of the substance having only secondary importance. Odoriferous substances are, strictly speaking, not themselves odorous, but rather the extremely labile, loose compounds formed by them on the surface of the colloidal plasm of the olfactory cells. These compounds may be either absorption compounds or, less probably, chemical reaction products, and they stimulate the olfactory nerves which lead to the brain. (*Cf.* Durrans, J., 1919, 479 A.)—G. F. M.

Acetanilide; Quantitative determination of ——. A. Reclaire. Perf. Ess. Oil Rec., 1921, **12**, 280.

A method, sufficiently accurate for technical purposes, for the determination of acetanilide, particularly for acetanilide used as an adulterant in artificial musk preparations, is carried out as follows: About 1·5 g. of the substance is boiled in an acetylation flask with 50 c.c. of 20% hydrochloric acid for 15 mins. The volume is then made up to 500 c.c., and to 25 c.c. 5 c.c. of strong hydrochloric acid and an excess of a standard potassium bromide-bromate solution are added. Tribromoaniline is precipitated and the excess of bromine is estimated by adding potassium iodide and titrating back with thiosulphate; 1 c.c. of *N*/10 thiosulphate corresponds to 0·00225 g. of acetanilide.—G. F. M.

Oxalic and citric acids; Detection of ——. M. Polonovski. J. Pharm. Chim., 1921, **24**, 167—168.

For the detection of oxalic acid, the acid radicles are converted into sodium salts by boiling with sodium carbonate in the usual way, and to the alkaline filtrate, acidified with acetic acid, a saturated solution of calcium fluoride is added. Calcium oxalate is precipitated under these conditions, its solubility in water at 15° C. being 0·00056%, whilst that of calcium fluoride is 0·05%. In the absence of fluorides from the original substance a saturated solution of calcium sulphate may be used instead of calcium fluoride. Citric acid may be detected in presence of any of the common organic acids by treating a solution at 50°—60° C. with a few drops of permanganate solution until the pink colour persists. 1 c.c. of bromine water is then added, with gentle warming until decolorised. In presence of citric acid a precipitate of perbromoacetone is formed; but still more characteristic are the irritant vapours which are evolved, the least trace of which cannot fail to be detected.—G. F. M.

Pinene hydrochloride; Tertiary ——. O. Aschan. Ofversicht Finska Vetenskaps Akad. Förhandl., 1914, 57, 35 pp. Chem. Zentr., 1921, 92, III., 629—631.

At temperatures below —10° C. the addition of hydrogen chloride to pinene gives rise to a fluid compound, $C_{10}H_{17}Cl$, tertiary pinene hydrochloride. This compound contains the same ring system as pinene, and on treatment with aniline it is partially re-converted, with evolution of heat, into a hydrocarbon consisting essentially of the original pinene, together with small quantities of dipentene. The hydrochloride is comparatively stable only at low temperatures, and even at 0° C. is rapidly isomerised to bornyl chloride (pinacolin conversion) with evolution of heat. In the preparation of bornyl chloride from pinene at ordinary temperatures the unstable tertiary hydrochloride is probably always an intermediate product. Nopinene gives at low temperatures the same tertiary pinene hydrochloride, and the formation of this substance, and subsequent treatment with aniline, therefore affords a simple method for the conversion of nopinene into pinene.—G. F. M.

Wormwood oil; Yield and composition of —— from plants at various stages of growth during successive seasons. F. Rabak. J. Ind. Eng. Chem., 1921, 13, 536—538.

The yield of oil from the wormwood plant, *Artemisia absinthium*, during the years 1907—1919, inclusive, varied from 0·12 to 0·24% of the weight of the fresh plant, the higher quantities being found in dry, hot years. The highest yield of oil is obtained during the flowering period, and the alcoholic constituents of the oil decrease in quantity as the plant approaches maturity. The characters of oils produced in several successive seasons were:—Free acid, as acetic acid, 0—0·25; esters, as thujyl acetate, 24·1—35·0; alcohols, as thujyl alcohol, 11·6—16·6%.—W. P. S.

Oligodynamy of copper and its oxides. R. Wernicke and A. Sordelli. Anal. Asoc. Quím. Argentina, 1921, 9, 145—182.

The experimental work of the authors shows that in the case of copper, activation is due to actual solution of copper. Such solution takes place in the presence of oxygen and carbon dioxide. (*Cf.* J.C.S., Oct.)—G. W. R.

Acetaldehyde; Production of —— from acetylene. Soc. Anon. de Prod. Chim. (Etabl. Malétra). E.P. 140,784, 24.3.20. Conv., 24.3.19.

In the generation of acetaldehyde from acetylene with an acid mercuric sulphate solution as catalyst, the process is rendered practically continuous by the periodic addition of ferric oxide to the bath. For example 9·26 kg. of mercury is triturated with 7·4 kg. of ferric oxide, 70 kg. of concentrated sulphuric acid and 191 kg. of water are added, and the mixture is heated to 70°—83° C., preferably about 80° C. Acetylene is led into the liquid thus prepared, and from time to time water is added equivalent to the aldehyde distilling off, so that the concentration of the sulphuric acid is maintained at 30—35% of the total liquid. After 280 kg. of acetaldehyde has been obtained a further 7·4 kg. of ferric oxide and 13·34 kg. of sulphuric acid are added, and the operation may be repeated to an almost unlimited extent. After about ten operations it is desirable to decant the liquid from the small quantity of tarry matter formed. It is essential that the acetylene be purified before use, particularly from hydrogen phosphide.—G. F. M.

Proteids charged with immune substances; Process for preparing ——. Elektro-Osmose A.-G. (Graf Schwerin Ges.). E.P. 146,260, 28.6.20. Conv., 11.7.18.

In immune sera the specific properties are not distributed uniformly among the proteins present in the blood, but these have different attractive powers for the specific immunising substance, the strongest affinity being exhibited by the pseudoglobulins, a small affinity by the euglobulins, and none at all by the albumins etc. It is therefore possible to withdraw from the euglobulins the immune substances united with them, by means of solutions of pseudoglobulins, so that specific activity can be imparted to unspecific pseudoglobulins or combinations of different kinds of immunising substances can be fixed on one and the same protein, the transference being equally successful even with globulins derived from the blood of different animals. The process consists in separating electro-osmotically the euglobulin from an immune serum, dissolving it in blood serum or better in a solution of pseudoglobulin from the blood serum of normal or immunised individuals, and again separating electro-osmotically the euglobulin from this mixture. By using different kinds of immunising sera in the above process, so-called multivalent sera can be prepared, having at the same time different antitoxic or bactericidal properties, as for example antidiphtheric-antitetanic serum.—G. F. M.

Terpin hydrate; Process for preparing ——. R. Marchand. E.P. 153,606, 10.11.20. Conv., 11.11.19.

Oil of turpentine or pinene is mechanically mixed with dilute sulphuric acid in an atmosphere of nitrogen or carbon dioxide, and vigorous agitation is continued for about 90 hours, by which time terpin hydrate will have crystallised out in almost theoretical quantity. In the example given 23 sulphuric acid is used with half its weight of turpentine.—G. F. M.

[Hydr-]oxyarylaldehydes [e.g., vanillin]; Manufacture of ——. H. Haakh. E.P. 157,850, 10.1.21. Conv., 6.2.18.

Hydroxyarylaldehydes are obtained by treating phenols with formaldehyde in presence of a nitroso-compound and an acid condensing agent. An azomethine is formed intermediately and is decomposed into aldehyde and amine. For example a solution of 60 g. of guaiacol and 109 g. of nitrosodiethylaniline hydrochloride (or the corresponding amount of nitrosophenol) in 500 g. of methyl alcohol is saturated with hydrogen chloride and boiled in a reflux apparatus. 70 g. of 23 % formaldehyde solution is slowly added and when the reaction is complete the alcohol is distilled off. From the residue after boiling for a short time in feebly alkaline solution, vanillin is extracted with ether after re-acidification, and purified in the usual way. —G. F. M.

2.4-*Diketotetrahydro-oxazoles; Preparation of disubstituted* ——. Soc. Chim. des Usines du Rhône. E.P. 159,153, 5.6.20. Conv., 16.2.20.

Disubstituted derivatives of 2.4-diketotetrahydro-oxazole of the general formula,  $RR'C<\begin{matrix}O—CO\\CO—NH\end{matrix}$ are obtained by the action of chloroformic ester on the correspondingly disubstituted glycollamide, preferably in the presence of an alkali carbonate and in solution in a neutral organic solvent. For example, 450 g. of phenylethylglycollamide dissolved in 3 l. of toluene is boiled for about 3 hrs. with 700 g. of anhydrous potassium carbonate and 300 g. of ethyl chloroformate gradually added. The product, on treatment with water and sulphuric acid, gives a nearly theoretical yield of a crystalline mass of 5.5-phenylethyl-2.4-diketotetrahydro-oxazole. This is purified by distillation *in vacuo* (b.p. 176° C. at 3 mm.) and the distillate forms on cooling crystals of m.p. 63° C. These oxazoles are slightly soluble in hot water, and form very soluble, well characterised salts when neutralised with the hydroxides or carbonates of the alkali and alkaline-earth metals. They have hypnotic, sedative, and narcotic properties.—G. F. M.

2-*Phenylquinoline-4-carboxylic acid; Manufacture of aralkyl esters of* ——. O. Imray. From Soc. Chem. Ind. in Basle. E.P. 167,066, 5.7.20.

The aralkyl esters of 2-phenylquinoline-4-carboxylic acid, *e.g.*, the benzyl ester, whilst having all the advantages of the alkyl or aryl esters, are in addition, much better solvents of uric acid. They may be prepared by any of the known methods for esterifying an acid. The benzyl ester, prepared for example by the action of 1·25 pts. of benzyl chloride on 2·5 pts. of sodium 2-phenylquinoline-4-carboxylate suspended in 10 pts. of acetone, forms citron yellow crystals, m.p. 77°—78° C., insoluble in water, soluble in hydrochloric acid, ether, benzene, etc. —G. F. M.

Catalytic oxidation; Process of ——. H. Wade. From The Barrett Co. E.P. 167,219, 1.4.20.

The temperature in the reaction chamber is controlled by arranging cooling elements comprising tubular coils, grids, or radiators above and beneath, and out of contact with the layers of the catalyst and its support. A mixture of vapours of an aromatic hydrocarbon and a gas containing oxygen s heated to the lowest possible temperature uitable for the inception of the reaction and then s admitted to the chamber. Complete combustion s prevented and products of partial oxidation are btained. The process is available for the oxidaion of benzene to maleic acid in presence of anadium oxide.—C. A. C.

ondensation reactions; Process for effecting ——. A. V. Blom. E.P. 167,582, 11.5.20.

ondensations which involve the elimination of alogen acids, and which can only be effected with fficient rapidity in presence of an alkali hydroxide, ith the possible danger of undesirable side actions occurring, can be conveniently conducted ithout such risk, by continuously generating free ydroxide in the reaction mixture by means of a multaneous caustifying reaction, using for ample a mixture of alkali carbonate and calcium droxide. Thus o-nitroanisol is conveniently prered by adding 82 pts. of potassium carbonate and suspension of 64 pts. of slaked lime in 250 pts of ater to a solution of 79 pts. of *o*-nitrochloronzene in 1000 pts. of methyl alcohol, and heating r 5 days under a reflux condenser with constant rring.—G. F. M.

Acetone; Production of —— *by distillation of sodium acetate etc.* V. Drewsen. U.S.P. 1,385,866, 26.7.21. Appl., 8.9.16.

Crystallised sodium acetate is melted, mixed at about 100° C. with about one-third of its weight of powdered caustic magnesian lime to dehydrate the acetate to a whitish powder, which is then dry distilled at 300°—400° C. in presence of superheated steam. The yield of acetone amounts to about 95% of the theory.—G. F. M.

Chlorhydrin; Manufacture of ——. W. E. Kirst, Assr. to The Dow Chemical Co. U.S.P. 1,386,118, 2.8.21. Appl., 9.12.18.

Aqueous glycol chlorohydrin or bromohydrin is dehydrated by adding benzene to the solution and evaporating or distilling the mixture, whereby water and benzene are removed, and the halogenhydrin is left behind.—G. F. M.

Acetic acid; Manufacture of —— *from acetaldehyde.* Farbenfabr. vorm. F. Bayer und Co. G.P. 299,782, 27.1.16.

Acetaldehyde is oxidised to acetic acid by treatment with air or oxygen in the presence of kieselguhr.—L. A. C.

Tetrasulphide-carboxylic acids; Process for the preparation of salts of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 336,021, 11.7.19.

The salts must be prepared in a non-aqueous medium, or else rapidly removed from the decomposing action of water. For example, the sodium salt of tetrasulphide-acetic acid is precipitated as a white mass, insoluble in ether, acetone, or chloroform, when an alcoholic solution of the acid is neutralised with alcoholic sodium hydroxide. It is soluble in water, but precipitation of sulphur soon commences. The potassium salt is immediately decomposed by water with liberation of sulphur. The salts are useful in medicine, as disinfectants, and for horticultural purposes.—G. F. M.

Hexamethylenetetramine; Preparation of a betaine of ——. J. D. Riedel A.-G. G.P. 337,939, 13.5.19. Addn. to 336,154 (J., 1921, 602 A).

The addition products of hexamethylenetetramine with α-halogenated acetic acids are treated with tertiary bases, instead of with silver oxide as in the earlier patent. For example, the addition compound of hexamethylenetetramine and monochloroacetic acid is dissolved in a small quantity of cold water, and pyridine is added in excess, with stirring. The betaine, $C_6H_{12}N_4.(OH)CH_2.COOH$, is precipitated in crystals and is purified by washing with alcohol, and recrystallising from concentrated aqueous solution by the addition of alcohol. —G. F. M.

Silver compounds of α-amino-acids; Manufacture of complex ——. F. Hoffmann-La Roche und Co. G.P. 339,036, 27.2.19. Conv., 23.12.18.

A complex silver compound of glycocoll is obtained by the action of glycocoll-silver or silver oxide on an excess of glycocoll. The product is soluble in water, and its solubility is increased by the addition of an amino-acid. Similar compounds are obtained by treating an excess of glycocoll with silver nitrate or sulphate. The products form crystalline masses which yield neutral aqueous solutions, not precipitated by alkalis and more stable than aqueous solutions of the simple silver salts. The compound from glycocoll and silver sulphate is much more soluble than silver sulphate. Similar complex compounds are obtained by treating an excess of glycocoll with silver acetate or urea-silver. In the former case the product is a white powder which is five times as soluble in water as silver acetate, and in the latter case a yellow powder is obtained, 3 pts. of which dissolves in 100 pts. of water, whereas urea-silver is insoluble in water. The aqueous solutions are alkaline to litmus. An alanine compound possessing similar properties to the complex silver compounds of glycocoll is prepared by treating α-alanine-silver with an excess of α-alanine.—F. M. R.

Camphylcarbinol; Manufacture of ——. H. Rupe. E.P. 157,227, 8.1.21. Conv., 2.6.16.

See G.P. 307,357 of 1916; J., 1918, 783 A.

Non-flammable volatile liquid. U.S.P. 1,386,497. *See* I.

Alcohol etc. from coal gas. G.P. 338,358. *See* IIa.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Desensitising Autochrome plates before development. A. and L. Lumière and A. Seyewetz. Bull. Soc. Franç. Phot., 1921, 8, 217—220.

Further comparisons between Aurantia and Phenosafranine as densitisers (*cf.* J., 1921, 529 A) show the former to have somewhat more regular and smaller effect on the subsequent development, more particularly on the time of appearance of the image; its use at a dilution of 1:1000 is recommended for desensitising Autochrome plates. —B. V. S.

Patents.

Colour photography. G. S. Whitfield. E.P. 167,793, 20.2.20.

In a three-colour process in which a regular colour screen is used in taking the negative, and key screens, blocking two of the colours, are used in making prints of only one colour of the negative, registration of the key screen and the negative is facilitated by having two coloured bands along the edges of the taking screen over the usual three-colour pattern. The colours of these strips are each opaque to two of the colours of the taking screen and to one another. When the key screen and negative are superposed lack of registration is at once apparent by the impurity of these coloured bands.—B. V. S.

Photography; Three-colour ——. A. Gleichmar. E.P. 148,737, 29.1.20. Conv., 25.7.19.

The prints from three colour-separation negatives, taken side by side on one support, are made on one film of thin celluloid or like material which has three colour fields side by side. Before printing, which is done through the back, the film is creased twice along lines corresponding with the negative. After development etc. correct registration is automatically obtained by folding the film along the creases.—B. V. S.

Gelatinous compositions for use in the reproduction of line documents; Manufacture of ——. F. Dorel. U.S.P. 1,386,995, 9.8.21. Appl., 2.12.18.

See E.P. 121,274 of 1918; J., 1919, 697 A.

Reduction of trinitrotoluol. E.P. 166,934. *See* IV.

XXII.—EXPLOSIVES; MATCHES.

Acetone in nitroglycerin powder; Determination of ——. F. Friedemann. Z. ges. Schiess- und Sprengstoffw., 1921, 16, 121—123.

A rapid method for determining acetone in explosives, particularly nitroglycerin powder, consists in introducing 2—5 g. of the material in shavings into a U-tube, one arm of which is fairly narrow and is connected with a nitrometer charged with 23% potassium hydroxide. The U-tube is initially filled with carbon dioxide, and a slow stream of the gas is passed through the whole apparatus until air is completely expelled. A water-bath at 75° C. is then placed round the U-tube, and the stream of carbon dioxide is continued at the rate of 2—3 bubbles a second for 3—4 hrs., whereby the acetone is completely expelled and absorbed by the alkali. The latter is then made up to 100 c.c. and the acetone determined in an aliquot portion by Messinger's method in the usual way. Alternatively the acetone may be expelled from the explosive by means of a stream of nitrogen and absorbed by means of water, and equally good results are obtained. With powder dried in the normal way the acetone content can with fair accuracy be expressed as 1·5 to 1·6 times the loss in weight on drying for 1 hr. at 50° C.—G. F. M.

Toluene; Nitration of ———. M. Giua. Gazz. Chim. Ital., 1921, 51, II., 113—115.

The author agrees with Drew's statement that the compound, m.p. 79·5° C., isolated from the oily residues obtained in the purification of 2.4.6-trinitrotoluene, is not the 2.3.6-compound, but an additive compound of the 2.3.4- and the 3.4.6-compounds (*cf.* J., 1921, 100 A). Drew's assertion that 2.3.6-trinitrotoluene is formed when toluene is nitrated directly is doubted, the product in question being probably the 2.3.4-compound. (*Cf.* J. Chem. Soc., Oct.)—T. H. P.

Patents.

(A) *Nitrostarch explosive.* (B, C) *Explosive.* W. O. Snelling, Assr. to Trojan Powder Co. U.S.P. (A) 1,386,437, (B) 1,386,438, and (C) 1,386,440, 2.8.21. Appl., (A) 3.10.18, (B) 6.8.19, (C) 11.2.20. (C) Renewed 21.1.21.

(A) Nitrostarch is mixed with a deliquescent salt and sufficient water to hold in solution a substantial amount of the deliquescent salt. (B) A mixture of a nitrated carbohydrate with water in excess of 3% and a hydroxide of a metal of the magnesium group having an atomic weight greater than that of magnesium. (C) An explosive contains nitrostarch desensitised by the presence of oil in an amount of not less than 10% of the nitrostarch. —H. C. R.

[*Explosives;*] *Method of treating undried organic nitrates and the like* [*in the manufacture of* ——]. W. O. Snelling, Assr. to Trojan Powder Co. U.S.P. 1,386,439, 2.8.21. Appl., 16.3.20. Renewed 21.1.21.

Water present in an undried organic nitrate is displaced by a concentrated solution of an inorganic nitrate.—H. C. R.

Explosive; Nitrostarch ——. C. E. Waller, Assr. to Trojan Powder Co. U.S.P. 1,386,478, 2.8.21. Appl., 15.1.19. Renewed 21.1.21.

A mixture of nitrostarch, ammonium nitrate, calcium nitrate, and water.—H. C. R.

Propellant and explosive. K. Schwab. G.P. 300,727, 19.3.15.

Nitrates or nitro-compounds containing at least three NO_3 or NO_2 groups to one atom of metal are used as the oxidising component. Nitrates of tri-valent zirconium, cerium or thorium, or of quadrivalent rare earth metals are used or the double salt of cerium nitrate and ammonium nitrate either pure or mixed with the nitrates of lanthanum, didymium, or similar elements obtained as by-products in the working up of monazite sand. Very powerful propellants and explosives are produced by mixing these salts with charcoal, naphthalene, and especially with organic nitro-compounds such as trinitrotoluene, trinitrobenzene and the like. The mixtures are very insensitive and difficult to burn unconfined. Very little smoke is produced by their combustion.—H. C. R.

Explosives; Production of gelatinous safety ——. Dynamit A.-G. vorm. A. Nobel und Co. G.P. 338,848, 1.6.19.

Liquid condensation products of formaldehyde with dicyanodiamide, urea, or similar compounds are added to explosives. For example 100 g. of dicyanodiamide is treated with about 200 g. of 30% formaldehyde and 15 g. of concentrated sulphuric acid, the whole being warmed with constant stirring to 80°—85° C. These condensation products form retarding agents for gelatinised explosives, and can be successfully used in place of glycerin, potato and wheat flour, lævulose, etc. to increase the elasticity and plasticity of the explosives.—H. C. R.

Nitroglycerin; Washing of crude ——. Dynamit A.-G. vorm. A. Nobel und Co. G.P. 339,031, 8.10.18.

Crude nitroglycerin is thoroughly washed with water, and the acid wash water is neutralised with ammonia and used for washing fresh quantities of crude nitroglycerin until a solution is obtained of sufficient concentration for the economic recovery of the ammonium salts.—H. C. R.

Match composition; Friction ——. M. Kubierschky. G.P. 293,007, 7.9.15.

To increase the inflammability carborundum is added in the place of powdered glass, emery, or quartz.—H. C. R.

XXIII.—ANALYSIS.

Blowpipe construction; New principle in ——. H. G. Becker. Sci. Proc. Roy. Dublin Soc., 1921, 16, 275—281.

Departing from the tubular type of construction, he author has designed a compact form of blowipe in which the size and/or character of the ame can be rapidly altered by a simple manipulaion. The apparatus comprises a fixed horizontal xial portion to which the gas and air leads are onnected and on which are mounted two interenetrating cylindrical casings rotatable either ogether or independently. Around the periphery the first casing 8 radial air jets, differing in bore, re arranged, each in a separate peripheral gas hamber. By rotating this casing, any desired jet an be brought into use; and if the second casing is otated with the first the gas supply is at the same me altered to correspond, so that a series of flames n thus be obtained differing in size but not in aracter. The character of the whole series of ames can be modified at will by rotating the second sing (which controls the gas supply) relatively to the first. The change from one jet to another can be effected very rapidly, a by-pass being provided for ignition.—J. H. L.

Gas combustion furnace for use in organic analysis. T. J. Hedley. Chem. Soc. Trans., 1921, 119, 1242—1243.

The disadvantages of the ordinary gas-combustion furnace for organic analysis, *i.e.*, non-portability, heavy gas consumption, lack of protection to operator from radiant heat, slow heating and cooling, and high initial cost, are obviated in the furnace described. It consists of a light steel frame carrying two angle-iron stays in which fit trough tiles forming the channel. Fixed screens of uralite at the back and base and a hinged uralite screen in front prevent loss of heat by radiation and protect the operator. The multiple flame burner, the distance of which from the tiles can be adjusted, is a tube partitioned down the centre, each half being separately supplied with gas. Individual flames are controlled by cone valves. The total weight is less than 30 lb., and the cost of construction is less than half that of any other type of furnace.—P. V. M.

Gases and liquids; Simple form of apparatus for observing the rate of reaction between ——, and its use in determining the rate of solution of oxygen by water under different conditions of mixing. H. G. Becker. Sci. Proc. Royal Dublin Soc., 1921, 16, 334—344.

The apparatus consists of two cylindrical glass vessels about 30 mm. in diameter, arranged vertically one above the other and connected together through a three-way tap, in one position of the tap directly, and in the second position through a manometer. The whole is enclosed in a cylindrical water jacket connected with a thermostat. The lower vessel contains the liquid under test, and is provided with a mechanically driven glass stirrer passing upwards through the bottom of the cylinder. The stirrer is so designed that when rotated at high speed it causes a stream of fine bubbles of the gas to circulate through the liquid. After calibration of the apparatus, the absorption of gas in the lower cylinder can be directly read off from the level of the manometer column, and this can be re-set after each reading by turning the three-way tap to open direct communication between the two cylinders. The apparatus was used to examine the variation in the rate of solution of oxygen in water with different rates of stirring. The rate of solution was found to vary directly as the rate of stirring.—G. F. M.

Arsenic tubes; Double ——. G. Lockemann. Z. angew. Chem., 1921, 34, 396.

A piece of combustion tubing of the diameter commonly used in the Marsh apparatus is drawn out so that three wide portions and three capillaries are all connected together in one length. The tube is used for two successive arsenic estimations, then reversed, and used for two more.—W. P. S.

Iron and cobalt; Dimethylglyoxime reactions of ——. W. Vaubel. Z. öffentl. Chem., 1921, 27, 163—164.

Ferrous salt solutions yield an intense Bordeaux red coloration when treated with dimethylglyoxime and ammonia; the coloration is distinct from that given by nickel, and a precipitate does not form. Ferric salts also give the reaction if a trace of ammonium sulphide is added before the ammonia. Cobalt solutions give a red-brown coloration and a blue-violet to deep red coloration if ammonium sulphide is also added.—W. P. S.

Nitrogen; Micro-determination of —— and its biological application. M. Polonovski and C. Vallée. J. Pharm. Chim., 1921, 24, 129—134.

A detailed procedure is given for the determination of nitrogen by Kjeldahl's method in 2 c.c. of solution containing 1—2 mg. of nitrogen; this quantity of solution is heated for 15 mins. in a test-tube with 1—2 c.c. of sulphuric acid and 1 g. of potassium sulphate. The mixture is cooled, diluted with 6 c.c. of water, rendered alkaline, the test-tube is connected with an absorption apparatus containing $N/50$ sulphuric acid, and a current of air, bubbled previously through warm water acidified with sulphuric acid, is aspirated through the whole apparatus for 20 mins.; the excess of sulphuric acid is then titrated. To determine albumin in the sample, 3 c.c. of the original solution is treated with 2 drops of acetic acid and a small quantity of sodium chloride, the mixture is heated to 90° C., cooled, submitted to centrifugal action, and the nitrogen is determined in an aliquot portion of the clear liquid; the difference between the two determinations gives the amount of coagulable albumin present.—W. P. S.

Cholesterol and allied substances; Critical study of the methods of estimating ——. J. A. Gardner and M. Williams. Biochem. J., 1921, 15, 363—377.

ψ-Coprosterol and β-cholestanol cannot be estimated colorimetrically. The precautions necessary in the colorimetric determination of other members of the sterol group, and the influence of these substances on the determination of cholesterol are described. (*Cf.* J.C.S., 1921, ii., 563.)—S. S. Z.

Patents.

Analysis of gases; Apparatus for the automatic ——. S. A. S. Krogh and P. H. Pedersen. E.P. 167,824, 10.5.20.

An apparatus intended more especially for the automatic recording of the carbon dioxide and monoxide content of flue gases, comprises a device for measuring the gas in pipettes, removing the gaseous constituent concerned, and re-measuring the remaining volume in a movable bell, the motion of which is recorded. The apparatus is operated by water power, the driving water being supplied at constant pressure to one or more measuring pipettes, the quantity being adjusted for each analysis in order to regulate the time interval between individual analyses. The water is supplied continuously to the apparatus, and is discharged periodically by siphon action. A device is provided which, when actuated by the water, revolves the recording drum or drums so as to provide a time scale. The overflow vessel surrounds another vessel, into which the measuring bell dips, whereby the same temperature is maintained in the measuring bell as in the pipette.—J. S. G. T.

Calorific value of gases; Method of determination of ——. "Union" Apparatebauges. m. b. H. G.P. 338,636, 4.1.20.

The explosion of the gas with oxygen is effected in a burette provided with stopcocks at top and bottom, and surrounded by a jacket containing liquid serving as calorimetric fluid. Hydrogen is employed in the apparatus for purposes of calibration, and its production and explosion, the production of oxygen necessary for the combustion of low-grade gases, and the combustion of the gas under examination are all effected in the same vessel, in the lower part of which sparking electrodes are disposed. The determination is thus carried out under uniform conditions of pressure, temperature, and saturation with water vapour, and the result gives the gross calorific value of the dry gas at N.T.P. without the necessity of correction.—J. S. G. T.

Glass vessels containing a wire adapted to be heated to incandescence. E.P 167,280. *See* VIII.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY.

Evaporator designs; Studies in ——. V. W. L. Badger. Amer. Inst. Chem. Eng., 7.12.20. Chem. and Met. Eng., 1921, 25, 458—463. (*Cf.* J., 1920, 647 A, 681 A, 711 A.).

Experiments were made to test the relation between hydrostatic head and heat transmission in a horizontal tube evaporator. Temperatures in the vapour space were obtained indirectly from the pressure; those of the steam chests were measured directly. Under any ordinary conditions the heat transmitted from superheat of the steam is small compared with the latent heat of condensation, and, whatever the effect of the former, it is not of importance. The results, as shown on curves, indicate that, at any rate for evaporators of design similar to that used in the tests, the maximum capacity occurs when the tubes are from half to two-thirds submerged in the liquid; the head corresponding to maximum capacity rises as the apparent temperature drop diminishes; the maximum apparent heat transmission coefficient is 105—108% of that when the heating tubes are completely submerged; the ratio of corrected heat transmission coefficients for different temperature drops is constant for all levels above the optimum. —C. I.

Filter press; An improved type of ——. C. D. Burchenal. Chem. and Met. Eng., 1921, 25, 476—480.

A modification of the plate and frame filter is described, in which a large filtering surface is maintained by preventing bedding of the cloths against the plates. The press (Duplex press) has double inlets and outlets and a pair of wide-mesh double crimp wire screens in each chamber acting as a support for the filter cloths; the screens are carried on widely spaced diagonal reinforcing ribs cast on each plate, those on one side being perpendicular to those on the opposite side of the chamber. The resulting freedom of filtering surface at all times allows each filter chamber to be of much larger capacity than is usual in the ordinary type of press. To prevent breakage of plates due to accidental plugging of the inlet to an adjacent frame, four wide flaring inlet openings to each frame are provided, the use of two of these in the upper corners when first filling thus allowing of the venting of air through one as it is displaced by the incoming liquid through the other. The use of two $\frac{3}{4}$-in. outlet channels at the bottom corners allows filtrate to be easily carried away when running at maximum rate. The drainage from the front face of each plate is connected with the right-hand channel only, while the back of each plate is connected with the left-hand channel only, the filtrate passing through a short sight-glass and stopcock and back into an nternal channel. By this means a defective cloth can be detected and the flow to it shut off without nterrupting the flow from the cloth on the other side of the plate. Washing can take place in either direction by admission of the wash water nto either the lower left hand or right hand eye. The inlets in the upper corners of the frames may also be used for washing, or compressed air for drying introduced in the same way or through one of the lower eyes. A drip-sheet, split longitudinally into two overlapping halves, each carried on a haft parallel to the axis of the press and inclined owards one of its lower edges, which is turned to orm its own gutter, can be swung down in its wo halves when not in use, and then serves as xtensions to the floor hopper below.—A. de W.

Patents.

Filter presses. Worthington Pump and Machinery Corp., Assees. of J. J. Berrigan. E.P. 140,798, 25.3.20. Conv., 9.3.18.

Two co-operating pressing members or platens forming the ends of the press are raised or lowered and thus moved away from or towards each other by fluid pressure devices, *e.g.*, a cylinder and piston acting through intermediate mechanism carrying the pressing members, the fluid pressure devices being so mounted as to be free from the weight of the pressing members. The intermediate mechanism may comprise a pair of levers fulcrumed on pedestals connected by tie members, each lever being pivoted at one end to one of the pressing members and at the other end to the cylinder or piston. Intermediate pressing members or partitions are freely suspended on supports carried by the end pressing members.—H. H.

Filter press for continuous filtration. J. Kunz. G.P. 339,403, 23.5.20.

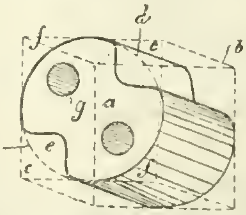
A longitudinal channel traverses the press, passing through apertures in the lower part of the filter plates and frame, and a stirring device is mounted in the channel. By the use of a smooth-working pressure device and slow stirring the material to be filtered is forced from the channel through slots in the hollow frame, and the liquid is displaced and the cake washed by washing liquid forced through channels in the upper part of the press. The residue is then detached and stirred into a paste by impulsive operation of the pressure of the washing fluid and vigorous operation of the stirring device. and discharged.—J. S. G. T.

Automatic supply of liquid to replace amounts discharged in processes of filtration, percolation, and the like; Apparatus for ——. W. T. Keeling. E.P. 168,262, 7.10.20.

Liquid is supplied as required to a filtering funnel, percolator, or like receiver by a siphon device controlled by the supply of air through a tube the lower end of which is sealed or opened by the rise or fall of the liquid level in the receiver. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 12,894 of 1897, 17,057 of 1908, 24,234 of 1910, and 19,094 of 1913.)—H. H.

Filling material for reaction or absorption columns or the like. G. Wunderlich u. Co. G.P. 335,471, 15.7.19.

A filling material, combining the advantages of cubical and spherical packing material, is derived from a cube by cutting away opposite edges so as to form re-entrant angles which are then rounded off (see fig.), while the two remaining parallel edges are rounded off as shown. Two holes are bored longitudinally from end to end of the material, and the surface is channelled irregularly. —J. S. G. T.



Packings for refrigerating machinery for the liquefaction of gases. G. F. Jaubert. E.P. 147,019, 6.7.20. Conv., 17.5.18.

The packings consist of pure graphitic carbon moulded and baked at a high temperature.
—B. M. V.

Drying colloids; Method of ——. G. P. Lunt. E.P. 159,465, 25.2.20.

A colloidal material (*e.g.*, smokeless powder) is dried by circulation of a gas (sulphur dioxide, carbon dioxide) which at one place takes up vapour of the solvent or disperse medium (ether) and at another place is freed from the solvent by washing with another liquid (alcohol) in which the first liquid is soluble. The composition of the drying medium is regulated by varying the volume and/or temperature of the washing liquid.—B. M. V.

Kilns; Cylindrical ——. W. J. Mellersh-Jackson. From Fuller-Lehigh Co. E.P. 168,245, 21.8.20.

The outer shell of a rotary kiln is formed of a number of similar longitudinal sections with radial flanges extending outwards along their longitudinal edges. Adjacent flanges of adjoining sections are fastened together so that a cylinder with a smooth interior surface is formed. The lining is formed of a number of longitudinal sections adapted to fit together to form a smooth cylindrical interior surface.—H. H.

Grinding or crushing machines. W. E. Trent. E.P. 168,551, 1.12.20.

A ball or rod mill is formed with an inner main grinding chamber in which the material to be ground travels in one direction and is then returned in the opposite direction through one or more auxiliary grinding chambers rotating with the main chamber and preferably containing smaller balls or rollers. Progression of the material may be caused either by water or an air blast, and the chambers are preferably tubular.—B. M. V.

Mixing, impregnating, washing, concentrating and grading processes; Method for controlling ——. K. Schultze and A. Stirm. G.P. 338,385, 29.12.18.

A substance possessing a high coefficient of absorption for Röntgen rays is added to the material to be treated, and the mixture exposed to Röntgen rays. The course of the mixing, impregnating, washing, etc. process can then be followed.—J. S. G. T.

Mixing granular, powdered, or like substances; Means for ——. A. B. Smith, H. A. Skelley, and Continuous Reaction Co., Ltd. E.P. 168,729, 2.7.20.

A rotary mixer is constructed of a number (preferably an odd number) of pockets or chambers of pyramidal shape, increasing in cross-section towards the axis of the mixer, and arranged with their bases forming the sides of a prism on the axis of which the mixer rotates. In the mixer illustrated there are three pockets or chambers of rectangular cross-section.

Surface condensers; Process of keeping —— *free from scale and sludge.* Maschinenbau-A.-G. Balcke. G.P. 339,395, 10.7.20. Addn. to 331,292 (*cf.* E.P. 135,189; J., 1921, 203 A).

Prior to treatment with hydrochloric acid, the water is passed over a device for exposing a large surface, and undergoes a preliminary softening treatment, so that only a relatively small proportion of acid is required for removing the residual hardness.—J. S. G. T.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Hydrocyanic acid; Absorption of —— *[from coal gas].* J. G. Taplay. Gas J., 1921, **155**, 589—590.

Hydrocyanic acid was completely removed from crude coal gas passed through 1 lb. of chalk at the rate of 20 cub. ft. per day until 550 cub. ft. of gas had passed. The chalk was used dry, and when saturated with hydrocyanic acid compounds contained 7% of free sulphur. When the chalk was sprayed with water no free sulphur was formed, but ammonium thiocyanate was carried away in solution. It is suggested that the chalk should be sprayed with ammoniacal liquor.—H. Hg.

Hydrocyanic acid and carbon bisulphide; Recovery of —— *from coke-oven and town's gas.* M. Minot. Chim. et Ind., 1921, **6**, 135—140.

The gas, cooled and freed from tar, is treated with a solution of sodium polysulphide containing about 80 g. per litre, and maintained at a temperature of 60° C. The resulting solution contains ammonium thiocyanate, sodium carbonate, ammonium thiocarbonate, and a little ammonium thiosulphate. The liquor is distilled and the ammonia recovered, the thiocarbonate decomposing yielding thiocyanate, which is recovered from the dried residue. Details are given of suitable plant and working costs.—W. P.

American crude oils; Viscosity-temperature curves of fractions of typical ——. E. W. Dean and F. W. Lane. J. Ind. Eng. Chem., 1921, **13**, 779—786.

Fractions of Pennsylvania, California, and Wyoming crude petroleums were prepared by distilling 300 c.c. of the oil in a glass flask provided with a Hempel column until a vapour temperature of 275° C. was reached. The flask and its contents were then cooled, and the Hempel column was replaced by a spray-catching device consisting of three inverted gauze cones. The flask was then attached to a vacuum system and distillation continued at a pressure of 40 mm. until a vapour temperature of 300° C. was reached. Fractions were separated at intervals of 25° C. The viscosity determinations were carried out in specially constructed Ostwald viscosimeters, each of which was standardised against · two liquids of known viscosity. Viscosity-temperature curves show with California fractions the greatest change, and with Pennsylvania fractions the least change in viscosity with change of temperature, whilst the Wyoming fractions show characteristics which are intermediate between the two. The viscosity-temperature curve of undistilled residue from the Pennsylvania crude oil is of the same type as the curves for the distilled fractions, and the curve for a mixture of the residuum and the distillate shows the same characteristics as for the unblended distillates. The curve for a mixture of Pennsylvania residuum and California distillate averages the characteristics of the two constituents. The kerosene fractions of each of the oils give curves which show the same qualitative relationships as those for the lubricating oil fractions. The viscosity-temperature curves may be represented by an equation of the form $V_K = 1/(K + At + Bt^2)$, where V_K is the kinematic viscosity, t the temperature, and K, A, and B are constants characteristic of each individual fraction from each crude oil. The results fail to indicate a reliable general method for calculating a viscosity-temperature curve for an oil unless at least three experimentally determined points are known.—S. S. A.

Asphalt in the tar sands of Northern Alberta; Chemical investigation of the ——. V. K. Krieble and W. F. Seyer. J. Amer. Chem. Soc., 1921, 43, 1337—1349.

The asphalt from the Alberta tar sands when analysed by Marcusson's method (J., 1916, 1099) gave 2·0% of saponifiable matter, 22·5% of asphaltenes, 24·0% of resins, and 51·5% of oily constituents. The free acids could not be estimated owing to the formation of emulsions, and they are, therefore, included in the saponifiable matter. The ultimate composition of the asphalt was 2·73% S, 84·49% C, 11·23% H, and 0·04% N. To extract the hydrocarbon oil from the asphalt the tar sands were extracted at the ordinary temperature with light petroleum, b.p. below 55° C. This removed the oil and resins. After allowing the fine sand to settle, the extract was filtered through fuller's earth, whereby the resins were retained. From the filtrate the petroleum was distilled off on a water-bath. The residual hydrocarbon oils could be distilled unchanged up to 300° C., without the aid of a current of carbon dioxide, provided the pressure was kept below 0·4 mm. Thirteen apparently pure hydrocarbons belonging to the series C_nH_{2n}, C_nH_{2n-2} and C_nH_{2n-4} were isolated.—W. G.

Patents.

Peat briquettes; Manufacture of —— from dried peat and concentrated sulphite cellulose waste liquor by the cold process without employment of high pressure. A. Röbelen. G.P. 339,401, 23.3.20.

The moulded briquettes whilst drying are turned over at intervals so that a uniform layer of sulphite-cellulose waste liquor forms over the whole surface and acts as an airtight crust. The hygroscopic properties of the waste liquor may be reduced by the addition of talc, kieselguhr, alum, asbestos, or alkaline solutions of resin or horn, to the mixture before forming the briquettes.—L. A. C.

Combustion of pulverulent fuel with production of Portland cement. T. Fujiyama. E.P. 168,406, 31.5.20.

Pulverulent fuel is mixed with such a quantity of lime, and if necessary quartzite or ganister, that upon combustion of the fuel the ash will combine with the added material to form · cement clinker containing 60%—67% lime, 19%—27% silica, and 7%—14% iron oxide and alumina. The mixture is fed to a burner between which and the boiler or heater there is placed a rotating chamber wherein the clinker is deposited. From the lower end of this chamber the clinker is discharged into a cooling device.—H. Hg.

Coke-ovens; Regenerative ——. C. Otto und Co., G.m.b.H. E.P. 147,741, 8.7.20. Conv., 10.1.18.

In connexion with sub-heated regenerative ovens such as are described in E.P. 147,231 (J., 1921, 501 a), separate connecting channels are provided between the preheating chamber and the air flue and waste-heat outlet flue respectively. Each channel contains a damper, and both dampers may be operated from the subway through one opening. —H. Hg.

Vertical [gas] retorts. C. W. Tozer. E.P. 168,229, 30.7.20.

Vertical retorts with intercommunicating distillation chambers arranged around a central tube, as described in E.P. 20,158 of 1909 (J., 1910, 685), are mounted in a furnace the hot zone of which extends both above and below the chambers. The lower end of each chamber is shaped to form a conical open end which is closed by a conical false bottom. A flange on the false bottom makes a gas-tight joint with the outer casing of the retort, while leaving a space between the open end of the retort and the false bottom. The outer casing is provided with external ribs arranged vertically or spirally. —H. Hg.

Gas; Production and utilization of [fuel] ——. C. B. Tully. E.P. 168,432, 8.6.20.

The gas escaping from the heating chamber of a retort superimposed upon a producer and which results from the admission of air to the producer for the purpose of raising the fuel therein to incandescence, is passed through a gas washing box for the recovery of tar and ammonia. The gas from several heating chambers may pass through one box and then be burnt in a boiler furnace.—H. Hg.

Mixed [fuel] gases; Retorts and apparatus for production of ——. F. H. Robinson. E.P. 168,535, 2.10.20.

A setting of horizontal retorts and a gas producer are arranged so that the open ends of the retorts communicate with a chamber placed directly over the producer. The blow gases escape through an uptake leading from below the level of the chamber and retorts; the chamber serves to retain any gas generated in the retorts during the blow. During the run water-gas passes into the chamber and thence through the retorts; any gas which escapes into the heating flues surrounding the retorts is burnt upon the admission of air through nostrils during the following blow. The discharge of the blow gases and the admission of air and steam to the apparatus are controlled by the operation of one hand lever.—H. Hg.

Filtration of blast furnace and like gases. Halbergerhütte, G.m.b.H. E.P. 168,279, 17.1.21. Conv., 1.12.20.

The gases are forced, under the pressure at which they leave the furnace, through a dust separator, a cooler, a superheater, a filter, and a final cooler in series. A fan is provided for withdrawing a portion of filtered gas from the filter outlet and forcing it through the filter in the reverse direction for cleaning purposes.—H. Hg.

Sulphur from gases; Process for removing ——. South Metropolitan Gas Co., E. V. Evans, H. Hollings, and H. Stanier. E.P. 168,482, 9.7.20.

Coal gas from which hydrogen sulphide has been removed is washed with creosote oil to which 5·5% to 6·0% of benzol has been added, the quantity of oil used being not less than 500 galls. per million cub. ft. of gas treated (*cf.* E.P. 2318 of 1899, J., 1900, 134). When carbon bisulphide has been previously removed the gas is passed at the rate of 2,000,000 cub. ft. per day through a washer supplied with 2500 galls. of oil-benzol mixture per day for the removal of thiophen etc. If carbon bisulphide is not previously removed from the gas a larger proportion of oil-benzol mixture is used. Instead of using an oil-benzol mixture the gas may be washed with benzol and then with oil to remove excess benzol from the gas, or the gas may be washed with oil only, after the addition of benzol vapour to the gas. Paraffin oil containing suspended alumina or charcoal may be used instead of creosote oil. The spent oil and benzol are purified and returned to the process. Naphthalene removal may be combined with thiophen removal if the oil is heated in steam during each cycle.—H. Hg.

Hydrogen sulphide from gases; Process for removing ——. South Metropolitan Gas Co., E. V. Evans, and H. Stanier. E.P. 168,504, 29.7.20.

Coal gas freed from tar and ammonia is washed with a solution of an organic compound capable of being alternately reduced by hydrogen sulphide and oxidised by air. It is necessary to use a catalyst of a basic nature; when pyridine or quinoline is used as a solvent it acts as such. Suitable compounds are certain of the azine, thiazine, oxazine, triphenylmethane, and indigoid dyestuffs, indamines, indophenols, and the sodium salts of their sulphonic acid derivatives. A saturated solution of Methylene Blue in a pyridine-water mixture containing 20% of pyridine and a saturated solution of Methylene Violet in coal tar bases are mentioned as examples of washing agents; benzol is added to each of these to prevent removal of light oils from the gas. Any solvent carried forward by the gas is arrested by washing with sulphuric acid. The reduced dyestuff is re-oxidised by blowing air through the solution and sulphur is recovered as such.—H. Hg.

Motor-fuel. E. W. Stevens, Assr. to Chemical Fuel Co. of America, Inc. U.S.P. 1,388,531, 23.8.21. Appl., 9.3.20.

A mixture of a petroleum oil, ethyl alcohol, methyl ethyl ether, and an oily material serving to blend the alcohol and oil and retain the ether, is suitable for use as a gasoline substitute.—L. A. C.

Liquid fuels; Diluent for ——. A. Wipfler. G.P. 339,139, 2.10.20.

Sulphite-cellulose waste liquor is added to oil or the like for spraying into combustion chambers.
—L. A. C.

Hydrocarbon oils; Distillation or cracking of ——. C. Dalley. From T. J. Greenway. E.P. 168,335, 26.2.20.

Oil is fed into the top of a vertical retort packed with shale, firebrick, or the like supported on a grate at the lower end. Air admitted below the grate serves for the combustion of unvolatilised oil, or of fresh oil or gas admitted into the retort above the grate. The retort may also be heated externally. Gases and vapour leaving the retort through an opening near the top pass through a heated flue, in which the vapour is subjected to a further cracking action, and thence into a condenser.—L. A. C.

Oils; Lubricating ——. H. M. Wells and J. E. Southcombe. E.P. 168,076, 17.2. and 17.12.20.

Oil-soluble organic bases, *e.g.*, 0·5% of *p*-toluidine, or amino-acids or their salts, *e.g.*, 0·1% of glycocholic acid, are added to lubricating oils without the addition of water.—L. A. C.

Oil-retorts; Process of heating —— and apparatus therefor. C. M. Alexander, Assr. to Gulf Refining Co. U.S.P. 1,387,677, 16.8.21. Appl., 14.3.16.

Furnace gases are brought in contact with a partition, constructed of heat-conducting material, spaced away from an oil-retort or the like. Heat is transmitted to the retort by radiation throughout the length of the partition. The gases subsequently pass between the retort and the partition.—L. A. C.

Hydrocarbon oils; Purifying ——. (a) E. B. Cobb and (b) C. I. Robinson, Assrs. to Standard Oil Co. U.S.P. (a) 1,387,835, and (b) 1,387,868, 16.8.21. Appl., (a) 28.4. and (b) 13.3.20.

(a) Oil is treated with strong sulphuric acid, oil-soluble sulphonates are removed, and, after further treatment with sulphuric acid, the oil is washed with isopropyl alcohol. (b) Sulphonated compounds are removed from acid-treated petroleum oil by mixing the oil with isopropyl alcohol, which is subsequently separated from the oil.—L. A. C.

Kerosene and like hydrocarbon oils; Method of lowering the boiling and flashing point of ——. W. M. Wheeler, Assr. to Ozmo Oil Refining Co. U.S.P. 1,387,876, 16.8.21. Appl., 7.8.18.

A mixture of kerosene or other oil vapour and steam is heated under slight pressure at a gradually increasing temperature. The pressure is reduced to that of the atmosphere, the vapour is heated to a higher temperature, and subsequently condensed. The oil is separated from the aqueous layer in the condensed liquid by gravitation.
—L. A. C.

Oil; Apparatus for treating ——. C. Ekstrand; M. Ekstrand, extrix. U.S.P. 1,388,415, 23.8.21. Appl., 21.11.17.

Oil is fed under pressure through a retort connected with an expansion and mixing chamber by two contracted nozzles of different sizes, fitted with valves, for admitting the vapour from the retort into the chamber and projecting it against a baffle-plate therein.—L. A. C.

Petroleum hydrocarbons; Distillation [and cracking] of ——. E. M. Clark, Assr. to Standard Oil Co. U.S.P. 1,388,514, 23.8.21. Appl., 14.12.15.

High-boiling oils are distilled under a pressure sufficiently high to effect decomposition to lower-boiling products. The vapours are led away, under the pressure prevailing in the still, to a condenser through a conduit which also serves for introducing fresh oil into the still.—L. A. C.

Hydrocarbons; Cracking ——. J. W. Coast, jun., Assr. to The Process Co. U.S.P. 1,388,629, 23.8.21. Appl., 27.9.17.

Low-boiling oil is heated in a cracking coil at high temperature and pressure and the contents of the coil are discharged into a still containing a high-boiling oil maintained at a lower temperature and pressure than the low-boiling oil.—L. A. C.

Oils; Manufacture of viscous water-white —— and other decolorised products of petroleum. Manufacture of medicinal oils and other viscous decolorised products of petroleum. E. B. Cobb, Assr. to Standard Oil Co. U.S.P. (a) 1,388,517, and (b) 1,388,832, 23.8.21. Appl., (a) 23.7.14, and (b) 7.6.17.

(a) Oil of viscosity above 40 secs. at 100° F. (38° C.) is treated with sulphuric acid, and, after removal of the acid sludge, is distilled with the use of a special agent to prevent decomposition of component hydrocarbons, thus obtaining a distillate of viscosity above 40 secs. at 100° F. The distillate, after treatment with sulphuric acid and subsequent removal of the acid sludge, is filtered through solid decolorising material. (b) Stock of viscosity above 80 secs. at 100° F. for the manufacture of decolorised hydrocarbon oil is composed of distillates, of different types of petroleum, which are as a whole of different viscosities, and the respective hydrocarbons of which have equal gravities over a range of gravities corresponding with the lighter end of the more viscous distillate. From 50 to 95% of the stock is distillate which as a whole is heavier and more viscous than the stock, and in which the hydrocarbons are less viscous than those of the same sp. gr. in the remainder of the stock.—L. A. C.

Hydrocarbons; Process for oxidising liquid —— and their oxidation products. G. Teichner. E.P. 148,358, 9.7.20. Conv., 15.5.19.

Hydrocarbon oil, such as refined Galician spindle oil, sp. gr. 0·87, is freed as completely as possible from hydrocarbons other than those of the methane series by treatment for ½—1 hr. at 60°—80° C. with about half its weight of 20% oleum. The residual oil is readily oxidised by air or oxygen in the presence of a catalyst, *e.g.*, zinc stearate, at 110° C., yielding a product of which the saponification value may vary between 150 and 360 according to the length of oxidation, *i.e.*, about 3 to 20 hrs.
—L. A. C.

Fatty acids; Process and apparatus for converting hydrocarbon into ——. Deutsche Erdöl A.-G. E.P. 148,892, 10.7.20. Conv., 12.7.19.

Liquid hydrocarbon material, *e.g.*, petroleum oil, is sprayed through atomisers into the top of a cylindrical vessel heated to about 80° C. and packed with filling material, *e.g.*, pumice stone, which may be impregnated with a catalyst such as nickel oxide. Oxygen, either alone or diluted with nitrogen or carbon dioxide, is pumped into the lower end of the cylinder; the gas leaves the apparatus at the upper end, and, after passing through condensers and scrubbers, is returned again to the cylinder, fresh oxygen being added as required. The hydrocarbon material passes from the lower end of the cylinder into the reservoir supplying the atomisers, and is passed again through the process until the desired degree of oxidation is attained.—L. A. C.

Producer-gas; Generation and utilisation of ——. A. H. Lymn. U.S.P. 1,388,052, 16.8.21. Appl., 18.8.20.

Gas analysis. G.P. 338,301. *See* XXIII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Wood; Distillation of —— in vacuo. O. Aschan. Brennstoff-Chem., 1921, 2, 273—276.

Birchwood was distilled *in vacuo* at 150°—160° C. The yield of acetic acid was about the same as at atmospheric pressure—about 6·9% reckoned on the dried wood. The yield of charcoal increased from about 33% to 45%. Acetone was probably not formed owing to the lower temperature of distillation, and to recover methyl alcohol it would be necessary to compress the more volatile portion of the distillation products.—W. P.

Patents.

[Tungsten] filaments and like bodies. The British Thomson-Houston Co., Ltd., From General Electric Co. E.P. 168,669, 5.6.20.

The tendency of tungsten filaments to disintegrate or vaporise when operated at high temperatures in incandescence electric lamps, discharge tubes, X-ray tubes, etc. is reduced by manufacturing the filaments from an alloy prepared by mixing tungsten with not more than 2% by weight of iron, and submitting the mixture to heat treatment for such a period that the iron content is reduced to materially less than 1% but not materially less than 0·1% by weight of the whole. Filaments made from the alloy are relatively fine grained and are stable at high temperature. When prepared by the wire-drawing process they show a reduced tendency to "offset" compared with filaments prepared from ordinary tungsten.—J. S. G. T.

Incandescence mantles; Manufacture of ——. Auerlicht-Ges.m.b.H., Kommanditges. G.P. 339,176, 17.2.20. Addn. to 306,621 (J., 1918, 618 a).

Water used in washing raw material for use in the manufacture of incandescence mantles is softened by replacing salts of heavy metals, earth metals, alkaline-earth metals, and alkali metals by readily volatile salts of ammonium or organic bases, *e.g.*, by treatment with an aluminate-silicate (permutite).
—L. A. C.

III.—TAR AND TAR PRODUCTS.

Nitro-compounds; Colour reactions of some ——. O. Rudolph. Z. anal. Chem., 1921, **60**, 239—240.

The following reactions are obtained when about 1 mg. of the substance is dissolved in 10 c.c. of alcohol or acetone and the solution treated with 2 c.c. of dilute sodium hydroxide solution or ammonia:—

	Alcohol solution.		Acetone solution.	
	With NaOH.	With NH_3.	With NaOH.	With NH_3.
o-Dinitrobenzene ..	Colourless	Colourless	Colourless	Colourless
m-Dinitrobenzene ..	Colourless	Colourless	Red-violet	Red to purple
p-Dinitrobenzene ..	Colourless	No characteristic colour	Yellow	Yellow
1.3.5-Trinitrobenzene	Yellowish red	Yellowish red	Red	Red
2.4-Dinitrotoluene ..	Blue	Colourless	Blue	Colourless
2.6-Dinitrotoluene ..	Colourless	Colourless	Faint red	Colourless
2.4.6-Trinitrotoluene	Yellowish red	Red	Purple red	Red
1.8-Dinitronaphthalene	Yellowish red	Red	Yellowish red	Red

Quinol. **Bezssonoff.** *See* XIXa.

Patents.

Organic bodies; Purification of —— by distillation. F. W. Berk and Co., Ltd., and J. J. Wood. E.P. 168,108, 24.4.20.

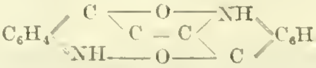
Crude organic substances are purified by fractional distillation in the presence of complex mineral oils boiling within certain limits depending on the boiling points of the substances to be separated. For example, a solution of crude resorcinol in amyl alcohol, obtained in the manufacture of resorcinol from benzene, is distilled with kerosene of b.p. 150°—320° C.; after water, amyl alcohol, and the lower-boiling fractions of oil have distilled, traces of phenol distil with the fraction 180°—190° C., while resorcinol begins to distil between 205° and 210° C., and is extracted from the distillate with water. Crude anthracene and anthraquinone are distilled with oils of b.p. 300°—450° C. and 250°—320° C. respectively; the products are separated from oil by filtering or centrifuging, and washed with light petrol. Alternatively, a mixture of compounds to be separated, such as carbazole, anthracene, and phenanthrene, may be heated with oil in a still to a suitable temperature for distilling the lowest boiling compound in the mixture, and steam is blown through the mass until the compound has all passed over; the treatment is then repeated at higher temperatures suitable for distilling the other constituents of the mixture.—L. A. C.

Resinous products. G.P. 338,854. *See* XIII.

IV.—COLOURING MATTERS AND DYES.

Indigo. W. Madelung. Z. angew. Chem., 1921, 34, 482—483, 486—488.

The question as to how far Baeyer's formula for indigotin is in agreement with the chemical behaviour and physical properties of indigotin, and known facts with regard to the relation between colour and chemical constitution, is critically discussed. It is concluded that the facts are more correctly interpreted by the following formula:—



The point of real importance in this formula is that the carbonyl and imino-groups are at each end of a five-membered conjugated system, thus $O-C-C=C-NH$. Such an arrangement is to be found in other vat dyes of both the indigoid and anthracene series. The stability and technical utility of these dyes is attributed to this atomic grouping, which is as important in this series as is the proximity of the carbonyl and hydroxyl groups in the dyes of the alizarin series, where the chain $O=C-C=C-OH$ plays a similar rôle. If this formula is accepted, indigotin is to be regarded as a derivative of the coloured and stable modification of dibenzoylethylene. (*Cf.* J.C.S., Nov.)—F. M. R.

Malachite Green; Electrolytic oxidation of the leuco-base of ——. A. Lowy and E. H. Haux. Trans. Amer. Electrochem. Soc., 1921, 99—104. [Advance copy.]

The results of forty-four experiments on the electrolytic oxidation of the leuco-base of Malachite Green are tabulated. No appreciable oxidation occurs in the absence of a catalyst, and the best result was obtained by the use of uranyl sulphate. Electrolysis at an elevated temperature is essential for efficient oxidation, and low concentration of the leuco-base promotes oxidation. The apparatus used consists of a large vessel in which an anode of two lead plates coated with an electrolytic deposit of lead peroxide is placed and a porous cup containing 8% sulphuric acid and a platinum cathode. 10 g. of dry leuco-base is suspended in 20 c.c. of water, 17 g. of concentrated sulphuric acid containing 0·1 g. of uranyl acetate is added, and the mixture is boiled until solution is complete. The solution is diluted to 2 l., poured into the anode compartment, and heated to 80° C. The electrodes are placed in position and the temperature maintained at 80° C. with continuous agitation for about 3 hrs. until oxidation is complete. A current of 1 amp. is used with a potential drop across the terminals of the cell of 4·5 volts. The electrodes and porous cup are removed, the free acid neutralised with sodium bicarbonate, the solution filtered, and 15 g. of zinc sulphate and 150 g. of salt are added with agitation. The zinc sulphate double salt of the dye crystallises after standing for 12—15 hrs. The yield of colour of standard strength is 57%, but in operating on a larger scale this yield would be increased materially.—F. M. R.

Patents.

Intermediate products and colouring matters therefrom; Manufacture of —— and their application in dyeing and printing. J. Y. Johnson. From Badische Anilin- und Soda-Fabr. E.P. 168,447, 16.6.20.

α-Naphthoquinone is heated in the presence of water, whereby it yields, in addition to α-naphthoquinol, a yellow condensation product which on reduction yields green vat and pigment dyestuffs. For example, 4 pts. of α-naphthoquinone is heated, under agitation, with 5 pts. of water in an autoclave for about 2 hrs. at 120°—130° C. The α-naphthoquinol is extracted with boiling water and after re-conversion into naphthoquinone can be used again. The residue is purified by boiling it with dilute caustic soda, vatting it in hydrosulphite made alkaline with sodium carbonate, and then reoxidising it, so as to obtain a greenish-yellow product which is extracted with boiling nitrobenzene and then crystallised from cresol in the form of pale yellow needles. These are insoluble in water, dilute acids and alkalis, and solvents of low b.p., and only soluble with difficulty in certain solvents of high b.p.; when heated above 300° C., the product decomposes without fusing. The yellow condensation product is obtained directly in crystalline form if 10 pts. of α-naphthoquinone dissolved in 60 pts. of phenol is boiled (water is added so that the b.p. is about 120° C.) so long as the crystalline precipitate gradually formed still remains yellow (about 40 hrs.). This is filtered off, after cooling, and freed from excess of phenol by means of alcohol or the like. For the reduction, 1 pt. of the yellow condensation product is dissolved in 10 pts. of concentrated sulphuric acid, and 2 pts. of zinc dust gradually added while the mixture is stirred and cooled with ice. The product is poured into ice-water and the insoluble pigment dyestuff, in the form of flakes, is then filtered off and dried or made into a 10% paste. It is insoluble in water, dilute acids and alkalis, and in solvents of low b.p., but it dissolves in concentrated sulphuric acid to give a brown solution and crystallises from nitrobenzene is matted green needles or steel-blue granules which slowly decompose without fusing at temperatures above 300° C. The green pigment may be used as a vat or sulphur dyestuff for dyeing and printing wool and cotton, since it is easily reduced by means of sodium hydrosulphite and sodium sulphide. It may also be used in paints.—A. J. H.

Ortho[hydr]oxyazo dyestuffs; Manufacture of ——. A. G. Bloxam. From Akt.-Ges. für Anilin-Fabrik. E.P. 168,681, 8.6.20.

A diazotised *o*-aminophenol derivative containing one or more halogen atoms, or one or more nitro-groups, or both, or a homologous compound, is coupled with an alkaline solution of 8-halogeno-α-naphthol-5-sulphonic acid. The products are mordant dyes for wool, and the chromium lakes possess good fastness. For example, the dyestuff from 4-chloro-2-aminophenol and 8-chloro-α-naphthol-5-sulphonic acid dyes wool a dark blue with chromium mordants, whilst the corresponding dyestuff from 4-nitro-2-aminophenol dyes wool from an acid bath in Bordeaux shades which become black on chroming.—F. M. R.

Dyestuffs and process of making the same. G. de Montmollin and H. J. Spieler, Assrs. to Society of Chemical Industry in Basle. U.S.P. 1,387,596, 16.8.21. Appl., 21.9.20.

A tetrahalogenated methane is condensed with a derivative of α-naphthol, in which position 4 is not substituted, in presence of an alkaline condensing agent and a catalyst.—F. M. R.

Indophenols or their leuco-derivatives; Manufacture of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 338,817, 10.10.14.

Equimolecular proportions of tetrahydro-α-naphthylamine or its mono- or dialkylamino-derivatives and *p*-aminophenol or its substitution products are oxidised in acid solution with sodium bichromate. The resulting indophenols may be reduced to the leuco-bases in the usual manner. These indophenols, which are dark blue, dissolve in sodium hydroxide with a powerful red coloration, and are used for the production of fast blue sulphur dyestuffs. The indophenols from *p*-aminophenol dissolve in concentrated sulphuric acid with a dark blue colour, whilst those from 2.6-dichloro-4-aminophenol dissolve with a violet coloration. The alcoholic solutions of the former are pale blue coloured, and of the latter bluish-green. The indophenols are readily reduced by sodium sulphide to the leuco-compounds, which form greyish-white crystalline powders.—F. M. R.

Trisazo dyestuffs for cotton; Manufacture of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 339,183, 22.5.15.

Diazotised 1-monoacidylamino-4-aminonaphthalene-6- or 7-sulphonic acid or the corresponding nitroamino-compound is coupled with 1-aminonaphthalene-6- or 7-sulphonic acid or a mixture of these acids. The product is diazotised, coupled with β-naphthol or 2.7-dihydroxynaphthalene, the acidyl-group hydrolysed or the nitro-group reduced, the product diazotised and coupled with resorcinol. Alternatively the 1-acidylamino-4-aminonaphthalene-6- or 7-sulphonic acid or the corresponding nitroamino-compound may be diazotised, coupled with β-naphthol or 2.7-dihydroxynapthalene, the product hydrolysed or reduced, diazotised, coupled with 1-aminonaphthalene-6- or 7-sulphonic acid or a mixture of these acids, diazotised, and coupled with resorcinol. The products dye cotton direct in clear greenish-blue shades fast to light, and on after-treatment with formaldehyde fast to washing. —F. M. R.

Disazo dye. W. M. Ralph, Assr. to National Aniline and Chemical Co. Reissue 15,182, 23.8.21, of U.S.P. 1.371,979, 15.3.21. Appl., 29.6.21.

See J., 1921, 294 a. After the final coupling the nitro-group is reduced.

Removing hydrogen sulphide from gases. E.P. 168,504. *See* IIa.

Triazoles. G.P. 338,926. *See* XX.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Wood; Effect of chemical reagents on the micro-structure of ——. A. Abrams. J. Ind. Eng. Chem., 1921, 13, 786—790.

Cross, radial, and tangential sections of pine wood were cut and placed in the depressions of a microscope cell slide, which was then filled with the reagent to be studied and a plain microscope slide laid over the cell slide but separated from it 0·1 mm. by pieces of thin cover-glass. The two slides were wired together and placed in a quantity of the reagent to be studied and a plain microscope slide cess to the section whilst destructive mechanical action on the anatomical structure of the material was prevented. The sections, after treatment, were washed carefully to remove adhering liquor and dirt and then stained and mounted. Concentrated hydrochloric acid dissolved the cellulose in a more or less polymerised form, the dissolved material, on standing, being hydrolysed with the production of dextrose; the cell walls were greatly swollen and in places the cells split away from the middle lamella, which itself apparently remained unchanged. Chromic acid oxidised the lignin complex of ligno-cellulose to carbon dioxide and acids of low molecular weight such as acetic acid, and the cellulose was converted into oxycellulose or decomposition products of lower molecular weight according to the severity of the treatment; the entire structure was attacked and where the cells split apart the middle lamella was removed. The medullary rays persisted but were distinctly attacked. In sections treated with *N*/1 sodium hydroxide for 8 hours at 150° C. under 65 lb. pressure and a further 3 hours at 180° C. under 125 lb. pressure, the cell walls swelled considerably and striation appeared; the resin ducts were attacked in the early stages, the rays and middle lamella were acted upon gradually, and the tracheids were separated from one another. The ratio between the thickness of middle lamella and cell wall remains constant during treatment with cellulose solvents, but varies greatly with other reagents, indicating similarity in amounts of cellulose in these structures but larger quantities of oxidisable substances in the cell walls than in the middle lamella.—S. S. A.

Cellulose incrustations obtained in treating mercerising liquor; Properties of ——. *(Estimation of α-cellulose.)* C. G. Schwalbe and E. Becker. Zellstoff und Papier, 1921, 1, 93—94. Chem. Zentr., 1921, 92, IV., 721.

In estimating α-cellulose in wood cellulose, mainly pentosans are dissolved, but the remaining cellulose is not completely unchanged on repeated treatment with strong sodium hydroxide solution as it contains a definite proportion of readily hydrolysed cellulose. The methyl content as well as the pentosan content of wood cellulose is considerably reduced by treatment with strong sodium hydroxide solution.—L. A. C.

Straw lignin prepared by treatment with alkali carbonate. F. Paschke. Z. angew. Chem., 1921, 34, 465. (*Cf.* J., 1920, 778 A.)

THE lignin was prepared by treatment of the straw with alkali carbonate, precipitation from the extract with acid, and purification by repeated solution in alkali and re-precipitation with acid. The equivalent weight, determined by solution in excess of standard caustic soda solution and titration with phenolphthalein and methyl orange as indicators, with which lignin behaves similarly to carbonic acid, had a value of 357. This is lower than that found by Beckmann (J., 1921, 539 A) for lignin from winter rye straw, viz., 462, but the high figure is due in part to colloidal lignin passing through the filter in the method he adopted. Elementary analyses of the straw lignin gave figures corresponding to an empirical formula of either $C_{27}H_{31}O_9$, or $C_{40}H_{45}O_{13}$ from which it is apparent that this lignin differs from Beckmann's essentially in its oxygen content, the formula assigned to Beckmann's product being $C_{40}H_{44}O_{15}$. The $C_{40}H_{45}O_{13}$ formula demands an equivalent weight of 366 which is in close agreement with that actually found.—G. F. M.

PATENTS.

Textile fabrics or other materials; Preparation for use in treating —— for stiffening and proofing the same. H. E. Butterfield. E.P. 168,174, 8.6.20.

A STIFFENING and proofing composition for textile fabrics, particularly buckram and felt, consists of a solution of ester gum (glycerin resinate) 10 pts. and resin 10 pts., in 80 pts. by weight of a volatile solvent such as amyl or butyl acetate, acetone, or petrol. Fabrics impregnated with this composition are unaffected by water, and are not highly inflammable.—D. J. N.

Vegetable, animal, or artificial fibres; Process for improving ——. H. Bucherer. G.P. 339,301, 24.8.18.

THE fibres, in any form (loose, yarn, cops, or woven material), are steeped once or several times in a solution of an alkali salt of a condensation product of a phenol with an aldehyde, particularly formaldehyde, and then treated with a solution of a salt of iron, copper, aluminium, chromium, or zinc. The fibre is protected in this manner with a sparingly soluble or insoluble compound.—F. M. R.

Protective material [for fireproofing]. Art of protectively treating materials. Protective treatment of materials. A. Arent. U.S.P. (A) 1,388,827, (B) 1,388,828, and (C) 1,388,829, 23.8.21. Appl., 29.1.21.

(A) A VARNISH containing a fire-retarding antimony salt in sufficient proportion to produce a non-inflammable coating is used for fireproofing and like purposes. (B) A mixture of a drying oil, a fire-retarding antimony compound, and a volatile solvent is used for waterproofing and decreasing the combustibility of fibrous materials. (C) Fibrous material is treated with a mixture of a tarry substance and a fire-retarding hydrolysable compound of antimony. (*Cf.* E.P. 132,813, 138,641, and 146,099; J., 1921, 43 A, 466 A, 577 A.)

Viscose silk; Manufacture of ——. Vereinigte Glanzstoff-Fabriken A.-G. E.P. 139,481, 24.2.20. Conv., 25.7.18.

THE acid precipitating bath described in E.P. 166,294 (J., 1921, 620 A) is maintained at a temperature of about 45° C., the thread being drawn off at the increased rate of 50—60 m. per minute. The higher temperature does not materially affect the strength and elasticity of the fibre.—D. J. N.

Artificial silk; Treatment of —— for industrial uses. Chem. Werke vorm. Auerges. m.b.H., Kommanditges. G.P. 338,653, 23.3.17.

ARTIFICIAL silk is steeped in solutions of salts of iron, chromium, or the like, hydro-extracted, dried, and treated with ammonia, which may be diluted with air to prevent excessive rise in temperature. The increase in weight with one treatment is about 50%. As this treatment colours the silk, precautions must be taken in dyeing the material to allow for the effect of the colour on the final shade.
—L. A. C.

Cellulose ethers; Process for the production of plastic bodies [insulators] of ——. G. Leysieffer. E.P. 156,752, 7.1.21. Conv., 10.1.20.

A CELLULOSE ether is kneaded into a pasty mass with a volatile solvent, *e.g.*, benzol, alcohol, acetone, etc., and passed in thin sheets between hot rollers to volatilise the solvent. The dry brittle sheets so obtained are finely powdered, and pressed into steel moulds at a temperature sufficiently high (*e.g.*, 160° C.) to melt the cellulose ether and give a homogeneous mass. The resulting product remains unchanged at temperatures up to 140° C., and makes a very efficient insulating material.—D. J. N.

Plastic [cellulose acetate] compound and process. W. G. Lindsay, Assr. to The Celluloid Co. U.S.P. 1,388,472, 23.8.21. Appl., 1.9.16.

PLASTIC material is composed of cellulose acetate, borneol, and a miscible medium.—J. S. G. T.

Paper and the like; Process for the manufacture of pulp for making —— [from peat]. A. L. Burlin. E.P. 168,355, 3.7.20.

FRESHLY dug peat, freed from foreign matter, is digested for about 2 hrs. with 0·2—2% caustic soda solution, or in the case of fine, fibrous peat with a 1—10% solution of soda crystals, then washed, and immersed in a 2% solution of bleaching powder for ½ hr., at the end of which a small quantity of sodium bicarbonate solution is stirred in. The pulp is then washed, acidified with very dilute acid, preferably sulphuric acid, and again washed until neutral. If a white fibre is required, the pulp is bleached for 2 hrs. with a 2% solution of bleaching powder; sodium bicarbonate solution is then added, and after a further ½ hr. the pulp is washed until it contains no black specks.—D. J. N.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Spent alkaline bleach liquors; Process for regenerating ——. M. Freiberger. Textilber., 1921, 2, 345—348.

Spent alkaline liquors may be used again after suitable treatment by which about 84% of their original alkali content is recovered at a cost not greater than one-third of the original value. Fat (1·5—2 g. per l.), cellulose, wood-gum (11·4 g. per l.), and colouring matters are the chief impurities in spent liquors. The cellulose content of spent liquors is about 2·65 g. per l., but it varies greatly with the method of kier boiling. For instance, when samples of American and "Maco" cotton were heated for 3 hrs. at 125° C. with distilled water, 2·48% and 0·62% of cellulose dissolved respectively. When cotton fabric was heated with an alkaline liquor, with and without exposure to air, 12·0% and 8·2% of cellulose dissolved respectively. Wood-gum, containing the natural brown colouring matters of cellulose, is only partially bleached by cold and warm solutions of hypochlorites and sodium peroxide, but it is completely and permanently bleached by means of a slightly acid solution of a hypochlorite. Hence warm acidified solutions of hypochlorites are recommended for large-scale bleaching processes. The addition of natural water to spent kier liquor produces a brown precipitate, hence the washing of fabrics after treatment in the kier must be carefully controlled. Spent alkaline liquor may be regenerated by treating it in the kier, while boiling, with lime and sufficient bleaching powder so that it becomes yellow but gains no oxidising power, and then adding a small quantity of a sulphite or bisulphite whereby its colour is further discharged and it gains in reducing power. The sludge containing calcium compounds and organic matter (wood-gum etc.) is then allowed to settle and withdrawn. (*Cf.* J., 1920, 101 a.)
—A. J. H.

Patents.

Textile fabric treating machines. L. Clarenbach. E.P. 168,712, 23.6.20.

The machine comprises a container provided with one or more compartments for the liquors, and a frame or frames carrying a number of rollers. The fabric in open width is passed through the liquors and over the rollers, and means are provided for reciprocating the frame or frames in a direction transverse to the direction of movement of the fabric as it passes from roller to roller. The fabric is kept taut, and liquor is removed by squeezing rollers as it leaves the machine. The machine is intended for washing, dyeing, waterproofing, fireproofing, etc. cloth in open width in a minimum time and in a uniform manner.—F. M. R.

Dyeing machine. J. A. Grundy, Assr. to J. Bromley and Sons, Inc. U.S.P. 1,389,444, 30.8.21. Appl., 25.3.21.

A machine for dyeing yarns and the like consists of a rectangular container for the dye liquor, and an inner tank with a perforated bottom, of equal width, but not so long, which is mounted below the level of the open top of the container. The circulation of the dye liquor is effected by fluid pressure through perforated tubes in the container. The hanks of yarn are suspended vertically in the inner tank by an arrangement which, when lowered, closes the container without restricting the flow of liquor to the inner tank.—F. M. R.

Reserves on steamed Aniline Black with dyestuffs which are fixed by chromium salts; Production of ——. C. Pilz. G.P. (a) 339,098, 1.6.15, and (b) 339,400, 13.7.15. Addns. to 337,888 (J., 1921, 622 a).

(a) The material, prepared with Aniline Black according to example 1 of the principal patent, is printed with a reserve containing a blue chrome-mordant dyestuff capable of being discharged, a yellow basic dyestuff which is not capable of being discharged, and zinc oxide. On steaming, the blue chrome-mordant dyestuff is fixed by the chromium salt of the Aniline Black prepare, and the yellow basic dyestuff is fixed by the zinc ferrocyanide formed. An olive shade is produced on a black ground. (b) In place of aniline, other oxidisable amines, diamines, aminophenols, or mixtures of these compounds with aniline may be used for preparing the ground, reserve effects being then produced on a brown ground.—F. M. R.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphate of ammonia; Manufacture of neutral —— *at the Bedford Gasworks.* J. B. Hansford. Eastern Counties Gas Managers' Assoc., Sept., 1921. Gas World, 1921, 75, 243—244.

Neutral ammonium sulphate is made by working the saturator bath to neutrality before the charge is removed. A small secondary saturator is fixed above the fishing or primary saturator and is fitted with two cracker pipes connected with the ammonia still gas pipe and the waste-gas pipe from the primary still respectively. On the secondary saturator a run-off pipe into the primary saturator is fixed just above the level of the cracker pipes. When the liquor in the primary saturator reaches 57° Tw. (sp. gr. 1·285) the waste gases leaving it are caused to pass through the secondary saturator. Before reaching 52° Tw. (sp. gr. 1·26) the charge is agitated by means of steam, and when the charge is neutralised (51° Tw., sp. gr. 1·255) the still gases are diverted to the secondary saturator. After fishing out the salt the contents of the secondary saturator are run into the primary saturator, both saturators are made up to 60° Tw. (sp. gr. 1·3) and the still gases again passed through the primary saturator. After draining, the salt is dried upon a gas-heated steel table revolving under stationary ploughs. Around the periphery of the table is a screen through which the dry salt may pass into a hopper by centrifugal force upon the removal of the ploughs. Any lumps retained upon the table are crushed by means of a roller which may be lowered upon the table.—H. Hg.

Sodium and potassium permanganates from ferromanganese; Electrolytic production of ——. R. E. Wilson, W. G. Horsch, and M. A. Youtz. J. Ind. Eng. Chem., 1921, 13, 763—769.

The electrolytic cell used in these experiments consisted of a cylindrical glass jar containing a porous porcelain cup which served as a diaphragm. The cathode (of 16-gauge sheet iron) was placed in the cup and the ferromanganese anode in the jar outside. Several cells were operated in series from a source of direct current. The circuit also contained an ammeter, a copper coulometer, and a rheostat. The anolytes used were sodium and potassium hydroxide and carbonate solutions. The average period of a run was 5 hours. The tabulated results of a large number of experiments are given, from which it is concluded that the most suitable anolyte is a solution of sodium carbonate, which gives a product uncontaminated by manganates, with the best efficiency and with the least expenditure of power. The percentage of manganese in the anode has little effect on the cell voltage, but increased manganese content gives increased current efficiency. With a 40% manganese anode (spiegel iron), practically no permanganate is produced. Commercial ferromanganese containing 80 manganese was found to be the most suitable material for technical operations, a higher percentage considerably increasing the cost and brittleness of the anodes. The presence of copper in the anode produced practically no effect, but with 2% of cobalt the efficiency was reduced almost to zero. The operating temperature should not be higher than about 10°—20° C., as increase of temperature lowers efficiency, increases the energy consumption, and gives rise to a "skin effect" which causes excessive voltages. A current density of about 6 amp. per sq. dm. gives the minimum energy consumption. At lower current densities the current efficiency falls rapidly; at higher current densities it rises slowly, but is accompanied by increased energy consumption. The effect of all variables such as current density, temperature, anolyte composition, etc., is stated to be due to the variations caused by these factors in the oxygen overvoltage, a high oxygen overvoltage being necessary for high current efficiencies in permanganate production. The above conclusions have been confirmed by observations on the continuous operation of a full-sized commercial cell using ferromanganese bars 5 in. × 1·5 in. × 35 in. as the anodes. —S. S. A.

Analysis of aqueous salt solutions; Application of the immersion refractometer to the ——. C. A. Clemens. J. Ind. Eng. Chem., 1921, 13, 813—816.

Where n is the refractive index of solution, n_0 the refractive index of water of the same temperature, and c the number of grams of solute per 100 c.c. of solution, $(n-n_0)/c$ is a constant. Thus $c/(n-n_0)$ is a constant independent of temperature, unaffected by dissociation, hydration, and the formation of complexes, and represents the percent. by volume of salt equivalent to one division of the immersion refractometer scale. In determining the composition of mixtures of two salts, one of known and the other of unknown concentration, the percentage of the salt of known concentration divided by its refractive index factor gives, in terms of scale divisions, the effect on the refractive index due to that salt, and when this value is subtracted from the refractive index of the solution containing the two salts the remainder is equivalent to the refractive index of the salt of unknown concentration in aqueous solution. In the case of two salts, both of unknown concentration, the specific gravities of the solutions at 20°/4° C. were taken, the value for water was subtracted, and the values thus obtained were divided by the respective percentages by volume of salt in the solutions; this gave the effect of the addition of 1% of salt upon the density of the solution at 20° C. The density of a solution at 20° C. can be calculated by means of the factors thus obtained by multiplying the factor by the percentage of the salt and adding the value for water. By reversing the process the percentage of salt can be found from the density. Knowing the refractive index of the solution and of water at the same temperature and the sp. gr. of the solution at 20°/4° C., the percentage by volume of the two salts can be calculated.—S. S. A.

Zinc sulphide; Phosphorescence of ——. R. Tomaschek. Ann. Physik, 1921, 65, 189—215. Chem. Zentr., 1921, 92, III., 854—855.

Carefully purified zinc sulphide does not phosphoresce, but if it is heated to bright redness with only 0·000006 g. Cu as sulphide the resulting product shows a beautiful phosphorescence, thus proving that the presence of a heavy metal is necessary. In order to make a product of good intensity a certain amount of a fusible salt, preferably a chloride, must be added; this addition has no effect on the nature of the spectrum bands. The products obtained by heating zinc sulphide with a heavy metal sulphide and an intensifying agent are more or less crystalline, usually of a yellowish-white colour, and almost always triboluminescent, showing colours which comprise the bands seen in the ordinary phosphorescence. Phosphorescent zinc sulphide containing manganese blackens in the light but returns to its normal colour after a few hours in the dark. Additions of the sulphides of bismuth, silver, lead, uranium, nickel, and cobalt to zinc sulphide also produce phosphorescent products, which after being cooled with liquid air and then warmed to ordinary temperatures often show a beautiful and characteristic glow. The brightest glowing zinc sulphide is obtained by heating material containing 0·01% Cu with sodium chloride and magnesium fluoride to 1000° C. for 100 mins. The phosphorescence is due to four bands: the α green band is the predominant one at ordinary temperatures and is the cause of the green glow; the violet β band is permanent only at low temperatures; the γ yellow band is very faint and rapidly disappears, while the δ reddish yellow band is only developed after very strong ignition. The glow of the manganese-zinc sulphide is of a yellowish-red colour and persists for a considerable time; it consists of the already known yellowish-red α band together with fainter blue and red bands. Zinc sulphide containing bismuth gives a feeble murky red afterglow showing three bands; that containing lead, after exposure to light at low temperatures followed by warming, gives a bright afterglow; that containing silver gives a very bright blue glow under the same conditions, and nickeliferous zinc sulphide yields a bright yellow afterglow.—A. R. P.

Oxides; Reversible reactions of hydrogen and carbon monoxide with metallic ——. G. Chaudron. Ann. Chim., 1921, 16, 221—281.

Sal ammoniac skimmings; Process for treating ——. A. L. Mond. From Metallbank u. Metallurgische Ges. A.-G. E.P. 145,085, 17.6.20.

A mixture of pulverised skimmings and the necessary amount of dry slaked lime is moistened with about 15% of its weight of water and treated with live steam at 110° C. introduced through the perforated bottom of the containing vessel. The ammonia evolved is recovered either in aqueous solution or as ammonium sulphate, and the residue is leached with water, yielding zinc oxide and a solution of calcium chloride.—L. A. C.

Permanganates; Process of making ——. J. R. MacMillan and J. L. K. Snyder, Assrs. to Niagara Alkali Co. U.S.P. 1,387,656, 16.8.21. Appl., 13.8.20.

Material containing manganates is made into a magma with a liquid containing dissolved permanganate, and the mixture chlorinated.—H. R. D.

Phosphoric acid, and compounds of same; Apparatus for the manufacture of ——. W. H. Waggaman and T. B. Turley. U.S.P. 1,387,817, 16.8.21. Appl., 15.7.20.

A combined open-hearth and blast furnace is provided with a shaft in which the material is heated to a smelting temperature by means of fuel. The molten material is discharged into a slag chamber the heat of which is maintained by hot blasts which play above the slag. The slag chamber is wider at the bottom than at the top and its hearth slopes from each end towards the middle. Means are provided for withdrawing the gaseous products and for removing the residual slag exhausted of its phosphoric acid content.—H. R. D.

Sulphur dioxide; Process for separating —— from gas mixtures. R. H. McKee. U.S.P. 1,387,857, 16.8.21. Appl., 26.5.19.

The gases are scrubbed with water, cooled, the moisture content reduced to a point below saturation, and the gases then brought into contact with a material containing a silica gel.—H. R. D.

Potassium; Extraction of —— from natural substances in which it occurs. S. McKirahan, Assr. to F. A. Fuller. U.S.P. 1,388,276, 23.8.21. Appl., 14.2.18.

Finely divided fluorspar is mixed with non-calcic silicate rock containing potassium compounds and heated to volatilise the potassium as potassium fluoride. Potassium salts are recovered from the volatile product.—H. R. D.

Alum cake; Manufacture of ——. R. Moldenke. U.S.P. 1,388,436, 23.8.21. Appl., 17.10.19.

Finely powdered aluminous material is mixed with a quantity of strong sulphuric acid corresponding to the available alumina present. The mixture is heated at a high temperature in an atmosphere of acid vapours to form aluminium sulphate and is vigorously agitated to cause it to take a granular form until reaction is complete. The product is mixed with that amount of water necessary to form crystallised aluminium sulphate, and the solution separated from insoluble compounds whilst the mixture is hot.—H. R. D.

Ammonia; Electric production of ——. H. Blumenberg, jun. U.S.P. 1,388,488, 23.8.21. Appl., 12.5.19.

An aqueous solution of an alkaline-earth nitrate is subjected to electrolysis, whereby the nitrate is first reduced to nitrite and the latter further reduced by the hydrogen generated to form ammonia and hydroxide of the metal.—H. R. D.

Hydrogen and nitrogen are subjected to heat and pressure in the presence of a catalytic screen containing palladium and nickel.—H. R. D.

Alkali metal cyanide; Manufacture of ——. F. J. Metzger. U.S.P. 1,388,586, 23.8.21. Appl., 16.3.18.

Nitrogenous gas is passed through a mixture of an alkali and carbonaceous material, which is subected to a high temperature and simultaneously tumbled in a retort.—H. R. D.

Magnesium chloride; Method of removing water of crystallisation from ——. H. H. Dow, Assr. to The Dow Chemical Co. U.S.P. 1,389,546, 30.8.21. Appl., 24.9.19.

Partially dehydrated magnesium chloride is interfused with the normal salt containing 6 mols. H_2O. —H. R. D.

Nitric oxide; Production of —— in combustion engines. R. Drawe. G.P. 338,940, 27.3.20.

A vortex motion to induce rapid combustion of the contents of the cylinder is produced by means of vapour or gas under pressure, prepared by heating in closed vessels a suitable oil, such as the lower boiling fractions from low-temperature tar. —L. A. C.

Sulphur; Method of making —— from sulphur dioxide. American Smelting and Refining Co., Assees. of G. C. Howard. E.P. 144,306, 3.6.20. Conv., 9.9.18.

Gases containing sulphur dioxide from roasting furnaces are cooled to remove flue dust and metallic fumes, then treated with water or other solvent to dissolve the sulphur dioxide. The latter is boiled off, dried by cooling and passing through strong sulphuric acid, and liquified. The liquid is fed to expansion coils where it is once again changed to the gaseous form, at the same time cooling a quantity of air so that it deposits the greater part of its moisture content. This air is mixed with the gaseous sulphur dioxide and the mixture, which is substantially free from moisture, is passed through a preheater into a reduction furnace packed with incandescent coke where the sulphur dioxide is reduced to sulphur, the air present helping to maintain the requisite temperature by burning a certain amount of the coke. The hot gases from the furnace serve to heat fresh entering gases in the preheater and are then passed to cooling towers and baghouses for collecting the contained sulphur. —A. R. P.

Calcium carbide; Manufacture of ——. Union Carbide Co., Assees. of F. M. Becket. E.P. 143,872, 26.5.20. Conv., 20.1.15.

See U.S.P. 1,137,567 of 1915; J., 1915, 612. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 14,486 of 1915; J., 1916, 963.)

Aluminium chloride; Process for producing anhydrous ——. P. Danckwardt. E.P. 168,643, 2.6.20.

See U.S.P. 1,343,662 of 1920; J., 1920, 545 a.

Nitrous gases; Process of absorbing ——. F. W. Howorth. From Norsk Hydro-Elektrisk Kvaelstofaktieselskab. E.P. 168,651, 2.6.20.

See U.S.P. 1,348,227 of 1920; J., 1920, 656 a.

Hydrogen; Manufacture of —— by means of silicon and its alloys. G. F. Jaubert. E.P. 147,519, 8.7.20. Conv., 9.3.18.

See U.S.P. 1,366,185 of 1920; J., 1921, 148 a.

Removing hydrogen sulphide from gases. E.P. 168,504. *See* IIa.

VIII.—GLASS; CERAMICS.

Patents.

Refractory articles and method of making same. The Carborundum Co., Ltd. From S. C. Linbarger. E.P. 168,261, 25.9.20.

A refractory article is built up in layers, one outer layer having fireclay as its predominating element and the opposite outer layer, forming the facing of the article, having silicon carbide in proportions ranging from 50 to 100%. In order to avoid spalling the amount of silicon carbide in the intermediate layers is proportioned so that the coefficient of expansion varies gradually on passing through successive layers.—H. S. H.

Plastic compositions. L. A. Deleglise. E.P. 168,445, 15.6.20. Addn. to 141,987 (J., 1920, 450 A).

A solution of 1050 pts. of gelatin in 2260 pts. of distilled water as it begins to set to a jelly is added to a homogeneous mixture of 750 pts. of paper, wood, or rag fibre, 955 pts. of talc, and 4475 pts. of modelling plaster contained in a mixing mill. After agitating for 15—20 mins. at 25°—70° C., 460 pts. of a soap solution, prepared by boiling 250 g. of white soap and 100 g. of gelatin with 4 l. of water until the volume is reduced to 3 l., is added to the mixture. The flexibility of the product is increased by the addition of, *e.g.*, 50 pts. of glycerin during mixing. Objects cut or stamped from the mixture are dried for 1—4 hrs., soaked in 10% formaldehyde solution containing 7% of alum, drained, and dried at a temperature rising gradually from 20° to 70° C. —L. A. C.

Filtering material; Manufacture of ceramic ——. A. B. Schwarz. G.P. 339,405, 12.10.18.

Incombustible fibrous material, such as slag wool, is intimately mixed with coarse-grained combustible material, such as sawdust, coal, etc., and the mixture is forced through a sieve, moulded with a damp stiff clay, and the whole coated with finely divided stoneware or porcelain mixture, and then fired. Artificial stone may be employed in place of a porcelain body for the covering layer, and the whole may be enclosed within a filter cloth or similar material, this affording a particularly efficient filtering device.—J. S. G. T.

Glasses, enamels, and glazes; Manufacture of white ——. H. Sachse. E.P. 148,816, 10.7.20. Conv., 19.7.18.

See G.P. 331,682 of 1918; J., 1921, 348 A. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 101,221; J., 1917, 291.)

Non-plastic materials; Production of masses or pastes capable of being poured from ——. A. Walter. E.P. 144,317, 4.6.20. Conv., 13.8.17.

See G.P. 336,661 of 1917; J., 1921, 586 A.

IX.—BUILDING MATERIALS.

Oak; "Fumed" and natural brown ——. C. K. Tinkler. Biochem. J., 1921, 15, 477—486.

The brown colour of "fumed" oak is due to the combined action of the ammonia employed and atmospheric oxygen. Ammonia or amines without oxygen give to English oak a reddish colour, subsequently changed by air to the ordinary colour of "fumed" oak. The relation of the tannin content of various kinds of oak to the coloration produced on "fuming," has been investigated, together with the adsorption of the tannin from oak extracts by means of silk, and the subsequent "fuming" of the silk. The reddish-brown colour of natural brown oak may be due partly to the interaction of the tannin with a nitrogenous compound of the wood, and partly to the presence of a phlobaphene. —G. B.

Microstructure of wood. Abrams. *See* V.

Patents.

Waterproofing composition [for cement, mortar and concrete]. K. Winkler. E.P. 156,621, 6.1.21. Conv., 24.10.18.

A waterproofing composition for mortar, cement, or concrete is made by mixing 3 pts. of potassium silicate solution (sp. gr. 1·075) with 2—2·5 pts. of freshly prepared calcium chloride solution (sp. gr. 1·05—1·075) and adding to the colloid thus produced 8—15% of its weight of finely divided pure calcium carbonate and 5—8% of fat or oil, emulsified with 7—18% of potassium hydroxide solution. 1 kg. of the paste is mixed with 12 l. of water for use. By varying the percentages of certain components this waterproofing composition can be made to impart special properties to the cement etc., with which it is incorporated, *e.g.*, a quick-setting waterproof cement is obtained by using a composition containing more calcium chloride, and proportionately less of the other components; excess of potassium silicate gives a product which sets almost instantaneously, while by increasing the potassium hydroxide a cement of great adhesive power is obtained. The development of undesirable effects consequent upon any such variation from the general formula is prevented by the addition of small quantities of one of the following substances, sugar, bauxite, manganese dioxide, potassium bichromate, chromate, or ferrocyanide. Potassium chlorate or chloride may also be used, except when potassium silicate is in excess. —D. J. N.

Stone-like material; Method of producing —— *including wood sawdust from magnesia and magnesium salts.* E. Wallin. E.P. 157,971, 10.1.21.

In the production of artificial stone of the type known as "Steinholz," magnesium nitrate, or salts from which by chemical conversion magnesium nitrate is formed, are used instead of magnesium chloride or sulphate. By this means strains in floors laid with the material are reduced, and it is possible to prepare a dry mixture of the constituents to which water is added just before use. —H. S. H.

Wood; Process of treating ——. A. C. Chandler. U.S.P. 1,388,513, 23.8.21. Appl., 9.8.20.

A solution of copper carbonate in an alkaline carbonate solution is injected into wood, and copper carbonate is subsequently allowed to precipitate in the wood.—L. A. C.

Portland cement. E.P. 168,406. *See* IIa.

Fireproofing etc. U.S.P. 1,388,827—9. *See* V.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Electrolytic iron; Magnetic properties of ——. E. Gumlich. Stahl u. Eisen, 1921, 41, 1249—1254.

The influence of annealing and melting *in vacuo* upon the magnetic properties of electrolytic iron is dealt with. For permanent magnetisation, where high permeability and magnetisation values are concerned, such as the yokes of electro-magnets, dynamos, etc., electrolytic iron after suitable treatment is unequalled, the higher first cost being compensated by economy in space and material. In treatment of the material a long annealing *in vacuo* can be replaced by a single melting *in vacuo*. Machining does not affect a part so treated, although mechanical working (rolling, hammering) does. Such material is not so suitable where weak magnetising powers are concerned, such as in armouring for certain galvanometers, telephones, etc.; alloy steels are more serviceable. Where cost does not play the most important part an alloy of the purest electrolytic iron and silicon is valuable for many purposes.—J. W. D.

Thomas pig iron; Connexion between the physical and chemical properties of ——. O. Holz. Stahl u. Eisen, 1921, **41**, 1285—1293.

The physical properties of the pig iron are more important for successful working of the Thomas process than the chemical properties. Most of the trouble experienced in the manufacture of Thomas steel is associated with the low temperature (about 1200° C.) and lack of fluidity of the pig iron leaving the mixer. The insertion of a tipping acid Martin furnace of about 25 tons capacity between the mixer and the converter is recommended to give a superheat of 40° to 50° C. There is no appreciable change in the composition of the pig iron, while a saving of 25% in the blowing time in the converter is obtained and there is very little loss and waste of iron. The blowing is better under control and the iron content of the slag is lower. There are fewer bad heats; better ingots are obtained and less ingot waste. The degree of fluidity of the iron as measured by its rate of flow from the ladle is more suitable for judging the physical properties of the iron than the degree of superheat.
—T. H. Bu.

[Steel;] Does the critical point [of ——] depend on the strength of the magnetising field? K. Honda. Iron and Steel Inst., Sept., 1921. [Advance proof.] 6 pages.

The magnetisation of three steels of varying carbon content, 0·0085—1·17%, was examined in the vicinity of their critical points by varying the magnetising field from 400 to 2150. The critical point was not affected by the magnetising field.
—J. W. D.

Damascene steel. N. T. Belaiew. Iron and Steel Inst., Sept., 1921. [Advance proof.] 4 pages. (*Cf.* J., 1918, 305 A.)

In damascene steel the degree of spheroidisation of the carbides is always very high. This spheroidisation was obtained incidentally during the numerous cautious forgings and heatings required when the greatest ductility was sought and obtained. In high-speed tool steels spheroidisation is also attained, and sufficient stress has never been laid on this point. If a proper examination were made of the "watering" of high-speed steel either in billets or in the finished article the results might prove useful. While damascene steels cannot be placed in the category of high-speed steels, there is a certain "high-speed hardness" about them which merits further investigation.—J. W. D.

Steel; Woody fibre fracture in ——. J. Hanny. Stahl u. Eisen, 1921, **41**, 1298—1300.

The origin of woody fibre fracture in gun steel containing 0·35—0·45% C, 1·5% Ni, and 0·5% Cr in cases not attributable to visible slag inclusions has been investigated. On etching with a solution of hydrochloric acid (1:1) the specimens exhibiting fibrous fracture were the more strongly attacked, showing a fibrous longitudinal and a porous transverse structure. It is probable that during solidification of the steel in the chill, reaction takes place between very fine dust-like slag or oxides and the carbon of the steel, whereby minute gas bubbles of carbon monoxide are formed which coalesce during orging. Specimens showing woody fibre fracture, had etching effects, and low transverse tests conained greater quantities of gas than specimens ree from fibrous fracture. Methods of steelmaking adopted to remove the defect are described. The best results were obtained by melting in a basic open-hearth furnace, casting into ingots, and re-melting in an acid open-hearth furnace in which the charge was so calculated that after standing for about 1 hr. the bath had the desired composition and was tapped without further additions.
—T. H. Bu.

Titanium in iron and steel; Determination of ——. T. Dieckmann. Z. anal. Chem., 1921, **60**, 230—234.

One g. of the sample is dissolved in dilute nitric acid, sulphuric acid is added, and the solution evaporated and heated until fumes of sulphuric acid are evolved; the residual solution is boiled with dilute sulphuric acid, filtered to remove silica, the filtrate treated with 10 c.c. of phosphoric acid (sp. gr. 1·3) and a few c.c. of hydrogen peroxide, and diluted to 100 c.c. A standard solution is prepared in the same way using 1 g. of iron free from titanium and to this solution standard titanium sulphate solution is added until the coloration obtained is equal in intensity to that of the test solution.—W. P. S.

Tungsten and molybdenum steels; Constituents found in ——. A. M. Portevin. Iron and Steel Inst., Sept., 1921. [Advance proof.] 4 pages.

An investigation of the structural variations resulting from annealing steel containing 0·1—0·4% W indicates that four constituents are present, *viz.*, a tungstitic ferrite, a tungsten carbide, a tungstitic troostite, and a new constituent which is a complex ferrite+Fe_2W. These amount, however, to but three phases: solid Fe-Fe_2W solution, WC, and Fe_2W, which is compatible with the equilibrium of the Fe-W-C system. In molydenum steels a new constituent is also found having a complex acicular structure with characteristics similar to those of the new tungsten constituent. Its distribution is slightly more irregular but the appearance is identical. The presence of these constituents indicates a state of equilibrium more stable than that previously encountered.—J. W. D.

Nickel and copper on nickel-plated or copper-plated iron; Determination of ——. H. Koelsch. Z. anal. Chem., 1921, **60**, 240—241.

Nickel or copper plating may be removed from iron by immersing the metal in warm sodium nitrite solution acidified with acetic acid; the iron itself is not attacked as long as nitrite ions are present. (*Cf.* G.P. 319,855 and 330,131; J., 1920, 661 A; 1921, 264 A.)—W. P. S.

Zinc; Recrystallisation of ——. G. Masing. Z. Metallk., 1921, **13**, 425—428.

A continuation and amplification of previous work (J., 1921, 351 A) on the growth of crystals in zinc on heating to temperatures below the melting point for varying periods. The first effect of heating zinc that has been hammered and rolled cold is to start the primary recrystallisation of the metal without the formation of nuclei. Between 170° and 190° C. secondary recrystallisation begins from a number of nuclei, and as the temperature rises further the secondary crystals entirely replace the primary and the metal exhibits a coarse crystalline structure which is coarser the lower the temperature and the longer the heating. Czochralski's recrystallisation theory (Int. Zeits. Metallog., 1916, **8**, 1) does not hold, therefore, for the secondary recrystallisation of zinc.—A. R. P.

Zinc dust; New method for the evaluation of ——. Bullnheimer. Metall u. Erz, 1921, **18**, 443—446.

One gram of zinc dust, ground to 90-mesh, is shaken with 20 c.c. of water till evenly suspended, a mixture of 20 c.c. of 10% sulphuric acid and 25 c.c. of 3% hydrogen peroxide is added, and the whole allowed to stand with occasional stirring for not more than 10 mins. when all should be dissolved except for a small amount of lead sponge. 20 c.c. of 40% sulphuric acid is then added and the excess hydrogen peroxide is titrated with permanganate (15 g. per l.) that has been standardised against sodium oxalate. (*Cf.* J.C.S., Nov.)—A. R. P.

Aluminium; Determination of metallic —— and of aluminium oxide in the commercial metal. J. H. Capps. J. Ind Eng. Chem., 1921, **13**, 808—812.

The metal is dissolved in caustic soda or acid in a special apparatus and the hydrogen liberated is collected in a measuring burette where its volume, temperature, and pressure may be read. The volume of gas is equivalent to unoxidised aluminium together with whatever iron is present when an acid reagent is used, or with the silicon when sodium hydroxide is used. The amount of oxide is calculated by difference from the estimated total aluminium present.—S. S. A.

Aluminium brass; Quenching of ——. A. Portevin and J. Philippon. Rev. Mét., 1921, **18**, 533—534.

While rolling hot a number of brass ingots (Cu 71%, Al 4·56%, Pb 1·0%, Zn rest), two were found to behave in an unusual manner. Micrographic investigations showed them to consist of one constituent only, *viz.* β-brass, whereas, as the coefficient of equivalence of the aluminium is 6, the alloy should resemble a 58% Cu brass and consist of a mixture of α and β brass. On annealing this material for an hour the normal α-β brass structure was obtained. Specimens of a normal bar, heated to a temperature varying between 500° and 800° C. and quenched in water, showed progressive disappearance of the α-constituent. Above 850° C. a new constituent developed and the structure consisted of closely-packed needles resembling those found in a martensitic steel. Apparently the two ingots that failed on hot rolling were "self-hardened," a property which appears to be characteristic of this type of aluminium brass.—A. R. P.

Heat treatment [of metals]; The origin of internal stresses during ——. W. Tafel. Stahl u. Eisen, 1921, **41**, 1321—1328.

A theoretical paper in which it is proved that every heat treatment of a conical, prismatic, or cylindrical body develops internal stresses in the body similar to those produced by drawing or pressing and that these stresses result in a certain amount of heat being evolved. If, during the heat treatment, the stresses developed at no time exceed the elastic limit of the material, then the internal stress at the end of the treatment will be the same as at the beginning, but, on the other hand, if at any time they do exceed the elastic limit then there is a tendency for the stresses to become equalised at the temperature of the treatment and, on cooling, new stresses are set up, which are greater the more rapid the cooling, while the elastic limit becomes, or approaches, zero. A body that has been quenched shows, in the first stage of the heat-treatment a contraction at the middle of the outer walls, while, in the later stages, they tend to bulge outwards. Examples are given showing the application of these principles to the practical heat treatment of steel.—A. R. P.

Alloys; Chemical [and electrochemical] properties of ——. G. Tammann. Z. Metallk., 1921, **13**, 406—419.

The alloys of metals that form a continuous series of mixed crystals behave differently towards reagents according to whether the composition does or does not exceed a certain definite value, which may be expressed generally as A_nB_{8-n}, where A the more electropositive metal and n is a whole number. Thus, yellow ammonium sulphide blackens all gold-copper alloys containing less than 50·8% Au (Au_2Cu_6), those richer in gold remaining untarnished even after prolonged immersion. If, however, the alloys are heated to 140° C. in hydrogen sulphide those containing even 1% Au begin to tarnish in a few days. Silver is completely dissolved by nitric acid from gold alloys with less than 52·5% Au (Au_3Ag_5), partly from alloys containing 52·5—64·6% Au (Au_4Ag_4), and not at all from alloys with more gold than this. In parting, therefore, it is unnecessary to add more than an equal weight of silver to the button. Cold rolling or hardening of the alloy tends to make it slightly more susceptible to attack by reagents. The behaviour of binary alloys in an electrolytic cell containing as electrolyte a solution of a salt of the more electropositive element and electrodes of that element and of alloys of varying composition is described and discussed with reference to the microstructure of the alloys, and a theoretical explanation of the results obtained is given. (*Cf.* J.C.S., Nov.)—A. R. P.

Electrolytic etching [of metals] for microstructure. W. Velguth. Chem. and Met. Eng., 1921, **25**, 567.

In order to develop the true orientation of the grain structure the specimen is made the cathode and etched electrolytically in a 10% sodium thiosulphate or hydroxide solution using a carbon anode and 1·55 amp. per sq. in. at 10 v. for 5—10 sec., then removed from the bath and without washing made the anode in a 10% hydrochloric acid solution with a current density of 0·62 amp. per sq. in. for 8—10 secs., using a carbon cathode. The specimen is then washed with water and dried in a current of warm air; in the case of nickel thermo-couple alloys, it is then of a bright blue, purple, or green colour which does not interfere with the details of the microstructure.—A. R. P.

Patents.

[Iron and steel;] Process of casting metals [especially ——]. F. Windhausen. E.P. 147,625, 8.7.20. Conv., 15.11.15.

The metal, *e.g.*, iron or steel, is cast into blocks which are allowed to cool, without the application of heat to any part to retard cooling, until the stage is reached at which the greater part of the metal has solidified leaving in the top of the block a pasty or liquid mass, which is enriched with impurities. This is poured or scraped out and the cavity filled with fresh metal from the ladle.
—A. R. P.

Alloys of silicon with metals of the iron and chromium groups. R. Walter. E.P. 142,847, 5.5.20. Conv., 20.3.18.

The constituent metals are heated to 1200°—1300° C., whereupon the exothermic heat of combination of the silicon with the metals suffices to effect fusion of the mixture.—J. W. D.

Iron and steel and alloys of the same. R. Walter. E.P. 160,792, 24.3.21. Conv., 24.3.20.

By addition of 0·001—0·1% boron to iron or steel or their alloys with metals of the iron and chromium group the mechanical properties are greatly improved. Steels containing 0·007—0·001% B are self-hardening, and special tool steels containing 0·001—0·1% B possess a cutting capacity hitherto unattained.—J. W. D.

Aluminium and its alloys; Production of castings of ——. Metallindustrie Schiele und Bruchsaler. E.P. 146,841, 5.7.20. Conv., 16.12.18. Addn. to 137,325 (J., 1920, 602 A).

In order to prevent contamination of aluminium or its alloys during melting by material derived from the walls of the crucible, the latter are coated with aluminium varnish and then slowly heated to 400° C. to burn off organic matter. This coating is oxidised during the subsequent melting operation and forms a layer of aluminium oxide sufficiently dense and adherent to prevent the molten charge from coming into contact with the crucible walls.—A. R. P.

Metallic alloys; Production of ——. H. Leiser, Assee. of L. Reimann. E.P. 148,533, 10.7.20. Conv., 17.8.14.

The metal or metals of highest melting point, *e.g.*, iron, chromium, nickel, in powdered form, are pressed into a porous body or body of comparatively low apparent specific gravity, and this is heated and dipped into a bath of the molten metal to be alloyed with it, *e.g.*, copper. The process may be carried out in a vacuum and the resulting alloy afterwards heated in a current of hydrogen. The powdered metal, before pressing, may be mixed with a certain amount of the powder of the melting bath metal or it may be coated with a metal of higher electropositive properties by immersion in a solution of its salts. If iron is treated as above and immersed in molten copper it can take up 30—60% of copper; the resulting alloy has a homogeneous structure and can be forged, rolled, and drawn.—A. R. P.

Alloy. H. Hecht and D. G. Black, Assrs. to Alloys and Products, Inc. U.S.P. 1,389,446, 30.8.21. Appl., 12.6.20.

An alloy containing 25—40% Cu, 20—40% Ni, 6—12% Cr, and 25—40% Fe.—F. M. R.

Electrostatic separation of finely divided material [ores]; Process and apparatus for the ——. G. R. Brown. E.P. 168,479, 7.7.20.

The finely divided material is fed through a hopper and supply pipe on to a rotating pan mounted in a casing provided with a dividing ring for guiding the separated particles into hoppers. The pan is flat-bottomed; its outer rim projects slantingly upwards and outwards so as to deflect the material into the electrostatic field and it is heated by means of electric heating elements fixed underneath, so that the ore is dried while being spread out by the centrifugal action of the rotating pan. A cover plate extends nearly to the outer rim of the pan, which is electrically charged and acts as one electrode, the other being above it in the form of a ring capable of being rotated and supported by insulating arms fixed to the fugal stem in such a way that the distance between the electrodes may be adjusted. A dividing disc is arranged outside the electrodes and may, if desired, form part of the bottom electrode; it is provided with circular channels arranged round it for the separated material to pass through into a discharge hopper having curved vanes on its floor and revolving in the opposite direction to the pan. Needle sparking gaps are fitted inside the hopper. If necessary a battery of these separators may be arranged one above another so that the tailings discharge from one becomes the feed to the next lower. In this case by-passes are arranged so that any one separator may be cut out of the circuit when required.—A. R. P.

Roasting furnace. S. Sokal. From Allis Chalmers Mfg. Co. E.P. 167,863, 19.5.20.

A furnace is subdivided into a number of sections or hearths, separated by sliding doors and arranged at different levels, each section being provided with a set of rabbles which can be operated independently.—J. W. D.

Annealing metals; Method of and means for ——. E. G. Budd and J. Ledwinka. E.P. 167,871, 20.5.20.

The article to be annealed is mounted in a closed chamber, and the terminals of the secondary circuit of an electrical transformer are respectively connected with the ends of the article. The chamber is exhausted of air or charged with a non-oxidising gas, and the article is electrically heated and then cooled before exposure to oxidising influences.—J. W. D.

Chemical and metallurgical processes; Method of carrying out —— *in a multiple hearth furnace.* W. Strzoda. G.P. 339,506, 14.3.20.

The furnace consists of a number of hearths arranged in steps, and the charge falls from one hearth to the next lower through slits and over sloping plates where separation of the metal from the slag takes place, the former being caused to flow along small channels to special collectors, while the latter flows to the slag chambers from which it is removed from time to time, while its heat is utilised in the furnace. The furnace is heated by hot gases passed in a horizontal direction between only the lower series of hearths, the upper being heated either by radiation or by the combustion of fuel that has been mixed with the charge. Any fume, *e.g.*, zinc, evolved during the process becomes oxidised and is carried in a horizontal direction over the hearth from which it is evolved and is collected in precipitation chambers. In this way it does not come into contact with any cold surface and, on account of the short distance through which the charge falls between successive hearths, is not contaminated with ore dust.—A. R. P.

Alloy steel. C. H. Wills. E.P. 150,343, 24.8.20. Conv., 9.6.17.

See U.S.P. 1,278,082 of 1918; J., 1919, 18 A.

Furnaces for smelting readily fusible metals from scrap. C. Gauschemann. E.P. 147,952, 9.7.20. Conv., 9.9.15.

See G.P. 295,739 of 1915; J., 1917, 601.

XI.—ELECTRO-CHEMISTRY.

Transformer oil sludge. C. J. Rodman. Trans. Amer. Electrochem. Soc., 1921, 105—112. [Advance copy.]

Three types of transformer oil sludge are described: the asphaltic, the soap, and the carbon sludge. The first two are caused by the use of insufficiently refined oil containing unsaturated compounds, water, resins, and other impurities, while the last is caused through electrical breakdowns, such as corona discharge or arc-formation in the oil. Asphaltic sludge, caused by oxidation of the impurities in the oil, although possessing good electrical properties, is liable to cause local overheating and consequent electrical breakdown. Formation of soap sludge is very slow, and as the sludge is partially soluble in oil it is very difficult to remove; this sludge possesses a low insulating power. Highly refined oil of the saturated paraffin series which is carefully filtered when the dielectric strength begins to diminish during operation can be used for many years.—L. A. C.

Electrical resistance material; Process of manufacturing ——. A.-G. Kummler und Matter. E.P. 153,602, 10.11.20. Conv., 10.11.19.

An electrical resistance material adapted for low, medium, and high temperatures, and having a negative temperature coefficient, is made by forming a mixture of silicon carbide as a base, calcium carbonate, oxides of metals, and graphite into a paste, moulding into the desired shape, embedding the shaped articles in a practically non-fusible sand mixture and heating to about 3000° C. —H. S. H.

Electrolysis of solutions and apparatus therefor. A. H. Hooker, Assr. to Hooker Electrochemical Co. U.S.P. 1,388,466, 23.8.21. Appl., 5.8.20.

In apparatus for the electrolysis of salt solutions, an aqueous electrolytic solution carrying a salt in solid phase is supplied to the electrolytic cell. —J. S. G. T.

Electrolysing solutions; Apparatus for ——. T. L. B. Lyster and K. E. Stuart, Assrs. to Hooker Electrochemical Co. U.S.P. 1,388,474, 23.8.21. Appl., 13.8.20.

Means for supplying electrolyte to an electrolytic cell comprise an external system for circulating electrolyte, a feed orifice for the cell, and a device included in the circulating system for maintaining a constant head at the feed orifice.—J. S. G. T.

XII.—FATS; OILS; WAXES.

Peanut [arachis] oil; Chemical composition of ——. G. S. Jamieson, W. F. Baughman, and D. H. Brauns. J. Amer. Chem. Soc., 1921, 43, 1372—1381.

Two samples of arachis oil, one from Spanish-type peanuts and the other from Virginia-type peanuts, were examined. The percentage compositions were respectively—unsaponifiable matter, 0·2, 0·3%; glycerides of oleic acid, 52·9, 60·6%; of linolic acid, 24·7, 21·6%; of palmitic acid, 8·2, 6·3%; of stearic acid, 6·2, 4·9%; of arachidic acid, 4·0, 3·3%; and of lignoceric acid, 3·1, 2·6%. In neither case could any hypogaeic acid be detected.—W. G.

Goose fat; Glycerides of ——. C. Amberger and K. Bromig. Pharm. Zentralh., 1921, 62, 547—548.

When goose fat is kept for a considerable time at ordinary temperature it separates into two portions. The solid portion, iodine value 52·3, constitutes about 15% of the whole fat, and contains α-stearodipalmitin, m.p. 57·4° C., and β-stearodipalmitin, m.p. 63·0° C.; at 15° C., 100 c.c. of ether dissolves 1·32 g. of the α-glyceride and 0·90 g. of the β-glyceride. The liquid portion of the fat (iodine value 77·0) consists mainly of triolein. Both portions contain a quantity of oleodipalmitin, m.p. 33·5° C.—W. P. S.

Oil seeds; S. American ——. G. T. Bray and H. T. Islip. Analyst, 1921, 46, 325—327.

Four varieties of S. American oil seeds yielded oils having the following characters:—Oil from *Theobroma grandiflorum* (cupu) seeds: Sp. gr. at 100°/15° C., 0·8522; m.p., 32·0° C.; n_D^{40}=1·456; acid value, 44; saponif. value, 187·8; iodine value (Hübl, 17 hrs.), 44·8; unsaponif. matter, 0·91%; soluble volatile acids, 0·08; insoluble volatile acids, 0·12. *Hymenæa Courbaril* seeds: These yielded 6·4% of oil, but the quantity obtained was too small to permit of its examination. Oil from *Parinarium* species kernels: Sp. gr. at 100°/15° C., 0·905; n_D^{40}=1·469; acid value, 16·2; saponif. value, 200·5; iodine value, 77·3; unsaponif. matter, 0·76%; soluble volatile acids, 2·68; insoluble volatile acids, 0·52. Oil from *Platonia* species seeds: Sp. gr. at 100°/15° C., 0·8782; m.p. 31·0° C., n_D^{40}=1·469; acid value, 46·4; saponif. value, 199·5; iodine value, 77·8; unsaponif. matter, 3·63%; soluble volatile acids, 0·13; insoluble volatile acids, 0·37. The results for the volatile acids are expressed in c.c. of N/10 alkali solution per 5 g. of oil. The *Parinarium* seed oil is different from that yielded by the species of *Parinarium* growing in Sierra Leone; the latter oil has drying properties, and polymerises to a solid mass when heated at 300° C. for 20 mins.—W. P. S.

Fatty acids; Quantitative separation of the lead salts of the saturated from the less unsaturated ——. A. Seidenberg. J. Amer. Chem. Soc., 1921, 43, 1323—1336.

A method based on the use of a mixture of the three solvents, alcohol, chloroform, and ether, is described. The two latter exert a greater solvent action than the alcohol, and can be more readily evaporated. After solution of the mixed lead salts the chloroform and ether are evaporated off by a current of air until the less soluble salts are precipitated. In this way a sharper separation is obtained than in the usual methods, and there is practically a complete removal of all the salts of the saturated acids. Within wide limits the results were independent of the amounts of the fatty acids used. From oils or fats containing the more unsaturated fatty acids it is not possible to obtain the saturated acids in an approximately pure state by either the above fractionation method or the lead salt-ether method. When, however, only the less unsaturated acids, such as oleic acid, are present the saturated fatty acids as isolated are practically free from unsaturated acids.—W. G.

Oil analysis; Micro-analytical methods in ——. A. H. Gill and H. S. Simms. J. Ind. Eng. Chem., 1921, **13**, 547—552.

The saponif. value is determined in the usual way and the iodine value by the Hanus method, but the quantity of oil used is only one drop; the apparatus is that ordinarily found in a laboratory or is easily made. The single-swing method is used for the weighings and all operations are described in detail. A small hydrometer of special construction is employed to determine the sp. gr.; the oil under examination (about 1 c.c.) is filled into a bulb on the stem of the apparatus just above the float bulb. The titration apparatus consisted of a 10 c.c. burette-pipette with a ball or bead valve, the nozzle tip terminating in a fine glass rod to produce small drops of liquid. The pipettes used had unusually fine stems and were filled by blowing into a capillary tube passing through the stopper of the reagent vessel, which also held the stem of the pipette. The chloroform in the iodine value determinations was measured in a pipette filled by means of a small syringe. Accurate results for saponif. and iodine values were obtained with 15 and 11 mg. of oil respectively.—W. P. S.

Fixed oils; Spectrometric examination of certain —— *as a means of identification.* H. C. T. Gardner. Analyst, 1921, **46**, 356—359.

Different oils exhibit dissimilar limits of visibility in their spectra, whilst oils of the same kind show practically the same spectra as regards length, *i.e.*, in the extent of the visibility of their spectra, under like conditions. The oils are observed in a covered trough, having a length of 3 in., and provided with a window at each end; a beam of light from a 0·5-watt electric bulb is directed through the trough, and the window next the spectroscope is fitted with a collar into which the collimator tube of the instrument is inserted. The visibility of the spectrum at the red end varies but little for different oils, and ends at about 43°, but is more marked in the blue; the point at which visibility in the blue ceases is as follows for various oils:—Almond, 57·3°; earthnut, 45·6°; castor, 45·3°; coconut, 47·3°; cottonseed, 46·6°; linseed, 45°; neatsfoot, 45·6°; olive, 45·3°; sesame, 45·6°. All the observations were made at 30°—40° C.
—W. P. S.

Soap; Rapid method for the determination of sodium chloride in ——. H. C. Bennett. J. Ind. Eng. Chem., 1921, **13**, 813.

A solution of 5·85 g. of soap is made in 150 c.c. of hot water, the soap and soluble fillers are precipitated by the addition of 25 c.c. of a 20% solution of magnesium nitrate, and the unfiltered mixture is titrated with $N/10$ silver nitrate, using potassium chromate as indicator. With these quantities 1 c.c. of silver nitrate is equivalent to 0·1% of odium chloride.—S. S. A.

Patents.

Fatty acids; Separation of free —— *from fats and oils.* C. und G. Müller Speisefettfabr., A.-G. G.P. 339,027, 23.11.18.

Fat or oil is dissolved in a fat-solvent miscible with water, such as pyridine or acetone, and sufficient water is added to the solution to precipitate the neutral oil, leaving the fatty acids in solution. The solution is then drawn off from the upper layer of oil, and more water is added in order to precipitate the fatty acids.—L. A. C.

Fat substitute; Manufacture of a glycerin-free ——. Byk-Guldenwerke Chem. Fabr., A.-G. G.P. 339,416, 25.12.17.

A product suitable, *e.g.*, for lubricating, for preventing rust, or for impregnating textile material or leather, consists of lactones or similar inner esters or polymerisation products of oxidised or unsaturated higher fatty acids, prepared, *e.g.*, by heating ricinoleic acid or fatty acids of marine animal oils at 200° C. until the evolution of water vapour ceases. Diluents such as mineral oil, tar oil, or fatty acid alkyl esters may be added to the product.—L. A. C.

Soap powder; Production of ——. A. Imhausen. G.P. 339,417, 13.10.18. Addn. to 310,122 (J., 1921, 594 a).

Liquefied soap is cooled and subsequently gradually warmed to the ordinary temperature by passage successively between strongly cooled and heated rolls.—L. A. C.

Mixtures [emulsions]; Productions of stable —— *containing a fat-solvent.* A. Welter. G.P. 339,026, 18.9.18.

A fat-solvent, *e.g.*, carbon tetrachloride, is emulsified with the colloidal material obtained by adding alkali carbonates or bicarbonates to liquid water-glass. The addition of soap increases the cleansing properties of the emulsion.—L. A. C.

Soap-stock; Process whereby neutral oils can be profitably recovered from their " foots " or ——. Sharples Specialty Co., Assees. of E. E. Ayres, jun. E.P. 145,089, 17.6.20. Conv., 21.5.17.

XIII.—PAINTS ; PIGMENTS ; VARNISHES ; RESINS.

Rosin; Hardened —— *and resin esters.* A. Murray. Chem. and Met. Eng., 1921, **25**, 473—475.

Lime for hardening rosin should be as free as possible from iron, as this discolours the finished product, whilst the presence of more than 1% of magnesia in the lime yields less fusible products giving solutions of undesirably high viscosity. Hardened rosin containing less than 30% of free rosin cannot be prepared owing to the high melting-point of the rosinate; to obtain this degree of neutralisation the rosin is heated with 9% of lime at 435°—440° F. (224°—227° C.) for 1 to 1½ hrs., the operation being preferably conducted in a covered aluminium vessel to avoid discoloration. A practically neutral, hard rosin ester can be produced by melting 600 lb. of rosin in a copper or aluminium vessel, raising the temperature to 400° F. (204° C.), slowly adding 72 lb. of glycerin, allowing the temperature to rise to 555° F. (290° C.), and maintaining this temperature for about 20 mins. until maximum esterification is obtained, as shown by an acid value of 5—10; 3 lb. of lime is then stirred in, the vessel removed from the fire, and the ester ladled into cooling pans. A hard ester can also be obtained by melting the rosin with about 10% of Congo copal, cooling to 550° F. (288° C.), adding 12 pts. of gly-

cerin, heating to 555° F. (290° C.) and proceeding as with pure rosin. It is not possible to esterify in a copper vessel mixed resins containing larger proportions of Congo gum, as copper acts as a polymerising catalyst on Congo copal, but in aluminium vessels, hard esters of acid values of 7·5 or less can be produced from 3 pts. of Congo to 1 of rosin, using 10 lb. of glycerin per 100 lb. of resins.
—A. de W.

Varnish testing. The attrition test. H. Wolff. Farben-Zeit., 1921, 26, 3111—3112.

A GLASS rod twice bent at right-angles and fitting loosely in a glass tube bearing, carries at its upper end a pulley, and at its lower end a shoe, *e.g.*, a cotton reel, surfaced with whatever material is chosen as abrasive for the test, *e.g.*, leather in the case of floor varnishes. The shoe rests on the varnished surface under examination and is weighted with slotted lead discs held in place by a tightly-fitting cork on the rod. On rotating the pulley the shoe moves over the varnished surface. To imitate the conditions of scrubbing, a piece of moist cotton wool may be attached to a thin wire fixed on to the lower face of the pulley, so that the moist cotton wool travels over the same path of the varnished surface as the shoe. Determinations may be made of the weight lost per unit area in unit time at constant pressure (weight), of the time necessary to cause removal of unit thickness at constant pressure, and of the pressure necessary to produce specific change in unit time.—A. de W.

Arsenic in colours. Utz. *See* XXIII.

PATENTS.

Black colouring matter [mineral black and black ochre]; Production of ——. E. A. J. Poncelet. E.P. 143,241, 12.5.20. Conv., 12.5.19.

GRAPHITOID schist, *e.g.*, from the Lion Mountains, near Oran, is prepared for use as a pigment by subjecting to atmospheric oxidation to dry it and to eliminate sulphur, crushing in a mill, mixing, "triturating" in an elutriator, and thereafter grading in a modified selector washing apparatus. The latter comprises a series of vertical hollow cylinders of increasing diameter and decreasing height, connected in series from the top of one to the lower portion of the next, and having adjustable conical valved outlets in conical bottoms. In each cylinder there is a false bottom formed of an inverted truncated cone, below the inlet. The material is carried from one cylinder to another by a stream of water under pressure admitted between the two conical bottoms, the heavier material falling through the false bottom. The material deposited in the second, third, and fourth cylinders is dried, pulverised, and graded in an air separator to yield a powder ("mineral black") passing a screen of 4900 meshes per sq. cm., the screenings being recrushed and treated further in the separator. The mud or sludge from the last cylinder of the washer when dried, pulverised, and graded in a wind separator constitutes "black ochre."—A. de W.

Paint medium; Preparation of a weather-resisting ——. A.-G. für Anilin-Fabr. G.P. 339,574, 8.11.19.

FERROUS linolate is dissolved in the usual organic solvents, *e.g.*, turpentine oil or dichlorobenzene, or in drying fatty oils or oil-acids.—A. R. P.

Resinous condensation products from coniferous wood tar; Manufacture of ——. Chem. Fabr. Flörsheim H. Noerdlinger. G.P. 338,854, 11.12.19.

CONIFEROUS wood tar is saponified with concentrated alkalis, separated from the unsaponifiable matter, warmed with formaldehyde until the product is viscous, separated from the aqueous portion, washed repeatedly with water, and dried. The hard, transparent, brown resin obtained is soluble in solvent naphtha and this solution is used, mixed with mineral colours, as a paint which is resistant to light, air, and damp.—F. M. R.

Artificial resin; Manufacture of ——. Badische Anilin- und Soda-Fabrik. G.P. 339,107, 1.6.18.

CYCLOHEXANONE, or one of its derivatives, is condensed with formaldehyde preferably in presence of a condensing agent such as sodium hydroxide or sulphuric acid. The glistening, transparent resin thus produced is almost colourless and odourless, brittle with a conchoidal fracture, and very hard. It is soluble in almost all organic solvents and yields colourless varnishes, which are glossy and clear when dry, and which do not darken.—F. M. R.

Aluminium and chromium oleates and sulphoricinates insoluble in water; Process for dissolving ——. F. Reisz. G.P. 339,009, 13.7.15. Conv., 14.4.14.

FREE sulpho-olein and free sulphoricinoleic acid are used as solvents. The metal soap solutions are employed alone or mixed with other oils, fats, or acids employed in the lacquer industry.—J. H. L.

Linoleum, lincrusta, artificial leather, etc.; Production of ——. G. Ruth and E. Asser. G.P. 339,318, 3.2.20. Addn. to 328,580 (J., 1921, 311 A).

To render the linoleum cement less brittle, resin oil, wood-tar oil, or vaseline oil is added to the mixture of metal naphthenate and resin described in the chief patent.—L. A. C.

Colouring matters. E.P. 168,447. *See* IV.

Fireproofing etc. U.S.P. 1,388,827—9. *See* V.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

PATENTS.

Rubber fabric; Process of and apparatus for recovering caoutchouc and textile material from ——. R. Haddan. From F. Waitz. E.P. 167,667, 9.7.20.

COARSE pieces of rubber fabric are placed in a perforated drum within an outer container steam-jacketed at the lower end, and treated under pressure with a rubber solvent such as petroleum ether, benzene, toluene, xylene, or ether, below the vulcanising temperature of caoutchouc, *i.e.*, below 130° C. The drum is rotated during the extraction, and the contents are kneaded by means of a fixed grid within the drum. When extraction is complete, the solution is run into a receiver, and solution adhering to the fabric is removed as completely as possible by rotating the drum at high speed after raising the grid above the level of the fabric. After similar treatment with a fresh supply of solvent, the fabric is dried by admitting hot, non-oxidising gas to the vessel.—L. A. C.

Rubber; Treatment of raw —— *when freshly coagulated from the latex.* S. C. Davidson. U.S.P. 1,388,453, 23.8.21. Appl., 13.2.20.

SEE E.P. 151,344 of 1919; J., 1920, 757 A.

XV.—LEATHER; BONE; HORN; GLUE.

Gelatin; Dynamics of the formation of —— *from ossein.* A. B. Manning and S. B. Schryver. Biochem. J., 1921, 15, 523—529.

OSSEIN was prepared from crushed bones, extracted with alcohol, ether, and cold acid. The rate of extraction of gelatin from this by water at 100° and 90° C. was determined; although it depends on the size of the fragments there is no true surface effect. Owing to porosity the actual surface is independent of the extent of crushing, and the rate of extraction of gelatin is conditioned by its diffusion through the pores.—G. B.

Gelatin; Osmosis and swelling of ——. C. R. Smith. J. Amer. Chem. Soc., 1921, 43, 1350—1366.

Gelatin, free from ash, was prepared by extracting gelatin in a filter with 10% sodium chloride solution containing 5 c.c. of concentrated hydrochloric acid per litre, until the washings showed no reaction for calcium. The washing was then continued with 1% sodium chloride solution without acid, the concentration of this solution being diminished as rapidly as control of the swelling would permit. The final washing was with distilled water until the washings were free from chloride. The gelatin was dried by washing with 90% alcohol and then by means of an electric fan. This material was used in osmosis experiments with different acids and alkalis at different concentrations (*cf.* J.C.S., 1921, i., 749). When immersed in univalent acids dry gelatin combines with equivalent amounts at the same hydrogen-ion concentration, and the amount of swelling is approximately the same for all, its maximum occurring at a hydrogen-ion concentration of 4×10^{-3}, when 1 g. of air-dry gelatin occupies about 46 c.c. Divalent ionising acids give much less swelling, but the maximum occurs at about the same point. Salt ions do not combine with gelatin, but increase the absorption of alkalis or acids. They markedly decrease swelling and osmotic pressure. Sulphuric acid gives the same swelling as calcium or barium hydroxide when the amount of swelling is small.—W. G.

XVI.—SOILS; FERTILISERS.

oil temperature; Factors determining ——. B. A. Keen and E. J. Russell. J. Agric. Sci., 1921, 11, 211—239.

rom a large number of records obtained, attempts e made to correlate variations in soil tempera- ure with air temperature, rainfall, solar radiation, c. The soil temperature is measured by a self- cording soil thermometer at a depth of 6 in. in re soil. In winter, the soil temperature at 6 in. pth varies much more slowly and to a smaller extent an in summer, when there is a considerable daily riation. The warming of the soil is much more pid than the cooling, maximum and minimum mperatures occurring about 4.30 p.m. and 8 a.m., spectively. Mean temperatures are passed about idday and midnight. Variations of soil tempera- re are affected much more by the intensity of lar radiation than by the actual number of hours sunshine. Wind has little effect on the tem- rature of the soil, but rainfall retards both rming and cooling. Although the surface soil quently reaches a higher temperature than the air, at a depth of 6 in. the maximum is roughly the same as that of the air in summer and about 3° C. lower in winter. The minimum temperature at 6 in. depth is 6°—8° C. above that of the air in summer and 3° C. above in winter. The average summer maximum at 6 in. depth is 22° C. The soil cools more rapidly on clear nights. Maximum temperatures show closer relationship to radiometer readings than do mean temperatures. The amount of soil moisture has a considerable effect on temperature—high moisture tending to retard temperature increase and *vice versâ*. Increases in the numbers of hours sunshine or of radiometer values bring about increases in the ratio soil amplitude:air amplitude (amplitudes being differences between a maximum and the next minimum). If the soil amplitude increases so does the air amplitude. An increase in soil amplitude or in air amplitude is associated with an increase in the ratio soil amplitude:air amplitude.—A. G. P.

Clay; Determination of —— *in heavy soils.* A. F. Joseph and F. J. Martin. J. Agric. Sci., 1921, 11, 293—303.

A method of soil analysis worked out by Beam (Cairo Scientific J., 1911, 107—119) is compared with the standard English and American methods. 100 g. of soil, dried at 100° C., is sifted through a 2 mm. sieve to remove "stones and gravel," and then through a 1 mm. sieve to remove a fraction classed with "coarse sand." 5 g. of the portion passing the 1 mm. sieve is stirred in a beaker with water added to a height of 10 cm., and allowed to stand at least 16 hrs. The clay suspension is poured off and replaced by 0·05% sodium carbonate solution. This and subsequent sedimentations are carried out with alternate periods of 8 and 16 hrs. After 3 or 4 decantations the soil is well puddled with a brush. All clay is removed after 6 to 9 decantations; the residue is dried at 100° C. and weighed, and the clay calculated by difference. Silt is separated by sedimentation for 7½-min. periods with a 10 cm. column of water. The residue is washed out, dried and weighed, and the silt calculated by difference. This residue consists of coarse and fine sand and is separated by sieves, the coarse sand removed previously by the 1 mm. sieve being added. The use of sodium carbonate instead of ammonia for the clay separation, together with the greater column of liquid employed, makes the analysis much more rapid than by the English and American methods, even if a centrifuge is used in place of ordinary sedimentation. The solubility of clay in dilute acid is noted as a cause of irregular results by the English method, when the clay is flocculated by acid previous to weighing. This is particularly noticeable when acidified clay suspensions are allowed to stand for some days prior to the actual weighing of the clay.—A. G. P.

Basic slag; Effect of —— *on grassland, and upon corn crops obtained when that grassland is ploughed up.* A. W. Oldershaw. J. Agric. Sci., 1921, 11, 287—292.

A poor, heavy grassland was dressed with basic slag, and the cropping results over a number of years are recorded. After eight years' grazing by sheep there was a gain of 500 lb. of nitrogen per acre in each of the top and second 9 in. of soil, compared with an untreated control. A considerable increase occurred in the live weight of the sheep from the slagged portion. After ploughing in the grass, increased crops of peas, beans, and wheat were obtained on the treated land, on which a much thicker turf had developed. The improved nitrogen content is ascribed to the increased growth of wild white clover, and amounted to a 10% gain, whilst increases in crops produced were much larger.

—A. G. P.

Phosphates; Behaviour of different plants towards slightly soluble ——. T. Pfeiffer, A. Rippel, and C. Pfotenhauer. J. Landw., 1921, **69**, 165—183.

VARIOUS crops were grown in sand culture experiments in which the effect of slightly soluble phosphates was compared with that of dicalcium phosphate as a standard. Comparative figures were obtained representing the decomposing power of the different plants for rock phosphates. These values differed from plant to plant. The possible influence of the reaction of the nutrient solution is discussed, as also is the effect of the phosphate dressing on the ratio $CaO:P_2O_5$ in the plant. A clear explanation of the results obtained, and of certain differences from the work of other investigators, is not yet forthcoming.—A. G. P.

Nitrate of soda, leguminous green manures, and stable manure; Comparative study of the value of —— *in cylinder experiments*, 1907—19. J. G. Lipman and A. W. Blair. J. Agric. Sci., 1921, **11**, 323—336.

CROPS were grown in 8 different types of soils in large galvanised cylinders. Five series are compared, viz., unmanured, phosphoric acid and potash alone, phosphoric acid and potash with sodium nitrate, stable manure, and leguminous green manure respectively. A rotation of rye, maize, potatoes, and oats was used, and the green manure was supplied by vetch, clover, or soya beans sown immediately after the grain crops and allowed to stand till preparing the soil for the next crop. Green manuring had more persistent effects than sodium nitrate or stable manure. Heaviest crops were obtained by the use of green manures, followed in order by sodium nitrate and stable manure. Nitrogen returned in the crops followed the dry-matter yields. Green manuring maintained the nitrogen content of the soil at the same level as stable manure and at the same time produced heavier crops.—A. G. P.

Ammonium sulphate; Effect of —— *upon plants in nutrient solutions supplied with ferric phosphate and ferrous sulphate as sources of iron.* L. H. Jones and J. W. Shive. J. Agric. Res., 1921, **21**, 701—728. (*Cf.* J., 1921, 232 A.)

WHEAT plants were grown in various nutrient solutions containing respectively potassium nitrate (*cf.* Tottingham, Physiol. Researches, 1914, **1**, 133—245) and ammonium sulphate in equivalent osmotic concentrations as sources of nitrogen. The plants invariably produced a marked decrease in the hydrogen-ion concentrations of the solutions containing potassium nitrate, whereas in the solutions containing ammonium sulphate there was an increase in the hydrogen-ion concentration during the early stages of growth. Ferric phosphate, in the quantities used (0·83 mg. of iron per l.), was not sufficiently available to supply the needs of the plants for iron in the solutions containing potassium nitrate, but was readily available in the solutions containing ammonium sulphate. Ferrous sulphate, used in the same proportion as regards iron, was sufficiently available in the solutions containing potassium nitrate to satisfy the needs of the plant for iron. The solutions containing ammonium sulphate with this form of iron in quantities of more than 0·01 mg. per l. were very toxic to the plants, the degree of toxicity increasing with the amount of iron. The nature of the nutrient solution with respect to the salt constituents and hydrogen-ion concentration appears to determine the availability and the efficiency of a given iron salt for growth. In the series of solutions containing ammonium sulphate, high yields of tops were generally associated with high yields of roots, but no such correlation existed in the solutions containing potassium nitrate.—W. G.

Fertilisers; Report of committee on methods of sampling ——. J. Assoc. Off. Agric. Chem., 1921, **4**, 594—597.

As a result of sampling tests on bags of mixed fertilisers it is found that any type of sampler removing a core from top to bottom of the bag, gives a representative sample, which agrees in analysis with a sample obtained by the standard method of quartering. Cores should be taken from at least 10 % of the bags in a consignment with a maximum of 20 cores, plus one for each additional ton of material. If less than 100 bags are present, not less than 10 should be sampled, and if there are less than 10 bags all should be sampled. The minimum sample for analysis should be 1 lb., which should previously be passed through a 10-mesh sieve.
—A. G. P.

Fertiliser samplers; Trial with two types of ——. L. D. Haigh. J. Assoc. Off. Agric. Chem., 1921, **4**, 597—599.

A SATISFACTORY sampler is made of brass or steel rod, 12 mm. in diam., and 750 mm. long, with a point at one end and a solid head at the other. A groove 7 mm. wide and 5 mm. deep is cut out of one side of the rod and extends to within 80 mm. of each end. The bag of fertiliser to be sampled is placed on its side and the sampler, groove downward, is pushed in as far as possible. It is turned till the groove is uppermost, withdrawn and the groove emptied. Ten samples make about 0·5 lb. Comparison with a double tube sampler shows the above to be equally effective.—A. G. P.

Borax in fertiliser materials and mixed fertilisers; Determination of ——. G. F. Lipscomb, C. F. Inman, and J. S. Watkins. J. Assoc. Off. Agric. Chem., 1921, **4**, 599—602.

A SAMPLE is extracted with boiling water and a portion of the solution corresponding to 1 g. of sample is acidified with $N/10$ hydrochloric acid, using methyl red as indicator. After boiling for 10 mins. under a reflux condenser to remove carbon dioxide, the solution is cooled, made neutral with sodium hydroxide in presence of methyl orange, 30 c.c. of neutral glycerol or 1 g. of mannitol is added, and the liquid titrated with $N/10$ sodium hydroxide using phenolphthalein as indicator. In the presence of ammonium salts, phosphates, and organic matter, a portion of the water extract, corresponding to 1 g. of substance, is evaporated nearly to dryness three times with sodium hydroxide to remove ammonia. The residue is treated with water and made just acid to methyl red with hydrochloric acid (1:10) and then alkaline with lime water. The precipitated phosphates are filtered off and washed 5—6 times with warm water. Boiling is to be avoided at this stage or insoluble borates of calcium may be precipitated. The filtrate and washings are evaporated to dryness on a water bath and ignited over a Bunsen burner to remove organic matter. The residue is treated with dilute hydrochloric acid, made alkaline with lime water, filtered, and acidified with $N/10$ hydrochloric acid and treated as before. After titration with sodium hydroxide and phenolphthalein a further 20 c.c. of glycerol or 0·5 g. of mannitol is added and the titration completed. A blank with reagents should be run. If total boron is to be estimated, 10 g. of sample is extracted for 30 mins. with 200 c.c. of water and 15 c.c. of hydrochloric acid (1:1).—A. G. P.

PATENTS.

Fertiliser; Process for obtaining a friable and non-deliquescent —— *from rock phosphates decomposed by nitric acid.* Badische Anilin- und Soda-Fabrik. G.P. 339,567, 4.10.19.

UREA, alone or with other material of fertilising value, is mixed with decomposed rock phosphate. The double salt $Ca(NO_3)_2,4CO(NH_2)_2$ is preferably used. If 60% nitric acid is used for the decomposition, little or no water need be evaporated from the reaction product.—A. G. P.

Plant diseases. G.P. 339,061. *See* XIXB.

XVII.—SUGARS; STARCHES; GUMS.

Sugar; Studies on some fungi and the deterioration of ——. P. A. van der Bijl. Int. Sugar J., 1921, **23**, 504—507.

A number of fungi responsible for the "sweating" of raw sugars were found to consist of members of the *Aspergillus* and *Penicillium* species (*cf.* Amons, J., 1921, 670 A). These moulds are regarded as being of greater importance in the deterioration of raw sugars than bacteria, which apparently play a part only when excessive amounts of water are present. As a result of the clarification treatment, the juice is rendered almost sterile, and after the massecuite has left the vacuum pan care must be taken to work under as nearly as possible aseptic conditions. Tanks, gutters, filters, etc. should be disinfected periodically with formaldehyde, bleaching powder, or sodium bisulphite. The sugar should be thoroughly dried before being bagged.—J. P. O.

Sugar analysis; Water concentration, a neglected factor in polariscopic methods of ——. C. A. Browne. Int. Sugar J., 1921, **23**, 516—519.

Replying to Jackson and Gillis (J., 1921, 671 A), he author maintains that the Clerget divisor hould bo based, not upon the sucrose content or upon the P—P′ value (*cf.* J., 1920, 634 A), but rather upon the total sugar content (or conversely he water content) of the solution used for the analysis. On analysing a solution containing 13 g. f sucrose and 13 g. of dextrose per 100 c.c. by Jackson and Gillis' Method II., the sucrose found was 49·93% when the divisor 134·4 for a concentraion of 26 g. was applied, but 50·34% when the divisor 133·3 for 13 g. of sucrose per 100 c.c. was used. Water concentration is a neglected factor of mportance in the double polarisation method, and n selecting the divisor to be used the water present n the liquid under examination should be ascerained, either by means of the refractometer, or referably with a "Clerget spindle," the stem of hich indicates directly tho appropriate value to e used. (*Cf.* J., 1921, 271 A, 361 A, 443 A.)—J. P. O.

mulsin from almonds; Action of —— on lactose in solution in 85% ethyl alcohol. M. Bridel. Comptes rend., 1921, **173**, 501—504.

rom the products of the action of emulsin on a 2% solution of lactose in 85% alcohol at the ornary temperature, ethyl β-galactoside was isolated nd characterised. Thus the lactose is hydrolysed y the lactase in the emulsin giving dextrose and alactose, which latter then yields ethyl galactode.—W. G.

arch. A. Reychler. Bull. Soc. Chim. Belg., 1921, **30**, 223—226. (*Cf.* J., 1921, 444 A.)

ome further observations are made respecting the version product previously described, and the atement that each starch grain possesses two hila, e on each side, is reaffirmed.—J. H. L.

arch; Use of taka-diastase in estimating ——. E. Horton. J. Agric. Sci., 1921, **11**, 240—257.

rom a large amount of experimental work it is ncluded that the method of estimating starch by drolysis with taka-diastase (J., 1914, 657) does t give trustworthy results. Different samples the enzyme, both commercial and laboratory preparations from *Aspergillus oryzæ*, gave very divergent figures. In order to obtain reliable results it is necessary to make check analyses, using pure starch, with each sample of enzyme before use and during the period it is kept. The use of different clarifying agents previous to the final sugar estimation may also cause variations in results obtained. It seems possible that the persistence of dextrins is the cause of the discrepancies observed. (*Cf.* J.C.S., Nov.)
—A. G. P.

Pentosans and pentoses. Ling and Nanji. *See* XXIII.

Patent.

Sugar; Process and apparatus for the cleansing or re-melting of —— after crystallisation. E. Mozer. G.P. 333,109, 3.7.18.

After the boiling of the massecuite is completed the vapour outlet of the vacuum pan is closed, and communication is opened with the air. To draw off the green syrup, communication is made between the bottom of the vacuum pan and a receptacle below it, in which a partial vacuum is maintained. The cleansing or re-dissolving of the crystals is carried out in the pan by admitting cleansing syrup, thin juice, or water. The bottom of the vacuum pan is provided with a sliding ring valve covered with a screen, by which communication can be made with a discharge pipe to the above-mentioned receptacle or with pipes for the introduction of syrup, thin juice, or water from receptacles containing these.—J. H. L.

XVIII.—FERMENTATION INDUSTRIES.

Fermentation industries; Determination of the yield of extract obtainable from the raw materials [malt] of the ——. C. Chabot and M. H. van Laer. Bull. Soc. Chim. Belg., 1921, **30**, 253—257.

The conventional method (German Congress method) of determining the extract yield of malt gives useful comparative values, but the yields thus found in the laboratory are often greatly exceeded in practice. On the basis of experiments described the authors recommend that for the determination of the maximum yield of extract obtainable from a malt a very fine grist should be used, the mash should be kept at 45° C. for 4 hrs. for peptonisation, and ½—¾ of the alkalinity of the malt to methyl orange should be neutralised. If the mash is rendered quite neutral to methyl orange, still higher results may be obtained, but this is not recommended, as saccharification is seriously retarded.—J. H. L.

Salicylic acid; Detection and determination of —— in wine. W. Fresenius and L. Grünhut. Z. anal. Chem., 1921, **60**, 257—266.

The salicylic acid is extracted from the wine with a mixture of ether and petroleum spirit and identified by the ferric chloride reaction. A preliminary boiling with sodium hydroxide solution to decompose salicylic esters is recommended in the determination of the acid; the mixture is then acidified and the salicylic acid extracted and determined colorimetrically.—W. P. S.

Distilled liquors; Report on ——. [Storage of aldehyde-free alcohol.] J. I. Palmore. J. Assoc. Off. Agric. Chem., 1921, **4**, 465—466.

Alcohol, freed from aldehyde, was supersaturated with carbon dioxide and stored in paraffin-sealed vessels, placed in a refrigerator. Samples taken periodically show that in a period of 2½ years only negligible quantities of aldehyde are formed as indicated by the sulphite-fuchsin test.—A. G. P.

Patents.

Beverages; Process for the aromatisation of aerated ——. E. dit G. Sarreau. E.P. 146,499, 5.7.20. Conv., 26.6.19.

The carbon dioxide to be used for carbonation is first treated in the liquid state either by passage through the aromatic substance or by addition of aromatic essences.—J. H. L.

Yeast; Method of making dry ——. W. B. D. Penniman, Assr. to Whitney Yeast Corp. U.S.P. (a)-(c) 1,386,359—1,386,361, 2.8.21. Appl., 6.3.18. (a) and (c) renewed 10.6.21.

(a) Living yeast separated from the mash is mixed with soluble and insoluble filling materials in a moist state, and the mixture is agitated and dried *in vacuo* at a temperature sufficiently low to prevent rapid fermentation. (b) Living yeast separated from the mash is mixed with a filler in powdered form, an inorganic salt and water, and dried *in vacuo* at about 50°—60° C. (c) A liquid yeast culture is, after fermentation, treated with a thickening agent and then granulated and dried *in vacuo* to a moisture-content of 10%.—J. H. L.

XIXa.—FOODS.

Cream formation. O. Rahn. Forsch. Geb. Milchw. Molkereiwes., 1921, 1, 133—154. Chem. Zentr., 1921, 92, IV, 536—527.

There is no simple relation between the viscosity of milk and the rate of formation of cream; the latter is accelerated by the addition of gelatin, peptone, or gum arabic to the milk and hindered by the addition of sodium silicate; sugar, in strong concentration, has a slight retarding effect. The slow formation of cream in the case of milk which has been heated at 65° C., appears to be due to alteration in the fat globules and not to changes in the other constituents. If cream is separated from milk, the skimmed milk heated at 65° C., cooled, and re-mixed with the cream, the latter "rises" at the same rate as in unheated milk. The addition of gelatin or gum arabic to heated milk imparts to the latter the character of unheated milk as regards the "rising" of cream. Whilst cream from heated milk is richer in fat than is that from unheated milk, cream from milk containing gelatin or gum arabic has a lower fat content than has the cream from the same milk without any addition.—W. P. S.

Casein; Determination of fat in ——. D. A. Gangolli and A. N. Meldrum. Indian Dept. of Industries, Bull. No. 5.

One g. of the finely powdered casein is dissolved in 15 c.c. of $N/2$ sodium hydroxide solution, the solution then extracted several times with ether, the ethereal solution is filtered and evaporated, and the residue of fat weighed. The colour of casein appears to depend largely on the presence of fat. To prepare casein of low fat content (0·04%), freshly precipitated casein is washed twice with alcohol and then extracted three times with petroleum spirit; ether should not be used, if the casein is for research purposes, as it is liable to contain peroxide which might lead to contamination of the casein.—W. P. S.

Egg pastes; Examination of so-called ——. E. Martin. Monit. Scient., 1921, 11, 151—152.

The material sold as egg paste, and consisting of a mixture of flour and eggs, should contain at least 3 eggs per kg. of paste; the contents of albumin, alcohol-ether extract, and phosphorus afford a measure of the amount of egg in the mixture. To determine the albumin, 30 g. of the powdered sample is made into a paste with 15 c.c. of water and kneaded with the fingers under a slow stream of water, the water being collected in a 500 c.c. flask; the contents of the latter are diluted to 500 c.c., mixed, filtered, 250 c.c. of the filtrate is boiled with the addition of 2 drops of acetic acid and the coagulated albumin is collected, dried, and weighed. Another portion of 50 g. of the sample is extracted for 36 hrs. with a boiling mixture of equal vols. of ether and alcohol, the extract is weighed, and the phosphorus in it is then determined. A paste containing 3 whole eggs per kg. will yield albumin, 9·6—11·0; extract, 33·0; P_2O_5, 0·24—0·31 g. per kg.—W. P. S.

Milk and butter; Factors influencing the value of —— as sources of vitamin A. J. C. Drummond, K. H. Coward, and A. F. Watson. Biochem. J., 1921, 15, 540—552.

The diet of the cow is undoubtedly the chief cause of variations in the amount of vitamin A in milk. Colostrum is richer than milk; butter is somewhat poorer, partly owing to mechanical loss and partly to destruction. "Blowing" and other methods of butter-making which involve exposure to air at high temperatures, may cause a loss of vitamin A. The vitamin content of butter produced in winter is low, sometimes very low, because the cattle are stall-fed on dry feeds of hay, roots, and cake; even a summer drought may lower the vitamin content. Storage of butter does not lower the vitamin A content unless there is oxidation, nor does development of rancidity *per se.* "Renovation" of rancid butter will entail further loss of vitamin, if the methods employed cause oxidation.—G. B.

Vitamin A: Formation of —— in living plant tissues. K. H. Coward and J. C. Drummond. Biochem. J., 1921, 15, 530—539.

Dried seeds have varying, generally small, quantities of vitamin A, which are not increased on germination. Green leaves form large quantities from inorganic salts, but the vitamin is not synthesised in the absence of chlorophyll. The vitamin is synthesised by green algæ and, to a lesser extent, by red algæ, but not by mushrooms. Vitamin A of green leaves is not associated with proteins; it may be extracted in the fat removed by solvents and appears in that fraction of the fat which resists saponification.—G. B.

Vitamins A and B. Value of steam-distilled palm-kernel oil as a control fat. Wheat bran as a source of vitamins A and B. A. D. Stammers. Biochem. J., 1921, 15, 489—493.

Palm-kernel oil (and probably any vegetable oil) which has been steam distilled for 3—4 hrs. at 230°—260° C. is quite free from vitamin A. Bran contains vitamin B and also some vitamin A. —G. B.

Antiscorbutic vitamin; Effect of heat and oxidation on ——. R. A. Dutcher, H. M. Harshaw, and J. S. Hall. J. Biol. Chem., 1921, 47, 483.

The antiscorbutic vitamin in orange juice resists half an hour's boiling at 100° C. under a reflux condenser, but is partially destroyed by hydrogen peroxide, especially on warming.—G. B.

Fruit juices; Antiscorbutic properties of concentrated ——. A. Harden and R. Robison. Biochem J., 1921., 15. 521—522.

About half the antiscorbutic vitamin was destroyed in dried orange juice kept at 29° C. for 14 months. —G. B.

Antiscorbutic extracts and quinol; Colour reaction common to ——. N. Bezssonoff. Comptes rend., 1921, **173**, 466—468.

A modified Folin-Denis phenol reagent prepared by adding an equal volume of $N/1$ sulphuric acid to a solution containing 100 g. of sodium tungstate, 20 g. of phosphomolybdic acid and 16·6 c.c. of concentrated phosphoric acid per litre, gives a blue coloration with plant extracts known to possess antiscorbutic properties, but not with extracts devoid of these properties. Of the various phenols examined the only one to give this blue colour with the reagent was quinol.—W.G.

Pectin; Behaviour of —— *towards alkalis and pectase.* F. Tutin. Biochem. J., 1921, **15**, 494—497.

Pectin (from apples) is decomposed by alkalis and by pectase in an identical manner, with formation of methyl alcohol, acetone (about twice as much as the alcohol), and a salt of pectic acid (with pectase this is the calcium salt). The pectic acid formed in either case contains 39·3% C, 5·1% H, and neutralises 20·9% NaOH.—G. B.

Trypsin; Digestion of fibrin and caseinogen by ——. E. S. Edie. Biochem. J., 1921, **15**, 498—506.

The amount of acid necessary to protect trypsin from destruction by heat depends on the amount of protein present. The more protein in solution, the more acid is required. The power of digesting fibrin suffers more than that of digesting caseinogen; the same applies to destruction by hydrochloric acid at moderate temperatures. The milk-coagulating power of pancreatic extracts is more easily destroyed by heat than the proteolytic power. These two powers are probably due to distinct enzymes.—G. B.

Silage; Bacteriological and chemical studies of different kinds of ——. C. A. Hunter. J. Agric. Res., 1921, **21**, 767—789.

Very little difference could be noticed between the fermentations taking place in silage composed of Canada field peas and oats, maize and soya beans, and maize only. There was a larger number of organisms of the bulgaricus group in maize silage than in the other types of silage. The production of acids in the silage was due to micro-organisms, for it did not take place in presence of 2% of chloroform. Yeasts apparently had little effect on the fermentation of silage except during the first few days. Plant enzymes were chiefly responsible for the hydrolysis of protein with formation of amino-nitrogen. The formation of ammonia was due to both enzymes and micro-organisms.—W. G.

Silage; Digestibility of oat and tare ——. T. B. Wood and H. E. Woodman. J. Agric. Sci., 1921, **11**, 304—309.

Feeding tests on sheep with oat and tare silage, using a basal ration of hay and linseed cake, are described. The silage protein gave high digestibility figures compared with those for the basal ation.—A. G. P.

Straw lignin. Paschke. *See* V.

Pentosans and pentoses. Ling and Nanji. *See* XXIII.

Patents.

Cream; Manufacture of artificial or imitation ——. J. G. Hay. E.P. 168,276, 15.12.20.

Concentrated or dried milk is mixed with egg lbumin, a mucilaginous or gelatinous substance, .*g.*, gum arabic, and water containing alkali to issolve the casein. The mixture is emulsified at 60° C. with a butter-flavoured oil and cooled rapidly in a refrigerator. The product can be whipped or clotted.—A. G. P.

Compounds for use in connexion with baking processes and the like. A. J. Clark. E.P. 168,362, 19.5.20.

A product suitable for use in baking cakes etc. is prepared by emulsifying at 80°—100° C. a mixture of 20 to 40 pts. of fat, such as suet or dripping, and 10 to 30 pts. of oil, such as arachis oil, cottonseed oil, or soya bean oil, with 5 to 60 pts. of a mucilage formed of edible hemicellulose or carbohydrate gums or mucilages, free from substances liable to promote mould growth. Borax, boric acid, salicylic acid, or similar preservatives may be added.
—L. A. C.

Protein foam; Production of a stable —— *from blood albumin.* Fattinger und Co. A.-G. G.P. 338,479, 15.5.17. Conv., 21.2.17.

A solution of blood albumin is treated with about 0·5% of alkali bitartrate or other salt which lowers its surface tension, and heated to a few degrees below the temperature of coagulation, after which it is rapidly cooled and beaten into foam. The product is intended chiefly for baking purposes.—J. H. L.

Edible fats; Production of aroma of lard in artificial ——. A. Granichstädten. E.P. 156,195, 3.1.21. Conv., 18.6.15.

See G.P. 337,169 of 1916; J., 1921, 630 a.

Dry yeast. U.S.P. 1,386,359—61. *See* XVIII.

XIXb.—WATER PURIFICATION; SANITATION

Incrustation of pipes; Iron bacteria in relation to the ——. D. Ellis. Sect. G., Brit. Ass., 1921. Engineering, 1921, **112**, 457—458.

Illustrations are given of *Leptothrix*, *Gallionella ferruginea*, *Cladothrix dichotoma*, *Crenothrix polyspora*, and *Spirophyllum*, all found in this country. As they are saprophytes particular attention should be paid to the organic matter contained in water passing through pipes; this should be measured by the number of bacteria that the water can support rather than by chemical analysis. Acid waters are more favourable to iron bacteria than alkaline or soft silicious waters; the bacteria can multiply in the absence of iron, but in its presence they promote the oxidation of ferrous compounds. *Gallionella* and *Spirophyllum* are responsible for the slimy streamers found on the walls of reservoirs and pipes. Although the water may contain only 1 pt. of iron in 1,000,000 this will accumulate in the cell walls of the bacteria; the dead organisms furnish organic matter for the next generation. Tubercular incrustations upon iron pipes result from the presence in the water of carbon dioxide, the concentration of which is locally increased by iron bacteria. Iron incrustations upon non-ferruginous surfaces are entirely due to bacteria. When iron bacteria are found in water the organic matter should be removed by aeration, by the growth of green plants, by bacterial action on filters, and by allowing animals to feed upon it at the surface of the water. Iron in the ferrous form combined with organic radicles will be partly removed by these methods.—H. Hg.

Sewage purification; Denitrification as a means of ——. E. A. Cooper. Biochem. J., 1921, **15**, 513—515.

The dissolved oxygen absorption figures for mixtures of tank liquids and nitrate solutions are very much lower than those for mixtures of tank liquors and water. In the former case there must be a considerable destruction of oxidisable carbonaceous matter; 5 pts. of nitrate in 100,000 produces an enormous degree of purification. In practice considerable economy could be effected by mixing part of the sedimentation tank liquor with the filter effluent and thus employing the nitrate present for destruction of the more readily fermentable material. By this means the filtering area required for sewage purification could be reduced.—G. B.

Power gas from sewage. J. D. Watson. Sect. G., Brit. Ass., 1921. Engineering, 1921, 112, 456.

In an experimental station at Birmingham, gas emanating from sewage sludge from which the liquid has been separated is used for generating power for purposes connected with the purification of the sewage. The installation consists of a 34-b.h.p. gas engine which drives a sludge pump, two sludge digestion tanks for the generation of gas, and a gas holder; it is designed to give 25 b.h.p. for 6 hrs. per day. The engine was designed to work on town gas, but no adjustments were necessary. The sewage gas contains 43·3% of methane in addition to hydrogen, nitrogen, and carbon dioxide. Under the low temperature conditions of this country a reliable supply of gas for power purposes may be obtained from the sewage sludge rather than from the liquid sewage. In the absence of the liquid, hydrogen sulphide is rarely generated.—H. Hg.

Patents.

Disinfecting liquids; Preparation of ——. M. Sarason. G.P. 339,154, 2.6.17. Addn. to 336,798 (J., 1921, 600 A).

Salts such as sodium sulphate, sodium formate, or sodium fluoride are used instead of sodium chloride in the preparation described in the chief patent.
—L. A. C.

Diseases in growing plants; Treatment of ——. R. Eberhard. G.P. 339,061, 9.1.19.

The plants are sprayed with compounds of fluorine at suitable dilutions or in alkaline solutions, or are dusted with powdered fluorine compounds. Fluorides, and particularly their double compounds with silicic acid, are used. Cupric fluoride exerts a powerful destructive action on fungi and insects, and is used, at a suitable dilution, for spraying fruit trees, grape vines, potato-tops, etc.
—F. M. R.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Shepherd's purse (Capsella bursa pastoris); Analysis of ——. C. Grimme. Pharm. Zentralh., 1921, 62, 495—499. H. Cappenberg. *Ibid.*, 560—567.

The following procedure is recommended for the determination of the choline and acetylcholine content of the fluid extract:—5 c.c. of the sample is mixed with 12 c.c. of alcohol and set aside for 24 hrs.; the clear liquid is then decanted from the gummy precipitate, and the filtrate is treated with 30 c.c. of 1% platinum chloride solution (in alcohol). The precipitate is collected after 23 hrs., washed with a small quantity of alcohol, dried at 100° C., and weighed. The preliminary treatment with alcohol removes "resins," which interfere (by retaining a quantity of the platinum compound), when the method described by Boruttau and Cappenberg (J., 1921, 276 A) is used. The characters of a good extract are:—Sp. gr., not less than 1·03; total solids, 14%; ash, 3%; platinum precipitate, not less than 5%, corresponding with 2·15% of choline compounds. Cappenberg agrees that the preliminary treatment with alcohol is an improvement, but points out that the quantity of choline compounds in the extract is not a measure of the value of the substance, other active principles being also present.—W. P. S.

Vanillin in vanilla extracts; Errors in gravimetric determinations of ——. H. J. Wichmann. J. Assoc. Off. Agric. Chem., 1921, 4, 479—482.

In the estimation of vanillin the purified alcoholic extract, freed from alcohol, may be either weighed direct, weighed after purification with petroleum ether, or sublimed at 105° C. (Hiltner. U.S. Bur. Chem., 1912, No. 152, and 1913, No. 162). Pure vanillin was prepared by distillation *in vacuo* at 140° C. to remove vanillinic and vanillic acids; and even this on sublimation left a gummy residue still containing some vanillin. The error due to Hiltner's sublimation method is shown to be small in the case of ordinary vanilla extracts, but becomes considerable with concentrated flavourings, in which case a +5% correction should be applied. The direct weighing method gives high results, whilst after purification with petroleum ether the results are frequently too low.—A. G. P.

Lipase of the liver; Hydrolysis of the esters of some dicarboxylic acids by the ——. A. A. Christman and H. B. Lewis. J. Biol. Chem., 1921, 47, 495—505.

The lipase from pig's liver only splits off one ethyl group from diethyl succinate and malonate. Monomethyl malonate and potassium ethyl malonate are not attacked by the lipase.—G. B.

Oxyhæmoglobin; Method for the preparation and recrystallisation of ——. H. W. Dudley and C. L. Evans. Biochem. J., 1921, 15, 487—488.

Washed horse corpuscles are dialysed in collodion tubes, and the hæmoglobin solution obtained is oxygenated, when the less soluble oxyhæmoglobin crystallises. Recrystallisation is effected by pumping off the oxygen at 37° C., cooling, and passing oxygen in again. (*Cf.* J.C.S., Oct.)—G. B.

Neuraltein [sodium salt of sulphomethylphenetidine]; Behaviour of —— with quinine salts: method for its identification. M. Cardini. Boll. Chim. Farm., 1921, 60, 253—258.

The colour reactions of the more important antipyretic compounds are given. Neuraltein may be distinguished from all other antipyretics by the following reaction:—0·02 g. of the substance is mixed with 0·01 g. of quinine hydrochloride in a porcelain dish and the mixture treated with a drop of water, a characteristic reddish-yellow coloration being obtained with neuraltein.—T. H. P.

Esters of aminobenzoic acids. H. C. Brill. J. Amer. Chem. Soc., 1921, 43, 1320—1323.

The preparation of a number of esters of the three aminobenzoic acids and two diaminobenzoic acids from the corresponding nitrobenzoic esters is described. In general, the effect of substituting a higher for a lower alkyl group is to increase the physiological activity of the compound. Thus, *n*-butyl 3.5-diaminobenzoate is a much more powerful local anæsthetic than is the ethyl ester. The order of activity of the compounds prepared is—most active: *n*-butyl, allyl, and isopropyl esters of *p*-aminobenzoic acid and *n*-butyl 3.5-diaminobenzoate; intermediate: *n*-butyl *o*-aminobenzoate, *n*-butyl *m*-aminobenzoate, and ethyl 3.5-diaminobenzoate; least active: *n*-butyl 2.4-diaminobenzoate. (*Cf.* J.C.S., Oct.)—W. G.

o-Diethylaminocyclohexanyl ester of p-aminobenzoic acid. A. E. Osterberg and E. C. Kendall. J. Amer. Chem. Soc., 1921, 43, 1370—1371.

o-Diethylaminocyclohexanyl *p*-aminobenzoate has been prepared by reduction of the nitrobenzoate with a view of studying its action as a local anæsthetic. (*Cf.* J.C.S., Oct.)—W. G.

Ether-water-alcohol mixtures; Determination of the composition of ——. L. Desvergnes. Monit. Scient., 1921, 11, 145—150.

The quantity of water or of ether required to produce a turbidity with a given volume of the mixture, or of alcohol required to produce a clear liquid in the case of a mixture which is not homogeneous, is determined; reference to graphs then gives the composition of the mixture. (*Cf.* Boutin and Sanfourche, J., 1919, 793 A.)—W. P. S.

Alcohols and phenols in essential oils; Determination of —— *by esterification with pyridine.* H. W. van Urk. Pharm. Weekblad, 1921, 58, 1265—1269.

The method of Verley and Bölsing (J., 1901, 1250) is not suitable where very accurate results are required. (*Cf.* J.C.S., Nov.)—S. I. L.

Quinol. Bezssonoff. *See* XIXA.

Patents.

Alkyl amides of aromatic sulphonic acids; Manufacture of ——. British Cellulose and Chemical Mfg. Co., Ltd., W. Bader, and D. A. Nightingale. E.P. 167,941, 2.6.20.

Aromatic alkylsulphonamides are obtained by the action of aromatic sulphonic chlorides on alkylamino salts in presence of an alkali carbonate or other suitable acid-neutralising agent and a small quantity of water, preferably not exceeding 5% of the reaction mixture. For example, monomethylxylenesulphonamide is obtained in almost theoretical yield by mixing together at 80°—100° C. 1400 lb. of xylenesulphonic chloride, 470 lb. of methylamine hydrochloride, and 900 lb. of sodium carbonate, the total moisture content not exceeding 5%. The product may be isolated by extraction with benzene followed by distillation *in vacuo.* —G. F. M.

Hexamethylenetetramine; Preparation of addition products of ——. J. D. Riedel, A.-G. G.P. 338,427, 11.5.19. Addn. to 334,709 (J., 1921, 412 A).

The free acids obtained by the process of the principal patent are converted into soluble salts of metals. Such salts are more stable towards solvents than the free acids. The potassium sodium, and ammonium salts of the acid derived from chloroacetic acid are neutral, soluble in water, and crystallise well. The aluminium salt is soluble in water, bactericidal and astringent, and the cadmium salt is very strongly bactericidal. The salts of the acid from monobromoacetic acid are more soluble in water than their chloroanalogues.—J. H. L.

Hexamethylenetetramine; Preparation of derivatives of ——. J. D. Riedel, A.-G., and F. Boedecker. G.P. 338,428, 31.8.19.

Hexamethylenetetramine is allowed to act upon alts of monohalogen derivatives of acetic acid in aqueous solution. The reaction proceeds smoothly with evolution of heat, and yields salts of quaternary bases of the type of betaine. The products may be employed therapeutically on account of heir antiseptic and astringent properties (*cf.* preceding abstract).—J. H. L.

Hydrazine and its alkyl or aryl derivatives; Production of ——. F. Sommer and O. F. Schulz. G.P. 338,609, 15.10.19.

Hydroxylamine isomonosulphonic acid (Sommer and Templin, Ber., 1914, 47, 1221) or its salts or derivatives, are allowed to react with ammonia or primary or secondary amines or with aromatic amines substituted in the nucleus, in presence of ammonia, preferably in aqueous solution. Hydrazine is formed when the sulphonic acid is added to an excess of concentrated ammonia and the liquid is heated to boiling:—$NH_3+NH_2.O.SO_3H=NH_2.NH_2+H_2SO_4$. A boiling alkaline solution of aniline treated with the free acid yields phenylhydrazine. Hydroxylaminedi- or tri-sulphonic acid or derivatives thereof, which yield the isomonosulphonic acid as intermediate product on hydrolysis, may also be used.—J. H. L.

Nitrosulphonic acids of hydrogenated cinchona alkaloids; Manufacture of ——. C. F. Boehringer und Söhne. G.P. 338,738, 26.4.19.

Nitrohydrocinchonidinesulphonic acid, formula $C_{19}H_{23}O_6N_3S$, yellow microscopic needles, is obtained by the action of potassium nitrate on a solution of the hyrocinchonidine base in concentrated sulphuric acid. It is soluble in alkali hydroxides and carbonates and in acids, and is converted into nitrocinchonidine and sulphuric acid by heating with hydrochloric acid, sp. gr. 1·126. Nitrohydroquininesulphonic acid, $C_{20}H_{25}O_7N_3S$, is obtained by the action of nitric acid on a solution of hydroquinine sulphate in sulphuric acid, or by dissolving nitrohydroquinine in concentrated sulphuric acid. It crystallises from dilute alcohol in yellow needles, which contain no water of crystallisation, and is sensitive to light, changing through green to brown. Nitroethylhydrocupreinesulphonic acid, $C_{21}H_{27}O_7N_3S$, forms yellowish crystals from dilute alcohol.—F. M. R.

Acetylsalicyloyl-compounds of quinine and its derivatives; Manufacture of ——. E. Merck, C. Diehl, and H. Mayen. G.P. 338,853, 3.12.18.

Equimolecular proportions of acetylsalicyloyl chloride and quinine or one of its derivatives are allowed to react; if necessary in presence of a suitable solvent. For example, an anhydrous ethereal solution of quinine is warmed with acetylsalicyloyl chloride. Acetylsalicyloylquinine hydrochloride separates in white needles or plates, m.p. 242° C. with decomp., soluble in alcohol, chloroform, and acetone, sparingly soluble in hot water, and scarcely soluble in benzene, toluene, ether, and light petroleum. Acetylsalicyloylethylhydrocupreine hydrochloride, white needles from water, m.p. 252° C. with decomp., is obtained similarly by the interaction of an anhydrous toluene solution of ethylhydrocupreine with acetylsalicyloyl chloride. When placed on the tongue, these products only produce a slight bitter taste after some time has elapsed.—F. M. R.

Triazoles (pseudoazimides) of the aromatic series; Manufacture of ——. Kalle und Co., A.-G. G.P. 338,926, 4.4.15.

o-Aminoazo dyestuffs, particularly such as contain additional amino or hydroxyl groups in the molecule, are treated with ammoniacal solutions of copper. For example, the dyestuff obtained by coupling diazotised sulphanilic acid with *m*-toluylenediamine is dissolved in water, ammonia added, followed by a solution of copper sulphate in water and 25% ammonia, and heated to 90° C. for several hours. The ammonium salt of sulphophenyl - 2 - aminopseudoazimino - 3 - methylbenzene crystallises on cooling. When benzeneazo-*m*-phenylenediamine is heated in an autoclave with an ammoniacal copper solution at 125° C. for 15 hrs., phenyl-2-aminopseudoaziminobenzene, m.p. 183° C., is obtained. These triazoles are to be used as intermediates for the production of dyes and pharmaceutical products.—F. M. R.

Valerianic acid and alkaline valerianates; Process for the manufacture of ——. L. Dupont, Assr. to Darrasse Frères. U.S.P. 1,389,187, 30.8.21. Appl., 20.12.19.

See E.P. 137,064 of 1919; J., 1921, 368 A.

Decolorised petroleum products. U.S.P. 1,388,517 and 1,388,832. *See* IIA.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

[*Photographic*] *sensitiveness* [*of silver salts*] *by means of dyes; Increasing the* ——. Lüppo-Cramer. Die Phot., 1921, Nos. 6 and 8.

The increase of general sensitiveness (*i.e.*, to white light) which is produced in a silver iodide-gelatin plate by treatment with certain dyes such as Rhodamine B and a "chemical" sensitiser, such as potassium ferrocyanide, is not obtained with ordinary, coarse-grained, silver bromide-gelatin plates. With very fine-grained plates, or "grainless" plates such as those used in the Lippmann process, however, the sensitiveness is increased up to about 16 times by all the "optical" sensitisers tested, including Pinachrome, Pinacyanol, Erythrosin, etc. The sensitising is obtained with or without a further treatment with sodium nitrite and is greater than the effect of the latter alone; it is also much more marked with physical development than with chemical development. There is no effect on the speed of development. The most important desensitisers—Phenosafranine, etc.—reduce the sensitiveness of the same plates about 10 times. The action of the sensitising dyes is probably chemical rather than optical, particularly as the increase occurs in the original (blue) sensitiveness of the plate. The colour-sensitising obtained by treatment of diapositive plates with, *e.g.*, Orthochrome, which is much more marked than that given by ordinary plates, is also accompanied by considerable increase of general sensitiveness. The general sensitiveness of silver chloride-gelatin emulsions is also considerably increased by treatment with Pinachrome, less by Pinacyanol, and not at all by Erythrosin. The increase of sensitiveness obtained with Lippmann plates still leaves them, however, excessively slow, so that this method of increasing the speed of a fine-grained plate without affecting grain size has as yet no practical application. The sensitising action of Pinaflavol (J., 1921, 324 A) is much more pronounced than that of the other dyes tested and is considerable with fine-grained chloride plates and with plates of medium size grain such as silver bromide diapositive and photomechanical plates. The sensitising with fine-grained plates is much stronger than that of nitrite, but the reduction of solarisation is much less. Further, the tendency to veil which was found with fast plates treated with Pinaflavol solution even as weak as 1:300,000 (König and Eder) does not occur with the slower plates even with solutions 1:10,000. The gradation of the plate is appreciably softened by the Pinaflavol treatment, and the plates have poor keeping quality.—B. V. S.

Dye precipitation in the Safranine process. Lüppo-Cramer. Die Phot., 1921, No. 6, 21.

In the preparation of concentrated developers of *p*-aminophenol, glycin, pyrogallol, catechol, or metol, along with Safranine, a precipitate of the dyestuff is formed which does not always dissolve immediately on dilution of the developer to the correct strength for use, especially if the solution has been prepared some time. If tested immediately after dilution the desensitising power is very low. On standing for 5 min., or warming the solution, or, in the case of *p*-aminophenol, adding a little caustic alkali, the precipitate re-dissolves and the desensitising action becomes normal. If quinol is present the precipitate does not re-dissolve in the same way, and it is therefore necessary in applying the Safranine process to developers containing quinol to add the dyestuff solution (preferably 1:2000) to the prepared, diluted developer.
—B. V. S.

Colour-sensitiveness of silver iodide. Lüppo-Cramer. Phot. Ind., 1921, 611-612.

A silver-iodide plate exposed to daylight under an Eder-Hecht sensitometer scale with coloured strips, and then developed with potash-amidol developer, shows the greater part of the sensitiveness to be in the blue; there is no image at all under the yellow strip, not even the fog which occurs on other unexposed parts of the plate. Slight positive images are obtained under the red and green strips. Treatment with Rhodamine solution before exposure produces strong colour sensitising, and the "reversing" action under the yellow strip disappears entirely; treatment with nitrite does not remove the reversing effect of yellow. Erythrosin, Pinachrome, and Pinacyanol also, to varying degrees, reduce the reversing effect of yellow light but differ somewhat amongst themselves and from Rhodamine in their effects on the red and green sensitiveness.—B. V. S.

Patent.

Three-colour photography. S. M. de Procoudine-Gorsky. E.P. 168,100, 20.4.20 and 12.1.21.

In a three-colour process in which positives are obtained by successive printings on the same support through the three negatives, the three stains used are Auramine in presence of aluminium acetate, Rhodamine in acetic acid, and Prussian blue. The taking filters are preferably made with Methyl Violet 6B, Brilliant Green, and Rose Bengal respectively, aesculin being used for absorption of ultra-violet. The first and second prints may be protected before re-sensitising either by hardening in chrome alum, formalin, or similar agent or by applying a thin coating of rubber in benzene followed by a thin coating of celluloid in acetone.
—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Colour reactions of nitro-compounds. Rudolph. *See* III.

Patents.

Explosives. A. Wohl. E.P. 157,058, 5.7.20. Conv., 9.1.20. Addn. to 146,258 (J., 1921, 562 A).

Polymerisation products of acetylene, either alone or mixed with other substances as described in the chief patent or E.P. 145,597 (J., 1921, 675 A), are used as carriers for liquid air in the manufacture of blasting cartridges.—L. A. C.

Chlorate capable of being cast; Manufacture and applications of ——. Sprengstoff A.-G. Carbonit. G.P. 307,080, 16.11.17.

The chlorate is heated with urea, amides of aliphatic carboxylic acids or similar products, alone or in admixture. The mixtures liquefy at a comparatively low temperature (70°—140° C.) and a product is obtained of high sp. gr., completely resistant to damp, and of increased detonating and explosive power.—F. M. R.

Priming mixtures. Carbonit A.-G. G.P. 337,621, 11.5.18.

Priming mixtures are prepared the ignition of which is automatic as the result of the interaction of the components, *e.g.*, a mixture of sodium thiosulphate, potassium chlorate and zinc chloride, alone or with addition of sulphur and/or potassium persulphate. The moment of the ignition of the mixture is regulated, according to the temperature of its surroundings or according to the period of time, by the proportions of the mixture, and may be instantaneous or after several hours.—F. M. R.

Detonating caps; Process for emptying —— for the recovery of the metal case, mercury and nitro-compounds. W. Friederich and W. Eschbach. G.P. 339,201, 25.6.20.

The detonating composition is separated from the nitro-compounds by means of a suitable solvent. The mercury fulminate is dissolved in a solution of potassium cyanide or sodium sulphide, or pyridine. In the case of detonating caps with an undercharge of a nitro-compound, such as tetranitromethylaniline, TNT., etc., the base of the cap is drawn off and the nitro-compound extracted with solvents, such as acetone, benzene, tetrachloroethane, etc. —F. M. R.

Illuminating grenade. J. Sonntag. G.P. 339,524, 24.5.17. Addn. to 300,760 (J., 1921, 101 A).

Metals other than those described in the previous patent, *e.g.*, tin, zinc, cadmium, antimony, lead, iron, or copper, or mixtures of the same with each other and/or with magnesium, aluminium, calcium, strontium, or barium, are employed for the charge. The addition of potassium, sodium, arsenic, molybdenum, or vanadium increases the intensity of the reaction.—L. A. C.

Drying colloids. E.P. 159,465. *See* I.

XXIII.—ANALYSIS.

Qualitative reactions; Sensitiveness of ——. II. Barium ions. O. Lutz. Z. anal. Chem., 1921, **60**, 209—223. (*Cf.* J., 1920, 584 A.)

Using 5 c.c. of the barium salt solution and 0·5 c.c. of reagent, the following are the minimum concentrations of barium which yield a distinct reaction with the different reagents:—With sodium arsenate, 1:175; potassium ferrocyanide and ammonium chloride, 1:430; ammonium oxalate, 1:4400; sodium phosphate, 1:6200; aniline silicofluoride, 1:6000; ammonium carbonate and ammonia, 1:28,000; sodium carbonate, 1:16,000; sodium sulphite, 1:160,000; ammonium chromate, 1:1,260,000; sulphuric acid, 1:1,600,000.—W. P. S.

Hydrogen ion concentration; Measurement of ——. G. W. Monier-Williams. Analyst, 1921, **46**, 315—324.

Detailed instructions are given for the construction of an inexpensive apparatus for the determination of hydrogen ion concentrations by electrical measurement.—W. P. S.

Acids and bases; Joint use of two indicators in the titration of ——. J. L. Lizius. Analyst, 1921, **46**, 355—356.

The use of two indicators, *e.g.*, phenolphthalein and thymolphthalein, or methyl-red and thymolblue, is advantageous, since the colour changes indicate the approach of the end-point of the titration.—W. P. S.

Potassium; Determination of —— in the presence of sodium, magnesium, sulphates and phosphates. H. Atkinson. Analyst, 1921, **46**, 354—355.

The mixture of salts (*e.g.*, KCl, 0·5, $Na_2SO_4,10H_2O$, 1, $MgSO_4,7H_2O$, 0·6, and NaH_2PO_4, 1·1 g.) is twice evaporated with perchloric acid until fumes of the acid are evolved, the residue is treated with 100 c.c. of methyl alcohol and the mixture boiled for 1 hr.; after a further 18 hrs. the potassium perchlorate is collected on a filter, washed with 50 c.c. of methyl alcohol containing 5% by vol. of perchloric acid (sp. gr. 1·12), then with 20 c.c. of ethyl alcohol, dried, and weighed. W. P. S.

Cadmium; Gravimetric determination of ——. L. W. Winkler. Z. angew. Chem., 1921, **34**, 466—467. (*Cf.* J., 1921, 607 A.)

The cadmium is precipitated as cadmium ammonium phosphate, $Cd(NH_4)PO_4,H_2O$, by the addition of an excess of 20% diammonium hydrogen phosphate solution to a very faintly acid, hot dilute solution (about 0·2%) of the cadmium salt containing about 2% of ammonium chloride. The precipitate, initially amorphous, becomes crystalline in the course of 1 hr. if occasionally stirred, and after keeping for 2 hrs. or overnight, it is filtered off, washed with 50 c.c. of cold water saturated with cadmium ammonium phosphate, and finally with methyl alcohol, and dried for 2 hrs. at 100° C. As a further check it may be converted by ignition in a platinum crucible into the pyrophosphate, $Cd_2P_2O_7$. The corrections to be applied to the weight of $Cd(NH_4)PO_4,H_2O$ obtained are as follows:—Weight of precipitate 0·2—0·3 g., add 0·2 mg.; 0·1 g., add 0·3 mg.; 0·05 g., add 0·4 mg.; 0·01 g., add 1·9 mg. The presence of ammonium salts, sodium, or potassium chloride, etc. in moderate amount does not materially affect the accuracy of the determination.—G. F. M.

Aluminium; Separation of —— from glucinum. H. T. S. Britton. Analyst, 1921, **46**, 359—366.

A solution, containing not more than 0·3 g. BeO or 0·4 g. Al_2O_3, is evaporated to a volume of 25 c.c., cooled, and 24% sodium hydroxide is added in quantity just sufficient to dissolve the precipitated hydroxides; the mixture is diluted to 500 c.c., boiled for 40 mins. to effect decomposition of the glucinate, and the precipitated glucinum hydroxide is collected at once on a filter, washed, ignited, and weighed.—W. P. S.

Arsenic; Determination of —— in fabrics and colours. Utz. Farben-Zeit., 1921, **26**, 3044—3045.

In estimating water-soluble arsenic, the material is extracted with water, the solution is concentrated, sufficient sulphuric acid is added to yield a 12% solution, and a small crystal of copper sulphate is added. Materials in which it is required to estimate the total arsenic, such as wallpaper, textile fabrics, or colours which are readily attacked by concentrated sulphuric acid, are heated with a few c.c. of sulphuric acid on the water bath, the solution is subsequently diluted to 12%, and a crystal of copper sulphate is added. The arsenic is then reduced electrolytically to hydrogen arsenide in a U-tube containing 12% sulphuric acid and fitted with electrodes of pure sheet lead. The cathode branch of the U-tube is connected by means of a tube filled with pumice stone or glass wool impregnated with alkaline lead solution to retain hydrogen sulphide, with a bulbed tube containing *N*/10 or

N/100 silver nitrate solution. The arsenic solution is run drop by drop from a dropping funnel into the cathode branch of the U-tube whilst the current is flowing. Subsequently the solution in the absorption tube is filtered and the excess of silver nitrate titrated with ammonium thiocyanate solution. Colours not readily decomposed by concentrated sulphuric acid are introduced into the cathode branch of the U-tube in a small glass vessel suspended by platinum wire through the stopper. (*Cf.* Thorpe, J., 1903, 965; 1906, 394.)—L. A. C.

Cobalt; Rapid electrolytic determination of —— in ammoniacal solution and its application to cobalt nitroso-β-naphthol. K. Wagenmann. Metall u. Erz, 1921, **18**, 447—449.

The solution, containing not more than 0·1 g. of cobalt as sulphate, is treated with 5 g. of ammonium chloride and 30 c.c. of strong ammonia, diluted to 125—150 c.c. with water, and electrolysed cold for 40—45 mins. with a current of 5 amps. using a double platinum gauze cathode rotating at 600—1200 revs. per min., 0·8—1 g. of hydrazine sulphate being added in small portions from time to time. Ignition of cobalt nitroso-β-naphthol to Co_3O_4 tends to yield high results owing to the danger of the precipitate having carried down impurities and to the difficulty of burning off the last traces of carbon. Accurate results may be obtained by fusing the ignited oxide with bisulphate and treating the solution of the melt as described above. (*Cf.* J.C.S., Nov.)—A. R. P.

Carbon monoxide; Detection of ——. C. R. Hoover. J. Ind. Eng. Chem., 1921, **13** 770—772.

An absorbent, Hoolamite (U.S.P. 1,321,061–2; J., 1920, 47 A), is prepared by mixing together 53—56% of fuming sulphuric acid, 10·6—12% of iodine pentoxide, and 33—35% of pumice stone. At ordinary temperatures carbon monoxide is oxidised by this reagent to carbon dioxide with liberation of iodine which reacts with excess of sulphur trioxide present to form a green substance indicative of the presence of carbon monoxide, and varying in depth of colour with the concentration of the gas. On standing or gentle warming the green colour changes to orange-yellow and disappears in a few minutes, so that the material can again be used as before until about twelve tests have been made, when the colour produced becomes irregular and a fresh supply of reagent is required. The colour produced in each case is compared with permanent colour standards prepared from a mixture of pumice granules with normal and basic copper acetate and chromium oxide. By this means a quantitative test can be made with gas mixtures containing up to 0·2% of carbon monoxide. Interfering gases such as unsaturated hydrocarbons, hydrogen sulphide, etc. are first removed from a gaseous mixture by passing it through dry, active charcoal. As little as 0·005% of carbon monoxide can be detected by passing 500 c.c. of a gas mixture through a glass tube containing a column of Hoolamite 50 mm. × 5 mm. A pocket size detector apparatus has been devised. —S. S. A.

Nitrate nitrogen; Source of error in Ulsch's method for the determination of ——. F. Mach and F. Sindlinger. Z. anal. Chem., 1921, **60**, 235—238.

The presence of small quantities of sulphide in the *ferrum reductum* used in the method cause the results obtained to be much too low; *e.g.*, 0·03% of sulphide sulphur will lower the apparent nitrogen content from 13·86 (true value) to 12·90%. Each new batch of iron purchased should be tested against pure potassium nitrate before it is put into actual use.—W. P. S.

Pentosans and pentoses; Volumetric estimation of phenylhydrazine and its application to the estimation of ——. A. R. Ling and D. R. Nanji. Biochem. J., 1921, **15**, 466—468.

Phenylhydrazine may be determined in acetic acid solution by adding a known volume to excess of iodine solution ($C_6H_5.NH.NH_2+2I_2=3HI+C_6H_5I+N_2$), and titrating the excess of iodine by means of thiosulphate solution. In the determination of pentoses and pentosans the furfural solution produced by distilling with hydrochloric acid is neutralised with sodium hydroxide, acidified with acetic acid, and excess of a standard phenylhydrazine solution (approx. 2%) added. When precipitation of the hydrazone is complete the solution is diluted and filtered, and the excess of phenylhydrazine determined in the filtrate as described above. The results obtained with this method as applied to arabinose and to the extract obtained by hydrolysing some Indian grasses agreed closely with those given by the phloroglucinol method.

Patents.

Gas analysis; Apparatus for ——. M. Arndt. G.P. 338,301, 27.6.15.

In a gas analysis apparatus operated by raising or lowering the level of the confining fluid, the gas-measuring burette communicates directly with the absorption vessel disposed below by means of a capillary tube traversing a part of the former. The reservoir containing the confining fluid is provided with a float valve closing automatically when the fluid is displaced from the reservoir. —J. S. G. T.

Absorption device [pipette] for gases. A. Wakenhut. G.P. 338,304, 23.12.19.

In a gas absorption device of the Orsat type consisting of an absorption pipette communicating with a reservoir for the absorbing fluid, a narrow capillary tube connects the upper and lower parts of the absorption vessel. The lower part of this capillary tube, through which gas is delivered to the absorption pipette, is partly disposed within the reservoir. A receptacle is disposed between the upper part of the absorption pipette and the lower part of the reservoir in such a manner that the absorbing fluid is cut off from the internal atmosphere by a layer of oil or like medium.—J. S. G. T.

Supply of liquid in filtration etc. E.P. 168,262. *See* I.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Barfred, George, and Seedorff. Tunnel furnaces or kilns. 26,347. Oct. 5.

Bellis Heat Treating Co. Pots or crucibles. 26,245. Oct. 4. (U.S., 18.10.20.)

Brooke, Dellwik, and Techno-Chemical Laboratories. Centrifugal separating apparatus. 25,692. Sep. 28.

Brown. Continuous evaporating and drying apparatus. 25,878. Sep. 30.

Chambers and Hammond. Heat treatment of materials. 25,750. Sep. 29.

Cox. 26,095. *See* XIII.

Cross, and Zynkara Co. Compositions for preventing corrosion and removing incrustations in boilers etc. 26,584. Oct. 7.

Dellwik, and Techno-Chemical Laboratories. Centrifugal separating machines. 25,691. Sep. 28.

Fairrie. Manufacture of ice. 26,379 and 26,380. Oct. 6.

Freakley and Wadsworth. Grinding mills. 25,644. Sep. 28.

Hill. Tube mills, ball mills, etc. 26,441. Oct. 6.

Hodgkinson and Ridge. Furnaces. 26,131. Oct. 3.

Humphries. Apparatus for bringing liquid into contact with gas. 26,121. Oct. 3.

Jackson. Non-freezing liquid. 25,429. Sep. 26.

Lodge Fume Co. 25,940. *See* X.

Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Treatment of pyrophoric materials to reduce their pyrophoric character. 26,230. Oct. 4. (Norway, 22.11.20.)

Standley. Production of elastic motive fluid. 25,481. Sep. 26. -

Testrup, and Techno-Chemical Laboratories. Drying by evaporation. 26,564. Oct. 7.

Complete Specifications Accepted.

9044 (1920). Beeton, and Trufood, Ltd. Drying rganic substances. (169,471.) Oct. 12.

16,320 (1920). Krause. Evaporating or inspissaing solutions and effecting chemical reactions. 145,079.) Oct. 5.

16,412 (1920). Sharples Specialty Co. Refining iquids from suspended impurities. (145,090.) Oct. 5.

16,936 (1920). Bergve. Manufacture of alkaline ondensing agents. (169,498.) Oct. 12.

17,538 (1920). United Filters Corp. Rotary sucion filters. (146,231.) Oct. 12.

19,134 (1920). Acton and MacKean. Separation f solids from liquids. (169,315.) Oct. 5.

19,267 (1920). Dorr Co. Selective recovery of rganic materials from liquids. (147,196.) Oct.12.

20,151 (1920). Schworetzky. Production of fire-xtinguishing foam. (148,227.) Oct. 12.

22,738 (1920). Fuller-Lehigh Co. Pulveriser mills. 153,889.) Oct. 12.

23,586 (1920). Kay. Removal of water from rotary dryers. (169,364.) Oct. 5.

34,814 (1920). Henning. Non-flammable volatile liquid. (169,648.) Oct. 12.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Berg. Process for dewatering peat. 25,832. Sep. 30.

Dunstan and Remfry. Treatment of petroleum etc. 25,684. Sep. 28.

Forwood and Taplay. Treatment of hydrocarbons. 26,555. Oct. 7.

Hatfield. Production of smoke. 26,211. Oct. 4.

Hutchins. Apparatus for distilling carbonaceous materials. 26,023. Oct. 1.

Koppers Co. Purification of gases. 26,472 and 26,482. Oct. 6. (U.S., 7 and 22.10.20.)

Lloyd. Manufacture of coal etc. briquettes. 26,353. Oct. 5.

Lucas, and V. M. L. Experimental, Ltd. Production of coloured smoke etc. 26,473. Oct. 6.

McBlain. Combustion of solid, liquid, or gaseous fuels. 26,198. Oct. 4.

Merz and McLellan, Statters, and Weeks. Retorts, gas-producers, etc. 26,542. Oct. 7.

Rakuzin. Treatment of crude oil. 26,138. Oct. 3.

Rosenberg. Suction-gas producer plant. 25,929. Sep. 30.

Complete Specifications Accepted.

6921 (1920). Chem. Fabr. Rhenania. *See* VII.

9484 (1920). Adams. Cracking of oils etc. (141,689.) Oct. 12.

16,898 (1920). Robin. *See* V.

18,457 (1920). Verity. Gas-producers. (169,308.) Oct. 5.

19,616 (1920). Cordes. Cleaving and converting heavy hydrocarbons into lower-boiling lighter products. (147,648.) Oct. 5.

20,887 (1920). Armstrong. Manufacture of briquettes. (169,322.) Oct. 5.

22,136 (1920). Maclaurin, and Scottish Bye-Products, Ltd. Manufacture of lubricating greases. (169,573.) Oct. 12.

22,637 (1920). Tozer. Low-temperature carbonisation and gasification of coal etc. (169,580.) Oct. 12.

28,778 (1920). Underfeed Stoker Co., and McEwen. Carbonisation of subdivided fuel. (169,389.) Oct. 5.

29,215 (1920). Bayer u. Co. *See* VII.

III.—TAR AND TAR PRODUCTS.

Complete Specification Accepted.

11,459 (1921). Imray (Soc. Chem. Ind. in Basle). Manufacture of α-aminoanthraquinone. (169,667.) Oct. 12.

IV.—COLOURING MATTERS AND DYES.

Applications.

Baddiley, Rodd, and British Dyestuffs Corp. Manufacture of dyestuffs of the triarylmethane series. 26,324. Oct. 5.

Bloxam (Akt.-Ges. f. Anilinfabr.). Manufacture of ortho-oxyazo dyestuffs. 25,586. Sep. 27.

Complete Specification Accepted.

16,199 (1920). Akt.-Ges. f. Anilinfabr. Manufacture of trisazo dyestuffs. (145,054.) Oct. 5.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

British Cellulose and Chem. Manuf. Co. (American Cellulose and Chem. Manuf. Co.). Treatment of cellulose derivatives. 25,562. Sep. 27.

Bronnert. Manufacture of artificial silk. 26,433. Oct. 6.

Bronnert. Manufacture of threads from viscose. 26,668. Oct. 8.

Chiba and Kumagae. Recovery of material for manufacture of paper. 25,435. Sep. 26.

Cook and Co., and Stott. Treatment of cotton, cotton waste, etc. 25,416. Sep. 26.

Dreyfus. Treatment of cellulose derivatives. 25,781. Sep. 29.

Kaye. 26,665. *See* XIV.

Complete Specifications Accepted.

8000 (1920). Bronnert. Manufacture of viscose silk. (169,190.) Oct. 5.

14,387 (1920). Atomised Products Corp. Treatment of waste sulphite liquors. (143,874.) Oct. 12.

16,546 (1920). Bennert. Treating and scouring wool, woollen yarns, etc. (145,448.) Oct. 5.

16,898 (1920). Robin. Treatment of fabrics, particularly those used in the manufacture of gas mantles. (169,277.) Oct. 5.

17,806 (1920). Muller. Manufacture of artificial threads, films, etc. from viscose. (145,627.) Oct. 5.

19,313 (1920). Zellstoff-Fabr. Waldhof. Treatment of wood and other cellulose-containing materials. (147,232.) Oct. 5.

35,076 (1920). Turner. Treatment of fibrous substances. (169,407.) Oct. 5.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Application.

Bouwman. Process for dyeing wood etc. under pressure. 25,483. Sep. 26. (Holland, 7.10.20.)

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Briggs. Manufacture of sulphate of ammonia. 26,571. Oct. 7.

Dallemagne y Paulin. Purification of fluorite. 25,582. Sep. 27.

Ford. Lime kiln for use with oil fuel. 25,980. Oct. 1.

Freeth and Munro. Production of ammonium chloride and sodium carbonate. 25,862. Sep. 30.

Lessing. Manufacture of sulphate of ammonia. 26,440. Oct. 6.

Levin. 26,214. *See* XI.

Wetzlar (Pauling). Method of transforming into sulphates metals and alloys insoluble in sulphuric acid. 25,937. Sep. 30.

Wetzlar (Pauling). 25,818. *See* X.

Complete Specifications Accepted.

6921 (1920). Chem. Fabr. Rhenania, and Projahn. Extraction of sulphur from gases containing sulphuretted hydrogen. (169,467.) Oct. 12.

7665 (1920). Nitrogen Corp. Production of nitrogen compounds. (140,394.) Oct. 5.

7967 (1920). Nitrogen Corp. Production of ammonia. (140,439.) Oct. 5.

10,608 (1920). Freeth and Munro. Removal of calcium and magnesium from rock salt brine or solutions of rock salt. (169,192.) Oct. 5.

16,586 (1920). Naef. *See* X.

16,731 (1920). Audianne. Apparatus for making sulphuric anhydride. (169,264.) Oct. 5.

16,936 (1920). Bergve. *See* I.

17,765 (1920). Howorth (Akt. Hoyangsfaldene Norsk Aluminium Co.). Preparation of alumina from clay. (169,301.) Oct. 5.

19,704 (1920). Verein Chem. Fabriken. Manufacture of hydrofluoric acid. (147,711.) Oct. 12.

29,215 (1920). Bayer u. Co. Obtaining sulphur or treating and purifying gases containing hydrogen sulphide. (153,297.) Oct. 5.

VIII.—GLASS; CERAMICS.

Application.

British Thomson-Houston Co. (General Electric Co.). Manufacture of glass. 26,432. Oct. 6.

Complete Specifications Accepted.

14,028 (1920). Hailwood. Glass manufacture. (169,481.) Oct. 12.

18,118 (1920). Frink. Glass-melting furnaces. (169,304.) Oct. 5.

18,163 (1920). Frink. Glass-annealing furnaces etc. (169,537.) Oct. 12.

21,937 (1920). Smith. Clay for use in the manufacture of pottery. (169,343.) Oct. 5.

23,987 (1920). Jackson (Stein et Cie.). Crucible glass-melting furnaces. (169,595.) Oct. 12.

IX.—BUILDING MATERIALS.

Applications.

Bouwman. 25,483. *See* VI.

Friedrich. Production of a cold glaze on concrete, brickwork, etc. 25,470. Sep. 26.

Garc. Treatment of wood. 26,502. Oct. 7.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Bellis Heat Treating Co. 26,245. *See* I.

Brindley. Production of rustless wire, sheetings, etc. 26,680. Oct. 8.

British Thomson-Houston Co. (Comp. Franç. Thomson-Houston). Production of boron etc. for use in purifying copper castings. 26,025. Oct. 1.

Clarke. Extracting metals from ore dumps. 26,531. Oct. 7.

Dubreul. Treatment of compound minerals. 26,351. Oct. 5. (Fr., 5.10.20.)

Goldschmidt A.-G. Bearing-metal alloy. 25,545. Sep. 27. (Ger., 1.10.20.)

Green. Flux for welding cast iron by oxy-acetylene process. 26,367. Oct. 6.

Hibbard. Puddling. 25,480. Sep. 26. (U.S., 11.5.21.)

Hodgkinson and Ridge. 26,131. *See* I.

Hyde. Flux-coated electrodes for electric arc welding. 25,569. Sep. 27.

Lodge Fume Co. (Metallbank u. Metallurgische Ges.). Separating difficultly condensable constituents from gases from roasting-furnaces etc. 25,940. Sep. 30.

Naito. Treatment of magnetic sand or finely divided iron ore. 25,751. Sep. 29.

Ormiston. Aluminium solder. 26,167. Oct. 4.

Soc. Anon. Le Fer. Production of electrolytic iron. 26,229. Oct. 4. (Fr., 19.10.20.)

Stóbie. Recovery of metals. 26,036. Oct. 1.

Stobie. Zinc condensing. 26,037. Oct. 1.

Turner. Manufacture of metals and alloys by the aluminothermic process. 26,637. Oct. 8.

Varlez. Treatment of ores and metallic waste. 26,444. Oct. 6.

Wetzlar (Pauling). Method of leaching ores with nitric acid. 25,818. Sep. 29.

Wetzlar (Pauling). 25,937. *See* VII.

Complete Specifications Accepted.

7663 (1920). Marks (Scovill Manufacturing Co.). Melting or melting and reducing non-ferrous metals and alloys. (169,188.) Oct. 5.

8957 (1920). National Malleable Castings Co. Steel and its heat treatment. (140,823.) Oct. 5.

13,830 (1920). Walter. Producing alloys conaining silicon with metals of the iron and chromium groups. (143,553.) Oct. 5.

16,107 (1920). Metallind. Schiele u. Bruchsaler. Welding aluminium to iron. (145,043.) Oct. 5.

16,586 (1920). Naef. Manufacture of nickel and nickel salts. (169,247.) Oct. 5.

17,092 (1920). Minerals Separation, Ltd. (Wilkinson). Ore concentration. (169,288.) Oct. 5.

18,179 (1920). Bonnard. Process for refining tin nd antimony. (145,789.) Oct. 5.

19,364 (1920). Ampere Ges. Production of ferrohromium poor in carbon. (147,458.) Oct. 12.

19,720 (1920). Metallindustrie Schiele u. Bruchaler. Production of castings of aluminium and its lloys. (147,723.) Oct. 5.

19,956 (1920). Mond (Metallbank u. Metallurg. es.). Lithium-aluminium alloys. (147,903.) Oct. 5.

21,033 (1920). Simon. Chloridising roasting of urnt pyrites and furnace therefor. (149,247.) ct. 5

24,585 (1920). Lavandeyra. Heat-treating aluminium alloys having a copper content. (159,852.) Oct. 5.

XI.—ELECTRO-CHEMISTRY.

Applications.

General Electric Co., and Ryde. Apparatus for electric discharge through gases. 25,700. Sep. 28.

Hyde. 25,569. *See* X.

Levin. Electrolytic cells for generating hydrogen and oxygen. 26,214. Oct. 4.

Oldham and Oldham. Galvanic batteries. 25,719. Sep. 29.

Soc. Anon. Le Fer. 26,229. *See* X.

White. Protective coatings of electric conductors. 25,733. Sep. 29.

Complete Specifications Accepted.

16,576 (1920). Forshee. Electrodes. (160,431.) Oct. 5.

17,750 (1920). Pollak (Werke Gautenbach). Production of insulating material. (169,527.) Oct. 12.

18,584 (1920). Saunders Electrical Co., and Saunders. Electric accumulators. (169,541.) Oct. 12.

21,655 (1920). Nolle. Absorbents for use in galvanic batteries. (149,330.) Oct. 5.

XII.—FATS; OILS; WAXES.

Applications.

Heys and Macpherson. Antiseptic and insecticidal soap or compound. 25,857. Sep. 30.

Plauson's Forschungsinstitut Ges. Manufacture of soaps. 26,008. Oct. 1. (Ger., 3.11.20.)

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Application.

Cox. Paint for removing and preventing incrustations in steam boilers etc. 26,095. Oct. 3.

Complete Specifications Accepted.

16,708 (1920). Ivinson and Roberts. Paint or composition impervious to oils, spirits, etc. (169,258.) Oct. 5.

22,078 (1920). Potter, Fleet, and Damard Lacquer Co. Manufacture of phenol-aldehyde condensation products. (169,347.) Oct. 5.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Applications.

Chopin, and Soc. d'Enterprise Meunière. Measuring elastic properties of rubber etc. 26,582. Oct. 7. (Fr., 7.10.20.)

Comrie and Leech. India-rubber compounds. 25,963–4. Oct. 1.

Kaye. Vulcanisation of rubber-latex paper. 26,665. Oct. 8.

XV.—LEATHER; BONE; HORN; GLUE.

Applications.

Byk Guldenwerke Chem. Fabr. Purification of tannin. 26,015. Oct. 1. (Ger., 1.10.20.)

Carmichael and Ockleston. Treatment of hides, skins, etc. for production of leather. 26,266. Oct. 5.

Gluck and Nicol. Manufacture of gelatin etc. 25,882. Sep. 30.

Moeller and Renner. Manufacture of bates and operation of bating. 25,705. Sep. 28. (Ger., 25.4.21.)

Complete Specifications Accepted.

8860 (1920). Ross, Marris, and Walker and Sons. Preserving animal matter or tissue such as hides or skins. (169,468.) Oct. 12.

10,998 (1920). Koetzle. Tanning materials. (144,617.) Oct. 5.

17,308 (1920). Fairweather (Luftfahrzeugbau Schütte-Lanz). Production of glue from blood. (169,509.) Oct. 12.

18,083 (1920). Breuer. Manufacture of leather. (145,742.) Oct. 12.

XVI.—SOILS; FERTILISERS.

Application.

Adelantado. Manufacture of superphosphates and manure. 26,042. Oct. 1.

Complete Specification Accepted.

21,006 (1920). Kernot, and British Glues and Chemicals, Ltd. Production of fertilisers. (169,323.) Oct. 5.

XVIII.—FERMENTATION INDUSTRIES.

Complete Specifications Accepted.

17,079 (1920). Wohl. Production of pure pressed yeast. (169,504.) Oct. 12.

17,797 (1920). Wohl and Scherdel. Production of yeast. (145,623.) Oct. 5.

19,515 (1920). Vasseux. Production of yeast from peat. (147,581.) Oct. 5.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Adams. Food product. 26,641. Oct. 8.

Fabry. Centrifugal machine for dewatering sewage sludge. 25,439. Sep. 26.

Heys and Macpherson. 25,857. *See* XII.

Nielsen. Sterilising fluids containing fat globules. 25,829. Sep. 30.

Complete Specifications Accepted.

7960 (1920). Sherman. Preserving meat. (169,189.) Oct. 5.

9044 (1920). Beeton, and Trufood, Ltd. *See* I.

16,894 (1920). Dunham. Casein-oil product. (169,276.) Oct. 12.

16,895 (1920). Dunham. Dry shortening material. (169,493.) Oct. 12.

23,663 (1920). Marshall and Sutcliffe. Production of a meat extract. (169,366.) Oct. 5.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Imray (Soc. Chem. Ind. in Basle). Manufacture of optically-active aromatic amino-alcohols. 26,247. Oct. 4.

Jones (Wülfing). Water-soluble compounds of diethylbarbituric acid and its homologues. 26,681. Oct. 8.

Marks (Abbott Laboratories). Production of esters of aromatic acids. 25,593. Sep. 27.

Complete Specifications Accepted.

13,562 (1920). Wesson. Isobornyl ester-camphene mixture. (169,198.) Oct. 5.

17,367 (1920). Pratt. Sulphur terpene compounds. (169,513.) Oct. 12.

17,551 (1920). Kolshorn. Manufacture of salts of compounds of lactic acid with tannic or gallic acids. (146,234.) Oct. 12.

18,115 (1920). British Cellulose and Chem. Manuf. Co., Badder, and Nightingale. Manufacture of alkyl amines. (169,536.) Oct. 12.

19,267 (1920). Dorr Co. *See* I.

34,814 (1920). Henning. *See* I.

13,981 (1921). Chem. Fabr. vorm. Sandoz. Manufacture of a derivative of hexamethylenetetramine. (165,084.) Oct. 5.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Application.

British Thomson-Houston Co. (General Electric Co.). Fluorescent screens. 25,596. Sep. 27.

Complete Specifications Accepted.

17,892 (1920). Shepherd, and Colour Photography, Ltd. Colour photography. (169,533.) Oct. 12.

25,762 (1920). Mimosa A.-G., and Formstecher. Toning-baths. (169,378.) Oct. 5.

XXII.—EXPLOSIVES; MATCHES.

Complete Specification Accepted.

13,811 (1920). Du Pont de Nemours and Co. Propellant powder and process of making same. (150,299.) Oct. 5.

XXIII.—ANALYSIS.

Applications.

Lamb. Apparatus for testing relative densities of colour intensities of liquids, transparent solids, etc., and for measuring the differences. 25,651. Sep. 28.

Slater. Estimation of small quantities of substances present in gases or liquids. 25,438. Sep. 26.

Complete Specifications Accepted.

15,716 (1919). Rudge-Whitworth, Ltd., and Heathcote. Ascertaining the composition, nature, and effect of gases and vapours. (169,465.) Oct. 12.

13,850 (1920). Hadfields (Merton), Ltd., and Bawtree. Viscometer. (169,204.) Oct. 5.

I.—GENERAL; PLANT; MACHINERY.

Catalysts; Adsorption of gases by metallic ——. H. S. Taylor and R. M. Burns. J. Amer. Chem. Soc., 1921, 43, 1273—1287.

The adsorption of hydrogen, carbon monoxide, carbon dioxide, and ethylene by finely divided nickel, cobalt, iron, copper, palladium, and platinum is a specific property quite different in nature from adsorption by inert adsorbents such as charcoal The amount of adsorption is a function of the mode of preparation and is less pronounced the higher the temperature at which the reduced metal has been prepared. In the two cases, nickel and hydrogen, and copper and carbon monoxide, adsorption increases rapidly with increasing partial pressures below 300 mm., and becomes practically independent of pressure beyond this point. (*Cf.* J.C.S., Nov.)—J. F. S.

Inert gas; Use of —— for the prevention of explosions. E. F. White. Chem. and Met. Eng., 1921, 25, 513—515.

An example of this use of inert gas is afforded by the operation of grinding sulphur. Small-scale experiments with an explosion tube containing sulphur dust agitated by a fan showed that while with free access of air a spark regularly produced ignition, this was prevented by the addition of 20—25% of inert gas to the atmosphere. A generator to produce 5000 cub. ft. of inert gas per hr. is described. It consists of a coke-fired stove, a chamber filled with chequerwork in which secondary air just completes combustion, and a dust scrubber. A mill of capacity 1—3 tons per hr. required 500—1000 cub. ft. of inert gas per hr.—C. I.

Rust; Formation of —— by carbon dioxide. G. Bruhns. Chem.-Zeit., 1921, 45, 885—887.

Condensed water from boilers may contain considerable quantities of free (dissolved) carbon dioxide; if this water is fed into the boilers, the carbon dioxide attacks the iron, yielding a very dilute solution of iron bicarbonate which decomposes readily giving free carbon dioxide and hydrated iron oxide, thus leading to the gradual formation of a deposit of rust.—W. P. S.

Patents.

Disintegrating mills; Rotary ——. T. and I. Hoffmann, legal representatives of J. Hoffmann. E.P. 139,814, 5.3.20. Conv., 18.5.17.

Toothed milling rings are fixed in the mill at both sides, and the beaters are formed as arms with lugs on both sides, co-acting with the rings. The arms have a rocking as well as a rotating motion. —B. M. V.

Grinding mill. Grinding mill and grinding medium therefor. H. W. Hardinge, Assr. to Hardinge Co. U.S.P. (A) 1,388,462 and (B) 1,388,463, 23.8.21. Appl., (A) 31.10.19, (B) 8.7.20.

A) A grinding unit consists of an integral body with conical ends and a central bore. (B) A grinding mill comprises a rotating drum containing a number of units each formed of two conical portions secured base to base, the heights of the cones being smaller han their diameters, and the resulting discushaped elements being free to slide on each other and o assume a position in which their axes are at an angle to the axis of the drum.—B. M. V.

Acid chambers, acid towers, acid mains, etc. P. L. Pfannenschmidt. E.P. 150,734, 6.9.20. Conv., 8.9.19. Addn. to 149,667 (J., 1921, 681 A).

NSTEAD of the window-shaped framework adjacent to the acid chamber described previously, a framework disposed outside of the acid-filled space is used, and the plates fastened to this framework are provided with reinforced edges along which they are directly contiguous to one another.—H. H.

Heat-interchanging means. E. L. Pease. E.P. 168,609, 2.3.20.

Tanks containing a heat-conducting medium and each formed with crossed sets of tubes are so arranged within a structure with division walls that the tubes are inclined to the horizontal or to the side walls or division walls, whereby fluid after traversing a set of tubes will flow into a space formed by and between adjacent tanks and the separate structure, and thence through a set of tubes of the next tank. A heating or cooling medium may be passed through one set of tubes of each tank, and a fluid to be heated or cooled through the other set. One or more of the tanks may accommodate a drum to receive steam, hot water, or electrical heating elements. The apparatus may be used for generating steam, cooling gas, etc.—H. H.

Furnaces; Gas-fired heating ——. F. T. Rennison. E.P. 169,034, 30.6.20.

The hearth of a furnace is supported on cellular bricks, forming a number of passages in both longitudinal and transverse directions. The upper set of passages (say the transverse ones) are used as combustion chambers, gas (and some air) being supplied to every chamber but alternately at opposite ends, the other (outlet) ends being in communication with the furnace chamber, and additional air may be added at either end of the combustion chambers, so as to provide a rich or poor flame as desired. Below the combustion passages are arranged transverse flues for air heated by the waste gases of combustion in the longitudinal flues.—B. M. V.

Furnace or other containers; Method of preventing the passage of gases of combustion through the walls of ——. C. M. Shipman. U.S.P. 1,387,739, 16.8.21. Appl., 26.12.16. Renewed 24.11.20.

The walls are treated with a slurry of clay, silica, and water-glass and then exposed to hot gases of combustion.—B. M. V.

Furnace; Continuous heating ——. W. H. Fitch. U.S.P. 1,388,419, 23.8.21. Appl., 27.1.20.

The furnace comprises a combustion chamber, a superposed heating chamber, a flue at one side for leading hot gases from the combustion chamber to the heating chamber, and another flue on the opposite side for leading the gases out of the heating chamber in the opposite direction, the gases thus being caused to pass completely around the heating chamber.—B. M. V.

Annealing [furnace]. C. M. Stein, Assr. to Soc. Anon. des Appareils de Manutention et Fours Stein. U.S.P. 1,388,976, 30.8.21. Appl., 18.8.19.

An annealing furnace is constructed with a muffle surrounded by a combustion chamber; a non-oxidising gas is led first into the muffle, then through openings in the wall of the muffle to the combustion chamber, where it is burnt with air which is also admitted.—B. M. V.

Drying gas [e.g. chlorine; Method of ——]. F. C. Frary and S. Temple. U.S.P. 1,359,047, 16.11.20. Appl., 15.3.19.

The gas is dried by passing it over a non-deliquescent material which is capable of forming a deliquescent substance with the gas at ordinary temperatures. For example, gas containing chlorine is brought into contact with pieces of iron

▲

whereby ferric chloride is formed, and this serves to dry the gas.—A. J. H.

Catalysers; Process of making ——. A. A. Backhaus and F. B. Arentz, Assrs. to U.S. Industrial Alcohol Co. U.S.P. 1,376,665, 3.5.21. Appl., 15.6.18.

To deposit a finely-divided catalytic metal upon a metal body, a salt of the catalytic metal is reduced *in situ* upon the body by aeriform agents. For example, to produce a catalyst for use in making aldehydes, metal gauze is coated with copper nitrate which is converted into the hydroxide by the action of gaseous ammonia, and the hydroxide reduced by means of hydrogen.—H. H.

Evaporator control. W. L. De Baufre. U.S.P. 1,387,475, 16.8.21. Appl., 6.9.16.

The evaporating compartment, having means for supplying to it solution to be evaporated, is fitted with a safety valve. The condensing compartment is supplied with heated vapour of a definite maximum pressure at a rate which is limited to less than the capacity of the safety valve, by passing the vapour through an orifice of definite predetermined capacity.—H. H.

Evaporation or concentration of solutions, and effecting chemical reactions; Process for ——. G. A. Krause. G.P. 309,172, 30.1.17. Addn. to 297,388.

In a process of evaporation, concentration, etc. carried out in accordance with the chief patent, the mist produced is dispersed over a spherical or cylindrical surface, whereby a greater area of dispersion is afforded than is the case with a horizontal plane.—J. S. G. T.

Extracting apparatus. J. B. Jenson. U.S.P. 1,388,718, 23.8.21. Appl., 8.6.18.

Elongated closed cylinders, superimposed and interconnected, are fitted with heating devices. A rotary conveyor is mounted eccentrically in each cylinder, leaving a clearance adjacent to the upper side of the cylinder, and means are provided for obstructing the passage of the material at the discharge end of each cylinder.—H. H.

Dryer. E. B. Ayres, Assr. to Philadelphia Textile Machinery Co. U.S.P. 1,388,790, 23.8.21. Appl., 23.9.19.

Air is circulated through a heating chamber and through two drying chambers disposed one at each side of the heating chamber. Conveyors move the materials in opposite directions through the two drying chambers, and a frame pivoted centrally at each end of the apparatus is arranged to swing in front of either drying chamber to carry the materials to the feed end of one chamber and to receive materials from the discharge end of the other chamber.—H. H.

Refrigerating machine; High-pressure air ——. Ges. für Lindes Eismaschinen A.-G. G.P. 336,768, 29.6.18. Addn. to 323,950 (J., 1921, 171 A).

In a refrigerating machine operated by high-pressure air in accordance with the chief patent, the conduit for the supply of air to the machine is so disposed that it is exposed simultaneously to the highest pressure and the lowest temperature occurring in the plant.—J. S. G. T.

Electrical precipitation apparatus; Means for supporting and insulating high-tension electrodes in ——. H. V. Welch. Assr. to International Precipitation Co. U.S.P. 1,391,436, 20.9.21. Appl., 27.1.19.

A hollow body of insulating material which serves to support the electrodes, is enclosed within a hood and provided at its lower end with an inlet for clean gas, and at its upper end with an outlet for passing clean gas into the space surrounding the insulator. —J. S. G. T.

Precipitation of particles held in suspension in gases; Process of [electrical] ——. Siemens-Schuckertwerke G.m.b.H. G.P. 339,625, 13.9.19.

Means are provided whereby a portion of the gas to be purified can be enclosed within a chamber, and while at rest therein submitted to the electric discharge between electrodes, the potential difference of which is suitably increased for the purpose. For example, a number of purifying chambers are disposed in juxtaposition in a common conduit, and are provided with quickly operated valves, by which they can be closed as desired.—J. S. G. T.

Evaporation or inspissation of solutions; Process and means for —— *and also for effecting chemical reactions.* G. A. Krause. E.P. 145,079, 16.6.20. Conv., 29.1.17. Addn. to 17,508 of 1913.

See G.P. 329,358 of 1917; J., 1921, 249 A.

Refining liquids from suspended impurities; Process for ——. Sharples Specialty Co., Assees. of E. E. Ayres, jun. E.P. 145,090, 17.6.20. Conv., 3.10.17.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Froth flotation of ——. F. B. Jones. Proc. S. Wales Inst. Eng., 1921, 37, 331—368.

In the cleaning of raw coal an efficient recovery of the free coal is essential. The degree of crushing required prior to treatment depends upon the extent to which the coal is interstratified with impurity. Gravity washers may be used for slack over

0·5 in. in size, but are inefficient for the cleaning of small unclassified slack; this, together with the residue from the washer if it contains coal, should be treated by froth flotation. Coking slack is most conveniently cleaned by flotation, since the uniform crushing of the material improves the coke. Flotation may be applied to any material below 0·1 in. in size, and is therefore suitable for cleaning finely interstratified coal; it will also remove impurities the density of which does not differ from that of coal. In the treatment of waste the efficiency of coal recovery is of secondary importance; examples are given showing the recovery of different grades of coal containing from 6·3% to 22·9% of ash from waste materials containing from 45·3% to 50·4% of ash. Coal may be recovered from washery silt by flotation, however finely divided it may be. In the flotation machine the pulp of coal and water passing through is subjected to alternate periods of agitation and quiescence. The apparatus consists of several units, each comprising a rectangular agitation box of square cross-section in communication with a frothing box of V-shape. A pipe from the lower end of a frothing box enters the agitation box of an adjacent unit just under an impeller keyed to a vertical spindle. The impellers serve to mix the material within the agitation boxes, draw in air necessary for flotation by creating a vortex, and keep the contents of the machine in translatory motion. A pulp of one part of coal and four to six parts of water, together with the necessary frothing reagent (*e.g.*, cresol), passes through the first agitation box into the first frothing box. From this the coal-laden froth is removed by a paddle, while the coal which fails to float passes with the impurities to the next agitation box. The treatment of pit waste on a commercial scale is illustrated by means of flow sheets. The coarse, crude material is disintegrated and passed through a wet screen prior to entering the flotation machine. The oversize from the screen contains little coal, and is rejected. In the flotation machine the coal is rough cleaned in the first five units and re-cleaned in the last four. The clean coal is de-watered down to about 10% in an Oliver vacuum filter. The results of numerous tests are given, together with examples indicating the general considerations which govern the design of plant to meet specific requirements. In connexion with the treatment of Durham coking coal it has been found that to produce one ton of pig iron required 26 cwt. of coke from raw coal, 24 cwt. of coke from coal cleaned in a jig washer, or 22 cwt. of coke from coal cleaned by flotation.—H. Hg.

Anthracite; Purification of ——. G. Schuchardt. Chem.-Zeit., 1921, 45, 991.

The use of anthracite in industry for the preparaion of carbon for electro-chemical and electroechnical purposes such as electrodes, electric light arbons, carbon brushes for dynamos, etc., is ependent on its degree of purity. The mineral mpurities, amounting to 2—5%, have been removed itherto by chemical means, but only incompletely, *g.*, by carbonisation in a furnace followed by grindng. The difference between the specific gravity of rbon of a particular size of granules and that of he mineral impurities permits separation to be fected by physical means. Fractional separation effected by washing with three solutions of lcium chloride of sp. gr. 1·32, 1·34, and 1·38; the rst solution gives a fuel with 0·2—1% of ash, he second one with 1—2%, and the third one with —3%.—F. M. R.

ignite containing common salt. Von Morgenstern. Z. öffentl. Chem., 1921, 18, 208—209.

he lignite examined had been used in a brickrks, and the bricks when made were found to glazed and unsaleable. The lignite contained reign matter in the form of small balls about the size of a pea. On analysis the lignite was found to contain 14·8% of ash and 1·87% of sodium chloride. The foreign matter was easily separated for analysis and contained 35·0% of alumina and 38·0% of sodium carbonate. The residual lignite contained 11·87% of ash and 3·93% of sodium chloride, and also 3·30% of total sulphur.—W. P.

Carbonisation in horizontal retorts. G. M. Gill. Inst. Gas Eng., 1921. Gas J., 1921, 156, 212—224.

The author describes details of carbonising plant and methods of operation which have been found suitable for manufacturing high-quality gas from Durham and Northumberland coals containing 2·43% of moisture, and 30·21% of volatile matter and 10·86% of ash on the dry basis. The best possible treatment of the coal is considered a more important economic factor than reductions in the costs of fuel, upkeep of plant, and wages. The producers described stand out in front of the retort settings, and are designed to heat two, three, or four half-settings of ten retorts each. Until recently the grate area of the producers was only 1·35 sq. ft. per 20ft. retort; this was increased by building two step grates instead of one and by connecting together the two bottom steps on each side of the furnace by a grating. This resulted in a diminution of clinker formation with consequent reduction in the loss of unburnt fuel. The design of the settings in which retorts are set in tiers of five provides for a Gothic combustion arch of silica material. The cross walls are built of firebrick, the expansion of which is counteracted by building in several courses of silica bricks above the top of the combustion arch. Material containing 86—92% of silica, which will neither expand nor contract, must be used if the temperature is to be raised above 1300° C. The cross walls are 4·5 in. thick and cover 41% of the surface of the retorts. The retorts are of oval cross section, 21 in. by 15 in., and contain silica 77·42%, alumina 19·66%, iron oxide 1·32%, lime 0·34%, magnesia 0·08%, and alkalis 1·18%. In an experimental setting the cross walls were built mainly of a mixture of unburnt clay and grog, which expanded slightly on burning. The setting was dried and fired in the usual manner and worked at temperatures up to 1400° C. without showing signs of failure. The importance of maintaining the retorts and fittings free from leaks in order both to prevent loss of gas and to produce a gas free from excessive inert constituents is emphasised. A charge of 10·5 cwt. of coal is carbonised in each retort in 10 hours; it occupies 65% of the retort space when charged and an additional 8% after coking. A modified coal drum divided into three sectors was fitted to the Arrol-Foulis stoking machines and the speed of working the machines was standardised in order to secure uniformity of charging with consequent increase of output from the plant. With a combustion chamber temperature of 1270° C. the coal is carbonised in 12 hours; at 1310° C. it is carbonised in 10 hours, and at 1400° C. in 8 hours. By working with the dip pipes in the hydraulic main unsealed and by the provision of a governor to each set of four or five settings it was found possible to maintain steadier pressure conditions within the retorts and to reduce to 10% the proportion of time during which it is necessary to reduce the vacuum within the retorts because of charging operations. This resulted in a reduction of the inert constituents in the gas to 9%.—H. Hg.

Peat; Carbonisation of —— *in vertical gas retorts.* Tech. Paper No. 4, Fuel Research Board, 1921, 16 pp.

Machine-won air-dried peat was disintegrated in a coal crusher and carbonised in the vertical gas retorts described in a previous report (*cf.* J., 1921, 333 r). Sufficient steam, 6·0—6·5% by wt. of the peat carbonised, was admitted to the base of the retorts to quench the coke. The peat tar required special arrangements for its recovery, as it was lighter than the liquor; the gas leaving the condenser was cooled to 20° C. and the liquid products issued in the form of a yellow emulsion. The tar separated on heating the emulsion to 50° C.; it set into a semi-solid mass showing crystals of paraffin wax on cooling. The peat as carbonised contained about 20% of moisture and 50% of volatile matter, the throughput per retort per day being 3 tons. With a carbonising temperature of 980° C. the gas produced per ton amounted to 14,900 cub. ft. with a calorific value of 325 B.Th.U. After supplying gas for heating the retorts 7940 cub. ft. of gas was available for disposal, together with 12·6 galls. of tar, and liquor equivalent to 29·2 lb. of ammonium sulphate. At lower temperatures, 820°—875° C., the yields were:—gas, 13,760 cub. ft., or 46·8 therms; coke, 5·4 cwt.; tar, 21·3 galls., and liquor equivalent to 24·8 lb. of ammonium sulphate per ton. The sp. gr. of the gas was 0·757, and it contained 18·2% CO_2; after storage in a holder it contained CO_2, 14·7%; C_nH_m, 3·7%; O_2, 1·0%; CO, 22·0%; H_2, 23·8%; $C_{1\cdot25}H_{4\cdot5}$, 14·4%; N_2, 20·2%. The coke containing 3·96% of volatile matter and 9·98% of ash was considered an excellent fuel for suction producers. The tar on fractional distillation gave:—Up to 170° C., 2·3%; 170°—230° C., 13·6%; 230°—270° C., 13·6%; 270°—310° C., 24·5%; 310°—347° C., 16·9%; pitch, 25·6%. Light spirits were removed by steam distillation, refined and distilled up to 170° C., the yield being 0·36 gall. per ton of peat. The equivalent of a further 2 galls. of light spirit per ton was recovered by scrubbing the gas. The liquor contained 0·72% of ammonia, 0·847% of acetic acid, 0·163% of methyl alcohol, and 0·129% of acetone.—H. Hg.

Nitrogen from coal and coke as ammonia; Liberation of ——. A. C. Monkhouse and J. W. Cobb. Inst. Gas Eng., 1921. Gas J., 1921, **156**, 234—240.

A Yorkshire bituminous coal containing 1·67% of nitrogen was carbonised in a crucible at 500°, 800°, and 1100° C. in order to obtain soft, medium, and hard cokes respectively. These cokes contained 1·87%, 1·34%, and 0·58% of nitrogen respectively; each coke was heated to temperatures of 600°, 800°, and 1000° C. successively in currents of nitrogen and hydrogen. The soft coke when heated in nitrogen yielded ammonia equivalent to 3·1% of its nitrogen content at 600°, 8·56% at 800°, and 0·06% at 1000° C., the total being equivalent to 9·2% of the nitrogen in the coal. When heated in hydrogen the coke yielded 12·47% of its nitrogen as ammonia at 600°, 20·30% at 800°, and 1·47% at 1000° C., the total being equivalent to 26·8% of the nitrogen in the coal. The coke prepared at 800° C. when heated in hydrogen up to 1000° C. yielded ammonia equivalent to 2·0% of the nitrogen in the coal; the hard coke when similarly treated gave no ammonia. When steam was mixed with the hydrogen a slow but steady evolution of ammonia occurred (*cf.* Salmang, J., 1919, 452 a). When the soft coke was treated at 800° C. with nitrogen, hydrogen, and steam successively, 10·1% of the nitrogen in the coke was recovered during treatment with nitrogen, 31·0% with hydrogen, and 38·1% with steam. Only the ash of the coke remained after the steam treatment. The high yields of ammonia during the hydrogen and steam treatments indicated that the dissociation of ammonia was arrested before equilibrium was reached. When the coke was treated with nitrogen and then with steam, the nitrogen left in the coke after heating in the stream of nitrogen at 800° C. was recovered as ammonia more rapidly than when treatment with hydrogen intervened. On raising the temperature of the coke more slowly between 500° and 800° C., less ammonia was obtained by treatment with nitrogen, but the ratio of ammonia to free nitrogen evolved from the coke was rather greater; it was also noted that all the ammonia obtainable up to 800° C. was evolved at or below 700° C. Determinations of hydrogen sulphide evolved during the experiments showed that the conditions governing its evolution were similar to those which determined the ammonia yield.—H. Hg.

Sulphur removal [from coal gas] by oil washing. E. R. Hamilton. Canadian Gas Assoc. Conv. Gas J., 1921, **155**, 729—730.

Coal gas containing carbon bisulphide etc. equivalent to from 35 to 160 grains sulphur per 100 cub. ft. is washed with refined paraffin oil in a series of three tower scrubbers. Not less than 8 galls. of oil per 1000 cub. ft. of gas is required to reduce the sulphur content by 50% at 70°—75° F. (21°—24° C.); the actual results obtained varied considerably according to the sulphur content of the gas and the temperature of gas and oil. The best operating temperature would be 60° F. (15·5° C.) or lower. Naphthalene and benzol equivalent to 0·5 gall. per ton of coal are also removed from the gas. The oil leaving the towers is steam distilled to remove carbon bisulphide, naphthalene, and some benzol; the temperature and speed of distillation determine the proportion of benzol left in the oil and the quantity of benzol subsequently removed from the gas. The maximum reduction in the calorific value of the gas when fresh oil is introduced into the system amounts to 25 B.Th.U. The freezing point of the oil is −3° C. when fresh and −5° C. after continued use and redistillation. The sp. gr. is 0·885; there is no accumulation of tar-oils or naphthalene after continued use. Combustion with sodium peroxide shows 0·303% of sulphur in the fresh oil, 0·347% in the redistilled oil, and 0·432% in the saturated oil.—H. Hg.

Flue gas analyses; Interpretation of ——. A. B. Helbig. Feuerungstech., 1921, **9**, 229—234.

A method for calculating the air requirements and efficiency of solid and gaseous fuels from flue gas analyses is described.—W. P.

[Gas] mains and services; External corrosion of ——. J. G. Taplay. Inst. Gas Eng., 1921. Gas J., 1921, **156**, 210—211.

Investigation of the external corrosion of a steel pipe laid in "made-up" ground showed that it was due to bacterial action resulting in the production of acetic acid. The ground was acid in character and contained decaying vegetable matter, dextrose, iron acetate, and calcium acetate, formate, nitrate, and nitrite. Corrosion of pipes laid in alkaline earth or in plaster walls was found to be due to the action of calcium bicarbonate and water. Machinings were obtained from various metals and 2 oz. of each was placed with 0·5 oz. of commercial powdered chalk in a vessel filled with freshly distilled water. Over a period of 73 days the following volumes of gas were evolved:—From wrought iron, 485 c.c.; high tensile steel, 8 c.c.; low tensile steel, 15 c.c.; mild steel, 360 c.c.; cast iron, 5 c.c. The average composition of the gas was:—CO_2, nil; O_2, 1·45%; H_2, 90·90%; CH_4, 3·43%; N_2, 4·22%. Ammonia and hydrogen sulphide were found in the water at the conclusion of the experiments.—H. Hg.

Explosion pressures; Piezoelectric method of measuring ——. D. A. Keys. Phil. Mag., 1921, **42**, 473—488.

The piezoelectric properties of tourmaline crystals are used in connexion with a special form of cathode ray oscillograph for the recording of rapid changes of pressure. The variations of electric charge acquired by tourmaline crystals under pressure are caused to deflect a beam of cathode rays which falls on a photographic plate and has a negligible inertia. The rise and fall of pressure in explosive mixtures of oxygen, hydrogen, and air were determined. With pure detonating gas the pressure rise was very rapid. The addition of air retarded the initial pressure rise appreciably. The velocity of explosion waves produced by detonating charges in water was measured and found to be slightly higher than that of sound.—J. R. P.

Paraffins; Rate of solidification of ——. K. Fricke. Chem.-Zeit., 1921, 45, 891—892.

To determine the rate of solidification of paraffins 100 g. of the sample is melted at a temperature not exceeding 65° C. and poured into a metal dish, 11 by 6 cm. and 3·5 cm. deep; fifty mins. after the first signs of solidification have been noticed a square iron rod (cross-section, 19 sq. cm.), weighing 205 g. and supporting a weight of 2 kg. is placed vertically on the surface of the paraffin at a distance of 2·5 cm. from the side of the dish, suitable supports being provided for keeping the rod in position. If the end of the rod sinks into the paraffin, the test is repeated after a further 5 mins., and so on until the impression made by the rod is negligible. The time taken for the paraffin to set to this consistence is noted and is termed the solidifying period. A paraffin to be used for candle making should solidify within 65 mins. when the temperature of the air ranges from 17° to 20° C.—W. P. S.

Peat fuel; Preparation of ——. S. C. Davidson. E.P. 169,111, 1.11.20. Addn. to 159,996 (J., 1921, 290 a).

Powdered pitch or coal is mixed with the dry peat and lime prior to incorporation with the wet peat. —H. Hg.

Lignite, earthy lignite, peat and similar substances; Preliminary treatment of —— *before dehydration.* Rabbow, Willink und Co. G.P. 339,254, 22.9.20.

The mass is subjected to pressure, with or without he addition of chemical reagents, at a temperaure not exceeding 200° C.—W. P.

eat and similar substances; Cylindrical or conical centrifugal drum for the dehydration of ——. Siemens - Schuckertwerke G. m. b. H. G.P. 339,255, 18.8.17.

he walls of the drainage chamber are arranged arallel to or at right angles to the axis of the entrifuge.—W. P.

uel; Solid —— *and process of making the same.* H. L. Fisher, Assr. to S. Sternau and Co., Inc. U.S.P. 1,389,638, 6.9.21. Appl., 9.4.17.

solid fuel consists of alcohol containing 4% of ater, together with stearic acid and its reaction roduct with caustic soda, the stearic acid being ee from oleic and palmitic acids.—H. Hg.

ecific gravity and flash-point of [combustible] liquids; Method of increasing the ——. L. W. Bates. U.S.P. (a) 1,390,229 and (b) 1,390,233, 6.9.21. Appl., (a) 11.11.19, (b) 16.6.20.

) Solid carbonaceous particles are added to a uid combustible in an amount which will produce free-flowing mixture having a specific gravity gher than that of water. (b) Solid carbonaceous rticles are added to a liquid hydrocarbon in nount to form a mixture having a higher specific gravity than that of water and a flash point above the temperature of preheat necessary for proper atomisation. Coal tar fractions of a peptising nature are then added, to stabilise the mixture. —A. G.

Carbonaceous substance; Method of transporting ——. L. W. Bates. U.S.P. 1,390,230, 6.9.21. Appl., 3.12.19.

The material is pulverised, incorporated with a liquid hydrocarbon carrier, and treated with a stabiliser which enables the particles to be carried in stable suspension. The mixture is conveyed through pipe lines, and upon arrival at its destination the solid carbonaceous substance is removed from the carrier.—A. G.

Fuel and method of producing same. L. W. Bates. U.S.P. 1,390,231, 6.9.21. Appl., 23.3.20.

The fuel consists of a homogeneous mixture of a relatively large proportion of washed, peptised, pulverised solid fuel with a smaller proportion of liquid hydrocarbon.—A. G.

Liquid fuel and method of manufacturing it. L. W. Bates. U.S.P. 1,390,232, 6.9.21. Appl., 12.4.20.

Solid fuel is pulverised in a liquid hydrocarbon of low viscosity, and a further quantity of a liquid hydrocarbon of high viscosity is subsequently blended with the mixture. The amounts of the various components are so regulated that a liquid fuel of density greater than that of water is produced. (*Cf.* E.P. 165,418 of 1919; J., 1921, 616 a.) —A. G.

Fuel; Method of burning —— *in furnaces.* J. Pintsch A.-G. E.P. 144,687, 9.6.20. Conv., 11.12.17.

A shaft which is not heated from the outside is used in conjunction with an open grate disposed in a furnace outside the shaft. Fuel is passed down the shaft and burnt on the grate; part of the products of combustion is drawn up the shaft and then treated for the recovery of low-temperature tar and ammonia evolved therein. The treated gas is returned to a burner above the grate. —H. Hg.

Heating by combustion without flame; Apparatus for ——. M. Mathy. U.S.P. 1,388,355, 23.8.21. Appl., 4.4.19.

The heating walls of a furnace are arranged in the form of boxes packed with refractory material within which flameless combustion of a gaseous mixture occurs.—H. Hg.

Gas-burner; Surface-combustion ——. M. Mathy. U.S.P. 1,388,357, 23.8.21. Appl., 21.9.20.

Parallel pipes for the admission of gas and air respectively are placed in a tubular furnace and surrounded by refractory granules. Apertures are provided over part of the length of the pipes so that gas and air may mix and burn without flame within the granules around the unperforated part of the pipes.—H. Hg.

Coke-ovens with regenerators; Construction of horizontal ——. C. Otto und Co., G.m.b.H. E.P. 147,230, 7.7.20. Conv., 15.8.16.

The flues underneath coke-oven regenerators are so arranged that the alternate admission of air is always from the same side of the oven battery, while the waste gases leave the regenerators on the opposite side. Alternate sole flues may communicate with one of a pair of main waste gas flues provided with main reversing valves.—H. Hg.

Coke-ovens. L. Wilputte. E.P. 169,101, 22.9.20.

The nozzles supplying gas to the base of vertical heating flues of coke-ovens are made of non-metallic refractory material and are formed with a short upper measuring orifice and a lower portion of larger cross-section. Passages are provided in the oven roof, registering with the flues, through which the nozzles may be inserted, cleaned or removed. —H. Hg.

Gas producers [carburettors]. W. Pickard and D. R. Dobson. E.P. 168,939, 4.5.20.

Acidulated water and a liquid hydrocarbon are admitted from separate float chambers through manually-controlled valves to a vessel which is in communication with the induction pipe of an internal combustion engine and within which the liquid is electrolysed.—H. Hg.

Gas generator. S. Moore. E.P. 168,951, 11.5.20.

A vertical retort surrounded by chequerwork regenerators is superimposed upon a gas producer. Coal enters the top of the retort through a valve-controlled hopper and coke or ash is mechanically discharged at the base of the producer. During the blow primary air enters the base of the producer and the lean gas is burnt within the regenerators by means of secondary air admitted through a heating chamber situated below the regenerators. Any explosive gas left in the regenerators is driven therefrom into the retort by means of steam. During the run steam is admitted either through the blast pipes at the base of the producer or through a superheating chamber at the top of the retort, and gas is conducted away either through the superheating chamber or through the blast pipes into a common wash-box. Each pipe entering the wash-box is provided with a valve. Occasionally during the up run steam is admitted below the blast pipe to quench the coke. At the top of the producer provision is made for the injection of liquid hydrocarbons for enrichment purposes.—H. Hg.

Carbonising in retorts arranged in a producer. A.-G. für Brennstoffvergasung. G.P. 338,192, 23.12.16.

Means are provided for leading off the distillation gases separately from the producer gas, and the retort is rotated to ensure uniform heating.—W. P.

Producer shaft with water-cooled hollow casing for production of air-gas, water-gas, and mixed gas. H. Werner. G.P. 338,370, 19.9.19.

The shaft is made up of a series of hollow columns or rings in connexion with a common water supply, so arranged as to allow of alteration of the blast or height of producer when dealing with different fuels.—W. P.

Gas scrubbing and washing apparatus. J. K. Frazer. E.P. 168,668, 5.6.20.

The wall of a tower is fitted with liquid sprays below which, within the tower, are perforated and non-perforated frusto-conical plates. The liquid passes through the perforated plates and over the edges of the non-perforated plates in the form of cascades. Gas ascends either through the perforations or through the cascades under the lower edges of the non-perforated plates. For the removal of traces of ammonia from coal gas additional sprays and plates are fitted at the top of the tower.—H. Hg.

Gas; Apparatus for washing ——. Means for washing gas. W. H. Geesman, Assr. to A. G. McKee and Co., F. E. Kling, and L. B. Weidlein. U.S.P. 1,388,812—3, 23.8.21. Appl., (A) 31.10.17, (B) 28.5.19.

(A) A cone is placed over the gas inlet to the washer to deflect the gas horizontally through a cascade of water falling from the upper surface of the cone. An annular screen is placed around the cascade to secure intimate mixture of gas and water. (B) The cone is truncated and gas is passed to the under side thereof through a central pipe leading from the top of the washer.—H. Hg.

Gases; Apparatus and process for purifying [fuel] ——. C. J. Ramsburg, Assr. to The Koppers Co. U.S.P. 1,389,980, 6.9.21. Appl., 7.10.20.

Gas is purified by contact with a purifying liquid circulated through the apparatus, and the spent liquid is subsequently heated and aerated.—L. A. C.

Gases; Process for purifying ——. D. L. Jacobson, Assr. to The Koppers Co. U.S.P. 1,390,037, 6.9.21. Appl., 22.10.20.

The gases are passed through an alkaline absorbent which is continuously removed from the purifying system, aerated to remove the absorbed impurities (hydrogen sulphide) and returned to the absorbing system.—A. G.

Thionate solutions [for gas purification]; Removal of sulphites and bisulphites from ——. W. Feld, Gasabteilung, G.m.b.H. G.P. 339,612, 3.9.18.

The solution containing thiosulphate is allowed to stand for such a time that sulphuric acid is generated from the polythionates and decomposes the sulphite. The polythionates required may be formed in the solution by introduction of sulphur dioxide. The solution may be previously warmed to accelerate the decomposition of the polythionates. —C. I.

Internal-combustion engines; Separating useful products from the exhaust of ——. A. J. Paris, jun. U.S.P. 1,388,480, 23.8.21. Appl., 12.4.19.

A heat-absorbing agent other than water is fed into the exhaust pipe of an internal-combustion engine and liquefiable products are subsequently condensed and separated.—H. Hg.

Oil-still. J. Primrose. U.S.P. 1,389,978, 6.9.21. Appl., 5.6.20.

Liquid and vapour separators are connected with and intermediate to adjacent heating surfaces in an oil-still containing a number of heating surfaces in which the oil is heated to different temperatures by the furnace gases. A control device, which can be closed when the oil rises to a predetermined level on account of a stoppage in its flow, is attached to the vapour outlet of each separator.—L. A. C.

Hydrocarbons; Process of refining ——. C. R. Burke, Assr. to L. P. Burke. U.S.P. 1,389,934, 6.9.21. Appl., 11.4.16.

The vapour from hydrocarbon material heated in a still under atmospheric pressure passes into a holder arranged above the still, capable of containing the greater part of the contents of the still. The portion of the vapour condensed in the holder returns to the still, scrubbing the ascending stream of vapour, and uncondensed vapour passes out of the top of the holder to a condenser.—L. A. C.

Hydrocarbons; Method of refining liquid ——. F. E. Wellman, Assr. to The Kansas City Gasoline Co. U.S.P. 1,390,002, 6.9.21. Appl., 27.11.17.

The total condensable products obtained on distilling oil under low or atmospheric pressure are cracked under high temperature and pressure. The heavier fraction is separated from the product and is again distilled and cracked, while the lighter fractions are condensed.—L. A. C.

Motor fuel. Chem. Fabr. Worms A.-G. G.P. 339,989, 24.2.18.

A mixture of acetaldehyde and one or more hydrocarbons of the benzene series.—A. R. P.

Fuel and method of producing same. L. W. Bates. U.S.P. 1,390,228, 6.9.21. Appl., 5.8.19.

See E.P. 165,418 of 1919; J., 1921, 616 a.

Gas-cleaning apparatus. J. Wells. U.S.P. 1,390,183, 6.9.21. Appl., 30.9.19.

See E.P. 151,443 of 1919; J., 1920, 742 a.

Hydrocarbon oils and the like; Process for the cracking of ——. J. Nelson. U.S.P. 1,391,568-9, 20.9.21. Appl., 27.10. and 23.12.19.

See E.P. 116,304 of 1917; J., 1918, 457 a.

Peat and the like; Cutting and pressing of ——. W. B. J. Robertson. E.P. 168,958, 7.1.21.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Methyl alcohol; Increased yield of —— *from wood.* U.S. Forest Products Lab., Madison, Wis., Tech. Note No. 154.

The addition of a small quantity of sodium carbonate to wood before distillation results in an increase of 50% in the yield of methyl alcohol without diminishing the production of acetic acid. Sawdust is saturated with a solution of sodium carbonate; pressure treatment is required with wood blocks. A sample of maple sawdust untreated yielded 1·61% of methyl alcohol and 5·22% of acetic acid; in presence of 1·5% of sodium carbonate the yields were 2·39% and 5·26% respectively. Untreated white oak similarly yielded 1·17% of methyl alcohol and 4·91% of acetic acid, and 2·58% and 5·09% respectively after impregnation with 0·5% of sodium carbonate.

Carbon monoxide; Production of —— *in [the flames of] incandescence burners.* A. Kling and D. Florentin. Chim. et Ind., 1921, 6, 305—308.

In continuation of previous work (J., 1920, 147 a) the authors detail results obtained by the operation of certain incandescence burners (with and without mantle) in a chamber of 3800 l. capacity. The "blood" test developed by d'Ogier and Kohn-Abrest was employed for determining carbon monoxide, the iodic acid test employed by Marcy (Ann. Services techn. d'hyg. de Paris, 1, 115) being considered unsatisfactory. The results indicate that with upright incandescence burners the production of carbon monoxide varied with different burners between the limits 0·04—0·50% of the gas consumed. With inverted burners, the carbon monoxide produced varied between 0·29% and 1·23% of the gas consumption. Production of carbon monoxide appears to depend upon the flame volume and not upon the degree of primary aeration (within limits). The percentage of carbon monoxide produced increases slightly with continued usage of the mantle employed. In the case of inverted burners, the production of carbon monoxide occurs owing to cooling of the flame by the mantle, which, moreover, prevents access of secondary air necessary for the omplete combustion of the gas. The attention of manufacturers of appliances for burning gas is directed to the necessity of avoiding contact between the flame and colder bodies of large heat capacity.—J. S. G. T.

Patents.

Volatile products from relatively fixed heat-resistant [carbonaceous] substances; Apparatus for recovering and securing ——. H. E. Lutz. U.S.P. 1,389,203, 30.8.21. Appl., 14.11.18.

The apparatus comprises means for retaining carbonaceous material in a thin body and uniformly heating it to a minimum distilling temperature. Passages are provided for the withdrawal of the distillate with an area at least as large as the heating surface of the retaining means.—H. Hg.

Gas mantles; Treatment of fabrics, particularly those used in the manufacture of ——. J. T. Robin. E.P. 169,277, 22.6.20.

Fabric, such as artificial silk impregnated with a solution of thorium and cerium nitrates, as used in the manufacture of gas mantles, is denitrated by drying and exposure to ammonia gas. The fabric is suspended within a chamber, and ammonia, produced by heating a solution thereof outside the chamber, is uniformly distributed throughout the chamber by a gauze screen. Means are provided for controlling a flue opening through which ammonia is discharged from the chamber on completion of the denitrating process. A number of chambers may be connected with a common flue, and each provided with an independent device for controlling the opening to the flue. Each chamber is provided with a clock face with movable hands to indicate the time of treatment.—J. S. G. T.

Ammonium salts and cyanogen compounds. G.P. 339,302. *See* VII.

III.—TAR AND TAR PRODUCTS.

Nitrogen dioxide I. Nitration with nitrogen peroxide. H. Wieland. Ber., 1921, 54, 1776—1784.

Pure nitrogen peroxide does not react with cold aromatic hydrocarbons; with benzene at 80° C. the main products are 1.3.5-trinitrobenzene and picric acid, with smaller amounts of unchanged benzene, nitrobenzene, carbon dioxide, oxalic acid, and aliphatic nitrogenous substances which are soluble in water. Nitrobenzene is indifferent towards nitrogen peroxide at 80° C. Phenol is readily nitrated when dissolved in a cold mixture of benzene and light petroleum and gradually treated with a solution of nitrogen peroxide in the same solvents; a mixture of *o*- and *p*-nitrophenol is obtained, the total weight of which is 125% of the phenol used. Tarry by-products are not observed. *o*-Cresol gives *o*- and *p*-nitro-*o*-cresol, *m*-cresol yields *o*- and *p*-nitro-*m*-cresol, whilst the *p*-compound gives *o*-nitro-*p*-cresol and *o*-dinitro-*p*-cresol. 1.3.4-*m*-Xylenol is converted into the corresponding 5-nitro-compound. α-Naphthol gives a mixture of 2-nitro-α-naphthol and 2.4-dinitro-α-naphthol. Reaction does not occur with anisole. Acetanilide in dry ethereal solution is transformed into benzenediazonium nitrate. Diphenylamine in ethereal solution yields diphenylnitrosamine, whereas in benzene solution it gives *p*-nitrodiphenylnitrosamine. The abnormal reactions in ethereal solution are explained by the observation that the anhydrous solvent is readily converted into ethyl nitrite by nitrogen peroxide. (*Cf.* J.C.S., Nov.)—H. W.

Carbazole derivatives; Typical reaction for the differentiation of ——. A. V. Blom. Helv. Chim. Acta, 1921, 4, 625.

A number of examples are quoted to show that the colour developed on the addition of nitric acid to a solution of a carbazole derivative in sulphuric acid is characteristic, and serves as an excellent criterion of purity.—J. K.

PATENTS.

Metaphenylenediamines; Manufacture of symmetrical alkylated ——. British Dyestuffs Corp., Ltd., A. G. Green, and A. Brittain. E.P. 168,689, 11.6.20.

SYMMETRICALLY alkylated *m*-phenylenediamines are obtained by the action at high temperatures of primary or secondary alkylamines or their salts on resorcinol in aqueous or alcoholic solution, and separating the alkylated *m*-phenylenediamine produced from any unchanged resorcinol and from amino-phenolic substances. The presence of sulphurous acid is advantageous to the reaction, and hence the alkylamine sulphites can conveniently be employed. For example, a 67% yield of *sym*-dimethyl-*m*-phenylenediamine is obtained by heating in an autoclave for 12 hrs. at 125° C. 55 pts. of resorcinol, 66 pts. of 35% solution of methylamine sulphite, and 125 pts. of 25% aqueous solution of methylamine. The product is separated from unchanged methylamine and resorcinol and from methyl-*m*-aminophenol by the usual methods, and is finally purified by distillation *in vacuo*, b.p. 170° C. at 10 mm. pressure.—G. F. M.

Naphthalenesulphonic acids; Process for the manufacture of ——. J. A. Ambler and H. D. Gibbs. U.S.P. 1,390,241, 6.9.21. Appl., 26.1.18.

IN a continuous process for the sulphonation of naphthalene, the latter is vaporised and the vapours are caused to meet a descending current of sulphuric acid.—A. G.

Paracoumarone resin. U.S.P. 1,389,791. *See* XIII.

IV.—COLOURING MATTERS AND DYES.

Leuco-bases of rosaniline dyestuffs as developers. Lumière and others. *See* XXI.

Isocyanines. Hamer. *See* XXI.

PATENTS.

Disazo dye. T. M. Susemihl, Assr. to National Aniline and Chemical Co., Inc. U.S.P. 1,378,388, 17.5.21. Appl., 14.7.20.

p-AMINOACETANILIDE is diazotised, the product coupled with *p*-methoxy-*m*-toluidine, the monoazo dye diazotised and coupled with 2-amino-5-naphthol-7-sulphonic acid, and the acetyl group eliminated from the resulting dye. *p*-Nitroaniline may be used in place of *p*-aminoacetanilide, in which case the dye is reduced. The product gives reddish-blue shades which are converted to blue to black when diazotised on the fibre and coupled with *β*-naphthol etc.

Trisazo-dyestuffs; Manufacture of ——. A.-G. für Anilin-Fabr. E.P. 145,054, 15.6.20. Conv., 4.6.15.

SEE G.P. 293,659 of 1915; J., 1916, 1150. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 7330 of 1893; J., 1894, 509 A.)

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Cotton; Deterioration of —— *on wet storage.* N. Fleming and A. C. Thaysen. Biochem. J., 1921, 15, 407—415. (*Cf.* J., 1920, 263 A.)

THE presence of a very large number of microorganisms in raw cotton indicates that the cotton has been exposed to damp. The presence of smaller numbers (up to a few millions per gram) of organisms is due to a contamination of the cotton during the various stages of growth and preparation. For the quantitative determination of the bacterial deterioration of cotton about 0·2 g. of a representative sample of the cotton is treated with 1·5 g. of carbon bisulphide and 1·5 g. of 15% sodium hydroxide solution for 10 minutes or more; when the optimum swelling has been attained the sample is thoroughly mixed and about 20 fibres are removed and placed on a miscoscope slide, the cover added, and a drop of water allowed to diffuse into the slide; the number of fibres which under the miscoscope appear to be attacked along their whole length gives an accurate measure of the percentage of decomposed fibres present. The results are more reliable than those of the alkali solubility test. The examination of cottons of different origin showed that American cotton was less susceptible to bacterial attack than Indian cotton, Egyptian being intermediate in this respect. Cotton grown in India from American seed appears to be as resistant to attack as American cotton.
—S. S. Z.

Botanical incrustations. I. Method of preparing botanical tissue substances in the pure condition. I. E. Schmidt and E. Graumann. Ber., 1921, 54, 1860—1873.

UNCHANGED carbohydrates, completely free from incrustations, can be prepared readily from portions of plants by the use of aqueous solutions of chlorine dioxide which have no effect on cellulose, mercerised cellulose, oxycellulose, mannan, xylan, starch, and fungus cellulose. The stability of the carbohydrates towards chlorine dioxide is confirmed further by the observation that their components, dextrose, mannose, galactose, lævulose, xylose, arabinose, maltose, and glucosamine hydrochloride, do not react with solutions of the gas. The presence of small amounts of incrustation is detected readily by the consumption of chlorine dioxide, and it is thus easily possible to estimate quantitatively the percentage of tissue substance and incrustation in portions of plants. In this manner, pine wood (*Pinus sylvestris L.*) is found to contain 63·28% of tissue substance and 36·72% of lignin, whereas Willstätter and Zechmeister found only 27·35% of the latter. The consumption of chlorine dioxide is small, amounting in the case of pine wood, to 13·50% of the weight of the wood. (*Cf.* J.C.S., Nov.)—H. W.

Polysaccharides. IX. Cellulose and lignin. P. Karrer and F. Widmer. Helv. Chim. Acta, 1921, 4, 700—702.

BY the action of acetyl bromide on cellulose in presence of acetic acid, acetobromocellulose and acetobromoglucose are formed, but in proportions far from quantitative. In this respect, cellulose differs from starch, which is quantitatively converted into acetobromomaltose (*cf.* p. 784 A). The reaction permits no decision as to whether cellulose is a polymeric anhydro-sugar or has a chain structure, since the conditions necessary are too drastic. Wood, straw, and similar materials are completely dissolved by acetyl bromide, and the solutions when treated with ice furnish a mixture of decomposition products of cellulose and lignin. This supports the view that lignin and cellulose are not chemically combined in wood. (*Cf.* J.C.S., Nov.)
—J. K.

Cellulose and cellobiose; The constitution of ——. A. C. von Euler. Chem.-Zeit., 1921, 45, 977—978, 998.

A STRUCTURAL formula for cellulose is advanced which is in agreement with its constitution as a high-molecular condensation product, and which may be reconciled with the properties of its derivatives and fission products. Two variations of the formula are proposed which contain the *p*-dioxan ring of Green's formula (J., 1904, 382), but which have the advantage over the latter that they contain a chain of hexose molecules of any desired length. The author was unaware of the work of Haworth and Leitch (J., 1919, 691 A) on the constitution of cellobiose when this paper was written. (*Cf.* J.C.S., Nov.)—F. M. R.

Cellulose; Hydrolysis of ——. Y. Kauko. Naturwissensch., 1921, 9, 237—238. Chem. Zentr., 1921, 92, III. 526.

SATURATION of moist cellulose with gaseous hydrogen chloride in the cold yields a thick solution which remains almost colourless on standing for 40 hrs., after which period its reducing power corresponds to about 40—60% of the theoretical yield of sugar. According to the duration of the treatment other substances also are formed which produce dextrose on heating in an autoclave. At 13° C. a 90% yield of sugar can be attained in 4 hrs., but above this temperature dark decomposition products are formed. It is probable that cellulose forms addition-products with hydrochloric acid. The treatment described could be applied for the determination of cellulose.—J. H. L.

Waste paper; Removal of printing ink from ——. B. Haas. Chem.-Zeit., 1921, 45, 913—917.

NEWSPAPERS are the most important source of waste paper, and this paper contains 80—85% of short-fibred mechanical wood pulp, 8—10% of longer-fibred cellulose, about 5% of filling material, and hardly appreciable amounts of binding material. For loosening or decomposing the binding substance of the printing ink so that it may easily be removed and washed away, the best results, technically and economically, were obtained by the use of soda ash, which does not cause any subsequent darkening or yellowing of the wood pulp portions of the mixed fibres and thereby eliminates the sorting of the waste material according to proportion of cellulose and wood pulp content. This reagent readily loosens the printing ink, which is then easily removed. The mixed waste is sorted, disintegrated, and then treated with the reagent in a grinding and washing hollander until the material becomes uniformly greyish-black in colour, when it is well washed and discharged. Alternatively, the material may be treated with the reagent in a circular, rotating, steam-heated boiler and subsequently washed in the hollander.—S. S. A.

ERRATUM.—This Journal, Oct. 31, 1921, p. 731 A, col. 2, line 28 from top should read "agent. By this means the reagent was allowed ac-"

PATENTS.

Vegetable fibres; Process for the treatment of —— [*from Hibiscus cannabinus*]. A. Wolkinzon. E.P. 147,080, 7.7.20. Conv., 17.4.19.

THE decorticated fibre is steeped in water for several days, and then immersed in 2% soda solution for 2—3 hrs., after which it is drained, and immersed n a bath containing mineral oil 4%, sulphuric acid .%, water 95%, for 3—4 hrs. If desired, the fibre nay be bleached with a solution containing 5% of otassium bichromate and 2% of sodium bisulphite. The dry fibres are supple and strong, and are preerably used in conjunction with animal fibres such s wool.—D. J. N.

Textile product derived from animal fibre and process for making same. W. H. Schweitzer, Assr. to Soc. "Technochemia" A.-G. U.S.P. (A) 1,389,274 and (B) 1,389,275, 30.8.21. Appl., 28.4.21.

(A) ANIMAL fibre is treated successively with an oxidising agent and excess of alkali, and subsequently impregnated with waterproofing and softening materials. (B) Animal fibre is first treated with a large excess of an oxidising agent, and then with a boiling soap solution, whereby the softness, lustre, and affinity for dyestuffs of the fibre are increased. —D. J. N.

Cellulose esters; Process of fabrication of ——. Soc. Chim. des Usines du Rhône, anc. Gilliard, P. Monnet, et Cartier. E.P. 146,092, 3.6.20. Conv., 20.6.19. Addn. to 13,696 of 1914 (*cf.* F.P. 473,399; J., 1915, 488).

THE preliminary treatment of cellulose (previous to acetylation) described in the original patent is carried out at lower temperatures (25°—30° C.) and with less sulphuric acid (3—5%), whereby esters are obtained, which, after precipitation with water, are insoluble in chloroform, or by partial hydrolysis before precipitation give products, some of which are insoluble in chloroform but soluble in acetone, while others are soluble in ethyl acetate.—D. J. N.

Artificial filaments; [*Recovery of solvents in*] *production of* ——. L. A. Levy. E.P. 168,986, 10.6.20.

ARTIFICIAL filaments are produced from solutions of cellulose within a closed chamber through which a current of air (dried if necessary) passes so as to remove the volatile solvent. The air is subsequently led over highly activated absorbent charcoal so that the solvent is absorbed and may afterwards be recovered by suitable methods. (*Cf.* E.P. 137,615; J., 1920, 214 A.)—A. J. H.

Artificial silk; Manufacture of ——. E. Bronnert. U.S.P. 1,387,882, 16.8.21. Appl., 2.9.20.

VISCOSE solution is spun into a precipitating bath containing sodium benzenesulphonate solution and sulphuric acid monohydrate.—D. J. N.

Artificial silk; Method and means of producing ——. I. Kitsee. U.S.P. 1,389,517, 30.8.21. Appl., 20.12.19.

THE artificial silk thread is subjected to pressure during its passage through the precipitating bath. —D. J. N.

Waste denitration liquors [*from artificial silk manufacture*]; *Process of treating* ——. H. P. Bassett. U.S.P. 1,390,329, 13.9.21. Appl., 18.6.20.

THE liquors resulting from denitrating artificial silk with sodium hydrogen sulphide are treated with an alkaline zinc compound, and the resulting precipitate removed.—H. S. H.

Viscose artificial silk manufacture; Removal of malodorous sulphur compounds from the waste gases from ——. C. G. Schwalbe. G.P. 336,878, 15.12.17. Addn. to 319,594 (J., 1920, 541 A).

FINELY divided wood, sawdust, or the like is introduced into the gas current after it has been mixed with oxidising gases such as nitric oxide, chlorine, or ozone. The wood itself may be treated with these gases or with liquids containing oxidising substances before introducing it into the gas current.—A. R. P.

Cellulose; Production of pure —— *of cotton- or wool-like character from vegetable materials by means of* (A) *acid sulphite liquors,* (B) *sulphite waste liquors.* A.-G. für Zellstoff- und Papierfabrikation. G.P. (A) 336,535, 22.5.19, and (B) 337,768, 2.12.19.

(A) THE sulphite liquors are treated with organic acids or salts thereof; *e.g.*, liquors rich in lime may be treated with small quantities of acetic acid, or acid liquors with calcium acetate, sodium formate, or calcium saccharate. With such liquors cellulose can be obtained pure without further treatment. (b) Inorganic acids may be added to the liquors in addition to organic acids or their salts or both. The digestion of the vegetable material may be carried out in two or three stages, first with ordinary sulphite liquor and afterwards with the organic compounds together with the inorganic acids, or with the latter separately as a third stage.—J. H. L.

Paper and fibre board; Method of making ——. A. L. Clapp. U.S.P. 1,389,936, 6.9.21. Appl., 23.6.20.

Cellulose material and beet pulp are digested with the aid of heat and pressure in the presence of sodium carbonate, and the dissolved constituents of the beet pulp are subsequently precipitated in and on the cellulose fibres.—L. A. C.

Paper; Manufacture of hard-sized ——. Holzverkohlungs-Ind. A.-G. G.P. 339,594, 28.3.16. Addn. to 338,395 (J., 1921, 690 a).

The pulp is treated with small quantities of condensation products of aldehydes, preferably formaldehyde, with hydroxylated naphthalene derivatives, in alkaline solution, and later with a precipitating agent, *e.g.*, an acid substance. Suitable condensation products may be prepared from α- or β-naphthol and formaldehyde; for the sizing of paper pulp addition of 2% of a 35—40% alkaline solution of such a product is sufficient.—J. H. L.

Viscose; Manufacture of artificial threads, ribbons, films, or sheets from ——. M. Müller. E.P. 145,627, 29.6.20. Conv., 6.9.18.

See U.S.P. 1,386,521 of 1921; J., 1921, 689 a.

Wood and other cellulose-containing materials; Treatment of ——. Zellstoff-fabrik Waldhof, H. Clemm, and R. Willstätter. E.P. 147,232, 7.7.20. Conv., 19.10.16.

See G.P. 304,214 of 1916; J., 1920, 60 a.

Paper or paper-like substances; Impregnation of ——. L. Heilbronner. E.P. 143,235, 11.5.20. Conv., 12.1.17.

See U.S.P. 1,387,004 of 1921; J., 1921, 690 a.

Dryers [for paper]; Means of and method for removing water from rotary ——. H. Kay. E.P. 169,364, 12.8.20.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Patents.

Bleaching; Method of and means for ——. C. Taylor. E.P. 168,995, 12.6.20.

In a bleaching process in which manual labour is reduced to a minimum, two separate lengths of cloth, after singeing, are made into rope form, passed simultaneously through a mangle and then separated and mechanically piled in two iron boiling kiers. After boiling, the ropes are mechanically withdrawn and piled separately in two wooden kiers where they are bleached, then withdrawn in rope form, passed through an expander, mangled and plaited down.—A. J. H.

Textile-fabric-treating machine. L. Clarenbach. U.S.P. 1,389,627, 6.9.21. Appl., 18.11.20.

Within the machine is a compartment containing a frame structure having rollers over which the fabric passes, and the frame is so operated that the fabric comes in contact with the liquid while in open width and in a vertical position.—A. J. H.

Printing with insoluble dyestuffs; Processes of ——. *Process of printing with dyestuffs.* Farbw. vorm. Meister, Lucius und Brüning. E.P. (a) 147,102, 7.7.20, and (b) 150,303, 14.7.20. Conv., 15.1. and 23.8.19.

(a) Ethylenethiodiglycol (dihydroxydiethyl sulphide), which can be easily obtained from ethylenechlorhydrin and an alkali sulphide, is an excellent solvent for insoluble organic dyestuffs (*e.g.*, Indulines) and is suitable as a substitute for acetin in printing pastes, deeper and purer shades being thereby obtained. (b) Ethylenedithioglycol is also suitable for general use in the preparation of printing pastes, but especially for use with Coeruleine, Alizarin Red, Alizarin Brown, Acid Alizarin Black, Gallocyanine, Dianil Chrome Brown Cr, Thiogene Cyanine BB extra, the azo dyestuff produced from 2.3-aminoanthraquinonesulphonic acid and acetoacetanilide, Fulling Scarlet 4 R conc., etc. When ethylenedithioglycol is used on grounds prepared with naphthol or Naphthol A.S., the subsequently developed colours are brighter and bluer than those hitherto obtained.—A. J. H.

Sizing of textile fabrics and the like. A. Poulson. E.P. 169,103, 24.9.20.

A sizing material containing no foodstuff and suitable for fabrics of cotton, silk, linen, or other material, is prepared by dissolving 1 pt. of neutral sodium silicate in 3 pts. of water and adding 1 pt. each of aluminium sulphate, china clay, and commercial gelatin. For economy in transport, the composition may be dried and ground to a powder. (*Cf.* E.P. 152,096; J., 1920, 779 a.)—A. J. H.

Textile fabrics and yarns; Machine for washing, saturating, and similarly treating —— *in rope form.* F. Roberts, Assr. to Calico Printers' Assoc., Ltd. U.S.P. 1,391,276, 20.9.21. Appl., 1.11.19.

See E.P. 132,672 of 1918; J., 1919, 897 a.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphur dioxide and trioxide; Determination of —— *in burner gases.* R. Dieckmann. Chem.-Zeit., 1921, **45**, 885.

The addition of stannous chloride solution to prevent oxidation of sulphur dioxide in the method described previously by the author (J., 1921, 297 a) appears to be unnecessary if the absorption is carried out in specially constructed absorption flasks. (*Cf.* Krull, J., 1921, 177 a.)—W. P. S.

Ammonia-soda process; Heat balance of the ——. H. Voss. Chem.-Zeit., 1921, **45**, 940—942, 968—970.

In the manufacture of 100 kg. of sodium carbonate the total heat liberated by the absorption of ammonia in the brine is 25,880 cals., of which 7560 cals. is utilised in warming the salt solution, the remaining 18,320 cals. being absorbed by cooling water. By the absorption of the carbon dioxide 23,765 cals. is liberated, of which 8490 cals. is used in raising the temperature of the liquor and 15,275 cals. is absorbed by cooling water. For the operation of the ammonia-recovery apparatus 53,825 cals. is required, and of this quantity 6040 cals. is supplied by the heat of reaction, thus necessitating a heat expenditure in this part of the plant of 47,785 cals. In the lime kiln 27,540 cals. is consumed. This amount is obtained from 4·10 kg. of coke. The total heat required in converting the bicarbonate into carbonate is 39,750 cals., equivalent to 5·7 kg.

of coal (each kg. of which gives 7000 cals.). The compressors for the carbon dioxide and ammonia, together with the driving mechanism, require 515 kg. of steam, which is equivalent to 73·6 kg. of coal, and this, with the 5·7 kg. required for heating purposes, gives a total coal consumption of 79·3 kg. The amount of heat required to dissolve the sodium chloride is much less than the heat liberated by the absorption of the ammonia and carbon dioxide, and the amount of cooling surface required for these gases can be calculated from the excess amount of heat. On account of radiation and conduction the amount of heat actually required in the ammonia regenerating and distillation system is two or three times the calculated amount. Similarly, the limekiln requires an amount of coke 20—30% in excess of the calculated quantity, and the decomposition of the sodium bicarbonate takes 80—100% in excess of the theoretical amount of heat. The excess of sodium chloride used in the reaction, the residual calcium chloride, the heat expended in recovering ammonia from the waste liquor, and the heat lost in radiation, conduction, and cooling in various parts of the system constitute the chief thermal losses of the process.—S. S. A.

Sodium carbonate; Alteration of —— in the air. H. Dubovitz. Chem.-Zeit., 1921, 45, 890—891.

Commercial sodium carbonate made by the ammonia-soda process almost always contains sodium bicarbonate; the amount of the latter may be determined by heating a portion of the sample in a tube connected with a calcium chloride tube; the loss in weight of the two tubes, weighed together, is a measure of the carbon dioxide formed by the decomposition of the bicarbonate, whilst the gain in weight of the calcium chloride tube is due to the water formed from the bicarbonate and to the moisture in the sample. When sodium carbonate is exposed in a thin layer to the atmosphere, up to 20% of bicarbonate may be formed in about 13 days; in a humid atmosphere containing much carbon dioxide, the conversion of the carbonate into bicarbonate is complete in 14 days.—W. P. S.

Sodium perborate; Electrolytic production of ——. P. C. Alsgaard. Trans. Amer. Electrochem. Soc., 1921, 173—190. [Advance copy.]

The work of Arndt (J., 1916, 111) and more especially of Valeur (Tids. Kemi, Farm. og Terap., 1916, No. 17, 18) on the electrolytic production of sodium perborate is reviewed. The most advantageous procedure as established by these investigators is to employ sodium carbonate as the oxygen carrier without addition of sodium hydroxide or of potassium carbonate which increase the solubility of sodium perborate, but with a little sodium silicate and potassium bichromate. The working concentration of sodium perborate, which very readily forms supersaturated solutions, should be as low as possible, as with increasing concentration it undergoes cathodic decomposition with a lowering of current efficiency. For the same reason the current density should be as low as possible, while the solution should be saturated with respect to sodium carbonate. Rise in temperature increases the instability of perborate, the best working temperature being 10°—12° C. The author carried out experiments for the technical application of the process in the light of the above results. The cathode consisted of a copper pipe coated with tin or nickel and carrying a cooling current of water. The anode was of platinum, 7 kg. being required for a production of 1 ton per day. The sodium carbonate used must be free from iron. Carbon dioxide is liberated at the anode by the ordinary process of electrolysis and is also produced in the reaction $Na_2B_4O_7+Na_2CO_3+4O=4NaBO_3+CO_2$. In order to effect the removal of this latter carbon dioxide the immersion of the anode in the liquid is reduced and sodium bicarbonate is added, so that an equal amount of carbon dioxide to that produced in the reaction is given off at the anode. The solution used contained 45 g. or borax, 130 g. of sodium carbonate, 45 g. of sodium bicarbonate, 2 g. of potassium bichromate, and 2 g. of sodium silicate per l. When equilibrium was reached the concentration of perborate corresponded to 1·5 c.c. of $N/10$ potassium permanganate per c.c. of electrolyte. The current efficiency was 40%. It is estimated that on the works scale to produce 1 ton of perborate per day will require 700 kg. of borax and 200 kg. of soda ash per day and 315 h.p. for direct current for the cells.—C. I.

Sodium hyposulphite [hydrosulphite]; Determination of ——. J. H. Smith. J. Amer. Chem. Soc., 1921, 43, 1307—1308.

Seyewetz and Bloch's method for the determination of hydrosulphite (J., 1906, 394) has been modified so as to make it more reliable and quicker. About 0·4 g. of the solid hydrosulphite is treated with double the theoretical quantity of an ammoniacal solution of silver nitrate when the following reaction occurs: $Na_2S_2O_4+2AgNO_3+4NH_4OH=2(NH_4)_2SO_3+2Ag+2NaNO_3+2H_2O$. The mixture must not be warmed. After a few minutes the solution is filtered through a Gooch crucible and the precipitated silver washed with an ammoniacal solution of ammonium nitrate. The crucible is then placed in nitric acid and boiled to dissolve the silver and remove nitrous acid, after which the solution is diluted and the crucible removed. The solution is then titrated with $N/10$ potassium thiocyanate using ferric alum as indicator. The method is both rapid and accurate. (*Cf.* J.C.S., Nov.) —J. F. S.

Bromate, bichromate, nitrite, and chloride ions; Electrometric determination of ——. W. S. Hendrixson. J. Amer. Chem. Soc., 1921, 43, 1309—1317. (*Cf.* J., 1921, 416 a).

Bromate may be electrometrically determined by titration with iodide and permanganate. The iodide solution in excess is placed in the titration vessel, which is fitted with a mechanical stirrer and electrodes, and sufficient $10N$ sulphuric acid added to make the solution $2N$. The bromate solution is added in such quantity that about 10% of the iodide is undecomposed. The stirrer is started and when the voltage becomes steady (5 mins.) the excess of iodide is determined by titration with potassium permanganate solution. The method is accurate to about 0·08% and is not influenced by the presence of chlorate. Iodide solutions may be directly titrated with bromate solution in the presence of $2N$ sulphuric acid, the end point being given by an abrupt rise in the potential. This determination may be carried out in the presence of hydrochloric acid, but difficulties are experienced which become greater the greater the concentration of the acid, and so render the accuracy in the presence of hydrochloric acid doubtful. Iodide may be directly titrated with bichromate in the presence of sulphuric acid of at least $2N$, if sufficient time (30 mins.) is allowed near the end point for the reaction to come to an end. The results are accurate to 1 in 6300. Nitrous acid and nitrites may be determined by the electrometric method as follows: a known quantity of permanganate solution is placed in the titration vessel, diluted, and $10N$ sulphuric acid added to make the final concentration $1{\cdot}5N$. The stirrer is started and nitrite solution slowly added, so as to leave 5—10% of the permanganate unchanged. After about 5 mins. a known excess of iodide is added and the titration completed with permanganate solution. The method gives results which are equally as good as those obtained by Laird and Simpson's method (J., 1919, 359 a). Chloride may be estimated by adding an excess of silver solution to a solution of chloride and stirring to coagulate the precipitate. The solution is filtered into the titration vessel, acidified with sulphuric acid, and treated with a measured excess of iodide solution, the excess of which is determined by titration with permanganate. The results are accurate to 1 part in 750, but the method is involved and long.—J. F. S.

Phosphates; Briquetting mineral ——. W. H. Waggaman, H. W. Easterwood, and T. B. Turley. Chem. and Met. Eng., 1921, 25, 517—522.

The processes of washing and screening mineral phosphate in Florida and Tennessee have resulted in the accumulation of dumps of low-grade finely divided phosphate. From this material phosphoric acid can be prepared by smelting with sand and coke under reducing conditions. For successful working in other than an electric furnace, the phosphate must be briquetted in intimate mixture with a reducing agent. Experiments with different binders are described. The best results were obtained with 20% or more of a clay occurring with the phosphate; 10% of water on the final mix was added with the sand and coke, balling of the clay thus being avoided. The correct ratio of silica to lime in the mixture is 59:41, the binding clay providing part of the former. Air-dried briquettes contained 12% of coke and 17% P_2O_5. These briquettes withstood a drop of 8 ft. on to a cement floor and of 20 ft. on to other briquettes, and did not split when heated to 1000° C. They were made in a hydraulic press under a pressure of 2500 lb. per sq. in. Owing to the difficulty of grinding coke, attempts were made to use coal or peat. Briquettes containing these materials burst into flame at 1000° C., but did not disintegrate, and in the case of coal the partial combustion resulted in a deposition of carbon from the volatile matter in the interior of the briquette. This enabled a smaller proportion of coal to be employed than would be calculated from its original fixed carbon content. Results with peat were less satisfactory owing to the greater porosity of the briquettes.—C. I.

Zirkite (impure zirconia); Electric furnace purification of ——. J. G. Thompson. Trans. Amer. Electrochem. Soc., 1921, 291—300. [Advance copy.]

By feeding into an arc furnace a mixture of zirkite (crude Brazilian zirconia ore) and sufficient coke to transform the silica only to silicon carbide, 90—95% of the silica may be volatilised as the carbide. With greater amounts of coke the removal of the silica is much less complete, probably due to the formation of complex double carbides or of solid solutions of silicon carbide in zirconium carbide. Heating the ore and carbide mixture in a resistance furnace removed very little silicon owing to the difficulty of maintaing the mass at temperatures above 2220° C., below which there is practically no volatilisation of silicon carbide. Iron and titanium are not appreciably affected by the heating, but the former may be removed from the remainder of the melt by heating it in an atmosphere of chlorine or phosgene gas. Zirconium carbide may be converted into oxide by ignition in air at a dull red heat.—A. R. P.

Iron oxide sludge [from manufacture of aluminium]; Use of —— *in glass and ceramic manufacture and its adaptation to the preparation of varnishes and paints.* O. Lecher. Chem.-Zeit., 1921, 45, 917—918.

Experiments with iron oxide sludge produced as a waste material in the manufacture of aluminium compounds, indicate that it may be used as a colouring material in the glass and ceramic industries, and in conjunction with boiled linseed oil varnish or size for the preparation of paints which possess good covering power and produce surfaces of good appearance—S. S. A.

Adsorption by precipitates. H. B. Weiser. J. Phys. Chem., 1921, 25, 399—414.

The amount of electrolyte which, added all at once to a colloid (ferrous hydroxide, arsenious sulphide), will cause coagulation, will not do so if added drop by drop over a long period. This is due to the adsorption of the precipitating ion by the neutralised colloidal particles. The amount of a precipitating ion carried down by a colloid on coagulation is determined by the adsorption of the electrically charged particles during agglomeration. The adsorption of equivalent amounts of the precipitating ion effects the neutralisation of the charged particles, but adsorption during agglomeration varies with the concentration and capacity for adsorption of the ion. (*Cf.* J.C.S., Nov.)
—J. F. S.

Manganese dioxide; Preparation of colloidal ——. E. J. Cuy. J. Phys. Chem., 1921, 25, 415—417.

Colloidal manganese dioxide may be prepared by adding, drop by drop, to a boiling solution of $N/20$ potassium permanganate, a solution of concentrated ammonia until the colour of the solution has passed through a wine-red tint and becomes deep coffee-coloured. The solution contains in addition to the colloid only potassium hydroxide, and since this is without action it is not removed. The colloid catalyses the decomposition of hydrogen peroxide and is stable in the presence of alcohol of all concentrations. (*Cf.* J.C.S., Nov.).—J. F. S.

Radioactive substance; Enrichment of —— *in ferruginous spring sediments.* F. Henrich. Ber., 1921, 54, 1715—1722.

The sediment is treated with hydrochloric acid yielding a soluble and an insoluble portion, the former being subsequently precipitated with ammonia. It is redissolved in hydrochloric acid, but enrichment of the solution in radioactive matter cannot be effected by fractional precipitation of ferric hydroxide. If, however, the iron is reduced to the ferrous state and slow crystallisation of ferrous sulphate is induced the initial deposits are completely inactive and the subsequent ones only slightly active, becoming, in general, completely inactive after a single crystallisation from water. A very considerable enrichment of the solution can thus be effected and the active material can then be deposited on ferric hydroxide by oxidation and subsequent addition of ammonia to the solution. If desired, the last traces of iron can be removed from the solution electrolytically, and the active substance then deposited on any desired carrier, but this procedure does not appear to offer any particular advantage. The insoluble portion (see above) is treated with hydrofluoric and sulphuric acids to remove silica, whereby the organic matter becomes charred and the carbon disseminated through the inorganic matrix. The latter may be removed almost completely by treatment with boiling hydrochloric acid (1:2). The residue invariably exhibits relatively great activity, which is yet more pronounced in the ash left after ignition. Attempts to secure an active deposit by treatment of the solutions with animal charcoal were unsuccessful. The filtrate from the treatment of the charred product is concentrated, when gypsum and alum separate successively in the inactive condition; subsequent concentration of the active matter is then effected by the ferrous sulphate method.
—H. W.

Topochemical influencing of reactions and development of habit. V. Kohlschütter and A. d'Almendra. Ber., 1921, 54, 1961—1974.

Specimens of zinc oxide become coated with a deposit of metallic silver when immersed in a dilute aqueous solution of silver nitrate which may also contain free acetic acid. The rate of the action depends on the physical condition of the oxide. Reaction occurs slowly in complete darkness and then appears to attain a maximum; it is remarkably catalysed by light. It appears to depend on the balanced change: $Ag^{\cdot}+H \rightleftarrows Ag+H^{\cdot}$ in which in neutral and acid solution the balance lies strongly towards the left side. Removal of hydrogen ions favours the change, and this is accomplished by means of the OH ions ultimately derived from the oxygen atoms of the oxide. The absence of the phenomenon in the cases of acidic oxides such as SiO_2 and SnO_2 and its observation in the presence of basic oxides, *e.g.*, Bi_2O_3, HgO, PbO, is thereby explained. In itself, however, the solubility of zinc oxide in water is insufficiently great to account for the observed facts, and it appears probable that layers of colloidal zinc oxide, impregnated with mother liquor, are formed throughout the solution which contains an excess of OH' ions on the one side and of $H^{\cdot}$ ions on the other side, and thus develop an electromotive force sufficient to cause the discharge of the $Ag^{\cdot}$ ions.—H. W.

Metallic hydrides. I. Alkali hydrides. F. Ephraim and E. Michel. Helv. Chim. Acta, 1921, 4, 762—781.

Sodium hydride is best obtained by leading a rapid stream of hydrogen directly on the surface of, not into, the metal at such a temperature, above 350° C., that a yellow glow is produced. The hydride, which is carried away as a white smoke, is precipitated electrically, and separated from the gas by filtration through glass wool. Potassium hydride is similarly obtained, the gas being led into the metal at 350° C. In each case the presence of metallic calcium assists the reaction. Rubidium and cæsium hydrides were prepared by heating a mixture of the carbonate with metallic magnesium in hydrogen at 650° and 580°—620° C. respectively. The metals are soluble in the hydrides, the stability of which increases from cæsium to sodium. (*Cf.* J.C.S., Nov.)—J. K.

Colloidal selenium. A. Gutbier and R. Emslander. Ber., 1921, 54, 1974—1978.

Very stable colloidal solutions of selenium are prepared by the regulated action of concentrated hydrazine hydrate solution on selenium dioxide or grey crystalline selenium, and subsequent dilution with water and purification by dialysis. According to the degree of dispersion, the colour varies from intense yellow to blood red. The dilute solutions are stable at the boiling point, but are coagulated readily by barium sulphate. Hydrochloric, nitric, sulphuric, selenious, and acetic acids change the yellow colour of dilute solutions to pink, which becomes violet and then bluish when the mixtures are gently warmed, thus indicating the formation of coarser aggregates. Ammonia has no effect; sodium hydroxide lightens the colour, whereas barium hydroxide causes immediate separation. The coagulating effect of calcium chloride, barium chloride, and alum is particularly marked, whereas that of sodium and potassium chlorides is weaker. Sodium and potassium carbonates appear to increase the stability of the system.—H. W.

Preventing explosions. White. *See* I.

Patents.

Acid manufacture. P. W. Webster, Assr. to Perry and Webster, Inc. U.S.P. 1,390,410, 13.9.21. Appl., 26.10.18.

An acid-collecting liquid is supplied to gases containing sulphuric acid mist, and the mixture simultaneously subjected to a strong centrifugal force. —H. R. D.

Zinc sulphide; Manufacture of ——. C. Clerc and A. Nihoul. E.P. 146,410, 2.7.20. Conv., 20.5.19.

Zinc blende is treated with hydrochloric acid and the resulting zinc chloride solution purified. Magnesia or magnesium carbonate is then added in such proportions that the solution at the end of the following operation is slightly acid, and the zinc is precipitated by the hydrogen sulphide formed from the blende. After separating the zinc sulphide, the solution is concentrated, magnesia added to precipitate the magnesium as basic chloride, and the latter decomposed by steam.—C. I.

Calcium and magnesium; Removal of —— from rock salt brine, or solutions of rock salt in water. F. A. Freeth and L. A. Munro. E.P. 169,192, 16.4.20.

To a solution of common salt containing 0·055% MgO and 0·252% CaO, maintained at a temperature of about 14° C., are added 0·63 g. of sodium carbonate and 0·102 g. of calcium hydroxide per 100 c.c., and the whole then vigorously stirred for a few minutes and allowed to settle before decanting the clear liquid.—H. R. D.

Potash alum; Process of making ——. T. H. Wright. U.S.P. 1,359,011, 16.11.20. Appl., 28.5.19.

A solution of potassium chloride is treated with magnesium sulphate and a solution of aluminium sulphate added to form a solution of not more than 40° B. (sp. gr. 1·384), which is heated to about 90° C. and cooled.—C. I.

Aluminium compounds; Process of precipitating ——. M. O. Sem, Assr. to Det Norske Aktieselskab for Elektrokem. Ind. U.S.P. 1,382,808, 28.6.21. Appl., 23.4.18.

A solution containing an aluminium mineral salt is electrolysed, whereby an aluminium compound is precipitated at the cathode. The process is described in connexion with the electrolysis of aluminium sulphate in a diaphragm cell; it is preferable to add a small quantity of an alkali salt (*e.g.*, sodium sulphate) to the electrolyte, which is maintained at 60°—80° C. and electrolysed at about 5 volts. The free acid generated in the anode compartment is used to dissolve further quantities of raw material (labradorite) to form aluminium sulphate. Basic aluminium sulphate is deposited on the cathode.—W. J. W.

Aluminium salts; Production of ——. C. A. Doremus. U.S.P. 1,391,172, 20.9.21. Appl., 28.10.19.

Alumina-bearing ores containing iron, silica, or titanium compounds as impurities, are roasted and mixed with an acid capable of dissolving the alumina, leaving the other constituents as an insoluble residue.—H. R. D.

Decomposing, transposing, dissolving, or rendering soluble difficultly-soluble bodies; Process of —— H. D. Rankin, Assr. to Corrosion Extraction Co. U.S.P. 1,378,485, 17.5.21. Appl., 24.4.16.

Substances which are practically insoluble in mineral acids or are very resistant to attack thereby are treated with sufficient of the acid (preferably sulphuric acid) just to wet the mass (*e.g.*, 1—1½ c.c. of acid to 2½ g. of substance) and heated to the boiling point of the acid, or if necessary to 350°—450° C., in a retort or autoclave, preferably with agitation. When subjected to this treatment orthoclase is said to be rendered soluble in 30—90 mins. In some cases a second treatment with a further small quantity of acid may be necessary. The process is suggested also for use in treating cassiterite, muscovite, mica, magnetite, titanites, sulphides of cobalt, nickel, mercury, etc., manganese oxides, chromite, etc.

Furnace-tube [for nitrogen fixation]. F. J. Metzger, Assr. to Air Reduction Co. U.S.P. 1,387,505, 16.8.21. Appl., 6.2.20.

A furnace-tube comprising a non-oxidisable outer shell and a relatively thin, inner, non-porous shell which is not affected by the reacting materials is used in the fixation of nitrogen by heating mixtures of alkali metal compounds and carbon in presence of nitrogen.—H. H.

Ammonium salts and cyanogen compounds; Preparation of —— from organic refuse. F. Muhlert. G.P. 339,302, 18.12.17.

Gases containing ammonia and organic bases from the distillation of organic matter or, preferably, the vapours produced on re-distillation of the condensed liquor from such gases, are passed through a sufficient quantity of acid to neutralise the ammonia, and the unabsorbed vapour is heated in the usual way to produce cyanides. By the separate recovery of the ammonia economy in ammonia and heat is attained.—C. I.

Ammonium sulphate; Saturator for the preparation of ——. O. Hellmann. G.P. 339,342, 22.6.19.

The lining and gas connexions are made of acid-resisting stone and are built into a concrete outer structure. This arrangement is more durable than the usual lead construction.—C. I.

Ammonia; Preparation of —— from metallic cyanides. H. Frischer. G.P. 339,627, 31.3.18.

The cyanides are heated with a material yielding steam or hydrogen, *e.g.*, hydrocarbons, carbohydrates, wood shavings, or coal. The residue is used for the preparation of carbides or cyanamides. —C. I.

Titanium-nitrogen compounds; Process of synthesising ——. Synthetic production of titanium-nitrogen compounds. F. von Bichowsky and J. F. Harthan. U.S.P. (A) 1,391,147 and (B) 1,391,148, 20.9.21. Appl., 1.6.20.

(A) A titanium compound containing oxygen is heated with carbon, an alkali salt, and a metal of the iron group in the presence of nitrogen to form a nitride. (B) The titanium compound is heated in presence of nitrogen and a hydrocarbon gas or vapour.—H. R. D.

Arsenate of lead; Suspended —— and method of making same. C. H. Sakryd and H. M. Rosencrans, Assrs. to Grasselli Chemical Co. U.S.P. (A) 1,390,647 and (B) 1,390,648, 13.9.21. Appl., 25.4.21.

(A) A small amount of digester liquor from paper-making processes or (B) molasses is added to acid lead arsenate before filter-pressing. The additions increase the capacity of the lead arsenate to remain in suspension.—H. R. D.

Sulphur or sulphur dioxide; Recovery of —— from calcium sulphides. Deutsche Petroleum-A.-G. G.P. 339,610, 5.11.18.

Steam at 1200° C. or above, and in excess or not, is passed over the sulphides which may be mixed with carbon. The steam may be mixed in varying proportions with a reducing gas such as methane or hydrogen.—C. I.

Sulphur dioxide; Recovery of —— from calcium sulphate. Chem. Fabr. vorm. Weiler-ter Meer. G.P. 339,611, 28.10.17.

In the method which involves heating gypsum with a reducing agent, insufficient of the latter for reduction to sulphide is used and a higher temperature employed.—C. I.

Sulphur; Recovery of —— from its ores. G. A. Bragg, Assr. to Texas Gulf Sulphur Co. U.S.P. 1,374,422, 12.4.21. Appl., 13.3.18. Renewed 12.9.19.

A pulp of finely divided ore in a suitable liquid (water) is heated to the melting point of sulphur, *e.g.*, by means of steam, and agitated so as to cause coalescence of the individual melted sulphur particles.—C. I.

Potassium sulphate; Manufacture of ——. P. Comment, Assr. to Fabr. de Prod. Chim. de Thann et de Mulhouse. U.S.P. 1,389,861–2, 6.9.21. Appl., 20.12.19.

See E.P. 137,296 and 137,519 of 1919; J., 1920, 516 A, 689 A.

Nitrogen-hydrogen mixtures; Process for manufacturing ——. W. Gaus and W. Wild, Assrs. to A. Kuttroff. U.S.P. 1,390,200, 6.9.21. Appl., 9.7.20.

See E.P. 145,058 of 1920; J., 1921, 508 A.

See also pages (A) 757, *Acid chambers etc.* (E.P. 150,734); *Drying chlorine* (U.S.P. 1,359,047). 762, *Thionate solutions* (G.P. 339,612). 772, *Silicic acid solutions* (E.P. 168,659). 776, *Tin oxidising furnaces* (E.P. 168,791). 777, *Nickel salts* (E.P. 169,247). 782, *Fertiliser* (E.P. 145,038); *Ammonium bicarbonate* (G.P. 336,100). 788, *Water-softening material* (U.S.P. 1,388,133).

VIII.—GLASS; CERAMICS.

Glass batches containing soda-ash and saltcake; Relative advantages of limestone, burnt lime, and slaked lime as constituents of common ——. F. W. Hodkin and W. E. S. Turner. J. Soc. Glass Tech., 1921, 5, 188-194.

Very small melts of soft-glass batches, both with and without magnesium, were examined. Soda ash-burnt lime batches in all cases melted the most rapidly and were the most fluid at corresponding temperatures. Soda ash batches containing slaked lime melted more rapidly than those containing limespar. With saltcake as the alkali the burnt lime batch was the slowest melting of all, and the slaked lime batch the most viscous. The batch mixtures soda ash—lime spar, soda ash—salt cake—lime spar, and soda ash—salt cake—lime showed no marked difference in rate of melting. Glasses with soda ash alone as alkali were marked with a slight scum.—A. C.

Glass tank furnace; Heat balance of a plant consisting of an air-steam blown gas producer and a ——. M. W. Travers. J. Soc. Glass Tech., 1921, 5, 166—183.

A detailed analysis of the combustion and melting processes, with consideration of heat losses, gave the following data:—In a tank working at 1400° C., with regenerators for preheating gas and air to 600° C., there would be a fuel efficiency of 35% (the remaining 65% being lost outside the furnace), whilst, of this energy, 26% would be lost through the furnace walls, and 9% only would be used in melting glass. The coal consumption per ton of glass would be 0·91 ton. In a similar tank where gas and air were preheated to 800° C. the fuel efficiency would be 45%, of which 12% would be used for melting glass, and 0·73 ton of coal would be used per ton of glass. Finally with air and gas preheated to 1000° C. the fuel efficiency would be

55% (14·5% used for melting glass), the coal consumption per ton of glass being 0·60 ton.—A. C.

Glasses containing aluminium; Thermal expansion of ——. S. English and W. E. S. Turner. J. Soc. Glass Tech., 1921, **5**, 183—187.

In the series of sodium-aluminium trisilicate glasses the substitution of alumina for sodium oxide was found to reduce the coefficient of thermal expansion much more than replacement of the soda by either lime or magnesia, while the molecular substitution of alumina for lime in sodium-calcium-aluminium trisilicate glass appreciably lowered the thermal expansion. No factor could be given from the results for the effect of alumina.—A. C.

Glass; Development of various types of ——. *Effect of joint presence of sodium and potassium on solubility of lead glasses.* C. J. Peddle. J. Soc. Glass Tech., 1921, **5**, 195—200.

In the series of glasses alkali-RO-SiO_2, where RO is either calcium oxide or lead oxide, and where the total alkali is less than 20%, the glass containing both potassium and sodium oxides in equal proportion by weight will be less soluble and more durable than the glasses which contain one of these alkalis only. This is true whatever the percentage of lead oxide, or of calcium oxide, and of silica. To obtain maximum durability in an alkali-lead oxide-silica glass the sodium and potassium oxides should be mixed in the ratio of 7 pts. of potash and 3 pts. of soda, a ratio which holds good for all percentages of alkali below 20 and which is independent of the amounts of lead oxide and of silica. A lead glass of the following percentage composition would be the most satisfactory in regard to colour, density, brightness, durability, melting, and working, for making high-grade cut-glass ware:—SiO_2 42, PbO 48, Na_2O 3, K_2O 7.—A. C.

Glass; Effect of rays from radium, X-rays, and ultra-violet rays on ——. J. R. Clarke. J. Soc. Glass Tech., 1921, **5**, 155—165.

A series of soda-lime glasses of similar composition, one free from colouring agent, some coloured brown by selenium and some blue by cobalt oxide, were exposed to the action of radium rays, X-rays, and ultra-violet rays. The first glass was only faintly coloured on the surface by radium rays, an effect shown to be due to α-rays. The cobalt oxide and selenium glasses under similar conditions developed a brown coloration in the region of penetration of the β-particles, which decreased in intensity towards the interior, and which increased with ncrease of selenium or cobalt oxide content. With prolonged exposure a maximum intensity was reached, the value of which varied with the amount of colouring agent present. None of the glasses was coloured by γ-rays, X-rays, or ultra-violet ays. Fluorescence occurred in all cases under the ction of radium rays and of rays from radium manation, but the effect was not produced by X-rays, and only to a slight degree with ultra-violet ays in the case of the pure soda-lime glass and the elenium glass. All glasses exposed to radium manation exhibited thermo-luminescence and loss f colour at temperatures of 100°, 160°, and 235° C. t was concluded that the coloration was due to ormation of colloidal particles by the action of α- r β-rays on dissociated ions in the glass, whilst uorescence was due to mechanical bombardment f glass molecules by the rays.—A. C.

efractories; Physical characteristics of specialised ——. M. L. Hartmann and W. A. Koehler. Trans. Amer. Electrochem. Soc., 1921, 129—136. [Advance copy.] (*Cf.* J., 1920, 365 A, 690 A.)

HE transverse breaking strength of 10 commercial refractory bricks was determined at 20° C. and at 1350° C. All materials except two specimens of bonded carborundum showed a great reduction in strength at the higher temperature. The values for the modulus of rupture in lb. per sq. in. at 20° and 1350° C. respectively for specimens of the materials mentioned were:—Bonded carborundum, carbofrax A, 2103, 2274; carbofrax B, 2651, 2129; carbofrax C, 2215, 1918; silica No. 1, 608, 145; silica No. 2 (both lime bonded), 491, 178; magnesia, 1388, 136; fireclay, grade A, 665, 113; bauxite, 1315, 99; chrome, 1392, 22.—C. A. K.

Kaolins; Absorption of sodium hydroxide by ——. R. F. Geller and D. R. Caldwell. J. Amer. Ceram. Soc., 1921, **4**, 468—473.

The amounts of sodium hydroxide completely absorbed by three kaolins were determined. The absorption increased with temperature, but appeared to be largely independent of the time. The experimental data could be expressed satisfactorily by the Freundlich adsorption isotherm.—H. S. H.

Elutriation test for potters. B. Moore. Trans. Ceram. Soc., 1920–21, **20**, 112—119.

An elutriator for works use is described, a sample of at least one pint being taken. The influence of the specific gravity in altering the coefficient in the formula $D=0{\cdot}0518V^{0{\cdot}636}/(S-1)$, where D=diam. of particles, V=velocity in mm. per sec., and S=specific gravity, was shown.—H. S. H.

Earthenware bodies; Effect of calcination of flints on ——. A. Heath and A. Lesse. Trans. Ceram. Soc., 1920–21, **20**, 121—126.

The importance of knowing the specific gravity of flint in order to know the weight of flint added, when the volume of the slop flint is measured, is stated. There was less tendency to crazing in bodies prepared from hard calcined flint than in those containing easy calcined flint.—H. S. H.

Sagger clay preparation. F. K. Pence. J. Amer. Ceram. Soc., 1921, **4**, 459—460.

Saggers can be improved in quality by installing a machine for the dry mixing of the ingredients leaving the dry pan. The "soaking pit" may then be eliminated and the clay and water fed directly to the pug mill.—H. S. H.

[Pottery] saggers. B. J. Moore. Trans. Ceram. Soc., 1920–21, **20**, 93—104.

Carborundum in sagger mixtures exerts a slow reducing effect and is costly. Saggers made from mixtures of china clay, ball clay, and fused silica (up to 50%) have stood 30 fires under very drastic conditions.—H. S. H.

White ware bodies; Cobalt stain in ——. A. S. Watts. J. Amer. Ceram. Soc., 1921, **4**, 451—452.

Cobalt oxide or cobalt sulphate added to a white ware body frequently causes a blue-grey cast when the body is slightly overfired. Uniformly good results have been obtained by the following procedure. The stain is prepared by dissolving 15 oz. of pure cobalt sulphate in 750 oz. of pure water, and then adding 7½ oz. of sodium carbonate, and stirring thoroughly. The stain is added after thoroughly blunging the ball clay with the body. For a body containing 10% of ball clay ½ oz. of stain is added for each 10 lb. of body. If the ball clay content is increased the amount of stain should be increased in the same ratio, but if the ball clay content exceeds 15% of the body it is impossible to produce a pure white product by increasing the cobalt stain. For neutralising the yellow tint of white-ware glazes 10 oz. of the stain is added to every 100 lb. of glaze being ground. If the glaze is very high in lead, the required amount of stain will be greater.—H. S. H.

Terra cotta body; Value of ageing the ——. R. L. Clare and R. N. Long. J. Amer. Ceram. Soc., 1921, 4, 453—458.

Ageing of a terra cotta body for 12 days materially increased the plasticity of the clay and its capacity for being worked, slightly increased the dry strength and reduced the tendency to warp in drying. Re-tempering of the body mixture, after ageing, produced a further slight increase in plasticity, increased slightly the tendency to warp in drying, and increased considerably the dry strength. The clay grains are softened on ageing, and re-tempering then produces a finer subdivision of the particles and a more intimate combination of the clay and grog.—H. S. H.

Felspar frits [for glazes]; Solubility and fusibility of some ——. H. H. Sortwell. J. Amer. Ceram. Soc., 1921, 4, 446—450.

Twenty frits were made with compositions varying from 10 to 50% of fused borax, 20 to 90% of felspar, and 0 to 30% of calcium oxide. All the products were sufficiently insoluble for use as frits in glazes, the solubilities being less than 1·5%. (The solubility was determined by shaking 5 g. of frit ground to 20- to 40-mesh size with 350 c.c. of water for 24 hrs.) A little calcium oxide in the frit reduced the solubility. The fusibilities varied from 660° to 1050° C. The substitution of calcium oxide, up to 10%, for felspar, maintaining the borax constant, increased the deformation temperature, but further substitution had only slight effect in this respect. The replacement of either felspar or calcium oxide by fused borax lowered the deformation temperature about the same amount in each case. It was estimated that approximately 800° C. was the maximum deformation temperature of the melted frit for easy working in the frit kiln.—H. S. H.

Enamelling; Application of electric heat to vitreous ——. L. E. Barringer. J. Amer. Ceram. Soc., 1921, 4, 461—467.

The heating chamber of the furnace described is an open tunnel without muffle, divided into two compartments by a fireclay damper, and wound with nichrome wire. The front compartment is used for preheating the enamel-coated ware to 300° C. and the second compartment for heating the goods to 900° C. The furnace is more economical and produces better results than the oil-fired furnace it replaced.—H. S. H.

Lignite containing common salt. Von Morgenstern. *See* IIa.

Iron oxide sludge. Lecher. *See* VII.

Patents.

China clay; Drying of ——. J. Adair. E.P. 167,917, 14.6.20.

To secure more uniform drying of china clay from the washing vats than is possible with the customary coal-fired drying floor, the wet kaolin is conveyed mechanically to a chamber containing a battery of inclined shallow hollow chambers. The hollow chambers may be made from two dished aluminium plates, riveted together, and are heated either by direct steam or by internal steam pipes. The construction may be varied, but the outer surface which comes into contact with the clay must be of aluminium to prevent contamination. During the drying process the clay is stirred by wooden rabbles between the heated chambers. The dried clay is removed through openings in the side of the drying chamber.—C. A. K.

Clay for use in the manufacture of pottery. S. Smith. E.P. 169,343, 22.7.20.

A potter's slip is made by thoroughly mixing powdered stone (5 lb.), milled china clay (5 lb.), ground felspar (1 lb.), potassium nitrate (2 oz.), and "liquid cobalt," with or without a small quantity of calcined bone, and adding sufficient water to form a slip of the desired consistency.—H. S. H.

Silicate [dental] cements and silicate phosphate cements; Manufacture of solutions of silicic acid and manufacture of —— therefrom. W. Carpmael. From Farbenfabr. vorm. F. Bayer und Co. E.P. 168,659, 4.6.20.

A dental cement is made by mixing a suitable inorganic base (*e.g.*, magnesium oxide or glucinum oxide) with a solution of silicic acid prepared by hydrolysis of organic compounds containing a high percentage of silicic acid, *e.g.*, tetramethyl silicate or hexamethyl disilicate. The hydrolysis is preferably carried out in the presence of phosphorus pentoxide or an alkyl-oxide of an alkaline earth or of magnesium or of aluminium, or both.—H. S. H.

Oven; Decorating or annealing ——. C. E. Frazier. U.S.P. 1,389,583, 6.9.21. Appl., 26.3.21.

A primary combustion chamber is situated between two secondary chambers and above a muffle, communication between the primary and secondary chambers being by means of flues passing around and underneath the muffle.—B. M. V.

Brick, tile, and the like; Material for and process of forming ——. L. Jones and C. Westlake, jun. U.S.P. 1,390,038, 6.9.21. Appl., 4.9.19.

A material for dry pressing bricks etc. contains 65—75% of silica, 20—30% of lime, 1½—3½% of magnesia, and 1½—3½% of sulphur.—A. G.

Refractory composition; Acid-proof ——. Basic refractory material. H. P. Bassett. U.S.P. (a) 1,390,327 and (b) 1,390,328, 13.9.21. Appl., 15.10.19.

(a) An acid-proof refractory composition comprises silica, a metal of the iron and aluminium group, an alkali metal compound, and a silicate binder. (b) A basic refractory material comprises a double burned dolomite, an oxide of a metal of the iron group, an alkali metal compound, and a silicon compound. —H. S. H.

IX.—BUILDING MATERIALS.

Calcium sulphate cements; Porosity, strength and absorbing power of certain ——. A. B. Taylor and E. Irvine. Trans. Ceram. Soc., 1920-21, 20, 83—92.

The effect of the amount of water used in gauging the plaster on the porosity, crushing strength, and Brinell hardness was studied. The porosity and the diameter of the Brinell impression increased and the crushing strength and tensile strength decreased as the proportion of water increased. The addition of 1% borax solution, by retarding the setting action, permitted the preparation of plasters of higher concentration than could otherwise be prepared, and the strengths of these plasters fell roughly on a continuous curve with the strengths of those mixtures made with water only. Mixtures containing 2·6—3·0 pts. of plaster to 1 of water plus 1% borax were of an almost plastic consistency and could be moulded by hand. The crushing and tensile strength of a mixture of 3 pts. of plaster and 1 of water was four to five times as great as that of the usual moulding mixture. A series of tests on the suction of moulds were carried out both with capillary action alone and under a definite applied pressure. The amount of water absorbed in a given time increased with increase in the amount of water used in gauging. The addition of borax to the plaster increased the absorption.—H. S. H.

Patents.

Artificial stones; Manufacture of —— [from slag]. C. H. Schol. E.P. 144,706, 10.6.20. Conv., 15.2.18.

Light and highly porous bodies produced from blast-furnace slags, generator slags, and similar scoriæ, with the addition of lime or cement, as described in E.P. 28,642 of 1912 (see Addition to F.P. 437,595; J., 1913, 1012), are hardened immediately after moulding and setting by the action of either low-pressure steam or high-pressure steam. The preliminary setting is effected by the action of either air or low-pressure steam.—H. S. H.

Mortar-forming material; Process for manufacturing a —— from anhydrite or the like. F. Hartner. E.P. 154,888, 5.11.20. Conv., 25.11.19.

Anhydrite or anhydrite-bearing rock is pulverised until the bulk of it is fine enough to pass through a 10,000-mesh sieve (particles of 0·006 mm. or less). The resulting powder sets and hardens without addition of other substances.—H. S. H.

Paving and other purposes; Mixtures for ——. W. J. Mellersh-Jackson. From The United States Asphalt Refining Co. E.P. 169,079, 30.7.20.

Dust electrically precipitated from the floating discharges of plants for grinding calcareous, argillaceous, or other mineral materials is added to bituminous material such as asphalt, yielding a product in which the filler does not tend slowly to settle to the bottom of the mixture.—L. A. C.

Artificial stone; Process of producing ——. W. J. de Bas. U.S.P. 1,390,244, 6.9.21. Appl., 14.12.18.

See E.P. 120,575 of 1918; J., 1919, 948 A.

Paint for concrete. E.P. 169,258. *See* XIII.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

[Steel.] *Constitution of martensite and troostite.* D. J. McAdam, jun. Chem. and Met. Eng., 1921, 25, 613—618.

The theory of slip interference as a general cause of hardening of metals (Jeffries and Archer, J., 1921, 515 A) is accepted as valid, at least as applied to hypoeutectoid steels. The similarity of curves howing the relation of the Brinell hardness and he Ar transformation with increasing carbon ontent indicates that the hardening effect of carbon n steel is nearly proportional to the lowering of the ransformation temperature of austenite. Reducing his temperature below 790° C. has little effect on he grain coalescence of the α iron formed from ustenite. The maximum hardness is reached at ·7% C, indicating that the grain refinement of the errite has reached its limit, and it seems probable hat the hardening effect in hypoeutectoid steels s due to the strengthening of ferrite by grain efinement. By tempering hypereutectoid austenitic lloy steel, and by quenching hypoeutectoid steel t suitable rates, "dark etching martensites" are btained which the author renames "hypereutectoid roostite." Study of the lattice arrangement would eem to indicate that in martensite every carbon tom with its surrounding iron atoms preserves the me spacing that existed in austenite. When pportunity is given for two of these carbide groups come into contact and to undergo "carbide conraction" in volume, cementite is produced. Martensite probably consists of α iron with austenitic carbide in suspension. In troostite the austenitic carbide has undergone carbide contraction to form cementite particles of the smallest size in which it can exist.—C. A. K.

Rust prevention by slushing. H. Styri. Trans. Amer. Electrochem. Soc., 1921, 113—128. [Advance copy.]

The development of rust on bright steel (tools, ball bearings), even though covered by grease, was found in certain cases to be due to the deposit of perspiration, moisture in the grease, and residual dirt from grinding operations. A hot neutral soap emulsion proved to be the best cleansing reagent before slushing in grease. Excess of alkali or the presence of salts promotes rusting. The oil film left after washing in soap solution gives a temporary protection but drains off if exposed to a humid atmosphere. Any grease or oil is satisfactory as a rust inhibitor provided that it is free from acid. —C. A. K.

Platinum; Preparation of pure ——. E. Wichers. J. Amer. Chem. Soc., 1921, 43, 1268—1273.

Commercial platinum containing small quantities of rhodium, palladium, and iridium and considerable quantities of iron, tin, and other base metals can be purified by four precipitations as ammonium chloroplatinate. The metal is dissovled in *aqua regia*, excess of nitric acid is removed by repeated boiling with hydrochloric acid, and precipitation effected by ammonium chloride. The precipitate is drained on a Buchner funnel, stirred with a large volume of 15—20% ammonium chloride solution, and again drained; the washing is repeated three or four times. The precipitate is dried and ignited to sponge in an electric muffle. The sponge is redissolved in *aqua regia* and the process repeated four times. The final precipitate is ignited to sponge in a porcelain dish over a gas flame, and during reduction a current of hydrogen is passed over the material. When platinum is melted in an oxyhydrogen flame on a lime slab it takes up considerable quantities of metallic calcium, so much so that it sometimes reacts alkaline to moist litmus paper. The amount of calcium, as detected by the thermo-electric effect, is reduced if an excess of oxygen is used in the oxyhydrogen flame used to melt the platinum. Melted in a magnesia crucible the platinum becomes brittle and may take up as much as 3% Mg. (*Cf.* J.C.S., Nov.)—J. F. S.

Electrodeposited metals; Structure and properties of alternately ——. W. Blum. Trans. Amer. Electrochem. Soc., 1921, 137—146. [Advance copy.]

If a number of relatively thin layers of nickel are interposed during the electrodeposition of copper the tensile strength of the deposit is very much greater than that of pure copper deposited under similar conditions, to an extent depending on the relative frequency with which the nickel layers are introduced much more than on the relative proportions of the two metals in the deposit. The nickel layers are preferably obtained from a solution containing 240 g. of crystallised nickel sulphate, 15 g. of the chloride, and 30 g. of boric acid per litre at a current density of 2 amp. per sq. dm. without agitation, while the copper is deposited with a current density of 6 amp. per sq. dm. from an agitated solution of 200 g. of copper sulphate crystals and 100 g. of sulphuric acid per litre. The strongest deposits were those containing 10 pts. of copper to 1 of nickel, the thickness of the nickel layers being 0·0063 mm. In the case of copper deposited alone the tensile strength of the deposits increased with the current density, but it was impracticable to use a higher density than 6 amps. per sq. dm. owing to "treeing" occurring. The interposition of nickel layers prevents this, and the structure of the metal is very fine-grained, to which fact it owes its increased strength. Similar results may be obtained by using silver instead of nickel, while a fine-grained structure may also be produced by depositing copper alternately from two different solutions, *e.g.*, sulphate and cyanide. The principle of the process has been adapted to the production of engraved plates.—A. R. P.

Tenax metal. W. Schulte. Giessereizeit., 1921, 18, 258—260, 268—270, 278—280. Chem Zentr., 1921, 92, IV., 906.

During the war a zinc alloy containing Cu, 2·56% ±0·35; Al, 4·42±0·2; Pb, up to 1·2%, and Fe up to 0·35%, and known as "Tenax" metal, was used for the manufacture of guide rings. It has a tensile strength of 7114 kg. per sq. cm. and an impact test number of 9·06. The author has examined its resistance to corrosion in air, water, acids, and oils, both in the uncoated state and after receiving coats of copper, brass, and nickel deposited electrolytically. Rods produced by the pressing process gave the best results and proved to be superior in mechanical strength and resistance to corrosion to those made of commercial zinc.—A. R. P.

Lead-tin alloys; Electrodeposition of ——. W. Blum and H. E. Haring. Trans. Amer. Electrochem. Soc., 1921, 147—164. [Advance copy.]

Lead and tin have nearly equal potentials in fluoborate solutions, that of tin being slightly lower under similar conditions. The two metals replace each other from fluoborate solutions according to the concentration of their respective ions, but for each acidity and total metal concentration there is an equilibrium between them; thus, for solutions which are $N/1$ in metal and $N/2$ in free hydrofluoboric acid equilibrium is reached at $0{\cdot}81N$ in tin and $0{\cdot}19N$ in lead. The cathode efficiencies are so near 100% that the composition of the deposits can be calculated from the weight of metal deposited by a given quantity of electricity as measured by a copper coulometer; it depends on the ratio of the metals in the electrolyte, being equal to this only when the solution has the equilibrium composition as described above. The amount of tin in the deposit may be increased, in solutions containing little tin, by increasing the current density or by the addition of glue; in each case the fineness of the crystal structure of the deposit is also increased. The composition of the deposit is not influenced by that of the anodes unless these cause changes in the composition of the solution. Continuous operation with anodes containing more or less tin than corresponds to the equilibrium solution (71% Sn) results in deposits that differ from the anodes in the direction of this equilibrium. In order to obtain deposits containing 50% Sn a lead fluoborate solution is electrolysed with a tin anode until the deposit is found, by calculation or analysis, to contain nearly 50% Sn, when the tin anode is replaced by a lead-tin alloy containing less than 50% Sn and the electrolysis is continued with a current density of 0·5—1·5 amp. per sq. dm. The electrolyte is made by dissolving 142 g. of basic lead carbonate in a solution containing 240 g. of 50% hydrofluoric acid and 106 g. of boric acid per litre with the addition of 0·2 g. of glue.—A. R. P.

Aluminium-copper or aluminium-iron alloys; Rapid determination of copper or iron in ——. P. Hulot. Bull. Soc. Chim., 1921, 29, 836—837.

From 2 to 5 grms. of the metal, according to the expected copper or iron content, is treated with cold 20% aqueous sodium or potassium hydroxide. The aluminium rapidly dissolves and the copper or iron is deposited. The deposit is washed by decantation, dried, and weighed. The result may be confirmed in the case of copper by dissolving the deposit in nitric acid and estimating the copper electrolytically. In the case of iron the deposit is dissolved in hydrochloric acid and the iron is estimated in the usual way by precipitation as ferric hydroxide.—W. G.

Calcium-barium-lead alloys comprising Frary metal; Electrolytically produced ——. W. A. Cowan, L. D. Simpkins, and G. O. Hiers. Trans. Amer. Electrochem. Soc., 1921, 237—258. [Advance copy.]

Calcium-barium-lead alloys are produced on a large scale by the electrolysis of a mixture of pure calcium and barium chlorides of low melting point above a bath of molten lead, which forms the cathode, and with a carbon rod as anode, until the lead has taken up sufficient of the alkaline-earth metals. "Frary metal," produced in this manner, contains up to 2% Ba and up to 1% Ca and is used extensively as a bearing metal in place of Babbitt metal. The hardness of the alloy can be doubled by ageing at a suitable temperature and does not decrease as rapidly as that of Babbitt metal with increase in temperature. The microstructure shows a mass of fine crystals of a hard constituent, Pb_3Ca, in a ground mass of a eutectic of Pb_3Ba and lead which is much softer and gives the required plasticity to the alloy. The lead-barium eutectic freezes at 281° C., while an alloy containing 1·2% Ba and 0·8% Ca begins to solidify at 440° C. and has practically all solidified at 316° C., a temperature range that compares favourably with that of the best Babbitt metal. There is no appreciable tendency of any of the constituents to oxidise more than is usual with lead alloys during the melting and casting operations.—A. R. P.

Alkali and alkaline-earth metals; Experiences with —— in connection with non-ferrous alloys. C. Vickers. Trans. Amer. Electrochem. Soc., 1921, 191—198. [Advance copy.]

Sodium, preferably added as a 5% sodium-tin alloy, is a suitable deoxidiser for copper and bronze and its use yields castings of superior torsional strength to those obtained by the use of phosphor-tin. Addition of small quantities of calcium alone to molten copper resulted in porous castings, while an alloy of 7—10% Si, 3—5% Ca, and the remainder copper gave unreliable results when used as a deoxidiser for copper.—A. R. P.

Metal pairs; Equilibrium between —— and sulphur. V. Copper-tin-sulphur. VI. Copper-iron-sulphur. Considerations on theoretical metallurgy. W. Guertler and K. L. Meissner. Metall u. Erz, 1921, 18, 466—468.

The triangular diagram for copper, tin, and sulphur being so complex due to the existence of two sulphides of each metal and three intermetallic compounds, the behaviour of a melt corresponding to the empirical formula Cu_2SnS was examined. On melting this mixture (Cu, 45·7%; S, 11·53%; Sn, 42·77%) thermal effects were noticed at 489°, 443°, and 206° C. on cooling and the mass separated into two layers, the upper consisting of cuprous sulphide and the lower of a mixture of lilac-coloured long plates of Cu_3Sn in a ground mass of CuSn, thus showing that copper has a greater affinity for sulphur than tin has. In the system Cu—Fe—S the mixture corresponding to the point of intersection of the two lines, Cu—FeS and Fe—Cu_2S, and containing 59·12% Cu, 14·91% S, and 25·97% Fe, was prepared and on melting and cooling was found to have separated into two layers, an upper one of Cu_2S and a lower consisting of copper and iron with emulsified drops of Cu_2S. Thermal effects were noticed at 1077° C. (freezing of Cu_2S) and at 1025° C. (freezing of the copper in the lower layer), but no special effect was noticed during the freezing of the iron. The whole series of experiments on metal pairs and sulphur has shown that copper has a greater affinity for sulphur than lead, bismuth, antimony, tin, and iron, but a less affinity than manganese.—A. R. P.

Metallic hydrides. Ephraim and Michel. *See* VII.

PATENTS.

Steel and its heat treatment. The National Malleable Castings Co., Assees. of W. G. Kranz. E.P. 140,822, 26.3.20. Conv., 21.5.15.

A STEEL free from oxides and containing C 0·3—0·5%, Mn 1·30—1·60% is made in an electric furnace, cast, heated to 825°—900° C., quenched in water to 25° C., reheated to 550°—590° C., and cooled slowly in air.—J. W. D.

Steel and its heat treatment. National Malleable Castings Co., Assees. of W. G. Kranz. E.P. 140,823, 26.3.20. Conv., 21.5.15.

AN alloy steel substantially free from oxide is made in the electric furnace by adding manganese and carbon to a refined bath of iron or scrap to bring the composition up to the following:—C 0·30—0·50%, Mn 1·30—1·60%. The heat treatment is carried out in an electric furnace and consists in heating to 800°—900° C. and quenching, reheating to 550°—600° C., and cooling in air.—T. H. Bu.

Steel and iron; Carburising ——. T. Tashiro. E.P. 146,504, 5.7.20. Conv., 13.8.18.

THE articles are imbedded in a mixture consisting of carbonaceous material and a metallic peroxide in a completely enclosed gas-tight chamber and subjected to external heat so that carbon monoxide is generated and acts on the metal in its nascent state at a pressure not more than 1 lb. per sq. in. above atmospheric pressure.—J. W. D.

[*Steel*] *furnaces; Regenerative Martin* ——. P. Schmieding. E.P. 151,936, 1.10.20.

ANTE-CHAMBERS are placed in front of the gas chambers of the regenerator to receive alternately the cold fuel gases before their entrance to the gas chambers and the gases of combustion flowing from the furnace to the chimney. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 2508 of 1891 and 114,222; J., 1918, 262 A.)
—J. W. D.

Steel; Vanadium-containing impact tool —— *for hot work.* P. A. E. Armstrong, Assr. to Ludlum Steel Co. U.S.P. 1,388,157, 23.8.21. Appl., 10.4.19.

STEEL for tools to be used for hot work contains 0·30—0·60% C, 0·30—1% Mn, 1—1·75% Cr, 5—6% Ni, and also vanadium.—C. A. K.

ron or steel; Treatment of —— *for prevention of oxidation or rusting.* L. S. Chadwick and M. Resek, Assrs. to Cleveland Metal Products Co. U.S.P. 1,388,325, 23.8.21. Appl., 1.10.17.

RON or steel is treated in a bath containing a mixure of di- and mono-hydrogen phosphates of a metal of lower basicity than iron.—C. A. K.

lloy steels. P. M. McKenna. U.S.P. (A) 1,389,679 and (B) 1,389,680, 6.9.21. Appl., 2.4.21.

HE steels contain (A) W 16—20%, Cr 2·5—5·0%, nd Ta 1—3%, (B) C over 0·2%, Cr 0·7—1·6%, and a 1—3%.—J. W. D.

ron and steel; Production of ——. E. Riveroll. U.S.P. 1,391,507, 20.9.21. Appl., 11.5.20.

RON sponge is reduced to the metallic state by heating with an electric current to form a body of molten metal with a body of slag directly above it, the current being introduced by means of an electrode passing through the slag, and reducing gas being supplied in the zone between the slag and the molten metal.—T. H. Bu.

Alloys containing silicon with metals of the iron and chromium group; Method of producing ——. R. Walter. E.P. 143,553, 19.5.20. Conv., 28.10.18.

To reduce the hardness and brittleness of acid-resisting alloys containing silicon and a metal of the iron and chromium groups, a small percentage of boron is added, depending on the quantity of silicon present. For example, 0·3 to 0·4% B added to an alloy of 15% Si and 85% Fe renders it capable of being drilled, turned, filed, etc.—T. H. Bu.

Iron, zirconium, and silicon; Alloy of —— *and process for the production thereof.* N. Petinot, Assr. to U.S. Ferro-Alloys Corp. U.S.P. 1,389,695, 6.9.21. Appl., 18.8.19.

AN alloy in which the ratio of zirconium to silicon is not less than 80:20, and not more than 85:15.
—J. W. D.

Nickel and iron; Alloy of —— *and process for production thereof.* N. Petinot and R. Turnbull. U.S.P. 1,389,696, 6.9.21. Appl., 17.11.19.

A COLD matte containing iron, nickel, and sulphur is charged into a basic electric furnace, carbon is added, together with lime in quantity sufficient to remove the sulphur as calcium sulphide, then the charge is melted, the slag skimmed off, a second lime-carbon slag added, and the smelting continued whilst the bath is strongly agitated with a rod.
—J. W. D.

Nickel and zirconium; Process of making an alloy of ——. N. Petinot. U.S.P. 1,387,663, 16.8.21. Appl., 18.8.19.

NICKEL is melted in an electric furnace and zirconium is formed in the bath in a nascent state.
—J. W. D.

Welding of aluminium and aluminium alloys to metals such as iron and the like. Metallindustrie Schiele und Bruchsaler. E.P. 144,707, 10.6.20. Conv., 3.6.18.

To provide sheet iron with a thin coating of aluminium it is necessary that the surfaces of both metals should be uniformly granulated (matt). This is effected by rolling sheet iron and aluminium separately in packs, or by etching, sand blasting, or other known process. The iron sheet completely wrapped with the aluminium foil is then heated to about 600° C. and rolled to give a maximum stretching of the aluminium without materially stretching the iron.—C. A. K.

Welding of aluminium to iron. Metallindustrie Schiele und Bruchsaler. E.P. 145,043, 14.6.20. Conv., 27.6.18. Addn. to 144,707 (*cf. supra*).

THE air-tight wrapping of iron sheet with aluminium foil having a granulated or matt surface has been found to be difficult on account of the delicacy of the foil. According to the present process aluminium foil, placed on the iron sheets with the granulated surfaces together, is attached to the iron in an air-tight manner by cold rolling under slight pressure.—C. A. K.

Welding cast iron. J. Churchward, Assr. to Wilson Welder and Metals Co. U.S.P. 1,389,476, 30.8.21. Appl., 27.10.20.

IN welding cast iron, a layer of metal is applied of such a composition as to absorb sufficient carbon to inhibit the formation of free cementite.—C. A. K.

Tin and antimony; Process of refining ——. G. Bonnard. E.P. 145,789, 2.7.20. Conv., 5.4.19.

By treatment of crude tin with anhydrous chlorine the liquid chlorides of tin, antimony, arsenic, and sulphur may be separated from the solid zinc chloride and the unattacked metals (copper, lead, silver, and titanium). Antimony is separated by heating the liquid chlorides from the reaction chamber to 115°—120° C., at which temperature antimony pentachloride is converted into the trichloride, which is solid. A solution of stannic chloride is obtained by treatment of the mixed chlorides with water, and the metal may be recovered electrolytically.—C. A. K.

Coating of metals with metals of a lower fusing point. H. G. Grinlinton. E.P. 146,830, 5.7.20. Conv., 4.7.19.

The coating metal or alloy—aluminium and its alloys excluded—in a fine state of division, is mixed with ammonium chloride solution and a suitable medium, such as zinc chloride in the case of brass or copper, and applied to the foundation metal, powdered stearic acid is sprinkled over the coated area to act as a flux, and heat applied insufficient to volatilise the flux but sufficient to fuse the coating metal.—J. W. D.

Treating ores, chemicals, minerals and the like. Method and apparatus for treating ores and other materials. W. E. Trent. E.P. (a) 146,939, 1.6.20, and (b) 146,942, 10.6.20. Conv., (a) 25.6.19, (b) 10.7.19.

(a) In a method in which finely divided materials are roasted, reduced, volatilised or otherwise treated in a blast and the products subsequently treated with water, the materials are projected into a chamber together with a liquid acting as a carrier and which may also be a reacting or fuel substance. The temperature of the blast may be regulated either by a jacket round the apparatus or by a liquid spray; the latter means may also be applied to remove the treated materials. In the case of pyrites burning, water is used as the carrier, and air as the main reacting agent, and if the temperature is sufficient to decompose steam, the nascent oxygen will cause almost complete oxidation to sulphur trioxide. (b) Materials treated similarly to above are collected (dry or molten) after the reaction by means of baffles, from which the deposited materials fall into collecting chambers. Several chambers may be used for collecting materials of different volatility, and the material may be graded by stratification.—B. M. V.

Castings of aluminium and its alloys; Production of ——. Metallindustrie Schiele und Bruchsaler. E.P. 147,723, 8.7.20. Conv., 19.3.19. Addn. to 137,325.

The treatment of moulds as described in the principal patent (J., 1920, 602 a) is applied to moulds made from sand or clay with the addition of a binding agent. The moulds are coated with a mixture of powdered aluminium and varnish and heated to 400° C. to burn out the varnish. Heating is then continued to the casting temperature (about 700° C.). Dense and uniform castings are produced even in thin sections.—C. A. K.

Lithium-aluminium alloy. A. L. Mond. From Metallbank und Metallurgische Ges. A.-G. E.P. 147,903, 9.7.20.

An alloy suitable for constructional purposes consists of aluminium with up to 40% Li, more especially those containing up to 6%, with or without the addition of one or more of the following, copper, zinc, manganese, nickel, or the like; for example, it may contain 83% Al, 12% Zn, 3% Cu, 1% Mn, 1% Ni or the like, and 0·5% Li. The alloys may be hardened by heating to temperatures between 100° and 550° C. and then slowly cooling, chilling, or quenching.—A. R. P.

Aluminium alloys having a copper content; Method of heat-treating ——. A. de Lavandeyra. E.P. 159,852, 21.8.20. Conv., 3.3.20.

The alloy is heated gradually to and kept at a temperature of 515°—530° C. for 30 mins., immersed in oil for 5—15 mins., and then allowed to stand in hot water for 1½ hrs.—C. A. K.

Ductile bodies of high-fusing metals and alloys; Manufacture of ——. E. Aoyagi. E.P. 168,697, 17.6.20.

Rods of metals or alloys of high fusing point are hung in a vessel containing natural or reducing gas, heated to their melting point by means of a heavy electric current; the elongation of the rods is used to stop the supply of heat automatically by closing an electric circuit which operates to cut off the current through the rods. By increasing the pressure of the gas within the vessel the metal is made more compact.—J. W. D.

Tin oxidising furnaces. W. H. Boorne. E.P. 168,791, 23.9.20.

Metal to be oxidised is placed in an open hearth situated over a combustion chamber extending the full length of the furnace. Auxiliary air is preheated by passing it through ducts on either side of the combustion chamber and the heated air joins the products of combustion immediately before entering the upper chamber. Oil or gas firing is preferred, and the entry of air is adjusted by means of perforated or slotted hollow cylindrical dampers. Gases and vapours leave the furnace through a vertical flue, and the furnace draught is controlled by the admission of air to the exit flue. Oxidation of the tin may be assisted by admitting steam or water into the air-preheating ducts.—C. A. K.

Casting; Electrical treatment of ferrous metals during ——. J. H. Wickett. E.P. 168,812, 3.6.20.

A rotary motion is imparted to molten metal whilst under the influence of a magnetic field, by causing the metal to enter and leave a conical receiver tangentially before passing into a moulding box. The intermediate receiver is situated between the ends of a transformer coil and, by regulation of the current and of the period which the metal is allowed to remain in the heating zone, the composition of the casting may be controlled. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 106,313; J., 1917, 887.)

Ores; Concentration of —— *by flotation.* E. Edser and L. A. Wood. E.P. 168,927, 20.3.20.

The method has particular reference to ores which contain amorphous metallic oxide impurities, *e.g.*, Cornish cassiterite and wolfram. Pulverised ore is mixed with water and a deflocculating agent, which may be acid, neutral, or alkaline (sodium silicate). Colloidal oxides are retained in suspension while definite ore particles settle and are treated later by a flotation process.—C. A. K.

Ore concentration. Minerals Separation, Ltd. From E. W. Wilkinson. E.P. 169,288, 23.6.20.

The products of decomposition of a wide variety of organic substances heated in a controlled atmosphere of air may be used as mineral flotation agents. Petroleum products, bituminous substances, wood, cottonseed oil, etc. may be treated in this manner.—C. A. K.

Thermo-couples; Production of metals and alloys for use in making —— and for other thermo-electric purposes. W. C. Heraeus G.m.b.H. E.P. 168,977, 9.6.20. Addn. to 138,648 (J., 1921, 474 a).

Base metals and alloys possessing uniform thermoelectric properties though prepared from different sources, are produced by melting chemically pure metals in accordance with the vacuum melting process described in the chief patent.—J. S. G. T.

Non-ferrous metals or alloys; Process of melting or melting and reducing ——. E. C. R. Marks. From Scovill Mfg. Co. E.P. 169,188, 15.3.20.

In order to reduce volatilisation losses during the melting of non-ferrous metals of relatively high conductivity, such metals are melted in an electric furnace in which the current employed is of high amperage and low voltage (*e.g.*, 2500—4200 amps., 18—40 volts). The electrodes are in close proximity to the metal, thus preventing excessive radiation of heat to the furnace walls. High frequency is obtained by the use of condensers, and the power input to the furnace is regulated during the melting to avoid overheating the molten metal round the electrodes before the whole charge is melted.
—C. A. K.

Nickel and nickel salts; Manufacture of ——. E. E. Naef. E.P. 169,247, 19.6.20.

Finely-divided nickel sulphides are mixed with solid caustic alkalis, either alone or with the addition of sodium carbonate, common salt, sodium sulphate, sodium sulphide, calcium oxide or hydroxide, and heated to fairly low temperatures, *e.g.*, 250°—600° C. The treatment may be carried out in the presence of hydrogen and/or finely-divided coal. The mass is stirred in water and the nickel obtained as a precipitate which may be separated and refined by known methods. The aqueous solution of caustic soda and sodium-sulphur compounds is evaporated and re-used for another melt, or the sodium-sulphur compounds are allowed to crystallise out. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 499 and 11,581 of 1893 and 6914 of 1894.)
—T. H. Bu.

[Aluminium] alloy. A. Pacz. U.S.P. 1,387,900, 16.8.21. Appl., 13.2.20.

A casting alloy capable of being machined contains 3—20% Si, at least 98% of the remainder being luminium.—J. W. D.

Alloy. A. W. Clement, Assr. to The Cleveland Brass Mfg. Co. U.S.P. 1,389,097, 30.8.21. Appl., 15.8.18.

An alloy contains not more than 80% Fe, not more han 25% Ti, not more than 30% Cr, and not more han 10% of a metal having the properties of aluninium, whereby the alloy is rendered substantilly non-oxidisable at high temperatures.—J. W. D.

lloy; Heat-resisting ——. J. T. Glekler, Assr. to The Cleveland Brass Mfg. Co. U.S.P. 1,389,133, 30.8.21. Appl., 14.1.20.

N iron alloy which does not warp or oxidise at high emperatures contains 15—40% Cr and 1—15% Ni.
—C. A. K.

old [alloy]; White ——. D. Belais and A. R. Bondy. U.S.P. 1,391,499, 20.9.21. Appl., 24.10.19.

white gold alloy is principally composed of gold ith smaller proportions of nickel and zinc and a inute quantity of platinum making the alloy caple of being drawn into seamless tubing.
—T. H. Bu.

Lead alloys [bullion]; Process of treating ——. J. O. Johnstone. U.S.P. 1,389,511, 30.8.21. Appl., 9.8.20.

The finely-divided alloy is treated with lead nitrate solution until the latter is largely converted into basic lead nitrite, and the solution is then separated from the residual slime, which contains the antimony, bismuth, and silver content of the bullion.
—D. J. N.

Lead; Alloys of —— with light metals. H. Hanemann and W. Stockmeyer. G.P. 339,640, 5.10.15.

The hardness and resistance to corrosion of lead is improved by the addition of two or more light metals, one of which is an alkali metal and another an alkaline-earth metal or magnesium, and by the further addition of one or more heavy metals, such as tin, antimony, copper, or zinc.—A. R. P.

Tungsten and similar metals; Process of extracting —— from ores. D. J. and J. E. Giles. U.S.P. 1,388,857, 30.8.21. Appl., 30.9.18.

The ore or concentrate is heated with a solution of a readily soluble alkaline compound under pressure, and the solution separated. The gangue is treated subsequently by a mechanical method to recover the ore residue.—C. A. K.

Accretions; Method of removing —— [from metallurgical furnaces]. S. R. Garr and R. F. Barker, Assrs. to American Smelting and Refining Co. U.S.P. 1,389,751, 6.9.21. Appl., 22.6.17. Renewed 15.1.20.

For removing accumulations from metallurgical furnaces crude oil is introduced into the furnace while still hot until the accumulated material is saturated, and the furnace is then restored to normal working conditions.—B. V. S.

Lead carbonate ores; Process of treating ——. N. C. Christensen. U.S.P. 1,390,603, 13.9.21. Appl., 30.9.19.

Lead is dissolved from the ore by means of a concentrated solution of sodium chloride containing an iron salt.—A. R. P.

Copper, zinc, and silver residues; Process for the extraction of —— (e.g., from pyrites cinder after chloridising roasting). W. Braumüller. G.P. 310,163, 8.5.18. Addn. to 307,648 (J., 1919, 910 a).

The hot residues are agitated with the liquor in vessels provided with a false bottom for filtration, separate filters not being used.—C. I.

Metals; Process for uniting different —— by alloying at the surface of contact. H. C. Grosspeter and W. Schuen. G.P. 336,219, 29.1.15.

The foundation metal is treated with a molten alkali- or alkaline-earth metal forming a skin of alloy, and the molten coating metal is then applied. An alkali-metal must be selected which forms tough, non-brittle alloys with the metals to be united.
—C. I.

Solder for aluminium castings; Preparation of a ——. E. Ohmenhäuser. G.P. 340,294, 28.12.19.

The solder consists of 6·5% Cu, 2% Fe, 1·5% Si, 85% Al, 0·5% Pb, and 4·5% Zn. The copper, iron, silicon, and part of the aluminium are heated to whiteness, the remainder of the aluminium is then added and finally the lead and zinc. This solder does not expand during use, and therefore the joints produced by it do not crack on cooling.
—A. R. P.

Burnt pyrites and the like; Process of chloridising roasting of —— and furnace therefor. J. Simon. E.P. 149,247, 12.7.20. Conv., 2.8.17.

See G.P. 317,601 of 1917; J., 1920, 373 a.

XI.—ELECTRO-CHEMISTRY.

Electrolytic processes; Graphic control of ——. B. G. Worth. Trans. Amer. Electrochem. Soc., 1921, 281—285. [Advance copy.]

The control of ion concentration in the electrolytic solution is of primary importance, and a graphic method of such control is illustrated in the case of the electrolytic production of potassium chlorate. —J. S. G. T.

Sodium perborate. Alsgaard. *See* VII.

Electric heat in enamelling. Barringer. *See* VIII.

Patents.

Galvanic batteries; Absorbents for use in [the plates of] ——. J. A. van der Nolle. E.P. 149,330, 19.7.20. Conv., 19.7.19.

Absorbent material suitable for mixing with the chemical constituents of the plates of secondary batteries is prepared by stirring finely-ground and sifted wood, straw, or turf, in an insulating vessel containing dilute sulphuric acid or alkaline lye. An electric current passes between electrodes disposed one at the bottom and the other near the top of the insulating vessel. In this manner, the wood or other material is rendered wholly free from acids, resins, albumin, and soluble matter. —J. S. G. T.

Electrolyte for storage batteries. W. Gardiner, Assr. to D.-G. Storage Battery Co. U.S.P. 1,389,750, 6.9.21. Appl., 22.8.18.

An electrolyte for storage batteries consists of an acid solution mixed with powdered glass.—B. V. S.

Separator for storage batteries and method of making. D. F. Gould, Assr. to General Lead Batteries Co. U.S.P. 1,390,355, 13.9.21. Appl., 24.8.16.

Wood practically free from substances injurious to the positive plate of a battery is shaped into the form of a separator, which is treated by immersion in a sulphite solution, at such a temperature and for such a time that it acquires the desired porosity owing to the removal of the greater part of the gums, resins, etc., but not an integral part of the true wood fibre.—J. S. G. T.

Carbon electrodes; Burning of —— *in electric furnaces.* S. E. Sieurin. E.P. 169,060, 19.7.20.

In the manufacture of carbon electrodes by calcining carbonaceous material and a binding material such as tar in an electric furnace, metallic cores are arranged in the furnace outside the electrodes to be burnt and embedded in the material surrounding the electrodes. Alternatively, metal jackets surrounding the carbon electrodes may be employed in place of the cores. The cores or jackets are employed for conveying current during the initial period of the burning, and may, if desired, be removed when the carbon electrodes become conducting.—J. S. G. T.

Electrical apparatus for electrochemical treatment of hydrocarbon vapours. L. B. Cherry. E.P. 169,063, 20.7.20.

See U.S.P. 1,345,431 of 1920; J., 1920, 716 A.

[Electric insulating] composition; Moulding ——. J. P. A. McCoy, Assr. to Westinghouse Electric and Mfg. Co. Reissue 15,199, 20.9.21, of U.S.P. 1,300,218, 8.4.19. Appl., 13.11.20.

See J., 1919, 472 A.

Electrolysing a solution of nickel salt; Method of ——. C. Heberlein. U.S.P. 1,389,829, 6.9.21. Appl., 7.12.18.

See E.P. 141,766 of 1918; J., 1920, 456 A.

Electric precipitating installations; Arrangement of the high tension insulators of ——. Siemens-Schuckertwerke Ges. E.P. 159,130, 11.2.21. Conv., 11.2.20.

Electrical precipitation. U.S.P. 1,391,436 and G.P. 339,625. *See* I.

Aluminium compounds. U.S.P. 1,382,808. *See* VII.

XII.—FATS; OILS; WAXES.

Olive oil; The Villavecchia reaction for [detection of sesamé oil in] ——. J. Prax. Ann. Falsif., 1921, 14, 270.

Certain olive oils, particularly Tunisian oils, yield a red coloration with Villavecchia's reagent similar to that given by mixtures of olive oil and sesamé oil; if these abnormal olive oils are shaken with their own volume of 90% alcohol containing 10% of ammonia, and then heated for 5 mins. on a water-bath to expel the alcohol and ammonia, the red coloration is not obtained when the Villavecchia test is applied.—W. P. S.

Oil from the seeds of Jatropha curcas [curcas oil]. C. Grimme. Seifenfabr., 1921, 41, 513—515. Chem. Zentr., 1921, 92, III., 1035.

The seeds consist of 38% of hard shell and 62% of kernel. The separated kernels contained 48·13% of protein, but cannot be used as a feeding stuff owing to the presence of the highly poisonous curcin. Cold pressing gave 16·5% of light yellow oil and hot pressing a further 18% of a darker product. Extraction with hot ether yielded a further 13·5% of light brown oil. The total yield of oil was thus 48%. The first runnings had no unpleasant flavour, but the later ones had a harsh taste. The cold-pressed oil had the following characters:—Sp. gr. at 15° C., 0·9213; m.p., −5° to −6° C.; n_D^{40} = 1·4618; acid value 3·18; saponif. value 189·2; iodine value (Wijs) 98·8; Reichert-Meissl value 0·72; acetyl value 8·85; Hehner value 95·73; glycerol 10·34%; unsaponifiable matter 0·73%. The oils obtained by hot-pressing and ether extraction yielded values very close to the above; the sp. gr., acid value, R.-M. value, Hehner value, and unsaponifiable matter were slightly higher and the other values slightly lower than for the cold-pressed oil. The separated fatty acids from the oils after the three stages of extraction had m.p. 17°—18°, 16·5°—17°, 15°—16° C.; titer 15°—16°, 14°—15°, 13·5°—15° C.; n_D^{40} = 1·4625, 1·4619, 1·4614; neutralisation value 194·2, 193·8, 191·6; iodine value (Wijs) 99·3, 99·0, 98·1; mean mol. wt. 289·2, 289·8, 293·1. The oil therefore belongs to the non-drying oils. It consists of glycerides of palmitic, myristic, and curcinoleic acid. The latter is a hydroxy-acid analogous to ricinoleic acid. Curcas seeds contain a fat-splitting enzyme which is partially destroyed by hot extraction. This enzyme is not so energetic as castor seed lipase. Its strongest action is exerted on oils containing hydroxy-acids.—H. C. R.

Liver-oil from the sea-wolf (Anarrhichas lupus, L.). T. Lexow. Chem. Umschau, 1921, 28, 213—214.

The yield obtained was 29·6% of the weight of the liver from the male and 34·5% from the female fish. Clear golden brown oils were obtained, giving the following values:—Sp. gr. at 15°/15° C., 0·9162, 0·9179; $[n]_D^{25}=1{\cdot}4733$, 1·4702; acid value, 13·11, 14·37; free fatty acids, 6·60%, 7·23%; saponif. value, 182·8, 185·2; iodine value (Wijs), 131·2, 118·1; unsaponifiable matter, 5·23%, 3·86%; fatty acids, 92·4%, 92·2%; m.p. of fatty acids, 24·5° C., 24·7° C.; mean mol. wt. of fatty acids, 276·8, 279·9; glycerol, 4·45, 7·11%. The oil is characterised by its low iodine value and high percentage of unsaponifiable matter, which enable it to be readily detected in admixture with coal-fish liver oil.—H. C. R.

Iodine value [of oils]; Use of Aschman's method for the determination of the ——. B. M. Margosches and R. Baru. Chem.-Zeit., 1921, 45, 898.

Aschman's method (Chem.-Zeit., 1898, 22, 59) depends on the use of an aqueous iodine monochloride solution (prepared by the action of chlorine on potassium iodide solution), a definite quantity of this reagent being added to the fat dissolved previously in carbon tetrachloride. The period of contact required is 24 hrs. The results obtained by the method agree fairly closely with those found by the Wijs and Hübl methods and the reagent keeps well.—W. P. S.

Fatty-acid distillation plants; Operation of ——. O. H. Wurster. Chem. and Met. Eng., 1921, 25, 651—656.

Details are given of the construction, testing, starting up, and running of a plant for the distillation of fatty acids. The yield of double distilled stock from acidulated cottonseed foots is 85% and of pitch about 12%. Garbage grease fatty acids yield about 90% of double distilled stock and 6% of tar. The less neutral oil left in the fatty acids, the higher the yield of distilled fatty acids. With he most recent plant of the best design the cost of producing double-distilled fatty acids from crude atty acids was 65 c. per 100 lb. in the early part f the present year.—H. C. R.

oap curd; Hydration of fibres of ——. Part I. Degree of hydration determined in experiments on sorption and salting out. J. W. McBain and H. E. Martin. Chem. Soc. Trans., 1921, 119, 1369—1374.

he fibres of soap curd are hydrated, the degree of ydration depending on the concentration of the lution from which they are salted out. Sodium lmitate, salted out with sodium chloride, of ncentrations from one-third to complete saturaon, contains sodium approximately equal to that quired to neutralise the fatty acids present. ence acid soaps are probably due to incomplete ponification. When salted out with nearly turated sodium chloride containing a small antity of sodium sulphate the increase in concenation of the sodium sulphate corresponds with hydration of the neutral curd fibre $\mathrm{NaP,2{\cdot}1H_2O}$. dium chloride is appreciably sorbed by the curd res—viz., up to 8·9 g. NaCl to 1 mol. sodium lmitate in saturated sodium chloride solution. us the empirical composition corresponds to $\mathrm{P,2{\cdot}1H_2O,0{\cdot}16NaCl}$; *i.e.*, the fibres contain 7% of anhydrous fatty acid and 3% of sodium oride. From more dilute lyes more water and s salt are sorbed. Sodium sulphate and to a slight ent sodium hydroxide are also sorbed except in presence of a large excess of a second salt.
—P. V. M.

Soap curd; Hydration of fibres of ——. Part II. Dew-point method. J. W. McBain and C. S. Salmon. Chem. Soc. Trans., 1921, 119, 1374—1383.

The positive sorption of sodium chloride by curd fibres is confirmed. The composition of soap curds investigated by the dew-point method agrees closely with that calculated from methods of sorption and indirect analysis. Dehydration of the curds was effected by drawing off water through calcium chloride tubes by a powerful filter pump, and estimating the loss of water by weighing. The composition of the solid curd fibres is independent of the way in which the curd is prepared. The degree of hydration depends mainly on the concentration of the solution, being least for most concentrated brines, and hence, if the curd is not much contaminated with salt, is probably a function of the aqueous vapour pressure. There is a definite small increase in hydration with lowering of temperature. The hydration of sodium palmitate is distinctly greater than that of either the laurate or stearate.

Viscometer. E.P. 169,204. *See* XXIII.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

White pigments; Analysis of ——. M. Lombard. Ann. Falsif., 1921, 14, 261—268.

Of eight samples of white pigment, sold as zinc white or zinc oxide, only two consisted of zinc oxide; the others contained barium sulphate (4·8—71·6%), calcium sulphate (5·46—20·99%), calcium carbonate (2·15—13·61%), lead carbonate (0·56—45·22), lead sulphate (1·1%), and zinc sulphide (9·34—28·82%), the latter being present in all six adulterated samples. The method used for the analysis consisted, briefly, in treating a portion of the sample with ammonium carbonate solution and an excess of ammonia; this dissolved the zinc oxide and left all the other constituents insoluble; another portion was treated with acetic acid and alcohol to obtain the zinc sulphide, calcium carbonate, and lead carbonate in solution. A third portion was treated successively with nitric acid and ammonium carbonate in order to convert all the metals into compounds readily soluble in dilute acid and to leave the barium sulphate as an insoluble residue.—W. P. S.

Inks for rubber stamps. India-Rubber J., 1921, 62, 578.

Experiments made in the Government Laboratory showed that of the materials commonly used as mediums or as thinners in rubber stamp inks, glycerin exerted no deleterious or injurious effect on the stamp. Whilst castor oil exerted practically no action on the rubber stamp, the thinners necessary to reduce it to working consistency, *i.e.*, turpentine or its substitutes, caused disintegration of the rubber. Rosin oil, rosin spirit, and paraffin oil caused the rubber to swell, the former, however, producing a lesser softening effect than the other two.—A. de W.

Drying oils; Mechanism of oxidation of —— elucidated by a study of the true oxygen absorption. Part II. Linolenic and linolic acids. S. Coffey. Chem. Soc. Trans., 1921, 119, 1408—1415.

Linolenic and linolic acids oxidise differently, and in this it is suggested lies the explanation of the mechanism of the "drying" of linseed oil. Mixed α- and β-linolenic acids, obtained from hexabromostearic acid by treatment with zinc, showed an oxygen absorption (*cf.* J., 1921, 630 A) of 41·5%, and evolved 6·8% of carbon dioxide. β-Linolenic acid obtained from the mixture by bromination, removal of the α-acid as hexabromostearic acid, and debromination of the residual β-acid bromide, absorbed 38·5% of oxygen and gave 4·6% of carbon dioxide. By difference, α-linolenic acid absorbed 51·4% of oxygen, corresponding to nine atoms of oxygen per molecule, giving as the main volatile products carbon dioxide and acetic acid in the ratio of 1:1. The percentage of oxygen absorbed by linolic acid, allowing for the 10% content of linolenic acid, is 24·4%, corresponding to four atoms of oxygen per molecule, giving probably linolic acid diperoxide. No volatile products are produced. From these data and from the known iodine values the composition of linseed oil is calculated as:—Saturated acids and unsaponifiable matter, 8·1%; glyceryl radicle, 4·3%; oleic acid, 5·0%; linolic acid, 48·5%; linolenic acid, 34·1%. The close agreement of these figures with those of Friend ("Chemistry of Linseed Oil," 1917, p. 56), lends support to the above view of the mechanism of the oxidation. Further confirmation is got from the identity of the curve of the oxygen absorption of linolic acid calculated on the unimolecular reaction law with that obtained for linolenic acid from the result of experiments on the linolenic acids. It is probable that the oxidation of linolic acid may be represented by a simple logarithmic expression, and that of linolenic acid by a more complex curve indicating two consecutive reactions.—P. V. M.

Boiled oils containing rosinate driers; Turbidities in ——. H. Wolff and C. Dorn. Farben-Zeit., 1921, 27, 26—29.

The turbidity in rosinate-boiled oils consists essentially of the lead soaps of saturated acids derived from the free fatty acids or glycerides of the oil, neither manganese nor resin acids contributing to the precipitation. Commercial lead-boiled "foots," owing to the practice of boiling without special precautions against oxidation of the oil, consist mainly of lead soaps of oxyacids and small quantities of extraneous bases from the material of the boiling kettle etc., together with silica, alumina, phosphoric acid, and nitrogen from co-precipitated albuminoid "foots." The presence of the latter would explain the occasional non-precipitation of "foots" with certain samples of boiled oil, the authors attributing a protective effect to the albuminoid present. Inhibition of precipitation may be effected by the use of acid (fused) rosinates, but the addition of small quantities of even powerful solvents such as tetralin has no such action. Complete precipitation of albuminoid "foots" from the oil only takes place when the oil is not agitated during the heat coagulation. This effect is not due to oxidation caused by agitation of the oil, for the same result is obtained in an atmosphere of carbon dioxide. Non-precipitation of lead "foots" is attributed to the protecting effect of the colloidally-dispersed albuminoid, agitation of the oil during heating having the effect of inhibiting the decrease in degree of dispersion necessary for the coagulation of the latter.
—A. de W.

Colophenic acid: W. Fahrion. Ber., 1921, 54, 1944.

In his recent publication (J., 1921, 439 A), Aschan appears to have overlooked the author's work on the autoxidation of colophony (J., 1907, 264); Aschan's colophenic acid is apparently identical with oxyabietic acid.—H. W.

Iron oxide sludge. Lecher. *See* VII.

Patents.

Plastic compositions; Production of ——. Usher-Walker, Ltd., and C. E. Soane. E.P. 169,003, 14.6.20.

Gelatin in plastic compositions is rendered infusible by heating with a pentose, *e.g.*, arabinose or xylose, with or without the addition of a reagent to assist the dehydration of the pentose, *e.g.*, hydrochloric acid, whereby furfural is produced *in situ*. A plastic composition adaptable for making printers' rollers, etc., is obtained, for example, by mixing 5·7% of wood pulp, 37·7% of glycerin, and 56·6% of glue that has absorbed half its weight of cold water and has then been melted, heating for an hour or more in a steam- or water-jacketed pan until the desired consistency is obtained and then adding 2·5% of arabinose syrup (75—80%). The composition is then run into moulds and heated until the desired degree of induration has been attained.
—A. de W.

Paint [for concrete] or composition impervious to oils, spirits, and other liquids. C. H. Ivinson and G. S. Roberts. E.P. 169,258, 21.6.20.

A mixture consisting of casein about 1000 pts., calcium hydroxide (or other alkali such as borax, sodium bicarbonate, etc.) about 300 pts., sodium fluoride about 100 pts., anhydrous ferric oxide or other oxide unaffected by lime about 160 pts., is used in the proportion of 1 pt. of the mixture to 2 pts. of water to form a coating composition for, *e.g.*, concrete tanks etc.; a subsequent application of a 40% solution of formaldehyde, 10% tannic acid, or other waterproofing agent renders the paint impervious to water.—A. de W.

Phenol aldehyde condensation products; Manufacture of ——. H. V. Potter, W. F. Fleet, and Damard Lacquer Co., Ltd. E.P. 169,347, 23.7.20.

A resinous substance which remains soluble and fusible on heating is produced by condensing phenol or its homologues with acetaldehyde or its polymers. Formaldehyde or its polymers may be added, if desired, at any stage of the process in order to reduce the solubility and fusibility of the resulting product.—A. de W.

Blanc fixe; Process of manufacture of ——. G. Moore. U.S.P. 1,388,285, 23.8.21. Appl., 13.8.19.

Finely-divided crude barytes is mixed with sodium chloride and alkali nitrates, subjected to fusion, and the fused mass then chilled by discharging it into cold water.—A. de W.

Titanium pigment and method of its production. V. M. Goldschmidt, Assr. to Titan Co. A./S. U.S.P. 1,389,191, 30.8.21. Appl., 27.9.18.

Titaniferous material is heated with a reducing agent until the titanium present is converted into the trivalent form.—A. de W.

[*Paracoumorone*] *resin; Process of producing artificial* ——. A. L. Tannehill. U.S.P. 1,389,791, 6.9.21. Appl., 27.3.19.

In the production of resin by the polymerisation of solvent naphtha from coal-gas or coal-tar, the polymerisation is arrested while the resin is in a highly fluid state.—A. de W.

Carbon-black or other solid reaction products; Manufacture of ——. W. D. Bancroft. U.S.P. 1,390,480, 13.9.21. Appl., 3.1.20.

A temperature-gradient is maintained in proximity to a reaction zone sufficient to effect a transfer of a material proportion of a finely-divided reaction product from the former to a cooler zone, the said solid product being then collected.—A. de W.

Paint; Cold-water —— *and process of making same.* W. E. Carson. U.S.P. 1,390,496, 13.9.21. Appl., 9.10.19.

A dry fine powder adapted for coating purposes consists of combined sugar and lime in the form of horny, elastic particles, soluble in water.
—J. S. G. T.

Linoleum, lincrusta, or artificial leather; Manufacture of ——. G. Ruth and E. Asser. G.P. 339,742, 21.6.19.

Aluminium or chromium naphthenates that have been previously heated to 160°—200° C. are mixed with an equal proportion of a metallic naphthenate that has been treated with lime, magnesia, or zinc oxide and heated for some time to 200° C. The mass has the properties of a linoleum cement, and the addition of resin, copal, or driers is unnecessary.

XV.—LEATHER; BONE; HORN; GLUE.

Tannins and allied substances. VIII. The tannin of the wood of the edible chestnut. K. Freudenberg and H. Walpuski. Ber., 1921, 54, 1695—1700.

The isolation of the crude tannin from the wood is described in detail, the total yield being more than 5% of the weight of the wood. Hydrolysis with dilute sulphuric acid gives a little quercetin, traces of gallic acid, 2% of sugar (chiefly dextrose), and 15—20% of ellagic acid all of which are present initially in the combined form; simultaneously, however, the tannin is itself extensively decomposed. It appears stable towards emulsin but is slowly hydrolysed by relatively large amounts of *aspergillus* tannase, finally giving a product from which less than 3% of ellagic acid is liberated by treatment with dilute sulphuric acid; simultaneously the quercetin component is hydrolysed whilst traces of gallic acid and small amounts of sugar, chiefly dextrose, are obtained. The purified tannin is a yellowish-red, strongly acidic substance which comprises more than half of the original crude product. It shows the usual reactions of tannins. It is not affected further by tannase and is not decomposed into simpler constituents by other hydrolysing agents. It does not appear to be an ester tannin or a catechin and is most closely allied to the product derived from the native oak (Freudenberg, Naturwiss., 1920, 8, 905).
—H. W.

Hide powder; Report of Tannin Analysis Committee on washing of ——. J. Soc. Leather Trades' Chem., 1921, 5, 274—275.

The use of tap water in washing hide powder for tannin analysis leads to serious irregularities, and only distilled water should be used.—D. W.

Hide powder; Swelling of ——. E. C. Porter. J. Soc. Leather Trades' Chem., 1921, 5, 259—267.

An account of the swelling of hide powder in buffer solutions ranging in p_{H} from 1 to 12·5. A maximum swelling appears at $p_{\mathrm{H}}=2\cdot4$, a minimum at $p_{\mathrm{H}}=4\cdot8$, and a second maximum probably at $p_{\mathrm{H}}=12\cdot5$. Neutral salts were kept, as far as possible, at constant concentration in the solutions.—D. W.

Hide; Post-mortem changes in ——. G. D. McLaughlin. J. Amer. Leather Chem. Assoc., 1921, 16, 435—438.

A rapid change occurs in a hide following the animal's death. This change is manifested by about 20% reduction in the ability of the corium to swell in lime water after standing for 4½ hrs. and by the production of acid.—D. W.

Elastin; Removal of —— *during bating.* R. H. Marriott. J. Soc. Leather Trades' Chem., 1921, 5, 280—283.

Wilson's statements on the effect of bating (J., 1921, 92 A) are contested. A piece of goat skin unhaired with acetic acid and tanned without bating was softer than a bated skin and yet it contained undigested elastin fibres as shown by Weigert's resorcinol fuchsin stain under the microscope. Pieces of goat skin and calf skin were taken from similar positions in the pelt, washed and unhaired rapidly. After deliming sections were cut and the residue was treated with trypsin. Portions were removed at intervals and microscopical investigation showed that the elastin was removed. The solution of the cementing substance is suggested as one of the essential features of true bating.—D. W.

Sumach; Microscopical analysis of ——. W. R. Atkin and R. H. Marriott. J. Soc. Leather Trades' Chem., 1921, 5, 275—276.

A small quantity of sumach was boiled with 5% sulphuric acid for ½ min., allowed to settle, the clear liquor poured off, then boiled for ½ min. with 5% sodium hydroxide, decanted, boiled for ½ min. with nitric acid of sp. gr. 1·2, decanted, a further quantity of nitric acid added, boiled and a small crystal of potassium chlorate added. The liquor was decanted and the sumach washed in clean water and examined under the microscope by means of polarised light. Photomicrographs are given showing the characteristic appearances of *Rhus coriaria*, *Tamarix Africana*, *Pistacia lentiscus*, and *Colpoon compressa*.—D. W.

Leather; Sampling of —— *and its preparation for analysis. Report of 1921 Committee of the American Leather Chemists Association.* J. Amer. Leather Chem. Assoc., 1921, 16, 394—430.

Sides of heavy, rough belting, Union sole, and curried belting leather were cut up into 40—50

pieces, their position marked on a diagram and complete analyses made of them. The results confirm the view that leather varies in composition, that some parts of the hide have a looser texture than others and that they will carry more weight. Variations in quality, composition, and analysis are inevitable in leather. Samples, $2\frac{1}{2}'' \times 8''$, as few and as small as possible, should be chosen from those parts of the hide which are divergent in composition, viz., belly, shoulder, butt, and side; $\frac{1}{2}''$ is removed from the uncut edge of the sample to avoid irregularities resulting from edge penetration of materials.
—D. W.

Tannins. Clarens. *See* XVIII.

Patents.

Tanning extracts or agents; Manufacture of readily soluble ——. Badische Anilin- und Soda-Fabrik; E.P. 144,657, 8.6.20. Conv., 29.1.14.

Vegetable tanning materials are extracted with hot aqueous solutions of 1° B. (sp. gr. 1·007) of the products described in E.P. 8511 and 24,982 of 1912, 7138, 18,258 and 18,259 of 1913 (*cf.* J., 1913, 246, 919; 1914, 366, 841, 877).—D. W.

Tanning extracts or agents; Manufacture of readily soluble ——. F. Hassler. E.P. 144,677, 9.6.20. Conv., 19.12.13.

Sulphonic acids of high-boiling coal tar hydrocarbons, or the condensation products obtained by heating such sulphonic acids, are added to natural tanning extracts or to the liquid used for extracting tanning materials.—D. W.

Tanning. J. K. Tullis, Assr. to Fulcra Tan Co. U.S.P. 1,390,735, 13.9.21. Appl., 24.9.18.

Hide is treated with a solution of sodium bichromate containing aluminium and magnesium sulphates and then the bichromate is reduced by treating the hide with a sulphite waste liquor.—D. W.

Tannic acids and extracts; Production of ——. F. Langford. U.S.P. 1,390,796, 13.9.21. Appl., 2.10.17.

The wood of *Sesquoia sempervirens* or other tannin-bearing wood is comminuted, mixed with pulverised aluminous earths and water, sulphur gases are injected into the mass, then air, and the product heated under pressure and leached.—D. W.

Plastic material; Manufacture of solid —— *from casein.* F. G. Maries. E.P. 169,405, 7.12.20.

Eight pts. of casein or milk curd is soaked for 12 hrs. in a solution of 1 pt. of glycerin in 32 pts. of water, the resulting mass heated to a temperature not exceeding 175° F. (79° C.), subjected to pressure without heat, and finally soaked for 1—4 days in a solution of 30 pts. of 40% formaldehyde, 10 pts. of glycerin, 3 pts. of calcium chloride, 1 pt. of acetone, and 45 pts. of water. The product is dried naturally.—D. W.

Tanning materials and method of producing same. A. Koetzle. E.P. 141,714, 13.4.20. Conv., 12.4.19.

See U.S.P. 1,344,950 of 1920; J., 1920, 606 a.

Tanning materials and method of producing same. A. Koetzle. E.P. 144,617, 20.4.20. Conv., 6.6.19.

See U.S.P. 1,344,951 of 1920; J., 1920, 606 a.

Tanning agent; Readily-soluble ——. F. Hassler, Assr. to A. Kuttroff. U.S.P. 1,390,205, 6.9.21. Appl., 9.7.20.

See G.P. 306,341 of 1913; J., 1921, 359 a.

Tanning [; Means for manipulation] of hides and skins [in ——]. J. I. Bamber and C. M. Owen. E.P. 168,937, 1.5.20.

Artificial leather. G.P. 339,742. *See* XIII.

XVI.—SOILS ; FERTILISERS.

Patents.

Fertiliser; Process for transforming ammonia into a salt for use as ——. J. Y. Johnson. From Badische Anilin- und Soda-Fabrik. E.P. 145,038, 14.7.20.

The mother liquor from the preparation of sodium carbonate by the ammonia-soda process is concentrated at 60°—80° C., and further at 100° C. until ammonium chloride begins to be deposited with the sodium chloride. The hot clear liquor is then transferred to a vacuum vessel, in which it is agitated by a small air-current. Ammonium chloride is precipitated from solution during the subsequent rapid cooling. (*Cf.* E.P. 144,659; J., 1921, 522 a.)—A. G. P.

Manures; Manufacture of —— *by breaking up phosphates with nitric acid.* Chem. Fabr. Rhenania, and G. A. Voerkelius. E.P. 148,242, 9.7.20. Conv., 31.5.18.

Rock phosphate is mixed with finely-ground potassium sulphate and treated with nitric acid; it is then dried, if necessary, at 90° C., and ground. The product consists of monocalcium tetrahydrogen phosphate, potassium nitrate, and gypsum. It is non-deliquescent, and no reversion of phosphate occurs during storage. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 5686 of 1886; J., 1886, 433.)—A. G. P.

Fertilisers; Production of ——. J. C. Kernot, and British Glues and Chemicals, Ltd. E.P. 169,323, 12.7.20.

Bones are treated at ordinary temperatures with hydrochloric or nitric acid. The liquor is siphoned off, neutralised with ammonia, and without filtration is evaporated to dryness. The product contains ammonium salts, complex nitrogenous substances, tricalcium phosphate, and soluble phosphates.
—A. G. P.

Fertiliser; Process for preparing a mixed urea-superphosphate ——. A.-G. für Stickstoffdünger. G.P. 303,852, 4.8.16.

Urea and superphosphate are heated together to obtain a product which is not hygroscopic.
—A. G. P.

Fertiliser; Process for preparing a mixed urea-superphosphate ——. A.-G. für Stickstoffdünger. G.P. 303,856, 5.11.16.

Urea and superphosphate are heated together in presence of water, which is afterwards evaporated. The product is easy to distribute, and has an increased water-soluble phosphate content.
—A. G. P.

Fertiliser; Process for preparing a mixed urea-superphosphate ——. A.-G. für Stickstoffdünger. G.P. 303,853, 16.8.16.

An incompletely decomposed superphosphate is used; the undecomposed portion fixes any free acid and prevents hygroscopicity of the mixture.
—A. G. P.

Fertilisers; Process for rendering slightly soluble forms of —— *soluble.* A.-G. für Stickstoffdünger. G.P. 303,854, 1.10.16.

Insoluble fertilisers, *e.g.*, basic slag or phonolite respectively, are mixed with mineral acid salts of urea to render the phosphates and the potassium soluble.—A. G. P.

Fertilisers; Process for preparing —— containing urea and phosphoric acid. A.-G. für Stickstoffdünger. G.P. 303,855, 5.11.16.

Cyanamide, superphosphate, and sulphuric acid are heated together with or without pressure. The acid prevents any reversion of phosphate due to the action of urea from the cyanamide.—A. G. P.

Fertilisers; Process for preparing ——. A.-G. für Stickstoffdünger. G.P. 308,441, 21.3.17.

Urea nitrate is mixed with basic substances in quantity more than equivalent to the nitric acid present. The caustic and hygroscopic nature of the urea nitrate is thus destroyed.—A. G. P.

Ammonium bicarbonate or mixtures containing it; Method of avoiding nitrogen losses from ——. Badische Anilin- u. Soda-Fabr. G.P. 336,100, 19.3.18.

The salts are kept in an atmosphere rich in carbon dioxide, or substances are added which liberate a small quantity of carbon dioxide from the bicarbonate. The process is applicable to mixtures of ammonium bicarbonate and superphosphate containing an excess of the former.—C. I.

Combating plant diseases. G.P. 339,587–8. *See* XIXb.

XVII.—SUGARS; STARCHES; GUMS.

Calcium sulphate; Solubility of —— in carbonated beet juices of varying alkalinity. V. Stanek. Z. Zuckerind. Czechoslov., 1921, **46**, 1—3.

As a result of the carbonatation of beet juice more calcium sulphate is separated and passes into the scums than one would expect to find from the values for its solubility in sugar solutions. This is not the result of the diminution of the alkalinity during the process of carbonating the limed juice, since determinations show that at 85° C. the solubility of calcium sulphate in first and second carbonatation juices increases as the alkalinity decreases, being, for example, 0·19 g. in 100 c.c. at an alkalinity of 0·997 g. CaO per 100 c.c., but 0·26 g. when the alkalinity has been lowered to 0·003 g. The separation of the calcium sulphate would appear to be due either to its entrainment by the precipitated calcium carbonate or to the formation of double compounds of calcium sulphate and calcium carbonate or basic carbonate.—J. P. O.

Sucrose; Temperature of inversion in the double polarisation method of determining ——. E. Freibauer. Z. Zuckerind. Czechoslov., 1921, **40**, 312.

In applying the Herzfeld modification of the double polarisation method to low-grade products, as beet molasses, it is unnecessary when inverting with hydrochloric acid to adhere closely to the limit of emperature prescribed for pure solutions, namely, 7°—70° C. A convenient modification, giving the ame result as inversion at 69° C., consists in placing the flask containing the solution to be inverted in a water-bath which has been heated to 0° C., and allowing it to remain for 10 min.
—J. P. O.

Dextrose; Influence of hydrochloric acid on the optical rotation of ——. Part 2. Change of rotatory power and reducing capacity of dextrose solutions in hydrochloric acid at 100° C. H. Murschhauser. Biochem. Zeits., 1921, **116**, 171—190.

The optical activity and reducing capacity of 20, 0, 5, and 2½% dextrose solutions in 5·1, 8·1, and ·1% hydrochloric acid solutions were determined ver a period of 12 hrs. at 100° C. In general both properties in the first 2 hrs. show considerable and irregular variation, but afterwards the fall of rotation and reducing power is a linear function of the time, and the greater the concentration of the acid the greater the effect produced. For 10 and 20% dextrose solutions a maximum of optical rotation is attained in the first 2 hrs., due probably to formation of isomaltose.—H. K.

Reducing sugars in sugar products which have been treated with basic lead acetate; Determination of ——. J. B. Harris. J. Ind. Eng. Chem., 1921, **13**, 925—926.

Juice which has been treated with basic lead acetate for its clarification or preservation is found to contain less reducing sugars than originally, the excess of lead remaining having been eliminated by the addition of sodium oxalate, carbonate, or chloride previous to the determination by means of Fehling's solution. If, however, the removal of lead be effected by the addition of oxalic acid to the liquid containing the lead precipitate (not to the filtered solution), then the insoluble compound formed between a portion of the reducing sugars and the lead is decomposed, and trustworthy results are obtained. Phosphoric acid gave less satisfactory results.—J. P. O.

Lactose; Determination of —— in presence of other reducing sugars. L. Le Grand. Ann. Falsif., 1921, **14**, 268—269.

In the determination of lactose by means of Barfoed's reagent (*cf.* J., 1921, 272 a, 555 a) the quantity of alkali or alkaline-earth salts in the sugar solution should not exceed 0·1%; larger amounts of these salts cause the precipitation of basic salts, which interfere with the determination.
—W. P. S.

Colour of sugar products treated with decolorising carbon; System of measuring the ——. V. Sazavsky. Z. Zuckerind. Czechoslov., 1921, **40**, 299—301.

For the provision of a colour standard the author proposes the use of an aqueous solution of fuscasinic acid, a product isolated by Stanek from beet molasses (Z. Zuckerind. Böhm., 1916–17, **14**, 298—306), the alkali salt of which is said to contribute about half the colouring matter of low-grade beet products. It is proposed to term the new unit the "fusca," that is the degree of colour produced by the solution of 1 mg. of fuscasinic acid in 100 c.c. of water; and as 1 fusca is also equal to 1° Stammer, a means of comparison with Ehrlich's saccharane system (J., 1910, 506) is afforded.—J. P. O.

Cane juice; Effect of decolorising carbons on the colloids of ——. J. F. Brewster and W. G. Raines, jun. J. Ind. Eng. Chem., 1921, **13**, 921—923.

About 3000 lb. of raw cane juice was treated (*a*) by the sulphitation process, and (*b*) by Zerban's method of successively heating with kieselguhr and decolorising carbon, samples of the filtered liquids thus clarified being submitted to dialysis in a collodion bag in running water. In general the total amount of dialysable solids remaining after the latter treatment was appreciably less than that found after sulphitation, being in one experiment 18·8 g. per 100 c.c., compared with 51·1.—J. P. O.

Dry substance in molasses, syrups, and juices; Determination of the —— using the Spencer electric oven. G. P. Meade. J. Ind. Eng. Chem., 1921, **13**, 924—925.

Employing the Spencer electrically heated drying oven (J., 1921, 191 a), and using fine asbestos for absorption of the sugar product (diluted 1:1), the author finds that the dry substance content of honey, syrup, and molasses may be accurately deter mined after heating for 20 mins. at 110° C. in a strong current of air. Dilution is unnecessary in the case of juice, and 10 mins.' heating suffices. Even a solution containing invert sugar and sodium chloride was found to give a result in very close agreement with the actual solids after 20 mins.' heating, indicating that no destruction of lævulose had taken place under the conditions of the determination.—J. P. O.

Fine grain present in final molasses; Recovery of the ——. W. D. Helderman. Archief Suikerind. Nederl.-Indië, 1921, 29, 694—697.

With the object of recovering that portion of the sugar at present passing into the final molasses in the form of fine grain, the low-grade massecuite in a factory in Java was very gradually cooled at rest during two months in tanks coated with non-conducting material. A yield of 28—31% of low-grade sugar was obtained on centrifuging, but one of about 22% in the case of the same massecuite which had been cooled in unlagged tanks in the manner customary in the factory. Moreover, this slow cooling produced a crystal which was larger and also more regular in shape than ordinarily, while the resulting final molasses was quite free from fine grain.—J. P. O.

Apparent grain in final molasses; Determination of the —— by Kalshoven's method. N. Schoorl. Archief Suikerind. Nederl.-Indië, 1921, 29, 1055—1059.

Kalshoven's method (J., 1920, 126 A) is known to give results higher than the truth when much water is used for the solution of the fine grain; the cause of this is not the contraction occurring on the dilution of the liquor as suggested by Dedek (J., 1921, 523 A) but rather the effect of the non-sugars, especially the salts, upon the refractive index of sugar at different concentrations. Experiments are described showing that the greater the amount of dilution applied, and the higher the ash content of the molasses, the more fine grain will be found on the application of Kalshoven's formula. —J. P. O.

Polysaccharides; Chemistry of ——. Preparation of pure polysaccharides. Mode of action of diastatic enzymes and the dextrin stage of polysaccharides. E. Herzfeld and R. Klinger. Biochem. Zeits., 1920, 107, 268—295.

For the preparation of pure starch, fresh plant tissue (*e.g.*, potato or inula tubers) was digested with 33% sodium hydroxide solution on the water-bath, insoluble matter was separated by centrifuging, and the solution was precipitated with 90% alcohol. The precipitate was redissolved and reprecipitated three times in succession, then again redissolved, neutralised with hydrochloric acid, and precipitated again with alcohol. By subjecting yeast to a similar treatment and treating the insoluble matter from the first alkaline digestion with boiling alkali and subsequently with alcohol, a cellulose-like substance was obtained. Cellulose was prepared by digesting cotton-wool with strong sodium hydroxide solution and small quantities of carbon bisulphide, centrifuging, and precipitating the viscous liquid with 90% alcohol, and the product was purified by redissolving, neutralising with hydrochloric acid and reprecipitating with alcohol. Glycogen was prepared from minced liver by a method similar to that used for starch. Agar was purified by digesting with water in an autoclave, heating with caustic soda solution, centrifuging, and precipitating with alcohol. The preparation of pure inulin and gum arabic is also described. Starch prepared as described, if not completely freed from alcohol, is easily soluble in water, the granules becoming transparent; after a short time, however, no more starch dissolves and the solution becomes turbid owing to the separation of coarsely-dispersed particles. Purified starch free from alcohol will not dissolve in water; on heating with water a coarsely-disperse colloidal suspension is formed, but most of the particles can be separated by centrifuging or by cooling. The polysaccharides are classified in four groups according to their colloidal properties and reaction with iodine, viz., the cellulose group, the starch group, the dextrinoid group (agar and yeast-dextrin), and the dextrins (glycogen, inulin, and other dextrins). A blue iodine reaction indicates a coarsely disperse condition (cellulose and starch), and a red-brown a highly disperse state. The dextrins are regarded, not as degraded starches, but as starches in more highly disperse form. The surface of starch granules can be dextrinised by means of agents which prevent solution (*e.g.*, formaldehyde), the coarsely-disperse particles being converted into the finely-disperse state. It is considered that diastase, the active principles of which are probably decomposition products of lipoids or albuminoids, has no direct hydrolytic power, but that its action results in altering the degree of dispersion of starch, converting the insoluble particles into a form which is capable of being dispersed by water, and hence is very readily hydrolysed.—S. S. Z.

Polysaccharides; Chemistry of the ——. E. Herzfeld and R. Klinger. Biochem. Zeits., 1920, 112, 55—60.

The suggestion made in a previous communication (*cf. supra*) that sugar is not formed by the action of diastase on polysaccharides is not correct. After the treatment of starch by diastase the presence of 10—20% of alcohol-soluble sugar only could be established; the residue left after the alcoholic extraction did not give the iodine reaction. On digesting the unsaccharified residue of three different polysaccharides with fresh diastase, quantities of sugar were obtained which were of the same order as those obtained from the first digestion. The unhydrolysed residues were dissolved in water, treated with 33% potasium hydroxide, precipitated with alcohol, neutralised, and finally washed with alcohol. The substances from the digested polysaccharides thus obtained gave the characteristic colour reactions with iodine. This is explained by the fact that previous to saccharification diastase disperses the substrate. The subsequent treatment with alkali and alcohol changes the condition of the surface and brings about the reappearance of the iodine reaction.—S. S. Z.

Polysaccharides. VIII. Starch and the amyloses. P. Karrer, C. Nägeli, O. Hurwitz, and A Wälti. Helv. Chim. Acta, 1921, 4, 678—699.

A close analogy exists between starch and the amyloses, as evidenced by their behaviour towards acetyl bromide, iodine, alkali hydroxides, and enzymes, and on distillation in a vacuum, and they are all considered to be polymeric anhydromaltoses. Their heats of combustion suggest that α-octoamylose is the most highly polymerised form of α-amylose possible, and that starch cannot be more highly polymerised, being probably a member of a series of products isomeric with the α-amyloses, and possibly corresponding with α-tetra-amylose or β-hexa-amylose. This conclusion is in harmony with molecular weight determinations of methylostarches (J., 1921, 342 A) and of soluble starch. The heat of combustion of starch exceeds the calculated maximum value for a compound composed of a chain of glucose-residues, but agrees closely with the values for the anhydro-sugars lævoglucosan and α-tetra-amylose. Since the same applies to cellulose, this is also considered to be an anhydro-sugar. (*Cf.* J.C.S., Nov.)—J. K.

Polysaccharides. XI. Compounds of anhydro-sugars with alkali hydroxides. Method of determining the parent molecule of polymeric anhydro-sugars. P. Karrer. Helv. Chim. Acta, 1921, 4, 811—820.

Solutions of poly-amyloses in sodium hydroxide contain additive compounds, precipitable by alcohol and in each case accurately corresponding to the empirical formula $C_{12}H_{20}O_{10},NaOH$. Hence polymeric anhydro-sugars combine with one molecule of sodium hydroxide per molecule of anhydro-sugar contained in the polymer, and it is therefore possible to determine the molecular weight of the anhydro-sugar. Thus β-hexa-amylose is a polymeric anhydro-maltose (*cf.* p. 784 a), inulin is derived from an anhydro-difructose, and xylan from anhydro-dixylose, whilst soluble starch furnishes a compound $(C_{12}H_{20}O_{10},NaOH)_n$. Such polysaccharides are considered to be crystalline substances, the lattice points of which are occupied by polymeric molecules, which in the case of starch are the complexes $(C_{12}H_{20}O_{10})_2$ or $(C_{12}H_{20}O_{10})_3$. The difficulty of isolating intermediate products from cellulose is possibly due to approximate equality in strength of the forces holding the polymeric molecules in the crystal, those responsible for the existence of the polymeric molecules, and those operating in the separate anhydro-molecules. (*Cf.* J.C.S., Nov.)
—J. K.

Anhydro-sugars; New method for the preparation of ——. P. Karrer and A. P. Smirnoff. Helv. Chim. Acta, 1921, 4, 817—820.

Acetobromoglucose combines in alcoholic solution with trimethylamine to form tetra-acetylglucosido-trimethylammonium bromide, $C_{17}H_{28}O_9NBr$, from which lævoglucosan is quantitatively obtained when its aqueous solution is warmed for a short time with caustic alkali or an alkaline hydroxide. (*Cf.* J.C.S., Nov.)—J. K.

Mytilitol, a naturally occurring cyclose. D. Ackermann. Ber., 1921, 54, 1938—1943.

The isolation of mytilitol from *Mytulis edulis* was effected by precipitating impurities from the aqueous extract by successive additions of tannin, baryta, sulphuric acid, lead oxide, and phosphotungstic acid; the filtrate from the latter on standing deposited hard crystals which were freed from their impurities by treatment with baryta water and then with carbon dioxide and crystallised from water. It forms colourless, shining crystals, m.p. 259° C., is optically inactive and does not contain a methoxy-group. It is converted by acetic anhydride into a penta-acetate, microscopic needles, m.p. 157°—158° C. and by acetic anhydride and concentrated sulphuric acid into the hexa-acetate, m.p. 180°—181° C. The parent substance is therefore regarded as methylcyclohexanehexol. It has been examined previously by Jansen who considered it to be cyclohexanepentol, but the author considers his formula to be more consistent with its properties.—H. W.

Hydrolysis of cellulose. Kauko. *See* V.

Patent.

Molasses; Process of refining ——. H. C. Cutler. E.P. 169,113, 8.11.20.

Low-grade molasses, in particular beet molasses, is endered suitable for human consumption by inverting part of the sucrose, *e.g.*, with hydrochloric acid, removing inorganic salts by dialysis, boiling under atmospheric pressure to remove volatile acids etc., during which process water is added to mainain the water-content at about 80%, filtering from coagulated proteins, and evaporating to the required consistency *in vacuo*.— J. H. L.

XVIII.—FERMENTATION INDUSTRIES.

Yeast; A wild —— which causes turbidity in beer. H. Christoph. Z. ges. Brauw., 1921, 119—121, 127—130, 135—137, 147—149, 153—154.

The characters of a small-celled bottom-fermentation wild yeast which caused turbidity in 8% bottle beer are described. The cells were 8 by 5μ in size and remained suspended for long periods, the yeast being of the powdery or non-agglomerating type. The yeast sporulated readily, producing 2 or 4 spores per cell, and in many cases fusion of two spores was observed to precede germination.
—J. H. L.

Tyrothrix of Kayser, its characters and its use in the laboratory and in industry. Bettinger. Bull. Assoc. Chim. Sucr., 1921, 38, 463—471.

The organism described, which is very similar to the Tyrothrix of Duclaux, was isolated from an adventitious culture in vegetable broth. It develops readily in meat broth, yeast water, unsugared cereal worts, peptonised starch paste, and milk, at 35° C., forming a white film consisting of chains of short rods 1μ by 5μ. In soya-bean wort it forms a red film. A neutral or alkaline reaction is more favourable to growth than an acid reaction. Large quantities of liquefying and saccharifying diastase are secreted, especially in certain culture media, and much more copiously at 50° than at 35° C. The organism has very pronounced proteolytic activity, yielding peptones and even ammonia. In experiments with soya meal and spent distillery grains it rendered soluble the major part of the nitrogen present within 6—8 days. Culture liquids in which the organism has been grown may be used in the laboratory as powerful diastatic agents for the liquefaction of starch. The organism has been applied experimentally with success to the ripening of cheese. Very palatable Camembert cheese with a fine bouquet was prepared by means of *Penicillium album* and the Tyrothrix, the former conferring a characteristic odour and the latter rendering the casein soluble and producing leucine, tyrosine, and traces of ammonium valerate. The intensity and speed of these transformations can be controlled by means of the temperature, but at 40° C. the organism develops so rapidly as to cause excessive ripening.—J. H. L.

Beer extract; Nutritive importance of ——. H. Lüers. Z. ges. Brauw., 1921, 143—146, 152—153.

Pigeons fed for 35 days solely on polished rice mixed with about 30% of dried beer extract, developed no symptoms of "alimentary dystrophy" (polyneuritis) although they lost weight; whilst control pigeons fed on polished rice alone not only lost weight but became incapable of flying, walking, or holding themselves erect, within 20 days. The beer extract was obtained by desiccating a 11% dark Munich beer at temperatures below 50° C.
—J. H. L.

Tannins; Fractional estimation of ——. Application of the laws of chemical kinetics to quantitative analyses in general and tannins of wine in particular. J. Clarens. Bull. Soc. Chim., 1921, 29, 837—852.

The curves obtained by plotting the oxygen-absorption curve of tannins in wine against time indicate the presence of at least four different substances. Taking these results in conjunction with the results obtained for the oxidation by potassium permanganate, the author details a method for calculating the relative amounts of the different types of tannins present.—W. G.

Carobs; Manufacture of alcohol from ——. J. Mezzadroli. Bull. Assoc. Chim. Sucr., 1921, 38, 510—517.

Alcohol is produced from carobs in a distillery at Catania, Sicily, where 30,000—40,000 kg. of the raw material is worked daily. The carobs, large quantities of which are produced in the district, have the following average composition:—moisture 17%, reducing sugar 15%, sucrose 25%, protein 4·7%, tannin 1·52%, fat 0·6%, ash 2·4%, nitrogen-free organic matter 22%, and cellulose 4·55%. They are crushed without breaking the seeds, and then freed from the latter and extracted in a battery of open diffusers at 95°—105° C. The clear juice is fermented by pure cultures of special yeasts acclimatised to antiseptics. By employing two yeasts symbiotically, with fermentation optima of 30° and 37° C., respectively, it is possible to ferment highly concentrated worts which after 32—42 hrs. fermentation contain 10—12 or even 14% of alcohol. The temperature of the wort is allowed to rise gradually from 30° to 37° C. to enable each of the yeasts to exert its maximum effect in turn. The yield of alcohol is 22—24 l. per 100 kg. of carobs and after rectification it is as fine as that from molasses. The by-products are carob seeds (locust beans), which are ground and exported to England, and the residue from extraction, which contains only 0·3—0·4% of sugar and which is dried and used as fuel; when coal has become cheaper it may be possible to recover tannin from the vinasses.—J. H. L.

Hydrolysis of cellulose. Kauko. *See* V.

Baker's yeast. Henneberg. *See* XIXa.

Patents.

Vapour filter [*for de-alcoholisation*]. W. J. Ruff. U.S P. 1,387,870, 16.8.21. Appl., 21.6.16.

A de-alcoholising device comprises a chamber provided with a discharge outlet for condensed liquid at the bottom and inlet and outlet openings for vapour opposite each other in the sides. The inlet opening is connected with distillation apparatus supplying alcoholic vapour, which enters the chamber and is directed against a filter covering the vapour outlet The filter is adapted to permit the passage of alcoholic vapour and arrest the passage of other vapours.—J. H. L.

Aeration of liquids, especially the fermentation liquid in the manufacture of pressed yeast. L. Peter. G.P. 338,886, 7.11.17. Addn. to 336,246 (J , 1921, 598 a).

Air is introduced into the liquid from a flat air chamber provided with a porous top, *e.g.*, of unglazed earthenware, which is disposed above the floor of the fermentation vessel and connected with an air supply. The fine bubbles which escape from the chamber are maintained in the liquid as long as possible by means of a stirring mechanism as in the principal patent.—J. H. L.

Vinegar-making; Apparatus for ——. E. Klein. E.P. 144,694, 10.6.20. Conv., 12.1.16.

See U.S.P. 1,272,277 of 1918; J., 1918, 601 a.

Yeast; Production of ——. A. Wohl and S. Scherdel. E.P. 145,623, 29.6.20. Conv., 15.1.15.

See G.P. 310,580 of 1915; J., 1919, 434 a.

Fusel-oil; Process and apparatus for the continuous treatment of ——. E. A. Barbet. U.S.P. 1,389,852, 6.9.21. Appl., 10.6.18.

Enzymic substance and process of making same. J. Takamine and J. Takamine, jun. U.S.P. 1,391,219, 20.9.21. Appl., 23.1.18.

See E.P. 152,792 of 1919; J., 1921, 23 a.

XIXa.—FOODS.

Yeast cells; Internal condition of —— *and its recognition in the case of baker's yeast.* Henneberg. Z. ges. Getreidew., 1921, 13, 73—79. Chem. Zentr., 1921, 92, IV., 818.

The characteristics of a good baker's yeast, possessing satisfactory keeping properties and high working power, are summarised as follows:—It is neither wet nor crumbly, is moderately rich in protein and glycogen, poor in fat, and rich in volutin or soon becomes so in sugar solutions; it is relatively resistant to poisons, heat, and shock, shows no buds or young daughter cells, has a homogeneous protoplasm, rapidly develops in sugar solutions, contains few dead cells and is free from foreign organisms. Yeasts possessing a high or a low content of protein or glycogen are unsatisfactory; those rich in protein are sensitive to poisons, heat, and shock, they do not keep well, their working power declines after a short time, and they are often infected with acetic or lactic bacteria and wild mycoderma yeasts.
—J. H. L.

Potato juice; Coloration of ——. H. Haehn. Z. Spiritusind., 1921, 44, 253—254, 277—278, 286, 325, 330. (*Cf.* J., 1920, 77 a, 422 a; 1921, 524 a.)

The enzymic conversion of tyrosine into the dark-coloured product, melanin, appears to be of wide occurrence in animal and plant tissues. The tyrosinase of potatoes acts best in media neutral to litmus; its action is inhibited by addition of free acid or alkali, but not by addition of monopotassium phosphate even in quantity sufficient to render the liquid decidedly acid to litmus. The thermolabile component of the tyrosinase of potato juice can be freed from accompanying activating salts more completely by dialysis through a suitable septum than by ultra-filtration. After dialysis for several days the residue is almost inactive towards tyrosine, but its activity is restored on adding the salt mixture removed by dialysis. Much greater activation is produced by adding very small amounts of single salts of certain metals. Salts of calcium, strontium, barium, magnesium, zinc, and cadmium are most active in this respect, whilst salts of potassium, sodium, aluminium, mercury, manganese, copper, and uranium have little or no effect. In general the reaction on tyrosine gives rise to a succession of colour changes passing through pink, red, reddish brown, violet and dark blue, to black, but in certain cases some of these stages appear to be omitted, and when zinc or cadmium salts are used as activators a deep blue coloration and precipitate are formed very rapidly. These colours are probably due to differences in the size of the melanin particles (*cf.* J., 1921, 713 a); if a solution containing red melanin is boiled it becomes black. It is suggested that the formation of melanin involves the following steps:—conversion of tyrosine into *p*-hydroxyphenylacetaldehyde by elimination of carbon dioxide, ammonia, and hydrogen, the last being taken up by an acceptor; introduction of a further hydroxyl group into the benzene nucleus; condensation with the previously liberated ammonia, and oxidation, to form dihydroxyindigo or melanin. This view of the constitution of melanin is supported by the fact that hydrosulphites yield a colourless leuco-compound, and also by the formation of derivatives of indole and pyrrole on fusing melanin with sodium hydroxide. The organic component of tyrosinase thus probably contains several enzymes, including a phenolase, an aminoacidase, and an unknown condensing enzyme. Some suggestions are made concerning the function of the inorganic component of tyrosinase.—J. H. L.

Tryptophane; Colorimetric experiments on ——. *Part 5. Melanoidin formation by the acid hydrolysis of proteins and its dependence on tryptophane complexes.* O. Fürth and F. Lieben. Biochem. Zeits., 1921, 116, 224—231.

By investigating the tryptophane content of various proteins colorimetrically and determining the amount of melanoidin formed by acid hydrolysis, a parallelism is observed between the tryptophane content and the melanoidin. The authors consider that the melanoidins are the condensation products of tryptophane molecules. The term "humin" is reserved for the results of change of carbohydrate complexes.—H. K.

Tyrothrix of Kayser. Bettinger. *See* XVIII.

Patents.

Coffee; Manufacture of a dry and soluble extract of roasted ——. A. Chalas. E.P. 161,920, 15.4.21. Conv., 16.4.20.

The extract of roasted coffee is concentrated under diminished pressure (a few mm. of mercury) in a vessel maintained at 0° C. (*cf.* E.P. 129,639; J., 1920, 382 a), and subsequently dried in a current of warm dry air, or *in vacuo* in presence of drying agents. The initial concentration at 0° C. avoids loss of aromatic substances.—A. G. P.

Flour and bread; Manufacture of ——. W. Watson, D. W. Kent-Jones, and Woodlands, Ltd. E.P. 168,938, 3.5. and 26.7.20.

Flour is treated with chlorine in a closed vessel until it contains 2—3% of combined chlorine. Chlorinated flour is added as an "improver" to ordinary flour at the rate of 0·5—1 lb. per sack of 280 lb. The process is applicable to barley, rye, rice, and bean flours or any of their constituents. —A. G. P.

Meat; Preserving ——. A. E. Sherman. E.P. 169,189, 17.3.20.

Freshly-killed meat is sprayed with disinfectant before cold storage. Numerous organic substances for this purpose are claimed, especially various constituents of essential oils.—A. G. P.

Meat extract; Production of —— *as food for animals.* J. C. Marshall and F. Sutcliffe. E.P. 169,366, 13.8.20.

Meat is boiled in a steam-heated bath for ½ hr., —6 lots of meat being treated successively in the ame liquor, which is then concentrated, preferably *n vacuo*.—A. G. P.

Casein oil [food] product and process of making same. H. V. Dunham. E.P. 169,276, 22.6.20. Addn. to 148,587 (see U.S.P. 1,302,487; J., 1919, 511 a).

Casein is dissolved in sodium bicarbonate solution, vegetable oil is added and thoroughly agitated to produce a homogeneous emulsion. Free acid or acid alts are added to precipitate the casein. The mass f finely divided casein and the incorporated oil is ried and powdered.—A. G. P.

Vegetables and fruits; Method of drying ——. B. S. Harrison, Assr. to Carrier Engineering Corp. U.S.P. 1,387,710, 16.8.21. Appl., 3.8.18.

Vegetables and fruits are sliced, treated with a aline solution to prevent oxidation, and then dried n an inert gas.—J. H. J.

Evaporator [dryer]; Rack ——. *Heating device for evaporators, particularly evaporators for drying fruit.* F. Williams. U.S.P. (a) 1,388,152 and (b) 1,388,153, 16.8.21. Appl., 25.2.21.

(a) A preparing room, an evaporating chamber, a wilting room, and sulphuring chambers are provided with alined tray supports to permit the passage of trays from one to another. (b) A furnace below one side of the evaporating chamber is fitted with a flue extending under the chamber to the other side, and passages from this flue lead to chambers disposed transversely beneath the evaporating chamber. Sets of vertical pipes extend from these transverse chambers through the evaporating chamber to horizontal radiator boxes communicating with outlet flues.—H. H.

Food product and process of preparing same. R. W. Crocker. U.S.P. 1,388,699, 23.8.21. Appl., 26.5.19.

Chopped meat is mixed with milk and flour, and the mixture is filled into moulds and heated, which causes a shrinkage and the formation of a skin around the mass. These masses are filled into tins, sterilised, and the tins sealed.—J. H. J.

Cereal food; Manufacture of ——. E. H. McKay, Assr. to Kellogg Toasted Corn Flake Co. U.S.P. 1,388,873, 30.8.21. Appl., 28.6.19.

The cereal particles are cooked, dried, and impregnated with steam before forming.—A. G. P.

Cheese; Swiss —— *and method for sterilising the same.* L. E. Carpenter and E. E. Eldredge, Assrs. to Phenix Cheese Co. U.S.P. 1,389,095, 30.8.21. Appl., 14.3.18.

Swiss cheese is ground with a small percentage of sodium citrate, water, and Neufchâtel cheese. The mass is heated to 165° F. (74° C.) for 30 mins., being constantly stirred, and is then enclosed in a container.—J. H. J.

Cheese, and process for sterilising the same. L. E. Carpenter and E. E. Eldredge, Assrs. to Phenix Cheese Co. U.S.P. 1,389,577, 6.9.21. Appl., 21.6.15. Renewed 14.3.18.

Cheese of the Camembert type is ground, mixed with a small quantity of sodium citrate, melted at 170° F. (77° C.), stirred for about 30 mins., and poured into containers.—A. G. P.

Food product and process of making same. C. H. Simpson. U.S.P. 1,389,389, 30.8.21. Appl., 28.10.19.

Fruit is cooked and the juice expressed. The residue is mixed with liquid to form a semi-liquid mass, from which the non-meaty portions are removed. Fruit juice is added and the mixture boiled.—J. H. J.

Food product, made from corn [maize]; Process of manufacturing ——. A. W. H. Lenders, Assr. to Penick and Ford, Ltd. U.S.P. 1,381,065, 20.9.21. Appl., 7.11.18.

Maize, with germ, husk, and fibre removed, is ground and subjected to a treatment which modifies the starch without any appreciable conversion into dextrin or sugar. The product is a dry flour-like substance consisting of maize protein and modified starch, and remains stable in water suspension. —A. G. P.

Food product and process for making the same. Food product and process for preparing. F. C. Atkinson, Assr. to American Hominy Co. U.S.P. (a) 1,391,160 and (b) 1,391,161, 20.9.21. Appl., 4.4. and 27.5.19.

(a) Cooked hominy, while still hot and soft, is converted into flakes, dried, crushed, and screened into various grades. (b) Moistened cereals are cooked at 85°—100° C., and while hot, crushed between rollers heated at 85°—110° C. The product is dried and ground.—A. G. P.

Food products; Production of new —— and process of producing the same. Merrell-Soule Co., Assees. of R. S. Fleming. E.P. 151,965, 18.6.20. Conv., 2.10.19.

See U.S.P. 1,361,238—9 of 1920; J., 1921, 95 a.

XIXb.—WATER PURIFICATION; SANITATION.

[*Swelling of jellies;*] *Procter-Wilson theory* [*of ——*] *as a working tool. Application to sewage disposal.* J. A. Wilson. J. Soc. Leather Trades' Chem., 1921, 5, 268—273.

The Procter-Wilson theory of the swelling of protein jellies in acids (*cf.* J., 1916, 404) has been applied to the filtration in filter-presses of sludge from the sewage of the city of Milwaukee. The addition of acid increased the rate of filtration, and at $p_H = 3{\cdot}2$ the time was reduced to one-fourth. Better results were obtained by the addition of aluminium sulphate and then adjusting the p_H to 4·3. The time then required for filtration was one-eighth of that required by untreated sludge.—D. W.

Patents.

Water; Apparatus for removing gases from ——. J. J. Wilson, Assr. to Anti-Corrosion Engineering Co. U.S.P. 1,387,748, 16.8.21. Appl., 24.2.21.

A covered tank contains a helical pipe connected with an inlet pipe at the lower end of the tank and terminating a little below the cover. The water to be treated is passed upwards through the helix, is discharged at the upper end, and passed away through a pipe in the bottom of the tank. The gases given off are collected under the cover and are discharged at the water level through a vent. —J. H. J.

Water-softening material; Method of manufacturing ——. J. B. Wherry, Assr. to The Refinite Co. U.S.P. 1,388,133, 16.8.21. Appl., 29.5.17.

A natural clay substance with base-exchanging properties is subjected to a sufficiently high temperature to dehydrate it completely without fusion. It is then re-hydrated with a solution of an alkali compound.—J. H. J.

Water; Process of automatically regulating the addition of a treating agent to ——. J. S. Simsohn. U.S.P. 1,388,613, 23.8.21. Appl., 25.10.18.

A reagent is supplied continuously to the flow of water, the rate of supply being varied according to the electrical conductivity of the water.—J. H. J.

Plant diseases; Substances for combating ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 339,587 and 339,588, 18.3. and 15.11.19.

Halogen amides or imides containing the group –CO.NHHal. or –CO.N(Hal.).CO—, such as acetochloramide, benzochloramide, succiniodoimide, phthalylbromo-imide, or other halogenated nitrogen compounds, such as *p*-toluenesulphodichloramide, or ethylchloramine, possess valuable fungicidal and insecticidal properties, and can be used either alone or better mixed with non-alkaline diluents such as bolus alba, kieselguhr, "osmotic" silicic acid, or talc for combating plant diseases or insect pests and for preserving wood. For example, powders containing 5% of acetochloramide or 10% of *p*-toluenesulphodichloramide dusted on the affected parts have been found effective for the treatment of mildew.—G. F. M.

Lead arsenate. U.S.P. 1,390,647—8. *See* VII.

Vitiated atmospheres. U.S.P. 1,390,497. *See* XXIII.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Green plants; Chemical constituents of ——. Part 13. Volatile basic substances of green plants. H. Franzen, A. Wagner, and A. Schneider. Biochem. Zeits., 1921, 116, 208—214.

Out of 28 plants examined all contained volatile basic substances; in the case of 13 ammonia was identified. The amount of other volatile basic substances is very minute even when employing 1 kg. of material.—H. K.

Lobelia plant; Alkaloids of the ——. I. H. Wieland. Ber., 1921, 54, 1784—1788.

The isolation of two crystalline alkaloids, lobeline and lobelidine, from *Lobelia inflata* of North America is described. The preparation of the former depends on the observation that its hydrochloride can be removed from its aqueous solution by repeated agitation of the latter with chloroform; the final purification is effected by crystallisation from alcohol, benzene, or ether. Lobeline, $C_{23}H_{29}O_2N$, crystallises in broad, colourless needles, m.p. 130°—131° C., $[\alpha]^{15}_D = -42{\cdot}85°$ in alcoholic solution. The sulphate, nitrate, bromide, and chloride are placed in order of increasing solubility in water; they are crystalline neutral salts. The base is monacidic. The oxygen atoms appear to be present in ethereal union since the substance does not react with the usual reagents for the ketonic or hydroxy groups and its stability towards alkali indicates the absence of the lactone ring. The methoxy group is not present. The nitrogen atom appears to be in tertiary form. An unusual property is the ready hydrolysis of the alkaloid to acetophenone, but the fate of the remainder of the molecule has not yet been elucidated. Lobelidine, $C_{20}H_{25}O_2N$, small irregular prisms, m.p. 106° C., is isolated from the final ethereal mother liquors obtained during the preparation of lobeline. Its hydrochloride has m.p. 165° C. after darkening at about 160° C.—H. W.

Cocaine, novocaine, and stovaine; Distinguishing tests for the hydrochlorides of ——, and their detection in binary mixtures. G. Batta and C. Genot. J. Pharm. Belg., 1921, 3, 449—457. Chem. Zentr., 1921, 92, IV. 737.

A new reaction for novocaine consists in adding to a solution of a trace of the substance in 1 or 2 drops of water, 3 drops of fuming nitric acid and a few drops of a 5% solution of resorcinol in 10% potassium carbonate. A red coloration increasing on the further addition of potassium carbonate solution indicates novocaine. The latter can also be detected by diazotisation and coupling with β-naphthol or resorcinol. Stovaine is characterised by the precipitate which it gives with sodium hydrogen phosphate.—G. F. M.

Thymus nucleic acid; Structure of —— and its possible bearing on the structure of plant nucleic acid. P. A. Levene. J. Biol. Chem., 1921, 48, 119—125.

The author's formula still expresses all the known facts regarding the structure of yeast nucleic acid. Hexothymidinediphosphoric acid and hexocytidinediphosphoric acid were isolated by a simplified process from the hydrolysis product of thymus nucleic acid and the barium salt of the first-named compound was obtained in a crystalline condition. Under the experimental conditions neither the mono-phosphoric nucleotides nor the dinucleotide previously obtained could be isolated. The former are, therefore, probably secondary products, while the existence of the latter is doubtful. On these grounds the author suggests a structure for thymus nucleic acid analogous to that of yeast nucleic acid. (*Cf.* J.C.S., Nov.)—E. S.

Animal nucleic acid; Preparation and analysis of ——. P. A. Levene. J. Biol. Chem., 1921, **48**, 177—183.

Improved methods for the preparation of nucleic acids from the spleen, pancreas, and liver are described and analytical results are given. For purposes of estimation the purine bases are separated in the form of their hydrochlorides by alcoholysis of the nucleic acid. No confirmation was obtained of the presence of mixed nucleic acids, *i.e.*, nucleic acids containing both hexose and pentose nucleotides.—E. S.

Liver lecithin. P. A. Levene and H. S. Simms. J. Biol. Chem., 1921, **48**, 185—196.

Liver lecithin, purified by means of the cadmium chloride compound, yields on hydrolysis palmitic and stearic acids. In addition two unsaturated acids are formed, one of which gives stearic and the other arachidic acid on reduction. The production of four acids suggests that liver lecithin is a mixture of different lecithins, and confirmation of this is obtained by molecular weight determinations of hydrolecithin. (*Cf.* J.C.S., Nov.)—E. S.

Olibanols. E. Fromm and R. Klein. Annalen, 1921, **425**, 208—216.

Of the three olibanols (α-, β-, and γ-) obtained from oil of incense, only α-olibanol is reduced by sodium and alcohol to a dihydro-compound, and only the β-isomeride gives pinononic acid on oxidation by cold permanganate. α-Olibanol is converted into β-olibanol on distillation at atmospheric pressure. (*Cf.* J.C.S., Nov.)—C. K. I.

Salvarsan; Derivatives of sulphur in commercial ——. H. King. Chem. Soc. Trans., 1921, **119**, 1415—1420.

The main sulphur-containing impurity in commercial salvarsan is 3.3′-diamino-4.4′-dihydroxy-5-sulphoarsenobenzene, associated with varying proportions of the sulphate of salvarsan base, and not, as previously thought (J., 1921, 636 A), the corresponding sulphino derivative. Oxidation gives 3-amino-4-hydroxy-5-sulphophenylarsinic acid, while hydrolysis gives the new 6-aminophenol-*o*-sulphonic acid, the position of the sulpho group being established by its synthesis from 4-aminophenol-*o*-sulphonic acid through 6-nitro-4-aminophenol-*o*-sulphonic acid and 6-nitrophenol-*o*-sulphonic acid. —P. V. M.

Benzaldehyde; Quantitative determination of chlorine in ——. Schimmel und Co. Ber. von Schimmel und Co., 1921, 56—61. Chem. Zentr., 1921, **92**, IV., 771.

The benzaldehyde is burnt in a small flask-shaped lamp, with a container of about 20 c.c. capacity. The lamp is provided with an asbestos thread serving as a wick which passes through a porcelain tube fitting into the neck of the container. The amount of substance burned is determined by weighing the lamp and its contents at the beginning and end of the experiment, a cap fitting over the neck being provided to prevent evaporation or oxidation during the weighing. The cap is replaced by a small lamp glass during the combustion. The lamp fits into the bottom of a vertical glass cylinder connected with two U-tubes in series, filled with glass beads and charged with $N/50$ potassium hydroxide solution to absorb the hydrochloric acid which is formed, a small bubbler being placed at the end to detect incomplete absorption. A slow current of air is drawn through the whole apparatus during the combustion, at such a rate that no water is deposited in the first cylinder and the flame is free from soot. About 1 g. of benzaldehyde is burnt per hr., and the chlorine is determined by making the filtered absorption liquid neutral to phenolphthalein and titrating the chloride present with $N/50$ silver nitrate.—G. F. M.

Catalytic hydrogenation of organic compounds with base metals at the temperature of the laboratory. Activity of nickel catalysts prepared at different temperatures. Influence of oxygen on the nickel catalyst. IV. C. Kelber. Ber., 1921, **54**, 1701—1705.

The author has been unable to confirm the observation of Willstätter and Waldschmidt-Leitz (J., 1921, 161 A) that metallic nickel, prepared by ignition of nickel oxalate, and reducing the oxide at 350°—360° C., is incapable of accelerating hydrogenation catalytically unless previously primed with air. He has further examined the behaviour of metallic nickel obtained by the reduction of basic nickel carbonate at different temperatures in the same vessel as is used for the subsequent hydrogenation experiments, thus avoiding any possible complication caused by exposing the product to air. The activity of the catalyst was examined in respect to aqueous solutions of sodium cinnamate. Metallic nickel prepared at 350°—360° C. is found to be but little inferior to that obtained at 300° C. and notably superior to that produced at 210° C. The material first described becomes completely inactive when shaken with oxygen at 18°—20° C. but, if treated with hydrogen at 70°—80° C. becomes again active at the temperature of the laboratory. The latter phenomenon was not observed by Willstätter and Waldschmidt-Leitz since they worked at 60° C., at which temperature the catalyst commences to regain activity.—H. W.

Catalysts; Influencing of the activity of ——. *IV. Oxidative catalytic dehydrogenation of alcohols. II.* K. W. Rosenmund and F. Zetzsche. Ber., 1921, **54**, 2033—2037. (*Cf.* J., 1921, 448 A.)

Catalytic dehydrogenation by means of oxygen in the presence of copper, quinoline, and aromatic nitro-compounds leads to the production of aldehydes from primary aliphatic, aromatic, and heterocyclic alcohols and of ketones from secondary alcohols, whereas tertiary alcohols remain unchanged. The method is useful in the cases of difficultly volatile and non-volatile alcohols, but has no advantage over the older processes when the more volatile alcohols are used. The optimal temperature varies considerably with the different alcohols. The lower limit may be considered to lie at 125°—130° C., at which temperature amyl alcohol is dehydrogenated; benzhydrol and furfuralcohol give satisfactory results at 145° C., benzyl alcohol at 165° C., and *o*-chlorobenzyl alcohol at 195° C.; the upper limit of temperature is 180° and 165° C. in the cases of benzyl alcohol and furfuralcohol respectively.—H. W.

Catalysts; Influencing of the activity of ——. *V. Catalytic reduction of esters and aldehydes.* K. W. Rosenmund, F. Zetzsche, and F. Heise. Ber., 1921, **54**, 2038—2042. (*Cf.* J., 1921, 368 A.)

Benzyl benzoate and diphenylmethyl benzoate undergo reductive fission to benzoic acid and the hydrocarbon by the action of hydrogen in the presence of palladinised barium sulphate, reaction occurring readily in boiling xylene, very slowly in boiling toluene; it can be inhibited almost completely by the addition of quinoline. Under similar conditions, benzaldehyde is mainly converted into dibenzyl ether, the production of which is repressed whereas that of benzyl alcohol is facilitated by addition of quinoline. Benzyl alcohol is transformed into dibenzyl ether by palladium. The reduction of benzoyl chloride takes place in accordance with the scheme: hydrocarbon←ester←benzoyl chloride→aldehyde→alcohol→ether; any particular member of the series may be made the main product of the change by suitably influencing the catalyst. (*Cf.* J.C.S., Nov.)—H. W.

Amines; Separation of aliphatic —— from one another and from ammonia. H. Franzen and A. Schneider. Biochem. Zeits., 1921, **116**, 195—207.

A method is described for the quantitative separation of ammonia and the methylamines. It depends on the fact that ammonium chloride and monomethylamine hydrochloride are insoluble in chloroform, and ammonia alone forms a compound with yellow mercuric oxide. Di- and trimethylamines are separated by means of iodine in potassium iodide which forms a periodide with trimethylamine. (*Cf.* J.C.S., Nov.)—H. K.

Ethyl hydrogen sulphate. H. B. Dunnicliff and G. S. Butler. Chem. Soc. Trans., 1921, **119**, 1384—1392.

For the estimation of ethyl hydrogen sulphate in alcoholic sulphuric acid two methods, in addition to one described previously (J., 1920, 146 T), were found satisfactory. A weighed quantity of alcoholic sulphuric acid is titrated with standard sodium or potassium hydroxide. The percentage of free acid (b) is calculated as H_2SO_4. Further alkali equivalent to (b) is added, and the ester completely decomposed by evaporating nearly to dryness and then heating for ½ hr. at 120° C. The excess of alkali is estimated in the residue. From the total quantity of alkali neutralised the percentage of sulphuric acid (a) present before esterification is calculated. Hence the percentage of ester is $2(a-b)\times126/98$, and the percentage esterification is $2(a-b)\times100/a$. In the second method a weighed quantity of alcoholic sulphuric acid is titrated with standard alkali and the percentage acidity (x) is calculated as H_2SO_4. The free sulphuric acid is estimated directly in a fresh portion by barium chloride. If in W g. of alcoholic sulphuric acid the free sulphuric acid is W_1, the percentage of ester is $2(x-100\times W_1/W)\times126/98$. The law of mass action is shown to hold when the molar proportion of alcohol to sulphuric acid varies between 4:1 (80% sulphuric acid) and 0·5:1 (35% sulphuric acid). Below 20% sulphuric acid the value of K rapidly increases. The law fails at high concentrations of either component. Claesson's observation (J. prakt. Chem., 1879, **19**, 246) that the ratio, actual esterification obtained to maximum esterification possible, is a minimum when molecular quantities of the reacting substances are used is confirmed. At ordinary temperature the attainment of equilibrium is very slow. For low concentrations (up to 13—18% H_2SO_4), the reaction is of the first order. —P. V. M.

Mercury compounds; Soluble [organic] ——. J. D. Riedel A.-G. E.P. 161,922, 15.4.21. Conv., 16.4.20.

Hydroxy-mercuric salicylic anhydride (170 g.) suspended in water, is treated with potassium cyanide (37 g.), whereby the amorphous mercury compound is rapidly converted into a crystalline mass, which, in the case where a considerable amount of water (800 g.) is present, consists of the potassium salt of the *o*-cyano-mercuric salicylic acid. With a lesser quantity of water (500 g.) the product consists of a mixture of this substance with the corresponding *p*-compound, which may be isolated by extracting the crystalline mass, after filtering off from the coloured mother liquor, with about three times its weight of water at 25° C., and cooling the extract to 0° C., when a woolly crystalline mass separates out and is purified by recrystallisation from hot water. The pure *o*-compound forms colourless short prisms with a satin lustre and is soluble in about 25 pts. of water at ordinary temperature. The pure *p*-compound forms colourless oblong tables, about four times more soluble in water than its isomeride. It reacts with ammonium sulphide more rapidly than the *o*-compound. Both compounds give with silver nitrate a silver salt of the formula $NC.Hg.C_6H_3(OH)CO_2Ag$.—G. F. M.

Perylene; Manufacturing ——. F. Hansgirg. U.S.P. 1,384,615, 12.7.21. Appl., 30.7.19.

A β-substituted derivative of naphthalene or of α-dinaphthyl is treated with halogenating agent, *e.g.*, phosphorus trichloride or aluminium chloride, and the product of the reaction is heated, preferably in presence of a reducing flux, such as phosphorous acid, and if desirable with addition of a ring-closing agent, *e.g.*, aluminium chloride. A yield of up to 60% (reckoned on the original material) of technically pure perylene is obtained. —G. F. M.

Cyanhydrins; Manufacture of alkylene ——. W. Bauer, Assr. to Röhm and Haas. U.S.P. 1,388,016, 16.8.21. Appl., 11.11.20.

Alkylene-cyanhydrins are obtained from alkylene-halogen-hydrins by the action of a cyanide in aqueous solution, with cooling.—G. F. M.

Aldehydes; Process of making ——. A. A. Backhaus and F. B. Arentz, Assrs. to U.S. Industrial Alcohol Co. U.S.P. 1,388,841, 30.8.21. Appl., 24.6.18.

An alcohol vapour is preheated to 250°—350° C., passed through a finely divided metallic catalyst maintained at the same temperature, and the aldehyde formed is separated.—G. F. M.

Liquorice-root extract; Process of preparing ——. K. Ito. U.S.P. 1,389,663, 6.9.21. Appl., 5.4.20.

A decoction of liquorice root is acidified with sulphuric acid and, after settling and decanting off the clear liquor, the solution is boiled and cooled to coagulate glycyrrhizic acid. The coagulated material is broken up, and, after neutralising the acid with an alkali carbonate, the solution is heated and filtered.—L. A. C.

Salt mixture containing all the salts of blood serum, and dissolving to a clear solution; Preparation of a dry ——. Sächsisches Serumwerk u. Institut für Bakteriotherapie G.m.b.H. G.P. 339,052, 15.7.20. Addn. to 329,309 (J., 1921, 279 A).

Instead of calcium chloride as prescribed in the original patent, an addition compound of calcium chloride with an amino-acid is added to the mixture of the remaining salts, for example, the double compound of calcium chloride and glycocoll, $CaCl_2,2CH_2(NH_2).CO_2H,4H_2O$. When this compound is dissolved in water with the salt mixture (Na_2HPO_4 and $NaHCO_3$) the precipitation of calcium phosphate or carbonate is completely prevented.—G. F. M.

Glycerophosphate of iron and albumin; Preparation of water-soluble preparations of ——. A. Stephan. G.P. 339,537, 2.8.19.

An aqueous solution of albumin or peptone is mixed with a 10% solution of ferrous glycerophosphate and a 50% solution of sodium glycerophosphate, and sugar syrup and alcohol are added. The sodium glycerophosphate protects the iron salt from decomposition by the hydrochloric acid of the stomach, and removes its property of precipitating albumin, thereby facilitating its assimilation when administered subcutaneously or by the mouth.—G. F. M.

Perylene; Method of obtaining ——. F. Hansgirg. E.P. 136,564, 11.12.19.

SEE U.S.P. 1,384,615 of 1921; preceding.

Isobornyl-ester-camphene mixture and process of making same. L. G. Wesson. E.P. 169,198, 17.5.20.

SEE U.S.P. 1,372,382 of 1921; J., 1921, 369 A.

Catalysts. U.S.P. 1,376,665. *See* I.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic emulsion; Orientation of the grains in a dried ——. L. Silberstein. J. Opt. Soc. Amer., 1921, 5, 363—365.

THE correction of an error in the previous paper on this subject (J., 1921, 340 A) reduces slightly the probable "efficiency coefficient."—B. V. S.

Silver bromide; Photochemical decomposition of ——. *I.* R. Schwarz and H. Stock. Ber., 1921, 54, 2111—2122.

THE behaviour of silver bromide towards daylight, the intensity of which is measured by a self-recording actinometer, has been investigated. The silver bromide was prepared by the gradual addition of potassium bromide solution (10%) in moderate excess to a dilute solution of silver nitrate acidified with nitric acid, mixing being effected by gently rotating the beaker; the preparations were effected in red light. The silver bromide was used in three forms, (*a*) a caseous, flaky modification prepared as lescribed, which passes when preserved into the plastic variety (*b*), and (*c*) the pulverulent modification obtained by shaking (*b*) with water. The silver bromide was allowed to settle in a thin uniform film on the bottom of small crystallising dishes and washed repeatedly with water until free from bromine ions. It was covered with water and xposed to light in an apparatus so arranged that a current of air carried the liberated bromine into n aqueous solution of potassium iodide. According o the intensity of the illumination, the production f bromine was evidenced at the end of 5—15 minutes. The experiments were generally continued for about four hours, at the end of which he bromide had assumed a pale grey to brown olour; variety (*a*) retained its caseous consistency, hereas the more compact form (*b*) suffered a urther contraction and sometimes became detached rom the edges of the dish, whilst form (*c*) remained nchanged except with respect to colour. Elimina-on of bromine occurred with the same regularities s are observed in the blackening of photographic mulsions. The sensitiveness of the various forms wards light diminished in the order *b*-*a*-*c*. The me allowed for the transformation of *a* into *b* was considerable importance since the sensitiveness gain diminished when *b* was more than 110 hours d. The most sensitive products were obtained ter 80—90 hours. It is probable that a gradual ange of form *b* into the less sensitive variety *c* curs even when agitation is avoided. Solarisation a property of pure silver bromide and is accom-nied by diminished elimination of bromine. ecimens of silver bromide obtained from potas-m bromide and an excess of silver nitrate, did not evolve bromine when illuminated. Evidence is adduced in favour of the hypothesis that the bromide actually suffers fission, but the liberated bromine reacts with adsorbed nitrate ions to give hypobromous acid; the latter subsequently reacts with the liberated silver giving silver bromide and hypobromite. Pre-illumination of the silver bromide (by cautious exposure to light during precipitation) causes a greatly increased liberation of bromine on subsequent exposure. (*Cf.* J.C.S., Nov.)—H. W.

Leuco-bases of dyestuffs derived from rosaniline; Developing properties of ——. A. and L. Lumière and A. Seyewetz. Bull. Soc. Chim., 1921, 29, 829—833.

WORKING with pure substances the authors were unable to repeat Abribat's results (*cf. ibid.*, 1921, 29, 265) on the use of the leuco-bases of Malachite Green and Fuchsin as developers. They consider that his results were probably due to impurities in the leuco-bases.—W. G.

Isocyanines; Comparison of isomeric ——. F. M. Hamer. Chem. Soc. Trans., 1921, 119, 1432—1444.

THE effect of introducing acetylamino, amino, and cinnamoylamino groups into the 5, 6, 7, 6′, and 7′ positions respectively of the 1.1′-dimethylisocyanine iodide nucleus was investigated by an examination of the photographic sensitising action and absorption spectra of the products. The cinnamoylamino- and acetylamino-derivatives were prepared by condensing quinaldine methiodide with the 6′- and 7′-substituted quinoline methiodides, and quinoline methiodide with the 5-, 6-, and 7-substituted quinaldine methiodides respectively. The amino derivatives could only be prepared indirectly by hydrolysis of the corresponding acetylamino derivatives. A cinnamoylamino group in the 6-position and an acetylamino group in the 6′-position produced derivatives which are powerful sensitisers, with intense bands in the red. Other members of both series show very low sensitising action, reaching a minimum in 5-cinnamoylamino-1.1′-dimethylisocyanine iodide, which has a maximum at 5600. The amino group in each case enhances the sensitising action. The absorption band lies 200—350 tenth metres further from the red end of the spectrum than the sensitising band. Nietzki's rule that increase in molecular weight causes a shift of bands towards the red is obeyed in the majority of cases, but in the 5-cinnamoylamino- and 5-acetylamino-compounds the reverse is the case.—P. V. M.

PATENTS.

Photographic reproduction by means of a phosphorescent medium. J H. Christensen. E.P. 160,739, 30.7.20. Conv., 25.3.20.

A PHOSPHORESCENT screen consisting of a film of gelatin containing finely powdered phosphorescent material, such as Balmain's powder, and provided on one side with a film of celluloid or similar material stained red, is made to phosphoresce strongly by exposure to light, the phosphorescent side is placed in contact with the print or other subject to be copied and the exposure continued through the red side. The phosphorescence is reduced most strongly at the whites of the print. A copy is then obtained by placing the screen in contact with a light-sensitive material on which a positive latent image is produced by the residual phosphorescence.—B. V. S.

Coloured [photographic] image and process of producing the same. J. I. Crabtree, Assr. to Eastman Kodak Co. U.S.P. 1,389,742, 6.9.21. Appl., 2.5.19.

A PHOTOGRAPHIC image is converted, wholly or partially, to an iron-toned image to which a suitable mordant dyestuff is then applied.—B. V. S.

XXIII.—ANALYSIS.

Collodion membranes; Preparation and standardisation of ——. A. H. Eggerth. J. Biol. Chem., 1921, 48, 203—221.

The membranes are moulded from a solution of 6 g. of dry collodion in 100 g. of alcohol-ether solvent. The permeability is regulated by the proportion of alcohol to ether in the solvent, being greater the larger the proportion of alcohol. Full details of the moulding operation are given, and the results of diffusion experiments with various grades of membranes for a number of colloids are described. (*Cf.* Farmer, J., 1918, 108 A.)—E. S.

Viscometer; Air-bubble ——. V. R. Abrams, J. T. Kavanagh, and C. H. Osmond. Chem. and Met. Eng., 1921, 25, 665—666.

The instrument consists of a glass tube 21 cm. long and 5·2 mm. internal diameter, with a spherical bulb at one end and the other closed with a ground-on cap. A groove in the ground end of the tube can be made to coincide with a hole drilled in the cap, so that the tube can be completely filled with liquid at any desired temperature. Two lines are engraved on the tube marking off a length of about 10 cm. in the middle of the tube. The tube is filled with the oil to be tested, of which only 4 c.c. is required, and placed in a holder in a water bath at the desired temperature until no further expansion takes place. The cap is then turned so as to seal the tube. The viscosity is determined by measuring the time taken for the bubble to travel from one mark to the other after inverting the tube. The tubes are calibrated against Saybolt viscometers using oils of various viscosities, and give an accuracy of 1% on oils having a Saybolt outflow time of not less than 80 secs.—H. C. R.

Surface tension; Determination of —— by rise in capillary tubes. S. Sugden. Chem. Soc. Trans., 1921, 119, 1483—1492.

A table of corrections has been constructed which renders possible the use of tubes of any diameter for the measurement of surface tension by the method of capillary rise. A simple apparatus which requires only small amounts of liquid has been devised. It consists essentially of two thin-walled glass tubes, free from optical irregularities, mounted so that both meniscuses can be seen at once in the field of a small reading microscope. Accurate measurement of the distance between the meniscuses is made by an adjustable travelling cross-wire in the eye-piece of the microscope.—P. V. M.

Gas analysis; Apparatus for continuous ——. R. Mezger and M. Müller. Gas und Wasserfach., 1921, 39, 633—634.

A series of Bunte gas burettes are used for measuring the gas before and after absorption etc., the gas being passed from the first burette, through the first absorbent, into the second burette where it is again measured, and into the succeeding burettes in turn through the proper absorbents.—W. P.

Arsenic; New procedure for the determination of ——. J. Cribier. J. Pharm. Chim., 1921, 24, 241—246.

Advantage is taken of the intensifying and fixing action of potassium iodide on the yellow stain produced by hydrogen arsenide on mercuric chloride paper to provide a new method for the quantitative estimation of small quantities of arsenic compounds. The apparatus required consists of a flask fitted with a vertical glass tube about 5 mm. in diameter and 30 cm. long. The lower end is drawn out into a dropping tube, and a hole in the tube about 2·5 cm. from the end allows of the exit of the gas. For each determination the flask is charged with 8 g. of zinc and 60 c.c. of 20% sulphuric acid, and the arsenic solution, previously oxidised by means of a few drops of permanganate in order to convert sulphur or phosphorus compounds into non-reducible sulphuric and phosphoric acids, is added all at once. The lower part of the glass tube contains a roll of filter paper about 10 cm. long, and then a band of the mercuric chloride paper 5 mm. wide and 12—15 cm. long, extending to within 2 cm. of the roll of filter paper, which protects it from moisture carried up mechanically by the gas. At the end of the experiment the mercuric chloride paper is immersed in 10% potassium iodide solution which acts specifically on the yellow arsenic stain, and turns it brown, and at the same time renders it permanent to light and moisture. The arsenic is then estimated by comparing the stain with those produced under similar conditions by known quantities of arsenic.—G. F. M.

Mercury in organic compounds; Determination of ——. H. Bauer. Ber., 1921, 54, 2079—2081.

The substance (0·2—0·3 g.) is weighed into a wide-necked Jena glass flask provided with a two-holed rubber stopper carrying a small dropping funnel and glass tube leading to a Peligot tube charged with water (about 5 c.c.); 10 c.c. of concentrated sulphuric acid (or fuming acid if the substance is in aqueous solution) is run into the flask, followed by hydrogen peroxide solution (30%, 3—5 c.c.) which is added slowly and with constant agitation and intermittent warming until a colourless solution is obtained; this operation is usually complete in a few minutes. The contents of the flask and Peligot tube are rinsed into a small beaker, and concentrated ammonia is added in slight excess, after which the mixture is covered and heated at its boiling point for about three minutes to destroy any Caro's acid which may have been formed. Approximately $N/5$ potassium cyanide solution (10 c.c.) is added to the cooled mixture followed by 5 drops of 10% potassium iodide solution. Excess of potassium cyanide is titrated with $N/20$ silver nitrate solution.—H. W.

Formaldehyde; Detection of —— by means of resorcinol and sulphuric acid. R. Cohn. Chem.-Zeit., 1921, **45**, 997—998.

Resorcinol in presence of sulphuric acid is a very sensitive reagent for the detection of formaldehyde. Two c.c. of 0·1% aqueous pure resorcinol solution is shaken with an equal volume of the solution to be tested, and about 2 c.c. of concentrated sulphuric acid added so as to form a layer below the solution. In the presence of formaldehyde a zone of white flocks with a violet-red base is formed at the junction of the two liquids. The zone of white flocks increases upwards on long standing, and a red precipitate, insoluble in water, separates. The reaction is immediate when the solution contains 0·01 g. of formaldehyde per 100 c.c., and is still distinct with only 0·05 mg. In the latter case the violet-red ring may be faint, but the separation of the characteristic white flocks is distinct. In presence of formic acid, oxalic acid, and tartaric acid (*cf.* J., 1921, 487 A), the ring of white flocks with a violet-red base is formed first, although the violet-red colour may be masked by the brown formic acid ring; below this is the blue oxalic acid ring, and, when the lower part of the mixture is heated carefully, the deep red tartaric acid ring is formed at the bottom. (*Cf.* J.C.S., Nov.)
—F. M. R.

Patents.

Analysis of gases; Recording analysing apparatus for the automatic ——. S. A. S. Krogh and P. H. Pedersen. E.P. 169,130, 10.5.20.

Two or more sets of gas analysis apparatus are connected in series, a separation and measurement of at least one of the constituents of the gaseous mixture being effected in each apparatus. Each apparatus is provided with its respective first measuring vessel, absorption vessel, and second measuring vessel, the first measuring vessel of the second and any subsequent apparatus being adapted to restore the original volume of the gas mixture by addition of air to the indrawn gas. In like manner, in a section of the apparatus serving to analyse an inflammable gas, the first measuring vessel is connected, at its upper end, with a combustion chamber, and with a suction pipe and a pipe open to the atmosphere, the area of the latter pipe relative to that of the former being adjustable, so that there is inhaled into the measuring vessel in addition to the gas mixture, a volume of air suitable for the combustion of the combustible constituent. The percentage of any constituent of the gaseous mixture is automatically recorded by registering the volume of the gaseous mixture after absorption etc. of such constituent or otherwise.—J. S. G. T.

Viscometer. Hadfields (Merton), Ltd., and A. E. Bawtree. E.P. 169,204, 19.5.20.

In a viscometer of the efflux (Redwood) type, the orifice is situated at the bottom of the measuring chamber, which is partially or wholly immersed in the sample to be tested, contained in a cylindrical vessel, provided at the top with a flange to which a cover may be secured by screws. The cover is provided with a three-way cock, for admitting air under pressure and for discharging air within the apparatus on completion of a test. A test is carried out by forcing the sample under air pressure upwards through the orifice and noting the time taken for the liquid surface to reach the index mark at or near the top of the measuring chamber.
—J. S. G. T.

Colorimeter and the like. M. Mooney. U.S.P 1,389,836, 6.9.21. Appl., 7.7.19.

The colour of the material under examination is combined with its complementary colour, and the latter colour is separately combined with a standard comparison colour so that a grey shade is produced in each case. Means are provided for observing the resulting colours simultaneously for purposes of comparison.—J. S. G. T.

Combustible and vitiated atmospheres; Method and apparatus for the detection of ——. E. M. and T. M. Chance. U.S.P. 1,390,497, 13.9.21. Appl., 17.4.17.

Changes in the composition of the atmosphere are detected by maintaining a device responsive to temperature changes, such as a thermometer, in operative relation to a source of heat maintained at a predetermined constant value, in such manner that the temperature indicated by the thermometric device depends upon the composition of the atmosphere. Means are provided for bringing the atmosphere into contact with the source of heat, and for causing the thermometric device to operate a signalling system when its temperature reaches a predetermined lower limit.—J. S. G. T.

Analysing gases; Absorption apparatus for ——. P. R. Boulton. U.S.P. 1,390,488, 13.9.21. Appl., 6.4.20.

Ironside. Distilling oil shales, coal, etc. 27,761. Oct. 19.

Joseph. Preparation of paraffin wax. 28,616. Oct. 28.

Kissock. Manufacture of artificial fuel blocks. 27,414. Oct 15.

Leadbeater. Liquid fuel. 27,805. Oct. 20.

Otto and others. 27,765. See XII.

Pellatt. Producer-gas plants. 27,062. Oct. 12.

Trenkler. Recovery of sensible heat of gases in Mond gas process. 28,756. Oct. 29.

Tully. Manufacture of gas for heating and lighting. 27,074. Oct. 12.

Waddell. Combustion of fuel. 27,479. Oct. 17.

Watt. Petroleum preheaters and fractionating stills. 26,985. Oct. 12.

Wells. Gas-producers. 27,182. Oct. 13.

Wildey. Apparatus for destructive distillation of shale, coal, etc. 28,432. Oct. 26.

Complete Specifications Accepted.

15,383 (1920). Benson. Process of distilling hydrocarbon oils. (169,763.) Oct. 19.

16,571 (1920) and 8220 (1921). Paterson, Tulloch, and Smith. Suction gas plants. (170,336.) Nov. 2.

17,274 (1920). Findley. Separating coal into different grades. (169,776.) Oct. 19.

18,574 (1920). Standard Oil Co. Obtaining products from petroleum. (146,472). Oct. 19.

18,863 (1920). Pintsch A.-G. Gas-producer of the revolving-grate type. (146,964.) Oct. 19.

18,874–5 (1920). Deutsche Erdöl A.-G., Seidenschuur, and Koettnitz. Manufacture of lubricating oils from bituminous or asphaltic substances. (146,974-5.) Oct. 26.

19,478 (1920). Pintsch A.-G. Gas-producers of the revolving-grate type. (147,514.) Oct. 19.

19,552 (1920). Knight. Petrol and other liquid fuels. (170,075.) Oct. 26.

19,709 (1920). Standard Oil Co. Process of distilling hydrocarbons. (147,715). Nov. 2.

19,846 (1920). Sesti. Motor spirit. (147,803.) Oct. 26.

20,383 (1920). Bergius. Manufacture of liquid organic compounds from coal. (148,436). Oct. 26.

20,533 (1920). Lloyd. Manufacture of coal or like briquettes. (170,092.) Oct. 26.

20,577 (1920). Pintsch A.-G. Gas-producers of the revolving-grate type. (148,573.) Oct. 26.

20,646 (1920). Benson. Purification of oils and hydrocarbons. (170,093.) Oct. 26.

21,379 (1920). Seidenschnur. Drying and carbonising lignite etc. to produce tar rich in undecomposed bitumen. (169,847.) Oct. 19.

22,373 (1920). Engelke. Distillation of hydrocarbon oils, asphalts, etc. (170,140.) Oct. 26.

23,031 (1920). Badische Anilin u. Soda Fabr. Desulphurising gases. (170,152.) Oct. 26.

29,307 (1920.) Glover, West, and West's Gas Improvement Co. Vertical retorts for the continuous destructive distillation of carbonaceous materials. (170,197.) Oct. 26.

34,429 (1920). Koppers. Ovens for producing gas and coke. (170,515.) Nov. 2.

311 (1921). Cravau. Coke ovens. (170,525.) Nov. 2.

10,410 (1921). Verity. Gas-producers. (169,940.) Oct. 19.

17,737, 17,738, and 17,740 (1921). American Coke and Chemical Co. Coke ovens etc. (165,733–4, 165,736.) Oct. 26.

III.—TAR AND TAR PRODUCTS.

Applications.

Barbet et Fils et Cie. 28,060. *See* II.

British Dyestuffs Corp., and Morgan. Manufacture of substituted α-naphthylamines and dyestuffs derived from them. 27,091. Oct. 12.

Rathsburg. Manufacture of *m*-dinitro-*o*-dinitrosobenzene and its salts. 27,903. Oct. 20.

Complete Specifications Accepted.

13,186 (1920). Lilienfeld. Producing viscous liquids from hydrocarbons occurring in tar oils (149,317.) Oct. 26.

15,383 (1920). Benson. *See* II.

16,179 (1920). British Dyestuffs Corp., Green, and Herbert. Manufacture of chlorinated derivatives of toluene. (170,056.) Oct. 26.

18,833 (1920). Melamid. Conversion of tar oils into neutral oils suitable for lubricating purposes. (146,898.) Oct. 19.

19,394, 19,409, and 19,449 (1920). Schroeter. Hydrogenation of naphthalene. (147,474, 147,476, and 147,478.) Oct. 26.

19,514 and 19,750 (1920). Tetralin Ges. Hydrogenation of naphthalene. (147,580 and 147,747.) Oct. 26.

20,646 (1920). Benson. *See* II.

21,379 (1920). Seidenschnur. *See* II.

22,373 (1920). Engelke. *See* II.

IV.—COLOURING MATTERS AND DYES.

Applications.

Akt.-Ges. f. Anilinfabr., and Lange. Manufacure of mordant dyestuffs. 26,789. Oct. 10.

British Dyestuffs Corp., and Morgan. 27,091. *ee* III.

Imray (Soc. Chem. Ind. in Basle). Manufacture f dyestuffs of the triarylmethane series. 28,325. ct. 25.

Complete Specifications Accepted.

9305 (1920). Atack and Clough. Manufacture of ompounds of the anthraquinone series. (169,732.) ct. 19.

16,523 (1920). Soc. Chim. Usines du Rhône. yestuffs of the indigo series. (152,634.) Nov. 2.

19,694 (1920). Ransford (Cassella u. Co.). Manufacture of vat dyestuffs. (147,704.) Oct. 26.

22,091 (1920). Imray (Soc. Chem. Ind. in Basle). Manufacture of azo dyestuffs. (169,863.) Oct. 19.

23,551 (1920). Carpmael (Bayer u. Co.). Manufacture of soluble chromium lakes of azo dyes. (170,155.) Oct. 26.

25,298 (1921). Akt.-Ges. f. Anilinfabr. Manufacture of dyestuffs of the acridine series. (169,460.) Oct. 26.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Burgess, Ledward, and Co., and Harrison. Production of cellulose derivatives. 28,731. Oct. 29.

Heath and Heath. 26,842. *See* I.

Heberlein, and Heberlein u. Co., A.-G. Imparting new properties to cotton and cotton fabrics. 27,887. Oct. 20.

McGill, and Velos Manufacture, Ltd. Treatment of fibrous materials. 27,316. Oct. 14.

Richter. Manufacture of a composite material from cellulose and cotton etc. 28,434. Oct. 26.

Complete Specifications Accepted.

10,195 (1920). Bronnert. Manufacture of viscose silk. (170,024.) Oct. 26.

11,886 (1920). British Cellulose and Chem. Manuf. Co., and Briggs. Treatment of cellulose acetate products. (169,741.) Oct. 19.

12,719 (1920). Bronnert. Manufacture of artificial silk. (170,029.) Oct. 26.

12,972 and 13,586 (1920). Bronnert. Manufacture of artificial silk. (170,313 and 170,316.) Nov. 2.

14,068 (1920). Bronnert. Manufacture of viscose silk. (170,322.) Nov. 2.

17,776 (1920). Moeller. Treatment of cellulose and products manufactured therefrom. (145,610.) Oct. 26.

18,503 (1920). Enge. Manufacture of fibrous material from wood etc. (169,802.) Oct. 19.

19,315 (1920). Zellstoff-fabr. Waldhof, and Hottenroth. Treatment of artificial threads etc. (147,416.) Oct. 26.

19,460 (1920). Verwertung Inlandische Produkte Ges. Treatment of root stocks of the water reed (*Arundo phragmites*) for textile purposes. (147,496.) Oct. 26.

8069 (1921). Mackenzie, Robinson, and Fort. Treatment and purification of yarns and fabrics composed of vegetable fibres. (170,534.) Nov. 2.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Burgess, Ledward, and Co., and Harrison. Means for dyeing cellulose acetate. 27,616 and 28,490. Oct. 18 and 27.

Edwards. Coating textile fabrics. 28,524. Oct. 27.

Haigh. Dyeing etc. machines. 28,513. Oct. 27.

McIntosh and McIntosh. Bleaching wool etc. in sliver or yarn. 27,374. Oct. 15.

Complete Specifications Accepted.

18,757 (1920). Meister, Lucius, u. Brüning. Production of white and coloured discharges on coloured grounds. (146,868.) Oct. 19.

19,321 (1920). Wardwell. Apparatus for treating cords, threads, etc., with fluids. (147,421.) Oct. 19.

20,056 (1920). Kaufmann. Apparatus for dyeing linen, union cotton, and other heavy piece goods. (148,149.) Oct. 19.

24,403 (1920). Meister, Lucius, u. Brüning. Production of fast dyeings on cotton and like fibres. (150,329.) Oct. 26.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Buchner. Production of pure alumina. 27,061. Oct. 12.

Cumberland Coal Power and Chemicals, Ltd., Jaques, and West. Manufacture of hydrogen or gases rich in hydrogen. 27,188. Oct. 13.

Cumberland Coal Power and Chemicals, Ltd., Jaques, and West. Manufacture of ammonium sulphate. 28,557. Oct. 27.

Imray (Aquazone Laboratories). Aqueous solutions containing oxygen and their production. 27,196. Oct. 13.

Jones and Kelly. Production of sodium pentaborate from boron ores. 28,293. Oct. 25.

Kelly. 28,435. *See* XVI.

Mai. Process of making arsenical solutions. 26,849. Oct. 11.

Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Production of concentrated nitric acid. 27,209. Oct. 13. (Norway, 27.10.20.)

Woodlands, Ltd. (Patek). Production of hydrogen peroxide. 27,114. Oct. 12.

Complete Specifications Accepted.

10,031 (1920). Lowy Laboratory. Arsenical compounds. (152,298.) Nov. 2.

14,373 (1920). Union Carbide Co. Manufacture of calcium carbide. (143,873.) Oct. 19.

15,055 (1920). Chem. Fabr. Albert, and Berend. Preparation of colloidal metallic elements and compounds thereof. (169,758.) Oct. 19.

16,309 (1920). Lie and others. *See* XX.

17,855 (1920). Dumont. Lime kilns. (169,786.) Oct. 19.

18,674 (1920). Mitsubishi Kogyo Kabushiki Kaisha. Synthetic production of cyanides. (146,819.) Oct. 19.

18,979 (1920). Westling. Production of manganese dioxide. (147,030.) Oct. 19.

19,121 (1920). Thede. Manufacture of sulphuric acid. (147,094.) Oct. 19.

20,905 (1920). Muth. Preparation of aluminium sulphate. (149,001.) Nov. 2.

26,661 (1920). Bacon (Oldbury Electro Chemical Co.). Manufacture of alkali formates. (170,185.) Oct. 26.

VIII.—GLASS; CERAMICS.

Applications.

British Thomson-Houston Co. (General Electric Co.). Working quartz. 26,933. Oct. 11.

Lorentz. Glass-blowing. 27,995. Oct. 21.

Parsons. Manufacture of glass. 28,120. Oct. 22.

Complete Specifications Accepted.

18,136 (1920). Frink. Tank glass melting furnaces. (169,789.) Oct. 19.

22,321 (1920). Thompson (Zip Manuf. Co.). Grinding-compounds. (169,868.) Oct. 19.

32,711 (1920). Roïboul. Manufacture of films of silica, alumina, and other refractory substances. (169,136.) Oct. 26.

IX.—BUILDING MATERIALS.

Applications.

British Thomson-Houston Co. (General Electric Co.). Manufacture of indurated materials. 27,439. Oct. 15.

Jones and Jones. Kilns for burning bricks, tiles, etc. 27,644. Oct. 18.

Myles. Concrete. 28,512. Oct. 27.

Sutcliffe, and Sutcliffe, Speakman, and Co. Production of bricks etc. 26,804. Oct. 10.

Complete Specifications Accepted.

17,693 (1920). Link. Production of artificial trass. (145,569.) Oct. 26.

18,736 (1920). Wade (Bombrini Parodi Delfino). Manufacture of slow-setting cement. (170,063.) Oct. 26.

18,737–8 (1920). Wade (Bombrini Parodi Delfino). Manufacture of cements. (169,807–8.) Oct. 19.

5105 (1921). Mellgren. *See* I.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Aitchison. Manufacture of iron and steel. 28,055. Oct. 21.

Ballantine. Manufacture of ferro-chromium alloys. 28,318. Oct. 25.

Bardt. Dissolving out metal constituents of metalliferous materials. 26,787. Oct. 10.

Bardt. Precipitation of metals from solutions. 26,788. Oct. 10.

Hoss. Recovery of light metals from chippings, residues, and ashes. 28,288. Oct. 25. (Ger., 11.2.21.)

Hibbard. Production of wrought iron. 28,251. Oct. 25.

Kernohan and Lochhead. Metallurgical furnaces. 27,770. Oct. 19. (U.S., 29.10.20.)

Licht A.-G. Manufacture of wires from metal having high melting-point. 27,846. Oct. 20. (Switz., 22.10.20.)

Metropolitan-Vickers Electrical Co. Determination of carbon in metals. 28,108. Oct. 22. (U.S., 23.10.20.)

Plauson's (Parent Co.), Ltd. (Plauson). Separation of minerals mechanically. 28,638. Oct. 28.

Smythe. Accelerating gravitation of mineral particles suspended in fluid for the recovery of tin oxide etc. 28,137. Oct. 24.

Trowbridge. Composition for cleaning, polishing, and plating metals. 28,445. Oct. 26.

Turner. Manufacture of low-carbon ferro-chromium. 26,968. Oct. 12.

Victoria Iron Rolling Co. Treatment of tin-plate scrap. 28,776. Oct. 29. (Australia, 30.10.20.)

Wirth. Method of coating metal. 28,097. Oct. 22.

Complete Specifications Accepted.

10,293 (1920). Cornelius. Melting zinc powder into liquid zinc. (170,026.) Oct. 26.

12,387 (1920). Walter. Alloys of silicon with metals of the iron and chromium groups. (157,054.) Oct. 26.

16,587 (1920). Naef. Manufacture of copper. (169,764.) Oct. 19.

19,037 (1920). Deutsche Luxemburgische Bergwerks- u. Hütten-A.-G. Preparation of iron and other metal swarf etc. for hot briquetting. (147,065.) Oct. 19.

19,363 (1920). Ampère-Ges. Production of ferro-tungsten. (147,457.) Oct. 26.

19,841 (1920). Bensa. Medium for preventing oxidation of iron etc. (147,800.) Nov. 2.

19,959 (1920). Mond (Metallbank u. Metallurgische Ges.). Production of zinc oxide suitable for metallurgical treatment from gypseous precipitates. (170,082.) Oct. 26.

19,988 (1920). Diefenthaler. Production of grey cast iron. (147,933.) Oct. 19.

20,248 (1920). Schlotter. Electrolytic production of dense and firmly adhering tin deposits. (148,334.) Oct. 26.

20,495 (1920). Briscoe, Richardson, and District Chem. Co. Autogenous welding or soldering of aluminium or its alloys. (170,343.) Nov. 2.

20,885 (1920). Diehl. Preparation and smelting of ores, roaster-residues, slags, etc. containing iron and zinc. (170,100.) Oct. 26.

21,911 (1920). Wade (Byers Co.). Manufacture of wrought iron. (170,124.) Oct. 26.

24,035 and 32,738 (1920). Brunskill. Preventing surface corrosion in certain aluminium alloys. (169,884.) Oct. 19.

34,668 (1920). Morrison and Wood. Flux and solder. (170,221.) Oct. 26.

13,621 (1921). Soc. d'Electro Chimie et d'Electro Métallurgie. Obtaining deposits of iron by electrolysis. (164,725.) Oct. 26.

XI.—ELECTRO-CHEMISTRY.

Applications.

Bardt. Manufacture of electrodes. 26,793. Oct. 10.

Bardt. Storage batteries. 26,801. Oct. 10.

Hooydank. Dry battery. 28,561. Oct. 27.

Illingworth. Manufacture of electrodes. 27,683. Oct. 18.

Loke. Electric furnaces etc. 27,293. Oct. 14.

Norske Akt. for Elektrokem. Industri. Electric furnaces. 28,194. Oct. 24. (Norway 1.11.20.)

Siemens-Schuckertwerke. Electric precipitating plants. 26,905. Oct. 11. (Ger., 28.10.20.)

Siemens-Schuckertwerke. Purifying gas by electricity. 27,089. Oct. 12. (Ger., 22.10.20.)

Siemens-Schuckertwerke. Apparatus for precipitating dust from gases by electricity. 28,241. Oct. 24. (Ger., 22.10.20.)

Complete Specifications Accepted.

15,498 (1920). Monnot. Storage-battery plates. (170,043.) Oct. 26.

15,614 (1920). Wyatt. Induction furnaces. (170,046.) Oct. 26.

15,924 (1920). Jungner. Primary batteries and electrodes therefor. (145,018.) Oct. 26.

20,248 (1920). Schlotter. *See* X.

20,688 (1920). Schmidthammer. Production of electric carbons. (148,872.) Oct. 26.

946 (1921). Wilke. Galvanic battery. (157,097.) Oct. 19.

13,621 (1921). Soc. d'Electro Chimie. *See* X.

XII.—FATS; OILS; WAXES.

Applications.

Cumming, and Klarit, Ltd. Decolorising and clarifying fats, oils, sugars, etc. 27,256. Oct. 14.

Douglas and Sons, and Nicol. Production of emulsions. 27,109. Oct. 12.

Otto, and Villiers London Co. Treatment of castor oil. 27,764. Oct. 19.

Otto, and Villiers London Co. Treatment of mineral, animal, or vegetable oils. 27,765. Oct. 19.

Otto, and Villiers London Co. Graphitising oils. 27,766. Oct. 19.

Rocca, Tassy, et de Roux. Purification of palm kernel oil. 28,548. Oct. 27. (Fr., 18.11.20.)

Complete Specifications Accepted.

9798 (1920). Whitehead and Scott. Extraction of oils from vegetable matter. (169,738.) Oct. 19.

17,540 (1920). Rocca, Tassy, et de Roux. Neutralising oils and fats. (163,272.) Oct. 19.

17,784 (1920). Blichfeldt. *See* XIX.

18,050 (1920). and 8428 (1921). Tseng. Manufacture of transparent soap. (170,060.) Oct. 26.

18,478 (1920). Versuchs- u. Lehranstalt f. Brauerei. Production of fat. (146,431.) Oct. 26.

19,251 (1920). Dorr Co. Treatment of waste liquors containing soapy or soap-making organic matter. (147,184.) Oct. 26.

19,511 (1920). Sittig and Granichstädten. Process for hydrogenation and production of catalysts. (147,578.) Oct. 26.

21,794 (1920). Farley. Soap. (169,858.) Oct. 19.

22,157 (1920). Kenyon and Couche. Cooling-apparatus for use in soap manufacture. (170,415.) Nov. 2.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Applications.

Dutt, Godfrey, and Wilson. Preparation of white pigment bases from titaniferous bauxites. 28,525. Oct. 27.

Gardner. Manufacture of paints. 26,897–8. Oct. 11.

Godfrey, and Linoleum Manuf. Co. Manufacture of linoleum. 28,565. Oct. 27.

Complete Specifications Accepted.

19,238 (1920). Filhol. Manufacture of phenol-formaldehyde condensation products. (147,173.) Oct. 19.

19,562 (1920). Muskett. Manufacture of shellac-like products. (169,829.) Oct. 19.

19,755 (1920). Thompson. Making white lead. (147,752.) Oct. 19.

19,828 (1920). Plönnis. Preparation of fireproof and waterproof paint. (147,799.) Oct. 26.

21,151 (1920). Johnson. (Badische Anilin u. Soda Fabr.). Manufacture of artificial resins. (170,351.) Nov. 2.

23,026 (1920). Smith. Pigments. (170,431.) Nov. 2.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Applications.

Alger and Frood. Production of coloured caoutchouc. 28,365. Oct. 26.

Fetter. Vulcanisation. 28,189. Oct. 24. (U.S., 10.1.21.)

Roa, Ltd., and Wickham. Apparatus for treating latex. 27,338. Oct. 14.

Smith. Extraction of gutta-percha. 28,052. Oct. 21.

XV.—LEATHER; BONE; HORN; GLUE.

Applications.

Edwards. Treatment of leather. 27,862. Oct. 20.

Gunn. Rendering gelatin etc. insoluble. 28,180. Oct. 24.

Complete Specifications Accepted.

8739 (1920). Ross, and Walker and Sons. Epilation of skins. (169,730.) Oct. 19.

10,229 (1920). Zignone. Manufacture of imitation leather. (141,712.) Nov. 2.

18,467 (1920) and 22,478 (1921). Johnson (Badische Anilin u. Soda Fabrik). Manufacture of tanning preparations. (146,427 and 169,943.) Oct. 19.

20,409 and 21,704 (1920). Stockly. Drying and hardening the surface of patent leather. (148,454 and 149,334.) Oct. 26.

XVI.—SOILS; FERTILISERS.

Applications.

Kelly. Treatment of mineral phosphates. 28,435. Oct. 26.

Klages, and Saccharinfabr. A.-G. vorm. Fahlberg, List u. Co. Production of a cauterising substance for seeds. 28,578. Oct. 27.

Complete Specification Accepted.

25,892 (1920). Johnson (Badische Anilin u. Soda Fabr.). Manufacture of fertilisers. (170,474.) Nov. 2.

XVII.—SUGARS; STARCHES; GUMS.

Applications.

Cumming and others. 27,256. *See* XII.

Jager and Rueger. Refining sugar liquors etc. 28,263. Oct. 25.

Plauson's (Parent Co.), Ltd. (Plauson). Extraction of sugar and purification of sugar solutions. 28,637. Oct. 28.

Complete Specifications Accepted.

13,350 (1920). Lilienfeld. Manufacture of compositions and products containing ethers of carbohydrates. (149,319.) Oct. 26.

19,314 (1920). Zellstoff-fabr. Waldhof, and Hottenroth. Obtaining sugar etc. from wood and other cellulose-containing materials. (147,415.) Oct. 26.

XVIII.—FERMENTATION INDUSTRIES.

Applications.

Jensen (Corby). Making, treating, and preparing yeast. 28,355. Oct. 25.

Kelly. Method of solidifying and preserving alcohol etc. 27,509. Oct. 17.

Scott. Fermentation etc. of beer. 28,404. Oct. 26.

Complete Specification Accepted.

20,737 (1920). Plesch. Manufacture of beer. (148,911.) Oct. 26.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Chitty, and Woodlands, Ltd. Treatment of wheat and manufacture of flour and bread. 27,115. Oct. 12.

Hartley and Hartley. Purification of sewage. 27,606. Oct. 18.

Kelly. Preserving fruits, plants, animal products, etc. 27,510. Oct. 17.

Klages and others. 28,578. *See* XVI.

Mai. 26,849. *See* VII.

Paenson. Preparation of fat emulsions from skimmed milk. 28,644. Oct. 28.

Parker and Parker. Manufacture of flour. 27,168. Oct. 17.

Complete Specifications Accepted.

XXIII.—ANALYSIS.

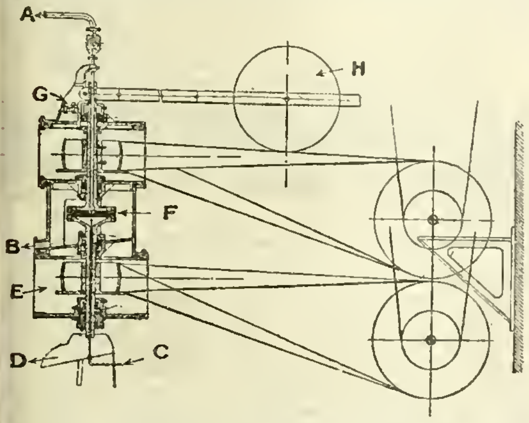
Application.

Metropolitan-Vickers Electrical Co. 28,108. *See* X.

I.—GENERAL; PLANT; MACHINERY.

Colloid mill and its applications. [*Preparation of viscose.*] H. Plauson. Z. angew. Chem., 1921, **34**, 469—472, 473—474.

Two types of machine are described (*cf.* J., 1920, 589 A; 1921, 169 A, 647 A), designed for the preparation by mechanical means of colloidal solutions. The first type resembles a disintegrator mill, but differs from this in that the rotating part is mounted eccentrically and that the force is concentrated at two points of impact. The efficiency of the mill and the fineness of the dispersed particles in the dispersion medium increase, the greater the velocity of rotation. Easy and rapid formation of a saturated colloidal solution can be more readily accomplished, the greater the proportion of dispersion medium used to the material to be dispersed. There is a definite point of saturation which depends on the nature of the disperse phase, the dispersion medium, and the temperature; excess of the disperse phase forms a gel. Thus, a saturated colloidal solution of copal in benzene contains 1·8%, in water 2·2%, in glycerin 2·8%, and in amyl alcohol 5% of the disperse phase. The saturation point can be raised by addition of a protective colloid or a dispersion accelerator, which may be called, for brevity, a dispersator, and



A.—From pump. B.—To pump. C.—Cooling water inlet. D.—Cooling water outlet. E.—Flange bearing. F.—Hard steel friction plates. G.—Adjustable pressure-bearing. H.—Pressure regulator.

hich may be compared with chemical catalysts. he second type of machine (see Fig.) depends n the pressure between two surfaces moving with espect to one another at a high velocity. Whilst he former type of machine is used for preparing olloidal solutions of typical colloidal substances, he latter is applicable for substances which are not pical colloids, such as minerals, dyestuffs, carbon, c. A new application of the colloid mill is in the reparation of viscose. It has been found that llulose, if treated in the colloid mill with a suit- ble dispersion medium, passes into the colloidal ate, and then reacts readily with the theoretical antity of alkali to form alkali-cellulose at the dinary temperature. On the addition of carbon sulphide, xanthate is formed smoothly without e simultaneous production of thio-salts. The vis- se solution obtained is pure and does not need to matured for most purposes. By this method eat economy of material and time is effected and artificial silk prepared from the viscose has reased tensile strength and better dyeing pro- rties than that prepared in the old way. Many er applications of the colloid mill are discussed, ecially in connexion with the preparation and servation of foodstuffs, the refining of oils, and preparation of lubricants.—E. H. R.

Adsorption of gases by charcoal, silica, and other substances. H. Briggs. Proc. Roy. Soc., 1921, **A 100**, 88—102.

A large number of substances were prepared and tested to ascertain their capacity for nitrogen and hydrogen at the temperature of liquid air and normal pressure, with the main object of obtaining a non-inflammable substitute for the activated charcoal used in metal vacuum flasks intended for holding liquid air. A sample of colloidal silica had a capacity for nitrogen at −190° C. about 66% greater than that of the best charcoal. This sample was made by drying the unwashed gel (from waterglass) at 300° C., plunging it whilst hot into hot distilled water, washing by decantation till free from chloride, again drying at 300° C., and repeating the cycle of operations until the material when dropped into water yielded no traces of chloride. Hydrogen was adsorbed in greater quantity than was nitrogen, the difference being much more marked with charcoal and carbonaceous adsorbents than with silica.—W P.

Patents.

Pulverizer mills. Fuller-Lehigh Co., Assees. of H. R. Collins. E.P. 153,889, 30.7.20. Conv., 8.11.19.

Improvements in a pulverising mill with air separation are claimed whereby all the moving parts, including the fan for producing circulation through the separator, and also the feeder are driven from a common shaft.—B. M. V.

Grinding-mill. L. T. Bachman, Assr. to Santa Cruz Portland Cement Co. U.S.P. 1,393,334, 11.10.21. Appl., 7.2.20.

A rotary grinding drum contains equal numbers of spherical grinding members and of short cylindrical members of softer material and higher specific gravity than the spherical members.—R. L. F. R.

Sand filters. L. E. Raimbert. E.P. 160,762, 21.2.21. Conv., 23.3.20.

Sand is retained as an annular mass by an inner and outer series of conical rings supported in a casing. The liquid to be filtered is admitted to the outside of the outer rings and after passing through the sand is exhausted from the inside of the inner rings. In the centre of the apparatus is a vertical pipe communicating with the sand compartment at each end, and the sand may be circulated through this pipe for washing purposes by means of a high-pressure water jet at the bottom of the pipe. The top pair of conical rings are extended vertically (cylindrically) upwards, and the inner one is also provided with a cap to prevent unfiltered liquid short-circuiting across.—B. M. V.

Separation of solids from liquids. W. Acton and W. M. MacKean. E.P. 169,315, 7.7.20.

The cake collected on a continuous filter operated by air pressure (or vacuum) is subjected to cataphoresis while in the drying stage, the cathode being formed by the filtering medium or its support and an anode being provided by an endless band of wire cloth running on rollers and in contact with the outside of the cake; on an electrical potential being established the liquid will be driven to the cathode, thus facilitating drying. To increase the effect a small quantity of a substance which is an electrolyte and is adsorbed by the solid matter may be added before filtration.—B. M. V.

Filter-press equipment. N. A. Lockwood. U.S.P. 1,390,531, 13.9.21. Appl., 22.9.20.

For moving the filter units longitudinally to open and close the press, means are provided for operating detachable conveyor elements coupled to the units so as to shift the units in reverse directions.—H. H.

Filtration and subsequent treatment of material; Process of continuous ——. J. Jung. G.P. 339,005, 19.12.17.

A filter-press within a housing is provided with filter elements capable of rotating about a common horizontal axis and extending up to the walls of the press so as to form closed compartments. The filter elements are exchangeable and the axle upon which they rotate rests upon a device serving to support separating and stripping bars extending throughout the length of the press. Material to be filtered is fed from below into the press on one side of these bars, and after rotating under pressure along with the filter elements, is delivered from the machine on the other side of the bars. Material can be subjected to any desired treatment, under a suitable pressure of water or gas, in the compartments of the press.—J. S. G. T.

Gases and vapours [e.g., in furnaces]; Ascertaining the composition, nature and effect of ——. Rudge-Whitworth, Ltd., and H. L. Heathcote. E.P. 169,465, 23.6.19.

A strip of metal is introduced into the furnace or other chamber in which the atmosphere is to be tested, and its electrical resistance measured (*e.g.*, by a small battery and a millivoltmeter or milliammeter). The resistance will rise rapidly as the strip heats up and then more slowly as oxidation or other chemical change takes place The strip may be conveniently attached to the ends of long and short rods of the same metal, stout enough to be substantially unaffected by the gases.—B. M. V.

Diffusing gases and vapours through liquids; Mechanism for ——. A. E. O'dell. From The Canadian American Finance and Trading Co., Ltd. E.P. 169,605, 23.8.20.

The gases are forced through superposed porous plates upon each of which rests a layer of liquid.
—B. M. V.

Digesting apparatus. Process of decomposing, transposing, dissolving, or rendering soluble difficultly soluble bodies. H. D. Rankin, Assr. to L. Sloss. U.S.P. (a) 1,364,803 and (b) 1,364,804, 4.1.21. Appl., 26.6.18. (*Cf.* U.S.P. 1,378,485; J., 1921, 769 A.)

(a) An apparatus suitable for decomposing substances by heating them under pressure with acids or acid salts as described under (b), consists of a closed heating chamber, connected with one or more closed heat-insulated chambers. When the pressure in the heating chamber reaches a certain limit, communication is opened with the first heat-insulated chamber and vapours are discharged into the latter from the heating chamber. Other heat-insulated chambers may be utilised in a similar manner as storage receptacles for excess vapours from the heating chamber. If, subsequently, owing to further reactions in the heating chamber, vapours are absorbed and the pressure falls, vapours may be re-admitted to the heating chamber from the storage chambers. (b) Substances such as magnetite, manganese ores, chromite, etc. are decomposed and rendered soluble by heating to 350°—850° C. at a pressure above 20 lb. per sq. in., a mixture of the substance and an alkali or alkaline-earth acid salt, such as a bisulphate; a chloride or nitrate may be mixed with the bisulphate.

Fusion process. H. H. Dow, Assr. to The Dow Chemical Co. U.S.P. 1,379,619, 31.5.21. Appl., 31.8.18.

In carrying out fusion processes in which decomposition is liable to occur in presence of oxygen (*e.g.*, in alkali fusions of organic compounds), the melt is "blanketed" with flue gas.

Calcining-kiln; Parallel-current [rotary] ——. H. E. Brookby. U.S.P. 1,390,335, 13.9.21. Appl., 10.3.19.

A combustion chamber projects into the rotary shell of the kiln, and the charge as it is introduced is made to pass over a portion of the combustion chamber, whereby it is preheated and the combustion gases are cooled somewhat before they mingle with the charge in the kiln.—H. H.

Burning liquid fuels and pulverulous coal; Furnace for ——. H. Horiuchi. U.S.P. 1,390,715, 13.9.21. Appl., 21.5.20.

Several combined air and fuel pipes communicate with a combustion chamber in such a manner that a rotary motion of the combustibles is produced. A restricted passage from the combustion chamber communicates with an expansion chamber of larger cross-section than the combustion chamber and provided with baffles to arrest the rotary motion of the gases as they issue from the expansion chamber. The combustion chamber is circular and the expansion chamber elliptical in cross-section.—B. M. V.

Slag furnace. E. E. James. U.S.P. 1,392,504, 4.10.21. Appl., 16.10.20.

A relatively long, horizontal, cylindrical boiler is surrounded by hot slag, which is kept in place by other boiler sections; the lower sections are removable to allow the slag to drop away when cool.
—B. M. V.

Still. W. D. Rial, Assr. to Marland Refining Co. U.S.P. 1,390,386, 13.9.21. Appl., 13.11.19.

To prevent settling of substances at the bottom of a still, a pipe, carrying a number of headers flexibly supported close to the bottom of the still, is suspended from the upper part, and a number of lateral pipes perforated on their under sides are provided so that liquid drawn from the still is discharged through the perforations.—H. H.

Evaporating liquids; Apparatus for ——. *Evaporating apparatus [; Vapour compression* ——]. W. L. De Baufre. U.S.P. (a) 1,390,676 and (b) 1,390,677, 13.9.21. Appl., 26.1. and 13.3.17.

(a) In a vapour compression evaporator with two units, the liquor from the first unit passes to the second unit, and the vapour from the first unit after compression passes to the condensing (heating) space of the same unit and then to that of the second unit, while the vapour from the second unit is discharged independently. (b) In a multiple effect evaporator as above, two or more units are arranged with two or more vapour compressors in parallel, and valves and passages are provided so that the number of vapour compressors in use may be varied, and so that vapour from the first unit may be compressed and passed together with live steam to the heating space of its own unit, and the vapour from any unit to the heating space of the next subsequent unit, the vapour from the last unit being discharged independently.—B. M. V.

Evaporator. B. S. Hughes, Assr. to Zaremba Co. U.S.P. 1,393,221, 11.10.21. Appl., 5.7.19.

A rectangular shell has a number of tubes extending across it from side to side, and a heating medium is supplied to the tubes by manifolds outside the shell, each row of tubes having a separate manifold connected with the tubes by removable nipples. The vapour chamber is above, and communicates with the interior of the shell.—B. M. V.

Evaporator. R. Kommerell. G.P. 338,508, 22.11.18.

The evaporator is constituted of a chamber wherein are disposed a number of vertical or inclined partitions, alternately fixed to the top and bottom walls of the chamber, so that the liquid to be evaporated in its passage through the chamber pursues a zigzag path. Heating elements, over which the liquid passes, are disposed between the partitions, which may themselves be employed as heating elements. The supply of liquid to the evaporator is automatically controlled by a throttle valve operated by a float placed within the last chamber but one of the evaporator. The device may be operated under reduced pressure.—J. S. G. T.

Drying of solutions etc.; Apparatus for ——. Aktiebolaget Indunstare. G.P. 338,483, 6.1.20.

The solution to be dried (evaporated) is delivered to a centrifugal device rotating about a vertical axis and is forced through orifices in the periphery thereof against the walls of a stationary outer chamber. The solution is thus distributed in a uniform state of division and flows on to a horizontal plate disposed below the centrifuge and rotating therewith, whence it is delivered in a fine state of division into the drying chamber, to which a gaseous drying agent is delivered along the axis of the rotating plate. The stationary chamber surrounding the centrifugal device is soldered to a hood forming a chamber disposed about the middle of the axle of the machine. A pipe connects this chamber with the storage vessel containing the solution to be treated, and the solution after passing this chamber is delivered to the centrifuge.
—J. S. G. T.

Transmitting heat; Method of and apparatus for ——. C. Hering. U.S.P. 1,390,783, 13.9.21. Appl., 17.7.16.

Heat is transmitted from a hot gas to a liquid by means of solid thermal resistances (*e.g.*, rods) of such magnitude that their hot ends reach a temperature about midway between that of the hot gas and the desired temperature of the liquid.
—B. M. V.

Oxidising gases; Process of ——. R. H. McKee. U.S.P. 1,391,332, 20.9.21. Appl., 5.4.19. Renewed 10.2.21.

The gases to be oxidised, together with oxygen, are passed in contact with a catalyst in the form of hydrated silica gel.—H. H.

Catalyst and method of making same. C. Bosch, O. Schmidt, and A. Mittasch, Assrs. to The Chemical Foundation, Inc. U.S.P. 1,391,666, 27.9.21. Appl., 4.6.14.

An intimate mixture of water, an organic nickel compound, and a soluble compound of silicon is dried and then reduced by hydrogen to form finely divided nickel intimately associated with dry, precipitated, non-colloidal silica.—B. M. V.

Cooling apparatus. H. E. Leavitt. U.S.P. 1,393,226, 11.10.21. Appl., 7.5.19.

A porous partition which is kept moist forms the oof of the cooling chamber and the floor of the hamber in which a vacuum is maintained.
—B. M. V.

Distilling, gas-washing and like columns, provided with horizontal perforated trays; Method of operating ——. C. Still. G.P. 335,552, 24.8.18.

The upward flow of gas or vapour through the olumn is so regulated in accordance with the umber and size of the perforations in the trays hat equilibrium results between the horizontal ayer of gas or vapour and the liquid resting above on any tray. Drains of special design are disosed so that the layers of liquid on the respective rays are connected one with another, the various ayers of liquid in the column thus operating as a ngle hydrostatic column. A number of columns ay be wholly or partly operated in this manner, nd the hydrostatic pressure utilised to transfer liquid from the bottom of one column to the top of the next. The process can be applied to the working up of crude benzol etc.—J. S. G. T.

Solution of solids; Apparatus for heating and continuous ——. A. Eberhard. G.P. 338,925, 21.12.19.

Two vertical tubes are disposed one within the other and their lower ends open into a filtering chamber, the outer tube opening above and the inner tube below the filter bed. The slit-width of the trumpet-shaped opening of the inner tube can be regulated by means of a disc which is adjusted from outside the filtering chamber by means of a lever. The hot solvent passes down the inner tube and then up through the filter bed and the material resting thereon and through the annular space between the two tubes.—J. S. G. T.

Electrically separating suspended bodies from non-conducting gaseous fluids; Process and apparatus for ——. E. Möller. E.P. 19,733, 1.9.13.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Liquid fuels in motors; Combustion of ——. F. Wehrmann. Z. Elektrochem., 1921, 27, 379—393. E. Terres, F. Wehrmann, and Lueg. *Ibid*, 423—441.

Experiments were carried out in a 40-h.p. four cylinder motor of modern type. The fuels used were benzol-spirit, containing about 50% of benzol, a high-boiling commercial benzol, and a medium benzol. Heat losses due to incomplete combustion.

and also those due to friction in and radiation from the cylinders were investigated. Two different carburettors were used with variable nozzles. The amount of unburnt gases in the exhaust was determined by combustion over copper oxide. Increase in the load increased and increase in piston speed decreased the efficiency of combustion. Excess of air or of fuel, and especially the latter, increased the proportion of gas unburnt. The possible effect of combustion of the lubricating oil is also discussed. (*Cf.* Fieldner and others, J., 1921, 111 A).—W. P.

Gaseous combustion at high pressures. Part II. Explosion of hydrogen-air and carbon monoxide-air mixtures. W. A. Bone and W. A. Haward. Proc. Roy. Soc., 1921, A **100**, 67—84.

The maximum pressures and the times taken for their attainment during the explosion of mixtures of hydrogen, oxygen, and nitrogen, have been measured, the initial pressure in each instance being 50 atm. With the mixture $2H_2+O_2+4N_2$ the maximum pressure, about 400 atm., was attained in 0·005 sec. The complete replacement of the nitrogen by oxygen resulted in an increase, and by hydrogen in a decrease, in the time taken. The time taken to develop maximum pressure was not constant with any given mixture of carbon monoxide and air, but depended on the hygroscopic state of the mixture. With the mixture $2CO+O_2+4N_2$ times varying between 0·18 and 0·24 sec. were obtained. The rate of cooling of this carbon monoxide mixture was only half that of the corresponding hydrogen mixture. Similar measurements of the rates of attainment of maximum pressures were made for combinations of these two mixtures. (*Cf.* Payman, J., 1920, 94 A.) —W. P.

Gas manufacture and tar recovery, with special reference to the gasification of lignites. K. Arnemann. Gas- u. Wasserfach, 1921, **64**, 665—673.

A description is given of plant for the gasification of lignite, with particulars as to costs, raw materials and yields. Processes are compared using lump lignite and lignite briquettes.—W. P.

Oil shales; Determination of the heat of reaction involved in the thermal decomposition of ——. R. H. McKee and E. E. Lyder. J. Ind. Eng. Chem., 1921, **13**, 678—684. (*Cf.* J., 1921, 650 A.)

A calorimetric method is described for determining the heat of reaction involved when shales are decomposed to form oil and gas; the value was found to be 421—484 cals. per g. of oil and gas produced. The primary product of the decomposition is not a mixture of oils, but a heavy solid or semi-solid bitumen. The decomposition temperature of the shale is 400°—410° C. Oils are not formed directly from the pyrobituminous material in the shale, but by a "cracking" process from the semi-solid bitumen. The coefficient of heat conductivity of shale is 0·00086 c.g.s. units.—W. P. S.

Petroleum oils; Evaporation test for light ——. M. Freund and G. Palik. Petroleum, 1921, **29**, 1029—1033.

Fifty c.c. of dry, filtered light oil at 20° C. is run from a stoppered, vertical pipette, with a capillary outlet adjusted to deliver 50 c.c. of distilled water at 20° C. in 5 mins. 35 secs., into a jacketed copper tube sloping at an angle of 20° to the horizontal and bent upwards to the vertical at the upper inlet end. Before running in the oil, the apparatus is heated to a steady temperature by passing a rapid current of steam through the jacket, and the current of steam is continued as the oil flows through the tube. Water condensed in the jacket escapes through a siphon at the bottom. The lower end of the tube leads into a vertical pipe, open at the top for the escape of vapour, and the residual oil flows through this pipe into a cooled 50 c.c. burette. The loss in volume is termed the evaporation value of the oil, and this, in conjunction with the sp. gr. of the oil, affords a good criterion of its technical value. The evaporation value, sp. gr., and further details of a number of samples of oil, and fractions of the same, are tabulated.—L. A. C.

Hydrocarbons; Pyrolysis of some ——. F. Denig. Chem. and Met. Eng., 1921, **25**, 751—753.

The vapour pressures generated by heating hexane, gasoline, kerosene, and vaseline to about 400° C. in a cylindrical bomb provided with a pressure-gauge and pyrometer, were measured, both during the heating and cooling stages, and residual gas and liquid were examined. Hexane and gasoline were not decomposed, but with kerosene the pressure rose rapidly above about 300° C., indicating decomposition. In two experiments kerosene was heated to approximately the same temperature, but in one the pressure was allowed to rise to 860 lb., and in the other to 1450 lb. per sq. in.; the residual gas, after cooling, contained 27% and 2·5% of olefines, and the liquid contained 14% and 25% of gasoline respectively, indicating that the olefines formed during cracking polymerised under increased pressure to form gasoline-like substances. Vaseline underwent extensive decomposition, 81% by volume being recovered as liquid, of which 34% and 54% distilled within the gasoline and kerosene ranges (below 150° C. and 150°—300° C.) respectively, these two fractions combined containing 20% of aromatic compounds and 9% of olefines.—L. A. C.

Petroleum oils; Catalytic oxidation of ——. C. E. Waters. J. Ind. Eng. Chem., 1921, **13**, 901—903.

To determine the effect of metals and metallic oxides on the oxidation of a paraffin base oil and a naphthene base oil, 10-g. samples of the oils were treated according to the general method for determining the carbonisation value, in 150 c.c. Erlenmeyer flasks in which strips of metal, 11 mm. × 72 mm. × 0·2—0·6 mm., were placed diagonally so as to be surrounded by a mixture of oil vapours and air, or to which 25 mg. of powdered oxide was added. Free access of air was allowed to the surface of the oil. The flask was placed in an air bath and the contents were heated to 250° C. in 30 min., maintained at this point for 2 hrs., and allowed to cool for 1 hr. The metal strips were thoroughly rinsed with 50 c.c. of petroleum ether before being removed from the flasks. The precipitates were filtered off, washed, dried, and weighed. In the case of the two oils investigated, zinc and aluminium did not act as oxygen carriers; cold-rolled steel, cast iron, nickel, and cobalt increased the asphalt content very slightly. Ferric oxide, made by igniting the hydroxide, had a greater effect. The oxides of nickel and cobalt caused a small increase in the rate of oxidation of the naphthene base oil, the former oxide being the more active. Copper caused a greater amount of oxidation than any other metal and was only exceeded in its effect by its oxide. The varnish-like coating formed on a brass strip in a test was found to have a protective action on the metal when this was used again, but when tried alone the varnish acted as a catalyst. The results obtained indicate that transformers should be constructed of zinc and aluminium, and that bearing metals should not contain copper.—S. S. A.

Petroleum and its distillates; Action of anhydrous stannic chloride on ——. G. Torossian. J. Ind. Eng. Chem., 1921, **13**, 903—904.

Stannic chloride reacts with and precipitates the tarry, resinous, oxygenated bituminous and sulphur-containing substances of crude petroleum and its crude distillates. The fact that a very small quantity of the reagent, 0·1—2%, produces a bulky precipitate from a heavy crude distillate is held to indicate polymerisation of the impurities. Precipitation takes place instantaneously, before all parts of the oil can have come into contact with the reagent, indicating that the action is physical as well as chemical, and that when part of the impurities is precipitated the remainder settles out as the result of disturbed equilibrium. The reagent is regenerated from the precipitates by strong sulphuric acid. It has no action on the saturated hydrocarbons of petroleum. The precipitates obtained with various types and fractions of crude petroleums are distinctive in appearance and quantity, so that the reaction may be used as a qualitative and quantitative test for petroleum products.—S. S. A.

Selenium; Action of —— on high-boiling mineral oils. K. Graefe. Z. angew. Chem., 1921, 34, 509.

The action of selenium at high temperatures on high-boiling mineral oils is analogous to that of oxygen and sulphur, and results in the liberation of hydrogen selenide and the formation of black asphaltic substances, accompanied by an increase in the mean molecular weight. The evolution of gas commences at about 160° C. and increases as the temperature rises to 300° C. The gas is free from hydrogen, and contains 2—4% of gaseous and heavy hydrocarbons, which may be largely eliminated by washing with mineral oil, and 70—80% of hydrogen selenide. The asphaltic residue contains about 1·3% of combined selenium, melts at 35·9° C., has a mean molecular weight of 450 compared with 368 for the original oil, and gives 33·7% of asphaltic substances insoluble in ether-alcohol.—G. F. M.

Hydrocarbon oil prepared from rape oil. A. Mailhe. Comptes rend., 1921, 173, 658—660. (*Cf.* J., 1921, 650 a.)

When rape oil is passed over a copper-aluminium catalyst at 550°—650° C., and the lighter liquid fractions are hydrogenated over reduced nickel at 180° C., a mixture of aromatic and cyclic hydrocarbons is obtained, the relative proportions of which vary with the activity of the nickel used.
—W. G.

Hydrogen from water-gas. Claude. *See* VII.

Patents.

Coal; Methods of separating —— into different grades adapted for various purposes. A. E. Findley. E.P. 169,776, 25.6.20.

Coal for the manufacture of metallurgical coke is isolated from slack by washing it with a solution of calcium chloride, zinc chloride, or sulphuric acid having a sp. gr. of 1·30. The residue is washed with similar solutions, having a sp. gr. of 1·48 for the isolation of coal containing 5—10% of ash. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 4473 of 1879.)—H. Hg.

Peat and similar substances; Process of treating ——. F. T. Dow. U.S.P. 1,393,435, 11.10.21. Appl., 24.10.19.

Water is drained from the peat and then air is alternately forced through the drained peat in one direction to loosen it and drawn through in the opposite direction.—H. Hg.

Peat; Process and apparatus for drying ——. E. Laaser and C. Birk. G.P. 333,209, 24.4.20.

In the liberation of water from the colloids of peat by heating (steaming) under pressure, the heat of he liberated water is utilised by carrying out the process in a bent tube, one limb of which acts as a preheater whilst the other serves as the heater or teamer. The hot water from the latter flows back y gravity and under the influence of the steam pressure, and preheats the fresh peat, after which it escapes through an outlet disposed at a level lower than the top of the steamer.—A. R. P.

Coke and gas oven. D. M. Rugg, Assr. to The Gas Machinery Co. U.S.P. 1,393,455, 11.10.21. Appl., 30.8.17.

The heating unit consists of two connected combustion chambers, built on opposite sides of the coking chamber. One of the combustion chambers of each heating unit is provided with an outlet, whilst the other chamber is connected by a duct with a pair of regenerator sections. The fuel gas is introduced into the latter combustion chamber.—A. G.

Gas producer of the revolving grate type. J. Pintsch A.-G. E.P. (a) 146,964, 6.7.20, and (b) 147,514, 8.7.20. Conv., 26.3.14 and 30.4.18.

(a) The shaft of the producer and the grate are both of annular type. (b) The inclination of the grate is steeper on the inner side than on the outer side.—A. G.

Gas producers. O. R. Verity. E.P. 169,940, 3.7.20.

The body portion of the producer is built of reinforced concrete, and is suspended from uprights by the aid of a reinforcing ring. Inside the body portion is a bell of refractory material, the space between the bell and the body being filled with a heat-insulating material.—A. G.

Gas producer. A. J. Bassett, Assr. to Milwaukee Reliance Boiler Works. U.S.P. 1,390,868, 13.9.21. Appl., 1.7.19.

Fuel is fed into the combustion chamber of a producer through a series of inclined tubes leading from a superimposed cylindrical distributing chamber; it enters the distributing chamber from a hopper through a valve movable vertically which facilitates the distribution of the fuel.—H. Hg.

Gas producer with preheater. Gebr. Hinselmann. G.P. 333,716, 14.3.17.

To obtain better control of the heating effect, the gases from the generator which are to heat the preheater are not passed directly into it but into a branched pipe, whence they pass into the lower and upper parts respectively of the preheating chamber and are removed through an intermediate zone, or they may pass from the branched pipe through independent heating chambers disposed within, but closed with regard to, the preheater.—A. R. P.

Lignite and the like; Drying and carbonisation of —— for the production of a tar rich in undecomposed bitumen. F. Seidenschnur. E.P. 169,847, 15.7.20.

Wet lignite is fed into the top of a drying chamber provided with step grates in zig-zag formation, superimposed upon a similar carbonising chamber. From the base of the carbonising chamber coke is either withdrawn or passed to a producer. Waste combustion gases are passed through the drying chamber and then, together with the steam evolved, are mixed with other waste gases and passed through the carbonising chamber at a temperature not above 500° C. A tar which is stiff at ordinary temperatures but which liquefies above 30°—40° C. is thereby produced.—H. Hg.

Pitch; Process and apparatus for coking ——. F. Puening, Assr. to American Tar Products Co. U.S.P. 1,392,879, 4.10.21. Appl., 12.1.18.

Pitch is charged into a number of vessels which are successively passed through a heated passage towards the hotter end thereof and from which the coked pitch is afterwards removed.—H. Hg.

Moisture from gas; Process and apparatus for separating ——. W. J. Baldwin. U.S.P. 1,393,335, 11.10.21. Appl., 23.3.21.

A gas purifier contains a hollow carrier having hygrometric material fixed upon its wall. Means are provided for rotating the carrier so as to propel the gas against the hygrometric material by centrifugal force.—R. L. F. R.

Gas; Process and means for removing suspended matter [tar] from ——. F. W. Steere and W. C. Woodland. U.S.P. 1,393,712, 11.10.21. Appl., 4.11.18.

An apparatus for removing tar from gas comprises a tubular collecting electrode, a discharge electrode, and means for heating the collecting electrode.—H. C. R.

Gas-washer; Rotating —— having a conical drum. Dortmunder Vulkan A.-G. G.P. 334,974, 10.3.20.

A drum having sides tapering towards the bottom and a perforated base rotates within a chamber containing the washing liquid. The gas is led into the drum through a central tube which rotates with the drum, and a spray of washing liquid is discharged into the inlet tube, so that intimate contact is effected between gas and liquid.—J. S. G. T.

Oils and the like; Cracking of ——. J. H. Adams. E.P. 141,689, 1.4.20. Conv., 11.4.19.

A vertical cracking vessel consists of a tube heated over the upper part of its length and attached at the upper end to the bottom of a wider tube serving as a reservoir. A rotating shaft extending throughout the length of both tubes is fitted with a cylindrical attachment in the heated portion of the tube so that only a thin annular layer of oil is subjected to the heating action of the walls of the tube. Scrapers for removing carbon from the walls of the tube and means for agitating the oil in the heated portion are also provided, and perforated plates attached to the shaft in the reservoir tube serve to break up ascending bubbles of vapour and thus increase the scrubbing action of the oil in the reservoir. Carbon settles to the bottom of the tube, and is removed periodically. Oil is fed under pressure into the apparatus either at the top of the reservoir, or below the heated zone. Vapour passes from the top of the reservoir through scrubbers into a condenser maintained under the pressure prevailing in the apparatus.—L. A. C.

Hydrocarbons; Process for cleaving and converting of heavy —— into lower boiling specifically lighter products. C. Cordes, Assee. of F. C. Thiele. E.P. 147,648, 8.7.20. Conv., 28.7.14.

Crude mineral oils are distilled in the presence of a catalyst consisting of a coarsely crushed hydrous silicate containing a high percentage of silicic acid readily soluble in alkalis, such as that found in the oligocene formation in South Georgia and Florida. The still is heated so that the temperature rises slowly to a maximum of 270° C., and when the distillate has sp. gr. 0·780—0·800, dry steam is admitted. When the distillate has sp gr. 0·860, the residue is discharged and treated to render it suitable for use as a lubricant, *e.g.*, by cooling to separate paraffin wax and subsequent distillation in another still to remove lighter fractions. Both the distillate and the residue discharged from the still are free from sulphur and asphaltic compounds.—L. A. C.

Hydrocarbon oils; Process of distilling ——. M. Benson. E.P. 169,763, 7.6.20.

Cold crude oil, *e.g.*, 1 pt. of 10·5° B. (sp. gr. 0·966) Mexican crude, and 3 pts. by weight of steam, superheated to, *e.g.*, 1000° F. (about 540° C.), are forced separately into a mixing chamber under a pressure of, *e.g.*, 100 lb. per sq. in., and the products pass through a regulating valve into an expansion chamber, whence the vapours pass to a condenser. A yield is claimed of 81% of undecomposed liquid distillate consisting mainly of gas oil. —L. A. C.

Motor fuel; Method of making ——. A. A. Backhaus, Assr. to U.S. Industrial Alcohol Co. U.S.P. 1,378,858, 24.5.21. Appl., 14.7.19. Renewed 16.10.20.

Ether (3 pts.) is added to gasoline (50 pts.), benzol (20 pts) is then added, and finally alcohol (27 pts.).

Gasoline; Manufacture of ——. G. H. Taber, jun., Assr. to Gulf Refining Co. U.S.P. 1,390,472, 13.9.21. Appl., 6.4.17.

Casinghead gasoline is "weathered" to produce vapours of mixed light and heavy gasoline; the heavy constituents of the vapours are dissolved in a heavier mineral oil, and, after subsequent separation from the mineral oil by distillation, are blended with another mineral oil.—L. A. C.

Hydrocarbons; Method for the purification of [non-liquid] ——. J. M. Treneer and C. S. Benjamin, Assrs. to A. J. Doremus and H. G. Turner. U.S.P. 1,392,370, 4.10.21. Appl., 4.6.20.

Non-liquid hydrocarbons are treated with benzol containing sulphur dioxide and the liquid impurities are subsequently separated from the mass. —L. A. C.

Petroleum-oils; Distilling ——. F. B. Lewis and T. S. Cooke, Assrs. to Standard Oil Co. U.S.P. 1,392,584, 4.10.21. Appl., 7.5.17.

A mixture of sufficiently and insufficiently cracked vapours, produced in a still for cracking petroleum oils under pressure, is passed through a series of separated bodies of petroleum oil maintained at temperatures such as to condense all insufficiently cracked fractions. The uncondensed sufficiently cracked vapour passes to a separate apparatus for condensation.—L. A. C.

Hydrocarbons; Process of converting [heavy into lighter] ——. C. P. Dubbs. U.S.P. 1,392,629, 4.10.21. Appl., 19.3.19.

A stream of oil flows through a zone in which it is heated to cracking temperature but is not vaporised, and thence passes to a zone in which vaporisation takes place. The unvaporised residue is removed from the apparatus without coming in contact with the oil in the heating zone, and the vapours are subjected to reflux condensation, the condensed fraction being returned for further cracking treatment. A pressure is maintained on the material during the process of distillation. —L. A. C.

Filtration [of paraffin wax from oil]; Art of ——. H. F. Glair, Assr. to Standard Oil Co. (of Indiana). U.S.P. 1,392,758, 4.10.21. Appl., 11.8.20.

The chilled oil is forced through a filter by the pressure of the oil applied uniformly over the surface of the filter, and subsequently the wax is melted and removed through the filter.—R. L. F. R.

Distilling solids and liquids [petroleum distillates] and cracking solids, liquids, and gases; Process of ——. A. J. Paris, jun. U.S.P. 1,392,788, 4.10.21. Appl., 3.5.15.

The material is passed through molten metal and the products are compressed and condensed. —L. A. C.

Lubricating greases; Manufacture of ——. R. Maclaurin, and Scottish Bye-Products, Ltd. E.P. 169,573, 24.7.20.

Crude oil obtained by a process for distilling coal in which the oil suffers minimum decomposition (*cf.* E.P. 24,426 of 1913; J., 1914, 1148), after preliminary treatment with dilute sulphuric acid and an alkali, with or without a subsequent heating to 200° C., is agitated with a dilute mineral acid, *e.g.*, 2½ gals. of 5% hydrochloric acid per 7 gals. of oil, and sufficient sodium nitrite to react with the acid, *e.g.*, 14 gals. of 3% solution, is then added. The greasy emulsion which gradually forms is suitable for use as a lubricant.—L. A. C.

Lubricating oils; Process of reclaiming used ——. W. L. Jordan, Assr. to Celite Products Co. U.S.P. 1,393,223, 11.10.21. Appl., 21.11.16.

THE oil is mixed with finely divided kieselguhr and filtered under pressure.—B. M. V.

Lubricating oil; Manufacture of —— *from producer-gas tar. Manufacture of a substitute for vaseline having the properties of petroleum vaseline.* L. Landsberg. G.P. (A) 340,074 and (B) 339,988, 15.10.18.

(A) PRODUCER-GAS tar is treated at 20°—50° C. with petroleum ether, petroleum, or gas-oil, undissolved asphalt is separated, the solution is agitated with sodium hydroxide solution to remove creosote, and is washed with water. The solvent is subsequently removed by distillation, leaving a residue of paraffin wax and oil. (B) The product obtained as described in (A) is converted into a substitute for vaseline by successive treatment with concentrated sulphuric acid or oleum and an alkali.—L. A. C.

Washing coal and concentrating ores and minerals; Method and apparatus for ——. T. M. Chance. U.S.P. 1,392,399, 4.10.21. Appl., 27.8.17.

SEE E.P. 119,038 of 1918; J., 1919, 754 A.

PATENTS.

arbonisation of subdivided fuel; Method and apparatus for ——. Underfeed Stoker Co., Ltd., and S. McEwen. E.P. 169,389, 11.10.20. Addn. to 154,253 (J., 1921, 37 A).

HE volatile products of carbonisation are passed rough a heat recuperator and a condenser; part of the uncondensed gas is then returned to the carbonising chamber, being used for blowing fuel into the chamber and for combustion. The recuperator is used to preheat the gas and/or the air required for combustion.—H. Hg.

Low temperature carbonisation and gasification of coal and other carbonaceous material. C. W. Tozer. E.P. 169,580, 30.7.20.

THE fuel is carbonised without the use of a binder at a temperature not exceeding about 600° C., preferably between 400° C. and 600° C., and under a vacuum of about 70—150 mm. of mercury. The yield of motor spirit is increased by subjecting the gases evolved, after the condensation of tar and the removal of tar fog, to compression, followed by sudden expansion. A further quantity of motor spirit is obtained by the usual method of washing with oil.—A. G.

Coal, wood, shales, etc.; Apparatus for devolatilising ——. C. M. Garlaud. U.S.P. 1,391,825, 27.9.21. Appl., 3.3.19.

THE retort proper extends through a heating chamber, and is provided inside with a number of parallel vertical partitions.—A. G.

III.—TAR AND TAR PRODUCTS.

Vacuum tar from bituminous coal. H. Tropsch. Brennstoff-Chem., 1921, 2, 312—313.

A SAMPLE of vacuum tar from a bituminous coal gave 27·6% of a low-boiling neutral oil, 40·2% of a neutral oil boiling above 150° C., 1·6% of a substance similar to bitumen, 21·0% of phenols, 0·49% of carboxylic acids, and 0·46% of other substances soluble in water and caustic soda solution.—W. P.

Naphthalene; Determination of —— *in tar and tar-oil.* M. Hofsäss, H. Herrmann, and R. Mezger. Gas- und Wasserfach, 1921, 64, 722—723.

IN correspondence relating to the method described previously (J., 1921, 502 A), it is pointed out that: hydrogen, on account of its lower density and the higher degree of purity of the commercial product, should prove more efficient than coal gas as a volatilising agent; homologues of naphthalene, such as acenaphthene, phenanthrene, and chrysene, are also volatilised and precipitated as picrate under the conditions described, but the small quantities present in commercial products can usually be neglected; it is doubtful whether the phosphoric acid would retain all the bases present in highly basic fractions of tar; the time required for the operation, *i.e.*, 3½ hrs., can often be considerably reduced as the disappearance of the deposit of naphthalene formed at first on the dry bulb marks the completion of the reaction. With slight modifications the method should be suitable for adoption as a standard method of analysis.—L. A. C.

α-Naphthol; Electrolytic oxidation of ——. *Electrolytic reactions of naphthalene and its derivatives. Part II.* K. Ono. Nippon Kwagaku Kwai Shi (J. Chem. Soc. Japan), 1921, 42, 559—578. (*Cf.* J., 1921, 253 A.)

USING a mixture of 6 g. of α-naphthol, 150 c.c. of acetone, and 100 c.c. of 20% sulphuric acid as anode solution, a lead peroxide plate as anode, and a lead plate as cathode, oxidation was effected by passing a current of 1·6 amp. for 3 hrs. at 18°—23° C. From the anode chamber α-naphthoquinone, a compound of α-naphthol and α-naphthoquinone (Ber., 1909, 42, 1153), phthalic acid, and a dark violet-coloured compound were isolated, while a red compound was obtained from the cathode chamber. By the electrolytic oxidation of αα-dinaphthol and the α-naphthol-α-naphthoquinone compound, α-naphthoquinone and a mixture of α-naphthoquinone and phthalic acid respectively were obtained. (*Cf.* J.C.S., i., 726.) —K. K.

Anthraquinone and its derivatives as reduction catalysts. C. Sunder and M. Bader. Bull. Soc. Ind. Mulhouse, 1921, 87, 187—189. (*Cf.* J., 1921, 655 A.)

The use of anthraquinone as an assistant in the reduction of compounds which are reduced with difficulty is due to its repeated reduction followed by the oxidation of the anthrahydroquinone formed. Neither benzoquinone nor naphthoquinone acts in this manner. Derivatives of anthraquinone, such as hydroxy-, chloro-, amino-, and sulphonated anthraquinones are also reduced to anthrahydroquinone derivatives; the only one of interest as a catalyst is 2-hydroxyanthraquinone, but its action is not so effective as that of anthraquinone. One derivative of anthraquinone, however, was discovered which acts four times as strongly as anthraquinone, and this derivative has been made the subject of a sealed note.—F. M. R.

Tungsten and naphthalene. Andrews and Dushman. *See* X.

Patents.

Boiling and evaporating oil, oil-containing liquids and other organic and pyrogenously decomposable liquids; Vessel for ——. A. J. G. J. Irinyi. E.P. 144,298, 3.6.20. Appl., 26.6.14.

The inner walls of a vessel are provided with ribs of sufficient height to project through a film of vapour adhering to the wall, while the pitch of the ribs is such that no vapour bubbles adhering to the surfaces of two consecutive ribs can join; thus, in a vessel for heating coal tar oil, the ribs may be about 1 in. in height, ¼ in. in thickness, and spaced about 1 in. apart.—L. A. C.

Alkylanilines; Production of ——. E. I. du Pont de Nemours and Co., Assees. of A. E. Houlehan. E.P. 145,743, 2.7.20. Conv., 7.7.17.

Alkylanilines are obtained by heating together at a high temperature aniline, an alcohol, and a catalyst containing iodine, such as methyl iodide. For example to obtain dimethylaniline, 93 pts. of aniline, 96 pts. of methyl alcohol, and 1·35 pts. of methyl iodide are heated in a digester at 220°—240° C. The liquids separate into two layers, one containing dimethylaniline and the other water, the excess of alcohol, and iodine compounds. The aqueous layer is distilled to recover the alcohol, and the residue evaporated to dryness. The dry product containing iodine is likewise catalytically active and may be employed instead of the methyl iodide in subsequent operations.—G. F. M.

Toluene; Manufacture of chlorinated derivatives of ——. British Dyestuffs Corp., Ltd., A. G. Green, and D. A. Clibbens. E.P. 169,025, 23.6.20.

The chlorination of toluene-*p*-sulphonic acid or its soluble salts in aqueous solution results in the formation of 2.5-dichloro- and 2.5.6-trichloro-toluene-4-sulphonic acids, which are readily separated from one another by taking advantage of the much smaller solubility in water of the sodium salt of the trichloro-acid. If 680 g. of toluene-*p*-sulphonic acid, neutralised with sodium hydroxide and dissolved in sufficient water to make about 11 l., is chlorinated until 10 c.c. of the liquid has acquired an acidity equivalent to 5·5 c.c. of *N*/1 alkali, nearly the whole of the sodium 2.5.6-trichlorotoluene-4-sulphonate separates out in crystals, and the dichlorosulphonate is recovered in a practically pure condition by evaporating the mother liquor. The sulphonates on hydrolysis give pure 2.5-dichloro- and 2.5.6-trichloro-toluene respectively. —G. F. M.

Tar oils; Process for converting —— into neutral oils suitable for lubricating purposes. M. Melamid. E.P. 146,898, 6.7.20. Conv., 11.3.19.

See G.P. 335,610 of 1919; J., 1921, 575 A.

Fusion process. U.S.P. 1,379,619. *See* I.

Coking pitch. U.S.P. 1,392,879. *See* IIa.

IV.—COLOURING MATTERS AND DYES.

Indigo; Fusion of phenylglycine-o-carboxylic acid for the production of ——. M. Phillips. J. Ind. Eng. Chem., 1921, 13, 759—762. (*Cf.* J., 1920, 685 A.)

When potassium hydroxide is used as the condensing agent, the best yield (89%) of indigo is obtained by fusing the mixture at 260° C. for 10 mins., and using 12—16 mols. KOH per mol. of phenylglycine-*o*-carboxylic acid. With sodium hydroxide the best yield (67%) is obtained by using 28—32 mols. NaOH per mol. of the carboxylic acid and fusing the mixture at 270° C. for 25—30 mins. If a mixed alkali is used, the yield of indigo increases with the proportion of potassium hydroxide present in the mixture of alkalis.—W. P. S.

Indigo; Constitution of the polysulphonated derivatives of ——. Grandmougin. Comptes rend., 1921, 173, 586—587.

Indigotintetrasulphonic acid on oxidation gives a potassium salt of isatindisulphonic acid, which is converted by bromine into 5.7-dibromoisatin. Hence the original indigo derivative must have been 5.5′.7.7′-indigotintetrasulphonic acid.—W. G.

Patents.

Brown sulphur dyestuffs; Preparation of ——. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. G.P. 340,124, 5.7.19. Conv., 12.12.17.

Nitro-*p*-toluic acids are fused with polysulphides. The acids are made from *p*-cymene, obtained as a by-product from sulphite-cellulose works, by oxidising with nitric acid to *p*-toluic acid, which is then nitrated to mono- or di-nitro-compounds. The dyestuffs are fast to light.—A. R. P.

Azo dyestuffs and intermediate products; Manufacture of ——. O. Y. Imray. From Soc. of Chem. Ind. in Basle. E.P. 169,863, 23.7.20.

See U.S.P. 1,359,969 of 1920; J., 1921, 464 A.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Cotton fabrics; Effect of certain fireproofing solutions on ——. R. L. Sibley. J. Ind. Eng. Chem., 1921, 13, 676—677.

A 3·5% sodium tungstate solution was as efficient as a stronger solution and had decidedly less injurious effect (as determined by the breaking strength) on the fabric than had solutions containing ammonium chloride and borax, ammonium chloride and boric acid, borax and dextrose, borax and magnesium sulphate, etc.—W. P. S.

Canvas; Water resistance of treated —— during continuous exposure to weather. F. P. Veitch and T. D. Jarrell. J. Ind. Eng. Chem., 1921, 13, 672—676.

Waterproofing compositions consisting of amorphous mineral wax with either beeswax, lead oleate, copper oleate, paraffin wax, asphalt, Japan wax, ceresin, resin, candelilla wax, etc., or mixtures of the same, were applied to strips of canvas which

were then exposed in the open air for about 1 year. All the treatments increased the water-resistance of the fabric sufficiently to render the latter efficient for use as a permanent cover in a smooth position (wagon tops, tents, etc.). The addition of lead oleate or asphalt increased the water-resistance, but copper oleate was not as effective as was lead oleate. Beeswax was much more effective as a waterproofing agent than any of the other hard waxes used, and amorphous mineral wax was better than paraffin wax. The results obtained, when expressed numerically, were lower than those found by tests (funnel and spray tests) applied in the laboratory.
—W. P. S.

Lignin in cellulose pulps; Comparative determinations of ——. E. Heuser and G. Wenzel. Papierfabr., 1921, **19**, 1177—1184.

The lignin in a sample of unbleached shredded Mitscherlich sulphite-cellulose was determined by a number of different methods. Becker's modification of König and Rump's method using 72% sulphuric acid gives too high results owing to the separation on dilution of colloidal products which contain no lignin, but are weighed as such. The results by König and Becker's modification of Krull's method using gaseous hydrochloric acid, and König and Rump's method using dilute hydrochloric acid under pressure are also too high owing to the incomplete saccharification of the cellulose. On the other hand, reliable determinations of lignin in cellulose are obtained by a modification of Willstätter and Zechmeister's method (J., 1913, 822) in which 1 g. of the sample is covered with 70 c.c. of 41·4% hydrochloric acid in a stoppered flask, frequently shaken during 18 hrs., diluted with ten times the volume of water, and boiled for 10 mins. (*Cf.* J.C.S., Dec.)—F. M. R.

Cellulose; Studies on ——. *I. The hydrogen capillary viscosimeter and its applications.* M. Nakano. Kōgyō-Kwagaku Zasshi (J. Chem. Ind., Japan), 1921, **24**, 918—926.

The viscosity of 0·5% cellulose solution in cuprammonium solution has been investigated, using the hydrogen capillary viscosimeter of Gibson and Jacobs (*cf.* J., 1920, 541 A). The viscosity was found to be constant for at least 2 hrs., and within this period can be determined very accurately. On long standing, the viscosity decreases very gradually, notwithstanding protection of the solution from light and air. Using the viscosimeter, the effect of heating in the air and of mercerisation upon the viscosity of cotton cellulose was investigated. The cotton was heated at 100°—105° C., 120°—125° C., 140°—145° C., 160°—165° C., and 180°—185° C., respectively, for 4 hrs., whilst for mercerisation 10 g. of cotton was treated with 11%, 17%, and 20% sodium hydroxide solution for 24 hrs. In all cases, the viscosity was reduced in proportion to the elevation of temperature and the increase in concentration of the alkali.—K. K.

Oxycellulose; The alkali-solubility and reducing powers of, and formation of furfural from ——. C. G. Schwalbe and E. Becker. Zellstoff u. Papier, 1921, **1**, 135—139. Chem. Zentr., 1921, **92**, III., 1117.

Four oxycelluloses and three hydrocelluloses have been compared with regard to their behaviour with alkalis, absorption of barium, acidity, reducing powers, and yield of furfural. The formation of furfural is not a characteristic property of oxycelluloses, and there are considerable differences in the resistance to alkalis, the copper numbers, and acidity. Two classes of oxycelluloses may be distinguished, viz., those oxycelluloses in which an acidic character predominates, and those in which an aldehydic character predominates. Comparison of oxycelluloses with hydrocelluloses shows that the acid character of the latter has almost entirely disappeared. Denitrated cellulose and denitrated Chardonnet artificial silk show at the same time the characteristics of oxycelluloses and hydrated celluloses, but the oxycellulose character is accentuated in the former case, whilst the hydrated cellulose character is accentuated in the latter case.
—F. M. R.

Soda and sulphate pulps from coniferous woods; Chemical constitution of —— *and their bleaching qualities.* S. D. Wells. J. Ind. Eng. Chem., 1921, **13**, 936—939.

Soda and sulphate pulps were prepared from pine chips in a tumbling digester under varying conditions of time, temperature, pressure, and strength of reagents, and portions of the pulped material were then bleached with bleaching powder at 100° F. (38° C.) in glass vessels provided with mechanical stirrers, the operation being continued until only a trace of active chlorine remained. The amount of bleaching powder used in each case was estimated. The bleached pulps were well washed, pressed and allowed to dry by exposure to the air at 70° F. (21° C.). During bleaching alkali-soluble constituents are formed in amount increasing with increase in the strength of the bleaching liquor. Cellulose degradation proceeds to a considerable degree before the colour is sufficiently removed, indicating the need for an improved method of bleaching. The amount of colour is small and it is possible to reduce the consumption of bleaching powder by bleaching in two stages with a washing operation between the two steps. The pentosan content was reduced by digestion but was unaffected by bleaching. The methoxyl contents of both soda and sulphate pulps are very low and indicate the absence of lignin. In this respect the sulphate pulp is better than the soda pulp. Bleaching further reduces the methoxyl figure. The sulphate process gives higher yields of pulp of better quality than the soda process, the resistant fibrous material being isolated with less loss.—S. S. A.

Paper sizing; Substitutes for use in ——. A. Kolb. Papier-Fabr., 1921, **19**, 1141—1144.

The alkali salts of fatty acids (soaps), and particularly the salts of stearic acid, may be used for sizing paper in place of rosin. Soaps, used in conjunction with sodium silicate, yield a paper of good body and exceptional imperviousness. Alum is used as precipitant, and the composition of the precipitate varies according to the procedure in precipitation. All the precipitated products, however, are liquid at 100° C., and are, therefore, particularly suitable for sizing. The sizing action is improved by increasing the surface of the particles of the size by an addition of sodium silicate. Alum should not be used in too great excess because, owing to its acidity, large aggregates of free fatty acid are formed which have not so great a covering power in sizing as the fine flocks of the aluminium salts of the fatty acids.
—F. M. R.

Sulphate-cellulose works; Removal of the odour in ——. C. G. Schwalbe. Zellstoff u. Papier, 1921, **1**, 69—72. Chem. Zentr., 1921, **92**, IV., 1019—1020.

Considerable quantities of evil-smelling gases can be rendered odourless by a small quantity of wood (*cf.* G.P. 319,594; J., 1920, 541 A), and the wood fibre is destroyed only after prolonged use. Wood which has lost its power of absorption can be used for wood pulp by boiling with alkali without production of any mercaptan smell. By using this cheap oxidising medium for the odourous substances, the hitherto necessary limitation of the quantity of sodium sulphide used in boiling can be avoided, and an increase in the quantity of sodium sulphide used results in improved yield and quality of the fibre.—F. M. R.

Preparation of viscose. Plauson. *See* I.

Patents.

Fibrous material [for constructional purposes]; Manufacture of ——. H. Wade. From The Barrett Co. E.P. 165,240, 1.4.20.

Comminuted waterproofing materials, such as pitch, asphalt, resin, etc., are incorporated with beaten pulp in such quantity that the resulting dry composition contains 50—90% or more of the waterproofing constituent. The mixture is made up into thin sheets, which are superimposed (preferably while wet), pressed, dried, and subsequently cemented together by heat and hydraulic pressure. The final product is waterproof, has a sp. gr. greater than 1, and possesses a smooth surface. —D. J. N.

Fibrous substances [flax]; Treatment of ——. C. R. Turner. E.P. 169,407, 13.12.20.

Fibrous materials such as flax, after retting and while still made up in bundles, are treated in a centrifugal separator to remove moisture, then freed from gums and similar substances by means of a spray of water directed outwards from the centre of the separator while it is in motion, and finally dried under similar conditions by means of hot air.—A. J. H.

Fibrous [insulating] material. W. W. Carter, Assr. to Industrial and Research Laboratories. U.S.P. 1,365,891, 18.1.21. Appl., 31.7.19.

Fibrous material, *e.g.*, paper stock, is mixed with an alkaline solution of an organic filling material, such as a resin or drying oil, and with an alkaline solution of cellulose xanthate, and the mixture is treated with a neutralising agent, preferably sodium bisulphite, whereby resin or the like is precipitated among the fibres. The material is then formed into sheets, and cellulose regenerated from the xanthate by the action of heat and pressure.

Fibrous filtering films; Process for making ——. C. H. Van Nostrand and H. E. Schulse. U.S.P. 1,392,989, 11.10.21. Appl., 8.2.18.

Loose fibrous material is spread evenly over a suitable surface, lightly rolled to produce a uniformly porous sheet, and brought into rolling contact with a mould of the desired shape. The sheet is picked up by, and formed on, the mould, which is then removed, leaving a shaped filtering film of uniform porosity.—D. J. N.

Cellulose acetate products; Treatment of —— *[to increase their affinity for dyestuffs]*. British Cellulose and Chemical Mfg. Co., Ltd., and J. F. Briggs. E.P. 169,741, 29.4.20.

Filaments, threads, or fabrics, made from the lower acetates of cellulose, *i.e.*, containing 2—2½ acetyl groups per mol. of cellulose $C_6H_{10}O_5$, and not obtained by the partial hydrolysis of higher acetates, may be made to show greater affinity for dyestuffs by subjecting them to a superficial hydrolysis with alkali, preferably caustic soda, in 0·1—1% solution at 40°—80° C., and in such quantity that the loss in weight of the material, due to hydrolysis, is not greater than 10%, and preferably not more than 5%. The best results are obtained with 0·1% caustic soda solution at 70°—75° C. The material may be superficially hydrolysed, washed, scoured, and transferred to a separate dye-bath, or the two operations, hydrolysis and dyeing, may be carried out concurrently in the same bath, in which case dyes must be used which are unaffected by weak alkali, *e.g.*, direct cotton dyes, sulphur dyes, and vat dyes. This treatment, while not materially affecting the weight, strength, and other desirable characteristics of cellulose acetate threads, renders them capable of being dyed with any of the dyestuffs used for non-acetylated cellulose threads and, moreover, by varying the degree of hydrolysis, any desired shade of colour may be obtained.—D. J. N.

Cellulose; Dissolving ——. I. Kitsee. U.S.P. 1,390,995, 20.9.21. Appl., 18.10.19. Renewed 4.8.21.

Cellulose is dissolved by subjecting it to a rubbing action in conjunction with copper in the presence of ammonia.—A. J. H.

Artificial silk; Manufacture of ——. E. Bronnert. U.S.P. (A) 1,393,197 and (B) 1,393,199, 11.10.21. Appl., 10.7. and 14.9.20.

(A) Viscose threads are treated in a coagulating bath containing a salt and an acid, the proportion of the latter being approximately inversely proportional to the square root of the size of thread desired. (B) Viscose is squirted into an acid precipitating bath the concentration of which is increased proportionately to the increase in the fineness of the thread desired, the increase in the consistency of the viscose used, and the increase in the size of the openings through which the viscose is forced. (*Cf.* E.P. 166,931 of 1920; J., 1921, 654 A.)

Artificial threads from viscose; Production of ——. H. Jentgen. G.P. 340,289, 16.11.20.

Viscose is spun through suitable jets into an aqueous extract of fir twigs or bark to which an acid or an acid salt has been added. The product can be uniformly dyed even in pale shades and possesses a high elasticity and tensile strength.—F. M. R.

Sulphite cellulose; Process for the production of high percentage ——. E. Bronnert. U.S.P. 1,392,047, 27.9.21. Appl., 13.9.20.

The material is boiled at low pressure with 1% sulphuric acid before the usual digestion with calcium bisulphite or magnesium calcium sulphite lye under pressure.—H. R. D.

Cellulose from straw or bamboo; Production of ——. F. Paschke. G.P. 340,338, 14.1.20.

A sodium carbonate lye containing a small quantity of sodium hydroxide is used; the latter improves the colour of the product without injury. The lye may be prepared from the waste alkali lyes or residues of the Leblanc process.—F. M. R.

Wood pulp and cellulose fodder from wood refuse etc.; Production of ——. "Drim" Futtermittel- u. Zellstoffges.m.b.H. G.P. 341,673, 7.8.18.

The wood or fibre mass which has been steamed and extracted is treated, in a comminuted moist condition, with gaseous chlorine in a continuously working counter-current apparatus.—F. M. R.

Paper-filler and process of making the same. W. N. Kohlins. U.S.P. 1,390,297, 13.9.21. Appl., 27.2.19.

The composition contains magnesium hydroxide, calcium sulphate, aluminium hydroxide, and calcium hydroxide.—A. J. H.

Sizing and method of making the same. W. P. Upham, Assr. to Ros-Aux Co. U.S.P. 1,392,988, 11.10.21. Appl., 29.1.17.

Starchy material, hydrolysed under pressure, is mixed with a saponified resin.—D. J. N.

Sulphite [-cellulose] liquors; Treating waste —— *and products [tanning material] obtained therefrom.* Atomized Products Corp., Assees. of W. H. Dickerson. E.P. 143,874, 26.5.20. Conv., 16.11.18.

The waste liquor is treated with a salt, such as chromium or aluminium sulphate, in sufficient quantity to precipitate the calcium and to combine with the magnesium compounds present. The treated liquor is sprayed through a nozzle under a pressure of 100—1000 lb. per sq. in. into a chamber where it meets air or flue gases heated to 150°—260° C. The dry powder obtained in this manner is non-hygroscopic, is substantially free from calcium, and is suitable for use as an adhesive or tanning material.—F. M. R.

[*Sulphite-cellulose waste liquor;*] *Process and apparatus for reclaiming by-products* [*from* ——]. P. A. Paulson. U.S.P. 1,393,241, 11.10.21. Appl., 12.4.20.

Sulphite-cellulose waste liquor is heated under suitable conditions of temperature and pressure, whereby lignin and resinous products are precipitated, the steam and sulphur dioxide liberated being utilised for digesting further quantities of wood. —D. J. N.

Sulphite-cellulose waste liquors; Utilisation of ——. L. Stein. G.P. (a) 339,741, 19.9.19, and (b) 340,453, 18.12.19.

(a) The liquor, after warming, if necessary, is treated with a small quantity of a substance such as glue sufficient to precipitate only a small fraction of the tannin and lignin substances in the solution and to give, after filtration, a clear liquor which may be used for dressing or sizing purposes. (b) The clarification of the solution is carried out in the presence of a colloid such as gum arabic, and gelatin or glue from leather is used as a coagulant. —A. R. P.

Yarn or the like; Apparatus for drying ——. G. Bailey, Assr. to H. F. Anderton. U.S.P. 1,383,510, 5.7.21. Appl., 31.1.17.

See E.P. 108,684 of 1916; J., 1917, 1092.

Fibrous material from wood or like cellulose-containing substances; Manufacture of ——. L. Enge. E.P. 169,802, 3.7.20.

See G.P. 302,424 of 1917; J., 1920, 444 a.

Viscose silk; Manufacture of ——. E. Bronnert. U.S.P. 1,393,198, 11.10.21. Appl., 30.8.20.

See E.P. 166,931 of 1920; J., 1921, 654 a.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Vat dyeing; Effect of the degree of alkalinity in ——. L. Kollmann. Textilber., 1921, 2, 379—381.

The effect of the degree of alkalinity of the vat on dyeing is reviewed, and a new method for the application of vat dyes, other than anthraquinone vat dyes, to animal fibres is outlined. A vat is prepared containing per litre 15 g. of 20% Indigo paste, 5 g. of hydrosulphite, and 5—15 g. of elutriated chalk or the equivalent quantity of zinc oxide, and wool is dyed dark blue by three immersions, lasting for 10 mins. each, in this vat at 75° C. A more or less complete solution is obtained at the boil, but on cooling, the leuco-compound crystallises in glistening plates. By altering the proportions to 3 pts. of Indigo, 15 pts. of prepared chalk, 10 pts. of hydrosulphite, 100 pts. of water, and 1 pt. of loose wool, and dyeing for ½—1 hr. at 75°—100° C., the dye-bath is almost completely exhausted, and the wool is dyed dark blue. The dyed shade is at least as fast to milling and rubbing as dyeings prepared from an alkaline vat, and there is no danger of injuring the wool. A satisfactory dark blue shade fast to milling and rubbing can also be dyed on wool from a vat containing 3 pts. of Hydron Blue R powder, 20 pts. of prepared chalk, 10 pts. of hydrosulphite, 80 pts. of water, and 1 pt. of wool for ¾ hr. at 95°—100° C. The dye-bath is completely exhausted, but the material requires several hours' exposure to air for complete oxidation. In this instance the prepared chalk cannot be replaced by zinc oxide. Satisfactory dyeings on wool can also be obtained by this method with Thioindigo Scarlet 2 G and Ciba Violet B.—F. M. R.

Formic acid thickening [*in printing*]. C. Sunder. Bull. Soc. Ind. Mulhouse, 1921, 87, 195—196.

A discharge paste prepared from starch in presence of formic acid and then neutralised is recommended and is particularly successful on Para Red. A mixture of 100—120 g. of starch, 7—10 g. of 90% formic acid, and 400 c.c. of water is boiled for 20 mins., cooled to 50° C., neutralised, and a concentrated solution of 50 g. of Rongalite C is added; the whole is then made up to 1 kg. In order to produce as effective a mixture, a greater quantity of acetic acid would be required, and consequently the paste would contain a large quantity of useless sodium acetate, whereas the small quantity of sodium formate contained in the above mixture does not diminish the power of the discharge.—F. M. R.

Patents.

Wool, woollen yarns and the like; Treatment and scouring of ——. C. Bennert. E.P. 145,448, 18.6.20. Conv., 8.2.15.

Wool is rendered more soft, elastic, and glossy by treatment, during or after scouring, with liquors containing protein degradation products (lysalbinic and protalbinic acids) prepared according to E.P. 146,519 (J., 1921, 691 a). Raw wool is scoured by immersion for a few minutes at 70° C. in a solution containing 6% of a mixture of 65 pts. of the protein product and 25 pts. of anhydrous sodium carbonate. Woollen yarn and cloth is scoured with a solution at 45° C., containing about 15 pts. of sodium carbonate, 5 pts. of soap, and 45 pts. of the protein product. Scoured wool is after-treated with a solution of the protein product alone at 45° C. —A. J. H.

Mercerisation. S. M. Jones and I. O. Harlow, Assrs. to Arnold Print Works. U.S.P. 1,392,833, 4.10.21. Appl., 21.6.21.

Textile fabrics composed of cotton and viscose silk are mercerised without injury to the latter by treatment with a solution of caustic alkali saturated with potassium acetate.—F. M. R.

Dyeing-machine. H. M. Dudley. U.S.P. 1,390,512, 13.9.21. Appl., 26.11.19.

A dyeing chamber contains two series of spaced parallel bars capable of holding skeins in a taut condition, and means are provided by which a liquid can be circulated in either direction through the dyeing chamber and parallel to the length of the skeins.—A. J. H.

Discharges on coloured grounds; Process of producing white and coloured ——. Farbw. vorm. Meister, Lucius, und Brüning. E.P. 146,868, 5.7.20. Conv., 8.8.19.

Azo dyes which are not discharged, or only incompletely discharged, by formaldehyde-sulphoxylates are discharged readily by acetaldehyde-sulphoxylates, leaving a white which satisfies all requirements. Thus, a Toluylene Orange R or α-Naphthylamine Bordeaux ground is printed with a paste of 200 g. of acetaldehyde-sulphoxylate, 350 c.c. of water, and 450 g. of wheat starch tragacanth thickening, steamed for 3 mins. at 101° C. in a Mather-Platt with exclusion of air, washed, and soaped. Acetaldehyde-sulphoxylates are eminently suitable for the production of coloured discharges, for example, by printing a discharge containing Rhodamine 6G on the brown ground obtained by developing cloth prepared with β-naphthol with tetrazotised benzidine. The time required for steaming may be reduced by discharging indigo with acetaldehyde-sulphoxylate in conjunction with Leucotrope W.—F. M. R.

Dyeing linen, union, cotton, and other heavy piece goods; Apparatus for ——. P. Kaufmann. E.P. 148,149, 9.7.20. Conv., 18.10.13.

See F.P. 463,779 of 1913; J., 1914, 418.

Textile fabrics; Finishing or lustring ——. J. B. Lomax. U.S.P. 1,393,296, 11.10.21. Appl., 10.4.20.

See E.P. 137,710 of 1919; J., 1920, 362 A.

Cellulose acetate products. E.P. 169,741. *See* V.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Greensand; Action of lime on ——. [*Extraction of potash.*] R. N. Shreve. J. Ind. Eng. Chem., 1921, 13, 693—695.

In a method for preparing potassium salts from greensand by heating the latter with water and calcium oxide, the best recovery of potassium (85%) is obtained when finely divided greensand, 1, calcium oxide, 0·9, and water, 5 pts. are heated together for 1 hr. at 470°—480° F. (249°—254° C.) under about 500 lb. pressure. If sodium nitrate is added to the charge, potassium nitrate and sodium hydroxide are the products of the reaction; the addition of calcium chloride leads to the production of potassium chloride, whilst potassium nitrate accelerates the reaction. Other salts act as accelerators by increasing the solubility of the calcium hydroxide.—W. P. S.

Radium minerals; Treatment of low-grade ——. E. Ebler and A. J. van Rhyn. Z. angew. Chem., 1921, 34, 477—480. (*Cf.* Ebler and Bender, J., 1915, 279.)

The minerals which are displacing pitchblende as sources of radium are American carnotite, which is a potassium uranyl vanadate, $K_2O,2(UO_3),V_2O_5,3H_2O$, and Portuguese autunite and chalkolite, the former of which is a calcium uranyl orthophosphate, $Ca(UO_2)_2(PO_4)_2,8H_2O$, whilst the latter is the corresponding cupric uranyl phosphate. These minerals occur more or less sparsely distributed in a magma of sandstone or decomposed granite. In the case of uranium micas (autunite and chalkolite) more than 40 times as much radium was found in the micaceous material as in the silicious magma but the proportion of radium to uranium in the mica, $1\cdot7\times10^{-7}$, was less than in the ground mass, $9\cdot8\times10^{-7}$, the latter being greater than the theoretical ratio, $3\cdot4\times10^{-7}$. This may be explained on the assumption that part of the radium has been dissolved out of the mica by infiltration, and then partly deposited in the absorbent silicious mass, which consists of a decomposed granite and contains 94·2% SiO_2. In ordinary granite over 60% of the radium present was contained in the mica and horn blende and the rest in the felspar, whilst the quartz was free from radium. Experiments on the extraction of the radium from such minerals as those described above were made with a Portuguese rock containing torbernite (chalkolite) with a radium content of $4\cdot5\times10^{-7}$%, a Colorado sandstone containing carnotite with 5×10^{-7}% radium, and a quartzite pitchblende containing $2\cdot84\times10^{-7}$% radium. The powdered ore was intimately mixed with about an equal weight of sodium or calcium chloride and calcium carbonate and heated to a sintering temperature (800°—1000° C.) for 5 or 6 hrs. After cooling, the mass was powdered and extracted with dilute hydrochloric acid with the addition of sulphuric acid and barium chloride. The muddy liquid which is obtained can be readily poured off from the heavy quartz particles, and from this liquid and the washings the crude radium sulphates are separated by filtration. In this way about 83% of the radioactive material originally present is concentrated in the form of sulphates equal to 7% by weight of the ore taken.—E. H. R.

Hydrogen: Manufacture of —— *by the partial liquefaction of water-gas.* G. Claude. Comptes rend., 1921, 173, 653—655.

Water-gas, from which a portion of the carbon monoxide has been removed by preliminary cooling, is cooled further by allowing it to expand whilst doing external work. Lubrication troubles due to the low temperatures have been overcome by the introduction of 5% of nitrogen which is liquefied and serves as a lubricant. Working in this way on a large scale 500 cub. m. of water-gas has been treated per hour under a pressure of 35 atm., giving 230 cub. m. of hydrogen containing 1·5% of carbon monoxide, which can be easily eliminated in the synthesis of ammonia under very high pressures. The energy necessary is very cheaply supplied by using one-quarter of the liquefied carbon monoxide in a gas engine. The remaining liquefied carbon monoxide can be used as a source of energy for the synthesis of ammonia.—W. G.

Carbon; Fusion of ——. E. Ryschkewitsch. Z. Elektrochem., 1921, 27, 445—452. (*Cf.* J., 1921, 178 A, 657 A.)

A smaller resistance furnace than that used previously is described, the resistance consisting of a rod of graphite, 1·5 cm. square in section and 4 cm. long, placed between carbon electrodes. This rod was reduced in section to 1 sq. cm. at the centre to obtain the maximum temperature at that point. It was not found possible to find the temperature at which the carbon melted. Good crystals of graphite could be obtained from the carbon vapour, and these consisted of pure carbon.—W. P.

Spent acid for nitric acid stills. Norton. *See* XXII.

Phosphoric acid. Copaux. *See* XXIII.

Patents.

Sulphuric anhydride; [*Contact*] *apparatus for the manufacture of* ——. P. Audianne. E.P. 169,264, 21.6.20.

The apparatus is designed to secure, in the Grillo process, uniform gas distribution and temperature throughout the catalytic mass. The latter is contained in a vertical cylindrical chamber with conical bottom, at the base of which the gas enters. It then passes up a number of open-ended vertical tubes fitted with helicoidal stoppers at their bottom ends. The catalytic mass is arranged between the tubes, from the top of which the gas passes downward with uniform increase of temperature to a number of outlets leading into an annular collecting chamber arranged round the catalyst. The apparatus thus acts as a heat-exchanger.—C. I.

Sulphuric acid; Manufacture of —— *from crude potassium salts.* L. Tietjens and J. Haedicke. G.P. 335,304, 12.10.19.

The crude salts are freed from potassium chloride, the kieserite is converted into sodium sulphate and magnesium chloride by interaction with rock salt, and the sodium sulphate in aqueous solution is treated with cold concentrated hydrochloric acid prepared from the magnesium chloride. The precipitated sodium chloride is filtered off and washed with alkaline sodium chloride solution. The acid filtrate is freed from hydrochloric acid by distillation and the residual sodium bisulphate heated to a high temperature to form sodium sulphate and sulphur trioxide.—C. I.

Sulphuric acid; Process for the intensive production of —— in circular, polygonal, oval, or elliptical lead chambers. W. Kauffmann. G.P. 340,030, 1.10.19.

The gases, under a pressure of 100 mm. of water or more, enter the chamber by one inlet, or by several at the same or different heights above the bottom, arranged so that the gases take a spiral course within the chamber.—C. I.

Hydrochloric acid gas; Process for the absorption of —— in towers. O. Zieren. G.P. 340,213, 28.3.19.

A circulating and cooling system is provided for the outflowing acid from each tower, by which it is continually returned to the top, a portion passing on to the next tower in the contrary direction to that of the gas.—C. I.

Phosphoric acid; Manufacture of ——. W. N. Hirschel, and Amsterdamsche Superfosfaatfabriek. G.P. 340,361, 15.8.20. Conv., 24.6.20.

Phosphate rock or bone meal is decomposed with sulphuric acid of such concentration that the water present converts the calcium sulphate formed into the dihydrate. When hydration of the calcium sulphate is complete, the free phosphoric acid is dissolved out from the reaction product.

Hydrofluoric acid; Manufacture of —— from natural fluorides. Verein Chem. Fabriken in Mannheim. E.P. 147,711, 8.7.20. Conv., 27.12.18.

Monohydrate sulphuric acid is absorbed by a suitable substance, *e.g.*, finely ground anhydrous calcium sulphate, the mass is mixed with a quantity of ground fluorspar equivalent to the sulphuric acid absorbed, and the mixture heated to 200°—300° C. in a muffle furnace fitted with mechanical stirring devices.—H. R. D.

Hydriodic acid; Process for the preparation of ——. G. B. Frankforter. U.S.P. 1,380,951, 7.6.21. Appl., 4.6.19.

Iodine is added to pinene or other unsaturated hydrocarbons, rosin oil, an aldehyde or an alcohol, and the resulting gas is purified.

Nitrogen compounds [hydrocyanic acid etc.]; Production of ——. The Nitrogen Corp., Assees. of J. C. Claucy. E.P. 140,394, 15.3.20. Conv., 1.9.17.

A catalyst is prepared by slowly heating barium cyanide to 400°—500° C. in an atmosphere of nitrogen. The reaction $2Ba(CN)_2+N_2=2BaCN_2+(CN)_2$ is believed to occur, the barium cyanamide being obtained as an expanded porous mass. The cyanides of other metals, *e.g.*, uranium and chromium, may be advantageously mixed with the barium cyanide but do not by themselves expand during the reaction. The prepared mass is cooled in an atmosphere of nitrogen. A mixture of hydrogen, nitrogen, and a hydrocarbon, *e.g.*, methane, is passed over this catalyst at 500°—900° C. and yields hydrocyanic acid and hydrogen. Carbon monoxide, if present, converts the barium cyanamide into barium oxide. This conversion may be effected at atmospheric pressure but proceeds more rapidly at 100—1000 lb. per sq. in., which pressure also allows a higher temperature to be used. If hydrogen is absent from the gas mixture, cyanogen is formed.—C. I.

Cyanides; Synthetic method of producing ——. Mitsubishi Kogyo Kabushiki Kaisha, Assees. of T. Hara. E.P. 146,819, 5.7.20. Conv., 7.7.19.

Carbon or carbonaceous matter is soaked with a solution of iron chloride, partially dried, and heated to redness in the presence of steam or carbon monoxide in order to decompose the iron chloride with formation of iron oxides. The material is then cooled, treated with anhydrous sodium carbonate and subjected to a temperature of 950° C. in a current of nitrogen. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 136,750 and 5617 of 1881; J., 1920, 156 a.)—H. R. D.

Ammonia; Production of ——. The Nitrogen Corp., Assees. of J. C. Clancy. E.P. 140,439, 17.3.20. Conv., 17.3.19.

Cyanamides, *e.g.*, calcium cyanamide, are ineffective as catalysts for the production of ammonia at pressures in the neighbourhood of atmospheric owing to simultaneous formation of hydrocyanic acid. If, however, a cyanamide is mixed with a metal which forms a not too stable nitride at 400°—600° C., *e.g.*, iron, manganese, or cobalt, and the mixture moulded into porous briquettes, an excellent catalyst is obtained. The suggested reactions are $CaCN_2+4Fe=CaC+2Fe_2N$; $CaC+N_2=CaCN_2$; $2Fe_2N+3H_2=2NH_3+2Fe_2$, the momentary formation of "calcium subcarbide" being assumed. The metal also serves to combine with sulphur present in commercial calcium cyanamide and prevent poisoning. Potassium, strontium, or barium cyanamide, but not others, may replace that of calcium.—C. I.

Ammonia; Process of making ——. K. P. McElroy, Assr. to Ferro Chemicals, Inc. U.S.P. 1,390,533, 13.9.21. Appl., 24.12.17. Renewed 7.2.21.

Air is passed through a pervious charge comprising lime, carbon, and "returned" potash at a temperature high enough to produce potassium cyanide fumes. The fumes are recovered from the hot gases, and the potassium cyanide is hydrolysed to produce ammonia and a potash-containing residue which is returned to form part of a charge.—H. H.

Ammonia; Preparation of —— and of caustic alkali from crude calcium cyanamide and alkali carbonate. Dr. Bambach und Co. G.P. 299,071, 23.2.13.

A mixture of crude calcium cyanamide with a quantity of alkali carbonate corresponding to the content of free lime present is heated at atmospheric pressure, yielding a steady stream of concentrated ammonia gas.—C. I.

Ammonium sulphate and alkali sulphate; Preparation of —— by treatment of ammonia and carbon dioxide with calcium sulphate. A. Bambach. G.P. 304,344, 12.5.14.

Ammonium carbonate is treated with a suspension of calcium or strontium sulphate in water, and the calcium or strontium carbonate removed and decomposed with alkali bisulphate.—C. I.

Oxides of nitrogen; Production of —— from ammonia by catalytic oxidation. J. Y. Johnson. From Badische Anilin und Soda Fabrik. E.P. 145,059, 15.6.20.

The gas mixture containing oxygen and ammonia is preheated to about 100° C. by means of steam, then passed through a metallic heat exchanger in counter current to the drawn-off reaction gases, whereby it is further heated to about 250° C.; the hot reaction gases are cooled from about 750° C. to about 400° C. by passing through a steam boiler before entering the heat exchanger. The final heating of the preheated oxygen-ammonia mixture to the reaction temperature is effected by radiant heat from the heated contact mass, and the gas mixture at this stage must come in contact only with materials which have no essential catalytic action upon it, preferably non-metallic materials such as china, fireclay, magnesia, etc. The yield of nitrogen oxides amounts to 90%, and at the same time a large amount of heat is recovered suitable for other purposes.—H. R. D.

Potash-bearing silicates; Method of treating ——. W. Glaeser, Assr. to Potash Extraction Corp. U.S.P. 1,379,914, 31.5.21. Appl., 9.2.16.

A mixture of felspar, or other silicate containing potassium, with calcium or sodium chloride and about 5% of a reducing catalyst (*e.g.*, iron or coke containing iron) is heated to about 1000° C. for several hours and the product cooled in absence of air. It may be used direct as a fertiliser or extracted with water to produce potassium chloride.

Potassium chloride; Process for the production of ——. Kaliwerke Grossherzog von Sachsen, A.-G., and K. Hepke. G.P. 337,209, 12.5.17.

The potassium chloride present as carnallite in mixed salts containing also "Hartsalz" or sylvine, is recovered by a cold process, and the residues which contain "Hartsalz" or sylvine are treated either alone or mixed with further quantities of mixed "Hartsalz," by a process of hot solution, followed by sudden artificial cooling, to separate most of the potassium chloride, the mother liquor being then employed to effect further solution of potassium chloride from the crude mixed salts.
—J. S. G. T.

Potassium bromide; Process of making ——. E. O. Barstow and C. W. Jones, Assrs. to The Dow Chemical Co. U.S.P. 1,392,905, 11.10.21. Appl., 17.5.17.

A solution containing potassium carbonate with a relatively small quantity of sodium carbonate is treated with bromine, the solution of mixed bromides thus formed is concentrated to a point beyond hot saturation, then allowed to cool to not lower than 50° C., whereupon substantially pure potassium bromide crystallises out.—H. R. D.

Potassium salts; Apparatus for the continuous crystallisation of hot solutions of ——. Maschinenbau-A.-G. Balcke. G.P. 340,022, 10.1.18.

The solution flows through a number of compartments, in which cooling discs rotate, and into which air is blown against the flow of the hot liquid. The salts in the form of large crystals are removed from the bottom by a screw conveyor.—C. I.

Nickel formo-carbonate and process for making same. C. Ellis. U.S.P. 1,390,686, 13.9.21. Appl., 28.4.19.

Freshly prepared nickel carbonate is treated with an amount of formic acid insufficient to convert the carbonate completely into the formate. The product is converted into a dry powder.—H. C. R.

Salt and the like; Steam system for manufacturing ——. C. L. Weil; E. S. Weil, admintrix. U.S.P. 1,391,811, 27.9.21. Appl., 23.11.18.

In the manufacture of salt by evaporation in a closed evaporator, where live steam is available at a relatively high pressure, and exhaust steam is produced in the evaporator at a lower pressure, the evaporation is controlled by passing the live steam and the exhaust steam in opposite directions through a series of loops so as progressively to lower the pressure of the live steam, and raise that of the exhaust steam, in a number of stages, and feeding steam to the evaporator from one of these stages at a pressure intermediate the pressures of the live steam and the exhaust steam.—H. R. D.

Barium chlorate; Process of producing ——. E. P. Schoch. U.S.P. 1,391,858, 27.9.21. Appl., 13.9.20.

A hot solution of barium hydroxide is treated with chlorine to form barium chlorate and barium chloride, and addition of the reacting substances is continued until the solution is saturated with barium chlorate. On cooling the solution mixed crystals of barium chloride and chlorate are precipitated, and subsequently barium chlorate is recovered in a substantially pure state.—H. R. D.

Element [aluminium] capable of forming a haloid; Process of recovering —— from ores, minerals, etc., containing the same. H. S. Booth and G. G. Marshall. U.S.P. (a) 1,392,043 and (b) 1,392,044, 27.9.21. Appl., 26.11.17.

(a) Ore containing aluminium or the like is mixed with a chloride that will react therewith in the presence of silica. The mixture is heated to a sufficiently high temperature to form and volatilise aluminium chloride, which is collected. (b) Silicate containing aluminium is mixed in an anhydrous condition with a reactive halide, and the mixture heated to a temperature below that at which the aluminium halide formed is volatilised. The aluminium halide is subsequently recovered by leaching.—H. R. D.

Aluminium nitride and other chemical substances; Process and apparatus for making ——. W. Hoopes, Assr. to Aluminium Co. of America. U.S.P. (a) 1,393,370, (b) 1,393,371, and (c) 1,393,372, 11.10.21. Appl., 19.9.19.

(a) Chemical reactions between gases and solids, especially such solids as are non-conducting when cold, are effected by disposing a pervious mass of the solids between suitable electrodes, the mass being heated preliminary to the passage of an electric current between the electrodes during the passage of gas through the mass. The process is applicable to the manufacture of aluminium nitride. (b) An apparatus for effecting the operations described under (a) comprises a chamber having electrodes at either end adapted to receive a charge between them, and devices at the sides of the chamber receiving current from the electrodes to heat the charge, these devices being withdrawable to provide a gas-receiving space around the charge. (c) In a process effected according to (a), the charge is insulated during the reaction.—J. S. G. T.

Aluminium hydroxide and the like; Precipitation of —— in an easily filtered form. M. Buchner. G.P. (a) 299,763, 1.2.14, and (b) 301,612, 31.5.14.

(a) A salt of aluminium or other metal forming a gelatinous hydroxide is treated in the solid state with alkali solution, or the salt is moistened with a very little water and subjected to the action of gaseous ammonia. (b) The salt is dissolved in its water of crystallisation and treated with ammonia, or a metallic oxide or hydroxide, with or without steam; or the precipitant may be mixed with a small quantity of water and added to the dissolved salt.—C. I.

Beryllium [glucinum]; Process of recovering —— from ores, minerals, etc. H. S. Booth and G. G. Marshall. U.S.P. (a) 1,392,045, and (b) 1,392,046, 27.9.21. Appl., 26.11.17 and 16.10.18.

(a) Crushed ore containing glucinum is mixed with an alkali or alkaline-earth halide, and heated in a furnace to a temperature at which glucinum halide is formed. (b) Material containing glucinum is

heated and then caused to react with a halogen, and the glucinum halide formed is recovered.
—H. R. D.

Sodium carbonate and potassium chloride; Method of separating —— from natural alkaline brines. J. W. Beckman. U.S.P. 1,393,603, 11.10.21. Appl., 23.7.19.

Natural brine is subjected to solar evaporation till the residual deposit is in a semi-solid condition, when it is leached with boiling water. The leaching liquor containing dissolved potassium chloride is removed, leaving a residual slurry containing sodium carbonate. The solution is evaporated first by solar heat, and subsequently by artificial heat, until crystallisation takes place in the evaporator, when it is filtered hot and cooled to recover potassium chloride by crystallisation. Water "containing $\frac{1}{3}$ ton of sodium bicarbonate containing liquid in the shape of carbonated slime" per ton of slurry treated is added to the residual slurry containing sodium carbonate, and the mixture agitated at about 40° C., filtered, washed, dried, and the resulting product calcined.
—H. R. D.

Sulphur; Process for recovery of —— from hydrogen sulphide. Chem. Fabr. Rhenania, and F. Projahn. G.P. 305,102, 17.9.16. Addition to 298,844.

The process described in the chief patent (J., 1920, 794 A) is modified in that in addition to or in place of the mixture of oxygen and hydrogen sulphide required for the reaction $H_2S+O=H_2O+S$, sulphur dioxide and hydrogen sulphide in quantities required for the reaction $SO_2+2H_2S=2H_2O+3S$ are introduced into the contact chamber. When working in entire absence of atmospheric oxygen the process is carried out between 300° and 150° C.
—H. R. D.

Sulphur; Process for obtaining —— or for treating and purifying gases containing hydrogen sulphide. Farbenfabr. vorm. F. Bayer und Co. E.P. 153,297, 15.10.20. Conv., 30.10.19.

Gases containing hydrogen sulphide mixed with air or oxygen are brought into contact with porous carbon prepared according to G.P. 290,656 (*cf.* E.P. 0,126 of 1914; J., 1915, 862). Finely divided sulphur is deposited and is subsequently removed by ublimation or extraction. If the gases are rich n hydrogen sulphide the heat of reaction melts the ulphur deposited. The oxidation is accelerated by he presence in the gas of small quantities of ammonia.—C. I.

Sulphur dioxide; Utilisation of waste gases containing ——. F. Siemens. G.P. 339,818, 7.3.20.

The gases are mixed with excess of air and used directly in the manufacture of sulphates and hydrohloric acid by processes of the Hargreaves type. n carrying out the process a large number of atteries of reaction cylinders are used, arranged ide by side. The process is specially applicable to waste gases obtained in the manufacture of glass nd water-glass.

Nitrogen and oxygen; Process for the simultaneous manufacture of pure ——. R. Mewes, Vater u. Sohn. G.P. 336,719, 3.2.20.

Air, slightly or not at all cooled, is brought into contact with a surface cooled by the contents of he column in which the liquefied air is separated into oxygen and nitrogen, and then passed into the atter at a point somewhat above the level of the oxygen outlet, with the object of employing the heat of the air for operating the column, either one or in conjunction with the usual high-pressure heating coil.—C. I.

Sulphuric acid; Manufacture of ——. J. Thede. E.P. 147,094, 7.7.20. Conv., 24.6.18.

See G.P. 312,024 of 1918; J., 1919, 680 A.

Calcium carbide; Manufacture of ——. Union Carbide Co., Assees. of F. M. Becket. E.P. 143,873, 26.5.20. Conv., 15.8.17.

See U.S.P. 1,310,465 of 1919; J., 1919, 631 A.

Manganese dioxide; Process for the production of ——. E. H. Westling. E.P. 147,030, 6.7.20. Conv., 14.3.18.

See U.S.P. 1,325,129 of 1919; J., 1920, 109 A.

Gases containing sulphuretted hydrogen; Process of and apparatus for the extraction of sulphur from ——. Chem. Fabr. Rhenania, and F. Projahn. E.P. 169,467, 6.3.20.

See G.P. 298,844 of 1916; J., 1920, 749 A.

Alkaline condensing agents; Manufacture of ——. E. Bergve. E.P. 169,498, 22.6.20.

See U.S.P. 1,354,451 of 1920; J., 1920, 722 A. (Reference is directed, in pursuance of Sect. 7, Subsect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 24,571 of 1910; J., 1911, 613.)

Caustic soda; Process for the manufacture of ——. C. Cramer, Assr. to Schweizerische Sodafabrik. U.S.P. 1,392,814, 4.10.21. Appl., 24.5.20.

See G.P. 332,003 of 1919; J., 1921, 301 A.

Decomposing difficultly soluble bodies. U.S.P. 1,364,804. *See* I.

Carbon. U.S.P. 1,392,266. *See* XI.

Silicate pigments and barium chloride. G.P. 320,863. *See* XIII.

Chlorine composition. U.S.P. 1,367,431. *See* XIXb.

VIII.—GLASS; CERAMICS.

Patents.

Glass-melting furnaces. R. L. Frink. E.P. 169,304, 2.7.20.

Cooling of the walls of a glass tank furnace is secured by attaching a metal plate to the outer side of the wall to be cooled, in intimate contact with the blocks, and directing water uniformly down the outside of this plate from a pipe or trough above, the water being collected in a channel at the bottom of the plate, and removed. Such a method of cooling results in little formation of insulating scale, and obviates the accumulation of gases; ease of cleaning and accuracy of adjustment are secured, and the use of thinner wall-blocks is made possible.
—A. C.

Glass annealing furnaces and the like. R. L. Frink. E.P. 169,537, 2.7.20.

In a glass-annealing lehr, the heating chamber consists of a muffle, constructed of corrugated iron plates, preferably of high silica and low carbon content to prevent oxidation. The upper plate of the muffle forms the floor of a combustion chamber, in which producer gas is burned, and from which waste gases pass by vertical flues at the sides of the muffle, thence, by alternate openings at either side, into horizontal flues below the same, and finally by other flues to a main conduit, leading to regenerators or to the chimney. The muffle, combustion chamber, and a short length of the lehr beyond, are surrounded by refractory material, but the rest of the lehr is composed of iron sheets, coated externally with a semi-refractory material, as asbestos or an asbestos-cement mixture. By this means glassware is heated uniformly as it passes through the muffle, the temperature of which can be easily regulated, the glass is protected from attack by products of combustion, and it cools rapidly when out of the annealing zone of the furnace.—A. C.

Glass melting furnaces; Crucible ——. W. J. Mellersh-Jackson. From C. M. Stein et Cie. E.P. 169,595, 17.8.20.

A glass-melting furnace, using producer gas, consists of two opposed vaults or chambers, containing the crucibles, and connected by a passage, in the centre of which opens a central burner. For each crucible a recuperator is provided, the crucible lying directly between the central burner and the escape port to the recuperator, to ensure maximum heating. Should only one recuperator be in use, the heat is concentrated on that special crucible, which can be heated almost independently of the others.—A. C.

Mica; Process of preparing sheet- —— from mica waste. P. Kertesz. G.P. 340,228, 6.11.20.

The mica-waste is powdered, mixed with a solution of a cellulose ester, and the mixture poured on to a smooth surface. The solvent is removed by drying and when it is thoroughly dry the mica sheet may be lifted off. It is resistant to acids, alkalis, and oils, does not melt when heated, and is equal to natural mica as an insulator.—C. I.

Graphite crucibles, carbons, etc.; Process of baking ——. F. K. Meiser. G.P. 340,021, 16.9.19.

The muffle in which the crucibles etc. are burnt is filled with indifferent or reducing gas, whereby the use of a filling material packed around the crucibles can be dispensed with.—C. I.

Gases containing sulphur dioxide. G.P. 339,818. *See* VII.

IX.—BUILDING MATERIALS.

Concrete; Effect of hydrated lime and other powdered admixtures in ——. D. A. Abrams, Structural Materials Res. Lab., Lewis Institute, Chicago, Bull. 8, Dec., 1920. 74 pages.

The addition of hydrated lime or other powdered materials (except Portland cement and slag) to concrete, reduced the compressive strength roughly in proportion to the amount added. For 1:4 and 1:5 concretes, the average reduction in strength was 0·59% for each 1% of lime added (reckoned in terms of volume of cement); richer or wetter concretes showed a greater reduction. In general, the "workability" and "flow" of lean concrete mixtures was slightly increased, but that of rich mixtures was little affected by the addition of hydrated lime; the addition of Portland cement had precisely the same effect. The resistance to wear and the absorption of concrete were not sensibly increased. The increase in the volume of the concrete was about 60% of the "loose volume" of lime added.—A. B. S.

Patents.

Cement; Heat-resisting ——. H. S. Ashenhurst. U.S.P. 1,365,077, 11.1.21. Appl., 24.9.19.

A mixture of finely-divided asbestos having a volume weight of 25—50 lb. per cub. ft. (*cf.* U.S.P. 1,317,852–3; J., 1920, 367 A), with about 4·5% of a soluble salt and water forms a mass which, when applied to iron and steel, adheres firmly after drying.

Artificial stone; Process for converting limestone into a compressible ——. C. L. V. Zimmer, Assr. to The Chemical Foundation, Inc. U.S.P. 1,391,710, 27.9.21. Appl., 7.2.18.

Stone containing lime is mixed with a bituminous substance containing "sulphated sebacic acid." (*Cf.* U.S.P. 1,237,852 and 1,319,918; J., 1917, 1095; 1919, 948 A.)—L. A. C.

Heat-insulating formed body and method of making same. A. H. Krieger and W. L. Jordan. U.S.P. 1,393,225, 11.10.21. Appl., 28.11.19.

Finely-divided diatomaceous earth which has been used for the filtration of sugar solutions is moulded and dried. The substances which have accumulated in the kieselguhr during use act as a bond.
—B. M. V.

Cement; Process for burning —— *in revolving or shaft furnaces.* G. Polysius. G.P. 339,820, 18.6.19.

A liquid fuel, such as low-temperature tar-oil, is added to the mixture of raw materials during the burning process. It may be sprayed on to the walls of the furnace or on to the charge, or it may be mixed with the latter during the preliminary grinding.—A. R. P.

Fibrous material. E.P. 165,240. *See* V.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Vanadium and chromium in ferrovanadium; Determination of —— *by electrometric titration.* G. L. Kelley, J. A. Wiley, R. T. Bohn, and W. C. Wright. J. Ind. Eng. Chem., 1921, 13, 939—941. (*Cf.* J., 1919, 583 A.)

A weighed amount of ferrovanadium is dissolved in nitric and hydrochloric acids and evaporated with the addition of sulphuric acid until fumes appear, to remove nitric and hydrochloric acids and effect complete decomposition of vanadium carbides. A portion of the solution is oxidised with ammonium persulphate and silver nitrate, and titrated with ferrous sulphate and potassium bichromate for chromium and vanadium. A further portion is oxidised by nitric acid and titrated for vanadium. The amount of chromium is calculated from the difference between the two titrations. The results obtained indicate that the treatment of vanadium by nitric acid under a fixed set of conditions gives a very regular degree of oxidation.—S. S. A.

Vanadium in ores and metallurgical products; Determination of ——. R. B. Schaal. J. Ind. Eng. Chem., 1921, 13, 698—699.

The method is based on the reduction of vanadic acid to vanadium dioxide by prolonged boiling with hydrochloric acid, the dioxide being titrated with permanganate solution. In the case of steel, 2 g. of the sample is dissolved in 60 c.c. of hydrochloric acid, 5 c.c. of nitric acid is added, and the solution is evaporated to 10 c.c.; for ores, 1—5 g. is digested with 60 c.c. of hydrochloric acid, 5 c.c. of nitric acid and 2 c.c. of hydrofluoric acid are added, and the mixture is evaporated to dryness, whilst with ferrovanadium 0·5 g. of the sample is heated with 5 c.c. of nitric acid and 2 c.c. of hydrofluoric acid, 40 c.c. of hydrochloric acid is then added, and the solution evaporated to dryness. To the solution or residue thus obtained is added 40 c.c. of hydrochloric acid, the solution is evaporated to 10 c.c., and this addition of acid and evaporation is repeated; 60 c.c. of water is then added, the mixture filtered, and the insoluble portion washed with 65 c.c. of cold water. The filtrate is treated with 60 c.c. of 15% ammonium phosphate solution, ammonia is added until a precipitate of ferric phosphate is formed, and this is dissolved by the addition of hydrochloric acid. Two c.c. of the latter is added in excess, the solution diluted to 300 c.c. and at once titrated with standardised permanganate solution. Iron, chromium, molybdenum, cobalt, nickel, uranium, titanium, and zirconium do not interfere with the method.—W. P. S.

Red brass; Influence of arsenic in ——. J. Czochralski. Z. Metallk., 1921, **13**, 380—383.

UP to 0·3%, arsenic increases the tensile strength, has no effect on the elongation or hardness, but greatly lowers the resistance to shock of red brass (86% Cu, 9% Sn, 5% Zn). Larger quantities of arsenic, up to 2%, lower the elongation and increase the hardness, but have little effect on the tensile strength. If 5% Pb is also present in the alloy arsenic increases the tensile strength, elongation, and resistance to shock up to 0·3%, after which the results obtained for these properties decrease. The hardness of the lead alloys first decreases to a minimum at 0·3% As, then rises to a maximum at 1% As, after which it again falls. The presence of arsenic in either the alloys containing lead or those that are lead-free cannot be detected microscopically.—A. R. P.

Magnesium in alloys; Determination of ——. E. Wilke-Dörfurt. Wiss. Veröffentl. Siemens-Konzern, 1921, I., 84—85. Chem. Zentr., 1921, **92**, IV., 937.

IN the determination of magnesium in zinc-aluminium-magnesium alloys containing little magnesium, by the usual method in which zinc sulphide and aluminium hydroxide are precipitated together and magnesium subsequently precipitated as phosphate, the values obtained are much too low owing to some of the magnesium being precipitated along with the zinc and aluminium. The following method avoids this source of error. 1 g. of alloy is dissolved as usual, the solution evaporated to dryness, and the residue dissolved in water. The solu-ion is filtered to remove silica, and 150 c.c. of dilute mmonium chloride solution, 15 g. of tartaric acid, nd 70 c.c. of strong ammonia solution are added. lagnesium is precipitated as phosphate by means f sodium phosphate, and after allowing to stand or 12 hours, the precipitate is collected, washed ith distilled water, and determined as magnesium yrophosphate. Zinc is precipitated as sulphide rom solution in acetic acid, and aluminium etermined by difference.—J. S. G. T.

ungsten and naphthalene; Reaction between —— at low pressures. M. R. Andrews and S. Dushman. J. Franklin Inst., 1921, **192**, 545—546.

APHTHALENE is decomposed into carbon and hydro-en by an incandescent tungsten filament at tem-eratures above 1500° K. The deposited carbon ffuses into the tungsten, and above 2300° K. the te of diffusion is greater than the rate of composition of naphthalene. The temperature the filament in the experiments ranged from 00° to 2600° K., and the pressure of naphthalene om 0·1 to 3·0 bars. The conductance of the fila-ent at room temperature decreased linearly with creased carbon content, attaining a minimum lue equal to about 7% of that of tungsten for a rbon content of 3·16%, corresponding to the com-sition W_2C. Thereafter the conductance in-ased to about 40% of that of tungsten when the bon content reached 6·1%, corresponding to WC, d with further increase of carbon content the nductance remained constant. The resistivity—temperature curves for filaments containing less than 3·16% carbon are parallel to the curve for pure tungsten. The two carbides decompose at about 2700° K. with volatilisation of carbon. The melting points of W_2C and WC are about 3150° K. and 3050° K. respectively.—J. S. G. T.

Metallic solders. L. Sterner-Rainer. Z. Metallk., 1921, **13**, 368—379.

THE properties of a good solder are discussed, and a method of measuring the hardness of a soldered joint by means of a Ludwik cone is described. The composition, melting point, tensile strength, and hardness of 77 alloys that have been suggested for use as solders for brass, aluminium, nickel-silver, and precious metal alloys, have been determined, and the results are embodied in tables.—A. R. P.

PATENTS.

Steel; Process for the manufacture of ——, the treating of iron, and the production of Portland cement. C. B. Hillhouse. U.S.P. 1,366,383, 25.1.21. Appl., 23.3.17. Renewed 18.12.19.

IRON ore is passed through a rotary kiln, and reduced to iron "sponge" by passing a reducing agent through the kiln at a temperature determined by the carbon content desired in the "sponge." Two "sponges" of different carbon content are prepared in this way, and are then melted separately with addition of preheated lime and mixed to produce steel of a desired carbon content. The basic slag in the fusion furnaces is kept highly heated, and before it is run off its composition is adjusted, by suitable additions, to that of Portland cement.—J. W. D.

Steel; Manufacture of ——. A. H. Henderson. U.S.P. 1,378,861, 24.5.21. Appl., 9.7.19.

ANHYDROUS borax, in the proportion of about 4 lb. to each ton of metal, is added to steel during fusion to produce a product suitable for casting or moulding into ingots.

Steel-iron alloy; High carbon ——. J. R. Speer. U.S.P. 1,391,215, 20.9.21. Appl., 16.6.20.

AN alloy with iron-steel characteristics contains chromium, molybdenum, silicon, sulphur, phosphorus, manganese, and not less than 1% of carbon.—J. S. G. T.

Steel-furnace; Electric ——. H. F. Priwer, Assr. to J. E. Galvin. U.S.P. 1,392,965, 11.10.21. Appl., 15.6.20.

IN an electric steel furnace the roof, the electrodes, and the power-operating mechanism therefor are all movable together, and means are provided for raising the roof.—J. S. G. T.

Ferro-chromium poor in carbon; Production of ——. Ampère-Ges.m.b.H. E.P. 147,158, 7.7.20. Conv., 6.5.18.

FERROCHROMIUM of high carbon content is melted in an electric furnace with refractory chrome-iron ores, *e.g.*, Serbian or Turkish chromite, with the addition of another metallic oxide, such as ferric oxide, preferably in the form of pyrite cinder or red ironstone. For example, 1000 kg. of ferrochromium containing 8—10% C is fused with 280 kg. of Serbian chromite and 85 kg. of red ironstone, whereby a product containing about 1·8% C is obtained.—A. R. P.

Ferrous-metal articles; Method of treating —— [to prevent corrosion]. F. L. Sorensen, Assr. to The Metal Protection Laboratories. U.S.P. 1,380,847, 7.6.21. Appl., 17.7.19.

A PASTE containing zinc powder (10 pts.), zinc oxide (10 pts.), and caustic alkali (1 pt.) is applied to the roughened surface of the article.

Iron surfaces covered with ferroso-ferric oxide; Cathodic cleaning of ——. Eisen- u. Stahlwerk Hoesch A.-G. G.P. 339,767, 6.5.19.

The treatment, which is especially applicable to wire, is carried out in a bath of ammonium sulphate solution. The removal of the oxide film can thus be effected with a lower voltage and in a shorter time than when a sodium sulphate bath is used, and a clean metallic surface is obtained.—J. H. L.

Heating [metals] without scaling; Process for ——. F. K. Meiser. G.P. 331,794, 17.8.19. Addn. to 327,362 (J., 1921, 476 A).

The gas supply used to maintain a slightly reducing action is cut off shortly after extinction of the flame, and the annealing chamber is disconnected from the gas supply during heating and cooling.—H. J. H.

Annealing of substances [metals] without oxidation; Process and apparatus for the ——. F. K. Meiser. G.P. 334,617, 27.3.20. Addn. to 327,362 and 331,794 (*cf. supra*).

The gas-flame which consumes the oxygen is produced in a gas circulation tube, outside the container, and provided with observation windows. The gases are ignited by means of a jet or by an electric spark. A fan and means for fixing or condensing the steam produced are provided in the circulation tube.—A. R. P.

Printing plates; Production of highly-resistant, rustless —— by electrolysis. M. Schlötter. G.P. 340,044, 21.2.19. Addn. to 339,127.

The electrolyte contains, in addition to an iron salt, a manganese salt instead of a chromium, nickel, or cobalt salt as specified in the principal patent (J., 1921, 704 A). This gives a deposit which is specially suitable for use with inks or printing colours containing manganese salts.—A. R. P.

Iron and other metal swarf and the like; Preparation of —— for hot briquetting. Deutsch-Luxemburgische Bergwerks- und Hütten-A.-G. E.P. 147,065, 6.7.20. Conv., 26.1.18.

See G.P. 311,118 of 1918; J., 1919, 540 A.

Copper [deposit]; Compound for automatic removal of —— from ordnance. A. E. A. Dagory. U.S.P. 1,366,167, 18.1.21. Appl., 30.9.20.

See E.P. 148,250 and 148,263 of 1920; J., 1921, 516 A.

Alloys; Manufacture of ——. H. L. Sulman and W. B. Ballantine. U.S.P. 1,392,462, 4.10.21. Appl., 21.6.19.

See E.P. 137,080 of 1918; J., 1920, 160 A.

Casting by means of compressed air; Process for ——. Process of casting metal. F. Dohle. E.P. 145,792 and 145,795, 2.7.20. Conv., 22.11.17 and 31.1.18.

Welding steel; Method of electrically ——. J. W. Plant. E.P. 169,773, 24.6.20.

Slag furnace. U.S.P. 1,392,504. *See* I.

XI.—ELECTRO-CHEMISTRY.

Electrolytic oxidation of α-naphthol. Ono. *See* III.

Electrolytic reduction of carboxylic acids. Inoue. *See* XX.

Patents.

Insulating material; Process for producing a material suitable as an ——. J. E. Pollak. From Werke Gantenbach. E.P. 169,527, 29.6.20.

Natural slate, preferably finely ground, is melted at about 1400°—1500° C. and cast. The casting is withdrawn from the mould and annealed by slow cooling from 1000° C. to 100° C. Slabs 3 mm. thick will withstand 25,000 volts.—J. S. G. T.

Tubes, muffles and the like; Electrically heated ——. The Morgan Crucible Co., Ltd., and G. I. Payne. E.P. 169,756, 2.6.20.

A resistor for use in electrically heated tubes, muffles, crucibles, etc. with all terminals at one end of the resistor or container, comprises a tube or the like which is divided by a longitudinal slot forming a gap extending from the terminal end to a point adjacent to the other end. The gap may, if desired, be filled in with a non-conductor or substance of high resistance. By dividing the resistor or container into three longitudinal portions connected together at the end remote from the terminals, three-phase current may be employed. The body of the crucible etc. may itself constitute the resistor. —J. S. G. T.

Electrodes for galvanic batteries; Production of ——. H. N. Cox, Assr. to New Jersey Patent Co. U.S.P. 1,366,559, 25.1.21. Appl., 12.4.19.

A mixture of about 100 pts. by weight of copper oxide and 2 pts. of an electrolyte, such as ammonium chloride or caustic soda, together with water, is moulded into the desired shape and dried, giving an electrode which is strong enough without baking and is suitable for batteries with alkaline electrolyte. Still stronger electrodes are obtained if zinc or iron powder is added to the mixture.

Carbon electrodes or pure retort carbon; Process for the manufacture of ——. Process for the manufacture of carbon electrodes. E. Szarvasy. U.S.P. (A) 1,392,266 and (B) 1,392,267, 27.9.21. Appl., 3.6.20.

(A) Methane is passed through a chamber externally heated to a temperature above the dissociation temperature of the gas. The heated parts of the chamber are made of pure carbon previously produced by the same process. Carbon deposited on the walls of the chamber is crushed along with the walls, and a part of the resulting mass used for the manufacture of decomposing chambers. (B) Natural gas is cracked by a continuous flow process in a decomposing vessel. The resulting mixture of soot and tar is moulded and burnt.—J. S. G. T.

Dry cell [depolarising] material and method of manufacture. O. E. Ruhoff, Assr. to French Battery and Carbon Co. U.S.P. 1,391,211, 20.9.21. Appl., 31.1.20.

Lampblack with a low content of volatile matter, for use as a constituent of a depolarising mixture for dry cells, is produced by submitting commercial lampblack to prolonged heat treatment at a high temperature.—J. S. G. T.

Battery [electrode]. A. P. Manchester and H. M. Spooner. U.S.P. 1,378,549, 17.5.21. Appl., 16.12.12.

See E.P. 2693 of 1913; J., 1913, 1161.

Electric furnaces and the like; Control for ——. E. F. Collins, Assr. to General Electric Co. U.S.P. 1,391,996, 27.9.21. Appl., 14.11.18.

See E.P. 143,737 of 1919; J., 1920, 521 A.

XII.—FATS; OILS; WAXES.

Linseed oil; The oil bromide test of ——. T. A. Davidson. J. Ind. Eng. Chem., 1921, 13, 801—806, 849.

Since the drying properties of linseed oil are due to the glycerides of linolenic acid, and not to linolenic acid itself, the author prefers to carry out the determination of the bromide value on the oil, and not, as is now the usual practice, on the mixed fatty acids, particularly as there is evidence that the linolenic acid is present in the oil in the form of a mixed glyceride. It is suggested that the term "oil bromide" be used for the insoluble brominated glycerides and "hexabromides" for the insoluble brominated acid. The following modification of the procedure proposed originally by Hehner and Mitchell (J., 1899, 77) is recommended:—4 g. of the oil is dissolved in ether, the solution is cooled to 0° C., and 1 c.c. of bromine is added slowly; the top of the tube containing the mixture is rinsed down with a further 5 c.c. of ether and, after being kept for 2 hrs. at 0° C., the mixture is submitted to centrifugal action. The supernatant liquid is decanted, the precipitate washed twice with 10 c.c. of ether, separation being effected in the centrifugal machine, then with 10 c.c. of alcohol, dried in the air, then in the water-oven for 30 mins., and weighed. All the ether used must be saturated previously at 0° C. with "oil bromide" (obtained from a preliminary experiment). The final washing with alcohol removes the last traces of ether and the "oil bromide" is obtained as a powder when dried. "Oil bromide" from linseed oil has m.p. 140°—145° C.; it is fairly soluble in chloroform, carbon tetrachloride, acetone, and acetic acid, slightly soluble in benzene, petroleum spirit, and ether, and practically insoluble in alcohol. It contains 57—58% Br and appears to consist mainly of dilinolenin-linolin bromide, $(C_{17}H_{29}Br_2COO)_2:C_3H_5.(C_{17}H_{31}BrCOO)$, mixed with a quantity of brominated glyceride of lower bromine content. The most trustworthy method of determining the bromine content consists in heating the "oil bromide" with about sixty times its weight of alcohol and nine times its weight of sodium for 1 hr. under a reflux condenser, then acidifying the solution with dilute nitric acid and titrating the sodium bromide according to Volhard's method.—W. P. S.

Soya bean oil; Factors which influence the production and composition of ——. C. R. Fellers. J. Ind. Eng. Chem., 1921, 13, 689—691.

The amount of oil in soya beans varies considerably, the yield from 26 different varieties of the bean ranging from 14·8 to 25·6%; the oil content is influenced by the length of the growing season, the date of planting, and the time required to reach maturity. There is also a considerable difference in the colour and drying properties of the oils derived from different varieties of beans; generally, the dark-coloured beans yield oil of rather poor drying power. The oils obtained from the 26 varieties of beans had the following characters: Sp. gr. 0·922—0·926; n_D^{25}=1·5720—1·4750; acid value, 0·2—2·6; saponif. value, 190—195; iodine value, 123·2—132·3. —W. P. S.

Fatty acids; Precipitation of solid —— with lead acetate in alcoholic solution. E. Twitchell. J. Ind. Eng. Chem., 1921, 13, 806—807.

The following method is preferred by the author to he lead salt-ether method for the separation of solid nd liquid fatty acids. A quantity of the mixed fatty acids containing 1—1·5 g. of solid acids is dissolved in 95% alcohol, heated to boiling, and a boiling solution of 1·5 g. of lead acetate in 95% lcohol added. (The total quantity of alcohol should e about 100 c.c.) After cooling slowly to room temperature and then for several hours, preferably over-night, at 15° C., the mixture is filtered and the filtrate tested for lead with alcoholic sulphuric acid. If the lead is not in excess, the analysis must be repeated using a larger proportion of lead acetate. The precipitated lead salts of solid fatty acids are washed with 95% alcohol until the washings remain clear when diluted with water, then dissolved by heating to boiling with 100 c.c. of 95% alcohol and 0·5 g. of acetic acid, and the solution cooled as before. The precipitate is collected, washed with 95% alcohol, washed from the filter into a beaker with ether, decomposed with dilute nitric acid, and the ethereal solution of solid fatty acids washed with water until the washings are no longer acid to methyl orange. The ether is then evaporated and the residue dried and weighed. The solid fatty acids thus separated usually have iodine values below 1%.—W. P. S.

Fatty oils; Drying and polymerisation of ——. P. Slansky. Z. angew. Chem., 1921, 34, 86.

Eibner's hypothesis (J., 1921, 551 A) as to exposure to light being necessary to produce normally drying linseed oil is not valid, since linseed oil expressed and exposed to air in absence of light dries normally. The author considers that the coagulation of oxidised glycerides plays an important part in the drying process. In an experiment cited, on blowing air through linseed oil, solidification took place between 15½ and 18 hrs., the iodine value dropping from 88 to 80 units and the oxidised fatty acids increasing from 39% to 40% only in this interval. Further, an oxidised linseed oil containing 40% of oxy-acids may be liquid whilst a solid form may only contain 35%. Solidification by oxidation is considered to be a two-stage process, the first consisting in oxidation of the glycerides and the second the coagulation of oxidised glycerides from the sol to the gel form. A determination of increase in weight on oxidation is regarded as of little value in determining drying power, the latter being bound up with the physical change of coagulation. The polymerisation of linseed oil on heating in absence of air proceeds similarly to the oxidation by air, solidification and the formation of an insoluble fraction taking place in an interval during which the iodine value changes by only a fraction of a unit. —A. de W.

Fatty acids; Anhydrides of the aliphatic ——. D. Holde and I. Tacke. Chem.-Zeit., 1921, 45, 949—950, 954—956.

The anhydrides of the fatty acids from linseed oil (*cf.* J., 1920, 790 A) dry less rapidly than the corresponding glycerides when exposed to air, but suffer a greater increase in weight owing to hydration to the corresponding acids and oxy-acids. Pure oleic anhydride crystallises in silvery scales, m.p. 22·2° C. and can be used for certain culinary operations. Its electrical conductivity in anhydrous acetone is considerably greater than that of oleic acid; glacial acetic acid is not a suitable solvent for this purpose as it is partly converted into acetic anhydride under the influence of oleic anhydride. When the anhydrides obtained from rape seed oil are distilled under 22 mm. pressure, about 30% distils over and the residue then suddenly acquires a porous rubber-like consistency; the behaviour of the anhydrides thus appears to resemble that of the glycerides. Hanus' method is strongly recommended for the estimation of iodine values on account of its accuracy and rapidity.—H. W.

Patents.

Oils and fats; Neutralising ——. Rocca, Tassy, et de Roux. E.P. 163,272, 28.6.20. Conv., 3.5.20.

The oil or fat dissolved in a suitable solvent is treated with anhydrous sodium carbonate, preferably in powder form. Twice the quantity theoretically required for the neutralisation of the free fatty acids is added.—H. C. R.

Oils; Extraction of —— from vegetable matter. M Whitehead and E. Scott. E.P. 169,738, 7.4.20.

The meal and solvent are intimately mixed and moved in opposite directions, the speed of movement of both being temporarily retarded at intervals, by passing them through a series of tanks in which the meal slides down an inclined screen immersed in the solvent and at the bottom of the screen is picked up by an inclined scraper-conveyor, from the perforated surface of which the mixture of oil and solvent drains back into the tank. At the top of the conveyor the meal passes between fluted rollers before entering the next tank. The liquid removed by the rollers drains back to the tank from which the meal has been removed. After passing through the last pair of rollers the meal is conveyed along a perforated, jacketed cylinder by means of a screw conveyor, vapour being passed through it and the mixture of vapour and solvent passing to a condenser. The mixture of oil and solvent is conveyed from tank to tank in the opposite direction to the flow of meal, and from the last tank to an evaporator.—H. C. R.

Catalysts [for hydrogenating fats]; Process for making ——. C. Ellis. U.S.P. (A) 1,390,683 and (B) 1,390,685, 13.9.21. Appl., (A) 12.12.16, (B) 11.4.18.

(A) A decomposable organic compound of a catalytic metal suspended in an inert hydrocarbon is subjected to the action of heat, in the presence of a reducing gas, whereby an active catalytic material is obtained. (B) An organic salt of nickel is heated dry to a temperature at least 10° above the initial temperature of reduction.—H. C. R.

Catalytic material; Process for regenerating ——. C. Ellis. U.S.P. 1,390,684, 13.9.21. Appl., 1.5.17.

The spent catalyst freed from a large proportion of the fatty or oily material, is dissolved in nitric acid, and the nickel precipitated as a basic compound. The latter whilst in the freshly precipitated condition is treated with formic acid to obtain nickel formate which is subsequently decomposed by heat.—H. C. R.

Fatty material; Process of adding hydrogen to unsaturated ——. C. Ellis. U.S.P. 1,390,687, 13.9.21. Appl., 16.3.16.

The entire amount of fat to be treated is converted into a fine mist by water-gas in the presence of a colloidal catalyst.—H. C. R.

Oil; Removal of catalyser from ——. C. Ellis. U.S.P. 1,390,688, 13.9.21. Appl., 30.12.15.

The oil, while containing free hydrogen, is made to flow past a stationary magnet, and is then filtered at a temperature above atmospheric.
—H. C. R.

Detergent. E. Reinfurth. G.P. 340,027, 6.3.18. Addn. to 332,649 (J., 1921, 356 A).

A salt of naphthalene-α- or β-monosulphonic acid which is soluble in water is mixed with the usual filling agents used for detergents, such as sodium carbonate, sodium silicate, china, clay, etc.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Turpentine; Detection and determination of coal-tar oils in ——. V. E. Grotlisch and W. C. Smith. J. Ind. Eng. Chem., 1921, 13, 791—793.

To determine small quantities of tar-oils (*e.g.*, toluene, xylene, and commercial solvent naphtha) in turpentine, 100 c.c. of the sample is cooled by a mixture of ice and salt and then saturated with dry hydrogen chloride; after 1 hr. the crystallised pinene hydrochloride is separated by filtration, and the filtrate is distilled under reduced pressure (10 in. of mercury) until 25 c.c. of distillate has been collected; the coal-tar oils are all concentrated in this distillate. The distillate is then added slowly to four times its volume of fuming sulphuric acid (4% SO_3), the mixture heated at 70° C. for 20 mins., cooled, diluted with an equal volume of water, and steam-distilled. In the case of pure turpentine a small quantity (less than 0·5 c.c.) of a yellow oil, n_D^{20} above 1·500, is obtained in the distillate; if the sample contains mineral oil, it is also recovered at this point. When oil ceases to distil, the steam supply is disconnected and the mixture is distilled directly over a burner, hot water being added to the flask from a tapped funnel drop by drop and at a slightly lower rate than that at which the mixture is distilling. The temperature of the mixture rises gradually and the sulphonated benzene hydrocarbons commence to decompose and the free hydrocarbons distil over. At about 170° C., excessive frothing begins and the distillation must be stopped. The volume of oil obtained in the distillate is multiplied by 2·2 to give the percentage of coal-tar oils in the turpentine. The distilled benzene hydrocarbons may be identified by the usual tests (nitration etc.). The method is not strictly reliable when applied to wood turpentines because the high temperature to which the wood is exposed during distillation decomposes the terpenes and resins partially with the formation of simple ring hydrocarbons; the recovery of more than 4% of hydrocarbons from a wood turpentine, however, throws suspicion on the purity of the sample.—W. P. S.

XIV. INDIA-RUBBER; GUTTA-PERCHA.

Rubber; Influence of certain organic accelerators on vulcanisation of ——. G. S. Whitby and O. J. Walker. J. Ind. Eng. Chem., 1921, 13, 816—819.

In a simple rubber-sulphur (90:10) mixture, piperidine piperidyldithiocarbamate acts as a comparatively powerful accelerator, 1% reducing the time of optimum cure to one-seventh; it increases the tensile strength and to a certain extent reduces the coefficient of vulcanisation at the optimum cure. The addition of 1% of hexamethylenetetramine to the rubber-sulphur mixture reduces the time of cure to two-thirds of the time required in the absence of accelerators, and slightly increases the tensile strength and coefficient of vulcanisation. In the absence of zinc oxide, thiocarbanilide is without accelerating effect on the vulcanisation, but it increases the vulcanisation coefficient. The products obtained with the aid of the accelerators mentioned aged normally during a test of seven months' duration.—W. P. S.

Vulcanised rubber; Modulus of hardness of ——. H. P. Gurney. J. Ind. Eng. Chem., 1921, 13, 707—712.

The modulus of hardness may be defined as the ratio of force to volume of depression; its dimensions are $\text{Mass}/(\text{Length})^2\times(\text{Time})^2$. The dynes per c.c. may be approximately estimated from the ordinary plastometer reading with the 0·125 in. ball by dividing $(2{\cdot}75\times10^{12})$ by the square of the plastometer number. The factors determining hardness of vulcanised rubber are sulphur ratio, heat treatment, and rubber content.—W. P. S.

XV.—LEATHER; BONE; HORN; GLUE.

[Tannin analysis;] Rapid washing of chromed hide powder [in ——]. R. W. Frey and I. D. Clarke. J. Amer. Leather Chem. Assoc., 1921, 16, 477—480.

The chromed hide powder is poured into a linen bag and washed by draining. Four successive portions of distilled water are added, each portion equal in amount to 15 times the weight of the air-dry powder used. The powder is not left in contact with each portion for 15 mins. as specified in the official method, but is squeezed as usual as soon as the wash water has subsided to the level of the powder in the bag. This method saves time, obviates decomposition of the powder, and gives as good results as the official method.—D. W.

Tannin; Determination of ——. J. A. Wilson and E. J. Kern. J. Ind. Eng. Chem., 1921 13, 772—774.

A method described previously (J., 1920, 522 a) is modified as follows: 2 g. of hide powder of known water content (previously washed with water and extracted with chloroform) is placed in a bottle, 100 c.c. of tannin liquor (of such strength that the 2 g. of hide powder is more than sufficient to remove all the tannin) is added and the mixture is shaken for 6 hrs. The tanned hide powder is then collected on a fine cloth filter fitted in a tubular funnel, washed for 12 hrs. by passing a slow current of water through the funnel, then dried for 12 hrs. in the open air and for a further 2 hrs. in a vacuum oven, and weighed. The increase in weight gives the amount of tannin in the 100 c.c. of liquor.—W. P. S.

Leather; Water extraction of ——. F. P. Veitch and R. W. Frey. J. Amer. Leather Chem. Assoc., 1921, 16, 491—510.

Leathers were extracted at different temperatures and for prolonged periods. In no case was a definite end point reached. After extraction for 40 hrs. at 45°—65° C. with 1900 c.c. of water, 0·60—0·78% was removed in the next 7 hrs. The nitrogen content did not indicate any decomposition of the hide substance. No great difference is evident between the total amount of water-soluble matter at 30° C. and at 50° C., but the soluble solids for the first 14 hrs.' extraction at 50° C. are appreciably higher than at 30° C.—D. W.

Leather; Extraction of oil and grease from ——. Report of committee of American Leather Chemists' Assoc. F. P. Veitch and I. D. Clarke. J. Amer. Leather Chem. Assoc., 1921, 16, 458—477.

Dry "Ivory" soap is practically insoluble in chloroform and petroleum spirit. In presence of moisture the quantity of soap fats extracted by both solvents is increased, but the quantity of moisture present in properly air-dried leather has only a small effect. The presence of tannic acid increases the solubility of soap fats, especially in chloroform. The grease extracts from materials containing uncombined tannic acid contain small quantities of tannic acid or similar compounds and lose weight indefinitely on drying. Magnesium soaps are very soluble in chloroform and petroleum spirit. Calcium soaps are extracted by chloroform but are practically insoluble in petroleum spirit. Chloroform is probably the most reliable solvent for grease in leather.—D. W.

Patents.

Leather; Process for manufacturing ——. H. Breuer. E.P. 145,742, 2.7.20. Conv., 14.12.17.

Hides or skins are tanned with iron salts mixed with the constituents extracted by means of alkalis from wood, straw, and other vegetable materials not capable of yielding independent tanning extracts.—D. W.

Tanning preparations; Production of ——. J. Y. Johnson. From Badische Anilin- und Soda-Fabrik. E.P. 146,427, 3.7.20.

Crude anthracene, anthracene waste, or a crude or waste mixture of anthracene, phenanthrene, carbazole and its associated products is dissolved in nitrobenzene or other suitable diluent, and chlorosulphonic acid introduced at a temperature below 100° C. The mixture is stirred for several hours, the diluent removed by distillation in steam or *in vacuo*, the product wholly or partially neutralised, and decolorised with hypochlorite solution at 40°—80° C.—D. W.

Tanning preparations; Manufacture of ——. J. Y. Johnson. From Badische Anilin- und Soda-Fabrik. E.P. 169,943, 3.7.20.

Sulphonated products of crude anthracene, crude carbazole, anthracene waste or similar crude or waste mixtures of carbazole with anthracene and its associated hydrocarbons, are decolorised by means of chlorine, hypochlorites, oxalic acid, formaldehyde, or the like at 40°—80° C. The products thus obtained produce a light-coloured leather.—D. W.

Hides or skins; Preserving animal matter or tissue such as ——. H. C. Ross, H. C. Marris, and W. Walker and Sons, Ltd. E.P. 169,468, 26.3.20.

Hides or skins are treated with the products formed by the action thereon of putrefying enzymes, *e.g.*, peptones, amino-acids, ammonia or the like, mixed with an inhibitor of enzyme action such as potassium oxalate, calcium chloride or the like, a germicide such as carbolic acid, xylene or the like, and a hygroscopic substance to keep the mixture in the form of a paste or liquid; 960 pts. of potassium oxalate, 30 pts. of peptone, 7 pts. of carbolic acid, and 3 pts. of glycerin is a suitable mixture.—D. W.

Epilation of skins. H. C. Ross, and W. Walker and Sons, Ltd. E.P. 169,730, 25.3.20.

Hides or skins are placed in a solution of ammonia or other end product of proteoclastic enzyme action and an easily dissociated calcium salt such as calcium polysulphide or lactate. Trypsin may be added to assist the action of the thrombase in the skins.—D. W.

Glue; Process for producing —— *from blood.* H. G. C. Fairweather. From Luftfahrzeugbau Schütte-Lanz. E.P. 169,509, 25.6.20.

Fresh blood is treated with a lime-binding substance such as oxalic acid, sodium citrate, or the like, evaporated *in vacuo* at 30°—40° C. so as not to produce coagulation, and dissolved in a small quantity of water rendered slightly alkaline.
—D. W.

Glues and cements; Producing ——. *Preparing casein glues.* A. A. Dunham, Assr. to The Casein Mfg. Co. U.S.P. (a) 1,391,768, (b) 1,391,769, and (c) 1,391,770, 27.9.21. Appl., (a) 16.3.18, (b) 1.8.19, and (c) 8.8.19.

(a) 100 pts. of dry casein is agitated with 200—300 pts. of water until it becomes soft, 5 pts. of dry caustic alkali added, the agitation continued until the casein has dissolved, then not less than 50% of an alkaline-earth hydroxide stirred into the mixture. (b) A mixture of 70 pts. of casein, 10 pts. of sodium phosphate, 20 pts. of calcium hydroxide, together with a small percentage of sodium silicate to govern the jelling or setting of the glue. (c) A mixture of 70 pts. of casein, 10 pts. of sodium phosphate, and 20 pts. of an alkaline-earth hydroxide, all in dry comminuted form.—D. W.

Tanning material. E.P. 143,874. *See* V.

XVI.—SOILS ; FERTILISERS.

Soil; Relation of the phosphoric acid of the —— *to pot experiments.* G. S. Fraps. Texas Agric. Exp. Stat. Bull. 267, Oct., 1920. 53 pages.

Crops were grown in a large number of soils during two years and comparison was made between soil composition and crops obtained. The crop yields increased with increased amount of active phosphoric acid (soluble in $N/5$ nitric acid) in the soil. Comparison of soils with similar contents of active phosphoric acid, showed a tendency of those with higher total phosphoric acid or higher total nitrogen to give up larger amounts of phosphoric acid to the crop. In many cases, surface soils gave up more phosphoric acid to the crop than subsoils with the same content of active phosphoric acid. More phosphoric acid was given up to the crop by a non-acid soil than by an acid one with an equal content of active phosphoric acid. There is a much closer relationship between the active phosphoric acid content of a soil and crop production, than between total phosphoric acid content and the crop.
—A. G. P.

Manurial efficiency of plant nutrients in soils. O. Lemmermann, L. Fresenius, and H. Wiessmann. Landw. Versuchs-Stat., 1921, 98, 155—185.

The manurial efficiency of the nitrogen, phosphorus, and potassium in different soils was compared in a series of pot experiments with oats, in which these elements were each supplied exclusively by soil added to pots in which the other essential elements were applied in highly available forms. From the yields obtained, the efficiencies of the nitrogen, phosphorus, and potassium in a series of soils were compared among themselves and against the efficiency of these elements in soluble fertilisers. An attempt was made to correlate the results obtained from pot experiments with analytical results for the soils in question. The efficiency of phosphorus and potassium is correlated with their solubility relative to the total amounts present. While in the case of potassium the relative solubility is best indicated by extraction with 10% hydrochloric acid, in the case of phosphorus 1% citric acid gives better results. Although ordinary soils are richer in potassium than in phosphorus, the latter element is more available.—G. W. R.

Soil; Effect of salt solutions on the ——. O. Nolte. Landw. Versuchs-Stat., 1921, 98, 135—153.

The effect of different solutions on soil permeability was studied by means of a specially devised apparatus. The results are in general agreement with current theory. (*Cf.* J.C.S., Dec.)—G. W. R.

Potassium in soils and fertilisers; Determination of ——. H. R. Christensen and N. Feilberg. Landw. Versuchs-Stat., 1921, 97, 27—56.

The method for the estimation of potassium by the use of sodium cobaltinitrite described by Mitscherlich (J., 1912, 350, 1055) has proved unsatisfactory particularly in the analysis of pure potassium salts. Better results were obtained in the case of soil extracts and other solutions containing a mixture of salts. A modification of the method is proposed in which in addition to the precipitating reagent, 5 c.c. of saturated sodium chloride solution is added. Working with potassium sulphate solutions of varying concentration, good agreement was obtained between calculated and observed values. The method as modified gives good results with fertiliser salts and soil extracts. In the latter, organic matter must first be destroyed. Where, as in the case of certain soil extracts, very small amounts of potassium are to be estimated, greater accuracy can be obtained by this method than by the platinichloride and perchlorate methods.—G. W. R.

Nitrogen; Causes of losses of —— *from excreta and similar organic substances.* O. Nolte and E. Pommer. Landw. Versuchs-Stat., 1921, 97, 245—260.

The losses of nitrogen during the storage of organic nitrogenous materials in general and farmyard manure in particular have been generally attributed to denitrification. The authors show that this explanation is improbable on theoretical grounds, since it presupposes nitrification, for which the conditions in an ordinary manure heap are unfavourable. In a series of experiments with solid and liquid excreta, no loss of nitrogen was observed even after long storage under conditions uniformly favourable for denitrification. The presence of nitrate was not established in any case. Similar results were obtained with "guanol" and gelatin.—G. W. R.

Potassium-ammonium nitrate; Reaction of —— with soil. N. Kempf. Landw. Versuchs-Stat., 1921, 97, 195—217.

Experiments on the absorption of ions by soil were carried out using solutions of potassium ammonium nitrate (*Kaliammoniaksalpeter*), a new fertiliser prepared from synthetic ammonium nitrate and "40% potash salts." The univalent metallic ions, sodium, potassium, and ammonium, were all absorbed to some extent, while approximately equivalent amounts of the divalent ions, magnesium and calcium, were displaced into solution. Absorption was practically instantaneous but slow changes in the amounts absorbed took place on standing. Nitrate was absorbed to a slight extent. (*Cf.* J.C.S., Dec.)—G. W. R.

Hydrolysing albuminous substances. Lo Monaco. *See* XIXa.

Phosphoric acid. Copaux. *See* XXIII.

XVII.—SUGARS; STARCHES; GUMS.

Sugar crystals; Examination of —— by projection. G. P. Meade. J. Ind. Eng. Chem., 1921, 13, 712.

The size of sugar crystals and their regularity may be observed conveniently by projecting their image on to a screen, the surface of which is marked out in squares of definite size. The author employs a Bausch and Lomb "balopticon" apparatus for the purpose; the projection lens is of 1⅝ in. focus, and a magnification of 10 diameters is obtained with the screen 7 ft. from the centre line of the lens. The sugar to be examined is mixed with a small quantity of alcohol and distributed over the bottom of a Petri-dish, and the latter is then placed in a horizontal position in a special holder fitted to the apparatus.—W. P. S.

Sucrose and raffinose; Revision of the optical method for analysing mixtures of ——. C. A. Browne and C. A. Gamble. J. Ind. Eng. Chem., 1921, 13, 793—797.

The Creydt formula (*cf.* J., 1887, 221) for analysing mixtures of sucrose and raffinose is revised owing to the change in the Herzfeld divisor of the Clerget formula from 142·66 to 143 (*cf.* J., 1892, 541). Taking −0·33 as the invert factor for sucrose and +0·514 as that for raffinose, and 1·852 as the ratio of the specific rotation of sucrose to that of raffinose, the percentages of sucrose (*S*) and raffinose (*R*) in a solution containing a sucrose normal weight of the sugars are given by the formulæ:—$S = 0{\cdot}514P - P'/0{\cdot}844$ and $R = 0{\cdot}33P + P'/1{\cdot}563$, where P and P′ are the direct and invert polarisations, respectively, both taken at 20° C. General formulæ for the same purpose and applicable at all temperatures are:—$S = \{P(0{\cdot}478 \times 0{\cdot}0018t) - P'(1{\cdot}006 - 0{\cdot}0003T)\}/(0{\cdot}908 - 0{\cdot}0032t)\ (1{\cdot}006 - 0{\cdot}0003T)$ and $R = \{P(0{\cdot}43 - 0{\cdot}005t) + P'(1{\cdot}006 - 0{\cdot}0003T)\}/(1{\cdot}681 - 0{\cdot}0059t)\ (1{\cdot}006 - 0{\cdot}0003T)$, where *t* and T are the temperatures at which the invert and direct polarisations, respectively, were observed. At 20° C., the two latter formulæ simplify to those first mentioned. —W. P. S.

Sugar beets; Process for producing palatable syrup from ——. S. F. Sherwood. J. Ind. Eng. Chem., 1921, 13, 799—801.

A syrup free from objectionable odour and flavour is obtained by heating beetroot slices with water at 80° C. for 1 hr., the quantity of water used being sufficient to cover the slices completely; the aqueous solution is then drawn off, passed through a sieve and heated at 108°—110° C. in an autoclave for about 1 hr., the steam being allowed to escape by opening a valve at frequent (*e.g.*, 15 min.) intervals. The extract is then evaporated to a syrup. Beetroot syrup thus prepared contains an average of 63·2% of sucrose and 2·73% of reducing sugars. —W. P. S.

Rare sugars; Purity and tests of ——. C. Pfanstiehl and R. S. Black. J. Ind. Eng. Chem., 1921, 13, 685—687.

Standards of purity are suggested for sugars which are used for differentiating micro-organisms by fermentation reactions; the sugars should be free from heavy metals, aluminium, calcium, and sulphates, and contain not more than a faint trace of chlorides; they should be neutral towards methyl red, and not yield iodoform when tested in the usual way (absence of alcohol etc.). In most cases the maximum limit for ash is 0·05% and for moisture 0·10%. The following are the specific rotations and melting points of certain carbohydrates:—*l*-Arabinose, $[\alpha]_D^{20} = +104{\cdot}6$; dulcitol, m.p. 188° C.; erythritol, m.p. 126° C.; *d*-galactose, $[\alpha]_D^{20} = +80{\cdot}3°$; dextrose, $[\alpha]_D^{20} = +52{\cdot}5°$; inositol, m.p. 224° C.; inulin, $[\alpha]_D^{20} = -38°$; lactose, $[\alpha]_D^{20} = +52{\cdot}43°$; lævulose, $[\alpha]_D^{20} = -92{\cdot}3°$; maltose, $[\alpha]_D^{20} = +131$; *d*-mannitol, $[\alpha]_D^{20} = +22{\cdot}5°$, m.p. 166·5° C.; *d*-mannose, $[\alpha]_D^{20} = +14{\cdot}25°$; perseitol, $[\alpha]_D^{20} = +0{\cdot}39°$, m.p. 188° C.; raffinose, $[\alpha]_D^{20} = +104{\cdot}5°$; rhamnose, $[\alpha]_D^{20} = +8{\cdot}37°$; sorbitol (anhydrous), m.p. 110° C.; sucrose, $[\alpha]_D^{20} = +66{\cdot}5°$; xylose, $[\alpha]_D^{20} = +18{\cdot}5°$. In some cases it is not possible to detect the presence of one sugar in another (*e.g.*, dextrose in lactose) by means of the polariscope, and fermentation methods must be used.—W. P. S.

Rare sugars; Standardisation of ——. H. T. Graber. J. Ind. Eng. Chem., 1921, 13, 687—688.

The following procedure is recommended for the analysis of the sugars:—Determinations are made of the specific rotation, moisture, ash, and solubility, and tests are applied to detect the presence of alcohol (iodoform reaction), chlorides, sulphates, calcium, barium, and heavy metals; the reaction of the solution is also tested towards litmus, methyl red, and phenolphthalein. Invert sugar should be free from sucrose and lactose must be free from nitrogen and protein.—W. P. S.

Honey; Sucrose content of ——. C. Bakker. Rec. Trav. Chim., 1921, 40, 600—603.

Direct determinations by Jolles' method (J., 1910, 1467) showed that the maximum sucrose content of honey is not greater than 1%. This was confirmed by estimations made with samples to which sucrose had been added. Jolles' method provides a means of detecting the addition of sucrose to honey in quantities as small as 2%. In cases where bees are fed on sucrose, it is practically all transformed and is thus not present in the honey as such.—H. J. E.

Starch and dextrin pastes; Consistence of ——. W. H. Herschel and C. Bergquist. J. Ind. Eng. Chem., 1921, 13, 703—706.

The Bingham and Green plastometer (*cf.* J., 1920, 495 a) is the most suitable type of instrument available for determining the consistence of plastic substances, but further modification in method is required so that the results obtained may be independent of the dimensions of the capillary. Adhesives of the concentration in which they are used are mostly plastic, but differences in "yield shear" value and rigidity of different samples having the same concentration are significant. For example four samples of maize dextrin (55% of total solids) had "yield shear" values of 200, 477, 229, and 524, whilst the respective rigidity values were 8·1, 7·0, 6·6, and 5·7. These values will indicate the body, spreading power, and setting or gelatinising power of starch and dextrin pastes.—W. P. S.

Patents.

Honey substitute; Manufacture of a ——. E., E. H., and B. M. Hohenadel. G.P. 339,785, 2.8.19.

A mash prepared from malt and sucrose, with or without malt-combs, is kept at a temperature favourable to the growth of lactic bacteria until the requisite acidity is attained, and afterwards the temperature is raised to permit diastatic saccharification of the starch and at the same time inversion of the sucrose by the lactic acid present. The filtered wort is concentrated to the consistency of honey.—J. H. L.

Heat-insulating body. U.S.P. 1,393,225. *See* IX.

XVIII.—FERMENTATION INDUSTRIES.

Barley; Determination of extract in ——, *and calculation of the loss of extract in malting.* L. Heintz. Z. ges. Brauw., 1921, 137—139, 149, 154—156.

A modification of the German Congress method for determining extract in malt, is proposed for determining the extract in barley. 25 g. of finely ground barley and 25 g. of a finely ground malt are mashed-in with 200 c.c. of water at 52° C. and maintained for 1 hr. in a water bath at this temperature. The temperature of the bath is then raised to 72° C. in 10 mins., and after addition of 100 c.c. of water at 70° C., the mash is kept at this temperature for 1 hr. and then cooled and treated as in the Congress method, allowance being made for the extract obtained from the malt. The results are lower than those obtained by some other methods, but form a suitable basis for valuation and for the control of malting operations.—J. H. L.

Beer and other alcoholic liquids; Bacteria as consumers of alcohol in ——. P. Lindner. Woch. Brau., 1921, 38, 206—207.

Various bacteria isolated from beer sediments, barley steep water, and vat brushes, but not characterised, were found to develop in beer of low alcohol-content at the expense of the alcohol, provided air was not excluded. One bacterium reduced the alcohol-content of a beer from 4% to 1·7% in ten days. The use of unboiled water for dilution, in the production of thin beers, may furnish sufficient oxygen for such bacteria, but a high alcohol-content, *e.g.*, 6%, appears to prevent their development.
—J. H. L.

Acetone, alcohol, and volatile acids; Fermentation process for the production of —— *from corn [maize] cobs.* W. H. Peterson, E. B. Fred, and J. H. Verhulst. J. Ind. Eng. Chem., 1921, 13, 757—759.

Maize cobs are readily hydrolysed when heated under pressure with dilute sulphuric acid, and yield 25—39% of their weight of reducing sugars, mainly xylose. The crude xylose syrup is almost completely fermented by *Bacillus acetoethylicum* (*cf.* J., 1919, 734 a, 786 a; 1921, 22 a); 100 lb. of the cobs yields 2·7 lb. of acetone, 6·8 lb. of alcohol (expressed as ethyl alcohol), and 3·4 lb. of volatile acids (formic and acetic acids). The best results are obtained by heating the cobs for 1 hr. under 20 lb. pressure with four times their weight of water and 8% of their weight of sulphuric acid. Excess of calcium carbonate must be present during the fermentation in order to neutralise the acids formed.—W. P. S.

Patents.

Yeast; Production of —— *from peat.* A. E. Vasseux. E.P. 147,581, 8.7.20. Conv., 19.1.18.

Peat is treated with molasses or suitable plant juices, preferably with the aid of heat, and the filtered wort is fermented under aerobic conditions for the production of yeast suitable for baking purposes. A clean, acid wort, rich in humates, may thus be obtained from 15—30 pts. of peat and 85—70 pts. of molasses. If the residue from the peat is not required to be used as a fertiliser, the original peat or the residue obtained as above may be digested by heating with acids or alkalis, and the extract obtained, neutralised to the required extent, may be treated with molasses and fermented as described.—J. H. L.

Beverages; Process of preparing low-alcoholic ——. H. Heuser. U.S.P. 1,390,710, 13.9.21. Appl., 16.6.20.

De-alcoholised beer is subjected to limited fermentation by yeast, during which process carbon dioxide, present before the commencement of fermentation, is maintained in the liquid.—J. H. L.

Beverages; Art of manufacturing cereal ——. R. S. Heuser. U.S.P. 1,390,711, 13.9.21. Appl., 2.8.20.

Fermented beverages are improved by addition of glycerol.—J. H. L.

XIXa.—FOODS.

Milk; Determination of watering and skimming in samples of altered ——. G. Andoyer. Comptes rend., 1921, 173, 588—589.

The coagulum of sour milk contains 15·6% of nitrogen, reckoned on the fat- and ash-free material, and this is the same as the value for nitrogen in casein. A known weight of the altered milk is acidified with acetic acid, filtered through a tared filter, and the coagulum washed with water. In the filtrate the ash and soluble nitrogen are determined. The coagulum is dried, extracted with ether to remove the fat, which is afterwards recovered and weighed, again dried, weighed, and incinerated. From these data the percentages of fat, casein, and ash in the original milk can be calculated and any adulteration detected.—W. G.

"Shortening"; Definition and measurement of ——. C. E. Davis. J. Ind. Eng. Chem., 1921, 13, 797—799.

The "shortness" of a cake or biscuit may be expressed in terms of the weight required to break or crush the material under standard conditions. An apparatus for determining this value is described and consists essentially of two parallel bars fitted on a horizontal base and a weighted vertical rod mounted above the bars; the cake to be tested is placed on the bars, the rod, the lower end of which is elongated horizontally, is placed on the upper surface of the cake, and weights are added to the upper end of the rod until the cake breaks. The weight required to effect the fracture is noted. Resistance to crushing is determined in a similar manner, the cake being placed on the flat base and a flat-bottomed rod placed vertically on it; the rod is then weighted until the cake is crushed. Comparative experiments showed that lard is the best shortening agent and that partial hydrogenation of an oil increases its shortening value.—W.P. S.

Albuminous substances and tissues; New method for hydrolysing —— in the cold. D. Lo Monaco. Arch. Farm. Sperim., 1920, **30**, 97—102. Chem. Zentr., 1921, **92**, IV., 968—969.

In studying the effect of gases used in poison-gas warfare, the author discovered that animal and human corpses are mummified by exposure for 24—48 hrs. in a closed room to the action of chlorine or bromine gas at the ordinary temperature, owing to extensive dehydration of the tissues. Material with a high hydrocarbon content turns black and brittle, develops a pungent odour, and gives off vapour containing chlorine after similar treatment, but nitrogenous material remains odourless. Human skin is rendered almost completely soluble in water, and muscle fibre yields an oily liquid containing a high percentage of nitrogen. About 33% of the nitrogen is converted into the amino form, indicating that albumins are hydrolysed to a great extent. The method of treatment has many practical uses: it may be used for preserving meat, grain, or the like; seeds treated with chlorine gas or allowed to germinate in dilute chlorine water produce healthier plants with a more vigorous growth of blossom and fruit than untreated seeds; the percentage of water-soluble salts and nitrates in soil is increased; and leather, waste material, and road-sweepings are converted into valuable manures.—L. A. C.

Maize; Removal of germ from ——. S. Weiser. Landw. Versuchs-Stat., 1921, **97**, 93—110.

The removal of the germ from maize for the purpose of obtaining maize oil from it was largely practised in Hungary during the war. The germ was removed by a milling process in which the yield varied between 6·4 and 9·4% of the maize used. The process was carried out most efficiently when the maize contained 15—15·5% of moisture. The oil content of the germ obtained was about 24%. Feeding experiments on pigs, using whole maize and germ-free maize in a ration, showed that, when allowance is made for the difference in composition, the two feeding stuffs are similar in value. By heating the fresh maize germ to 70°—80° C., the development of rancidity during storage may be prevented.—G. W. R.

Maize cake, its composition and feeding value. E. Pommer. Landw. Versuchs-Stat., 1921, **98**, 243—248.

Maize cake, the residue left after the extraction of oil from whole maize by pressure, is similar in composition and feeding value to maize of medium quality and may be used similarly. It must not be confused with maize germ cake, the residue after the extraction of oil from maize germ (*cf. supra*). —G. W. R.

Straw; Digestion of —— with sodium hydroxide solution and lime water in the cold. O. Nolte. Landw. Versuchs-Stat., 1921, **98**, 129—134.

The digestion of straw with lime water does not produce such a marked increase in digestibility s is produced by digestion with sodium hydroxide olution. By addition of sodium chloride to lime ater the alkalinity can be increased. Sodium hloride was accordingly added to lime water in he proportion shown by preliminary experiments o produce maximum alkalinity, and the solution as used for the cold digestion of straw. For comarison other experiments were made, using lime ater alone and sodium hydroxide solution. No ncrease in the amount of decomposition resulted rom the use of sodium chloride, and it is concluded hat the digestion process is not a simple function f the hydroxyl ion concentration, but is conditioned by tho cation present.—G. W. R.

Straw; Utilisation of —— [as fodder] by heating with sodium hydroxide solution under pressure and similar methods. S. Weiser and A. Zaïtschek. Landw. Versuchs-Stat., 1921, **97**, 56—92.

The digestibility and starch value of straw may be increased by heating with sodium hydroxide solution under pressure. Using 100 pts. of straw, 1·7 pts. of sodium hydroxide, and 200 pts. of water, and heating for 4 hrs. under a pressure of 4 atm., a product was obtained of acid reaction and marked taste and smell which proved equal in feeding value to 122·7 pts. of good hay. The product contained no digestible protein, and actually depressed the digestibility, but not the utilisation, of the protein of other fodders given with it. The use of larger quantities of sodium hydroxide did not give better results. Heating without pressure and also under pressure in the absence of sodium hydroxide gave smaller increases in digestibility. The substitution of lime for sodium hydroxide resulted in a similar product, which, however, had the disadvantage that a portion of the lime remained in it as hydroxide.—G. W. R.

Straw treated by different digestion methods; Feeding value of ——. II. Treatment with lime water, with and without pressure. F. Honcamp and F. Baumann. Landw. Versuchs-Stat., 1921, **98**, 1—41.

By digesting 150 kg. of rye straw for 4 hrs. with 24 kg. of lime (containing 35% CaO) and 525 l. of water, and removing excess of liquid from the digested straw, a product containing about 30% of dry matter is obtained. The digestion may also be carried out under pressure. The result of the treatment is to increase the feeding value of the straw. This result is obtained not simply by removal of incrusting materials (silicic acid and lignin), but by a separation of the constituents of the raw fibre, whereby they are rendered more easily attacked by intestinal bacteria. No advantage was found in heating under pressure, the losses in dry matter being greater and the product less palatable to animals. The increase in feeding value by the lime digestion is nearly the same as that obtained using sodium hydroxide, and is associated with increase in the digestibility of cellulose and pentosans.—G. W. R.

Straw treated by different digestion methods; Feeding value of ——. III. Treatment with sodium carbonate solution. F. Honcamp and F. Baumann. Landw. Versuchs-Stat., 1921, **98**, 43—63.

The treatment of straw with sodium carbonate solution is carried out in similar fashion to the treatment with sodium hydroxide solution and lime water (*cf. supra*). The increases in feeding value are almost the same as those obtained by the use of sodium hydroxide and are somewhat greater than those obtained by the use of lime water. —G. W. R.

Straw treated by different digestion methods; Feeding value of ——. IV. Digestion with sodium hydroxide solution under pressure. F. Honcamp, O. Nolte, and E. Pommer. Landw. Versuchs-Stat., 1921, **98**, 249—363.

In continuation of previous work on the subject, the changes produced by the digestion of different straws with sodium hydroxide solution under pressure were investigated. Losses occur in the case of all constituents except crude fibre. The feeding value of the digested product as measured by its starch equivalent is, however, considerably increased. The increase cannot be entirely attributed to simple removal of incrusting materials, but is probably due also to a loosening of the association between encrusting materials and cellulose whereby the latter is more readily attacked by bacteria. Although larger quantities of sodium hydroxide produce more decomposition, the losses are greater and the product less palatable than when an amount equivalent to 3½% of the straw is used. Non-cereal straws would appear to be unsuitable for the process.—G. W. R.

Hemicellulases in resting seeds and their supposed occurrence in higher animals. A. Rippel. Landw. Versuchs-Stat., 1921, **97**, 179—193.

The author has demonstrated the presence of an autolytic enzyme concerned in the decomposition of hemicelluloses in seeds of *Lupinus angustifolius*, L. Similar results were obtained with *Galium Aparine*, L., and *Asparagus officinalis*, L. The occurrence of hemicellulase in the alimentary tract of higher animals is regarded as improbable. (*Cf.* J.C.S., Dec.)—G. W. R.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Atropine; Decomposition of ——. D. B. Dott. Pharm. J., 1921, **107**, 286.

Atropine and hyoscyamine are hydrolysed to tropine to a considerable extent when their solutions are left for several hours even in the cold in presence of an excess of ammonia or sodium carbonate. Appreciable hydrolysis occurs even with sodium bicarbonate. The pharmacopœia method of assay should therefore be amended, sodium bicarbonate to be used instead of ammonia, and a caution given against the use of a large excess and against delay in extracting the liberated alkaloids with chloroform from the alkaline solution. —G. F. M.

Theophylline and theobromine; Phenacyl and dihydroxyphenacyl derivatives of —— and their corresponding secondary alcohols. C. Mannich and S. Kroll. Ber. deuts. Pharm. Ges., 1921, **31**, 291—310.

With the object of preparing new caffeine derivatives in which the stimulating action of caffeine on the nerve system was eliminated whilst the action on the heart was retained, substances were prepared in which the phenacyl radicle,

$C_6H_5.CO.CH_2-$, and the $(OH)_2C_6H_3.CH(OH).CH_2-$ group, characteristic of adrenaline, were introduced into the xanthine molecule. The desired physiological result was not obtained, however; phenacyltheophylline and phenacyltheobromine showing no advantage over theophylline, and the caffeine-adrenaline derivatives being apparently quite inactive physiologically. The phenacyl-derivatives were prepared by condensing ω-bromoacetophenone with sodium-theobromine and sodium-theophylline respectively. They were both sparingly soluble substances, having a ketonic character, and were reduced by palladium and hydrogen to the corresponding secondary alcohols. The adrenaline derivatives were prepared by condensing the sodium salts with ω-bromoacetoveratrone, eliminating the methoxyl groups, acetylating, reducing to the secondary alcohol, and eliminating the acetyl groups by hydrolysis. (*Cf.* J.C.S., Nov.)—G. F. M.

Alkaloid content of lupins; Determination of the ——. F. Mach and P. Lederle. Landw. Versuchs-Stat., 1921, **98**, 117—124.

Lupin meal is extracted with chloroform-ether and a little sodium hydroxide solution. An aliquot portion of the chloroform-ether extract is diluted with ether and washed three times with 1% hydrochloric acid. After removal of chloroform and ether, the alkaloids are precipitated with 10% silicotungstic acid. The precipitate is collected in a Gooch crucible, washed with 1% hydrochloric acid, dried to constant weight at 120° C., and ignited. The amount of alkaloids is estimated from the loss in weight on ignition and also from the weight of the ignited residue, using a factor. Two factors are given, namely, 0·2475 for lupinine, the principal alkaloid in yellow lupins, and 0·1744 for lupanine which occurs in other species.—G. W. R.

d-Lupanine, $C_{15}H_{24}N_2O$. G. Molander. Ber. deuts. Pharm. Ges., 1921, **31**, 265—270.

Contrary to the statements of Beckel (Arch. Pharm., 1911, **249**, 329; 1912, **250**, 691) the action of alcoholic bromine on lupanine hydrochloride does not result in a decomposition into two new bases, but gives a brominated compound of the composition $C_{15}H_{24}N_2O,HBr,Br_2$ or $C_{15}H_{22}Br_2N_2O,HBr$ in yellow crystals, from which bromine is readily eliminated with the formation of colourless crystals of lupanine hydrobromide, m.p. 240° C. *d*-Lupanine is very resistant also to the action of fuming hydrochloric acid under pressure, and 50% potassium hydroxide. By boiling alcoholic potassium hydroxide it is decomposed, and a hydrochloride m.p. 158° C. was isolated from the product.
—G. F. M.

Saponins of nuts of Pseudophœnix vinifera, Beccari, and their magnesium and calcium salts. A. W. van der Haar. Rec. Trav. Chim., 1921, **40**, 542—552.

Saponins may be divided into three groups, precipitable respectively by normal lead acetate, by basic lead acetate, and by basic lead acetate in presence of ammonia; the saponin of *Pseudophœnix vinifera* belong to the third class. Methods of quantitative determination hitherto used do not give reliable results. The author found 0·7% of saponin in the nuts of *Pseudophœnix vinifera*, and regards this as high. On hydrolysis the saponin yields rhamnose (24·4%), -fructose (19%), and *d*-galactose (1·5%), and amorphous and crystalline sapogenins, of which two were isolated, melting respectively above 328° C. and at 215°—216° C.; the latter appears to be a phytosterol, $C_{20}H_{22}O$.—H. J. E.

Lichens; Certain substances contained in ——. G. Bargellini and C. Moncada. Gaz. Chim. Ital., 1921, **51**, II., 173—180.

Stictaic acid, extracted from Italian *Sticta pulmonaria* by means of acetone, agrees in properties with the acid obtained by Hesse (J., 1898, 807; 1905, 42), its composition being in agreement with the formula $C_{19}H_{14}O_9$. Stereocaulic acid, obtained from various species of *Stereocaulon*, appears to be identical with stictaic acid. (*Cf.* J.C.S., Dec.)
—T. H. P.

Kawa-root; Constituents of the ——. *II. Kawa-resin.* W. Borsche and A. Roth. Ber., 1921, **54**, 2229—2235.

Kawa-resin (from *Piper methysticum*) is readily dissolved by warm 10% aqueous sodium hydroxide solution from which sodium kawaate separates on cooling. The corresponding acid, $C_{13}H_{12}O_3$, crystallises in yellow needles, m.p. 164°—165° C., and is decomposed readily into carbon dioxide and a dark yellow resin which yields cinnamylideneacetone in considerable quantity when distilled. Catalytic hydrogenation of sodium kawaate by Paal's method gives tetrahydrokawaic acid, which passes smoothly when distilled into δ-phenylbutyl methyl ketone. Kawaic acid appears to be either α- or γ-cinnamylideneacetoacetic acid, probably the latter. (*Cf.* J.C.S., Dec.)—H. W.

Coumarins; Production of —— from maleic and malic acids. G. C. Bailey and F. Boettner. J. Ind. Eng. Chem., 1921, **13**, 905—906.

On heating together phenol and maleic acid in the presence of various dehydrating agents no coumarin was produced; with malic acid, also, no appreciable quantities were formed. *m*-Cresol and malic acid in the presence of sulphuric acid produced methylcoumarin, a 54% yield on the weight of malic acid being obtained with a very pure *m*-cresol, and a 38—40% yield with an 84% *m*-cresol. Tests carried out on the white mouse indicate that methylcoumarin is only one-tenth as toxic as coumarin. The perfume value of methylcoumarin is claimed to be equal to that of coumarin and its taste is similar to but slightly less intense than that of the natural product.—S. S. A.

Dimethylphenetidine; Antipyretic action of some derivatives of ——. H. Rhode. Ber. deuts. Pharm. Ges., 1921, **31**, 271—279.

In the dimethylphenetidine series, as in the phenetidine series, the acetyl derivative has an antipyretic action stronger out of all proportion than other acyl derivatives, but nevertheless it is considerably weaker in its action than phenacetin, although with rabbits free from fever dimethylphenacetin caused a greater reduction in temperature than an equal dose of phenacetin. The acetyl-, salicylyl-, and *p*-aminobenzoyl-dimethylphenetidines were stronger in their action than the formyl- or valeryl-derivatives, but weaker than dimethylphenetidine itself. Phenetidine is a stronger febrifuge than phenacetin, but ethoxydimethylphenacetin is more powerful than diethoxydimethylphenetidine. No logical connexion can therefore be traced between chemical constitution and physiological action in the case of these phenetidine derivatives.—G. F. M.

Lactones; Action of various —— on worm muscles. L. Lautenschläger. Ber. deuts. Pharm. Ges., 1921, **31**, 279—291.

Further experimental evidence is adduced in support of Trendelenburg's theory (Arch. exp. Path. und Pharm., 1915, **79**, 190) that the anthelmintic action of santonin and similarly constituted compounds is to be ascribed to the lactone structure, and comparative experiments have shown further that the lactone group must be attached to a carbon ring, open-chain lactones having no anthelmintic action. The naphthalene nucleus in santonin can be replaced by a simpler cyclic group; for example, phthalide and meconin (dimethoxyphthalide) are as powerful in their action as santonin, and the replacement of one of the methylene hydrogen atoms by a simple alkyl group still further increases the activity.—G. F. M.

Catalytic hydrogenation of organic compounds by base metals at the atmospheric temperature. I. Influence of the nature and position of the halogens in organic haloid compounds on the removal of halogen by catalytic hydrogenation. C. Kelber. Ber., 1921, **54**, 2255—2260.

The rate of absorption of hydrogen by a solution of 1 g.-mol. of a number of organic halogen compounds in an excess of aqueous potassium hydroxide solution in the presence of 3 g. of nickel catalyst has been determined. The catalytic removal of halogen becomes easier with increasing atomic weight of the halogen and is, in general, more readily effected with aromatic than with aliphatic compounds. The distinction between the two classes, however, becomes less marked with increasing atomic weight of the halogen. In aromatic compounds in which a second substituent is present, the halogen atom in the ortho position is least readily, and that in the para position most easily, replaced by hydrogen.—H. W.

Oxidation processes; Mechanism of ——. *IV.* [*Action of hydrogen peroxide.*] H. Wieland. Ber., 1921, **54**, 2353—2376.

Hydrogen peroxide can behave as a hydrogenating agent by loss of hydrogen and liberation of molecular oxygen, as a dehydrogenating agent by reacting with hydrogen to form water and, in many reactions, as a true oxidising agent. Many examples of its many-sided activity are cited, the paper dealing successively with the oxidative decolorisation of Indigo Carmine, the oxidation of aldehydes, the catalytic decomposition of hydrogen peroxide, the peroxides as hydrogen acceptors, and the biological significance of catalases. (*Cf.* J.C.S., Dec.)—H. W.

Boric acid; Influence of —— *on the conductivity of phenolcarboxylic acids.* J. Boëseken and P. Ouwehand. Rec. Trav. Chim., 1921, **40**, 574—577.

Salicylic acid and its *o*-hydroxy analogues show a much greater increase of electrical conductivity in presence of boric acid solutions than the corresponding *meta* and *para* compounds. This difference in properties may be used to distinguish between the *o*-hydroxy aromatic acids and their isomers.—H. J. E.

α - Hydroxy - acids $R_1.CHOH.COOH$ *and* $R_1R_2.COH.COOH$; *Differentiation of* —— *by the boric acid method, and the space configuration of these substances.* J. Boëseken. Rec. Trav. Chim., 1921, **40**, 578—581.

The di-substituted acids show greater increase in conductivity than the mono-substituted acids in boric acid solution. (*Cf.* J.C.S., Nov.)—H. J. E.

Electrolytic reduction of some carboxylic acids. H. Inoue. Kōgyō-Kwagaku Zasshi (J. Chem. Ind., Japan), 1921, **24**, 906—918.

The author has investigated the electrolytic reduction of phenylacetic acid, using a mixture of 20 g. of phenylacetic acid, 70 g. of 75% sulphuric acid, and 60 g. of 96% alcohol as cathodic solution, 20—30% sulphuric acid as anodic solution, and a lead plate covered with lead peroxide as cathode, at 60° C., the current density per sq. dm. being 10 amp. and the total sum of the electric current 40 amp.-hrs. After reduction, the electrolyte was extracted with ether, the solvent evaporated, and the residual liquid distilled with steam. The volatile part contained phenylethyl alcohol and the ethyl and phenylethyl esters of phenylacetic acid; the total phenylethyl alcohol isolated was 53·45% of the theoretical value. From the residual part *r*-phenylacetopinacone (βγ-dihydroxy-αδ-diphenylbutane), m.p. 114·5° C., was isolated. Electrolytic reduction of cinnamic acid in a similar manner gave phenylpropyl alcohol in 38·46% yield and *r*-3.4-dihydroxy-1.6-diphenylhexane. Benzyl alcohol was obtained in 78% yield of the sample used by the electrolytic reduction of benzoic acid.—K. K.

Acetic anhydride; Preparation of —— *by the action of sulphur chloride on acetates.* M. Mashino. Kōgyō-Kwagaku Zasshi (J. Chem. Ind., Japan), 1921, **24**, 1023—1039.

Acetic anhydride can be prepared by heating sulphur monochloride and sodium acetate under agitation, using powdered metallic antimony as catalyst and acetic anhydride as diluting agent, the optimum conditions of the reaction being as follows:—Reaction temperature, 100° C.; time, 2 hrs.; quantity of sodium acetate, 2—6% excess over that required by theory; quantity of antimony, about 5% of the sulphur monochloride used. The utilisation of the acetate is 78·7% of the theoretical value and of sulphur chloride 80·6%. Tin, iron, and sulphides of antimony and iron etc. may also be used as catalysts, but are less effective, the utilisation of the acetate ranging from 57·2 to 68·8% and that of sulphur chloride from 58·8 to 70·2%. Zinc and magnesium act as anti-catalysts. The purity of the acetic anhydride used as diluent is almost without influence. Glacial acetic acid and calcium and ammonium acetates do not produce the anhydride by reaction with sulphur monochloride. Sulphur dioxide in the product is removed by distillation, chlorine by treatment with sodium acetate, and sulphur by phosphoric anhydride. The author suggests that in the reaction acetyl chloride is first produced by the action of the catalyst, and is converted into the anhydride by reaction with excess of the acetate.—K. K.

Methyl bromide; Preparation of ——. W. Steinkopf and G. Schwen. J. prakt. Chem., 1921, **102**, 363—364.

When bromine is added to a mixture of phosphorus and methyl alcohol at the ordinary temperature, flame sometimes appears and may explode the air and alcohol vapour. The bromine may be added quite safely if the alcohol is previously boiled for about 15 mins. and is kept gently boiling during the addition; under these conditions the reaction proceeds regularly and the yield of methyl bromide, calculated on the bromine, is increased from 44·5 to 77%. This method is considerably cheaper than that in which potassium bromide, methyl alcohol, and sulphuric acid are used.—T. H. P.

Ethylene; Preparation of —— *by hydrogenation of acetylene.* W. H. Ross, J. B. Culbertson, and J. P. Parsons. J. Ind. Eng. Chem., 1921, **13**, 775—778.

Metallic nickel reduced from the oxide at 300° C. adsorbs more hydrogen at ordinary temperature than does coconut charcoal; if a mixture of equal volumes of hydrogen and acetylene is passed through an evacuated tube one-third filled with freshly-reduced nickel, the hydrogen adsorbed in the nickel, together with that added, may be sufficient to reduce the acetylene completely to ethane. By repeating the process of evacuating the tube and introducing the hydrogen-acetylene mixture the excess of hydrogen is used up, and then on continuing the process a product may be obtained which contains over 80% of ethylene. The best yields seem to be obtained when the hydrogen is present in the mixture in slight excess, but with further increase in the quantity of hydrogen the amount of ethylene formed decreases and there is an increased formation of ethane. The adsorbed hydrogen in active nickel may be eliminated by repeated treatment with acetylene; the activity of the catalyst is not destroyed by this treatment, but the metal is then without action on either ethylene or acetylene alone.—W. P. S.

Sesquiterpene group. II. Machilol and atractylol. S. Takagi. J. Pharm. Soc. Japan, 1921, No. 473, 1—10. Chem. Zentr., 1921, 92, III., 1082—1083.

MACHILOL, $C_{15}H_{26}O$, needles, m.p. 79°—80° C., b.p. 160° C. at 14 mm., $[\alpha]_D^{25} = -30{\cdot}08°$, is obtained by the fractional distillation *in vacuo* of machilus oil, the product of the distillation of the wood of *Machilus kusanoi*. On dehydration with formic acid it is converted into machilene, $C_{15}H_{24}$, and by oxidation with permanganate it yields dihydroxymachilol, $C_{15}H_{26}O(OH)_2,H_2O$, needles, m.p. 120° C., which is identical with α-dihydroxyatractylol. This latter compound was isolated by repeated crystallisation of the dihydroxyatractylol produced by oxidation of atractylol by permanganate (*cf.* Arch. Pharm., 1903, 241, 22).—G. F. M.

PATENTS.

Lactic acid; Manufacture of salts of compounds of —— with tannic or gallic acid. E. Kolshorn. E.P. 146,234, 28.6.20. Conv., 13.6.19.

ALKALINE-EARTH or magnesium or aluminium salts of gallolactic or tannolactic acid are obtained in a solid form, almost insoluble in water, by heating a solution of a normal salt of lactic acid in aqueous alcohol or acetone with gallic or tannic acid until solution is effected. On cooling, the new compound separates out. Alternatively lactic acid may be heated in aqueous alcoholic or acetone solution with basic tannates or gallates. Calcium tannolactate contains 1 equiv. of Ca to 1 mol. of tannic acid and 1 mol. of lactic acid.—G. F. M.

Cyanamide derivatives of α-halogenated acids; Manufacture of ——. W. Carpmael. From Farbenfabr. vorm. F. Bayer und Co. E.P. 146,289, 24.6.20.

A HALIDE of an α-halogen-substituted aliphatic acid s allowed to react with an aqueous solution or suspension of a metallic compound of cyanamide. For example, 51·6 pts. of diethyl-α-bromoacetyl bromide s slowly added to a solution of 18—20 pts. of sodium cyanamide (95%) in 80 pts. of water, at 30° C. Sulphuric acid is added to the resulting solution until no further separation of oil occurs. The yield of diethylbromoacetylcyanamide in the form of a yellowish reactive syrup is about 85—90% of the theoretical.—G. F. M.

Hexamethylenetetramine; Process for the manufacture of a new derivative of ——. Chem. Fabr. vorm. Sandoz. E.P. 165,084, 18.5.21. Conv., 12.6.20.

A PRODUCT of therapeutic value in the treatment of gall-stones is prepared by treating natural gall bile) acids of animal galls, which are soluble with ifficulty in water and have previously been freed from slimy impurities, with an equimolecular quantity of hexamethylenetetramine, either in alcoholic olution or by grinding in the presence of water. The solvent is evaporated *in vacuo*, yielding a white, salt-like product readily soluble in water. —L. A. C.

lkylamines; Manufacture of ——. British Cellulose and Chemical Mfg. Co., Ltd., W. Bader, and D. A. Nightingale. E.P. 169,536, 2.7.20.

MONOMETHYLAMINE is obtained in a yield of over 80% of the theoretical by treating acetamide with calcium hypochlorite and hydroxide, and sodium carbonate, borate, phosphate, or any other salt capable of forming sodium hydroxide by reaction with an alkaline-earth hydroxide. In this manner the first stage of the reaction occurs in the absence of strong alkali, whilst the final stage is brought about by the gradual formation of sodium hydroxide. The temperature is kept low during the exothermic reaction. The process is applicable to the manufacture of other monoalkylamines, such as ethylamine etc.—F. M. R.

Chlorination [of hydrocarbons]; Process of ——. F. Sparre and W. E. Masland, Assrs. to E. I. du Pont de Nemours and Co. U.S.P. 1,379,367, 24.5.21. Appl., 31.10.12. Renewed 1.3.17.

IN order to avoid explosions during chlorination, especially of saturated hydrocarbons, chlorine is passed into the liquid hydrocarbon in a vessel from which light is excluded, and the resulting liquid is led into a vessel exposed to the light, in which free space is avoided as far as possible. The gas escaping during the introduction of chlorine may be absorbed in water and the liquid mixed with the chlorinated hydrocarbon.

Ester of the stearo-ricinate-di-iodide; Process for the production of a crystallised ——. F. Boedecker. U.S.P. 1,381,057, 7.6.21. Appl., 9.7.20.

THE ethyl ester of "stearoricinate-di-iodide" is obtained in crystalline form by the action of iodine on "stearoricinate" (octadiene-9-ol-12-acid-1) and esterifying the product, or by the action of iodine on ethyl stearoricinate.

Oxymercury nitrophenolate. J. F. Schamberg, G. W. Raiziss, and J. A. Kolmer, Assrs. to Dermatological Research Laboratories. U.S.P. 1,390,972, 13.9.21. Appl., 21.4.20.

AN oxymercuric nitrophenolate is prepared by treating an excess of mercuric acetate with an alkali salt solution of nitrophenol.—L. A. C.

Digitalis glucosides; Production of tannic acid compound of the ——. R. Tambach, Assr. to The Chemical Foundation, Inc. U.S.P. 1,391,705, 27.9.21. Appl., 18.1.17.

A SOLUTION of digitotannates, prepared by treating digitalis glucosides with a tannic acid compound, is extracted with a solvent, the solvent removed by distillation, and the residue dissolved in alcohol is mixed with an alcoholic solution of tannates. On evaporating to dryness the digitoglucotannic acid compound is obtained as a greyish-brown amorphous powder insoluble in water and dilute acids, soluble in ethyl alcohol and in alkalis.—G. F. M.

Pentachloroacetone; Production of ——. H. E. Buc, Assr. to Standard Oil Co. U.S.P. 1,391,757, 27.9.21. Appl., 4.11.20.

ISOPROPYL alcohol is treated with chlorine under conditions suitable for the production of chloroacetones which are separated from the reaction product and further chlorinated to pentachloroacetone. —G. F. M.

Chlorination; Art of ——. [Preparation of chloropropanes.] H. E. Buc, Assr. to Standard Oil Co. U.S.P. 1,391,758, 27.9.21. Appl., 22.11.20.

CHLOROPROPANES are prepared by passing chlorine into isopropyl alcohol, the temperature being maintained above 65°—70° C.—G. F. M.

Olefines; Process for producing ——. H. F. Saunders, Assr. to The Glysyn Corp. U.S.P. (A) 1,393,248 and (B) 1,393,249, 11.10.21. Appl., 6.5 and 24.9.20.

(A) A LIQUID containing paraffins together with higher olefines and propylene and dissolved inert gases is subjected to a pressure of 15—20 atm. in a vessel the lower end of which is kept at about 80° C. and the upper end at about 10° C. The gas which separates is passed into another vessel maintained at the same pressure but with its lower end kept at 0° C. and its upper end at −70° C. Liquid propylene is drawn off from the bottom of the second vessel. (B) The first vessel is kept at a pressure of 25—35 atm. and a temperature ranging from 80° C. at the bottom to 10° C. at the top, and the liquid portion from this vessel passes to a second vessel kept at 1—35 atm. pressure and at a temperature ranging from 0°—80° C. at the bottom to −25°—0° at the top. Gaseous propylene is drawn off from the top of the second vessel.—R. L. F. R.

Tetra-substituted ureas; Process of producing ——. T. J. Albert, jun., Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,393,597, 11.10.21. Appl., 25.9.18.

Tetra-substituted ureas are prepared by treating a secondary amine with carbonyl chloride in the presence of an aqueous solution of a basic inorganic compound capable of neutralising hydrochloric acid. —R. L. F. R.

Chloroform; Manufacture of —— *from acetaldehyde.* Consortium für Elektrochem. Industrie G.m.b.H. G.P. 339,914, 14.12.13.

Hypochlorites, preferably in aqueous solution or suspension, are allowed to act upon acetaldehyde, *e.g.*, a 20% solution of the latter is slowly added to a 10% sodium hypochlorite solution with constant stirring and cooling, the alkali formed being afterwards neutralised and the chloroform recovered by distillation. Considerably higher yields are obtained than when ethyl alcohol is used as raw material.—J. H. L.

Cinchona alkaloids; Production of aminosulphonic acids of hydrogenised ——. C. F. Boehringer und Soehne. G.P. 339,947, 26.4.19.

The corresponding nitrosulphonic acids (G.P. 338,738; J., 1921, 749 A) are reduced with ferrous sulphate and alkali. Aminohydroquininesulphonic acid, obtained from the nitro-compound by reduction with ferrous sulphate and barium hydroxide in water or methyl alcohol, crystallises from the latter in yellowish needles, m.p. 222°—224° C., and yields yellow solutions in alkalis and red solutions in acids. It is fairly soluble in hot water, slightly soluble in cold methyl and ethyl alcohols, forms a red crystalline sulphate, and is hydrolysed by concentrated hydrochloric acid, forming aminohydroquinine, m.p. 216°—218° C. The products may be employed as raw materials for the preparation of such substitution products of hydrogenised cinchona-alkaloids as are required to undergo transformations in alkaline aqueous solutions.—J. H. L.

Arseno-compounds of the pyrazolone series; Manufacture of ——. Farbw. vorm. Meister, Lucius, u. Brüning. E.P. 146,870, 5.7.20. Conv., 15.12.17.

See G.P. 313,320 of 1917; J., 1921, 637 A.

Diphenylamine; Process for the manufacture of ——. A. E. Houlehan, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,392,942, 11.10.21. Appl., 25.5.17.

See E.P. 138,372 of 1917; J., 1920, 280 A.

Ethereal salts of ethylenic halogen-hydrins; Process for the manufacture of ——. J. Altwegg and J. Landrivon, Assrs. to Soc. Chim. Usines du Rhône. U.S.P. 1,393,191, 11.10.21. Appl., 13.6.19.

See E.P. 128,911 of 1919; J., 1920, 247 A.

Fusion process. U.S.P. 1,379,619. *See* I.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Desensitising with potassium iodide. Freund's method. T. Bolas. Brit. J. Phot., 1921, 68, 532—534. O. F. Bloch and F. F. Renwick. *Ibid.*, 627—628.

Freund's method of desensitising photographic plates before development by treatment with potassium iodide solution, a historical account of which is given, is stated to be quite satisfactory and in some respects, chiefly that of not using coloured reagents, to have advantages over the dye methods of desensitising. The potassium iodide, which is used as a 4% solution, should not contain any free iodine, being treated, if necessary, with alkali carbonate to remove it. Bromide plates give better results with the process than bromo-iodide plates. A quinol-carbonate developer, containing pure sulphite, is preferable to any other. Iodide acts as a restrainer and bromide as an accelerator in development. Development may be effected in white light. The plates should be fixed in plain "hypo" (not acid), and "hypo" is preferable to cyanide. In comparative experiments on Ilford Empress plates with potassium iodide solution, as described above, Bloch and Renwick obtained lower image densities than by the use of the iodide-sulphite-thiocyanate solution previously described by Renwick (J., 1920, 156 T), the quinol developer recommended by Bolas was less effective than an alkaline amidol developer (*loc. cit.*), the addition of bromide to the quinol developer had no accelerating effect, and development of a plain iodised plate by artificial white light led to a still further loss of image. The image densities obtained by amidol development after treatment in the iodide-sulphite-thiocyanate solution were less than those obtained by pyro-soda development without preliminary desensitising.—B. V. S.

Patents.

Colour photography. J. F. Shepherd, and Colour Photography, Ltd. E.P. 169,533, 30.6.20.

In a process by which two colour-record negatives, green and red, are taken and positives from these, suitably coloured, are superposed in register, a better colour rendering is obtained by colouring the positive from the green negative magenta and that from the red negative blue-green, and superposing in register with these a third positive taken through the combined negatives and coloured yellow. —B. V. S.

Coating for photographic plates. G.P. 339,905. *See* XIII.

XXII.—EXPLOSIVES; MATCHES.

Spent acid; Use of nitroglycerin —— *as charging acid for nitric acid stills.* S. G. Norton. J. Ind. Eng. Chem., 1921, 13, 677—678.

The use of spent acid, strengthened by the addition of fuming sulphuric acid, in nitric acid stills, yielded unsatisfactory results; there was a continuous evolution of nitrogen peroxide, the yield of nitric acid decreased, and poor separations were obtained in the subsequent nitroglycerin operations. These difficulties increased cumulatively with each passage of the acid through the system and the use of the spent acid had to be abandoned. —W. P. S.

Patents.

Explosive composition. W. C. Cope, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,390,671, 13.9.21. Appl., 13.6.18.

A detonating composition contains an organic filling material and an aromatic acid adapted to inhibit the growth of living organisms.—H. C. R.

Propellent bulk smokeless powder. R. G. Woodbridge, jun., Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,390,740, 13.9.21. Appl., 11.12.19.

Bulk smokeless power in the form of grains, at least partially colloided, is mixed and agitated with graphite.—H. C. R.

Explosives; Protective mixture for high ——. W. T. Schiele, Assr. to the Government of the United States. U.S.P. 1,391,796, 27.9.21. Appl., 9.12.19.

A mixture of 2% of aniline, 2% of hydrocarbon, and 96% of carbon bisulphide is added to nitro explosives.—L. A. C.

Explosive. W. B. Sturgis, Assr. to General Explosives Co. U.S.P. 1,393,463, 11.10.21. Appl., 16.5.21.

A mixture of dinitrotoluene, a perchlorate, an oxidising agent, a metallic sulphide, and a reducing substance.—H. C. R.

Nitrocellulose explosives; Method of removing and recovering solvent from ——. F. W. Stetson and J. L. Essex, Assrs. to E. I. du Pont de Nemours and Co. U.S.P. 1,393,713, 11.10.21. Appl., 30.1.20.

The powder is first washed with ethyl alcohol of a strength to remove ether without substantial removal of alcohol, and then with water to remove the alcohol.—H. C. R.

Picric acid; Process for producing ——. C. M. A. Stine and J. L. Gilson, Assrs. to E. I. du Pont de Nemours and Co. U.S.P. 1,393,714, 11.10.21. Appl., 25.8.19.

One part of dinitrophenol is suspended in 1½—3 pts. of concentrated sulphuric acid, and a mixture of nitric and sulphuric acids added, the temperature being maintained between 160° and 200° F. (71°—93° C.). The resulting mixture is heated at 200°—235° F. (93°—113° C.) for about 1 hr. and then cooled.—H. C. R.

Distillation and rectification of solvents used in explosives manufacture; Removal of residues during ——. Maschinenbau-A.-G. Golzern-Grimma. G.P. 300,127, 15.9.16.

The deposition of distillation residues in the rectifying column is avoided by continuous rinsing with water.—W. J. W.

Explosives; Process for producing ——. W. Schrauth. G.P. 300,149, 21.3.16.

Nitro-compounds of tetrahydronaphthalene and its substitution products are used, either alone or mixed with other substances. These compounds have, in addition to high explosive power and low sensitiveness to blows and friction, the advantages of homogeneity, crystalline structure, high density, and comparatively low melting point.—H. C. R.

Nitrocellulose; Stabilisation of ——. Claessen. G.P. 308,430, 24.4.18. Addn. to 306,400 (J., 1921, 603).

By carrying out the original process at increased pressure still better stabilisation is attained.
—H. C. R.

Chlorate and perchlorate explosives. Chem. Fabr. Griesheim-Elektron. G.P. 309,297, 13.2.15.

Chlorates or perchlorates of bases of the urea group are used, *e.g.*, guanidine perchlorate, thiourea perchlorate, dicyanodiamidine chlorate. These salts are formed by direct union of the components or by double decomposition of suitable salts, and can be used either alone or mixed with other explosives. For example, a very powerful explosive is produced by mixing together to a paste equal parts of guanidine perchlorate and trinitrotoluene and allowing the mass to solidify.—H. C. R.

Nitroglycerin powders; Recovery of acetone or other solvent from ——. Westfälisch-Anhaltische Sprengstoff-A.-G. G.P. 340,016, 18.2.19.

The powder is soaked in water at 35°—45° C. for 3—24 hrs., or the temperature of the water is gradually increased from 20° to 45° C. during soaking. From 40 to 60% of the original solvent can be recovered.—H. C. R.

XXIII.—ANALYSIS.

Zinc [in foods etc.]; Determination of small quantities of ——. M. Bodansky. J. Ind. Eng. Chem., 1921, **13**, 696—697.

A turbidimetric method, using ferrocyanide as the reagent, is described for the determination of small quantities (*e.g.*, 5 mg. or less) of zinc in foods etc. The sample is treated with sulphuric acid and nitric acid, incinerated, the ash is dissolved in dilute hydrochloric acid, the solution filtered, and the filtrate evaporated to dryness. The residue is dissolved in 2 c.c. of hydrochloric acid and 50 c.c. of water, copper, if present, is removed as sulphide, the solution then boiled to expel hydrogen sulphide, cooled, and neutralised with ammonia. After the addition of 10 c.c. of 50% citric acid solution the solution is again boiled, and calcium carbonate is added in small quantities at a time until a precipitate of about 1 g. of calcium citrate is formed. Hydrogen sulphide is then passed into the solution, the precipitate is collected after 2 hrs., washed with 2% ammonium thiocyanate solution and dissolved in hot dilute hydrochloric acid. A reddish coloration indicates the presence of iron and in such case the zinc should be re-precipitated. The solution is diluted to 45 c.c. in a Nessler cylinder, 5 c.c. of 3·5% potassium ferrocyanide solution is added, and the turbidity produced is compared with standards containing known amounts of zinc.—W. P. S.

Patents.

Thermo-couple. M. A. Hunter, Assr. to Driver-Harris Co. U.S.P. 1,393,375, 11.10.21. Appl., 17.2.20.

A thermo-couple is constituted of a refractory alloy of copper, nickel, and chromium, highly resistant to oxidation, and a second member affording a linear relation between the thermo-electromotive force and the temperature of the junction.
—J. S. G. T.

Moisture; Automatic indicator of the proportion of ——. M. Chopin, Assr. to Soc. Anon. des Grands Moulins de Vilgrain. U.S.P. 1,392,116, 27.9.21. Appl., 7.8.20.

See E.P. 155,486 of 1920; J., 1921, 131 A.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Bendixen. Apparatus for mixing and disintegrating substances in fluids. 29,820. Nov. 9.

Cloke. Separating and/or concentrating materials. 29,403. Nov. 4.

Commin, Hughes, and Teague. Manufacture of semiplastic material in sheet form. 30,123. Nov. 11.

Elcomb. Drying chambers. 29,846. Nov. 9.

Fawcett, Preston, and Co., and others. 29,358. *See* VII.

Gibbs. Method of cooling condensers. 29,072. Nov. 2.

Hall, and Silver Springs Bleaching and Dyeing Co. Treating waste liquors and obtaining valuable products. 30,096. Nov. 11.

Humphries. Promoting heat exchange between gases and liquids. 29,958. Nov. 10.

Kilburn (Sulzer Frères). Cooling distillation products. 29,103. Nov. 2.

McNeil. Clarifying apparatus for liquids. 28,962. Nov. 1.

Mather. Settings for stills etc. 29,020. Nov. 1.

Oertel. Furnaces. 29,662. Nov. 7. (Ger., 6.11.20.)

Wheatley. Compositions for coating interiors of tanks etc. 29,567. Nov. 7.

Complete Specifications Accepted.

14,379 and 34,732 (1920). Thermal Industrial and Chemical Research Co., Duckham, and Morgan. Heating liquids by introduction into molten metal. (170,617.) Nov. 9.

18,394 (1920). Berger. Manufacture of a nickel catalyst. (146,407.) Nov. 16.

22,583 (1920). Hopwood. Regulating combustion conditions in furnaces. (170,683.) Nov. 9.

24,052 (1920). Kestner. *See* VII.

2799 (1921). Cartner, Clewer, and Mather and Platt, Ltd. Vacuum filtration apparatus. (170,788.) Nov. 9.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Becker. Coking retort ovens. 29,644. Nov. 7. (U.S., 8.11.20.)

Bibb. Fuel and process of making same. 28,854. Oct. 31.

Brinsley. 29,456. *See* VII.

Cumming, and Klarit, Ltd. Manufacture and use of decolorising carbon. 29,555—7. Nov. 7.

Davidson. Manufacture of producer gas. 28,925. Oct. 31.

Eccles and Wiseman. Composition for use in petrol, benzol, etc. 28,911. Oct. 31.

Hovey. Obtaining light hydrocarbon distillates from heavier hydrocarbons. 28,900. Oct. 31.

Hudspeth, Richards, Stroud, and Thompson Low-temperature carbonising plant. 28,839. Oct. 31.

Lang and Nielsen. Distillation etc. of carbonaceous materials. 30,032. Nov. 10.

McHarry. Gas-producers. 29,728. Nov. 8.

Mantius and Simonson. Reclaiming sludge acid in petroleum refining. 29,763. Nov. 8. (U.S., 19.11.20.)

Melamid. Production of low-boiling hydrocarbons for motor fuel etc. 29,870—1, 30,018—9. Nov. 9 and 10. (Ger., 11.11.20, 15.1 and 25.5.21.)

Stettiner Chamottefabr. A.-G. Gas-heated ovens and retorts. 29,420. Nov. 4. (Ger., 12.1.21.)

Thom and Thom. Retort for distilling carbonaceous matter. 29,086. Nov. 2.

Tully. Manufacture of gas for heating and lighting. 30,180. Nov. 11.

Vogel. Production of gaseous fuel. 29,787. Nov. 8.

Complete Specifications Accepted.

18,825 (1920). Cummins. Vertical gas-retort settings. (170,904.) Nov. 16.

20,746 (1920). Griggs. *See* VII.

22,427 (1920). Soper, Terrell, and Terrell. Manufacture of incandescent mantles. (170,679.) Nov. 9.

23,354 (1920). Fischer. Converting combustible substances into soluble organic compounds. (149,974.) Nov. 9.

23,455 (1920). Barrett Co. Manufacture of coke. (155,226.) Nov. 16.

III.—TAR AND TAR PRODUCTS.

Applications.

British Dyestuffs Corp., and Wyler. Manufacture of phenylglycine or compounds thereof. 29,289. Nov. 3.

British Dyestuffs Corp., Clemo, McLeod, and Perkin. Mononitro and monoamino derivatives of *p*-halogenated dialkylanilines. 29,902. Nov. 9.

Schranth and Schroeter. Preparation of reduction products of nitro-compounds of tetrahydronaphthalene and its derivatives. 28,928. Oct. 31. (Ger., 16.3.16.)

Complete Specifications Accepted.

11,833 (1920). Barrett Co. *See* XIII.

17,347 (1920). Irinyi. Distillation of tar etc. (146,183.) Nov. 16.

IV.—COLOURING MATTERS AND DYES.

Applications.

Atack and Whinyates. Manufacture of dyestuffs from carbazole. 29,074. Nov. 2.

British Dyestuffs Corp., and Green. Dyestuffs from products obtained in the manufacture of dialkylrhodamines. 30,264. Nov. 12.

Complete Specifications Accepted.

16,200 (1920). Akt.-Ges. f. Anilinfabr. Manufacture of trisazo dyestuffs. (145,055.) Nov. 9.

16,906 (1920). Akt.-Ges. f. Anilinfabr. Manufacture of sulphurised dyestuffs. (145,522.) Nov. 9.

18,202 (1920). Akt.-Ges. f. Anilinfabr. Manufacture of dyestuffs of the acridine series. (145,802.) Nov. 16.

22,016 (1920). Arnot. Azo dyes and process of manufacture. (149,354.) Nov. 9.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Bader, and British Cellulose and Chem. Manuf. Co. Treatment of cellulose derivatives. 29,137. Nov. 2.

Charlesworth. Wool-washing machines. 29,713. Nov. 8.

Clavel. Treatment of union or mixed fabrics. 29,734. Nov. 8.

Dreyfus. Manufacture of cellulose derivatives. 29,735. Nov. 8.

Fürst. Cleaning cellulose solutions. 29,776. Nov. 8. (Ger., 11.11.20.)

Kämpf. Manufacture of articles of viscose. 29,990. Nov. 10. (Ger., 21.4.21.)

Leech. Removal of pectic matter from vegetable fibres. 29,002. Nov. 1.

Whitehead (Clavel). Treatment of cellulose derivatives. 29,135—6. Nov. 2.

Complete Specifications Accepted.

11,362 (1920). Bronnert. Manufacture of artificial silk. (170,608.) Nov. 9.

11,415 (1920). White. Manufacture of fibrous materials from zoophytes and other sea materials. (170,869.) Nov. 16.

11,843 (1920). McIntyre, and Milne and Son. Extraction of moisture from paper pulp etc. (170,871.) Nov. 16.

12,051 (1920). Bronnert. Manufacture of artificial silk. (170,874.) Nov. 16.

21,902 (1920). Cogblan. Treatment of wool. (170,645.) Nov. 9.

23,036 (1920). Bronnert. Production of high-percentage sulphite-cellulose. (170,964.) Nov. 16.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Akt.-Ges. f. Anilinfabr. Dyeing animal or mixed ibres. 29,044. Nov. 1. (Ger., 26.11.20.)

Ashworth. Dyeing yarns. 28,942. Nov. 1.

Bloxam (Akt.-Ges. f. Anilinfabr.). Dyeing skins, airs, etc. 28,921. Oct. 31.

Hall and others. 30,096. *See* I.

Complete Specifications Accepted.

17,503 (1920). Freiberger. Treatment of fibres, abrics, leather, etc. with liquids. (146,225.) ov. 16.

22,969 (1920). Ferrand and Riley. Apparatus for reating textile materials with fluids. (170,956.) ov. 16.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Briggs and Harris. Treatment of iron liquors ntaining zinc and sodium sulphate. 29,198. ov. 3.

Brinsley. Bringing about water absorption of nmonia. 29,456. Nov. 5.

Chem. Fabr. Griesheim-Elektron. Production of rbon bisulphide from its elements. 29,835. v. 9. (Ger., 14.1.21.)

Commin, Hughes, and Teague. Fixation of atmos-eric nitrogen. 30,124. Nov. 11.

Dietrich. Manufacture of oxide of barium. ,907. Oct. 31.

Fawcett, Preston, and Co., Harris, and Lang. ncentration of salt solutions and manufacture of ts. 29,358. Nov. 4.

Gibbs. Manufacture of salt. 29,071. Nov. 2.

Manuf. de Prod. Chimiques du Nord Etabl. Kuhlmann. Mechanically-operated furnaces for roasting pyrites. 29,658. Nov. 7. (Ger., 10.6.21.)

Soc. l'Air Liquide. Apparatus for synthesis of ammonia. 30,005. Nov. 10. (Fr., 14.1.21.)

Complete Specifications Accepted.

12,039 (1920). South Metropolitan Gas Co., and Parrish. Manufacture of ammonium sulphate. (170,613.) Nov. 9.

12,630 (1920). Matheson. Manufacture of sulphuric acid. (170,880.) Nov. 16.

20,746 (1920). Griggs. Production of hydrogen. (170,908.) Nov. 16.

21,779 (1920). Wolffenstein, and Chem. Fabr. vorm. Goldenberg, Geromont u. Co. Production of solutions containing aluminium formate and an alkali salt. (170,911.) Nov. 16.

24,052 (1920). Kestner. Filling material for use in Glover towers etc. (170,982.) Nov. 16.

24,847 (1920). Norske Akt. for Elektrokemisk Ind. Production of alumina from aluminium nitrate solutions. (151,259.) Nov. 16.

30,142 (1920). Hauenschild. *See* IX.

VIII.—GLASS; CERAMICS.

Applications.

Llewellyn. Plastic mixture for saggers for firing pottery etc. 29,478. Nov. 5.

N. V. Philips' Gloeilampenfabr. Materials or receptacles for handling molten glass. 29,877. Nov. 9. (Holland, 4.12.20.)

IX.—BUILDING MATERIALS.

Applications.

Osborne. Compositions for building walls etc. 29,901. Nov. 9.

Vielle. Manufacture of road-dressing materials. 29,724. Nov. 8.

Complete Specifications Accepted.

16,532 (1920). Guillot. Manufacture of imitation marble. (145,443.) Nov. 9.

16,946 (1920). Brettschneider. Manufacture of bricks etc. (170,622.) Nov. 9.

30,142 (1920). Hauenschild. Shaft furnaces for burning cement, magnesite, etc. (170,764.) Nov. 9

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Lane. Coating metal with metal. 29,155. Nov. 2.

MacKay. Recovering metals from complex ores. 30,115. Nov. 11.

Miyaguchi. Cementation of boron into surface of iron or steel. 29,293—4. Nov. 3.

Miyaguchi. Manufacture of iron and steel. 29,295. Nov. 3.

Miyaguchi. Manufacture of ferroboron and boron steel. 29,296. Nov. 3.

Myers. Flux for welding. 30,210. Nov. 12.

Plauson's (Parent Co.), Ltd. (Plauson). Extraction of gold or silver. 29,215. Nov. 3.

Complete Specifications Accepted.

17,525 (1920). Maschinenfabr. Esslingen. Manufacture of iron alloys. (146,230.) Nov. 16.

18,378 (1920). Otsuka. Apparatus for concentrating ores by flotation. (146,396.) Nov. 16.

22,066 (1920). Harris and Bardeen. Restoring the strength of steel. (170,659.) Nov. 9.

22,763 (1920). Wood, Sellers, and Minerals Separation, Ltd. Ore concentration. (170,944.) Nov. 16.

22,907 (1920). Terrisse and Levy. Acid-proof castings. (151,974.) Nov. 16.

25,018 (1920). De Bats. Melting and casting metals. (170 995.) Nov. 16.

27,510 (1920). Lofts. Alloy for use in electric heating appliances. (171,019.) Nov. 16.

XI.—ELECTRO-CHEMISTRY.

Application.

Grund. Storage batteries. 29,139. Nov. 2.

Complete Specifications Accepted.

12,263—4 (1920). Pouchain. Accumulator electrodes. (170,614—5.) Nov. 9.

14,500 (1920). Pouchain. Electric accumulators. (170,618.) Nov. 9.

25,965 (1920). Davey, and Electro Metals, Ltd. Operating electrodes of electric furnaces. (171,003.) Nov. 16.

27,510 (1920). Lofts. *See* X.

XII.—FATS; OILS; WAXES.

Application.

Cook and Co., and Gray. Manufacture of soap powder. 29,495. Nov. 5.

Complete Specifications Accepted.

22,386 (1920). Nicholson. Apparatus for extracting fats and oils. (170,921.) Nov. 16.

34,831 (1920). Tseng. Manufacture of soap. (170,781.) Nov. 9.

1022 (1921). Fauth. Extraction of oil from oilseeds etc. (157,155.) Nov. 9.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Application.

Whyte. Conversion of sulphate of lead water paste into oil paste. 30,089. Nov. 11.

Complete Specification Accepted.

11,833 (1920). Barrett Co. Manufacture of resin from naphthas. (142,806.) Nov. 16.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Complete Specifications Accepted.

22,491 (1920) and 11,055 (1921). Schidrowitz, and Catalpo, Ltd. Manufacture of caoutchouc and caoutchouc-like products. (170,682.) Nov. 9.

33,793 (1920). Bilbrough. Rubber compounds. (171,046.) Nov. 16.

XV.—LEATHER; BONE; HORN; GLUE.

Applications.

Knopf. Production of substitutes for leather and horn-like compositions. 29,444. Nov. 4.

Levy. Depilatory compound. 29,397. Nov. 4.

Reubig. Manufacture of leather. 29,186. Nov. 2. (Ger., 2.11.20.)

Complete Specification Accepted.

17,503 (1920). Freiberger. *See* VI.

XVI.—SOILS; FERTILISERS.

Application.

Pease. Production of fertiliser. 29,784. Nov. 8.

Complete Specification Accepted.

9372 (1921). Soc. l'Azote Française. Manufacture of fertilisers. (160,810.) Nov. 9.

XVII.—SUGARS; STARCHES; GUMS.

Applications.

Cumming and others. 29,555—7. *See* II.

XVIII.—FERMENTATION INDUSTRIES.

Application.

Swiss Ferment Co. Manufacture of durable preparations of active animal amylases. 29,169. Nov. 2. (Switz., 24.11.20.)

Complete Specifications Accepted.

18,333 (1920). Dubourg. Brewing beer. (146,365.) Nov. 16.

20,670 (1920). Jarraud and Roussel. Maturing and improving wines, spirits, vinegar, etc. (148,829.) Nov. 9.

7945 (1921). Briscoe. Brewing beer etc. (171,069.) (146,365.) Nov. 16.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Adams. Sewage purification. 29,841. Nov. 9.

Boidin and Effront. Simultaneous production of demineralised amylaceous substances and lower nitrogenous matter for food. 29,866. Nov. 9. (Fr., 23.11.20.)

Gusmer. Clarifying fruit juices. 30,260. Nov. 12.

Hastings. Preparing, blending, etc. foodstuffs. 29,252. Nov. 3.

Swiss Ferment Co. 29,169. *See* XVIII.

Vielle. Manufacture of disinfectants. 29,423. Nov. 4.

Complete Specifications Accepted.

19,887 and 20,352 (1920). Bielmann and Bielmann. Manufacture of juices and jellies. (147,838 and 148,407.) Nov. 9.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Marks (U.S. Industrial Alcohol Co.). Production of high-grade esters. 30,142—3. Nov. 11.

Napp (Hoffmann-La Roche u. Co.). Manufacture of a compound of isopropylallylbarbituric acid. 29,042. Nov. 1.

Pollak. Manufacture of condensation products. 29,035. Nov. 1. (Austria, 3.11.20.)

Schatzkes. Purification of lactic acid. 29,034. Nov. 1. (Ger., 27.12.20.)

Stockholms Superfosfat Fabr. Akt. Manufacture of a catalyst for producing acetone from acetic acid etc. 29,872. Nov. 9. (Sweden, 9.11.20.)

XXII.—EXPLOSIVES; MATCHES.

Application.

Hatakeyama. Manufacture of matches without heads. 29,031. Nov. 1.

Complete Specification Accepted.

35,030 (1920). Stringfellow. Matches. (171,050.) Nov. 16.

XXIII.—ANALYSIS.

Application.

Chemicals and By-Products, Ltd., and Cohen. Indicator for determining weak acids or bases in presence of strong acids and bases etc. 30,119. Nov. 11.

I.—GENERAL; PLANT; MACHINERY.

Patents.

Controlling the temperature of chemical reactions; Process of and apparatus for ——. The Barrett Co., Assees. of C. R. Downs. E.P. 144,614, 1.4.20. Conv., 11.6.19.

The temperature of an exothermic reaction is maintained constant by the use of mercury to absorb the heat merely as latent heat of vaporisation, and the desired temperature of vaporisation of the mercury is varied by controlling the pressure thereon. The apparatus comprises a reaction chamber into which extends a closed container partially filled with mercury. Examples of reactions so controlled are the oxidation of naphthalene to phthalic acid, using vanadium oxide as catalyst, and the oxidation of anthracene to anthraquinone, toluene to benzoic acid, or benzaldehyde and benzene to maleic acid. (*Cf.* U.S.P. 1,374,720—1; J., 1921, 381 A.)—H. H.

Washing or otherwise treating liquids with liquids or vapours; Apparatus for ——. B. de M. de Vivies. E.P. 147,742, 8.7.20. Conv., 26.3.19.

A receptacle for the continuous treatment of a liquid with a solvent or washing liquid of different specific gravity and not miscible therewith is provided with superposed fixed baffles by which the liquids are constrained to move in a sinuous path to promote their intimate association. The solvent is delivered above the liquid and discharged from below it, or *vice versâ*, according to whether its specific gravity is greater or less than that of the liquid. A pipe extending through the baffles is provided to promote circulation of the liquid. The solvent and the liquid may be caused to circulate in opposite directions from one receptacle to another. The vapour of a volatile solvent may be condensed as it enters the receptacle.—H. H.

Filters used in dry-gas purifying plants; Process for removing the dust which clings to the surfaces of the ——. W. E. Evans. From Deutsche Maschinenfabrik A.-G. E.P. 148,799, 10.7.20.

The filter surfaces are formed as pockets which are moved past the cleaning nozzles or past which the nozzles are moved, and the pressure of the fluid blown through the nozzles is such as to distend the pockets. Subsequently the pressure of the impure gas causes the walls of the pockets to spring back, thus dislodging the dust particles not loosened by the fluid from the nozzles.—H. H.

Electrical treatment of gases; Apparatus for the ——. H. J. Kennard, Assr. to Research Corp. U.S.P. 1,394,771, 25.10.21. Appl., 7.5.18.

The gas to be treated is passed between a disc-shaped electrode capable of rotation, and a stationary filamentary electrode substantially parallel to the side of the disc.—J. S. G. T.

Electrostatic precipitation of particles from gases or liquids; Apparatus for ——. P. Kirchhoff. G.P. 337,490, 10.8.19.

Supplementary electrodes are disposed between the principal electrodes, so that the drop of potential between the principal positive and negative electrode occurs in a series of steps. Moreover, in order to use both polarities, two additional permeable electrodes, each operating in the same manner as its neighbouring electrode, are placed between two plate electrodes. The use of both polarities effects economy of current and permits the precipitation of particles which become charged by friction with the gas or liquid. In addition, particles carrying charges of opposite sign coalesce to form larger masses, with consequent greater ease of precipitation.—J. S. G. T.

Insulators used in the electrical purification of gases; Device for protecting ——. P. Kirchhoff. G.P. 338,058, 15.10.19.

A non-conducting plate of any desired shape, composed of an insulator, a poor conductor, or both these in conjunction with a conductor, is disposed about the insulators so as to be either in contact with or at a very small distance from the walls of the dust chamber.—J. S. G. T.

Electrical purification of gases; High-tension electrodes for ——. Siemens-Schuckertwerke Ges.m.b.H. G.P. 338,357, 11.7.19. Addn. to 314,775 (J., 1920, 162 A).

The lower ends of electrodes suspended in the precipitation chamber transversely to the gas stream, in accordance with the chief patent, are connected consecutively by a conductor traversing the chamber longitudinally. The dead space in the chamber is thereby further reduced and the electrode system acquires rigidity against vibration.—J. S. G. T.

Separation of liquids from gases or vapours. E. A. R. Chenard. E.P. 148,811, 10.7.20. Conv., 24.12.18. Addn. to 130,992 (J., 1920, 92 A).

The gases or vapours are caused to flow upwards against the downward passage of liquid through a number of metallic screens closely clamped together. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 130,992; J., 1920, 92 A).—H. H.

Gases; Removing particles of vapour, liquid, or solid from ——. W. Freytag. G.P. 340,652, 8.7.20. Addn. to 331,321 (J., 1921, 334 A).

In the process described in the chief patent, very moist gas is passed through a cooled filtering material saturated with crude oil. The oil is fed into the lower part of the apparatus, and mixes with the deposited matter. The oil is subsequently separated from water and sludge, and is returned to the apparatus.—L. A. C.

Refrigerant. H. W. Seaman, Assee. of A. G. Crawford. E.P. 148,875, 10.7.20. Conv., 5.2.18.

A mixture of propane, propylene, butane, and butylene is used as a substitute for ammonia etc. in refrigerating machines.—B. M. V.

Mixing apparatus also suitable for preparing solutions. K. Pfisterer. E.P. 152,649, 18.10.20. Conv., 18.10.19.

A jet of liquid is discharged vertically upwards by an ejector nozzle within a tube the upper part of which is enlarged to form a receptacle for the material to be mixed with or dissolved in the liquid. The jet impinges on a distributing sieve and falls in a spray on the material to be mixed or dissolved. The solution flows down through the tube, and at the bottom suspended particles are drawn into the ejector and re-circulated, whilst the solution flows through narrow passages into an outer container, wherein it flows upward through a filter to an outlet.—H. H.

Filtering liquids; Apparatus for ——. F. Bloor. E.P. 169,870, 30.7.20.

The shell of a rotary drum vacuum filter is formed of V-section bars disposed longitudinally of the drum with their wider ends at the interior, and perforations are provided in the shell between the bars. The wide inner ends of the bars are machined to provide a smooth surface. To remove solid matter from the filtering fabric enclosing the drum while it is above the liquid being filtered, a stationary chamber is provided within the drum, open at its outer face to some of the perforations but making a tight joint with the machined faces of some of the bars and within the ends of the shell, and fluid under pressure is supplied from the tubular axis of the drum to this chamber to pass outwards through the fabric.—H. H.

Filtering or inspissating liquids. P. Vageler. E.P. 170,225, 17.12.20.

The liquid to be treated is fed to a reservoir with a conical, inclined, or horizontal bottom and cylindrical or conical sides, through a conical feeder opening near the bottom of the reservoir, the mouth of the feeder and the annular space between it and the sides of the reservoir being about equal in area. Scrapers mounted by means of hinges or flexible supports on a central rotary shaft move over the bottom of the reservoir. The parts are so proportioned that a banking-up of the liquid occurs in the lower part of the reservoir, a rising column of drifting particles is formed at or near the lower part of the feeder, below a region of clear liquid in the upper part of the reservoir, and the precipitated matter is delivered continuously to the bottom discharge opening.—H. H.

Recovering gases which have been absorbed by solids. Thermal Industrial and Chemical (T.I.C.) Research Co., Ltd., and J. S. Morgan. E.P. 170,323, 21.5.20.

The charcoal or other absorbent is dipped under molten metal, preferably in several successive baths with increasing temperature, the exhausted charcoal being returned from the hottest bath to a cooler one to recover some of the heat taken up by the charcoal.—B. M. V.

Fractional distillation; Method of and apparatus for ——. Thermal Industrial and Chemical (T.I.C.) Research Co., Ltd., and A. McD. Duckham. E.P. 170,324, 21.5.20.

The temperature of one or more sections of the condenser is regulated by the flow therethrough of the material to be distilled; the rate of flow may be regulated by a thermostat, or reliance may be placed on the fact that on reaching a certain temperature vapours will be evolved, the latter being conveyed to the still together with the fluid part of the material to be distilled.—B. M. V.

Condensing apparatus. J. Y. Piscek, Assr. to J. Gullas. U.S.P. 1,395,502, 18.10.21. Appl., 20.4.20.

The cooling water and vapour to be condensed pass separately in a zig-zag manner through an inner casing, the sides and top of which are surrounded by liquid contained in an outer casing. —B. M. V.

Fire extinguishers; Charges for chemical ——. G. J. Money. E.P. 170,390, 19.7.20.

An aqueous extract of a froth-forming substance, such as bark, liquorice root, etc., is mixed with sodium bicarbonate, the mixture is baked, and introduced into the extinguisher with (in a separate vessel) sulphuric acid of sp. gr. about 1·1 which has been boiled with the residues of the froth-forming substance.—B. M. V.

Furnaces. A. Smallwood. E.P. 170,428, 31.7.20.

A number of fire-boxes are arranged around the circumference of a treating chamber, each fire-box communicating by means of an uptake flue and two lateral branches with two ports in the treating chamber. The waste gases leave the treating chamber by ports in the floor leading to a number of flues under the furnace, alternating with air flues in which air is preheated and from which it is taken to the lateral branches of the uptakes to promote secondary combustion.—B. M. V.

Oven. S. Trood. U.S.P. 1,393,650, 11.10.21. Appl., 24.9.20.

A heating chamber, through which the articles to be heated travel, is provided with means for maintaining along it zones of approximately uniform temperature separated by zones of changing temperature.—H. H.

Shaft furnaces; Process and apparatus for heating gas-fired ——. Bunzlauer Werke Lengersdorff u. Co. G.P. 331,833, 6.11.18.

In a shaft furnace, intended more especially for burning lime, cement, dolomite, magnesite, etc., preheated air, drawn from an enlarged region of the cooling shaft situated below the combustion shaft, is collected in a distributing channel surrounding the latter and delivered therefrom to the burners. Cold air in regulated amount can be supplied to each separate burner.—J. S. G. T.

Washing coal and concentrating ores and minerals; Method for ——. *Method and apparatus for classifying materials.* (A) T. M. Chance. U.S.P. 1,392,400, 4.10.21. Appl., 27.8.17. (B) H. M. and T. M. Chance. U.S.P. 1,392,401, 4.10.21. Appl., 8.7.18.

(A) See E.P. 119,038 of 1918; J., 1919, 754 A. The fluid mass of liquid with solid matter in suspension is maintained by agitation in a number of zones of relatively different specific gravity, in which different fractions of the material under treatment collect and from which they are removed separately. (B) The solid constituent of the fluid mass is of such a character that it will remain suspended in a hydraulic current that will not support the material under treatment, and the latter is separated into fractions by means of differences in falling velocity through the fluid mass.—B. M. V.

Drying apparatus. E. B. Ayres and H. Bogaty, Assrs. to The Philadelphia Textile Machinery Co. U.S.P. 1,393,003, 11.10.21. Appl., 1.12.19.

An endless-chain conveyor with pans pivoted on the chain is arranged within a drying chamber. Each pan is provided with a lip at each end shaped to interlock with the lip of the adjoining pan, and means are provided for feeding material to the pans, for releasing the interlocked lips of adjoining pans, and for discharging the pans at each end. —H. H.

Dryer; Shelf ——. P. Rüters. G.P. 336,137, 29.6.18.

A circulation of air through the drying chamber is maintained by a fan in such manner that either fresh air, air already used, or a mixture thereof in desired proportions can be circulated. The channel for the return of air to the fan is provided with a valve, and the apertures for discharging air from the drying chamber are covered with cloth or gauze. By suitable choice of the dimensions of the openings and of the mesh of the gauze, discharge of air from the chamber may be made to occur when any predetermined pressure has been attained in the chamber.—J. S. G. T.

Liquid mixtures [*e.g., oil-water emulsions*]; *Process and apparatus for refining* ——. S. F. Alden and H. C. Eddy; H. C. Eddy, Assr. to Petroleum Rectifying Co. of California. U.S.P. 1,394,462, 18.10.21. Appl., 23.12.16.

An electric field is maintained between electrodes immersed in, *e.g.*, an oil-water emulsion, and the intensity of the field is alternately increased sufficiently to cause a current to flow through the mixture, and decreased to prevent passage of the current. The coalesced particles separate into distinct liquids.—L. A. C.

Heating device for evaporators. A.-G. Kummler u. Matter. G.P. 337,937, 13.5.20. Conv., 5.1.18.

The heating device is provided with vertical annular channels for the liquid to be evaporated and arranged concentrically around the heating elements. The inlet and outlet for heating medium are at the bottom of the heating element, so that the heating surfaces can be kept clean by scrapers projecting downwards into the channels and caused to rotate around the vertical axis of the heating element. The heating element has an inner cylindrical surface and an outer conical surface, so that the cross-section of the channels for the liquid being evaporated increases from below upwards, corresponding to the progressively increasing quantity of vapour bubbles in the same direction. —J. S. G. T.

Thick inorganic slimes; Process and apparatus for removing —— from conical settling tanks. T. Steen. G.P. 339,025, 16.12.17.

The apparatus consists of a shallow cylindrical tank ith a deep conical bottom provided with an outlet ube. The tank is filled with the pulp, and a flat late with an outline corresponding to that of the ank and having a specific pressure corresponding o the density and inner friction of the thick slime, s placed on the top of the liquid, through which it inks to a depth where its pressure equals the upard pressure of the slime, thus forming a protectng cover to the layer of settled slime, at the same ime leaving an annular opening between its perihery and the walls of the cone. On opening the ock at the bottom of the cone the hydrostatic presure at first prevents the slime under the plate from eing drawn off until that between the edges of the late and the walls and the small amount of thinner lime above the plate has been removed, after which he level of the thicker slime is forced down until he plate fits the cone completely, when the flow of ulp stops.—A. R. P.

olloids; Process and apparatus for concentrating aqueous solutions of mineral, vegetable, or animal ——. Elektro-Osmose A.-G. (Graf Schwerin Ges.). E.P. 151,002, 28.8.20. Conv., 11.9.19.

ee G.P. 333,575 of 1919; J., 1921, 457 a.

oncentrating, evaporating, and dehydrating liquids by treatment with gases. P. W. Webster and V. K. Boynton. E.P. 154,182, 27.10.20. Conv., 20.11.19.

ee U.S.P. 1,361,940 of 1920; J., 1921, 72 a.

iltering; Apparatus for ——. Braden Copper Co., Assees. of N. B. Down. E.P. 156,583, 23.12.20. Conv., 2.1.20.

e U.S.P. 1,348,159 of 1920; J., 1920, 619 a.

ulverulent materials; Apparatus with several tubes for treating ——. A. P. E. Bourdet. U.S.P. 1,394,269, 18.10.21. Appl., 10.1.20.

e E.P. 153,479 of 1919; J., 1921, 1 a.

um [rotary kiln] for burning and agglomerating. J. S. Fasting, Assr. to F. L. Smidth & Co. U.S.P. 1,394, 293, 18.10.21. Appl., 10.6.19.

e E.P. 149,764 of 1919; J., 1920, 691 a.

inding in ball-mills. J. S. Fasting, Assr. to F. L. Smidth & Co. U.S.P. 1,394,294, 18.10.21. Appl., 15.3.21.

e E.P. 160,423 of 1921; J., 1921, 682 a.

filters. H. Wittemeier. E.P. 148,545 and 48,846, 10.7.20. Conv., 2.1. and 19.12.17.

flammable liquids; Storage of ——. V. Scharagl. E.P. 152,672, 20.10.20. Conv., 1.8.14.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Froth flotation as applied to the washing of industrial ——. E. Bury, W. Broadbridge, and A. Hutchinson. Trans. Inst. Min. Eng., 1920—1921, **60**, 243—253.

The coal should be crushed in the dry state and passed through a 0·1-in. screen; the employment of water during crushing and for classification as in metallurgical practice is not advisable. A general description is given of a coal crushing, screening, flotation, and drying plant (*cf.* Jones, J., 1921, 758 a). The water used for washing naphthalene from coke-oven gas contains, after separation of naphthalene, sufficient frothing reagents to treat all the coal required for the coke ovens. By adjustment of reagents the low-ash coal may be first separated from the bone-coal and shale or clay; about 0·33 lb. of paraffin oil per ton of original coal is then added in the appropriate cell of the flotation machine, whereupon the bone-coal floats and is removed as a separate product. As this contains 12%—15% of ash, it is more suitable for steam raising than for the manufacture of blast-furnace coke. The tailings contain 60%—85% of ash, and flow away with the water to a settling ground or Dorr thickener; in some cases they consist of high-grade fireclay. Although pyrites may be concentrated by flotation processes, the reagents employed for floating coal are such that the sulphur content of the coal is actually reduced. The washed coal after partial drying is converted into coke containing 4·8%—5·0% of ash and of very high physical strength. It is estimated that the use of this coke for smelting Cleveland ironstone will result in a saving of 2 cwt. of coke and 1·5 cwt. of limestone per ton of pig-iron when compared with the use of coke from modern washery product coal. —H. Hg.

Lignite; Nitration of ——. J. Marcusson. Z. angew. Chem., 1921, **34**, 521—522.

Air-dried lignite containing 25% of water was finely powdered, added to five times its weight of a mixture of 3 pts. of concentrated sulphuric acid to 2 pts. of nitric acid of sp. gr. 1·42, and allowed to stand for 1 hr. The mixture was then poured into water and filtered. The washed precipitate was found to consist of a nitro-compound completely soluble in acetone. This product, which is reddish-brown and is decomposed by heat, contains 3·8% N, and is also soluble in pyridine, chlorhydrin, or a mixture of benzol and alcohol. The pyridine solution is miscible with water, and gives precipitates with mineral acids, barium chloride, etc. The calcium salt of the compound corresponds to an equivalent weight of 425 for the nitro-compound. On heating with hydrochloric acid one-third of the nitrogen is removed, suggesting that it is rather an oxonium than a nitro-compound. The acetone solution on evaporation leaves a varnish-like film.—C. I.

Ethylene and air mixtures; Propagation of flame in ——. W. R. Chapman. Trans. Chem. Soc., 1921, **119**, 1677—1683.

The limits of inflammability of ethylene and the speed of the uniform movement of flame in its mixtures with air as determined in a glass tube 2·5 cm. in diameter are recorded. In harmony with other hydrocarbons, the speed of the flame increases rapidly to a maximum as the percentage of ethylene is increased, and then decreases, while the speed of the flame at the limits tends to a value of 20 cm. per second, which appears, therefore, to be a constant for hydrocarbons. The speed-percentage curve for the uniform movement of flame in mixtures of air with ethylene is in all respects intermediate in character between those for methane and acetylene. The maximum calorific effect is shown by mixtures containing ethylene and oxygen in combining proportions (*i.e.*, containing 6·5 % C_2H_4), while the maximum speed of uniform movement is obtained with mixtures containing 7 %—7·25 % C_2H_4. Formulæ are given whereby the maximum-speed mixture and the speed obtainable when a composite gas of known proportions is mixed with air can be calculated from the composition of the maximum-speed mixtures with air of the individual constituent gases and the speeds of flame in them (*cf.* Payman, J., 1920, 94—95 A, 181 A). As regards the speed of uniform movement of flame, the higher olefines correspond more closely to the paraffins than does ethylene.—P. V. M.

Combustion; Intra-molecular energy during ——. W. T. David. Phil. Mag., 1921, **42**, 860—870. (*Cf.* J., 1921, 111 A.)

In the pre-pressure period of the explosion of mixtures of coal-gas and air (interval between passage of igniting spark and commencement of an increase of pressure) there is a considerable amount of gentle ignition, but no rise of pressure and no appreciable radiation. In the earlier explosion periods the pressure rises slowly, indicating a moderated combustion, which is accompanied by radiation of long wave length (up to 11·0 μ). As the combustion becomes more vigorous the radiation becomes greater and then includes shorter infra-red radiation also. In the later stages of combustion the action is more vigorous and is accompanied by a rapid rise of pressure and a radiation which contains more of the short infra-red waves the more vigorous the combustion. (*Cf.* J.C.S., Dec.) —J. F. S.

Acetylene; Hydrogenation of —— for the preparation of fuel oils. K. Oda. Kōgyō-Kwagaku Zasshi (J. Chem. Ind., Japan), 1921, **24**, 1161—1166.

A catalyst composed of nickel and mercury, which is active at a lower temperature than nickel alone, was prepared by converting a mixture of 20 g. of nickel nitrate and 2 g. of mercuric nitrate into the oxides by heating at 250°—300° C., and then reducing to the metals by heating in a current of hydrogen at 300° C. A mixture of equal volumes of purified acetylene and hydrogen was passed over the catalyst at 25°—35° C., at a rate of 3—4 l. per hr. A light oil (olefines) and some heavy oil of b.p. 200°—300° C., which remained in the catalyst, were obtained, the total yield being 51·7 %.—K. K.

Vertical [gas] retorts; Observations on the practice of ——. F. Davies. Mid. Junior Gas Assoc., 10.11.21. Gas J., 1921, **156**, 501—503.

The following yields per ton of coal were obtained in a modern installation of Woodall-Duckham retorts:—17,000—18,000 cub. ft. of gas with a calorific value of 450 B.Th.U., 9 cwt. of available coke, 14·9 galls. of tar, and ammonia equivalent to 31·7 lb. of ammonium sulphate. The combustion chamber temperature was 2300° F. (1260° C.) at the top and 2000° F. (1090° C.) at the bottom. Superheated steam at 20 lb. pressure was admitted to the base of each retort through a $\frac{3}{16}$-in. orifice. The coke used in the steaming was 1·25 cwt. and in the producers 2·5 cwt. The production of coke dust was not more than 0·25 cwt. per ton of coal.—H. Hg.

Gas sampler for testing purposes; Continuous ——. B. P. Bezant. Gas J., 1921, **156**, 433.

Gas is drawn into a closed tank, through a supply pipe connected with the top of it, by running off water through a U-tube connecting the bottom of the tank with a ball-cock in an open tank from which water is discharged at a uniform rate through a valve. The gas sample is then supplied under pressure to a testing apparatus by admitting water from a main supply at a controlled rate to the base of the closed tank. Absorption of gas by the water is prevented by a layer of oil on the surface of the water.—H. Hg.

Colorado shale oils. A. J. Franks. Chem. and Met. Eng., 1921, **25**, 731—735, 778—782. (*Cf.* J., 1921, 336 A, 571 A.)

Repeated distillations of oil from Colorado shales from the De Beque region were made at atmospheric pressure. A current of hydrogen was passed through the boiling liquid when a temperature of 300° C. was reached. In the first distillation, taking 10 % fractions, the sp. gr. of the distillates was 0·782—0·975, % saturation 52·2—11·6, % S 0·75—0·52, % N 0·599—2·084. The light oils (below 270° C.) were stable under repeated distillation, but the heavy oils decomposed extensively under a single cracking distillation, with the formation of new saturated compounds. It has been proved that the unstable heavy oils are unsaturated bitumens (boiling above 320° C.) containing sulphur, nitrogen, and oxygen, but practically no unsaturated hydrocarbons. They are probably intermediate products of the distillation of oil shale. It is thought that the distillation of the "kerogen," or organic material of the shale, produces less complex heavy unstable oils of high boiling point by depolymerisation, which oils then decompose further to a varying degree, with the formation of simpler stable products.—C. A. K.

Mineral oils; Treating —— with alkaline liquor. H. Burstin. Petroleum, 1921, **17**, 1169—1171.

In the present method of treating mineral oils with strong alkaline solutions, *e.g.*, sodium hydroxide solution of 15° B. (sp. gr. 1·116), after a previous treatment with sulphuric acid, there is considerable waste of alkali and also of acid in the subsequent neutralisation to precipitate naphthenic acids, which moreover are obtained in a highly impure state. Thus, in treating 50,000 kg. of petroleum distillates, 60 kg. of liquor of 15° B. was employed, containing about 6 kg. of sodium hydroxide, whereas 0·5 kg. would have sufficed to dissolve the crude naphthenic acid present. Experiments on purified oil to which a known weight of naphthenic acid had been added showed that extraction is complete by shaking with less than twice the theoretical weight of *N*/10 sodium hydroxide solution. By shaking gas oil with sodium hydroxide solution of 1°, 5°, and 10° B. (sp. gr. 1·007, 1·037, and 1·075) crude naphthenic acids having acid values of 106, 121, and 41, and saponif. values 115, 135, and 44 respectively were obtained on subsequent acidification. After agitating petroleum distillates and gas oil with sodium hydroxide solution of 3°—5° B (sp. gr. 1·022—1·037) on the works scale, the aqueous and oily layers separated rapidly with a relatively small intermediate layer of emulsion, while the naphthenic acids obtained from the extract were of high quality. Further extraction yielded mainly resins, creosote, and phenols, with only traces of naphthenic acid.—L. A. C.

Lubricating oil for cylinders; Effect of high temperatures on ——. W. Ernst. Petroleum, 1921, **17**, 1180—1187.

The use of hot water from the condensers of steam engines as feed water for the boilers involves a partial separation from the water of varying quantities of lubricating oil carried forward from the cylinders, and the introduction of accumulating traces of oil into the boilers. An apparatus for testing the effect of temperature and pressure on lubricating oils consisted of a heat-insulated iron cylinder holding 1 l., provided with inlet and outlet tubes, a thermometer tube, and a pressure gauge, and containing inside an electrically controlled heating spiral of "nickelin" wire. The cylinder was filled with a sample of the oil, of which the flash-point and b.p. had previously been determined, and heat was applied gradually with the outlet tube open until vapour began to escape. The outlet tube was then closed, nitrogen was admitted from a cylinder until the pressure rose to 1 atm., and the temperature was raised under constant pressure until vapour was again evolved, as indicated by a rise in pressure and by taking samples of gas by momentarily opening the outlet tube. After recording the temperature at which this occurred, the process was repeated a number of times up to a maximum pressure of 15 atm. The results obtained by testing a number of samples of oils are tabulated, and in most cases show a steady rise of vapour pressure with temperature, although with certain samples a rapid rise of pressure under constant or even decreasing temperature indicates rapid decomposition at that point. The flash-points of the oils lay between 230° and 290° C., and the b.p. approximately 100° higher. It was found that the flash-point is independent of the pressure, *i.e.*, inflammable gas is evolved at and above the flash-point, even when the oil is under pressure, and that decomposition of the oil at high temperatures not only thickens the oil but reduces its viscosity. Thus the efficiency of the oil as a lubricant in the cylinders is reduced; tarry constituents, if present, tend to separate and increase friction, and oil carried to the boilers is gradually decomposed to a pitchy residue which reduces the conductivity of the boiler plates and may eventually lead to local overheating and consequent deformation of the plates and loosening of rivets.—L. A. C.

Calorimeter bomb. Roth and others. *See* XXIII.

Patents.

Coal or like briquettes; Manufacture of ——. H. G. Lloyd. E.P. 170,092, 10.7.20.

Pitch or bitumen is treated at a temperature above its flowing point but below its cracking point, with 4—15% of water or steam in order to produce a froth which is used as a binding agent for briquettes. The water may be incorporated with the material to be briquetted and the mixture added to the molten binding agent. (*Cf.* E.P. 5439 of 1897, 4779 of 1902, 22,424 of 1911, and 107,344; J., 1897, 613; 1903, 289; 1912, 577; 1917, 956.) —H. Hg.

Coke from waste fuel and residues; Plant for separating ——. W. Weber und Co. Ges. für Bergbau, Industrie und Bahnbau. E.P. 155,269, 13.12.20. Conv., 24.11.19.

A mixture of coke and clinker is passed over a screen to remove fine ashes and is then caused to slide slowly into a tank containing water. The floating coke is immediately separated from the heavier clinker by a surface current produced by a jet of water discharged under pressure from a nozzle. The two streams of coke and clinker are further separated by a trap, the position of which is adjustable. The coke and clinker are then allowed to settle separately upon two conveyor belts whereby they are removed from the tank.—H. Hg.

Mobile fuel; Method of fireproof-storing ——. L. W. Bates. U.S.P. 1,394,060, 18.10.21. Appl., 5.8.19.

A stable mixture of liquid and pulverised fuels having a specific gravity greater than that of water is covered with a layer of water.—H Hg.

Coke-ovens. R. Cravau. E.P. 170,525, 4.1.21.

Regenerators extending throughout the length of the heating piers of coke-ovens are provided with an inlet for air or gas and an outlet for waste gas at each end. Communication between the regenerators and the outside air or the waste gas collector galleries is controlled by double-acting valves. —H. Hg.

Coke ovens or the like. American Coke and Chemical Co., Assees. of A. Roberts. E.P. (a) 165,733, (b) 165,734, and (c) 165,736, 10.7.20. Conv., 11.7.19.

(a) A secondary supply of gas is admitted to the central portion of the heating wall of an oven through a vertical duct in the partition wall between the heating walls of two adjacent ovens and through ports in large blocks which project into the heating wall. Shearing planes being established on the upper and lower surfaces of the blocks, the partition and heating walls may expand or contract independently without breaking the continuity of the gas passage. (b) The heating wall is divided into zones by a number of vertical partitions in order that temperatures may be adjusted locally with particular reference to the increased width of the oven at the coke-delivery end. The air suppply to each burner is controlled by dampers, and is obtained from a common horizontal duct extending throughout the length of the partition wall. The spent gases from each zone discharge into a common flue under the oven and thence through dampers into two shorter flues; by adjustment of these dampers the draught in each zone may be equalised. (c) Air nozzles are situated on opposite sides of each gas burner at the top of the heating wall so that gas enters the combustion chamber surrounded by an envelope of air. The partially burnt gas and air then pass downwards into a mesh-work of interconnected passages to which a secondary supply of gas is admitted and wherein combustion is completed.—H. Hg.

Vertical retorts for the continuous destructive distillation of carbonaceous materials. S. Glover, J. West, and West's Gas Improvement Co., Ltd. E.P. 170,197, 16.10.20.

A chamber of larger cross-sectional area than the retort is provided between the base of a vertical retort and a worm coke extractor. The chamber may be of conical form, conforming to the shape of the retort at its upper end and of circular section at its base; it may be heated externally if desired. Steam is admitted to the chamber and reacts with the coke therein, which is broken up by the withdrawal of its lateral support and by the action of the rotating extractor.—H. Hg.

Generating combustion products under pressure for heating and power purposes; Process and apparatus for ——. F. Riedel. E.P. 147,026, 6.7.20. Conv., 27.2.19.

Combustion of a gaseous mixture is effected in a chamber provided with controlled inlet and outlet valves, scavenging air being admitted to the chamber through lateral valves disposed at a point in advance of the inlet valve for the combustible mixture, in such manner as to prevent the premature ignition of the combustible charge and likewise to assist in compressing the charge and to support its combustion. The entering combustible charge induces air to initiate the combustion. The gas inlet and exhaust valves are coupled so that the outlet valve is opened and the inlet valve closed by the pressure of the explosion, and the valves act upon an adjustable pendulum which on its return stroke effects the reverse movement of the valves to admit a fresh charge of gas and to retain the outlet valve closed while the mixture is compressed in the chamber. The inlet and exhaust valves of a series of combustion chambers may be controlled by a single pendulum.—J. S. G. T.

Gas producers of the revolving grate type. J. Pintsch A.-G. E.P. 148,573, 10.7.20. Conv., 18.5.18. Addn. to 146,964 and 147,514 (J., 1921, 803 A).

The revolving grate of a producer having an annular shaft is so formed that its apex extends in a serpentine relative to a circle concentric with the centre of the shaft; by this means lateral motion is given to the ash.—H. Hg.

Suction gas plants. J. H. Paterson, T. G. Tulloch, and D. J. Smith. E.P. 170,336, 18.6.20 and 16.3.21.

Gas from a suction producer is drawn through a scrubber and supplied under pressure to an engine or heating apparatus by means of a centrifugal fan. There are two branches on the gas-delivery pipe from the fan, one communicating through a throttle valve with the engine and the other through a waste valve with the atmosphere; thus gas may be discharged and the temperature within the producer maintained when the load is off the engine. A device for mixing air with the gas is placed either between the throttle valve and the engine or between the producer and the fan, in which case screens are fitted in the pipe between the throttle valve and the engine. The fan may be provided with a return by-pass pipe having a control valve connected with the throttle valve. In the periphery of the fan casing, at a point opposite the gas-delivery pipe, there is a chamber in which any dust or liquid deposited within the casing is collected and from which the deposit may be removed through a valve.—H. Hg.

Gas generation. H. F. Smith, Assr. to The Gas Research Co. U.S.P. 1,394,043, 18.10.21. Appl., 20.11.18.

Heavy hydrocarbons are removed from producer gas and returned to the producer above the combustion zone of the fuel bed.—H. Hg.

Fuel; Plant for the gasification of bituminous ——. Akt.-Ges. für Brennstoffvergasung. G.P. 313,643, 26.4.18.

The gas-generating chamber is divided by transverse partitions inclined alternately in opposite directions, so that a series of distillation and gasification spaces are formed. The fuel is charged in from hoppers and the partitions are perforated so that gases from the gasification chambers can pass through into the distillation chambers. The furnace chamber underneath is also divided into separate compartments by partitions. These partitions stiffen the structure and also allow of different working of the various parts of the plant. —A. G.

Gas producers; Process for the operation of ——. A.-G. für Brennstoffvergasung. G.P. 337,853, 21.6.18.

In gas producers provided with a distillation zone, a gasification zone, and an intermediate nitrogen-recovery zone, the distillation zone and intermediate zone are heated by means of a stream of hot gas passed in through the column of fuel. The formation of ammonium compounds is favoured by the addition of steam in the intermediate zone. The gases are withdrawn through ports in the wall of the shaft.—A. G.

Illuminating gas; Treatment of —— with debenzolisation. H. Koppers. G.P. 340,127, 15.5.19.

The hydrocarbons removed from the gas are separated and the volatile hydrocarbons of low vapour pressure, except benzol, *e.g.*, xylol etc., are added again to the gas. Debenzolisation is thus carried out without the corresponding disadvantages, viz., troublesome naphthalene obstructions, and deterioration of the leather parts of gas meters.—A. G.

Preheating blast-furnace gases in dry gas cleaning plant; Process of ——. Dinglersche Maschinenfabr. A.-G. G.P. 339,341, 18.1.14.

The gas to be purified is preheated by means of the hot products of combustion of a portion of the purified or crude gas, the temperature being controlled by regulating the supply of gas to the combustion chamber or chambers and/or by mixing air or other incombustible gas with the combustion products. Two combustion chambers are preferably used, one for crude gas and the other for filtered purified gas.—J. S. G. T.

Liquid organic compounds from coal; Manufacture of ——. F. Bergius. E.P. 148,436, 10.7.20. Conv., 22.8.16. (*Cf.* E.P. 18,232 of 1914 and 5021 of 1915; J, 1916, 167, 732.)

Powdered coal containing not more than 85% of carbon, after ash and water have been deducted, is agitated for 6 hrs. at about 400° C. with tar-oil or petroleum in the presence of hydrogen under a pressure of about 100 atm. By treating coal containing 74·48% of carbon with twice its weight of tar-oil, approximately 87% of the coal is converted into a liquid or semi-liquid product.—L. A. C.

Coal, hydrocarbons, and the like; Process for decomposing ——. S. Löffler. G.P. 301,683, 28.4.15.

In the decomposition of coal, hydrocarbons, etc. by heating at high temperatures and pressures, heat losses and risk of danger are minimised by providing closed combustion chambers within the reaction chamber. Air and fuel are supplied to the combustion chamber by devices controlled from outside the reaction chamber and the hot combustion products are utilised to heat the charge in the reaction chamber either directly or by means of a liquid heat-transmitting medium.—W. J. W.

Motor spirit. C. G. Sesti. E.P. 147,803, 9.7.20. Conv., 31.5.19.

Alcohol is mixed with carbon bisulphide which has previously been treated with quicklime.—L. A. C.

Oils and other hydrocarbons; Purification of ——. M. Benson. E.P. 170,093, 10.7.20.

Crude oil or the like is refined and freed from sulphur by agitation under a pressure of 100 lb. per sq. in. with quicklime and sufficient superheated steam to raise the temperature to 250° F. (about 120° C.); the mixture is then pumped into a compression chamber in which it is treated with sufficient superheated steam to volatilise the whole or greater part of the volatile constituents of the oil as it passes from the compression chamber into an expansion chamber. Further purification can be effected by treating the vapours with lime in the expansion chamber, whence they are led to a fractionating tower.—L. A. C.

Oil-distilling apparatus and the like. Whitehall Petroleum Corp., Ltd., and J. S. Smith. E.P. 165,178, 18.3.20.

A horizontal cylindrical vessel with provision for the admission of steam contains trays along which oil flows, ultimately reaching the bottom of the vessel. No external heating is employed.—A. E. D.

Distillation of hydrocarbon oils, tars, asphalts, and the like. E. F. Engelke. E.P. 165,230, 27.3.20.

Oil, tar, or asphalt is fed continuously over a series of trays and overflows from the lowest tray to the bottom of the still. Each tray may be provided with partitions so as to distribute the flow. Hydrogen or an industrial gas, such as oil-gas, natural gas, or the like, is introduced into each compartment and passes through a continuous cycle, being separated from condensable vapours, passed into a gas-holder, and then back into the still. Steam may be introduced into the bottom of the still.—A. E. D.

Distillation of hydrocarbon oils, asphalts, and the like. E. F. Engelke. E.P. 170,140, 27.7.20.

Crude oil, *e.g.*, Mexican crude oil, passes through a series of stills in which it is subjected to the action of a gas containing hydrogen, which, besides passing through the body of the oil, may also be admitted to the vapour space at the top. The flash-point of the residual oil issuing from the last still is raised by admitting superheated steam in addition to gas into the last still, or into any desired number of stills. The vapour leaving each still passes to a dephlegmator and thence to a water-cooled condenser. Uncondensed gas is purified, *e.g.*, by successive treatment with sulphuric acid, alkaline litharge, and water, and is treated for recovery of gasoline, *e.g.*, by scrubbing with a high-boiling oil, or by cooling and compression, before it is returned to the circuit, or employed for burning under the stills.—L. A. C.

Liquid hydrocarbon; Apparatus for treating —— in distilling and other processes. A. F. G. C. P. J. von Groeling, Assr. to National Refining Corp. U.S.P. 1,378,066, 17.5.21. Appl., 21.12.18.

A still is provided with an electrical heating resistance and automatic temperature control. —A. E. D.

Petroleum products; Apparatus for cracking and refining ——. W. H. Young. U.S.P. 1.378,307, 17.5.21. Appl., 5.11.17. Renewed 10.1.21.

Two interconnected and superimposed coils are placed over a source of heat. Steam and oil are fed into the upper coil, gradually flow downwards, and are then led to the bottom of the more intensely heated lower coil, through which the mixture flows in an upward direction.—A. E. D.

Oil-cracking process. A. Rogers. U.S.P. 1,378,424, 17.5.21. Appl., 1.6.20.

Oil at 600° F. (315° C.) is mixed with sufficient steam to vaporise it. The vapour mixture as a moving thin annular layer is heated to about 800° F. (about 430° C.).—A. E. D.

Oil etc.; Retort for extracting ——. A. V. Young. U.S.P. 1,378,643, 17.5.21. Appl., 20.2.19.

Oil-bearing material is fed into the upper end of an inclined retort and is caused to pass through the retort by means of a chain conveyer operating along the bottom of the retort which is arched longitudinally.—A. E. D.

Oil; Process of catalysing [cracking] —— and apparatus therefor. C. M. Alexander and G. H. Taber, jun., Assrs. to Gulf Refining Co. U.S.P. 1,381,098, 14.6.21. Appl., 14.3.16.

Oil is cracked by being heated in the vapour state with the vapour of a reactive metallic halide. —A. E. D.

[Mineral] oils; Process of treating ——. A. B. Foster. U.S.P. 1,394,486, 18.10.21. Apl., 15.10.17.

Separate jets of a mineral oil product and a material capable of reacting with it meet each other at an angle and with sufficient velocity to disintegrate each other.—L. A. C.

Hydrocarbons; Process of fractionally distilling mixtures containing ——. E. H. French. U.S.P. 1,394,488, 18.10.21. Appl., 10.7.19.

A complex mixture of hydrocarbons is heated in transit from a reservoir, to a temperature below the average b.p. of the fraction to be distilled while in the mixture, but sufficiently high to vaporise the fraction from the mixture upon subsequent atomisation with an inert gas in a separating chamber. The vaporised fraction is condensed, and the residue is removed immediately from the chamber. —L. A. C.

Hydrocarbons; Apparatus for treating ——. R. Seeger, Assr. to New Process Oil Co. U.S.P. 1,394,688, 25.10.21. Appl., 15.9.17.

Cracking tubes for treating oils are contained within, but not in communication with the interior of an outer casing, which is filled with liquid or gas under a pressure approximately equal to that in the tubes.—L. A. C.

Condensing and treating [oil] distillates; Apparatus for ——. R. Fleming, Assr. to The Richard Fleming Co. U.S.P. 1,394,987, 25.10.21. Appl., 6.12.19.

The vapours from a pressure oil-cracking still are discharged at high velocity under the pressure prevailing in the still, and sufficient liquid is supplied to envelop and condense the vapours as they are discharged.—L. A. C.

Petroleum oils; Process and apparatus for treating —— to produce gasoline. R. Yates. U.S.P. 1,395,075, 25.10.21. Appl., 14.8.20.

High-boiling petroleum oils are passed through vertical cylinders heated externally to 650°—850° F. (about 340°—450° C.), each containing a rotating drum into which the oil and vapour are introduced under the pressure of the vapour. The oil is expelled by the vapour through an opening in the bottom of the drum into the annular space between the drum and cylinder walls, and serves to protect the vapour from local overheating by the cylinder walls.—L. A. C.

Lubricating oils; Process for obtaining viscous —— of high flashing point from bituminous materials. Process for manufacturing lubricating oils from asphaltic materials. Deutsche Erdöl-A.-G., F. Seidenschnur, and C. Koettnitz. E.P. 146,974—5, 6.7.20. Conv., 6.11. and 3.3.16.

See G.P. 307,166 and 305,105; J., 1920, 182 a.

Distilling hydrocarbons; Process of ——. Standard Oil Co., Assees. of R. E. Humphreys. E.P. 147,715, 8.7.20. Conv., 26.6.14.

See U.S.P. 1,119,700 of 1914; J., 1915, 20.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Harcourt standard pentane lamp; Atmospheric corrections for the ——. E. B. Rosa, E. C. Crittenden, and A. H. Taylor. J. Opt. Soc. Amer., 1921, 5, 444—452.

For correcting the candle-power of the Harcourt 10-candle pentane lamp on account of variation of humidity of the atmosphere, the mean factor determined at the National Physical Laboratory is 0·645, while the result obtained at the U.S. Bureau of Standards is 0·567, the factor in each case representing the percentage decrease in candle power due to an increase of 1 litre of water vapour per cub. m. of air. The discrepancy in the two values is traced to a difference of atmospheric temperature in the two cases, and it is shown that the experimental values are brought into agreement by using two factors, viz., a factor 0·52% decrease in candle-power per litre of water vapour per cub. m. of air (in the absence of any temperature difference) and a factor 0·08% decrease per degree rise of temperature. The factor 0·52% agrees with the recently determined value found at the Bureau of Standards and is in agreement with results found by Takatsu and Tanaka in Japan. It is suggested that 15° C. should be taken as the normal atmospheric temperature for calculation of the candle-power of the lamp.—J. S. G. T.

Wood tar distillation residues. Marcusson and Picard. *See* III.

Patents.

Gas fires; Fuel [radiant] for ——. W. Dowler and A. T. Guinness. E.P. 170,372, 16.7.20.

Radiants for gas fires are formed from a mixture of blue clay, wood chips, and coal dust, together with logwood, green copperas, "rock ammonia," and alum. The mixture is shaped as desired, and heated in a furnace between alternate layers of coke.—J. S. G. T.

Incandescence mantle; Inverted —— *for use with low-grade gas.* A. Kiesewalter. G.P. 340,750, 4.12.19.

Gas is delivered to the upper end of a cylindrical mantle, while air passes up through the opening in the lower end thereof. The products of combustion pass quickly through the mesh of the mantle. —J. S. G. T.

Vacuum electric discharge apparatus; Production of metal films, particularly for use as electrodes in ——. The British Thomson-Houston Co., Ltd., Assees. of I. Langmuir. E.P. 148,130, 9.7.20. Conv., 6.6.14.

See U.S.P. 1,273,628 of 1918; J., 1918, 571 A.

III.—TAR AND TAR PRODUCTS.

Tar; Determination of water in ——. K. Kisskalt. Gas- und Wasserfach, 1921, 64, 736—737.

Discrepancies in the estimation of water in tar are caused mainly by difficulties in sampling, especially when the tar is delivered in barrels. The barrels should be provided with a bung-hole at the bottom as well as at the side; by standing the barrels on end for some time before sampling, greater accuracy could be attained, both in estimating the depth of the aqueous layer and in obtaining representative samples. For estimating the depth of the aqueous layer, a glass tube 50 cm. long and 1·5 to 2 cm. in diam. is dipped 5—10 cm. into the tar itself, and, after removing tar from the exterior of the tube, the length of the column is measured. Several estimations should be made, using a clean tube for each. The sample of tar is taken by means of a sheet-iron tube of 5 cm. diam. which can be closed at the lower end by means of a valve operated by an iron rod passing through the tube; this is dipped below the water layer with the valve closed, the valve is then opened, the tube is slowly pressed down until it reaches the bottom of the vessel, the valve closed, and the sample withdrawn. The tube is cleaned on the exterior before allowing the sample to flow into the container, and a number of samples are taken and thoroughly mixed before testing a portion. The xylol distillation method is recommended for the actual estimation of water in the sample.—L. A. C.

Wood-tar distillation residues. J. Marcusson and M. P. Picard. Chem. Umschau, 1921, 28, 257—258.

The composition of beech-wood tar and pine-wood tar is respectively:—unsaponifiable matter 18%, 53·5%; hydroxy-acid anhydrides 9·5%, nil; hydroxy-acids 52·3%, 14%; resin acids 7·7%, 17%; fatty acids 3·2%, 6%; phenols 9·3%, 9·5%. The residues (pitches) obtained after distilling these tars are composed respectively of:—neutral tar resins 14%, 1·5%; unsaponifiable matter 6%, 19·7%; phenols 1·5%, 8%; hydroxy-acids and anhydrides 77%, 31·8%; resin acids nil, 35·2%; fatty acids 1·5%, 2·8%; mineral matter nil, 1%. Wood tar pitches can easily be distinguished from other artificial asphalts by the high content of hydroxy-acids and the presence of phenols.—H. C. R.

Organic bases. Resenthaler. *See* XX.

Patents.

Hydrocarbons; Process of producing viscous liquids [lubricants etc.] from —— *occurring in tar oils.* L. Lilienfeld. E.P. 149,317, 12.5.20. Conv., 1.8.19.

Highly viscous oils suitable for use as lubricants and for therapeutic purposes are prepared by treating fractions of tar oils boiling above 140° C. with acetylene in the presence of 0·5%—10% of aluminium chloride until absorption is complete. After separating the catalyst, the oil is purified by distillation under reduced pressure.—L. A. C.

α-Aminoanthraquinone; Manufacture of ——. O. Imray. From Society of Chem. Ind. in Basle. E.P. 169,667, 20.4.21.

α-Aminoanthraquinone is prepared by heating α-anthraquinonesulphonic acid with ammonia under pressure in presence of the sulphonic acid of an aromatic nitro-compound. *Example.*—165 pts. of potassium α-anthraquinonesulphonate, 500 pts. of 24% aqueous ammonia, and 60 pts. of sodium nitrobenzenesulphonate are heated at 160°—165° C. for 12 hrs., and, after cooling, the pure crystalline α-aminoanthraquinone is filtered off. The yield amounts to 80% of the theoretical, and anilinesulphonic acid may be recovered from the filtrate. —G. F. M.

Anthraquinone series; Manufacture of compounds of the ——. F. W. Atack and G. W. Clough. E.P. 169,732, 31.3.20.

α-Chloro- or α-bromo-anthraquinones are converted into β-halogen derivatives by heating with concentrated sulphuric acid for some hours at about 200° C. As the halogen always takes up the *meta*-position with respect to its original position, the reaction only occurs with substances in which the β-position *meta* to the original α-position is unoccupied. Further, those substances are excluded which are decomposed by hot sulphuric acid, such as 1-hydroxy-4-chloroanthraquinone, in which case the dihydroxy-compound is produced, or 1-amino-4-chloroanthraquinonesulphonates in which the chlorine is expelled.—G. F. M.

Anthraquinone derivatives; Manufacture of —— *and new products resulting therefrom.* A. Lüttringhaus and L. Eiflaender, Assrs. to A. Kuttrolf. U.S.P. 1,394,851, 25.10.21. Appl., 3.11.20.

An amino-derivative of anthraquinone is treated with a metallic arylide in the presence of an aromatic amine, whereby an arylaminoanthraquinone is formed.—F. M. R.

m-Nitro-p-cresol; Production of ——. C. G. Derick, W. M. Ralph, and L. H. Flett, Assrs. to National Aniline and Chemical Co., Inc. U.S.P. 1,394,150, 18.10.21. Appl., 9.3.20.

In the production of *m*-nitro-*p*-cresol 107 pts. of *p*-

toluidine is dissolved in 265—290 pts. of sulphuric acid (sp. gr. 1·84), and diluted with 400 pts. of water. A further 1100 pts. of water is added, and the solution diazotised with sodium nitrite.

Patents.

Vat dyestuffs; Manufacture of ——. R. B. Ransford. From L. Cassella und Co. E.P. 147,704, 8.7.20.

Vat dyestuffs containing sulphur are obtained by condensing arylamines or their substitution products with the thio-derivatives of quinones of the benzene series or their halogen substitution products described in F.P. 357,600 (J., 1906, 175), particularly quinone mono- and dithiosulphonic acids, quinone-mercaptans, diquinone mono- and disulphides, and the halogen derivatives of these compounds. These sulphurised quinone-arylides dye animal fibres from the hydrosulphite vat in yellow to brown shades, fast to washing, milling, potting, and light. The new dyestuffs may be converted into products which dye deeper shades by treatment with acids or reducing agents in acid solution.—F. M. R.

Dyestuffs of the Indigo series. Soc. Chim. des Usines du Rhône. E.P. 152,634, 18.6.20. Conv., 14.10.19.

The shades produced by 5.5′-dimethylindigotin on cotton or wool are too dull to be of value, but the properties of this colouring matter are entirely modified by halogenation. 5.5′-Dimethyldibromo-ndigotin, for example, dyes cotton from the vat in dark level blue shades, fast to soap, very similar in hade to the dyeings of 5.7.5′.7′-tetrabromoindigotin, whilst its affinity for wool much exceeds that of ndigo and its known derivatives, for a single dip produces dark shades very fast to milling. The monobromo-derivative possesses properties intermediate between those of 5.5′-dimethylindigotin and ts dibromo-derivative. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents nd Designs Acts, 1907 and 1919, to E.P. 13,429 f 1902; J., 1903, 548.)—F. M. R.

Lakes of azo dyes; Manufacture of soluble chromium ——. W. Carpmael. From Farbenfabr. vorm. F. Bayer und Co. E.P. 170,155, 11.8.20.

Monoazo dyestuffs obtained from diazotised anthranilic acid, or its chloro-, nitro- or sulpho-derivatives, coupled with *β*-naphthylamine or its sulphonic acids, are boiled in aqueous solution with chromium fluoride for several hours, and the soluble chromium lakes are isolated by adding salt to the reddish-violet solution. These products are converted into insoluble reddish-violet to bluish-violet lakes with barium, calcium, or aluminium in the usual manner, and are extremely fast to lime, water, and light.
—F. M. R.

Nitro-diazo-compounds; Process of making ——. W. B. Jones, Assr. to Butterworth-Judson Corp. U.S.P. 1,394,556, 25.10.21. Appl., 6.3.20.

The process consists in nitrating a metallic salt of 1-diazo-2-naphthol-4-sulphonic acid.—F. M. R.

Dyestuffs of the acridine series; Manufacture of ——. A.-G. für Anilinfabr. E.P. 169,460, 2.7.20. Conv., 22.4.15.

See G.P. 292,848 of 1915; J., 1916, 1056.

[o-Hydroxyazo] dyestuffs; Green acid —— *containing chromium and process of making same.* A. Grob, Assr. to Soc. of Chem. Ind. in Basle. U.S.P. 1,394,823, 25.10.21. Appl., 17.8.18.

See E.P. 129,782 of 1918; J., 1919, 757 a.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Cotton; Investigation of the cuticle of ——. R. Haller. Text. Forschg., 1921, **3**, 20—26. Chem.-Zentr., 1921, **92**, IV., 286.

A film of copper ferrocyanide, produced on small rods of cellulose gel separated from a viscose solution, was treated with ammoniacal copper oxide solution; the outer lamella remained unattacked, but complete loosening of the membrane resulted in a short time. From the membrane fragments the copper ferrocyanide was slowly dissolved by ammonia, and an opaque mass of the original gel remained, which dissolved readily in ammoniacal copper oxide. Iron and zinc ferrocyanide behaved similarly. It is concluded that the cuticle does not consist of an independent membrane, but that it includes the outer sheath of the fibres, consisting of cellulose, which becomes modified owing to incorporation of cutin. The cuticle is regarded as an adsorption compound produced by adsorption of the cutin substances by the cellulose.—W. J. W.

Cotton cellulose; Action of dilute sulphuric acid on —— *and an improved method of testing for oxycellulose.* E. Knecht and F. P. Thompson. J. Soc. Dyers and Col., 1921, **37**, 270—272.

Cotton which has acquired an increased affinity for Methylene Blue, and a decreased affinity for Diamine Sky Blue by treatment with dilute sulphuric acid, is not oxidised cellulose, but contains fixed sulphur, which is not removed by washing with boiling water or alkali. The characteristic affinity of Chardonnet silk for basic colours is due to the sulphur (or sulphuric acid) fixed during the nitration with mixed acid and not during denitration. The affinity of oxidised cellulose for leuco-Methylene Blue is very slight, whereas it is very marked in the case of the sulphuric acid product. Oxidised cellulose and cellulose which has been treated with sulphuric acid may be distinguished by boiling with weak alkali and then dyeing with a direct colour (Diamine Sky Blue), the affinity of the former for the dyestuff being restored by the alkali treatment.—F. M. R.

Textile fabrics; Electrolytic waterproofing of ——. The Tate process. H. J. M. Creighton. J. Franklin Inst., 1921, **192**, 497—510.

In the Tate process the fabric, previously cleaned to remove any grease or starchy matters, and then saturated with a solution of sodium oleate, is passed between a graphite cathode, over which flows a solution of aluminium acetate, and an aluminium anode which is completely enclosed in a heavy woollen pad. The latter is the most important and distinctive feature of the process; without its use irregular and unsatisfactory results are obtained. The graphite cathode is divided into 8 bars separated by metal guides inclined downwards towards the anode, which consists of a vertical aluminium plate. The graphite bars are capable of moving backwards along the guides to permit the passage of seams through the apparatus without tearing, and are provided with a number of ducts on the contact faces so arranged as to give an even and regular distribution of the aluminium acetate over the surface of the fabric. Cotton goods must be treated four times with alternate reversals of the electrodes, and woollen and silk goods twice. The waterproof qualities of the treated fabric are probably due to two distinct electrochemical actions: first, the formation of aluminium hydroxide at the cathode and the distribution of this through the capillaries of the fabric due to cataphoresis, and secondly the formation on the surface of the fabric of a film of basic aluminium oleate insoluble in water and, also, unlike the normal oleate, in liquid hydrocarbons. Electrolytically waterproofed fabric is fully shrunk, mildew-proof, and much superior in lustre and waterproof qualities to that waterproofed by the older immersion processes.—A. R. P.

Cellulose; Dispersion of —— in concentrated aqueous solutions of neutral salts. P. P. von Weimarn. Kolloid-Zeits., 1921, **29**, 197—198.

An answer to a criticism of Herzog and Beck (J., 1921, 254 A) of the author's work on the dispersion of cellulose in concentrated aqueous solutions of neutral salts (J., 1912, 768). Cellulose may be dispersed in aqueous solutions of sodium iodide, calcium bromide, calcium iodide, strontium iodide, barium, strontium, and calcium thiocyanates under atmospheric pressure, but in solutions of sodium, potassium, and barium chlorides, only when an increased pressure is employed.—J. F. S.

Cellulose; Swelling and dispersion of —— in concentrated aqueous solutions. P. P. von Weimarn. Kolloid-Zeits., 1921, **29**, 198—199.

Cellulose may be dispersed in a solution of any easily soluble salt of a sufficiently great concentration, and the degree of dispersion is so much greater the more soluble and the more hydrated the salt. Dispersion and swelling of cellulose may also be effected by bringing it into contact with water under a high external pressure. The swelling and dispersion produced by salt solutions increases in the following order: sodium chloride, barium chloride, potassium iodide, strontium chloride, calcium bromide, and lithium chloride, at ordinary temperatures and pressures. With sodium chloride the swelling is hardly noticeable after the materials have been in contact for over five years, whilst with lithium chloride complete swelling has occurred in a much shorter time.—J. F. S.

Acetic acid, acetone (methyl alcohol), and furfural from raw fibrous material; Production of ——. H. Pringsheim. Cellulosechem., 1921, **2**, 123—123.

In attempting to prepare fodder substitutes, fibrous material, such as straw, was treated with high-pressure dry steam and gaseous hydrogen chloride at 120°—140° C., but the digestibility of the cellulose was not increased thereby. It was observed, however, that appreciable quantities of valuable volatile products were formed during the process. The volatile products from straw are formed from the pentosans and lignin, and consist, under the most favourable conditions, of about 9% of furfural, 1% of acetone, and 4% of acetic acid. The technical utility of the process is dependent on a use being found for the residue of hydrocellulose. The process might be important if the saccharification of cellulose meets with technical success.—F. M. R.

Rosin size; Studies on ——. R. Sieber. Zellstoff u. Papier, Apr., 1921. Pulp and Paper Mag., 1921, **19**, 1051—1052.

To a rosin suspension prepared by running an alcoholic solution of rosin into distilled water and allowing the coarser particles to settle during 24 hrs., were added increasing amounts of aluminium sulphate solution, the total volume of the mixture being kept constant. Observations were made after standing for 2 hrs. at 20° C. It was found that there was an upper and a lower limiting value below and above which respectively no precipitation occurred, the lower value being 0·08 millimol and the upper about 0·6 millimol of aluminium sulphate per litre. In the non-precipitating zone between the two values, precipitation occurred only after 24—36 hrs., whilst rapid and even precipitation took place in the precipitating zones. The precipitates in the upper precipitating zone contained aluminium hydroxide and a trace of sulphate, and it is concluded that in the lower precipitation zone adsorption of positively-charged aluminium hydroxide by the negatively-charged rosin particles causes precipitation, after which re-peptisation occurs in the non-precipitation zone in consequence of the disperse phase acquiring a positive charge in the external (acid) solution; adsorption of sulphate ion by the positively-charged disperse phase then causes the second coagulation in the upper precipitation zone. Similar behaviour was shown with ferric chloride as a precipitant, but the lower limit of the upper coagulating zone was at a concentration of 25 millimols per litre, thus showing the more feeble effect of the univalent chloride anion to positively-charged sols. The effect of the simultaneous addition of several electrolytes was less than the sum of the separate effects, although hard water was capable of causing coagulation without the amount of any one salt being beyond the limiting value. The rosin sol examined required more aluminium sulphate for complete precipitation in the upper zone than did the partly saponified rosin used in technical practice, but it would be much more stable to a very hard water.—A. de W.

Printing ink; Removal of —— from waste paper. W. Schrauth. Chem.-Zeit., 1921, **45**, 1090—1091.

The observation of Spring (J., 1909, 430; 1910, 99, 363) on the adsorption of soap by carbon pigment resulting in peptisation of the latter, suggests that a study of soaps of different kinds in this connexion might prove fruitful. The problem is complicated by the presence of linseed oil, tar, mineral oil, etc., in the printing ink and sizing in the paper, and the use of an organic solvent in combination with the soap either as an aqueous solution or as an emulsion is indicated.—A. de W.

Oxalic acid from lignin. Heuser and Winsvold. *See* XX.

Patents.

Cellulose materials; Process for hardening and waterproofing ——. F. Moeller. E.P. 145,610, 29.6.20.

Water-resistant qualities are imparted to cellulose materials, such as paper etc., by exposing them for a short time to the action of liquid thionyl chloride, either with or without the addition of indifferent solvents, such as carbon tetrachloride, chloroform, etc. Good results are also obtained by exposing the material to thionyl chloride vapour for a short time. The treated paper is washed with water or weak alkalis.—D. J. N.

Cellulose and products manufactured therefrom; Treatment [waterproofing] of ——. F. Moeller. E.P. 145,611, 29.6.20. Conv., 24.2.19. Addn. to 145,610 (*cf. supra*).

Cellulose-containing substances such as wood, cork, straw, artificial silk, etc., and cellulose derivatives, such as oxycellulose, are hardened and waterproofed by exposing the dried material to the action of liquid or gaseous thionyl chloride or sulphur chloride for a few seconds. Any acid formed is removed by washing the material with water or weak alkali, or by exposure to ammonia gas. This process is also applicable to such carbohydrates as starch and dextrin, and also to cellulose-containing substances that have been hardened by the action of parchmentising acid or zinc chloride solution. —D. J. N.

Water reed (Arundo phragmites); Method of treating root stocks of the —— for textile purposes. Verwertung Inländischer Produkte, G.m.b.H. E.P. 147,496, 8.7.20. Conv., 20.12.16.

The disintegrated root stocks are boiled with water, and fermented, whereby sugars are converted into alcohol. Alternatively the pulped roots are mixed with 1—2% of malt, digested with water at 60°—70° C. for 10—30 mins. to hydrolyse starch, boiled, cooled, and fermented with yeast for 3—4 days. The fibre is removed and washed, and may be used for textile purposes or converted into paper pulp. The fermented liquor is distilled to recover alcohol, and the residue used for food purposes. —D. J. N.

Yarns and fabrics composed of vegetable fibres; Treatment and purification of ——. R. W. R. Mackenzie, E. H. Robinson, and M. Fort. E.P. 170,534, 4.12.20.

Dry or moist fibrous materials are thoroughly freed from organic impurities by extraction with organic solvents (of b.p. above 100° C.) at a temperature higher than that of boiling water under the same conditions. In the case of wet fabrics, these are first freed from water by exposing them to the vapour of the solvent, which is removed, condensed, and the solvent separated from the aqueous layer thereby formed. Suitable solvents are benzene, toluene, xylene, and solvent naphtha. Fabrics purified by this method have superior "beetling" and "finishing" properties.—A. J. H.

Artificial threads and the like; Treatment of ——. Zellstoff-fabrik Waldhof, and V. Hottenroth. E.P. 147,416, 7.7.20. Conv., 7.10.18.

A precipitating bath for artificial silk solutions, particularly viscose, is made by hydrolysing sawdust or other cellulose-containing material with mineral acids, preferably sulphuric acid. The acid liquor is filtered and used alone, or in conjunction with other precipitating media, such as formic and lactic acids or alum.—D. J. N.

Viscose silk; Manufacture of ——. E. Bronnert. E.P. 170,024, 12.4.20.

The spinning bath described in E.P. 166,931 (J., 1921, 654 a) may be modified by the addition of ammonium sulphate, in which case, in calculating from the formula (given in the original patent), the minimum concentration of acid to give a thread of the desired fineness, 2 pts. of ammonium sulphate should be taken as equivalent to 1 pt. of sulphuric acid, *e.g.*, if, from the formula, the minimum concentration of acid to produce a thread of 1·2 deniers is found to be 350 g. per l., this may be taken as equivalent to 600 g. of ammonium sulphate and 50 g. of sulphuric acid per l.—D. J. N.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Gambier cutch [for silk weighting]. J. Zubelen. Bull. Soc. Ind. Mulhouse, 1921, 87, 279—283.

When native gambier extract is used in silk weighting there is considerable loss owing to the presence of impurities, and to the fact that catechin possesses little affinity for silk weighted with tin. The much purer extract made in a factory at Indragiri, Sumatra, has proved inferior in action to the Chinese product. Catechin can be readily separated from the catechutannic acid in Indragiri gambier, and whilst the latter shows a great affinity for silk weighted with tin, the former not only has no weighting action, but reduces the tin weighting by 0·5—3%. Similar behaviour is shown by chemically pure hæmatoxylin as compared with logwood extract. On the other hand, when a bath of gambier extract or catechin is used a second time for weighting silk, there is a considerable increase in weight owing to the fact that the catechin has undergone some transformation when heated in the presence of air. The contrary effect is observed with catechutannic acid, which possesses less weighting action after heating in the presence of air. Pure gambier extract boiled for 4—5 hrs. in the presence of air yields a clear extract which no longer deposits catechin, and may be preserved unchanged for years. During the process the catechin reacts with the catechutannic acid to form a product suitable for silk weighting.—F. M. R.

Cotton dyeing; Substantive ——. R. Auerbach. Kolloid-Zeits., 1921, 29, 190—193.

The velocity of diffusion of a number of cold-dyeing substantive cotton dyestuffs from a 0·1% solution into a 4% gelatin jelly is at 20° C. about 3·5 mm. per day, whereas that of warm-dyeing dyestuffs is only 0·9 mm. per day under the same conditions. Potassium bichromate will dye cotton, but if the dyed material is washed with either water or alcohol the bichromate is all removed. Washing with mixtures of alcohol and water removes less of the bichromate the greater the alcohol content of the mixture up to a maximum which lies at 65% of alcohol; beyond this point more bichromate is removed with increasing alcohol concentration. The degree of dispersion of potassium bichromate is at a minimum in the presence of 65 alcohol. —J. F. S.

Basic colours on the fibre; Process for fixing ——. F. V. Kallab. Sealed Note No. 999, 17.9.97. Report by J. Brandt. Bull. Soc. Ind. Mulhouse, 1921, 87, 287—290.

Basic azo colours are produced most suitably directly on the fibre by passing the material padded with β-naphthol through a bath containing diazotised Safranine or the like, squeezing, and without washing, developing in tannin, and then tartar emetic. Faster and more level shades are obtained in this manner than by dyeing calico mordanted with tannin and tartar emetic with Indoine Blue or other Safranine-azo dyes. The process also possesses the advantage that the dyeing may be shaded by mixing the diazonium compounds of other amines with the diazotised Safranine.—F. M. R.

Printing metallic powders on cotton fabrics. J. Frossard and C. Rebert. Bull. Soc. Ind. Mulhouse, 1921, 87, 284—286.

The process for printing metallic powders on textiles described previously (J., 1913, 1105) gives imperfect results when printing large surfaces of coloured cloth, owing to coagulation of the sericose (cellulose acetate) in presence of water. Albumin, provided it is pure, has proved more satisfactory. The thickening is prepared by steeping 275 pts. of egg-albumin and 450 pts. of cold water for 24 hrs., stirring, and adding 275 pts. of egg-albumin. The metallic printing paste consists of 200 pts. of bronze powder and 800 pts. of the above thickening. A small quantity of sodium arsenate is added to preserve the mixture. The fastness is good, and the printed material may be submitted to the usual finishing processes.—F. M. R.

Azo derivatives of diketohydrindene. Das and Ghosh. *See* IV.

PATENTS.

Dyeing machine. J. H. Thompson, Assr. to Hussong Dyeing Machine Co. U.S.P. 1,395,165, 25.10.21. Appl., 23.11.18.

A dye vat has, at one end, a solid structure having vertical cylindrical passages of an even diameter throughout, within which are rotating propellers of approximately the same size.—A. J. H.

Animal fibres; Process for reducing or destroying the affinity of —— for dyes. F. Bayer und Co. G.P. 340,454, 14.8.15.

Naphthalenesulphonic acids, naphtholsulphonic acids, or benzidinesulphonic acid, and sulpho-derivatives of fatty acids, such as Turkey-red oil, are precipitated on the fibre by a salt of tin, with or without addition of other salts. When the treated fibre is woven with untreated wool and dyed, white or pale coloured effects are produced. —F. M. R.

Animal fibres; Process for reducing or destroying the affinity of —— for dyes. F. Bayer und Co. G.P. 340,455, 5.1.16. Addn. to 337,887 (J., 1921, 622 A).

The condensation product of formaldehyde with an organic amino, aminohydroxy, or hydroxy compound, except resorcinol, *e.g.*, 1.8-dihydroxynaphthalenesulphonic acid, benzidine-*o*-disulphonic acid, or resorcinoldisulphonic acid, is precipitated on the fibre without the presence of metallic salts. —F. M. R.

Marbled effects; Method for producing upon the surface of textiles and other materials ——. W. Carpmael. From C. Jäger Ges., and R. W. Carl. E.P. 148,187, 9.7.20.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid; Electrolysis of hot concentrated ——. H. Hoffmann. Z. Elektrochem., 1921, 27, 442—445.

At 50° C., independently of the current strength, hydrogen, hydrogen sulphide, and sulphur are produced at the cathode in the electrolysis of 98·3% sulphuric acid, whilst at higher temperatures sulphur and sulphur dioxide are produced and at 300° C. only sulphur. Oxygen is liberated at the anode at these temperatures, but at 200° C. it is mixed with sulphur dioxide produced by the oxidation of sulphur which has diffused from the cathode by the nascent oxygen and the hot sulphuric acid. From 280° C. upwards the quantity of oxygen and sulphur dioxide liberated is in keeping with Faraday's law. The gas element SO_2/O_2 gives an EMF smaller than expected and is incapable of furnishing large currents because of the incomplete charging of the electrodes and the small velocity of the electrode reactions. The technical possibilities of the cell for the production of sulphuric acid are therefore hopeless. The primary products of electrolysis are hydrogen and oxygen, sulphur dioxide being a secondary product.—J. F. S.

Perchloric acid; Electrolytic oxidation of hydrochloric acid to ——. H. M. Goodwin and E. C. Walker. Trans. Amer. Electrochem. Soc., 1921, 377—386. [Advance copy.]

The apparatus used consisted of two concentric cylinders, an inner platinum tube, 22 cm. long and 0·55 cm. diam. serving as anode, and an outer copper tube 20 cm. long and 6 cm. diameter as cathode. The temperature of the cell was regulated by passing a current of water through the anode and up and around the copper cylinder, the whole being placed in a beaker. Preliminary experiments showed that the yield of perchloric acid depended on the duration of electrolysis, the anode current density, the concentration of hydrochloric acid, the temperature of electrolysis, and the nature of the anode. In dilute solutions, say, $N/10$, as much as 50% of the original hydrochloric acid may be converted into perchloric acid, the larger part of the remainder being lost as chlorine. On increasing the concentration, the percentage rapidly decreases to 10% in $N/2$ solutions; the amount of chloric acid formed increases with increasing initial concentration. Increasing the temperature from 20° C. to 40° C. tends to decrease the yield of perchloric acid but increase that of chloric acid. Based on these results a cell was constructed in which electrolysis was carried out successfully on a scale to yield 800 g. of 60% perchloric acid per 24 hrs. The cell was in the form of a long narrow rectangular trough of sheet silver supported in a copper mesh frame and provided with a silver outlet tube at the bottom. The cell served as cathode and was immersed in a water-bath, and cooling water was sprayed over both sides during operation. The sheet platinum anode was suspended in the middle of the cell from a copper rod protected by bakelite.

The electrolysed solution was run off into "vitreosil" dishes arranged in cascade in which the perchloric acid was concentrated to 60% strength. Using hydrochloric acid of $N/2$, average current, 150 amp.; average voltage, 8 volts; anode current density, 0·16 amp. per sq. cm.; rate of flow of liquor through cell, 2·5—3 l. per hr.; temperature, 18° C., the concentration of hydrochloric acid at the end of the run was 0·0179N, that of chloric acid 0·0255N, and that of perchloric acid 0·0738N. The concentration of perchloric acid could be increased by making up the hydrochloric acid concentration to 0·5N and again electrolysing, and in practice it would be advisable to use two cells working with a fairly strong acid, high temperature, and medium current density in the first so as to favour the formation of chloric acid, and with a more dilute solution, low temperature, and high current density in the second, *i.e.*, under the most favourable conditions for the oxidation of chloric to perchloric acid.—H. R. D.

Caustic soda; Electrolytic manufacture of —— by the bell process. M. Yasuda. Kōgyō-Kwagaku Zasshi (J. Chem. Ind., Japan), 1921, **24**, 1006—1022.

The author has found that hydrogen bubbles produced by electrolysis of alkali chloride solution with moderate current density always contain alkali hydroxide in their films, either as a solution or sometimes in the solid state. Experiments were made with an electrolyser constructed on the bell system, a small and short inverted porcelain box, containing a small iron plate as cathode, being set at an inclination of 12°—13° to the horizontal. The hydrogen bubbles flowed along under the inverted cathode, and were discharged to outside the bell from the opening of the inclined bottom. With a current of 3 amp. per sq. dm. of horizontal cross-section of the bell, and 4 volts or more, a concentration of 130—140 g. of caustic soda per litre was obtained, as compared with 80 g. by the usual method. In tests extending over 59 days with 24 cells in series, using 110 volts and 120 amp., the following average results were obtained: Current yield, 83·68%; energy for 1 lb. of caustic soda, 1·69 kw.h.; concentration of caustic soda, 130·78 g. per l.—K. K.

Ammonia; Formation of ——. Electronic synthesis of chemical compounds. I. E. Hiedemann. Chem.-Zeit., 1921, **45**, 1073.

By passing a mixture of pure hydrogen and pure nitrogen through an electron tube, maintaining a tension a few volts above the ionisation tension of both gases, a relatively large yield of ammonia was obtained, though the actual quantity formed was so small that the synthesis is not technically practicable.—E. H. R.

Ammonium sulphate; Melting point and boiling point of ——. E. Jänecke. Z. angew. Chem., 1921, **34**, 542—543. (*Cf.* J., 1920, 818 A.)

A further study of the equilibrium between ammonia, sulphuric acid, and water shows that there are maxima in the curve at 48°, 147°, and 251° C. corresponding to an acid sulphate, $NH_4.H_3(SO_4)_2$, ammonium hydrogen sulphate, NH_4HSO_4, and ammonium pyrosulphate, $(NH_4)_2S_2O_7$ respectively, and minima at —20°, 39°, 138°, and 195° C. corresponding to eutectic mixtures of sulphuric acid and the acid sulphate, the acid sulphate and the hydrogen sulphate, the hydrogen sulphate and the normal sulphate, and the pyrosulphate and the normal sulphate respectively. On heating, ammonium sulphate decomposes in two ways giving either ammonia and ammonium hydrogen sulphate or ammonia, water, and ammonium pyrosulphate which latter is the stable phase at the boiling point. A compound of ammonia and ammonium sulphate $(NH_4)_2SO_4,3NH_3$ is also known. (*Cf.* J.C.S., Dec.)—A. R. P.

Sodium bisulphate; Manufacture of sodium carbonate and caustic soda from ——. E. Berl, R Defris, and W. von Boltenstern. Z. angew. Chem., 1921, **34**, 517—521.

Berl's process for the complete utilisation of nitre-cake is indicated by the reactions:

$$2CaCN_2+2H_2O=Ca(OH)_2+Ca(HCN_2)_2;$$
$$Ca(HCN_2)_2+Ca(OH)_2+2NaHSO_4+2H_2O=2(CaSO_4.2H_2O)+2NaHCN_2;$$
$$2NaHCN_2+5H_2O=Na_2CO_3+4NH_3+CO_2.$$

By employing additional lime the soda is obtained as hydroxide instead of carbonate. The ammonia gas produced is pure and suitable for direct catalytic oxidation. The sulphur impurities in the calcium cyanamide are found as sodium sulphide in the soda-liquor. The first two reactions are exothermic and efficient cooling is necessary, as at higher temperatures dicyanodiamide is formed which, though not affecting the yield of ammonia, reduces that of soda. The decomposition of calcium cyanamide with water was found to be complete in 1 hr. with vigorous stirring. The best yield of dissolved nitrogen is obtained by using high strength calcium cyanamide and as much water as possible. If the theoretical quantity of finely powdered bisulphate, or the same in strong solution, is added at the beginning, the reaction is complete in about the same time. The best yield of soda (87%) was obtained at 16°—20° C., the nitrogen recovery as ammonia in the solution at this temperature was 87%. A rise of temperature slightly assists the decomposition of the solid calcium cyanamide, but at the expense of ammonia-losses and a reduced yield of soda. The acid sodium cyanamide solution was found to decompose completely when heated to a moderate temperature at 4 atm. pressure. The finely powdered gypsum produced is very suitable for the conversion of ammonium carbonate into sulphate, and does not require the special filtration apparatus necessary for natural gypsum.—C. I.

Sodium cyanide; Preparation of —— from calcium cyanamide. C. Fujioka. Kōgyō-Kwagaku Zasshi (J. Chem. Ind., Japan), 1921, **24**, 1119—1130.

In the manufacture of sodium cyanide from calcium cyanamide, carbon, and sodium carbonate or chloride, the addition of metallic zinc, aluminium, or magnesium greatly improves the yield. An intimate mixture of 5 pts. of calcium cyanamide, 1 pt. of charcoal, 3 pts. of sodium carbonate, 6 pts. of sodium chloride, and 2·5 pts. of metal was heated in a closed iron vessel at 900°—1000° C. for 10—20 min., and then suddenly cooled. When zinc was used, 80% of the nitrogen in the cyanamide was utilised, yielding 14% crude sodium cyanide; with aluminium 85% of the nitrogen was recovered and 15% cyanide was produced; with magnesium the reaction took place quantitatively, producing 17% cyanide.—K. K.

Calcium cyanamide; Graphitic nature of the carbon of crude ——. N. Kameyama. Kōgyō-Kwagaku Zasshi (J. Chem. Ind., Japan), 1921, **24**, 1131—1142.

The carbon in crude calcium cyanamide was isolated by treating the material with concentrated hydrochloric acid and 55% hydrofluoric acid. It contained 0·17—0·67% of ash, formed graphitic acid on oxidation, and agreed in specific gravity, heat of combustion, electrical conductivity and other properties with graphite.—K. K.

Thiocyanates; Determination of —— in the presence of salts which give precipitates with silver nitrate. A. Dubosc. Ann. Chim. Analyt., 1921, 3, 297—298.

A suitable quantity of the thiocyanate is dissolved in 50 c.c. of water, the solution is treated with 50 c.c. of 4% barium chloride solution, and 50 c.c. of a solution containing 2% of active chlorine is added; this solution is prepared by electrolysing a mixture of sodium chloride and magnesium chloride solutions. After 10 mins., the solution is acidified with 10 c.c. of hydrochloric acid, boiled, cooled, and the precipitated barium sulphate collected and weighed. The sulphur in the thiocyanate is oxidised completely to sulphuric acid by the reagent mentioned.—W. P. S.

Dolomite; Separation of lime from ——. H. G. Schurecht. J. Amer. Ceram. Soc., 1921, 4, 558—569.

Magnesium carbonate in dolomite is decomposed by calcining for 1 hr. at 800° C., but to decompose the calcium carbonate completely calcining at 960°—1040° C. for 1 hr. is necessary. On adding sufficient sulphuric acid to milk of dolomite to react with the lime present, a bulky precipitate of magnesium hydroxide is formed, which may be partially separated from the fine calcium sulphate by screening through a 120-mesh sieve. The residue on the screen contains about 68% MgO, and represents over 50% of the dolomite treated. The best results by flotation were obtained after removing the fine material from the raw dolomite and then calcining at 920° C., but the concentrates removed by flotation represented only 25% of the dolomite originally treated; wood creosote was the best flotation agent. By a treatment involving leaching with water and screening a product containing about 80% MgO can be obtained, and by an elutriation treatment a residue containing over 85% MgO, and representing about 30% of the original dolomite.—H. S. H.

Oxides of lead; Physical chemistry of ——. I. Solubility of lead monoxide. S. Glasstone. Trans. Chem. Soc., 1921, **119**, 1689—1697.

A close relationship exists between the forms of lead monoxide, the yellow forms being probably agglomerates of small particles almost identical with the finely-divided red form. Solubility determinations and microscopical examination confirm this view. The red form has the largest particles, 3μ to 5μ, which on heating to 700° C. and then cooling form yellow agglomerates, 10μ—20μ, these breaking down under pressure to fine red-brown particles, $0{\cdot}7\mu$—$1{\cdot}5\mu$, identical with the brown powder obtained by grinding any form of the monoxide. The identical solubility of the yellow and red-brown forms—rather higher than that of the coarse-grained red form—may be accounted for by the breaking down of the yellow agglomerate in contact with the solvent into the small red-brown particles. The energy at the surface of separation of lead monoxide and $N/1$ sodium hydroxide is calculated as 1860 ergs per sq. cm. at 20° C. If water replaces sodium hydroxide solution the value does not differ greatly.—P. V. M.

Nickel-carbonyl; Preparation of ——. E. Tassilly, H. Pénau, and E. Roux. Bull. Soc. Chim., 1921, 29, 862—864.

In the preparation of nickel-carbonyl by passing carbon monoxide over reduced nickel deposited on puzzuolana the optimum temperature was 45° C. at a pressure of 3 cm. of mercury. Within reasonable limits the yield of carbonyl from a given volume of carbon monoxide was independent of the rate of flow of the gas, provided the velocity was not so great as to prevent adequate condensation of the product. The coefficient of utilisation of the metal was 84%, and of the gas 37%.—W. G.

Helium-bearing natural gas. G. S. Rogers. U.S. Geol. Survey, Prof. Paper 121, 1921. 113 pages.

A detailed account of the chemical composition, distribution, and chief sources of helium-bearing natural gas is given. Helium constitutes from 0·5 to 2% of certain natural gases occurring in Kansas, Oklahoma and Texas. The helium content usually decreases with increasing depth of the strata in which the gas occurs. Helium has been found in European natural gas to the extent of 0·38%. Only a few species of minerals are free from helium. The gases of many European mineral springs contain as much as 10% of helium. The helium generated by the radio-elements disseminated through ordinary rocks amounts to about ½ cub. ft. per year per cub. mile of rock. The available supply of helium in the United States, taking into account every field producing at least 3,000,000 cub. ft. of raw gas containing at least 0·35% of helium, amounts to 6,000,000 cub. ft. of helium per week, and this supply could be maintained for 2½—3 years. No commercial supplies of helium-bearing natural gas have been discovered outside N. America. Of the processes available for the extraction of helium from natural gas, the Linde process, though more elaborate and expensive than the Claude and Jefferies-Norton processes, has hitherto given the best results. The helium obtained by the process is of 93% purity. It should be possible to treat natural gas containing only 0·25—0·3% of helium by the Jefferies-Norton process, and it is anticipated that the cost of production can be reduced from \$100 to \$60—\$80 per 1000 cub. ft. (*Cf.* Cottrell, J., 1919, 123 T.)

Patents.

Nitric acid; Process for concentrating aqueous —— by means of concentrated sulphuric acid. H. Frischer. G.P. 340,905, 26.3.19.

The sulphuric acid used in the process is previously saturated with the oxides of nitrogen that are not recovered by condensation in the cooler during the distillation of a previous charge.—A. R. P.

Nitric oxide; Gas engine for the production of ——. F. Gerhardt. G.P. 340,725, 7.4.20. Addn. to 303,255 (J., 1919, 891 A).

By working the apparatus in a two-stroke cycle, the temperature of compression is raised and combustion is more complete.—L. A. C.

Nitrous gases; Process for the sudden cooling of hot ——. R. Mewes. G.P. 304,372, 30.4.14. Addn. to 298,846 (J., 1920, 190 A).

The gases are cooled suddenly by means of liquid air under the same or higher pressure. For carrying out the process the combustion chamber is inserted between the apparatus used for the production of the liquid air and the expansion machine, and the cooled gases pass direct from the chamber into the latter machine. The cooling capacity of liquid air is twice as great as that of the compressed air specified in the principal patent, so that the space occupied by the apparatus is much smaller.

—A. R. P.

Sulphur dioxide; Method and apparatus for recovery of —— from furnace gases and other gases containing the same. A. H. Eustis. E.P. 168,627, 4.5.20.

Sulphur dioxide is absorbed from furnace or smelter gases by means of water or a solution of aluminium sulphite or the like. The extraction of sulphur dioxide from the resulting solution is performed by reducing the partial pressure of sulphur dioxide in the atmosphere in contact with the liquid by dilution with a copious supply of another gas which is condensed at a lower pressure and/or higher temperature than sulphur dioxide. Steam is preferably used as diluting gas, and the liberated sulphur dioxide is recovered by condensing the steam. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 26,152 of 1908 and 1882 of 1909; J., 1910, 160.)—H. R. D.

Ammonia-soda and ammonium chloride; Process for manufacture of ——. Bayerische Stickstoffwerke A.-G., and N. Caro. G.P. 303,843, 5.5.17.

Lime prepared by calcining limestone is converted into carbide and then into calcium cyanamide, and ammonia prepared from the latter and the carbon dioxide from the limestone and from the decomposition of sodium bicarbonate at a later stage of the process are used in the ordinary ammonia-soda process. After separation of the sodium bicarbonate, solid ammonium chloride is recovered from the solution by any of the known processes.—W. J. W.

Potassium nitrate; Preparation of ——. Bayerische Stickstoffwerke A.-G. G.P. 310,661, 9.11.16.

Calcium cyanamide is allowed to react with a solution of potassium sulphate, whereby calcium sulphate is precipitated and potassium carbonate and hydroxide and ammonia are formed. The latter is removed from the solution by boiling and converted into nitric acid, which is utilised to neutralise the potassium compounds with the production of potassium nitrate. The calcium sulphate precipitate is converted into ammonium sulphate by first recovering the contained sulphuric acid by known methods and then neutralising this with part of the ammonia produced in the first part of the process. —A. R. P.

Cerite earths; Purification of the crude sulphates of the ——. Ges. für Verwertung Chem. Prod. m.b.H., Kommanditges. G.P. 340,457, 29.1.19.

The crude sulphates are dissolved in water at a low temperature to give metastable supersaturated solutions, which are then heated to 50° C., whereby anhydrous or nearly anhydrous sulphates of the earths are precipitated. The precipitate is filtered from the warm liquor, which is then cooled and used for the preparation of further quantities of the supersaturated solution.—A. R. P.

Argon; Recovery of —— from nitrogenous gas mixtures. Osram Ges.m.b.H., Kommanditges. G.P. 340,987, 15.5.18.

The residual gases from the synthesis of ammonia by the catalytic process are worked up in known ways for the recovery of the contained argon. —A. R. P.

Aluminium sulphate; Process of preparing ——. G. Muth. E.P. 149,001, 12.7.20. Conv., 13.5.19.

See G.P. 319,420 of 1919; J., 1920, 517 a.

Alumina; Process of manufacture of pure ——. E. Martin. U.S.P. 1,394,854, 25.10.21. Appl., 19.8.19.

Lime kilns. E.P. 169,786. *See* IX.

VIII.—GLASS; CERAMICS.

Glass; Composition of barium ——. R. J. Montgomery. J. Amer. Ceram. Soc., 1921, 4, 536—545.

The relation between the composition of barium glasses and their optical constants is discussed. Dispersion is not affected to any extent by barium. A linear relation holds between the increase of the index of refraction and the barium content up to 42% Ba, while from 42% to 54% Ba little change in the index occurs. There is a decided drop in the silica content as the barium increases. The amount of alkali in the glass increases with the silica; the alkali is not necessary to obtain the desired optical properties, but is used for controlling the melting and working properties of the glass. The relation between the proportion of BaO and the other RO bases is shown graphically, as are those between B_2O_3 and SiO_2 and the optical properties, and between the relative percentages of B_2O_3 and Al_2O_3. Zinc oxide may be present up to 11%, but has little effect on the optical properties.—H. S. H.

Glasses; Determination of the relative expansions of ——. F. E. Wright. J. Opt. Soc. Amer., 1921, 5, 453—460.

Polarised light is transmitted through a plate of the glass under test, and subsequently passes through a sensitive-tint plate of quartz or selenite, and finally through an analyser. From the interference colours observed, the state of radial compression or tension of the various parts of the sample can be inferred, comparison of the colours with those afforded by a sample of homogeneous glass under compression or tension being readily made. Glass under compression behaves as a negative uniaxal crystal, the principal axis of which coincides with the direction of application of the load. For the determination of the relative expansions of two samples of glass, the samples are fused or welded together, and examined as above. The method is applicable to the investigation of strains due to cords or striæ in glass, or those due to "stones" or metal wire. Disturbing effects due to irregular boundary surfaces may be largely avoided by immersion of the samples in a liquid of the same refractivity.—J. S. G. T.

Glass; Determination of sulphate, chloride, and carbonate in soda-lime ——. M. Ikawa. Nippon Kwagaku Kwai Shi (J. Chem. Soc. Japan), 1921, 42, 768—785.

Finely-powdered glass was decomposed by warming with acid ammonium hydrogen fluoride solution, and sulphate and chloride in the solution were determined as barium sulphate and silver chloride respectively. Sulphur was oxidised by bromine water and determined as sulphate. Carbon dioxide was determined by the Fresenius-Classen method, after the sample had been decomposed with the 30% fluoride solution. Analytical results obtained with glass of Belgium and American manufacture were as follow: SO_4 as Na_2SO_4, 0·667—1·045%; S as Na_2SO_4, 0·000—0·108%; Cl as NaCl, 0·066—0·154%, and CO_2 as Na_2CO_3, 0·021—0·055%.—K. K.

Fireclay tiles; Transverse strength of —— at furnace temperatures. R. F. Geller. J. Amer. Ceram. Soc., 1921, 4, 608—615.

Commercial fireclay tiles, as well as tiles of known compositions made in the laboratory, were supported at their ends on special fireclay pieces and heated uniformly in a furnace. The load was applied at the selected temperature until failure occurred; in some tests specimens 2 in. thick with a span of 12 in. failed under a wedge-shaped load of 20 lb. applied over a width of 6—12 in. at temperatures below 1350° C. Sufficient data have not been obtained to warrant definite conclusions, but it seemed that at 1350° C. fireclay tiles had very little transverse strength (about 29 lb. per sq. inch), and that transverse strength decreased rapidly with rise of temperature. Tiles containing fine grog graded to produce a body of minimum porosity possessed the greatest transverse strength at high temperatures.—H. S. H.

Metallography of the oxy-acetylene weld as affected by enamelling. E. P. Poste. J. Amer. Ceram. Soc., 1921, 4, 608—615.

The temperature in the enamelling furnace was higher than the necessary annealing temperature for any steel which would be used in enamelling. An examination of metallographic sections of plates and welds before and after enamelling showed that a thorough annealing of the weld had been accomplished.—H. S. H.

Patents.

Films of silica, alumina, or other refractory substances: Manufacture of —— and apparatus for use therein. M. de Roïboul. E.P. 169,136, 19.11.20. Conv., 16.9.20.

Films of refractory materials are drawn from a molten bath of the substance by means of parallel wires of a more refractory metal travelling through the molten material. Two parallel iridium wires may be caused to pass round an iridium guide roller immersed in the molten refractory substance, and out of the bath on to a collecting drum placed in close proximity to the furnace. The molten material forms a film between the wires by capillarity, and is sufficiently cooled by the time it reaches the drum to prevent the adhesion of successive layers. The cooled film may be unwound and detached from the wires by cutting rolls, and is flexible up to a thickness of about 0·003 mm. —C. A. K.

Refractory materials from zirconia and silicon carbide; Production of ——. Dr. North Kommandit-Ges. G.P. 340,303, 15.11.19.

Granular zirconia is mixed with very finely ground silicon carbide and a binder. Part of the zirconia may also be very finely ground. The product is not very sensitive to changes in temperature. —A. B. S.

Glass; Process of manufacture of a —— using natural silicates, such as micaceous minerals, asbestos, and the like. P. B. Crossley. U.S.P. 1,394,973, 25.10.21. Appl., 27.9.19.

See E.P. 152,780 of 1919; J., 1920, 820 a.

[Ceramic] pastes that may be poured; Method for producing ——. E. Weber. U.S.P. 1,394,241, 18.10.21. Appl., 15.6.20.

See G.P. 336,661 of 1917; J., 1921, 586 a.

IX.—BUILDING MATERIALS.

Portland cement; Crystallisation and other changes in the hardening of ——. Schott. Zement, 1921, 10, 294—295, 306—308, 328—332. Chem. Zentr., 1921, 92, IV., 997.

When a column of plates (1—2 mm. thick) of Portland cement is stored under water in a closed glass vessel, the plates become cemented together owing to the formation of crystals of hydrated calcium oxide. Crystals of monocalcium silicate contaminated with lime form on the walls of the container. The hardening of cement under water is thus due to the cementing action of the slowly-formed crystals of hydrated lime which fill all the interstices and unite the particles.—A. B. S.

Lime-silica-iron oxide. H. Kühl. Zement, 1921, 10, 361—364, 374—376. Chem. Zentr., 1921, 92, IV., 997—998.

Alumina is not an essential component of hydraulic cements. The production of cements rich in iron oxide requires the presence of silica in a highly reactive form. The sintering of such cements is similar to that of Portland cement. The hydraulic constituent is tricalcium silicate. The area occupied by cements rich in iron oxide in a triaxial diagram of the system lime-silica-iron oxide is in nearly the same position as that of the Portland cements in the system lime-silica-alumina.—A. B. S.

Cement; Behaviour of —— in solutions of calcium sulphate. Strebel. Zement, 1921, 10, 385—386, 397—398, 409—411, 421—423. Chem. Zentr., 1921, 92, IV., 998.

Mixtures in the proportions 1:2, 1:5, 1:6, 1:7, 1:8, 1:9, and 1:10, were prepared from Portland cements rich and poor in lime respectively, from iron-Portland cement, and from an "ore-cement," and test-pieces were immersed in a solution of calcium sulphate for 5 years. The "ore-cement" mixtures and the 1:2, 1:8, 1:9, and 1:10 mixtures from the other cements were unaffected, but the 1:5 and 1:7 mixtures disintegrated. The 1:5 mixtures showed the greatest increase in SO_3 and greatest loss of lime, both these values decreasing with the leaner mixtures.—A. B. S.

Concrete; Behaviour of —— in solutions of ammonium salts. R. Grün. Zement, 1921, 10, 425—426. Chem. Zentr., 1921, 92, IV., 998.

Concrete should be protected from ammonium salts, which have a detrimental action on it similar to that of acids, the acid radicles in the salts combining with lime, forming soluble salts and liberating ammonia.—A. B. S.

Magnesia cements; Plastic ——. P. H. Bates and R. N. Young. J. Amer. Ceram. Soc., 1921, 4, 570—596.

Crystalline magnesite from Washington was crushed to three sizes, viz., to pass a No. 6 sieve but retained on a No. 10; between a No. 10 and a No. 30, and to pass a No. 60 sieve. These lots were burned separately in an electric rotary kiln at 600°, 650°, 700°, 800°, and 900° C. respectively. The activity of the magnesia towards moisture decreased as the calcining temperature increased. Three flooring mixtures were made up of magnesia, flint, and asbestos, containing respectively 50%, 42·5%, and 35·0% of magnesia, and three mortar mixtures containing 33%, 22%, and 11% magnesia, 67% sand, and the remainder flint, were prepared. The time of set, consistency, soundness, fineness, and effect of density of the magnesium chloride solution used were determined. The tensile and compressive strengths were measured after 1, 7, and 28 days and the coefficient of expansion was determined after 2, 4, 7, 28, and 90 days. The rate of reaction of the magnesia with the chloride decreased with increased temperature of burning, and also with increased fineness of the raw material. Decreasing the concentration of the magnesium chloride (down to 22° B., sp. gr. 1·18) accelerated the set of freshly calcined magnesite and retarded that of magnesia which had become hydrated through exposure. The disintegration ("unsoundness") of the composition was due to the hydration of free magnesia after the mixture had hardened and was therefore dependent upon the extent to which the magnesia had reacted with the chloride, water, or carbon dioxide before hardening took place and upon the amount of hydration which subsequently occurred. The steam or cold water tests were not satisfactory tests for the soundness of the magnesia mixture. Under the conditions of the tests the best materials with regard to setting time and strength were produced at a temperature of 800° C., but the magnesia burned at 650° C. and which gave comparatively low strength when gauged with a 22° B. (sp. gr. 1·18) solution of magnesium chloride gave excellent results with more concentrated solutions. No relation was found between the volume change and any other property of magnesia, though leaner mixtures showed less change in volume in the laboratory than the richer ones, but laboratory tests of volume changes were no index as to the behaviour of the material under actual service. The lean mortar mixture was the most suitable of any tested and in this case the tensile strength furnished as much, if not more, information than the compressive strength.—H. S. H.

Patents.

Trass; Process for the production of artificial ——. E. Link. E.P. 145,569, 29.6.20. Conv., 9.7.17.

Material possessing the properties of natural trass is obtained by mixing $\frac{1}{2}$—$\frac{2}{3}$ pt. of blast-furnace slag with $\frac{1}{2}$—$\frac{1}{3}$ pt. of burnt clay (*e.g.*, building brick), and grinding the mixture to a fine powder. When mixed with lime slip the mortar sets and hardens slowly to a tough, pliant substance. —C. A. K.

Lime kilns. P. Dumont. E.P. 169,786, 30.6.20.

In an annular shaft kiln for burning lime, in addition to the grid at the lower end supporting the cooling lime descending from the calcining zone, there is a supplementary grid some distance below the charging opening to support the charge and prevent undue crushing of the material in the calcining zone. The waste gas flues are bifurcated several times, their ramifications being arranged uniformly round the upper part of the furnace walls so as to withdraw the products of combustion uniformly from each part of the periphery of the kiln. The width of the discharge hoppers at the top, immediately below the shaft, measured radially to the fire, is greater than the corresponding dimensions of the lower part of the annular space under the lower grid, so that between the hopper and the central column spaces are formed, into which the lime does not fall during its descent, but through which the air required for combustion is introduced from pipes below a series of bridges (one below each hopper). Under the discharging mouths are oscillating spouts or small wagons, all actuated by a single eccentric, which deliver the burned lime to a transverse conveyor.—A. B. S.

Cement mixtures; Manufacture of ——. *Manufacture of cements.* H. Wade. From Bombrino Parodi-Delfino. E.P. (A) 169,807 and (B) 169,808, 5.7.20.

(A) A cement-mixture for use in agglomerates, resistant to sea-water and to water containing sulphates, is prepared by mixing a cement, made as described in E.P. 170,063 (*cf.* U.S.P. 1,372,015; J., 1921, 349 A), with a puzzuolanic substance such as trass, basic slag, etc., and grinding the mixture o a fine powder. The proportions of the ingredients are such that the lime liberated on the hydraion of the cement is fixed by the puzzuolanic subtance and by the silicious sand with which the ement-mixture is mixed for use. (B) Cements of he Portland cement type are made from leucite ($K_2O,Al_2O_3,4SiO_2$) and limestone, both free from ron oxide, the product being coloured by the addiion (prior to burning) of 0·5—2·5% of oxide of manganese, chromium, copper, cobalt, or the like. The potash in the leucite enables the burning to be ffected at the same temperature as that of Portand cement, the potash being afterwards recovered s a by-product.—A. B. S.

Plastic calcined gypsum; Process of making ——. W. E. Emley. U.S.P. 1,392,574, 4.10.21. Appl., 3.2.21.

The plasticity of calcined gypsum is increased by grinding it in such a manner as to eliminate the water present, but not allowing the water to escape from the grinding plant and causing it to be reabsorbed by the gypsum before grinding is stopped. —A. B. S.

Cement; Manufacture of slow-setting ——. H. Wade. From Bombrini Parodi-Delfino. E.P. 170,063, 5.7.20.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron smelting; Future of electrothermic ——. A. Helfenstein. Stahl u. Eisen, 1920, 41, 1481—1487, 1572—1576.

If a is the saving in coal for electric smelting as compared with the blast furnace, b the value of the gases obtained in the electric process, c the value of the surplus blast-furnace gas, d the cost of electric power, e the cost of electrodes, and f the cost of the blast for the blast furnace (all in the same units), then when $a+b-c$ is equal to or greater than $d+e-f$, for the same cost of raw materials and labour the electric process is superior, for it has considerable advantages over the blast furnace. This method of comparison also shows the possible direction of improvement of the electrothermic process, for only the value of b shows prospects of improvement. Electric smelting processes may be divided into those which completely use the furnace gases for the production of iron and those which aim at obtaining valuable gases as well as improved iron. The first type will always depend on cheap electricity, and do not come into question for general application. In the second type the use of the gases produced may so affect the cost of the iron that coal and power costs may no longer play preponderating rôles. This type of process seems to possess prospects of successfully competing with the blast furnace. A low or thin charge is used, and hence the process is more independent of the ore and coal qualities than the blast furnace, and it gives a valuable gas suitable for illuminating gas, chemical syntheses, and high-temperature processes. The electric iron and gas process can be worked in small furnace units and makes possible the use of peak power, for variations in power and interrupted working are permissible. The most important feature of the electric low-charge process is that the two phases of carbon combustion—carbon to carbon monoxide and carbon monoxide to dioxide—can be carried out independently in space and time, and the electric energy can be largely regenerated.—T. H. Bu.

Iron; Metallic —— *as a reducing medium in the production of technical iron.* W. Heike. Stahl u. Eisen, 1921, 41, 1569—1572.

In fluid iron the reversible equation

$$Fe+MnO \rightleftarrows Mn+FeO$$

tends to an equilibrium between the slag and iron determined by the law of mass action. Substances such as sulphur, carbon, and phosphorus, which tend to prevent equilibrium, favour reduction. In the case of silicon the influence of mass action on the equilibrium condition of the equation

$$FeSiO_3+3Fe \rightleftarrows 3FeO+FeSi$$

is considered. The reduction of silicon is determined by the silicon content in the iron and the ferrous oxide present. A basic slag high in ferrous oxide completely oxidises the silicon. With acid slags an equilibrium is not reached and silicon goes into the iron. The conditions for the reduction and oxidation of phosphorus are similar to those for silicon, and phosphorus is readily removed by slags rich in ferrous oxide. With basic lime slags a reaction takes place according to the equation

$$Fe_3P_2O_8+4CaO \rightleftarrows Ca_4P_2O_9+3FeO,$$

consideration of which shows that in agreement with practice, with a slag free from ferrous oxide, an iron may be obtained free from phosphorus. If on over-blowing a bath the phosphorus again increases in the iron, it occurs as phosphate and not as phosphide. As the equation taking place towards the right is exothermic, and phosphorus is more soluble in hot iron, an explanation is obtained of why a low bath temperature is better for burning out the phosphorus. Re-phosphorisation after refining is due to the destruction of equilibrium conditions.—T. H. Bu.

Titanium; Occurrence and behaviour of —— in a pig-iron mixer. B. Osann. Stahl u. Eisen, 1921, 41, 1487—1489.

Fragments of the magnesite lining of a mixer contained small cubic copper-coloured crystals embedded in a matrix. Analysis showed that the matrix consisted of pig iron with high sulphur and manganese content. The crystals contained 77·5% Ti, 18·4% N, and 3·6% C, and were composed of the same compound as that found by Wöhler in blast-furnace "sows." It is probable that the crystals are set free from a layer high in sulphides formed between the pig iron and slag, which as a rule is removed with the slag, but under certain conditions is transferred to the mixer, in which case, being the first substance to solidify, it is deposited in the joints in the lining and the crystals separate out from solution.—T. H. Bu.

Steel; The surface of liquid ——. C. Johns. Brit. Assoc., Sect. B, 13.9.21. Engineering, 1921, 112, 619.

When steel is poured into an open chill mould it retains its optically clean surface for several seconds, but as the freezing point is approached a film of oxide spreads over the surface. Tests made by the author indicate that the reason for the persistence of the clean surface is that the metal surface is protected by a film of metallic vapour. Samples of the fume that is observed above a bath of molten steel were collected by means of a magnet and by condensation, and the products analysed. In the case of an alloy steel, the fume was richer in the elements of low boiling point and poorer in those of high boiling point than the metal bath; hence the fume could not be due to spitting, but must actually consist of metallic vapour, which acts as a protection of the surface of the metal against oxidation.—A. R. P.

Steels; Uranium ——. H. S. Foote. Chem. and Met. Eng., 1921, 25, 789—792.

The presence of uranium exerts little direct influence upon the critical or transformation points of steel up to a content of 2·0%. More than this quantity lowers the Ar transformations and induces martensitic structure in the metal. Ferrite-cementite in steels containing up to 0·6% U is finer than in corresponding carbon steels, and with 1% U pearlite loses its lamellar structure and a carbidic compound of uncertain nature is formed. Uranium appears to emphasize the characteristic properties of the alloying element in steel, *e.g.*, nickel steels containing uranium are harder when heat-treated, possess superior dynamic toughness and resistance to fatigue, and have higher elastic limits for the same ductility, than pearlitic nickel steels. Uranium tends to promote the formation of complex carbides in high-speed steels, a valuable property in regard to cutting efficiency and red hardness.—C. A. K.

Platinum; Detection and estimation of —— in [low-grade] ores. C. W. Davis. U.S. Bureau of Mines, Techn. Paper 270, 1921. 27 pages.

The finely ground ore is mixed with similar fluxes to those used for a gold assay and 0·05 g. of silver chloride is also added to assist in collecting the platinum. The lead button obtained should weigh about 30 g., so that if the platinum content of the ore is small several buttons (each from 1 assay ton) should be scorified to about this weight. The charge is fused at a higher temperature than usual and kept molten for 1 hr.; it should not be stirred with an iron rod, as this leads to loss of iridium. After cooling the crucible is broken, the button cleaned and cupelled at a high temperature. If the silver bead contains more than 0·3% Pt the latter may be detected microscopically; if more than 1·6%, by the frosted appearance of the bead. Iridium gives a rough surface of fine texture; palladium, an embossed surface, and ruthenium discolours the bead and leaves a black scum on the cupel. The bead is parted with nitric acid, first with 1:4, then with 1:1, finally with 2:1 acid, whereby platinum, palladium, and silver dissolve, and gold and the other platinum metals remain in the residue, together with a little platinum, if much is present. The solution is treated with just sufficient hydrochloric acid to precipitate silver (the silver chloride, if pink, is re-dissolved in ammonia and re-precipitated) and the filtrate evaporated to dryness on the water bath. Nitrates are destroyed by repeated evaporation with hydrochloric acid; the residue is treated with a few c.c. of cold water and the last traces of silver chloride removed by filtration. The filtrate is made slightly alkaline with sodium carbonate and boiled for ½ h. with formic acid to precipitate the platinum and palladium, which are filtered off, washed, ignited, and weighed. Palladium is extracted from this residue by warming with 1:4 nitric acid and the platinum is filtered off, ignited, and weighed, palladium being found by difference or by a repetition of the formic acid treatment on the filtrate from the platinum. The residue from the nitric acid extraction of the bead is digested with 1:5 *aqua regia* and the insoluble matter weighed as iridium, rhodium, ruthenium and osmium, but the result will be low owing to losses during the cupellation. The *aqua regia* solution is evaporated to dryness with hydrochloric acid twice, the residue treated with cold water, the solution filtered and boiled with oxalic acid to precipitate gold. The filtrate from the gold is treated with formic acid as before, and any platinum precipitated added to that already found. For quantities of platinum less than 0·2 mg. the following colorimetric method gives accurate results. The platinum obtained as described above is dissolved in *aqua regia*, nitrates are destroyed by evaporation with hydrochloric acid to dryness, the residue is treated with 2 c.c. of acid (33 c.c. of concentrated hydrochloric acid diluted to 1 l.), two drops of a stannous chloride solution (5 g. $SnCl_2,2H_2O$ in 10 c.c. of the above acid) added, and the red colour compared with that of solutions containing known quantities of platinum prepared in a similar way.

—A. R. P.

Platinum black and other finely divided metals; Effect of temperature on ——. R. Wright and R. C. Smith. Trans. Chem. Soc., 1921, 119, 1683—1689.

The metals copper, gold, silver, platinum, palladium, and iron in a fine state of division show a considerable decrease of specific surface due to incipient melting together of the particles or low-temperature sintering when heated to temperatures much below their melting point. This effect may be parallel to the abnormal vapour pressure and solubility of finely divided material. These metals show their highest specific surface and their maximum activity as catalysts when produced by reduction at low temperature. If the metal be mounted on asbestos, whereby the individual particles are kept apart, the sintering effect on heating may be partially prevented. The first initial rise in catalytic activity after heating to a low temperature may be explained by the evolution of occluded gases which increases the roughness of the surface and possibly helps catalysis by the removal of a catalytic poison.—P. V. M.

Zinc cyanide plating solution. C. J. Wernlund. Trans. Amer. Electrochem. Soc., 1921, 346—364. [Advance copy.]

Almost any sodium zinc cyanide solution which contains an excess of sodium cyanide will give a smooth grayish-white deposit of zinc on iron cathodes for the first 2 or 3 hrs., after which the deposits become stained and the anodes badly coated with zinc hydroxide, while the current density falls to half its initial value. By adding a further quantity of sodium cyanide to give an excess of this salt the solution behaves as though freshly made up, and continues to give clean deposits as long as there is free sodium cyanide present. The addition of sodium carbonate to the bath is beneficial, as it decreases the chemical solubility of the zinc anodes and the tenacity of the zinc hydroxide coatings on them, and at the same time increases the conductivity of the solution. Whiter, smoother, denser, and non-treed deposits nay be obtained by adding various organic substances, the best results being obtained by the use of a mixture of sodium fluoride, gum arabic, and naize syrup (glucose). Tests over a long period howed that the most satisfactory solution was as ollows:—Zinc cyanide 8 oz. per gall. (60 g. per l.), odium cyanide 7 oz. per gall. (52·5 g. per l.), sodium ydroxide 1—2 oz. per gall. (7·5—15 g. per l.), odium carbonate 4 oz. per gall. (30 g. per l.), odium fluoride 1 oz. per gall. (7·5 g. per l.), maize ugar syrup 1 oz. per gall. (7·5 g. per l.), gum rabic ⅛ oz. per gall. (1·1 g. per l.). This was used t 40°—50° C. and an E.M.F. of 3—5 volts, depending on the amount of material to be plated. The olution was maintained by the addition of sodium nc cyanide when necessary, as shown by analysis, nd by adding from time to time small quantities the last three compounds in the above proportions if the deposit showed a tendency to darken. e current efficiency of the solution was somewhat w (about 75%), but this was beneficial, as the drogen evolved kept the deposit bright. Zinc posits from this solution had a greater protective wer against the rusting of iron than those from lphate solutions, as they were less porous and at e same time more evenly distributed over egular surfaces, while the solution itself cleaned e iron and so ensured greater adherence of the posit.—A. R. P.

nc cyanide plating solutions. W. Blum, F. J. Liscomb, and C. M. Carson. U.S. Bureau of Standards, Techn. Paper 195. J. Franklin Inst., 921, **192**, 516—517.

S isfactory zinc deposits are obtained from solut ns containing either 45 g. of zinc oxide, 75 g. of s ium cyanide, and 15 g. of sodium hydroxide per 1 or 65 g. of zinc cyanide, 20 g. of sodium cyanide, a l 60 g. of sodium hydroxide per l. Plating should b effected below 40° C. in order to reduce cyanide c sumption, and at current densities up to 2 amp. p sq. dm., although 3 amp. may be employed for s oth surfaces. As the presence of large amounts o arbonates causes rough or striated deposits, they should be removed from time to time by precipitation with barium cyanide or hydroxide, or by cooling to low temperatures. (*Cf. supra.*)—A. R. P.

Brass; Rapid electro-analysis of ——. A. and A. Lassieur. Comptes rend., 1921, **173**, 772—775.

The following details should be strictly adhered to:—0·5 g. of brass in thin foil is dissolved in a boiling mixture of 20 c.c. of sulphuric acid (50% by weight) and 1 c.c. of nitric acid (36° B., sp. gr. 1·33), and the solution, after cooling, is diluted with water to 70 c.c. and electrolysed, using rotating electrodes and a current of 4—5 amp. At the end of 40 mins. the whole of the copper is deposited and the nitric acid is completely reduced. The electrodes are rinsed into the solution and to it are added successively 25 c.c. of sodium hydroxide (36° B.), 15 c.c. of glacial acetic acid, and 10 c.c. of a saturated solution of sodium fluoride. The liquid is cooled to the ordinary temperature and electrolysed, using a copper-coated cathode and a current of 4 amp. to deposit the zinc. In some cases at the end of the first electrolysis a slight deposition of zinc is noticed, but the zinc passes into solution again as soon as the current is stopped.—W. G.

[Aluminium;] Unusual grain growth [in ——] due to critical strain. A. P. Knight. Chem. and Met. Eng., 1921, **25**, 829—830.

An aluminium vessel, made by cold drawing a circle of the metal through dies into the form of a shell, annealing this at 800° F. (about 430° C.) and then enlarging it at the bottom to form a tapered shell, was found to have a rough surface in the middle of the bottom which was due to the development of very large crystals, some ½ in. long. It was concluded that this part of the metal was in a "critically strained" condition before annealing, due to the metal having been worked within certain critical limits (*cf.* Carpenter and Elam, J., 1921, 85 A). By annealing the aluminium at 700° F. (370° C.) no development of this rough surface was noted, and the metal consisted entirely of uniformly fine grains and was soft and ductile.—A. R. P.

Aluminium alloys; Researches on ——. *Summary of the Eleventh Report to the Alloys Research Committee.* W. Rosenhain, S. L. Archbutt, and D. Hanson. Inst. Mech. Eng., 21.10.21. Engineering, 1921, **112**, 613—615, 644—645.

The physical properties of a large number of aluminium alloys with zinc, copper, magnesium, and silicon have been examined, together with their behaviour under various mechanical and heat treatments. Zinc-copper-aluminium alloys are only satisfactory for use at ordinary temperatures, as they become brittle on heating; an alloy containing 12·5—14·5% Zn and 2·5—3% Cu has a tensile strength of more than 11 tons per sq. in. and an elongation of 4% on 2 in. at 15° C.; the tensile strength falls to 4 t. at 250° C. and to 1·5 t. at 350° C. The strength of copper-aluminium alloys is increased by addition of manganese or nickel, and in each case is greater at 250° C. than at 15° C. The further addition of magnesium to the copper-nickel-aluminium alloys results in a great increase of strength at all temperatures; thus an alloy containing 8% Cu, 2% Ni, and 1% Mg has a tensile strength of 13 t. per sq. in., compared to the 8 t. per sq. in. of a similar alloy without the magnesium. "Y" metal containing 4% Cu, 2% Ni, 1·5% Mg, rest Al, has a tensile strength of 13 t. per sq. in. at 15° C., 11 t. at 250° C., and 5 t. at 350° C.; the elongation at the latter temperature is 15%, and the alloy readily lends itself to rolling and forging. Tensile strengths of over 24 t. per sq. in. with an elongation of 20% may be obtained by quenching this alloy in boiling water from 520° C. The alloy has a greater resistance to alternating stresses, both at 20° C. and 150° C., than any other alloy studied, is immune from season cracking, and shows a very remarkable resistance to corrosion. In making the alloy the nickel is added as a 20% Ni-aluminium alloy, and the magnesium as large pieces of pure metal, which are pushed under the surface of the molten aluminium just before pouring. Details of the results obtained for the tensile strength of a number of the most promising aluminium alloys after cold working, followed by different annealing and ageing treatments, are given. These properties gradually altered in the course of years, but the changes do not suggest any serious deterioration of the alloys, nor do they result in dimensional change of any serious magnitude. Some of the copper-zinc-aluminium alloys of high zinc content exhibit the phenomena of season cracking if annealed at too high a temperature, but this tendency in the over-annealed metal may be greatly overcome by hot working, so as to effect a total reduction of cross-sectional area of 50%; the alloys of this series also corrode badly on exposure to sea water, although they are stable in the air. The constitution of the alloys is discussed, and the mechanism of the age-hardening explained.

—A. R. P.

Plastic deformation of ductile metals [aluminium, copper, tungsten]; Mixed orientations developed in crystals by ——. E. C. Bain and Z. Jeffries. Chem. and Met. Eng., 1921, 25, 775—777.

Specimens cut from coarse-grained aluminium and copper ingots were examined by the X-ray spectrometer to determine whether deformation of the metal is accompanied by rotation of crystal fragments and by the production of new orientations. When the grains were elongated by rolling the specimens to about $\frac{1}{4}$ the original diameter, spectrograms indicated some new orientations, and when the metal was reduced to $\frac{1}{8}$—$\frac{1}{15}$ of the original diam., the patterns produced showed a complete assortment of orientations, characteristic of an extremely finely grained metal. Annealing reduced the number of orientations, the films obtained being typical of a grain size of 0·005—0·01 in. Distinct evidence of the development of mixed orientation by cold work was observed from a longitudinal section of a twisted tungsten wire, in which a change of direction was apparent for every 90° of turn. It was evident that the steps by which the slip takes place must be small but fairly regular.

—C. A. K.

Mercury; Purification of —— [in the laboratory]. C. Harries and F. Evers. Z. angew. Chem., 1921, 34, 541—542.

In the purification of mercury containing 1% lead by the air oxidation method (J., 1921, 588 A) there was a loss of 2% of mercury, and the residual metal was free from lead. Purification by dropping it in a thin stream through a column of dilute nitric acid removed the lead after two treatments, but resulted in a loss of 3·7% of mercury. Tin was not completely removed from a 1% amalgam after 15 hrs.' treatment by the air method, nor by three treatments with nitric acid. Complete elimination of tin was obtained, however, by heating the metal to 150°—160° C. for 12 hrs. in a current of air that had previously been passed through fuming hydrochloric acid, followed by washing the residual mercury with strong hydrochloric acid. In this case only 2·5% of the mercury was lost. Prausnitz's failure to obtain satisfactory results (J., 1921, 661 A) was due to his using nitric instead of hydrochloric acid for washing the metal after oxidation.—(*Cf.* J.C.S., Dec.)—A. R. P.

Lead-thallium alloys; Electrolytic corrosion of ——. C. G. Fink and C. H. Eldridge. Trans. Amer. Electrochem. Soc., 1921, 335—344. [Advance copy.]

With the object of making a lead anode that would resist the corrosive action of an acid copper sulphate solution containing small quantities of nitric and hydrochloric acids, various lead-thallium alloys were prepared and the corrosion loss determined per 100 lb. of copper deposited. Ordinary lead showed a loss of 65 lb., whereas on the addition of thallium to the lead the loss quickly diminished, reaching a minimum of 8 lb. between 20 and 60% Tl. Addition of bismuth or tin to the lead showed minimum losses with 12% Bi and 15% Sn, but the losses were larger than with the thallium alloys. An alloy of Frary metal (lead with 2—3% Ca+Ba) containing 10% Tl and 20% Sn showed a loss of only 1·2 lb., and gave the best results of all the alloys tested. The resistance of thallium-lead anodes to corrosion is due to the formation on the surface of a closely adhering brownish-black film of peroxide.

—A. R. P.

Metal spraying process with especial reference to its application to electrotechnology, chemistry, and electrochemistry. N. Meurer. Elektrochem. Zeits., 1921, 27, 102—105, 114—116; 28, 5—6, 13—16. Chem. Zentr., 1921, 92, IV., 1063.

Metal coatings up to 6 mm. in thickness may be applied by the spraying process. A thin layer is first sprayed, and this is consolidated by heating it to the melting point of the metal by means of a "heat pistol," after which further coats are applied and similarly treated. The spraying process does not give coatings of very great density and elasticity, but they serve to protect the coated metals from rust and, if aluminium is the sprayed metal, from acid attack also. Aluminium may be sprayed on copper as a preliminary to silver-plating it, and on iron fire-bars to prevent the clinker from attacking them. Tests carried out in the latter connexion in locomotive fire-boxes showed that the aluminium-coated bars lost 2 kg. less in 12 weeks than the uncoated bars. Examples are given of other uses of the process, and of its application to the preparation of various electrical apparatus.

—A. R. P.

Idaho [zinc-lead, copper, and antimonial silver] ores; Flotation tests of ——. C. A. Wright, J. G. Parmelee, and J. T. Norton. U.S. Bureau of Mines, Bull. 205, 1921. 70 pages.

The complex lead-zinc ores of the Cœur d'Alene district of Idaho consist principally of very finely crystallised galena and blende, with smaller amounts of pyrites and chalcopyrite, all of which are finely disseminated throughout a quartzite-siderite or quartzite-schist matrix, so that crushing even to 200-mesh does not entirely free the minerals from the gangue or from one another. A large number of flotation tests using various flotation agents and chemicals on several ores ground to varying degrees of fineness were carried out, and the results are described in detail with analyses of the products obtained. The results show that ores of very similar character behave differently towards the same flotation agent, but that once the correct mixture has been found better results are obtained by flotation than by gravity concentration. Fine grinding is essential, and a pulp ratio of $2\frac{1}{2}$—$3\frac{1}{2}$:1 gives the best differential selection at normal temperatures. Selective flotation of galena is best obtained from alkaline or neutral solutions rather than from those that are acid, and addition to the pulp of sodium carbonate, hydroxide, silicate, or chloride, lime, coal tar creosote, alcohol, gasoline, and charcoal assist this selective recovery of galena in the presence of blende and pyrites. After the lead has been removed, the blende may be floated by addition of copper sulphate or carbonate and some variety of pine or fuel oil to the pulp. Flotation tests on a copper ore consisting of finely intercrystallised chalcopyrite and pyrrhotite in a schistose gangue

failed to effect a complete separation of the two sulphides, but with a mixture of coal tar and wood creosote oils over 80% of the copper was recovered as a concentrate assaying 25% Cu and 30% Fe. A series of tests was carried out on an antimonial silver ore (polybasite) disseminated throughout massive quartz. The ore contained 81 oz. of silver per ton, and by flotation with mineral or vegetable oils gave a concentrate containing 80% of the silver and assaying up to 1000 oz. per ton. Better extraction in a lower-grade product was obtained by previously agitating the pulp with very dilute sodium sulphide, while the grade of the product was improved by addition of sodium cyanide to the pulp. A few tests carried out on a copper sulphide ore containing gold and silver showed that the best results were obtained from an alkaline pulp, and that the bulk of the gold and silver accompanied the copper into the concentrate.

Mine waters; Acidity of ——. F. W. Watson and R. A. Cooper. J. Chem. Met. Soc. S. Afr., 1921, 22, 30—32.

Analyses of a number of corrosive mine waters from the Raud mines showed that there was always a marked deficiency of the sulphate radicle below that necessary to saturate the bases present, and that the corrosive action of these waters on the centrifugal pumps was due chiefly to the presence of ferric and aluminium sulphates. On the gradual addition of lime to the waters ferric iron was precipitated when the hydrogen ion concentration had been reduced to $[\mathrm{H}^{\cdot}]1\times10^{-3\cdot4}$, and the water was then neutral to methyl orange. This precipitate consisted of 95% Fe_2O_3 and 5% Al_2O_3. Further addition of lime water precipitated all the aluminium at $[\mathrm{H}^{\cdot}]1\times10^{-6}$; the precipitate contained 96% Al_2O_3, 2% Fe_2O_3, and 1% NiO, and the solution was neutral to methyl red. With still nore lime water ferrous and nickel sulphates are lecomposed simultaneously at $[\mathrm{H}^{\cdot}]1\times10^{-9}$, the oint of exact neutrality just being passed, and it s to this stage that it is necessary to carry the lime reatment before the water can be handled safely by igh-pressure pumps or used in the reduction works. here is some difficulty in practice in determining he exact amount of lime to be added to the water, ut good results are obtained by determining the cidity by rapid titration with $N/10$ caustic soda olution, using rosolic acid as indicator and taking he first appearance of a transient pink colour as he end-point, hydrogen peroxide of known acidity eing first added if much ferrous sulphate is present. n practice, the treatment of the water is carried ut with an automatically controlled lime feeder, nd the complete settling of all precipitates is arried out underground in large reservoirs, preerably constructed in a disused stope closed at the ottom and fitted with sludge valves.—A. R. P.

Patents.

ast iron; Production of grey ——. A. Diefenthaler. E.P. 147,933, 9.7.20. Conv., 9.5.16.

HE process consists in conducting the casting and oling operations in such a manner that lamellar arlite without free ferrite predominates in the ished casting. Metal of this character is suitable r machine parts which are subjected to frictional resses. The rate of cooling for any particular sting has to be determined empirically and varies cording to the composition of the metal and the oss-section of the finished article.—C. A. K.

Iron; Process for obtaining deposits of —— *by electrolysis.* Soc. d'Electro-Chimie et d'Electro-Metallurgie. E.P. 164,725, 13.5.21. Conv., 9.6.20.

Electrolytic iron is prepared by the electrolysis of a solution of an iron salt, such as ferrous chloride, and aluminium chloride, to which hydrochloric acid is added either prior to or during the electrolysis to dissolve any alumina precipitated. A suitable solution contains 200—250 g. of iron and 5—15 g. of aluminium per litre, and electrolysis is effected at 75°—80° C., with a current density of from 5 to 30—40 amp. per sq. dcm. of cathode surface.—J. S. G. T.

Ferro-tungsten; Process for producing ——. Ampère-Ges.m.b.H. E.P. 147,457, 7.7.20. Conv., 6.5.18.

To tungsten ores or substances containing tungsten smelted in the electric furnace, sulphur in its natural state, or as sulphide (*e.g.*, iron pyrites), or a sulphide-forming material (*e.g.*, a mixture of gypsum with coal) is added in small quantities. A considerably higher yield of ferro-tungsten is obtained without the alloy receiving too large a quantity of sulphur for use in steel manufacture.
—J. W. D.

Iron and steel; Method of cleaning ——. O. Vogel. G.P. 309,264, 11.6.18.

Iron or steel articles are cleaned by pickling in an acid liquor containing crude anthracene, sulphite-cellulose waste liquors, residues from the preparation of naphthalene or analogous substances, acid resins or waste acids from the purification of mineral oils, wood or lignite tars, paraffin or the like. The metal after treatment with this mixture does not become brittle and has less tendency to rust than it has after the ordinary acid pickle.
—A. R. P.

Spraying fusible substances [*metals*]*; Method of and apparatus for melting and* ——. The British Metal Spray Co., Ltd., Assees. of F. Herkenrath. E.P. 147,902, 9.7.20. Conv., 21.3.14.

The apparatus consists of a gas conduit of electrically conductive material heated by means of an electric current and containing a granular mass, such as carbon. The conduit has a discharge orifice and an adjacent annular concentric blast nozzle. The conduit may be partly enclosed in a tube, with the discharge orifice projecting, and a stream of gas is fed into the tube and conduit. The fusible substance is placed in the path of the heated stream of gas issuing from the orifice or blast nozzle.
—J. W. D.

Tin deposits; Electrolytic production of dense and firmly adhering ——. M. Schlötter. E.P. 148,334, 9.7.20. Conv., 15.3.17.

An electric current is passed through an electrolyte consisting of an acid solution of a tin salt of a monobasic or dibasic acid, free from alkali or ammonium, to which is added one or more colloidal or capillary active substances.—J. W. D.

[*Acid-resisting*] *alloys of silicon with metals of the iron and chromium groups.* R. Walter. E.P. 157,054, 4.5.20. Conv., 14.1.20.

Metals of the iron and chromium groups are heated with ferrosilicon, alloys being formed by the exothermic reaction between the silicon and the metals. The alloys consist of silicides of the metals in homogeneous form only and in some cases their eutectic mixtures.—J. W. D.

Alloys for the manufacture of chemically resistant and mechanically strong articles. R. Walter. G.P. 340,067, 2.5.18. Conv., 11.5.17.

The nickel or cobalt in the known alloys of the iron and chromium groups is replaced partly or completely by silicon. In each case the alloy contains 3—35% Cr and small additions of manganese, tungsten, molybdenum, vanadium, or titanium to improve the mechanical properties. If the nickel or cobalt is partly replaced the silicon content should be from 0·2 to 8·0%, while if wholly replaced, it should be from 0·5 to 15%. The alloys are resistant to dilute acids and may be readily worked. —A. R. P.

Metals and alloys containing boron; Preparation of ——. R. Walter. G.P. 340,185, 18.10.18.

Boron is produced directly by the reduction of naturally occurring compounds such as tincal, borocalcite, or the like, or of manufactured compounds such as borotungstic, boromolybdic, or borovanadic acid or the like, with or without carbon, in the presence of the molten metal or alloy with which it is to be incorporated, or a mixture of one of the above compounds and the oxide or oxides of the metal may be reduced directly to give an alloy containing boron.—A. R. P.

Alloy. F. Milliken, Assr. to S. F. Weaver and J. M. Repplier. U.S.P. 1,393,388, 11.10.21. Appl., 18.8.20.

An alloy having a tensile strength ranging from 45,000 to 183,000 lb. per sq. in., as the hardness varies "from dead-soft to 16 numbers hard," contains 60—70% Cu, 19—24% Zn, 9—12% Ni, 1—2·5% Fe, and a trace of manganese.—C. A. K.

Aluminium alloys; Treatment for the prevention of surface corrosion in certain ——. W. B. Brunskill. E.P. 169,884, 18.8. and 19.11.20.

Aluminium alloys, rich in aluminium, are treated with a boiling alkaline solution, *e.g.*, of sodium hydroxide, then subjected to the action of steam, and finally to a solution containing a mixture of zinc and iron phosphates.—C. A. K.

Aluminium and its alloys; [Flux for use in the] autogenous welding or soldering of ——. H. V. A. Briscoe, D. Richardson, and The District Chemical Co., Ltd. E.P. 170,343, 10.7.20.

A flux for soldering or welding aluminium and its alloys consists of an alkali halide and one or more salts of bases with difficultly volatile polybasic acids, *e.g.*, an alkali pyrosulphate or pyrophosphate, which do not contain acidic hydrogen and which do not themselves react with the alkali halide, but can do so in the presence of aluminium oxide. The salt mixture is fused, before use, in a vessel free from metallic oxides soluble in the flux, *e.g.*, silica ware, and may consist of 45% KCl, 30% NaCl, 7% KF, 15% LiCl, and 1—10% of an alkali pyrosulphate or pyrophosphate.—A. R. P.

Aluminium alloys; Heat treatment of ——. E. Blough, Assr. to Aluminium Co. of America. U.S.P. 1,394,534, 25.10.21. Appl., 30.11.17. Renewed 28.12.20.

The tensile strength of certain aluminium alloys is improved by maintaining them for some time at a temperature above 400° C., then for a further period at a lower temperature.—A. R. P.

Copper; Manufacture of ——. E. E. Naef. E.P. 169,764, 19.6.20.

Finely divided copper is obtained by heating a mixture of pulverised copper sulphide ore and sodium or potassium hydroxide at 300°—400° C. The alkali may be replaced partly by sodium carbonate, chloride, sulphate or sulphite or calcium oxide. A small proportion of carbon may be added to the fusion mixture, or the reaction may be carried out in a reducing atmosphere. Separation of metallic copper is effected either by pouring off the upper molten layer or by leaching the cold mass with water. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 624 of 1871.)—C. A. K.

Zinc powder; Melting of —— *into liquid zinc, and furnace therefor.* C. E. Cornelius. E.P. 170,026, 13.4.20.

Zinc powder is introduced continuously into a rotating heating drum, wherein it is subjected to a rubbing or agitating action to separate the metallic content, and the residue is discharged from the drum through a separate outlet from that for the metallic zinc, the discharge being adjusted so as automatically to regulate the introduction of the zinc powder.—J. W. D.

Zinc oxide; Process for recovery of —— *suitable for smelting, from precipitates containing calcium sulphate.* Metallbank u. Metallurgische Ges. A.-G. G.P. 331,637, 18.5.19.

A mixed precipitate of zinc oxide and calcium sulphate, obtained by treating solutions containing zinc sulphate with lime, is heated with sodium and/or calcium chloride solution and zinc chloride, yielding calcium chloride and insoluble basic zinc sulphate. The latter when calcined yields zinc oxide suitable for smelting.—C. I.

Zinc oxide suitable for smelting; Process for producing —— *from zinc sulphate or zinc solutions containing sulphate.* Metallbank u. Metallurgische Ges. A.-G. G.P. 334,432, 27.11.19. Addn. to 331,637 (*cf. supra*).

The solution containing zinc sulphate is precipitated slowly at a high temperature with dilute milk of lime, so that the precipitate is decomposed as it forms into basic zinc sulphate and calcium chloride.—C. I.

Electric arc-welding and like operations; Electrodes for ——. C. J. Holslag. E.P. 170,039, 4.6.20.

An electrode for welding and repairing thin sheet metal and cast iron consists of a metal rod coated, completely or partially, with a mixture of sodium silicate and carbon, the former preponderating. The coating may also contain calcium carbonate, finely-divided asbestos, magnesium, or boron. For ease in starting the arc, the coating is made thicker at the points where the arc is struck. —J. S. G. T.

Ores, roaster-residues, slags and the like containing iron and zinc; Preparation and smelting of ——. L. H. Diehl. E.P. 170,100, 12.7.20.

The material, previously desulphurised and sintered so that the sintered material contains less than 0·5% sulphur, is first agglomerated, then smelted in a blast furnace in the presence of a suitable chloride, together with an appropriate flux and other ingredients. The molten iron is tapped off and the zinciferous material carried away by the gases is collected in alkaline wash water, washed, and calcined.—J. W. D.

Flux and solder. J. Morrison and C. Wood. E.P. 170,221, 8.12.20.

A flux and solder, especially for use with cast iron, contains zinc chloride 40%, salammoniac 45%, and metallic zinc 15%.—J. W. D.

Ores; Process and apparatus for recovering metallic values from ——. F. B. Church, Assr. to International Precipitation Co. U.S.P. 1,393,428, 11.10.21. Appl., 5.9.19.

Chlorine contained in the gaseous constituents produced in a chloridising-volatilisation process of treating ores is recovered by passing the gases into a basic absorbing medium.—C. A. K.

Vanadium; Method of recovering —— from solutions. L. S. Copelin. U.S.P. 1,392,745, 4.10.21. Appl., 28.5.20.

Solutions containing vanadium are treated with a magnesium salt.—C. A. K.

Furnace; Open hearth ——. V. B. Browne. U.S.P. 1,393,493, 11.10.21. Appl., 28.6.19. Renewed 8.8.21.

In a furnace having a regenerator at either side of the hearth, the hearth is separated from the regenerator by a wall provided with a through port. —C. A. K.

Metals; Electrolytic refining of ——. F. D. Crane. U.S.P. 1,394,147, 18.10.21. Appl., 18.12.20.

An electric current is passed through a solution of a metallic salt in which a finely-divided conducting material is suspended. The thin layer of suspended material forms the cathode, and metal from the solution is deposited on the particles, whereby a continuous electrode is produced.—F. M. R.

Flotation agent. Concentration of minerals. C. L. Perkins, Assr. to Metals Recovery Co. U.S.P. 1,394,639—40, 25.10.21. Appl., 3.12.18. Renewed 12.3.21.

The flotation agent consists of a solution of a solid amino-compound in a liquid amino-compound that is readily miscible with water. A small quantity of the agent is added to the mineral pulp and the mixture subjected to a flotation operation. —A. R. P.

Chromium-manganese-nickel bronze. F. Lange. G.P. 340,379, 19.5.20.

An alloy, suitable for the manufacture of cylinders for hydraulic presses and for axle bearings, and having the physical properties of a phosphor-bronze combined with a higher tensile strength and elongation, consists of 74% Cu, 16·75% Zn, 2% Al, 1·5% Mn, 3·35% Fe, 0·90% Cr, and 1·5% Ni.—A. R. P.

Wrought iron; Manufacture of ——. H. Wade. From A. M. Byers Co. E.P. 170,124, 21.7.20.

See U.S.P. 1,370,622 of 1921; J., 1921, 307 a.

Rust-resisting alloy of iron. G. H. Charls. Reissue 15,208, 18.10.21, of U.S.P. 1,363,564, 28.12.20. Appl., 21.3.21.

See J., 1921, 120 a.

Spraying molten metal and other fusible substances; Method of and apparatus for ——. The British Metal Spray Co., Ltd., Assees. of M. U. Schoop. E.P. 147,901, 9.7.20. Conv., 19.2.14.

See U.S.P. 1,133,507 of 1915; J., 1915, 557.

Zinc oxide suitable for metallurgical treatment; Production of —— from gypseous precipitates. A. Mond. From Metallbank und Metallurgische Ges. E.P. 170,082, 9.7.20.

XI.—ELECTRO-CHEMISTRY.

Storage battery plates; Preparation of —— using scaly, electrolytically-deposited lead powder as active material. H. Tanaka. Kōgyō-Kwagaku Zasshi (J. Chem. Ind., Japan), 1921, 24, 995—1005.

The author prepared several kinds of storage battery positive plates, using scaly, electrolytically-deposited lead powder as active material, and studied their capacity, the relation between the capacity of the plates and the fineness of powder, the pasting liquid, and the porosity of active material, and also the effects of the fineness of the scaly lead powder and of the pasting liquids upon the durabilities of the plates. The nature of the pasting liquid (water, ammonium sulphate, and sodium hydroxide solutions) appeared to have little influence, but the effect of the fineness of the lead powder was very great, the finest powder, which passed a 160-mesh sieve, having the longest life, though its capacity at the beginning was small. With regard to durability, the plates prepared by the author, using the finest lead powder as active material, were compared with commercial plates made with lead peroxide. The loss of lead peroxide in g. per amp.-hour was 0·029—0·036 for the author's plates, and 0·063—0·149 for the commercial plates. —K. K.

Electrolytic oxidation and reduction in presence of metallic salts. M. Schlötter. Z. Elektrochem., 1921, 27, 394—402.

Experiments were made to investigate the part played by small quantities of metallic salts, for example, a manganese salt or a chromate, when added to the electrolyte in the electrolysis of chloride solutions in the manufacture of chlorate. Under certain conditions they affect favourably the current efficiency by minimising reduction at the cathode. The effect depends not only on the chemical character of the added salt, but also on its concentration and on the kind of electrode used. Using platinum electrodes, certain metals, such as copper (0·5 g. $CuCl_2$ per l.) and lead (0·21 g. PbO_2 per l.), eliminated reduction entirely. When 0·5 g. of stannous chloride per l. was added very little effect was observed, but one-tenth of this quantity of the same salt brought reduction down to a very low figure. It was always observed that several hours must elapse after the addition of the salt before the cell settles down to a steady state. This is probably due to the time required for the deposition of the added metal on the electrode. Since the best results are obtained when very small quantities of the metallic salt are used, it is probable that the cathode does not become completely covered with a deposit of the metal, but that the latter forms a kind of network over the electrode metal. The favourable results obtained are brought about by the complex system electrode metal—deposited metal—hydrogen. This conclusion received support from the results of experiments in which metals other than platinum were used as cathode. With a copper cathode, copper salts had no effect on the amount of reduction. With an iron electrode, addition of a copper salt had an unfavourable effect by increasing the amount of reduction taking place, whilst the addition of an iron salt when a copper cathode was used lowered the percentage reduction, although the reduction value of a pure iron electrode is much higher than that of a pure copper electrode. The favourable action of the iron salt is explained by the fact that electrolytically-deposited iron absorbs more than one hundred times its volume of hydrogen, forming a stable system in which the activity of the hydrogen is reduced to a very low value. The potential energy of the hydrogen at the cathode depends on the nature of the deposited metal, and it should be possible, by choosing a suitable cathode system, to realise conditions for the quantitative reduction of any substance.—E. H. R.

Patents.

Primary galvanic batteries and electrodes for such batteries, and methods of manufacturing such electrodes. E. W. Jungner. E.P. 145,018, 12.6.20. Conv., 17.6.19.

Porous carbon electrodes for use in primary batteries in which an active or depolarising gas is taken up by the pores of the electrodes, are prepared by mixing carbon in the state of fine dust with a crystalline or crystallisable substance also in the form of dust, a liquid binding agent such as tar or molasses, and a volatile liquid such as water, the resulting paste being moulded, and the moulded electrode burnt. Other substances may be incorporated in the electrodes, which are impregnated with a small quantity of a substance such as paraffin, to prevent the entrance of electrolyte into the pores, whilst not materially reducing the porosity of the electrodes.—J. S. G. T.

Electric carbons [e.g., brushes for dynamos]; Process and apparatus for the production of ——. G. L. Schmidthammer. E.P. 148,872, 10.7.20. Conv., 20.3.18.

The mixture of powdered carbon, powdered metal etc., and binding material employed in the manufacture of dynamo brushes etc., is submitted during the burning process to a movement which ensures a uniform distribution of the binding material and a rapid separation of any gases evolved. In the manufacture of dynamo brushes, the carbons are placed vertically in a furnace and rotate with the furnace about a horizontal axis.—J. S. G. T.

Furnace electrodes; Manufacture of ——. S. E. Sieurin. E.P. 170,106, 12.7.20.

The moulded electrodes, surrounded by sand, carbon powder, chamotte (firebrick), or other porous material, are baked in a gas-tight container heated either externally or internally by means of electric current, the gases evolved being delivered to a condenser. Subsequently the electrodes are finished by burning in the usual manner or in an electric furnace.—J. S. G. T.

[Electrical] resistance material. R. W. Stearns, Assr. to General Electric Co. U.S.P. 1,394,949, 25.10.21. Appl., 19.2.20.

A resistance material is composed of a substantially non-conducting base, constituted mainly of concrete, with a small proportion of lampblack.
—J. S. G. T.

Diaphrams for electrochemical purposes. H. Kölsch. G.P. 340,752, 13.4.20.

Ordinary paper fabric is used. It is stable in alkaline solutions even on heating, and is sufficiently dense to be impermeable to gases. It can easily be repaired.—A. G. P.

XII.—FATS; OILS; WAXES.

Lindera obstiroba ("tohaku") oil; Properties of —— and its composition. Y. Iwamoto. Kōgyō-Kwagaku Zasshi (J. Chem. Ind., Japan), 1921, 24, 1143—1160.

The seed of *Lindera obstiroba*, B.L. ("tohaku"), which is found in Corea, contains 60—65% of oil, which is used as a hair oil. It is a yellowish-brown liquid with a characteristic unpleasant odour, which is destroyed almost completely by steaming. The physical and chemical characters of the oil are as follow: sp. gr. at 15°/4° C., 0·9329; $n_D^{20}=1·4653$; solidif. pt., −14·4° C.; acid value, 4·30; saponif. value, 263·80; iodine value (Wijs), 70·82; Reichert-Meissl value, 2·61; Polenske value, 9·85; acetyl value, 16·42; Hehner value, 90·08; and unsaponifiable matter, 1·60%. By the lead salt-ether method the oil gave 60·05% of liquid acids and 29·16% of solid fatty acids. Capric acid and a large quantity of lauric acid were identified in the solid acids, and oleic acid and an acid of the formula, $C_{12}H_{22}O_2$, which occurs also in cochineal fat, in the liquid acids. The absence of linolic and linolenic acids and stearic and palmitic acids was proved.—K. K.

Iodine value [of oils and fats]; Modification of Aschman's method of determining the ——. B. M. Margosches and R. Baru. Chem. Umschau, 1921, 28, 229—232, 245—247. (*Cf.* J., 1921, 779 a.)

The iodine monochloride solution is prepared as follows:—15 g. of potassium iodide is dissolved in 50 c.c. of water, and chlorine is passed through until the iodine at first precipitated is completely re-dissolved. The solution is allowed to stand for 5 hrs., and is then decanted from the crystalline precipitate, which is washed, and the solution and washings made up to 500 c.c. with water. This solution is even more stable than Wijs' solution. 0·5—0·1 g. of the oil or fat (according to the iodine value expected) is dissolved in 10 c.c. of carbon tetrachloride, and 10 c.c. of the iodine monochloride solution added. The mixture is then shaken, and the shaking is repeated two or three times during the first half of the absorption period, which varies from 2 to 4 hrs. for fats, 6 hrs. for non-drying, 8 hrs. for semi-drying, and 24 hrs. for drying oils when only 60% excess of iodine is used. The time can be reduced by using a larger excess (75%), when 6—8 hrs. is sufficient even for drying oils. The excess of iodine is titrated in the usual way. An iodine monochloride solution of half the above concentration can be used equally well. To obtain accurate results the instructions as to shaking must be carefully adhered to. The values obtained usually lie between the corresponding Hübl and Wijs values.—H. C. R.

Fatty acids and their mixtures; Surface tension of salts of ——. E. E. Walker. Trans. Chem. Soc., 1921, 119, 1521—1537.

A comparative examination of the lowering of the surface tension of water by the sodium salts of the fatty acids has been made at varying concentrations (0·005 to 1 g. of acid per 100 g. of solution) and temperatures (from 15° to 90° C.) The power of lowering the surface tension rises to a maximum with increase of molecular weight in a homologous series, with increase of temperature and of concentration, and then falls off. This behaviour is explained on the basis of McBain's theory of soap solutions (which regards soap in aqueous solution as containing colloidal aggregates in equilibrium with simple molecules) and on the hypothesis that the lowering of surface tension depends on the size of the colloidal particles as well as on their concentration in the surface layer. The extent to which mixtures of soaps lower the surface tension of the water in which they are dissolved cannot be determined from the properties of the constituents, but application of the theory makes it possible to determine whether the lowering of surface tension by a soap mixture will be greater or less than the weighted mean of the constituents. The maximum lowering of surface tension for each variable factor tends to be the same for all soaps, indicating that at this point the surface layers of all soaps are similar. Sodium oleate differs from all other soaps at 0·1% concentration in that its efficiency in lowering the surface tension remains high over a wide range of temperature.—P. V. M.

Soap curd; Hydration of the fibres of ——. III. Sorption by sodium palmitate. M. E. Laing. Trans. Chem. Soc., 1921, **119**, 1669—1676.

In a mixture of one mole of sodium palmitate with 1000 g. of water and 330 g. of sodium chloride, together with 5—10 g. of acetone, phenol, potassium chromate or iodide, sodium acetate, thiosulphate or hydroxide respectively, from $\frac{1}{6}$ to $\frac{1}{3}$ of the added substance was sorbed by the curd fibres. Sodium sulphate and glycerol were quantitatively left in the lye, their apparent presence in the curd being due to emmeshed lye; hence there is a possibility of removing the glycerol from soaps by a process of "salting out." Confirmatory evidence that the hydration of the fibres of wet soap curd under these conditions amounts to $NaP,2H_2O$ was obtained. Sodium hydroxide was sorbed to an extent probably not exceeding 0·02 equivalent of sodium hydroxide to 1 equivalent of sodium palmitate. The presence of $N/10$ sodium hydroxide eliminates hydrolysis completely and also renders the curd fibres alkaline when salted out with concentrated sodium chloride solution.—P. V. M.

Patents.

Hydrogenation; Process for —— and production of catalysts. E. Sittig and A. Granichstädten. E.P. 147,578, 8.7.20. Conv., 7.7.17.

A mixture of an aqueous solution of a nickel salt and of a salt of magnesium or aluminium is precipitated with an alkali silicate, the precipitate being washed and dried at a temperature not exceeding 100° C., finely powdered, and heated in a current of hydrogen to 300°—500° C. The chlorides of the metals may be used. The catalyst probably consists of a double silicate or absorption compound of the silicates of nickel and aluminium or magnesium. The hydrogenation is carried out by heating the neutral oil or fat to 140°—150° C., introducing a quantity of catalyst corresponding to 0·2—0·25% of the weight of oil and passing hydrogen in the usual way at a pressure of 3—4 atm. The temperature at first rises rapidly to 160°—180° C., and afterwards falls, and is kept at 150°—160° C. until the required degree of hydrogenation is reached. A product of m.p. 38°—42° C. is obtained in 15—20 mins. It is colourless and free from any unpleasant smell and taste even when the oil treated s dark and of bad taste and smell.—H. C. R.

Fats and oils; Process of rendering ——. C. F. Kamrath. U.S.P. 1,394,736, 25.10.21. Appl., 15.11.19.

Animal and vegetable fats yield neutral edible products when heated to 145°—170° F. (63°—77° C.) under a vacuum of 12—20 ins. and agitated. —H. C. R.

Transparent soap; Manufacture of ——. J. Tseng. E.P. 170,060, 2.7.20 and 18.3.21.

A solution in 95% alcohol of a soap made by aponifying a mixture of fats, rosin and oils is eated for about 24 hrs. at 80°—84° C. and afterwards at 75° C. prior to filtration; or the mixture f fats, rosin and oils may be melted together, the emperature raised to 75° C., the caustic solution dded, and the mixture heated at 80° C. for 3 hrs. ith intermittent stirring. The soap thus formed dissolved in 95% alcohol, and the solution heated or 18 hrs. at 80° C., with intermittent stirring, hen for 6 hrs. at 84° C. The solution is then oled to 75° C. prior to filtration, or may be cooled o 65° C., treated with hydrogen peroxide to bleach he soap, and the mixture kept at 65° C. for at ast 1 hr. prior to filtration. Alternatively the ixture of fats, oils and rosin may be saponified in alcoholic solution by heating to 80° C. for 8 hrs., then, after allowing to stand for about 14 hrs., reheating to 65° C., adding hydrogen peroxide, reducing the temperature to 60° C., and maintaining at this temperature for $1\frac{1}{2}$ hrs., when it is raised to 90° C. for about 1 hr. to distil off the alcohol.—H. C. R.

Fat; Production of —— [by micro-organisms]. Versuchs und Lehranstalt für Brauerei. E.P. 146,431, 3.7.20. Conv., 10.5.15.

See G.P. 306,365 of 1915; J., 1920, 417 a.

Soap manufacture; Cooling apparatus for use in ——. J. Kenyon and C. W. Couche. E.P. 170,415, 24.7.20.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Ochre minerals; Different methods of analysis of ——. A. Raynaud. Bull. Soc. Chim., 1921, **29**, 905—910.

The simplest and most rapid method for the analysis of ochres is as follows:—0·5 g. of the finely powdered mineral, previously dried at 100°—105° C., is weighed into a platinum crucible and strongly ignited for a few minutes and then weighed again. The loss of weight represents water of combination and traces of carbonate and organic matter. To the residue are added 4—5 c.c. of dilute sulphuric acid and 8—10 c.c. of fuming hydrofluoric acid, and the mixture is evaporated to dryness at a gentle heat, and finally heated more strongly till fuming ceases and then ignited. The residue consists of oxides of iron and aluminium, and is weighed, the loss of weight by the acid treatment being reckoned as silica. The residue is fused with potassium bisulphate and, after rapid cooling, the melt is extracted with water, the iron is reduced to the ferrous state and estimated by titration with permanganate. The results are quite comparable with those obtained by more complicated methods. —W. G.

Varnishes; Chemistry of ——. [Turbidities in boiled oils containing rosinate driers.] H. Wolff and C. Dorn. Chem.-Zeit., 1921, **45**, 1086—1089.

The proportion of stearic acid in the free fatty acids of linseed oil is insufficient to account for the stearic acid content of the precipitated lead foots formed by adding lead rosinate to the oil (*cf.* J., 1921, 780 a). When the free acids from a linseed oil and lime-hardened rosin varnish were removed by solution in ether-alcohol and neutralisation with alkali, the solvent-free neutral portion extracted with petroleum ether, and the petroleum ether removed from this latter solution, cooling to −10° C. caused a small quantity of foots to separate. On repeatedly dissolving in petroleum ether and cooling the solution, this residue was obtained in crystalline form, and consisted of a mixed resin and fatty acid glyceride corresponding to 2 mols. of palmitic acid to 1 mol. of resin acid. The precipitated lead rosinate used throughout the experiments consisted of nearly equal parts of normal and acid lead rosinate. (*Cf.* Ragg, J., 1914, 208.)—A. de W.

Resins; Solubility of some new ——. P. Nicolardot and C. Coffignier. Bull. Soc. Chim., 1921, **29**, 917—921.

The solubilities of the resins of *Hopea ricopei*, *Aucoumea Klaïneana*, Dammar Cambodge, and light red Dammar (*Thorea vulgaris*) (*cf.* J., 1919, 951 a) in the following solvents are given:—Ethyl, methyl, and amyl alcohols, ether, chloroform, benzene, acetone, turpentine, carbon tetrachloride, benzaldehyde, aniline, amyl acetate. None of these resins presents any particular interest to the varnish manufacturer.—W. G.

Resins from Cochin China; Solubility of some ——. P. Nicolardot and C. Coffignier. Bull. Soc. Chim., 1921, 29, 921—932.

Using the same solvents (*cf. supra*) the authors have determined the solubilities of the resins of *Hopea odorata*, *H. dealbata*, *Shorea vulgaris*, *S. hypochra*, *Thorea thorelli*, *H. pierrei*, *Anisoptera*, *Natica astrotica*, and the resin from the Chinese pine (*cf.* J., 1920, 198 A). With the exception of the resin of *Thorea thorelli*, the resins appear to be semi-hard, and they might be used for the preparation of satisfactory varnishes, although they would never give varnishes of the first order. —W. G.

Patents.

Acrolein; Polymerisation products of —— and processes of producing same. C. Moureu and C. Dufraisse. E.P. 141,058, 31.3.20. Conv., 31.3.19.

To an aqueous solution of pure acrolein (Moureu, J., 1919, 923 A; 1920, 42 A) is added 1% of a resinifying agent, *e.g.*, mineral or organic bases or salts of heavy metals, sufficient to yield a voluminous white precipitate. This is immediately filtered off, washed, and dried *in vacuo*, when it forms an impalpable white powder melting between 80° and 110° C., insoluble in water and hydrocarbons, but soluble even in the cold in the majority of other organic solvents. Any chemical equivalent of this process may be employed to produce the fixed soluble resin described, which is suitable for use as a varnish when dissolved in a solvent.—A. de W.

Phenol - formaldehyde condensation products; Manufacture of ——. J. Filhol. E.P. 147,173, 7.7.20. Conv., 26.6.19.

The soluble fusible product obtained by condensation of a phenol and formaldehyde or its polymers in the presence of ammonium carbonate or basic ammonium phenoxide ($C_6H_5ONH_4+NH_3$) is dehydrated as completely as possible, polymerised by heating at 75°—80° C., and converted into an insoluble and infusible product by dissolving in 2—3 times its volume of ethyl alcohol and adding 0·5—5·0% of its weight of ethyl hydrogen sulphate, when resinification takes place spontaneously at temperatures between 14° and 45° C. in from 1 to 36 hrs.—A. de W.

Casing for "sticks" of fragile and soft materials for drawing, writing, and the like purposes. Soc. Anon. des Anc. Etabl. J. M. Paillard. E.P. 147,522, 8.7.20. Conv., 25.3.19.

A casing for lead pencils or the like is composed of a mixture of about 30% of vegetable material, such as finely divided wood, cork, or rags, 6% of mineral material, such as talc, clay, lime, or gypsum, 10% of an agglomerating material, such as casein, an alkali silicate, glue, resin, or gum, and 54% of water. The mixture is applied in two or more layers, each layer being dried before applying the next, and the proportions of the constituents are adjusted to render each layer harder than the preceding.—L. A. C.

Floor coverings; Manufacture of ——. R. Jeschke. E.P. 149,661, 2.7.20. Conv., 8.8.19.

In the process described in E.P. 146,367 (J., 1921, 479 A), the viscose is wholly or partially omitted from the mixture, and artificial resins obtained by condensing phenol and formaldehyde in the presence of alkalis are used in place of saponified resins. Glycerin may be replaced by other hygroscopic substances which hinder drying, *e.g.*, an aqueous solution of potassium thiocyanate. —L. A. C.

Ox-gall; Preparation of ——. R. H. Parry. E.P. 169,917, 10.11.20.

A preparation of ox-gall for use in bookbinders' ink etc., free from objectionable smell and sliminess, is obtained by concentrating commercial dilute ox-gall in presence of a salt, *e.g.*, magnesium sulphate, in the proportions of, *e.g.*, 1 pint to 1 lb., until a thick product is obtained. The preparation is used in the proportion of 1 pt. to 80 pts. of water. —A. de W.

"Sulphate turpentine oil"; Process for improving the odour of ——. L. Schmidt. G.P. 340,126, 27.2.19.

"Sulphate turpentine oil," obtained as a by-product in the manufacture of sulphate-cellulose, is heated with sodium peroxide in open vessels or under a reflux condenser for about 2 hrs., filtered from the voluminous yellowish-brown slime which separates, and steam distilled.—A. de W.

Paint; Preparation of fireproof and waterproof ——. R. Plönnis. E.P. 147,799, 9.7.20. Conv., 16.9.16.

See G.P. 301,783 of 1916; J., 1921, 311A.

Lakes. E.P. 170,155. *See* IV.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Vulcanisation of rubber; Relative activities of certain accelerators in the ——. H. A. Endres. Caoutchouc et Gutta-Percha, 1921, 18, 11,089—11,097.

Using a mixture of rubber 50, sulphur 4, and zinc oxide 45 pts. with varying proportions of accelerators, and vulcanising under a steam pressure of 45 lb., aniline (4 pts.) and *o*-toluidine (4 pts.) were not very powerful in their effect, the physical condition of the rubber attaining an optimum in about 60 mins.; *p*-toluidine (4 pts.) was more effective, the "optimum period" being 40 mins., whilst dimethylaniline (4 pts.) was practically ineffective, the period exceeding 90 mins. *p*-Nitrosodimethylaniline (0·59 pt.), *p*-phenylenediamine (0·59 pt.), and aldehyde-ammonia (1½ pts.) were almost equally effective, reducing the optimum period to 30 mins. One pt. of hexamethylenetetramine was as active as 2½ pts. of thiocarbanilide (optimum period 50 mins.), but 5 pts. of the latter reduced the time of optimum vulcanisation to 5 mins. Of the common inorganic accelerators, red lead is the most powerful, 1 pt. requiring a vulcanisation period of 60 mins. for optimum physical results. With 18 pts. of litharge the necessary time was only 20 mins., whilst with a mixture of lime (3 pts.) and calcined magnesia (2 pts.) the period was 50 mins.—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Tannin analysis; Wilson-Kern method of ——. G. W. Schultz. J. Amer. Leather Chem. Assoc., 1921, 16, 349—367.

The previous results obtained by Schultz and Blackadder (J., 1921, 480 A) have been confirmed. A chestnut extract was shaken with hide powder and the hide powder washed fifteen times. 0·90% tannin was obtained from the detannised solution and the first washings and 0·55% from the second, third and fourth washings. A quebracho extract was similarly treated and the washings shaken with two successive portions of hide powder which were subsequently washed and analysed and yielded 2·65% and 2·18% of tannin respectively. There was no possibility of this tannin having been formed from the non-tannin matter as claimed by Wilson and Kern (J., 1920, 522 a). A solution of chestnut extract when diluted, gave no gelatin salt reaction for tannin, but when concentrated and diluted again the reaction was given. On concentrating a second time and diluting the reaction failed. This disproves Wilson and Kern's theory of the formation of tannins by the concentration of non-tannins. The amount of extract absorbed by different amounts of hide powder when shaken with a tannin solution according to the official American method and with 15 and 20 washings has been plotted against the amount of hide powder used. The curves show there is no essential difference in the absorption by the three methods. There is a constant difference in the methods due to the removal of tannin by washing, whereas if Wilson and Kern's assumptions were correct, the amount of absorbed matter after thorough washing should be independent of the amount of hide powder employed. The Wilson and Kern method is based on a series of false assumptions. Three main factors influence the absorption of tannin by hide powder, viz.:—the amount of hide powder, the concentration of the tannin solution, and the volume of solution. The effects of these are as pronounced after washing as they were before. These influences are recognised in the limitations imposed by the official method, which embodies principles for obtaining the maximum absorption of tannin, and all indications point to the error in this method being very small.—D. W.

Leather analysis. Report of committee of French Section of Society of Leather Trades' Chemists. P. Chambard. J. Soc. Leather Trades' Chem., 1921, 5, 313—322.

Thickness and texture of hides and skins influence the composition after tannage. The hide substance in one side of sole leather varied from 43% towards the tail end of the butt to 35·5% in the flanks and shoulder. A sample 60 cm.×5 cm. wide should be cut from the juncture of the butt with the shoulder and 6 cm. should be cut off each end. Analysis of different samples cut in this way from the same tannage of bends showed only 1% differences in hide substance figures. Part of the sample is cut up for the hide substance determination and the rest is divided by rasping. Moisture is determined at 105°—110° C., and the dry sample should be weighed in a covered dish to prevent absorption of moisture from the air. The water-soluble matter is determined by extracting 5 g. of rasped leather with 250 c.c. of distilled water for 16 hrs. or by shaking the leather with the water without agitation for 5 hrs., in both cases at the ordinary temperature. The fat extraction and the hide substance determination are carried out in the usual way. —D. W.

Moisture in leather; Effect of atmospheric humidity on the determination of ——. F. P. Veitch and T. D. Jarrell. J. Amer. Leather Chem. Assoc., 1921, 16, 547—562.

The loss in weight in drying leather in flat-bottomed dishes is greater than in weighing bottles. The higher the relative humidity of the atmosphere, the lower the apparent moisture and the higher the total solids in leather and tanning materials. A difference of 35% in the relative humidity produces a difference of ±0·5% moisture in ungreased leathers and tanning materials and ±0·2% in greasy leathers. The greatest loss in weight in drying samples of leather is obtained by use of the vacuum oven at 97°—98° C.—D. W.

Leather-grease; A new ——. W. Fahrion. Chem. Umschau, 1921, 28, 244—245.

Mineral oils are not suitable for fat-liquoring leather, as the latter becomes hard and brittle. The addition of calcium soap to the mineral oil overcomes this disadvantage. In order to make the mixture emulsify with water and so suitable for treating wet leathers neutral fat or fatty acids must be added. In a patented process a mixture of fatty acids and mineral oil is heated to 110° C. and the calculated quantity of calcium hydroxide gradually stirred in. After allowing the mixture to stand, it is transferred warm to a mixing pan, warm water added, and the whole stirred until cold. The product has a very smooth texture and the appearance of dégras. A grease containing 8% of calcium soap, 8% of neutral fat, 64% of mineral oil, and 20% of water has been found quite satisfactory. It is also applicable to chrome leathers under certain conditions. It is considerably cheaper than the animal fats in use up to the present.—H. C. R.

Gelatins; The gold value of commercial ——. F. A. Elliott and S. E. Sheppard. J. Ind. Eng. Chem., 1921, 13, 699—700.

The gold value of colloids expresses the number of mg. of colloid necessary to prevent the precipitation of 10 c.c. of standard gold solution by 1 c.c. of 10% sodium chloride solution. The gold solution is prepared by heating to 100° C. a mixture of 2·5 c.c. of 0·6% gold chloride solution, 3·5 c.c. of 0·18*N* potassium carbonate solution, and 120 c.c. of conductivity water, and adding 0·3% formaldehyde solution, drop by drop, until the addition of a further drop produces no colour change and a deep red, clear solution is obtained. Seventeen different gelatins of all grades were examined and showed but little difference in their protective action; classification of gelatins on the basis of their gold value is approximate only and the value does not appear to bear any simple relation to those properties which are of chief interest to users of gelatin.—W. P. S.

Patents.

Tanning agents; Manufacture of vegetable ——. H. Renner and W. Moeller. E.P. 146,165, 25.6.20. Conv., 10.2.14.

An "acid resin" obtained by treating certain mineral products with strong sulphuric acid (*cf.* G.P. 262,333; J., 1913, 878) is mixed with vegetable tanning materials or extracts (*e.g.*, quebracho, mangrove) in the cold or while heating, with or without pressure. 1—5% of "acid resin" produces an extract soluble in warm water, whilst with 10—15% a cold soluble extract of brighter colour and containing less insoluble matter is produced. (Reference is directed, in pursuance of Sect. 7, Subsect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 18,259 of 1913; J., 1914, 877.)—D. W.

Patent leather; Drying or hardening the surface of ——. J. J. Stoeckly. E.P. 149,334, 19.7.20. Conv., 8.8.19.

The surface of varnished leather is dried by means of ultra-violet rays produced by a high-frequency electric spark discharging 30—60 times per second, each spark consuming about 0·7 kilowatt.—D. W.

Leather; Process for drying or hardening the surface of patent ——. J. J. Stoeckly. E.P. 148,454, 10.7.20. Conv., 13.4.18.

See G.P. 333,403 of 1918; J., 1921, 359 a. Methyl alcohol may be used in place of ethyl alcohol.

Hides and skins; Process of making a depilatory for ——. A. H. Stone. U.S.P. 1,394,588, 25.10.21. Appl., 23.5.19.

Lime and sodium sulphide solution are subjected to

prolonged agitation while hot, whereby the depilatory is obtained in solid form and latitude in the character of the ingredients used is afforded.
—D. W.

Glue; Manufacture of liquid ——. (A) D. K. Tressler, Assr. to W. A. Hamor. (B) D. K. Tressler. U.S.P. (A) 1,394,653 and (B) 1,394,654, 25.10.21. Appl., 6.12. and 27.12.20.

Glue is mixed with (A) an alkaline-earth salicylate or (B) thiourea to form a liquid glue.—D. W.

Horn; Process for making the colouring of natural —— water-resisting. M. Lambeck. U.S.P. 1,395,191, 25.10.21. Appl., 12.8.21.

See E.P. 154,200 of 1920; J., 1921, 400 A.

XVI.—SOILS; FERTILISERS.

Soils; Influence of temperature on the absorbent properties of ——. Stoquer. Comptes rend., 1921, 173, 731—733.

The absorbent power of soils for ammonia when shaken with solutions of ammonium sulphate decreases with rise in temperature and increases with the concentration of the ammonium sulphate solution. At the ordinary soil temperature some soils lose ammonia to solutions containing 2 pts. of ammonium sulphate per 100,000.—W. G.

Soil acidity and bacterial activity. R. E. Stephenson. Soil Sci., 1921, 12, 133—144.

Soils were treated with dung, cottonseed meal, green and dried timothy and clover in duplicate sets, with and without lime. Comparison was made of the lime requirement and the activity of ammonifying and nitrifying organisms under the various treatments. The decay of organic material produced no acidity except where there was a large production of nitric acid. Lime favoured nitrification, but ammonification proceeded more rapidly in unlimed soils. Green manures decayed more rapidly than dried material. Soil organisms remained active even in soils of moderate acidity. (*Cf.* J.C.S., Dec.)—A. G. P.

Soil reaction; Effect of organic matter on ——. R. E. Stephenson. Soil Sci., 1921, 12, 145—162. (*Cf.* J., 1919, 474 A.)

Soil was fertilised with oatstraw, green soya beans, green rape, soya bean hay, and dried blood in a series of parallel experiments. Oat straw reduced ammonification and nitrification below that of untreated soil. Straw mixed with blood reduced the total nitrogen as ammonia and nitrates in soil below that with blood alone. This reduction increased with larger applications of straw. In all cases the lime requirement was reduced until nitrification commenced. During the decomposition of the organic matter of blood the amount of reserve carbonates in soil diminished considerably. Determination of hydrogen-ion concentration showed that in most cases organic treatment reduced the true acidity of soils. Changes in soil reaction, particularly during the use of dried blood, followed closely the excess or otherwise of ammonia over nitric nitrogen. These processes may influence the production of acid soils. Organic and clay soils, unlike sands possess great buffering capacity. Sulphuric acid, ammonium sulphate, and physiologically acid salts tended to increase hydrogen-ion concentration in soils, but citric acid caused no increase. The utmost alkalinity produced by limestone corresponded to $p_H=8$.—A. G. P.

Soil solution; Methods of studying the concentration and composition of the ——. F. W. Parker. Soil Sci., 1921, 12, 209—232.

In obtaining samples of soil solution by displacement with another liquid, the most satisfactory displacing liquid is ethyl alcohol. The amounts of soluble material thus obtained from the soil are independent of the content of soil-moisture and of the nature of the displacing liquid. All portions of the extract have the same composition. Comparison with water extraction methods shows that the extraction of 1 pt. of soil with 5 pts. of water gives an extract containing almost identical dissolved matter with that obtained by displacement. The composition of aqueous extracts of soil varies with the relative amounts of soil and water used. Freezing point determinations do not give a measure of the amount of dissolved substances in the soil solution. Finely divided material, clay, etc., lower the freezing point of the soil solution when in the form of a thin film or capillary. Freezing point depressions of a number of soils at the moisture equivalent (*i.e.*, after subjecting to a centrifugal force of 1000 times gravity) were found to be very nearly constant.—A. G. P.

Straw; Effect of —— on biological soil processes. T. J. Murray. Soil Sci., 1921, 12, 233—259.

The addition of straw has a harmful effect on nitrate accumulation in soil after a given time; and the injurious effect increases with the amount of straw. If losses of nitric nitrogen occur this is due to a transformation to another form and is not a dead loss to the soil. Straw acts as a source of energy to nitrogen-fixing bacteria, but the amount of nitrogen fixed is not proportional to the amount of straw. Ammonification is inhibited with over 0·9% of straw in the medium, the harmful effect increasing with the proportion of straw. Bacterial numbers increase with the amount of straw present. Straw has no effect on the kind of bacteria present in the soil, the same types predominating in soil treated with straw as in untreated soil. Nitrates which are used by the bacteria do not reappear as nitrites but as some form of organic nitrogen. Cellulose either from straw or from filter-paper has no effect on nitrifying organisms.—A. G. P.

Alkali soils; Solubility of anions in ——. W. P. Kelley and S. M. Brown. Soil Sci., 1921, 12, 261—285.

In preparing aqueous soil extracts the use of compressed air in filtering did not materially affect the content of carbon dioxide in the extract. The amount of solids extracted varied with the time of shaking, but it is concluded that after 1 hr. soil and water have reached an equilibrium. The amounts of carbon dioxide (dissolved and as bicarbonates) in extracts varied in some cases with the ratio of water: soil. The amounts of chloride and nitrate dissolved did not vary appreciably with the water:soil ratio. The amount of OH ions was lowest with a water: soil ratio of 2:1, and reached a maximum at a ratio of 10 and over :1. In successive water extracts, greater amounts of normal carbonate appeared in the second extract than in the first, whereas the greater part of the chlorides, sulphates, and nitrates appeared in the first extract. It would appear that alkaline salts are adsorbed or held in loose combination by the soil to a much greater extent than neutral salts.—A. G. P.

Toxicity of soluble salts [to micro-organisms]; Rôle of osmotic pressure in the ——. J. E. Greaves and Y. Lund. Soil Sci., 1921, 12, 163—181.

The toxicity towards ammonifying and nitrifying organisms and the osmotic pressure of soils to which were added the chlorides, sulphates, carbonates, and nitrates of potassium, sodium, calcium, magnesium, iron, and manganese, are compared. Cryoscopic and conductivity methods were used for osmotic measurements. Excepting in the cases of manganese and ferric nitrates, and sodium carbonate, toxicity and osmotic pressure bear a close relationship, salts becoming toxic at a pressure of about 3 atm. The retarding effect of the salts on the organisms is not due entirely to the osmotic pressure. Probably there is a physiological action on the living protoplasm. All salts reduced ammonification to less than half-normal at 15 atm. osmotic pressure, although ammonia was still formed when the pressure reached 20 atm. With the exception of sodium chloride, ferric chloride, and manganese nitrate all salts became toxic to nitrifying organisms at an osmotic pressure of 1—2 atm., and at 6 atm. nitrification was reduced to less than half-normal. Generally speaking the retardation of nitrifying and ammonifying organisms is similar, but the former occurs at lower osmotic pressures.—A. G. P.

Soils; Aqueous vapour pressure of ——. M. D. Thomas. Soil Sci., 1921, 11, 409—434.

An elaborate apparatus is described and figured for use in measuring the aqueous vapour pressure lowerings of soil, accurately to 0·01 mm. at 25° C. The method is a combination of the methods of Berkeley (Proc. Roy. Soc., 1906, 77, 156) and Washburn (J. Amer. Chem. Soc., 1915, 37, 309). Preliminary measurements with four different soils show that the vapour pressure is proportional to the reciprocal of the moisture content. In the absence of dissolved material the position of each vapour pressure-moisture curve depends almost wholly on the texture of the soil. Correlations are given between the vapour pressure and the following soil properties:—hygroscopic coefficient, wilting coefficient, moisture equivalent, "solid water" (unfree water, Bouyoucos, J., 1921, 231 A), capillary potential, surface tension, and curvature of the moisture surface.—W. G.

Peat; Acid amide fraction of the nitrogen of ——. E. J. Miller and C. S. Robinson. Soil Sci., 1921, 11, 457—467.

Both glutamic and aspartic acids are obtainable from peat by hydrolysis with hydrochloric acid. Attempts to separate glutamic acid directly from the hydrolysate were not successful, but by means of Foreman's method (Biochem. J., 1914, 8, 463) in a slightly modified form both glutamic and aspartic acids were separated and the amount of pyrrolidonecarboxylic acid estimated.—W. G.

Nitrogen losses under intensive cropping [of soils]. J. G. Lipman and A. W. Blair. Soil Sci., 1921, 12, 1—19.

The nitrogen losses from a loam soil, which had been for 20 years under a five-course rotation of maize, oats, oats, wheat, and timothy, were studied in cylinders with natural drainage. Twenty series of three cylinders each were studied, the series receiving different forms of nitrogenous fertilisers alone or in combination with dung. All the cylinders received a liberal dressing of lime at the commencement and then no more for ten years, after which two out of the three cylinders in each series received an application of ground limestone at 5-year intervals. One of these two cylinders in each series grew two leguminous green manure crops in each rotation. During the first ten years the average loss of nitrogen from the soil, exclusive of that removed by the crops was equivalent to 103 lb. per acre. The same figure was found during the next five years, but during the last five years the average loss was considerably less, and for certain cylinders on which the green manuring crops was grown there was some gain. Carbon determinations made on the soil at the end of the 20 years showed a gain in carbon for nearly all the cylinders receiving both dung and nitrogenous fertilisers, no change in those receiving dung alone, and an appreciable loss where nitrogenous fertilisers were used alone.—W. G.

Phosphate; Relation of organic matter and the feeding power of plants to the utilisation of rock ——. F. C. Bauer. Soil Sci., 1921, 12, 21—41.

No evidence could be obtained of a solvent effect of decaying organic matter on rock phosphate under various conditions when mixed with sand or soil. In some cases mixtures of organic matter and rock phosphate applied to pot cultures produced increases in the growth of maize over and above the combined separate increases due to organic matter and rock phosphate alone. A study of the growth of fifteen different species of plants on rock phosphate in sand cultures showed a wide variation in the amount of dry matter produced, but there was no definite relationship between the amount of plant growth and the extent of root systems, the phosphorus content, or the acidity of the plant juices. Some plants with a high calcium content showed a greater ability to feed on rock phosphate, sweet clover being particularly marked in this connexion.—W. G.

Sulphur; Influence of varying amounts of —— in the soil on crop yields, hydrogen-ion concentration, lime requirement, and nitrate formation. J. G. Lipman, A. L. Prince, and A. W. Blair. Soil Sci., 1921, 12, 197—208.

Barley and soya beans were grown in succession on plots receiving various dressings of inoculated and uninoculated sulphur. Germination of barley was not greatly affected by the sulphur, but injury was apparent later on plots receiving 1000 lb. of sulphur per acre, and plants on plots receiving 4000 lb. per acre were practically all killed. The germination of soya beans was normal with sulphur dressings up to 500 lb. per acre, but decreased considerably with heavier applications. In quantities up to 500 lb. per acre sulphur did not greatly affect the hydrogen-ion concentration, but 1000 lb. per acre caused a considerable increase in from 4 to 8 weeks, acidity developing most rapidly towards the end of July and early August. Variations of lime requirement (revised Veitch method; J. Assoc. Off. Agric. Chem., 1920, 3, 371) followed closely those in H-ion concentration, but there was not a direct correlation. Nitrates were usually higher on the untreated plots (these were also uncropped), but appeared in considerable amounts even in the most acid plots.—A. G. P.

Sulphates; Relation of —— to plant growth and composition. H. G. Miller. J. Agric. Res., 1921, 22, 101—110.

The sulphates of calcium and sodium caused increased nodule development in clover grown in previously sterilised soil; but when the soil was inoculated with *B. radicicola* at the time of seeding no stimulatory action of sulphates was observed. The ratio nitrogen:sulphur in the portion of the clover plant insoluble in acetic acid remained practically constant throughout the growing period. Total nitrogen and total nitrogen insoluble in acetic acid were higher in plants cut just previous to blossoming. By reducing the nitrate supply to clover in sand cultures, not only were growth and nitrogen content decreased, but sulphur assimilation was limited. No direct relation between nitrogen and sulphur assimilation of rape was found. Rape assimilates large quantities of sulphur, but the addition of sulphates to the soil produced no increase in crop. Treatment with nitrate *plus* sulphate gave higher yields than with nitrate alone.
—A. G. P.

Borax; Effects upon the growth of potatoes, corn [maize] and beans resulting from addition of —— to the fertiliser used. J. R. Neller and W. J. Morse. Soil Sci., 1921, **12**, 79—132.

Crops were grown in pots to which fertilisers containing borax were added. Generally, the injuries take the form of stunted growth, yellowing of tips and margins of leaves, followed by gradual discoloration and death of the leaf. Roots have browned and rotten tips. The maximum amount of anhydrous borax which could be applied without injury to plants was 3 lb. per acre with beans and about 5 lb. per acre for maize and potatoes. Borax applied with the fertiliser below the seed was more toxic than when applied above the seed. Thorough mixing of the borax with the surface soil slightly decreased the injury and slightly raised the amount that could be applied with safety. Treatment of the soil with lime reduced the toxic effects of borax in the case of potatoes and beans, but dung and gypsum had no ameliorative effect. All three materials reduced the injury to maize. No conclusive evidence of a stimulative effect was obtained.—A. G. P.

Dicyanodiamide; Effect of —— on plant growth. E. Johnsen. Nordisk Jordbruksforsoking, 1919. Chem. Zentr., 1921, **92**, III., 1147.

During the granulation of crude calcium cyanamide the treatment with water frequently causes the formation of dicyanodiamide. If the efficiency of urea, ammonium sulphate, and sodium nitrate be taken as 100, the efficiency figures for various fertilisers containing dicyanodiamide are:—Oiled calcium cyanamide containing 3% of dicyanodiamide, 99; Norwegian crude calcium cyanamide with 21% of the nitrogen as dicyanodiamide, 99; mixture of ⅓ of dicyanodiamide + ⅔ of urea, 99; granular calcium cyanamide containing 7% of dicyanodiamide, 80; mixture of ⅔ of dicyanodiamide + ⅓ of urea, 59; granular calcium cyanamide containing 10% of dicyanodiamide, 45. The lower concentrations of dicyanodiamide produced no ill effects on grain and straw production, nitrogen assimilation, or protein formation. No injurious effects on germination were noted. The injurious effects of dicyanodiamide depend entirely on the concentration in which it is present.—A. G. P.

Phosphoric acid extract [from phosphorites]; Enrichment of the —— by means of successive decomposition of further quantities of phosphorites. E. Bobko and O. Sokolowa. Z. angew. Chem., 1921, **34**, 548—550.

Low-grade Russian phosphate rock cannot be completely decomposed by dilute sulphuric acid in the usual way, only 60—70% of the phosphoric acid being rendered soluble. The following method, however, has been found to effect practically complete decomposition and to give, at the same time, a solution very much richer in phosphoric acid than the original rock. Sulphuric acid in slight excess is allowed to run in a thin stream into a thin pulp of finely ground rock and water (2:3 to 2:4) which is kept constantly stirred. After ½ hr. the sludge is filter-pressed and washed twice with water, the liquor and each wash-water being kept separate. A further quantity of the rock powder is then stirred into the liquor followed by sulphuric acid sufficient to decompose it. After filtering the cake is washed first with the two wash waters in succession, then with pure water, each liquor being kept separate. The process is repeated five times with the mother liquor, one fresh wash water being obtained each time. The mother liquor, which contains 8—9% P_2O_5 from the first extraction, then contains 25—30% and is sufficiently rich, so that the next portion of rock is stirred with the first wash water and so on. By this process a solution sufficiently concentrated for further treatment is obtained without evaporation and the relative purity of the solution is not reduced by the successive extractions, tests having shown that the quantity of sesquioxides dissolved by sulphuric acid does not depend on the amount of acid used but on the actual concentration of the acid in the solution.—A. R. P.

Wheat plants; Relation of the hydrogen-ion concentration of nutrient solutions to growth and chlorosis of ——. A. G. McCall and J. R. Haag. Soil Sci., 1921, **12**, 69—77.

Wheat plants were grown for two months on sand cultures supplied with four different nutrient solutions, each of which was modified in such a way as to have three distinctly different p_H values without materially altering the solutions with respect to the concentrations of the six essential ions. The results indicate that hydrogen-ion concentration exerted a very marked influence upon the rate of growth and was also an important factor in the control of chlorosis. There was some evidence that the plants grown on solutions having p_H values ranging from 4·02 to 7·0 were suffering from the lack of available iron or from faulty metabolism.—W. G.

Clover and wheat; Nutrient requirements of —— in solution cultures. J. J. Skinner and F. R. Reid. Soil Sci., 1921, **12**, 287—299.

The nutrient requirements of the clover plant in solution cultures have been tested by the triangular plan as used previously in the case of wheat (*cf.* Bot. Gaz., 1910, **50**, 1; J. Amer. Soc. Agron., 1918, **10**, 225). The weights of crop and the relative amounts of potash, nitrate, and phosphate absorbed by the clover plants have been determined. On the whole the results are in harmony with the generally accepted idea that normally clover is a potash-loving plant.—W. G.

Fertiliser salts; Influence of certain —— on the growth and nitrogen content of some legumes. A. MacTaggart. Soil Sci., 1921, **11**, 435—455.

The fertilisers used were dried blood, disodium phosphate, potassium chloride, and gypsum, either singly or in combination, all the pots having received a dressing of calcium carbonate. Of the four fertilising elements phosphorus was most effective in increasing the dry matter, total nitrogen, and percentage of nitrogen in the three crops, alfalfa (lucerne), Canadian field peas, and soya beans. Nitrogen had very little, if any, beneficial effect on the legumes. The action of potassium was not uniform on the three crops. Sulphur, as gypsum, favoured to some extent the growth of lucerne but not of peas or beans. There appeared to be some correlation between the plant dry matter produced and subsequent soil nitrification.—W. G.

Soya beans; Fixation of atmospheric nitrogen by inoculated ——. E. B. Fred. Soil Sci., 1921, **11**, 469—477. (*Cf.* J., 1920, 200 A.)

On a poor, light sandy soil which had not carried a leguminous crop for 20 years, inoculation trebled the yield of soya beans per acre. It increased the weight of nitrogen in the crop from 8·33 lb. to 65·36 lb. per acre, approximately 87% of this increase being in the tops of the plant. The increased nitrogen content of the roots and nodules of the inoculated plants greatly benefited the rye crop in the succeeding year.—W. G.

Nodules on roots of certain legumes; Effect of soil temperature on the development of ——. F. R. Jones and W. B. Tisdale. J. Agric. Res., 1921, **22**, 17—31.

The plants studied were alfalfa (lucerne), red clover, peas, and soya beans. Although the plants varied in their resistance to temperature changes, in all

cases maximum nodule production occurred at about 24° C. Maximum nodule production does not correspond with maximum production of tops or roots, but is usually associated with high nitrogen content of the tops. Soil moisture, hydrogen-ion concentration, and nitrate content of the soil seem to have no effect on the production of nodules.
—A. G. P.

Inoculation of canning peas; Field tests on the ——. E. B. Fred, W. H. Wright, and W. C. Frazier. Soil Soc., 1921, **11**, 479—491.

On a heavy, rich, slightly acid clay loam, which had been cropped to peas for years, inoculation had apparently no effect. On a rich silt loam, having a lime requirement by the Truog method (J., 1916, 699) of 3 tons per acre, inoculation caused an increase in the yield of pea plants and of peas and in the nitrogen content of the peas and of the soil on which they were sown. Similar results were obtained on a silt loam, which was neutral in reaction and had been heavily manured for years.—W. G.

Iron; Distribution of —— in plant organs. L. Maquenue and R. Cerighelli. Bull. Soc. Chim., 1921, **29**, 899—905.

Plants only contain a comparatively small amount of iron. In general its distribution is similar to that of copper (*cf.*, Maquenne and Demoussy Comptes rend., 1920, **170**, 87), the young organs, buds or leaves, containing more than the old ones. Like copper iron is capable of migrating towards the centres of active life and reproduction.—W. G.

Patents.

Superphosphate and similar masses; Apparatus for opening up, conveying and disintegrating —— in a continuous manner. G. A. Bruhn. E.P. 147,134, 7.7.20. Conv., 28.7.15.

The conveyor is an endless chain of boxes with sides only, thus forming a moving channel into which the mixture of phosphate and acid is fed. At a suitable place in the chain rotating knives remove the solidified superphosphate in thin slices.—A. G. P.

Potash-bearing silicate rocks; Utilisation of —— especially as fertilisers. Chem. Fabr. Rhenania, and A. Messerschmidt. G.P. 300,642, 14.12.13.

Leucite or similar rocks (or basic potassium calcium ilicates obtained by their treatment with lime or ime and phosphates), in fine powder, are treated vith sodium salts at a high temperature and ressure. The slightly soluble portion of the rection product may be removed for further treatent or the whole product may be dried. Sodium itrate may be used as the sodium salt. The uantity of sodium salts for the decomposition is ade sufficiently small that the product is largely otassium nitrate which can be removed from the xtract by fractional crystallisation, and the sodium alts are used in the form of saturated solutions or f solutions holding solid salt in suspension.
—A. G. P.

alcium cyanamide; Process for rendering crude —— free from dust. A.-G. für Stickstoffdünger. G.P. 304,282, 21.3.17.

rude calcium cyanamide is mixed with urea itrate. During the mixing of the constituents, moist gas or water vapour is passed over them, or e final mixture is exposed to the action of moist ses or water vapour.—A. G. P.

odium nitrate; Process for preventing the caking of ——. A.-G. für Anilin-Fabr. G.P. 340,224, 30.4.19.

he nitrate is mixed with a deliquescent salt, *e.g.*, 00 kg. of nitrate is mixed with 100 kg. of calcium chloride and 50 kg. of water. A serviceable product for use as a fertiliser is obtained without drying.
—A. G. P.

Fertiliser; Process for manufacturing a ——. Chem. Fabr. Kalk. G.P. 340,595, 22.6.17.

Rock phosphate, sodium bisulphate, and a neutral ammonium salt (preferably the sulphate), are melted together. The ammonium salt lowers the melting point of the mixture sufficiently to prevent any reversion of the decomposed phosphates. The process differs from that in which the rock phosphate is heated with sodium bisulphate alone, since in this the temperature is high enough to bring about some reversion of the superphosphate.—A. G. P.

[Calcium] cyanamide; Process for granulating ——. L. Barbé, Assr. to Soc. des Produits Azotés. U.S.P. 1,394,532, 25.10.21. Appl., 24.10.19.

See E.P. 140,331 of 1919; J., 1920, 379 a.

XVII.—SUGARS; STARCHES; GUMS.

Cane juice; Effect of varying H-ion concentration upon the decolorisation of —— with carbon. J. F. Brewster and W. G. Raines, jun. J. Ind. Eng. Chem., 1921, **13**, 1043—1044.

On treating 220 c.c. portions of cane juice of varying p_H values with 2 g. of decolorising carbon, heating to boiling point, filtering, and determining the colour remaining by means of the Hess-Ives tint-photometer, figures were obtained demonstrating that an increase of the H-ion concentration facilitates the adsorption of colour. Since inversion may commence even at an acidity as low as p_H 5 (that of cane juice extracted under normal circumstances) it is impossible to take advantage of acidification in practice without a careful control of the time and temperation of reaction. Good results, however, have been obtained by heating the juice mixed with the carbon to boiling point, adding phosphoric acid to an acidity of p_H 4, allowing to stand for a short time, and neutralising with milk of lime, the addition of which is stopped at about p_H 6·5.—J. P. O.

Sugar beet juices; Precipitation of amino-acids [and acid amides] in the carbonatation process of clarifying ——. V. Stanek. Z. Zuckerind. Czechoslov., 1921, **45**, 45—48.

Under the conditions of the carbonatation process, that is when about 2% of calcium oxide as milk of lime was added to the solution under treatment, and the latter heated to 85° C. for 15 min. and carbonated at the same temperature, about 62% of aspartic acid, 16% of asparagine, 40% of glutamic acid, and 6% of leucine, passed from solution into the precipitate formed. On increasing the amount of lime to 4%, a greater amount of protein derivative passed into the scums, viz., about 80% in the case of aspartic acid. When, after this first carbonatation, the filtered liquid was again limed and treated with carbon dioxide or sulphur dioxide a further precipitation occurred, viz., 14% with aspartic acid and 7% with glutamic acid when 0·2% of lime had been used.—J. P. O.

Sucrose; New clarifying agent for the Clerget (double polarisation) method of determining ——. H. Klashoven and C. Sijlmans. Arch. Suikerind. Nederl.-Indië, 1921, **29**, 989—999. Int. Sugar J., 1921, **23**, 627—629.

A combination of the basic lead nitrate and aluminium sulphate methods of clarification (*cf.* Deerr, J., 1915, 503) gives results which in the case of Java cane molasses average about 0·28% higher than with the use of basic lead acetate, but with a much better decolorisation. 35·816 g. (=26·048 g. ×5/2×1/2×11/10) of the sample is introduced into a 250 c.c. flask, 30 c.c. of normal lead nitrate solution (600 g. per l.) added, the liquid mixed, 30 c.c. of sodium hydroxide solution (80 g. per l.) added, the liquid again mixed, made up to the mark with water, and filtered. A 100—110 c.c. flask is filled to the lower mark with the filtrate, and a cold saturated solution of aluminium sulphate added to complete the volume almost to the 110 c.c. mark, the exact adjustment being made with water, after which a little kieselguhr is added, and the liquid shaken and filtered. This filtrate observed in the 400 mm. tube gives the direct polarisation; and the inversion reading is made after hydrolysing 50 c.c. in a 100 c.c. flask according to the method of Herzfeld, Steuerwald (J., 1914, 96) or Walker (J., 1917, 153), using the 400 mm. tube, and applying the appropriate Clerget divisor in the calculation of the result.—J. P. O.

Sugar; Extraction of —— from beet molasses by the calcium, barium, and strontium processes. M. Potvliet. J. Ind. Eng. Chem., 1921, 13, 1041—1042.

Out of 48·5% of sugar present in the molasses treated, the yield of granulated sugar given by the calcium, barium, and strontium processes was: 35·45, 43·97, and 43·18% respectively. As the result of washing the saccharate cake, a small amount of sugar is re-dissolved in all three processes, but mostly when using strontium. On decomposing the saccharate cake with carbon dioxide and filtering, the "juices" obtained were lightest in colour in the strontium process, and darkest in the calcium process. Apart from the cost of material, the strontium and barium processes are considered more economical, besides being more convenient in operation. No trace of either barium or strontium could be detected in the finished sugars.—J. P. O.

Mannose; Preparation of —— from ivory-nut shavings. P. M. Horton. J. Ind. Eng. Chem., 1921, 13, 1040—1041.

About 175 g. of ivory-nut in the form of powder is stirred into 1% sodium hydroxide solution which has previously been heated to boiling point, and the liquid filtered at the end of 1 hr. About 130 g. of the perfectly dried residue is treated with 130 g. of 75% sulphuric acid, allowed to stand for 6 hrs., diluted with water to about 150 c.c., heated to boiling point, and simmering continued for 6—8 hrs. After cooling to room temperature, 50 g. of calcium hydroxide in 300 c.c. of water is added with brisk stirring, and the liquid (which should still be faintly acid) filtered. It is treated at 90° C. with decolorising carbon, cooled, and after adding excess of calcium or barium carbonate again filtered. This filtrate (which should be neutral to litmus) is concentrated *in vacuo* to a light syrup, poured into an equal volume of 95% alcohol, treated at 90° C. with decolorising carbon, and again filtered. After concentrating *in vacuo* to 96% of solids (by refractometer), the almost solid mass is dissolved in warm glacial acetic acid, and allowed to stand for about 3 days, crystallisation being assisted by seeding, by the addition of small portions of acetic acid, and if necessary by first freezing, then thawing. After washing the mannose crystals successively with acetic acid, alcohol, and ether, they are ground to powder with ether, and finally filtered and dried at 40° C. A yield of about 40 g. of a white product requiring no further purification for ordinary purposes is thus obtained.—J. P. O.

Patent.

Sugar etc. from wood. G.P. 340,212. *See* XVIII.

XVIII.—FERMENTATION INDUSTRIES.

Yeast; Resistance of pressed —— and beer yeast towards relatively large quantities of sulphuric acid, in relation to the internal condition of the cells. W. Henneberg and M. Böhmer. Woch. Brau., 1921, 38, 237—238, 245—246.

The injury caused to yeast by sulphuric acid at concentrations higher than those usually employed in the purification treatment with this acid, depends on the physiological state of the cells, and a "sulphuric acid test" affords information respecting the latter which is difficult to obtain otherwise. In experiments with a good baker's yeast, 3—4 days old, treatment with 5% sulphuric acid for 80 mins. left 80% of the cells in a healthy condition and only 3% of the cells were stained by Methylene Blue; and even after treatment with 9% acid for 15 mins. 80% of the cells remained healthy. On the other hand, a bottom fermentation beer yeast just collected from the vat was very sensitive, largely owing to its high protein-content; almost all the cells were killed by 1% acid in 60 mins., or by 3% acid in 15 mins. As a rule yeasts rich in protein are very sensitive to acid, whilst those rich in glycogen are resistant. Yeast in the resting state is resistant, but it becomes sensitive while assimilating nutriment, and also before and during reproduction. A yeast crop collected too soon, *i.e.*, before it is "ripe," is accordingly abnormally sensitive. Resistance is increased by aeration, and this is one reason for the marked difference between baker's and brewery yeast in this respect. Resistance in a baker's yeast is no indication of high working power, but it is such a strong indication of good keeping qualities, whether in a baker's or a brewer's yeast, that the "sulphuric acid test" is of great practical value in the examination of yeast. Mycoderma yeasts vary in resistance according to their physiological condition, in the same way as culture yeasts. When present in baker's yeast they can be destroyed by suitable treatment with sulphuric acid, provided they are in a more sensitive (unripe) condition than the culture yeast, as is not infrequently the case in the course of yeast manufacture.—J. H. L.

[Fermentation] vats; Economy by use of closed —— [in distilleries]. E. Lühder. Z. Spiritusind., 1921, 44, 332—333, 348—349. (*Cf.* J., 1920, 732 a.)

There is no real difference between closed and open vats in respect of intensity of fermentation or degree of attenuation attained, nor is the cost of upkeep and manipulation less for closed than for open vats. The chief advantage of the closed system is that it enables loss of alcohol by evaporation during fermentation to be avoided, and renders more easy the attainment of technically pure fermentations owing to the ease with which closed vats can be sterilised. The saving involved by the substitution of closed for open vats varies according to the efficiency with which the latter have previously been operated. With the closed system a yield of 65 l. of (absolute) alcohol per 100 kg. of starch can be attained, as compared with 62 l. with an efficiently operated open system.
—J. H. L.

Brewing water; Influence of wort-concentration on the biological investigation of ——. R. Heuss. Z. ges. Brauw., 1921, 162—164, 167—170.

In testing brewing waters by incubating samples in sterile wort, with or without yeast, to ascertain if organisms are present capable of developing under practical brewing conditions, it is important that the wort used should have the same concentration as that used in the brewery. Experiments showed that light worts are more susceptible to attack by foreign organisms than worts of higher gravity. For water employed for diluting beers after fermentation a higher standard of biological purity should be imposed than for waters for ordinary brewing use.—J. H. L.

Wine; Detection of saccharin in ——. W. Fresenius and L. Grünhut. Z. anal. Chem., 1921, **60**, 353—359.

Five hundred c.c. of the wine is evaporated to remove alcohol, diluted to 450 c.c., acidified with 5 c.c. of sulphuric acid (sp. gr. 1·11), and extracted twice (60 c.c., 25 c.c.) with ether; the solution is then evaporated to 200 c.c., and extracted three times with ether (200 c.c. each time). The united ethereal extracts are distilled to a small bulk, this residual solution is evaporated to dryness, the residue dissolved in 50 c.c. of water, the solution evaporated, water is added and the evaporation repeated, the residue then dissolved in 5 c.c. of $N/4$ sodium hydroxide solution, the solution heated and oxidised with permanganate, the excess of the latter destroyed by the addition of sulphurous acid, and the cooled solution extracted with ether. The residue obtained on evaporating the ethereal extract is tasted; a sweet taste indicates the presence of saccharin, and this is confirmed by evaporating the remainder of the residue with a drop of sodium hydroxide solution in a silver crucible, adding 0·5 g. of powdered sodium hydroxide, heating the mixture at 250° C. for 30 mins., then dissolving it in water, acidifying the solution and extracting it with ether; the salicylic acid thus obtained is identified by the coloration it gives with ferric chloride.—W. P. S.

Acetone and n-butyl alcohol manufacture; Bacteriology of the process for ——. A. C. Thaysen. J. Inst. Brew., 1921, **27**, 529—542.

The strain of *Amylobacter* used for the manufacture of acetone and butyl alcohol in this country (*cf.* J., 1919, 271 T *et seq.*) is described. It is an actively motile bacillus which takes the ordinary aniline dyestuffs and is Gram positive. It measures 4—6μ by 1—1·2μ when alive, and 3—4μ by 0·9—1·0μ when stained. The size of the spores varies from 1·2 to 1·5μ, and as they are formed in the centre or towards the end of the cell they cause the latter to assume a spindle-shaped form. The organism develops best under anaerobic conditions, but in a fairly thick mash of well-gelatinised grain inoculated liberally with a vigorous culture growth takes place readily in tubes exposed to the air. The bacillus produces proteolytic and diastatic enzymes. A 7% maize mash inoculated with 2% of a culture 24 hrs. old is completely fermented within 24—36 hrs. at 37° C., or several hours sooner at 39°—40° C. About 12 pts. of acetone and 24 pts. of butyl alcohol are formed per 100 pts. of starch decomposed, and large quantities of hydrogen and carbon dioxide are produced in the proportion 1:2 (*cf.* Speakman, J., 1920, 760 A). Before the formation of acetone and butyl alcohol the acidity of the mash increases (*cf.* Reilly and others, J., 1920, 421 A), and after reaching a maximum it falls again to a fairly constant value. If owing to the presence of foreign acid-forming bacteria the acidity continues to increase, the production of acetone and butyl alcohol is seriously reduced and may be arrested. The most dangerous infection from this point of view is due to a lactic bacillus, *Bacterium volutans*, n. sp., Fleming, Thaysen, the characters of which are described. Like the acetone bacillus, it occurs in soils and therefore on plants, and withstands high temperatures. Unlike the former, however, it produces large quantities of lactic acid, besides traces of butyric and acetic acids from maltose and dextrose, but it does not attack starch. It may be distinguished from the acetone bacillus by the presence of volutin granules, which are stained deep purple by Methylene Blue. Some other organisms which have been found in the factory mashes are referred to briefly. The preparation of cultures of the acetone bacillus for industrial use is described (*cf.* Gill., J., 1919, 273 T).—J. H. L.

Micro-organisms producing acetone. A. Berthelot and E. Ossart. Comptes rend., 1921, **173**, 792—794.

In addition to the anaerobic organisms used by Fernbach in the manufacture of acetone, there exist, widely distributed in nature, many other organisms both aerobic and facultative anaerobes capable of producing acetone, though to a lesser extent. The amounts of acetone produced by a given organism vary considerably with the medium. —W. G.

Glycerol; Determination of —— in fermentation glycerin. K. Fleischer. Z. anal. Chem., 1921, **60**, 330—338.

One hundred g. of the dilute glycerin solution, without previous treatment, is distilled under reduced pressure from a flask fitted in a hot-air bath; superheated steam is admitted to the flask and the temperature is raised eventually to about 250° C. The delivery tube of the flask enters a receiving flask which is provided with a reflux condenser the top of which is connected with an ordinary condenser, receiver, and exhaust pump. The receiving flask stands in a water-bath at 70° C., and the jacket of the reflux condenser is supplied with water at 70° C. When glycerol ceases to distil over into the receiving flask, the steam supply is cut off, and the contents of the flask are heated at 100°. under reduced pressure until practically all water has been removed, a small current of air being admitted to the flask through a capillary. The flask and its contents are cooled, weighed, the sp. gr. of the distilled glycerol is determined, and the actual quantity of glycerol present thus obtained.—W. P. S.

Yeasts and moulds; Toxicity of metals for ——. G. and G. Villedieu. Comptes rend., 1921, **173**, 797—799.

The toxicity of metals in the form of thin sheet for yeasts and moulds growing on nutrient agar, having an acidity of $N/20$ due to citric acid, is in the following ascending order:—Mercury, copper, zinc, iron, magnesium. This apparently abnormal result is explained on the basis that the metal attacks, more or less readily, the nutrient solution in contact with it, the nascent hydrogen produced combining with free oxygen and thus interfering with the growth of the aerobic yeasts and moulds.—W. G.

Development of moulds. Bitting. *See* XIXa.

Patents.

Yeast; Process for the production of pure pressed ——. A. Wohl. E.P. 169,504, 23.6.20.

In the production of yeast from molasses the latter is sterilised before dilution, or after only a slight dilution, by treatment with strong sulphuric or other mineral acid, without boiling. The quantity of acid used may be such as would otherwise have to be added to the molasses wash before fermentation. Where phosphate or superphosphate is employed as yeast food, it may be heated with the acid before the latter is added to the molasses. The calcium sulphate thus formed, which may be reinforced by addition of a further quantity of this salt, effects a removal of part of the potassium from the acidified molasses, in the form of potassium calcium sulphate. In washing the yeast in a filter-press the latter is only partially filled with the yeast, in order to enable the adhering coloured liquid to be com-

pletely removed, after which some clean yeast is introduced to make up the charge before pressing.
—J. H. L.

Sugar and dextrins; Manufacture of —— from wood and other cellulose-containing material. Zellstoff-fabr. Waldhof, and V. Hottenroth. G.P. 340,212, 12.12.19. Addn. to 309,150 (J., 1920, 204 A).

In the process described in the chief patent, sulphuric acid in the sugar solution is precipitated as calcium sulphate by the addition of calcium carbonate, with or without a previous partial neutralisation by means of ammonia. The calcium sulphate is subsequently converted into ammonium sulphate and calcium carbonate, of which the latter is used for neutralising the acid in fresh solution, the carbon dioxide evolved being utilised in treating the calcium sulphate.—L. A. C.

Sugar [for fermentation] and similar products; Process for obtaining —— from wood and other cellulose-containing materials. Zellstoff-fabrik Waldhof, and V. Hottenroth. E.P. 147,415, 7.7.20. Conv., 18.4.17.

See G.P. 309,150 of 1917; J., 1920, 204 A.

Beer; Manufacture of —— and apparatus therefor. K. Plesch. E.P. 148,911, 10.7.20. Conv., 23.8.16.

See G.P. 314,464 of 1916; J., 1920, 245 A.

Fumaric acid. E.P. 146,411. *See* XX.

XIXa.—FOODS.

Cream; Formation of ——. O. Rahn. Forsch. Geb. Milchw. Molkereiw., 1921, 1, 213—233. Chem. Zentr., 1921, 92, IV, 878. (*Cf.* J., 1921, 746 A.)

Aggregations of fat globules in milk are broken up when the milk is heated, hence cream separates more slowly in heated milk. Substances which accelerate the formation of cream increase the aggregation of the fat globules. The fat content of the cream from unheated milk is about 5·4% lower than that of cream from heated milk. It would appear that there is a colloidal membrane which accounts for the aggregation of fat globules in milk and that this colloid is destroyed by heat. When gelatin is added to milk, the cream contains a greater proportion of gelatin than does the skim milk, the protein seeming to condense on the fat globules. The fat globules in heated milk are not "weighted" by coagulated albumin, since the cream from heated milk is always richer in fat than the cream from unheated milk.—W. P. S.

Cheese; Microscopical study of the bacteria in ——. G. J. Hucker. J. Agric. Res., 1921, 22, 93—100.

In the study of the ripening of cheese, the microscopical examination of microtome sections gave valuable information as to the number and type of organisms present. Ordinary cultural methods gave lower bacterial counts than the microscopical examination. This is largely due to the selective action of the media used and to the difficulty of separating satisfactorily the organisms from the cheese mass.—A. G. P.

Gemsbok beans. G. T. Bray. Analyst, 1921, 46, 401—402.

Gemsbok beans are obtained from *Bauhinia esculenta*, a plant indigenous to S. Africa; the beans, which are spherical (0·5 in. diam.) and edible, consist of 49% of shell and 51% of kernel. The kernels have the composition: Water, 4·0; oil, 41·6; proteins, 32·8; crude fibre, 1·3; other carbohydrates, 17·2; ash, 3·1%. The oil has a golden yellow colour and an agreeable taste; its characters are: Sp. gr. at 15°/15° C., 0·9211; $n_D^{40°}=1·464$; acid value, 0·6; saponif. value, 190·0; iodine value (Hübl, 17 hrs.), 95·6.—W. P. S.

Georgia velvet bean [Stezolobium deeringranum]; Biological analysis of ——. B. Sure and J. W. Read. J. Agric Res., 1921, 22, 5—15.

The shelled, ground bean was included in the food ration of white rats, and was found to be injurious in quantities comprising 40% of the total ration. Autoclaving for 1 hr. at 15 lb. pressure partly destroys injurious constituents and the product in quantities up to 60% of total ration is not harmful although 80% again shows signs of injury. The seed is rich in fat-soluble vitamins, which are not destroyed by autoclaving. The content of water-soluble vitamin is low. Both protein and salts of the bean are of a deficient character for growth.
—A. G. P.

Sulphites [in foods]; Routine tests for the presence of ——. A. E. Parkes. Analyst, 1921, 46, 402—403.

Ten g. of the material (*e.g.*, dried fruit, meat, fish, etc.) is mixed with 20 c.c. of water, then transferred to a flask, 10 c.c. of dilute sulphuric acid and a few small pieces of marble are added, and the mouth of the flask is covered with a piece of starch paper; a drop of 1% iodine solution is placed on the paper. If sulphite is present the blue colour of the iodine-starch is discharged more or less quickly according to the quantity of sulphite present. Hydrogen sulphide in small quantity does not interfere, but in testing meats it is better to add 1 c.c. of 5% copper sulphate solution to the reaction flask in order to retain any hydrogen sulphide present.—W. P. S.

Moulds; Effects of certain agents on the development of some ——. K. G. Bitting. Pp. 54+62 plates.

A record of an investigation, extending over 15 years, with three moulds, viz., *Penicillium expansum*, Link, *Alternaria solani* (E. and M.), Jones and Grout, and *Oidium lactis*, Fresenius. Nutrient broth prepared from tomatoes, in which all the moulds develop readily, was treated with one or other of the substances under investigation, and then sterilised, inoculated with mould spores (or mycelium in the case of *Alternaria*), and kept at about 23° C. The time elapsing before visible growth and the macroscopical and microscopical appearance of the moulds are recorded in tables, and 179 photomicrographs are appended. The first of the 7 groups of substances investigated comprised sugar, sodium chloride, and potassium nitrate. At high concentrations these retarded and restricted growth by inducing plasmolysis without killing the organisms. Sodium chloride at the highest concentration employed (15%) did not completely inhibit the development of *Penicillium*, nor did sugar at 50% concentration. The preservative action of potassium nitrate proved very slight, less than one-half that of sodium chloride. The second group comprised a number of spices and aromatic substances of household use. Of these only allspice, cinnamon, cloves, and mustard showed any marked antiseptic power, but the amounts of these required to exert a useful preservative action on foodstuffs would be so great as to render the flavour of the latter intolerable, even in the case of ketchups. The third group included various organic acids. Acetic acid had a notable retarding influence on the growth of *Penicillium*, the least susceptible of the moulds, a 1% solution delaying growth for 4 days; a similar effect was produced by butyric acid at a concentration of only 0·2%. Lactic, malic, and citric acids showed negligible preservative power except at very high concentrations, and tannic and tartaric acids were not much more effective against *Penicillium*. The fourth group comprised well-known preservatives. Benzoic acid proved the most effective, a 0·1% concentration delaying the development of *Penicillium* for 6 days, and results of the same order were obtained with boric acid or borax at 0·5%, formaldehyde at 0·1%, and formic acid at 0·1% concentration; growth took place within 4 days in presence of 0·2% salicylic acid. The free acids were in general more effective than their sodium salts. The fifth group included certain inorganic salts, viz., copper sulphate, ferrous sulphate, lead acetate, sodium sulphate and sulphite, stannous oxide, phosphate, chloride, and sulphate, and zinc chloride. The results with these were very irregular as between one mould and another. Thus 2% of sodium sulphate produced a notable retardation and restriction of the growth of *Penicillium* but scarcely affected *Oidium*, and 0·2% sodium sulphite delayed the growth of *Penicillium* and *Alternaria* for 5 and 8 days respectively but had very little effect on *Oidium*. The sixth group included some strong mineral acids and alkalis. Sulphuric acid proved more injurious than hydrochloric or nitric acids, 0·2% of the former having about the same effect on *Penicillium* as 0·5% of hydrochloric or nitric acid, growth being retarded for about 3 weeks. *Oidium* was rather more resistant to these acids. The seventh group included some alkaloids, which were not notably antiseptic at the concentrations employed, and also mercuric chloride, phenol, and oxalic acid. *Oidium* proved the most resistant to the last three substances, developing rapidly in presence of 0·02% of mercuric chloride, 0·1% of phenol, and 0·5% of oxalic acid. Mixtures of two or more antiseptic substances were found, in general, to be less effective than the single ingredients.—J. H. L.

Hydrocyanic acid in Sudan grass C. O. Swanson. J. Agric. Res., 1921, 22, 125—138.

THE maximum production of hydrocyanic acid from Sudan grass was obtained by macerating the material and digesting with water at room temperature for 6 hrs. or more. Practically all the acid was obtained from the leaves, none being present in well-developed stems. More hydrocyanic acid was obtained from young than from old plants, but this is probably due to the larger proportion of stem to leaf in the latter. When leaves only are extracted the age of the plant makes little difference to the yield, except that the yield decreases when the plants approach maturity. Hydrocyanic acid does not occur free in the green plant, and is not liberated by the action of acids, but is a product of enzyme action during the maceration of the plant tissue. It is also produced in wilted plants. Inhibition of the enzyme action, *e.g.*, by treatment with hot water, prevents any formation of hydrocyanic acid.—A. G. P.

Quercetin; Occurrence of —— in Emerson's brown-husked type of maize. C. E. Sando and H. H. Bartlett. J. Agric. Res., 1921, 22, 1—4.

QUERCETIN and a glucoside of quercetin were isolated from the alcoholic extract of the brown-husked maize. Both are lemon-yellow in colour. The glucoside has m.pt. 220°—222° C. and resembles that isolated from rag-weed pollen (J., 1919, 756 A).
—A. G. P.

Acid taste. Wo. Ostwald and A. Kuhn. Kolloid-Zeits., 1921, 29, 266—271.

THE hydrogen ion concentration is not a quantitative measure of either the taste or swelling power towards gelatin) of an acid. The stronger the swelling power of an acid, the greater the hydrogen ion concentration must be before an acid taste is detectable. Strong swelling acids taste less acid than weak swelling acids of the same hydrogen ion concentration. Solutions of acid salts and buffer-mixtures taste more strongly acid than solutions of their acids of the same hydrogen ion concentration. (*Cf.* J.C.S., Dec.)—J. F. S.

Yeast. Henneberg and Böhmer. *See* XVIII.

PATENTS.

Food; Manufacture of an article of ——. Vollbrot Verwertungs-Ges.m.b.H. E.P. 146,371, 2.7.20. Conv., 8.9.17.

As a development of the process of E.P. 146,370 (*cf.* U.S.P. 1,213,627; J., 1917, 401) the grain, after being soaked in water at 60°—65° C., whipped with wire brushes to separate the husks, and reduced in known manner, is dried and reduced to flour.—H. H.

Fruit and vegetable refuse; Method for the utilisation of ——. W. Matzka. E.P. 147,833, 9.7.20. Conv., 8.6.18.

FRUIT and vegetable waste materials, *e.g.* the skins or peelings of asparagus, peas, beans, bananas, etc., are treated with water and crushed to extract the juice, break up the cellular material, and separate the fibres, which are then further extracted with boiling water, and treated for the production of textile fibres. The extracts are concentrated for use as flavours, soups, etc.—H. H.

Alimentary substances and manufacture thereof. P. Claes. E.P. 148,488, 10.7.20. Conv., 15.10.17.

MILK by-products, etc., *e.g.*, whey, buttermilk, or sour milk, are sterilised, and the lactic acid is neutralised. The resulting liquid is made homogeneous and is concentrated *in vacuo* below 70° C. to obtain on cooling a pasty mass. Crude lactose may be separated by crystallisation either from the filtered partly-concentrated liquid or from a hot-water extract of the product.—H. H.

Drying of organic substances. F. E. Beeton, and Trufood, Ltd. E.P. 169,471, 27.3.20.

AN organic liquid, such as milk, is dried in a spraying apparatus having an air tube passing down the centre of the tube conveying the liquid, both tubes terminating in a tapered block with peripheral grooves and central opening and with an enclosing cap so fitting as to leave a conical annulus between block and cap. The liquid, after preliminary concentration, is supplied at a pressure of about 200 lb. per sq. in., while air or other gas is supplied at a pressure 40—80 lb. lower. By this means skimmed milk concentrated to 22° B. (sp. gr. 1·18) may be dried successfully. The product is soluble in water without mechanical mixing.—J. H. J.

Food; Desiccating ——. J. F. Kelly. U.S.P. 1,393,540, 11.10.21. Appl., 4.8.19.

A SOLUTION containing a reducing sugar is applied to cut surfaces of raw succulent vegetable and fruit products prior to desiccation in the usual way.
—H. H.

Shortening material; Dry —— and process of making same. H. V. Dunham. E.P. 169,493, 22.6.20.

STARCHY material and water in the proportion of 1:10 are heated together to form starch paste which is emulsified with 2 pts. of melted coconut fat. The emulsion is passed through a homogenising apparatus to render the product stable. It is then passed over drying cylinders and the flaky product is ground to a fine powder.—J. H. J.

Albumin; Nutriment-containing —— and the method of producing it. A. Herzfeld, Assr. to The Chemical Foundation, Inc. U.S.P. 1,391,683, 27.9.21. Appl., 15.4.18.

Waste moist yeast is sterilised by addition of alkali and heating, and its water evaporated. Sugar juice containing sucrose is added to the mass, which is concentrated to a syrup, partly inverted by the addition of fresh yeast, and then heated nearly to boiling.—J. H. J.

Coffee; Process for producing soluble concentrated ——. J. W. Scott, Assr. to Arbuckle Bros. U.S.P. 1,393,045, 11.10.21. Appl., 24.9.18.

A coffee extract is prepared by percolating ground coffee in successive vessels with a hot liquid in such a way that the liquid at the highest temperature permeates the most spent portion of the coffee, and passes at decreasing temperatures to coffee of successively increasing strength, whereby an extract rich in aroma is obtained. This extract is atomised into a highly heated blast containing aromatic and volatile products from coffee-roasting operations. Instantaneous concentration of the extract is thus effected without damaging the aroma of the product.—G. F. M.

Grain; Apparatus for processing —— under high pressure and high temperature. Treating wheat-grains and product therefrom. C. V. Rowell. U.S.P. 1,395,014–5, 25.10.21. Appl., 12.2.20.

See E.P. 140,457 of 1920; J., 1921, 445 a.

Milk; Apparatus for treating [condensing] and canning ——. The Borden Co., Assees. of B. E. Taylor. E.P. 148,496, 10.7.20. Conv., 7.11.18.

Preservation of corpses, carcases, and the like [meat, fish, etc., by injection of preserving liquids or gases]. R. Ihlenfeldt and G. Scheib. E.P. 149,222 and 149,225, 12.7.20. Conv., 15.5.16 and 18.12.18.

XIXb.—WATER PURIFICATION; SANITATION.

Waters; Determination of phosphates in ——. D. Florentin. Ann. Chim. Analyt., 1921, 3, 295—296.

Ten c.c. of the water is treated with a few drops of molybdic acid reagent (10% ammonium molybdate solution, 100, and 50% sulphuric acid, 300 c.c.) and one or two drops of stannous chloride solution (tin, 0·1 g., dissolved in hydrochloric acid, 2 c.c., and diluted to 10 c.c.). A blue coloration develops if phosphates are present, as little as 0·01 mg. P_2O_5 per l. yielding a distinct colour. The latter reaches its full intensity in 10 mins. and may be compared with a series of standards containing known amounts of phosphate.—W. P. S.

Permutite; Function of water of crystallisation in the behaviour of ——. Günther-Schulze. Z. Elektrochem., 1921, 27, 402—406.

The permutites of the alkali and alkaline-earth metals contain $5H_2O$, and it is generally considered that, of these, 3 mols. are water of crystallisation and 2 mols. "water of constitution." Experiments with potassium permutite, however, showed that the water content varies continuously with the temperature and the vapour pressure, and that no such distinction is justified. The molecular volume was determined at successive stages of hydration, and it was found that the increments of volume became successively greater with each molecule of water added. So long as the permutite has not been completely dehydrated, it can again be fully hydrated, but after ignition it takes up only about $1\frac{1}{2}H_2O$. The permutites of copper, silver, chromium, and aluminium, formed by basic exchange from hydrated alkali permutites contain 6—$8H_2O$, but when formed from ignited alkali permutite the water deficiency persists in the derived permutite. Ignited permutite reacts more slowly with metallic salts than hydrated permutite, but the same equilibrium is eventually reached. (*Cf.* J.C.S., Dec.) —E. H. R.

Toxicity of salts. Greaves and Lund. *See* XVI.

Toxicity of metals to yeasts and moulds. Villedieu. *See* XVIII.

Patents.

Sewage and other liquids; Separation or settlement of matters in suspension in —— from such liquids. Activated Sludge, Ltd., and J. A. Coombs. E.P. 170,032, 13.5.20.

Continuous deposition of sludge in settling tanks, normally kept full, is effected by supplying the liquid from the treating tanks alternately to one tank or set of tanks and to a second tank or set of tanks, thus allowing a completely quiescent period for settling during cessation of supply. The alternation of supply and cessation of supply is effected by using an air-lock system between the treating and the settling tanks. This air-lock system is actuated by controlling the air pressure in the conduits by the supply of air or liquid to a float vessel. —H. H.

Sewage treatment. H. W. Morgan, Assr. to The Dorr Co. U.S.P. 1,392,197, 27.9.21. Appl., 10.11.20.

Sewage is submitted to sedimentation and decantation in a basin provided with means for drawing the sludge to an outlet in the bottom. The sludge when withdrawn is supplied to a deep body of similar sludge undergoing biological digestion. —J. H. J.

(a) *Sewage treatment; Process of ——.* (b, c) *Treatment of sewage.* (d) *Apparatus for treating sewage.* C. L. Peck, Assr. to The Dorr Co. U.S.P. 1,392,211–4, 27.9.21. Appl., (a, b) 27.3.20, (c) 31.7.20, (d) 14.10.20.

(a) Sewage is subjected to the action of an organism favourable to its clarification and at the same time air is forced through it in the presence of an iron compound, whereby atmospheric nitrogen is fixed and the products of fixation are absorbed. (b) Nitrogen-rich solid matter in sewage is comminuted to a size which is smaller than that of the nitrogen-poor solid matter. The sewage is then screened whereby the nitrogen-poor solid matter is retained on the screen. The sewage containing the nitrogen-rich solid matter is submitted to biological clarification. (c) Sewage is inoculated with biological growths favouring clarification, the p_H is adjusted between 3 and 9, and there is introduced some agent conducive to a favourable environment for biological action. (d) A receptacle is divided by a transverse tray into an upper settling chamber with openings near its periphery communicating with a lower chamber. Mechanical means are provided for working solids deposited on the tray towards the periphery.—J. H. J.

Sterilising; Process of ——. J. C. Baker. U.S.P. 1,378,644, 17.5.21. Appl., 13.9.19.

An aqueous solution of nitrogen trichloride is used as a sterilising agent, the substances necessary for its formation being brought together continuously during the period of use and at the same rate as the product is consumed.

Disinfecting liquids; Manufacture of ——. M. Sarason. G.P. 340,374, 23.8.17. Addn. to 336,798 and 339,154 (J., 1921, 600 A, 748 A).

Solutions containing up to 40% of cresols in sulphite-cellulose waste liquor are obtainable by the addition of 2—5% of alkali salts of fatty or naphthenic acids.—L. A. C.

Waste liquors containing soapy or soap-making organic matter; Treatment of ——. The Dorr Co., Assees. of C. L. Peck. E.P. 147,184, 7.7.20. Conv., 1.7.19.

See U.S.P. 1,349,530 of 1920; J., 1920, 663 A.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Harmine and harmaline. Synthesis of norharman. W. O. Kermack, W. H. Perkin, jun., and R. Robinson. Trans. Chem. Soc., 1921, **119**, 1602—1642.

Norharman was synthesised by the following reactions:—1-methyl-indole-2-carboxylic acid, prepared from phenylmethylhydrazine and pyruvic acid by the method of Fischer and Hess (Ber., 1884, **17**, 561), was converted into the chloride by means of acetyl chloride and phosphorus pentachloride and the chloride was converted into 1-methylindole-2-carboxyacetalylamide by treating in the cold with aminoacetal in chloroform. On adding the acetalylamide to a saturated solution of hydrochloric acid n alcohol, 2-keto-1-methyl-2.3-dihydro-4-carboline was obtained, and this on reduction with zinc dust and hydrogen was converted into 4-carboline (norharman). Two methods are described for the degradation of harmine to norharman. Demethylaion of harmine gives harmol which by fusion with lkali yields norharmolcarboxylic acid. Heating with glycerol converts this acid into the base, norharmol, which is reduced by zinc and hydrogen o norharman. In the second method harmane btained from harmine through aminoharmane or y condensing tryptophane with acetaldehyde in ulphuric acid and oxidising with chromic acid, n boiling with benzaldehyde gives benzylidenearmane, which is oxidised by permanganate in yridine to norharmancarboxylic acid, the latter ielding norharman on heating with glycerol. The ynthesis of norharman affords independent conrmation of the correctness of the constitution ssigned to harmine (Perkin, J., 1919, 791 A). A eneral method for the preparation of chlorides of ndole-2-carboxylic acid and allied acids consists in lowing the acid to react with phosphorus pentahloride in the presence of acetyl chloride and at he end of the reaction removing the excess of acetyl hloride and phosphoryl chloride by distillation in high vacuum.—P. V. M.

rganic bases; Iodic acid as a microscopical reagent for the detection of ——. L. Rosenthaler. Schweiz. Apoth.-Zeit., 1921, **59**, 477—479. Chem. Zentr., 1921, **92**, IV, 1055—1056.

he addition of iodic acid to solutions of organic ases produces precipitates which possess a characristic structure under the microscope. Thus rychnine gives clusters of fine needles; cinchonine, eaves of pointed needles; morphine, free iodine nd needles or small stars; codeine, clusters of ystals with a flattened or bevelled surface; drastinine, layers of cubes united into large ystals; narceine, piles of small, fine black needles; ridine, spherical crystals; quinoline, needles rrounded by fine dark needles; aniline, large ystalline masses with individual spear-shaped ystals. Other alkaloids and organic bases form morphous precipitates which are of a characteristic colour. Thus, pyramidone, bluish-violet to brown; physostigmine, gradual formation of bluish-violet; brucine, yellowish-red.—F. M. R.

Phenylacetaldehyde; Quantitative determination of ——. A. Reclaire. Perf. Ess. Oil Rec., 1921, **12**, 341.

In the determination of the aldehyde content of samples of phenylacetaldehyde by treatment with sodium bisulphite in a cassia flask, the non-aldehydes are apt to settle to the bottom of the flask and their volume cannot be read off. The addition of brine causes precipitation of the bisulphite compound which also causes difficulties in reading the volume. These difficulties are overcome by using a flask with a narrow graduated extension in the bottom. Five c.c. of aldehyde and 20 c.c. of 30% bisulphite solution are vigorously shaken for some minutes, and the whole is then placed in a boiling-water bath. After some time boiling water is added until the solid compound first produced is redissolved. More water is then added and the non-aldehydes settle down into the graduated tube and the volume is read off when cold.—G. F. M.

Oxalic acid from lignin; Formation of ——. E. Heuser and A. Winsvold. Cellulosechem., 1921, 2, 113.

When 4 g. of lignin is heated with 50 g. of potassium hydroxide for 40 mins. at 280° C. a 20% yield of oxalic acid is obtained. (*Cf.* J.C.S., Dec.) —F. M. R.

Citronellol and citronellal; Estimation of —— *by formylation.* C. T. Bennett. Perf. Ess. Oil Rec., 1921, **12**, 351.

The formic acid method for the determination of citronellol and citronellal is absolutely unreliable. With pure citronellol the results were high when 100% acid was used, and low with a weaker acid. (*Cf.* Pfau, J., 1921, 674 A.)—G. F. M.

Cineol; The cresineol method for the determination of ——. T. T. Cocking. Perf. Ess. Oil Rec., 1921, **12**, 339.

In the determination of cineol by the "cresineol" method (J., 1920, 610 A, 704 A, 832 A) in oils containing less than about 45%, only a very small quantity of cresineol crystallises out owing to its high solubility in terpenes etc., and a definite freezing point cannot be obtained. Satisfactory results can be obtained by the method, however, if the oil is previously enriched by the addition of an equal weight of pure cineol, or better still, by the use of an equivalent weight of pure recrystallised cresineol. 3 g. of the oil is mixed with 2·1 g. of melted *o*-cresol, and if no crystals have formed when the temperature has dropped to 24° C. the oil contains less than 45% of cineol, and 5·1 g. of cresineol is accordingly added, the mixture warmed until liquid, and the freezing point determined in the usual manner. The percentage of cineol corresponding with this is obtained from the curve, and that in the original oil is obtained by subtracting 50 and doubling the remainder. The method was applied to the determination of cineol in the oils of lavender, spike, and rosemary. The results showed that English lavender oil is intermediate in its cineol content between French oil and spike oil. —G. F. M.

Piperitone; Constitution of ——. *Essential oil from Andropogon iwarancusa, Jones.* J. L. Simonsen. Trans. Chem. Soc., 1921, **119**, 1644—1654.

The main constituent (about 80%) of the oil of *Andropogon iwarancusa*, Jones, is a ketone identical with *d*-piperitone. Racemisation with dilute alkali gives a ketone, the identity of which with *dl*-piperitone is proved by the formation of a benzylidene derivative and a hydroxylamino-oxime, by oxidation to thymol with ferric chloride, and by reduction to menthol. Consideration of the products, *l*-γ-acetyl-α-isopropylbutyric acid and *dl*-Δ^1-isopropylglutaric acid, formed by oxidation with cold alkaline permanganate establish the ketone as *d*-Δ^1-*p*-menthen-3-one. The oil has the following characters:—Sp. gr. at 30° C., 0·9203; n_D^{30}=1·481; $[\alpha]_D^{30}$=51·68°; acid value, 0·7; saponif. value, 12·0; saponif. value after acetylation, 47·4; besides the ketone it contains a hydrocarbon approximating to $C_{10}H_{16}$.—P. V. M.

Essential oil of Mosla japonica, Maxim. Y. Murayama. Yakugakuzasshi (J. Pharm. Soc. Japan), 1921, No. 475, 769—786.

A new terpene, moslene, $C_{10}H_{16}$, was isolated as its nitrosochloride, white crystals, m.p. 111°, from the terpene fraction, b.p. 173°—175° (59°—60° C. at 10 mm.), of the essential oil of *Mosla japonica*, Maxim, previously freed from *p*-cymene. Moslene appears to be a dihydro-*p*-cymene. In the sesquiterpene fraction of the oil, caryophyllene was identified.—K. K.

Moslene; Occurrence of —— in essential oils containing p-cymene. Y. Murayama. Yakugakuzasshi (J. Pharm. Soc. Japan), 1921, No. 475, 786—790.

Moslene (*cf. supra*) has been identified in the terpene fractions of ajowan oil and the oil of *Mosla grossescrrata*, Maxim.—K. K.

Essential oils of the Leptospermum; A new phenol in the ——. A. R. Penfold. Perf. Ess. Oil Rec., 1921, 12, 336.

The essential oil obtained from the leaves and terminal branches of *Leptospermum flavescens* contains a phenolic substance varying in amount from 1 to 8% according to the locality from which the material was collected. The phenol, leptospermol, formed an almost colourless, viscous liquid, possessing a pleasant odour and giving with ferric chloride in alcoholic solution a brilliant orange-red coloration, and with copper salts an intense blue. It has the following characters: B.p. 145°—146° C. at 10 mm., and 275°—278° C. at 770 mm., sp. gr. at 20° C. 1·073, n_D^{20}=1·5000. Leptospermol strongly resembles tasmanol, a constituent of certain eucalyptus oils, in many of its properties.—G. F. M.

Camphorated oils; Determination of camphor in ——. D. A. Wallace and S. B. Plummer. Amer. J. Pharm., 1921, 93, 600—604.

Five g. of the camphorated oil is heated at 120° C. for 5 hrs. if the oil present is cottonseed oil, for 4 hrs. if the oil is olive oil or earthnut (arachis) oil, or for 3 hrs. if the oil is sesamé oil; the loss in weight is then corrected by 0·0142 g., 0·0108 g., 0·0138, or by −0·0015 g., respectively, to obtain the amount of camphor in the 5 g. of sample, these corrections representing the gain in weight of the oil itself during the heating. The percentage of camphor may also be calculated from the optical rotation of the sample; when the observation is made at 20° C. in a 200 mm. tube, each angular degree of rotation is equivalent to 0·98—0·99% of camphor.—W. P. S.

Acetic acid etc. from fibrous materials. Pringsheim. *See* V.

Patents.

Fumaric acid; Manufacture of ——. C. Wehmer. E.P. 146,411, 2.7.20. Conv., 28.9.15

Fumaric acid is obtained by the fermentation of saccharine liquids, such as beer wort, grape juice, or solutions of dextrose, maltose, beet sugar, etc., containing the requisite nutritive material, with a pure culture of *Aspergillus javanicus*, otherwise known as *A. fumaricus*. *Example:* 100 g. of sugar in 1 l. of water is sterilised and inoculated with the fungus; 35 g. of chalk and the usual nutritive salts for the fungus are added, and after fermentation for 2—3 weeks at 20° C., 120 g. of crystalline calcium fumarate is deposited from the solution. From this salt fumaric acid is obtained by treatment with the requisite amount of sulphuric acid and extraction from the calcium sulphate with alcohol.
—G. F. M.

Nitrogen-containing addition and condensation products from acetylene and ammonia; Manufacture of ——. Chem. Fabr. Rhenania A.-G., B. C. Stuer, and W. Grob. E.P. 147,067, 6.7.20. Conv., 20.11.13.

Condensation products of acetylene and ammonia are obtained by passing the mixed gases, either dry or moist, at normal or increased pressure, over catalysts, particularly the oxides of iron, or natural ores of iron, such as bog-ore, bauxite, or chrome-ironstone. The temperature of the reaction may vary within wide limits; the higher the temperature, the further condensation proceeds. For example, at about 300° C. the reaction $C_2H_2+NH_3=CH_3.CN+H_2$ predominates. Further condensation between 2 and 3 mols. of acetylene and 1 mol. of ammonia results in the formation of pyrrole and picoline respectively, and at 550° C. the formation of these substances and their homologues becomes more pronounced.—G. F. M.

Ethylene chloride [from distillation gases]; Production of ——. Th. Goldschmidt A.-G., and F. Bergius. E.P. 147,909, 9.7.20. Conv., 29.2.16.

The mixed gases obtained from the distillation of coal, lignite, peat, oil, or other carbonaceous matter, after subjection to the usual purification process for removal of ammonia, tar, sulphur, etc., are cooled below 120° C., and brought into contact with the approximately theoretical quantity of chlorine in presence of a suitable catalyst, such as the chlorides of iron, copper, or antimony. The unsaturated hydrocarbons (chiefly ethylene) are chlorinated and the products separated from the gaseous mixture by refrigeration, compression, or other suitable means. In this way ethylene dichloride is obtained directly from the distillation gases without reducing their calorific power.—G. F. M.

Arsenical compounds. Lowy Laboratory, Inc., Assees. of O. Lowy. E.P. 152,298, 9.4.20. Conv., 4.10.19.

Stable aqueous solutions of arsenobenzene derivatives, such as arsphenamine (salvarsan), are obtained by dissolving the substances in water which has been rendered air-free by subjection to a vacuum, the solution being again subjected to a vacuum. Sodium hydroxide, in excess of the proportion necessary for neutralisation is added in order to minimise decomposition. The oxygen-free solution is then enclosed in hermetically sealed, evacuated containers.—D. F. T.

Isobornyl-ester-camphene mixture and process of making same. L. G. Wesson. E.P. 169,198, 17.5.20.

See U.S.P. 1,372,382 of 1921; J., 1921. 369 A. The mixture of pinene hydrohalide and an organic acid is heated in presence of a free metal (silver, copper, arsenic, bismuth, antimony, mercury, palladium, gold), then a small quantity of zinc chloride, or of metallic zinc or a zinc compound capable of being converted into the chloride, is added, and the heating continued.

Colloidal metallic elements and compounds; Method of preparing ——. Chem. Fabr. K.. Albert, and L. Berend. E.P. 169,758, 3.6.20.

Metals, *e.g.*, copper, silver, mercury, cerium, antimony, arsenic, or their reducible compounds are heated with cellulose waste liquors at a temperature above 100° C. until they are converted into colloidal form. The cellulose liquor acts both as a reducing agent and as a protective colloid, and alkaline conditions should be maintained throughout the process. Other reducing agents, *e.g.*, hydrogen sulphide, may be added. Separation of the colloids is effected by precipitation with alcohol, and insoluble inorganic substances may be mixed with the colloidal products.—C. A. K.

Alkali formates; Manufacture of ——. G. C. Bacon. From Oldbury Electro Chemical Co. E.P. 170,185, 17.9.20.

A mixture of an alkali (sodium) carbonate and an alkaline-earth (calcium) hydroxide is treated with carbon monoxide above 100° C. at a pressure of 70 to 100 lb. per sq. in.—L. A. C.

Thyroid product and process of preparing the same. E. C. Kendall, Assr. to University of Minnesota. U.S.P. 1,392,767, 4.10.21. Appl., 7.6.16.

Thyroid tissue is broken down by heating the desiccated fat-free substance with 80—95% alcohol containing 1—2·5% of sodium or potassium hydroxide and a small amount of zinc oxide, until decomposition of the thyroid proteins into simpler constituents is effected.—G. F. M.

Thyroid substance and process of making it. E. C. Kendall. U.S.P. 1,392,768, 4.10.21. Appl., 20.8.19.

Thyroid proteins are hydrolysed with an alkali, the solution filtered from insoluble impurities, acidified at a temperature below 25° C., and the flocculent precipitate separated and dissolved in sodium hydroxide solution. The filtered solution is again acidified below 25° C. and the precipitate dissolved in 85—95% ethyl alcohol containing a little hydrochloric acid, insoluble matter being filtered off. The filtrate after first neutralising with sodium hydroxide and filtering off any precipitate, is again slightly acidified with hydrochloric acid, stirred with barium hydroxide and heated to produce a precipitate containing thyroxin, which is filtered off. To the filtrate aqueous barium hydroxide is added, the alcohol is evaporated, and the products remaining in the resulting aqueous solution are separated into portions respectively soluble and insoluble in barium hydroxide. The above-mentioned precipitates containing thyroxin are heated with distilled water to dissolve out any further soluble portions, and the insoluble residues are dissolved in dilute sodium hydroxide solution, carbon dioxide being excluded. The solutions containing portions soluble in barium hydroxide are treated with sufficient sodium sulphate to precipitate all the barium, and the filtered solution, and the above solution of insoluble portions in sodium hydroxide, are both treated with carbon dioxide and precipitates of similar degrees of purity having been combined, they are dissolved in hot dilute sodium hydroxide solution and sufficient sodium chloride is added to make a 25% solution. On cooling crystalline precipitates are formed which are again subjected to the purification process above described with barium hydroxide etc. until the precipitates obtained by heating the 20% sodium chloride solutions and cooling are colourless and highly crystalline. These crystalline precipitates are then dissolved in 85—95% ethyl alcohol containing a small quantity of sodium hydroxide, the solution is acidified with acetic acid and heated to boiling. On cooling a fine white crystalline precipitate containing 65% of iodine is obtained.—G. F. M.

Ferruginous preparations; Manufacture of ——. F. Stohr. U.S.P. 1,393,049, 11.10.21. Appl., 3.3.21.

A ferruginous preparation is made by adding to milk a reducing agent, a mixture of sucrose with a larger amount of invert sugar, commercial ferrisaccharate, and an alkali to neutralise any acidity of the mixture, which is then evaporated to the desired consistency *in vacuo*.—G. F. M.

Chlorhydrins; Process of making ——. B. T. Brooks, Assr. to Chadeloid Chemical Co. U.S.P. 1,394,664, 25.10.21. Appl., 24.9.19.

Chlorhydrins are produced by passing a mixture of chlorine and petroleum still gases in suitable proportions into an emulsion of a solvent immiscible with water and an aqueous saline extraction medium. The chlorine and still gases react with formation of hydrogen chloride and chlorhydrins, the latter being recovered subsequently from the resulting solution.—D. F. T.

Alkylene cyanhydrins; Manufacture of ——. Chem. Fabr. Röhm und Haas. E.P. 150,708, 1.9.20. Conv., 3.9.19.

See U.S.P. 1,388,016 of 1921; J., 1921, 790 a.

Ergot; Highly-active preparation of —— *and process of making same.* A. Stoll, Assr. to Chemical Works formerly Sandoz. U.S.P. 1,394,233, 18.10.21. Appl., 11.4.19.

See E.P. 125,396 of 1919; J., 1920, 349 a.

Viscous liquids from tar oils. E.P. 149,317. *See* III.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Silver iodide-bromide emulsions; Photochemistry of primary ——. C. A. Schleussner and H. Beck. Z. wiss. Phot., 1921, 27, 105—112.

The optimum of the iodide content of a primary silver iodide-bromide emulsion is dependent on the method ot emulsification, and lies between 1 and 5% of silver iodide referred to the silver bromide. The steeper gradation of silver iodide-bromide emulsions for light and the smaller sensitiveness for Röntgen rays is explained by the sensitising action of silver iodide for light. The precipitation of silver iodide along with silver bromide makes the crystallisation of the emulsions more difficult. Sensitising by Erythrosin is unfavourably affected by high content of silver iodide.—J. F. S.

Desensitising with potassium iodide. Freund's method. Lüppo-Cramer. Phot. Ind., 1921, 840.

A re-investigation, by sensitometric methods, of Freund's process for desensitising photographic plates by treatment with potassium iodide, on the lines recommended by Bolas (J., 1921, 828 a), resulted in a confirmation of the previous objections raised against the process. Exposure must be increased about ten times to compensate for the destructive effect of the iodide on the latent image, the resulting negative is flat, and fixation in "hypo" is very slow.—B. V. S.

Patents.

Ozobrome process of photography. L. Ratier. E.P. 148,462, 10.7.20. Conv., 16.6.19.

To avoid the use of alum in the Ozobrome process the carbon paper is previously prepared by treatment with ferricyanide, bichromate, and bromide or two of these. The pigmented paper may be bathed in a solution of the salts or the salts may be added to the pigment preparation with which the carbon paper is coated. Where only two of the constituents are used in the previous preparation of the paper the third is used as a bath just before applying the carbon paper to the silver print.—B. V. S.

Toning baths. Mimosa A.-G., and F. Formstecher. E.P. 169,378, 7.9.20.

See G.P. 337,869 of 1920; J., 1921, 639 A.

XXII.—EXPLOSIVES; MATCHES.

Mixed [sulphuric and nitric] acids; Method for the direct estimation of water in ——. E. Berl and W. von Boltenstern. Z. angew. Chem., 1921, 34, 527—528.

The water content of mixed acids, on which in the manufacture of nitrocellulose the nitrogen content of the product depends, may be estimated calorimetrically. 200 c.c. of distilled water is placed in a vacuum bottle fitted with an agitator and a thermometer graduated in $\frac{1}{10}$ degrees, and stirred for a few minutes, the temperature being read every minute. 20 c.c. of the mixed acid is then run in through a fine glass tube dipping below the surface of the water, the addition taking about 75 secs. Temperatures are read for several minutes more and the true temperature rise obtained by applying corrections in the way used with the Mahler bomb calorimeter. The water content of the mixed acid is read off from a curve constructed from successive dilutions of a sample of known composition. For different proportions of the two acids different curves are necessary, but the variations are relatively slight. Variations in the N_2O_3-content also require a correction, but the method is not affected by the presence of organic matter. The method is accurate to within 0·05—0·06% H_2O, and is very rapid.—C. I.

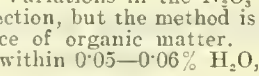
Patents.

Fuses or ignitors containing carboniferous substances and liquefied gas, such as liquid air. Fuses or ignitors in which liquefied gases are used. A. Kowastch and C. A. Baldus. E.P. (A) 148,534 and (B) 148,535, 10.7.20. Conv., 16.8.16 and 16.7.15.

(A) Explosives such as lead azide, mercury fulminate, or trinitrotoluene are thoroughly mixed with about equal quantities of soot, powdered cork dust, or other substances capable of absorbing a liquefied gas. The mixture is afterwards saturated with the liquefied gas. (B) The fuse consists of a metal container perforated with holes, which allow the liquefied gas to soak into the carbonaceous carrier. It can be saturated with liquefied gas before being introduced into the borehole.
—H. C. R.

Explosive; Manufacture of a new ——. O. Imray. From Soc. of Chem. Ind. in Basle. E.P. 170,359, 14.7.20.

Cyanuric triazide



is prepared by treating aqueous solutions of sodium azide with a cyanuric halide, or by diazotising solutions of cyanuric trihydrazide. It is non-poisonous, not affected by moisture or light, and does not react with metals used for detonator casings. It melts at 94° C. and can be cast into capsule shells, having a density of 1·5 when so filled. It explodes when heated to 170° C. and is not more sensitive to friction or shocks than mercury fulminate. Its detonating power is superior to that of mercury fulminate and lead or silver azide.—H. C. R.

Explosives; Manufacture of —— containing chlorates or perchlorates. Manufacture of fireworks etc. Explosive or propellant. "Hassia" Sprengstoff-Fabr., G.m.b.H. G.P. (A) 300,128, 6.10.15, (B) 305,530, 8.4.17, and (C) 303,280, 23.9.16.

(A) Powdered chlorates or perchlorates are mixed with sulphite-cellulose waste liquor, and the pasty mass is allowed to harden, yielding a dark, powdery explosive material suitable for use in rifle cartridges or match compositions. (B) Similar mixtures may be used in fireworks or illuminating shells etc. (C) A mixture of an aqueous solution of an oxygen-carrier and animal or wood charcoal is rapidly dried, *e.g.*, on a drum-dryer, the product thereby being rendered safer for handling and transit than if dried by the usual means.—L. A. C.

Explosive; Manufacture of an ——. Chem. Fabr. Griesheim-Elektron. G.P. 309,298, 10.4.15.

An explosive of high shattering power, consisting of a mixture of guanidine perchlorate and diguanidine perchlorate, is prepared by heating a mixture of ammonium perchlorate and dicyanodiamide.
—L. A. C.

Incendiary filling for shells. Sprengstoff A.-G. Carbonit. G.P. 305,520, 23.12.16.

A mixture of aluminium, the sulphate of an alkaline-earth (*e.g.*, plaster of Paris), and a nitrate of the same alkaline-earth, is filled into a container capable of being melted by the ignited filling and provided with one or more openings. The filling has a high temperature of burning, and burns sufficiently slowly to ensure the destruction of airships.—H. C. R.

Smoke signals; Production of ——. H. Rathsburg. G.P. 340,779, 3.7.18.

A mixture for the production of smoke signals is composed of 1 pt. of magnesium mixed with about 4 pts. of lead nitrate, lead monoxide, or potassium permanganate.—J. S. G. T.

Explosive and process for manufacturing it. C. I. Tisell. U.S.P. 1,393,984, 18.10.21. Appl., 23.7.18.

See E.P. 116,890 of 1918; J., 1919, 513 A.

XXIII.—ANALYSIS.

Distillation apparatus [; Laboratory ——]. P. Gross and A. H. Wright. J. Ind. Eng. Chem., 1921, 13, 701—703.

An efficient fractionating column consists of a straight glass tube with a series of small bulbs drawn in on opposite sides of the tube, each pair of bulbs lying between the pair next above and below; the bulbs permit of rapid heat exchange with the air outside. A micro-distillation flask has a bulb at the top of the neck, the bulb being provided with a side tube leading to a small condenser. A narrow well is formed at the top of the bulb; this well contains a drop of mercury into which dips the end of a copper-constantan thermo-couple. A receiver for vacuum fractionations, a modified McLeod gauge, and a method for protecting corks from certain vapours (by means of a small glass ball-condenser just below the cork to condense the vapours before they reach the latter) are also described.—W. P. S.

Calorimeter combustion bomb; New type of —— made of Krupp's special steel. W. A. Roth, R. Macheleidt, and I. Wilms. Z. angew. Chem., 1921, 34, 537—538.

A new combustion bomb designed to replace the usual type with enamelled or platinised interior is made of Krupp's special acid-resisting "V_2A" steel (20—23% Cr, 6—9% Ni, 0·1—0·3% C). The bomb, which may be of either the Langbein or

Kroeker type, is provided with a quartz or porcelain dish, in which the substance to be burnt is placed, and which is hung in the interior of the bomb from hooks in each of the electric leads. The insulated lead consists of a rod of the chrome-nickel steel, and the other is a tube (made of silver, as it has not yet been possible to make a small bent steel tube) which serves for the admission of oxygen and the exit of the gases arising from the combustion. The bomb can be used for the combustion of all ordinary organic substances, including nitro-compounds, but not with substances containing halogens or a very high percentage of sulphur. In combustions of substances of the first class, including coals, no nickel goes into solution, and only about 0·2 mg. of iron, which would develop 0·2 g. cal., but with the latter type of compound several mgrms. of both iron and nickel are dissolved from the surface of the bomb. The susceptibility of the metal to attack, however, appears to grow still less with use, and substances with a comparatively high sulphur content can then be successfully burnt. —G. F. M.

Hydrogen ion concentration; Colorimetric method of determining ——. Some applications in the analytical laboratory. N. Evers. Analyst, 1921, **46**, 393—400.

A DETAILED description of the colorimetric or indicator method for determining hydrogen ion concentration, the method being based on the fact that the colour change of various indicators extends over a characteristic zone of hydrogen ion concentration. The method may be applied to clear, turbid, colourless, or coloured liquids and is useful for determining the reaction of such substances as sodium salicylate, morphine hydrochloride, calcium chloride, potassium iodide, etc.—W. P. S.

Silica; New method of determining ——. Travers Comptes rend., 1921, **173**, 714—717.

THE silica is converted into alkali silicate by the usual fusion process. The silicate is dissolved in water, and to the solution in a silver basin at least 1 g. of potassium fluoride is added for every 0·15 g. of silica expected. The liquid is just neutralised with hydrochloric acid, and a further 2 c.c. of acid and an excess of potassium chloride (7—10 g. for every 50 c.c. of solution) are added. The silicon is completely precipitated as potassium silicofluoride, which is filtered off on a hardened paper in an ebonite funnel and washed with a 20% solution of potassium chloride until free from acid. The wet precipitate is titrated in boiling aqueous suspension with $N/5$ potassium hydroxide, free from carbonate. 1 c.c. of $N/5$ potassium hydroxide is equivalent to 0·005 g. of silica. The method is accurate in the presence of fluorine and aluminium, and details are given of its application to the detection of traces of silica in alkalis, to the analysis of quartz and silicates, and to fluo- and aluminosilicates.—W. G.

PATENT.

Gas-testing apparatus. [*Specific gravity meter.*] G. G. Oberfell and A. M. Ballard. U.S.P. 1,395,201, 25.10.21. Appl., 27.4.20.

THE specific gravity of a gas is determined by forcing air and gas alternately into a chamber under pressure, allowing the air or gas to escape through an orifice and noting the respective times for the pressure in the chamber to fall between definite limits.—J. S. G. T.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

23,446 (1920). Meister, Lucius, u. Brüning. Manufacture of methane. (161,924.) Nov. 23.

23,809 (1920). Charpy. Coke-ovens. (150,996.) Nov. 30.

23,992 (1920). Wells. Gas-producers. (171,488.) Nov. 30.

24,270 (1920). Barrelle. Manufacture of coke for metallurgical purposes. (171,203.) Nov. 23.

24,481 (1920). O'Dell (Canadian American Finance and Trading Co.). Distilling bituminous sand, coal, oil shale, etc. (171,213.) Nov. 23.

26,276 (1920). Davidson. Gas calorimeters. (171,246.) Nov. 23.

27,278 (1920). Wallace. Apparatus for distilling carbonaceous materials. (171,563.) Nov. 30.

27,395 (1920). Burnell and Dawe. Motor spirit. (171,566.) Nov. 30.

28,344 (1920). Thermal Industrial and Chemical Research Co., and Morgan. Manufacture of coal gas. (171,282.) Nov. 23.

15,776 (1921). Standard Oil Co. Distilling petroleum and other hydrocarbon oils under pressure. (164,358.) Nov. 30.

17,739 (1921). American Coke and Chemical Co. Coke ovens or the like. (165,735.) Nov. 30.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Barrett Co. Purification of hydrocarbons. 30,471. Nov. 15. (U.S., 15.12.20.)

Hewison. Treatment of tar etc. 30,995. Nov. 19.

COMPLETE SPECIFICATIONS ACCEPTED.

18,944 and 19,519 (1920). Bloxam (Meister, Lucius, u. Brüning). Manufacture of anthraquinone derivatives. (147,001 and 160,433.) Nov. 30.

29,517 (1920). Johnson (Badische Anilin u. Soda Fabr.). Manufacture of anthraquinone derivatives. (171,292.) Nov. 23.

IV.—COLOURING MATTERS AND DYES.

COMPLETE SPECIFICATION ACCEPTED.

18,760 (1920). Meister, Lucius, u. Brüning. Manufacture of monoazo dyestuffs for dyeing wool. (146,871.) Nov. 23.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Bliss, and British Research Assoc. for Woollen and Worsted Industries. Treatment of yarns. 31,196. Nov. 22.

Bliss, Briggs, and British Research Assoc. for Woollen and Worsted Industries. Treatment of wool etc. prior to spinning. 31,197. Nov. 22.

Bloxam (Heberlein u. Co.). Producing linen-like effects in cotton yarns and fabrics. 31,279. Nov. 22.

Bronnert. Manufacture of fine viscose silk. 30,332. Nov. 14.

Clavel. Treatment of cellulose derivatives. 30,945–6. Nov. 19.

Cross (Technochemia A.-G.). Manufacture of artificial silk etc. 31,497. Nov. 24.

Duclaux. Treatment of washing waters for wool etc. 31,246. Nov. 22. (Fr., 23.11.20.)

Dorbritz. Removing grease from hairs of pelts of rabbits etc. 31,238. Nov. 22.

Jentgen. Production of artificial threads etc. from viscose. 30,466. Nov. 15. (Ger., 15.11.20.)

McRae. Treatment of vegetable fibres. 30,387. Nov. 15.

Reichard. Filling paper pulp with mineral fillers. 31,443. Nov. 24. (Ger., 15.3.21.)

Zdanowich. Cellulose acetates. 31,233. Nov. 22.

COMPLETE SPECIFICATIONS ACCEPTED.

13,187 (1920). Lilienfeld. Production of cellulose ethers. (163,016.) Nov. 23.

13,188 (1920). Lilienfeld. Production of ethers of carbohydrates of the formula $nC_6H_{10}O_5$. (163,017.) Nov. 23.

13,286 (1920). Lilienfeld. Manufacture of alkali cellulose. (149,318.) Nov. 23.

13,387 (1920). Bronnert. Manufacture of viscose artificial silk. (171,125.) Nov. 23.

19,154 (1920). Romer and others. *See* XV.

19,957 and 20,278 (1920). Mond (Cellon-Werke Eichengrün). Production of moulded articles from cellulose acetate etc. (147,904 and 171,432.) Nov. 30.

23,864 (1920). Raitt. Extraction of cellulose or paper pulp from fibrous vegetable materials. (171,482.) Nov. 30.

30,041 (1920). Sandeman. Treatment of jute and like fibrous material. (171,602.) Nov. 30.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Larivei. Machines for treating with fluids and centrifuging textile goods. 31,423. Nov. 24.

McHaffie, and Stevenson, McKellar and Co. Process of finishing textiles. 30,276. Nov. 14.

COMPLETE SPECIFICATION ACCEPTED.

4912 (1921). Hablutzel. Apparatus for treating hanks of yarn with liquid. (159,134.) Nov. 30.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Dutt, Godfrey, and Wilson. Manufacture of titanium dioxide and vanadium oxide from bauxite ores. 31,055. Nov. 21.

Herrmann. 30,490. *See* VIII.

Mehner. Formation of cyanic compounds. 31,611. Nov. 25. (Ger., 26.11.20.)

Moritz. Mechanical sulphate furnaces. 31,087 and 31,240. Nov. 21 and 22. (Belg., 23.11.20.)

Moritz. Manufacture of sulphuric acid. 31,239. Nov. 22. (Belg., 23.11.20.)

Moritz. Apparatus for measuring acids etc. 31,241. Nov. 22. (Belg., 23.11.20.)

Shelley. Drying salt etc. 31,118. Nov. 22.

Complete Specifications Accepted.

11,676 (1920). Nauerz. *See* I.

12,655 (1920). Norris and Hoseason. Preparation of chlorine compounds which may be rendered dispersible. (171,418.) Nov. 30.

19,459 (1920). Kersten. Decomposition of alkali chlorides. (147,495.) Nov. 30.

19,705 (1920). Verein Chem. Fabr. in Mannheim. Manufacture of sulphur dioxide by heating sulphates. (149,662.) Nov. 23.

19,739 (1920). Still. *See* II.

23,020 (1920). Mooney. Manufacture of a solution of chromic sulphate. (171,149.) Nov. 23.

24,248 (1920). Nöding. Retort furnace for generating hydrogen from iron and steam. (171,495.) Nov. 30.

9203 (1921). Benko. Manufacture of iodine compounds. (164,306.) Nov. 23.

VIII.—GLASS; CERAMICS.

Applications.

British Scientific Instrument Research Assoc., Haigh, and Jackson. Manufacture of abrasives. 30,483. Nov. 15.

Deussing. Production of artificial meerschaum. 30,884. Nov. 18. (Ger., 23.11.20.)

Dowell, and Dowell and Sons. Furnace for manufacture of glassware etc. 31,234. Nov. 22.

Feldenheimer and Plowman. Treatment of clay. 31,099. Nov. 21.

Freuler. Manufacture of glassy material. 30,468. Nov. 15. (Switz., 16.11.20.)

Herrmann. Manufacture of micanite. 30,490. Nov. 15. (Fr., 21.12.20.)

Hilger, Ltd., and Twyman. Annealing. 30,326. Nov 14.

Complete Specifications Accepted.

16,047 (1920). Porzellanfabr. Kahla. Cement for joining porcelain bodies after burning. (145,026.) Nov. 30.

25,982 (1920). British Thomson-Houston Co. (General Electric Co.). Treating the surface of glass. (171,549.) Nov. 30.

29,700 (1920) and 4974 (1921). Bailey. Kilns for firing pottery and other ware. (171,294.) Nov. 23.

30,797 (1920). Scholes, Nicols, and Kaufman. Removing striæ from molten glass. (171,608.) Nov. 30.

IX.—BUILDING MATERIALS.

Applications.

Connelly and Stewart. Metallic cement. 30,567. Nov. 16.

Curties. 30,831. *See* II.

Curties. Manufacture of bricks from Norfolk etc. oil shales. 30,832. Nov. 18.

Tralls. Utilisation of bituminous minerals and earths. 31,584. Nov. 25. (Ger., 30.11.20.)

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Aluminium Co. of America. Aluminium alloys. 30,510–1. Nov. 15. (U.S., 27.11.20.)

Archer, Jeffries, and Johnston. Metallic alloys. 31,390. Nov. 23. (U.S., 27.11.20.)

Britten, and District Chemical Co. Welding cast iron. 31,715. Nov. 26.

Britten, and District Chemical Co. Welding copper or its alloys. 31,716. Nov. 26.

Collis and Lewis. Aluminium solder. 31,505. Nov. 24.

Davies. Coating metals or alloys with metals or alloys. 30,933. Nov. 19.

Ford. Manufacture of wrought iron. 31,651. Nov. 25. (U.S., 31.1.21.)

Goldschmidt A.-G. Bearing-metal alloy. 30,829. Nov. 18. (Ger., 23.11.20.)

Heyen. Manufacture of iron and steel. 31,167. Nov. 23.

Hilger, Ltd., and Twyman. 30,326. *See* VIII.

Hyde. Brazing, soldering, etc. 31,206. Nov. 22.

Imray (Jackson and Co.). Treatment of ores etc. 31,740. Nov. 26.

Kröning. Hardening and treatment of steel. 31,352. Nov. 25. (Ger., 13.5.21.)

Waldberg. Electrometallurgy or electrodeposition of metals. 30,852. Nov. 18.

Complete Specifications Accepted.

12,386 (1920). Walter. Alloys of silicon with metals of the iron and chromium groups. (156,561.) Nov. 23.

24,102 (1920). Wood and Wood. Cupolas or melting or heating furnaces. (171,491.) Nov. 30.

24,270 (1920). Barrelle. *See* II.

30,785 (1920). Haworth. Alloy for repairing defective castings. (171,607.) Nov. 30.

XI.—ELECTRO-CHEMISTRY.

Applications.

Lodge Fume Co. (Metallbank u. Metallurgische Ges.). Method of working electrical gas-purifiers. 30,461. Nov. 15.

Lodge Fume Co. (Möller). Separating suspended particles from gases. 30,625. Nov. 16.

Morris. 30,520. *See* XX.

Neumann and Neumann. Electric accumulators. 31,407. Nov. 23. (Ger., 17.8.21.)

Waldberg. 30,852. *See* X.

Complete Specifications Accepted.

23,201 (1920). Smith. *See* XIX.

24,198 (1920). Mauri. Three-phase electric furnaces. (171,494.) Nov. 30.

24,331 (1920). Automatic Telephone Manuf. Co., and Roseby. Electric furnaces for obtaining high temperatures. (171,207.) Nov. 23.

24,456 (1920). Seward. Electrolytic apparatus. (171,502.) Nov. 30.

XII.—FATS; OILS; WAXES.

Applications.

Hayward. Washing-powder. 31,602. Nov. 25.

Lemmens. Refining oils. 31,107. Nov. 22.

Lemmens. Manufacture of margarine etc. 31,524. Nov. 24.

Lemmens. Cooling molten fats etc. 31,726. Nov. 26.

Complete Specifications Accepted.

35,723 (1920). Böhme A.-G. Production of fat-dissolving substances. (155,595.) Nov. 30.

36,081 (1920). Starrels. Production of fatty acids of high purity and melting point. (155,782.) Nov. 30.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Application.

Alexander (Stokes). Synthetic resin composition. 30,688. Nov. 17.

Complete Specifications Accepted.

23,422 (1920). Fischer. Production of resinous bodies from phenols and oxygen. (149,979.) Nov. 23.

23,454 (1920). Barrett Co. Production of resin. (149,982.) Nov. 30.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Applications.

Matthew. Vulcanising rubber goods. 31,328. Nov. 30.

Monork Vulcanizing Co., and Smith. Vulcanising. 31,211. Nov. 22.

XV.—LEATHER; BONE; HORN; GLUE.

Applications.

Dorbritz. 31,238. *See* V.

Gerb- u. Farbstoff-Werke Renner u. Co. Process of tanning and manufacture of agents therefor. 30,484. Nov. 15. (Ger., 15.11.20.)

Wilson, and Wilson and Co. Apparatus for tanning butts or hides. 30,773. Nov. 17.

Complete Specifications Accepted.

19,154 (1920). Romer, and Deutsch-Koloniale Gerb- u. Farbstoff Ges. Obtaining tanning materials from cellulose waste sulphite lyes. (171,136.) Nov. 23.

19,826 (1920). Röhm. Manufacture of iron-tanned leather. (147,797.) Nov. 30.

23,019 (1920). Rautenstrauch. Unhairing skins and hides. (160,435.) Nov. 30.

XVI.—SOILS; FERTILISERS.

Applications.

Deutsche Gold- u. Silber-Scheideanstalt. Treatment of seeds for agricultural purposes. 31,277. Nov. 22. (Ger., 22.11.20.)

Holmes. Plant fertilisation. 31,165. Nov. 22.

Complete Specification Accepted.

23,162 (1920). Broadbridge and Edser. Production of fertiliser. (171,155.) Nov. 23.

XVII.—SUGARS; STARCHES; GUMS.

Complete Specifications Accepted.

13,188 (1920). Lilienfeld. *See* V.

17,961 (1920). Kantorowicz. Preventing formation of lumps when starch which swells in cold water is dissolved. (145,689.) Nov. 30.

XVIII.—FERMENTATION INDUSTRIES.

Complete Specifications Accepted.

28,189 (1919). Robbins. Natural conditioning of alcoholic beverages. (171,413.) Nov. 30.

23,849 (1920). Walkey and Bargate. Preparation of alcohol. (171,479.) Nov. 30.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Activated Sludge, Ltd., and Coombs. Treating sewage etc. 31,161. Nov. 22.

Fabry. Continuous roller press for de-watering sewage sludge. 30,414. Nov. 15.

Hartley and Hartley. Purification of sewage. 31,462. Nov. 21.

Hewson. Preserving milk etc. 30,995. Nov. 19.

Lee. Treatment of whey. 30,871. Nov. 18.

Marshall. Sweet fat or oil for cattle feeding. 31,318. Nov. 23.

Naaml. Vennoots. Industrieele Maatsch. Conserving meal or flour. 31,554. Nov. 24. (Holland, 26.9.21.)

O'Shaughnessy. 31,194. *See* I.

Quain. Sterilisation of water etc. 31,113. Nov. 22.

Soc. Ricard, Allenet et Cie. Purification of liquids. 31,278. Nov. 22. (Fr., 26.3.21.)

Vielle. Manufacture of insecticidal and fungicidal preparations. 30,317. Nov. 14.

Complete Specifications Accepted.

13,635 (1920). Noseworthy. Drying fish, fruit, etc. (171,422.) Nov. 30.

23,201 (1920). Smith. Electrical treatment of foods etc. (171,157.) Nov. 23.

611 (1921). Ward Baking Co. Manufacture of leavened bread. (156,635.) Nov. 23.

2692 (1921). Cholet. Preserving organic matters and particularly meat and fish. (171,637.) Nov. 30.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Holzverkohlungs-Industrie A.-G., and Róka. Chlorination of methane. 31,276. Nov. 22.

Imray (Soc. Chem. Ind. Basle). Manufacture of derivatives of dihydro-isoquinoline. 30,612. Nov. 16.

Morris. Electrolysis of acetone solutions. 30,520. Nov. 16.

Complete Specifications Accepted.

15,126 (1920). Granger and others. *See* II.

19,152 (1920). Grünstein. Manufacture of butyric aldehyde and butyl alcohol from crotonic aldehyde. (147,118.) Nov. 23.

19,153 (1920). Grünstein. Manufacture of aldol from acetaldehyde. (147,119.) Nov. 23.

19,960–1 (1920). Matter. Production of polyvalent alcohols. (147,906–7.) Nov. 23.

23,849 (1920). Walkey and Bargate. *See* XVIII.

28,343 (1920). Howards and Sons, and Blagden. Manufacture of calcium, magnesium, and lithium acetylsalicylates. (171,281.) Nov. 23.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Application.

Akt.-Ges. f. Anilinfabr. Converting silver prints into colour pictures. 31,406. Nov. 23. (Ger., 17.5.21.)

Complete Specification Accepted.

2720 (1921). Dorian. Colour photography. (158,511.) Nov. 30.

XXII.—EXPLOSIVES; MATCHES.

Application.

Friederich. Manufacture of priming compositions. 31,273. Nov. 22.

XXIII.—ANALYSIS.

Complete Specification Accepted.

26,276 (1920). Davidson. Gas calorimeters. (171,216.) Nov. 23.

I.—GENERAL; PLANT; MACHINERY.

Adsorption-capacity of an active charcoal; Influence of water content on the ——. H. Herbst. Biochem. Zeits., 1921, 118, 103—119.

The highest adsorption is obtained with dry charcoal. For practical purposes, 10% of water is not harmful, since the presence of water has a catalytic effect.—H. K.

Patents.

Catalytic oxidation processes. J. McC. Selden, and The Selden Co., Inc. E.P. 170,022, 7.4.20.

Vanadium pentoxide operates more efficiently as an oxidising catalyst if it is previously heated to a temperature, at least 500° C., sufficient to cause it to darken in colour, to become more dense and crystalline, and to sinter, or even to such a temperature as to cause it to fuse, viz., a little above 658° C. The re-solidified dark bluish-black crystalline mass is broken up into lumps or granules of suitable size, and used, without admixture or supporting material, as a catalyst in the usual way. Thus at 400° C sulphur dioxide is oxidised to sulphur trioxide, benzene to quinone and maleic acid, and anthracene and naphthalene to anthraquinone and phthalic anhydride, respectively, whilst at 300° C. methane is oxidised to formaldehyde and toluene to benzaldehyde and benzoic acid.—G. F. M.

Heat exchange apparatus. J. G. McKean and R. F. Jones. E.P. 170,450, 19.8.20.

The liquid to be heated passes through a number of longitudinal channels in the body of the apparatus, each channel being provided with a steam heating element consisting of a steam supply tube open at the ends, surrounded by another tube with one end closed. The channels for the liquid to be heated are connected by ports and passages in the end covers, so that the liquid can flow either in several streams in parallel or through several channels in series, the arrangement for a viscous liquid being preferably for the liquid to flow first through a few channels in parallel, and then through the remainder in series. The steam heating elements may be guided into their respective channels by means of a loose perforated plate sliding on them, and means are described whereby the supply chamber for the steam tubes may be removed without disconnecting the supply pipe to the chamber, and for discharging the condensed water above the level of the apparatus.—B. M. V.

Heating liquids [e.g., distillation of tar, oils, and the like] by introduction into molten metal. Thermal Industrial and Chemical Research Co., Ltd., A. M. Duckham, and J. S. Morgan. E.P. 170,617, 26.5. and 8.12.20.

The liquid, *e.g.*, tar, is forced beneath the surface of molten metal through a hood with an annular opening, the sides of which are notched, thus preventing freezing of the metal as a result of local cooling and ensuring even distribution of the liquid. The hood may be fitted with a slightly inclined plate beneath the surface of the molten metal to increase the time of heating.—C. I.

Furnaces; Regulation of combustion conditions in ——. J. M. Hopwood. E.P. 170,683, 29.7.20.

In order to regulate the combustion in a vapour generator heated by a fluid fuel, means are provided whereby the rate of flow and/or the pressure of the vapour from the generator governs the rate of feed of fuel, and the rate of feed or the pressure of the latter governs the air for combustion. The pressure of the combustion gases in the furnace may govern the exhaust thereof.—B. M. V.

Vacuum filtration apparatus. A. T. Cartner, R. Clewer, and Mather and Platt, Ltd. E.P. 170,788, 21.1.21.

A liquor trap is provided between the receiver and air pump of a vacuum filtration apparatus. The inlet pipe from the receiver extends nearly to the bottom of the trap and the outlet pipe to the pump terminates near the top and is provided with a valve seat adapted to be closed by a floating ball. Another valve operated by a float is adapted to admit air to break the vacuum in the event of the liquor rising too high. Perforated diaphragms are also provided within the trap on which may be placed an absorbent for any corrosive gases given off by the filtered liquor.—B. M. V.

Filling material for use in Glover towers and similar apparatus. P. Kestner. E.P. 170,982, 18.8.20. Addn. to 131,502 (J., 1919, 746 A).

The rings of ceramic material are made by stamping them in the form of truncated cones from a layer of ceramic paste by means of cutting punches. —J. S. G. T.

Dryers; Process in direct-action ——. I. M. Justice, Assr. to The Manufacturers Equipment Co. U.S.P. 1,393,788, 18.10.21. Appl., 3.5.19.

Hot gases of combustion pass from a furnace through a heating tunnel underneath, and extending the full length of, a drying tunnel, then pass up through end flues to longitudinal heating channels above the drying tunnel, through which they pass to a stack situated halfway along the furnace. Air is admitted to the end of the drying tunnel remote from the heating device passes the full length of the furnace within, and half the length of the furnace in channels above the drying tunnel and out to the same stack as the gases of combustion. The material to be dried passes through the drying tunnel in the same direction as the air.—B. M. V.

Separating partly miscible compounds; Process of ——. A. Stevens. U.S.P. 1,394,232, 18.10.21. Appl., 10.3.20.

Partly miscible compounds of constant boiling-point are separated by distilling the mixture, thus producing a distillate containing a mixture of the compounds and an excess of one of them. This compound is separated from the mixture, which is returned to the mixture being distilled.—H. H.

Comminuting-mill. R. C. Newhouse, Assr. to Allis-Chambers Mfg. Co. U.S.P. 1,394,334, 18.10.21. Appl., 23.8.17.

A rotary shell is divided into successive chambers by a pair of transverse walls. The chamber between the walls contains no comminuting members. The comminuted material passes through openings in the walls adjacent to the shell into the intermediate chamber, which is provided with means for elevating the fine material.—H. H.

Centrifugal separator. F. H. Lindenberg, Assr. to The Jeffrey Mfg. Co. U.S.P. 1,395,193, 25.10.21. Appl., 8.3.17.

A perforated conical basket with the wider end uppermost is adapted to revolve about a vertical axis and is mounted for universal rotation about a centre in the axis. Spiral vanes within the basket are arranged to revolve differentially in the same direction as the basket to control the upward movement of material upon the surface of the basket. The basket and the vanes are revolved at speeds bearing a definite ratio by means acting in the transverse plane of the centre of rotation.—H. H.

Condenser. J. A. Bishop. U.S.P. 1,395,898, 1.11.21. Appl., 26.5.19.

The vapour to be condensed flows through a number of vertical tubes cooled by a horizontal current of air which impinges upon the tubes and is deflected against adjacent brick walls that are kept moist by water sprays on their upper parts.—B. M. V.

Volatile solvents; Process of recovering ——. H. P. Bassett and S. S. Sadtler. U.S.P. 1,395,940, 1.11.21. Appl., 17.9.20.

A vapour which is relatively insoluble in water but soluble in alcohol is absorbed in aqueous alcohol containing 40—70% of alcohol by volume.—B. M. V.

Removal of solid suspended matter from gases; Dry process for ——. W. Schärfe. G.P. 339,626, 14.12.18.

A number of co-axial vertical cylinders, closed above and open below, are disposed within the conduit for crude gas or in a chamber connected therewith, with their lower ends immersed in a mass of filtering material, through which the gas to be treated passes with a velocity of about 8 m. per sec., finally being discharged to the outlet conduit by way of the innermost cylinder. When necessary, the filtering material may be withdrawn through a funnel-shaped chamber disposed underneath the cylinders and normally kept closed below, and fresh filtering material supplied through the upper parts of the cylinders.—J. S. G. T.

Electrical separation of dust or mist from gases; Process of ——. H. Püning. G.P. 339,879, 12.5.20.

Linen or other textile material, or paper, either alone or forming a covering to tinplate etc., and kept moist by a slow trickle of water, is employed as collecting electrode. The plant can be worked for considerable periods without requiring cleaning. —J. S. G. T.

Gas-separating apparatus; Regulating means for ——. E. A. Barbet. U.S.P. 1,395,466, 1.11.21. Appl., 25.6.19.

See E.P. 129,648 of 1919; J., 1321, 33 a.

Heat exchangers for use with fluids; Construction of ——. Soc. Franco-Belge de Fours à Coke. E.P. 159,489, 13.9.20. Conv., 23.2.20.

Steam generator. E.P. 155,558. *See* IIa.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coals; Determination of the degree of oxidation of ——. G. Charpy and G. Decorps. Comptes rend., 1921, 173, 807—811.

A known weight of the powdered, sifted coal is digested for 2 hrs. at 100° C. with 50% aqueous sodium hydroxide, using 10 c.c. for each grm. of coal. The resulting solution is diluted and filtered, the filtrate being acidified with sulphuric acid and made up to a known volume. To an aliquot portion of this liquid an excess of standard potassium permanganate solution is added and the mixture left for 2 hrs. at the ordinary temperature, after which the excess of permanganate is titrated. From the result it is possible to calculate the oxidation index, *i.e.*, the number of grms. of oxygen required to oxidise the organic matter dissolved by the alkali from 1 kg. of coal. Coals which give a resistant coke have, as a rule, an oxidation index not exceeding 2. Curves are given showing the variation with time of the total weight and the oxidation index for two different samples of coal kept at 150° C. In one case, an English coal, the weight increased at a gradually decreasing rate, and after about 450 hrs. remained practically constant, the total increase being about 4·3%. The oxidation index increased continuously and at an increasing rate. After 2000 hrs. the increase of weight was still about 4·3% and the oxidation index, originally 0·15, had risen to 270. In the case of the other coal, from Northern France, the weight had increased by 6·75% after about 220 hrs., but then commenced to decrease again slowly. The oxidation index increased continuously from the beginning. After 2000 hrs. the weight was slightly less than the original value and the oxidation index had risen to 860, whilst the coal had become almost completely soluble in caustic soda solution. (*Cf.* J., 1917, 24.) —W. G.

Coal; Determination of volatile matter in ——. H. P. Wilkinson, jun. Chem. and Met. Eng., 1921, 25, 925.

The standard method of determining volatile matter may give varying results depending upon such factors as the condition of the crucible and lid, the quality of the gas, and the condition of the burner used. Furthermore, coke-oven conditions, particularly as regards re-deposition of carbon, are not reproduced. A method which gives results comparable with those obtained in coke ovens involves the use of an electric resistance furnace consisting of a vertical cylinder 2 in. diam. and 4 in. long. The top and base fit with ground joints and are held by a clamp, and a gas-outlet tube and a thermocouple are fitted in the top. The furnace is heated to the temperature of the ovens, the top is removed, and 100 g. of the coal sample is poured into the cylinder. The top is quickly replaced and the coking allowed to proceed to completion at constant temperature. The furnace is then removed from its base, and the coke removed, quenched, dried, and weighed.—H. Hg.

Sulphur and chlorine [in petroleum products]; Estimation of —— *by the lamp method.* S. Bowman. J. Inst. Petroleum Tech., 1921, 7, 334—338.

In estimating sulphur in petroleum products by the lamp method a certain amount of the sulphur is always absorbed by the wick, and a method of obviating this source of error is described. 5 c.c. of petrol, white spirit, or kerosene, or about 0·5 g. of gas oil, lubricating oil, fuel oil, or residues, diluted with 10 c.c. of amyl acetate, is burnt in a glass lamp, provided with 4 in. of cotton wick (20 strands), under a glass chimney 7 in. by 1½ in. The gases generated are drawn by suction successively through a 50-c.c. distillation flask, two 150-c.c. Drechsel wash bottles, and a trap vessel, each containing 25 c.c. of water and 1 c.c. of 10% sodium carbonate solution. The gas inlet in each vessel dips below the level of the liquid. After burning to dryness, the lamp is washed twice with a few c.c. of amyl acetate, again burning to dryness each time. The wick is then burnt in a 6-in. length of combustion tubing attached to the wash bottles in place of the distillation flask. The vessels, chimney, and all connexions are washed out and the solution, together with the ash from the wick, is boiled with 1 g. of sodium peroxide, acidified with nitric acid, and the sulphate is precipitated with barium nitrate. After filtering off the precipitate, which is washed and ignited, the filtrate is treated with a few c.c. of silver nitrate solution and the chlorine estimated by comparing the turbidity with that of a blank solution containing the same reagents and a known volume of $N/100$ hydrochloric acid.—L. A. C.

Calorific values of certain unsaturated hydrocarbons; Methods of determining the ——. Royal Aircraft Establishment Report, No. H.G. 410. J. Inst. Petroleum Tech., 1921, 7, 339—342.

Samples of "Special Motor Fuel (F. 7)" from Birmingham, which had been obtained by cracking heavy oils and consisted largely of olefines, showed signs of incomplete decomposition and a tendency to detonate when burnt in the bomb calorimeter, yielding inconsistent results. After unsuccessful attempts to overcome this difficulty by using a sealed bulb and by employing mixtures of the fuel with benzol and xylol, results agreeing to within 1% were obtained by employing oxygen diluted with about 20% of carbon dioxide for the combustions.—L. A. C.

Petrols; Calorific values of —— *and of petrol fractions.* Royal Aircraft Report, No. H. 861. J. Inst. Petroleum Tech., 1921, 7, 342—351.

Investigations were made on the calorific values of various motor fuels to find the relationship between these values and other physical and chemical properties. The fuels tested included Shell "A" aviation spirit from Sumatra, two samples of American petrol, and samples of petrol from Sumatra and Borneo prepared to meet the requirements of the French "extra-aviation" specifications. The calorific values of benzol, toluol, and xylol, and of fractions obtained by distilling petrol were also determined. In calculating the net calorific value of a fuel, *i.e.*, the amount of heat available in the engine, the weight of water formed from the fuel was calculated from the % of hydrogen present as estimated by the copper oxide method. Experimental details are given of the methods of working adopted, and the results obtained are tabulated and plotted. In the petrol samples, the calorific values, which differed from each other by little more than 1%, increased with an increase of hydrogen content, and decreased with increased sp. gr. and with increased content of aromatic compounds. In the petrol fractions there was a fall in calorific value of about 3% in ascending the scale from pentane to octane, and the calorific values of the aromatic hydrocarbons tested showed a regular increase with decreasing sp. gr.—L. A. C.

Spontaneous ignition temperatures [of hydrocarbons]; Relation between alcohol-water solubility and ——. W. R. Ormandy and E. C. Craven. J. Inst. Petroleum Tech., 1921, 7, 325—334.

Experiments were made with a number of aliphatic and aromatic hydrocarbons and other organic compounds, and also of mixtures of petrol with benzene and xylene, to ascertain whether there is a relationship between the solubility in alcohol (92% by wt.) and the spontaneous ignition temperatures in oxygen. Although in the case of aliphatic and aromatic hydrocarbons there is an irregular rise in ignition temperature with increased solubility in alcohol, it was concluded that there is no general relationship between the properties. The same conclusion was arrived at in comparing alcohol solubilities with "toluene values," *i.e.*, the maximum effective compression ratio for fuels, assigning to toluene an arbitrary value of 100. The solubilities in alcohol (92% by wt.) of the compounds and mixtures tested are given in tables.—L. A. C.

Determination of ammonia. Sander. *See* VII.

Constitution and heats of combustion. Binder. *See* XX.

Patents.

Combustible substances; Processes for converting —— *into soluble organic compounds.* F. Fischer. E.P. 149,974, 9.8.20. Conv., 10.6.19.

Finely powdered coal is agitated with a dilute sodium carbonate solution at 230° C., a current of air at 30 atm. pressure being passed through the suspension for 10 hrs.; organic acids are isolated from the resulting solution. Soap may be added as an emulsifier and iron or manganese salts as catalysts. The sodium carbonate solution may be replaced by water or by neutral or acid aqueous solutions or by other non-combustible liquids. —H. Hg.

Coke; Manufacture of —— *[from tar or pitch].* The Barrett Co., Assees. of R. P. Perry. E.P. 155,226, 10.8.20. Conv., 10.12.19.

Coal tar or pitch is subjected to a preliminary distillation, during which an inert gas is passed through the liquid, until a pitch with a m.p. above 400° F. (204° C.) is obtained. The gas leaving the still is passed through a condenser and re-circulated. The pitch is then coked in a second still at about 700° F. (370° C.) without the usual difficulties caused by foaming.—H. Hg.

[Gas] retort or like furnaces and steam generating plant; Combined ——. J. Frisch. E.P. 155,558, 3.6.20. Conv., 18.12.19.

A number of vertical gas retorts, a steam generator, and a superheater are built around a central producer and within a cylindrical casing. The steam generator consists of an upper boiler placed vertically above, and connected by a number of tubes with a lower boiler. Waste gases from the combustion chamber of the retorts pass into an annular collecting flue and then through the superheater and the upper boiler to the chimney. Hot coke is discharged from the retorts on to an annular conveyor which is concentric with the retorts and consists of an iron grating placed over a water trough. The conveyor is mounted in the middle on a rail and at the sides on ball bearings; it carries the coke under the lower boiler and then passes under a bridge which discharges the cooled coke. The coke-conveying chamber is gradually enlarged towards the boiler in order to facilitate the passage of coke; air is excluded from this chamber. Circulation within the steam generator is promoted by the transfer of heat to the inner series of the tubes connecting the boilers from the central producer. The width of the combustion chamber is reduced between each two adjacent retorts in order to secure more efficient heating and permit of a construction capable of expansion.—H. Hg.

Vertical gas retort settings. F. Cummins. E.P. 170,904, 6.7.20.

An independent vertical combustion chamber is provided on each of two sides of each retort. Producer gas enters each chamber from a common horizontal chamber passing round the base of the retorts and burns with a controlled supply of secondary air. The burning gases ascend through apertures in the horizontal supporting tiles of the retorts and mix with an auxiliary air supply higher up the setting. The waste gases from each chamber pass through independent dampers into a horizontal collecting flue common to, and above, each row of chambers, and thence through another superimposed horizontal flue and damper to the chimney. Both the horizontal waste flues pass alongside the top portion of a row of retorts. Thin portions are provided in some of the vertical cross walls opposite inspection holes to enable the temperatures behind the walls to be judged. The retorts are provided with silica jackets where combustion first takes place.—H. Hg.

[Mineral] oil-refining apparatus. H. L. Allan. U.S.P. 1,390,742, 13.9.21. Appl., 18.4.16.

See F.P. 481,134 of 1916; J., 1917, 127.

Gas-retorts and the like; Apparatus for charging and discharging ——. C. Hollander. E.P. 170,713, 21.3.21.

Distillation of oils. E.P. 170,617. *See* I.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Miner's flame safety-lamps; Relative safety of brass, copper, and steel gauzes in ——. L. C. Ilsley and A. B. Hooker. U.S. Bureau of Mines, Tech. Paper 228, 1921. 33 pages.

The lamps tested comprised samples of the Koehler, Seippel, Clanny, and Davy lamps. The lamps were exposed to currents of explosive mixtures of gas and air moving in a horizontal direction, the tests being carried out in a flame testing gallery, through which the mixture could be passed in various directions. For high temperature conditions, steel gauze was superior to either brass or copper. For low temperatures there was little difference between steel, brass, and copper. The brass tested contained a high percentage of copper and proved more satisfactory than copper. The least safe of all lamps tested was the single-gauze unbonneted Davy lamp. The double-gauze unbonneted lamp was somewhat safer than a single-gauze lamp, but was not dependable in high-velocity mixtures. The single-gauze bonneted lamp was safer than either type of unbonneted lamp, while the safest lamp tested was the double-gauze bonneted lamp. Previous tests had shown that the Hailwood combustion-tube lamp was as safe as a double-gauze bonneted lamp of the Koehler type. The results obtained indicate that the specification of gauzes drawn up by the Bureau of Mines in 1915, though perhaps not detailed enough, rests on a sound foundation, and that a lamp meeting these requirements would have a high standard of safety. It is suggested that only bonneted lamps be permitted for use in gaseous mines. The use of monel metal or nickel for flame-lamp gauze merits investigation.—J. S. G. T.

Adsorption capacity of charcoal. Herbst. *See* I.

Patents.

Charcoal and like materials; Process and apparatus for producing ——. *Wood distillation.* J. S. Pearce. U.S.P. (a) 1,395,866 and (b) 1,395,867, 1.11.21. Appl., (a) 31.3.19, and (b) 4.5.20.

(a) Gaseous products of combustion are passed through a mass of heated refractory catalytic material and then used to effect the distillation of wood waste. (b) Claim is made for a non-crumbling semi-vitrified charcoal with uniformly distributed surface strains and with surfaces of uniform consistency.—H. Hg.

Wood spirit and gray calcium acetate; Production of —— *from pyroligneous acid.* W. Pavlicek, and Chem. Werke "Marienglück" Huckendick und Co. G.P. 339,948, 14.11.19.

The vapours generated in the distillation of pyroligneous acid are neutralised by means of mechanically agitated milk of lime in an absorption column; methyl alcohol vapour passes from the top of the column to a condenser, and calcium acetate solution flows out of the bottom of the column.—L. A. C.

Gas mantles; Manufacture of incandescent ——. J. P. H. Soper, T. Terrell, and T. Terrell, jun. E.P. 170,679, 28.7.20.

In the manufacture of incandescence mantles, especially of the "soft" variety, artificial silk or other fabric after impregnation with salts of the rare earths in the usual manner, is dried, treated with a solution of a metallic fluoride, *e.g.*, sodium or potassium fluoride, whereby the rare earths are converted into fluorides, then washed, and dried. Such mantles show less shrinkage during the burning-off process than ordinary oxide-impregnated mantles and possess greater lighting efficiency.—J. S. G. T.

Glow discharge lamps; Electric ——. H. Filippo, D. Lely, jun., and Naaml. Vennoots. Philips' Gloeilampen-Fabrieken. E.P. 145,400, 10.5.20. Conv., 20.6.19.

In an electric glow discharge lamp with normal cathode drop, in which the emission of light originates from glowing gas surrounding the cathode, a smaller quantity of a rare gas of higher atomic weight than such glowing gas is added thereto, whereby the electrode drop of potential is kept below the value at which disintegration of the electrodes occurs. For use with continuous current, the cathode is provided with a pointed portion disposed opposite the anode.—J. S. G. T.

[Carbon] arc electrodes; Manufacture of ——. W. Mathiesen. G.P. 341,240, 31.7.20.

Carbon prior to the burning process is subjected to pressure considerably higher than that employed in the moulding process. Such carbons used in the arc afford a higher crater temperature and greater light emission.—J. S. G. T.

III.—TAR AND TAR PRODUCTS.

Dibromoanthraquinones; Homonuclear ——. Grandmougin. Comptes rend., 1921, 173, 839—840. (*Cf.* J., 1921, 841 a.)

1.2-Dibromoanthraquinone was prepared from α-aminoanthraquinone by brominating it in acetic acid solution and replacing the amino group in the resulting 1-amino-2-bromoanthraquinone by bromine by way of the diazo compound. 2.3-Dibromoanthraquinone was prepared in a similar way from 2-amino-3-bromoanthraquinone, obtained by removing bromine from 1.3-dibromo-2-aminoanthraquinone (Ullmann and Junghans, Annalen, 399, 336; G.P. 158,474). 1.3-Dibromoanthraquinone (*cf.* Ullmann and Eiser, J., 1916, 1104) may be obtained by eliminating the amino group from 1.3-dibromo-2-aminoanthraquinone, or from 1-amino-2.4-dibromoanthraquinone formed quantitatively by the dibromination of α-aminoanthraquinone (G.P. 115,048). 1.4-Dibromoanthraquinone was obtained by reducing 1-bromo-4-nitroanthraquinone and then replacing the amino group by bromine, but the product was not quite pure, and it is preferable to start from 1.4-diaminoanthraquinone (*cf.* Battegay and Claudin, J., 1921, 340 a). The melting points of the four homonuclear dibromoanthraquinones are: 1.2, 221° C.; 2.3, 283° C.; 1.3, 210° C.; 1.4, 196° C.—W. G.

Azo compounds and hydrocarbons. Pummerer and Binapfl. *See* IV.

Patents.

Distillation of tar, or the like, and other liquids; Process and apparatus for the ——. A. Irinyi. E.P. 146,183, 25.6.20. Conv., 25.11.18.

Tar or the like contained in a retort flows by gravity into an externally heated still, whence the vapours return to the retort and heat the body of tar therein. The vapours generated in the retort pass through an outlet pipe at the top into a condenser, and residual pitch is drawn off continuously from the bottom of the still. Two retorts may be connected alternately with one still, in which case, while one retort is in operation, the other is filled with tar and preheated by the waste gases from the furnace heating the still.—L. A. C.

Toluene; Manufacture of chlorinated derivatives of ——. British Dyestuffs Corp., Ltd., A. G. Green, and A. E. Herbert. E.P. 170,056, 15.6.20.

The chlorination of toluene-o-sulphonic acid or its soluble salts in cold aqueous solution results in the formation of a mixture of the 4-chloro- and 6-chloro-derivatives, which may be readily separated from one another by reason of the much greater solubility of the salts of the 4-chloro-acid. By chlorinating in more dilute solution at a temperature not exceeding 60° C. a mixture of dichloro- and trichloro-toluene-o-sulphonic acids is produced, from which the latter can readily be isolated on account of their lesser solubility. *Example:* 1·5 g.-mols. of toluene-o-sulphonic acid is dissolved in water, neutralised with sodium hydroxide, water added to make 1 l., and chlorine passed into the solution at 0°—5° C. for 9 hrs. with constant stirring. Pure sodium 6-chlorotoluene-2-sulphonate separates, and the mother liquors on evaporation give practically pure sodium 4-chlorotoluene-2-sulphonate.—G. F. M.

IV.—COLOURING MATTERS AND DYES.

Desoxyindigo. W. Borsche and R. Meyer. Ber., 1921, 54, 2854—2856.

When an alcoholic suspension of indigo, hydrazine, and sodium hydroxide is boiled for several hours, a deep green solution is formed, from which, on oxidation with air, a yellow crystalline precipitate of desoxyindigo is deposited. It crystallises in greenish-yellow needles, m.p. 317° C. Neither desoxyindigo, in which one of the CO groups of indigotin is replaced by a CH_2 group, nor the green solution from which it is obtained is suitable for dyeing. When sulphonated with concentrated sulphuric acid for ¾ hr. at 40°—50° C., desoxyindigo forms a monosulphonic acid the sodium salt of which dyes wool golden-yellow shades which are very fugitive to light. Similar desoxy-compounds are formed by the action of hydrazine and sodium hydroxide on 5.5′-dimethylindigotin, 7.7′-dimethylindigotin, and dibromoindigotin, but Thioindigo Red is merely reduced to its leuco-compound. (*Cf.* J.C.S., Jan., 1922.)—F. M. R.

Oxindigo synthesis; Course of the reaction in the ——. K. Fries and H. Hasenjäger. Ber., 1921, 54, 2931—2934. (*Cf.* J., 1911, 124.)

When 6-methyl-3-coumaranone reacts with coumarandion-2-(*p*-dimethylaminoanil) or 3-coumaranone reacts with 6-methylcoumarandion-2-(*p*-dimethylaminoanil) in each case the products possess the composition $C_{25}H_{22}O_4N_2$, but they are isomeric and not identical. Both products are, however, converted by strong acids into *p*-aminodimethylaniline and 6-methyloxindigo, from which it follows that the primary reaction product of the anil with the coumaranone is the compound $C_{25}H_{22}O_4N_2$ and not the methyloxindigo. (*Cf.* J.C.S., Jan., 1922.) —F. M. R.

Azo compounds and their salts; Behaviour of —— *with hydrocarbons and aluminium chloride.* R. Pummerer and J. Binapfl. Ber., 1921, 54, 2768—2784.

Benzene reacts with aluminium chloride at 40° C., but no hydrogen can be detected, and it is uncertain whether diphenyl is formed, for the greater part of the benzene is converted into viscous high-molecular condensation products. *bis*-Diphenylene-ethylene, however, in dry xylene solution, when treated with 5 mols. of aluminium chloride for 12 hrs. at 35°—40° C., is converted into *bis*-diphenylene-ethane in 67% yield. The hydrogenating action of dry benzene, free from thiophene, and aluminium chloride on azobenzene for ¾ hr. at 60° C. results in the formation of hydrazobenzene in 18% yield. In presence of hydrogen chloride phenylation occurs with the formation of aminodiphenyl in 70—80% yield, together with 10% of benzidine, some aniline, and 7—10% of a substance which is possibly a semidine base. The main reaction is $C_6H_5.N{:}N.C_6H_5+2C_6H_6=2C_6H_5.C_6H_4.NH_2$. This reaction is not limited to the use of azobenzene hydrochloride and benzene, for a similar reaction proceeds with even greater ease when the latter is replaced by toluene or xylene. (*Cf.* J.C.S., Jan., 1922.)—F. M. R.

Fuchsine-sulphurous acid and its colour reactions with aldehydes. H. Wieland and G. Scheuing. Ber., 1921, 54, 2527—2555.

Hantzsch and Oswald's hydrochloride of pararosaniline leuco-sulphonic acid (J., 1900, 236) was obtained by Dürrschnabel and Weil as the free base (J., 1905, 1295), which is actually a trihydrate of pararosaniline leuco-sulphonic acid. The latter authors' neutral and acid sulphites of pararosaniline are the pararosaniline salt of pararosaniline leuco-sulphonic acid and the monohydrate of pararosaniline leuco-sulphonic acid, respectively. Pararosaniline leuco-sulphonic acid is not the substance which gives rise to colour reactions with aldehydes, for no reddish-violet colour is produced by adding acetaldehyde to a very dilute hydrochloric acid solution of pararosaniline leuco-sulphonic acid. The colour reaction occurs only when the solution contains sulphurous acid. The solution of pararosaniline leuco-sulphonic acid in sulphurous acid is regarded as containing the N-sulphinic acid,

$$(NH_2.C_6H_4)_2C(SO_3H).C_6H_4NH.SO_2H.$$

The colouring matter produced in the ordinary colour reaction with acetaldehye possesses the constitution,

$$[CH_3.CH(OH).O.SO.NH.C_6H_4]_2C{:}C_6H_4{:}NH,$$

and the instability of this colouring matter on keeping is due to the hydrolysis of the aldehyde-sulphurous acid complex as such, for this does not give rise to colour reactions. (*Cf.* J.C.S., Jan., 1922.)—F. M. R.

Anthocyan; Formation of —— *in the flowers of Cobœa scandens at the expense of pre-existing glucosides.* St. Jonesco. Comptes rend., 1921, 173, 850—852.

Experimental evidence is given as proof of the formation of anthocyan from pre-existing glucosides in the flowers of *Cobœa scandens.*—W. G.

Beta vulgaris; Formation of the red pigment of —— *by oxidation of the chromogens.* A. Kozlowski. Comptes rend., 1921, 173, 855—857.

The chromogens extracted from white sugar beet resemble saponins in certain of their physico-chemical properties, and on oxidation give a coloured pigment having the same spectroscopic properties as the red pigment extracted from red beetroots and showing similar colour changes with acids and alkalis.—W. G.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Textiles; Use of X-rays in examination of ——. R. Truesdale and C. Hayes. J. Textile Inst., 1921, 12, 418—419.

The effects of the various processes to which a textile fabric, such as canvas, may be subjected subsequent to its manufacture, whereby its structure may be masked by a film of some opaque material, are best studied by means of radiography. For this purpose the canvas should be constructed so as to include threads, both warp and weft, which have been treated with some substance impervious to X-rays. These threads should occur at equal intervals so that a radiograph of the fabric would show them up as a check pattern. The most satisfactory impregnating material is lead chromate precipitated on the fibre by soaking the yarn in a strong solution of lead acetate containing 5% of glue and about 0·5% of glycerin, and then adding a hot 20% solution of potassium bichromate. A canvas constructed on these lines may be radiographed before and after any particular treatment, and from the prints, preferably contact prints, any changes in arrangement or length of the fibres are readily determined.—D. J. N.

Paper for textiles; Testing the water-absorption capacity of ——. F. Herig. Papierfabr., 1921, 19, Fest- u. Ausland-Heft, 32—35.

The majority of the paper-yarn spinning mills have discarded the method of damping by immersion of the narrow reels and now employ damping arrangements on the spinning machine or on the slitting machine. Damping during slitting has the advantage of allowing time for the uniform distribution of the moisture before twisting; damping on the twisting machine, however, enables more moisture to be given and avoids the distortion and bursting of the narrow reels. The most suitable paper is one which combines high tensile strength with quick absorption. It is suggested that the absorbent power of the paper may be measured by floating the paper on the surface of water and noting the time required for penetration, a dry aniline dyestuff powder being strewn on the upper surface of the paper to serve as an indicator. Suitable dyestuffs recommended are "Mahogany Red" and Methyl Violet, but it is to be noted that Methyl Violet requires about twice as long to dissolve under the test conditions as Mahogany Red, and indications obtained with it are divided by two. The aniline dyestuff is finely powdered and stored in a desiccator. The means for applying the powder is as follows: Two pieces of cardboard are glued together, the upper one having a regular figure cut out. The hollow space thus formed is filled with dyestuff powder and the strips of paper to be tested are pressed against the figure by a pad of cotton-wool. The coarser grains adhering to the paper are shaken off and the strips are floated on water at a standard temperature with the dyestuff upwards. The time is measured by a stop-watch until the figure appears with a certain intensity. This intensity is recognised by the phenomenon that, after the dyestuff has shown the first signs of dissolving, it spreads over the paper as a flat colour in two stages of intensity, and the end-point is judged by the second stage. For paper of 43—45 g. per sq. m. a water value of 30—40 secs. appears to be acceptable.—J. F. B.

Sulphite [boiling] tests of average wood, infected wood, and chipper dust. J. S. Bates. Pulp and Paper Mag., 1921, 19, 607—610.

Three trial runs were made using "average wood," consisting of about 75% of balsam fir and 25% of spruce, affected by rot to the extent of about 10%; infected wood, which was practically all balsam fir, attacked to the extent of about 50%; and chipper dust, produced during the chipping operation using "average wood." The rot was mainly confined to discoloration of the wood. Conditions of boiling were normal except in the case of the chipper dust, which, to ensure more uniform digestion, was cooked at a lower temperature and consequently for a longer period. The results show that infected wood is still suitable for sulphite pulp, providing the decay is limited to discoloration. The pulp from chipper dust, though containing much short fibre, was comparatively good in colour and appearance, and could undoubtedly be used if properly mixed with ordinary sulphite pulp. —D. J. N.

Sulphite wood pulp; Steam consumption in digesting and drying ——. H. Alfthan. Papierfabr., 1919, 19, 657—659.

Records were taken by means of the Bayer steam meter of the consumption of steam at the various stages of the manufacture. *In the digesters.* Conditions for the manufacture of "easy bleaching" pulp: Ritter-Kellner process; digester charge, 90 cub. m. of chips, giving an average of 12,500 kg. of cellulose; steam main pressure, 6—7 atm.; finishing temperature, 140° C.; average time under pressure, 13 hrs.; liquor heated up from 26° C.; no preliminary steaming of the chips. Steam consumption, average, 2·4 kg. per kg. of cellulose, distributed approximately as follows: 69·6% consumed in heating up to 105° C. and 30·4% in digesting from 105° to 140° C. For the digestion of "strong" pulp, the yield from a digester was 13,300 kg., with an average time under pressure of 5 hrs. Steam consumption, average 2·1 kg. per kg. of cellulose. *On the drying machine.* The machine was fitted with 16 drying cylinders, 1250 mm. in diam., and working width 2600 mm.; steam pressure in the cylinders 1·6 atm.; each cylinder fitted with condensed water ejector and trap. The dry substance of the pulp taken at the couch roll was 20·46%; taken after the 1st press, 35·60; taken after the 2nd press, 38·15%. Drying was assisted by blowing heated air between the cylinders; temperature of the hot air, 51° C.; this air does not take part in the evaporation, but serves to carry away the water vapour generated at the surface of the hot pulp and its use increased the rate of production of the machine by 13·6%. The sheet of pulp was sprayed on the wire of the machine with hot water at 41° C. in order to assist the draining. By the use of the hot water spray a sheet of 600—700 g. per sq. m. could be made, whereas without the hot water the heaviest sheet which could be run was 350 g. per sq. m., owing to crushing at the couch roll and tearing on the drying cylinders. Steam consumptions on the drying machine were as follow: For "easy bleaching" pulp, in the drying cylinders, 1134 kg.; in the air-heater, 306 kg.; in the hot water spray, 368 kg.; total, 1808 kg. of steam per ton of air-dry pulp; production, 1142 kg. per hr. For "strong" pulp, in the drying cylinders, 1238 kg.; in the air heater, 321 kg.; in the hot water spray, 385 kg.; total 1944 kg. per ton of air-dry pulp; production 1091 kg. per hr. The superior results for the bleaching pulp are attributed to the freer condition of the fibres which part with their water more readily. If the steam traps of the drying cylinders are not working properly the steam consumption at this point may easily increase to 40% above the normal amount.—J. F. B.

Oat-hulls; Utilisation of —— in the manufacture of straw boards and paper pulp. S. D. Wells. Pulp and Paper Mag., 1921, 19, 1139—1143.

Laboratory experiments using the sulphate process indicated that mixtures of oat-hulls with about 70% of cotton linters or 35% of cotton hull fibre, obtained by the Segundo process (*cf.* J., 1918, 118 T), give good yields (63% and 58% respectively) of an easily washed, easy-bleaching fibre, which would probably be useful to replace bleached soda pulp in the manufacture of magazine papers etc.; estimated costs of production show that this pulp could be sold at a cheaper rate than bleached soda pulp. The possibility of using the hulls for straw boards by the lime boiling process was also investigated and the results were sufficiently encouraging to justify mill trials; 15·4% of lime (99% CaO) was used, the pressure being maintained at 11 lb. per sq. in. for about 3 hrs., and subsequently raised to 21 lb. per sq. in. for 15 hrs. Trial boils were made with oat hulls alone, oat hulls mixed with straw, and oat hulls with about 7% of air-dry second cut cotton linters. Results showed that the working costs for oat hull would not exceed those for straw, and, since the pulp from the former gives up its water more readily on the presses, less steam would be required for drying. Sheets made from oat hull alone are weaker than those from straw, but by boiling equal quantities of the oat hull and straw with the addition of a small percentage of cotton linters excellent sheets are obtained, which are stronger than those made from straw alone. Oat hulls intended for papermaking must be removed from the groat by a special milling process, in which practically no grinding action takes place; ground oat hulls are quite unsuitable for papermaking.—D. J. N.

Wood pulp; Bleaching —— with liquid chlorine. E. Opfermann. Papierfabr., 1921, 19, Fest- u. Ausland-Heft, 62—65.

In the process introduced in 1912 by De Vains and Peterson (F.P. 449,497; J., 1913, 482) for bleaching the pulp in the hollander with chlorine water ("chlorine hydrate"), a lead pipe is carried through the wall of the hollander below the surface of the stuff and is connected with an external cylinder in which chlorine water is prepared by means of an injector arrangement, consisting of concentric nozzles delivering water through a wide nozzle and chlorine gas through a small one. The chlorine water mixes with the pulp in the hollander and chlorination is complete after about 1½ hr., as judged by the colour and smell of the stuff. The yellow pulp is washed and concentrated, then neutralised with caustic soda, washed again, and finally bleached warm with hypochlorite. In this way about 75% of the usual consumption of bleaching powder may be replaced by liquid chlorine, and so far as cost of chemicals is concerned a saving is recorded, as compared with the ordinary method of bleaching, this economy being greater the greater the resistance of the pulp to the normal bleaching process. A similar economy may however be effected by modifying the ordinary bleaching process by bleaching first cold with a portion of the hypochlorite, washing, treating with alkali, washing again, and finishing warm with a further portion of hypochlorite, the loss of fibre being from 1 to 3% less than by the chlorine water method.—J. F. B.

Cellulose acetates [and nitrocellulose]; Viscosity of ——. A. von Fischer. Kolloid-Zeits., 1921, 29, 260—265.

The suitability of cellulose acetate for the production of plastic materials cannot be decided from the absolute value of the viscosity of its solutions, but curves plotted from the results of viscosity determinations on solutions in mixtures of alcohol (96%, denatured with 0·5% of camphor) and acetone in varying proportions are useful for this purpose. A good cellulose acetate always shows a minimum viscosity in an acetone-alcohol mixture containing 80% by vol. of acetone, but the converse is not always true. A minimum viscosity in a mixture containing 90 vol. % of acetone invariably indicates a poor quality cellulose acetate. The addition of Japanese camphor or triacetin to an acetone solution of cellulose acetate increased the viscosity (*cf.* J.C.S., Dec.). Dichlorhydrin and *p*-toluenesulphamide increased viscosity with some samples and decreased it with other samples of cellulose acetate. In the case of nitrocellulose, samples suitable for the manufacture of celluloid gave solutions in alcohol, containing camphor, in which the viscosity diminished with increasing camphor content, whilst unsatisfactory samples gave solutions in which the viscosity increased with increasing camphor content.—J. F. S.

Wood pulps; Evaluation of —— on the basis of lignin content. H. Krull. Papierfabr., 1921, 19, Fest- u. Ausland-Heft, 65—70.

An analytical scheme is proposed for the classification of commercial sulphite wood pulps whereby the purity is measured by the percentage of lignin and the chemical condition by Schwalbe's "copper value." For the estimation of lignin, the method proposed by König and Becker (J., 1919, 530 A) with gaseous hydrogen chloride is employed; for the copper values, the total copper value is corrected by the "hydrate" copper value (*cf.* Schwalbe, J., 1919, 407 A). The following classification is suggested:—For Mitscherlich pulps: hard, 6·5—7·0% of lignin; normal, 5·5—6·0%; soft (easy bleaching), 5·0—5·5%; bleached, 1·0—2·0%. For Ritter-Kellner pulps: hard, 7·5—9·5%; normal, 6·5—7·5; soft (easy bleaching), 4·5—6·5% of lignin. In the table below the analytical results of a number of typical pulps are recorded and indications may be deduced as to their suitability for certain purposes. Sample No. 1, a hard Mitscherlich pulp, is particularly suitable for grease-proof parchment papers and the modifications which it undergoes in beating conform to the specification of Schwalbe (J., 1919, 858 A) for cellulose mucilage, namely, that for a good grease-proof pulp the corrected copper value should show a large increase and the hydrate copper value should remain relatively low during beating. Sample No. 13 illustrates a Ritter-Kellner pulp used for grease-proof paper, but not very suitable, since the increase in the corrected copper value is small and the hydrate value has not increased at all, while the high increase in ash indicates an abnormal consumption of power during beating. Sample No. 3 is an easy-bleaching type of Mitscherlich pulp and No. 4 is the same pulp bleached with 4% of active chlorine. Sample No. 5 is a "crêpe" pulp largely used in the artificial silk industry; No. 6 is a similar pulp used for smokeless powder, and No. 7 is a surgical quality.

—J. F. B.

Lignin. I. Sulphite liquor lactone. B. Holmberg. Ber., 1921, 54, 2389—2406.

VARIOUS reactions and derivatives of the lactone isolated from sulphite-cellulose waste liquor (J., 1921, 113 A) are described. (*Cf.* J.C.S., Dec.) —T. H. P.

Lignin. II. Dimethyl-sulphite liquor-lactone. B. Holmberg and M. Sjöberg. Ber., 1921, 54, 2406—2417.

TREATMENT of the lactone previously described (*cf. supra*) with dimethyl sulphate gives its dimethyl derivative (α-dimethyl-sulphite-liquor-lactone), which is converted by sodium ethoxide into optically inactive β-dimethyl-sulphite-liquor-lactone, this being not racemic but apparently diastereomeric with the α-compound and hydrolysable to an optically active, stereochemically individual hydroxy-acid. (*Cf.* J.C.S., Dec.)—T. H. P.

Lignin. III. Alkali-lignins. B. Holmberg and T. Wintzell. Ber., 1921, 54, 2417—2425.

FROM the so-called black liquor obtained as waste product in the soda-cellulose process, acids form precipitates separable into α-lignin, $C_{40}H_{42}O_{13}$, insoluble in alcohol, and λ-lignin, $C_{40}H_{44}O_{12}$, soluble in alcohol. Both lignins are greyish-yellow to yellowish-brown, amorphous powders, readily yield colloidal solutions, and behave like complex phenolic compounds, and each contains four methoxy groups per C_{40}; two further methoxy groups are introduced by treatment with methyl sulphate. (*Cf.* J.C.S., Dec.)—T. H. P.

Typha fibre for paper-making; Utilisation of ——. F. Rühlemann. Papierfabr., 1921, 19, Fest- u. Ausland-Heft, 28—31.

TYPHA (bulrush) fibres were incorporated with rag fibres in specimens of paper prepared by Schäffer in 1771. At the present time the spinning mills which employ rush fibres for textile purposes dispose of their short-fibre waste to paper mills. The manipulation of this material is not more difficult than that of jute or hemp, and it is shown by photomicrographs that the fibre is well adapted for paper manufacture.—J. F. B.

Silicate of soda in papermaking. J. G. Vail. Chem. and Met. Eng., 1921, 25, 823—824.

SODIUM silicate as a sizing material makes a paper resistant to oil inks, and also produces a harder and smoother sheet than resin size, and increases the bursting strength by about 12%. Papers intended for printing may be sized with silicate, or silicate and starch, without any addition of resin size; such papers do not discolour on prolonged exposure to light as do resin-sized papers. The sodium silicate, preferably one in which the ratio of soda to silica is 1 to 4, is added to the beater, and completely precipitated with alum, after which the stuff may be resin-sized, tinted, and loaded in the usual manner. Retention of the flocculent precipitate, which probably contains aluminium silicate, aluminium hydroxide, and hydrated silica, represents about 66% of the total silica added, when 3·48% of liquid silicate (34% of total solids) is used, but with higher percentages the retention appears to increase; an addition of 10% of silicate, however, causes the stuff to run appreciably slower on the machine.—D. J. N.

Colloidal resin; Sizing [paper] with ——. F. Stöckigt and A. Klingner. Papierfabr., 1921, 19, Fest- u. Ausland-Heft, 50—60.

COLLOIDAL resin is prepared by dissolving 3 g. of powdered resin in 30 c.c. of 96% alcohol at 50° C., pouring the solution into distilled water, and diluting the emulsion with water to 500 c.c. Comparative experiments have been made with American colophony and German spruce resin prepared in this manner and applied to the sizing of paper pulp. These emulsions have no sizing effect when used alone but are extremely effective when subsequently coagulated by the addition of aluminium sulphate. Magnesium sulphate and sodium bisulphate also bring about the complete coagulation of the emulsions, but nevertheless have no appreciable sizing effect. From experiments in which the proportions and order of addition of the resin and aluminium sulphate were varied, it is concluded that sizing takes place in two stages: first an adsorption compound is formed between the resin as a negative colloid and the aluminium hydroxide as a positive one, and secondly this adsorption compound is adsorbed by the fibre. The behaviour of the resin emulsions towards electrolytes in the absence of paper pulp follows the general laws of colloids, sodium bisulphate being inferior in coagulating power to magnesium sulphate and this again inferior to aluminium sulphate. In the absence of fibre, with increasing concentrations of electrolyte alternate phases of complete and incomplete precipitation recur at irregular intervals. In the presence of the fibre this irregularity is not observed. The smallest quantity of resin required to produce sizing effects is 0·5% of the air-dry pulp and the minimum quantity of aluminium sulphate, as $Al_2(SO_4)_3,18H_2O$, is 100% of the weight of the resin. This efficiency is much higher than that obtained with emulsions prepared by partial saponification; moreover the difficulty of saponifying the natural resins is overcome and the efficiency of spruce resin is equal to that of colophony when prepared in this manner.—J. F. B.

"Batik" designs on paper. L. Kollmann. Papierfabr., 1921, 19, Fest- u. Ausland-Heft, 39—43.

FOR the production of batik designs on paper a sufficient sizing and a moderate thickness (about 0·1 mm.) of the paper are necessary to secure white resists. Paraffin wax, m.p. 52° C., is a suitable medium for executing the designs; the most satisfactory results are produced with wax at a temperature of 80°—100° C. For flat effects the wax should be applied with a hair brush and for line effects a special copper stylus with a fine tubular point controlled by a conical valve is used. Provided the wax

is employed at the right temperature a single application on one side only is sufficient to produce the desired resist. The cracking of the wax is best performed by irregular crumpling by hand under cold water. The sheet is then transferred without drying to the dye bath, the temperature of which should not be above 35° C. A suitable concentration of dyestuff is 1—2 g. per litre. Any dyestuff suitable for cellulose may be used, and, in addition, acid dyestuffs capable of being fixed by the components of the sizing of the paper. After dyeing, the wax is removed by steeping the paper in light petroleum spirit. Combination shades and variegated resists can be executed by a second application of wax designs after the removal of the wax from the first one. Discharge effects may be produced in a similar manner by the action of hydrosulphite upon azo dyestuffs giving colourless reduction products.
—J. F. B.

Sulphite-cellulose waste liquors; Evaporation of —— by the application of the heat-pump. E. Wirth. Papierfabr., 1921, **19**, Fest- u. Ausland-Heft, 70—74.

The heating value of 1 kg. of dry substance from unfermented waste liquor is 4300 to 4500 cals. Previous fermentation greatly facilitates the problem of evaporation owing to the clarification thereby effected; for a satisfactory solution, however, it would be necessary to deal also with unfermented liquor. The requirements for a satisfactory solution of the problem include cheap and effective neutralisation, plant constructed of ordinary materials, and counteraction of the injurious effect of the calcium sulphate incrustation. One litre of ordinary waste liquor requires about 6 g. of caustic soda for its correct neutralisation. Plant has been tested in Switzerland which will evaporate the liquor to a sp. gr. of 1·47, giving a syrup, containing about 15% of water, which solidifies on cooling. In this process of evaporation the separation of calcium sulphate has no ill-effects. The evaporator is worked on the "heat-pump" system in which the heat generated by compressing the vapours given off from the evaporating liquid is utilised for the evaporative work. The compressor is driven by a steam engine, the exhaust steam of which is used in the cellulose manufacture. Comparing the results obtained with the heat pump with the best results from the quadruple effect vacuum evaporator, and expressing them in terms of sulphite fuel required for the evaporation of the liquor, it was found that the heat pump consumed only 6·3% of the fuel produced by it, while the quadruple effect consumed 34·5%. Thus the heat pump utilises its heat 22 times, while the vacuum evaporator cannot give more than a four-fold utilisation. Evaporation at a high temperature is more economical than evaporation at a low temperature, and the low temperatures of the multiple effect are only employed in order to obtain the necessary temperature-differences, which can be selected at will with the heat-pump. A vacuum evaporator cannot concentrate the liquor to a sp. gr. of 1·47 owing to the high viscosity at the low temperature; moreover the heat-pump delivers the condensed water at a higher temperature than the multiple effect. It is necessary, however, to subject the liquors to a preliminary chemical treatment whereby the compressor is protected from the possible action of acid constituents; in that case the compressor can be constructed of ordinary material without danger of corrosion. The sulphite fuel is turned out in a single operation with a content of 15% of moisture; this is very much more economical than drying it down to 7·5% of moisture by a secondary evaporation on a drum, which can only work as a single effect evaporator. Allowing for the moisture in the fuel, the net yield of heat units in the form of fuel by the heat-pump evaporation alone is 88·9% of the fuel value of the total solids of the liquor.—J. F. B.

Patents.

Wool; Treatment of —— to prepare it for manufacture. T. A. Coghlan. E.P. 170,645, 21.7.20.

Raw wool is subjected to several treatments with commercial trichloroethylene, b.p. 90° C., at 45° C., in a series of vessels, after which the residual trichloroethylene is removed from the wool by washing with water at 45° C., or by means of a current of carbon dioxide. The solvent is distilled and recovered, together with the wool grease. Wool prepared by this process is cleaner, the fibres are stronger, and yield stronger yarn than is the case with wool prepared in any other manner. Moreover, the fibre remains unaffected by the acid during the subsequent carbonisation.—F. M. R.

Zoophytes and other sea materials; Manufacture of fibrous materials from —— and by-products therefrom. P. J. White. E.P. 170,869, 24.4.20.

Zoophytic or polyzooic material freed from foreign matter is treated chemically to produce fibrous materials consisting substantially of chitin. Incomplete chemical treatment, *e.g.*, extraction with dilute acids, such as hydrochloric acid (1:4) for 1 hr., gives a non-chitinous filament in a chitinous sheath. The material thus produced may be used for a variety of purposes, *e.g.*, as a stuffing material, or may be further treated by boiling with 20% caustic soda or 40% sodium carbonate solution for 24 hrs., and, if desired, bleached. The resulting product resembles wool, is extremely absorbent, and might be used for textile purposes, medical purposes, or as an absorbent material in the explosives industry.
—D. J. N.

Impregnation of materials [to render them air-tight and waterproof]. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. E.P. 154,570, 23.10.20. Conv., 24.11.19.

Sulphurised fatty oils, made by heating vegetable, animal, or fish oils, or mixtures of these, with 20—80% of sulphur at 200° C. until a sample on cooling is found to be stringy, are mixed while hot with $\frac{2}{3}$—$1\frac{1}{2}$ times their weight of sulphurised tar, pitch, or the like, made by heating tar or pitch at 100° C. with 10—20% of sulphur for $\frac{1}{4}$—1 hr. The mixture, to which may be added fillers, such as chalk, is kept at 170°—200° C., with constant stirring, for about $\frac{1}{2}$ hr., and is then ready for use. Materials impregnated with this composition are impervious to air and water, and resist chemical action.
—D. J. N.

Porous or bibulous materials; Method of impregnating —— and product thereof. W. R. Seigle. U.S.P. 1,395,744, 1.11.21. Appl., 28.6.20.

Porous material is impregnated with an unsaturated oil, which has been partially saturated by an added reagent, and is then heated to polymerise the partially saturated oil. Brake linings and the like are made by impregnating porous materials with gilsonite and partially hydrogenated tung oil, polymerised by heat.—D. J. N.

Waterproofing composition, and method of making same. W. G. Abbott, jun. U.S.P. 1,395,885, 1.11.21. Appl., 23.9.18.

Viscous water-resisting compositions are obtained by treating glycerides with lead acetate at temperatures above 100° C.—D. J. N.

Viscose silk; Manufacture of ——. E. Bronnert. E.P. 169,190, 17.3.20.

The process for producing fine viscose threads from apertures of 0·1 mm. (E.P. 166,931; J., 1921, 654 a) is modified, in that well-ripened viscose solution is spun into a solution of sodium sulphate, fully saturated at 45° C., and kept at this temperature, and containing only 25 g. of sulphuric acid monohydrate per l.—D. J. N.

Artificial silk; Manufacture of ——. E. Bronnert. E.P. 170,313, 10.5.20.

A PRECIPITATING bath for viscose solutions consists of a saturated solution of common salt or "Stassfurt waste salt" (which contains about 70% NaCl, 20% $MgCl_2$, and small quantities of potassium sulphate), with addition of sulphuric acid in such quantity as will give a thread of the desired titre. Strong, lustrous, evenly-dyeing threads are obtained by spinning viscose into a bath containing 120 g. of sulphuric acid monhydrate and 260 g. of common salt or 400 g. of "waste salt" per l. This bath works well at ordinary temperatures, and there is no escape of hydrochloric acid fumes.—D. J. N.

Artificial silk; Manufacture of ——. E. Bronnert. E.P. 170,608, 23.4.20.

FRESHLY-PRECIPITATED threads of cellulose hydrate are dried in a current of air or other inert gas uniformly heated throughout to 100°—140° C., and having a minimum velocity of 3 m. per second. Apparatus for carrying out the process comprises a series of drying chambers, the current of air being re-heated to its initial temperature and re-mixed as it passes from one chamber to the next. This method of drying enables viscose threads to be dried rapidly without injury or discoloration.—D. J. N.

Artificial silk; Manufacture of ——. E. Bronnert. E.P. 170,874, 30.4.20.

FINE threads are produced by spinning viscose into concentrated solutions of bisulphites, with or without addition of glucose of formaldehyde; *e.g.*, a thread of 2 deniers is obtained by using a bath containing 360 g. of sodium bisulphite per l. For the production of finer threads (1—1·5 deniers) a saturated solution of ammonium bisulphite is used at 30°—80° C., the thread being allowed a longer travel in the bath, and drawn off at about 40 m. per min. (*Cf.* E.P. 163,817; J., 1921, 505 A.)
—D. J. N.

Cellulose-ether solvent and composition. J. M. Donohue, Assr. to Eastman Kodak Co. U.S.P. 1,394,505, 18.10.21. Appl., 10.1.21.

AN alkyl ether of cellulose is dissolved in a mixture of chloroform and alcohol to give a viscous solution, capable of being used for the production of films.
—D. J. N.

Cellulose acetate; Method of treating —— and the product thereof. G. W. Miles, Assr. to American Cellulose and Chemical Mfg. Co., Ltd. U.S.P. 1,394,752, 25.10.21. Appl., 14.11.19.

UNIFORM distribution of small quantities of glycerin in cellulose acetate is effected by heating the latter with a large quantity of glycerin, the excess of which is subsequently removed by washing with water.—D. J. N.

Cellulose acetate; Manufacture of solutions, preparations, or compositions having a basis of ——. H. Dreyfus. U.S.P. 1,395,401, 1.11.21. Appl., 29.8.19.

CELLULOSE acetate is mixed with cyclohexanone.
—D. J. N.

Cellulose-ether composition. H. T. Clarke, Assr. to Eastman Kodak Co. U.S.P. 1,395,905, 1.11.21. Appl., 16.2.21.

A CELLULOSE ether is mixed with a salicylic acid ester of a monohydroxy aliphatic alcohol containing 4—5 carbon atoms.—D. J. N.

Pulp and fibrous material; Method and apparatus for washing ——. E. C. R. Marks. From The Brown Co. E.P. 170,310, 13.4.20.

AN apparatus for the continuous counter-current washing of fibrous material consists of a series of, preferably 9, storage tanks, the height of liquor in each of which is so adjusted that tank 1 overflows into tank 2 and so on through the system. Above each storage tank is a washing tank, preferably separated into two compartments by an adjustable dam: one compartment contains an agitating device, while the other contains a partially-submerged, revolving steel cylinder, which maintains contact with a press roll situated above it and made to run at the same speed. The cylinder is perforated with holes $\frac{1}{16}$th—$\frac{1}{8}$th in. diam., and water entering through the perforations is discharged through the ends of the cylinder. The boiled pulp is introduced into the agitator compartment associated with storage tank 9, and circulates into the adjacent cylinder compartment, where it is picked up by the revolving drum, squeezed by the press roll, to which it adheres, to be subsequently removed by a doctor into the agitator compartment associated with tank 8, the washing liquor being continuously pumped up into the agitator tank from the corresponding storage tank, to which it returns through the hollow axis of the revolving cylinder. A small quantity of fresh washing water is continuously introduced into the first storage tank to keep up the flow of water through the system. The apparatus is specially suitable for washing sulphate pulp.—D. J. N.

Sulphite-cellulose; Process for the production of high percentage ——. E. Bronnert. E.P. 170,964, 4.8.20.

SEE U.S.P. 1,392,047 of 1921; J., 1921, 808 A.

Paper pulp and like substances; Means for extracting moisture from ——. J. McIntyre, and J. Milne and Son, Ltd. E.P. 170,871, 29.4.20.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Cotton; Effect of prolonged bleaching on ——. P. Heermann and H. Frederking. Textilber., 1921, 2, 395—396.

THE investigation of the effect of bleaching on cotton, using the same strength of bleach liquor and method of bleaching as previously described (J., 1921, 578 A), has been continued. After fifty successive bleaching treatments of 15 mins. each, the strength of cotton fabric had decreased 8·5%, its elasticity had increased 13·6%, and its weight had decreased 2·6%. When the period of bleaching was increased to 75 mins., the other conditions remaining the same, the decrease in strength was 15·7%, the increase of elasticity was 10·2%, and the loss of weight was 3·5%. During short periods, the loss of strength of cotton by bleaching is not directly proportional to the duration of bleaching, since when the duration is increased five times the loss of strength is only doubled. In an editorial note it is pointed out that if allowance is made for the corresponding loss in weight, *i.e.*, if the breaking lengths are calculated, the loss of strength of cotton fabric, after fifty bleaching treatments of 15 and 75 mins. each respectively, is *nil* and about 7%.—A. J. H.

PATENTS.

Fibres, fibrous materials, fabrics and leather; Treatment of —— with liquids. M. Freiberger. E.P. 146,225, 28.6.20. Conv., 13.2.17.

THE penetrating powers of liquids such as are used for dyeing, bleaching, cleaning, mercerising, etc., are improved if pyridine, quinoline, other heterocyclic bases, or simple derivatives of these bases are added. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 5717 of 1898.) —A. J. H.

Textile materials; Apparatus for treating —— with fluids. F. Ferrand and F. Riley. E.P. 170,956, 4.8.20.

In a machine for treating textile materials with bleaching or dyeing liquors and the like, the materials are placed within a double-walled vessel and are there treated with liquors which are also circulated through a coil, situated between the two walls, where they may be heated by means of exhaust steam obtained from the steam engine used for pumping the liquors. Dilution of the liquors during heating is thus avoided.—A. J. H.

Dyeing machine. H. M. Dudley. U.S.P. 1,395,669, 1.11.21. Appl., 1.12.19.

The machine consists of a series of perforated dyeing chambers carried by a revolving sleeve on a shaft within a container. The dye-liquor is circulated simultaneously and continuously into all portions of one end of the container, and then passes through the dyeing chambers.—F. M. R.

Cotton fabrics; Process for improving [producing transparent effects on] ——. G. A. Bosshard, Assr. to A.-G. Seeriet, Bleicherei, Filiale Arbon. U.S.P. 1,395,472, 1.11.21. Appl., 9.7.20.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Lead chambers; Damage to —— caused by wood wasps. F. Pax. Jahresheft Ver. Schlesische Insektenkunde. Reprint, 12 pp.

A large number of circular perforations, from 6 mm. diam. downwards, discovered in the bottoms of the lead chambers of a new Silesian acid works, were proved to be caused by newly hatched wood wasps, *Sirex gigas* and species of *Paururus*, whose larvæ were found in the flooring. In some cases the wasps had died before completely boring through the lead, causing minute leaks very difficult to detect. As the time of development of these insects varies from two to four years, and no means could be devised to kill the larvæ within the wood, sheet iron had to be placed between the lead and wood over the whole of the chamber floors as the only guard against further attacks. Provision was made for the removal of the iron at the end of two years. Such infection of timber can be avoided by employing sound wood felled in winter, removed from the forest before May, and preferably creosoted or tarred at the sawmills.—C. I.

Sulphates; Conversion of ammonium sulphide and of thiosulphates into ——. W. Gluud. Ber., 1921, 54, 2425—2426.

In aqueous solution at 100° C. ammonium sulphide may be rapidly and completely converted into ammonium sulphate by air at a pressure of 10 atm., and under similar conditions sodium thiosulphate undergoes a similar change if sufficient alkali is present to unite with the sulphuric acid formed from the sulphur; otherwise elementary sulphur separates.—T. H. P.

Persulphates; Stability of ——. K. Elbs and P. Neher. Chem.-Zeit., 1921, 45, 1113—1114.

Sodium, potassium, and ammonium persulphates can be kept for years almost unchanged if dry and protected from sunlight. At ordinary temperatures aqueous solutions show appreciable decomposition after some days, and with increasing temperature the rate of decomposition rapidly increases, and is further accelerated by sunlight; at 100° C. decomposition is practically complete in about 1 hr., though the actual velocity varies to a considerable extent with the concentration, and with the cation, the sodium salt being somewhat more stable than the potassium and ammonium salts. The addition of sodium sulphate distinctly diminishes the velocity of decomposition, whilst the presence of 5% of sulphuric acid increases it 5—10 times. As an oxidising agent sodium persulphate is the most useful salt, and it is often advantageous to diminish the velocity of the reaction, and so prevent the formation of molecular oxygen, by adding 45% of crystallised sodium sulphate.—G. F. M.

Permanganate, bichromate, and chromic salts; Volumetric determination of mixtures of ——. N. G. Chatterji. Chem. News, 1921, 123, 232—233.

When a solution containing permanganate and bichromate is treated with a mixture of manganese sulphate and zinc sulphate, the permanganate is converted into hydrated manganese dioxide, whilst the bichromate is not affected; titration of the solution with ferrous sulphate solution, before and after such treatment (and removal of the manganese dioxide by filtration) gives the quantities of permanganate and bichromate present. The determination of chromium salts in the presence of permanganate or bichromate depends on the oxidation of the chromium salt to bichromate by heating with hydrated manganese dioxide in dilute sulphuric acid solution.—W. P. S.

Silver bromate. J. H. Reedy. J. Amer. Chem. Soc., 1921, 43, 1440—1445.

The author describes some of the properties of silver bromate and shows that it may be used as a standard in iodimetry. 1 g. of bromate and an excess of potassium iodide are added to 150 c.c. of water in a 250 c.c. flask, the mixture heated on a water-bath to effect double decomposition, cooled, and made up to 250 c.c. Samples of 25 c.c. are acidified with dilute hydrochloric acid and titrated with sodium thiosulphate. Arsenious oxide gives results about 0·2% higher than silver bromate, but after recrystallising the oxide from hydrochloric acid this figure is reduced to 0·05%. This indicates that while silver bromate may have a somewhat higher oxygen equivalent than arsenious oxide, this defect is fully compensated by its greater definiteness.—J. F. S.

Erbium earths; Concentration of ——. P. H. M.-P. Brinton and C. James. J. Amer. Chem. Soc., 1921, 43, 1397—1401.

The basic nitrate method is recommended for the separation of erbium, holmium, dyspresium, and the less basic earths from yttrium. The separation of holmium and dysprosium from yttrium is best effected by the crystallisation of the chlorides from hydrochloric acid (1:1). The basic nitrate method consists in adding a solution of sodium hydroxide to a boiling solution of the nitrate until fine shining crystals are seen floating about the solution. On cooling, a crystalline mass separates in which the erbium is largely concentrated. (*Cf.* J.C.S., Jan.) —J. F. S.

Radioactive elements; Oxidising properties of certain ——. P. Lemay and L. Jaloustre. Comptes rend., 1921, 173, 916—918.

The bromides of mesothorium, radiothorium, thorium X, and radium act as catalysts of certain oxidation reactions (oxidation of quinol, guaiacum tincture, ferrous salts, and potassium iodide). Their action is independent of the formation of ozone and is due to α-radiation. For the small amounts of material used it is the same for the four elements.—W. G.

Iodine in the Laminaria. P. Freundler, Y. Menager, and Y. Laurent. Comptes rend., 1921, 173, 931—932.

The iodine content of *Laminaria* is higher in July than in March and is highest in the youngest tissues. Other factors being equal it is independent of the locality in which the algæ grow. The distribution throughout the plant varies with the particular species. During drying the *Laminaria* lose some of their iodine, the loss in some cases amounting to as much as 50% of the original iodine content.—W. G.

Sulphides. Willard and Cake. *See* X

Patents.

Sulphuric acid; Manufacture of —— [from alunite]. A. Matheson. E.P. 170,880, 6.5.20.

Alunite is calcined in a shelf burner of the type described in E.P. 158,923 (J., 1921, 233 a), the bottom hearth being externally heated to 700°—900° C. The sulphuric anhydride from the mineral is partly decomposed on the bottom hearth but is regenerated on the upper ones, the iron oxide present serving as catalyst. The evolved gases, which are not diluted with air, pass on to a condenser. If necessary water is introduced as steam or by a spray either to the furnace or the condenser. —C. I.

Nitric acid; Concentration of ——. O. Jensen, Assr. to Norsk Hydro-Elektrisk Kvaelstofaktieselskab. U.S.P. 1,395,577, 1.11.21. Appl., 24.2.20.

Nitric acid is heated in an evaporator, the vapours are passed through a separator from which the condensate is returned, and the nitric acid vapour is further dried in a scrubber with sulphuric acid. —C. I.

Ammonia synthesis; Production of a mixture of hydrogen and nitrogen for ——. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. G.P. 340,753, 18.4.20. Conv., 23.5.19.

Hydrogen and nitrogen are produced by the action of water and air respectively upon sulphides, *e.g.*, pyrites, blendes, etc., both reactions being carried out at high temperature. Sulphur dioxide evolved during the reaction is combined with lime, ammonia, etc., to form sulphites, solutions of which, more especially ammonium sulphite, are employed to remove the last traces of oxygen from the nitrogen produced.—J. S. G. T.

Ammonium sulphate; Manufacture of ——. South Metropolitan Gas Co., and P. Parrish. E.P. 170,613, 30.4.20.

An ammonium sulphate saturator may be maintained at the low acidity desirable for the preparation of neutral salt, without risk of discoloration, if cyanogen compounds in the gas are converted into thiocyanate by treatment with a polysulphide and thus prevented from entering the saturator. The ammoniacal liquor may be treated with a polysulphide before being distilled, or the vapours from the still may be passed through spent oxide, or polysulphide may be generated in the liquor by blowing with air. In the direct process the gases are treated with polysulphide in a washer before entering the saturator.—C. I.

Alumina; Production of —— from aluminium nitrate solutions. Det Norske Aktieselskab for Elektrokem. Ind. Norsk Industri-Hypotekbank. E.P. 151,259, 27.8.20. Conv., 19.9.19.

An aluminium nitrate solution is evaporated at 140° C., water being added to prevent the temperature rising, whereby 70% of the nitric acid is distilled off and recovered. A readily filtered basic nitrate is then precipitated by heating in an autoclave. From this precipitate on heating without fusion oxides of nitrogen are completely driven off. The iron content of the original solution is largely left in the mother liquor. Lime may be added to the original solution in sufficient quantity to neutralise 30% of the nitric acid. The mother liquor, containing 20—30% of the original alumina, is further concentration with addition of nitric acid. Normal aluminium nitrate separates out and is returned to the process, and eventually the calcium and sodium nitrates present are recovered to be used as a fertiliser.—C. I.

Hydrogen; Production of ——. A. R. Griggs. E.P. 170,908, 10.7.20.

In the production of hydrogen by the treatment of heated iron with water-gas and steam alternately, several retorts are used which are at any one time at different stages of the reduction phase. The waste gases from those at a later stage containing much combustible gas are used in the retorts in the initial stage of reduction after condensation of water vapour. The retort is first heated by the internal combustion of some of this gas with a limited amount of air. The heat removed in the condensation of the water vapour is restored by the use of heat-exchangers. The gases are also used for the external heating of the retorts.—C. I.

Perborates; Manufacture of ——. O Liebknecht, Assr. to The Roessler and Hasslacher Chemical Co. U.S.P. 1,395,684, 1.11.21. Appl., 27.1.17.

See E.P. 106,460 of 1916; J., 1917, 1047.

Hydrogen; Process for the extraction of —— from gaseous mixtures. G. Claude, Assr. to L'Air Liquide, Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude. U.S.P. 1,395,389, 1.11.21. Appl., 14.3.18.

VIII.—GLASS; CERAMICS.

Glass; Development of various types of ——. XII. Interaction of silica, sodium oxide, and barium oxide. C. J. Peddle. J. Soc. Glass Tech., 1921, 5, 201—211. (*Cf.* J., 1920, 515 a; J., 1921, 216 a, 509 a, 771 a.)

Two series of melts were made, of the molecular types $100SiO_2$, $40Na_2O$, $xBaO$, and $100SiO_2$, $20Na_2O$, $xBaO$, where x varied from 5 to 40. All glasses fluxed and plained well except $100SiO_2$, $20Na_2O$, $5BaO$, which deposited silica. The colour was deeper in the first series and increased with increase of BaO content. Density increased in both series with increase of BaO, whilst for glasses with less than 16 mols. BaO increase of Na_2O increased the density. The rate of increase of density per mol. BaO was greater in the series with lower Na_2O content, and fell as the BaO increased in amount. Increase of density per 1% rise of BaO was about 0·019 for the first series and 0·024 for the second. In both series η_D increased with increase of BaO, the molecular rate of increase being greater in the second series. With constant molecular amounts of BaO, η_D increased with increase of Na_2O content until a BaO content of 26 mols. was reached. The greater the Na_2O content the smaller was the effect of additional BaO on the value of η_D, and the greater the amount of BaO the smaller was the effect of added Na_2O. Although glasses $100SiO_2$, $40Na_2O$, 26BaO and $100SiO_2$, $20Na_2O$, 26BaO had the same value of η_D (1·561), the total dispersions differed, being 0·01037 and 0·00992 respectively. In both series total dispersion increased with increasing BaO content, whilst where the molecular amounts of SiO_2 and BaO remained constant increase of Na_2O increased total dispersion. The rate of increase of total dispersion with increasing molecular content of BaO was slightly greater in the second series. The values of ν were greater in the second series, and decreased with increasing BaO content, the rate of decrease being less the greater the amount of BaO present. Both red and blue ends of the spectrum were lengthened by increase of the number of BaO mols. present, the lengthening being greater in the second series. Glasses $100SiO_2$, $20Na_2O$, 30BaO and $100SiO_2$, $20Na_2O$, 40BaO devitrified on slow cooling. Devitrification tests (heating to 900° C. for 6 hrs. and cooling in 12 hrs.) proved that glasses containing more than 68% SiO_2 tend to devitrify and deposit silica; those with more than 17% Na_2O may contain 35% BaO without devitrifying, but with a lower Na_2O content 20% BaO tends to cause a deposit of barium silicate. The solubility in boiling water fell with increase of BaO, and where the BaO was constant solubility increased with increase of Na_2O. None of the first series fell within the standard of optical durability, whilst in the second series $100SiO_2$, $20Na_2O$, 30BaO, and $100SiO_2$, $20Na_2O$, 40BaO fell in Class III. and $100SiO_2$, $20Na_2O$, 20BaO in Class V., but through tendency to devitrification they were useless for optical purposes.—A. C.

Glass; Development of various types of ——. XIII. Interaction of silica, potassium oxide, and barium oxide. C. J. Peddle. J. Soc. Glass Tech., 1921, 5, 212—220.

The two series studied were $100SiO_2$ $40K_2O$, xBaO and $100SiO_2$, $20K_2O$, xBaO, x varying from 5 to 40. All gave plain glasses without devitrification on cooling, the colour increasing with BaO content, particularly in the first series. Where the content of BaO was less than 16 mols. addition of K_2O increased density, whilst added BaO increased the density in both series. The rate of increase of density per mol. BaO was greater in the series with lower K_2O content and fell with increasing BaO. In both series η_D increased with rising BaO content, the rate being greater in the second series. With the same BaO content the first series had a higher value of η_D until the BaO content reached 28 mols. In both series the greater the K_2O content the less was the effect on η_D of added BaO, whilst the greater the BaO content the less the effect of K_2O. Total dispersion increased with increasing BaO content, and where SiO_2 and BaO remained constant the glass with more K_2O had a larger total dispersion. The rate of increase of total dispersion with increase of molecular BaO content was slightly greater in the second series. Although glasses $100SiO_2$, $20K_2O$, 28BaO and $100SiO_2$, $40K_2O$, 28BaO had the same value of η_D (1·561) their total dispersions were 0·01007 and 0·01020 respectively. The effect of BaO on total dispersion decreased much less rapidly than the effect of potash, as the amount of BaO increased. Values of ν were greater in the second series; they decreased with an increasing number of mols. of BaO present, and the rate of decrease was less the greater the BaO content. Both red and blue ends of the spectrum were lengthened by molecular increase of BaO in the glass, increase of K_2O and BaO both spreading the blue end more than the red. Devitrification tests showed no separation of silica if this was below 70%. With K_2O above 25%, up to 32% BaO can be introduced without devitrification, whilst with the K_2O below 17%, a glass with 25% BaO will tend to deposit barium silicate. Durability increased with increase of BaO, whilst if the BaO was constant increase of K_2O decreased durability. None of the first series fell within the limits of durability for optical glasses. In the second series, glasses $100SiO_2$, $20K_2O$, 30BaO and $100SiO_2$, $20K_2O$, 40BaO fell in Class IV., but would be unsuitable since they devitrify on slow cooling.—A. C.

Glass; Development of various types of ——. XIV. Interaction of silica, barium oxide, and the oxides of sodium and potassium. C. J. Peddle. J. Soc. Glass Tech., 1921, 5, 220—228.

The two series studied were $100SiO_2$, $20Na_2O$, $20K_2O$, xBaO and $100SiO_2$, $10Na_2O$, $10K_2O$, xBaO, x varying from 5 to 40. No glasses devitrified on cooling. The colour increased with increase of BaO content. In both series increase of BaO increased the density, whilst below 28 mols. BaO, increase of alkali oxides also increased the density. The value of η_D in all cases increased with increase of BaO, the rate of increase being greater in the second series. The first series had a greater value of η_D up to the point where 27 mols. BaO was present. In both series, the greater the amount of alkali oxide, the less the effect of added BaO on the value of η_D, and the greater the amount of BaO, the less was the effect of alkali oxide. Total dispersion increased in each case with rise of BaO content, whilst, where the number of mols. of SiO_2 and BaO were constant, increase of the alkali oxides increased total dispersion. The rate of increase of total dispersion with increase of BaO was greater in the second series. Values of ν were greater in the second series and decreased in both series with increase of BaO. Both red and blue ends of the spectrum were lengthened as the amount of BaO rose, the blue end spreading relatively more than the red. None of the glasses in cooling from 1350° C. in 12 hrs. showed devitrification. Devitrification tests proved that where the silica is greater than 70%, it tends to separate on second heating and cooling. With more than 20% of alkali up to 35% of BaO can safely be added, but with less than 15% of alkali barium silicate tends to separate out if the BaO content exceeds 20%. Solubility, in each series, fell rapidly with increase of BaO content, whilst if the BaO remained constant the solubility increased with increasing alkali. None of the glasses of the first series had the requisite durability for optical glass, whilst of the second series $100SiO_2$, $10Na_2O$, $10K_2O$, 40BaO was in Class III., $100SiO_2$, $10Na_2O$, $10K_2O$, 30BaO and $100SiO_2$, $10Na_2O$, $10K_2O$, 20BaO were in Class IV., and $100SiO_2$, $10Na_2O$, $10K_2O$, 15BaO was in Class V. None of these, however, could be made without devitrification on slow cooling.—A. C.

Glass; Development of various types of ——. XV. Comparison of the alkali-barium oxide-silica glasses. C. J. Peddle. J. Soc. Glass Tech., 1921, 5, 228—256.

A correlation of results from the foregoing three papers and from an additional series of melts in which the glasses were built up on a basis of composition by weight. The densities of glasses of the molecular series $100SiO_2$, $40Na_2O$, xBaO and $100SiO_2$, $20Na_2O$, xBaO were greater than those of the corresponding potash glasses, when x was more than 7 mols. The mixed alkali glasses gave values intermediate between those for potash alone and those for soda alone. Where percentage by weight was considered, glasses containing only Na_2O as alkali had a greater density than those containing the same amount of K_2O as alkali, whilst glasses in which K_2O and Na_2O occurred in equal amounts gave intermediate values. The following constants for density increase were found:—with SiO_2 constant, 1% of Na_2O replaced by 1% of BaO, 0·015; 1% of K_2O by 1% of BaO, 0·014; with Na_2O constant, 1% of SiO_2 by 1% of BaO, 0·023; with K_2O constant, 1% of SiO_2 by 1% of BaO, 0·023. The soda glasses of both molecular series had a higher value of η_D when the BaO content was less than 11 mols.; above this, potash glasses had the greater value. The total dispersion of the series with $40Na_2O$ was greater than that of the series with $40K_2O$, whilst the reverse held for the series with $20Na_2O$ and $20K_2O$. Values of η_D and total dispersion for series with $20K_2O$, $20Na_2O$ and $10K_2O$, $10Na_2O$ were intermediate between those of the corresponding soda and potash series. In glasses containing the same weight of Na_2O or K_2O, the soda glasses had a higher value of η_D and total dispersion than the potash glasses. Replacement of 1% of Na_2O by 1% of BaO (SiO_2 constant) increased η_D by 0·0011 and decreased $(\eta_F-\eta_C)$ by 0·00002; of 1% of K_2O by 1% of BaO (SiO_2 constant) raised η_D by 0·0010 and lowered $(\eta_F-\eta_C)$ by 0·00002; of 1% of SiO_2 by 1% of BaO (Na_2O constant) increased η_D by 0·0023 and $(\eta_F-\eta_C)$ by 0·00006; of 1% of SiO_2 by 1% of BaO (K_2O constant) increased η_D by 0·0024 and $(\eta_F-\eta_C)$ by 0·00007. Soda was a better flux than potash, where the amount present by weight was the same. In corresponding soda and potash glasses the one containing soda had the lower melting point. Devitrification with precipitation of silica more readily occurred in soda glasses, but, in glasses with high BaO content, precipitation of barium silicate took place sooner in potash glasses. In glasses with less than 20% of alkali, those with equal amounts of Na_2O and K_2O were less soluble than those with a single alkali, the mixed alkali type being more durable. With more than 25% of BaO they became iridescent on exposure, if containing more than 25% of alkali, but with only 10% of alkali no iridescence appeared until the BaO reached 40%. Glasses in the region of the following percentage compositions by weight were capable of ordinary use:—Class III., $60SiO_2$, $10K_2O$, 30BaO. Class V., $60SiO_2$, $15K_2O$, 25BaO; $65SiO_2$, $7{\cdot}5Na_2O$, $7{\cdot}5K_2O$, 20BaO; $65SiO_2$, $15K_2O$, 20BaO; $70SiO_2$, $7{\cdot}5Na_2O$, $7{\cdot}5K_2O$, 15BaO. The second and third only were suitable for optical work, the others devitrifying on heating. All these glasses had a greater tendency to devitrification than the corresponding lime glasses and were much worse in weathering properties, factors outweighing increase of brilliance and density in replacing CaO by BaO in Hard Crown glass. To obtain durable barium glasses other oxides must be introduced, such as ZnO, Al_2O_3, PbO, and B_2O_3.—A. C.

Glass; Development of various types of ——. XVI. Comparison of the alkali-barium silicate and alkali-lead silicate glasses. C. J. Peddle. J. Soc. Glass Tech., 1921, 5, 256—268.

In the molecular series $100SiO_2$, $40R_2O$, xBaO, $100SiO_2,40R_2O,x$PbO, $100SiO_2,20R_2O,x$BaO and $100SiO_2$, $20R_2O$, xPbO, where R_2O represents either Na_2O or K_2O or a mixture of these, and x varies from 5 to 40, the replacement of 1 mol. BaO by 1 mol. PbO gave a large increase of density in all cases. The molecular rate of increase of density with RO increase was greater for PbO than BaO. The replacement of BaO by PbO, weight for weight, gave an increase of density whatever the alkali, if the PbO or BaO was over 5%. In glasses containing less than 65% SiO_2 and less than 25% alkali, the rise in density per 1% replacement of BaO by PbO was about 0·003 (only cases where all the BaO was replaced were studied). Where the percentage of SiO_2 was constant, replacement of alkali by PbO raised the density more than its replacement by BaO. With constant amount of alkali the rise of density, due to replacement of SiO_2 by PbO, was greater than that for replacement of SiO_2 by BaO. In all series of both PbO and BaO glasses replacement of 1% of SiO_2 by 1% of alkali increased the density by 0·008. In the molecular series, replacement of BaO by PbO, molecule for molecule, largely increased both η_D and total dispersion. Increase of PbO in a glass had a much greater effect in increasing η_D and total dispersion than increase of BaO. In all cases examined (*i.e.*, SiO_2, 50—70%; R_2O, 10—25%; RO, 5—40%) the lead glasses had a higher value of η_D and a lower ν than glasses containing an equal weight of BaO, whilst lead glasses containing soda had a greater total dispersion than barium-soda glasses when the RO was greater than 4%, and lead-potash than barium-potash when RO exceeded 8%. Where SiO_2 was constant and RO replaced alkali by weight, η_D increased at the same rate for both lead and barium glasses, the total dispersion increased for lead but decreased for barium glasses, whilst ν decreased for lead and increased for barium glasses. Where alkali was constant and SiO_2 was replaced by RO, η_D and total dispersion increased more rapidly in the lead series, whilst ν fell more rapidly with the same glasses. Where alkali replaced SiO_2 (RO constant) η_D and total dispersion increased more rapidly for lead glasses. Lead glasses spread the spectrum towards the blue end more than barium glasses. In both equimolecular and equivalent weight series lead glasses were the less soluble. Two types of weathering were noticeable for both lead and barium glasses, one when the alkali content was large, and filming occurred through atmospheric attack, another in which iridescence was produced, due to high PbO or BaO content (alkali often being small). A study of the action of various gases proved the iridescence in lead glasses to be chiefly due to the action of hydrogen sulphide (carbon dioxide, sulphur dioxide, and acid vapour also contributing), whilst in barium glasses acid vapours were chiefly responsible. In both cases organic impurity, as grease, increased the iridescence.—A. C.

Glasses containing aluminium; Density of ——. S. English and W. E. S. Turner. J. Soc. Glass Tech., 1921, 5, 277—280.

A series of glasses varying from $2Na_2O$, $6SiO_2$ to $1{\cdot}4Na_2O$, $0{\cdot}6Al_2O_3$, $6SiO_2$ and a series of three glasses containing aluminium and calcium were examined. Carefully annealed grains of 10- to 30-mesh were used, the immersion fluid for the first series being toluene, and for the second, water. Molecular substitution of Al_2O_3 for Na_2O caused considerable decrease in density, soda-alumina glasses being lighter than corresponding soda-magnesia glasses. Weight for weight, alumina decreased the density less than magnesia. The results do not substantiate the density factors suggested by Baillie (J., 1921, 141 T), who gave as the effect of 1% Al_2O_3 a value 2·75, and for 1% MgO 3·25, according to which, when equal weights are present, magnesia glasses should have a greater density.—A. C.

Glassware; Cords and surface markings in ——. F. E. Wright. J. Amer. Ceram. Soc., 1921, 4, 655—661.

Cords and surface markings in glassware are distinguished by immersing the glass under test in a liquid of the same refringence, and looking through the liquid and glass towards a distant light. Under these conditions surface markings disappear altogether while the cords stand out more distinctly

than before. The relative refringence of a cord compared with that of the adjacent glass can also be determined at the same time. Monochlorobenzene is a suitable immersion liquid for ordinary crown glasses, and its refractive index can be raised by adding carbon bisulphide or monochloronaphthalene, and lowered by the addition of benzene.
—H. S. H.

Fireclays; Shrinkage, porosity, and other properties of British —— after being fired at high temperatures. E. M. Firth and W. E. S. Turner. J. Soc. Glass Tech., 1921, 5, 268—277.

The examination of fireclays (26 British and 1 German) fired to 1400° C. has previously been described (J., 1920, 628 A). The present paper deals with the same clays when firing is continued to 1500° C. Ten of the clays, Mansfield, Coalbrookdale (*a*) and (*b*), Grossalmerode, Halifax 4, 5, and 6, Ruabon, and Stourbridge C and D, undergo permanent linear expansion between 1400° and 1500° C. Seven, namely, Mansfield, Kilwinning, Grossalmerode, Halifax 4 and 5, Ruabon, and Stourbridge C, decrease in apparent specific gravity. Halifax 4 and 5 show appreciable increase of porosity and give indication of overfiring before 1500° is reached; Grossalmerode seems to have reached its limit of usefulness at 1500° C., whilst Kilmarnock and Stourbridge A and C slightly blister. Coalbrookdale and Stourbridge G need slow firing to prevent black coring.
—A. C.

Refractories under load conditions. H. J. Knollman. J. Amer. Ceram. Soc., 1921, 4, 759—770.

The ability of fireclay slabs etc. to carry load at high temperatures is of great importance in the abrasive wheel industry. The strength of the raw slab must be sufficient to prevent undue cracking before burning, the quantity of high shrinking clay used must not be too great, the grog and clay must be properly proportioned, the mixing must be thorough, and a suitable working consistency and pressure used. The slabs must be set tightly in the kiln to prevent warping, and those requiring burning a few cones higher than the temperature at which they are subsequently used have a longer life than those requiring the same heat treatment for maturity. The slabs should have a porosity of 10—11%. The manner of setting grinding wheels causes the slabs to be subjected to transverse bending stress. The smaller slabs are made in one piece, but the life of the larger slabs is increased by making them in sections. Slabs fail by warping as well as by cracking, and also by the gradual decrease in mechanical strength from burn to burn when subjected to transverse load.—H. S. H.

Furnace [for refractories]; High-temperature testing ——. W. M. Hepburn. J. Amer. Ceram. Soc., 1921, 4, 755—758.

The furnace is lined with an alundum mixture and fed by seven burners supplied with gas and air from a mixture box. The test pieces are placed in an alumina crucible, which is supported by, and separated from the lining by lumps of refractory material which permit surface combustion to occur. A maximum temperature of 1870° C. is attained. The advantages claimed are simplicity, low fuel consumption, ease of observation and measurement of temperature, and ability to produce either oxidising, reducing, or neutral atmospheres.—H. S. H.

Zirconia cements. M. Sheppard. J. Amer. Ceram. Soc., 1921, 4, 662—668.

Seven cements were made containing zirconia (90%) and ball clay (10%), the zirconia consisting of varying percentages of raw and calcined material. The added clay did not seriously reduce the refractoriness. The cements were mixed with 18% of water to a rather wet mortar, spread on one face of a firebrick, dried, and heated for 5 hrs. at 1400° C. The shrinkage was found to be excessive in a cement containing raw zirconia and clay, but the addition of 50% or more of calcined zirconia practically eliminated this shrinkage and the cracking which accompanied it. The cements had a rather low dry strength but became strong at 1200° C., and were very strong when burned to 1700° C. Load tests on pieces at 1500° C. showed that joints of these cements did not fail in any way at this temperature. For use up to 1700° C. the replacement of crude zirconia by the refined material did not improve the cement noticeably. An industrial test of zirconia cement used as a wash for bungs in a malleable iron furnace showed that the life of a bung was increased about 25% by the use of a zirconia wash, but the necessity for a thick protective coat (about $\frac{3}{8}''$ thick) of the cement was evident.—H. S. H.

Porcelain glazes; High-fire ——. H. H. Sortwell. U.S. Bureau Standards, Tech. Paper 196. J. Amer. Ceram. Soc., 1921, 4, 718—730.

A wide range of high-fire porcelain glazes of the Seger cone formula type were investigated to determine the limits for glazes suitable for chemical porcelain etc. The fusibility and commercial acceptability of the glazes, which matured at cones 12 to 18, were studied. The composition of the glazes was 0·7 CaO, 0·3 K_2O; $x SiO_2$; $y Al_2O_3$ where x varied from 3·0 to 13·0 and y from 0·3 to 3·25. The glazes were ground in small ball mills for 3 hrs. and a small quantity of each glaze was evaporated to dryness and moulded into test cones and the deformation temperature determined. The glazes were applied to porcelain cups fired to cone 08, the composition of the body being kaolin (43 pts.), ball clay (5 pts.), flint (34 pts.), and felspar (18 pts.). They were fired to cones 10, 12, 14, and 16 respectively. Reducing conditions were maintained to cone 8 but afterwards allowed to diminish until a neutral or slightly oxidising atmosphere existed at the finish. The deformation temperatures of the glazes were between 1100° and 1400° C. Starting with 0·3 Al_2O_3 and any SiO_2 content, increasing the Al_2O_3 to 0·6 Al_2O_3 lowered the deformation temperature, but further increase in Al_2O_3 increased this temperature. Increase in silica content up to 11 SiO_2 had little effect on the deformation temperature, but a further increase in SiO_2 increased the deformation temperature more rapidly. At cone 10 there were few good bright glazes and crazing occurred when the alumina content was low. Increase in burning temperature increased the number of good bright glazes, reduced crazing, and reduced the number of immature glazes. Overburning occurred in the more fusible glazes as the temperature increased. Increase in Al_2O_3 in this type of glaze corrected crazing. Increase in SiO_2 would not correct crazing, but if increased sufficiently sometimes caused it to occur. From cones 12—16 the best glazes had alumina and silica contents corresponding to the approximate formula $Al_2O_3 = 0{\cdot}3 + \frac{1}{12} SiO_2$.—H. S. H.

Fish scaling of enamels for sheet iron and steel; Causes and control of ——. R. R. Danielson and W. H. Souder. J. Amer. Ceram. Soc., 1921, 4, 620—654.

Typical single- and three-coat enamels were applied to small metal plates and fired in an electrical muffle furnace. Fish scaling was found to increase with the temperature or length of firing beyond normal firing conditions. Too low a temperature or too short a firing period produced blistering and bubbling, while high temperatures and long periods resulted in burning off of the enamel. The most effective flux in reducing fish scaling was cryolite, others following in the order fluorspar, sodium oxide, and boric oxide. Cryolite was also most effective in lengthening the burning range of the enamels, the others in decreasing effectiveness being fluorspar, boric oxide, and sodium oxide, while the fluxing action of the materials followed the order cryolite, sodium oxide, fluorspar, and boric oxide, cryolite giving the most fusible enamels. The coefficients of expansion and contraction of the various irons and steels examined were nearly the same, but the expansion was from 3 to 40% greater than that of the enamels, so that the latter were under compression, which factor caused fish scaling. The various constituents of the enamel had varying effects on the coefficient of expansion. Up to 200° C. the coefficient of expansion was from 20 to 40% lower than that for steel, but the rate of expansion increased very rapidly above 200° C. The coefficient values computed from the chemical composition of the enamels by means of Mayer and Havas' table (J., 1911, 543) were not accurate. The enamels shrank when held at a constant temperature between 200° and 300° C. Annealing of the enamelled ware eliminated fish scaling, thus showing the advantage of using continuous tunnel enamelling furnaces. Variations in enamelling results as regards fish scaling did not appear to be due to the chemical composition of the metal, but the adherence of the enamel to the metal was influenced by the physical condition of the surface of the metal produced by mechanical treatment. Fish scaling did not occur with cold-rolled steel and was considerably reduced with cold-rolled iron. The composition of the enamel as affecting its elastic strength, underfiring resulting in the enamel not being fused to the metal, and the cleanness of the metal surface were also factors influencing fish scaling. Felspar replacing flint in ground coat enamels increased the coefficient of expansion, as did the substitution of cryolite for fluorspar, while boric acid gave the lowest value and sodium oxide and cryolite gave the highest values followed by that for cryolite alone. The composition of an enamel should be adjusted so as to increase the coefficient of expansion (*e.g.*, by decreasing the boric acid content) and to develop an enamel with a wide range of compressional elasticity, while unnecessary volatilisation of such fluxes as soda and cryolite should be avoided by correct firing.—H. S. H.

Enamels; Some relations of composition to solubility of —— in acids. H. F. Staley. J. Amer. Ceram. Soc., 1921, 4, 703—717.

The solubilities in acids of 70 enamels were studied. The test pieces were cast iron cups with oval bottoms which were coated with a rather refractory ground coat and the cover enamel applied on top by sifting. A 20% solution of hydrochloric acid was placed in the cups, which were heated on steam baths for 1000 hrs. unless the enamel failed previously. The cups were washed out and filled with fresh acid every 7 hrs. Loss in weight of the enamels was no criterion of solubility, and failure was recorded when the surface of the enamel had softened sufficiently to permit of being definitely scratched with a pointed knife blade. When substituted one for another, in each case in equal percentage amounts, various oxides and minerals increased the resistance of various enamels to the action of the acid in the following order of effectiveness: alumina, cryolite, soda, litharge, barium monoxide, lithium oxide, magnesia, fluorspar, zinc oxide, strontia, lime, boric oxide. The first five were especially effective. The remainder were undesirable materials from the standpoint of resistance to acid. Zirconia and titania when substituted for small amounts of silica increased the resistance of various enamels to attack by acids, zirconia being the more effective, but in this case the tendency to chipping was increased. Enamels containing titania gave less chipping than those containing either zirconia or silica, and were more resistant to acid than those containing silica. Formulæ are given for enamels showing the best resistance to acid.—H. S. H.

Patents.

Glass composition and method of making same. E. E. Fisher. U.S.P. 1,394,296, 18.10.21. Appl., 13.12.20.

A glass comprises more than 60% of silica, one or more oxides of the second periodic group having a thermal expansion of less than 4 as compared with silica, and not more than about 6% of alkali oxides of the first periodic group.—H. S. H.

Antidimming composition [for glass]. H. A. Kuhn. U.S.P. (a) 1,394,773 and (b) 1,394,774, 25.10.21. Appl., (a) 24.1.21 and (a) 13.5.21.

An antidimming composition comprises the reaction products of a salt of (a) sulphonated rape oil or (b) sulphonated cotton-seed oil, an alkali, a mineral oil, and a binder.—H. S. H.

Magnesia and alumina; Bonded article of ——. R. C. Purdy, M. F. Beecher, and A. A. Klein, Assrs. to Norton Co. U.S.P. 1,394,442, 18.10.21. Appl., 7.10.19.

A bonded article of magnesia and alumina is made by mixing pre-shrunk granules of one ingredient with the other ingredient in finely divided condition and heating the mixture below the melting point of any eutectic of the magnesia-alumina system so as to bond the materials into one mass. —H. S. H.

Artificial meerschaum; Production of ——. P. Deussing. G.P. 340,533, 24.11.20. Addn. to 334,749 (J., 1921, 625 a).

The levigated quartz is replaced by kieselguhr to reduce the relative weight of the product and make it harder and less brittle.—A. B. S.

Enamelling ware; Method of ——. R. Roadhouse, Assr. to T. E. McCaig. U.S.P. 1,395,732, 1.11.21. Appl., 9.3.21.

The furnace comprises a closed chamber provided with means for burning fuel therein, for stopping the combustion, for scavenging the products of combustion, and for closing the chamber during the baking operation.—A. B. S.

Glass-melting furnace. L. Le B. Mount. U.S.P. 1,395,591, 1.11.21. Appl., 6.5.20.

IX.—BUILDING MATERIALS.

Calcium aluminates; Cementing qualities of the ——. P. H. Bates. U.S. Bureau of Standards, Tech. Paper 197. J. Franklin Inst., 1921, 192, 668—669.

The four calcium aluminates, $3CaO,Al_2O_3$, $5CaO,3Al_2O_3$, CaO,Al_2O_3, and $3CaO,5Al_2O_3$, were prepared in the pure state by heating lime and alumina in suitable proportions.

The products were finely ground, gauged with water, and their cementitious qualities determined. The two compounds higher in lime reacted very energetically, with evolution of much heat, and set almost instantaneously. The other two compounds reacted like Portland cement but showed a higher strength at earlier periods than the latter. These two compounds were next prepared in larger quantities from commercial materials, their composition being varied so that the impurities, silica, iron oxide, and magnesia, reached maximum limits of 17·38, 3·10, and 3·66% respectively. The process of manufacture was similar to that used for Portland cement, the mixtures being burned in a 20 ft. by 2 ft. rotary kiln. Tensile and compression tests of 12 in. by 6 in. cylinders made of gravel concrete in the proportion of 1:1·5:4·5 showed the very high strength of more than 2800 lb. per sq. in. after 24 hrs. and concretes in the proportion of 1:3:9 showed a strength of more than 1500 lb. at the same period. Consistent increase in strength continued up to one year, when one of the rich concretes had a strength of 8220 lb. per sq. in. Test pieces stored in water or in a damp closet lost strength with age as the cementing agents (hydrated $3CaO,Al_2O_3$ and hydrated alumina) formed are colloidal and very susceptible to changes in moisture content. When large amounts of water are absorbed, with consequent swelling of the colloid, the strength of the concrete is reduced.—A. B. S.

Patents.

Concrete pipes; Manufacture of resistant, porous ——. H. Bassmann. E.P. 142,487, 29.4.20. Conv., 30.11.17.

Porous and highly resistant concrete pipes are made by stamping in moulds a mixture of sharp gravel or the like, composed of particles 2—4 mm. diam., cement and water (but without sand), by means of plungers having knife-like or other pointed members such as staggered spikes, so that the particles of gravel are arranged with their relatively flat surfaces superposed.—A. B. S.

Imitation marble; Manufacture of ——. P. J. Guillot. E.P. 145,443, 18.6.20. Conv., 21.6.19.

An imitation marble is made by mixing 1 kg. of pure silica, 1 kg. of powdered basalt, 2 kg. of sea water, 270 g. of cellulose dissolved in ammoniacal copper solution, 100 g. of powdered Cape asbestos, 2 kg. of heavy calcined magnesia, 200 g. of "tereline" (equal weights of spirit of turpentine and linseed oil), 100 g. of ochre and diverse colours. The resulting soft paste is poured into moulds, and allowed to remain for 10 hrs., or it may be compressed hydraulically.—A B. S.

Cement goods or objects; Producing or treating ——. N. P. Nielsen. E.P. 170,497, 26.10.20.

Cement goods are impregnated with asphalt by heating them above 200° C., or at 300°—500° C., and then bringing them into contact with the impregnating material which is heated to about the same temperature.—H. S. H.

Shaft furnaces for burning cement, magnesite and similar substances. A. Hauenschild. E.P. 170,764, 25.10.20.

A shaft kiln is provided with a rotary grate which has also a vertical motion produced by supporting it on eccentric rollers, or by providing a series of inclined planes on the underside of the grate which pass over plain rollers. The grate may be rotated alternately in opposite directions by means of a worm-gear.—A. B. S.

Cement-kiln plant and method of operating the same. J. E. Bell. U.S.P. 1,393,738, 18.10.21. Appl., 2.8.18.

A cement kiln plant comprising rotary kilns, a waste heat boiler section, and a flue into which the individual kilns open at points at varying distances from the boiler section and which connects the latter with the series of kilns, is operated by throttling the connexion between each kiln and the flue to such an extent that the pressure drop between each kiln and the flue is greater than the total pressure drop in the flue. Such draught conditions are maintained throughout the connected parts of the system as will compensate for the resistance created by the throttling of the connexions and will bring about a sufficient and an approximately even draught in the kilns.—H. S. H.

Paving composition and process of making the same. C. A. C. de Caudemberg. U.S.P. 1,395,396, 1.11.21. Appl., 15.1.21.

A composition having colloidal properties and a high fusing point, and suitable for paving purposes, is made by combining 1—1·5 pts. of rubber with 100 pts. of bitumen.—A. B. S.

Bricks; Manufacture of ——. W. W. Crawford. U.S.P. 1,395,990, 1.11.21. Appl., 5.1.21.

See E.P. 162,683 of 1919; J., 1921, 472 a.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron; States of —— *in nitric acid.* J. G. Brown. J. Phys. Chem., 1921, 25, 429—454.

From experiments with cells: Fe/nitric acid solution/concentrated nitric acid/Pt, measurements of electromotive force being made both with the iron in motion and at rest, it is concluded that ordinary iron is essentially ferric, that active iron sends only ferrous ions into solution, and that passive iron sends ferric ions into solution.—J. F. S.

Steel; Tests of centrifugally cast ——. G. K. Burgess. U.S. Bureau Standards, Tech. Paper 192, 1921. 22 pages.

Five cylinders cast by the Millspaugh centrifugal process were examined. The cylinders were cast in a mould revolving about its axis; the thickness of the walls ranged from ½ in. to 3 in., and the nature of the metal varied from two low-carbon steels (0·17, 0·23% C) to three nickel steels (0·33—0·66% C, 2·35—2·92% Ni). Segregation of carbon, sulphur, phosphorus, and nickel occurred towards the inner surface of the metal which would solidify last, but silicon and manganese appeared equally distributed. Increasing hardness followed the chemical segregation, and internal stresses were of the order of the elastic limit of the material, the inner ring being in tension and the outer zone in compression. Heat treatment, particularly double quenching and drawing, greatly improved the mechanical properties of the castings and in certain cases made these properties equal to those of forgings of similar composition. The coarse-grained structure of the original casting was refined only by repeated heat treatment, and the nickel steels contained more slag inclusions than is usual in ordnance steel. Small blowholes occurred near the inner skin, which was rough.—C. A. K.

Chromium steels; Constitution of ——. T. F. Russell. Iron and Steel Inst., 1921. [Advance proof.] 49 pages.

A portion of the iron-chromium-carbon field with a maximum limit of 1% C and 12% Cr was examined. Heating at 1200° C. for 5—8 hrs. was sufficient to diffuse thoroughly the constituents in low-chromium steels without altering their nature. Increase in the Cr content progressively raised the Ac1 point until it exceeded the Ac2 point, and it was uncertain whether the latter transformation was exothermic or endothermic. The Ac2 point, 770° C. for most steels, tends to be lower as the Cr content becomes greater. Analysis of the residue of a 12% Cr steel dissolved in sulphuric acid indicated a compound carbide, FeCrC. When added to a carbon steel chromium first associates itself with the carbide up to the limit represented by FeCrC, and further additions result in a solid solution with iron. Some part of the excess chromium has been found under particular conditions to exist as a carbide Cr_3C_2.—C. A. K.

Sulphides [and sulphur in steel]; Volumetric determination of —— by oxidation to sulphate. H. H. Willard and W. E. Cake. J. Amer. Chem. Soc., 1921, 43, 1610—1614.

Sulphur in steels is determined as follows: 5 g. of steel is placed in a flask through which hydrogen may be passed and which is connected with a 10-bulb tube for absorption of the hydrogen sulphide. The absorption bulbs contain 6—7 g. of sodium hydroxide in 50—60 c.c. of water. Air is removed from the apparatus by hydrogen and 100 c.c. of hydrochloric acid (sp. gr. 1·1) added. After the reaction has moderated the solution is heated just to boiling for 5 mins. after the steel has dissolved. The contents of the bulb are washed, with as little water as possible, into a flask containing 10 c.c. of 0·3*N* sodium hypobromite in 2·5*N* sodium hydroxide or 10 c.c. of 0·3*N* sodium hypochlorite in 4*N* sodium hydroxide, and allowed to stand for 3—4 mins., then 2—3 g. of potassium iodide is added, the solution diluted to 150 c.c., neutralised with concentrated hydrochloric acid and 5 c.c. excess acid added. It is then titrated with *N*/10 sodium thiosulphate. Sulphides which are soluble in hydrochloric acid are determined in the same way. Insoluble sulphides are ignited with powdered iron in an atmosphere of hydrogen or carbon dioxide, thus producing ferrous sulphide. The determination is then completed as above. The method is accurate to within about 0·1%.—J. F. S.

Copper metallurgical process; A proposed ——. P. Burbidge. Proc. Austral. Inst. Min. Met., 1921, 1—14.

As a result of numerous laboratory tests the following process is suggested: Sulphide copper ores are ground to 30-mesh and roasted in a specially constructed revolving furnace at about 560° C. so as to obtain the maximum proportion of sulphate in the calcines. The hot furnace discharge passes to a cone mixer to which is added sufficient sulphuric acid (spent electrolyte) to form a 1:1 pulp and to dissolve all the copper and other soluble substances. The pulp is agitated with hot air until nothing further dissolves, the mud is allowed to settle, and the clear liquor decanted. The residue is washed by decantation on the counter-current principle, the wash liquors being stored separately. A quantity of the strong liquor sufficient to provide, after removal of the copper by electrolysis, enough acid to dissolve the acid-soluble copper in the next charge, to acidify the purified mother liquor from the next charge before electrolysis, and to dissolve the copper and iron from the calcium sulphate residue from the ammonia treatment described below, is thoroughly oxidised by compressed air and treated with finely ground limestone to neutralise the acidity and precipitate the bulk of the iron. The remaining iron is removed by agitating the filtered liquor with a slight excess of copper oxide obtained from the ammonia process, the precipitate being returned to the roasting furnace. The purified solution is mixed with sufficient spent electrolyte from a previous process to make the acidity of the resulting liquid equal to 1% H_2SO_4 and electrolysed with a current density of 12 amp. per sq. ft., using graphite anodes and passing sulphur dioxide from the calciner into the solution during the process. The remainder of the strong leach liquor together with the first wash liquors is treated separately with compressed air and limestone and the filtrate is agitated with milk of lime, as free from carbonate as possible, until all the iron and a little copper is precipitated. The precipitate is returned to the calciner and the filtrate agitated with a further quantity of milk of lime to precipitate all the copper as hydroxide. The filtered liquor is used to dilute the acid used in leaching and the precipitate is extracted in a sealed agitation vat with 20% ammonia solution, the residue being washed with weaker ammonia solutions. The ammonia solutions are boiled with steam to precipitate copper oxide, which is reduced to metal by water-gas and eventually melted. The ammonia is recovered and used again. The process is claimed to be very economical in reagents, which are all recovered, in water and in power; there are no foul or discarded solutions and no copper is tied up in unfinished products. Precious metals are recovered from the tailings by cyaniding.—A. R. P.

Wolfram, bismuth, molybdenite ores; Treatment of —— at Burma Queensland Corporation Mill, Wolfram, N.Q. [Determination of molybdenum in low-grade products.] W. H. Bowater. Proc. Austral. Inst. Min. Met., 1920, 259—270.

A detailed account with flow-sheets of the method of treating the complex ores, consisting of wolfram, bismuth, bismuth sulphide, molybdenite, and a little scheelite and bismuth carbonate in a quartz gangue, is given. Wolfram-bismuth concentrates are obtained by dressing the carefully crushed and graded ore on jigs, vanners, and tables, and the wolfram is separated from the concentrates by electro-magnetic separators. The molybdenite in the tailings from the tables is recovered by oil flotation. The methods of analysis employed in controlling the work are described and the following colorimetric method for the determination of molybdenum in low-grade products is recommended. 1 g. of finely ground ore is evaporated to a paste with *aqua regia*, the mass is warmed with 30 c.c. of water and 10 c.c. of hydrochloric acid, 15 c.c. of ammonia is added, and, after boiling, the solution is filtered into a 250 c.c. flask, cooled, acidified with an excess of 10 c.c. of acetic acid, and adjusted to the mark. 2 c.c. of a standard molybdenum solution (1 c.c. = 0·0001 g. Mo), made by treating ammonium molybdate in a similar manner to the assay, is measured into a 50 c.c. Nessler tube, 2 c.c. of tannic acid solution (0·5 g. per 100 c.c.) added and water to 50 c.c. Into a second tube containing 48 c.c. of water and 2 c.c. of tannic acid solution the assay solution is added slowly from a burette until the colour matches the standard.—A. R. P.

Metals electro-deposited on rotating cathodes; Structure of ——. W. E. Hughes. J. Phys. Chem., 1921, 25, 495—509.

The polished surface often observed on deposits formed on rotating cathodes is due to the smallness of the grains composing the deposit, this smallness being a consequence of the constancy of metal concentration at the cathode surface. Mechanical movement can maintain a constant metal concentration, and it is concluded that rotation of the cathode operates in this way and not, as has been suggested, by way of burnishing the deposit.—J. F. S.

Patents.

Steel; Process and apparatus for restoring the strength of ——. F. W. Harris and H. A. Bardeen. E.P. 170,659, 23.7.20.

Steel articles that have become fatigued by repeated mechanical stressing are toughened and their mechanical strength is improved by passing an alternating current through them until they become red-hot (750°—900° C.) and at the same time subjecting them to a considerable longitudinal pressure. The article, *e.g.*, a steel rail or steel pipe used for drilling oil-wells, is clamped between two head-pieces on a long hearth provided with an adjustable heat-insulating hood which encloses the article during heating, and heated by means of an alternating current of 10,000 amps. at 40 volts. Pressure is produced by expansion of the rod and by magnetic effects due to the current.—A. R. P.

Steel; Method of preparing —— for casting. J. B. McGlynn, Assr. to The West Steel Casting Co. U.S.P. 1,394,103, 18.10.21. Appl., 17.4.19.

A charge of steel, containing scrap steel, is melted and refined until the required proportion of carbon to silicon is attained. The hot metal is then transferred to a converter and "blown" until the carbon, silicon, and manganese contents are reduced to the amounts desired.—C. A. K.

Steel; Process for making ——. J. Hundley. U.S.P. 1,394,172, 18.10.21. Appl., 23.7.19.

Carbonising material is projected upon heated iron or a mixture of iron and steel in a furnace. Mixing is effected in the furnace, and the metal is made more uniform by hammering or rolling.—C. A. K.

Castings; Acid-proof ——. H. Terrisse and M. Levy. E.P. 151,974, 3.8.20. Conv., 27.9.19.

Acid-proof metal which can be cast without difficulty contains 5—20% of silicon and 2—20% of tungsten or vanadium, or a mixture of the two metals. Ferro-silicon containing 10—30% Si and having a melting point of 1200°—1300° C. is melted and ferro-tungsten or ferro-vanadium is then added to give the desired composition. The silicide of tungsten or vanadium may be added in place of the iron alloy.—C. A. K.

Moulds, cores or the like; Coatings or linings for ——. J. E. Hurst. E.P. 170,677, 28.7.20.

A salt or mixture of salts, *e.g.*, sodium and potassium chlorides or sulphates, that fuses between 650° and 850° C. to form a thin viscous flexible skin of comparatively low thermal conductivity, is applied as a fine powder to the rapidly rotating mould before casting. The resulting castings have smooth and clean surfaces.—A. R. P.

Metals; Method of melting and casting ——. J. H. L. de Bats. E.P. 170,995, 30.8.20.

Metal contained in a crucible is melted out of contact with air in a furnace which is mounted above an enclosed casting chamber. When the metal reaches the casting temperature the furnace bottom and the crucible are lowered and the molten metal is poured into a channel communicating with the mould. The casting chamber is maintained under vacuum, or alternatively may be filled with a neutral gas.—C. A. K.

Ore concentration. L. A. Wood, W. G. Sellers, and Minerals Separation, Ltd. E.P. 170,944, 30.7.20.

Viscous substances produced by the distillation of coal, wood, etc., are neutralised with an alkali (sodium hydroxide) at 50°—100° C., and the emulsion is employed either directly or as a base for a mineral flotation agent. Typical viscous oils include coal tar, wood tar, blast-furnace tar, gas tar, viscous fuel oil, and viscous tar oil.—C. A. K.

Alloy for use in electric heating appliances. G. H. Lofts. E.P. 171,019, 28.9.20.

An alloy for safety fuses for electrical appliances contains 96% Zn and 4% Cd. This alloy is fractured easily at a temperature lower than its melting point and the inconvenience of the adherence of a molten fuse to the working parts is avoided.—C. A. K.

Vanadium ores and solutions; Method of treating ——. A. H. Carpenter and G. A. Baumann, Assrs. to The Colorado Vanadium Corp. U.S.P. 1,393,748, 18.10.21. Appl., 13.5.20.

An insoluble compound of vanadium is precipitated by the addition of an alkali acid sulphate to a solution of a vanadium salt.—C. A. K.

Blast furnace. A. B. Carstens, Assr. to The American Metal Co. U.S.P. 1,393,749, 18.10.21. Appl., 8.12.19.

The tuyères of a blast furnace are enlarged and lined with a refractory material so as to form the combustion chamber for a fuel jet which is inserted axially into the tuyère. Fuel is burned within the tuyère, and the products of combustion pass into the furnace together with the normal blast.—C. A. K.

Copper; Hydrometallurgy of ——. G. A. Bragg, Assr. to Metals Research Co. U.S.P. 1,395,755, 1.11.21. Appl., 16.8.20.

Oxidised copper ores, roasted matte, or similar material containing copper oxide is leached with sulphuric acid, and the resulting copper sulphate solution is treated with sulphur dioxide to reduce the ferric sulphate present.—A. R. P.

Zinc-bearing ores; Treatment of —— [for the production of metallic zinc and lithopone]. H. W. Gepp, Assr. to Electrolytic Zinc Co. of Australasia Proprietary, Ltd. U.S.P. 1,395,811, 1.11.21. Appl., 7.11.19.

Roasted zinc ore is leached with acid solutions or spent electrolyte, and the solution, after purification with limestone and zinc dust, is electrolysed for the production of metallic zinc, the solutions being used to extract further portions of the calcines. A part of the solution, sufficient to prevent the accumulation of large amounts of impurities in the electrolyte and to permit the washing of the residues without increasing the bulk of the electrolyte, is withdrawn from the circuit after the limestone treatment and the cobalt and manganese are removed from it, after which it is electrolysed for zinc, the spent electrolyte being neutralised with the calcined ore, the solution purified with bleaching powder, and treated with barium sulphide for the production of lithopone.—A. R. P.

Iron alloys; Manufacture of ——. Maschinenfabr. Esslingen. E.P. 146,230, 28.6.20. Conv., 19.11.17.

Roasting furnaces; Rabble stones for ——. Rheinisch-Nassauische Bergwerks- u. Hütten-A.-G., W. Hocks, and G. Stohn. E.P. 163,023, 21.10.20. Conv., 5.5.20.

Preventing oxidation of iron E.P. 147,800. *See* XIII.

XI.—ELECTRO-CHEMISTRY.

Patents.

Electric accumulators; Negative electrode for ——. Electric accumulators. A. Pouchain. E.P. (A) 170,615, 3.5.20, and (B) 170,618, 27.5.20.

(A) A thin plate of metal which is a good conductor and is not attacked by the electrolyte is slotted so as to form bands, through which strips of zinc are interlaced. (B) In electric accumulators with zinc negative electrodes, attack of the zinc on open circuit is prevented by using as electrolyte a solution of sulphates of zinc, aluminium, potassium, and mercury together with not more than 4% of glycerin or other polyhydric alcohol of the fatty series.—J. S. G. T.

Electrodes of large cross-section; Process for the manufacture of furnace ——. Ges. für Teerverwertung. E.P. 155,297, 15.12.20. Conv., 27.11.19.

See G.P. 329,904 of 1919; J., 1921, 267 A.

Electrical purification of gases. G.P. 339,879. *See* I.

Alloy for electric heating appliances. E.P. 171,019. *See* X.

XII.—FATS; OILS; WAXES.

Lumbang [candlenut] oil; Composition, solubility, and oxidation of ——. A. P. West and Z. Montes. Phillipine J. Sci., 1921, **18**, 619—636.

A sample of lumbang oil prepared from the kernels of the nuts of *Aleurites moluccana* by pressing had saponif. value 214, iodine value (Hübl) 140, sp. gr. 0·9206 at 31°/4° C., and had the following composition:—linolenin 6·5%, linolin 33·4%, olein 56·9%, glycerides of solid acids 2·8%. The oil is insoluble in cold ethyl and methyl alcohols and acetic acid. It behaves in much the same manner as linseed oil on oxidation, and is an excellent drying oil.—H. C. R.

Acid value of fats and fatty acids; Determination of —— by conductivity measurements. R. Kremann and F. Muss. Seife, 1921, **7**, 161—167. Chem. Zentr., 1921, **92**, IV., 1151.

The determinations were made in alcoholic solution and gave results agreeing with titrations with phenolphthalein as indicator and with the theoretical values except in the cases of caproic and ricinoleic acids, the anomalous behaviour of which is attributed to the presence of impurities. $N/10$ alcoholic sodium hydroxide was used with fats, $N/2$ with the fatty acids. The precipitation of soap causes variations in the conductivity when near the neutral point. The titration is best carried out at room temperature.—H. C. R.

Rapic acid; The so-called ——. A. Grabner. Seife, 1921, 7, 167—168. Chem. Zentr., 1921, 92, III., 1273.

Portions of 100 g. of rape oil were saponified with 400 c.c. of 10% alcoholic potassium hydroxide, the acids liberated with dilute sulphuric acid, washed, dissolved in alcohol, and precipitated with alcoholic zinc acetate. After standing for 24 hrs. the solution was filtered and the precipitate washed with alcohol. The zinc salts were extracted several times with cold ether, and most of the ether distilled off from the combined extracts. The residue was recrystallised from alcohol. The acid was then liberated with tartaric acid. The constants for this acid show without doubt its identity with ordinary oleic acid. Rapic acid has therefore no separate existence.—H. C. R.

Fatty acids from sugar. Neuberg and Arinstein. *See* XVIII.

Patents.

Nickel catalyst [for hydrogenating fatty oils etc.]; Manufacture of ——. H. Berger. E.P. 146,407, 2.7.20. Conv., 10.11.16.

Nickel carbonate precipitated from a solution of a nickel salt, preferably by means of a bicarbonate in the cold, or precipitated nickel hydroxide, is reduced superficially to metal by means of hydrogen at about 220° C.—J. S. G. T.

Oil; Extraction of —— from oil-seeds and the like. P. L. Fauth. E.P. 157,155, 8.1.21. Conv., 5.6.19.

The material is subjected alternately to the action of the solvent and to pressure in a continuous apparatus, comprising an enclosed jacketed worm-conveyor, on the shaft of which is mounted a loose cone connected with a weight. The material is pressed by passing through the annular space between this cone and the tubular walls of the conveyor-casing, and then falls into another similar unit where it is treated with a further quantity of solvent and again pressed. This may be repeated as often as desired and the meal then dried as usual. The oil content may be reduced from 40—50% to 4—5% in from 45 mins. to 2 hrs.—H. C. R.

Oils and fats; Apparatus for the extraction of ——. A. C. Nicholson. E.P. 170,921, 27.7.20.

The valves controlling the flow of liquid or vapour to or from extraction apparatus take the form of a sleeve, the inner ends of which are covered by wire gauze or perforated plates flush with and forming part of the inner surface of the extraction vessel. A movable piston or plate closes the perforations and supports the perforated screen when the valve is closed. The closing plate may be provided with pegs which pass into the perforations of the screen when the valve is closed and so clear them of any obstructions. The piston is moved by a rod passing through a stuffing-box.—H. C. R.

Soap; Manufacture of [transparent and floating] ——. J. Tseng. E.P. 170,781, 9.12.20. (*Cf.* E.P. 170,060; J., 1921, 857 A.)

Soap is obtained transparent immediately on manufacture by mixing glycerin with the melted fats and oils before saponification. The hard soap is then dissolved in alcohol by heating and stirring for about 12 hrs. at 80°—85° C. Sugar dissolved in its own weight of water at 75° C. may be used instead of glycerin, but must be added to the soap solution after 12 hrs. heating. The soap is filtered at 75° C. and kept at this temperature for 4 hrs., when it is run into a frame. If a floating soap is required, the soap is stirred continuously after filtering until about to solidify.—H. C. R.

Fatty acids; Process for separating —— from vegetable and animal fats. L. Schmidt, Assr. to M. Arbini. U.S.P. 1,395,998, 1.11.21. Appl., 20.3.20.

See E.P. 144,176 of 1919; J., 1920, 551 A.

Colloidal suspension of polymers of tung oil. U.S.P. 1,395,242. *See* XIII.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Paint and rubber pigments; Photomicrographic method for the determination of particle size of ——. H. Green. J. Franklin Inst., 1921, **192**, 637—666.

The "diameter" of the particles is measured by taking a photomicrograph of a carefully prepared, mounted sample and further enlarging this by means of a stereopticon, the measurements being made on the screen with a millimetre scale. Calculation is made of the probable error, and the uniformity of the particle-size is expressed by a "uniformity coefficient."—D. F. T.

Rosin; Chemical constitution of American ——. E. Stock. Farben-Zeit., 1921, 27, 156—157, 221—222, 287—288, 353—354, 416—417.

The author has employed the process of distillation of rosin and its constituents in the high vacuum of the cathode ray to effect separation and purification of individual constituents. A preliminary trial showed that American rosin could be completely distilled without appreciable decomposition when the degree of exhaustion of the apparatus corresponded with that of the production of a green cathode ray. Having regard to the small difference of temperatures between the vapour above the liquid in the distilling flask and that of the latter, it was concluded that no polymerised substance of high molecular weight was present in the rosin. Previous saponification of rosin and separation of the resin acids by acidification was found to be of no advantage as a means of purification before vacuum distillation, as the terpene substances were not entirely removed and the rosin underwent some autoxidation. No positive results were yielded by an attempted fractional distillation *in vacuo*, and anomalous results were obtained with the melting-points of the fractions, since the same substance showed great differences according to whether it was in the crystalline or amorphous condition. The determinant as to the condition of dispersity in which resin acids appear is the heat treatment to which they are subjected. Thus, α-, β- and γ-abietic acids are converted from the amorphous to the crystalline condition by maintaining *in vocuo* at the following temperatures for the times stated: 95° C., 12 hrs., 90° C., 36 hrs., and 85° C., 12 hrs., respectively. The acids in the crystalline condition then show a sharp and higher melting-point than in their previous amorphous condition. Examination of the three constituent acids of rosin according to Tschirch's method of separation gave the following constants for the α, β and γ acids respectively: Distillation under 0 mm. pressure, 192° C., 163° C., and 172° C.; constant boiling-point under 0 mm. pressure, 162° C., 163° C., and 172° C.; melting-point, 66° C., 72° C., and 66° C. The author has modified Tschirch's method of separation of the individual resin acids as follows: 100 g. of rosin is dissolved in 200 c.c. of ether, the solution filtered, and the ether evaporated. 50 g. of the purified rosin is dissolved in 150 c.c. of alcohol, and alcoholic lead acetate solution is added to the moderately warm rosin solution until the precipitate appears white. The precipitate is washed with water and dried in a desiccator over sulphuric acid. The salt is then dissolved in ether and shaken with hydrochloric acid (1:1) in a separating funnel. The precipitated lead chloride is removed, the ethereal solution washed free from acid with water, and evaporated. The β-acid can be obtained from the alcoholic solution from which the α- and γ-acids have been precipitated as lead salts. The α-abietic acid can be separated from the γ-acid by addition of an 8% solution of sodium in methyl alcohol to an ethereal solution of the acids, the sodium salt of the α-acid being precipitated as brown flocks. From elementary analyses and molecular weight determinations, the three acids were found to be isomers of the empirical formula $C_{20}H_{30}O_2$. On reduction with zinc dust, and subsequent distillation *in vacuo*, both the α- and β-acids yielded two fractions each, of boiling-points respectively 94° C. and 106° C. (0 mm. pressure), both corresponding to the empirical formula $C_{20}H_{26}$. γ-Abietic acid split off both carbon monoxide and dioxide during reduction. From the experimental data obtained it is concluded that the composition of American rosin is α-abietic acid 31%, β-abietic acid 31%, γ-abietic acid 19%, resenes 10%, essential oil and bitter principles 0·5%, impurities 0·5%, and the assumption previously made by the author that rosin is an anhydride of abietic acid is withdrawn.—A. de W.

Patents.

Iron and the like; Method of producing a medium [from pyrites ashes] for preventing the oxidation of ——. F. Bensa, Assee. of L. Bizzi. E.P. 147,800, 9.7.20. Conv., 5.11.18.

Pyrites ashes, after weathering for more than a year to eliminate the greater portion of the acid, are mechanically freed from silicic acid, dried, any globules screened out, and ground in a ball or hammer mill provided with a dust-collector and thereby separated as ferrous oxide of 80—86% purity. The substance obtained when ground in the proportion of 85 pts. to 15 pts. of crude linseed oil can be used as a protective coating.—A. de W.

Pigments. J. C. Smith. E.P. 170,431, 4.8.20.

Colloidal barium sulphate is produced by the interaction of dilute solutions of barium chloride and sulphuric acid, or sodium, magnesium or other sulphate, in the presence of a dilute suspension of a uniformly fine "carrier" or pigment, *e.g.*, lead sulphate, basic lead sulphate, antimony trioxide, titanium oxide, zinc oxide, or the like, with which it is maintained in contact for not less than 6 hrs., at a temperature not exceeding 60° F. (15·5° C.), which may subsequently be raised to 90° F. (32° C.) or higher to facilitate filtration. Finely-divided barium sulphate is thereby precipitated on the "carrier," the resulting pigment being separated, dried, and ground. Alternatively, the effects of extreme dilution may be simulated by fractional precipitation of the barium sulphate, portions of the precipitating solution being added periodically, stirring being maintained in the intervals. The manufacture of a composite antimony oxide-barium sulphate pigment containing about 20% of barium sulphate from 100 lb. of antimony oxide suspended in 100 gals. of water, 21 lb. of barium chloride dissolved in 2000 or 200 gals. of water respectively, and 32½ lb. of Glauber's salt dissolved in 10 gals. of water, by the first and the alternative method is claimed.—A. de W.

Resin; Manufacture of —— from naphthas. The Barrett Co., Assees. of C. M. Dennis. E.P. 142,806, 28.4.20. Conv., 5.5.19.

A uniform resin of good quality is obtained, *e.g.*, by polymerising in presence of sulphuric acid, from naphtha of b.p. between 135° and 230° C. containing 30% of resin-forming constituents, prepared by suitably blending naphthas containing respectively more and less than 30% of resin-forming constituents.—L. A. C.

Colloidal suspension of polymers [of tung oil] and process of making same. J. W. Phillips. U.S.P. 1,395,242, 25.10.21. Appl., 6.3.19.

Tung oil is dissolved in a solvent and the dispersed oil polymerised.—A. de W.

Paints, varnishes, enamels or the like; Method of drying or setting ——. H. B. and F. E. Hartman, Assrs. to Electric Water Sterilizer and Ozone Co. U.S.P. 1,395,569, 1.11.21. Appl., 10.8.20.

Compositions such as paint, varnish, or enamel are caused to dry by treatment with ozone during their application.—D. F. T.

Varnish materials; Method for making ——. W. F. Sterling, V. E. Grotlisch, and F. P. Veitch. U.S.P. 1,395,874, 1.11.21. Appl., 15.9.21.

Erratum.—This Journal, October 15, 1921, p. 709 A, col. 1, line 10 of the abstract of J. B. Tuttle's paper, for "(hexamethylenetetramine)" read "(the addition product of carbon bisulphide and dimethylamine)."

Patents.

Rubber compounds and process of manufacture. C. F. S. Bilbrough. E.P. 171,046, 30.11.20.

Fresh latex is concentrated to the consistency of honey and is then mixed with a suitable pigment and filling materials such as sulphur, peat, china clay, finely divided recovered rubber, hair, and a sterilising agent. The mixture, which should have the consistency of soft putty, is formed into any desired shape, dried and, if necessary, vulcanised. —D. F. T.

Caoutchouc and caoutchouc-like products; Manufacture of ——. P. Schidrowitz, and Catalpo, Ltd. E.P. 170,682, 28.7.20 and 15.4.21.

For the production of a rubber-compounding ingredient capable of accelerating vulcanisation, an additive compound of carbon bisulphide and an organic base is synthesised on purified—preferably colloidal—clay (*cf.* E.P. 106,890 and 121,191; J., 1917, 879; 1919, 41 A), or other materials, such as French chalk, magnesium carbonate, and zinc oxide. The material is impregnated with one component of the additive compound, *e.g.*, with piperidine, and is then treated with the other constituent in the form of spray or vapour. Application of the organic accelerator in this form facilitates its uniform distribution.—D. F. T.

Paving composition. U.S.P. 1,395,396. *See* IX.

XV.—LEATHER; BONE; HORN; GLUE.

Gelatin solutions; Viscosity of ——. C. E. Davis, E. T. Oakes, and H. H. Browne. J. Amer. Chem. Soc., 1921, 43, 1526—1538.

Gelatin solutions increase in viscosity with age at different rates depending on the nature and concentration of the gelatin and the hydrogen ion concentration. For any given gelatin solution a maximum viscosity is attained when the solution is about 24 hrs. old. A decrease in viscosity after the maximum is reached indicates bacterial decomposition. The maximum viscosity is reached at hydrogen ion concentrations of $p_H=3·0-3·5$ at 25° C., and it is not a simple function of the concentration of the gelatin. Both hydrogen and hydroxyl ions catalyse the hydrolysis of gelatin in solution, but the action of the hydroxyl ion is more powerful than that of the hydyrogen ion. High temperature accelerates the hydrolysis of gelatin, whilst actual boiling of the solutions causes very rapid hydrolysis. (*Cf.* J.C.S., Jan.)—J. F. S.

XVI.—SOILS; FERTILISERS.

Soils; Some effects of potassium salts on ——. R. S. Smith. Cornell Univ. Agric. Exp. Sta., Mem. 35, June, 1920, 571—602.

Three typical American soils were treated with potassium chloride and sulphate in varying quantities. No toxic effects on wheat were noted with the sulphate, and the chloride only produced decreased yields with heavy dressings of the order of 1000 lb. per 2 million lb. of soil. Wheat seedlings were grown in 1:5 water extracts of the treated soils. With the chloride the greatest stimulation of root development occurred with treatments of 200—500 lb. per 2 million lb. of soil. Sulphate produced greatest stimulation with a dressing of 300 lb. With heavier dressings of both salts there occurred decreased stimulation and toxicity. Lime counteracted this even in the case of the heaviest treatments. Potassium chloride decreased the accumulation of nitrates, but the sulphate caused an increase. Lime partially overcame the adverse effects of the chloride. Dressings of 500 lb. of the chloride reduced the nitrifying power of the soils. This was partly corrected by liming. The sulphate stimulated nitrification except with the heaviest dressings. No iron or aluminium was found in the water extracts of the soils, but calcium and magnesium were found in increased amounts after the potash treatment. Calcium is more easily replaced by potash in the soil than is magnesium. Soils with the highest content of water-soluble manganese had the lowest nitrifying power, the smallest crops of wheat in pot cultures, and the poorest growth of wheat seedlings in water-extract cultures.—A. G. P.

Soil; Inversion of cane sugar [*sucrose*] *by mineral-acid* ——. S. Osugi. Ber. Ohara Inst. Landw. Forsch., 1920, 1, 579—597. (*Cf.* Rice and Osugi, J., 1918, 666 A.)

In experiments with a number of soils, digestion of 10 g. of the sample with 100 c.c. of 5% sucrose solution for 1 hr. at 85° C. yielded amounts of invert sugar ranging from 0·47 g. downwards. The inversion process was found to be unimolecular and subject to the same temperature coefficient as ordinary inversion by acids. Aqueous extracts of the soils had a relatively insignificant inverting power and a very low hydrion concentration, but the inverting power of the soils themselves was closely related to the acidity of extracts obtained by digestion with potassium chloride solution. The hydrolytic agents are thus insoluble in or absorbed by the soil particles, and from experiments described it is concluded that the chief agents are acid aluminium silicates.—J. H. L.

Seeds; Possibility of determining the value of —— by a biochemical method. A. Numec and F. Duchon. Comptes rend., 1921, 173, 933—935.

The activity of the various hydrolysing enzymes present in seeds diminishes with the germinative capacity but may be still marked after the value of the latter has reached zero. Catalase behaves differently and there is some indication that the activity of the catalase, measured under comparable conditions, may serve as a suitable means of determining rapidly and simply the agricultural value of seeds.—W. G.

Patent.

Fertilisers; Manufacture of ——. L'Azote Français Soc. Anon., Assees. of P. A. Guye. E.P. 160,810, 29.3.21. Conv., 29.3.20.

Nitrophosphates obtained by addition of 2 mols. of nitric acid to 1 mol. of tricalcium phosphate gradually decompose with loss of nitrogen oxides. The product may be rendered stable by addition of sufficient calcium cyanamide to neutralise the acidity. The mixtures are hygroscopic, but are obtained in granular or powder form by addition of more calcium cyanamide, powdered phosphate, or potassium salts.—C. I.

XVII.—SUGARS; STARCHES; GUMS.

Reducing sugars; Conditions affecting the quantitative determination of —— by Fehling solution. Elimination of certain errors involved in current methods. F. A. Quisumbing and A. W. Thomas. J. Amer. Chem. Soc., 1921, 43, 1503—1526.

A modified procedure for the determination of reducing sugars by means of Fehling's solution is described. The solutions required are a copper sulphate solution containing 82·4 g. of $CuSO_4,5H_2O$ per l., an alkaline tartrate solution containing 376 g. of Rochelle salt dissolved in water in a litre flask, and the calculated amount of sodium hydroxide solution added to make 1 l. of the solution contain 130 g. of hydroxide. The hydroxide solution is made from material purified by alcohol which is kept in concentrated solution for several days to allow carbonates and other insoluble impurities to separate. To make a determination 25 c.c. of copper sulphate solution and 25 c.c. of alkaline tartrate solution with 50 c.c. of sugar solution are heated at 80° C. on a water bath. After exactly 30 mins. the cuprous oxide is collected in a Gooch crucible and washed. It may be either dried and weighed as cuprous oxide, or dissolved in nitric acid and estimated electrolytically. The amount of sugar is computed from the weight of copper obtained either from tables or by means of the following equations, in which x is the number of mg. of copper obtained from y mg. of sugar: Dextrose, $y=0{\cdot}474x+0{\cdot}000115x^2$; lævulose, $y=0{\cdot}526x+0{\cdot}000078x^2$; lactose, $y=0{\cdot}813x+0{\cdot}000003x^2$; maltose, $y=0{\cdot}990x+0{\cdot}0000005x^2$; invert sugar, $y=0{\cdot}504x+0{\cdot}0000870x^2$. The method is designed for use in the analysis of saccharine materials containing the above-named sugars. It is not claimed that the method can be used for the accurate quantitative estimation of 0·1% or less of invert sugar in an approximately pure sucrose. (*Cf.* J.C.S., Jan.)
—J. F. S.

Dextrose and lævulose in a solution; Quantitative determination of ——. H. Murschhauser. Biochem. Zeits., 1921, 118, 120—128.

The optical rotation of the solution is first determined and then the total reducing power in terms of cuprous oxide by Pflüger's method for dextrose (Arch. ges. Physiol., 1906, 114, 242). Pflüger's table of reducing powers of dextrose in terms of cuprous oxide is used as the standard of reference for dextrose and an analogous table is experimentally determined for lævulose. Knowing the rotation of dextrose and lævulose separately, the content of lævulose is determined graphically or by a simple calculation.—H. K.

Dextrose; Optical rotation of —— in solutions of trisodium phosphate. Mutarotation as an analytical method. H. Murschhauser. Biochem. Zeits., 1921, 117, 215—225.

The mutarotation of dextrose is accelerated by trisodium phosphate. It follows a unimolecular law, the velocity constants being also a linear function of the concentration of sodium phosphate. As the mutarotation is a function of the hydroxyl ion, its use is indicated for distinguishing salts of different degrees of alkalinity.—H. K.

Starch; Contribution to our knowledge of ——. J. J. L. Zwikker. Rec. Trav. Chim., 1921, 40, 605—615.

Colloidal solutions of four different kinds of starch have been examined with regard to their degree of dispersion. On ultrafiltration, amylose is obtained in the filtrate from solutions made up in the cold, but not from those that have been heated. The adsorptive power of starch is conditioned by the nature of the cations that are present, the effect of calcium being very marked. The author expresses the opinion that starch is more closely allied to cellulose than has hitherto been supposed.—H. J. E.

XVIII.—FERMENTATION INDUSTRIES.

Trogoderma khapra [in malt houses]; Laboratory note on the control of ——. T. Parker and A. W. Long. Bull. Bur. Bio-Techn., 1921, No. 4, 102—104.

Pentachloroethane can be successfully used for killing "free" larvæ of *T. khapra* in malt-bins and the like, but insects in the interior of the grain are not destroyed. In a closed chamber of 27 l. capacity containing pentachloroethane corresponding to 1 pint per 1000 cub. ft., 77% of the larvæ in the chamber were killed within 1000 mins. Chloropicrin is more effective, but it is far more unpleasant to use, and it affects the germinating power of barley. Most of the pentachloroethane may be removed from treated malt by thoroughly re-drying on the kiln and repeatedly turning the grain meanwhile, and any remaining traces are completely dispelled when the wort is boiled in the open coppers, so that no deleterious effect is produced on the flavour of the beer.—J. H. L.

Yeast; Acclimatisation of —— to ammonium fluoride and its reversion in wort. E. I. Fulmer. J. Phys. Chem., 1921, 25, 455—472.

Alcohol increases the toxicity of ammonium fluoride towards yeast. It is unnecessary to start with dilute solutions in acclimatising yeast to ammonium fluoride; the cells may be planted at once in the more concentrated solutions of fluoride and wort and will grow if left long enough. The time elapsing between seeding and active fermentation depends on the method of preparing the wort, on the character of the individual yeast cells, and on the previous history of the culture. The highest concentration of ammonium fluoride in which yeast will grow is 7 g. per l. Yeast acclimatised to ammonium fluoride is more resistant than normal yeast to phenol; it may be grown in fluoride-free wort agar for 12 days or in fluoride-free wort for 190 hrs. without completely reverting to normal. When yeast is planted in wort containing ammonium fluoride, a proportion of the cells die, that is they will not reproduce on fluoride-free wort agar. The number of living cells decreases, passes through a minimum, which may be less than 1 in 1200 of those originally present, and then increases. Cells which are not killed outright on placing in ammonium fluoride solutions undergo a period of paralysis, after which they reproduce fluoride-resisting cells.—J. F. S.

Butyric acid and butyl alcohol fermentation; Nature of ——. Fixation of acetaldehyde as a decomposition product. Transformation of pyruvic acid-aldol into butyric acid. Production of the higher fatty acids from sugar. C. Neuberg and B. Arinstein. Biochem. Zeits., 1921, **117**, 269—314.

Dextrose in a nutrient medium of inorganic materials and in the presence of a fixative, *e.g.*, sodium sulphite, is fermented by *Bacillus butylicus*, Fitz., with production of about 10% of acetaldehyde. By use of a culture of amylobacter, acetaldehyde could also be qualitatively recognised. The intermediate stage in the butyric fermentation is not acetaldehyde or its condensation product, aldol, but the aldol of pyruvic acid, α-keto-γ-valerolactone-γ-carboxylic acid, which gave butyric acid on fermentation. Starch syrup fermented by a culture of *B. butylicus*, Fitz. in an inorganic nutrient medium gave small quantities of the higher fatty acids, of which capric acid was identified.—H. K.

Fermentation without yeast. E. Baur and E. Herzfeld. Biochem. Zeits., 1921, **117**, 96—112.

Mixtures of substances in imitation of yeast press juice (peptones, dextrose, dextrin, sodium bicarbonate, casein lipoids, and bile salts) produced carbon dioxide and alcohol (iodoform test) in small amounts. The formation from dextrose of acidic substances liberating carbon dioxide from the sodium bicarbonate only accounts for a portion of the gas formed.—H. K.

Amylases; Conditions of action of ——. Studies on enzymes. VIII. W. Biedermann and A. Rueha. Fermentforsch., 1921, 5, 56—83.

The effects of acidity and alkalinity on the activity of diastatic enzymes are fully discussed. (*Cf.* J.C.S., Dec.)—T. H. P.

Invertase action; Some errors in the study of ——. W. C. Vosburgh. J. Amer. Chem. Soc., 1921, 43, 1693—1705. (*Cf.* Nelson and Vosburgh, J., 1917, 560.)

Invertase solutions show loss of activity on dilution, the magnitude of the loss varying with the particular invertase preparation and with the substances present in the water used for dilution. With distilled water the loss is smallest and concordant values are obtained. The loss is less if sucrose is present in the diluting solution than if it is absent. The velocity of hydrolysis of sucrose by invertase is greater when a citrate or an acetate buffer is used as the source of hydrogen ions than when citric or acetic acid respectively is so used. Both dilute and stock solutions of invertase lose strength on standing, the former faster than the latter.—W. G.

Fermentation; Inhibitive action on —— of some chlorine derivatives of methane, ethane, and ethylene. H. Plagge. Biochem. Zeits., 1921, **118**, 129—143.

Ethylidene chloride, ethylene dichloride, dichloromethane, chloroform, and tetrachloroethane are toxic to the yeast cell. The determining factor is not the concentration of the solution but the actual dose administered.—H. K.

Invertase; Action of quinine on ——. Contribution to the study of toxicity. P. Rona and E. Bloch. Biochem. Zeits., 1921, **118**, 185—212.

The inhibitory action of quinine hydrochloride on invertase is dependent on the p_H of the solution. The more alkaline the solution the greater the toxic effect. This indicates that the free base is the active agent. The same applies to the action on paramœcia. Optoquin, eucupin, and vuzin behave similarly, the two former being equivalent to quinine; vuzin is considerably more active. Quinidine has a greater toxic effect than quinine. —H. K.

Serum-lipase; Action of quinine on ——. Contribution to the study of toxicity. P. Rona and D. Reinicke. Biochem. Zeits., 1921, **118**, 213—231.

Quinine hydrochloride inhibits the action of lipase similarly to the inhibition produced by atoxyl. The action depends on the p_H of the solution, being more pronounced with increasing p_H, and is independent of the particular salt of quinine used. The inhibiting action on animal sera is only obtained at concentrations of quinine 100 to 1000 times that observed in human sera.—H. K.

Invertase; Action of m- and p-nitrophenols on ——. Contribution to the study of toxicity. P. Rona and E. Bach. Biochem. Zeits., 1921, **118**, 232—253.

The inhibitory action of these phenols is a time process. There is also a distinct threshold value for each, beyond which only a relatively small variation of concentration is possible without producing complete inhibition. The process is not reversible, this being attributed to an irreversible destruction of the enzyme.—H. K.

Diastase; Action of metallic copper and silver on ——. A contribution to the so-called oligodynamic phenomena. A. Luger. Biochem. Zeits., 1921, **117**, 153—160.

Diastase inactivated by contact with metals is more or less re-activated by treatment with certain salts such as potassium cyanide and sodium thiosulphate. —H. K.

Patent.

Soy; Quick method for brewing ——. M. Togano. U.S.P. 1,394,236, 18.10.21. Appl., 19.2.20.

Soya-bean-koji is treated with salt water of about 20° B. (sp. gr. 1·16), the mixture is maintained at about 40° C. to decompose the albumin, and the soy is extracted.—H. H.

XIXa.—FOODS.

Fat in butter; Modified Babcock method for determining ——. N. W Hepburn. Cornell Univ. Exp. Stat. Mem. 37, June, 1920, 669—690.

In sampling butter, two samples should be drawn from each tub, at points about equidistant from the centre, by means of a sampler drawing a core the whole length of the tub. The whole sample is warmed on a water bath till semi-liquid, then cooled slowly with vigorous shaking till of the consistency of thick cream, when a portion is weighed out for analysis. The Babcock bottle recommended is the "9 in.—9 g. bottle"; total height 223·5 mm., neck 139 mm., and diameter of graduated portion of neck 9·07 mm. Alternatively the "6 in.—6 g. bottle," of dimensions 165·09, 93·5, 9·04 mm. respectively, is suitable. Using the former, 9 g. of butter is weighed into the bottle, 9 c.c. of lukewarm water added, and 17·6 c.c. of commercial sulphuric acid slowly stirred in with constant shaking. Water is added to the base of the graduated neck, and the bottle is centrifuged for 5 mins.; if necessary water is again added to bring the liquid to the graduations. After centrifuging for another 4 mins. the bottle is placed in a water bath at 125°—130° F. (52°—54° C.), and the volume of fat read off. The meniscus is preferably removed by "Glymol" (Hunziker and others, Purdue Univ. Agr. Exp. Stat. Bull. 149, 1910). Results are concordant and agree with those obtained by chemical analysis.—A. G. P.

Grape juice; Occurrence of methyl anthranilate in ——. F. B. Power and V. K. Chesnut. J. Amer. Chem. Soc., 1921, 43, 1741—1742.

Methyl anthranilate is a natural and apparently constant constituent of grape-juice. Its presence, therefore, in commercial juices must not necessarily be taken as an indication of adulteration.—W. G.

Lupins; Removal of bitter substances from ——. B. Rewald. Chem.-Zeit., 1921, 45, 1053.

By extracting lupin seeds for some hrs. with several successive quantities of water at 65° C., much of the bitter substance is removed, and the seeds are then suitable for feeding horses; the residue of bitter substance is removed only by a subsequent extraction with 0·25% hydrochloric acid.—W. P. S.

Odorous constituents of peaches and apples. Power and Chesnut. *See* XX.

Patents.

Drying of fruit, vegetables, meats, and like food products. W. J. H. Strong. E.P. 170,393, 19.7.20.

The material is exposed in horizontal layers to the action of hot combustion gases thoroughly mixed and tempered with a large proportion of air, the mixture being blown across the layers by a cross-current of air from a fan or blower. The layers are disposed in a receptacle open at both ends, and the hot gases and air rising from a stove at the bottom of a vertical flue adjacent to one end are blown through the receptacle by air from a fan disposed in axial line with the receptacle. A flat baffle in the upper part of the flue over which the air from the fan sweeps assists the mixing of the air and gases.—H. H.

Fresh fish and other foodstuffs; Preservation of ——. H. B. Casebourne and H. J. G. Krause. E.P. 170,500, 10.11.20.

Biborate, nitrate, and permanganate of sodium or potassium are incorporated with the ice used.
—H. H.

Cereal food; Process of preparing ——. J. Friedman. U.S.P. 1,393,997, 18.10.21. Appl., 19.11.19.

The dry cereal is subjected to a cooking heat and pressure in a completely closed vessel.—H. H.

Juices and jellies; Manufacture of —— with conserve or marmalade from fruits or like vegetable constituents. C. and O. Bielmann. E.P. 147,838, 9.7.20. Conv., 24.11.16.

See G.P. 303,995 of 1916; J., 1920, 525 a.

Bread and other like foodstuffs; Process of producing ——. R. Graham. U.S.P. 1,387,387, 9.8.21. Appl., 23.4.19.

See E.P. 123,883 of 1918; J., 1919, 302 a.

XIXb.—WATER PURIFICATION; SANITATION.

[Rubberised fabrics of] oxygen breathing apparatus; Permeation of —— by gases and vapours. A. C. Fieldner, S. H. Katz, and S. P. Kinney. U.S. Bureau of Mines Techn. Paper 272, 1921, 24 pages.

Tests on ordinary commercial breathing bags of rubberised fabric in an atmosphere containing 34% of casinghead gasoline vapour showed that up to 2·6% of the vapour was in the bag after 15 mins. exposure. A description of an apparatus designed to test the permeability of any fabric to gases and vapours is given together with a large number of results obtained with it for different fabrics and gases. All the fabrics used by the Bureau of Mines except the "Fleuss," consisting of heavy sheet rubber $\frac{1}{16}$ in. thick, were found to be permeable to gasoline, benzene, and similar organic vapours but not to carbon monoxide or natural gas. A fabric made of two rubberised sheets cemented with a mixture of glue and glycerin and only one-third as thick as the rubber sheet was completely impermeable and did not deteriorate on exposure to weather, hot dry air, or freezing temperatures, or after rough mechanical treatment. A cloth fabric impregnated and coated on one side with pyroxylin varnish allowed only a small amount of gasoline or benzene vapour to pass through it in 2 hrs. and probably, with a thicker coat of varnish, could be made impermeable.—A. R. P.

Silicofluorides [as poisons and preservatives]. A. Cobenzl. Chem.-Zeit., 1921, 45, 1116.

The author calls attention to the toxic action of hydrofluosilicic acid and its salts on the lower animals such as mice, rats, etc. The sodium or potassium salts are readily eaten by these animals when mixed in the proportion of about 1:10 with meal and made into a paste, and death follows in about 30 mins. The silicofluorides also act as preservatives for gelatin solutions, and might find use in photographic emulsion processes or for preserving adhesives.—G. F. M.

Patents.

Sewage; Continuous method for the purification of ——. L. C. Trent. U.S.P. 1,394,698, 25.10.21. Appl., 14.2.21.

The sewage is caused to flow through a number of connected oxidation vessels in which it is agitated. Liquid is withdrawn from the upper portion of each vessel and is discharged through the lower portion "under circulation in excess of the normal flow of liquid into and out of the vessels." Air is admitted into the liquid as withdrawn from the vessels, and the liquid from the last vessel is delivered into a sludge-thickening vessel.—H. H.

Carbon monoxide respirator. L. A. Levy and R. H. Davis. E.P. 170,404, 20.7.20.

A mouthpiece or face-mask is fitted with apparatus for the destruction of carbon monoxide by oxidation and with means for detecting carbon monoxide escaping such oxidation when the apparatus is becoming exhausted or otherwise fails. The oxygen may be derived from the inspired air, a catalyst such as silver oxide being used, or from an auxiliary oxygen supply, and means are provided for cooling the purified air. The detector may act by the release or production of small quantities of iodine, phosgene, or other irritant or easily detected vapour, or by the increased brightness of an electrically-heated platinum wire. (*Cf.* J., 1921, 234 T.) —H. H.

Insecticide. J. F. Moseley. U.S.P. 1,395,860, 1.11.21. Appl., 18.5.18.

SEE E.P. 117,916 of 1917; J., 1918, 604 A.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Cocaine; The Vitali reaction for ——. P. Hardy. J. Pharm. Chim., 1921, 24, 325—330.

PURE cocaine does not yield a coloration with the Vitali test in the cold (evaporation of the alkaloid with a few drops of nitric acid and treatment of the residue with a drop of alcoholic potassium hydroxide solution); when the mixture is warmed a yellow coloration develops. Substituted cocaines generally give a yellow or brown coloration, but isatropylcocaine yields a violet coloration with the test and it is due to the presence of a small quantity of this substance in cocaine that some specimens of the latter yield a violet coloration.—W. P. S.

Digitalis; Effect of daylight on the content of active material in ——. O. von Dafert. Biedermann's Zentr., 1921, 50, 422—425.

THE most toxic extract can be obtained from digitalis leaves by gathering them in the afternoon and killing them at once by immersion in 96% alcohol. —W. G.

Phellodendron amurense; Constituents of ——. K. Shimo. Sci. Rep., Tohoku Imp. Univ., 1921, 10, 331—338.

THE cortex of *Phellodendron amurense* contains in addition to berberine, palmitic acid, linolic acid, and a small quantity of linolenic acid. The acids are not combined with the berberine. A small quantity of a neutral substance was found but not identified. Two samples of the cortex gave 2·473% and 3·75% respectively of berberine (estimated as berberine-acetone).—G. W. R.

Saligenin; Some derivatives of ——. M. C. Hart and A. D. Hirschfelder. J. Amer. Chem. Soc., 1921, 43, 1688—1693.

WITH a view of studying their pharmacological properties, ethyl, propyl, *n*-butyl, isoamyl, and benzyl ethers have been prepared from saligenin by heating its potassium salt under a reflux condenser with the corresponding alkyl or aryl iodide. The monoacetate and the monobenzoate were prepared by the action of the corresponding acid anhydride on the potassium salt, and the dibenzoate by benzoylation in pyridine solution. 2-Hydroxy-5-iodobenzyl alcohol is best prepared by the action of iodine in aqueous potassium iodide on an aqueous solution of saligenin. (*Cf.* J.C.S., Dec.)—W. G.

Diazoamino compounds of arsanilic acid and its derivatives. Aromatic arsenic compounds. IX. W. A. Jacobs and M. Heidelberger. J. Amer. Chem. Soc., 1921, 43, 1632—1645. (*Cf.* J., 1920, 41 A, 42 A.)

IT has been shown by Ehrlich and Bertheim (*cf.* Ber., 1907, 40, 3292) that arsanilic acid can be diazotised and the resulting diazo compound coupled without difficulty yielding azo dyestuffs. It is now shown that this reaction can be extended to the preparation of well-defined diazoamino compounds containing the arsonic acid residues. Several groups of such substances have been prepared by using as components dialkylamines, simple arylamines, and aminobenzoic acids, arylglycines, and aminophenoxyacetic acids (*cf.* J.C.S., Dec.). For the treatment of experimental trypanosomiasis these compounds possess certain inherent disadvantages and their use has been discontinued.—W. G.

Azo dyes derived from arsanilic acid. Aromatic arsenic compounds. X. W. A. Jacobs and M. Heidelberger. J. Amer. Chem. Soc., 1921, 43, 1646—1654. (*Cf. supra.*).

CERTAIN classes of aromatic compounds yield aminoazo dyestuffs at once when coupled with diazotised arsanilic acid, or give diazoamino compounds which rapidly undergo rearrangement giving the dyestuffs. In most cases the reaction between the amino compound and the diazotised arsanilic acid proceeds smoothly but the isolation and purification of the resulting dyestuffs is difficult. Such dyestuffs prepared from N-alkylanthranilic acids, *m*-aminophenoxyacetic acid and its substitution products, the aminoveratric acids and the *o*-methyl and *o*-alkoxy derivatives of N-phenylglycine are described (*cf.* J.C.S., Dec.).—W. G.

Benzyl esters; Preparation and hydrolysis of ——. E. H. Volwiler and E. B. Vliet. J. Amer. Chem. Soc., 1921, 43, 1672—1676.

THE comparative rates of hydrolysis of certain benzyl esters were determined in order to obtain a basis for the correlation of chemical properties and physiological action. The rates of hydrolysis of the esters examined increase in the following order: salicylate, benzoate, stearate, cinnamate, acetate, succinate and fumarate. The rate of hydrolysis of the benzyl group in benzyl acetylsalicylate is of the same order as in benzyl salicylate.—W. G.

Furfural; Reaction of —— with orcinol. E. Justin-Mueller. J. Pharm. Chim., 1921, 24, 334—336.

FIVE c.c. of the solution to be tested, 5 c.c. of hydrochloric acid, and 0·02 g. of orcinol are heated to boiling in a test-tube; if furfural is present a blue or bluish-green coloration develops. The sensitiveness of the test may be increased by shaking the mixture with amyl alcohol in which the blue colour is soluble; in this way 1 pt. of furfural in 600,000 pts. may be detected.—W. P. S.

Constitution and heats of combustion [of organic compounds]. F. O. H. Binder. Chem.-Zeit., 1921, 45, 1114—1116.

THE mean heat values of the following valencies have been worked out from the consideration of a large number of hydrocarbons: carbon valency attached to hydrogen 55,560 cals., carbon attached to carbon 16,258 cals., free carbon valency 24,495 cals., which latter compares with 24,240 cals. the actual calorimetric value obtained from wood charcoal. The heat of combustion of a compound is accordingly $\mathrm{CH}.55{,}560+y24{,}240+z34{,}170$ cals., where CH is the number of C valencies bound to hydrogen, *y* the number of C valencies bound neither to hydrogen nor oxygen, and *z* the number of free valencies. The mean heat value of the C valency bound to nitrogen was obtained by subtracting the above appropriate values from the heats of combustion of cyanogen and hydrogen cyanide, and closely agreeing figures were obtained, the mean value being 35,301 cals.—G. F. M.

Acetic anhydride; Preparation of —— from alkali acetates by means of sulphur monochloride and chlorine. G. Cappelli. Giorn. Chim. Ind. Appl., 1921, 3, 356—357.

ACETIC anhydride free from secondary products, often difficult to remove, may be obtained from alkali acetates by using as chlorinating agent sulphur monochloride which has taken up, at −14° C., 50% of its weight of chlorine previously dried over sulphuric acid; a yield of 76% of the pure anhydride is obtainable in this way.—T. H. P.

Methyl alcohol and water; A reaction between —— and some related reactions. J. A. Christiansen. J. Amer. Chem. Soc., 1921, 43, 1670—1672.

When suitable mixtures of methyl alcohol and water in the form of vapour are passed over finely-divided reduced copper at 230°—250° C. carbon dioxide and hydrogen are produced according to the equation, $CH_3OH+H_2O=CO_2+3H_2$. Formaldehyde and water behave similarly.—W. G.

Isosafrol; Geometrical isomerism of ——. S. Nagai. J. Coll. Eng. Tokyo, 1921, 11, 83—110.

By gentle isomerisation of safrol with a small quantity of alcoholic potassium hydroxide at 82°—86° C. a new unstable form of isosafrol was obtained, which easily changes to the stable form under the influence of heat and a more concentrated potash solution. The new isomeride, which is shown to be the *cis*-form, boils at 242°—243° C., and has sp. gr. 1·1162—1·1168, and $n_D^{15}=1·5630$, compared with the *trans*- or stable form which boils at 247°—248° C., and has sp. gr. 1·1230, and $n_D^{15}=1·5730$. Oxidation of both *cis*- and *trans*-isosafrol with potassium bichromate or with ozone gave practically identical yields of piperonal. (*Cf.* J.C.S., Dec.)—G. F. M.

Peaches; Odorous constituents of ——. F. B. Power and V. K. Chesnut. J. Amer. Chem. Soc., 1921, 43, 1725—1739. (*Cf.* J., 1920, 609 A.)

The odorous constituents of the pulp of choice ripe peaches consist chiefly of the linalyl esters of formic, acetic, valeric, and caprylic acids, together with a considerable proportion of acetaldehyde and a very small amount of an aldehyde of higher molecular weight. Probably the volatile acids are present to some extent in the free state. No trace of hydrocyanic acid or benzaldehyde could be detected in the distillate from the pulp. The yield of essential oil was about 0·00074% of the fresh pulp and the oil contained, in addition to the linalyl esters, a little acetaldehyde and furfural, probably some cadinene and a very small amount of an unidentified paraffin hydrocarbon. The oil is very unstable and on exposure to air for any length of time loses its original fragrance and is converted into a black, viscid mass. The emanation from the entire ripe fruit contains a minute amount of acetaldehyde.—W. G.

Apples; Odorous constituents of ——. F. B. Power and V. K. Chesnut. J. Amer. Chem. Soc., 1921, 43, 1741.

Inasmuch as esters derived from leucic acid do not occur in apples (*cf.* J., 1920, 609), the title of a paper by Kodama on this subject (J. Tokyo Chem. Soc., 1920, 41, 965) is misleading.—W. G.

Toxicity of quinine etc. Rona and Bloch. Rona and Reinicke. Rona and Bach. *See* XVIII.

Patents.

Dialkylxanthines and their N-acyl derivatives; Production of neutral soluble double compounds of ——. Knoll and Co. G.P. 340,744, 4.8.16.

Alkali benzoates and salicylates form additive compounds with dimethylxanthines, *e.g.*, theophylline and theobromine, and their N-acyl derivatives, the molecular proportion of salt to base being 2:1, whilst that of salt to acyl derivative is 1:1. The compounds crystallise easily and their solutions are suitable for subcutaneous or intravenous injection. —D. F. T.

Chlorinated acetyl chlorides; Production of ——. Consortium für Elektrochemische Industrie. G.P. 340,872, 18.7.19.

Chlorine substitution products of ethylene are treated with oxygen in the presence of suitable catalysts. Trichloroethylene in the presence of bromine, iodine, nitric acid, or sulphuric acid is oxidised to dichloroacetyl chloride; symm. dichloroethylene and perchloroethylene similarly yield chloroacetyl chloride and trichloroacetyl chloride respectively.—D. F. T.

Esters of hydrogenated N-alkylpyridine-3-carboxylic acids; Production of ——. R. Wolffenstein. G.P. 340,873, 20.12.17.

By treating the quaternary ammonium additive compounds derived from esters of pyridine-3-carboxylic acid and an alkyl halide with a metal and halogen hydracid in the presence of a stable solvent, it is possible to obtain esters of the corresponding hydrogenated N-alkyl-substituted acid; these are of therapeutic value. The methochloride of methyl pyridine-3-carboxylate in methyl alcohol at 100° C. or in formic acid at the ordinary temperature is thus reduced by tin and hydrogen chloride to methyl N-methylhexahydropyridine-3-carboxylate b.p. 86°—89° C. at 21·5 mm.—D. F. T.

Quaternary ammonium derivatives of esters of pyridine-3-carboxylic acid (nicotinic acid); Production of ——. R. Wolffenstein. G.P. 340,874, 22.12.17.

Methyl pyridine-3-carboxylate when treated for 48 hrs. with a methyl alcohol solution of methyl bromide at 100° C. is converted into the methobromide, m.p. 71° C.; the corresponding methiodide melts at 130° C. and the methochloride at 98° C. The compounds find therapeutic application on account of their resembling arecoline in action. —D. F. T.

Hydrocarbons [naphthenes]; Manufacture of ——. C. Weizmann and D. A. Legg. U.S.P. 1,395,620, 1.11.21. Appl., 10.11.17.

See E.P. 165,452 of 1916; J., 1921, 675 A.

Catalytic oxidation processes. E.P. 170,022. *See* I.

Converting combustible substances into soluble organic compounds. E.P. 149,974. *See* IIa.

XXI. — PHOTOGRAPHIC MATERIALS AND PROCESSES.

Silicofluorides as preservatives for gelatin. Cobenzl. *See* XIXb.

Patent.

Coloured [photographic] pictures; Process for making ——. A. Traube. E.P. 163,337, 7.7.20. Conv., 3.12.18. Addn. to 147,005 (J., 1921, 325 A).

By reducing the amounts of copper sulphate and of potassium ferrocyanide in the copper toning bath from about 1% to less than 0·5%, while leaving the potassium citrate at about 8% strength, the toned image has a varnished appearance and great transparency instead of a matt and turbid appearance. The effect is increased by using less copper than ferrocyanide. The results are particularly suitable for projection purposes.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Nitrocelluloses; Study of ——. G. de Bruin. Rec. Trav. Chim., 1921, 40, 632—664.

The relations between nitrogen content and stability at 95° and at 132° C. and between nitrogen content and solubility in alcohol-ether mixtures have been investigated. Owing to the variation in properties which arises from differences in the methods of manufacture, a wide range of samples was examined. The stability at 95° C. was determined by heating 2·5 g. of air-dried nitrocellulose in a phial by means of an alcohol-water mixture boiling at that temperature, for a series of 8-hr. periods. The samples were examined after 4 hrs. and at the end of each period by placing the phial, if necessary, before a white screen. Results are shown graphically, 8-hr. days being plotted against percentage of nitrogen. In the case of the higher temperature, the method of Bergmann and Junk (J., 1904, 953) was used, but with considerable modification in the direction of simplicity. Results are shown graphically, c.c. of nitric oxide being plotted against nitrogen content. The curve obtained by this means exhibits a sharp change in direction at a point corresponding to 12·83% of nitrogen. The solubility curve shows little difference between specimens containing from 11% to 12·25% of nitrogen, but from this point onwards, solubility decreases rapidly with increase of nitrogen. The results obtained are interpreted as indicating the existence of simple nitrocelluloses with nitrogen content about 12% to 12·75% and of isomeric forms, differing in solubility, containing 12·75% of nitrogen. A general formula for nitrocelluloses $[C_{24}H_{40-n}O_{20-n}(NO_3)_n]_x$ is suggested.—H. J. E.

Matches; Manufacture of damp-proof ——. R. Dubrisay. Mèm. Manuf. de l'Etat, Sept., 1921. (*Cf.* U.S.P. 1,363,095 of 1920; J., 1921, 130 A.)

The paste is mixed in two parts. The first consists of potassium chlorate, resorcinol, and sodium hydroxide solution, the second of manganese dioxide, red phosphorus, and formaldehyde. After being prepared separately the two mixtures are stirred together. The paste hardens at room temperature, or if kept at 40°—50° C. for ½ hr. Matches prepared with the paste have been kept over water for nearly a year without deterioration. They can be left for a few moments in either fresh or salt water and used again after wiping or allowing to dry in the air.—H. C. R.

Patents.

Organic nitrates and the like; Method of treating undried ——. W. O. Snelling, Assr. to Trojan Powder Co. U.S.P. 1,395,776, 1.11.21. Appl., 16.3.21.

The water content is reduced without drying by mixing the material with a concentrated solution of a substance very soluble in water and removing the excess solution.—H. C. R.

Priming composition. M. Witzgall. G.P. 298,449, 31.12.16.

The composition comprises an intimate mixture of black powder or its components with a resin, such as colophony. A mixture of 1 pt. of rosin with 4 pts. of black powder burns at a rate of about 0·2 cm. per sec. The rate of burning can be varied between wide limits by varying the proportions in the mixture.—H. C. R.

Picric acid; Manufacture of ——. D. B. Macdonald. U.S.P. 1,396,001, 1.11.21. Appl., 10.7.17.

See E.P. 126,675—6 of 1915; J., 1919, 480 A.

XXIII.—ANALYSIS.

Suspensoids; Quantitative methods of coagulation of ——. F. V. von Hahn. Kolloid-Zeits., 1921, 29, 226—236.

The electrolyte coagulation process for determining the stability of sols is best carried out by the Schulze mixture process (J. prakt. Chem., 1882, 25, 431). The titration process is unsuitable for quantitative work because the results are strongly influenced by the rate of addition of the electrolyte. The effect of filtration on a sol may be used to determine the stability, particularly in the case of very dilute sols. The method consists in placing a drop of the sol on a filter paper and measuring the ratio of the radius of the surface moistened by the unchanged sol, to that of the surface moistened by the dispersion medium. This ratio is the "capillary number" and is characteristic of the sol. The boiling test of stability is easily effected, but is unsuitable for dilute sols and is only to be regarded as a confirmatory test to the electrolyte coagulation method, or as a substitute for this in cases where chemical reaction occurs between the electrolyte and the sol. Coagulation by boiling depends on an adsorption process at the vapour-liquid interface. The time required for a definite electric current to effect coagulation of a sol can be taken as a measure of the stability. (*Cf.* J.C.S., Dec.)—J. F. S.

Fluorine; Determination of small quantities of —— *by means of Hempel and Scheffler's gasometric method.* H. Sertz. Z. anal. Chem., 1921, 60, 321—330.

Small quantities (*e.g.*, a few mg.) of fluorine may be determined in vegetable materials by means of a method described by Hempel and Scheffler (Z. anorg. Chem., 1899, 20, 1); the method consists essentially in mixing the ash of the substance with silica, decomposing the mixture with sulphuric acid, collecting the evolved carbon dioxide and silicon tetrafluoride in a burette over mercury, and adding water to decompose the silicon tetrafluoride and potassium hydroxide to absorb the carbon dioxide. The diminution of the volume of the gas after these treatments gives the volume of the silicon tetrafluoride, allowance being made for the residual volume of air and for the quantity of carbon dioxide dissolved by the water. When the ash contains much carbonate, a preliminary treatment with 10% acetic acid is recommended. The method indicates about 80% of the fluorine present.—W. P. S.

Fluorine; New process for the determination of —— *in the cold.* Travers. Comptes rend., 1921, 173, 836—838.

The fluorine is converted into alkali fluoride and to its alkaline solution a known amount of silica, as potassium silicate, is added. Usually twice the theoretical amount of silica required to convert the fluorine into silicofluoride is sufficient. The liquid is made neutral to methyl orange by hydrochloric acid and a further 2 c.c. of acid is added. Solid potassium chloride is added until the solution contains 20%, the precipitated potassium silicofluoride is filtered off, washed free from acid with 20% potassium chloride solution, and titrated with N/5 potassium hydroxide as previously described in the estimation of silica (J., 1921, 873 A). 1 c.c. of N/5 potassium hydroxide is equivalent to 0·0057 g. of fluorine.—W. G.

Zinc; Use of membrane filters in the volumetric determination of ——. G. Jander and H. C. Stuhlmann. Z. anal. Chem., 1921, 60, 289—321.

Membrane filters (*cf.* J., 1919, 928 A) are particularly suitable for the collection of zinc sulphide precipitates and the latter can be washed readily on the filter. The zinc sulphide should be precipitated from an acetic acid solution containing sodium acetate. Volumetric methods for the determination of zinc sulphide were investigated; of these, Mann's method (decomposition of the zinc sulphide with moist silver chloride, separation of the silver sulphide by filtration, and titration of the chloride in the filtrate) yielded trustworthy results, as did also the acidimetric titration methods (with sulphuric acid or hydrochloric acid).—W. P. S.

Copper; Sensitive reaction for ——. P. Falciola. Giorn. Chim. Ind. Appl., 1921, 3, 354—355.

For the detection of cupric salts in dilute solution, the author recommends a reagent prepared by mixing alkali thiocyanate solution with cold, saturated gallic acid solution. With 0·0001N copper sulphate solution a distinct turbidity is produced and in more concentrated solutions voluminous precipitates; if a 0·00001N copper sulphate solution is shaken vigorously with a few c.c. of the reagent in the cold, a perceptible white turbidity forms after a short time. The presence of free mineral acid hinders the appearance of the precipitate, although, after its formation, this is virtually insoluble in acids; silver, lead, and bismuth must also be absent. More or less sensitive reactions are given if the gallic acid is replaced by tannic acid, catechol, or quinol.—T. H. P.

Manganese, iron, and cobalt; Reaction of ——. D. Balarew. Z. anal. Chem., 1921, **60**, 392—393.

When a manganese salt solution is treated successively with a few drops of sodium hydroxide solution, silver nitrate solution, and an excess of ammonia or dilute acetic acid, a precipitate is obtained which is black or yellowish-brown according to whether ammonia or acetic acid has been used in the test. The reaction is given by a solution containing as little as 0·2 mg. Mn per litre. Ferrous and cobalt salts yield a similar reaction, but not ferric, nickel, aluminium, zinc, titanium, or uranium salts.—W. P. S.

Iron and vanadium; Modified method for the determination of —— *after reduction by hydrogen sulphide.* G. E. F. Lundell and H. B. Knowles. J. Amer. Chem. Soc., 1921, **43**, 1560—1568.

Determination of iron or vanadium by reduction with hydrogen sulphide followed by titration with permanganate or bichromate ordinarily leads to high values, which are not due to the presence of sulphur or organic matter, but to polythionic acids which are not destroyed by boiling with moderately strong sulphuric acid but are volatilised slowly from dilute acid and more rapidly from concentrated acid solutions on boiling. Reasonably accurate determinations may be made by restricting the volume of solution to 100 c.c., acidifying with sulphuric acid to make 2·5% by vol., and reducing cold with hydrogen sulphide for 30 mins. and for a further 15 mins. during which the solution is raised to the boiling point. The hot solution is then treated with 15 c.c. of sulphuric acid (1:1) and boiled for 30—60 mins. until the volume is reduced to 50 c.c.; during this boiling and the subsequent cooling a stream of carbon dioxide is passed through the solution. The cold solution is titrated with permanganate. In some cases it is advisable to filter off the separated sulphur after the hydrogen sulphide treatment, and treat the filtrate for a further 10 mins. with hydrogen sulphide and complete as above. The average errors of the process are iron 0·5%, vanadium 0·1%. For accurate determinations of iron and vanadium in solutions containing platinum (as in rock analysis), a preliminary separation of the hydrogen sulphide group of metals, followed by expulsion of the hydrogen sulphide, complete oxidation with permanganate, and reduction with sulphur dioxide is recommended.—J. F. S.

Aluminium; Separation of —— *from beryllium* [*glucinum*]. H. T. S. Britton. Analyst, 1921, **46**, 437—445. (*Cf.* J., 1921, 751 A.)

Addition of ammonium carbonate to cold or hot solutions containing aluminium and glucinum yields a precipitate containing the greater part of the aluminium together with much glucinum. Ammonium sulphite precipitates all the aluminium with much glucinum, but a satisfactory separation may be effected by means of a double precipitation of the aluminium by sodium bicarbonate (Parsons and Barnes, J., 1907, 720) if the concentration of neither metal exceeds 0·15 g. per 100 c.c. and the solution is vigorously stirred during precipitation. (*Cf.* J.C.S., Dec.)—A. R. P.

Blood; Reaction for —— *with hydrogen peroxide in statu nascendi.* A. Patzauer. Chem.-Zeit., 1921, **45**, 1056.

Instead of using hydrogen peroxide in the Weber (guaiacum tincture) or benzidine tests for blood, a small quantity of magnesium peroxide is mixed with water and a few drops of dilute acetic acid and, when violent evolution of gas ceases, guaiacum tincture or benzidine dissolved in acetic acid is added, followed by the ethereal extract to be tested.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

1.—GENERAL; PLANT; MACHINERY.

Applications.

Allis-Chalmers Mfg. Co. Crushers. 32,360. Dec. 2. (U.S., 3.1.21.)

Bonnard. 32,481. *See* II.

Carpmael (Chem. Fabr. auf Aktien, vorm. E. Schering). Process for solidifying volatile bodies. 32,768. Dec. 6.

Cockey and Sons, Harrison, and Hiller. Apparatus for washing and scrubbing gases 32,494. Dec. 3.

Crosfield and Sons, and Wheaton. Means for removing and recovering vapours from gases. 31,961. Nov. 29.

Dried Milk Dairy Products, Ltd., and Sierra. Separation of solid particles from air or gases. 32,969. Dec. 8.

Ford. Drying-cylinders. 33,068. Dec. 9.

Hey. Clarifying liquids. 32,473. Dec. 3.

McIntyre. Grinding, refining, and mixing machines. 33,202. Dec. 10.

Oswald. Grinding-machines and pulverisers. 32,664. Dec. 6.

Picard and Sulman. Apparatus for separating finely-divided solids suspended in gases. 32,200. Dec. 1.

Plauson's (Parent Co.), Ltd. (Plauson). Concentration of solutions of colloidal dispersions. 32,335. Dec. 2.

Plauson's (Parent Co.), Ltd. (Plauson). Grinding solid materials. 32,575. Dec. 5.

Haddan (Gulf Refining Co.). Manufacture of lower-boiling oils. 32,880. Dec. 7.

Johnson (Elektrizitätswerk Lonza). 32,704. *See* XX.

Lubricant Laxatives Corp. Mineral oil emulsions. 33,240. Dec. 10. (U.S., 11.12.20.)

Plauson's (Parent Co.), Ltd. (Plauson). Refining mineral oils, petroleum, etc. 31,876. Nov. 29.

Plauson's (Parent Co.), Ltd. (Plauson). Recovery of oil, tar, resin, etc. from shale, bleaching-earths, peat, etc. 32,336. Dec. 2.

Complete Specifications Accepted.

20,777 (1920). Hennebutte. Vertical retorts and gas-producers. (148,943.) Dec. 7.

22,628 (1920). Lewis. Combination of solid and liquid fuels. (172,065.) Dec. 14.

24,387 (1920). Naef. *See* VII.

24,480 (1920). O'Dell (Canadian American Finance and Trading Co.). Hydrogenating and distilling hydrocarbons from bituminous substances. (171,785.) Dec. 7.

25,255 (1920). Woodall, Duckham, and Jones, Ltd., and Duckham. Gasification of coal. (171,805.) Dec. 7.

27,798 (1920). Wallace. Distilling carbonaceous material. (172,173.) Dec. 14.

30,925 (1920). Leadbeater. Manufacture of metallurgical coke. (172,199.) Dec. 14.

31,082 (1920). Wells. Gas-producers. (171,884.) Dec. 7.

34,262 (1920). Merz and McLellan, Bottomley, and Weeks. Low-temperature distillation of fuel.

218 (1921). Dolbear. Treatment of oil shales. (171,918.) Dec. 7.

III.—TAR AND TAR PRODUCTS.

Applications.

Bergius and Löffler. 32,146–7. *See* II.

Plauson. 32,336. *See* II.

Complete Specifications Accepted.

14,094 (1920). Lilienfeld. Production of oily bodies of high boiling-point from aromatic hydrocarbon mixtures. (163,271.) Dec. 7.

30,558 (1920). Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Production of dinitrophenol. (153,265.) Dec. 7.

IV.—COLOURING MATTERS AND DYES.

Applications.

Bloxam (Akt.-Ges. f. Anilinfabr.). Manufacture of dyestuffs. 31,838. Nov. 28.

Imray (Soc. Chem. Ind. in Basle). Manufacture of β-thionaphthisatin. 32,234. Dec. 1.

Complete Specifications Accepted.

22,090 and 22,163 (1920). Imray (Soc. Chem. Ind. in Basle). Manufacture of easily soluble diazotisable azo dyestuffs. (172,056–7.) Dec. 14.

28,008 (1920). Imray (Soc. Chem. Ind. in Basle). Manufacture of dyestuffs. (172,177.) Dec. 14.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Dreyfus. Treatment of cellulose derivatives. 32,086–8. Nov. 30.

McIntosh and McIntosh. Sulphurising of wool etc. 32,791. Dec. 7.

Olier. Manufacture of paper pulp. 32,247. Dec. 1.

Walters. Drying fabrics, fibres, etc. 32,283. Dec. 2.

Complete Specifications Accepted.

13,287 (1920). Lilienfeld. Manufacture of ethers of carbohydrates such as cellulose, starch, dextrin, etc. (163,018.) Dec. 7.

13,568 (1920). Lilienfeld. Manufacture of ethers of cellulose or its conversion products or derivatives. (149,320.) Dec. 7.

14,030 (1920). Doverdale. Reclaiming paper pulp from waste waters of paper-making machines. (171,718.) Dec. 7.

14,314 (1920). Dreaper. Manufacture of artificial threads or filaments. (171,719.) Dec. 7.

14,632 (1920). Bronnert. Manufacture of artificial silk. (172,038.) Dec. 14.

21,459 (1920). Borzykowski. Production of artificial threads. (149,295.) Dec. 7.

21,460 (1920). Borzykowski. *See* I.

23,867 (1920). Lilienfeld. Manufacture of compositions and products containing ethers of carbohydrates etc. (171,661.) Dec. 7.

24,277 (1920). Brougham (Technochemia A.-G.). Manufacture of artificial silk and like threads. (171,776.) Dec. 7.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Foulds, and Tootall Broadhurst Lee Co. Treatment of cotton etc. fabrics and silk. 32,633. Dec. 6.

La Fayette. Apparatus for treating textile fabrics. 32,885. Dec. 7. (U.S., 2.7.21.)

Larivei. Machines for treating with fluids and centrifuging textile fibres etc. 32,635. Dec. 6.

Complete Specifications Accepted.

16,783 (1920). Mitchell. Waterproofing fabric. (171,726.) Dec. 7.

25,294 (1920). Willows, Pollitt, and Leach. Production of pattern effects in cotton and other vegetable fibre fabrics and silk. (171,806.) Dec. 7.

30,140 (1920). Calico Printers Assoc., Ashmore, and Cochrane. Production of colour effects on fabrics. (172,193.) Dec. 14.

2418 (1921). Morgan. Machines for treating textiles etc. with liquids. (172,238.) Dec. 14.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Aktieselskabet Labrador. Precipitation of iron in alumina solutions. 31,941. Nov. 29. (Norway, 16.12.20.)

Bichowsky and Harthan. Production of titanium-nitrogen compounds. 32,859. Dec. 7.

Duffield and Longbottom. Manufacture of dolomite. 32,485. Dec. 3.

Laing and Nielsen. Manufacture and utilisation of formic acid. 32,504. Dec. 3.

Weyman. Neutralising and drying sulphate of ammonia. 32,216. Dec. 1.

Complete Specifications Accepted.

23,818 (1920). Heinemann, and Hoesch u. Co. Recovery of pure caustic alkalis from impure lyes. (171,751.) Dec. 7.

24,193 (1920). Hirschel, and Amsterdamsche Superfosfaatfabriek. Manufacture of phosphoric acid. (165,759.) Dec. 7.

24,387 (1920). Naef. Recovery of sulphur from sulphuretted hydrogen and ammonium sulphide and gases containing such. (172,074.) Dec. 14.

24,579 (1920). Tyrer. Extraction of alumina. (172,087.) Dec. 14.

26,001 (1920). Goldschmidt A.-G. Production of alkali sulphate and hydrochloric acid. (150,962.) Dec. 7.

31,350 (1920). Schantz. Manufacture of mercury bichloride. (172,205.) Dec. 14.

VIII.—GLASS; CERAMICS.

Applications.

Hailwood. Annealing-lehr. 32,308. Dec. 2.

Pease and Partners, Ltd., and Wilson. Manufacture of silica bricks. 32,996. Dec. 8.

Sobawa. 31,946. *See* XXI.

IX.—BUILDING MATERIALS.

Applications.

Grunder and Morin. Production of a stone-like devitrified mass. 32,554. Dec. 5.

Lyte. Production of artificial marble etc. 33,003. Dec. 8.

Munro. Manufacture of cement. 32,300. Dec. 2.

Tetlow. Manufacture of cement compositions imitating granite, marble, etc. 32,175. Dec. 1. (Fr., 3.1.21.)

Young. Fire-resisting asphalt etc. 32,671. Dec. 6.

Complete Specification Accepted.

3673 (1921). Dunstan and Davis. Evacuation of wood-impregnating tanks or retorts. (171,928.) Dec. 7.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Alloy Welding Processes, Ltd., and Jones. Electrodes for soldering and depositing metals. 32,277. Dec. 1.

Backer. Coating magnesium and magnesium alloys. 32,853. Dec. 7. (Norway, 4.1.21.)

Blackford, Smith, and Webb. Nickel-plating aluminium and its alloys. 32,636. Dec. 6.

Cunningham, and Welding Specialists, Ltd. Production of aluminium alloys. 32,800. Dec. 7.

Girouard and Jones. Reduction of ores. 32,974. Dec. 8.

Kubasta, and Röchlingsche Eisen u. Stahl Ges. Avoiding insufficient passive hardness of steel. 32,837. Dec. 7.

Marks (Eureka Metallurgical Co.). Concentration of ores and minerals. 33,254. Dec. 10.

Marks (Merrill Co.). Treatment of ores. 32,607. Dec. 5.

Mathansohn. Recovery of lead. 31,857. Nov. 28. (Ger., 13.10.21.)

Miami Metals Co. Open-hearth furnace. 32,866. Dec. 7. (U.S., 26.9.21.)

Miles. Metal alloys. 32,832. Dec. 7.

Morton and Rathbone. Soldering. 32,721 and 32,978. Dec. 6 and 8.

Perkins, Picard, Sulman, and Taplin. Treatment of ores containing oxidised copper compounds. 33,100. Dec. 9.

Perkins. Treatment of copper ores. 33,101. Dec. 9.

Wade (Vanadium Corp. of America). Manufacture of refractory metal alloys. 32,150. Nov. 30.

Wyrill. Protecting surface and interior of magnesium alloys. 32,567. Dec. 5.

Complete Specifications Accepted.

13,570 (1920). Moffat. Treatment of ores. (143,525.) Dec. 7.

14,484 (1920). Cornelius. Production of zinc or zinc and lead. (171,722.) Dec. 7.

15,516 (1920). Thermal Industrial and Chemical Research Co., and Morgan. Process for detinning iron. (172,046.) Dec. 14.

23,745 (1920). Fisher and Chambers. Cementation of iron and iron alloys. (171,750.) Dec. 7.

24,924 (1920). Perkins. Treatment of complex sulphide ores. (172,101.) Dec. 14.

26,508 (1920). Lavandeyra. Aluminium alloys. (172,155.) Dec. 14.

30,925 (1920). Leadbeater. *See* II.

32,028 (1920). Seiffert. Production of zinc dust. (155,572.) Dec. 14.

7425 (1921). Liebreich. Electrolytic separation of chromium. (159,887.) Dec. 7.

XI.—ELECTRO-CHEMISTRY.

Applications.

Siemens-Schuckertwerke. Apparatus for electrically precipitating suspended particles from fluids. 33,151 and 33,171. Dec. 9. (Ger., 14.1. and 28.6.21.)

Complete Specifications Accepted.

22,260 (1920). Vesme. Apparatus for production by electrolysis of gas under pressure. (171,743.) Dec. 7.

34,117 (1920). Metropolitan-Vickers Electrical Co. Electrolytes for use in electrolytic cells. (155,579.) Dec. 7.

1291 (1921). Cattley. Accumulator plates. (171,921.) Dec. 7.

7425 (1921). Liebreich. *See* X.

XII.—FATS; OILS; WAXES.

Applications.

Bedford. Manufacture of soap. 32,490. Dec. 3.

Plauson. 32,336. *See* II.

Complete Specifications Accepted.

6670 (1921). Henkel et Cie. Treatment of liquid soaps containing water or their fatty acids. (172,250.) Dec. 14.

7086 (1921). Williams. Powder for making washing liquor. (172,251.) Dec. 14.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Applications.

Plauson. 30,083. *See* XIV.

Plauson. 32,336. *See* II.

Complete Specifications Accepted.

14,065 (1920). Nelson. Manufacture of carbon for pigmental and other purposes. (172,035.) Dec. 14.

25,811 (1920). Barrett Co. Manufacture of resins. (160,148.) Dec. 7.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Application.

Plauson's (Parent Co.), Ltd. (Plauson). Production of mixtures of rubber and artificial resins. 30,083. Nov. 30.

Complete Specification Accepted.

25,095 (1920). Speedy and Crouch. Rubber mixing. (171,803.) Dec. 7.

XV.—LEATHER; BONE; HORN; GLUE.

Applications.

Wade (Tsavo Industries, Ltd.). Treating, tanning, and waterproofing hides, skins, etc. 32,272–4. Dec 1.

Complete Specifications Accepted.

17,203 and 17,340 (1920). Bloxam (Gerb- u. Farbstoffwerke Renner u. Co.). Manufacture of tanning agents. (171,729 and 172,048.) Dec. 7 and 14.

23,903 (1920). Elektro-Osmose A.-G. Tanning or impregnating hides and skins. (152,641.) Dec. 7.

XVII.—SUGARS; STARCHES; GUMS.

Complete Specifications Accepted.

13,287 (1920). Lilienfeld. *See* V.

26,074 (1920). White (Perkins Glue Co.). Modifying or converting starch. (172,145.) Dec. 14.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Shaw, and Shaw and Co. Plant for dewatering sewage. 32,439. Dec. 3.

Tatham. Preparation of a food product. 32,408. Dec. 3.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Brougham (Klingenfuss). Radium preparation for therapeutic purposes. 32,356. Dec. 2.

Calvert. Manufacture of substances containing a methyl radicle. 32,152. Nov. 30.

Elektrizitätswerk Lonza. Manufacture of metaldehyde. 32,586. Dec. 5. (Switz., 3.3.21.)

Johnson (Elektrizitätswerk Lonza). Manufacture of metaldehyde and obtaining a combustible substance therefrom. 32,704. Dec. 6.

Lubricant Laxatives Corp. 33,240. *See* II.

Strubell. Obtaining partial antigenes of pathogenic bacteria non-resistant against acids. 31,818. Nov. 28. (Ger., 11.2.14.)

Complete Specifications Accepted.

1203 (1921). Serghison. Production of a medical compound. (171,920.) Dec. 7.

5103 (1921). Zinke. Manufacture of perylene. (165,770.) Dec. 7.

5104 (1921). Zinke. Manufacture of dioxyperylene. (165,771.) Dec. 14.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Application.

Sobawa. Production of photographic designs on glass, porcelain, etc. 31,946. Nov. 29.

XXIII.—ANALYSIS.

Complete Specifications Accepted.

21,785 (1920). Levy and Davis. Apparatus for the detection and estimation of carbon monoxide. (171,739.) Dec. 7.

24,264 (1920). Frink. Determining the viscosity of highly viscous materials. (171,774.) Dec. 7.
