Oxides of nitrogen; Process and apparatus for obtaining —— *from atmospheric air.* F. I. du Pont. U.S.P. 1,370,295, 1.3.21. Appl., 15.7.19.

The apparatus includes a tubular reaction chamber with a central enlarged portion, a cylinder surrounding the parts near this enlargement, and electrodes in the two ends of the tubular chamber. —C. I.

Oxides of nitrogen; Process of making ——. A. H. White. U.S.P. 1,370,867, 8.3.21. Appl., 19.6.19.

An alkaline-earth cyanamide is hydrolysed, and the ammonia liberated is conducted into an absorbent till no more phosphine is generated from the cyanamide; the ammonia, free from phosphine, is then mixed with air and passed over a catalyst. —W. J. W.

Oxides of nitrogen; Preparation of —— by the catalytic oxidation of ammonia. Badische Anilin- u. Soda-Fabr. G.P. (A) 303,331, 10.12.14, and (B) 307,001, 6.2.16.

Base metals or their oxides or mixtures or compounds are used as catalysts, and the gas mixture preheated to over 400° C. is allowed to come into contact only with (A) silica or glazed ware high in silica, or (B) oxides or carbonates of calcium, magnesium, or aluminium or a mixture thereof in massive form, before reaching the catalyst.—C. I.

Nitrous gases; Manufacture of —— from the air or other oxygen-nitrogen mixtures by means of the electric arc. O. Lummer, and Rütgerswerke A.-G. G.P. 331,040, 20.9.18.

The nitric oxide formed under high pressure in the reaction vessel is cooled *in situ* at a constant rate until it attains a temperature below which it does not dissociate under atmospheric pressure, *i.e.*, 130° C., when it is led into vessels for subsequent treatment.—L. A. C.

Nitrogen; Regenerative furnace for the combustion of ——. Gewerkschaft des Steinkohlenbergwerks Lothringen, and M. Kelting. G.P. 331,488, 31.12.19.

Two rows of narrow jets are arranged on the circumference of a cylindrical reaction chamber, and are connected with a pipe conveying fuel. The jets, which are graded as regards diameter, enter the walls of the chamber at an acute angle, and are provided with several openings arranged in one plane in the form of a fan. The fuel may be gaseous, liquid (as a spray), or solid (as powder). The pointed flames effect a quick mixing of the gases in the reaction chamber.—C. I.

Nitrogen oxides; Process for the preparation of ——. "Azot" Ges.m.b.H. G.P. 331,591, 27.10.18.

Highly-heated nitric oxide or a mixture thereof with air is allowed to expand in a chamber maintained at 150°—300° C., and air or oxygen is admitted. The nitrogen of the air is oxidised along with the nitric oxide. The reaction may be accelerated by a platinum catalyst.—C. I.

Aluminium nitrate, sulphate, or chloride; Process for the removal of iron from solutions of ——. B. E. D. Kilburn. From Det Norske Aktieselskab for Elektrokem. Ind. Norsk Ind. Hypotekbank. E.P. 139,470, 19.2.20.

In order to precipitate iron in a readily filterable form 2—10% of the equivalent in calcium carbonate of the aluminium present is added to the solution and a quantity of ferric oxide. The iron is then precipitated with an alkali. The ferric oxide may be washed and used again.—C. I.

Sea water; Concentration of —— [for salt manufacture]. T. A. Reid. E.P. 159,592, 28.11.19.

An apparatus with which salt can be profitably manufactured from sea water in temperate climates comprises a salt pan in three parts, and either provided with its own fireplace or heated by flue gases from a boiler. In the front part sea water is warmed to at least 26° C., and it then passes to the back part, which is fitted with a series of wooden towers down which the warm sea water flows until concentrated to a sp. gr. of 1·2. It then passes to the central pan, in which the deposition of salt takes place. If a boiler is in use, it may be fed with sea water, which passes on to the evaporating pan when concentrated, and the exhaust steam used for heating another pan.—C. I.

Catalytic iron [for ammonia synthesis]; Manufacture of —— or catalysts containing catalytic iron. The Nitro-Fixation Synd., Ltd., and H. C. Jenkins. E.P. 159,960, 5.12.19.

A solution of commercially pure ferric nitrate is freed from phosphorus and arsenic, then from chloride by addition of its equivalent of silver nitrate, and is then evaporated and the residue heated. Before nitrous fumes cease to be given off the heating is stopped and the mass lixiviated and washed. The washings carry away, along with part of the nitrate, the sulphur impurities. The mass is then ignited and reduced by hydrogen or preferably ammonia. If desired, pumice or asbestos freed from impurities may be added to the chloride-free solution. Such promoters as ammonium molybdate, potassium osmate, titanium or uranium nitrate, or an alkali tungstate may be added to the ferric oxide before reduction.—C. I.

Ammonia synthesis catalyst, and method of making same. J. C. Clancy, Assr. to The Nitrogen Corp. U.S.P. 1,352,177, 7.9.20. Appl., 25.6.18.

A number of processes for producing porous cyanamide catalysts at comparatively low temperatures are described. For example, calcium cyanide is obtained by passing hydrogen cyanide into a solution of calcium in liquefied ammonia, and calcium cyanamide by adding calcium to a solution of cyanamide in liquefied ammonia.

Chemical syntheses [ammonia formation]; Apparatus for effecting exothermic —— at high temperature and pressure. G. Claude, Assr. to Soc. l'Air Liquide, Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude. U.S.P. 1,371,299, 15.3.21. Appl., 2.2.20.

The apparatus comprises an outer resisting wall separated by a heat-insulating medium from an inner wall forming a reaction chamber, and having gas outlets. Through this chamber passes an axial tube through which the reacting gases are introduced. Projections on this tube act as supports for catalytic material, and means are provided for delivering an electric current to the tube whereby it can serve as a heating element for the reaction. —W. J. W.

Nitrogenous compounds; Process of and means for forming ——. J. C. Clancy, Assr. to The Nitrogen Corp. U.S.P. 1,352,176, 7.9.20. Appl., 1.9.17.

Barium cyanide is heated in presence of nitrogen at 400°—500° C. to produce a porous cyanamide especially suitable for use as a catalyst, *e.g.*, in the preparation of hydrocyanic acid from a mixture of hydrogen, nitrogen, and methane or acetylene.

Carbon bisulphide; Method of making ——. K. P. McElroy. U.S.P. 1,369,825, 1.3.21. Appl., 27.5.19.

Fuel and sulphur are charged into a shaft similar to a gas-producer with an air inlet at the base, and the gases generated are scrubbed with oil to recover carbon bisulphide.—C. I.

Borax; Process of recovering —— from saline waters. G. B. Burnham. U.S.P. 1,370,278, 1.3.21. Appl., 30.6.19.

The borax is separated from chlorides, sulphates, and carbonates of sodium and potassium by fractional crystallisation.—C. I.

Alkali sulphates, alkaline-earth oxides, and hydrochloric acid; Manufacture of ——. Salzwerk Heilbronn A.-G., G. Kassel, and T. Lichtenberger. G.P. 302,496, 9.6.16. Addn. to 299,775 (J., 1920, 749 A).

Mixtures of naturally-occurring salts of alkalis and alkaline-earths, or of magnesium, containing chlorides with or without sulphates, *e.g.*, mixtures of carnallite with kainite, or with polyhalite, are melted and treated with steam.—W. J. W.

Alumina; Treatment of clays for production of ——. P. Askenasy and V. Gerber. G.P. 306,355, 28.3.17.

ALUMINA is obtained from clays and similar materials by heating them at a moderate temperature with barium compounds and lime, in presence of a fluxing agent, such as sodium chloride. The barium aluminate solution is then treated with alkali carbonates or sulphates, and the precipitated barium compounds may be re-utilised in the process.—W. J. W.

Alumina; Preparation of —— from silicious clays. Aktieselskabet Höyangfaldene Norsk Aluminium Co. G.P. 332,389, 5.7.19.

THE clay is heated with calcium carbonate and a quantity of an alkali compound insufficient to convert the aluminium content of the clay into alkali aluminate, and the product is washed with sodium carbonate solution in two stages.—C. I.

Sulphur dioxide; Production of —— from calcium sulphate. Chem. Fabr. vorm. Weiler-ter Meer. G.P. 307,772, 20.10.17.

A MIXTURE of calcium sulphate and calcium sulphide is heated above 1000° C., whereby sulphur dioxide is formed in accordance with the equation: $3CaSO_4+CaS=4CaO+4SO_2$.—L. A. C.

Bleaching powder; Apparatus for manufacture of ——. A. Pfülf. G.P. 329,844, 25.7.19.

To promote the interaction between lime and chlorine, the former is introduced into a shaft-shaped chamber in which are a number of devices, consisting of hollow or solid cylinders, prisms, or rods of star-shaped cross-section, which are mounted on parallel axes and can be rotated. Slot-shaped openings are formed between these devices, through which the material is caused to pass from one side of the chamber to the other.—W. J. W.

Alkali hypochlorites; Preparation of stable solid solutions of ——. R. Mandelbaum. G.P. 330,192, 11.1.19.

NON-CRYSTALLINE solid solutions of alkali hypochlorites are obtained by mixing them with colloids, or mixtures of these with water-absorptive agents. Thus, sodium silicate solution (38° B.; sp. gr. 1·357), 500 pts., is evaporated to about two-thirds of its volume, and the cooled semi-solid solution is added to 10 pts. of sodium hypochlorite solution (35° B.; sp. gr. 1·320), with or without addition of calcined sodium carbonate.—W. J. W.

Perborates; Manufacture of —— with maximum oxygen content. Aschkenasi. G.P. 329,845, 27.11.19.

N the manufacture of perborates by any suitable nethod, the oxidation is not carried beyond a stage orresponding to 23% of active oxygen. In perorates containing 28·4% of available oxygen, the mount is reduced to 21·5% within a year.
—W. J. W.

rude calcium cyanamide; Manufacture of —— in a rotary furnace. G. Polysius. G.P. 329,961, 18.10.19.

DHERENCE of material to the walls of the rotary urnace is overcome by cooling the walls, *e.g.*, with ater. The most effective procedure is to cause e cooling material to strike the walls obliquely that part where the material is banked up.
—W. J. W.

Primary alkali phosphates; Manufacture of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 330,342 and 330,343, 11.9.17.

DISODIUM phosphate is decomposed with hydrochloric acid, the solution is concentrated and separated from the alkali chloride, heated to expel hydrogen chloride, and a secondary phosphate then added to combine with the free phosphoric acid. The mixture of 96% of dihydrogen-sodium phosphate and 4% of sodium chloride obtained may be used for enriching animal fodder.—W. J. W.

Chlorates, bromates, and iodates; Preparation of ——. H. Schulz. G.P. 330,941, 11.3.19. Addn. to 328,211 (J., 1921, 147 a).

CHLORINE, bromine, iodine, or their hydrogen compounds mixed with air are introduced with or without pressure into water containing a suspended or dissolved salt and a catalyst. By leading hydrochloric acid and air into a suspension of calcium carbonate and manganese dioxide, over 95% of the chlorine is obtained as calcium chlorate.—C. I.

Copper sulphate; Manufacture of —— from residues containing copper. A. Friedlaender. G.P. 331,144, 5.9.18.

THE residues are dissolved in a solution made strongly acid with sulphuric acid in an electrolytic cell, without a diaphragm, in which the residues act as anode. The copper sludge deposited on the cathode is mixed to a paste with the acid from the cell, or with fresh acid, and is treated with hot air and steam.—L. A. C.

Mechanical sulphate kilns; Apparatus for feeding sulphuric acid to ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 331,238, 31.7.19.

THE acid is introduced through a small vessel attached to the spindle of the agitator and revolving with it.—C. I.

Sodium sulphate; Preparation of anhydrous ——. A. Hoffmann. G.P. 331,489, 17.5.18.

GLAUBER'S salt or its solution, pure or mixed with other salts, is treated with volatile substances readily soluble in or miscible with water, or with their vapours, at a temperature above the transition point between the hydrated crystallised salt and the anhydrous salt.—C. I.

Potash manufacture; Process for treating residual liquors from ——. R. Mewes. G.P. 331,886, 8.7.15. Addn. to 305,082 (J., 1920, 404 a).

THE liquor is treated with crude calcium cyanamide. The nitrogen of the latter is converted into ammonia, or ammonium sulphate or chloride, and the metals precipitated as oxide, carbonate, or sulphate.—C. I.

Potassium nitrate; Process for the production of —— from crude calcium cyanamide. E. Hene and A. van Haaren. G.P. 332,002, 14.4.20.

CRUDE calcium cyanamide, potassium sulphate, nitric acid, and water are stirred together at a temperature below 100° C., preferably 25°—35° C., and the liquor filtered.—C. I.

Causticisation of soda in the cold; Process for the ——. Schweizerische Sodafabr. G.P. 332,003, 5.6.19.

A MIXTURE of soda solution and lime is treated in a revolving mixer similar to a centrifugal machine, when interaction is speedy and complete without heating, 10 cub. m. of liquor being causticised in 10 mins.—C. I.

Magnesium chloride liquors; Treatment of ——. W. Esch. G.P. 332,153, 12.6.19.

Part of the magnesium, after addition of magnesium oxide or hydroxide, is obtained as basic carbonate by treatment with ammonium carbonate below 50° C. The remainder is obtained as hydroxide, with recovery of the ammonia or carbon dioxide and ammonia, the liquor being first freed from sulphate by addition of calcium chloride solution.—C. I.

Colloidal metallic oxides; Process for the electrical preparation of ——. A. Wander A.-G. G.P. 332,200, 4.9.19.

A main circuit with direct or alternating current passes through an electrode of the metal the oxide of which is required, placed in a medium for dispersion, to which a protective colloid may be added. The metal is oxidised electrolytically, and the layer of oxide is dispersed by the discharge of a condenser placed in a circuit parallel to the main circuit. Oxides of copper, nickel, and iron and oxides and hydroxides of lead, zinc, and cadmium are mentioned.—C. I.

Oxygen and nitrogen; Processes for separating —— and apparatus therefor. M. Zack. E.P. 152,643, 3.9.20. Conv., 15.10.19.

A cooled gaseous mixture of oxygen and nitrogen at a certain pressure is introduced into a turbo-engine actuated by an electric motor, and there undergoes further cooling through expansion. By the action of electro-magnets attached to a rotating hollow ring, cooled by liquid air, oxygen, being paramagnetic, is drawn from the turbo-engine at its periphery into the ring, while the nitrogen passes through an outlet parallel to the shaft of the turbo-engine into a centripetal turbine, operated by a second electric motor at a different speed from the first, and thence to an outlet. The gaseous mixture freed from part of the nitrogen passes into a second cooled hollow ring, which is also provided with electro-magnets and is rotated by the second electric motor. Periodically the current to the electro-magnets of the first ring is interrupted, and the oxygen passed into the second ring, from which both gaseous and liquid oxygen can be drawn off through two outlets.—W. J. W.

Nitrogen; Production of —— [from producer gas] suitable for the catalytic manufacture of ammonia. Badische Anilin- und Soda-Fabr. G.P. 306,302, 3.7.15.

Producer gas is burnt with a small excess of oxygen or air, pure hydrogen is added to combine with the excess of oxygen, and carbon dioxide and other impurities are subsequently removed from the gas.—L. A. C.

Hydrogen manufacture by iron contact process; Utilisation of heat retained by generated hydrogen and excess steam in ——. F. Lang. G.P. 330,800, 7.11.16.

By means of a system of heat exchangers the waste heat from the hydrogen and steam may be utilised for generating further steam, for preheating the boiler feed water, and for removing air from the cooling water.—W. J. W.

Hydrogen production by the iron contact process; Process and apparatus for utilisation of the waste heat available in ——. F. Lang. G.P. 332,111, 8.11.16. Addn. to 330,800 (*cf. supra*).

The heat of the hydrogen and water vapour leaving the converter and also the heat of the gases leaving it during the reduction, washing, heating, and air blast periods are used for generating the steam required for the process or for the heating of boiler feed water. The apparatus consists of a heat exchanger with suitable inlet connexions and an exhaust for the waste gases or a two-chambered exchanger heated on one side by the hydrogen and on the other by the waste gases.—C. I.

Sulphur dioxide; Oxidation of —— and catalyst therefor. F. Slama and H. Wolf, Assrs. to General Chemical Co. U.S.P. 1,371,004, 8.3.21. Appl., 9.10.14.

See E.P. 23,541 of 1913; J., 1915, 833. It is specified that the catalyst be distributed on a very finely divided carrier, not exceeding 60 microns in diameter.

Aluminium nitride; Manufacture of ——. V. Gerber. E.P. 139,195, 18.2.20. Conv., 18.2.19.

See U.S.P. 1,350,149 of 1920; J., 1920, 657 A.

Cyanamides; Process for the production of ——. L. E. Friderich, Assr. to Soc. F. Gros et Bouchardy. U.S.P. 1,371,616, 15.3.21. Appl., 17.10.18.

See E.P. 132,622 of 1918; J., 1919, 818 A.

Tin oxide and zinc oxide; Production of ——. D. de Ros. U.S.P. 1,372,407, 22.3.21. Appl., 30.10.19.

See E.P. 142,157 of 1918; J., 1920, 448 A.

Nitrogen of the atmosphere; Fixation of the ——. R. Pearson. U.S.P. 1,372,541, 22.3.21. Appl., 13.2.19.

See E.P. 130,693 of 1918; J., 1919, 718 A.

Tin salts. E.P. 159,659. *See* X.

Calcining magnesia. E.P. 160,231. *See* XI.

VIII.—GLASS ; CERAMICS.

Kaolins and clays; Shrinkage of —— on drying. A. Bigot. Comptes rend., 1921, 172, 755—758.

A comparison of certain kaolins and clays and an argillaceous sand from different sources shows that the free silica contained in the clays renders the material less plastic. The plasticity is obtained by dividing the colloidal water (water of plasticity, water adsorbed by the colloids present) by the total water absorbed and multiplying this quotient by the shrinkage on drying. Elevation of temperature or of pressure diminishes both the colloidal and the interposed water (water filling the spaces between the particles), but the diminution of the latter is very slight as compared with that of the former.—W. G.

Kaolins, clays, and bauxites; Variation of volume of —— under the influence of heat. A Bigot. Comptes rend., 1921, 172, 854—857. (*Cf. supra.*)

Samples of kaolins, clays, and bauxites were powdered, sieved, mixed with water, and compressed in moulds. The lengths of the samples were measured from 0° C. at each successive 100° up to the temperature at which they showed signs of fusion. The results are shown graphically and indicate that bauxites, kaolins, and clays, which do not contain any free silica, commence to contract below 1000° C. Any clay or bauxite which expands below 1000° C. contains free silica. Clays and kaolins when heated rapidly puff up before reaching their melting-point, but bauxites do not show this puffing. The swelling or puffing up is due to the volatilisation of silica or silicates.—W. G.

Heat losses of metallurgical furnaces. Rosin. *See* X.

Patents.

Glass melting furnaces; Gas-fired ——. S. G. Curd. E.P. 159,559, 20.11.19.

Two gas producers are used and are operated alternately, the gas being produced by passing a mixture of superheated steam (preferably at 800° F. and 30 atm. pressure) and hot air through burning fuel. The gas and hot air are admitted simultaneously to the melting tank, the flow of gas through the furnace being periodically reversed in direction. The steam is generated and superheated by the waste gases, which also preheat the air. The gas is slightly superheated before use.—H. S. H.

Lehrs or kilns; Annealing —— *for glass and other articles.* S. and J. E. Laycock. E.P. 160,282, 19.12.19.

An annealing lehr having an internal endless chain conveyor for carrying the material has the gas ports constructed to pass the heating gases into direct contact with the material being treated in the annealing chamber. A regenerative chamber for the gas is placed directly under the furnace part of the lehr, so that the gas is preheated before it enters the lehr and a better pressure of gas is maintained. Waste hot air from round and about the melting furnace is collected and mixed with the gas before it enters the lehr.—H. S. H.

Glass composition and articles made therefrom. E. C. Sullivan and W. C. Taylor, Assrs. to The Corning Glass Works. U.S.P. 1,369,988, 1.3.21. Appl., 3.5.19.

A glass contains silica, soda, and two divalent oxides in the molecular proportions of 100 of silica to at least 20 of alkali and at least 6 of divalent oxides.—H. S. H.

Glass; Method of and apparatus for removing striæ from melted ——. S. R. Scholes, L. W. Nicols, and W. F. Kaufman. U.S.P. 1,370,673, 8.3.21. Appl., 8.10.19.

The formation of striæ in molten glass is prevented by agitating the pot and its molten contents at a uniform temperature until complete mixing of the constituents takes place. This is accomplished by providing means for moving the pot and its contents around an axis inclined to the horizontal. —H. S. H.

Refractory and [electrical] insulating product and process for the manufacture of same. G. L. Dimitri and J. E. Delaunay. E.P. 142,512, 1.5.20. Conv., 21.11.16.

A natural silicate of magnesium and a flux conisting of one or more natural or artificial multiple ilicates (*e.g.*, felspar) are mixed in the powdered tate, moulded or compressed, and after complete esiccation cut or fashioned into the required form nd baked at about 1450° C.—H. S. H.

Refractory articles made from china clay and method of manufacture. The Osmosis Co., Ltd., D. Northall-Laurie, and W. R. Ormandy. E.P. 159,737, 22.1.20.

he clay is brought into the sol condition by the ddition of a suitable electrolyte, the coarser parcles are allowed to settle, and the fine clay parcles are separated from the suspension by electromosis or by precipitating the sol suspension by eans of a solution of aluminium sulphate or other agulant. A slip is made from the purified clay and e articles are cast from it. The treated clay will nter at a temperature between 1400° and 1500° C., d the use of felspar is thus avoided. Grog consting of vitrified china clay may be added to rece the firing shrinkage. Articles made in this y are more refractory than those prepared from kaolin and felspar and resist temperature changes more effectively than porcelain prepared by any known process.—H. S. H.

Oven or kiln; Gas-fired —— *for use in the manufacture of tiles, pottery, and other ware or other purposes.* J. H. Marlow. E.P. 159,522, 23.7.19.

Three heat-distributing conduits extend throughout the length of the oven, and between the central conduit and each of the side conduits wheeled carriers travel. Each conduit communicates with a combustion chamber placed under it and is perforated so as to allow heat and gases to pass into the interior of the oven. The air is heated before entering the combustion chamber.—H. S. H.

China clay and other plastic materials; Drying of ——. C. J. Grace. E.P. 159,525, 23.8.19 and 25.2.20.

The china clay sludge is pumped into a tubular filter which is connected with a heated tubular drying chamber. The cake of clay is moved from the filter to the drying chamber either intermittently by means of a ram or continuously by conveyor vanes.—H. S. H.

Glass; Method and apparatus for the manufacture of ——. A. Ferguson, Assr. to F. W. Passmore. U.S.P. 1,371,084, 8.3.21. Appl., 7.9.20.

See E.P. 154,251 of 1919; J., 1921, 46 a.

Firing porcelain. G.P. 331,924. *See* X.

IX.—BUILDING MATERIALS.

Patents.

Cement materials, magnesite, and the like; Method for burning or calcining —— *and apparatus therefor.* A. Hauenschild. E.P. 159,780, 28.4.20.

The charge is inserted with the fuel in the form of a continuous vertical column, the mineral being in direct contact with the fuel on all sides and the usual vertical alternations of fuel and mineral being absent. An annular fuel shoot extends downwards some distance into the kiln shaft and prevents the fuel from mixing with the mineral. Air under pressure enters by blast nozzles at the sides of the kiln shaft. A cover on the shoot prevents the hot gases from escaping without permeating the mineral.—H. S. H.

Gypsum products; Process of ageing calcined —— *and product thereof.* H. E. Brookby, Assr. to United States Gypsum Co. U.S.P. 1,370,581, 8.3.21. Appl., 8.3.20.

A calcined gypsum product comprises a dry powder of unset commercial plaster of Paris with a small amount of water-soluble deliquescent substance intimately incorporated.—H. S. H.

Plastic composition and process for making the same. R. G. Erwin, Assr. to International Bituconcrete Co. U.S.P. 1,370,637, 8.3.21. Appl., 6.7.20.

A plastic composition is produced by suspending a mixture of mineral dust (all of which will pass a 200-mesh sieve, 60% being smaller than 0·02 mm.), sodium chloride, and sodium sulphate in preheated bitumen, and adding pulverised sulphur to the mass. The whole is agitated in a vat subjected to suction and heated sufficiently to combine the ingredients and their derivatives. The composition is then mixed with comminuted vegetable particles of various sizes in sufficient quantity to fill the pores within and the voids between the vegetable particles and to coat and bind them together, and the mass is agitated in a vat under the influence of sustained heat and suction. After removing the composition from the vat it is compacted to shape. —H. S. H.

Keene's cement; Manufacture of ——. W. Hoskins, Assr. to The Best Bros.' Keene's Cement Co. U.S.P. 1,370,968, 8.3.21. Appl., 13.5.18.

Gypsum is ground very fine and passed continuously at a uniform rate through a rotary, internally-fired kiln, after which it is mixed with sufficient lime to neutralise all acidity.—A. R. P.

Heat-insulating material and method of making same. C. H. Bennett, J. F. Palmer, and F. V. Wedlock, Assrs. to Bentex Co. U.S.P. 1,371,016, 8.3.21. Appl., 18.6.20.

A rigid, cellular, heat-insulating material is made from a "dough" having the following percentage composition by weight:—Asphaltum, 27·0; infusorial earth, 11·0; magnesium carbonate, 5·0; crude rubber, 26·9; sulphur, 14·9; sulphur-treated corn (maize) oil, 2·6; petroleum tailings, 5·8; sodium bicarbonate, 6·0; alum, 0·8. The mixture is heated under pressure to a sufficient temperature and for a sufficient time for vulcanisation. The material is rolled while still hot and finally cooled. It maintains its rigidity at the ordinary temperatures of artificial refrigeration.—H. S. H.

Mortar-forming material. F. Hartner. U.S.P. 1,371,762, 15.3.21. Appl., 1.8.19.

See G.P. 312,239 of 1917; J., 1919, 905 A.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron, carbon, and oxygen; Chemical equilibrium between ——. A. Matsubara. Trans. Amer. Inst. Min. and Met. Eng., Feb., 1921. 52 pages.

Equilibrium compositions of the gaseous phase in the system, CO-CO$_2$-Fe, were measured at 863° C., 1070° C., and 1175° C. The systems, CO-CO$_2$-FeO (Fe) and CO-CO$_2$-Fe$_3$O$_4$ (FeO), were studied at several temperatures higher than 700° C., also systems containing iron carbide. At a temperature of about 1200° C., under a pressure of 1 atm., the dissociation pressure of the carboniferous iron phase is equal to that of carbon monoxide, and neither carburisation nor decarburisation occurs even in a current of pure carbon monoxide. Lower temperature or higher pressure values increase the relative pressure of carbon monoxide in the gaseous phase. From the data obtained the existence of oxygen-bearing iron is inferred, and the equilibrium conditions are discussed with relation to case hardening, malleable casting, and blast furnace conditions. —C. A. K.

Iron; Influence of copper on the rate of solution of —— *in acids.* F. K. Bell and W. A. Patrick. J. Amer. Chem. Soc., 1921, 43, 452—465.

Experiments with pure iron-copper alloys containing from 0·1% to 5·0% Cu showed that the copper had a marked retarding effect on the rate of solution of the iron in 28·7% hydrochloric acid, as compared with pure reduced iron. The rate of solution was determined by measuring the rate of evolution of hydrogen from a polished surface of the metal in contact with the acid. Mere contact with copper wire had a marked retarding effect on the rate of solution of pure iron, whilst platinum and silver were without effect. Experiments with 57% sulphuric acid gave erratic results. It is emphasised that no conclusions regarding the behaviour of these alloys with dilute acids can be drawn from these experiments with strong acids. (*Cf.* J.C.S., May.) —E. H. R.

Nickel steel; Static and dynamic tension tests on ——. J. J. Thomas and J. H. Nead. Trans. Amer. Inst. Min. and Met. Eng., Feb., 1921. 13 pages.

An attempt to determine the relation between static and dynamic tensile tests as measured by the work required to break test specimens slowly in a tensile testing machine, and rapidly, by means of a falling weight. Using a nickel steel, tempered to varying degrees of hardness, the results show that for hard steel the total work of rupture is very low under either a slowly or rapidly applied load. As ductility increases the work of rupture increases, and ductility, as measured by elongation and reduction of area in the ordinary tensile test, is important as an indication of strength as measured by work units. Experiments indicate that steel is in its best condition when quenched and drawn at a temperature slightly lower than its critical point.—C. A. K.

Ferromanganese; Manufacture of —— *in the electric furnace.* R. M. Keeney and J. Lonergan. Trans. Amer. Inst. Min. and Met. Eng., Feb., 1921. 36 pages.

Comparing blast furnace and electric furnace production of ferromanganese, the same recovery (72%) of manganese was made in the electric furnace smelting ore containing 34·8% Mn as in the blast furnace smelting 40% ore. The slag and stack losses were practically the same in each case. On the same grade of ore the electric furnace would show at least 5% greater recovery than the blast furnace, and at the present price of coke, fuel and power costs balance. In smelting oxide ore better operating results were obtained when any necessary iron was added in the form of manganiferous ore rather than in the form of steel turnings. Among the general operating difficulties encountered with the electric furnace, formation of carbide was the most serious. This tendency was modified by the use of lignite as a reducing agent in preference to anthracite or bituminous coal and also by not attempting to produce a slag containing less than 12% Mn. Intermittent charging gave better results than continuous working in so far as output, power, and labour costs were concerned. Magnesite is preferred as a material for furnace bottoms, though carbon and firebrick bottoms are in use. In a 1100-k.w. furnace smelting 34·8% manganese ore and producing ferromanganese containing 73·6% Mn, the power consumption was 4457 k.w.-hours, and the electrode consumption 125 lb. per short ton. —C. A. K.

Gold; Extraction of —— *from its ores.* R. Paulin. Chem.-Zeit., 1921, 45, 285—287.

For regulating the flow of pulp to the amalgamating plates so as to ensure removal of heavy antimony sulphide, whilst at the same time preserving sufficient time of contact for amalgamation, a device is installed between the tube-mills and the plates. It consists of a gutter bent twice at right angles and provided with cross-baffles which retard the flow and cause deposition of coarse particles of gold. Near the plates the gutter is expanded to their width, and at this point an automatic regulator is inserted, which interrupts the flow of pulp to allow of amalgamation and then again accelerates it to admit of the antimony sulphide being carried away. Experiments have shown that ball mills are not very efficient in separating gold from its ores; gold apparently free was found to be enclosed in a thin layer of quartz and contained only 12·5% of actual free metal capable of amalgamation; substitution of roller mills or tumbler mills may be advantageous. To reduce loss of amalgam from the plates, a "catcher" consisting of a cast-iron cup with rim and overflow is placed below them. The slime enters by means of a central tube and any amalgam gradually separates on the bottom of the cup. It is periodically transferred to a cast-steel drum containing a few steel balls, in which it is treated with fresh mercury, and then washed with water, and pressed to recover solid amalgam. —W. J. W.

Platinum and gold; Microscopical detection of —— in the Siegerland "grauwacken." H. Schneiderhöhn. Metall u. Erz, 1920, 17, 511—514.

The rock is a medium-grained grey sandstone with a sericite binding material. It contains very thin dark streaks running parallel to each other, which, under the microscope, are seen to be enrichment zones of heavy minerals, mostly zircon and rutile. Sections of the mineral were cut and carefully polished by means of magnesia on a piece of flannel. On viewing the prepared specimens under the microscope in transmitted light a few bright yellow particles of metallic appearance could be seen which readily became grey and rough on adding a small drop of mercury to the specimen, thus indicating gold. Platinum could not be detected with certainty in this manner. 150 g. of the finely powdered rock was then treated with hydrofluoric and sulphuric acids for several days on the water-bath. The residue, under the microscope, showed bluish-white and yellow grains of platinum and gold, which were confirmed microchemically as potassium, rubidium, and thallium chlorplatinates and as thallous chloroaurate respectively.—A. R. P.

Zinc; Value of —— in the ore and the economic basis of its recovery. Paul. Metall u. Erz, 1920, 17, 439—449, 475—578, 514—519; 1921, 18, 59—66, 126—135.

The customary formula on which zinc ores are sold is V=P (t−8)−K, where V is the value of 1000 kg. of the ore, t is the zinc content %, P is the market price of one unit (=10 kg.) of spelter, and K is the returning charge. The latter varies with the nature of the ore, and the author shows that it should be higher for roasted ores than for raw blende in a proportion which is greater the higher the sulphur content and the price of spelter and the lower the zinc content of the original ore. With equal returning charge the value of zinc in an ore per unit increases rapidly with the zinc content; on the other hand low-grade ores may become of negative value when the price of zinc is low (*cf.* J., 1919, 18 A). The above formula is examined from every point of view and reasons are advanced to show that it does not fairly represent the value of an ore. Thus the returning charge is the same for rich and poorer ores, while the proportion of "free" units is relatively smaller with rich ores, and hence there is not such a great proportionate margin for losses, there-ore the richer ores are dearer than they should be n relation to the poorer. Again the cost of smelting depends not on the amount of ore smelted, but n the capacity of the furnace, and this varies ccording to the apparent specific gravity of the harge. No account of this is taken in the formula, or of the value of the sulphur. The author there-ore suggests two new formulæ, one for roasted and ne for unroasted ores. In the case of sulphide res a 1% loss of zinc on roasting is assumed and loss in weight of (t_s-15)%, where t_s is the sulphur ntent of the ore. It is also assumed that 95% of e sulphur removed is recovered as sulphuric acid 60° B. (sp. gr. 1·71). If the cost of roasting is pproximately 15 M. per ton of roasted ore, while at of making a ton of sulphuric acid is 8·5 M. d its selling price is 25 M., then the value of a it (10 kg.) of zinc in the ore in M. is given by e equation

$$V=0{\cdot}08415(P-E)-(115-t_s)K/100\delta.t_z+(0{\cdot}56878283t_s-24{\cdot}275)/t_z,$$

where P is the market price of 100 kg. of spelter, E is the profit on every 100 kg. of zinc recovered, K is the cost of 1 cub. m. of retort room, δ is the apparent sp. gr. of the ore, t_z is the zinc and t_s the sulphur content of the ore. With oxidised ores this simplifies to $0{\cdot}085(P-E)-K/\delta t_z$.—A. R. P.

Zinc; Sources of loss in the distillation of ——, and the mechanism of the volatilisation of the metal. O. Mühlhaeuser. Metall u. Erz, 1921, 18, 1—22, 45—51.

Beginning with a new retort, the author carried out a series of zinc distillations from roasted blende and anthracite in a small experimental furnace and tables are given showing the yield of metal and of by-products together with the losses. The loss of zinc in the low-grade residues was about 3% and remained practically constant throughout the tests. The loss due to escape of zinc vapours from the receiver was comparatively high with the first charges, but eventually, after 10—12 distillations had been carried out in the same retort, sank to an approximately constant figure of 1·2—1·6%. The proportion of zinc that escaped through the pores and minute cracks in the retort was about 2—3% with a new retort, but after several distillations the loss from this source fell to 0·8—1·2%. The most serious loss of zinc with new retorts appears to be that due to combination of the zinc oxide with the material of the retort with the formation of zinc spinel. This loss may be as high as 25% or more of the total zinc in the charge, but on continued use of the retort it falls to an average of a little over 1%. The total average loss for the first eight charges was about 19% and for the next ten 7%. The mechanism of the volatilisation of zinc is discussed and the need of research to reduce the losses is emphasised.—A. R. P.

Brasses; Tensile strength of various —— at high temperatures. F. Doerinckel and J. Trockels. Int. Zeits. Metallogr., 1920, 12, 340—358. Chem. Zentr., 1921, 92, II., 553.

A number of tests were carried out on brass cylinders, 18 mm. diam. and 36 mm. high, in a 40-ton testing machine at various temperatures up to 800° C. The test pieces were heated by enclosing them in a resistance tube-furnace and the temperatures were measured by means of a thermocouple and, after testing, calorimetrically. The tensile strength in general falls with rising temperature, and at 800° C. has a value only ⅓ that obtained at 500° C.; only with a 58% Cu brass is a minimum value reached at 700° C. The maximum value of both the hardness and tensile strengths of the copper-zinc series is obtained in the region corresponding to the α-mixed crystal phase, *i.e.* with alloys containing about 85% Cu. Alloys containing 67—72% Cu exhibit irregularities, which seems to show that the α-brasses require further investigation.—A. R. P.

Tin ore; Electric smelting of ——. H. Krebs. Metall u. Erz, 1921, 18, 77—78.

Tin ores become conductors of electricity at moderate temperatures, so that by using large pieces of ore as a resistance, sufficient heat can be developed to melt it and reduce it to metal on the addition of coal. It is not generally necessary to add any slagging material, as the ore usually is self-fluxing, nor is it necessary to protect the tin oxide from going into the slag. It is preferable to carry out the process in a trough furnace with a low charging shaft and two or more electrodes dipping into the bath. Ore and coal are charged in as required and the metal is tapped from the bottom until the hearth is nearly full of slag, which should be rich in tin. This is cleaned by adding a charge of coal only to separate its tin contents as metal. In this way very pure metal may be obtained and the tin content of the slag reduced to as low as 0·3%, while the losses by volatilisation are much less than by the reverberatory or shaft furnace process.—A. R. P.

Copper-antimony system; The compounds Cu_5Sb_2, Cu_3Sb, and Cu_2Sb in the ——. H. Reimann. Z. Metallk., 1920, 12, 321—331. Chem. Zentr., 1921, 92, I., 484.

The work of Carpenter (J., 1913, 979) brought about changes in the copper-antimony equilibrium diagram, but some points remained to be cleared up. The present investigation has been confined to alloys containing 25 to 33 atoms % Sb. The maximum of the melting-point curve lies not at 25 atoms % Sb, corresponding with a compound Cu_3Sb, but at 29 atoms % Sb or the compound Cu_5Sb_2 (m.p. 682° C.). This compound forms mixed crystals with copper or antimony over the range from 18 to 33 atoms % Sb; the saturated mixed crystals with 33 atoms % Sb undergo decomposition and form a eutectoid at 27 atoms % Sb (430° C.).—E. H. R.

Bearing metals and their technological evaluation. J. Czochralski. Int. Zeits. Metallogr., 1920, 12, 371—393. Chem. Zentr., 1921, 92, II., 552—553.

The mechanical properties and uses of various bearing metals are discussed and compared, together with the technique of casting and testing the finished alloys. Copper-tin bearing metals with about 10% Sn consist of a single constituent, α-CuSn, which contains generally all the other components of the alloy in solid solution. As the suitability of an alloy for use as a bearing metal depends on its heterogeneous structure, copper-tin alloys that have been rendered homogeneous are not of any use as bearing metals. The utility of a copper alloy as bearing metal depends on the gradual wearing away of the unevenness of structure, whereas that of a tin bearing metal (white metal) depends on the flexibility of the ground mass. Copper alloys are more suitable for bearings that have to withstand a considerable pressure, while lead alloys are preferable if the pressure on the bearings is small. Tin alloys occupy an intermediate position, but they are better than those containing calcium or barium instead of tin. These latter are difficult to prepare on account of the readiness with which they oxidise. It is recommended to cast these alloys at a temperature of 200° C.—A. R. P.

Heusler's alloys. II. Magnetic measurements of Heusler's aluminium-manganese bronzes of high iron content. O. von Auwers. Ann. Physik, 1920, 63, 867—899. Chem. Zentr., 1921, 92, I., 485. (*Cf.* J., 1920, 27 A.)

Addition of iron, from 13·5 to 18%, to aluminium-manganese-bronzes does not appreciably affect their magnetic behaviour. It is possible that the manganese content is more important than the iron content. At low temperatures the magnetisability of the Fe-Al-Mn-bronzes generally increases. With a bronze containing 9·2% Al, 17·8% Mn, 13·5% Fe, and 59·6% Cu, the opposite effect was observed at −190° C., but not at −78° C.—E. H. R.

Dental amalgam; Volume changes in a —— *as a result of a transformation at 70° C.* A. W. Gray. Phys. Rev., 1920, 15, 524—525. Chem. Zentr., 1921, 92, II., 552.

On heating dental amalgams that had been allowed to harden to their transformation points, those containing several per cent. of zinc rapidly formed crystals, while those free from zinc showed no change. Freshly prepared amalgams, on the other hand, showed the crystal formation in all cases. The crystals consisted of hexagonal plates belonging to the hexagonal or orthorhombic system. The temperature-volume curve for the zinc-free alloys rises in a straight line to a maximum at the transformation point, rapidly falls to a minimum, and then rises sharply for a short distance, after which a further fall takes place. On re-heating a similar curve is obtained, except that the change point is not so strongly marked, especially with alloys with a low silver and high copper content. Amalgams that contain zinc give a curved line up to the change point, after which the line rises rapidly. This rapid expansion ceases after several hours or if the temperature is kept constant or allowed to fall.
—A. R. P.

Aluminium-mercury alloys; Electromotive behaviour of ——. R. Kremann and R. Müller. Z. Metallk., 1920, 12, 289—303. Chem. Zentr., 1921, 92, I., 482—483.

Aluminium amalgam was best prepared using a solution of mercuric chloride. The E.M.F. of cells of the type, $Hg/0{\cdot}1N\ KAl(SO_4)_2/Al_x\ Hg_y$, was measured. The potential of mercury against the normal calomel electrode was +0·2, that of aluminium −0·82 (constant values could not be obtained on account of the formation of surface layers), and that of the amalgam −1·314 to −1·352 volt, almost independent of the composition. The results indicate the formation of a compound of mercury and aluminium, the composition of which could not be determined. Similarly, in combinations of the type $Hg/0{\cdot}1N$ NaI in pyridine $/Al_xHg_y$ the potential of the amalgam is, independent of its composition, about 0·25 voltless "noble" than that of aluminium.—E. H. R.

Magnesium-mercury alloys; Electromotive behaviour of ——. R. Kremann and R. Müller. Z. Metallk., 1920, 12, 303—312. Chem. Zentr., 1921, 92, I., 483.

The potential of pure magnesium, as determined from the combination, $Pb/0{\cdot}5$ to $1{\cdot}0N\ MgSO_4/Mg$, is −1·48 to −1·68 volts. Slight amalgamation brings the value to −1·71 to −1·79 volts. Magnesium and mercury readily combine at the boiling point of the latter. Magnesium amalgams when exposed to the air quickly become covered with a brownish-black skin of MgO, $Mg(OH)_2$, and $MgCO_3$, coloured with finely divided mercury; oxidation also occurs in a desiccator. Traces of magnesium bring the potential of mercury to a value 0·3 volt less "noble" than that of magnesium; this value persists up to 85 atoms % Mg, then rises a further 0·17 volt to a maximum at 91 atoms % Mg, afterwards falling again. The maximum may be due to a compound, $Mg_{10}Hg$, less "noble" than either component, which is solid at ordinary temperatures and forms mixed crystals with magnesium and probably with mercury.—E. H. R.

Alloys of magnesium with lead and cadmium; Electromotive behaviour of ——. R. Kremann and J. Gmachl-Pammer. Z. Metallk., 1920, 12, 403—406. Chem. Zentr., 1921, 92, I., 484.

Experiments on the E.M.F. of the combination $Pb/0{\cdot}5$ molar $MgSO_4/Pb_xMg_{1-x}$ indicate the existence of a compound $PbMg_2$. Alloys with 0—33 atoms % Pb have practically the potential of pure magnesium, those with 33 atoms % Pb up to nearly pure lead have a potential only 0·14 volt "nobler." The heat of formation of the compound is therefore relatively small. The compound rapidly decomposes in air to a black metallic powder consisting of black magnesium suboxide, lead, and, probably, lead suboxide. Similar experiments with magnesium-cadmium alloys agree with the equilibrium diagram for these alloys, indicating the existence of a compound MgCd 0·10 volt "nobler" than

magnesium, 0·86 volt less "noble" than cadmium. This compound also disintegrates quickly in air.
—E. H. R.

Metallurgical furnaces; Basis of the heat losses of ——. P. Rosin. Metall u. Erz, 1920, 17, 463—475; 1921, 18, 37—45, 78—88, 99—104.

A THEORETICAL and mathematical investigation into the factors governing the loss of heat by radiation and convection from furnaces. The four factors governing the magnitude of the losses are the shape of the furnace, the nature of the materials used in its construction, the difference in temperature between the inside and outside surface of the walls, and the time consumed by a unit charge in passing through the furnace. For every furnace on steady work there is a lower limit to the amount of heat lost by conduction, and this amount cannot be reduced by thickening the walls. If the charge completely fills the furnace, less heat proportionately is lost than if it only partly does so, while a large furnace loses relatively less heat than a smaller one. The ideal form for a cylindrical furnace is one in which the height is equal to the diameter; for a rectangular furnace, a cube; and for a prismatic furnace, one having its height equal to the cross-section. A method of determining the heat conductivity of furnace bricks is described, and a table is given showing the results obtained at various temperatures for the principal varieties of firebrick.—A. R. P.

PATENTS.

Steel; High-speed ——. C. M. Johnson. U.S.P. 1,370,020, 1.3.21. Appl., 12.12.19.

A STEEL containing C 0·20—0·75%, Si 0·35—0·80%, Mn 0·35—0·55%, W 12—18%, Cr 3—5%, V 1·1—1·5%, Mo 0·25—1·0%.—J. W. D.

Iron; Method of making wrought ——. J. Aston, Assr. to A. M. Byers Co. U.S.P. 1,370,622, 8.3.21. Appl., 14.11.19. Renewed 30.6.20.

MOLTEN metal from a steel-making process is granulated (*e.g.*, by dropping vertically) and caused to fall into a bath of iron silicate slag in a container of such shape that a coherent ball or sponge of mixed metal and slag is formed below the level of the slag bath.—C. A. K.

Iron and steel; Method of and apparatus for the production of ——. E. Riveroll, Assr. to California Electric Steel Co. U.S.P. 1,370,915, 8.3.21. Appl., 12.5.19.

IRON ORE is heated by means of reducing and carburising gas under such conditions as to temperature and time that part of the ore is reduced to carburised sponge iron and the other part is unchanged; the reaction is completed by heating the mixture thus formed to complete the reduction and melt the reduced iron.—B. V. S.

Ferro-chromium; Producing low-carbon ——. F. Krupp A.-G. E.P. 145,709, 26.6.20. Conv., 27.7.16.

HIGH-CARBON ferro-chromium is introduced in molten form into a converter and blown for a longer or shorter period according to the carbon content desired.—J. W. D.

Ferro-chrome alloys; Production of ——. W. B. Ballantine. E.P. 159,568, 24.11 and 18.12.19, and 13.1.20.

A CHROMIUM compound, *e.g.*, chromite, is reduced by means of a cheap reducing agent, such as calcium carbide, and the resulting crude molten alloy submitted to the action of an oxidising blast in a Bessemer or like converter. The chromium content of the refined alloy is adjusted, before or after apping from the converter, by means of a thermo-reducing mixture containing a chromium compound.—J. W. D.

Electrodes; Arc-welding ——. Wilson Welder and Metals Co., Inc., Assees. of J. Churchward. E.P. 148,265, 16.12.19. Conv., 21.7.19.

A FILM of rust is formed on the cleaned electrode rod by immersion in acidulated water, and the rod is then dipped in milk of lime and dried, the dipping process being repeated until a deposit of sufficient thickness is obtained. After baking at 300° F. (150° C.) the rod may be drawn through a wire-drawing die to the required size. The lime coating becomes incorporated with the porous oxidised surface of the metal, and is not detached by subsequent abrasion or bending of the electrode.
—C. A. K.

Electrodes for electric arc welding. H. Ogden, and The British Arc Welding Co., Ltd. E.P. 159,742, 24.1.20.

A BARE electrode is coated uniformly with a flux paste containing not more than 5% of glue or casein by inserting it through an adjustable hole in the end of a rectangular vessel containing the flux mixture. The paste is of such consistency as not to extrude through the hole in the containing vessel.—C. A. K.

Furnace for subjecting ores or other materials to the action of gases, or the like. British Oxygen Co., Ltd., S. W. Bray, and I. H. Balfour. E.P. 159,530, 9.10.19.

AN inclined retort extends through a furnace provided with gas burners or other means for heating the retort. The material to be treated is fed into the upper end of the retort in definite quantities from a hopper by means of a sliding or plunger valve. A similar device allows the discharge of the heated material into a closed receiver. Scoops fixed to a rotating longitudinal shaft agitate the material in the retort, and the required atmosphere is obtained by passing a suitable gas into the lower end of the retort and providing an outlet at the upper end.—C. A. K.

Copper alloys. Sir W. G. Armstrong, Whitworth, and Co., Ltd., C. J. G. MacGuckin, and O. Smalley. E.P. 159,537, 24.10.19.

ALLOYS containing Cu 80—91%, Al 7—10%, Mn 1—6%, Fe 1—4%, retain their strength up to 450° C., and are especially suitable for the manufacture of turbine blades.—J. W. D.

Tin; Purification of —— *or production of tin salts from crude tin.* J. J. Collins. E.P. 159,659, 10.12.19.

IMPURE or crude tin, in a more or less finely divided state, is subjected to the action of stannic chloride, whereby the tin is dissolved and stannous chloride produced, and chlorine gas is injected into the latter so that it continuously absorbs chlorine and gives it up to the metallic tin for the production of further quantities of stannous chloride.
—J. W. D.

Solder. A. H. Phillips and C. G. Arnold. E.P. 159,797, 13.7.20.

A SOLDER (m.p. 257° C.), especially suitable for use with cast iron, has the composition 2·2% Co, 10·0% Cu, 0·6% Ag, 0·6% Sb, 86·6% Sn. The cobalt is melted first, and the other metals are added in the above order.—C. A. K.

Tungsten [-silicon] alloy. The British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 160,373, 17.4.20.

TUNGSTIC acid, containing a small quantity of silicic acid, is mixed with sufficient magnesium to reduce the silica, and the mixture is heated in hydrogen. Alternatively the mixture of tungstic acid and silica may be reduced in hydrogen, and the resulting X-metal (*cf.* E.P. 155,851; J., 1921, 265 A) mixed with the requisite quantity of magnesium powder to reduce the silica and again heated. In either case the magnesium oxide is extracted from the metal powder by means of hydrochloric acid. The resulting metal, containing 1—3% Si, when worked into wire gives a filament that does not sag and shows great resistance to shock.—A. R. P.

Tungsten; Extraction and recovery of ——. A. G. de Golyer and A. E. Lund. U.S.P. 1,335,277, 30.3.20. Appl., 11.5.16.

The powdered ore is heated and agitated with an alkali hydroxide or carbonate solution, and a salt of calcium, barium, mercury, lead, or silver is added to the filtered alkali tungstate solution to precipitate an insoluble tungstate.

Aluminium; Process for making powdered or granulated ——. L. B. Tebbetts. U.S.P. 1,327,743, 13.1.20. Appl., 4.12.17.

Aluminium is heated above its melting point and then agitated while it cools. The metal is very brittle at temperatures just below the m.p., and can be readily disintegrated.

Manganese-silver ores; Treating ——. L. W. Austin. U.S.P. 1,327,974, 13.1.20. Appl., 11.4.19.

Refractory manganese-silver ores are rendered much more amenable to cyanide treatment if they are mixed with pyrites and sulphuric acid, and the product washed with water.

Ore concentration. B. H. Dosenbach, Assr. to E. M. Dosenbach. U.S.P. 1,350,364, 24.8.20. Appl., 16.11.17.

A modification of the flotation process in which the ore pulp is treated with a gaseous modifying agent such as coal gas or other gas obtained by distillation which has been previously treated with water to remove soluble matter and which effects flotation of certain constituents of the ore.—A. R. P.

Flotation of minerals. (A) C. L. Perkins, (B) (C) R. E. Sayre, Assrs. to Metals Recovery Co. U.S.P. (A) 1,370,357, (B) 1,370,366, and (C) 1,370,367, 1.3.21. Appl., (A) 13.7.20, (B) (C) 2.7.20.

After an addition to the mineral pulp of a small quantity of (A) terpene hydrate, (B) a dihydric alcohol, or (C) a thio-aldehyde compound, a flotation operation is carried out.—C. A. K.

Flotation of minerals. R. E. Sayre, Assr. to Metals Recovery Co. U.S.P. 1,370,843, 8.3.21. Appl., 2.7.20.

A small quantity of a ketone condensation product is added to mineral pulp to assist in the mineral concentration during a subsequent flotation operation.—C. A. K.

Precious metals; Process for extracting ——. C. P. Priest. U.S.P. 1,352,832, 14.9.20. Appl., 21.8.19.

Ores or sands containing precious metals are ground in a solution of sodium chloride, then mixed with a solution of a mercury compound (*e.g.*, mercuric chloride), and the resulting slime electrolysed to produce hydrogen and effect amalgamation of the metal.

Alloy. T. Kosugi. U.S.P. 1,369,818, 1.3.21. Appl., 30.6.20.

An alloy containing Cu 75—90%, Al 7—12%, Ni 2—7%, and Fe 1—6%.—J. W. D.

[Alloy for] production of gears. R. D. Babson, Assr. to Baush Machine Tool Co. U.S.P. 1,371,214, 15.3.21. Appl., 3.3.20.

An alloy containing aluminium about 94%, magnesium about 0·5%, manganese, and copper is subjected to excessive working, then heated to about 500°—525° C., and quenched.—W. J. W.

Metallic oxides; Reduction of ——. C. M. Johnson. U.S.P. 1,370,021, 1.3.21. Appl., 9.6.20.

The reduction of the oxide is effected by smelting in the presence of both ferrosilicon and ferrochromium.—J. W. D.

Leach liquor; Treatment of ——. C. R. Hayward, H. M. Schleicher, and F. O. Stillman, Assrs. to Moa Iron and Development Corp. U.S.P. 1,370,646, 8.3.21. Appl., 8.12.19.

A solution containing the sulphates of metals of different valencies is first converted into a chloride solution, and the metals are then selectively precipitated by suitable reagents.—A. R. P.

Metal surfaces; Ornamenting and protecting ——. O. Hommel. U.S.P. 1,370,967, 8.3.21. Appl., 16.5.18. Renewed 5.8.20.

A solution of a metallic salt is applied to the surface of a metallic article containing aluminium so as to produce an even coating of the salt thereon. The article is then heated to such a temperature that the aluminium reduces the metallic salt with the formation of a coating of the metal which adheres to the underlying metal.—A. R. P.

Nickel-plating. T. A. Edison. U.S.P. 1,371,414, 15.3.21. Appl., 17.6.19.

A nickel sulphate solution is used as an electroplating bath, and portions of it are continuously withdrawn, treated with nickel hydroxide, and returned to the bath.—A. R. P.

Lead-coating process. R. J. Shoemaker, Assr. to Leadizing Co. U.S.P. 1,371,445, 15.3.21. Appl., 11.12.20.

A permanently adherent coating of lead is formed on iron or steel articles by immersing the metal in a solution containing not less than 35% of lead acetate.—C. A. K.

Briquetting [metal fragments]. O. C. Duryea and M. C. White, Assrs. to American Briquet Machine Co. U.S.P. 1,371,671, 15.3.21. Appl., 14.2.17.

Small metallic fragments are pressed into an approximately solid mass by applying a comparatively mild pressure. A high pressure is then exerted by explosive force, whereby the metal becomes practically welded together.—C. A. K.

Substances sensitive to oxidation; Process for heating or firing —— *e.g., iron, steel, porcelain, and the like.* H. Koppers. G.P. 331,924, 14.5.18.

The articles are heated by means of gas, the quantities of gas and air used being so regulated that in the immediate neighbourhood of the articles a reducing atmosphere free from carbon dioxide is maintained. Iron articles are given a protective coat of clay and graphite or other carbonaceous material that will not carburise the iron, while porcelain articles that are burnt in saggers are covered with a quantity of specially-prepared wood charcoal. This method prevents the scaling of iron or the discoloration of porcelain during heating.—A. R. P.

Iron and phosphorus; Recovery of —— *from slags from iron-smelting.* Eisen- und Stahlwerk Hoesch A.-G. G.P. 332,118, 24.6.19.

The molten slag is treated with chlorine or with chlorine and carbon monoxide together or successively, and the sublimed iron chlorides are collected in a cooled receiver. The residue may be used as a fertiliser, or worked up for the recovery of its phosphorus content by mixing it with carbon and heating the mixture to 700°—800° C. while passing chlorine or carbon monoxide and chlorine through it, whereby chlorides of phosphorus are evolved and condensed in suitable receivers. The original slag may, alternatively, be mixed with carbon and treated with chlorine when, according to the conditions under which the treatment is carried out, iron or phosphorus chlorides are evolved.—A. R. P.

Aluminium; Process for deoxidising and refining ——. *Process for deoxidising and refining copper.* A. Strasser. E.P. 141,324 and 142,441, 24.12.19. Conv., 9.4 and 26.4.19.

See U.S.P. 1,348,457–8 of 1920; J., 1920, 631 a.

Alloys. F. Milliken. E.P. 160,708, 6.7.20.

See U.S.P. 1,354,988 of 1920; J., 1920, 754 a.

Ores and other materials; Method of and means for treating finely-crushed ——. E. T. Middlemiss. U.S.P. 1,370,898, 8.3.21. Appl., 20.5.20.

See E.P. 158,320 of 1919; J., 1921, 223 a.

Electro-deposition; Manufacture of plates or sheets by ——. S. O. Cowper-Coles. E.P. 160,554, 22.12.19.

Patents.

Electrolysers. R. Pechkranz. E.P. 146,184, 25.6.20. Conv., 27.6.19.

In an electrolyser in which the surface of the electrolyte is open to the atmosphere, parasitic electrolysis on the edges of the electrodes is prevented by employing vertical electrodes alternating with vertical diaphragms and united integrally therewith. The electrodes are mounted in a grooved frame, but do not extend to the lateral and lower outer edges of the frames, which are immersed in the electrolyte. The block of electrodes carried by the frames is surmounted by a multicellular cover made of insulating material and serving as a eparating chamber for emulsions and as a collecting hamber for the gases evolved.—J. S. G. T.

Electrolytic cell. L. W. Chubb, Assr. to Westinghouse Electric and Manuf. Co. U.S.P. 1,348,207, 3.8.20. Appl., 4.4.17.

HE cell comprises a container of "film-forming material" (*e.g.*, aluminium, tantalum, magnesium) nd a number of electrodes of the same material rranged in an electrolyte, alternate electrodes eing connected with terminals of opposite polarity. ach outer electrode has a superficial area about ne-half that of an intermediate electrode.

cid-proof and insulating materials. F. J. Harden. E.P. 159,956, 4.12.19.

N acid-resisting, insulating material is made by elting together about 10 pts. by weight of asphalm and 5 pts. of coal tar pitch, grinding the cold ixture and mixing therewith 2 pts. of flowers of lphur, 4 pts. of pumice or other inert powder, pts. of silicate of iron or other metal, 3 pts. of npblack or finely divided carbon, and 1·5 pts. of raffin wax. The whole is damped with petroleum and heated for about ½ hr. to a temperature not exceeding the melting point of sulphur. The material may be employed in the manufacture of boxes or containers for electric batteries.
—J. S. G. T.

Fireproof insulating masses from silicates and combustible substances; Preparation of ——. L. Kern. G.P. 331,026, 30.10.19.

Mineral acids or their salts, excepting aluminium salts or alums, are added before or after mixing the combustible substance with silicates, and the mixture is thereafter formed, dried, and burnt in known manner. The mineral acids or their salts are dissolved in water and added, in quantities of 0·1—0·5%, to the coal or to the mixture of coal, carbonaceous matter, and silicates.—A. de W.

Electric furnaces. E. C. R. Marks. From Scovill Manufacturing Co. E.P. 160,082, 15.3.20.

In a furnace working on polyphase current delivered to the charge by electrodes disposed so as to produce an inner rotating magnetic field, and a weaker outer magnetic field between the electrodes and the furnace wall, an additional magnetic field rotating in planes parallel to the surface of the molten charge is produced by connecting the electrode leads with bus-bars carried down the sides of the furnace and supported either inside or outside the furnace casing. The effect of this field is increased by employing a distributed current carrier comprising a number of bus-bars, which may extend underneath the charge. The additional field, according to its direction, co-operates with either the inner or outer fields, whereby the efficiency of heating and mixing of the charge is increased.—J. S. G. T.

Electric furnace for calcining magnesia and for similar purposes. F. S. Newall. E.P. 160,231, 9.12.19.

Within a vertical cylindrical retort is a central stationary cylindrical resistance element, forming an annular chamber through which the material to be calcined travels in direct contact with the resistance element. The retort is supported by a carrier mounted on rollers, and means are provided for imparting a rotary or vibrating motion to it. An internal screw or the like within the retort retards the fall of the material to be calcined and ensures thorough agitation.—J. S. G. T.

Electric furnaces; Electric system for ——. H. A. Greaves and H. Etchells. U.S.P. 1,370,016, 1.3.21. Appl., 12.9.18.

In an electric furnace with three, or a multiple of three, upper electrodes, and a hearth forming an electric resistance, combined with the "inverted star" system of three-phase transformer grouping, the insertion of a fourth transformer between the common terminal junction of the secondary windings of the original three transformers and the hearth electrode connexion, provides a means of varying the amount of electrical energy used for heating the hearth.—W. J. W.

Electric furnace. W. R. Clark, Assr. to Bridgeport Brass Co. U.S.P. 1,370,632, 8.3.21. Appl., 8.9.19.

A combustion chamber is arranged in the upper part of an electric furnace of the induction type provided with a secondary circuit below the upper surface of the charge, in order to prevent chilling or incrustation of that surface.—J. S. G. T.

Storage batteries; Filling for [dry] ——. C. A. Allison. From S. Narabayashi. E.P. 160,317, 8.1.20.

A filling for dry storage batteries consists of 70% of pumice-stone powder freed from metallic compounds and 30% of shredded asbestos or nitrated cotton. The filling is packed between the battery plates and soaked with a solution of sulphuric acid.—J. S. G. T.

Storage battery; Electric ——. C. J. V. Féry. U.S.P. 1,371,746, 15.3.21. Appl., 24.3.19.

A LEAD negative electrode is arranged horizontally at the bottom of a lead jar containing a "fixed" solution of sulphuric acid, and a positive electrode of lead peroxide is arranged vertically above the negative electrode. The horizontal cross-sectional area of the positive electrode is such that, during the charging operation, an upward movement of SO_4 ions occurs throughout the height of the jar, whereby the concentration of the acid is maintained constant, and the gases evolved at the negative electrode may escape without reacting with the positive electrode.—J. S. G. T.

Storage-battery separator. G. Steerup, Assr. to U.S. Light and Heat Corp. U.S.P. 1,370,064, 1.3.21. Appl., 7.6.19.

WOOD is treated so as to increase its porosity, and is then impregnated with ammonia gas. The free ammonia is volatilised and the wood treated with steam at such a temperature and for such a time as would injure the cellular structure of untreated wood.—J. S. G. T.

Pasting; Two-solution method of ——. [*Manufacture of electrolyte for dry cells.*] W. B. Schulte, Assr. to Burgess Battery Co. U.S.P. 1,370,056, 1.3.21. Appl., 10.6.20.

A PASTE for use as electrolyte in a dry cell is prepared by adding a solution of zinc chloride and ammonium chloride in water to a suspension of starch in a solution of zinc and ammonium chlorides, whereby gelatinisation of the electrolyte is effected.—J. S. G. T.

Electrolytic gas-generator. I. H. Levin, Assr. to Electrolytic Oxy-Hydrogen Laboratories, Inc. U.S.P. 1,372,442, 22.3.21. Appl., 22.5.17.

SEE E.P. 127,937 of 1918; J., 1919, 587 A.

XII.—FATS; OILS; WAXES.

Tallows used for launching ships. J. J. King-Salter. Inst. Naval Arch., 18.3.21. Engineering, 1921, 111, 405—407.

EXPERIMENTS carried out on five samples of tallow showed that the gradients of the temperature-hardness and temperature-compression curves were proportional to the titre tests (solidif. pt. of insoluble fatty acids). The samples examined had the following titre values: mutton tallow with 15% of stearine, 48·6° C.; mutton tallow, 48·1° C.; beef tallow, 46·1° C.; beef tallow and "C" grade beef tallow, 48·25° C.; "C" grade beef tallow, 42·2° C. Hardness tests were carried out in a modified Brinell tester, in which a steel ball ⅝″ in diam. was crushed into the surface of the tallow by the impact from a weight of 0·25 lb. falling a distance of 6″ on to a steel rod or piston in contact with the upper surface of the ball. Depth of sinkage was registered directly by a lever acting from a collar on the piston to a scale reading to 0·001″ by means of a vernier. Both hardness (expressed in arbitrary units) and compression (in tons per sq. ft.) were found to be proportional at a number of temperatures below the titre figure to the titre number, and the hardness test is recommended for ascertaining the suitability of tallows for launching purposes. The load-sustaining power and also the titre value of an unknown tallow can be conveniently determined by interpolation from reference to curves correlating these figures on known samples. The load-sustaining power at different temperatures may similarly be interpolated. Purified recovered tallow is unsatisfactory owing to its brittle and crumbly character. As a lubricant for use between the general ways and the sliding way, a mixture of "Vaxel" (a lime-resin-oil soap softened with mineral oil) and soft soap proved the most efficacious in inhibiting amalgamation of the tallow surfaces. The effect of boiling a natural tallow for 4 hrs. was to increase the hardness, the hardness factor falling from 101 units to 71 units (a hardness factor of zero on the scale corresponding to an actual hardness of infinity).—A. de W.

Oxidation of paraffin wax. (1) Fischer. (2) Fischer and Schneider. (3) Schneider. (4) Schneider and Jantsch. *See* IIA.

Montan wax. Fischer and Schneider. *See* IIA.

PATENTS.

Fatty acids in fats and oils; Neutralisation of ——. E. R. Bolton and E. J. Lush. E.P. 159,587, 28.11.19.

THE free fatty acids in an oil or fat are neutralised by subjecting the oil or fat in an inert gas to the action of the chemically equivalent proportion of mono- and di-glycerides of the fatty acids separately prepared, at a temperature of, *e.g.*, 250° C. for about 3 hrs. The neutralised product is subsequently heated *in vacuo* in the same reaction vessel to evaporate the water chemically formed. The neutralised oils can be refined by ordinary processes, *e.g.*, for the production of edible oils.
—A. de W.

Fat; Manufacture of —— *from spent sulphite-cellulose lyes.* W. Jeroch, and Reichsausschuss für pflanzl. u. tier. Oele und Fette Ges. E.P. 146,430, 3.7.20. Conv., 24.1.17.

Fat and glue-water. E.P. 137,842. *See* XV.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Resins used for making varnishes; Characters of ——. P. Nicolardot and C. Coffignier. Chim. et Ind., 1921, 5, 150—156. (*Cf.* J., 1911, 815.)

AN apparatus for determining the relative hardness of different resins consists essentially of a support for a test-block of the resin and a vertical weighted rod carrying at its lower end a steel ball which presses on the surface of the resin. Usually the ball has a diameter of 2 mm. and the rod is weighted with 5 kg.; the diameter of the impression made in the resin is measured after 5 secs. and again after 10 mins., or at other periods during which the pressure is applied. The test is applied at 0° C. or at 25° C. Resins are classified as follows: — *Hard resins:* Zanzibar, Madagascar, Demerara. *Semi-hard resins:* Congo, Benguela, Cameroon, Angola red, Kissel, Brazil, Angola white, Sierra Leone. *Soft resins: Aucoumea Klaineana, Hopea odorata, H. dealbata. Various:* Yellow amber, cloudy amber, kauri, Manila, pontianac.—W. P. S.

Gum-oleoresin of Boswellia serrata; Extraction of turpentine, resin, and gum from the —— without the use of solvents. G. J. Fowler and M. A. Malandkar. J. Ind. Inst. Sci., 1921, 4, 27—42.

The turpentine is first removed from the oleoresin by distillation with wet steam. The yield amounted to 8—9%, and the oil, which was pale yellow, had the following constants: sp. gr. 0·8435 at 30° C., $[\alpha]_D = +4° 54'$, fraction distilling below 160° C. 81%, 160°—180° C. 14·4%. The gum-resin remaining after the removal of the turpentine is heated with about three times its weight of water in an autoclave at 30 lb. pressure, whereby the hydrated resin rises to the surface and solidifies on cooling, whilst the gum forms a flocculent precipitate or mucilage on the bottom of the vessel. The resin after dehydration by heating to about 130° C. forms a brown transparent mass, amounting to 54% of the original gum-resin and not differing appreciably in appearance from that extracted by a solvent. It has the following constants: acid value 51·6, saponif. value 61·3, iodine value 108·1. The gum on drying forms a dark grey mass, amounting to 23% of the original gum resin. It forms a mucilage with water of but feeble adhesive power.—G. F. M.

Colophony; Constitution of the resin acids of ——. A. Grün. Z. Deuts. Oel- u. Fettind., 1921, 41, 49—52. Chem. Zentr., 1921, 92, I., 496.

From a consideration of earlier experiments (*cf.* J., 1919, 506 A), the author considers that abietic acid does not contain two double bonds, but, like pinene, one double bond and a bridge linkage. A formula is proposed which is claimed to explain better than those hitherto suggested the known properties of the compound and to be in conformity with its origin from pinene. The formation of abietic acid takes place by union of one molecule each of α- and β-pinene, and subsequent oxidation of a methyl to a carboxyl group. By different modes of combination of the two molecules of pinene, a series of abietic and pimaric acids could be formed and others could be formed in an analogous manner from camphene or fenchene.—A de W.

Low-temperature tar. Fischer and Ehrhardt. *See* III.

Patents.

[Concrete paint or] composition impervious to oil, spirit, water, and the like. Anti-corrosive paint or composition. C. H. Ivinson and G. S. Roberts. E.P. (A) 159,542, and (B) 159,543, 28.10.19.

(A) A composition for coating concrete, etc., consists of the double chlorides of zinc and/or magnesium and ammonium, together with oxides of magnesium and/or zinc, and finely-divided iron, with or without the addition of fillers or extenders, *e.g.*, to every 15 pts. by weight of a mixture of 25 pts. of zinc oxide, 1 pt. of silica, 0·5 pt. of sodium biborate, and 0·75 pt. of powdered glass, are added 14 pts. of zinc chloride and 1 pt. of ammonium chloride. About 1 pt. of water may be added to 2 pts. of the combined powders, or the water may be added in the form of a saturated solution of the mixed chlorides. (B) A protective paint for zinc, concrete, wood, and the like, consists of a mixture of asphaltum and a volatile solvent with acid-resisting or anti-corrosive substances, *e.g.*, aluminium, calcium, or magnesium oleates or stearates, gum elemi, masticated rubber, gutta-percha, or paraffin wax, and fillers, *e.g.*, asbestos, silica, etc., together with lime-proof pigments ground in a suitable medium, *e.g.*, ferric oxide, lithopone, or zinc oxide ground in linseed oil, tung oil, thinners, or a drying oil varnish.
—A. de W.

Paint or varnish and method of making the same. M. Darrin, Assr. to The Koppers Co. U.S.P. 1,370,195, 1.3.21. Appl., 10.5.19.

A paint or varnish comprises a resin obtained from solvent naphtha subjected to an autoclave process, and linseed oil.—A. de W.

Paint; Water-resistant ——. R. Plönnis. G.P. 301,783, 17.9.16.

The paint consists of calcium carbonate as a pigment and a mixture of potassium silicate (water-glass) and potassium hydroxide as a medium.
—A. R. P.

Gum from grass trees (Xanthorrhœa); Process for the extraction of ——. H. J. Pooley and J. L. Strevens. E.P. 160,080, 12.3.20.

The outside portions of the grass tree are extracted, at a temperature of not less than 160° F. (71° C.), with the alcoholic solvent derived from the fermentation and rectification of the sweet wort obtained by exhaustion of the inner core of the tree with warm water, such solvent being concentrated to a strength of at least 70% of alcohol. Extraction of the gum may be carried out either by percolation or exhaustion with the vapour of the alcoholic solvent, and the dissolved gum may be separated from the solvent by distillation.—A. de W.

[Rosin soap] emulsions; Method of making ——. J. A. De Cew, Assr. to Process Engineers, Inc. U.S.P. 1,370,884, 8.3.21. Appl., 11.11.20.

Hot rosin soap containing free rosin is diluted by agitating 1 pt. of hot size with 7 pts. of hot water, with subsequent addition of cooler water.—L. A. C.

Linoleum, lincrusta, artificial leather, etc.; Production of ——. G. Ruth and E. Asser. G.P. 328,580, 21.6.19.

A mixture of equal parts of chromium or aluminium naphthenate heated to 250°—260° and of a metal salt of naphthenic acid heated to 160° C. is used. A naphthenate partly decomposed by heating to 200° C. may also be used.—H. J. H.

Oils, boiled oils, varnishes, oily pastes, and luting compositions; Preparation of ——. Rostschutz-Farbwerke Liebreich, G.m.b.H. G.P. 330,670, 25.12.19.

The oils etc. are heated to at least 240° C. with metals or oxides of metals (CuO, ZnO) conferring little or no siccative properties, whereby the compound formed remains unsaponified in the presence of alkaline lyes etc. The oils may also be heated with driers and metallic oxides together.—A. de W.

Shoe-creams, wax-, metal-, wood- and leather-polishes; Preparation of ——. P. Friesenhahn. G.P. 331,050, 5.7.19.

The usual solid constituents of such preparations are dissolved or emulsified in cyclohexanols or cyclohexanones or their homologues either alone or together with other solvents. The syrupy nature of the products of the hydrogenation of phenols is favourable to the retardation of the drying of the finished products and facilitates emulsification of the solid constituents.—A. de W.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Polythionic chlorides. Bruni and Amadori. *See* VII.

Patents.

Rubber; Manufacture of ——. S. C. Davidson. E.P. 159,602, 1.12.19 and 19.1.20.

Fresh latex is treated with a dilute alkaline solution of phenol (E.P. 11,470 of 1912, 13,438 of 1913, and 22,138 of 1914; J., 1913, 799; 1914, 758; 1915, 1020), which acts as a preservative and permits the postponement of further treatment for any desired period. The latex is subsequently coagulated by the addition of a suitable acid or of a suitable mixture of a salt such as magnesium sulphate with sulphuric or pyroligneous acid (*e.g.*, in the apparatus described in E.P. 22,489 of 1914), the dehydration of the resulting coagulum being facilitated by fine perforations in the manner already described (E.P. 151,344; J., 1920, 757 A). The coagulum is then rolled into sheet or crêpe and, if desired, pressed into block. By this procedure the rubber is brought into a marketable condition in a much shorter time than usual.—D. F. T.

Rubber mix and process of compounding rubber. R. C. Hartong, Assr. to The Goodyear Tire and Rubber Co. U.S.P. 1,370,965, 8.3.21. Appl., 30.1.19.

Rubber is well mixed with water containing aluminium hydroxide in suspension and the water is driven off from the mixture, which is then vulcanised in the usual manner.—A. R. P.

Plastic, rubber-like material from cellulose esters; Manufacture of ——. F. Clouth, Rheinische Gummiwaarenfabr. m.b.H. G.P. 324,944, 18.12.17. Addn. to 319,723 (J., 1920, 568 A).

Other high-boiling oils, such as creosote oil, are used instead of anthracene oil, as described in the chief patent.—L. A. C.

Rubber-like products; Hindering oxidation in synthetic ——. Badische Anilin- und Soda-Fabr. G.P. 330,741, 27.2.18.

The addition of 1% of α- or β-naphthol, resorcinol, or quinol, to the material before vulcanisation yields a product which does not deteriorate during storage.—L. A. C.

Adhesive solutions; Manufacture of highly —— from varieties of artificial rubber which are insoluble or soluble with difficulty in the usual solvents, or give solutions of little adhesive power. Akkumulatoren-Fabr. A.-G. G.P. 331,031, 6.12.17.

The rubber is heated in air to at least its melting point, *i.e.*, about 140° C., under a pressure of about 1 atm., and is subsequently cooled, cut up, and dissolved in petroleum spirit.—L. A. C.

Substance resembling rubber; Manufacture of a ——. F. de la Rosée. G.P. 331,334, 15.2.18.

Resin, *e.g.*, balsam resin, is melted with calcium chloride, and repeatedly distilled with further additions of calcium chloride and bleaching powder. A mixture of the oily product with rubber or rubber regenerates is then vulcanised.—L. A. C.

Caoutchouc; Art of vulcanising ——. C. W. Bedford, Assr. to The Goodyear Tire and Rubber Co. U.S.P. 1,371,662—4, 15.3.21. Appl., 6.1.17, 19.3.19, and 17.5.19.

See E.P. 130,857 of 1918; J., 1919, 731 A.

XV.—LEATHER; BONE; HORN; GLUE.

Depsides and tannins. K. Freudenberg. Collegium, 1921, 10—19.

A historical account of Fischer's synthesis of gallotannic acid and tannin-like substances. Carbomethoxybenzoic acid was prepared from *p*-hydroxybenzoic acid and was converted, by means of the Schotten-Baumann reaction, into an ester anhydride of *p*-hydroxybenzoic acid. This was termed a depside. By partial saponification of triacetylgallic acid to diacetylgallic acid and combination of the free hydroxyl group with triacetylgalloyl chloride, a penta-acetyl-*m*-digallic acid was obtained, which proved to be a true tannin, like the corresponding didepsides of the dihydroxybenzoic acids. There yet remained the 7% of dextrose obtained from gallotannic acid, which was not easily liberated, and hence was not present in the form of a glucoside. The absence of free carboxyl groups in gallotannic acid indicated that the carboxyl groups in gallic acid were united to the hydroxyl groups in the dextrose. Fischer and Bergmann prepared pentadigalloylglucose and found it very similar to Chinese gallotannic acid. It was not identical, since the natural product consists of a mixture of isomers, whilst the synthetic product was a single substance. The synthesis of fully methylated gallotannic acid was also effected. The comparison of pentagalloylglucose with Turkish gallotannic acid was rendered difficult owing to the presence of an ellagic acid tannin in the natural product. Glucogallin, a constituent of rhubarb, was identified by Fischer and Bergmann as 1-galloyl-β-glucose, and was synthesised from acetobromoglucose and silver triacetylgallate. Fischer worked out a new method for preparing partially acetylated glucose derivatives. Two molecules of acetone are combined with one of dextrose in presence of a little hydrochloric acid, forming a diacetoneglucose. The free hydroxyl group is combined with an acid chloride and the acetone is split off one molecule at a time. Further developments have been along the lines of analysis with tannase which has helped to explain the constitution of chlorogenic acid ($C_{16}H_{18}O_9$). By its aid, hamameli-tannin was shown to consist of a new sugar esterified with two molecules of gallic acid. Chebulinic acid from myrobalans contains a digalloylglucose combined with an unknown acid. There are four groups of tannins, ester tannins, catechins, oak and chestnut, and ellagic acid tannin. Crystalline tannins are difficultly soluble in water, amorphous tannins are more readily soluble.—D. W.

Oakwood extracts; Cause of the development of gas in ——. F. Liebert. Collegium, 1921, 76—77.

A sample of strongly fermenting extract was inoculated on a plate of malt extract-gelatin and kept at 22° C. for 2 days. A pure yeast culture was obtained which closely resembled *Saccharomyces apiculatus*. This is an extraordinary instance of selective growth of yeasts to the exclusion of bacteria and moulds. The infection was traced to exposure of the concentrated extract to the air after being run out of the evaporator. Covers and disinfection prevented it. The acidity of the extract also helped the growth of the yeast, and an extract neutralised with calcium carbonate would not ferment.—D. W.

Tannin analysis. I. V. Kubelka and B. Köhler. Collegium, 1921, 77—83.

After shaking solutions of certain solid pine bark and oak wood extracts with hide powder in accordance with the provisions of the official method of analysis, and filtering, the filtrate gave a precipitate with gelatin and with iron salts and was coloured. A fresh portion of hide powder absorbed a large amount of matter from this filtrate and rendered it "tannin-free" according to qualitative tests. Similar observations were made with liquid extracts, but the maximum amount of matter absorbed from the first filtrate (10%) was obtained with solid extracts. Samples of an oak bark extract tested by four different analysts gave results showing variation in tans from 38·6% to 45·7% by the "shake" method. In tanning practice with some materials, the hide is first entered into nearly exhausted liquors, whereas in the analysis the powder is treated with freshly made liquor. The "shake" method was worked out for certain tanning materials and is not suitable for some new products. The principle of the official method is wrong, since all those substances which are not quickly absorbed are classified as non-tans, although they may be capable of being absorbed by hide powder and react with gelatin and iron salts. In the filter method of analysis, the first layers of hide powder are saturated with tannin from the fresh strong tannin solution and then the other layers come into contact with the partially detannised solution. Where the "shake" method does not give completely detannised solutions, the "filter" method should be employed. Tables are appended showing the suitability of the "shake" method of analysis for quebracho, mimosa, chestnut, and sumach extracts and the efficacy of the double shake method and filter bell method with oakwood, oak and pine bark extracts.—D. W.

Tanning [and dyeing] rabbit skins for furs. G. Desmurs. J. Soc. Leather Trades' Chem., 1921, 5, 84—87.

Skins of rabbits and similar animals are tanned in liquors made up from a mixture of 100 pts. of unsulphited quebracho tannin (40% tans), 10 pts. of sumuch extract (22% tans), 2½ pt. of anhydrous sodium sulphate, and ½ pt. of aluminium sulphate. A similar mixture is also suitable for tanning sheepskins in the paddle. After a preliminary treatment with sodium carbonate, ammonia, or caustic soda, the furs are dyed black with logwood and fustic and mordanted with copper sulphate or pyrolignite of iron. Grey, brownish-black, or greyish-brown shades can be obained with *p*-phenylenediamine, *o*- and *p*-aminophenol, *m*-toluylenediamine and hydrogen peroxide.—D. W.

Aldehyde tannage. VI. W. Moeller. Collegium, 1921, 20—31. (*Cf.* J., 1920, 36 a, 730 a.)

Formaldehyde is absorbed in large amounts by animal charcoal under special conditions. The volume and concentration of the formaldehyde solutions and the time factor have been overlooked in previous researches. The assertion that formaldehyde does not act on agar-agar is not borne out by experiment. The action of dilute solutions of formaldehyde on hide powder has been determined. 14·55% of the formaldehyde present in a 3·5% solution was adsorbed by the hide powder after 14 days' contact. The amount of formaldehyde adsorbed increases with the length of time of contact. Similar results were obtained with neutralised solutions of formaldehyde, but much less was absorbed from concentrated solutions. The addition of alkali even to neutralise the formaldehyde solution causes the Cannizzaro inversion to proceed to a certain extent, the polymerisation of the formaldehyde, and further the reaction of the hide decomposition products with a certain portion of the formaldehyde to form methyleneamino-acids. These reactions must cause the neutralised formaldehyde solution to react acid, and three different solutions of formaldehyde were found to be acid after being in contact with hide powder for 14 days. The methyleneamino-acids have a hydrolysing action, hence the "proteolytic-constant" of hide powder is increased by formaldehyde solutions. The lack of permanency in formaldehyde-tanned leathers is easily explained by insufficient washing of the tanned leather. Methyleneamino-acids remain in the leather and they slowly hydrolyse the fibres, causing brittleness. There is not as much loss of hide substance with 15—30% solutions of formaldehyde owing to the more intense tannage. The total acid formed in these concentrated solutions is the same as that formed in the dilute solutions. Samples of powder tanned with formaldehyde solutions of different strengths were extracted with water and those tanned in concentrated solutions were found to be less stable to the solvent action of water, and powders tanned in neutral formaldehyde solutions were less stable than the others. The small amount of formaldehyde-tannin taken up in alkaline solution gives all the desired properties required for aldehyde-leather, and the absolute amount of formaldehyde-tannin taken up is not a vital factor.—D. W.

Mineral tannages. IV. W. Moeller. Collegium, 1921, 67—75.

Neutralised and unneutralised solutions of ferric chloride of different strengths (1·1%—10·9% Fe_2O_3) were allowed to be in contact with hide powder for periods varying from 1 day to 3 months. Half the total iron absorbed was taken up the first day, after which there was very little increase for a month. Neutralisation of iron salts does not produce a fully satisfactory tanning solution. The electrolytic dissociation of iron salts is excessive and results in hydrolytic decomposition of the hide after prolonged contact. As much as 67% of the hide powder was dissolved by the strongest solutions after 3 months' contact. This explains the "loose" fibre and tendency to become brittle of iron-tanned leathers. The ready dissociation of all iron salts even in neutral solution causes the difficulties connected with iron tannages and renders it difficult to obtain a permanently peptised system. The acid peptiser is continuously dissociating and the acid portion effects the hydrolysis of the hide and the decomposition of the leather. Unlike other tannages, there appears to be no limit to the amount of iron which can be absorbed by the hide. The assertion that mineral salts such as chromium and ferric salts can tan without the addition of soda is not borne out by experiment. The hydrions in such unneutralised solutions decompose the hide with which they are in contact and the hide decomposition products act just like any other alkali. The basic groups combine with the acids and a more or less peptised system results from the presence of these basic decomposition products. The longer such a solution is in contact with the hide substance the more tanning effect it will exert upon the hide. Such a process of tanning is useless for practical purposes, since it does not give a satisfactory leather. Modern processes for iron tannages provide acceptors for the hydrions in the tanning salts in order to obviate their hydrolytic action during tannage and storage.—D. W.

Gelatin jellies; Elastic properties of ——. S. E. Sheppard and S. S. Sweet. J. Amer. Chem. Soc., 1921, 43, 539—547.

Measurements of the modulus of rigidity of gelatin jellies under torsion show that they follow Hooke's law nearly to the breaking point, the elastic limit nearly coinciding with the tenacity (*cf.* J., 1920, 758 a). The expression $E=kc^n$ expresses the relation between the modulus of elasticity, E, and the concentration, c, but the constants k and n differ for different grades of gelatin. The elasticity is not a simple function of hydrogen ion concentration in the case of acid jellies. Alcohol and glycerol increase the jelly strength up to a certain concentration. Jellies with more than 40% of alcohol separate into two phases under torsion. The bearing of the results on theories of jelly structure is discussed. (*Cf.* J.C.S., May.)—E. H. R.

Colloidality; The zone of maximum ——. Its relation to viscosity in hydrophile colloids, especially karaya gum and gelatin. J. Alexander. J. Amer. Chem. Soc., 1921, 43, 434—440.

The viscosity of reversible emulsoid or hydrophile colloids sometimes increases as the dispersed phase becomes finer, as in oil emulsions, and sometimes as it becomes coarser, as in the case of soaps. There appears, in fact, to be a "zone of maximum colloidality," the size of particles giving maximum viscosity being probably different for different substances. This zone of maximum colloidality is not limited to so-called emulsoid colloids. Thus with steel the Fe_3C—Fe dispersion reaches its maximum hardness in martensite and becomes softer if the dispersion becomes greater (austenite) or less (troostite, sorbite, pearlite). Experiments in which karaya gum of different degrees of fineness was dispersed in water showed that the viscosity increased with increasing fineness of the gum particles from 5- to 10-mesh (about 4 mm.) to 200-mesh (about 0·1 mm.). The hydration and dehydration of karaya gum and gelatin is discussed. The decrease in the viscosity of highly degraded glue or gelatin is probably due to an increase in the dispersion. Both the jelly strength and viscosity of cold aqueous dispersions of commercial ground glues and gelatins increase with decrease in size of particle, but the optimum conditions for maximum viscosity are not identical with those for maximum jelly strength. (*Cf.* J.C.S., May.)—E. H. R.

Proteins [gelatin]; Method of purifying certain kinds of ——. A. M. Field. J. Amer. Chem. Soc., 1921, **43**, 667—668.

In consequence of its amphoteric properties (J., 1919, 331 A), any protein with iso-electric point at a hydrogen-ion concentration greater than that of water will lose any combined basic elements when dialysed sufficiently long against dilute acid, and the resulting protein-acid compound can then be completely converted into protein by dialysis against water. Gelatin purified by this procedure forms an opaque white jelly, free from ash. Similarly, proteins with iso-electric points less than that of water in respect of hydrogen ions may be successively treated with dilute alkali and water. —J. K.

Proteins [gelatin]; Ion series and the physical properties of ——. *III. Action of salts in low concentration.* J. Loeb. J. Gen. Physiol., 1921, **3**, 391—414.

The Hofmeister lyotropic series is founded on an error due to a failure to notice the influence of the added salt on p_H. At the same p_H the effect of ions on the swelling, osmotic pressure, and viscosity of gelatin depends only on the sign and valency of the ions, and univalent ions of the same sign have practically the same effect. Divalent and still more trivalent ions have a greater effect but do not differ much among themselves if they have the same sign. (*Cf.* J.C.S., May.)—G. B.

Proteins [gelatin]; Colloidal behaviour of ——. J. Loeb. J. Gen. Physiol., 1921, **3**, 557—564.

The potential difference between gelatin chloride solutions inside a collodion bag and an aqueous solution outside is depressed by a neutral salt in the same proportion as the osmotic pressure is depressed; the potential difference can be calculated by Nernst's formula if it is assumed to be due to the difference in the p_H measured inside and outside the bag, which latter difference seems to result from the Donnan membrane equilibrium. (*Cf.* J.C.S., May.)—G. B.

Anthrax spores. Müller. *See* XIXB.

Patents.

Tanning of hides and skins; Apparatus for rapid ——. F. Gilardini. E.P. 160,422, 5.12.19. Addn. to 114,631 (J., 1919, 297 A).

Relates to mechanical improvements in the apparatus described in the chief patent.—D. W.

Colouring-matter for leather and method of using the same. J. H. Pfingsten, Assr. to Presto Color Co. U.S.P. 1,371,572, 15.3.21. Appl., 2.7.17.

Pulverulent, insoluble pigment is suspended in water, and the leather is agitated therein in the presence of heat, so that the pigment is uniformly deposited in the interstices of the leather.—D. W.

Glue-water; Apparatus for treating mixtures of fat and —— *derived from boiling and drying organic substances.* K. Niessen. E.P. 137,842, 13.1.20. Conv., 2.10.16.

Two receptacles are arranged side by side with their lower parts connected by a siphon for equalising the pressure. One receptacle of such size that it can hold not only the maximum output of fat from the steriliser but also a small quantity of glue water, serves as fat separator and the other as glue-water holder and evaporator. Both receptacles are connected with a steriliser and glue extractor by means of a series of pipes fitted with valves. By operating the valves the glue-water and fat separate in the fat separator, which is emptied by means of another valve, and the glue-water is returned to the extractor.—D. W.

Ferro-leather; Process for producing ——. W. Mensing. U.S.P. 1,371,803, 15.3.21. Appl., 23.1.17. Renewed 27.1.21.

See G.P. 314,885 of 1916; J., 1920, 199 A.

Artificial leather. G.P. 328,580. *See* XIII.

XVI.—SOILS; FERTILISERS.

Soils; Rate of formation of soluble substances in several organic ——. M. M. McCool and L. C. Wheeting. Soil Sci., 1921, **11**, 233—247.

In organic soils, for a given moisture content, the rate of formation of soluble material varies with the temperature. At higher temperatures (25° C.) optimum moisture conditions tend to bring greater amounts of material into solution than when the soil is saturated. The reverse is true at lower temperatures (7° C.). In moist soils the concentration of soluble substances generally increases on standing up to a certain point and then decreases. In organic soils the amount of soluble substances present and the rate at which they are produced vary with the depth. In general the ability to yield soluble materials decreases regularly from the surface to the water-table, the muck soils studied being very inactive below a depth of 2 ft. The zone of weathering and the region of greatest activity coincide.—W. G.

Determination of potash as perchlorate. Jarrell. *See* XXIII.

Patents.

Fertilising material, and process of producing same. M. O. Johnson. U.S.P. 1,370,117, 1.3.21. Appl., 15.12.19.

Vegetable fibrous and fruity matter and coagulated vegetable proteids (*cf.* U.S.P. 1,362,868; J., 1921, 127 A) are compressed into a cake, for use as a fertiliser.—W. J. W.

Fertilisers, especially calcium cyanamide; Prevention of dustiness in ——. W. Schwarzenauer. G.P. 304,965, 28.3.16.

Oils, obtained by distillation of bituminous shale, are absorbed by a suitable material, such as pulverised shale or the residue from the shale distillation, and the mixture is incorporated with the fertiliser.—W. J. W.

Potassium perchlorate; Separation of —— from mixtures of salts containing it, e.g., ammonium nitrate explosives [to obtain fertilisers]. Verein Chem. Fabr. in Mannheim. G.P. 329,960, 23.11.18.

To remove perchlorate from ammonium nitrate explosives with the object of using these for fertilising purposes, they are digested with a concentrated solution of a potassium salt, or of carnallite, at about 0° C. After the treatment the mixture is warmed and the solution is separated from the slightly soluble potassium perchlorate.—W. J. W.

Fertilisers; Process for the production of ——. Badische Anilin- und Soda-Fabr. G.P. (a) 332,114, 18.2.17, and (b) 332,117, 24.2.17.

(a) Fertilisers having an acid reaction, *e.g.*, superphosphates or mixtures of these with salts of a volatile acid, are treated with ammonium bicarbonate. (b) Superphosphates are treated first with a small quantity, then, after standing some time, with a larger quantity of urea. Addition of earthy, sandy, or carbonaceous materials is, in this case, unnecessary. (*Cf.* G.P. 308,659; J., 1918, 48 a.)—A. R. P.

Phosphates; Process for treatment of raw ——. Process for the recovery of fertiliser salts from solutions. Badische Anilin-und Soda-Fabr. G.P. (a) 332,115, 28.3.17, and (b) 332,116, 24.4.18.

(a) The phosphate is dissolved in nitric acid, and the solution treated with ammonia and/or ammonium carbonate, or with both together, or with one after the other, in order to produce a precipitate of di- or tri-calcium phosphate alone or mixed with calcium carbonate, and a solution from which ammonium nitrate may be recovered by evaporation. (b) The hot concentrated solution of the salts is cooled by being subjected to a vacuum, whereby the dissolved salts are recovered in an easily distributable form.—A. R. P.

Superphosphate of lime and similar compounds; Apparatus for manufacture of ——. Chemical Construction Co., Assees. of R. E. Forbis. E.P. 139,803, 3.3.20. Conv., 4.3.19.

See U.S.P. 1,318,063 of 1919; J., 1919, 956 a.

Slags from iron smelting. G.P. 332,118. *See* X.

XVII.—SUGARS ; STARCHES ; GUMS.

Ammonia; Recovery of —— in beet sugar manufacture. K. Andrlik and V. Skola. Z. Zuckerind. Czechoslov., 1921, **45**, 179—182, 187—190, and 195—198.

Experiments carried out in a beet sugar factory showed the amount of ammonia liberated reckoned as a percentage of the weight of roots sliced was 0·0019 (12·5% of the total amount) during carbonatation, and 0·0058 (38·4% of the total) during heating; while 0·0074 (49·0% of the total) was dissolved in the condensed waters drained from the quadruple effect evaporator. (*Cf.* J., 1920, 379 a; 1921, 233 a.)—J. P. O.

Saccharimeter; Re-testing the 100° point of the ——. I. Detection of small amounts of invert sugar in the presence of much sucrose. A. Kraisy. Z. Ver. Deuts. Zucker-Ind., 1921, 123—144.

A method of determining reducing sugars which is said to be capable of detecting at least 0·005% in the presence of 10 g. of sucrose is described. Shortly before use 25 c.c. of a solution containing 2 g. Cu (7·86 g. CuSO$_4$+5H$_2$O) per litre is mixed in a 250 c.c. Erlenmeyer flask with 25 c.c. of a solution containing 3·292 g. of sodium carbonate and 20 g. of Rochelle salt per litre. At the same time, in a second Erlenmeyer flask, 50 c.c. of the sugar solution containing 10 g. of sucrose is mixed with 5 c.c. of $N/10$ KHCO$_3$. Both liquids are separately heated to boiling, the first added to the second, and ebullition continued for exactly 10 min., at the end of which time 50 c.c. of cold, recently boiled distilled water is added. After leaving the flask for 5 min. in cold water, 1—1·25 c.c. of 4N HCl is run in, followed immediately by standard iodine (1 c.c. =1 mg. Cu, that is $N/63{\cdot}57$), the excess of which is then titrated with thiosulphate, using starch solution as indicator. Using this so-called "neutral Fehling's solution," the copper reduced in the case of refined sugars purified by crystallisation from alcohol was 1·5—4·6 mg. Cu; using Striegler's solution, 5·4—9·2; and using ordinary alkaline Fehling's solution it was 36—43, operating in all three cases in the presence of 10 g. of sucrose and under exactly the same conditions. It is concluded that whereas ordinary Fehling's solution is capable of detecting not less than 0·05% of reducing sugars, the reagent now proposed is sufficiently sensitive to establish the presence of 0·002% in samples of refined sugar.—J. P. O.

Sugars; Chemistry of the ——. H. Kiliani. Ber., 1921, **54**, 456—472.

Many examples are given of a new method of using nitric acid with the sugar group. The substance is treated with slightly more than the calculated amount of nitric acid, generally of sp. gr. 1·2 (32% HNO$_3$); in certain cases a more concentrated acid is used, or, when reaction is difficult, mixtures of the ordinary acid and the fuming acid, or of the fuming acid and water. In all cases it is important that the room temperature should be maintained throughout the oxidation. Arabinose, xylose, and rhamnose are smoothly oxidised to the corresponding monocarboxylic acids or their lactones, but reaction with dextrose appears rather more complex, leading, however, under certain specified conditions to the formation of calcium glycuronate. Under like conditions ketoses do not appear to be affected. A new method for the preparation of lævulose from sucrose and of treating the mixtures of sugars obtained by the hydrolyses of glucosides is thus indicated. As demonstrated by the conversion of metasaccharin into calcium trihydroxyadipate and of *l*-mannonic acid into the lactone of *l*-mannosaccharic acid, a convenient process for the preparation of dicarboxylic acids is given. Further, glyceric and tartronic acids, and probably also glyceraldehyde, are readily prepared from glycerol. Finally, the process forms an excellent means of oxidising (and in many cases of nitrating) organic substances which are attacked by nitric acid of any concentration at the ordinary temperature; thus castor oil is converted into azelaic and, apparently, suberic acids, whilst cinnamic and benzoic acids give mainly *m*-nitrobenzoic acid.
—H. W.

Sugars; Unsaturated products of reduction of —— and their transformations. I. The glucal problem. M. Bergmann and H. Schotte. Ber., 1921, **54**, 440—455.

Elucidation of the constitution of glucal triacetate (Ber., 1920, **53**, 509) has made the formula,

$$OH.CH_2.CH(OH).\underbrace{CH.CH(OH).CH{:}CH}_{O},$$

highly probable for the parent substance, but this fails to account for the reducing properties of glucal preparations hitherto examined, unless they can be attributed to the unknown influence of the 2.3-dihydrofuran ring. Examination of the analogously constituted rhamnal,

$$\underbrace{CH{:}CH.CH(OH)CH}_{O}.CH(OH)(CH_3)$$

shows that this is not the case, since the latter does not behave as an aldehyde. By the use of alcoholic ammonia in place of aqueous barium hydroxide for the hydrolysis of glucal triacetate the authors have succeeded in preparing crystalline glucal, needles, m.p. about 60° C., $[\alpha]^{19}_{D}=-7\cdot2$ in aqueous solution, which, like rhamnal, does not show aldehydic properties. One of the impurities which confers strong reducing powers on syrupy "baryta" glucal is 2-desoxyglucose. On oxidation with benzoper-acid glucal is converted into mannose. (*Cf.* J.C.S., May.) —H. W.

Karaya gum. Alexander. *See* XV.

Starches. Arpin. *See* XIXA.

XVIII.—FERMENTATION INDUSTRIES.

Saccharase [invertase] preparations; Preparation of highly active ——. O. Svanberg. Z. physiol. Chem., 1920, **109**, 65—98. (*Cf.* J., 1920, 636 A, 795 A; 1921, 191 A.)

HIGHLY active invertase preparations were made by autolysing yeast, extracting the residue with water, and fractionating by means of alcohol, protein being removed from the resulting enzyme solutions by treatment with kaolin. A purer preparation was obtained by dialysis.

Yeast; Nutritional requirements of ——. III. Synthesis of water-soluble B. V. E. Nelson, E. I. Fulmer, and R. Cessna. J. Biol. Chem., 1921, **46**, 77—81.

A YEAST was sub-cultured 180 times on a salt and sucrose medium, and yet contained enough vitamin B to cure rats. The vitamin, therefore, must have been synthesised by the yeast, which result invalidates Williams's method of estimating this vitamin (*cf.* following abstract). (*Cf.* J.C.S., May.) —G. B.

Vitamins and yeast growth. R. J. Williams. J. Biol. Chem., 1921, **46**, 113—118.

THE author's quantitative test for vitamin B (J., 1919, 692 A; 1920, 608 A) gives results fairly concordant with Osborne and Mendel's rat-feeding experiments, but bakers' yeast, by the yeast method, shows a much higher vitamin content than brewers' yeast, whereas for animal experiments the reverse holds good. "This is interpreted to mean that there is some specificity in growth stimulants, but not necessarily two totally different substances stimulating growth of the two varieties of yeast" (*cf.* preceding abstract).—G. B.

Acetone fermentation process in India. G. J. Fowler, Y. D. Wad, and A. G. Gokhale. J. Ind. Inst. Sci., 1921, **4**, 1—15.

As raw material for the acetone fermentation process, mahua flowers (*Bassia latifolia*), containing 40—60% of total sugars, 0·65—1·1% of nitrogen, and little or no starch, were tried under various conditions but gave very unsatisfactory results. Good fermentations were obtained, however, with starch-containing materials, such as rice, but jawari (cholam) flour was preferred on account of its cheapness. In small scale experiments 1200 g. of jawari flour containing about 52% of starch and 1·2% nitrogen gave about 70 c.c. of acetone and 128 c.c. of butyl alcohol. The most vigorous fermentation took place with cultures only two or three generations from spores, and it is important to ensure that the cultures do not lose their power to sporulate, as they tend to do after continued subculture in simple maize mash. This was achieved by inoculating in a mash containing meat extract, peptone, or gelatin. The chief difficulty in large scale work is the maintenance of sterility up to the point of inoculation 4 hrs.' heating under 15 lb. steam pressure was found to be requisite. The problem of the disposal of the effluent, which amounts to 50,000 galls. per ton of acetone produced, was studied. A cake utilisable for cattle food is obtained by pressing the husk along with the sludge resulting from plain sedimentation. The turbid liquid remaining is clarified by treatment with excess of lime, and gives a further sludge which has valuable manurial properties. In connexion with the above work rough experiments were made on the flashing and explosive concentrations of mixtures of acetone vapour and air, indicating that a concentration of acetone vapour up to 2·3% was safe. The mixture flashes above this concentration, reaching a maximum violence at a concentration of 5·61% of acetone, and settling down to a quiet flame at 10·2% of acetone vapour.—G. F. M.

Iron; Determination of small quantities of —— in organic liquids, especially in wines. P. Malvezin and C. Rivalland. Ann. Chim. Analyt., 1921, **3**, 90—92.

THE ash from a portion of the liquid (*e.g.*, from 20 c.c. of wine) is dissolved in 10 c.c. of 5% hydrochloric acid, the solution filtered and treated with 0·5 c.c. of hydrogen peroxide; after 15 mins., the solution is boiled to decompose excess of peroxide, 5 c.c. of 1% copper sulphate solution and 1 c.c. of 2% sodium salicylate solution are added, the mixture is boiled and titrated with thiosulphate solution, the end-point being denoted by the disappearance of the violet coloration (ferric salicylate). The copper sulphate acts as catalyst in the reduction of the ferric salt.—W. P. S.

XIXA.—FOODS.

Dough; Relation between the mechanical properties of —— and bread-making. M. Chopin. Bull. Soc. d'Encour., 1921, **133**, 261—273.

AN apparatus is described and figured by means of which it is possible to measure the tenacity of a dough in terms of the effort necessary to cause a sample to assume a given shape in a constant time, and to measure the capacity of the dough to stretch into a thin membrane. It is shown that temperature, composition of the dough, method of working the dough, age of the flour, and length of time the dough is allowed to stand, all have an influence on the results. Measurements with numerous samples of flour show that the difference between the specific volume of bread which can be obtained with a flour and the initial specific volume of the dough from this flour is proportional to the square root of the coefficient of extension of this dough developed in a thin membrane. Thus it is possible to determine the index of swelling during bread-making and the yield of bread from a given flour.—W. G.

Starches, flours, etc.; Commercial classification of ——. Arpin. Ann. Chim. Analyt., 1921, **3**, 74—84.

It is suggested that the word flour be used to describe ground cereals, that the word starch be reserved for the amylaceous products obtained from cereals and grains, and that the amylaceous products of tubers, roots, etc., be called "fecula." Analyses and microscopical characters of these different classes of material are given.—W. P. S.

Milk; Titration of organic acids in ——. B. Kramer and C. H. Greene. Proc. Amer. Soc. Biol. Chem. J. Biol. Chem., 1921, **46**, xxxviii—xxxix.

The application of Van Slyke and Palmer's method for the estimation of titratable organic acid in urine (J. Biol. Chem., 1920, **41**, 567) to milk is described. 10 c.c. of milk, 50 c.c. of distilled water, 2—5 c.c. of 20% $CuSO_4$, and 10 c.c. of 10% suspension of $Cu(OH)_2$ are successively put into a 100 c.c. volumetric flask, repeatedly shaken, made up to 100 c.c. after 15 min., and filtered through a Buchner funnel. 50 c.c. of the filtrate is titrated with $N/10$ hydrochloric acid, using first 0·5 c.c. of 1% phenolphthalein as indicator, and when this has been decolorised ($p_H=8$), adding 5 c.c. of 0·02% "tropaeolin 00" and titrating further until the solution matches the standard (0·6 c.c. of 0·2 N HCl, 5 c.c. of "tropaeolin 00," and water to 60 c.c.). Similar large test tubes are used, and a corrective is applied for the 0·1 N hydrochloric acid used in the blank titration of distilled water from p_H 8·0 to 2·7.—G. B.

Milk; Dialysis indicator method for the determination of the hydrogen ion concentration of ——. B. Kramer and C. H. Greene. Proc. Amer. Soc. Biol. Chem. J. Biol. Chem., 1921, **46**, xlii—xliii.

The dialysis indicator method of Levy, Rowntree, and Marriott is used. 5 c.c. of milk is dialysed in a collodion sac against an equal volume of 0·9% sodium chloride solution; the level of the salt solution is above that in the sac. After at least 5 mins. the external solution is colorimetrically compared with phosphate or acid phthalate standards and Clark and Lubs' indicators. Parallel electrometric estimations showed excellent agreement. The following values for p_H were found: Human milk, 6·8; cow's milk, 6·4; protein milk, 4·8; butter-milk, 4·4. (*Cf.* Lovatt Evans, J. Physiol., 1921, **54**, 353.) —G. B.

Goat's milk; Acidity of —— in terms of hydrogen ion concentration, with comparisons to that of cow's and human milk. E. W. Schultz and L. R. Chandler. J. Biol. Chem., 1921, **46**, 129—131.

Average goat's milk has p_H 6·53, when fresh, and 3·92 when fully soured. For fresh cow's milk Van Slyke and Baker (J., 1920, 130 a) found 6·5—7·2, mostly 6·5—6·76, and other authors 6·52—6·8; the maximum acidity of soured cow's milk is 4·65. Human milk has p_H between 6·86 and 7·46.—G. B.

Milk; Iron as the cause of formaldehyde and diphenylamine reactions [*for nitrates*] *of* ——. F. Reiss. Z. Unters. Nahr. Genussm., 1921, **41**, 26—29.

Milk containing iron yields reactions with formaldehyde and diphenylamine-sulphuric acid reagents indicating the presence of nitrates. The iron may be derived from the cans in which the milk is kept; the colorations obtained can be attributed to the presence of nitrates only when the milk is proved to be free from hydrogen peroxide and from dissolved iron.—W. P. S.

Milk-powder; Determination of moisture in ——. N. Schoorl and S. C. L. Gerritzen. Pharm. Weekblad, 1921, **58**, 370—378.

The determination of moisture in milk-powder by heating for 3—4 hrs., either at 95° or at 103° C., gives results which are 1·6—1·9% too low, as compared with the correct moisture found by exposure *in vacuo* over phosphorus pentoxide for 24 hrs. at 95° C. Addition of sand to the sample does not influence the results. On prolonged heating at 95° C. a very gradual loss in weight takes place, but even after 29 hrs. the correct moisture is not indicated. If drying is continued at 103° C., there is a progressive loss of weight, and at a certain stage decomposition of the milk sugar sets in owing to presence of phosphates in the milk-powder. By drying in air which has been passed through sulphuric acid, a correct moisture figure may be obtained after 36 hrs. A rapid method for moisture determination, giving results correct within 0·1—0·3%, consists in heating the milk-powder in undried air at 110° C. for a period not exceeding 2 hrs., the weighing bottles being placed on an asbestos sheet in the oven to avoid risk of decomposition.—W. J. W.

Casein solutions; Chemical and physical behaviour of ——. J. Loeb. J. Gen. Physiol., 1921, **3**, 557—564.

Extension to casein solutions of conclusions previously arrived at for gelatin and egg albumin that the forces determining the combination between proteins and acids or alkalis are the same forces of primary valency which also determine the reaction between acids and alkalis with crystalloids, and that the valency and not the nature of the ion in combination with a protein determines the effect on the physical properties of the latter. (*Cf.* J.C.S., May.)—G. B.

Proteins; Digestibility of —— in vitro. I. Effect of cooking on the digestibility of phaseolin. H. C. Waterman and C. O. Johns. J. Biol. Chem., 1921, **46**, 9—17.

The protein of the navy bean is rendered more digestible by cooking; 5 minutes' cooking gave a detectable, and 45 minutes' cooking a maximum increase in digestibility.—G. B.

Proteins; Physicochemical method of characterising ——. E. J. Cohn. Proc. Amer. Soc. Biol. Chem. J. Biol. Chem., **46**, iii—iv.

The hydrogen ion concentration at iso-electric point gives the ratio of the acid to the basic dissociation constants (1). By plotting the ratio of acid to protein—and of protein to base (expressed as mols. of HCl or NaOH added to 1 g. of anhydrous iso-electric protein)—against hydrogen ion concentration, a titration curve is obtained, and a slope of a tangent to this curve at the iso-electric point represents the apparent strength of the multivalent protein as acid or base (2). Values of (1) and (2) together with the hydrogen ion concentration at the iso-electric point are tabulated for five proteins and show considerable differences.—G. B.

Lecithin. III. Fatty acids of lecithin of the egg-yolk. P. A. Levene and I. P. Rolf. J. Biol., Chem., 1921, **46**, 193—207.

Methods are given for obtaining lecithin (from egg yolk powder) free from fats, cerebrosides, and saturated lipoids, and with a minimum content of amino nitrogen. On hydrolysis about half the fatty acid was found to be oleic acid, the other half a mixture of palmitic and stearic acids. These facts suggest the existence of more than one lecithin in egg-yolk.—G. B.

Foods; Determination of alkalinity and phosphates in the ashes of ——. J. Tillmans and A. Bohrmann. Z. Unters. Nahr. Genussm., 1921, **41**, 1—17.

A portion of the ash is boiled with an excess of $N/10$ acid, 30 c.c. of 40% calcium chloride solution is added, and the excess of acid is titrated with $N/10$ alkali, using phenolphthalein as indicator; the number of c.c. (A) of $N/10$ acid used is a measure of the alkalinity (carbonate plus oxide). The carbonate may be determined separately. Another portion of the ash (at least 0·2 g.) is boiled for 1 hr. with 100 c.c. of $N/10$ hydrochloric acid, cooled, filtered, and titrated with $N/10$ sodium hydroxide solution, using methyl orange as indicator; the number of c.c. of $N/10$ acid neutralised by the ash is noted (B). Twenty c.c. of saturated sodium oxalate solution is added and the titration is continued until the mixture is neutral to phenolphthalein (C). If the ash is alkaline, orthophosphates (Y) only can be present and their quantity, in mg. of PO_4, is given by the formula $Y=3/2(B-A)\times 3{\cdot}167$. When the ash is not alkaline, and C has a positive value, orthophosphates and pyrophosphates (Z) are present; in this case $Y=3C\times 3{\cdot}167$ and $Z=2(B-2C)\times 4{\cdot}75$. If C has a negative value, pyrophosphates and metaphosphates (U) are present; then $Z=2B\times 5{\cdot}75$ and $U=-C\times 9{\cdot}5$. Milk ash contains very little true alkalinity, and about 30—40% of phosphate ions in the form of orthophosphate; pyro and metaphosphates are not present. Flour ash is free from true alkalinity and contains a mixture of phosphates. Meat (beef and horse) ash is also free from oxides and carbonates but contains a mixture of ortho and pyrophosphates (6—7% as ortho and 47—50% as pyrophosphate ions). Fruit juice ashes consist mainly of carbonate and the phosphate is present wholly as orthophosphate. The alkalinity of cocoa ash consists of about one-third oxide and two-thirds carbonate; orthophosphate is present.—W. P. S.

Pepsin; Use of edestin in determining proteolytic activity of ——. J. F. Brewster. J. Biol. Chem., 1921, **46**, 119—127.

A modification of the method of Fuld and Levison (J., Chem. Soc., 1907, ii., 76) and a method for preparing pure edestin from hemp seeds are described. After mixing various amounts of 1% edestin and $N/10$ hydrochloric acid solutions with equal amounts of 10% sodium chloride in a series of tubes, equal amounts of 1% pepsin are added, and the time necessary to produce a clear solution is noted. —G. B.

Antiscorbutic properties of commercially dried orange juice. J. F. McClendon, W. S. Bowers, and J. P. Sedgwick. Proc. Amer. Soc. Biol. Chem. J. Biol. Chem., 1921, **46**, ix—xi.

The dried preparation (*cf.* following abstract) was about as active in preventing guinea-pig scurvy as an equivalent of fresh juice, so that drying did not significantly impair the antiscorbutic properties. —G. B.

Fat-soluble vitamin. H. Steenbock, M. T. Sell, E. M. Nelson, and M. V. Buell. Proc. Amer. Soc. Biol. Chem. J. Biol. Chem., 1921, **46**, xxxii—xxxiii.

As in the case of yellow and white maize, the fat-soluble vitamin content runs parallel to the content of yellow pigment in different varieties of carrots, sweet potatoes, and squash. In yellow maize the vitamin is localised in the endosperm, which, in distinction from the embryo, contains most of the pigment. Carotin after numerous crystallisations, is still active on rats, but, on the other hand, very active cod-liver oil may be free from yellow pigment. Light, which destroys the pigment, also destroys vitamin. The latter, obtained from alfalfa (lucerne) hay, was not destroyed by hot saponification, nor by hydrogen peroxide or nascent hydrogen. Crystalline acetyl derivatives of the non-saponifiable vitamin fraction were prepared without destruction of the vitamin.—G. B.

Orange juice; Commercial drying of —— *retaining its antiscorbutic properties.* J. F. McClendon and S. M. Dick. Proc. Amer. Soc. Biol. Chem. J. Biol. Chem., 1921, **46**, x—xi.

A dehydrating unit consists of an octagonal chamber 20 ft. in diameter and 20 ft. high, with 12 hot-air ports in three tiers. The upper tier admits air at a velocity of 300 ft. per min., the middle at 600 ft., and the lower at 150 ft. per min. A centrifugal spray is in the centre, and just below the level of the upper tier of ports. It consists of a hollow shaft (admitting the juice) and a head made of a series of concave discs serrated at their margins (12 in. in diameter). Between the discs is a series of grooved collars distributing the juice from the hollow shaft to the concave sides of the discs. The shaft rotates at 5000 revolutions per minute and transforms the juice into a fog. The air currents retard the falling of the spray. The exhaust ports are at the bottom of the cell and so large as not to retard the falling of the dried juice in the dead air space. The incoming air is at 55°—70° C., but evaporation prevents the juice reaching this temperature; moreover, a droplet is only exposed for 1 min. to hot air. Orange juice is one-eighth solids; on evaporation to one-fifth of its original weight the pectin forms a clot from which a syrup oozes, but on evaporation to one-sixth no clot separates. The high content of monosaccharides makes the dried juice hygroscopic. The taste is not affected by drying. Milk may be dried in the same apparatus and then mixed with the orange preparation to restore the antiscorbutic substance lost in pasteurisation.—G. B.

Antiscorbutic property of some desiccated fruit juices. M. H. Givens and I. G. Macy. Proc. Amer. Soc. Biol. Chem. J. Biol. Chem., 1921, **46**, xi—xii.

The juices of lemons, grapes, tomatoes, raspberries, grape fruit, and orange, dried by the Merrell-Soule Co., Syracuse, N.Y., were examined for antiscorbutic substance in regard to guinea-pigs; all except dried grape and raspberry juices still contained a significant amount; in most cases the products were tested 14—20 months after desiccation. Orange juice was still active when tested two years after being desiccated.—G. B.

Available carbohydrate in thrice boiled vegetables. L. O'Reilly and E. H. McCabe. J. Biol. Chem., 1921, **46**, 83—89.

Boiling vegetables three times has been advocated in order to remove carbohydrate for diabetics. After such treatment canned string beans, cauliflower, pumpkin, cabbage, and carrots still retained 0·5% of carbohydrate as determined by means of takadiastase. Boiling with 0·05—0·1% sodium carbonate is much more efficient.—G. B.

Sea water; Method for utilisation of the nutritive salts of ——. J. F. McClendon. Proc. Amer. Soc. Biol. Chem. J. Biol. Chem., 1921, **46**, xxvii.

Ocean water is treated with phosphoric acid (6g per l.) and evaporated to complete dryness, giving a non-hygroscopic, non-bitter product containing iodine for the thyroid, fluorine for the teeth, etc. The product may be added to common salt to prevent caking and improve the nutritive qualities of the latter.—G. B.

Fe *the salt or sodium chloride content of* ——. ps and S. Lomanitz. Texas Agr. Exp. ull. No. 271, 1920. 14 pages.

mine the quantity of added salt in fodders, of the sample is treated with sufficient water ake up 200 c.c. and the mixture shaken for r.; 80 c.c. of the solution is treated with 1 g. of rbon black or 1 g. of lead acetate, filtered, and 50 c.c. of the filtrate is acidified with nitric acid, an excess of $N/10$ silver nitrate solution is added, and the excess then titrated with $N/10$ thiocyanate solution, using ferric alum as indicator. All unmixed fodders contain but small quantities of sodium chloride, with the exception of alfalfa (lucerne) (1·0%), molasses (1·12%), and some meat products (1·3—2·8%).—W. P. S.

Patents.

Oxidising nitrogen [e.g., for use in flour bleaching]; Electrodes for ——. F. H. Loring. E.P. 159,709, 31.12.19.

A flaming continuous arc is drawn out by means of reciprocating metallic electrodes in a magnetic field, the main axis of which coincides with the axis of the electrodes. For this purpose the lower ferromagnetic electrode or an extension thereof is preferably surrounded by a magnetising coil. The upper electrode may be of copper in tubular form or solid, and in the former case air may be drawn through the tube and passed through the arc. The electrode chamber may be of cast iron to serve as return circuit for the magnetic lines.—J. S. G. T.

Bread-making. C. J. Patterson and R. W. Mitchell. U.S.P. 1,370,354, 1.3.21. Appl., 17.11.19.

The moisture content of dough of a given consistency is increased by the addition of calcium peroxide, not exceeding 0·007% of the weight of flour.
—C. A. K.

Milk food products; Manufacture of ——. C. S. Townsend. E.P. 160,234, 10.12.19.

Skim milk and vegetable fatty matter each warmed to 75°—100° F. (24°—38° C.) are agitated together, the mixture is emulsified and allowed to stand until lactic acid ether is produced, whereupon the mass is concentrated or dried.—H. H.

Buttermilk; Condensed ——, *buttermilk powder, and process for making same.* I. S. Merrell, Assr. to Merrell-Soule Co. U.S.P. 1,370,828, 8.3.21. Appl., 8.4.16.

XIXb.—WATER PURIFICATION; SANITATION.

Ice; Water softening for the manufacture of raw water ——. A. S. Behrman. J. Ind. Eng. Chem., 1921, 13, 235—237.

Dissolved solids and impurities in natural waters have a detrimental effect on the quality of the ice prepared from them. Calcium and magnesium compounds, present as "temporary hardness," form milky patches and bubbles, and frequently an opaque under crust, which is deposited as a sediment on melting. Permanent hardness is less objectionable, especially if magnesium compounds, which form white ice, are replaced by calcium compounds. Traces of iron give ice a reddish-brown colour; a muddy or bright yellow colour results from the presence of organic matter; and silica and alumina give the ice a muddy appearance and form a slimy sediment on melting. Sodium salts are deposited as white solids and tend to cause brittleness and cracking. During the process of freezing with air agitation most of the above solids collect as a central "core," and may to a certain extent be removed by suction pumping, followed by introduction of fresh water; this, however, involves considerable labour and expense. A satisfactory method of treatment is found in softening the water with lime; calcium chloride and sulphate retained in the water are not appreciably detrimental, and in any case less so than sodium salts; for this latter reason lime is preferable to soda ash. The objections attaching to sodium salts also render the use of zeolites for softening undesirable.
—W. J. W.

Anthrax spores; Resistance of —— *to chlorine, pickling liquors, formaldehyde, and mercuric chloride.* A. Müller. Arch. Hyg., 1920, 89, 363—372. Chem. Zentr., 1921, 92, I., 501.

A 1·5% chlorine solution killed the spores in 8 hrs., 0·5% solution in 21 hrs. A pickle containing 0·5% of hydrochloric acid was ineffective even after 31 days, 4% hydrochloric acid solution at 37° C. killed the spores after 2 days, 2% hydrochloric acid after 6 days, 1% and 0·5% after 7 days, 0·5% formaldehyde solution killed the spores in 6 days, 5% in 5 days; 0·1% mercuric chloride solution was ineffective in 1 day, and 2% solution in 88 days. At 37° C. 0·1—5% solution of mercuric chloride killed the spores in 20—5 days.—D. W.

Sulphiformin or methanal-sulphurous acid. P. Malvezin. Bull. Assoc. Chim. Sucr., 1921, 38, 210—220.

"Sulphiformin" or formaldehyde-sulphurous acid, $HO.CH_2.SO_3H$, may be prepared by acting on 40% formaldehyde solution with gaseous or dissolved sulphur dioxide, or in a more concentrated form by the interaction of gaseous sulphur dioxide with moist formaldehyde vapour in a suitable apparatus. Various reactions of the product are described, but in a footnote it is stated that the substance first formed on mixing solutions of formaldehyde and sulphurous acid is formaldehyde sulphoxylate, $HO.CH_2.SO_2H$, and this is slowly oxidised to formaldehyde-sulphurous acid. Sulphiformin is readily resolved into its components and accordingly exerts a strongly antiseptic action. A 1% solution has been employed for spraying vines, and experiments described illustrate its toxic action on yeast and bacteria.—J. H. L.

Nitrous fumes in air. Moir. *See* XXIII.

Adsorption by asbestos. Kolthoff. *See* XXIII.

Patents.

Water-treating apparatus. J. Roche and R. J. Parker, Assrs. to Electric Twin Water Purification Corp. U.S.P. 1,371,814, 15.3.21. Appl. 7.2.19.

An apparatus for water treatment comprises a container which is divided into compartments by a series of perforated partitions of electrically conducting material. The compartments contain a filtering agent consisting in alternate compartments of a layer of carbon with a superposed layer of quartz and of quartz alone. Means are provided for connecting alternate partitions with the opposite poles of an electric circuit.—W. J. W.

Distilled water; Process for producing ——. B. Hilliger. G.P. 329,264, 27.5.19.

Steam is distilled from water at less than atmo-

spheric pressure, and is condensed in a chamber surrounding the distillation vessel, whereby the latent heat evolved on condensation is utilised in heating the water remaining in the distillation vessel. The apparatus is very compact, rendering conduction and radiation losses extremely small.
—J. S. G. T.

Filter-elements. E.P. 134,228. *See* I.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Yohimbine; Determination of —— in yohimbé bark. A. Schomer. Pharm. Zentralh., 1921, 62, 169—171.

Fifteen g. of the powdered bark is shaken for 10 mins. with 150 g. of ether, 10 g. of 15% sodium hydroxide is then added, and, after 1 hr., 100 g. of the ethereal layer is drawn off and extracted with successive quantities (20, 10, and 10 c.c.) of 1% hydrochloric acid; the acid extracts are shaken with chloroform to remove impurities, then rendered alkaline with sodium carbonate solution, and extracted with chloroform. The chloroform extract is evaporated, the residue dissolved in alcohol to which is added a few drops of hydrochloric acid, the alcohol is evaporated, the residue treated with ether and evaporated, and finally warmed with 50 drops of alcohol. When most of the alcohol has evaporated 50 g. of chloroform is added, the mixture cooled at 0° C. for 30 mins., and the crystals of yohimbine hydrochloride then collected, dried at 100° C., and weighed. Three samples of bark examined yielded 0·78—1·26% of yohimbine. The crystals of the hydrochloride obtained had m.pt. 272° C., whilst pure yohimbine hydrochloride has m.pt. 285°—290° C.—W. P. S.

Humins and humic acids; Synthesis of ——. J. Marcusson. Ber., 1921, 54, 542—545. (*Cf.* J., 1919; 350 A; 1920, 180 A.)

Furan when treated with concentrated hydrochloric acid gives a pale brown infusible resin, which is converted by fusion with potassium hydroxide into a humic acid. The course of the reaction appears to be: Furan → αδ-dihydroxydivinyl, HO.CH:CH.CH:CH.OH → succinaldehyde. The latter yields the aldol and subsequently the α-peri-difuran, which polymerises with formation of humin. The acidity of the humic acids has been ascribed by Eller and Koch (J., 1920, 717 A) to the presence of phenolic hydroxyl groups; the ready, if incomplete, esterification of these substances when heated with alcoholic hydrogen chloride (3%) and the elimination of carbon dioxide at 250° C. in the presence of superheated steam, however, indicates the presence of carboxyl groups. (*Cf.* J.C.S., May.)—H. W.

Yeast-nucleic acid. S. J. Thannhauser and P. Sachs. Z. physiol. Chem., 1920, 109, 177—182.

No precipitate of the brucine salt of uridinephosphoric acid was obtained by shaking Böhringer's yeast-nucleic acid with water for 24 hrs., concentrating the filtrate under reduced pressure, boiling with brucine, and treatment with alcohol. It is concluded therefore that the yeast-nucleic acid does not contain free uridinephosphoric acid, and that the barium salt obtained by Steudel and Peiser by fractionating yeast-nucleic acid with barium acetate (J., 1921, 60 A) is not that of uridinephosphoric acid.

Nucleic acids of the lymphatic ganglions and of the thymus; Physiological properties of the ——. Conditions for obtaining a thymonucleic acid very active to blood. Doyon. Comptes rend., 1921, 172, 820—821.

The ganglions of the mesentery, carefully freed from membranes and fat, when treated according to Neuman's method, yield a nucleic acid preparation, which is quite white and permits of the preparation of a very stable, limpid, colourless blood plasma. In preparing nucleic acid from the thymus of a calf, the material should be crushed, mixed with water, and allowed to putrefy for 15—18 hrs. before applying Neuman's method, and only 200—300 g. should be used. This gives a very active preparation.—W. G.

Arsphenamine [salvarsan]; Arsenical compounds related to ——. G. W. Raiziss and J. L. Gavron. J. Amer. Chem. Soc., 1921, 43, 582—585.

The undesirable symptoms which sometimes follow intravenous injection of salvarsan are conceivably due to chemical impurities. Some of those possibly present have therefore been examined. 3.5.3′.5′-Tetramino-4.4′-dihydroxyarsenobenzene tetrahydrochloride, from the corresponding dinitrohydroxyphenylarsinic acid and sodium hydrosulphite, exerts a curative influence on trypanosome infections, and exists in two forms, one easily soluble in methyl alcohol, the other sparingly. The preparation of 3.5-diamino-4-hydroxy- and 3-amino-4-hydroxy-phenylarsinic acids (G.P. 224,953; J., 1910, 1178) and the reduction of their acetyl derivatives to arsenobenzene derivatives are described. (*Cf.* J.C.S., May.)—J. K.

Neoarsphenamine [neosalvarsan]; Chemistry of —— and its relation to toxicity. G. W. Raiziss and M. Falkov. J. Biol. Chem., 1921, 46, 209—221.

Three commercial samples were examined, particularly as regards the distribution of the sulphur. A lower arsenic content may be due to the presence of uncombined sodium formaldehyde-sulphoxylate, sulphate, or choride. The arsenic:nitrogen ratio equals the theoretical in good samples and may be taken as an index of purity. The amount of iodine necessary for complete oxidation is in excess of that required merely by arsenic; this is attributed to uncombined sulphoxylate; sulphoxylate combined with the amino group does not react with iodine. The amount of combined sulphoxylate indicates that the samples were mixtures of mono- and di-substituted products.—G. B.

Neoarsphenamine [neosalvarsan]; Examination of ——. A. D. Macallum. J. Amer. Chem. Soc., 1921, 43, 643—645.

The best criterion of the purity of neosalvarsan consists in the determination of the sulphoxylate group, $\cdot CH_2OSONa$, by subtracting from the total reducing power, determined by iodine, that due to free reducing substances and to arsenic, and multiplying the result by 3·9553. Details of the estimations are given, although it is not possible to obtain a product in which the ratio sulphoxylate group:arsenic is exactly 1:2, the best preparations approximate closely to this value.—J. K.

Adrenaline solutions; Preparation and preservation of ——. F. Richard and M. Malmy. J. Pharm. Chim., 1921, 23, 209—214.

A solution which keeps well is prepared by dissolving 1 g. of adrenaline in 100 c.c. of 0·75% sodium chloride solution containing 1 g. of dissolved sulphur dioxide and then diluting the mixture to 1000 c.c. with 0·75% sodium chloride solution which has been sterilised previously.
—W. P. S.

Saccharin; Detection of ——. A correction. L. Thevenon. J. Pharm. Chim., 1921, 23, 215.

A reaction described recently (J., 1921, 60 A) is not characteristic of saccharin, since one of the

reagents used (β-naphthol) itself yields a red coloration with nitrous acid in dilute acid solution.
—W. P. S.

Aristol. G. H. Woollett. J. Amer. Chem. Soc., 1921, **43**, 553—561.

By the action of one, two, and four equivalents each of iodine and alkali hydroxide on thymol, iodothymol, a gum almost completely soluble in alcohol, and aristol are respectively obtained, and iodothymol can be converted into the other products by treatment with appropriate amounts of iodine and alkali hydroxide. Ordinary aristol is a mixture of the gum (ca.40%) with a faintly yellow product, insoluble in alcohol, resembling the leuco derivative of Lautemann's Red (Annalen, 1861, **120**, 309) in its oxidisability to a red product, $(C_{10}H_{11}IO)_n$, sparingly soluble in alcohol. The colour of fresh aristol is due, not to adsorbed iodine, but to this oxidation product, which suffers gradual reduction and liberates iodine from the gummy portion. Lautemann's Red similarly liberates iodine from iodothymol. (*Cf.* J.C.S., May.)—J. K.

Dicyanodiamide; Action of sulphuric acid on ——. T. L. Davis. J. Amer. Chem. Soc., 1921, **43**, 669—672.

It is shown that the formation of guanidine by the action of 61% sulphuric acid on dicyanodiamide is slow at 100° C., but an 85% yield is obtained after six hours at 140° C. and the yield is only slightly improved at 200° C. At the higher temperature carbon dioxide is produced in excess of that calculated, probably owing to some further hydrolysis of guanidine. (*Cf.* J.C.S., May).—J. K.

Perchloromethylmercaptan. O. B. Helfrich and E. E. Reid. J. Amer. Chem. Soc., 1921, **43**, 591—594. (*Cf.* Frankland and others, J., 1920, 256 t).

Perchloromethylmercaptan is best obtained by chlorinating carbon bisulphide at 20°—30° C. in diffused light in presence of 0·3—0·4% of iodine until its volume is doubled. Sunlight, a temperature above 30° C., and over-chlorination favour production of carbon tetrachloride, and no other "carrier" than iodine is suitable. By reduction with iron and hydrochloric acid, thiophosgene and carbon tetrachloride are obtained, and the latter is the sole product of boiling the compound with iron alone. Zinc and hydrochloric acid apparently convert it into methane. (*Cf.* J.C.S., May.)—J. K.

Nitrotartaric acid. A. Lachman. J. Amer. Chem. Soc., 1921, **43**, 577—581.

Nitrotartaric acid is the dinitrate of tartaric acid, $CO_2H.CH(ONO_2).CH(ONO_2).CO_2H$, since it yields by hydrolysis with fairly concentrated mineral acid nitric and tartaric acids, but with water alone gives rise to nitrous and dihydroxytartaric acids, with some tartronic and oxalic acids, whilst the last two are the only organic acids produced in presence of alkali. In explanation of these reactions, it is suggested that the acid reacts in a pseudo-form, $CO_2H.C(OH)(ONO).C(OH)(ONO).CO_2H$. Although the moist acid decomposes with some violence below 100°, it is stable at the boiling point of xylene when dry. (*Cf.* J.C.S., May.)—J. K.

[Organic] acids; Identifiation of ——. *VI. Separation of acids by means of phenacyl esters.* J. B. Rather and E. E. Reid. J. Amer. Chem. Soc., 1921, **43**, 629—636.

A number of illustrations, chosen from naturally occurring organic acids, are given to show that the constituents of a mixture of such acids may frequently be identified by preparation of their phenacyl esters from the sodium salts (J., 1920, 501 a), followed by fractional crystallisation.—J. K.

Alkylamines; Detection of volatile —— *in the presence of ammonia and volatile tertiary alkylamines in the presence of volatile primary and secondary alkylamines.* H. E. Woodward and C. L. Alsberg. J. Biol. Chem., 1921, **46**, 1—7.

Incipient decomposition of foodstuffs may be recognised by the presence of traces of amines, which are, however, difficult to distinguish from the ammonia also present. In dilute alkaline solution ammonia reacts with formaldehyde to form hexamethylenetetramine, but methylamines (*e.g.*, 10 c.c. of 0·01—0·02 *N* amine distilled into 1 c.c. of 40% formaldehyde) furnish methyl alcohol and formic acid. The formic acid is detected by a solution containing 180 g. of mercuric bromide and 120 g. of potassium bromide per litre, which gives on warming a white precipitate of mercurous bromide, when a quantity of formic acid corresponding to 0·5 mg. of amine nitrogen is present. Ammonia, mono- and dimethylamine also give a white precipitate with mercuric bromide, but this is soluble in excess of formaldehyde. Trimethyl and triethylamine form with potassium mercuric iodide (450 g. HgI_2 and 330 g. KI per litre), yellow crystalline compounds melting at 136° and 77° C. respectively, if excess of potassium iodide be avoided. Trimethylamine is still precipitated at 3 mg. in 5 c.c.; dimethylamine requires to be at least six times as concentrated. At suitable concentrations the tertiary amine only is precipitated, and then may be obtained pure by distilling the mercuric iodide compound with sodium hydroxide and sulphide.—G. B.

Catalytic hydrogenations over copper. P. Sabatier and B. Kubota. Comptes rend., 1921, **172**, 733—736.

The catalyst is prepared by slowly reducing black tetracupric hydroxide at 200° C. When benzaldehyde and hydrogen are passed over this catalyst at 350° C. the main products are benzene and carbon monoxide, together with some toluene. Under similar conditions acetophenone yields ethylbenzene, and ethyl phenyl ketone yields propylbenzene. Benzoylpropanone is, however, decomposed, giving acetophenone, acetaldehyde, ethyl alcohol, and a little ethylbenzene. Benzoquinone gives almost exclusively quinol. Phthalic anhydride at first yields benzene and carbon monoxide, but soon the action changes and phthalide is formed, together with some toluene and carbon monoxide as products of an accessory change.—W. G.

Catalysts; Influencing of —— *and specifically active catalysts.* K. W. Rosenmund and F. Zetzsche. Ber., 1921, **54**, 425—437.

The catalytic reduction of acid chlorides to aldehydes (J., 1918, 442 a) by means of hydrogen in the presence of palladinised barium sulphate is somewhat uncertain, and the effect of a large number of substances on the conversion of benzoyl chloride into benzaldehyde in benzene, toluene, and cumene solution has therefore been investigated. With pure materials, practically no aldehyde is formed; the most effective addition is "sulphured" quinoline (quinoline boiled under a reflux condenser for 5—7 hrs. with one-sixth of its weight of sulphur); specimens of the latter which have been used previously appear to be even better reagents than the freshly-prepared material, the yields reaching 88%. Under similar conditions, *o*-chlorobenzoyl chloride gives *o*-chlorobenzaldehyde (more than 70%), *p*-nitrobenzoyl chloride yields *p*-nitrobenzaldehyde (91%), and phenylacetyl chloride is converted into phenylacetaldehyde (80%). This appears to be the first recorded instance in which a specific catalyst has been artificially produced by the addition of a chemically well-defined substance. (*Cf.* J.C.S., May.)—H. W.

Halogen united to nuclear carbon and its replacement by other substituents. III. Preparation of arsinic and sulphonic acids. K. W. Rosenmund. Ber., 1921, **54**, 438—440.

Phenylarsinic acid is obtained in small yield when bromobenzene, normal potassium arsenite, water, and copper sulphate are heated at 180°—200° C. Similarly, potassium *o*-bromobenzoate, potassium arsenite, copper powder, and aqueous alcohol give *o*-carboxyphenylarsinic acid at about 90° C. Benzenesulphonic acid is prepared from bromobenzene, sodium sulphite, and copper sulphate in the presence of water at 180° C., and subsequently at 200° C. Similarly, *p*-bromotoluene gives toluene-*p*-sulphonic acid. Sodium *o*-bromobenzoate and sodium sulphite in like manner yield *o*-sulphobenzoic acid at 120°—130° C., or when boiled under a reflux condenser. *m*-Sulphobenzoic acid is prepared from *m*-bromobenzoic acid at 170°—180° C. —H. W.

Cyanic acid; Synthesis of —— by oxidation of organic substances. New methods of detecting this substance. R. Fosse. Bull. Soc. Chim., 1921, **29**, 158—203.

A *résumé* of work already published (*cf.* J., 1919, 655 A; 1920, 747 A, 781 A).—W. G.

N-Butyl alcohol and water; Specific gravities of mixtures of ——. Y. D. Wad and A. G. Gokhale. J. Ind. Inst. Sci., 1921, **4**, 17—25.

The specific gravities of mixtures of *n*-butyl alcohol and water covering the entire range of miscibility were determined at temperatures of 20° and 25° C., and from the results curves were made and tables are given showing the specific gravities of aqueous butyl alcohol of all concentrations, from which the following figures are taken:—

% Water.	Sp. gr. at 20° C.	Sp. gr. at 25° C.	% Water.	Sp. gr. at 20° C.	Sp. gr. at 25° C.

Aliphatic alcohols; Purification and some physical properties of certain ——. R. F. Brunel, J. L. Crenshaw, and E. Tobin. J. Amer. Chem. Soc., 1921, **43**, 561—577.

Owing to their hygroscopic nature it was not found possible to obtain satisfactorily exact boiling points of the alcohols tested, except in presence of drying agents. Of these aluminium amalgam (J., 1895, 898) was the most satisfactory owing to the rapidity of its action; lime and baryta were ultimately equally effective, but metallic calcium, whilst speedy in its action, is not as valuable for this purpose, possibly owing to the presence of an impurity. Boiling points, densities, and refractivities of a number of alcohols are recorded (*cf.* J.C.S., May).—J. K.

Methyl alcohol; Process for the purification of ——. A. Lanzenberg and J. Duclaux. Bull. Soc. Chim., 1921, **29**, 135—136.

Commercial methyl alcohol usually contains appreciable amounts of acetone in addition to other impurities of higher boiling point. For its purification 1 pt. of alcohol is mixed with 7·5 pts. of chloroform, the mixture distilled, and the fraction boiling at 52·5°—53·5° C. collected. From this fraction the alcohol is extracted with water, the aqueous alcohol being subsequently distilled and rectified in the usual manner.—W. G.

Pepsin. Brewster. *See* XIXa.

Patents.

Immunising serum; Process for purifying and enriching ——. Elektro-Osmose A.-G. (Graf Schwerin Ges.). E.P. 104,688, 7.3.17. Conv., 7.3.16.

Serum which has been freed from euglobulin and electrolytes, preferably by an electro-osmotic process, is placed in the middle chamber of a three-cell electrolytic apparatus; the anodic diaphragm consists of an animal substance, such as hide or bladder, which behaves positively, and the cathodic diaphragm of a vegetable material, such as parchment paper, which behaves negatively to the electric current. The albumins migrate to the anode chamber, whilst the fatty substances separate in the middle chamber. The serum obtained is clear and may be evaporated under reduced pressure to dryness or to any desired concentration. The electric current is applied preferably at high tension and by previous treatment with a relatively low tension it is possible to eliminate the mineral constituents and globulins in the same apparatus.—D. F. T.

Dialkyl sulphates; Manufacture of ——. L. Lilienfeld. E.P. 143,260, 14.5.20. Conv., 15.12.13.

Dialkyl sulphates are prepared by the direct action of sulphur trioxide on aliphatic alcohols in presence of dehydrating agents, such as phosphorus pentoxide or anhydrous sodium sulphate or copper sulphate, and in presence or absence of inert diluents, such as chloroform, carbon tetrachloride, and the like.—J. H. L.

Caffeine; Extraction of —— from coffee beans. H. C. E. Lombaers. E.P. 144,998, 19.3.20. Conv., 13.6.19.

In order to avoid condensation of steam and consequent depreciation of the coffee beans during the preliminary "opening up" before the removal of caffeine, the beans are previously raised to the steam temperature. The subsequent steam treatment occupies about 3 hrs., and causes no loss of the valuable extractable and aromatic constituents. After the extraction of the caffeine the beans are again heated before the application of steam for the removal of the extraction agent.—D. F. T.

Methane; Manufacture of ——. Farbw. vorm. Meister, Lucius, und Brüning. E.P. 146,114, 22.6.20. Conv., 1.7.19. Addn. to 146,110 (J., 1921, 26 A).

In the catalytic reduction of carbon monoxide to methane by means of hydrogen, a product of greater purity and free from hydrogen and carbon monoxide is obtained by using carbon dioxide in the later stages of the reaction in the proportion of somewhat more than 1 vol. to every 4 vols. of hydrogen present. Nearly all the hydrogen is thereby converted into methane and water, the latter being periodically separated, whereas with carbon monoxide deposition of carbon commences when the proportion of hydrogen is allowed to become less than 5 vols. for every vol. of monoxide present. The excess of carbon dioxide is finally removed from the product by absorption by lime or other means, and traces of hydrogen by passing over heated copper oxide.—G. F. M.

Tobacco; Process for the treatment of ——. O. Braemer. E.P. 160,128, 25.10.20.

Tobacco is impregnated with a solution of caffeine. —D. F. T.

1-*Methyl-2-amino-4-isopropyl-5-nitrobenzene.* C. E. Andrews, Assr. to The Selden Co. U.S.P. 1,314,923, 2.9.19. Appl., 22.9.17.

Cymene is treated with a mixture of sulphuric and nitric acids and the nitrocymene reduced to 1-methyl-2-amino-4-isopropylbenzene. This is converted into the 2-acetamino derivative, which on nitration and hydrolysis yields 1-methyl-2-amino-4-isopropyl-5-nitrobenzene, or, if reduced before hydrolysis, the 2.5-diamino compound.

Dimethyl-di-isopropylbenzidine and process of making same. C. E. Andrews, Assr. to The Selden Co. U.S.P. 1,314,924, 2.9.19. Appl., 15.9.17.

Crude mononitrocymene is reduced in alkaline solution to hydrazocymene, which when subjected to the benzidine transformation (treatment with hydrochloric acid) is converted into dimethyl-di-isopropylbenzidine, b.p. 250° C.

Methyl-amino-isopropylbenzenesulphonic acid and process of making same. C. E. Andrews, Assr. to The Selden Co. U.S.P. 1,314,927, 2.9.19. Appl., 14.9.17.

Aminocymene is heated with 98% sulphuric acid for 10 hrs. at about 200° C., the product is neutralised with alkali, boiled with charcoal, and precipitated with acid. 1-Methyl-2-amino-4-isopropylbenzene-5-sulphonic acid is obtained.

Arsenical compound. W. A. Jacobs, W. H. Brown, M. Heidelberger, and L. Pearce, Assrs. to Rockefeller Institute for Medical Research. U.S.P. 1,315,127, 2.9.19. Appl., 13.6.18.

A solution of N-(arsenoaryl)bis-α-aminoacylarylamines (U.S.P. 1,280,123; J., 1919, 268 a) in an alkali hydroxide is evaporated under reduced pressure or precipitated with alcohol to produce alkali salts of, *e.g.*, N-(*p*-arsenophenyl)bis-glycyl-*m'*-aminophenol,

$$\begin{gathered}\mathrm{MO.C_6H_4.NH.CO.CH_2.NH.C_6H_4.As:}\\ \mathrm{As.C_6H_4.NH.CH_2.CO.NH.C_6H_4.OM,}\end{gathered}$$

which are of value in trypanosomal or spirochætal diseases.

Organic substances; Process for electrolytic treatment of —— without the use of a diaphragm. Farbenfabr. vorm. F. Bayer und Co. G.P. 310,023, 20.10.16.

The electrolyte is made up of liquids of different density, one of which contains the organic substance to be treated in solution. Means are provided to prevent the gases liberated at the opposite pole from coming into contact with the liquid containing the substance undergoing treatment. The method may be used for the preparation of piperidine from pyridine and of pinacone from acetone.—A. R. P.

Organic compounds; Production of —— from compounds containing a smaller percentage of hydrogen. C. Neuberg, A., K., and R. Welde, and E. Heisler. G.P. 330,812, 21.3.14.

Reduction of organic compounds, *e.g.*, benzaldehyde to benzyl alcohol, nitrobenzene to aniline, aldol to butyleneglycol, nitromethane or nitroethane to methyl- or ethylamine, or quinone to quinol, is effected by the addition of yeast preparations, or a fermenting mixture of yeast and sugar solution, to the compounds. When reduction is complete, the product is isolated from the mixture. —L. A. C.

Double salt of glycerophosphoric and lactic acids; Process for the preparation of a ——. E. Merck, Chem. Fabr., and L. Weber. G.P. 331,695, 14.4.20.

Calcium or ferric glycerophosphate is allowed to react with the corresponding lactate, and the resulting dark red-brown solution is evaporated at a low temperature to recover the readily soluble double salt. The solutions on boiling do not deposit either calcium or ferric glycerophosphate.—A. R. P.

Chlorides of aromatic carboxylic acids; Process for the preparation of ——. Badische Anilin- und Soda-Fabr. G.P. 331,696, 17.7.14.

Good yields of aromatic acid chlorides are obtained by heating the corresponding trichloride (1 mol.) with water (1 mol.) in the presence of concentrated sulphuric acid and ferric chloride as catalysts. Thus benzotrichloride yields benzoyl chloride, and 2.4-dichlorobenzotrichloride yields 2.4-dichlorobenzoyl chloride as a colourless oil boiling at 152°—155° C. under 30 mm. pressure.—A. R. P.

Albumins; Combination of metals with ——. K. Kottmann, Assr. to Society of Chemical Industry in Basle. U.S.P. 1,371,380–1, 15.3.21. Appl., 27.9.16 and 26. 5.17.

See E.P. 110,936 and 115,686; J., 1917, 1289; 1918, 442 a.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic density, light intensity, and exposure time; Relation between ——. F. E. Ross. Communication No. 93 from Research Lab. of Eastman Kodak Co. J. Opt. Soc. Amer., 1920, 4, 255—273.

The formulæ previously suggested by Abney, Hurter and Driffield (J., 1890, 455), Elder, and Channon to express the relation between exposure and image density are examined mathematically and as to their agreement with the experimental values for two emulsions of different type, the one (a) having a high development factor and a short foot, the other (b) having a low development factor and a long foot. Each one is shown to fail on some theoretical consideration and shows also appreciable discrepancy between calculation and experiment, which is more marked with emulsion A than with emulsion B. Taking as the simplest assumptions warranted by available data that the sensitive grains of a plate may be divided into n groups, each having the same silver content and increasing in sensitiveness by the constant factor, r, and that each group as a whole obeys the mass action law, the formula deduced is

$$\mathrm{D}=d_m\left[1-\frac{1}{n}\sum_{S=0}^{S=n-1} e^{-\kappa r^{s} I t}\right]$$

where d_m is the maximum density obtainable, κ is the sensitivity factor, r the common ratio of the sensitivities of the various groups, I the acting intensity, and t the exposure time. The method for determining the various constants is developed and calculated compared with experimental values for plates A and B as before; agreement is close for B but not for A. The equations suggested by Schwarschild [$I\ t^p=\mathrm{C}$] and by Kron

$$\left(\phi=t.I.10^{-\frac{a}{2}\sqrt{(\log I/I_0)^2+1}}\right)$$

to express the relation between I and t for equal effects on a photographic plate (which does not obey the reciprocity law), are discussed mathematically and some pecularities deduced which necessitate further experimental work. Assuming Schwarzschild's expression to hold, a method is deduced for determining p from the values obtained for the development factors for a time scale and an intensity scale exposure.—B. V. S.

Grain size and sensitometric properties of [photographic] emulsions. E. P. Wightman and S. E. Sheppard. Brit. J. Phot., 1921, **68**, 169—172.

This is chiefly a discussion and comparison of papers by Ross (*cf. supra*), Slade and Higson (J., 1921, 27 A), Svedberg (J., 1920, 705 A), and Higson (J., 1921, 98 A). Higson's suggestion that the size of a developed grain is approximately four times that of an undeveloped grain is shown to be inconsistent with data taken from his own and Svedberg's work.—B. V. S.

"Photographic plate; Action of light on the ——," and "The photochemical law of the silver halide grain": a criticism. L. Silberstein and S. E. Sheppard. Phot. J., 1921, **61**, 205—206.

Objection is raised to the conclusion, in the paper by Slade and Higson (J., 1921, 27 A) on which that of Higson (J., 1921, 98 A) is based, that light is not absorbed in quanta by the photographic plate; the statement is based on the observed fact that the rate of conversion of silver bromide grains to the developable condition is not proportional to the light intensity and to the number of grains still unchanged, a fact which has no reference to the quantum theory. It is pointed out that after defining "P," the probability of any grain becoming developable in unit time, from the equation $dx/dt = P(a-x)$, it is assumed that P is a function of only I and t and not of x. Further it is stated that the method of arriving at the complete law for the photographic plate by multiplying together the two functions obtained by consideration of the cases when I is variable and t constant and when t is variable and I constant, is mathematically invalid, and the resulting equation is not therefore justified. Other minor criticisms are also put forward.
—B. V. S.

Colloid chemistry and photography. LII. Acceleration of development by dyes and neutral salts. Lüppo-Cramer. Kolloid-Zeits., 1921, **28**, 174—175.

The accelerating effect of certain basic dyestuffs on alkaline developers, notably that of Phenosafranine on quinol, has its analogue in a recently observed accelerating effect of certain acid dyes on acid (physical) developers. Thus plates bathed in Erythrosin solution and developed in an acid silver-amidol bath show quicker development; it is preferable, as in all cases of physical development, to treat the plates, before development, in iodide solution which opens up the grain ("lays bare the exposure germ"). Phenosafranine under the same conditions gives a reduction of speed of development. Physical developers are also quickened by addition in considerable concentration of neutral salts such as potassium nitrate and sodium sulphate.
—B. V. S.

High-speed radiography and radiometallography. T. Thorne-Baker and L. A. Levy. Phot. J., 1921, **61**, 158—166.

By coating a plate first with a special type of light-sensitive emulsion and then with a solution of gelatin containing calcium tungstate in suspension, a composite plate of very high speed to X-rays is obtained. The silver bromide emulsion has as nearly as possible a spectral sensitiveness corresponding with the fluorescence produced by calcium tungstate when excited by X-rays, the spectrograph of which shows maxima at $\lambda = 24$ to $25\mu\mu$, $31\mu\mu$, and $48\mu\mu$ respectively. The ultra-violet sensitiveness is particularly high and the plate is liable to fog in development when using dark room light filters which are not completely opaque to ultra-violet. The gelatin for the emulsion is specially hardened to stand soaking in water at 115°—120° F. (46°—49° C.) without softening. The calcium tungstate for the upper film is prepared as an amorphous powder by precipitation, then carefully purified, treated with a very small quantity of impurity, and heated to 1000° C. in a carefully controlled electric furnace. The fine crystals which are thus produced are graded, the medium sized ones, having a diameter a little less than that of ordinary silver-bromide plate grains, being used. The calcium tungstate is applied to the light-sensitive film in a solution of a very soft gelatin which easily dissolves in water at 100° F. (38° C.). The coating conditions are such that the grains of tungstate settle into close contact with the sensitive film, thus giving maximum efficiency and enabling a small quantity of salt so applied to have as great an intensifying effect as the much larger quantity required for an ordinary intensifying screen. In use the plates after exposure are placed in water at about 105° F. (40° C.) which softens and washes away the upper film, the plate being then developed in the usual way, but preferably with an increase of concentration of the developer because of the lower permeability of the film. A hard X-ray tube gives better results and shorter exposures than a soft tube, the full advantage as to speed being obtained with the former only. For this reason the plates are also particularly suitable for radio-metallography.—B. V. S.

Pinaflavol, a new [photographic] sensitiser for green. J. M. Eder. Phot. Korr., 1921, **58**, 29—31. E. König. Phot. Runds. Brit. J. Phot., 1921, **68**, Col. Suppl., 16.

Pinaflavol (M., L., and B) is one of a new class of basic yellow dyes which are soluble in water and, like Pinacyanol, are stable towards acetic acid but are decolorised by mineral acids. Applied to the photographic plate either by addition to the emulsion or by bathing, Pinaflavol confers a marked sensitiveness in the green and yellow, extending to the D line and practically without the gap in the blue-green shown by plates sensitised by Erythrosin. In three-colour work Pinaflavol plates have the advantage over Pinaverdol plates, in that the relatively sharp ending of the spectral sensitiveness in the yellow enables their use for exposure to green light behind a yellow screen instead of behind a green screen; exposures are considerably reduced because of the greater transparency to green of yellow dyes.—B. V. S.

Desensitisers. E. König and Lüppo-Cramer. Phot. Runds., 1921, 37—38.

Dyestuffs of other classes than the Safranine group (*cf.* J., 1921, 99 A), containing several amino groups, *e.g.*, Chrysoïdine, are somewhat active as desensitisers; those with only one amino group, such as Congo Red, are quite without action. The replacement of the hydrogen of the amino group by methyl has no effect on the desensitising power.
—B. V. S.

Desensitisers: New application of ——. (Handling of X-ray plates in yellow light without use of a preliminary bath and without addition to the developer). Lüppo-Cramer. Phot. Korr., 1921, **58**, 40—43.

X-ray plates treated with Phenosafranine or similar desensitiser have their sensitiveness to light reduced much more than that to X-rays. This is explained as being due to the fact that light action occurs only on the surface of the silver bromide grains which is protected in the desensitising process by deposition of the dye, while the action of X-rays occurs throughout the whole grain, the interior of which is not protected by dye deposition. After a treatment with Phenosafranine (1/20000), measurements by E. Mauz showed a reduction of X-ray sensitiveness of 25 to 30% in the neighbourhood of the threshold density values, but practically no reduction in the more exposed parts, while the reduction of light sensitiveness permitted development by a strong light.—B. V. S.

Desensitising—an oxidation process. Lüppo-Cramer. Phot. Ind., 1921, 259.

It is suggested that the action of desensitisers is an oxidising action on the latent image, which is bleached if exposed to light in the presence of certain desensitising dyes. Plates which are uniformly exposed, then dyed and then exposed to a subject, give reversed images showing definite sensitiveness. If silver bromide diapositive plates are exposed, converted into iodide, and then stained, the silver iodide complex is strongly colour-sensitive.—B. V. S.

Colour-toning and negative intensification; The mordant dye process for ——. F. E. Ives. Brit. J. Phot., 1921, 68, 186—187.

The mordant dye process previously described (*cf.* J., 1921, 99 A) for the production of three-colour transparencies is adaptable to the toning of prints on glass or celluloid but not on paper. The bleaching bath recommended is potassium ferricyanide 5 pts., ammonium bichromate 1 pt., glacial acetic acid 110 pts., and water 13,000 pts. The print is placed dry in the bleaching bath for ½ to 2 mins., no bleaching action being visible, washed for about 5 mins., and transferred to the dye bath. Suitable dyes are Malachite Green, Safranine, Phenosafranine, Rhodamine, and Auramine, made up to a strength of about 1:17000 in water slightly acidified with acetic acid. The process is also adaptable to negative intensification if suitable non-actinic colours are selected, for which purpose a mixture of Victoria Green and Safranine is recommended. —B. V. S.

Silver removal process; New photographic ——. A. Steigmann. Kolloid-Zeits., 1921, 28, 175—176.

Silver is removed, easily and completely, as the metal, in comparatively pure state, from silver solutions such as used "hypo" baths by the use of hydrosulphite. A litre of used "hypo" requires 6—8 g. of hydrosulphite and about the same quantity of caustic soda, about 4 g. of metallic silver being precipitated. It is preferable to work at 50°—60° C. "Hypo" baths so treated may be used again, since the oxidation of hydrosulphite results in the formation of sulphite and thiosulphate. —B. V. S.

Photographic registration of chemical reactions. Jolibois. *See* XXIII.

Patents.

Coloured pictures; Process for making ——. A. Traube. E.P. 147,005, 6.7.20. Conv., 1.2.16.

A picture consisting of a silver image which has been copper-toned (converted to mixed silver-copper ferrocyanide) is further toned by treatment with a solution of a basic dyestuff, about 5 mins. in a dye bath of 1/1000 strength being generally sufficient; the excess of dye is removed from the gelatin by a short washing in water. The transparency of the dyed copper picture is very high and may be still further increased by the removal of the silver ferrocyanide contained in it by treatment with a weak soda fixing solution. A large number of basic dyes are suitable for use in this process, so that almost any desired tone can be obtained.—B. V. S.

Photographic developer and method of developing latent images. A. S. McDaniel and A. H. Nietz, Assrs. to Eastman Kodak Co. U.S.P. 1,370,896, 8.3.21. Appl., 10.4.17. Renewed 4.9.20.

Diaminophenolsulphonic acid, in alkaline solution, is used as a photographic developer. —B. V. S.

Photographic film. P. C. Seel, H. Combs, and R. Kemp, Assrs. to Eastman Kodak Co. U.S.P. 1,370,922, 8.3.21. Appl. 10.5.20.

A film of nitrocellulose containing aliphatic alcohols with four or five carbon atoms and castor oil to increase the flexibility is provided with a substratum coating before application of the sensitised coating.—B. V. S.

Negative tracing paper [blue print paper]; Process for improving the keeping quality of ——. E. Merck, Chem. Fabr., and L. Weber. G.P. 331,745, 10.2.20.

An indifferent salt, such as acid ammonium oxalate or acid ammonium phosphate, which is neither light-sensitive nor produced as a consequence of the reactions following light exposure, is added to the sensitising ferric oxalate preparation.—B. V. S.

Photographic material; Colour-sensitised ——. F. F. Renwick and O. Bloch, Assrs. to Ilford, Ltd. U.S.P. 1,372,548, 22.3.21. Appl., 21.11.18.

See E.P. 133,770 of 1918; J., 1919, 926 A.

XXII.—EXPLOSIVES; MATCHES.

Detonation; Transmission of ——. E. Kayser. Z. ges. Schiess- u. Sprengstoffw., 1921, 16, 9—10, 25—27, 33—35.

In tests for determining the transmission of detonation by air or various solid surfaces, the following results were obtained with a safety explosive consisting of ammonium nitrate, 81%; trinitrotoluene, 17%; and flour, 2%: in air, 6 cm.; on hard ground, 7½ cm.; on a 10 mm. iron plate, 8 cm.; on loose sand, 8½ cm.; and in an iron tube of 37 mm. int. diam. and 2·5 mm. thickness, buried in the ground, 60 cm. The influence of the position of the detonator in the charge was illustrated by firing three charges in which the detonator was placed at the end remote from the test charge, in the centre, and at the end adjacent to the test charge, respectively; detonation was communicated at distances of 7, 5, and 3 cm. Although detonators do not transmit the detonation shock beyond ½ cm., their own sensitiveness to detonation was evidenced by placing them concentrically at different distances from a vertical cartridge with their open ends towards it; positive results were obtained at a distance of 66 cm. The application of the formula $d=m\sqrt{P}$ (d is the distance through which detonation is transmitted, P is the mass of the explosive, and m is a constant) for measuring the intensity of transmitted shock in the case of cartridges used in practice was investigated in eleven tests each with cartridges of different dimensions and weights. The distance through which transmission is effective, measured from the centre of gravity of the cartridge, is proportional to the length and diameter of the charge. The average value for m was found to be 1·230. Although reduction of sensitiveness of an explosive both to the initial detonation impulse and to mechanical shock is accompanied by reduced power of transmission, increased sensitiveness does not necessarily imply readier detonation or improved propagation. Thus, addition of charcoal to ammonium nitrate and TNT explosives, or of calcium silicide to ammonium nitrate and dinitronaphthalene explosives, increases the sensitiveness to the falling weight, but causes increased inertness to detonation and reduces the distance through which the detonation shock is transmitted.—W. J. W.

Potassium chlorate. Wolcott. *See* VII.

Patents.

Explosives. E. von Herz. E.P. 145,791, 2.7.20. Conv., 25.1.19.

Cyclotrimethylenetrinitramine prepared by nitration of a cyclotrimethylenetriamine derivative, specially hexamethylenetetramine or cyclotrimethylenetrimethyltriamine, is a white, crystalline powder, m.p. 200° C., sp. gr. 1·82, insoluble in water, slightly soluble in alcohol, and more readily soluble in acetone and glacial acetic acid. It is stated to have exceptionally marked explosive properties, whilst being at the same time non-sensitive to shock and friction, and stable even at high temperatures. Its velocity of detonation at maximum density is 8500 m.p.s.; heat of explosion, 1597 cals. per kg.; volume of gas liberated, 905 l. per kg. Either alone, or mixed with other explosives or constituents, it may be used for bursting charges for projectiles, for blasting purposes, or in detonators and fuses.—W. J. W.

Explosives; Process of producing desensitised —— and products thereof. K. A. Gillespie, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,370,015, 1.3.21. Appl., 3.6.18.

An explosive contains undried nitrostarch which is desensitised by the presence of water and an oil. —W. J. W.

Explosive, and process of making explosives. J. Barab, Assr. to The Commercial Research Co. U.S.P. 1,371,215, 15.3.21. Appl., 14.7.17.

A liquid explosive, which is insensitive to friction, consists of an olefine glycol dinitrate.—W. J. W.

Fertilisers from ammonium nitrate explosives. G.P. 329,960. *See* XVI.

XXIII.—ANALYSIS.

Platinum resistance thermometers and immersion heating coils of low lag; Construction of ——. T. S. Sligh, jun. J. Amer. Chem. Soc., 1921, **43**, 470—475.

Changes in the construction of the strain-free type of platinum resistance thermometer from that described in U.S. Bureau of Standards Bull. **6**, 150 (J., 1910, 205), consist in the sealing of the thermometer tube to prevent condensation of atmospheric moisture in the thermometer at low temperatures, the use of a simpler thermometer head composed of a brass shell with bakelite base and cap, and the use of thermometer leads consisting of a 4-strand cable insulated with a double silk wrapping and a silk braid, each strand consisting of three No. 28 insulated copper wires twisted together and covered with silk. Calorimetric thermometers of the type described in Bull. **9**, p. 483 (1913), have been found to show low values of the δ constant in the Callendar difference formula, leading to slight errors in calibration. This is due to a strained winding. The strain may be avoided by thoroughly annealing before winding the coil, careful winding and flash-annealing afterwards. The δ value of commercial thermometers can be raised from 1·44 to 1·50 by flash-annealing without opening the thermometer case. An all-metal thermometer case of German silver is described, and also a convenient type of heating coil for laboratory use, made by winding resistance ribbon on a flat strip of mica, insulated by means of thin mica side plates, and enclosed in a flattened copper tube or sheath.—E. H. R.

Simmance total-heat recording calorimeter; Report on the ——. T. Gray and A. Blackie. Fuel Research Board, Tech. Paper No. 2, 1921, 23 pages.

For a period of five months a Simmance total-heat recording calorimeter was supplied with town gas, and the readings of the recorder compared with the value of the calorific power of the gas as determined by means of the calorimeter forming part of the instrument. Occasional adjustments of the recorder pen were made, and it was found that the recorded values usually differed from the directly determined values by less than 10 B.Th.U. and seldom by as much as 15 B.Th.U. On two occasions when a greater difference than this occurred, the discrepancy was traced to the accumulation of oxidised metal on the top of the gauze of the burner. The calorimeter was later supplied with various mixtures of coal gas, water-gas, and hydrogen ranging in sp. gr. (air=1) from 0·303 to 0·528, and in calorific value from 326 B.Th.U. to 514 B.Th.U. The greatest difference between the recorded calorific value and that determined by an independent calorimeter was 16 B.Th.U. With the calorimeter run on homogeneous gas, periodic variations occurring at intervals of about an hour were observed, and were due to the accumulation and subsequent sudden removal of air bubbles in the water circuit of the calorimeter. Occasional irregularities of the order of 20 B.Th.U. were attributable to restriction of the water flow by particles of rust etc. Experiments made in order to ascertain the origin of regular differences of the order ±10 B.Th.U. showed that the variations of recorded calorific values were roughly parallel with the variations in the gas factor for correcting the gas volume to 60° F. and 30″ pressure; that the rate of flow of gas through the meter varied proportionately with the gas factor, and that the claim that the gravity meter automatically corrects the flow of gas for varying pressure and density is substantially true; that variations of the external temperature caused a variation of the recorded calorific value amounting to ±1·4 B.Th.U. per ±1°F.; and that owing to the change of viscosity of water with temperature, a change of ±1° F. in the water supply produces a total effect on the recorder reading amounting in some cases to nearly ±1%.—J. S. G. T.

Photometric methods and apparatus for the study of colloids. S. E. Sheppard and F. A. Elliott. J. Amer. Chem. Soc., 1921, **43**, 531—539.

Two types of photometer, distinguished as vertical and horizontal types, for the study of colloids, are described. The vertical type can be modified for use as a nephelometer, colorimeter, microphotometer, dispersimeter, or turbidimeter. The horizontal type is a transmission and scatter photometer, chiefly of use for determining size of particles, comparative turbidities, and coagulation velocities.—E. H. R.

Photographic registration of chemical reactions accompanied by a variation of pressure; Method of ——. P. Jolibois. Comptes rend., 1921, **172**, 809—811.

The apparatus, which is figured and described, is a simple adaptation of the double galvanometer of Le Châtelier and Saladin for the measurement of pressures in function of temperatures. It permits of the registration in one operation of the vapour pressure of a substance or the dissociation pressure of a compound. Velocities of reaction can be compared and, for a given velocity of heating, the temperature at which a reaction assumes an appreciable velocity can be determined.—W. G.

Adsorption; Importance of —— in analytical chemistry. VIII. Adsorption by asbestos. I. M. Kolthoff. Pharm. Weekblad, 1921, **58**, 401—407.

Impure asbestos adsorbs positive ions in accordance with the adsorption law. Lead especially is readily adsorbed from dilute solutions, being afterwards easily removed by means of acids; this may be made the basis of a method for the estimation of lead in drinking water. Impure asbestos should be made suitable for analytical work by repeated extraction with acid. (*Cf.* J.C.S., May.)—S. I. L.

Potash [; Perchlorate method for the determination of ——]. T. D. Jarrell. J. Assoc. Off. Agric. Chem., 1920, **3**, 315—321.

The perchlorate method is accurate and, if a sufficient quantity of perchloric acid is used, the results obtained are not influenced by the presence of phosphates and sodium, magnesium, and calcium salts. Sulphates and ammonia must be removed before the perchloric acid is added. After the potassium salts have been extracted from mixed fertilisers with hot water, the addition of ammonia and calcium oxalate is unnecessary.—W. P. S.

Calcium group; Simplified methods of analysis in the ——. E. Ludwig and H. Spirescu. Bul. Soc. Chim. România, 1920, **2**, 35—37.

Strontium is in every case detected by the flame test. After precipitation of the metals of the group with ammonium carbonate in the presence of ammonium chloride the filtrate will contain sufficient calcium and barium, if these elements are present, to permit of their detection with ammonium oxalate and sulphuric acid respectively. Alternatively ammonium oxalate is used as the group precipitant. The filtrate will then contain sufficient barium for its detection with sulphuric acid, and calcium may be detected microchemically in the precipitate by treatment with sulphuric acid. (*Cf.* Behrens-Kley, Microchem. Analyse, 1915.)
—W. G.

Calcium and magnesium; Determination of —— in different saline solutions. E. Canals. Bull. Soc. Chim., 1921, **29**, 152—158. (*Cf.* J., 1920, 283 A, 706 A.)

Magnesium is not precipitated as oxalate along with calcium oxalate if the dilution of the magnesium ion is greater than 1%. Any magnesium which is precipitated, owing to higher concentrations, may be removed by repeated washing with boiling water, it being necessary in some cases to use 500 c.c. of water.—W. G.

Ferric, aluminium and chromium hydroxides; New method for the separation of ——. M. and M. Lemarchands. Ann. Chim. Analyt., 1921, **3**, 86—87.

A mixture of the freshly-precipitated hydroxides is washed until free from ammonia, and then boiled with 10% sodium hydroxide solution to which sodium perborate is added; the chromium and aluminium hydroxides dissolve as sodium aluminate and sodium chromate, respectively, whilst the ferric hydroxide remains insoluble. The latter is separated by filtration; on boiling a portion of the filtrate with the addition of an excess of ammonium chloride, the aluminium hydroxide is re-precipitated. The chromium may be precipitated from another portion of the filtrate as lead chromate.
—W. P. S.

Nickel; Cyanometric assay of ——. G. H. Stanley. J. S. Afr. Assoc. Anal. Chem., 1921, **4**, 10—12.

The nickel solution is rendered slightly ammoniacal, a known amount of silver nitrate (allowance is made for this subsequently) and a small quantity of potassium iodide are added, and the mixture is titrated with standardised cyanide solution until the precipitate is dissolved completely. If iron is present, the nickel solution is treated with an excess of the cyanide solution, the required amount of ammonia is added rapidly, the mixture filtered, and the excess of cyanide titrated in the filtrate, the nickel being taken by difference. Copper must be removed previously, zinc is eliminated by adding sodium carbonate instead of ammonia to the solution already treated with cyanide, whilst the interference of manganese can be prevented by using ammonium carbonate in place of ammonia. Stannic compounds do not interfere.—W. P. S.

Cobalt; New method for the detection and determination of ——. S. A. Braley and F. B. Hobart. J. Amer. Chem. Soc., 1921, **43**, 482—484.

Solutions containing cobalt give, with a solution of dimethylglyoxime containing ammonia or sodium acetate, a brown coloration which is characteristic for cobalt inasmuch as, unlike the coloration given by other metals, it is not discharged by mineral acids. In absence of copper and iron it provides a sensitive qualitative test for cobalt. The colour can also be made to serve for a colorimetric estimation of cobalt in presence of nickel. The solution, prepared as for the determination of nickel, is slightly acidified, treated with sodium acetate, heated to boiling, and then the dimethylglyoxime added in slight excess. The nickel precipitate is filtered off, the solution cooled slowly, and when cold compared colorimetrically with standards.
—E. H. R.

Mercury and copper; Electrolytic separation of ——. W. Böttger. Z. angew. Chem., 1921, **34**, 120—122.

In presence of chlorine ions the separation of mercury from copper is most effectively achieved by first removing both metals from the solution at a sufficiently high voltage, *e.g.*, 2·2—2·4 volts. They are then dissolved in dilute nitric acid, and the solution, after neutralisation and addition of acid and alcohol, is electrolysed at 1·4 volts. When potassium cyanide is added to a mercury-copper solution containing chlorine ions, the addition of a few c.c. of concentrated ammonia is advantageous in preventing decomposition of the cyanide. Separation of copper from such a solution takes place at normal temperature with a voltage of 3·2 volts; without ammonia the necessary voltage is 3·8—4·5 volts. At 65° C., an appreciably lower voltage, *e.g.*, 2 volts, may be used. (*Cf.* J.C.S., May.)—W. J. W.

Uranium, vanadium, and chromium; Qualitative separation and detection of —— when present together. P. E. Browning. J. Amer. Chem. Soc., 1921, **43**, 114—115.

A solution containing chromic and vanadic acids and a uranium salt is made faintly alkaline with ammonia and then faintly acid with acetic acid and treated with ammonium phosphate. Uranium phosphate is precipitated, filtered off, and washed. The identity of the uranium phosphate is confirmed by the addition to the precipitate of a drop of potassium ferrocyanide, when a red-brown stain is produced. The filtrate is treated with excess of sulphur dioxide to reduce the chromic and vanadic acids; the excess of sulphur dioxide is boiled off, an excess of bromine added, and the excess removed by boiling; this oxidises the vanadium to vanadic acid, but does not affect the chromium. Ammonia is added whereby the chromium separates as a green precipitate of phosphate and hydroxide. The filtrate from the chromium is made alkaline and saturated with hydrogen sulphide, which gives the pink or violet oxysulphide of vanadium.—J. F. S.

Gallium ferrocyanide; Use of —— in analysis. L. E. Porter and P. E. Browning. J. Amer. Chem. Soc., 1921, 43, 111—114.

Gallium ferrocyanide passes through asbestos or filter paper in a Gooch crucible or filter paper in a funnel when suction is applied, but it can be filtered satisfactorily by using a pad made of shredded filter paper placed on a double filter paper and applying gentle suction. The precipitate after washing is ignited and weighed as the mixed oxides of gallium and iron. Gallium may be recovered from the ferrocyanide by solution in sodium hydroxide and precipitation of gallium hydroxide with carbon dioxide. An alternative method consists in treating the alkaline solution of gallium ferrocyanide with hydrogen peroxide to oxidise the sodium ferrocyanide to ferricyanide and then boiling with ammonium chloride, when pure gallium hydroxide is precipitated. When zinc is present neither method is available. In this case the metals are precipitated together as ferrocyanides which are dissolved in sodium hydroxide and the hydroxides precipitated by carbon dioxide. These are dissolved in hydrochloric acid and the gallium precipitated by boiling with ammonium bisulphite. Alternatively the alkaline solution of ferrocyanides is treated with hydrogen sulphide and the zinc precipitated, the gallium then being obtained by either of the methods described above.—J. F. S.

Nitric nitrogen; Comparative results with Scales' method and Devarda's alloy for reducing ——. A. P. Harrison. J. Biol. Chem., 1921, 46, 53—56.

Scales' zinc-copper couple gives as accurate results as Devarda's alloy, and has the advantage of not requiring to be weighed. 200 c.c. of solution with 0·1 mg. N per c.c. is poured into a flask containing about 80 g. of freshly prepared zinc-copper couple; about 5 g. of sodium chloride and 1 g. of magnesium oxide are added, and 150 c.c. is distilled into a flask containing 50 c.c. of 4% boric acid. Bromophenol blue is used as indicator in the titration. —G. B.

Arsenate and arsenite; Separation and detection of ——. G. W. Sears. J. Amer. Chem. Soc., 1921, 43, 466—470.

Determinations of the solubility of silver arsenate and silver arsenite respectively in sodium hydroxide solution show that, whereas the former is readily dissolved in the cold by 0·5 to 1·5*N* sodium hydroxide, the latter is practically insoluble. The arsenate dissolves according to the equation

$$2Ag_3AsO_4+2NaOH+H_2O=2NaH_2AsO_4+3Ag_2O.$$

Higher concentrations of sodium hydroxide react slowly with silver arsenite with formation of arsenate and metallic silver. To separate arsenate and arsenite, their nitric acid solution containing excess of silver nitrate is neutralised with sodium hydroxide until the silver oxide precipitate just fails to re-dissolve. The washed precipitate is then shaken with about 25 c.c. of a solution containing about 3 c.c. of 6*N* sodium hydroxide solution. This is sufficient to dissolve at least 0·45 g. of silver arsenate. The arsenate and arsenite can be detected in the filtrate and residue respectively by usual methods.—E. H. R.

Air; Determination of nitrous fumes in —— with special reference to fuse-igniters. J. Moir. J. S. Afr. Assoc. Anal. Chem., 1921, 4, 3—7.

A method, similar to that of Ilosvay, but applicable to both small and large amounts of nitrite or nitrous acid, is described. The liquid under examination is treated with 1—10 c.c. of *p*-nitraniline solution (*p*-nitraniline, 1·5 g., concentrated hydrochloric acid, 40, water to 500 c.c.) and heated at 50° C.; 1—10 c.c. of α-naphthol solution (α-naphthol, 2, sodium hydroxide, 1·1, sodium acetate, 10 g., water to 500 c.c.) is then added and, after 1 hr., the orange-red precipitate is collected and weighed; 92 g. of NO_2, or 69 g. of $NaNO_2$, yields 293 g. of precipitate. The latter dissolves in sodium hydroxide solution with an intense blue-violet colour, and very small quantities may be determined colorimetrically. To determine NO_2 apart from nitrite in the fumes from fuse igniters, a definite volume of the gases may be left in contact with neutral hydrogen peroxide solution for 24 hrs., and the solution then titrated, using methyl orange as indicator; 1 c.c. of *N*/10 alkali is equivalent to 0·0060 g. NO_2. Alternatively, neutral potassium iodide solution may be used in place of the hydrogen peroxide and the liberated iodine titrated with thiosulphate solution; each c.c. of *N*/10 thiosulphate solution = 0·0051 g. NO_2.—W. P. S.

Iodoform reaction; Sensitive modification of the ——. N. Schoorl. Pharm. Weekblad, 1921, 58, 209—210.

Ammonium persulphate is used with potassium iodide in alkaline solution. The reaction will detect 1 pt. of acetone in 100,000. (*Cf.* J.C.S., April.) —S. I. L.

Miscible liquids; Separation of —— by distillation. S. F. Dufton. Phil. Mag., 1921, 41, 633—646.

The still-head described previously by the author (J., 1919, 45 T) gives a complete separation of simple binary mixtures and renders possible the examination of the rationale of separation by distillation. The physical processes occurring in the still-head are discussed mathematically and amplified by experimental data. Comparison of continuous and discontinuous distillation shows that the former is much more economical; further, a column can be employed at its maximum efficiency throughout, whilst the length must be variable if the highest efficiency in discontinuous distillation is to be obtained.—W. P. S.

Patents.

Gas analysing apparatus. Aktiebolaget Ingeniörsfirma F. Egnell. E.P. 106,265, 29.9.16. Conv., 8.5.16.

In gas analysing apparatus provided with an oxidation chamber and a vessel for absorption of carbon dioxide, a cock is arranged between the gas generator and the analysing apparatus and is of such construction that the gas to be analysed can be passed from the generator through the cock to the absorption vessel, thence, through the cock to the oxidation chamber and finally through the cock to the analysing apparatus, or directly through the cock to the latter. If desired, the gas may be led directly from the absorption vessel to the analysing apparatus, and the gas generator may be shut off from the rest of the apparatus. The cock is provided with a device for closing and breaking the electric circuit for heating the oxidation chamber. —J. S. G. T.

Gases and vapours capable of being absorbed; Continuous determination of ——. Badische Anilin- und Soda-Fabrik. G.P. 329,386, 27.4.18.

The gaseous mixture is simultaneously delivered through two parallel circuits, each provided with a pair of throttle valves. In the one circuit, absorption of the gas or vapour concerned is effected, and the difference of pressure in the two circuits arising therefrom at constant temperature enables the amount of the absorbed constituent to be ascertained.—J. S. G. T.

Thermo-element for the measurement of high temperatures. F. Hesse. G.P. 330,726, 5.3.18.

The thermo-junction is constituted of tantalum and molybdenum and is fused into a sheath filled with basic refractory material to prevent oxidation. —J. S. G. T.

Heating-value indicator. U.S.P. 1,370,945. *See* II A.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Acheson. Deflocculating solid substances. 11,199. Apr. 18. (U.S., 1.5.20.)

Akt.-Ges. f. Stickstoffdünger. Treatment of feed-water for steam generators etc. 10,608. Apr. 11. (Ger., 12.4.20.)

Beldimano, Robertson, and Stanley. Evaporating or heating liquids. 10,953. Apr. 14.

Brown. Carbon bleaching or filtering material, and method of making same. 11,580. Apr. 21. (U.S., 12.8.20.)

Chaudière. Furnaces, gas-producers, etc. 11,321. Apr. 19. (Belg., 20.4.20.)

Johnston. Machines for centrifugally separating solids from liquids. 10,901. Apr. 14.

Leubli. Grinding-mills. 10,963. Apr. 14.

Marks (Shell Co.). Re-run still. 11,438. Apr. 20.

Mercer. Pulverising or disintegrating machines. 10,634. Apr. 12.

Powdered Fuel Plant Co., Ltd. Means for separating suspended solid from a gaseous medium. 11,014. Apr. 15. (Fr., 12.8.20.)

Reid. Furnaces. 10,704. Apr. 12.

Rigby. Drying-cylinders. 11,278–9. Apr. 19.

Complete Specifications Accepted.

15,265 (1918). Gal. Furnaces. (122,395.) Apr. 20.

19,287 (1919). Harris. Drying process and apparatus. (161,598.) Apr. 27.

19,639 (1919). Junquera. Manufacture of concentrated solutions. (144,240.) Apr. 27.

29,288 (1919). Coleman. Mixing and agitating machines. (161,617.) Apr. 27.

169 (1920). Paget. Grinding, refining, or reucing apparatus. (161,257.) Apr. 20.

325 (1920). Still. Filters. (161,639.) Apr. 27.

1176 (1920). Hirsch. Apparatus for generating as by the action of liquids on solid reagents. 161,681.) Apr. 27.

3707 (1920). Barbet et Fils et Cie. Condensing rrangements of rectifying apparatus. (138,869.) pr. 20.

5224 (1920). Kennedy. Gyratory crushing apparatus. (139,216.) Apr. 27.

5714 (1920). Dorr Co. Rotating screen filtering apparatus. (139,493.) Apr. 20.

8943 (1920). Johnson (Fischlein). Centrifugal apparatus for straining liquids. (161,822.) Apr. 27.

20,141 (1920). Danhardt. Asbestos cloth, especially for dry separation of solid matter from blast-furnace gases etc. (153,558.) Apr. 20.

20,289 (1920). Rudisill. Pulveriser. (148,369.) Apr. 20.

24,280 (1920). Hardinge. Grinding and disintegrating mills. (150,997.) Apr. 27.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Accioly. Manufacture of an alcoholic liquid (synthetic) gas for use as combustible. 11,419. Apr. 20.

Bowler. Distilling crude petroleum. 11,623. Apr. 22.

Burnet. Vertical retorts for destructive distillation. 10,834. Apr. 13.

Burton. Gas-retort mouthpieces. 11,134. Apr. 16.

Carratt. Gas-producers. 11,393. Apr. 20.

Chaudière. 11,321. *See* I.

Clapp, and Ferolite, Ltd. Gas-producers, electric furnaces, crucible furnaces, etc. 11,065. Apr. 15.

Davidson, and Low Temperature Carbonisation, Ltd. Retorts. 11,222. Apr. 18.

Dehn (McComb). Converting heavy liquid hydrocarbons or liquid hydrocarbons of higher boiling point into lighter hydrocarbons or hydrocarbons of lower boiling point. 11,116. Apr. 16.

Frentrup, Kiederich, and Meyer zu Eissen. Increasing the consistency of hydrocarbon oils etc. 10,692. Apr. 12.

Glawe. Mixing briquette-forming materials with fluid binding agent. 10,919. Apr. 14.

Keith, Whatmough, and Keith and Blackman Co., Ltd. Liquid fuel, and process for production thereof. 11,444. Apr. 20.

Marks (Shell Co.). 11,438. *See* I.

Powdered Fuel Plant Co., Ltd. Apparatus for pulverising coal etc. 11,012–3. Apr. 15. (Fr., 17 and 31.8.20.)

Deuts. Gold- u. Silber-Scheideanstalt. Production of sodium cyanide. 11,717. Apr. 22. (Ger., 10.6.20.)

Feldenheimer and Plowman. Process for grading alkaline-earth carbonates. 11,358. Apr. 19.

Mirat and Pipereaut. Manufacture of sulphuric acid. 10,792. Apr. 13. (Belg., 6.5.20.)

Pease. Manufacture of compounds of ammonia etc. 11,039. Apr. 15.

Riedel A.-G. 11,068. *See* XX.

Complete Specifications Accepted.

10,401 (1918). Deuts. Gold- u. Silber-Scheideanstalt. Manufacture of alkali percarbonates. (117,085.) Apr. 27.

24,875 (1919). Spence and Sons, Spence, and Llewellyn. Manufacture of aluminous compounds. (161,606.) Apr. 27.

30,611 (1919). Patrick. Silica gels and process of making same. (136,543.) Apr. 20.

32,756 (1919). Douglas. Manufacture of ammonia. (161,244.) Apr. 20.

353 (1920). Kelly. Manufacture of acid sodium pyrophosphate. (161,273.) Apr. 20.

822 (1920). Mackay. Obtaining strontium and barium sulphates from their native sulphates. (161,655.) Apr. 27.

823 (1920). Mackay. Obtaining copper sulphate direct from metallic copper. (161,656.) Apr. 27.

1231 (1920). Wildman. Extraction of alumina and its salts from clay. (161,310.) Apr. 20.

10,004 (1920). Clayton. Apparatus for manufacture of oxygen compounds of sulphur. (161,439.) Apr. 20.

17,437 (1920). Röhm. Production of a solid non-hygroscopic iron salt. (146,214.) Apr. 20.

VIII.—GLASS; CERAMICS.

Applications.

Clark, Taylor, and Universal Transfer Co. Process for pottery printing. 10,741. Apr. 13.

Rigby. Treatment of china clay etc. 11,093. Apr. 16.

Wallis. Composition for manufacture of crockery-ware. 11,139. Apr. 18.

IX.—BUILDING MATERIALS.

Applications.

Brant. Building etc. materials. 10,781. Apr. 13.

Lyno. Cement brick. 11,574. Apr. 21. (Denmark, 27.4.20.)

Miller, Miller, and Williams. Damp-insulating material for buildings etc. 11,249. Apr. 19.

Complete Specifications Accepted.

13,164 (1920). Wennerstrom. Manufacture of cement. (143,243.) Apr. 27.

16,297 (1920). Schiff. Manufacture of dental cements. (161,868.) Apr. 27.

17,312 (1920). Larsen. Manufacture of porous cement or mortar products. (146,172.) Apr. 27.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Beielstein, and Chem. Fabr. Griesheim-Elektron. Recovery of light metals from scrap. 11,066. Apr. 15.

British Thomson-Houston Co. (General Electric Co.). Electro-metallurgy. 11,049. Apr. 15.

Chandler, and South Metropolitan Gas Co. Gas-fired metallurgical furnaces. 11,699. Apr. 22.

Clapp and others. 11,065. *See* II.

Coles. Manufacture of bronze powders. 11,520. Apr. 21.

Continuous Reaction Co., Merson, and Skelley. Manufacture of ferrotungsten and ferromolybdenum. 11,786. Apr. 23.

Continuous Reaction Co., Skelley, and Smith. Manufacture of ferrous alloys. 11,787. Apr. 23.

Danforth. Open-hearth furnaces. 11,437. Apr. 20.

Hervey and Taylor. Treatment of iron. 10,707. Apr. 12.

Rogers (Calorizing Corp. of America). Calorizing furnace and process. 11,310. Apr. 19.

Rogers (Calorizing Corp. of America). Metallic alloys. 11,311. Apr. 19.

Sweeney. Manufacture of composite metallic sheets. 10,846. Apr. 13.

Trent Process Corp. Process of reducing ores. 10,830. Apr. 13. (U.S. 4.10.20.)

Complete Specifications Accepted.

24,480 (1919). Morgan Crucible Co., and Speirs. Electrically heated melting and other furnaces. (161,603.) Apr. 27.

821 (1920). Mackay. Obtaining iron and tin from tin scrap. (161,654.) Apr. 27.

3692 (1920). Vigeon and McConway. Preleaching apparatus for treating calcined ore and the like. (161,375.) Apr. 27.

4146 (1920). Crosthwaite Eng. and Furnace Co., and Crosthwaite. Furnaces for heating crucibles employed for melting or heating metals etc. (161,386.) Apr. 20.

20,141 (1920). Danhardt. *See* I.

23,238 (1920). Tugwood (Dwight and Lloyd Metal-urgical Co.). Ore-sintering mechanisms. (161,491.) Apr. 20.

658 (1921). Agostini. Solder for aluminium and other metals. (156,665.) Apr. 20.

XI.—ELECTRO-CHEMISTRY.

Application.

Clapp and others. 11,065. *See* II.

Complete Specifications Accepted.

24,480 (1919). Morgan Crucible Co., and Speirs. *ee* X.

25,052 (1919). Trembour. Electric furnaces. 33,954.) Apr. 27.

27,150 (1919). Boorne and Darge. Covering etal cores in the manufacture of electrodes. 61,212.) Apr. 20.

66 (1920). Bultemann. Manufacture of an ectric insulating material. (137,326.) Apr. 20.

29,780 (1920). Smalley. Electric furnaces. 52,686.) Apr. 27.

XII.—FATS; OILS; WAXES.

Applications.

Eppenberger. Rendering fat-containing granular products impalpable. 10,940. Apr. 14. (Switz., 1.3.21.)

Fenton. Treating oil-bearing solids. 10,710. Apr. 12.

Kobayashi. Manufacture of hydrocarbons from fatty oils. 11,712. Apr. 22. (Japan, 13.10.20.)

Plauson's (Parent Co.), Ltd. (Plauson). Compositions of oils etc. 10,616. Apr. 12.

Plauson's (Parent Co.), Ltd. (Plauson). Manufacture of viscous oily compositions. 10,852. Apr. 13.

Complete Specifications Accepted.

30,543 (1919). Heyerdahl. Extraction and refining of oil. (137,514.) Apr. 20.

8354 (1920). Quick. Refining and decolorising animal and vegetable oils. (161,813.) Apr. 27.

18,752 (1920). Elektro-Osmose A.-G. Purification of glycerin. (146,865.) Apr. 27.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Application.

Dargan. Luminous ink. 11,163. Apr. 18.

Complete Specifications Accepted.

17,490 (1919). Ivinson and Roberts. Anti-corrosive paint or composition. (161,201.) Apr. 20.

24,916–7 (1919). Melamid. Production of resin-like bodies. (133,712–3.) Apr. 27.

469 (1920). Baker. Process of making pigments. (161,280.) Apr. 20.

13,161 (1920.) Bayer u. Co. *See* VI.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Applications.

Catalpo, Ltd., and Schidrowitz. Manufacture of caoutchouc and caoutchouc-like products. 11,055. Apr. 15.

Moler. Manufacture of regenerated rubber. 11,053. Apr. 15.

Complete Specifications Accepted.

748 (1920). Gare. Reforming or vulcanising rubber, ebonite, vulcanite, etc. (161,648.) Apr. 27.

799 (1920). Farrel Foundry and Machine Co. Mixing or masticating rubber etc. (137,820.) Apr. 20.

4264 (1920). Helbronner. Manufacture of india-rubber products. (142,083.) Apr. 27.

6670 (1920). Bruni. Vulcanisation of rubber. (140,387.) Apr. 27.

18,916 and 18,920 (1920). Wade (Goodyear Tire and Rubber Co.). Manufacture of rubber products. (161,482–3.) Apr. 20.

XV.—LEATHER; BONE; HORN; GLUE.

Applications.

Richter. Removal of hairs from hides etc. 10,775. Apr. 13.

Soc. Pichard Frères. Process for unhairing hides. 11,638. Apr. 22. (Fr., 12.5.20.)

Complete Specifications Accepted.

27,772 (1919). Malcolm and Townsend. Manufacture of vegetable gelatin. (161,612.) Apr. 27.

2652 (1920). Boys. Apparatus for mixing or agitating lime in tannery pits. (161,362.) Apr. 20.

8681 (1920). Bray (Indian Wood Products Co.). Manufacture of catechin and catechu-tannic acid. (161,431.) Apr. 20.

XVI.—SOILS; FERTILISERS.

Complete Specification Accepted.

4803 (1920). Sams. Fertiliser and process of making same. (161,777.) Apr. 27.

XVII.—SUGARS; STARCHES; GUMS.

Applications.

Brown. Washing starch. 11,581. Apr. 21. (U.S., 12.8.20.)

Courtaulds, Ltd., Lloyd, and Stokes. Production of compounds or mixtures of starch and sulphuric acid. 11,767, 11,782. Apr. 23.

Tiemann. Purifying sugar juices by filtration and decantation. 11,561. Apr. 21. (Ger., 21.4.20.)

Complete Specifications Accepted.

1972 (1920). Barbet et Fils et Cie. *See* XIX.

11,691 (1920). Classen. Manufacture of sugar and furfurol from wood and other cellulosic substances. (142,480.) Apr. 27.

12,609 (1920). Terrisse and Levy. Obtaining glucose from wood. (143,212.) Apr. 20.

18,744 (1920). Wohl. Saccharification of cellulose-containing materials. (146,860.) Apr. 27.

22,019 (1920). Tavroges, Roche, and Martin. Manufacture of lactose or milk sugar. (161,887.) Apr. 27.

XVIII.—FERMENTATION INDUSTRIES.

Complete Specifications Accepted.

12,490 (1917). Fernbach. Production by fermentation of acetone and higher alcohols, particularly butyl alcohol. (109,969.) Apr. 20.

694 and 8114 (1920). Power Gas Corp., and Langwell. Fermentation of cellulose. (161,294.) Apr. 20.

16,395 (1920). Romer, and Deutsch-Koloniale Gerb- u. Farbstoff-Ges. Fermentation process. (161,870.) Apr. 27.

21,673 (1920). Stouffs. Preservation of byproducts of brewing, distilling, etc., for use as animal foods. (161,885.) Apr. 27.

23,828 (1920). Warwick. Apparatus for fermentation of beer etc. (161,496.) Apr. 20.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Abbott, McNeill, Macredie, and Remus. Production of meat powder. 10,682. Apr. 12.

Akt.-Ges. f. Stickstoffdünger. 10,608. *See* I.

Chalas. Manufacture of a dry and soluble extract of roasted coffee. 11,046. Apr. 15. (Fr., 16.4.20.)

Complete Specifications Accepted.

32,239 (1919). Forget-Me-Not, Ltd., and Hutchinson. Manufacture of alimentary products containing water-soluble vitamines. (161,238.) Apr. 20.

643 (1920). Farmachidis. Food preparation. (161,291.) Apr. 20.

1135 (1920). White (Collis Products Co.). Desiccating buttermilk etc. (161,678.) Apr. 27.

1800 (1920). Collis Products Co. Apparatus for desiccating buttermilk, sour milk, etc. (138,092.) Apr. 27.

1972 (1920). Barbet et Fils et Cie. Manufacture of grape honeys and fruit syrups. (153,548.) Apr. 27.

2695 (1920). Linden. Apparatus for treating effluent and other liquids. (161,735.) Apr. 27.

3645 (1920). Clements. Producing materials suitable for purifying air. (138,649.) Apr. 27.

21,673 (1920). Stouffs. *See* XVIII.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Alby United Carbide Factories, Ltd., and Dodd. Manufacture of salts of guanidine. 11,646. Apr. 22.

Büchler. Production of borodisalicylic acid. 11,553. Apr. 21

Courtaulds, Ltd., and Delph. Manufacture of carbon bisulphide. 11,771. Apr. 23.

Riedel A.-G. Soluble mercury compounds. 11,068. Apr. 15. (Ger., 16.4.20.)

Complete Specifications Accepted.

2787 (1916). Weizmann and Legg. Manufacture of secondary butyl alcohol. (161,591.) Apr. 27.

12,490 (1917). Fernbach. *See* XVIII.

1140 (1920). Ellis (Soc. Chim. Usines du Rhône). Manufacture of oxyaldehydes and their derivatives. (161,679.) Apr. 27.

2196 (1920). Thomson. Detoxication of the tubercle bacillus and other germs for the preparation of vaccines. (161,341.) Apr. 20.

11,691 (1920). Classen. *See* XVII.

24,192 (1920). Elektro-Osmose A.-G. Process for making specific vaccines. (150,319.) Apr. 20.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Applications.

Davies. Manufacture of photographic papers. 10,949—10,951. Apr. 14.

Marks (Daylight Film Corp.). Photographic reproduction. 10,586. Apr. 11.

Martinez. Colour sensitised supports for colour photography etc., and treatment thereof. 10,773. Apr. 13.

Warneuke. Colour photograhy. 11,294. Apr. 19.

Wolff. Colour photography and kinematography. 11,556. Apr. 21. (Ger., 14.8.20.)

XXIII.—ANALYSIS.

Applications.

Allen and Hanburys, Ltd., and Lizius. Titration and neutralisation of chemical compounds. 11,659. Apr. 22.

Svenska Aktiebolaget Mono. Gas-analysing apparatus. 11,359. Apr. 19. (Sweden, 23.4.20.)

I.—GENERAL; PLANT; MACHINERY.

Water; Heat conductivity of —— between 0° and 80° C. M. Jakob. Ann. Phys., 1920, [4], 63, 537—570. Chem. Zentr., 1921, 92, 11., 689—690.

The heat conductivity of water in C.-G.-S. units (cals. per cm. per sec. per 1° C.), between 0° and 80° C., is given correct to 1% by the equation $\lambda=0{\cdot}001325\ (1+0{\cdot}002984t)$.—A. R. P.

Patents.

Liquids, pulpy masses, and the like; Process and apparatus for solidifying in fine powder ——. [Manufacture of soap powder.] Metallbank und Metallurgische Ges. A.-G. E.P. 145,048, 15.6.20. Conv., 16.4.18.

The liquid (*e.g.*, molten soap) is sprayed centrifugally and subjected to the action of a current of cold air which is continuously circulated through the spraying apparatus and a cooler.—B. M. V.

Reaction towers [; Filling for ——]. H. Schmidt. E.P. 147,213, 7.7.20. Conv., 11.4.19.

Metallic strip is perforated and corrugated with corrugations of equal pitch, the strips being laid together with the tops of the corrugations touching so that a honeycomb structure is formed.
—B. M. V.

Vapours of volatile liquids; Process and apparatus for the recovery of —— from their mixtures with air. E. Barbet et Fils et Cie. E.P. 149,691, 3.8.20. Conv., 1.8.19.

Air escaping from a storage vessel containing a volatile liquid is passed through a washing column. The column contains a suitable solvent (*e.g.*, heavy tar oil for benzene) which is fed from a storage tank only when there is positive pressure in the storage vessel, *i.e.*, when air is escaping. The control of the solvent feed is effected by a float in a two-compartment tank, closed at the top, and partially filled with the solvent liquid; the two compartments communicate only below the level of the liquid. One compartment (preferably the larger) contains the float and valve for supplying the solvent liquid, which flows from the other compartment to the washing column through a hand-adjusted outlet situated just above the level reached by the liquid when the float valve closes. The arrangement is made very sensitive by putting the air space above the float in communication with the air space in the storage vessel. A separate liquid seal device is provided through which air can be drawn into the storage vessel if the pressure therein falls below a predetermined limit.
—B. M. V.

Drying apparatus. L. Eberts. E.P. 160,717, 19.8.20.

The material to be dried is admitted into a casing within which rotates a drum heated by a fluid which is admitted and exhausted through the hollow trunnions of the drum. Stirrers attached to the drum gradually propel the material to an outlet, and additonal heating surface is provided by means of tubes projecting radially from the drum, either bent to a U-shape and having both ends communicating with the drum or having their outer ends connected with longitudinal tubes which are in turn connected with spiral tubes leading to the outlet. The radial tubes may be wedge-shaped in cross-section.—B. M. V.

Drying apparatus. T. Izumi. U.S.P. 1,372,352, 22.3.21. Appl., 10.6.20.

A vertical cylindrical drying chamber is fitted with shelves revolving around a central cylindrical heat radiator, and means are provided for drawing air from the bottom of the chamber and causing it to escape through a passage around the chamber, air pipes within the passage serving to supply fresh air to the top of the chamber. The lowest part of the chamber communicates with a fluid pit provided with a lid.—H. H.

Drying apparatus. Z. Yamamoto. U.S.P. 1,372,585, 22.3.21. Appl., 28.11.19.

A drying apparatus comprises a casing in which is mounted a movable frame carrying a zig-zag shoot having an inlet at its top and an outlet at its bottom. Means are provided for heating the interior of the casing, and the shoot has openings to permit the heated air to enter.—H. H.

Dryer. W. F. Schaller, Assr. to E. and I. H. Schaller. U.S.P. 1,373,767, 5.4.21. Appl., 11.9.18.

Three walls of the drying chamber are surrounded by a hot-air chamber below which is a fire chamber with flues for the products of combustion, and there are also provided flues for supplying fresh air to the drying chamber and for heating it, a flue extending downwards from one end of the drying chamber and formed with an opening at its lower end for mixing the incoming air, and a flue at the opposite end of the drying chamber for escape of the heated air.—H. H.

Cooling towers. L. R. Morshead. E.P. 160,990, 17.1.20.

Jets of water are arranged at the bottom of the tower, pointing upwards, in order to induce a more powerful current of air, especially in those parts where by natural draught there would be little or no current and to prevent water being blown out by cross winds. Falling water which would fall directly on the jets may be deflected by louvres.
—B. M. V.

Heating and cooling liquids; Apparatus for ——. C. W. Desobry. U.S.P. 1,373,953, 5.4.21. Appl., 17.3.19.

The liquid to be cooled flows downwards in a zig-zag path over vertical inner walls of chambers which are divided into two similar sections, hinged at one side so that they can be opened and closed. Heating or cooling means may be installed between the inner and outer walls of the chambers.
—B. M. V.

Electrical precipitation [of vaporised substances from gases]. A. F. Nesbit. U.S.P. 1,371,995, 15.3.21. Appl., 10.12.20.

The gases are passed through an apparatus containing several pairs of electrodes, each pair consisting of a discharge electrode and a tubular collecting electrode, producing between them an ionisation field which is cooled by a refrigerating jacket surrounding the collecting electrode and in which vaporised substances are deposited from the gases. Traps are provided at intervals along the collecting electrodes.—J. H. L.

Cleaning gases; [Electrical] method of and apparatus for ——. F. R. McGee and A. F. Nesbit. U.S.P. 1,372,710, 29.3.21. Appl., 13.3.18.

The gas is passed through a hollow electrode in which a corona discharge is maintained. A whirling motion is imparted to the column of gas, whereby impurities are impelled centrifugally to the periphery. The central core of clean gas and the peripheral layer of gas laden with impurities are passed into separate chambers.—J. S. G. T.

Dust separator; Centrifugal ——. H. Milliken, Assr. to J. B. Taylor. U.S.P. 1,372,714, 29.3.21. Appl., 20.9.19.

A centrifugal dust separator for gases comprises a tubular envelope provided with one or more helical slits affording a free passage radially and extending around the periphery of the envelope. A structure within the envelope affords a continuous helical passage in the same general direction as the helical slit or slits.—J. S. G. T.

Gases; Process and apparatus for removing vaporised, liquid and solid substances from —— by washing. W. Freytag. G.P. 331,321, 20.8.18.

The gas is passed through a rotary wheel-shaped filtering apparatus containing a porous material which is automatically moistened, but not overcharged, with crude oil, tar, heavy oil or the like. When the filtering material is no longer effective it is automatically replaced by fresh. Materials such as porous lignite or peat are preferably employed so that after use they can be distilled in order to recover the oily washing liquid.—J. H. L.

Feed-water heater, evaporator, and the like. H. C. Davis, Assr. to American Marine Equipment Corp. U.S.P. 1,372,010, 22.3.21. Appl., 19.9.18.

A horizontal shell has an inlet and outlet for steam, inlet and outlet connexions for water, and a nest of straight horizontal tubes in communication with the water connexions, each tube being provided with a longitudinal indentation extending spirally around it.—H. H.

Filter apparatus. O. Congleton; J. T. Lewis, exor. U.S.P. 1,372,119, 22.3.21. Appl., 4.4.18.

Filtering material is disposed between an upper chamber and a tapering lower chamber of a filter tank. The lower chamber has a valved outlet, and a connexion is provided from a supply tank to the lower chamber, such connexion having an upwardly inclined portion entering the tapering wall of the lower chamber. A series of such filter tanks may be provided, the valved outlets from the lower chambers leading to a common pipe, and each upper chamber having a pipe connexion to the lower chamber of the succeeding tank. The upper chamber of the final tank is provided with an outlet pipe, and the supply tank is connected with the upper chambers of the various filter tanks.—H. H

Filtration process. D. P. Hynes, Assr. to Roseberry Surprise Mining Co., Ltd. U.S.P. 1,373,887, 5.4.21. Appl., 26.1.20.

A basic compound of zinc is added to a pulp containing solid and colloidal substances and substantially free from acid, whereby the colloidal substances are changed to a form which does not inhibit filtration.—A. de W.

Distilling column. G. W. Crupe, Assr. to Semet-Solvay Co. U.S.P. 1,372,649, 22.3.21. Appl., 23.10.20.

In a distilling column having a series of superimposed pans with an external overflow passage from pan to pan, there is a vent pipe connexion from the upper part of each such passage, and the vent pipe has a discharge orifice within the column, above the opening from the pan to the passage. —H. H.

Still. C. D. Crane. U.S.P. 1,372,865, 29.3.21. Appl., 18.7.17.

In a still of the type in which the main shell is divided into a lower generator compartment and an upper compartment for condensing medium, the division wall forming the condensing surface, a settling chamber is arranged external to the main shell. A fluid supply conduit leads from the upper compartment of the still to the settling chamber, and an overflow connexion leads from the settling chamber to the lower compartment of the still. —H. H.

Distilling and purifying apparatus for volatile liquids. H. A. Hills. U.S.P. 1,372,880, 29.3.21. Appl., 18.8.16.

A still having a sloping bottom, a vapour outlet at the top, and a liquid inlet is provided with a nozzle having its discharge opening directed against the bottom. A sleeve forms an annular chamber around the nozzle, and an opening is provided at the rear of the chamber through which fluid is supplied by suction simultaneously with the exhaust from the nozzle.—H. H.

Crucible furnace. J. H. L. De Bats, Assr. to Lava Crucible Co. U.S.P. 1,372,676, 29.3.21. Appl., 3.3.17. Renewed 5.8.20.

A crucible furnace comprises a main chamber with a bottom, adapted to be lowered and lifted, on which is erected a crucible-receiving chamber with non-perforated heat-conducting walls of refractory material, spaced from the walls of the main chamber to provide a fire space. The bottom of the space surrounding the crucible-receiving chamber is formed as a grate.—H. H.

Catalytic material and process of making the same. A. A. Backhaus, Assr. to U.S. Industrial Alcohol Co. U.S.P. 1,372,736, 29.3.21. Appl., 19.12.18.

A catalytic material is made by applying syrupy phosphoric acid to coke, using a diminished pressure before and during the application, then restoring the pressure and reducing the acid content to about 15%.—H. H.

Centrifugal separation; Process for ——. E. W. Beach. U.S.P. 1,373,219, 29.3.21. Appl., 31.1.21.

For separating a heavier solid from a lighter fluid constituent of a mixture, a centrifugal machine is used having a discharge passage near its outer wall and another discharge passage relatively close to its centre of rotation, and there is introduced into the machine a sealing and carrying fluid of a specific gravity intermediate between the specific gravities of the constituents to be separated. Sufficient of the sealing liquid is used to form a layer against the outer wall to close completely the outer discharge passage. This layer prevents the lighter constituent from passing through that passage while allowing the heavier constituent to be removed with the sealing material.—H. H.

Centrifugally separating substances; Method and mechanism for ——. L. D. Jones, Assr. to The Sharples Specialty Co. U.S.P. 1,373,743, 5.4.21. Appl., 4.9.20.

Three substances of differing densities are separated by subjecting them to centrifugal force and controlling the distance of the contact surfaces of the stratified constituents from the centre of revolution so that either contact surface of the intermediate layer may vary substantially without substantially varying its other contact surface. H. H.

Emulsions; Method of resolving ——. P. T. Sharples. U.S.P. 1,373,773, 5.4.21. Appl., 21.10.18.

A three-phase emulsion is centrifuged to effect separation with the separate discharge of the lightest phase. The discharge is retarded so as to hold a relatively large volume of the lightest phase in the centrifuge, and this is subjected to the highest centrifugal force which is practicable without any substantial discharge of the lightest phase with the heavier phases.—H. H.

Centrifugal separation; Method of and machine for ——. W. H. Peck. U.S.P. 1,374,098, 5.4.21. Appl., 14.11.19.

The mixture is stratified centrifugally, the heavier matter is discharged through ports, and fluid under pressure is caused to act through the ports against the outflow of the heavier particles and then to discharge with the lighter particles through other ports.—H. H.

Extracting valuable components [soluble salts] from raw materials; Process of ——. J. W. Hornsey. U.S.P. 1,373,731, 5.4.21. Appl., 29.6.16.

Raw material containing the soluble salt together with other ingredients is caused to move in contact with and in a counter direction to a mother liquor saturated with other ingredients, within the range of working temperatures employed. The liquor is agitated, solid and liquid are separated, and the liquid is removed from a quiet zone remote from the agitated zone.—J. S. G. T.

Thickener (sewage type). Automatic separator. C. Allen. U.S.P. (a) 1,374,134, and (b) 1,374,135, 5.4.21. Appl., 11.3 and 8.6.20.

A settling vessel is provided with an overflow rim and with a discharge pipe for settled material which extends nearly to the bottom. In (a) the discharge pipe is brought out through the side of the vessel near the top (siphon action) and the rate of discharge controlled by a valve actuated by a float at about the level of the settled material. In (b) the fixed discharge pipe extends vertically upwards above the vessel; the vessel itself is mounted on springs and provided with a valve which closes the discharge pipe when the vessel is light but opens when the vessel reaches a pre-determined weight, the discharge being effected by a fluid pressure pipe opening into the discharge pipe, *e.g.*, by an air lift.—B. M. V.

Furnace. A. Smallwood. U.S.P. 1,373,152, 29.3.21. Appl., 17.7.20.

See E.P. 153,042 of 1919; J., 1920, 809 a.

Charging apparatus for furnaces, kilns, and the like. C. Candlot. E.P. 137,297, 29.12.19. Conv., 10.7.17.

Pulverised coal and other material; Feeding —— to furnaces [by means of air under pressure]. P. E. van Saun. E.P. 160,866, 8.10.19.

Drying chamber. E.P. 147,562. *See* XIII.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Development of electrical conductivity in —— and its variation as a result of heating. F. Fischer and G. Pfleiderer. Ges. Abhandl. Kennt. Kohle, 1919, **4**, 394—408. Chem. Zentr., 1921, **92**, II., 521—522. (*Cf.* Sinkinson, J., 1920, 591 a.)

Coal, peat, lignite, and wood when carbonised all develop an appreciable electrical conductivity at the same temperature, *viz.*, 700°—750° C. The change of conductivity as a result of heating was explored up to a temperature of 1100° C. The temperature coefficient of conductivity was greater with the moderately heated specimens than with the more highly heated specimens. The low-temperature (up to 600°) carbonisation products of the different fossil coals were all in the same condition as regards electrical conductivity. The results suggest a means for distinguishing between low and high temperature cokes, for determining their temperature of carbonisation, and for controlling the uniformity of heating in the charge of coke ovens. —H. J. H.

Coals; Methods for the identification and valuation of ——. F. S. Sinnatt. J. Soc. Dyers and Col., 1921, **37**, 108—113.

A knowledge of the agglutinating power of a coal (J., 1920, 83 t) enables the consumer to compensate for the variation in caking power by varying the amount of coke mixed with the coal, or by varying the size of the particles of the coke breeze, so as to ensure efficient combustion of the coal in steam raising. The rate of combustion of the coal can be modified by the addition of water (up to 8%) prior to introduction into the grate. A further factor in efficient combustion is the average actual size of the pieces of coal.—W. P.

Lignites; Some constituents of ——. R. Ciusa and A. Galizzi. Gazz. Chim. Ital., 1921, **51**, I., 55—60.

The xyloid lignite of Fognano, near Montepulciano, contains a hydrocarbon, $C_{15}H_{20}$, m.pt. 61°—62° C., b.pt. 314°—316° C., or 208°—210° C. at 23 mm. pressure, which represents a new mineral species and is named simonellite; and also three unsaturated hydrocarbons: $C_{15}H_{28}$, b.pt. 222°—228° C. at 25 mm.; $C_{15}H_{28}$, b. pt. 240°—244° C. at 25 mm., and $C_{15}H_{26}$, b.pt. 253° C. at 25 mm. A lignite deposit near Terni contains a hydrocarbon, $C_{20}H_{34}$, m.pt. 74°—75° C., which is possibly identical with hartite. The material known commercially as Forli lignite has more the character of peat and contains lignoceric acid. (*Cf.* J.C.S., May.)—T. H. P.

Tar; Increase in yield and quality of —— by cooling the crude gas between the retort and hydraulic main. Binder. Gas- u. Wasserfach, 1921, **64**, 129—130.

In the experimental apparatus used the gas was sprayed with the ammoniacal liquor in the horizontal offtake to the hydraulic main. It was then passed through a tar separator, a cleaning tower packed with cotton wool, and a tower packed with ferric oxide. The water from the main was led off into two tanks, from the second of which it ran to waste quite clear and from the first of which the tar could be drained off and any scum removed. With the adoption of spraying, 60·3% of the tar was recovered in the hydraulic main, whilst without spraying the quantity recovered in the main was 19·3% of the total. From one ton of coal there was obtained by spraying 41·1 kg. of tar, whilst without spraying there was obtained only 32·8 kg. of tar and 4·6 kg. of pitch. It is claimed that such spraying prevents the formation of pitch in the mains, and the quality of the tar is improved.—A. G.

Gases; Behaviour of explosive mixtures of —— at low pressures. A. Stavenhagen and E. Schuchard. Z. angew. Chem., 1921, **34**, 114—115. (*Cf.* J., 1920, 812 a.)

The critical pressure depends on the diameter of the explosion tube; as the diameter increases the critical pressure decreases. This is due to the greater cooling effect of the walls of the larger tubes. When a spark is passed continuously through a mixture of oxygen and hydrogen maintained below the critical pressure at which explosion occurs, the gases combine slowly and without producing light.—W. P. S.

Ignition of gaseous mixtures by induction coil sparks; Phenomena of the ——. J. D. Morgan and R. V. Wheeler. Chem. Soc. Trans., 1921, **119**, 239—251.

Measurements of the minimum currents ("igniting currents") required in the primary to produce sparks in the secondary of an induction coil at a gap of constant width capable of igniting mixtures in various proportions of methane and air, indicated that the igniting current increases as the percentage of methane in the mixture increases or decreases

on either side of a critical value of 8·2—8·4%. The voltage of the sparks bears a similar relation to the methane percentage, as does also the width of the igniting gap with a constant current of 1 amp. in the primary, so that the energy represented by a given igniting gap bears the same relationship to the mixture ignited as does the energy corresponding to the igniting current for that mixture. As, however, it was shown by thermal measurements made on the sparks that the total energy of the sparks bore a very different relationship to the percentage of methane in the mixture ignited, whilst the voltage of the sparks produced at given igniting gaps bore a relationship similar to that found in the ignition experiments, it is concluded that the igniting power of the induction coil sparks is to be ascribed to the energy of their "capacity components" only ($J_1=\frac{1}{2}CV^2$), and not to their total energy. The assumption involved in this deduction, that ignition is essentially a thermal process involving the heating of a sufficient volume of the mixture to a sufficient temperature for a sufficient length of time, is shown to be justifiable.
—G. F. M.

Air-benzine mixtures; Determination of higher and lower limits of explosion of ——. W. Reinders. Chem. Weekblad, 1921, **18**, 157—159.

For determining the higher and lower limits of explosibility of air saturated with benzine vapour, an apparatus is used consisting of a wide glass tube, surrounded by a jacket containing water or a freezing-mixture, with two platinum wires fused in the top, and with its upper end terminating in a narrow tube with funnel and tap. The tube is connected with a levelling tube. The apparatus is first filled with water and a layer of benzine and a few c.c. of air are then introduced. After bringing the mixture to any desired temperature, the explosibility of the air-vapour mixture is tested by passing a spark through it. Results obtained with many benzine fractions are tabulated. With the light benzine fractions used in motor-cars air saturated with the vapour at temperatures above 0° C. is not explosible; on the other hand, the heavier fractions (b.p. 100°—200° C.; sp. gr. 0·74—0·75) may constitute a risk, and their displacement from storage reservoirs in garages should be effected by means of inert gases, such as nitrogen or carbon dioxide.
—W. J. W.

Paraffin wax; After-treatment of solution obtained in pressure oxidation of ——. F. Fischer and W. Schneider. Ges. Abhandl. Kennt. Kohle, 1919, **4**, 94—100. Chem. Zentr., 1921, **92**, II., 522—523.

When preparing soaps by the pressure oxidation of paraffin wax (*cf.* Schneider, J., 1921, 290 A) the soda solution employed should be neutralised as completely as possible. The soaps can be separated by direct evaporation of the solution, or, better, by removing the supernatant layer of paraffin and allowing to stand over-night, when the salts of the fatty acids separate in the solid state. Brown soaps may be bleached by sodium hypochlorite or by further treatment in the autoclave at 160° C. Still more effective is treatment of the warm solution with acid or with carbon monoxide under pressure at 180°—200° C. The carbon monoxide, behaving as formic anhydride, liberates free fatty acids with the production of sodium formate. This may be converted into formic or oxalic acid or calcined to regenerate the sodium carbonate originally used. The fatty acids precipitated may be purified by distillation either with superheated steam or *in vacuo*. Neutral substances remaining are removed by distillation under diminished pressure at 250° C., followed by extraction with benzene in the cold. In the preparation potash or mixtures of potash and soda may replace sodium carbonate to give correspondingly different types of soap. All the soaps lather well.—H. J. H.

Colorado shale oils; Investigation of ——. A. J. Franks. Chem. and Met. Eng., 1921, **24**, 561—564.

Shale oils from the low-temperature carbonisation of shales from various strata were distilled, and each 10% (by vol.) of the distillate was examined separately. Curves plotted to show the relation between temperature and percentage distilled show a similarity in character of the oils; a sharp bend occurs at 350°—360° C., representing the temperatures between which cracking occurs, although this takes place slightly even at 300° C. Curves obtained with composite samples from the secondary and primary condensers indicate that it is not possible to condense the oil vapours fractionally with success. Specific gravity curves confirm the similar general character of the oils. Saturation (percentage of volume not attacked by sulphuric acid) decreases with increase in boiling point and specific gravity, up to the point where cracking begins, and it is remarkable that cracking of unsaturated oils in the heavy fractions produces lighter oils of higher saturation. This phenomenon is so far without adequate explanation.—W. J. W.

Decomposition of hydrocarbons. Kohlschütter and Frumkin. *See* III.

Gas from strawboard factory waste waters. Hermann. *See* V.

Patents.

Peat; Process for dehydrating ——. E. Laaser and C. Birk. G.P. 331,692, 28.12.19.

The peat pulp is heated under pressure which is then released. Evolution of moist vapours occurs and the vapours are compressed and used for the drying of the peat pulp. As a result of the compression the vapours acquire a temperature somewhat higher than that of the liquid in the peat pulp, and this temperature difference is sufficient for evaporation of the liquid.—H. J. H.

Coke ovens. E. Hurez. E.P. 153,272, 12.3.20. Conv., 29.10.19.

A regenerative coke oven is adapted to be heated either by rich gas from the oven itself or by producer gas or blast-furnace gas. Two adjacent superposed sub-flues establish communication between the heating flues of the oven and two series of regenerating chambers, the arrangement being such that when the oven is heated with poor gas all the even chambers serve alternately for the passage of the waste gases and for the preheating of the air, and the odd chambers serve alternately for the passage of the waste gases and for the heating of the poor gas. When rich gas from the oven is used, the air necessary for combustion is heated by the entire series of regenerating chambers.
—A. G.

Coke ovens. Foundation Oven Corp. E.P. (A) 160,625 and (B) 160,626, 29.1.20, and (C) 160,628, 30.1.20.

(A) The regenerator, which is located in the sole of the oven, consists of an air passage of narrow rectangular cross-section returning parallel to itself once or several times along the whole length of the sole, and having one of its wide faces in close proximity to a waste gas passage for the whole or part of its length. One or several superposed waste gas passages are in close proximity to, and surrounded laterally by, the air passages, which pass back and forth in the same horizontal plane as the waste gas passages. The flues in adjacent rows are so arranged that the combustion flues in one row are opposite the waste gas flues in the adjacent rows, so as to distribute equally the heat throughout the oven. Two waste gas flues correspond to each combustion flue, one of the former being placed on either side of the latter. (b) A regenerator and gas preheating duct system are provided for each row of flues. The gas preheating ducts can be cut out and air and hot waste gases can be conducted alternately through a common horizontal flue in the sole of each coking chamber, which flue communicates with alternate flues in the two heating walls of the coking chamber. Two gas ducts under each heating wall are connected with alternate combustion flues in each wall. Each regenerator is divided longitudinally into two superposed portions and communicates with the common air or hot gas flue at the outer end of the oven only. The gas admission and discharge ends of the preheating ducts are exposed in front of the oven and are adapted to be easily connected respectively with a gas main and with a gas duct leading to alternate combustion flues or to be closed altogether. A three-way valve is provided outside the oven which can open communication of the discharge end of the gas preheating system with either of the two gas ducts leading to the combustion flues of each heating wall. The combustion flues are staggered, so that the vertical combustion flues in one heating wall are opposite the vertical hot gas flues in the adjacent heating walls. Each pair of combustion flues is provided with a separately adjustable valve by which the quantity of air can be adjusted separately at successive points along the line of the combustion flues so as to control the distribution of heat along this line. The air from the horizontal flue can be admitted to each pair of combustion flues independently. (c) The coke oven has combustion flues, gas ducts, and a preheating passage for the gas, the outer ends of the gas ducts comprising a box or casing providing two chambers in communication with the respective gas ducts and having ports opening communication between the respective gas ducts and the preheating passage. The ports are provided with valves, and a single device on the outside of the oven is provided for operating the valves alternately.—A. G.

Gas; Method of manufacturing ——. W. D. Wilcox. U.S.P. 1,372,731, 29.3.21. Appl., 1.4.18.

The plant comprises two vertical cross-connected retorts disposed above and discharging into two corresponding generators. One of the generators is blown with air and the blast gases are conveyed through a valve into heating flues adjacent to the retorts. A partial vacuum is concurrently created at an outlet in the lower portion of the second generator sufficient to draw the gases and vapours distilling off in the retorts through the preheated material in the second generator and through the outlet. The second generator is then subjected to an air blast and the process repeated, using alternate generators and retorts. A maximum pressure is maintained within the plant at a point in the lower portion of the retort above the generator in blast.—A. G.

Gas producer. J. C. Miller and A. Isles, Assrs. to The W. R. Miller Co. U.S.P. 1,373,443, 5.4.21. Appl., 14.6.19.

The cylindrical body and ash-pan of the producer are revolved at the same rate and in the same direction. The body carries a grate which is inclined inwards and surrounded by a stationary bustle pipe, water troughs sealing the joint between the bustle pipe and the body portion. The blast devices extend through the bustle pipe.—A. G.

Gas; Method of producing ——. L. W. Bates. U.S.P. 1,373,704, 5.4.21. Appl., 19.2.20.

A mixture of a liquid hydrocarbon and a pulverised solid fuel is injected into a mixture of air and steam in a generator heated to a temperature sufficient to transform the particles of solid carbonaceous substance and the liquid hydrocarbon into gas. The ash is removed from the gas, which is then washed with a liquid hydrocarbon to remove tar and carbon.—A. G.

Chamber oven plant. H. Bröcker. G.P. 330,347, 17.4.19. Addn. to 315,099 (J., 1920, 478 a).

The producers are first heated with coke and then charged with coal which is carbonised by heat from the coke below, which after some degree of cooling is withdrawn. The producers thus behave as gas retorts—a convenience in small installations.

—H. J. H.

Distillation of coal; Apparatus for ——. A. Niewerth. G.P. 331,508, 24.8.12.

A central vertical retort is provided with two inclined heating chambers, one at each side, containing coal or coke, used as fuel. The free spaces of the side chambers and of the central retort are in communication and one side chamber is connected with the top of the retort, the other with the bottom. Producer gas developed by a blast in one side chamber is passed from the top of the inner retort to the bottom and thence into the hot coal in the other side chamber. The process can be reversed so as to maintain a continuous distillation.

—H. J. H.

Vertical retort for continuous carbonisation of coal. Rombacher Hüttenwerke, and J. I. Bronn. G.P. 332,102, 14.7.18.

Most coking coals, when being carbonised, have completed the stage of melting, caking, and swelling by about one-quarter to one-third of the time for complete coking. Afterwards no further change in dimensions occurs, and if an enlargement of the sectional area of the retort is made at the point where this stage is reached, the hanging up of the charge can be prevented.—H. J. H.

Gas-making furnace. B. Ludwig. G.P. 332,103, 31.3.18.

The furnace is provided with superposed heating flues in which gas and air are led separately, but the flues are perforated so as to permit a gradual admixture and combustion and divided into two groups in which the heating gases travel in opposite directions. Gradual combustion and even heating of the furnace are achieved.—H. J. H.

Fuels; Treatment of dusty, bituminous —— for recovery of nitrogenous by-products by carbonisation. "Gafag," Gasfeuerungsges. Wentzel und Co. G.P. 332,507, 5.8.19.

The fuels are "briquetted" by means of sodium silicate, whereby the passage of gases through the charge during carbonisation is facilitated.

—W. J. W.

Low-temperature tar; Method for producing tar of aliphatic compounds or —— [in gas producers]. G. A. Pestalozzi. E.P. 145,408, 9.6.20. Conv., 20.6.19.

Immediately above the fuel bed in a gas producer a cooling zone is established, the temperature of which is kept below 400° C. by injecting water, steam, gases or the like, whereby detrimental decomposition of the gases and vapours produced in the distilling zone of the generator is avoided.

—A. G.

Mixed gas from the distillation of coal and of wood, peat, or lignite; Production of ——. C. O. Rasmussen. G.P. 332,057, 17.11.18.

The gases are not mixed until the tars have been separated and then the mixture goes through the customary purification processes. Whereas in coal gas tars basic compounds predominate, in tars from wood, peat, etc. acid constituents are in excess. If the crude gases are mixed stoppages occur readily, while the tars are commercially more valuable when separate than when mixed.—H. J. H.

Gas; Production of lighting and heating —— *from bituminous shale.* E. von der Burchard and A. Rau. G.P. 332,155, 22.5.19.

Crude gas obtained in the distillation of shale is passed through a layer of red hot carbonaceous material, *e.g.*, coke or charcoal, contained either in the retort or in a separate "cracking" chamber. Oils are thereby cracked to form permanent gas, and carbon dioxide from the shale is reduced to carbon monoxide. A comparatively high-grade gas (310—400 B.Th.U. per cub. ft.) is produced.—H. J. H.

Blast-furnace and generator gases; Purification of ——. N. Klärding. E.P. 153,263, 28.10.20. Conv., 31.10.19.

The crude gas is passed through granular material, which moves continuously downward through an enclosed chamber, and the dust is removed from the material by passing a branch stream of purified gas through the material in an auxiliary chamber, into which the material is discharged by a shaking screen in the lower part of the main chamber.—A. G.

Hydrogen sulphide [in producer and coke-oven gases]; Oxidation of ——. W. Schumacher. G.P. 331,287, 6.3.17.

The hydrogen sulphide in producer gas, coke-oven gas, and the like is oxidised to sulphur and oxides of sulphur by passing the gas mixture, together with the requisite amount of air, over charcoal which is heated to a temperature below that at which the gas ignites. The process can be carried out at 100° C.; the charcoal remains unchanged and the sulphur deposited on it can be recovered afterwards without difficulty.—J. H. L.

Iron oxide solutions; Preparation of stable, alkaline —— *for gas purification.* Badische Anilin- und Soda-Fabr. G.P. 333,755, 3.4.18.

The addition of a small quantity of a disinfectant, *e.g.*, phenol, cresol, naphthol, or crude tar, to the alkaline solution prevents decomposition by bacteria of the organic compounds, such as tartaric acid or oxalic acid, added to keep the iron compounds in solution.—L. A. C.

[Alcohol] distillation process. E. W. Stevens, Assr. to Chemical Fuel Co. U.S.P. 1,372,465, 22.3.21. Appl., 9.3.20.

Commercial aqueous alcohol is mixed with a hydrocarbon oil and fusel oil and the mixture is redistilled to obtain a fraction consisting mainly of alcohol and substantially free from water, for use in making composite motor-fuels.—A. R. P.

Shale and the like material; Method of and apparatus for treating ——. L. B. Ard. U.S.P. 1,373,698—9, 5.4.21. Appl., 3 and 4.2.21.

The shale is conveyed to the bottom of a cylindrical retort containing molten metal by a helical vertical conveyor, concentric with a helical vane surrounding the conveyor which retards the upward flow of the shale, so that the whole of the volatile matter is evolved during the upward movement of the shale through the molten metal.—A. G.

Oil-shale retort. F. Jones. U.S.P. 1,373,890, 5.4.21. Appl., 29.5.18.

A continuous retort for the destructive distillation of oil-sands and oil-shale comprises a series of superposed intercommunicating annular hearths, combustion or heating chambers interposed between the hearths, the floors of the latter constituting the roofs of the combustion chambers, a central hollow shaft with hollow arms and rabbles for advancing the material from one hearth to another, and means for supplying steam to the shaft and arms, the latter being perforated to allow steam to be directed on to the material under treatment.—A. de W.

Petroleum; Extraction of —— *from oil-bearing sands and rocks.* W. Horwitz. G.P. 332,100, 1.4.19.

The material is heated in a suitable vessel by pressure water or live steam, which is introduced tangentially or at an angle to the sides for preference. The mixture of oil-sand and hot water passes through the vessel without losing pressure. Substances are introduced either continuously or intermittently to facilitate extraction, *e.g.*, benzene, toluene, common salt, sodium sulphate, etc. —H. J. H.

Hydrocarbons; Apparatus for cracking ——. J. W. Coast, jun., Assr. to The Process Co. U.S.P. 1,372,937, 29.3.21. Appl., 22.5.17.

A horizontal cylindrical cracking still is provided with rows of scrapers in staggered relation attached to an oscillating frame provided with journals at the horizontal axis of the still. All the scrapers slide in the frame and fall by gravity, so as to be continually in contact with the still bottom for the purpose of removing coke deposits.—L. A. C.

Petroleum products; Method of distilling ——. C. Kroll. U.S.P. 1,373,251, 29.3.21. Appl., 11.4.18.

The vapours obtained by distilling the hydrocarbons percolate through a body of absorbent material contained in a chamber insulated to prevent loss of heat. The vapours of the high-boiling hydrocarbons are extracted in the chamber, and the remaining vapours are condensed.—L. A. C.

Hydrocarbon oils; Treating ——. D. T. Day. U.S.P. 1,373,391, 29.3.21. Appl., 30.4.18.

A mixture of high-boiling hydrocarbon oils and petroleum residues having a higher cracking point than the oils is subjected to heat treatment above 600° F. (315° C.), but below the temperature necessary to crack the residues. Low-boiling hydrocarbons are separated from the product, and the residues are added to a further quantity of the high-boiling oil.—L. A. C.

Gasoline from crude oil; Process for the production of ——. *Process for the production of hydrocarbons of low boiling-points from hydrocarbons of high boiling-points.* P. Danckwardt. U.S.P. (A) 1,373,653 and (B) 1,373,654, 5.4.21. Appl., 27.8.17.

(A) Material containing high-boiling hydrocarbons is caused to react with a heated mixture of carbon, a halide, and a metal, and fractions of low and high boiling points are condensed separately from the vapours. (B) Air and steam are passed through an ignited mixture of carbon, nickel, and nickel chloride, hydrocarbon oil is added to the mixture, and the vapour generated is passed through a mixture of oil with carbon, nickel chloride, and nickel. That portion of the vapour which boils at or below 150° C. is condensed separately from portions boiling at higher temperatures.—L. A. C.

Catalysis; Process of ——. E. W. Stevens, Assr. to Chemical Fuel Co. of America. U.S.P. 1,374,119, 5.4.21. Appl., 18.3.20.

In the catalysis of gaseous carbon compounds by means of hot metallic catalysts which are used under conditions whereby carbon would be deposited, the surface of the catalyst is sparked during the process.—A. J. H.

Hydrocarbons such as petroleum spirit; Production of light ——. Allgem. Ges. für Chem. Ind. m.b.H. G.P. 333,168, 5.12.17.

The oils obtained by distilling petroleum or lignite tar are purified by treatment with liquid sulphur dioxide, and are then distilled with aluminium chloride, yielding 70% or more of light petroleum spirit.—L. A. C.

Petroleum oils; Recovery of —— *from the acid resin obtained in refining petroleum.* Harburger Chem. Werke Schön und Co. G.P. 333,169, 11.12.18.

The acid resin, after removal of free acid, is dried and agitated at 120°—125° C. with concentrated sulphuric acid. The product on distillation yields a moderately high boiling oil which can be employed for lighting or heating, as a lubricant, or for other purposes. The residual resin, which has a higher m.p. than the original material, is suitable for use as an insulator.—L. A. C.

Still for cracking or distilling hydrocarbons, tar, or the like. A. Sommer. G.P. 333,216, 21.10.15.

A metal still is provided with a close fitting, thin-walled metallic lining which can be replaced when encrusted with carbon deposits.—L. A. C.

Lubricating oil; Production of —— *from wood tar.* O. de F. Skibsted. G.P. 330,276, 27.6.19.

The fractions boiling above 250° C. are neutralised with powdered lime, oxidised by a current of air, and then distilled. The treatment can be carried out in the tar still and during the distillation, which is interrupted for the purpose.—H. J. H.

Lubricants; Production of —— *from tar distillates.* Verkaufsvereinigung für Teererzeugnisse G.m.b.H., and F. Schreiber. G.P. 330,970, 24.6.19.

The heated tar oil is treated with sulphur in presence or absence of air. Anthracene and phenanthrene are thereby converted into soft, pitchy substances, which increase the lubricating properties of the oil. Lubricants for axles, ropes, and briquette-rolls can be prepared in a similar manner from the crude anthracene press-cake alone or with addition of oils.—H. J. H.

Asphalt substitute; Production of ——. Harburger Chem. Werke Schön & Co., and W. Daitz. G.P. 330,650, 6.7.18.

Soft pitch is heated and stirred for a long time with a paste made by incorporating with water mineral matter such as magnesia, alumina, silicates of mag-esium and aluminium, or precipitated iron oxide. A temperature of 110°—115° C. is maintained, at which the water is evaporated and a product resem-ling Trinidad asphalt obtained.—H. J. H.

Montan wax; Process for saponifying —— *with simultaneous bleaching of the soap produced.* F. Fischer. G.P. 334,155, 18.3.19.

rude or purified montan wax is heated below 0° C. and under increased pressure with aqueous lutions of bases or other compounds which com-ne with fatty acids, *e.g.*, sodium or potassium rbonate, in the presence of oxygen. By acidification of the solution a clear, hard, resinous product is tained.—L. A. C.

Tar-extractor and scrubber for gas. J. Wells. U.S.P. 1,373,280, 29.3.21. Appl., 13.9.19.

See E.P. 153,109 of 1919; J., 1920, 813 a.

Hydrocarbons; Process of converting liquid —— *into hydrocarbons of lower boiling point.* W. M. McComb. E.P. 160,907, 24.12.19.

See U.S.P. 1,337,144 of 1920; J., 1920, 396 a.

See also pages (a) 346, *Hydrogen sulphide from gases* (G.P. 299,163 and 331,322). 356, *Emulsions* (U.S.P. 1,373,661). 359, *Tanning material* (G.P. 333,403). 367, *Waste water from gas-works* (G.P. 333,703). 369, *Fatty acids and aldehydes* (G.P. 332,478).

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

"Kelpchar," a new decolorising carbon. J. W. Turrentine, P. S. Shoaff, and G. C. Spencer. Science, 1919, **50**, 507.

Supplementing the work of Zerban (J., 1919, 527 a, 873 a) it was shown that a decolorising carbon of high activity could be produced in large quantity, the method of heating being of importance. Carbonising in one stage failed to yield a product of uniform quality, but by carbonising in two stages consistently satisfactory results were obtained. After leaving the retorts, the porous char was extracted with hot water to remove potassium chloride and iodide, the residue heated with dilute hydrochloric acid, washed with water to neutrality, and dried. The carbon obtained in this way compares favourably with "Norit."—J. P. O.

Patents.

Retort [for wood distillation]. H. M. Barr. U.S.P. 1,373,702, 5.4.21. Appl., 24.5.20.

A metallic shell lined with asbestos is divided by a false bottom of reticulated material into an upper retort chamber and a lower heating chamber. A pair of flues extends along the heating chamber for heating the retort, each flue including two stationary sections, one seated in one wall of the shell and leading to the source of heat, and the other seated in the opposite wall and leading to the stack. A "floating" flue section is suspended within the heating chamber between the stationary sections and is spaced from the walls of the heating chamber. The "floating" section consists of a split asbestos sleeve having a central convex portion, a split metallic sleeve having a corresponding convex portion, and clamping bands for securing the ends of the sleeve to the respective flue sections. —A. G.

Wood and other vegetable products; Recovery of volatile compounds from ——. E. Heuser. G.P. 332,298, 8.4.19.

The raw material is heated with inorganic acids at normal or elevated pressure, with or without the introduction of steam, and is afterwards subjected to dry distillation. A good yield of volatile organic compounds results without any reduction in the yield of tar or gases.—W. J. W.

Low-temperature tar; Apparatus for production of ——. G. de Grahl. G.P. 332,109, 19.3.19.

The raw material (coal, peat, or similar substances) is continuously forced or drawn through tubes enclosed in spiral heating flues, the tubes being arranged singly or in series. The products are delivered into a chamber, where separation of the gas from the solid residue occurs, so that the time of contact of gas and solid is reduced to a minimum.—H. J. H.

III.—TAR AND TAR PRODUCTS.

Hydrocarbons; Decomposition of —— by canal rays. V. Kohlschütter and A. Frumkin. Ber., 1921, **54**, 587—594.

The vapours of naphthalene, benzene, diphenyl, anthracene, phenanthrene, fluorene, decane, and petroleum have been subjected to the action of canal rays in a vessel so designed that the vapour can be passed at a desired pressure between an anode of aluminium wire and a specially constructed cylindrical cathode. In every case the latter becomes more or less rapidly coated with a deposit which ultimately is of sufficient thickness to impede the passage of the current. The properties of the deposit depend on the potential of the cathode and not on the mode of union of the carbon in the decomposed product. With low potentials the deposits are transparent and coherent, and evolve large quantities of gas and tar when heated; at higher potentials they consist of practically pure carbon, which closely resembles anthracite in appearance. Graphite does not appear to be formed. (*Cf.* J.C.S., June.)—H. W.

Phenols; Pressure oxidation of ——. F. Fischer and H. Schrader. Ges. Abhandl. Kennt. Kohle, 1919, **4**, 293—309. Chem. Zentr., 1921, **92**, II., 606—607.

The oxidation of phenols by air under 45 atm. pressure was examined to see if resinous substances were obtainable, with the ultimate object of producing substances similar to bakelite from the phenols of low-temperature tar without the use of formaldehyde. The products obtained were partly insoluble condensation products and partly degradation products. Under suitable conditions fairly clear resinous substances were obtained, the colour being dependent on the reaction and concentration of the original mixture. Phenol at 100° C. in presence of a 2·5 *N* soda solution yielded a considerable quantity of brown resinous product, but less at 150°—200° C. The three isomeric cresols were oxidised in presence of soda solution and *o*-cresol in presence of an excess of sodium hydroxide. Colouring matters and degradation products were obtained, but little resinous matter. The colouring matters were apparently fuchsine derivatives resulting from condensation of cresol and aldehydes. In presence of *N*/1 H_2SO_4 above 150° C. *o*-cresol was extensively oxidised, yielding solid products. At 150° C. the products were a hard, lustrous, orange-coloured resin, soluble in benzene and alcohol, and also a brown substance insoluble in benzene, and small quantities of colouring matter.—H. J. H.

Naphthols and naphthylamines; Reaction of —— with bisulphite. P. Friedländer. Ber., 1921, **54**, 620—624.

The reactivity of naphthols with bisulphite has been considered by Bucherer to be due to the intermediate formation of highly reactive naphthyl sulphites, but this view is not in harmony with the established properties of these substances. It is simpler to assume that the naphthols react in the tautomeric ketonic form, and that the products are normal ketone bisulphite additive compounds. Evidence in favour of this view is found in the observation that hydroxynaphthoic acid and bisulphite react with *as*-methylphenylhydrazine in exactly the same manner as with phenylhydrazine and yield N-methylnaphthophenocarbazole,

$$C_{10}H_6—N(CH_3)—C_6H_4.$$

This reaction is not possible if Bucherer's view be accepted. (*Cf.* J.C.S., June.)—H. W.

Toluenesulphonyl chlorides; Melting point of mixtures of o- and p- ——. L. Harding. Chem. Soc. Trans., 1921, **119**, 260—262.

The melting points of mixtures of pure *o*- and *p*-toluenesulphonyl chlorides in various proportions were determined and the melting point curve obtained. Following are some of the figures recorded: 0·0 % of *para*-isomeride, m.p. 10·17° C.; 10·0%, 5·8°; 17·5% (eutectic), 1·6°; 20·0%, 7·9°; 50·2%, 39·8°; 78·2%, 57·3°; and 100·0% of *para*-isomeride, 67·2° C. The pure *o*-toluenesulphonyl chloride was prepared by fractional precipitation of the *o*-sulphonamide from its sodium salt, hydrolysis of this substance to sodium *o*-toluenesulphonate, and treatment of the latter with phosphorus pentachloride. It had the following constants: b.p. 126° C. at 21 mm., sp. gr. 1·3383 at 20°/4° C., m.p. 10·17° C., n_D=1·5575.—G. F. M.

Dinitroanthraquinones. M. Battegay and J. Claudin. Bull. Soc. Ind. Mulhouse, 1920, **86**, 628—631.

When the crude product of the dinitration of anthraquinone is reduced the whole of the 1.5-, almost the whole of the 1.8-, and a large proportion of the 2.6-diaminoanthraquinone can be separated. The residue of mixed diaminoanthraquinones has been diazotised, converted into the corresponding dihydroxyanthraquinones, and separated into 2.6-, 1.8-, 1.6-, 1.7-, and 2.7-dihydroxyanthraquinones. Based on these results, it is calculated that the dinitration of anthraquinone yields 37% of 1.5-, 37% of 1.8-, 4·2% of 1.7-, 3·6% of 1.6-, 6% of 2.6-, and 4% of 2.7-dinitroanthraquinone. Dhar (J., 1920, 685 A) claimed that 1.2-, 1.3-, 2.6-, and 1.5-dinitroanthraquinones are formed by the dinitration of anthraquinone, and identified these products by conversion into the corresponding dibromoanthraquinones. Repetition of his experiments has led to the isolation of 1.5- and 1.8-dibromoanthraquinones, and has shown that the products regarded by Dhar as 1.2- and 1.3-dibromoanthraquinones cannot be homonuclear dibromoanthraquinones. (*Cf.* J.C.S., June.)—F. M. R.

Dibromoanthraquinones. M. Battegay and J. Claudin. Bull. Soc. Ind. Mulhouse, 1920, **86**, 632—635.

There are ten possible dibromoanthraquinones, and that used by Graebe and Liebermann as the intermediate product in their classical synthesis of alizarin might be assumed to be the 1.2-derivative, but a study of various dibromoanthraquinones has shown that that is not the case. The dibromoanthraquinone of Graebe and Liebermann has been stated to be formed by the direct bromination of anthraquinone at 100° C. or by the oxidation of tetrabromoanthracene, but the two products are not identical. In the former case the product is 2.7-dibromoanthraquinone, yellow spangles, m.p. 252° C., whilst in the latter case, after many crystallisations from benzene and toluene, 2.3-dibromoanthraquinone, yellow needles, m.p. 283° C., is obtained. When 1.4-nitrobromoanthraquinone is reduced, the bromine is eliminated, and α-aminoanthraquinone is formed. (*Cf.* J.C.S., June.)
—F. M. R.

Patents.

Tar oils; Production of pure —— from the crude oils. M. Melamid and L. Grötzinger. G.P. 332,112, 5.4.17. Addn. to 264,811 (E.P. 9856 of 1912; J., 1913, 820).

Crude tar oils, or fractions thereof, are treated with phosphoric acid or similar compounds in the cold, followed, if necessary, by distillation. Unsaturated hydrocarbons are polymerised and separate with the phosphoric acid as resinous masses.—H. J. H.

Phthalic anhydride; Manufacture of ——. A. Wohl. E.P. 145,071, 16.6.20. Conv., 28.6.16.

Phthalic anhydride is obtained by passing a mixture of naphthalene vapour with air or oxygen over a suitable catalyst maintained below 500° C. The gas mixture may conveniently be obtained by passing air through or over naphthalene at 100°—120° C., and a suitable catalyst is prepared by soaking pumice (18 pts.) in a solution containing vanadic acid (2 pts.), and drying. The best results are obtained when the contact mass is maintained at 320°—330° C.—G. F. M.

Diphenyl oxide; Process of forming ——. J. M. Johlin, Assr. to Semet-Solvay Co. U.S.P. 1,372,434, 22.3.21. Appl., 24.7.19.

A mixture of sodium benzenesulphonate and sodium hydroxide in such proportions that a portion of the sodium benzenesulphonate remains uncombined is heated to produce sodium phenoxide, and the heating is continued at such a temperature that the sodium phenoxide combines with the unchanged sodium benzenesulphonate to yield diphenyl oxide. —L. A. C.

Nitrotetrahydronaphthalenes; Preparation of reduction products of ——. *Preparation of polycyclic, hydroaromatic hydrocarbons* (*octohydroanthracene and octohydrophenanthrene*). Tetralin Ges.m.b.H. G.P. (a) 333,157, 17.3.16, and (b) 333,158, 15.3.19.

(a) The nitro derivatives of tetrahydronaphthalene, or its homologues, yield on reduction with different reducing agents not only the corresponding amines, but also intermediate reduction products, such as hydroxylamines, which by intramolecular conversion yield derivatives of *p*-aminophenol, azoxy-, azo-, and hydrazo-compounds, the last of which undergo the benzidine conversion. A mixture of 1- and 2-nitrotetrahydronaphthalene on reduction, *e.g.*, with tin or stannous chloride and hydrochloric acid, yields a mixture of the corresponding amines, which can be separated by fractional crystallisation of the hydrochlorides or the acetyl compounds; 1- and 2-acetaminotetrahydronaphthalenes melt respectively at 156°—158° C. and 105°—106° C.; 1-aminotetrahydronaphthalene is a colourless liquid when freshly distilled, b.p. 146° C. (12 mm.), and 2-aminotetrahydronaphthalene forms colourless crystals, m.p. 38·5°—39·5° C., b.p. 146°—147° C. (12 mm.). Pure 1-nitrotetrahydronaphthalene, prepared by partial reduction of 6 mols. of a mixture of the 1- and 2-nitro compounds with 10 mols. of hydrogen and subsequent shaking with acid to dissolve the amines, on reduction with sufficient zinc dust and alcoholic sodium hydroxide to give 4 atoms of hydrogen, yields 1-azotetrahydronaphthalene, which forms ruby red prisms from hot acetic acid, m.p. 175°—177° C., and can be converted by further reduction with zinc dust and sodium hydroxide to 1-hydrazotetrahydronaphthalene, m.p. 180°—182° C. This compound is readily oxidised to the azo compound, and on treatment with mineral acids gives 4.4′-diamino-1.1′-octohydrodinaphthyl. 4-Nitro-2-aminotetrahydronaphthalene, m.p. 94°—96° C., is prepared by nitrating 2-acetaminotetrahydronaphthalene, by reducing a solution of 1.3-dinitrotetrahydronaphthalene in boiling alcohol and ethyl acetate with sodium hydrosulphide, or by partial catalytic reduction of the dinitro compound; complete catalytic reduction of the dinitro compound with hydrogen at 125° C. under pressure ields 1.3-diaminotetrahydronaphthalene, b.p. 201°—203° C. (13 mm.) and m.p. 72°—74° C. A solution of 3-nitro-2-aminotetrahydronaphthalene in ecahydronaphthalene on treatment with hydrogen t 150° C. under pressure, in the presence of nickel, ields 2.3-diaminotetrahydronaphthalene, m.p. 135°—136° C., which on boiling with acetic acid forms an iminazole,

$C_{10}H_{10}\left\langle{}^{N}_{NH}\right\rangle C.CH_3$

of m.p. 251°—252° C. (b) A mixture of, *e.g.*, 1000 pts. of tetrahydronaphthalene and 15—20 pts. of aluminium chloride is heated for about 6 hrs. below 100° C. The product is washed with acidified water, and distilled. Benzene and unchanged tetrahydronaphthalene pass over in the first fractions, while octohydrophenanthrene, octohydroanthracene, and a polycyclic, hydroaromatic hydrocarbon distil respectively at 160°—170° C., 170°—180° C., and 230°—235° C. (11 mm.); these compounds on heating with sulphur or distillation with zinc dust yield respectively phenanthrene, anthracene, and an aromatic hydrocarbon of m.p. 168°—169° C. The octohydroanthracene has m.p. 72°—73° C., and is not identical with the compound previously described. The products or mixtures of the same are suitable for use as lubricants.—L. A. C.

See also pages (a) 339, *Still* (G.P. 333,216); *Lubricating oil* (G.P. 330,276); *Lubricants* (G.P. 330,970); *Asphalt substitute* (G.P. 330,650). 349, *Asphalt-like material* (G.P. 332,634).

IV.—COLOURING MATTERS AND DYES.

Halogenated indigos; Halogenated nitrobenzaldehydes and ——. L. C. Janse. Rec. Trav. Chim., 1921, **40**, 285—317.

p-Aminobenzaldehyde when brominated in solution either in dilute hydrochloric acid or in acetic acid gives an almost quantitative yield of 3.5-dibromo-4-aminobenzaldehyde. In this latter compound the amino group may be replaced more or less readily by chlorine, bromine, iodine, or hydrogen, and the products on nitration give substituted *o*-nitrobenzaldehydes, which may be converted by treatment with acetone and alkali into halogenated indigos (*cf.* Baeyer and Drewsen, Ber., 1882, **15**, 775; 1883, **16**, 2188). A whole series of such compounds is described. (*Cf.* J.C.S., June.)—W. G.

Auxochromes; Combined ——. H. Kauffmann. Ber., 1921, **54**, 795—802.

Such auxochrome-like groups of atoms as exhibit increased auxochromic character on account of the presence in them of true auxochromes are termed combined auxochromes. Their properties are examined in the particular instance of the dimethoxystyryl group, the *p*-nitrophenyl residue being used as chromogen. The utility of styryl in this connexion depends on the immediate attachment of its ethylenic linkage to the benzene nucleus, since substances such as 4-nitro-2.4′-dimethoxychalkone are only feebly coloured. The whole dimethoxystyryl complex is to be regarded as a new auxochromic unit. The combined auxochromes, like the simpler ones, are able to facilitate fluorescence. (*Cf.* J.C.S., June.)—H. W.

Patents.

Hydroxyazo dyes; Manufacture of ——. G. T. Morgan, and British Dyestuffs Corp., Ltd. E.P. 160,848, 17.7.19.

Diazotised o-aminophenols, *o*-aminonaphthols, and their nitro, sulphonic, and carboxyl derivatives are coupled with 4.6-diamino-1.3-xylene, yielding products which dye animal fibres brown shades in conjunction with metallic mordants.—L. A. C.

Azo dye. T. H. Leaming, Assr. to National Aniline and Chemical Co., Inc. U.S.P. 1,372,439, 22.3.21. Appl., 27.2.20.

A disazo dye is claimed, having the probable formula $NH_2.C_6H_4.(4)N_2(2).C_{10}H_3((1)NH_2,(4)SO_3Na,(8)OH)$.

$(7)N_2.C_6H_4.(4)NHC_2H_3O$, which yields *p*-phenylenediamine and triamino-8-naphthol-4-sulphonic acid on saponification and reduction with stannous chloride and hydrochloric acid, and dyes cotton, wool, natural and artificial silk greenish-black shades which can be developed on the fibre.
—L. A. C.

Condensation products resembling indophenol; Preparation of ——. Act.-Ges. für Anilin-Fabr. G.P. 333,897, 28.11.16.

p-Nitrosophenol, *p*-nitroso-*o*-cresol, or *p*-nitroso-*o*-chlorophenol is condensed with a phenol alkyl ether which is not substituted in the para position to the alkoxy group, such as anisol, *o*-chloroanisol, phenetol, *o*-cresol ethyl ether, or resorcinol dimethyl ether, in the presence of sulphuric acid of about 60° B. (sp. gr. 1·71), or concentrated hydrochloric acid. The products separate from the acid solution as brown or red compounds, which are coloured blue by the addition of alkalis, dissolve in concentrated sulphuric acid to give blue solutions, and in aqueous sodium sulphide to give feebly coloured solutions which turn blue in the presence of air, and yield the corresponding leuco compounds on the addition of acids.—L. A. C.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Cotton and other textile fibres; Action of sea-water on ——. C. Dorée. Biochem. J., 1920, 14, 709—714.

Fabrics of cotton and silk are destroyed by immersion in sea-water for three weeks, wool lasting somewhat longer. This destructive action is, in the case of cellulose, due to micro-organisms, and not to oxygen, light, or the salts present. In its nature it resembles the "mechanical" breakdown of cotton sometimes observed under the "beetling" process (*cf.* Cross, J., 1920, 58 A). If cotton is acetylated to the monoacetate stage so that its structural qualities are preserved, the resulting material is very resistant to sea-water. Cellulose acetate silk withstands the action of sea-water for months.
—J. C. D.

Fibrous materials; Molecular structure of ——. R. O. Herzog and W. Jancke. Umschau, 1921, 25, 53—54. Chem. Zentr., 1921, 92, II., 573.

From experiments with Röntgen rays it is concluded that in plant fibres the cellulose is present in a crystalline form disposed symmetrically with respect to the axis of the fibre. Artificial silk consists of an irregular felted mass of crystalline fragments of unchanged cellulose; artificial silk made from cellulose acetate is amorphous and consists of a mixture in which the cellulose acetate has undergone considerable degradation. Natural silk shows a crystalline character and a similar symmetrical structure to that of cellulose. Animal hair is amorphous, and probably consists of two or more substances. Starch and pure fats are crystalline.
—J. H. L.

Polysaccharides. III. Cellulose. P. Karrer and F. Widmer. Helv. Chim. Acta, 1921, 4, 174—184.

Comparison of the yields of cellobiose octo-acetate obtained by treating cellulose, cellobiose, methylcelloside, cellulose triacetate, cellobiose acetate, and methylcelloside acetate with acetic anhydride and sulphuric acid under similar conditions leads to the conclusion that cellulose must contain at least about 50%, and possibly more, of ready-formed cellobiose complex. Hess and Wittelsbach's formula for cellulose (J., 1920, 512 A) cannot, therefore, be accurate, as it indicates only 33% of pre-formed cellobiose. Methylation of cellobiose by means of alkali and methyl sulphate gives unsatisfactory results, but methylation of methylcelloside in this way gives an almost quantitative yield of hexamethylmethylcelloside. The latter may be further methylated, by means of dry methyl iodide and silver oxide, to heptamethyl-β(?)-methylcelloside, and hydrolysis of this by boiling 5% hydrochloric acid solution yields products from which β-tetramethylglucose may be isolated. (*Cf.* J.C.S., May.)
—T. H. P.

Cellulose. III. Asymmetric structure of cellulose and the influence of ammoniacal copper hydroxide [Schweizer's reagent] on the rotation of carbohydrates. K. Hess and E. Messmer. Ber., 1921, 54, 834—841.

Levallois' observation that solutions of cellulose in ammoniacal copper hydroxide solution are optically active is confirmed, and the activity is proved to be due to the cellulose content. Under slightly varying conditions the values $[\alpha]$=ca. −950° and −1000° are found, but accurate work is particularly difficult with the blue light. On the other hand, the "regenerated" cellulose is optically inactive in concentrated hydrochloric acid solution, as are also ethereal solutions of ethylcellulose, aqueous alkaline solutions of xanthate (viscose) cellulose, and jellies of cellulose in neutral salt solutions. Cellulose presents, therefore, a marked example of "latent asymmetry," thus resembling mannitol, and it appears that ammoniacal copper hydroxide behaves towards it in the same manner as boric acid or borax to the simpler carbohydrates. (*Cf.* J.C.S., June.)—H. W.

Cellulose. K. Freudenberg. Ber., 1921, 54, 767—772.

Cellobiose octa-acetate can be isolated in yield corresponding with the presence of 35—36% of cellobiose in the original material in a single operation when cellulose is treated with a mixture of acetic anhydride and concentrated sulphuric acid at a low temperature, the operation requiring about 14 days. An indirect estimation of the loss of octo-acetate which occurs during the change makes it probable that cellulose is composed of cellobiose to the extent of more than 60%. This result is not in harmony with Hess's conception of cellulose (J., 1920, 512 A) as composed of pentaglucosidylglucose residues, but is in agreement with the hypothesis that it is built up of cellobiose residues arranged in a uniform polysaccharide chain of ten or more members. (*Cf.* J.C.S., June.)—H. W.

Wood cellulose [; Action of sodium hydroxide on ——]. W. G. Harding. J. Phys. Chem., 1921, 25, 201—203.

The product remaining after heating wrapping paper with 1% sodium hydroxide solution at 100° C. amounted to about 60% of the original material, although absolute equilibrium was not reached even after 30 hrs.' treatment. With 6% sodium hydroxide the same result was obtained in about 6 hrs. Lignocellulose could be detected in the material after treatment.—W. J. W.

Pinewood; Content of soluble carbohydrates in ——. S. Schmidt-Nielsen. Tekn. Ukeblad, 1920, 67, 354—355. Chem.-Zeit., 1921, 45, Rep., 32.

Pinewood felled in the spring was finely rasped, and after extraction with ether was repeatedly extracted by alternate boiling with water or 0·3% acetic acid and treatment with alcohol. By more than 20 successive extractions a yield of soluble matter was obtained equal to 12·04% of the original wood or 13·9% of the dry substance. In determinations of reducing sugar by Kjeldahl's method 1 g. of the dried extract, before inversion, reduced 0·1898 g. of copper, and after inversion with 2%

hydrochloric acid it reduced 0·6165 g. of copper. A substantially similar extract was obtained from pinewood felled in the winter, but the yield in this case was only one-seventh of that mentioned above. Pentosan determinations on the extract indicated about 23% of xylose.—J. H. L.

Lignified cell membranes; Contribution to the knowledge of ——. P. Casparis. Pharm. Monats., 1920, **1**, 121—129, 137—146, 153—160. Chem. Zentr., 1921, **92**, II., 584.

Lignified cell walls may be distinguished from those consisting of unaltered cellulose by means of a 15—40% solution of cobalt thiocyanate which colours lignified membranes blue. The reaction is probably due entirely to adsorption; it is more sensitive and trustworthy than Maule's permanganate reaction or the phloroglucinol-hydrochloric acid test.—J. H. L.

[Sulphite] pulp; Automatic cooking control for chemical ——. C. H. Allen. Techn. Assoc. Pulp and Paper Ind., 1920, **III**, 19—21.

It is suggested that by controlling automatically the digestion of sulphite pulp, an increase in production will be obtained, together with an improvement in the quality. The control system described consists essentially of a power-driven steam valve, electrically connected with a steam flow meter on the digester steam line, an automatic relief valve, and relief strainers.—J. C. K.

Sulphite and sulphate [pulp] fibres; Tests for unbleached ——. R. E. Lofton and M. F. Merritt. Techn. Assoc. Pulp and Paper Ind., 1920, **III**, 1—7.

For distinguishing between unbleached sulphite and sulphate (kraft) pulps, the use of a mixture of 1 pt. of a 2% aqueous solution of Malachite Green and 2 pts. of a 1% solution of Fuchsine (Magenta), is recommended. The solutions, which should be used not more than a few hours after being mixed, should be tested with a standard mixture of sulphite and sulphate fibres. The colour contrast not only enables the presence of one or both of these fibres to be detected, but is sharp enough to allow of an approximately correct estimate of the percentages of the two kinds of fibres to be made. —J. C. K.

Paper; Measurement of translucency and opacity of ——. R. Fournier. Paper, Feb. 9, 1921, **32**, 44.

The translucency and opacity of paper can be measured by an apparatus in which the eye of the observer is replaced by a selenium plate which forms part of an electric circuit; the electrical resistance of the selenium varies according to the amount of light which it receives at the time the determination is made. By a slightly modified form of the apparatus the reflecting power of a sheet of paper may also be determined.—J. C. K.

Strawboard factory waste waters; Gas from ——. A. Hermann. Het Gas, 1920, **40**, 131—135. Chem.-Zeit., 1921, **45**, Rep., 32.

A commission appointed by the Dutch Government recommends storage in settling tanks followed by irrigation treatment or filtration as the best and cheapest means of purifying the effluent from strawboard factories. In a pulp factory employing this process it has been found that in absence of air the effluent undergoes a fermentation due to rodlet bacteria which, at an optimum temperature of 35° C., produce a gas containing 23—30% of carbon dioxide and 70—77% of methane. One volume of effluent evolves 2 volumes of gas, which is collected in bell covers, conducted to a gas holder and employed for the production of electric current for power and lighting in the factory, and the surplus is taken by the local gas works and mixed with coal gas in the proportion of 25%. An analysis of the gas showed carbon dioxide 24·7%, methane 64·3%, other hydrocarbons 0·6%, hydrogen 4·9%, oxygen 0·4%, nitrogen 5·1%; it contained traces of carbon bisulphide but no hydrogen sulphide or carbon monoxide.—J. H. L.

Sulphite spirit. Sieber. *See* XVIII.

Patents.

Fibres suitable for spinning; Method for producing —— *from papyrus.* J. J. Gähler. E. P. 144,249, 31.1.20. Conv., 3.6.19.

Papyrus, which has been retted in the usual manner, is subjected to a mechanical alternating right and left-hand twisting movement whereby the fibres are loosened. The attached substances are then removed by brushing and combing, and also by means of a second retting treatment, if a very clean fibre is desired.—A. J. H.

Wool; Process for producing spun material resembling —— *from viscose solutions.* Glanzfäden A.-G. E.P. 152,351, 13.11.19. Conv., 15.8.18. Addn. to 135,205 (J., 1921, 254 A).

In the preparation of viscose solutions, as described in the chief patent, aerial oxidation of the cellulose takes place. This is prevented by the addition of about 5% (on weight of cellulose) of sugar (preferably cane sugar) to the aqueous caustic soda solution in which the cellulose xanthate is dissolved. —A. J. H.

Lace, fabrics and the like; Fireproofing, metallising, and waterproofing ——. A. Norweb. E. P. 160,627, 30.1.20.

Lace or fabric is padded with an emulsion formed from a solution of sodium silicate and sodium biborate, a metallic powder, and a solution of rubber in naphtha and amyl acetate, and is then dried. —A. J. H.

Artificial silk thread; Production of ——. G. F. J. Bouffe. E.P. 160,859, 3.9.19.

Cellulose threads which issue from a squirting nozzle are immediately drawn through a chamber which is exhausted of air or contains such gases as sulphur dioxide, carbon dioxide, etc., or through which a current of air is drawn, and are then wound on spools. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 28,733 of 1904, 14,087 of 1906, 11,729 and 24,707 of 1910, and 10,857 of 1915; J., 1905, 1299; 1906, 844; 1910, 1004; 1911, 126; 1916, 533.)—A. J. H.

Cellulose fibres; Production of easily bleached ——. B. Possanner von Ehrenthal. G.P. 331,802, 8.8.19.

Material such as flax or hemp straw, jute, reeds, nettles, potato haulms, willow bark, or the like, with or without a preliminary mechanical treatment, is treated at 40°—50° C. with a 0·5 to 2% solution of an organic or inorganic acid or acid salt to hydrolyse the binding material, and is subsequently heated, under normal or increased pressure, with a weak alkaline solution containing a small proportion of an organic solvent such as alcohol, carbon bisulphide, acetone, petroleum, higher hydrocarbons, or the like. The individual fibres are separated from the fibrous product by steeping in a warm solution or emulsion of fatty or oleic acids, or their salts, esters, sulphonic acids, or amides.—L. A. C.

Bast; Production of —— *from fibrous plants.* Nessel-Anbau-Ges.m.b.H. G.P. 331,896, 2.2.18.

The bast is loosened without destruction of its natural ribbon or tubular form by the action on the plant (ramie, nettles, reeds, hops, flax, etc.) of water or a solution of sugar (molasses), and is subsequently separated into fibres by mechanical and chemical means.—L. A. C.

Fibres from the needles of pines and other conifers; Production of textile ——. R. Guttmann and J. Siegert. G.P. 332,096, 8.5.19.

The dried needles are heated to 60°—70° C. in dilute mineral acid to loosen the epidermal silicious layer, and resinous material is removed from the fibres by subsequent treatment with a 3% solution of alkali. The alkaline resin solution can be employed for sizing paper.—L. A. C.

Bast fibre plants; Retting ——. P. Krais and K. Biltz. G.P. 332,097, 24.8.19.

The addition of a small proportion of bicarbonates as well as chalk or other insoluble carbonate to the liquor accelerates the retting process, improves the quality of the fibre, and diminishes the formation of products with a repulsive odour.—L. A. C.

Flax; Process for retting ——. P. Krais. G.P. 332,514, 26.3.20.

The raw flax is steeped in water or an alkaline solution and is stored moist in the dark at a moderate temperature to promote the formation of fungi, such as species of *Aspergillus*, and retting bacteria, such as *Plectridium pectinovorum.* After 3 to 4 days the retting is complete, and the material is dried at 80° C. or above to kill the fungi and bacteria.—L. A. C.

Peat wool; Production of chemically pure, curly —— from peaty cotton-grass. O. Linker. G.P. 332,169, 26.10.18.

The raw fibrous material, after preliminary treatment for ½ hr. at 50° C. in a 0·5% solution of an alkali, or sulphuric, hydrochloric, or hydrofluoric acid, or other suitable solvent, is rinsed and allowed to ferment for at least 4 hrs. in wooden vessels containing 1 kg. of malt or diastase per 1 cub. m. of water, or 0·5% acid solution, at 50°—60° C., or 11 kg. of yeast per 1 cub. m. of water at 30°—40° C. The fibres are then boiled for at least ½ hr. in an alkaline or acid solution, and are subsequently rinsed with cold water and bleached.—L. A. C.

Fibrous plants; Process for the simultaneous production of textile fibres and paper pulp from ——. Nessel-Anbau-Ges.m.b.H. G.P. 332,170, 16.8.19. Addn. to 328,596 (J., 1921, 211 A).

The hydrocarbons or halogen derivatives of hydrocarbons employed in the process as described in the chief patent are of the same sp. gr. as the aqueous solution, and thus readily remain in suspension in the same. A sodium hydroxide solution of 5°—8° B. (sp. gr. 1·037—1·060) is recommended, in which case the material is treated for 4½ to 5 hrs. under 8 atm. pressure.—L. A. C.

Waterproofing and sizing composition; Adhesive ——. A. E. Craver. U.S.P. 1,373,412, 5.4.21. Appl., 8.6.20.

The composition contains a protein, a suitable aqueous solvent, and a substance capable of liberating formaldehyde.—A. J. H.

Impregnating agents [for fabrics, wood, leather, etc.]. Farbenfabr. vorm. F. Bayer und Co. G.P. 302,531, 9.2.17.

Halogen derivatives of benzene homologues or of coal-tar hydrocarbons containing side-chains, are condensed with tar oils or their constituents (anthracene, naphthalene, benzene, etc.) or derivatives thereof. The oily or resinous products are very suitable for impregnating fabrics, paper yarn, wood, leather, etc., as they adhere firmly to the material, are scarcely soluble in water, and possess preservative properties.—J. H. L.

Impregnating agents; Removal of —— from fabrics. G. Bonwitt. G.P. 331,285, 18.7.18.

The fabrics are extracted, in a suitable apparatus, with solvents of high b.p., such as ethyl lactate, acetylene tetrachloride, or furfural, or with mixtures of such solvents with others of low b.p., *e.g.*, ethyl lactate and formate, acetylene tetrachloride and acetone, cyclohexanone and ethyl acetate, or furfural and ether, or with solvents containing substances which lower the viscosity of the material undergoing extraction; alcohol, for example, lowers the viscosity of solutions of cellulose esters.
—J. H. L.

Wood or other substances containing cellulose; Treatment of —— for the purpose of obtaining cellulose and artificial resin, asphalt, lac, and the like. C. Claessen. E.P. 160,482, 17.10.19.

Cellulosic materials, such as wood, straw, grass, etc., are heated for a few hours at about 100° C. and under reduced pressure with phenol or other phenolic substances either in concentrated form or diluted with water, alcohols, benzol, or aliphatic hydrocarbons; 0·01% of hydrochloric acid (on weight of phenol) is added as a catalyst. The snow-white cellulose pulp produced is removed, part of the phenol is recovered by distillation, and lac or resin is obtained from the liquid residues by precipitation or distillation.—A. J. H.

Cellulose compounds; Manufacture of ——. Deutsche Celluloid Fabr. G.P. 332,203, 10.1.18.

Mercerised cellulose is treated with chloroacetic acid, or its homologues, in the presence of alkali hydroxides. The alkali salts produced swell in hot or cold water, and finally dissolve to form clear, viscous solutions which on evaporation yield films of a material resembling glue or gelatin and inflammable with difficulty. The free cellulose-acetic acid is a white fibrous substance, insoluble in water, but soluble in alkaline solutions; with lead, copper, or aluminium oxides in the presence of water it forms insoluble salts. The alkali salts of cellulose-acetic acid and cellulose-propionic acid may be used as substitutes for gelatin.—L. A. C.

Paper, pasteboard, and the like; Process for sizing ——. W. Merckens. E.P. 147,006, 6.7.20. Conv., 7.12.15.

Animal or vegetable size (10% on the weight of the fibre) may be directly worked up with half-stuff in the hollander if it be added in a gelatinous form and melts in the subsequent drying process. If necessary, formalin, chrome alum, or other hardening agent is added to the size.—A. J. H.

Paper-making machinery [; Means for washing the woollen wet felts of ——]. C. Walmsley and Co., Ltd., and J. Law. E.P. 160,861, 13.9.19.

Drying coated or enamelled paper, waterproofed cloth, and such like; Apparatus for ——. C. F. Howden. E.P. 160,940, 31.12.19.

Fruit and vegetable refuse. G.P. 331,005. *See* XIX

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

[Printing.] Oxidation by steaming a mixture of chlorate and an aldehyde-bisulphite compound A. Pellizza. Sealed Note 1469, 6.5.04. Bull. Soc Ind. Mulhouse, 1920, 86, 640—641. Report by A Lipp. *Ibid.*, 641.

The reduction of a chlorate by an alkali bisulphit occurs in the cold with too great violence to b applied in printing, but when acetone-bisulphite c formaldehyde-bisulphite is used, the chlorate is only reduced at about 100° C. and the reaction may be regulated by the presence of small quantities of certain salts. For example, by printing a mixture of a chlorate, acetone-bisulphite, and the salt of an aromatic amine, followed by steaming for several minutes, Turkey Red, chrome mordants, etc. are discharged and Aniline Black is developed. The fibre is not attacked more than is the case when the ordinary mixture of ferrocyanide and chlorate is used. Lipp confirms these claims and agrees that the mixture can be used as an oxidising agent for the development of Aniline Black and as an oxidising discharge. In the case of white discharges, the white is not as clear as that obtained by the use of chlorate, ferrocyanide, and tartaric acid.—F. M. R.

Discharges; Coloured —— on azo-grounds with sulphoxylate-formaldehyde and basic dyes. Justin-Mueller. Sealed Note 1931, 15.12.09. Bull. Soc. Ind. Mulhouse, 1920, 86, 636—637. Report by C. Sunder. *Ibid.*, 637—639.

The preparation of the fabric with potassium ferrocyanide (J., 1908, 320) complicates the process, as drying is necessary. In order to simplify the process and render it analogous to the usual antimony tannate method, it is modified by the omission of the preliminary preparation, and after steaming the fabric is passed through a potassium ferrocyanide bath. When New Methylene Blue N is used, fuller and brighter discharges are obtained with the modified zinc-ferrocyanide process than is the case with antimony tannate. Sunder reports that the process is worthy of attention in view of the brightness of the shade and the possibility it affords of producing rose-coloured discharges with Rhodamine.—F. M. R.

Patents.

Dyeing and waterproofing [fabrics]; Process for ——. A. O. Tate. U.S.P. 1,374,122, 5.4.21. Appl., 20.4.20.

Fabric is padded with the usual Aniline-Black liquor, aged, impregnated with sodium palmitate and an aluminium salt, and then subjected to an electric current while passing between electrodes, one of which is of aluminium.—A. J. H.

Dyeing fur, hair and the like. Chem. Fabr. Griesheim-Elektron. G.P. 334,012, 15.12.16.

Soft leathers and hair may be dyed shades fast to light by means of the mineral acid salts of amino- and imino-compounds and oxidising agents. The dissociation of the mineral acid is diminished by the addition of neutral salts. By the addition of copper sulphate, a bichromate, sodium perchlorate, and hydrochloric acid to aniline hydrochloride dissolved in a 10% sodium chloride solution, a grey shade fast to light is obtained. Under similar con-litions, monobenzylaniline hydrochloride gives a luish-grey; monobenzyl-2.6.-toluylenediamine ıydrochloride gives a bright yellowish-grey, and nono-β-naphthyl-2.6.-toluylenediamine hydro-hloride gives a bright fawn shade.—A. J. H.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

itrous acid; Decomposition of ——. [Detection of nitric acid in presence of nitrous acid.] E. Oliveri-Mandalà. Gazz. Chim. Ital., 1921, 51, I., 138—140.

ydrazoic acid and nitrous acid react quantita-vely according to the equation, $HNO_2+HN_3=$ $_2O+N_2O+N_2$, no trace of nitric acid being formed. is reaction serves for the detection of nitric acid presence of nitrous acid, other methods for such detection yielding uncertain results owing to the formation of appreciable traces of nitric acid by partial decomposition of the nitrous acid. The test is carried out as follows:—Either a few c.c. of dilute hydrazoic acid solution or a little of its sodium salt is added to the solution containing nitrous and nitric acids, this being first acidified with acetic acid when the nitrous acid is present as salt. The liquid is boiled to expel, so far as possible, the excess of hydrazoic acid, a portion of the liquid being then tested with an acetic acid solution of naphthylamine and sulphanilic acid to ascertain if all the nitrous acid has been destroyed, and the remainder examined for nitric acid.—T. H. P.

Reduction by metals in acid solutions. I. Reduction of acid ferric sulphate solutions by zinc and magnesium. S. Sugden. Chem. Soc. Trans., 1921, **119**, 233—238.

Quantitative determination of the "percentage reduction" (that is, the percentage of that theoretically possible if no hydrogen were evolved) of acid ferric sulphate solutions, containing varying concentrations of ferric oxide and of sulphuric acid, by means of zinc and magnesium establishes the fact that with both metals increase in the concentration of ferric salt is accompanied by an increase in the percentage reduction, and also the further addition of sulphuric acid to a nearly neutral solution causes a decrease in the percentage reduction. Whilst, however, with magnesium this latter decrease continues progressively as the acid concentration increases, with zinc a minimum is reached, after which the percentage reduction increases rapidly and a new type of reaction apparently sets in, the zinc becoming dull grey in colour, and dissolving much more slowly with a scarcely perceptible evolution of gas. This peculiar behaviour of zinc is most marked with the solutions containing the higher concentrations of ferric oxide.—G. F. M.

Fluorine; Preparation of —— from molten potassium bifluoride. F. Meyer and W. Sandow. Ber., 1921, 54, 759—766.

The method is a development of that proposed by Argo and others (J., 1919, 413 a). A cylinder of Acheson graphite, which acts as crucible and cathode, is closely surrounded by an electrically-heated copper cylinder. The anode, also of Acheson graphite, is made wider at the lower than at the upper end, and is provided with six vertical grooves to increase the amount of surface exposed. The diaphragm consists of a copper cylinder to the lower end of which four conical copper rings are successively attached and, finally, a reversed ring fastened to a horizontal piece of copper foil. Potassium bifluoride, which gives a thin, clear melt at 240° C., is used as electrolyte, this having proved superior to mixtures of the bifluoride with sodium fluoride or bifluoride, lead or strontium fluorides in point of fluidity and loss of hydrogen fluoride. The crucible is slowly heated to a temperature not exceeding 250° C. and, since the molten salt obstinately retains traces of water, the electrolysis is started with a small current which is continued till the water is completely decomposed, after which the electrolysis proper is commenced. The evolved fluorine is contaminated with hydrogen fluoride, which can be removed by passage over granular sodium fluoride, and, initially, with ozone, which disappears after ½—¾ hr. The electrodes are but little attacked, and the gas does not contain more than 0·2% of carbon tetrafluoride. The current yield is more than 75% of that theoretically possible. (*Cf.* J.C.S., June.)—H. W.

Phosphorus; Oxidation and luminescence of ——. H. B. Weiser and A. Garrison. J. Phys. Chem., 1921, 25, 61—81.

The reaction between phosphorus and oxygen probably takes place in the vapour phase, and hence the velocity of reaction, V, may be expressed by the equation $V = kC_p^x . C_o^y$. Since C_p will be constant in presence of solid phosphorus, the velocity should be proportional to some power of the oxygen concentration $V = k_1 C_o^y$. This, however, is not the case below 25° C., and above a certain partial pressure of the oxygen, owing to the formation of a film of oxide on the phosphorus. If the oxygen pressure is great enough, the reaction takes place near the surface of the phosphorus, which will be coated with a film of oxide. By decreasing the partial pressure of the oxygen, this film is destroyed. The same effect may be obtained by increasing the rate of evaporation of the phosphorus. The pressure (boundary pressure) above which a protecting film prevents the oxidation and the vaporisation of the phosphorus is not constant. The intermittent luminescence in the narrow critical region between the boundary pressure and the glow pressure is probably due to the periodical break-down and reformation of this film.—J. C. K.

Melting point of potassium chlorate. Carpenter. *See* XXIII.

Sodium sulphantimonate. Langhans. *See* XXIII.

Patents.

[Lead] oxides; Method of converting metallic lead into ——. J. A. Thibault. E.P. 137,288, 29.12.19. Conv., 30.12.18.

Granulated lead is heated to 250° C. for 6 hrs. in a closed rotating drum with compressed air at 60 lb. per sq. in. pressure and a small quantity of water vapour, whereby it is converted into litharge of a yellow-ochre colour and of an extra fine texture. Red lead may be produced in the same apparatus by increasing the temperature to 425° C. as soon as all of the lead has been converted into litharge, and continuing the heating for a further period of 4 hrs. The product is a bright red impalpable powder containing over 30% of lead peroxide.—A. R. P.

Electrolysing vat [for making chlorine]. H. Loeb. U.S.P. 1,372,176, 22.3.21. Appl., 10.1.19.

An electrolysing vat for making chlorine consists of a vessel of glazed pottery surrounded by a wooden casing, the intervening space being packed with asphalt.—J. S. G. T.

Calcium carbonate; Manufacture of ——. L. Roon, Assr. to The Equitable Trust Co. U.S.P. 1,372,193, 22.3.21. Appl., 26.4.19.

Milk of lime is atomised, and the resulting mist allowed to react with carbon dioxide.—C. I.

Calcium carbonate; Manufacture of ——. J. Faldner. G.P. 334,014, 26.11.19.

Quicklime is dissolved in a solution of an ammonium salt and impurities are removed by precipitation and filtration. The liquid is then saturated with carbon dioxide under pressure to precipitate calcium carbonate and regenerate the original ammonium salt for use again in the process. —A. R. P.

Aluminium chloride; Production of ——. E. C. Baum and De W. O. Jones, Assrs. to Armour Fertilizer Works. U.S.P. 1,372,332, 22.3.21. Appl., 24.3.20.

Aluminium nitride is subjected to the action of chlorine.—C. I.

Arsenic trioxide; Process of purifying ——. C. P. Linville, Assr. to American Smelting and Refining Co. U.S.P. 1,372,443, 22.3.21. Appl., 21.7.16. Renewed 18.12.19.

Colouring matter due to selenium is removed by mixing with a reagent capable of forming a non-volatile selenide at a comparatively low temperature and separating the arsenious oxide by sublimation. —C. I.

Zinc oxide; Manufacture of ——. W. L. Coursen, Assr. to The New Jersey Zinc Co. U.S.P. 1,372,486, 22.3.21. Appl., 28.6.20.

In the production of zinc oxide by the retort volatilisation process, a substantial quantity of molten zinc is maintained in the retort during the whole of the operation, volatilisation losses being made good by the addition of solid zinc to the contents of the retort from time to time.—A. R. P.

[Zinc] oxide; Manufacture of French ——. J. A. Singmaster, Assr. to The New Jersey Zinc Co. U.S.P. 1,372,462, 22.3.21. Appl., 31.3.20.

The contents of the retorts in which the zinc is volatilised are kept nearly constant by the addition from time to time of molten zinc.—A. R. P.

Bichloride of mercury; Manufacture of ——. C. Schantz. U.S.P. 1,373,357, 29.3.21. Appl., 6.12.20.

Mercury is passed through an atmosphere of chlorine into a bath of a liquid which does not readily absorb chlorine.—A. R. P.

Fixation of gases [atmospheric nitrogen]; Process for the electric ——. G. T. Southgate. U.S.P. 1,373,639, 5.4.21. Appl., 22.11.20.

Streams of gas or gases are passed through porous electrodes between which an electric arc is established.—J. S. G. T.

Calcium cyanamide; Production of —— *from carbide and nitrogen.* A.-G. für Stickstoffdünger. G.P. 299,142, 15.10.15.

Calcium carbide and calcium chloride or fluoride are ground together as finely as possible and the mixture, in layers 40—100 cm. deep, is exposed to nitrogen at a lower temperature than has been necessary hitherto, *e.g.*, 650°—700° C., when calcium chloride is used and 700°—750° C. when fluoride is used.—J. H. L.

Calcium cyanamide; Process and furnace for the production of high-grade crude ——. Bayerische Stickstoff-Werke A.-G. G.P. 326,613, 15.3.18.

A number of small charges are arranged together in a furnace and brought to the ignition point simultaneously. The nitrogen gas necessary for the reaction is brought into the furnace through channels in the wall. Other spaces in the wall are filled with powdered or granular insulating material.—J. H. J.

Gases; Treatment of —— *for removal of hydrogen sulphide.* Badische Anilin- u. Soda-Fabrik. G.P. (a) 299,163, 2.7.16, and (b) 331,322, 22.10.16.

(a) Gases are freed from hydrogen sulphide by treating them with a solution of a compound of iron and oxygen in presence of an alkali, the reduced iron compound being subsequently regenerated by means of air or oxygen. In the case of gases containing little or no carbon dioxide, admission of carbon dioxide, which may be introduced in the form of an alkali carbonate, assists the re-oxidation of the iron compound. A suitable gas-washing solution is prepared by treating 300 kg of potassium carbonate in 600 l. water with 90 kg of oxalic acid and 135 kg. of 40% ferric chloride solution, and diluting the product to 1 cub. m (b) The washing solution may contain oxalic acid together with tartaric acid, and a suitable mixture consists of 200 kg. of potassium carbonate, 20 kg of crude acid potassium tartrate, 10 kg. of oxalic acid, and 90 kg. of 40% ferric chloride solution diluted to 1 cub. m.—W. J. W.

Alkali cyanide solutions; Decomposition of ——. W. Salge und Co., Techn. Ges. m. b. H. G.P. 332,297, 9.4.20.

The alkali cyanide is decomposed, and the hydrocyanic acid is removed by passing a current of carbon dioxide into the solution, which contains at least 50% of alkali carbonate. Hydrocyanic acid is distilled without decomposition when carbon dioxide is passed into an alkali cyanide solution containing 50—60% of alkali carbonate at 90° C. —C. A. C.

Calcium hydride; Process for making ——. K. Kaiser. G.P. 333,305, 11.2.20.

Hydrogen is passed over calcium chloride at 600°—700° C. until no further evolution of hydrogen chloride takes place. The residue of pure calcium hydride may be utilised for the hydrogenation of liquid fats and crude petroleum, or for the conversion of acetaldehyde into alcohol as well as for the production of ammonia from the air.—A. R. P.

Ammonia soda; Manufacture of ——. J. Delmar. G.P. 333,748, 19.11.16.

The lime required for the regeneration of ammonia from the ammonium chloride liquors is transformed into calcium cyanamide before being used in the process, whereby further quantities of ammonia are developed as well as a certain amount of carbon dioxide, which is utilised in the first stage of the ammonia soda process. Any excess of ammonia over that required in the latter process may be converted into a suitable salt. 1000 kg. of calcium cyanamide yields 800 kg. of sodium carbonate.—A. R. P.

Sulphur; Process and apparatus for burning —— in easily combustible substances, e.g., spent oxide. Chemische Industrie A.-G. G.P. 333,818, 25.3.15.

The material is charged into a multiple-hearth furnace, underneath the top hearth, through a special charging apparatus, the lower opening of which is kept closed by building up the charge around it. This apparatus is provided with an arrangement to prevent the material sintering and sticking in the neck of the charging cone.—A. R. P.

Potassium salts containing kieserite; Process for utilising the sulphur content of crude ——. J. Kiermayer, and Hannoversche Kaliwerke A.-G. G.P. 333,963, 12.11.19. Addn. to 310,072 (J., 1920, 406 a).

The operation of heating the fused salts with wood charcoal is carried out while passing a current of steam through the mass. Instead of charcoal, liquid or solid hydrocarbons may be used in the process. —A. R. P.

Carbon; Production of pure ——. F. C. Dyche-Teague. E.P. 160,561, 23.12.19.

Coke is converted into carbon monoxide by interaction in a gas-fired retort with carbon dioxide produced in a subsequent stage of the process. The arbon monoxide is decomposed into carbon and arbon dioxide by the catalytic action of finely ivided iron or ferric oxide in a separate airooled chamber after filtration through firebrick. he carbon deposit and catalyst are blown out of he chamber and separated by a magnetic field or by ravitation.—C. I.

ydroxides; Manufacture of metal ——. M. Buchner. E.P. 16,597, 24.11.15.

ee U.S.P. 1,337,192 of 1920; J., 1920, 488 a.

xidation of hydrogen sulphide. G.P. 331,287. *See* IIa.

ydrating lime. E.P. 160,556. *See* IX.

VIII.—GLASS; CERAMICS.

Glass; Heat absorption in ——. A. Q. Tool and C. G. Eichlin. J. Opt. Soc. Amer., 1920, **4**, 340—363. Chem. Zentr., 1921, **92**, II., 698—699.

On heating glass of constant heat conductivity through a certain well-defined temperature interval some change takes place in the structure of the glass, accompanied by an absorption of heat. An apparatus is described for measuring this heat absorption by comparing the temperatures of a powdered sample of the glass and a sample of clay under the same conditions of heating. The temperature at which the absorption commences varies from 460° to 610° C., and that at which it attains its maximum is 30°—40° C. higher, according to the kind of glass tested. The maximum in the case of quartz is at 580° C. It is shown that on annealing glass not only must the tension be equalised in all parts, but the structure should be made homogeneous; further, annealed glass may undergo a slow transformation into the stable crystalline phase at ordinary temperatures, which gives rise to volume changes, and consequently renders such glass unsuitable for thermometers. —A. R. P.

Refractory materials; Behaviour of —— under load at high temperature. K. Endell. Stahl u. Eisen, 1921, **41**, 6—9.

The behaviour of small cylinders, 50 mm. long and 50 mm. diam., when heated to various temperatures under a pressure of 1—8 kg. per sq. cm. was investigated. The test-pieces were heated in an electric resistance furnace, the pressure—usually 1 kg. per sq. cm.—being applied by a weighted lever through specially hard electrode carbons. The temperature of the test-pieces was measured by a Holborn-Kurlbaum optical pyrometer. The test-pieces were heated so that the maximum temperature was attained in about 4½ hrs, but the results were not appreciably different when only half this time was required. According to their behaviour when heated under a pressure of 1 kg. per sq. cm., refractory materials may be divided into four groups:—(1) Fireclay bricks with a refractoriness of about cone 33 (1730° C.) began to soften at 1300° C., a 50 mm. cylinder being reduced to 30 mm. in a test lasting 4½ hrs., in which the maximum temperature reached was 1500° C. Bricks containing very plastic clay softened at 1150° C. The deformation was uniform, the sides of the cylinder bulging as its height was diminished. (2) Magnesite bricks with a refractoriness above 2000° C. began to soften at 1500° C. on account of the binding agent. A 50-mm. cylinder was reduced to 10 mm. in height in a test lasting 4¾ hrs., the maximum temperature attained being 1650° C. The hot cylinders were feebly plastic and broke at the sides under compression. (3) Silica bricks with a refractoriness of cone 35 (1750° C.) did not soften below 1650° C., but broke in pieces in 4⅙ hrs. at a maximum temperature of 1680° C. The actual deformation was small. (4) Carbon bricks with a refractoriness above 2000° C. did not soften under pressure, and apart from a slight loss in volume (about 4%), due to some of the carbon burning away, the cylinders were not affected in a test of 5 hrs., in which a temperature of 1720° C. was reached.—A. B. S.

Patents.

Glass and vitreous materials; Manufacture of ——. A. A. Kelly and B. D. Jones. E.P. 160,495, 20.11.19.

In mixtures for making glass and vitreous materials sodium pentaborate is substituted for borax or boric acid, the necessary adjustment of the alkali content being made in any suitable manner. A more homogeneous product is secured with an absence of striæ and air bubbles.—H. S. H.

[Glass] annealing furnace or leer. W. O. Amsler. E.P. 160,710, 12.7.20.

A furnace has its annealing chamber heated by the hot products of combustion circulated through a number of passages from combustion chambers placed over the top of the muffle. A heating zone is created in which the temperature is maintained above the critical temperature of the articles to be annealed, and a cooling zone which has a predetermined uniform temperature gradient. The articles pass through the muffle from the high temperature zone through the region of decreasing temperature.—H. S. H.

Opaque glazes, enamels, and glasses; Production of white ——. H. Sachse. G.P. 331,682, 20.7.18.

White opaque glasses, enamels, and glazes are made by means of natural compounds of zirconium, tin, and beryllium in combination with fluorine compounds, such as alkali fluorides or fluosilicates, fluorspar, and either natural or artificial cryolite, in sufficient quantity to prevent the production of colour by the impurities in the other ingredients. The large proportion of fluorine compounds ensures good covering power, ready fusibility, high gloss, and great resistance to chemicals and heat.
—A. B. S.

Plastic masses; Manufacture of —— and new industrial products obtained therefrom. L. Gauthier. E.P. 145,514, 22.6.20. Conv., 18.4.19. Addn. to 128,905 (J., 1920, 450 A).

A plastic mass which is capable of being run whilst hot, for the manufacture of hollow bodies, which are unbreakable and capable of being washed (such as vases, dolls' heads, etc.), is prepared by incorporating about 60% of talc with about 30% of gelatin and about 10% of hide glue. The hide glue is melted in a water bath, and the gelatin caused to swell by soaking in water, before being used in the mixture, which is then melted and cooled to form a paste. Slices are cut from the paste, melted in a water bath, and the fluid mass run into a mould and allowed to cool until the desired thickness is attained before pouring out the excess paste. After drying, the hollow body is polished, washed in a solution of Castille soap, and finally treated in a solution of alum and 10% formol.
—H. S. H.

Plastic masses; Process for the production of —— from matter non-plastic by nature, as refractory oxides etc. E. Podszus. G.P. 326,841, 13.7.13.

During the grinding process a colloidal solution is produced within the mass either by the known methods of colloid chemistry or by chemical action. For example, at least two non-plastic materials of different basic properties, as alumina and silicic acid, are brought into the most intimate contact with one another by grinding together for a long time in presence of a dispersion medium. The proportions of the two substances are so chosen that sufficient quantities of a colloidal solution are formed to enable the mass to be cast.—J. H. J.

Refractory material. E. D. Frohman. U.S.P. 1,372,016, 22.3.21. Appl., 8.12.19.

A refractory material comprises a mixture of finely-divided dry fireclay, silicious material, and a vegetable compound capable of forming a binder when mixed with water.—H. H.

Refractory brick. C. W. Berry, Assignor to Laclede-Christy Clay Products Co. U.S.P. 1,373,854, 5.4.21. Appl., 4.4.18.

The process consists in mixing raw magnesite and bauxite with water, calcining the mixture at a temperature sufficient to expel moisture and gas, re-grinding the product, mixing it with water, forming it into bricks and burning them to produce a hard refractory material.—A. B. S.

Tunnel-kiln. G. E. Norman. U.S.P. 1,372,773, 29.3.21. Appl., 17.2.20.

The walls and crown of a tunnel-kiln of the customary shape are provided, throughout their full length, with longitudinal air-passages leading into an "exhaust air directing compartment."
—A. B. S.

Tunnel furnace with reversible regenerative heating. H. Koppers. G.P. 331,703, 14.9.18.

The furnace is designed for heating refractory materials or iron and steel billets with maximum thermal efficiency, by exposure to the highest temperature just before leaving the furnace. The preheated gas and air are brought together at this point and burn while moving counter to the goods in the furnace. Two parallel tunnels are employed.
—H. J. H.

Ceramic materials: Grouped direct-fired furnaces for ——. H. Herda. G.P. 328,389, 23.4.19. Addn. to 324,977 (J., 1920, 821 A).

The waste gas from a fired furnace and the hot air from a cooling furnace are conducted through flues beneath the furnaces, and are mixed and conducted into the firing duct of the furnace which is to be heated next and into the latter furnace itself. By this means any chamber not in use in the group may be fired as a separate furnace, whether for annealing, melting, or glazing, without interfering with the working of others.—J. H. L.

Ceramic mass of great strength; Production of an easily fusible porcellanous ——. H. Becker, H. Fehringer, and H. Johnke. G.P. 332,578, 21.9.18.

A readily fusible porcellanous ceramic mass of great strength is made by adding to an alkali-lime glass batch a quantity of fluorspar at least equal to the quantity of silica. The sand may be partly replaced by silicate rock, ashes, or slags. The high fluorspar content makes the fused mass very mobile and prevents the material from being sensitive to sudden changes in temperature, so that large articles do not need prolonged annealing. The ware is opaque.—A. B. S.

Heat treatment of articles [glass bulbs]; Method of —— and apparatus therefor. Corning Glass Works, Assees. of J. Bailey. E.P. 140,374, 17.1.20. Conv., 17.3.19.

Glass; Manufacture [drawing] of ——. F. J. Brougham. From Virginia Plate Glass Corp. E.P. 141,737, 15.4.20.

IX.—BUILDING MATERIALS.

Patents.

Refractory and insulating products; Manufacture of ——. G. L. Dimitri and J. E. Delaunay. E.P. 142,513, 1.5.20. Conv., 16.7.18.

Hard, refractory, and insulating products are made by compressing a mixture of hard powdered materials (particularly magnesium silicate and multiple silicates) in a press box from which the air is exhausted. A steel plate or washer slightly smaller than the internal diameter of the press-box is placed on the powdered material, and the press-box is evacuated through an aperture in the air-tight cover whilst the material is being compressed by a rising plunger. When the steel plate is

pressed against the aperture the compression is complete. The pressed pieces are subsequently burned, and are said to be exceptionally hard.
—A. B. S.

Porous material [for building and insulation]; Manufacture of ——. Det Norske Aktieselskab for Elektrokem. Ind. Norsk Industri-Hypotekbank. E.P. 143,500, 6.5.20. Conv., 16.5.19.

A MATERIAL of uniform porosity, suitable for building and insulation purposes, is made by blowing air or steam into molten slag, stirring vigorously so as to convert the slag into a foam, cooling the foam rapidly by passing it between water-cooled rollers until it has a temperature at which its porosity remains constant and the mass remains plastic, compressing the mass into the desired shape in moulds, and then cooling it further by gas or air under pressure.—A. B. S.

Oil-proof concrete bodies and method of making same. J. Marcusson. E.P. 145,673, 30.6.20. Conv., 1.7.18.

HOLLOW bodies made from concrete, cement, mortar, etc., are coated with an artificial resin obtained by acting with formaldehyde on phenols or other cyclic compounds. After exposure to the air for a certain time the coating is rendered insoluble, and in this state permanently resists the action of mineral or fatty oils.—H. S. H.

Lime; Apparatus for the hydration of —— and for similar purposes. E. R. Sutcliffe. E.P. 160,556, 22.12.19.

THREE or more cylinders are arranged one above the other with their axes parallel. A shaft carrying vanes is mounted axially within each cylinder, and on rotation causes the material to be hydrated to move slowly along the cylinders. The material is fed into one end of the top cylinder and passes successively through the cylinders. Water is sprayed into the first cylinder, and the others are provided with steam jackets. The product is delivered completely hydrated and in a dried condition.—H. S. H.

Roads; Manufacture of compositions for covering —— and for like purposes. M. Monnoyer and H. T. E. Kirkpatrick. E.P. 161,061, 17.3.20.

A COMPOSITION for covering roads similar to that mentioned in E.P. 4349 of 1914 (F.P. 466,878; J., 1914, 965) is made by incorporating 0·6—1% of fibrous material, such as sawdust, impregnated with tar and bitumen, with a concrete mixture containing 2000—2250 kg. of solid matter.—A. B. S.

Cement; Manufacture of slow-setting ——. F. Ferrari, Assr. to Bombini Parodi-Delfino. U.S.P. 1,372,015, 22.3.21. Appl., 23.8.20.

A RAW mixture of the ordinary type used for Portland cement but having a ratio of Fe_2O_3 to Al_2O_3 between 1 and 1·563 is converted into slag to prepare a slow-setting cement free from the binary calcium compounds of alumina or iron generally used.
—H. H.

Wood-impregnating retorts; Condenser and separator for ——. J. H. Dunstan and R. A. Davis. U.S.P. 1,374,069, 5.4.21. Appl., 13.10.19.

In order to create rapidly a high vacuum in a wood-mpregnating retort the latter is connected with a barometric condenser. A pipe leads from the condenser into the side of a barometric separator, and another pipe connects the top of the separator with a vacuum pump. A discharge pipe leads downwards from the bottom of the separator and has its ower end submerged in liquid in a hot well, whereby the separator is able to discharge constantly whilst the vacuum is maintained.—A. B. S.

Building material; Process for the production of —— into which nails can be driven. A. Hambloch. G.P. 326,963, 23.5.18.

A MIXTURE of coarse-grained volcanic sand, tufa, or pumice with a calcareous and fine-grained silicious cement, is shaken to obtain the highest possible density. The moulded articles are hardened with steam under pressure.—J. H. J.

Lump plaster; Manufacture of ——. G. Polysius. G.P. 330,065, 12.9.19.

RAW gypsum is heated in the annular space between two inclined, concentric cylinders which are heated both externally and internally.—A. B. S.

Shipbuilding material; Production of ——. S. Rosenstein. G.P. 331,674, 23.1.19.

A LIGHT material for shipbuilding etc. is made of a pulverised mixture of "1 pt. of cement, 10—25% of lime, and 20—35% of a white silicious and acid-resisting magnesium silicate of the talc group," which after being mixed with porous materials is allowed to stand and finally is mixed with sand or other aggregate and water. The product is so elastic that it can be used to produce richer mixtures than usual without risk of cracking, and it has an extraordinary toughness and a great resistance to blows.—A. B. S.

Slag wool; Production of waterproof articles from ——. H. Brunck. G.P. 331,675, 9.9.19.

SLAG wool is converted into "flocks," the adventitious grains separated by a current of air, and the short fibres and sand grains removed by a sieve. The long fibres aggregate to balls, which are either mixed with a fusible waterproofing material and moulded hot or are placed in a perforated drum and coated by immersion in molten pitch, asphalt, or a resinous mixture, and afterwards shaped in moulds under light pressure.—A. B. S.

Light porous bricks; Process for hardening ——. C. H. Schol. G.P. 332,294, 21.6.18.

LIGHT porous bricks are first exposed to air and are afterwards hardened by exposure to steam under high or low pressure. The preliminary aeration prevents ill effects otherwise produced on exposing such bricks to steam.—A. B. S.

Mortar material; Production of —— from dolomite in a rotary tube furnace. F. M. Meyer. G.P. 332,583, 6.8.12.

THE dolomite is burned for so long and at such a high temperature that the magnesium carbonate is wholly and the calcium carbonate about half converted into oxide.

Lime-sand bricks; Production of —— by means of raw chalk or quarry waste and clay. H. Servange. G.P. 332,631, 25.6.14.

LIME-SAND bricks are hardened in brick kilns at 530° C. in a current of steam and carbon dioxide, the latter being advantageous in the hardening of monocalcium hydrosilicate. The fired bricks harden still further on exposure to air.—A. B. S.

Artificial stone resembling asphalt; Production of ——. A. Flexer. G.P. 332,634, 5.11.18.

IN the manufacture of resin acids for soap making from wood tar by oxidation, a pitch is obtained as a by-product. Artificial stone, resembling asphalt, of great resistance and strength, is made by washing, purifying, and drying this pitch and then mixing it, in the molten condition, with 4—5 times its volume of silica, sand, or other aggregate, and allowing the mixture to cool in sheets or moulds.
—A. B. S.

Cement mix; Preparation of —— prior to burning. G. Polysius. G.P. 332,705, 4.12.19.

Hot cement clinker (preferably from a rotary kiln) is mixed with raw cement mix or cement slurry, and later is separated therefrom by means of sieves. This enables the heat in the clinker to be used in preheating the raw material, and the usual cooling drums are rendered unnecessary.—A. B. S.

Bricks from ashes and slaked lime; Production of ——. G. de Bruyn. G.P. 332,755, 14.6.19.

Bricks are made of a mixture of lime, ashes, plastic clay, and water, which is moulded like concrete. The bricks "ring" when struck, are waterproof, and show little "scum." The strength of the bricks and the facility with which nails may be driven into them may be varied by the addition of porous materials such as sawdust, pumice, etc. —A. B. S.

Impregnating agents. G.P. 302,531. *See* V.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Malleable iron; Influence of manganese on the mechanical properties of ——. E. Leuenberger. Stahl u. Eisen, 1921, 41, 285—287.

A higher content than 0·4% Mn is permissible in malleable cast iron, the tensile strength of which increases with the manganese content. Up to about 1% manganese has no influence on the elongation; with higher percentages the elongation diminishes. The tensile strength decreases with the period of annealing while the elongation increases. The longer the time of annealing, the higher may the manganese content be without unfavourably affecting the elongation.—T. H. Bu.

Fluorspar; Addition of —— to Martin [open-hearth steel] furnaces. S. Schleicher. Stahl u. Eisen, 1921, 41, 357—361.

If fluorspar is added to a Martin slag, it will only be decomposed up to a certain limit, lying between 2 and 2·5% of calcium fluoride. The fluorspar addition at first drives off silicic acid from the slag. This silicic acid is, however, continually renewed from the lining of the furnace. Fluorspar has also a desulphurising action, the sulphur being driven off and the renovated slag taking up more sulphur from the bath.—T. H. Bu.

Electric steel arc furnaces; Regulation of —— using movable electrodes. W. G. Mylius. Trans. Amer. Electrochem. Soc., 1921, 213—225. [Advance copy.]

The different types of automatic electrode regulators are described, including a newer type which operates with greater precision and higher speed than earlier forms. The electrode is moved at high speed until the current per phase is within 15%, on either side, of its normal value, at which point the continuously running stage is replaced by a slower vibrating motion.—C. A. K.

Steel and iron; Gasometric determination of carbon in ——. H. Burkardt. Chem.-Zeit., 1921, 45, 342.

In adapting Strohlein's apparatus (*cf.* J., 1916, 1085) to the gasometric determination of carbon in steel, the author prefers to use a furnace fitted with carborundum supports, to dispense with the condenser, and to use ordinary wash-bottles for the oxygen in place of those supplied with the apparatus.—W. P. S.

Iron and steel; Influence of copper on the physical properties of ——. E. A. and L. T. Richardson. Chem. and Met. Eng., 1921, 24, 565—567. (*Cf.* J., 1920, 752 A.)

The addition of even small amounts of copper to iron causes brittleness in forging, but this effect is produced only within a certain range of temperature, above or below which the alloy can be successfully forged. This interval during which "red-shortness" occurs increases with the percentage of copper in the alloy; thus iron containing 4·65% Cu can be forged only at a very low temperature. The phenomenon is probably due to an intergranular film of copper or of one of its alloys or compounds. By the addition of manganese or chromium brittleness is overcome, but the amount added must be proportional to the percentage of copper in the alloy; 0·32% of manganese added to an alloy containing 0·48% Cu removed brittleness, whilst the same amount added to an alloy with 0·92% Cu proved insufficient. The smaller liability of steel to brittleness is explained by its manganese content. The cold-working properties, such as filing, grinding, chiselling, and bending, of iron low in carbon, are not impaired by the presence of copper up to 5%. Manganese makes iron harder, and if the amount exceeds 2% the resulting alloy is too brittle and hard for working; the same proportion of chromium causes hardness and toughness but not brittleness.—W. J. W.

Iron and steel; Anomalies encountered in a study of immersion tests of ——. A. S. Cushman and G. W. Coggeshall. Trans. Amer. Electrochem. Soc., 1921, 249—267. [Advance copy.]

A large number of tests by the immersion of plates in different corroding solutions tend to show that copper-bearing iron is less resistant to corrosion than iron free from copper. After immersion in dilute (5%) mercuric chloride solution steels containing copper were amalgamated with mercury while metal substantially free from copper retained its characteristic grey surface. It is inferred that copper passes into solution with the iron ions, is plated back, and forms a mirror surface with reduced mercury. The passivity of iron in solutions of an alkali bichromate is partially or wholly destroyed in the presence of a copper salt, and it was found that 4—6 times more chromic acid per unit volume is required to prevent corrosion of a copper-bearing steel than is needed to protect iron free from copper. Galvanised sheets immersed in a 10 or 20% solution of aluminium sulphate corrode rapidly, hydrogen being liberated and the zinc coating stripped off. The reaction speed is then reduced greatly if the metal is pure iron, but with copper steels the reaction continues until the iron is dissolved entirely. The system usually turns to a hydroxide gel. A copper steel lost 5 oz. per sq. ft. in a 30-hr. test in boiling aluminium sulphate solution as compared with 2·5 oz. loss for a commercial pure iron. Results from acid tests are not definite, as such tests are sensitive to many electrochemical variables. Dilute sulphuric acid acted rather more vigorously on low copper stee (0·038% Cu) than on steel containing 0·20—0·25% Cu. The order of corrosion was reversed in hydrochloric acid.—C. A. K.

Iron and steel; Corrosion of ——. J. A. Aupperl and D. M. Strickland. Trans. Amer. Electro chem. Soc., 1921, 167—177. [Advance copy.]

The resistance to corrosion of varying grades o pickled iron and steel was determined by suspend ing plates (6×6 in.) in a solution containing 0·7% of sulphuric acid, 1·98% of ferrous sulphate, an 0·15% of ferric sulphate. The corroding solutio was circulated and aerated continuously and wa maintained at constant acidity. The loss in weigh n 60 days was as follows:—Pure open-hearth iron ·622 oz. per sq. ft., copper open-hearth steel 0·257% Cu) 0·75, open-hearth steel 0·779, copper Bessemer steel (0·224% Cu) 2·060, copper acid open-earth steel (0·209% Cu) 3·263. Metallic copper n contact with various kinds of iron and steel had ittle effect upon the corrosion of any of the metals vith the exception of copper-bearing steel, which vas attacked in areas surrounding the contact opper.—C. A. K.

orrosion of iron by acids; Effect of copper and silver salts on ——. O. P. Watts and H. C. Knapp. Trans. Amer. Electrochem. Soc., 1921, 135—140. [Advance copy.]

ORROSION of iron by sulphuric acid is increased in he presence of copper or silver salts in solution. n $N/1H_2SO_4$ containing 2·5 g. Cu per l., corrosion ue to voltaic action on copper steel (about 0·25% u) was nearly four times the direct corrosion by he acid, and in acid solution containing 0·1 g. Cu er l. the ratio of voltaic to direct corrosion was ·85. Loss by voltaic corrosion of mild steel was of he same order, but the ratio (0·01) appears low wing to the great loss by direct acid corrosion. igures obtained in tests in which silver salts were dded to $N/1$ sulphuric acid indicate less action by large quantity of silver (2·5 g. per l.) than by ither of the lesser quantities (0·1 and 0·01 g. Ag er l.). This is due to the formation of a deposit f spongy silver which retards diffusion of the acid o the steel. In $N/50$ sulphuric acid voltaic action n copper steels and Armco iron appears to be 1—3 imes the amount of corrosion due to the acid lone, but wide differences were observed in dupli-ate experiments. The serious effect of voltaic ction is shown by the destruction of a monel etal yacht in which the steel parts in contact ith monel metal were corroded away in three onths.—C. A. K.

in and zinc; Recrystallisation of ——. *Recrystallisation of cold-worked metals.* G. Masing. Int. Zeits. Metallog., 1920, 12, 457—493. Chem. Zentr., 1921, 92, II., 700—701.

HE surface tension theory of the recrystallisation f worked metals not only presents theoretical ifficulties but also does not explain all the observed acts, *e.g.*, the formation of nuclei, the growth of mall crystals at the expense of their larger neigh-ours, and the failure of unworked metal to re-rystallise. Czochralski's stratification theory Int. Zeits. Metallog., 1916, 8, 1) satisfactorily xplains these phenomena but at the same time it ives rise to a new series of problems, such as the ature, stability, and inner structure of a stratified rystal. The recrystallisation of cold-rolled tin egins with the formation of primary grains, the ze of which depends on the recrystallisation tem-erature, and which, after at time, commence to ite, but more slowly than they form. The forma-on of nuclei cannot be observed, the nuclei of the imary grains being already present in the rolled n. The size of the grains depends, according to ochralski's theory, on the amount of rolling that e metal has undergone as well as on the re-ystallisation temperature. If a worked piece of i is subjected to a smaller secondary deformation a different kind to the first (*e.g.* shearing after ling, or rolling after hammering) a rapid forma-n of specially large crystals takes place as the ult of two different stratifications. It only ues if the metal has originally been subjected to stronger primary deformation and is caused by rapid grain-growth and by the formation of lei, which becomes quicker with rising tempera-e and with increase of secondary deformation, tends to be reduced by the effect of the pre-ing primary deformation. The size of the secondary crystals is in inverse proportion to the number of nuclei formed and the resulting metal is not changed immediately to an even granular structure but exhibits a series of recrystallisation steps with different but characteristic remains of stratification in the grains. Cold-rolled zinc shows a secondary formation of nuclei at 150° C. without being subjected to a secondary deformation; after this, however, recrystallisation commences at 70° C. as the metal is then in a specially unstable condition, which on continued working may again be changed to the normal state, so that the ordinary primary recrystallisation sets in.—A. R. P.

Aluminium utensils; Blackening of ——. J. Czochralski. Z. Metallk., 1920, 12, 430—443. Chem. Zentr., 1921, 92, II., 599.

BLACKENING occurs readily in aluminium utensils in which water is kept warm. It is due to the deposition of a precipitate containing iron, silicon, and sulphur in greater proportion than the metal itself. No blackening is produced normally by aqueous solutions of iron salts; the blackening which occurs when aluminium is treated with a concentrated solution of ferric chloride in strong hydrochloric and is an etching effect. Blackening occurs when tap water is boiled in an aluminium vessel, and the effect reaches a maximum when all carbonic acid is expelled (20 mins.). The presence of free acids is inhibitory and the phenomenon is connected with the alkalinity of the water. The absence of blackening in domestic practice may be due to the alternations of acid and alkaline conditions in cooking operations. The process is electrolytic and takes place at the eutectic Al—$FeAl_3$, precipitation occurring on the aluminium. It is dependent on the degree of alkalinity and the most pronounced effect was caused by lime water. Synthetic tap water free from iron and spring water behaved like ordinary tap water, while rain water and distilled water produced no effect.—H. J. H.

Nickel; Ductile electrolytic ——. C. P. Madsen. Trans. Amer. Electrochem. Soc., 1921, 269—276. [Advance copy.]

THE most satisfactory electrolyte for the production of thick uniform deposits of nickel was found to be nickel sulphate solution containing a small amount of alkali sulphate, a little boric acid and some nickel chloride. Cold-rolled malleable nickel anodes of the composition 95·3% Ni, 2·13% Fe, 0·25% Cu, 0·33% Mn, 0·30% C, and 0·23% Si, gave the best results in this electrolyte when the area of the anode was 1·77 times that of the cathode, the current density 72 amps. per sq. ft. of anode, and the temperature of the bath 55° C. If the cathodes were periodically lifted out of the bath, exposed to the air for a short time, and again immersed in the bath within a certain limiting time, the resulting nickel had a very great ductility, tensile strength, and hardness compared with ordinary nickel. The tensile strength of the deposited metal was about 72,000 lb. per sq. in.; after drawing down to wire of 0·002 in. diam. the tensile strength had increased to 250,000 lb., while the hardness increased from 130 to 150. The metal contained 99·7% Ni, 0·01% Fe, and 0·02% Cu. A tendency of the deposit to form pits was overcome by altering the composition of the anode.—A. R .P.

Nickel deposition; Use of fluorides in solutions for ——. W. Blum. Trans. Amer. Electrochem Soc., 1921, 227—247. [Advance copy.]

THE use of fluorides in conjunction with boric acid in nickel plating baths produces nickel deposits that have a finer texture and a higher tensile strength and hardness than those produced in chloride solutions, but the deposit usually contains more iron and copper. The following two solutions are recommended as electrolytes: 255 g. of nickel sulphate, 12 g. of nickel carbonate, 8 g. of 50% hydrofluoric acid, and 31 g. of boric acid dissolved in water and made up to a litre; or 281 g. of nickel sulphate, 8·4 g. of sodium fluoride, and 31 g. of boric acid dissolved in water and made up to 1 litre. Adherent deposits for electroplating are obtained by using a current density of 3—4 amps. per sq. dm., while 1·5 to 2 amps. is sufficient for electrotyping. Methods for the analysis of the baths are discussed. —A. R. P.

Chrome-nickel heating wires; Structure of ——. M. von Schwarz. Z. Metallk., 1921, **13**, 125—127.

Satisfactory chrome-nickel wires for electrical heating purposes show a fine-grained structure both before and after prolonged use. The used wires show superficial oxidation and some slag inclusions below the surface. Inferior wires which have appeared on the market within the last few years have a similar fine-grained structure before use, but after use the structure becomes coarser and the wires become very brittle. Good wires contain about 86·5% Ni, 10·1% Cr, and only small quantities of iron, whilst a sample of the new inferior wire contained 52·7% Ni, 10·7% Cr, and 32·3% Fe. The inferiority of the latter is due to the replacement of so large a proportion of the nickel by iron.—E. H. R.

Smelting; Theory of ——. II. W. Guertler. *Equilibria between pairs of metals and sulphur. I. The system copper-lead-sulphur.* K. L. Meissner. Metall und Erz, 1921, **18**, 145—152.

Guertler (Metall u. Erz, 1920, **17**, 192) has shown that when sulphur is added to a mixture of copper and lead, Cu_2S is first formed, then PbS, and finally CuS, and these relations were illustrated by means of a triangular diagram. In this diagram the ternary system is divided into three partial systems, Pb—Cu—Cu_2S, Pb—Cu_2S—PbS, and Cu_2S—PbS—S. Various mixtures corresponding with points in each of these partial systems have now been examined thermally and microscopically. Each pair of constituents in the first ternary system shows incomplete miscibility, and consequently an area of incomplete miscibility would be expected in the ternary system, with three separate phases. Actually only two layers are formed, the upper consisting essentially of Cu_2S, the lower being an emulsion of lead and copper, in which the lead shows a pronounced tendency to liquate downwards. Through this emulsion formation, copper and lead can be made practically completely miscible by addition of 1—1·5% of sulphur. Addition of lead to the Cu—Cu_2S system extends the miscibility gap. In the partial system Pb—Cu_2S—PbS, a miscibility gap extends almost up to the Cu_2S—PbS line. In the absence of free lead, *i.e.*, on the Cu_2S—PbS line, only eutectic mixtures are formed. In the third ternary partial system, Cu_2S—PbS—S, it was expected that the line PbS—CuS would correspond with a quasi-binary series of mixtures, but, owing to the decomposition of CuS into Cu_2S and sulphur on melting, equilibrium was established between PbS, Cu_2S, and an apparently ternary crystalline phase. —E. H. R.

Alloys; Use of shear tests for judging the mechanical properties of ——. R. Krulla. Z. Metallk., 1921, **13**, 137—139.

A shear test is made on a test-piece having a cross-section of 0·5 sq. cm., and from the area of the shear diagram, measured by means of a planimeter, the shearing work is determined in kg.-m. per sq. cm. This quantity, divided by the Brinell hardness (previously determined on the same test-piece) gives a number Q, which serves to indicate the relation of strength to hardness in the alloy. Thus for copper, Q=4·96, for the brass Cu 69·5%, Zn 30·5%, Q=8·34, and for Cu 49%, Zn 51%, Q=0·85. —E. H. R.

Mercury; Physical properties of ——. A. Schulze. Z. Metallk., 1921, **13**, 105—113, 139—148.

A review of the literature dealing with the determination of the magnitudes of the physical properties of mercury, grouped under the headings mechanical, thermal, electrical and magnetic, and optical.—E. H. R.

Reduction by metals in acid solutions. Sugden. *See* VII.

Patents.

Pig iron from iron and steel scrap; Production of high-grade ——. F. Rottmann. G.P. 332,208, 13.3.19.

Clean iron and steel scrap is melted with a pure slag made from quartz, lime, or clay shale. Iron low in phosphorus may thus be obtained.—H. J. H.

Iron and steel baths; Preventing the re-phosphorising of —— during deoxidation and carburising. Deutsch-Luxemburgische Bergwerks- und Hütten-A.-G. G.P. 333,749, 19.4.16.

The bath of molten iron or steel is treated with calcium carbide, at or towards the end of the deoxidation or carburising operations. The method is especially applicable to the Thomas process where tho slag is high in phosphorus, and to the manufacture of hard steel.—A. R. P.

Ferro-chromium; Process for producing low-carbon ——. F. Krupp A.-G. E.P. 145,710, 26.6.20. Conv., 3.10.16. Addn. to 145,709 (J., 1921, 307 A).

Crude ferro-chromium is treated in an acid-lined converter until a low carbon content is obtained. Basic material, *e.g.* lime, is then added to the charge, whereby silicon is oxidised and the loss of chromium is reduced.—C. A. K.

Ferrotitanium; Process for producing low-carbo ——. H. C. Sicard, Assr. to U.S. Ferro Alloy Corp. U.S.P. (a) 1,374,035 and (b) 1,374,036 5.4.21. Appl., 18.8.19.

(a) Commercial ferrotitanium is mixed with a excess of titanic oxide and heated in an electric fu nace so as to decompose carbides of titanium an iron and form a protective titanium oxide sla (b) A double carbide of titanium and iron is treate in a molten state with aluminium. Carbo separates as graphite and is skimmed off, and t underlying metal is reheated and cast.—C. A. K.

Ferro-zirconium; Production of low-carbon —— Process for producing zirconium steel. H. Sicard. U.S.P. (a) 1,374,037 and (b) 1,374,03 5.4.21. Appl., 23.7.20.

(a) A high-carbon ferro-zirconium alloy is deca bonised by means of titanic oxide. (b) An alloy zirconium and silicon is added to molten steel. —B. M. V.

Roasting and sintering ores and the like. R. Lloyd. E.P. 160,477, 4.9.19.

An improved machine for carrying out mecha cally the operations of charging, igniting, sint ing, and discharging in the Dwight-Lloyd proc as described in E.P. 25,985 of 1907 (J., 1908, 1025 —B. M. V

Solid substances capable of reaction with a gase reagent; Process of treating ——. [Roast sulphide ores.] E. C. R. Marks. From Ore Ro ing Development Co. E.P. 161,103, 6.7.20.

A multiple-hearth mechanical roaster is provi with by-pass ore passages, so that a portion of

: can fall direct from the second or any subse- ent hearth to some lower hearth. One or more -passes may be provided, so that after initial ıting on the top hearths the ore will divide into o or more streams which will subsequently be ited into one before final discharge from the paratus. Air, or other gas, may also be admitted several different places, preferably near the out- s of the by-passes, and some of the products of nbustion may be readmitted.—B. M. V.

ctrode for use in electric welding or fusion de- position of metals. Quasi Arc Co., Ltd., and A. P. Strohmenger. E.P. 160,957, 7.1.20.

electrode wire is wrapped spirally with a yarn of e asbestos. The asbestos fibres are pulped with olution of sodium silicate and rolled into a thin eet, which is cut into strips and spun into a rally twisted yarn.—C. A. K.

g; Process of cleaning converter ——. H. H. Stout, Assr. to Phelps Dodge Corp. U.S.P. ,372,047, 22.3.21. Appl., 3.2.19.

R the removal of copper from converter slag the cific gravity and silica content of the latter are usted to those of the reverberatory slag before two are mixed.—D. F. T.

ctrolytic recovery of metals from solutions; Elec- rode for ——. U. C. Tainton. U.S.P. 1,373,273, 29.3.21. Appl., 4.11.19.

PERMEABLE electrode suitable for the electrolytic position of metals from solutions is composed of a per sheet in which is incorporated a comminuted ıducting material.—J. S. G. T.

ctrolytic process [for treating copper ores]. W. E. Greenawalt. U.S.P. 1,373,557, 5.4.21. Appl., 22.3.20.

PPER ores are treated with an acid solution, and pper is deposited electrolytically from the result- solution containing also salts of elements of riable valency (iron etc.). These latter salts are luced from the higher to the lower valency by itating the electrolyte in the presence of sulphur xide and finely divided charcoal.—J. S. G. T.

rnace; Revolving ——. L. P. Basset. U.S.P. 1,372,392, 22.3.21. Appl., 12.9.19.

inclined rotating cylindrical furnace has its ımeter increased at the lower end to form a ıction chamber adapted to form a pocket for lten metal.—B. M. V.

rnace [; Open-hearth ——]. N. F. Egler, Assr. to Blair Engineering Co. U.S.P. 1,372,613, 22.3.21. Appl., 1.3.19.

EANS are provided whereby air may be passed from regenerators to combined air and fuel ports at h end of the furnace, which are narrow com- red with the hearth, and also through other ınnels direct to the interior of the furnace; the ter channels may be shut off if desired.—B. M. V.

lting furnace [; Electric brass ——]. T. F. Baily nd F. T. Cope, Assrs. to The Electric Furnace Co. U.S.P. 1,373,787, 5.4.21. Appl., 16.2.20.

electric furnace for melting brass, in which the t is produced by the resistance of an annular ugh of coarsely powdered carbon, is fitted with a denser connected with the upper part of the ting chamber and provided with an inclined k communicating with the heating chamber near hearth of the furnace.—A. R. P.

st furnaces; Process for operating —— with the se of lignite. F. Weeren. G.P. 331,596, 11.1.12.

ARGE proportion of the coke or charcoal in the rge is replaced by lignite briquettes, and the ore and limestone are added in small lumps or as a powder. In the upper part of the furnace the bituminous constituents of the lignite reduce the iron oxide in the ore, and the carbonised briquettes break up into small pieces which serve for smelting and carburising the iron.—L. A. C.

Copper; Process of case hardening ——. A. S. Gundersen. U.S.P. 1,372,423, 22.3.21. Appl., 1.12.15.

THE surface of the copper is exposed to zinc at a temperature between the melting points of copper and zinc.—B. M. V.

[Aluminium] ores; Process for the reduction of ——. C. G. Collins, Assr. to C. A. Stevens. U.S.P. 1,372,483, 23.3.21. Appl., 26.3.20.

THE finely ground ore is mixed with a carbonaceous material and sodium chloride, and the mixture is heated out of contact with the air.—A. R. P.

Aluminium; Process for coating metallic objects with ——. Metallhütte Baer und Co. Kommanditges. G.P. 330,917, 11.4.19.

FOR the coating of objects made of metals harder than aluminium a mixture of hard sand with powdered aluminium, in which the particles of the latter are larger than those of the former, is projected against the surface of the object by means of air under a pressure of 1—4 atm.—J. H. L.

Aluminium; Electrolytic manufacture of ——. Allgem. Elektrizitäts-Ges. G.P. 332,669, 1.3.18.

ALTERNATING current is passed through the bath for the purpose of heating, without any heating resistances, whilst at the same time electrolysis is effected by a direct current. The danger of the solidification of the bath is thus avoided in case of defects at the generator of the direct current, and losses in the transformation of the generally available alternating current into direct current are minimised. —C. A. C.

Precious metals [gold and silver]; Method of recovering —— from solutions. R. H. McKee. U.S.P. 1,372,971, 29.3.21. Appl., 13.5.20.

SOLUTIONS containing gold and silver are brought into contact with carbon which has previously been subjected to an alkaline treatment at a suitable temperature and subsequently leached before use. —A. R. P.

Silver; Method of extracting —— [from ores or residues]. P. R. Middleton, Assr. to J. C. Lalor. U.S.P. 1,372,973, 29.3.21. Appl., 11.5.20.

ORES or residues containing metallic silver are subjected to treatment to convert the silver into sulphide, which is then chlorinated.—A. R. P.

Zinc and cadmium; Process for separating and recovering —— by acid treatment. J. Leibu. G.P. 329,172, 9.6.17. Addn. to 322,142 (J., 1920, 788 A).

THE residues containing cadmium are heated before treatment with acid. The formation of malodorous substances is thereby avoided.—J. H. L.

Metals; Process for recovering —— from ores. H. Dahlem. G.P. 332,445, 4.2.20. Addn. to 330,290 (J., 1921, 265 A).

IN the process described in the chief patent the furnace is so designed that air or gas for reduction can be blown independently into the furnace through all the tuyères, both at the sides and at the bottom of the furnace.—L. A. C.

Metallic coatings; Production of —— by spraying atomised liquid metals. P. Künzler. G.P. 330,916, 20.9.13.

THE metal is melted for the spraying operation by conducting it, in a comminuted but not pulverulent form, through a duct which is strongly heated from without. By this means metals which are difficult to melt and readily oxidisable, such as aluminium and copper, can be used in the spray coating process.—J. H. L.

Coating articles by spraying with a dispersed liquid material. P. Künzler. G.P. 332,047, 21.10.13. Addn. to 330,916 (*cf. supra*).

The coating material is used in form of pieces of regular shape, especially balls. The method is of special value in the case of easily oxidisable metals, *e.g.*, aluminium, which might solidify and oxidise when fused in large quantities.—C. A. C.

Etching and stamping processes; Plates for ——. Verein. Elektrochem. Fabr. O. Hahn. G.P. 330,948, 21.11.19.

The plates are made of magnesium or magnesium alloys; they are very hard and suitable for etching and engraving.—J. H. L.

Sludge from wet purification of blast-furnace gas; Removal and utilisation of ——. F. Eckert. G.P. 332,628, 30.11.19.

By mixing the sludge with the slag from the blast-furnaces the water content of the sludge is evaporated by the heat of the slag, whilst the dry residue adheres to the granulated slag. The hydraulic properties of the slag are improved by the admixture of the sludge.—C. A. C.

Steel; Manufacture of ——. A. Pacz, Assr. to General Electric Co. U.S.P. 1,373,908, 5.4.21. Appl., 17.8.17.

See E.P. 152,371 of 1918; J., 1920, 787 A.

Alloys. F. Milliken. E.P. 161,104, 6.7.20.

XI.—ELECTRO-CHEMISTRY.

Electric furnaces; Electro-dynamic forces in ——. C. Hering. Trans. Amer. Electrochem. Soc., 1921, 201—211. [Advance copy.]

The author discusses the nature of the mechanical forces which may be directed to cause an increased directional motion of a liquid conductor, *e.g.*, molten metal, in an electric furnace. The "pinch" effect (J., 1909, 1143) is now applied to many furnaces. The author reiterates his view that a component of the electro-dynamic force may act in an axial direction when two currents are inclined to each other. The rising of metal on the outer side of the ring of an induction furnace is explained as due to the "stretching" of the current-carrying bath of metal, and not indirectly as the result of hydraulic forces.—C. A. K.

Patents.

Electric [arc] furnaces. The British Thomson-Houston Co., Ltd., H. C. Hastings, and N. Laycock. E.P. 160,529, 19.12.19.

In electric arc furnaces to which power is supplied from single-phase or two-phase four-wire circuits, and in which there are two arcs in series per phase, one of the arcs being controlled by the arc current and the other by the voltage across the arc as described in E.P. 119,228 (U.S.P. 1,255,613; J., 1918, 213 A) a system of magnetic relays operates to prevent the voltage-controlled electrode from being lowered when the current is abnormally high, and to prevent the current-controlled electrode from being lowered when the arc voltage is abnormally high. Relays are provided whereby one or both of the electrodes per phase may be raised at a higher speed than the normal operating speed during the period when the current in the arcs exceeds a predetermined value.—J. S. G. T.

Storage battery electrode and process of making same. H. C. Hubbell, Assr. to Hubbell-Fuller Battery Co.. U.S.P. (A) 1,373,733 and (B) 1,373,734, 5.4.21. Appl., 9.7.15. Renewed 13.8.20.

(A) A storage battery electrode is made by heating nickel oxide with finely divided cadmium. (B) Precipitated cobaltous hydroxide is converted into oxide by heating it without substantial exposure to air. The oxide is cooled under the same conditions and mixed with a material containing nickel, and the mixture formed into tablets and assembled in a conducting container.—J. S. G. T.

Storage battery plates; Process of making ——. W. H. Grimditch, Assr. to Philadelphia Storage Battery Co. U.S.P. 1,374,076, 5.4.21. Appl., 24.7.20.

Lead oxide containing red lead is mixed in definite proportion with a solution of ammonium sulphate of a definite strength, at a predetermined temperature, such that the mixture has the plasticity required for applying it to the battery grid.
—J. S. G. T.

Lead peroxide-zinc cells or batteries; Process of making —— *capable of being kept.* Ringe und Co. G.P. 333,299, 6.1.18.

Substances such as the hydroxides of calcium, magnesium or barium, are added to the electrolyte or to the positive electrode, or to both, in order to prevent the formation of lead chloride.—A. R. P.

XII.—FATS; OILS; WAXES.

Twitchell reagent; The ——. E. Hoyer. Z Deuts. Oel- und Fettind., 1921, **41**, 113—115 Chem. Zentr., 1921, **92**, II., 665—666.

In the Twitchell process, the aromatic sulpho-fatt acid serves to emulsify the fat or oil, whilst th free sulphuric acid present effects the hydrolysis removal of the sulphuric acid by washing or trea ment with normal sodium sulphate, sodium b sulphite, or sodium acetate retards the hydrolysi as also does the addition of formic, acetic, sulphurous acid. The Petroff reagent consisting sulphonic acids obtained as a waste product in t purification of petroleum is considered superior the Twitchell reagent. The discoloration whi occurs during hydrolysis depends on the amount

sulphuric acid present, so that it is advisable to use as little of this acid and of the reagent as possible; the resulting fatty acids are more susceptible to discoloration than are their parent fats and oils.
—D. F. T.

Oil of Gilletiella congolana; Properties and composition of the ——. A. Boulay. Bull. Sci. Pharmacol., 1920, 27, 626—628. Chem. Zentr., 1921, **92**, I., 576.

The seeds of *G. congolana* collected in the neighbourhood of Matadi were at most 45 mm. long, and 25 g. in weight. The oil extracted by petroleum spirit is clear, but deposits crystals in the course of a few days. It has the following characters:—Sp. gr. 0·9159, free oleic acid 0·79%, saponif. value 192·5, iodine value 93·8, Hehner value 90, soluble volatile acids 0·77%, acetyl value 7·0, unsaponifiable matter 1·14%, m.p. of fatty acids 29°; the fatty acids consist of 35% of solid acids (palmitic etc.), and 65% of liquid acids (linolic and oleic acids).
—G. F. M.

Fats; Law of probability applied to the formation of —— *from carbohydrates.* E. J. Witzemann. J. Phys. Chem., 1921, 25, 55—60.

If the relative abundance of occurrence of the various fatty acids is plotted against the number of carbon atoms in the molecule, and the points corresponding to the relative abundance of the various acids are connected, instead of obtaining a smooth curve on both sides of C_{18}, the curve shows prominences at several points, and therefore does not conform with the typical probability curve. But, if the prominences are connected, such a curve is obtained. The numbers of carbon atoms at the prominences are all divisible by six, but C_{18} fatty acids occur considerably more frequently than others; this affords support for Fischer's hypothesis of the formation of fatty acids from sugars. The less frequent occurrence of intermediate acids may be due to their formation from higher and unsaturated acids, or by synthesis from short carbon chains.
—J. C. K.

Catalytic activity of platinum; Influence of mercury, sulphur, arsenic, and zinc on the ——. E. B. Maxted. Chem. Soc. Trans., 1921, **119**, 225—233. (*Cf.* J., 1921, 89 a.)

The inhibitive action of mercury, sulphur, arsenic, and zinc on the catalytic activity of platinum when employed for the catalytic hydrogenation of oleic acid under standard conditions was studied by similar means to those previously employed in the case of inhibition by lead (*loc. cit.*), and the existence of a similar linear poisoning law has been established. For the above substances the linear law appears to hold between the limits of zero concentration of inhibitant up to a region in the neighbourhood of total extinction, where a point of inflexion occurs from which the poisoning curve slopes far less steeply towards complete inactivity.—G. F. M.

Hexabromide value of fatty oils; Determination of ——. A. Eibner. Farben-Zeit., 1921, 26, 1314—1315.

The method of Bailey and Baldsiefen (J., 1921, 51 a) gives lower values than those obtained by the methods of Eibner and Muggenthaler (J., 1913, 242), Wolff (J., 1920, 417 a), and Steele and Washburn (J., 1920, 197 a). The presence of fish oils as adulterants of linseed oil may be detected by testing the solubility of the octobromides in boiling benzol and determination of the melting point of the solute. A further useful method of recognition of fish oils is that of Tsujimoto (J., 1920, 825 a) depending on the separation of clupanodonic acid as the lithium salt.—A. de W.

Partly hydrolysed fats (soap-stock); Analysis of ——. W. Fahrion. Chem. Umschau, 1921, **28**, 68—69.

The aqueous layer from the alkali refining of vegetable oils yields on acidification a product which contains neutral fat in addition to fatty acids, and is largely used in soap manufacture. Errors may occur when the free fatty acid content of the material is calculated from the ratio of the acid value to the saponification value, since the equivalent weight of fatty acid is less than that of its corresponding glyceride by the equivalent weight of the glyceryl radicle. Error is also caused by the small differences existing between neutralisation and saponification values of free fatty acids. In many cases, however, these errors compensate one another sufficiently for all practical purposes. The author recommends the following procedure: A weighed quantity of the soap stock is warmed with alcohol and the acid value determined. A measured amount of alcoholic alkali is then added and the ester value determined in the usual way. The neutral soap is then rendered alkaline, diluted to an alcoholic strength of 50—20%, and the unsaponifiable matter (y) extracted with petroleum-spirit, or ether. The free fatty acid (x) then corresponds to $(100-y) \times$ acid value/saponif. value, and the percentage of neutral fat is obtained from the difference: $100-(x+y)$.—A. de W.

Patents.

Fats and oils; Process for the removal of fatty acids, resins, bitter and mucilaginous substances from ——. H. Bollmann. U.S.P. 1,371,342, 15.3.21. Appl., 22.6.20.

A continuous current of diluted solvent for the impurities is passed upward through a systematic leaching apparatus comprising a number of vessels each containing a body of stationary filling material, whilst a continuous current of the oil to be purified passes through in a downward direction, whereby intimate contact of oil and solvent is produced without violent agitation of the materials, and the quantity of difficultly separable emulsion formed is reduced to a minimum.—A. de W.

[Vegetable] oils; Process of treating [purifying] ——. *Treatment of castor oil.* A. Schwarcman, Assr. to S. Kellogg and Sons, Inc. U.S.P. (a) 1,372,631 and (b) 1,372,632, 22.3.21. Appl., 19.2. and 20.4.20.

(a) Vegetable oils are agitated with an amount of strong caustic soda solution corresponding to the content of free fatty acids in the oil, the temperature is raised to about 180° F. (82° C.), and hot water passed, in finely divided form, into and through the mixture. (b) Castor oil is mixed with a limited amount of soda solution of moderate strength to neutralise the free fatty acids, hot water added with thorough agitation, the aqueous layer allowed to settle, the oil washed with hot water, and finally dried.—A. de W.

Fatty acids; Distillation of ——. J. W. Bodman, Assr. to W. Garrigue and Co., Inc. U.S.P. 1,372,477, 22.3.21. Appl., 9.8.19.

To remove their dark colour fatty acids are brought, in the form of spray only, into contact with a gaseous carrier, in a vacuum, under heat conditions suitable for the complete distillation of the acids. The evaporated fatty acids are condensed.—A. de W.

Fatty matter; Extraction of —— from garbage and other fat-containing materials. V. Bredlik and L. C. Whiton, jun. U.S.P. 1,372,479, 22.3.21. Appl., 15.5.19.

In extracting the fatty matter from garbage and other material containing grease or oil by means of a solvent, the material to be extracted is subjected to a preliminary treatment of alternately higher and lower gaseous pressures in the absence of the solvent.—A. de W

Fatty acids and their glycerides; Production of ——. Oelverwertung G.m.b.H. G.P. 330,811, 22.8.12. Addn. to 292,649.

A mixture of nickel oxide with fat or a fatty acid is heated in a current of hydrogen, and the colloidal product is used as a catalyst in the hydrogenation of oils. By this means only a small proportion of the oil need be heated to the high temperature necessary for the colloidal distribution of the catalyst. A hard fat with a setting pt. about 50° C. may thus be prepared from cottonseed oil, and dihydroxystearic glycerol ester from castor oil. —J. H. L.

Saponaceous compositions; Manufacture of ——. F. G. Chadbourne. E.P. 160,892, 1.12.19.

Fatty acids are melted in a steam-jacketed pan and incorporated in a rotary mixer with 20—50% by weight (on the final product) of a finely divided hydrated aluminium silicate, *e.g.*, china clay, together with colouring matter. The required quantity of alkaline solution is then run in, the mixing operation continued for about 1 hr. at a temperature below boiling-point, steam being admitted through a steam coil, and the mass is concentrated to the desired consistency.—A. de W.

Emulsion and method of producing it. E. M. Johansen, Assr. to The Atlantic Refining Co. U.S.P. 1,373,661, 5.4.21. Appl., 14.12.20.

Mineral oils are emulsified with water in the presence of water-soluble sulphonates, obtained by the acid treatment of mineral oils or products therefrom, to the extent of about 1·5 to 8% of the weight of mineral oil.—L. A. C.

Detergent. Chem. Fabr. vorm Weiler-ter Meer. G.P. 330,355, 24.2.17. Addn. to 327,683 (J., 1921, 186 A).

Instead of pulverulent insoluble substance a mixture of soluble salts is used which gives rise to a fine precipitate when introduced into water, *e.g.*, xylene mixed with magnesium sulphate and sodium carbonate and sulphate, or chlorobenzene mixed with aluminium sulphate and sodium carbonate. —J. H. L.

Detergent which lathers well; Production of a ——. E. Reinfurth. G.P. 332,649, 1.8.16.

Soluble salts of α- or β-naphthalenemonosulphonic acid, or of both α and β acids, preferably alkali or ammonium salts, are added to a soap during or after the production of the latter, and a filling agent, such as clay, may also be added. As much as 50—70% of the fatty acid may be replaced by the abovementioned acids without any loss of lathering power.—J. H. L.

Detersive and emulsive agents; Manufacture of ——. R. Macpherson and W. E. Heys. U.S.P. 1,373,900, 5.4.21. Appl., 23,5.16.

See E.P. 8478 of 1915; J., 1916, 852.

XIII.—PAINTS ; PIGMENTS ; VARNISHES ; RESINS.

Ferric oxide; Anhydrous yellow ——. J. H. Yoe. J. Phys. Chem., 1921, 25, 196—200.

In an extension of Scheetz's work on the stabilisation of the colour of anhydrous yellow ferric oxide (J., 1917, 1270), aqueous solutions of ferrous and aluminium sulphates were precipitated with calcium and barium hydroxides, and the precipitate heated to 1000° C.; a yellow or buff colour persisted in mixtures containing up to about 8% of ferric oxide, but above this amount the colour gradually darkened. Similar results obtained with ferrous and aluminium chlorides indicate that the presence of calcium or barium sulphate in the mixture is not essential for stabilisation, but that alumina alone is sufficient to prevent agglomeration and to maintain the yellow colour of the ferric oxide. This conclusion is confirmed by precipitating both sulphates and chlorides of iron and aluminium with ammonia solution. In regard to calcium and barium sulphates, it is found that if these are present in large excess they act as stabilising agents; thus a product containing 6% of ferric oxide and 94% of barium sulphate is of a light buff colour similar to that obtained in presence of alumina. Attempts to retain the colour in products stabilised with alumina after removal of the latter by sodium hydroxide were unsuccessful. as agglomeration of the ferric oxide with corresponding change of colour to red, occurred in each case.—W. J. W.

Paint films; [The "Paint-Film Gauge," an] instrument for measuring the thickness of wet ——. A. H. Pfund. J. Franklin Inst., 1921, 191, 517—523.

The instrument consists of a plano-convex lens of 25 cm. radius of curvature mounted in a short tube sliding freely, in an outer tube. The two tubes are held together by springs, and by applying pressure the inner tube can be forced outwards and the convex surface of the lens brought into contact with *e.g.* a wet paint film. The diameter (D) of the circular spot of wet paint left on the lens when the pressure is released is measured to 0·1 mm., and the thickness (t) of the paint film can then be calculated by the formula: $t = D^2/16R$, where R is the radius of curvature of the lens. Good agreement was shown in practice between results obtained by the instrument and results of actual spreading trials with paints and varnishes. Shrinkage of paint films on drying may be determined by means of the instrument, the thickness of the dry film being measured with a micrometer. The variation in brightness of paint films on drying may be measured by determining the thickness of the film at the point of critical opacity in a wedge-shaped pool of the paint, the thickness at several points at various other distances from the apex of the wedge being also determined. After drying, the change in position towards or away from the wedge apex of the point of critical opacity is observed and the thickness of the wet paint film formerly overlying this spot is obtained from the previous measurements. It was found that opacity in paints does not vary with shrinkage but increases directly as the brightness.—A. de W.

Ink; Acidity of —— and the influence of bottle glass on ink. C. A. Mitchell. Analyst, 1921, 46, 129—134.

The stability of iron-gall inks depends chiefly on the amount of acid present, and this amount must be kept within definite limits; the acid usually added is hydrochloric acid. Certain inks, consisting essentially of iron gallate solution, do not re-

uire the addition of mineral acid, but it is held
enerally that these inks lack "body." To deter-
nine mineral acid in ink, a portion of the sample
s distilled with the addition of sodium acetate until
he whole of the liberated acetic acid has passed
ver into the distillate; the acidity of the latter
s then titrated. The total acidity of the ink is
etermined by boiling 5 c.c. of the sample with
0 c.c. of hydrogen peroxide under a reflux condenser
ntil the colour has been discharged and then
itrating the cooled mixture with sodium hydroxide
olution, using phenolphthalein as indicator. Log-
vood inks require to be boiled with alkaline
ydrogen peroxide solution in order to destroy the
olour; an allowance is made for the amount of
lkali added. Results of determinations of acidity
f commercial inks are recorded; usually the total
cidity is equivalent to 1·6—5·6 c.c. of $N/1$ alkali
olution per 10 c.c. of ink, and the mineral acidity
o 0·3—2·46 c.c. of $N/10$ alkali solution per 10 c.c.
nvestigation of certain deteriorated inks showed
hat the damage had been caused by alkali dissolved
rom the glass bottles.—W. P. S.

ine resin; Acid constituents of ——: d- and l-pimaric acids. G. Dupont. Comptes rend., 1921, **172**, 923—925.

y the use of aqueous alcohol as solvent it has been
ound possible to isolate appreciable quantities of
-pimaric acid from the resin of the leaf buds of
inus maritima. This acid is readily isomerised
o the dextro-acid under the conditions usually
mployed for the extraction of pimaric acid from
his source.—W. G.

osin; Action of trichloroethylene on ——. F. Goldschmidt and G. Weiss. Z. Deuts. Oel- und Fettind., 1921, **41**, 99—100. Chem. Zentr., 1921, **92**, II., 651.

BLACK deposit in the salting out of soaps prepared
rom a mixture of equal parts of stearin and rosin
vhich had been extracted with trichloroethylene
vas traced to the presence of less volatile impurities
n this solvent. Rosin dissolved in an unsaturated
ompound such as turpentine or allyl alcohol yields
lark-coloured products when treated with air in
he presence of iron.—D. F. T.

urfural; Some synthetic resins from ——. G. H. Mains and M. Phillips. Chem. and Met. Eng., 1921, **24**, 661—663.

HE condensation of furfural, which can now be
roduced very cheaply on a large scale from maize
obs, with various amines and ketones has been
tudied and the optimum conditions for the produc-
tion of fusible resins suitable for use in varnishes
are given. One part of furfural heated with an
equal weight of aniline for 1 hr. at 200° C. or with
twice its weight of α-naphthylamine for 3 hrs. at
200° C. gives a black resin which is hard and brittle
t 25° C. In some cases addition of hydrochloric
cid to the reaction mixture is necessary; thus one
pt. of furfural condenses with 2 pts. of o-toluidine
r with 1 pt. of crude xylidine only in the presence
f 0·2 pt. of strong hydrochloric acid at 150° C. to
ield a hard black resin. Condensation products
vith acetone or methyl ethyl ketone are obtained
n heating suitable mixtures in the presence of
0% sodium hydroxide solution. A black resin is
btained by heating furfural with 25% caustic soda
or 1 hr. and treating the solution with hydrochloric
cid. All the resins obtained softened between 25°
nd 100° C., were practically insoluble in water,
omewhat soluble in turpentine, readily soluble in
enzene, acetone, and alcohol, and very soluble in
urfural. Solutions of the resins in benzene,
cetone, or furfural give shades on wood ranging
om golden brown to black, according to the nature
nd concentration of the solution.—A. R. P.

Varnishes; Testing of ——. H. Wolff. Farben-Zeit., 1921, **26**, 1186—1187.

FILMS of the various varnishes under examination dried under similar conditions of time, etc., on both glass plates and tinned iron plates, are hung up in large glass bell-jars filled with a mixture of moist sulphur dioxide and carbon dioxide for a period of from 8 days to 8 weeks. Other tests comprise leading the mixed gases, both at ordinary temperatures and heated by passage through a tube immersed in a boiling water-bath, over the surfaces of the films (locomotive varnish test). Criteria as to the relative resistance of the varnishes can then be obtained by macroscopical and microscopical inspection, rubbing with the finger, etc. —A. de W.

Lead, manganese, and cobalt as driers. W. Flatt. Farben-Zeit., 1921, **26**, 1441.

THE relative speed of drying at 10° C. of oils boiled with various driers was found to be as follows: Lead drier (1 pt. Pb in 100 pts. of oil), 20 hrs.; manganese (1 in 400), 20 hrs.; cobalt (1 pt. 1200), 16 hrs. The form in which the base is dissolved in the oil is without influence on the drying power. A boiled oil containing 1% Pb is, however, extraordinarily heavy-bodied, and eventually becomes turbid and deposits "foots" possessing the same siccative power as the soluble part of the lead. The speed of drying at different temperatures of boiled oils varies with the nature of the drier; thus, exposure at 5° C. of the boiled oils referred to above in the order named, results in dry films being obtained in 24, 44, and 36 hrs. respectively. The progress of oxidation is dissimiliar with the three bases; thus with a lead drier the oil showed definite signs of oxidation (thickening etc.) in 12 hrs., with cobalt there were no signs of drying before 18 hrs., whilst with manganese the oil showed no alteration before 20 hrs.' exposure. A mixture of oils boiled with a lead drier and a manganese drier respectively dried in 16 hrs., the component oils when tested separately drying in 20 hrs. and 24 hrs. respectively. In a similar manner a 20-hr. lead-boiled oil mixed with a 16-hr. cobalt-boiled oil dried in 16 hrs. Relatively small amounts of manganese produce considerable acceleration of drying in oils boiled with lead driers. Manganese-boiled oils increase in drying power on ageing to a degree equal to that obtainable by mixing with lead-boiled oils. —A. de W.

Pressure oxidation of phenols. Fischer and Schrader. *See* III.

PATENTS.

White lead; Apparatus for the manufacture of ——. E. W. Dahl. E.P. 160,395, 2.7.20.

THE apparatus consists of two wooden boxes each provided with an endless belt enclosed in a casing. The material, *e.g.*, comminuted lead, acetic or nitric acid, and water is transferred by one belt from the lower portion of one box to the upper portion of the second, where it is discharged and falls over a series of inclined baffle plates and on to the lower portion of the second belt, the operation being repeated continuously and the reacting material continually passing from one box to the other. The belts are carried on wooden rollers mounted on driving shafts. The boxes are provided with charging hoppers and discharging traps, manholes, and means for the inlet and discharge of carbon dioxide, air, and steam.—A. de W.

Drying chambers, more particularly for dye-, varnish-, lacquer-, and enamel-coatings. Standard Lack Werke, G.m.b.H. E.P. 147,562, 8.7.20. Conv., 21.10.13.

A CLOSED drying chamber is provided with two heating coils on opposite sides, near the bottom, behind baffles, in order to induce an upward circulation of heated air. A cooling coil is set in the middle plane of the drying chamber close below the roofing and is provided with a trough to receive condensed water. A "transferring device" influenced by the humidity of the chamber acts upon a valve either to admit water to the cooling coil, thereby effecting a reduction of humidity in the chamber by causing condensation, or to allow cold water to pass directly to the open trough beneath the coil, thereby increasing the humidity.—A. de W.

Phenolic bodies; Condensation of —— with aldehydic compounds. Vickers, Ltd., The Ioco Proofing Co., Ltd., and W. H. Nuttall. E.P. 160,258, 15.12.19.

Phenolic substances and aldehydic compounds or compounds capable of producing formaldehyde are condensed by the aid of a catalyst comprising a salt or salts of hexamethylenetetramine, *e.g.*, the chloride, sulphate, phthalate, and/or a double compound thereof with phenol, pyrogallol, ethyl bromide, potassium antimony tartrate, etc., the proportion of the catalyst being such that the quantity of hexamethylenetetramine does not exceed 2% of the weight of the main ingredients of the composition. The character of the product may be varied by altering the relative proportions of phenolic substance and aldehydic compound and the nature of the catalyst or mixture of catalysts. —A. de W.

Moulded article [from tung oil] and method of making same. L. H. Baekeland, Assr. to General Bakelite Co. U.S.P. 1,372,114, 22.3.21. Appl., 12.1.18. (*Cf.* U.S.P. 1,312,093; J., 1919, 730 A.)

Tung oil is heated to a relatively high temperature short of that at which solidification occurs, the treated oil mixed with an inert filling material, the mixture moulded, baked, and an insoluble external coating applied.—A. de W.

Resinous composition; Fusible odourless —— and process of making same. W. E. B. Baker and H. Weaver. U.S.P. 1,373,044, 29.3.21. Appl., 23.4.20.

A fused resin is caused to react with an oxidising compound adapted to liberate nascent oxygen and destroy the odoriferous constituent originally present in the resin without substantially affecting the properties of the main constituent of the resin. —A. de W.

Fumigant paint. H. A. Gardner. U.S.P. 1,373,499, 5.4.21. Appl., 27.12.20.

A fumigant coating composition contains a chlorinated derivative of benzol. (*Cf.* J., 1921, 187 A.)—A. de W.

Sulphonated resin and method of making same. A. Horwitz. U.S.P. 1,373,886, 5.4.21. Appl., 19.11.18.

A sulphonated resin soluble in water is obtained by the treatment of a resin with sulphuric acid. —A. de W.

Resins; Process for bleaching ——. G. Ruth and E. Asser. G.P. 329,186, 21.12.19.

The resin is dissolved in a solvent, neutralised if necessary, and saturated, preferably warm, with hydrogen sulphide. Iron compounds present as impurities are thus precipitated.—J. H. L.

Glycerides of aliphatic acids; Method for rendering soluble the solidified (polymerised) ——. O. Nagel. G.P. 331,870, 9.3.20.

Subsequent to or during the polymerisation process, colloids soluble in the desired solvent are added. Polymerised linseed oil after treatment with casein or vegetable gum will give with water or a hydrocarbon solvent a solution or emulsion which can be applied in the same way as paint.—D. F. T.

Resinous condensation products; Production of ——. Akt.-Ges. für Anilin-Fabr. G.P. (A) 332,334, 28.6.18, and (B) 332,391, 9.1.18.

(A) Formaldehyde or substances capable of yielding formaldehyde are made to interact with halogen-substituted derivatives of naphthalene in the presence of acids. From α-chloronaphthalene there are thus obtained clear elastic resins, soluble in benzene, chlorobenzene, fatty oils, or turpentine, and suitable for use in varnishes and for the preservation of leather. (B) Resinous products insoluble in alcohol, but soluble in benzene, turpentine, and linseed oil are obtained by the action of a metal halide on an additive compound of naphthalene with a halogen, or on halogen-substituted derivatives of hydronaphthalenes either alone or mixed with aromatic hydrocarbons. Typical products are those obtained from the action of aluminium chloride on a solution of naphthalene tetrachloride in toluene, of ferric chloride on a mixture of 1-chloronaphthalene tetrachloride with naphthalene, and of antimony pentachloride on a solution of a similar mixture dissolved in tetrachloroethane.—D. F. T.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Amyrin and lupeol in the rubber from Ficus Vogelii. A. J. Ultée. Ber., 1921, 54, 784—785.

Spence (J., 1907, 422) has described the isolation of α- and β-albans, m.p. 201°—205° C. and 154° C. respectively, from *Ficus vogelii*. The former is shown to be identical with α-amyrin acetate, m.p. 218° C.; the latter contains lupeol, probably as the acetate. The terms, α- and β-alban, should be deleted from the literature.—H. W.

Patents.

Rubber goods and materials; Process for obtaining vulcanised —— containing substances which are adversely affected by certain vulcanising processes. S. J. Peachey and A. Skipsey. E.P. 160,499, 24.11.19.

Filling materials, such as sawdust, cork dust, leather waste, and wool waste, which are adversely affected by ordinary vulcanisation, also lake pigments, can be used satisfactorily in compounding rubber which is to be vulcanised by the special method described in E.P. 129,826 (J., 1919, 688 A). D. F. T.

Rubber; Process of compounding lubricated sulphur and —— and vulcanising. D. Repony, Assr. to Manhattan Mfg. Co. U.S.P. 1,372,041, 22.3.21. Appl., 24.9.19.

Sulphur, which has been treated with a lubricant, is introduced into the previously formed mixture of rubber and the other compounding ingredients. —D. F. T.

Caoutchoucs; Pre-treatment of commercial artificial —— which are difficult to work on the rolls owing to insufficient adhesiveness and elasticity. Akkumulatoren-Fabr. A.-G. G.P. 329,171, 3.1.17.

The material is exposed to a temperature above 100° C., and if necessary washed and kneaded at the same time. The product dried in the usual way exhibits when worked almost the same adhesiveness, elasticity, "nerve," and capacity for filling materials as natural rubber.—J. H. L.

Rubber; Increasing the elasticity of vulcanisates from artificial or natural ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 332,347, 16.1.19.

Before vulcanisation, an aryl or aralkyl ether, *e.g.*, % of dibenzyl or dixylyl ether, is added to the ubber.—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Gallotannin. XII. M. Nierenstein, C. W. Spiers, and A. Geake. Chem. Soc. Trans., 1921, **119**, 275—286.

Further evidence obtained cn the constitution of gallotannin seems to throw doubt on the correctness of the pentadigalloylglucose formula of Fischer and Freudenberg (J., 1912, 503). The formation of ellagic acid from gallotannin occurs in two distinct tages, the first producing a maximum of 60%, and he second giving only traces of ellagic acid, but about 8% of dextrose. Similarly, partially hydrolysed gallotannin gave ellagic acid in two distinct tages, whereas from the pentadigalloylglucose formula simultaneous production of ellagic acid and dextrose would have been expected. Further, the methylated derivative of the above partially hydrolysed gallotannin, and also of gallotannin itself, gave on hydrolysis tetramethylglucose. These results are fundamentally opposed to the pentadigalloylglucose formula, since apparently four hydroxyl groups of the glucose in gallotannin are free unless the methylation with diazomethane had caused a replacement of the acyl groups, which, however, was shown to he excluded by the fact that dextrose, and not tetramethylglucose, was formed by the hydrolysis of the methylation product obtained by the action of diazomethane on a synthetic pentagalloylglucose.—G. F. M.

Patents.

Tanning material; Production of a ——. H. Hassler. G.P. 306,341, 9.12.13.

Crystalline sulphonic acids of unsubstituted tricyclic aromatic hydrocarbons, or the condensation products of aromatic sulphonic acids, may be used either alone, or mixed with other natural agents, for tanning hides. An acid reaction is maintained during the process, and the resulting leather is of a bright appearance. Suitable compounds are anthracenedisulphonic acids, and condensation products of naphthalenesulphonic acid, as well as sulphonic acids of phenanthrene and fluorene.—W. J. W.

Patent leather; Process for hardening ——. J. J. Stöckly. G.P. 331,871, 14.4.18.

Hardening of the surface of enamelled or patent leather is accelerated by treatment with ethyl alcohol. It is further advantageous to add an alkali to neutralise acidity developed during drying, which exerts a retarding action on the hardening.
—W. J. W.

Tanning material; Production of a ——. H. Renner and W. Moeller. G.P. 333,403, 12.12.18. Addn. to 262,333 (J., 1913, 878).

Acid resin or acid tar from the refining of mineral oils is treated with alkali or alkaline-earth sulphides, polysulphides, or hydrosulphides instead of with hydroxides or carbonates as described in the chief patent. If calcium (or barium) sulphide s employed, the precipitate of sulphate formed carries down with it the highly coloured impurities, and the clear liquor obtained after filtration can be used immediately for tanning, yielding a light-coloured leather.—L. A. C.

Catgut; Sterilisation of ——. O. Frey. G.P. 331,169, 13.3.19.

The intestinal skins are treated with solutions of diaminomethylacridinium chloride (Trypaflavin). They may further be dressed, *e.g.*, with tannin or potassium iodide solution containing iodine.
—J. H. L.

Catgut; Preparation of ——. C. Braun. G.P. 332,383, 1.8.18.

By treatment of the intestines with a solution of chlorine or bromine, previous to or instead of the usual treatment with iodine solution, surface hardening is avoided and the disinfecting solution more easily penetrates into the body of the material.
—B. V. S.

Casein; Production of —— in a form suitable for the manufacture of translucent horn-like materials. R. Weiss. G.P. 331,440, 26.10.17.

After separation of albumin from milk, the casein is precipitated with aluminium acetate, and then freed from fat by treatment with a mixture of alcohol and another solvent. Owing to the shrinkage caused by the aluminium acetate precipitation, enough moisture is retained by the casein to permit of its being moulded into a transparent, horny material.—W. J. W.

XVI.—SOILS; FERTILISERS.

Soils; Adsorption phenomena in ——. VI. Determination of adsorbed bases, and their significance for processes which take place in the soil. D. J. Hissink. Versl. Landbouwk. Onderzoek. Rijkslandbouwproefstat., 1920, 144—150. Chem. Zentr., 1921, 92, II., 594—595. (*Cf.* J., 1919, 918 a.)

Bases occur in the soil in two forms between which there is little interchange, viz., in an adsorbed form, probably as ions, easily replaced by other ions, *e.g.*, by treatment with ammonium salts, and on the other hand in a form soluble in acids. The adsorbed bases form the supply immediately available for plant nutrition. To determine adsorbed lime or magnesia, 25 g. of soil (or 50 g. in the case of humic sandy soil) is treated with 100 c.c. of warm $N/1$ sodium chloride solution and left to stand. On the following day it is filtered and washed with $N/1$ sodium chloride solution until two litre flasks have been filled in turn with the filtrate and washings. The difference between the lime-content of the first and second litres represents the amount of adsorbed lime in the soil, and similarly for magnesia. To determine adsorbed soda and potash 25 g. of soil is treated as above with $N/1$ ammonium chloride solution, and two successive lots of ½ l. each of filtrate are collected, the difference between their contents of potash or soda representing the amount adsorbed in the soil. Average results for a number of clay soils showed 30 mg.-equivalents of calcium ions, 5 of magnesium, 0·8 of potassium, and 2·5 of sodium ions per 100 g. of soil; *i.e.*, of 100 adsorbed cations 79 were calcium, 13 magnesium, 2 potassium, and 6 sodium ions. Importance is attached to the "state of saturation" of a soil, *i.e.*, the ratio of the number of adsorbed cations to the number which the soil is capable of adsorbing, but there is at present no accurate method of determining the latter value. In moist sea climates the soils are unsaturated and are liable to become "acid." A soil which had been spoiled by flooding with sea water contained per 100 adsorbed cations 56·9 of calcium, 20·2 of magnesium, 3·7 of potassium, and 19·2 of sodium. The flooding had also spoiled the organic matter, by converting calcium humate gels into sodium humate sols.—J. H. L.

Soil; Experiments on chemical and bacteriological changes in ——. F. Münter. Landw. Jahrb., 1920, **55**, 62—138. Chem. Zentr., 1921, **92**, II., 68—69.

Many experiments were performed upon the influence of saline fertilisers on soil. Monobasic calcium phosphate raised the solubility of silica and lessened the solubility of iron and calcium salts. Neutral and basic calcium salts lessened the solubility of silica. The solubility of tribasic calcium phosphate in ammonium chloride was increased in soils poor in lime and rich in silica, whereas the solubility of calcium carbonate in ammonium chloride was lessened. The solubility of lime in water was increased by the presence of potassium chloride, potassium sulphate, and ammonium sulphate. The solubility of magnesia in water and in dilute hydrochloric acid was increased by acid calcium phosphate. In soils containing much iron and clay, the addition of caustic lime diminished the solubility of phosphoric acid in dilute hydrochloric acid. In aqueous solution phosphoric acid is absorbed by lime, iron, and clay, and then behaves similarly to tribasic calcium phosphate. Whilst almost all added phosphoric acid can be recovered by acid from soils rich in lime, 70% of it is retained by soils poor in lime but rich in iron and clay. With regard to the solubility of phosphates, it was found that although ammonium oxalate and acetate could dissolve many of them, yet the best and quickest solvent was citric acid. The influence of moisture upon the nitrogenous changes was investigated and it was found that the heavier the soil, the higher must its water content be for the same amount of decomposition to take place in the organic nitrogenous substances. The rapidity of the formation of ammonia and nitric acid in presence of little moisture increased as the lightness of the soil increased. In soils with much moisture the highest nitrate content was found in sandy soils, because in heavy soils nitrate was decomposed, as much as 32% being lost in a loam soil compared with 9% in a sandy soil. The presence of zeolites caused a sandy soil to behave like a loam soil with respect to ammonification and nitrification. Actinomycetes in soil were found to obtain their nitrogen supply from inorganic as well as organic sources and their carbon supply from carbohydrates and organic acids. Urea, thiourea, and dicyanodiamide served only as sources of nitrogen. Alkali salts were tolerated up to 5%; larger amounts of the alkaline-earths were rendered harmless owing to conversion into carbonates. These fungi effected ammonification, but nitrification was only slight, and evolution of nitrogen did not occur at all; neither did nitrogen fixation, even in the presence of other organisms.—J. H. J.

Soils; Relation of the calcium content of some Kansas —— to the soil reaction as determined by the electrometric titration. C. O. Swanson, W. L. Latshaw, and E. L. Tague. J. Agric. Res., 1921, **20**, 855—868.

The total calcium and calcium in forms soluble in $N/5$ and $N/1$ hydrochloric acid, present in a number of Kansas soils, and the hydrogen-ion concentration of suspensions of 10 g. of the soil in 100 c.c. of water were determined. In soils with a high calcium content, a larger percentage of the calcium was in forms soluble in the dilute hydrochloric acid than in soils with a low calcium content. As a rule soils with a high calcium content had a higher hydroxyl-ion concentration than those with a low calcium content, but the amount of $N/25$ calcium hydroxide necessary to change a soil from a lower to a higher hydroxyl-ion concentration was dependent rather upon the amount of colloidal clay present than upon the calcium content. The amount of $N/25$ calcium hydroxide required to change the p_H value of acid soils to 7, when calculated in terms of calcium carbonate per acre, compared moderately well with the results from the Hopkins method for determining lime requirements. Subsoils, as a rule, had a higher calcium content than surface soils and required more calcium hydroxide to change their p_H values over a given range.—W. G.

Azotobacter. Kayser. Comptes rend., 1921, **172**, 939—940. (*Cf.* J., 1921, 155 A.)

A further study of the effect of colour on Azotobacter at different stages of its culture and the influence of temperature in varying the results. At 27° C. the generations from yellow and blue growths gave practically the same results in respect to total nitrogen fixed and nitrogen fixed per gram of mannitol consumed. The utilisation of mannitol became less satisfactory as the time of incubation was extended. It was more satisfactory at 8°—16° C. than at 27° C., although the total nitrogen fixed at the lower temperature was much less.
—W. G.

Arsenic, antimony, and fluorine compounds; Poisonous action of —— on plant cultures. A. Wöber. Angew. Botanik, 1920, **2**, 161—178. Chem. Zentr., 1921, **92**, I., 35—36.

Among the plants most susceptible to poisons were beans, peas, barley, oats, wheat, maize, and rye. In water cultures 0·01 g. of arsenious oxide per litre had a very poisonous effect, arsenic pentoxide being less poisonous, and at a concentration of 0·1 g. per l. all plants died. Antimony compounds had much lower toxic powers than this. Sodium fluoride had an injurious effect at a strength of 0·1 g. per l. When dusted on soil arsenious oxide had a less poisonous effect than arsenic pentoxide, and antimonious oxide was still less poisonous and was about on a par with sodium fluoride. When sprinkled on green plants, solutions of arsenic acid were more injurious than those of arsenious acid, whereas their sodium salts behaved in a converse manner. Sodium fluoride had a caustic effect in 1% strength.—J. H. J.

Patents.

Phosphatic fertiliser; Process for the manufacture of ——. F. J. Tromp. U.S.P. 1,372,051, 22.3.21. Appl., 11.6.19.

For the production of phosphates soluble in citric acid, iron phosphate or aluminium phosphate is treated with a mixture of lime and a caustifiable compound of an alkali metal in the presence of water.—D. F. T.

Fertilisers; Manufacture of ——. Badische Anilin- und Soda-Fabr. G.P. 333,671, 31.3.18. Addn. to 332,114 (J., 1921, 315 A).

Coarsely crushed superphosphate is mixed directly with ammonium bicarbonate and the mixture ground.—A. R. P.

Seeds; Treatment of ——. Chem. Fabr. L. Meyer. G.P. 327,310, 10.8.19. Addn. to 321,797 (J., 1920, 667 A).

Phenols may be used in admixture with mercury or silver salts without injuring the germinating capacity of the seeds.—J. H. J.

XVII.—SUGARS; STARCHES; GUMS.

Clerget method [of determining sucrose by double polarisation]; Application of the —— to dilute solutions. R. F. Jackson and C. L. Gillis. Int. Sugar J., 1921, **23**, 217—220.

Replying to Browne's criticism (J., 1921, 271 a), it is pointed out that, while the optical rotation of sucrose in the presence of ammonium chloride, sodium chloride, etc. (J., 1920, 634 a) is increased in dilute solution, that of invert sugar, on the other hand, is diminished, the effect of the salt added being compensating (within the limit of error) in the two polarisations. In any case, the effect is small, a value, for example, of 19·17° S. being obtained in the case of 5 g. of sucrose in the presence of 3·392 g. of ammonium chloride per 100 c.c., whereas the value would have been 19·12° if the rotation had been strictly proportional to the concentration. Results of analyses are reproduced showing the average error in the proposed method of neutral polarisation to be only 0·02% in the case of pure solutions of sucrose containing 3—7 g. per 100 c.c.—J. P. O.

Sugars; Iodometric determination of ——. J. L. Baker and H. F. E. Hulton. Biochem. J., 1920, **14**, 754—756.

The method of Willstätter and Schüdel (J., 1918, 556 a) is accurate. The reagents must be added in the order sugar, iodine, alkali, and the time of oxidation need be only 3—5 mins. (*Cf.* J.C.S., May.)—J. C. D.

Sugar analysis; Iodometric determination of copper and its use in ——. I. Equilibria in the reaction between copper sulphate and potassium iodide. P. A. Shaffer and A. F. Hartmann. J. Biol. Chem., 1921, **45**, 349—364.

The influence of the equilibrium between copper sulphate and potassium iodide on the estimation of sugars has been investigated. For the determination of cupric salts potassium iodide must be added to give a final concentration of about 0·25 *M* (4—5 g. per 100 c.c). For the determination of cuprous salts the final concentration of copper and of iodide should not exceed about 5 millimolar each. A number of the methods in use (Gooch and Heath, J., 1907, 991; Maclean, J. Physiol., 1916, **1**, 168; Biochem. J., 1919, **13**, 135; Scales, J., 1915, 1264) comply with the requirements. (*Cf.* J.C.S.. May.) —J. C. D.

Sugar analysis; Iodometric determination of copper and its use in ——. II. Methods for the determination of reducing sugars in blood, urine, milk, and other solutions. P. A. Shaffer and A. F. Hartmann. J. Biol. Chem., 1921, **45**, 365—390.

The principles outlines in a previous paper (*cf. supra*) have been applied to the methods for the estimation of reducing sugars in biological fluids. —J. C. D.

Polysaccharides. II. Constitution of diamylose. P. Karrer and C. Nägeli. Helv. Chim. Acta, 1921, **4**, 169—173. (*Cf.* J., 1920, 795 a.)

Acetyl bromide at the ordinary temperature converts α-tetra-amylose (*cf.* Pringsheim and Langhans, J., 1912, 1001) first into acetylated α-diamylose and then into acetobromomaltose, which is obtained in quantitative yield. α-Diamylose is therefore an anhydride of maltose and is the first known anhydride of a disaccharide. (*Cf.* J.C.S., May.) —T. H. P.

Polysaccharides. IV. Degradation of potato starch. P. Karrer and C. Nägeli. Helv. Chim. Acta, 1921, **4**, 185—202.

The experiments of Karrer (J., 1920, 795 a) have been completed and extended. Methylation of purified potato starch by means of methyl sulphate and baryta water leads to a methylostarch having the molecular weight in water 990—1026, or, allowing for inorganic matter present, 1200 at most. Aqueous or chloroform solutions of this compound contain colloidal particles, but are rendered optically empty by ultra-filtration; these are, therefore, true crystalloidal solutions, and they may be evaporated to dryness in a vacuum without alteration in the properties of the solute. This methylostarch, $C_6H_8O_3(OCH_3)_2$, is attacked neither by diastase nor by ptyalin; *Bacillus macerans*, which degrades ordinary starch to crystalline dextrins, does not develop in its solutions or cause its depolymerisation. The authors consider that the starch molecule contains not more than six dextrose residues united by chemically normal linkings; the number may, indeed, be less than six, since it is not certain that the limits of depolymerisation are reached by the methylation. (*Cf.* J.C.S., May.)—T. H. P.

Polysaccharides. VI. Constitution of starch and glycogen. P. Karrer and C. Nägeli. Helv. Chim. Acta, 1921, **4**, 263—269.

Dry potato starch is attacked by acetyl bromide at the ordinary temperature, with formation of acetobromomaltose in large proportions. As experiments with other polysaccharides have shown that the glucosidic linking is stable towards acetyl bromide, it is assumed that in the starch molecule not more than two dextrose residues are united by normal glucosidic valencies. Starch may also be hydrolysed, with formation of well-defined products, by enzymes, by acid, and by *Bacillus macerans*, and consideration of these reactions indicates that starch is a polymerised maltose anhydride (diamylose). The degree of polymerisation is probably not very high, the high value usually attributed to the molecular weight of starch being presumed, erroneously, from its insolubility. Glycogen also must be regarded as a polymerised diamylose, the degree of polymerisation being different from that of starch.—T. H. P.

Patents.

[Sugar juices and other] liquids or liquors; Process for the purification and separation or filtration of ——. Filtering, decolorising, and purifying processes for liquids and liquors, juices, liquefied bodies, and the like. J. N. A. Sauer. E.P. (a) 155,609 and (b) 155,611, 20.6.19.

(a) In a systematic process successive portions of the liquid, at progressive stages of purification, are passed in turn through a filter containing highly active, finely divided decolorising carbon. The filter is then recharged with fresh carbon (which may first be mixed with the most advanced liquid portion and transferred to the filter with the latter), and the cycle of operations is repeated, each portion of liquid being advanced one stage at every cycle. Any portion may be passed several times through the filter if necessary. The raw liquid introduced as the last portion in each cycle may have received a preliminary purification, and instead of being merely passed through the filter containing the nearly exhausted carbon it may be mixed with the latter and filtered. (b) In the treatment of liquids with highly active, finely divided decolorising carbon, instead of employing just the amount necessary for one quantity of liquid so that the carbon is spent thereby, a considerably greater amount is used so that it will serve for several successive quantities of liquid of the same degree of purity or colour. The time required for the treatment of a given quantity of liquid is very much reduced by this means.—J. H. L.

Sugar; Decolorising and purifying ——. D. Grant. E.P. 159,640, 6.12.19.

Raw or incompletely refined sugar is mixed with a suitable proportion (0·5—6%) of dry active decolorising carbon, or kieselguhr, or both. In this form the sugar may be shipped in bulk and transported pneumatically, and it undergoes relatively little bacterial deterioration during storage. The refining of sugar thus treated is more economical in respect of purifying materials and time than in the case of untreated raw sugar.—J. H. L.

Sugar-cane and similar materials; Treatment of ——. F. H. Lindenberg. Assr. to The Jeffrey Manufacturing Co. U.S.P. 1,369,180, 22.2.21. Appl., 13.1.16.

For the complete extraction of the juice the cane is thoroughly disintegrated so as to form a homogeneous pulp from which the fibrous matter is afterwards separated. The disintegration of the cane may be carried out in stages.—J. H. L.

Sugar-beets; Process of making a palatable syrup from ——. S. F. Sherwood. U.S.P. 1,370,372, 1.3.21. Appl., 19.5.20.

Sugar-beets are heated in water and the extract, separated from the solid matter, is heated at about 109° C. in an autoclave for 1 hr., in the course of which considerable quantities of steam are blown off at intervals of about 15 mins., whereby objectionable flavouring substances are eliminated. —J. H. L.

Sugar; Manufacture of —— direct from the juice. E. Delafond. U.S.P. 1,371,997, 15.3.21. Appl., 24.7.20.

Sugar juices and syrups are purified by passing them between electrodes, and at the same time keeping them in sufficiently rapid motion to prevent any substantial deposition on the electrodes. —J. H. L.

Sugar; Counter-current apparatus, in particular for the extraction of plant slices containing ——. Maschinen und Werkzeugfabr. A.-G. vorm. A. Paschen. G.P. 331,129, 17.12.19.

In apparatus with separating chambers for the temporary separation of the liquid from the slices by means of overflow walls, according to G.P. 267,133, 269,925, and 278,067 (*cf.* U.S.P. 1,077,296 and 1,134,152; J., 1913, 1123; 1915, 567), the separating chambers are provided with a wide outlet orifice for the liquid. There is no danger of slices entering through this orifice, owing to the strong counter-current of liquid.—J. H. L.

Sugar for consumption; Production of —— from massecuites and their drainings. A. Müller. G.P. 329,890, 17.1.20.

The boiling of the massecuite is arrested at a higher moisture content than usual, and it is brought to the density necessary for satisfactory centrifuging by adding, either in the vacuum pan or preferably in the cooler, dry or moist sugar, massecuite of low moisture content, or a mixture of grainy sugar and thick syrup or the latter alone. The strongly coloured solutions obtained in boiling out or steaming out the evaporating plant are worked up separately. With careful working, sugars for direct consumption may be obtained even from second products without re-melting. —J. H. L.

Molasses; Process for the desaccharification of ——. A. Gräntzdörffer. G.P. 330,640, 11.4.20. Addn. to 311,212 (J., 1919, 550 A).

The addition of second syrup and dissolved sugar to first products in the vacuum pan may be made before the formation of grain in the latter. The whole of the centrifugal runnings from first product sugar may be added to the next charge of first syrup, the major part being added before the formation of grain and the rest at the close of the boiling process.—J. H. L.

Root fruits [beetroots]; Method for extracting juices from ——. O. Mengelbier, Assr. to the Chemical Foundation, Inc. U.S.P. 1,372,891, 29.3.21. Appl., 11.5.14.

See F.P. 470,980 of 1914; J., 1915, 192.

Sugar beets. G. P. 324,641 and 325,392. *See* XIX A.

XVIII.—FERMENTATION INDUSTRIES.

Barley; Harvesting, storage and drying of ——. A. Cluss, W. Kluger, and V. Koudelka. Z. ges. Brauw, 1921, 4—18.

Experiments similar to those of 1913 (J., 1921, 22 A) were carried out in 1914 with the same kind of barley. Owing to difference in weather and other conditions the 1914 barley was drier and richer in starch and extract than the 1913 crop, and its germinative power developed much more rapidly. By deferring the harvesting of the grain until it was "dead ripe" (a week after it had attained "full ripeness") the brewing quality of the barley was found to be improved. The advantages of drying the grain artificially, although well marked, were much less so than in the case of the previous crop, and were practically the same whether the drying was carried out immediately after threshing or after 6 weeks' storage. Storage in the ear proved less advantageous than in the earlier experiments. —J. H. L.

Hops; Drying of ——. A. H. Burgess. J. Inst. Brew., 1921, 27, 180—184.

To obtain data respecting the influence of various factors on the drying of hops under practical conditions, 11 kilns of various types were visited and records were made of 15 oastings. The data thus obtained are tabulated. The depth of the hops on the kilns varied from 11½ to 19 ins., artificial draught being used in most cases for the deeper loadings. The average temperature throughout the process ranged from 57° to 84° C., the most usual being about 70° C. The highest maximum recorded was 103° C. and the product in this case was considered satisfactory. The time required to complete the drying varied from 8½ to 15¾ hrs., average 10¾ hrs. The time taken does not depend solely on temperature, depth of load, and moisture-content of the hops. Hops wet with rain dried in some cases as rapidly as those picked in fine weather, and some oastings at comparatively high temperatures dried more slowly than others worked at a lower temperature. The most important factors are probably temperature and air supply, but the latter could not be estimated with any approach to accuracy. —J. H. L.

Yeasts; Break of ——. H. Lüers and R. Heuss. Z. ges. Brauw., 1921, 18—22.

The flocculation or "break" of yeast, in aqueous suspensions, is closely related to the viscosity of the suspensions. Calcium or cerium chloride increased the viscosity and promoted flocculation to a much greater extent than equimolecular proportions of potassium chloride. The viscosity of 12%

suspensions of washed living yeast varied greatly with the reaction of the liquid, attaining a very well-defined maximum point when the reaction was slightly acid (p_H = about 4), and this point corresponded also with the maximum of flocculation. Similar suspensions of yeast killed by chloroform or heat showed no flocculation, and their viscosities were relatively low and varied to only a slight extent with the reaction of the liquid.—J. H. L.

Yeast; Cultivation of —— in solutions of purified nutrients. M. B. MacDonald and E. V. McCollum. J. Biol. Chem., 1921, **45**, 307—311.

It appears probable that yeast can synthesise the growth-stimulating principle known as vitamin B for purposes of its own growth.—J. C. D.

Iron; Determination of —— in wines. L. Mathieu. Ann. Chim. Analyt., 1921, **3**, 106. (*Cf.* Malvezin and Rivalland, J., 1921, 316 a.)

The author prefers the colorimetric method, using potassium thiocyanate; the ash of the wine is dissolved in warm 10% sulphuric acid, any ferrous iron oxidised by the addition of a few drops of nitric acid, and the solution then treated with thiocyanate.—W. P. S.

Sulphite spirit; Acetaldehyde content of ——. R. Sieber. Chem.-Zeit., 1921, **45**, 349—350.

The quantity of aldehyde present in sulphite spirit is proportional to the amount of sulphurous acid in the wort before fermentation; with an SO_2 content rising from 0·132 to 0·330 g. per 100 c.c., the aldehyde increases from 0·044 to 0·220 g. per litre of spirit. The SO_2 content does not alter appreciably during fermentation, and the portion which is presumably combined with the aldehyde is resistant to oxidation by aeration.—W. P. S.

Azotobacter. Kayser. *See* XVI.

Toxicity of phenol towards yeast. (1) Fraser. (2) Fulmer. *See* XIXb.

Patents.

Barley; Process for removing testinic acids and their compounds from ——. Nathan-Institut A.-G. G.P. 330,341, 24.5.17. Addn. to 327,498 (J., 1921, 235 a).

Barley is treated in the steep with dilute alkalis to dissolve the testinic acid, and then completely freed from the latter by washing. The treatment improves the flavour, head-retaining power, and stability of beer produced from the barley, and also renders low-grade barleys suitable for brewing. It may be applied also to oats.—J. H. L.

Glycerin; Production of —— by fermentation. A. Koch. G.P. 331,694, 20.11.17.

Sugar solutions of high concentration, *e.g.*, 40%, are fermented by large quantities of yeast, and alcohol is removed either continuously by means of a vacuum or from time to time by distillation under reduced pressure. The yield of glycerin amounts to at least 15% of the sugar fermented.—J. H. L.

Adhesive for belts and the like [from fermentation residues]. H. Haselberger. G.P. 328,881, 31.7.18.

Residues from the distillation of fermented liquids, ontaining glycerol and other hygroscopic subtances, are treated with a protective agent against ust and made into a syrup with water or other iquid.—J. H. L.

lcohol distillation. U.S.P. 1,372,465. *See* IIa.

ugar beets. G.P. 324,641 and 325,392. *See* XIXa.

XIXA.—FOODS.

Milk; Vitamin content of ——. F. G. Hopkins. Biochem. J., 1920, **14**, 721—724.

The author has repeated and confirmed the results of his earlier experiments on the influence of the vitamins in very small quantities of milk on the growth of rats (*cf.* J. Physiol., 1912, **44**, 425). —J. C. D.

Vitamin A in butter; Effects of heat and aeration upon ——. F. G. Hopkins. Biochem J., 1920, **14**, 725—733.

The refining processes ordinarily employed for ground-nut (arachis) oil and palm kernel oil do not appear to affect the amount of vitamin present, which is very small. The vitamin present in butter fat is not appreciably destroyed by heat alone at temperatures up to 120° C., but is readily rendered inactive by aeration of the hot fat. The vitamin would appear to be a substance prone to oxidative change.—J. C. D.

Butter; Effect of heat and oxygen on the nutritive value of ——. J. C. Drummond and K. H. Coward. Biochem J., 1920, **14**, 734—739.

The vitamin in butter is rapidly destroyed by contact with air at high temperatures. Destruction occurs at temperatures as low as 37° C. if contact with air or oxygen is extensive. (*Cf. supra.*) —J. C. D.

Vitamin A in fats; Action of ozone on ——. S. S. Zilva. Biochem J., 1920, **14**, 740—741.

The vitamin A in butter and cod liver oil is rapidly destroyed by exposure to ozone. (*Cf. supra.*) —J. C. D.

Lard; Nutritive value of ——. J. C. Drummond, J. Golding, S. S. Zilva, and K. H. Coward. Biochem J., 1920, **14**, 742—753. (*Cf.* J., 1921, 81 t.)

The pig resembles other animals which can store up the vitamin A in their body fats, but this is only effected when the diet contains ample amounts of that factor. Fat derived from grass-fed pigs is fairly rich in the vitamin, but the amount may be considerably reduced by the processes of lard manufacture, which frequently involve contact of the hot fat with air.—J. C. D.

Vitamin A; Differentiation of —— from yellow plant pigments. M. Stephenson. Biochem. J., 1920, **14**, 715—720.

The author confirms Drummond's observation (J., 1919, 435 a) that the vitamin A is not one of the lipochromes. Butter fat filtered through charcoal loses its pigment, but retains the vitamin.—J. C. D.

Diets free from vitamin A; Critique of experiments with ——. T. B. Osborne and L. B. Mendel. J. Biol. Chem., 1921, **45**, 277—288.

A general discussion of the technique employed for testing substances for the presence of the vitamin A, with especial reference to the divergent results obtained by different workers.—J. C. D.

Hay; Results of investigation into the self-heating of ——. G. Laupper. Landw. Jahrb. Schweiz, 1920, **34**, 1—54. Chem. Zentr., 1921, **92**, I., 162—163.

The view put forward is that the moisture from withered hay in a stack is able to activate the oxidases present in dried green hay with consequent chemical action and heat evolution. Micro-organisms play no part in the process. The following sequence of events was ascertained: At

20°—35°, activation of the oxidases, commencement of heating; at 35°—45°, caramelisation of sugar; at 45°—70°, evolution of ammonia and formic acid; at 60°—70°, acceleration of the exothermic reaction; at 70°—90°, decomposition of pectins, pungent odour; at 90°—100°, first decomposition of protein, formation of hydrogen sulphide and furfural; at 110°—170°, formation of nitric acid by oxidation of ammonia, explosive union between ammonium nitrate and caramel carbon; at 170°—250°, rapid progress of the exothermic reaction; at 250°—280°, decomposition of cellulose and protein, formation of hydrogen sulphide and furfural, ignition of pyrophoric iron; at 300°, region of inflammability through access of oxygen; at 320°—340° C., final decomposition of carbohydrates, formation of furfural and pyrophoric manganese. The injection of carbon dioxide into the stack does not remove the danger of fire.—J. H. J.

Reducing sugars in milk etc. Shaffer and Hartmann. *See* XVII.

Lactic acid in baking powder. Hartwig and Saar. *See* XX.

Patents.

Concentration of fruit juices in the manufacture of grape honey and fruit syrups; Process and apparatus for the ——. E. Barbet et Fils et Cie. E.P. 135,175, 6.11.19. Conv., 9.11.18.

For the economical concentration of fruit juices in vacuum multiple-effect apparatus, the different effects are used for different juices according to their sensitiveness to heat. Thus the first effect may be used for sulphured juice from white grapes which, for the end in view, is not injured by boiling at 70° C. or above, whilst the second effect is used for the more sensitive juice from red grapes, which would be impaired by boiling at temperatures above 55° C. Each effect may comprise more than one evaporator, and the concentration of each juice may be carried out in two stages between which the juice is allowed to cool and deposit tartar. An arrangement of apparatus for carrying out the process is described.—J. H. L.

Fruit and other vegetable matter; Method of and apparatus for the extraction of juices, pectin, and the like from ——. J. Nicholson. E.P. 159,311, 24.11.19.

Pomace or other suitable material, preferably freed from sugar, is introduced into a strainer immersed in water, and simultaneously heated and agitated, *e.g.*, by injection of steam, to obtain an extract suitable for use in the manufacture of jam. The apparatus comprises a bag-shaped strainer of copper gauze, suspended in a pulp container, which is provided with a steam-tight cover and may be fitted with perforated steam pipes around and within the strainer.—J. H. L.

Milk food. C. S. Townsend. E.P. 159,362, 10.12.19.

Liquefied jelly obtained from *Chondrus crispus* (Irish moss) is emulsified with whole-cream milk, and the product is dried.—J. H. L.

Food and food products; Preparation of ——. J. G. Goodhue and H. L. Trube. U.S.P. (a) 1,365,909 and (b) 1,365,910, 18.1.21. Appl., 4.10. and 19.11.17.

(a) A drying chamber is provided with passages for conveying a number of air currents over material to be dried and back again. Means are provided for inducing the air currents and for heating them independently of the drying chamber. Mechanical means are provided within the chamber for keeping the foodstuff moving forward during the process. (b) A drying chamber is divided into smaller chambers by transverse partitions. Each chamber contains a receptacle for the material to be dried with its end placed at the transverse partition, which is provided with openings placed alternately on opposite sides of the receptacles and forming passages between adjacent chambers, so as to provide a path for a drying current across the receptacles. An air current is circulated by means of a blower at one end of the main chamber and a heater at the opposite end.—J. H. J.

Flour and other cereal products; Process of bleaching and maturing ——. J. C. Baker. U.S.P. 1,367,530, 8.2.21. Appl., 14.2.20.

Nitrogen trichloride gas is passed through the flour.—J. H. J.

Coffee extract; Method of making water-soluble —— *and the product. Method of adding segregated aromas to coffee extract.* D. S. Pratt and C. W. Trigg, Assrs. to J. E. King. U.S.P. (a) 1,367,715 and (b) 1,367,716, 8.2.21. Appl., 31.5.18.

(a) The aroma is separated from a coffee infusion and is brought into contact with lactose which absorbs it. The infusion is evaporated to dryness and the impregnated lactose is mixed with the residue. (b) A coffee extract is sprayed with a solution of coffee aroma in a volatile solvent. —J. H. J.

Aromatic and flavouring constituents; Process for recovery of ——. *Process for recovery of escaping aromas of food etc. Recovery of aromas etc. escaping during comminution of coffee-beans.* C. W. Trigg, Assr. to J. E. King. U.S.P. (a) 1,367,724, (b) 1,367,725, and (c) 1,367,726, 8.2.21. Appl., (a, b) 19.11.17, (c) 31.5.18.

(a) An infusion of roasted ground coffee is evaporated to dryness, the vapour given off being condensed. From the condensed product the caffeol is separated by a solvent and is added to the coffee extract, the solvent being subsequently removed. (b) A coffee infusion is evaporated in a vacuum, the vapours condensed, and the caffeol extracted. The chamber is then exhausted and the gases passed into a closed chamber where they are compressed above atmospheric pressure and passed through a caffeol solution, and then passed into a coffee extract chamber under pressure. When the extract has absorbed the caffeol solution, the pressure is reduced and the solvent allowed to escape. (c) Roasted coffee beans are ground in a closed chamber from which air is excluded. An inert gas is passed through the chamber to remove the aroma and brought into contact with a water-soluble coffee extract, which absorbs the aroma.—J. H. J.

Sterilising milk and other liquids; Process and apparatus for ——. O. Lobeck, Assr. to The Chemical Foundation. U.S.P. 1,369,345, 22.2.21. Appl., 18.2.15.

The milk, by a rotary device, is formed into an extremely thin layer, and in this condition is heated under reduced pressure at a temperature below its boiling point. (*Cf.* G.P. 306,924; J., 1918, 669 a.)—J. H. L.

Drying food products and other materials; Apparatus for dehydrating or ——. W. D. Edwards. U.S.P. 1,369,411, 22.2.21. Appl., 26.2.19.

The apparatus comprises a number of independent chambers arranged side by side, perforated supports for the material to be dried extending diagonally across the chambers so as to divide each into two compartments larger at one end than the other, and means for introducing air into all the chambers at one end, for controlling the air-inlet of each chamber, and for introducing moisture into the air at the inlet ends of the chambers. —J. H. L.

Fish; Food obtained from —— and process of making the same. S. Satow. U.S.P. 1,370,049, 1.3.21. Appl., 5.5.17.

The cooked residue from the manufacture of fish oil is crushed or ground to a paste, dried *in vacuo* below 50° F. (10° C.), ground to powder, and subjected to the action of a proteolytic enzyme, after which the soluble protein is extracted with water, evaporated *in vacuo* at a low temperature, and powdered.—J. H. L.

Evaporated vegetables; Method of preparing ——. R. S. Wittenberg, Assr. to The Pacific Evaporator Co. U.S.P. 1,372,112, 22.3.21. Appl., 17.4.19.

The vegetables are sliced, the cut surfaces subjected to the abrasive action of a jet of fluid of such force and so directed as to remove the free substances exposed by the slicing, and the slices then dehydrated.—A. de W.

Culinary product. Edible oil material and process of producing same. C. Ellis. U.S.P. (A) 1,372,614 and (B) 1,372,615, 22.3.21. Appl., 25.1.19 and 24.4.18.

(A) A food product (nut butter) of a consistency about that of butter is produced by mixing several oils (coconut and peanut oils) together and completely hydrogenating them with the aid of a catalyst. (B) A product of lard- or butter-like consistency is formed from a mixture of a normally liquid nut oil, hydrogenated to a hardness at least as great as that of tallow, with a substantially greater amount of an unhydrogenated nut oil having an iodine value below 25 and a saponification value above 240.—B. M. V.

Sugar beets; Process for purifying and deodorising comminuted ——. Betavit-Ges. m.b.H. G.P. (A) 324,641, 14.12.17, and (B) 325,392, 12.11.18.

(A) Steam at 100°—104° C. is passed through the material until the flavour and odour of beets have been removed. The product has a pleasant vanilla-like odour and may be used for the production of beer or other beverages. Sugar beet flour may be obtained by atomising and desiccating the juice, and the slices, separated from the juice, may be used for the preparation of foodstuffs or fodder. (B) A current of dry gas, *e.g.*, air or carbon dioxide, is employed instead of steam, whereby dilution of the material is avoided.—J. H. L.

Maize meal or maize grits; Removal of bitter substances from ——. P. Schuffelhauer and O. Fauser. G.P. 328,425, 1.11.16.

The material, enclosed in a bag or similar container, is treated several times with boiling brine and then allowed to cool and taken out of the container. The skin which has formed on the surface is removed and the material ground and dried in hot air. The maize oil may be extracted from the brine and the skin.—J. H. L.

Fodder grasses; Process for rendering withered —— stable by spontaneous fermentation. "Herba" A.-G. G.P. 328,781, 31.5.17. (*Cf.* G.P. 305,562; J., 1918, 960 A.)

N order to secure uniform fermentation throughout he whole mass of fodder, the layers of which are xposed to the cooling influence of the floor, walls, nd roof of the containing chamber, the fodder is reated with lactic bacteria; usually 150—180 c.c. f a pure culture in whey is sufficient for 1 cb. m. of odder.—J. H. L.

traw; Process for the preparation of digested ——, in which the production of waste liquors and losses by washing are avoided. W. Thomann. G.P. 328,782, 16.5.18.

HE alkaline digested straw is neutralised with sour whey, sour buttermilk, or sour skim milk. The lactates formed improve the flavour of the fodder. —J. H. L.

Straw (e.g., from cereals or leguminous plants); Production of fodder from —— by digestion with ammonia. E. Beckmann. G.P. 332,363, 25.2.19.

The comminuted straw is digested below 80° C. with aqueous ammonia, preferably of 0·5—8% concentration, or with equivalent quantities of ammonium salts or mixtures which produce ammonia. —J. H. L.

Fodder from straw; Preparation of a ——. Veredelungsges. für Nahrungs- und Futtermittel m.b.H. G.P. 333,746, 29.3.18. Addn. to 305,641 (J., 1919, 789 A).

The straw is digested with a solution of an alkali sulphide, with or without the addition of an alkali hydroxide instead of with an alkali solution as described in the chief patent.—L. A. C.

Fruit and vegetable refuse of all kinds; Complete utilisation of ——. Malz- und Nährextrakt-Werke A.-G. G.P. 331,005, 9.6.18.

Waste materials such as pea shells, banana skins, and the like, are crushed and then extracted by boiling and pressure if necessary. The extract is concentrated and employed as a foodstuff and the residue is further digested with alkalis in order to obtain a liquid cattle fodder and a fibrous residue. Fibres thus obtained from asparagus waste can be used for textile purposes.—J. H. L.

Quinoa; Preparation of a food product rich in protein from ——. E. Heilmann. G.P. 331,547, 11.8.18.

A foodstuff and also an oil and saponin are obtained by drying the finely ground material below 60° C., extracting with dry ether or other fat solvent, and then treating the residue with alcohol, *e.g.*, methyl alcohol, at 60° C. or under to extract the saponin.—J. H. L.

Bread; Process for increasing the yield of ——. E. C. Sutherland, Assr. to Naaml. Vennoots. Ind. Maatschappij v.h. Noury en van der Lande. U.S.P. 1,372,842, 29.3.21. Appl., 18.9.17.

See E.P. 115,410 of 1917; J., 1919, 266 A.

XIXb.—WATER PURIFICATION; SANITATION.

Water analysis. Determination of hardness. L. W. Winkler. Z. angew. Chem., 1921, 34, 115—116.

The following modification of Wartha's method is recommended: 100 c.c. of water is treated with 2 drops of methyl orange solution and the "alkalinity" is titrated with $N/10$ hydrochloric acid. The mixture is then transferred to a 200 c.c. cylinder, 50 c.c. of $N/10$ sodium hydroxide-sodium carbonate solution is added, and the whole diluted to 200 c.c. After about 24 hrs., 100 c.c. of the clear solution is drawn off and the excess of alkali is titrated with $N/10$ hydrochloric acid.—W. P. S.

Water analysis. L. W. Winkler. Z. angew. Chem., 1921, 34, 143.

To effect saving in the use of ethyl alcohol, soap solution for the determination of hardness in water may be prepared with propyl alcohol, the palmitic acid or oleic acid being dissolved in this solvent and neutralised with potassium hydroxide solution. Directions are also given for the determination of calcium and magnesium in waters. —W. P. S.

Phenol and phenol salt solutions; Methylene blue as an indicator of the toxicity of —— towards yeast. C. G. Fraser. J. Phys. Chem., 1921, 25, 1—9.

Solutions of phenol and of phenol and sodium chloride, which are in equilibrium with solutions of phenol in toluene or kerosene (*cf.* J., 1920, 799 A), are isotoxic with these towards yeast cells if ability to stain with methylene blue be adopted as a criterion of death. If, however, inability to form colonies on wort-agar be taken as indication of death, the solutions containing sodium chloride are more toxic. The inability to form colonies on wort-agar seems to mark an earlier stage in the loss of vitality, and the time it takes to reach this stage seems to depend on other factors than the temperature and chemical potential of the phenol in the solution, amongst them the osmotic pressure of the toxic liquid.—J. C. K.

Phenol; Effect of alcohol on the toxicity of —— toward yeast. E. I. Fulmer. J. Phys. Chem., 1921, 25, 10—18. (*Cf. supra.*)

Yeast cells derived from one original cell, and grown under the same conditions in wort, may show very different degrees of resistance to phenol. When wort is seeded with yeast, the first evidence of the fermentation is the formation of white flecks or foam on the surface. The time at which these flecks appear is quite definite. After this first stage, another is reached of active fermentation; while, in a third stage, the fermentation grows slower and finally ceases. When the alcohol produced by fermentation has reached a certain concentration, the cells are much more resistant to phenol than normal cells. If alcohol is added to the wort before seeding with yeast, the formation of abnormal "resting cells," which appear only in the third stage mentioned above, is hastened. By taking as a criterion of death the inability to grow colonies on wort-agar, it was found that a solution containing water, phenol, and 3·75% of alcohol is more toxic to normal yeast cells than a chemically equivalent solution without alcohol; but if, on the other hand, the ability to stain with methylene blue is taken as a criterion, the solutions are found to be equally toxic. Immersion in 8% solutions of alcohol in water increases the number of cells capable of staining with methylene blue, and, consistently with this, a solution containing phenol, water, and 7·5% of alcohol increases the percentage of stained cells more rapidly than a chemically equivalent solution of phenol in water.—J. C. K.

Strawboard factory waste waters. Hermann. *See* V.

Patents.

Water; Apparatus for separating gases, iron, manganese, and other hardening admixtures from ——. H. Wehner. E.P. 7272, 14.5.15.

The water in a finely divided state is mixed with air in a chamber under partial vacuum, the air serving to absorb deleterious gases and being then separated together with such gases. The admixture of the air and water is effected in a "diffuser," comprising a rotor having blades which work between fixed blades in a casing through which the water is drawn by suction, a suitable quantity of air being admitted through numerous small orifices in the circumference of the diffuser. From the diffuser the aerated water passes to a chamber under partial vacuum where the added air is again separated from the water, which is then drawn through a strainer (composed of slag or of a substance which, if desired, will effect the separation of iron etc.) by means of a centrifugal pump on the same shaft as the rotor of the diffuser, and delivered to a suitable tank. If desired a pipe having a series of constrictions, or closely packed with balls, and provided with a porous cell through which air may be forced, may be interposed between the diffuser and the vacuum chamber.
—G. F. M.

Water; Process for the sterilisation and purification of —— [by means of decolorising carbon]. J. N. A. Sauer. E.P. 155,610, 20.6.19.

Water is treated with finely divided decolorising carbon, such as Eponit or Norit, which has previously been subjected to the action of alkalis and/or acids and/or high temperatures; *e.g.*, the carbon may be heated with dilute sodium hydroxide or ammonia solution, then with dilute hydrochloric or other volatile acid, and finally heated alone to 1200° C. or above.—J. H. L.

Water; Treatment of —— for softening, sterilising, and like purposes. H. J. Magrath. E.P. 158,498, 13.9.20.

The plant consists of a tank divided into two parts, the lower of which contains a filtering medium, such as natural or artificial zeolite, and the upper a chamber for a regenerating solution with a removable filter and a ball cistern. The two parts of the tank are connected by pipes with a cock which can be set so as to pass either the water to be treated or the regenerating solution through the lower part. The plant is connected with the main water supply pipe in such a manner that it may be cut out of the circuit without disturbing any of the connexions. It is specially suitable for use in inhabited buildings. (*Cf.* E.P. 18,867 of 1914; J., 1915, 1030.)
—J. H. J.

Sterilising liquids [water]; Process and apparatus for —— applicable also to like operations. W. Paterson. E.P. 158,578, 1.8.17.

Chlorine is passed through a measuring valve to an absorber to which a regulated amount of water is also admitted. The solution obtained accumulates in a reservoir, from which it passes to a feeding tank with a tapered outlet valve controlled by a float resting in the main body of water to be treated as it flows over a weir. In this way the flow of the main body of water determines the amount of solution to be added. When the accumulation of solution in the reservoir reaches a certain amount, the supply of gas and water is automatically cut off and is not resumed until the accumulation is reduced again.—J. H. J.

Water; Process for the softening or purification of ——. B. F. Rushton. E.P. 158,620, 3.11.19.

A tank with curved bottom contains the water to be treated. Electrodes of carbon, zinc, or iron are suspended from a bar across the top of the tank. In the lower portion of the tank is an agitator worked by an electric motor mounted above the tank. A current of about 25 volts is passed through the water for about 1 hr., after which the electrodes are removed, slaked lime is introduced in the proportion of 3 lb. to 1000 galls. of water, and th agitator is set in motion for 10 mins. The water i then allowed to stand for about 1 hr. and is run of through a valve in the lower portion of the tank The sludge is removed from the bottom of the tan through a sluice valve. The process is suitable fo the treatment of any mineral water except se water.—J. H. J.

Water; Purification of —— by means of bariu carbonate and quicklime. H. Riesert G.m.b.H G.P. 333,994, 25.1.18.

Barium carbonate is suspended in a rising colum of water which, at the moment when the reactio between the barium carbonate and the sulphate in the water is complete, is treated with quicklime which tends to prevent the fine particles of barium sulphate from being carried over with the purified water.—A. R. P.

Sewage and analogous liquids; Apparatus for the purification of ——. Air distributing apparatus connected with the purification of sewage and analogous liquids. W. T. Lockett and A. Herring-Shaw. E.P. (a) 156,816 and (b) 156,817, 11.8.17.

b) An aerating device for the aeration of sewage onsists of one or more revolving arms made in the orm of a sector of a circle and projecting horiontally from a central pivot in a treatment tank. he arm is of hollow section and its upper surface s of porous material. It is supplied with compressed air from a central shaft or otherwise. The pper surface of the arm may be of a continuous lat form or may be composed of units of circular or ther shape, graduated in size so as to give a ufficient air discharge at any position between the entre of rotation and the extremity of the arm. n another form, the arm consists of a pipe with series of short branch pipes from its upper side erminating in flat circular air chambers with orous upper surfaces of graduated diameter ccording to their distance from the centre of otation. (a) In order to lift deposited solids from he floor of the tank and bring them into the sphere f action of the air supply, the advancing side of he rotating arm is made with an inclined surface, loping forwards from above downwards.—J. H. J.

Vaste water from gas-works and tanneries; Process for rendering innocuous ——. C. Bozenhardt. G.P. 333,703, 14.3.19.

mmoniacal waste water from gas-works is allowed o mix with the waste water from chrome leather anneries containing salts of chromium, in order o recover the latter as chromium hydroxide and to ender the resulting liquid safe for direct discharge nto a river.—A. R. P.

nsecticides, fungicides, animal dips; Materials for use as —— and like purposes. A. E. Hawker. E.P. 160,511, 15.12.19.

ight wood oil, obtained by the redistillation of the arry layer formed by the controlled distillation of ard woods at an initial temperature of 300° F. about 150° C.), raised subsequently to 800° F. about 430° C.), is used in combination with soap or ther emulsifying agent, in tablet, powder, or liquid orm, as an insecticide, fungicide, etc. The fraction f the distillate employed is preferably that colected up to the point at which the sp. gr. reaches bout 0·98, but other fractions may be used if esired. A maximum of 50% of kieselguhr, fuller's arth, or other absorbent is used in making the owder form of the preparation, whilst water, lycerin, or other solvent is employed for the liquid orm.—G. F. M.

heep dips and cattle washes. J. McDougall and F. Howles. E.P. 160,597, 7.1.20.

fluid sheep dip or cattle wash containing a high oncentration of sodium arsenite is prepared by disolving arsenious oxide in one-fourth or more of ts weight of sodium hydroxide in concentrated queous solution, adding a colloid, such as hydroysed starch or glue, casein, or soap, to the extent the case of the hydrolysed starch of about onewentieth of the weight of the arsenic, and vaporating the whole to a concentration of 50% or ore of arsenious oxide. The mixture remains uite fluid on cooling and can be more easily diluted the required strength for use than concentrated dium arsenite preparations in the solid form.
—G. F. M.

Parasiticide for plants and animals. Farbenfabr. vorm. F. Bayer und Co. G.P. 333,327, 4.7.19.

The parasiticide consists of an ether containing at least one aralkyl group, such as dibenzyl ether, chlorobenzyl ethyl ether or xylyl phenyl ether. The ethers may be used in the liquid or vapour form, as pastes, absorbed in a porous powder, in soaps or ointments, or as solutions in alcohol or ethyl acetate, if necessary also in admixture with other substances.—A. R. P.

Phenols; Preparation of solid mixtures [disinfectants] soluble in water and containing ——. Chem. Fabr. von Heyden, A.-G. G.P. 331,583, 23.3.13.

Solid, insoluble or only slightly soluble complex compounds of phenols with alkali salts of the same or other phenols, are mixed with such solid salts of organic acids as yield aqueous solutions capable of dissolving phenols. The products dissolve readily in water and yield clear solutions possessing only slight alkalinity, and such alkalinity may be avoided by incorporating with the original mixture a solid acid or acid salt which forms with the free alkali a salt exerting a solvent action on the phenols.—J. H. L.

Fatty matter from garbage. U.S.P. 1,372,479. *See* XII.

Fumigant paint. U.S.P. 1,373,499. *See* XIII.

Treatment of seeds. G.P. 327,310. *See* XVI.

Purifying liquors. E.P. 155,609 and 155,611. *See* XVII.

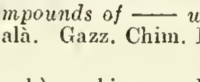
XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Antipyrine; Compounds of —— with mercury. E. Oliveri-Mandalà. Gazz. Chim. Ital., 1921, 51, I., 125—130.

Antipyrine (1 mol.) combines readily with unstable mercury compounds (1 mol.), such as HgCl.OH, HgI.OH, and $HgCl.NH_2$; the antipyrine apparently behaves as an unsaturated compound, the nitrogen atom joined to a methyl group uniting with the negative portion of the added molecule. Pyramidone (dimethylaminoantipyrine) combines with mercuric chloride, but not with $Hg(OH)_2$, HgCl.OH, or $HgCl.NH_2$, replacement of the methinic hydrogen of the antipyrine molecule by the dimethylaminogroup present in pyramidone evidently destroying the mobility of arrangement of the valencies of the nucleus. (*Cf.* J.C.S., May.)—T. H. P.

Sweetening materials; Cyclic imide ethers of diglycollic acid as ——. M. Sido. Ber. deuts. Pharm. Ges., 1921, 31, 118—129.

Whilst the substitution of the imino hydrogen in saccharin by alkyl groups entirely destroys the sweetness of that substance, the position is completely reversed in the case of diglycolimide, which, though itself tasteless, yields alkylimides of the general formula



$$O\begin{cases}CH_2\cdot CO\\CH_2\cdot CO\end{cases}NR$$

increasing in sweetness with an increasing number of carbon atoms in the alkyl group up to a maximum in the N-propyl derivative. The aryl derivatives on the other hand are almost tasteless. The substituted imides were prepared by heating the acid alkylamine or arylamine diglycollates in a vacuum, whereby water was expelled, and the residual imide was purified by distillation under reduced pressure and crystallisation if necessary from absolute alcohol. Diglycolmethylimide and diglycolethylimide are solid crystalline substances, whilst the N-propyl- and N-butylimides are colourless, oily liquids having an intensely sweet taste. All four substances are extremely hygroscopic, and as they are rapidly reconverted by the action of water into the tasteless alkylamine hydrogen diglycollates, they can have no practical application as sweetening agents. (*Cf.* J.C.S., June.)—G. F. M.

Catalysts; Influencing of the activity of ——. II. Reduction of acid chlorides to alcohol and ester. K. W. Rosenmund, F. Zetzsche, and F. Heise. Ber., 1921, 54, 638—647. (*Cf.* J., 1921, 321 A.)

The reduction of benzoyl chloride with the aid of uninfluenced catalysts leads mainly to the production of hydrocarbons. In the presence of sulphur-nitrogen compounds, aldehydes are formed. The joint influence of toluene and xanthone causes benzyl benzoate to be the main product. In xylene solution, benzyl esters undergo reductive fission into alcohol and toluene, which is, however, inhibited by addition of the latter. Quinoline favours the production of benzyl alcohol, dibenzyl ether being formed simultaneously. (*Cf.* J.C.S., June.)—H. W.

Glyoxal; Preparation of —— by the action of acetylene on gold chloride or bromide. K. Kindler. Ber., 1921, 54, 647—649.

Gold is precipitated quantitatively from aqueous solutions of auric halides by acetylene if the gold content does not greatly exceed 1·5%. The acetylene is converted into carbon dioxide (12%) and glyoxal (about 86%), the latter appearing to be the sole organic product of the change. The finely-divided gold can be readily re-converted into the halide by treatment with chlorine or bromine.—H. W.

Oxalic acid; Volumetric determination of ——. A. Abelmann. Ber. deuts. Pharm. Ges., 1921, 31, 130—131.

To the oxalic acid or oxalate solution in a 100 c.c. flask, 30—40 drops of $5N$ nitric acid, and a measured excess of $N/10$ mercuric nitrate solution, containing sufficient nitric acid to produce a clear solution, are added, followed by about 50 c.c. of saturated potassium nitrate solution and sufficient water to make 100 c.c. After standing for 15 mins., the solution is filtered and an aliquot portion of the filtrate titrated with $N/10$ ammonium thiocyanate with ferric ammonium sulphate as indicator.
—G. F. M.

Lactic acid; Detection of ——. L. Hartwig and R. Saar. Chem.-Zeit., 1921, 45, 322.

About 0·2 c.c. of a solution containing not more than 0·2% of lactic acid is mixed with 2 c.c. of concentrated sulphuric acid, the mixture heated at 100° C. for 2 mins., cooled, and treated with 2 drops of 5% alcoholic guaiacol solution; a red coloration is obtained. Formic, acetic, malic, benzoic, and salicylic acids do not give a coloration with the test; citric acid yields a yellow, tartaric acid a faint pink, and tannin a blackish-violet coloration. To detect lactic acid in baking powder, the sample is moistened with water, acidified with phosphoric acid, then mixed with sand and plaster of Paris, and the mixture extracted with ether; the residue obtained on evaporating the ethereal solution is diluted with water and tested as described.
—W. P. S.

Calcium salt; A new ——. L. Gaucher and G. Rollin. Comptes rend. Soc. Biol., 1921, 84, 303—304. Chem. Zentr., 1921, 92, 1., 562.

By the action of phosphorus tri-iodide on concentrated lactic acid a substance of the formula, $C_6H_9O_6P$, is obtained. It melts at 120° C., and is converted by water into the tribasic dipropanoloiphosphorous acid, $HO.P.(O.CH(CH_3).CO_2H)_2$. The calcium salt of this acid, $Ca_3(C_6H_8O_7P)_2,8H_2O$, is very suitable for subcutaneous injection. In neutral or weak acid solution it remains unchanged in the cold, but in presence of alkali it is converted into insoluble calcium phosphite.—G. F. M.

Acetone; Action of ammonia on ——. T. S. Patterson and A. McMillan. Chem. Soc. Trans., 1921, 119, 269—271.

In the course of the preparation of diacetonamine from acetone and ammonia by the usual method, what appears to be an intermediate product of the constitution,

$$CH_3.CO.CH_2.C(CH_3)_2.NH.C(CH_3)_2.NH_2,$$

was deposited in thin prismatic crystals when the ammoniacal acetone was cooled in a freezing mixture. The substance melts at 45° C., and behaves as a di-acid base when titrated with hydrochloric acid in aqueous solution. A monohydrochloride is precipitated when the ethereal solution is treated with dry hydrogen chloride. The substance readily decomposes, and it is suggested that when the reaction mixture is worked up in the usual way it is decomposed by the treatment with oxalic acid into ammonium oxalate and diacetonamine hydrogen oxalate.—G. F. M.

Camphor; Reaction for distinguishing natural and artificial ——. Utz. Farben-Zeit., 1921, 26, 1065.

Lenz's hydrochloric acid reaction (J., 1911, 766) for distinguishing between natural and artificial camphor is untrustworthy, whilst the colour reactions with fuming nitric acid and sulphuric acid observed by Zimmermann (Apoth.-Zeit., 1920, 35, 382) were most probably due to fortuitous impurities. The author recommends the vanillin-hydrochloric acid and vanillin-hydrochloric-sulphuric acid tests for distinguishing between natural and synthetic camphor (*cf.* Bohrisch, J., 1915, 1224). In cases where determinations of synthetic camphor in natural camphor are required, polarimetric examination should be resorted to.
—A. de W.

Patents.

Valeric acid and alkaline valerates; Manufacture of ——. Darrasse Frères et Cie., and L. Dupont. E.P. 137,064, 24.12.19. Conv., 3.12.18.

Salts of valeric acid are obtained by heating an excess of amyl alcohol with sodium or potassium hydroxide in an autoclave provided with an adjustable discharge valve for the escape of hydrogen at 235°—240° C. under 18 atm. pressure. When the whole of the alkali has been converted into valerate according to the equation $C_5H_{12}O+NaOH=C_5H_9O_2Na+2H_2$, the excess of amyl alcohol is distilled off in a current of steam, and valeric acid is isolated from the resulting alkali valerate solution by the usual methods.—G. F. M.

Acetaldehyde from acetylene; Process for the manufacture of ——. Chem. Fabr. Griesheim-Elektron. E.P. 143,891, 27.5.20. Conv., 10.8.16.

In the conversion of acetylene into acetaldehyde in presence of mercury compounds the catalyst is continuously regenerated in the absorption vessel itself by an anodic oxidation process in which the reduced mercury forms the anode, the acid reaction liquid the electrolyte, and mercury, lead, or platinum the cathode. The cathode may either be arranged in a chamber closed by a diaphragm from which the hydrogen is discharged, or it may be placed without a diaphragm in the acid reaction liquid, the hydrogen which gradually accumulates in the circulating gas being removed at intervals. By this process larger quantities of mercury salt, xceeding 10% of the weight of the acid reaction iquid, can be employed, with a consequent increase n the rate of absorption of the acetylene. —G. F. M.

orneol; Manufacture of ——. Fabr. de Prod. Chim. de Thann et de Mulhouse. E.P. 144,604, 8.12.19. Conv., 12.6.19.

URPENTINE or crude pinene is heated with a uarter of its weight of tetrachlorophthalic acid n a reflux apparatus with continual stirring for 2 hrs. at 106°—108° C. The temperature is then lowly raised to 140° C., at which it is maintained or 6 hrs. After cooling, the unattacked terpenes re distilled off with steam or in a vacuum, and the esidue, which forms a glassy mass consisting of ibornyl tetrachlorophthalate, is hydrolysed with lcoholic sodium hydroxide. The borneol, precipiated by the addition of water, is purified by the sual methods. It is optically active, and, unlike he product obtained by the action of other organic cids on pinene, it is quite free from isoborneol. 'he yield may be as high as 18% of the crude inene used, and in addition there is a considerble quantity of pinene recovered, which, if deired, can be returned to the manufacture. The etrachlorophthalic acid can be almost quantiatively recovered.—G. F. M.

sobornyl ester and camphene; Conversion of pinene compounds into a mixture of ——. L. G. Wesson. U.S.P. 1,372,382, 22.3.21. Appl., 30.6.19.

INENE hydrochloride or hydrobromide when heated ith a carboxylic acid in presence of not more than % of zinc is converted into a mixture of an isoornyl ester and camphene.—G. F. M.

-Aminophenol and of its O-alkyl ethers; Manufacture of derivatives of ——. E. Kolshorn. E.P. (A) 145,614, 29.6.20. Conv., 13.6.19. (B) 155,575, (C) 155,576, 24.11.20. Conv., 12.12.19.

A) WATER-SOLUBLE derivatives of *p*-aminophenol or f its O-alkyl ethers are obtained by their converion into N-dihydroxypropyl compounds of the eneral formula,

$$RO.C_6H_4.NH.CH_2.CH(OH).CH_2OH,$$

y causing the amino-compounds to react either irectly or in a neutral solvent with monochlorydrin, or with epihydrin alcohol, in the former ase either with or without the addition of an alkali ydroxide. Thus 22 gr. of *p*-aminophenol when ently heated with 15 g. of epihydrin alcohol glycide) in benzene solution is converted into N-ihydroxypropyl-*p*-aminophenol, m.p. 192° C., eadily soluble in water, giving a solution which as a powerful reducing action on silver salts, and s specially suitable as a photographic developer. N-Dihydroxypropyl-*p*-phenetidine, m.p. 93° C., is btained by the action of α-monochlorhydrin (11 g.) n *p*-phenetidine (14 g.) in presence of alcoholic otassium hydroxide. It is easily soluble in water nd has valuable therapeutic properties. (B) The ame derivatives of *p*-aminophenol and its ethers re obtained by condensing the bases with epihlorhydrin, with or without the addition of a eutral solvent, and treating the chloro-compound, $RO.C_6H_4.NH.CH_2.CH(OH).CH_2Cl$, produced, with he theoretical amount of alcoholic potassium ydroxide. (C) Instead of epichlorhydrin, αα- or β-dichlorhydrin may be used in presence of pyriine or alcoholic potassium hydroxide to eliminate he halogen acid, the chloro-intermediate product eing treated with alkali hydroxide as before to iminate chlorine.—G. F. M.

landular extractive product [from the infundibular lobe of the pituitary gland]; Process of manufacturing ——. A. M. Clover, Assr. to Parke, Davis and Co. U.S.P. 1,373,551, 5.4.21. Appl., 3.3.13.

HE gland is extracted with hot, acidified water, insoluble material is separated from the solution, and the active constituent is precipitated by saturating the solution with sodium chloride. —L. A. C.

Trihydroxyisopentane; Preparation of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 309,111, 12.8.17.

TRIHYDROXYISOPENTANE (dimethylglycerol) is obtained by the oxidation of 3-methylbutenol, or by the saponification of the corresponding chlorine derivative. It is a solid, m.p. 49° C., b.p. 122° C., and is more hygroscopic and more strongly bactericidal than glycerin.—B. V. S.

Anti-gonorrhœa preparation; Production of ——. P. Bergell. G.P. 330,348, 1.4.19.

A CULTURE of gonococci is prepared under optimum conditions at 36° C. and then the organisms are killed by maintaining a temperature of 41°—42° C. for a long time. The destroyed organisms are suspended in physiological salt solution with the addition, if necessary, of a disinfectant. If the temperature is raised to 45° C. the anti-toxic properties of the culture are reduced.—H. J. H.

Ovaries and similar organs; Preparation of nitrogenous compounds from ——. L. Seitz and H. Wintz. G.P. 332,165, 25.1.16. Addn. to 320,857.

THE method of the chief patent (J.,1920, 675 A), is extended to the ovary and the placenta, the former yielding a substance with a preventive effect and the latter one with a loosening effect on menstruation. The latter substance may also be obtained in pure form from the dried, powdered organ by extraction with alcohol and chloroform.—B. V. S.

Glycerin substitute [from lactates]. Chem. Fabr. vorm. Goldenberg, Geromont und Co. G.P. 332,167, 9.8.18. Addn. to 303,991 (J., 1920, 756 A).

MIXTURES of alkali lactates with lactates of suitable di- and trivalent metals are employed. Lactates of calcium, zinc, and magnesium obtained in the manufacture of lactic acid may thus be utilised. —J. H. L.

N-Alkyl-acylhomopiperonylamines; Manufacture of ——. E. Merck, Chem. Fabr. G.P. 332,474, 26.3.12.

THE alkali salts of N-acylhomopiperonylamines are treated with alkylating agents. For example, by condensing the potassium compound of formylhomopiperonylamine (obtained by treatment with potassium in toluene solution) with methyl iodide, methylformylhomopiperonylamine, a thick, strongly refracting oil, b.p. 194° C. at 6 mm., is formed quantitatively. The sodium compound prepared in a benzene solution may be allowed to react in a similar manner on methyl chloride.—C. A. C.

Fatty acids and aldehydes; Manufacture of ——. C. Harries, R. Koetschau, and E. Albrecht. G.P. 332,478, 11.6.16. Addn. to 324,663 (J. 1920, 765 A).

THE decomposition of the ozonides is effected by reducing agents, as sulphur dioxide, sulphites, zinc or the like and acids. The dark-coloured soaps and acids obtained by alkali fusion of hydrocarbons (G.P. 314,745; J., 1920, 151 A) may also be transformed into ozonides and the latter decomposed by steam, caustic alkali, or sulphuric acid, or by reducing agents, as sulphur dioxide, sulphites, zinc, and acids. Technically valuable light yellow to colourless products of low molecular weight are formed, consisting chiefly of carboxylic and dicarboxylic acids. During the action of ozone on the dark, alkaline solutions, *e.g.* of acid resins from the refining of petroleum, the ozonides are decomposed *in statu nascendi*.—C. A. C.

Bismuth-alkali iodide solutions; Preparation of —— for therapeutic use. Chem. Fabr. auf Aktien (vorm. E. Schering). G.P. 332,552, 21.4.16.

The capacity to precipitate albumin or gelatin from solution is removed by the addition to the bismuth iodide of a large excess of an alkali iodide and a small quantity of an acid such as tartaric, glycollic, citric, lactic, or hydriodic acid. The solution may contain, for example, 0·5 g. of sodium-bismuth iodide, 7·5 g. of sodium iodide, and 1 g. of tartaric acid in 500 c.c. of water. The solutions have a strong germicidal action.—B. V. S.

Chloral and a phenol; Manufacture of a compound of ——. O. Hinsberg. G.P. 332,678, 15.4.17.

By the interaction of chloral and *p*-acetaminophenol, with or without a solvent, chloral-acetaminophenol, $CH_3.CO.NH.C_6H_4.O.CH(OH).CCl_3$, is obtained. It forms a colourless and tasteless crystalline powder, m.p. about 160° C. When heated quickly it is decomposed with frothing and evolution of chloral vapour. Chloral is also liberated on boiling with water. The product acts as a soporific in smaller doses than chloral, and its action also differs appreciably from that of the latter.—C. A. C.

Glycol diacetate; Manufacture of ——. K. H. Meyer. G.P. 332,677, 29.7.19.

Ethylene dichloride and anhydrous sodium acetate are heated in presence of glycol diacetate. At 230° C. a smooth conversion takes place which would only be effected in a small degree without a solvent. Glycol diacetate, like the monoacetate, is a good solvent and gelatinising agent.—C. A. C.

Urea; Manufacture of —— from carbonic acid compounds of ammonia. Badische Anilin- und Soda-Fabr. G.P. 332,679, 11.7.15.

A "melt" of ammonium carbamate, or of the product of the interaction of carbon dioxide and ammonia together with a small amount of water, is prepared in a separate vessel and is then forced under pressure into a reaction vessel. By making the reaction vessel part of a pressure-proof system the process may be made continuous. For example, a "melt" of 10 pts. of ammonium carbamate and 1 pt. of water, prepared at 90° C. under a pressure of 15 atm., is passed through a heated pressure-proof spiral pipe, heated at 135°—140° C. If the time occupied in passing through the spiral pipe is 2 to 3 hrs., then on relieving the pressure 25% of the carbamate will have been converted into urea. —C. A. C.

Urea melts obtained from carbon dioxide compounds of ammonia; Treatment of ——. Badische Anilin- und Soda-Fabr. G.P. 332,680, 11.7.15.

The ammonium salts which have not been converted are distilled under pressure from the urea autoclave into another pressure-proof vessel at a lower temperature. The greater part of the ammonium carbamate and carbonate is easily and quickly precipitated in a solid or molten condition respectively. The pressure-proof receiver may either be a second urea autoclave or with advantage the vessel used for preparing the melt (*cf. supra*). The ammonium salts remaining in the urea autoclave are afterwards distilled off under normal or reduced pressure.—C. A. C.

Guanidine salts; Manufacture of ——. F. Hofwimmer. G.P. 332,681, 12.9.17.

Alkaline-earth salts of cyanamide are heated together with ammonium salts to a suitable temperature; *e.g.*, calcium cyanamide is added to a melt of ammonium nitrate and then heated to 200°—220° C. The following reaction takes place: $CaCN_2+3NH_4NO_3 = C(NH)(NH_2)_2.HNO_3+Ca(NO_3)_2+2NH_3$. By solution, filtration, and crystallisation carbon, calcium nitrate, and guanidine nitrate are separated. The calcium nitrate remaining in the mother liquors is worked up to ammonium nitrate by means of the ammonia obtained.—C. A. C.

Aldehydes; Preparation of ——. K. W. Rosenmund. G.P. 333,154, 28.3.17.

Acid halides, or solutions of the same, are treated with hydrogen in the presence of a catalyst and a substance capable of combining with acid. Stearic aldehyde is prepared from a solution of stearic acid chloride in benzol in the presence of 5% of palladinised barium sulphate and calcium carbonate; benzaldehyde, *p*-hydroxybenzaldehyde, and butyraldehyde are prepared respectively from benzoyl bromide (or chloride), *p*-carbomethoxybenzoyl chloride, and butyryl chloride, using palladinised silicic acid as catalyst.—L. A. C.

Urea or ammonia; Production of —— from [calcium] cyanamide. S. Giertsen. E.P. 160,857, 14.8.19.

See U.S.P. 1,326,045 of 1919; J., 1920, 174 A.

Denitrating nitric esters. G.P. 333,708. *See* XXII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic emulsion; Orientation of the grains in a dried ——. L. Silberstein. J. Opt. Soc. Amer., 1921, **5**, 171—177.

A mathematical analysis is given of the probable average orientation of silver halide grains in a sensitive film, making certain simple assumptions as to the nature of the drying process. It would appear highly probable that the "efficiency coefficient," *i.e.*, the ratio between the average projected area of the grain and its actual area, regarding all the grains as flat plates of small thickness, is very nearly unity in the dried film.—B. V. S.

[Photographic] reduction of developing-out papers; Sensitometric study of ——. L. A. Jones and C. E. Fawkes. J. Franklin Inst., 1921, **191**, 503—516.

In testing the effects of photographic reducers on developing-out papers, graded prints, obtained in the usual way by exposure in a non-intermittent sensitometer, and development, were measured by means of a reflectometer, then reduced, and again measured. A comparison of the curves obtained from these measurements shows both the extent and the nature of the reducing effect. Ten reducers were tested, full particulars being given of six of them, divided into 3 types. Potassium permanganate solution and Belitski's reducer (ferric chloride, sodium oxalate and thiosulphate) are of type 1, the contrast of the print being unaltered. Type 2, in which contrast is increased by reason of more vigorous action on the lower densities, includes iodine-cyanide and Farmer's (ferricyanide-thiosulphate) reducers. The third type, in which contrast is reduced, includes ammonium persulphate and the Nietz-Huse proportional reducer (permanganate-persulphate).—B. V. S.

Patents.

Colour photography. W. Friese-Greene, J. N Thomson, and Colour Photography, Ltd. E.P 160,540, 20.12.19 and 15.4.20.

A toning solution, chiefly intended for productio of the red constituent in two- or three-colour photo graphy, contains potassium ferricyanide, uranium nitrate, Rose Bengale, Naphthol Yellow, and acetic acid along with iodine and/or Sensitol Red (Pina-yanol).—B. V. S.

Photographic developers. J. Hauff und Co. G.P. 327,111, 24.10.18, and 328,617, 10.12.18.

The carboxylic and sulphonic acids of *o*- and *p*-aminophenol, of *o.p*-diaminophenol and of their homologues, *e.g.*, *p*-aminosalicylic acid, are used in austic alkaline solution. The developers show no endency to the formation of veil. The resulting ilver image is brownish-black in colour.—B. V. S.

Photographic flash light; Production of ——. K. Hempel. G.P. 330,531, 15.10.19.

Metallic aluminium and magnesium, together or ingly, are mixed with manganite and/or permanganate of barium or mixtures of these, together with paraffin wax. Production of smoke is inconiderable owing to the absence of potassium.
—H. J. H.

Photographic silver films; Intensifying ——. H. Franke. G.P. 333,094, 17.4.20.

By the use of solutions of selenium compounds, such s a selenosulphate, selenium is deposited on the ilver grains. It may be removed again by treatment with, *e.g.*, permanganate solution slightly cidified with hydrochloric acid.—B. V. S.

Coloured photographic pictures; Method and apparatus for producing ——. J. H. Christensen. U.S.P. 1,373,053, 29.3.21. Appl., 2.8.18.

ee G.P. 313,836 of 1918; J., 1920, 45 a.

-Aminophenol derivatives. E.P. 145,614 and 155,575-6. *See* XX.

XXII.—EXPLOSIVES; MATCHES.

Mercury fulminate; Characteristic reaction for the detection of ——. A. Langhans. Z. anal. Chem., 1921, **60**, 93—94.

f mercury fulminate is moistened with alcohol, ater added, and the mixture shaken with 20% odium sulphantimonate solution, a yellow precipiate forms which gradually turns olive-green and hen black. The filtrate from the precipitate gives bright red colour with nitric acid; the colour is oluble in ether.—W. P. S.

Patents.

Nitroglycerin; Process for separating —— from wash-waters. Westfälisch-Anhaltische Sprengstoff A.-G. G.P. (a) 299,030, 5.11.15, and (b) 299,720, 5.2.16.

a) Both suspended and dissolved nitroglycerin may e removed from the wash-waters by treating them ith nitrocellulose. (b) Nitroglycerin is separated rom a solution in aqueous acetone, containing up o 30% of acetone, by shaking the solution with, or ltering it through, nitrocellulose. The process hould be conducted at a low temperature in order o minimise loss of acetone.—W. J. W.

mokeless powders; Process for comminuting ——. Westfälisch-Anhaltische Sprengstoff A.-G. G.P. 332,284, 25.1.19.

owders with a hard grain or surface are softened y means of gelatinising agents, or preferably, ueous volatile solvents, and are then pulverised th addition of water in kneading machines.
—W. J. W.

Nitric acid esters of carbohydrates and glycerol; Process for completely or partially denitrating ——. H. Bucherer. G.P. 333,708, 14.12.18.

The ester, *e.g.*, nitrocellulose, is mixed with or dissolved in sulphuric acid, and an aromatic compound, such as benzene, is added with vigorous agitation. The nitro groups migrate to the aromatic compound and the product settles into separate layers of benzene and sulphuric acid containing respectively nitrobenzene and cellulose in solution. Sulphonic acids or acid sulphates can be employed instead of sulphuric acid.—L. A. C.

XXIII.—ANALYSIS.

Melting points; Determination of —— [*especially of inorganic substances*]. [*Melting point of potassium chlorate.*] C. D. Carpenter. Chem. and Met. Eng., 1921, **24**, 569—571.

The apparatus employed consists of a lagged beaker, with observation holes in the lagging, a platinum resistance thermometer, and a stirrer of which the speed can be adjusted. For the heating bath a mixture of potassium and sodium nitrates (m.p. 220° C.) is used. For temperatures above 600° C. both bath and melting point tube must be constructed of transparent quartz. In determining the melting point of potassium chlorate, the substance was melted and then cooled, and this process was repeated several times, the temperature being kept within narrow limits, and the crystals never being allowed to disappear completely. The temperatures at which new crystals formed on cooling were noted in terms of the resistance. By plotting the results on a graph, the resistance was found to be 116·435 ohms, corresponding to 357·10° C.
—W. J. W.

Sodium sulphantimoniate; Reactions of —— *with some metallic salts.* A. Langhans. Z. anal. Chem., 1921, **60**, 91—93.

The coloration of the precipitates obtained when metallic salt solutions are treated with freshly-prepared sodium sulphantimonate solution is as follows: Iron, nickel, cobalt, and bismuth, black; aluminium, chromium, silver, copper, and lead, brown; manganese, orange; zinc and cadmium, yellow. Mercuric oxide is coloured black by the reagent, as are also mercuric oxalate and mercurous nitrate, whilst mercuric bromide is coloured yellow. Mercuric cyanide is at first coloured yellow and then black; mercuric chloride yields a reddish-yellow compound. Sodium stannate and arsenate do not give reactions. (*See also* Cl. XXII.)
—W. P. S.

Adsorption; Importance of —— *in analytical chemistry. IX. Glass wool as a filter material.* I. M. Kolthoff. Pharm. Weekblad, 1921, **58**, 463—471.

Glass-wool should not be used for filtering warm dilute solutions of salts of metals or alkaloids, as considerable losses occur. (*Cf.* J.C.S., June.)
—S. I. L.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Adams, Adams, and Linkie. Mixing-machines. 13,051. May 7.

Beldimano, Robertson, and Stanley. Evaporating or heating liquids. 13,082. May 7.

Blair, Campbell, and McLean, Ltd., and Wright. Apparatus for effecting intimate contact of liquids and gases. 13,004. May 6.

Buxton. Drying systems. 12,497. May 2.

Curtis and Jones. Drying apparatus. 13,045. May 7.

Evans (Allgem. Elektricitäts-Ges.). Apparatus for effecting perfect combustion of coal, coke, etc. in furnace plants. 12,394. Apr. 29.

Frischer. Apparatus for carrying out chemical and physical processes. 12,984. May 6.

Jewell. Stills. 12,220. Apr. 28.

Kenyon and Reynolds. Separating or grading powdered or granular materials, and treatment thereof by gases etc. 11,860. Apr. 25.

Paterson. Filtering-apparatus. 11,972. Apr. 26.

Pessi. Preventing incrustation in steam boilers. 12,981. May 6. (Ital., 6.5.20.)

Roberts. Grinding-mills. 11,876. Apr. 25.

Sklenar. Reverberatory furnace. 12,078. Apr. 27.

Thompson (Sharples Separator Co.). Centrifugal emulsifiers. 12,048. Apr. 27.

Thorne. 12,483. *See* IX.

Complete Specifications Accepted.

11,142 (1919). Miller, and Fletcher and Co. Filters. (161,993.) May 4.

22.661 (1919). Philip. Stills. (162,000.) May 4.

32,408 (1919). Patrick, Lovelace, and Miller. Separating and recovering gases. (137,284.) May 4.

2703 (1920). Meston. Separating suspended matter from liquids. (162.390.) May 11.

6962 (1920). Malkin. Grinding-mills. (162,481.) May 11.

7182 (1920). Soc. l'Air Liquide. Protection for walls of enclosures in which reactions take place at high temperatures and pressures. (140.083.) May 11.

9432 (1920). Holmes and Co., Henshaw, and Whittell. Apparatus for bringing liquids and gases into intimate contact. (162,166.) May 4.

10.852 (1920). Soc. des Condenseurs Delas. Cooling viscous liquids. (142,454.) May 4.

15.019 (1920). Rambaud. Evaporating and concentrating apparatus for syrups etc. (144,631.) May 11.

15.182 (1920). Petree. Apparatus for separating impurities in suspension from liquids. (162.206.) May 4.

20.214 (1920). Petzel. Separation of gas mixtures. (148,302.) May 11.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Amend. Refining petroleum distillates. 12,461. Apr. 30.

Bamber and Parker. Gas producers or generators. 12 789. May 4.

Bismarckhütte. Coking-chambers for generators. 12 974. May 6. (Ger., 6.5.20.)

Catton. Fuel. 12,951. May 6.

Clewlow. Disintegrating, dehydrating, etc. peat. 11,828. Apr. 25.

III.—TAR AND TAR PRODUCTS.

Applications.

Barrett Co. Manufacture of products of oxidation of aromatic hydrocarbons. 12,153. Apr. 27. (U.S., 18.6.20.)

Bismarckhütte. Separating water from coal tar. 12,974. May 6. (Ger., 6.5.20.)

Bradley, Glossop, and Willsdon. Distillation of tar etc. 12,524. May 2.

Commin. Treatment of pitch. 12,388. Apr. 29.

Complete Specification Accepted.

20,585 (1920). Sudfeldt u. Co. Obtaining salts of sulpho acids from lignite tar oils. (148,763.) May 11.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Dreyfus. Manufacture of cellulose derivatives 11,851. Apr. 25.

Forster. Obtaining transparent effects on cotton fabrics. 12,463. Apr. 30. (Ger., 30.4.20.)

McRae. Treatment of bamboo, bagasse, etc. for extraction of cellulose. 12,919. May 5.

Plauson's (Parent Co.), Ltd. (Plauson). Manufacture of cellulose compounds. 12,190. Apr. 28.

Soc. Pichard Frères. Process for carrotting hairs. 12,259. Apr. 28. (Fr., 15.5.20.)

Complete Specifications Accepted.

24,519 (1919). White and White. Wool-washing machines. (162,313.) May 11.

2721 (1920). Great Northern Paper Co. Paper-making. (141,022.) May 4.

27,169 (1920). Great Northern Paper Co. Paper-making. (151,623.) May 4.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Crowther. Machines for treating textile fibres with liquids. 13,061. May 7.

Fergusson and Rhodes. Treatment and dyeing of woollen yarns etc. 12,713. May 4.

Complete Specification Accepted.

13,731 (1920). Kershaw. Bleaching of fabrics. (162,198.) May 4.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Aluminium-Industrie A.-G. Manufacture of nitrate of calcium. 12,901. May 5. (Switz., 19.5.20.)

Boorman and Browning. 12,157. *See* XVI.

Brightmore. Fixation of atmospheric nitrogen. 12,146. Apr. 27.

Chem. Fabr. Griesheim-Elektron, and Suchy. Electrolytic production of potassium carbonate from potassium chloride solutions. 12,573. May 2.

Constant and Raisin. Production of boron. 11,947. Apr. 26. (Fr., 30.4.20.)

Heenan and Froude, Ltd., and Walker. Concentration of brine. 12,600. May 3.

Norris. Recovering sodium sulphate and a liquor of high acidity from nitre-cake. 13,029. May 7.

Parrish, and South Metropolitan Gas Co. Manufacture of neutral sulphate of ammonia. 12,116, Apr. 27.

Complete Specifications Accepted.

17,624 (1917). Buchner. Production of aluminium hydroxide. (162,303.) May 11.

26,589 (1919). Pease. Extraction of ammonia from gases. (162,314.) May 11.

31,936 (1919). Field, and Metals Extraction Corp. Purification of zinc solutions. (162,030.) May 4.

1240 (1920). Ellis. *See* X.

2325 (1920). American Coke and Chemical Co. Ammonia saturators. (138,129.) May 11.

VIII.—GLASS; CERAMICS.

Applications.

Stafford. Glass etc. furnaces. 11,893–4. Apr. 25.

Travers. Glass furnaces. 12,673. May 3.

Complete Specifications Accepted.

8949 (1920). Thompson. Annealing furnaces for glassware etc. (140,817.) May 11.

26,561 (1920). Harvey Gas Furnace Co., and Harvey. Furnaces for melting glass. (162,232.) May 4.

IX.—BUILDING MATERIALS.

Applications.

Briscoe and Faber. Rotary kilns for calcining Portland cement etc. 12,884. May 5.

Stoederum and Zondervan. Building material. 2,346. Apr. 29.

Tabary. Manufacture of material for buildings, roads, etc. 12,277. Apr. 28.

Thorne. Heat-conducting powder for covering boilers, pipes, etc., and for forming walls etc. 12,483. May 2.

Complete Specifications Accepted.

26,168 (1919). Fried. Production of building materials and artificial stones. (134,230.) May 11.

26,504 (1919). Dyring. Building material. (134,538.) May 11.

28,509 (1919). Bayer. Manufacture of stone-like materials of foam-like structure. (162,318.) May 11.

2080 (1920). Jones. Manufacture of disintegrated asbestos for use in making fireproof composition. (162,359.) May 11.

7389 (1920). Wallace. Treating clayey materials for making bricks, slabs, etc. (162,483.) May 11.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Akt. Ferrolegeringar. Manufacture of manganese alloys poor in carbon, or silicon, or manganese. 12,232. Apr. 28. (Sweden, 12.5.20.)

Akt. Ferrolegeringar. Production of chromium or its alloys. 12,233. Apr. 28. (Sweden, 12.5.20.)

Ashcroft. Precipitating precious metals from cyanide solutions. 12,347. Apr. 29.

Bansen, and Faconneisen-Walzwerk Mannstädt u. Co. Hearth smelting or heating furnaces. 12,793. May 4.

Blei- u. Silberhütte Braubach A.-G. Treating materials containing precious metals. 12,205. Apr. 28. (Ger., 12.8.20.)

Burgess. Reduction of aluminium oxide. 12,129. Apr. 27.

Hibbard. Metallurgical furnaces. 12,391. Apr. 29. (U.S., 1.11.19.)

Howse. Preserving steel or iron work against corrosion or rusting. 12,507. May 2.

Jones and Owen. Production of metallic dust. 13,018. May 6.

Koppers. Desulphurising large masses of iron and steel. 12,244. Apr. 28. (Ger., 28.4.20.)

Leon and Lister. Dyeing aluminium. 12,413. Apr. 30.

Patent-Treuhand Ges. Production of drawn tungsten wires. 13,010. May 6. (Ger., 7.5.20.)

Soc. Anon. Usines Métallurgique de la Basse-Loire. Production of basic steel. 12,260. Apr. 28. (Fr., 18.5.20.)

Complete Specifications Accepted.

31,791 (1919). Elmore. Treatment of argentiferous lead-zinc sulphide ores. (162,026.) May 4.

31,936 (1919). Field and others. *See* VII.

1240 (1920). Ellis. Production of powdered metals and suboxides. (162,038.) May 4.

2433 (1920). Magnet. Reducing fused slag to a granular form. (162,375.) May 11.

2580 (1920). Rare Metals Reduction Co. Production of alloys. (138,348.) May 11.

2710 (1920). Fletcher. Electrodeposition of metals on iron and iron alloys. (162,391.) May 11.

5723 (1920). Bradbury, and Rolls-Royce, Ltd. Aluminium alloys. (162,467.) May 11.

18,964 (1920). Manuf. de Prod. Chim. du Nord Etabl. Kuhlmann. Removing dust from the gases derived from the roasting of ores. (147,020.) May 11.

24,471 (1920). Krupp A.-G. *See* II.

6912 (1921). Morgan Crucible Co., and Speirs. *See* XI.

XI.—ELECTRO-CHEMISTRY.

Applications.

Chem. Fabr. Griesheim-Elektron, and Suchy. 12,573. *See* VII.

Hart Accumulator Co., and Holmes. Secondary batteries. 12,703–4. May 3.

Niblett. Primary and secondary batteries. 11,911. Apr. 26.

Complete Specifications Accepted.

21,585 (1919). Kreher. Electrodes for accumulators. (132,259.) May 11.

2710 (1920). Fletcher. *See* X.

16,726 (1920). Metallbank u. Metallurg. Ges., and Lilienfeld. Electrical gas purification (145,477.) May 11.

6912 (1921). Morgan Crucible Co., and Speirs. Electrically-heated melting and other furnaces. (162,246.) May 4.

XII.—FATS; OILS; WAXES.

Application.

Hildesheimer and Lion. 12,701. *See* XIX.

Complete Specifications Accepted.

25,932 (1919). Melamid and Grotzinger. Manufacture of products soluble in or forming emulsions with water. (134,223.) May 11.

2108 (1920). Schwarzkopf. Refining oils and fats. (138,115.) May 11.

2410 (1920). Bolton. Continuous hydrogenation of unsaturated oils, fats, etc. (162,370.) May 11.

2544 (1920). Bolton and Lush. Maintaining the activity of metallic catalysts during the hydrogenation of oils, fats, etc. (162,382.) May 11.

7059 (1920). Stiansen. Refining oils and fats. (141,028.) May 4.

16,786 (1920). Stiepel. Deodorisation of soaps. (145,502.) May 4.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Application.

Attwater and Crossthwaite. Synthetic resin varnish. 12,442. Apr. 30.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Applications.

Alger and Frood. Fireproofing caoutchouc etc. 12,419. Apr. 30.

Davidson. Preparation of preservative substances for rubber latex. 12,343. Apr. 29.

Lambert. Vulcanisation of rubber. 12,132. Apr. 27.

Complete Specifications Accepted.

4288 (1920). Peachy. Vulcanisation of caoutchouc. (162,429.) May 11.

10,497 (1920). Marshall. Vulcanising processes and apparatus for making highly-expanded vulcanised rubber etc. (162,176.) May 4.

10,599 (1920). Stevens. Preservation of vulcanised rubber goods. (162,528.) May 11.

16,438 (1920). Goodyear Tire and Rubber Co. Method and apparatus for vulcanising. (145,425.) May 11.

2578 (1921). Farrel Foundry and Machine Co. Mixing or masticating rubber etc. (158,279.) May 4.

XV.—LEATHER; BONE; HORN; GLUE.

Application.

Blücher and Krause. Manufacture of plastic material from casein. 12,385. Apr. 29. (Ger., 3.5.20.)

Complete Specifications Accepted.

812 (1917). Bartels. Manufacture of casein specially adapted for producing imitation horn. (162,301.) May 11.

5439 and 5691 (1920). Melamid. Manufacture of artificial tanning substances. (148,268 and 148,738.) May 11.

XVI.—SOILS; FERTILISERS.

Application.

Boorman and Browning. Treatment of nitrates for fertilisers etc. 12,157. Apr. 27.

Complete Specifications Accepted.

31,584 (1919). Grinnel and Field. Treatment of organic matter for fertiliser purposes. (136,829.) May 4.

16,084–5 (1920). Badische Anilin- u. Soda-Fabrik. Manufacture of fertilisers. (145,036–7.) May 11.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Chamberlain. Non-poisonous disinfectant. 12,628. May 3.

Fitzgerald. Preserving fluidity of blood. 12,867. May 5.

Hildesheimer and Lion. Preparation of a fat for culinary purposes. 12,701. May 3.

Improved Chilling and Transport, Ltd., and Slann. Antiseptic, disinfectant, or preservative agents, and preserving food products. 12,997. May 6.

Jaquet. Treatment of grain. 12,535. May 2.

Plauson's (Parent Co.), Ltd. (Plauson). Dissolving dried or concentrated milk. 12,189. Apr. 28.

Slann. Preservation of food products. 11,971. Apr. 26.

Wade (Sykes). Dehydrating apparatus for foods etc. 13,076. May 7.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Barrett Co. 12,153. *See* III.

Blagden, Nierenstein, and Howards and Sons. Manufacture of amino-derivatives of hydrogenated cinchona alkaloids and their derivatives. 13,004. May 6.

Rosen. Local anæsthetic. 12,091. Apr. 27.

Complete Specifications Accepted.

17,796 (1920). Boehringer Sohn. Obtaining the active ingredient of *Lobelia inflata*. (145,622.) May 11.

18,362 (1920). Friederich. Manufacture of trinitroresorcin. (162,578.) May 11.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Applications.

Shawcross. Preparation and treatment of photographic ferric films for lithographic transfer purposes. 12,616. May 3.

Wedmark. Production of photographic negatives. 12,537. May 2.

XXII.—EXPLOSIVES; MATCHES.

Application.

Vautin. Separation of nitro-aromatic compounds from explosives etc. 12,458. Apr. 30.

Complete Specifications Accepted.

18,362 (1920). Friederich. *See* XX.

23,564 (1920). Silberrad. Explosive propellants. (150,002.) May 11.

I.—GENERAL; PLANT; MACHINERY.

Corrosion of boiler tubes by carbon dioxide; Unusual ——. B. G. Worth. Trans. Amer. Electrochem Soc., 1921, 329—335. [Advance copy.]

Severe corrosion of a water-tube boiler using natural water softened by a standard lime-soda process was found to be due to the presence of a soluble bicarbonate of iron, $H_2Fe(CO_3)_2$. The bicarbonate lecomposed into ferric hydroxide and carbon dioxide on heating the water, and after the introduction of a preheater and the removal of liberated carbon lioxide before entering the boiler, corrosion practically ceased.—C. A. K.

Rust formation. E. Sauer. Chem.-Zeit., 1921, 45, 421.

Rapid corrosion of the condensed water outlet pipes of the radiators of a large drying plant was traced to the presence of carbonic acid in the boiler feed-water. When the feed-water was treated by the ime-soda process on the Breda system, thereby relucing the total hardness to about 3 degrees, and eliminating the carbonic acid, the corrosive action of the condensed water practically ceased.—G. F. M.

Patents.

Rectifying apparatus; Condensing arrangements of ——. E. Barbet et Fils et Cie. E.P. 138,869, 6.2.20. Conv., 8.2.19.

The cooling coils of the bubbling plates of a rectifyng column as described in E.P. 13,599 of 1914 (F.P. 69,979 of 1913; J., 1915, 16) are fed with a portion of the rectified spirit from the combined condenser and cooler, and the rectified spirit thus preheated n the coils is admitted to the top of the column as he reflux fluid. This arrangement prevents formaion of scale in the cooling tubes, and may also prevent it in the condenser, for there is no objection to using so large a quantity of condensing (and refrigerating) water that it never reaches the scale-orming temperature. The reflux rectified spirit nstead of passing through the worms in the trays may, if desired, be passed through other tubes (or a plate) at the head of the column which will act as a preliminary condenser.—B. M. V.

Still-head; Spherical ——. O. Heublein and E. Weiler. G.P. 328,824, 23.7.19.

The spherical head is constituted of two spherical ackets, one inside the other, the intervening space being evacuated and the surfaces of the jackets ilvered after the manner of a Thermos flask. A ube provided with a cruciform end placed within he spherical head allows of the passage of the apours to the condenser, such vapours passing hrough the ends of the cross and through holes n the part of the tube just below the wall of the pherical head. The bottom side of the cross is nclined so that condensed liquid drains back into he distilling vessel.—J. S. G. T.

istillation in vacuo; Plant for [*continuous*] *fractional* ——. E. Lühr. G.P. 332,001, 1.1.20.

HE still can be connected in turn with any one of number of condensers, each of which may be parately connected with evacuating apparatus nd, after evacuation, shut off by a cock. The aterial to be distilled, *e.g.*, petroleum tar, is supied from a vessel provided with cocks for shutting connexion with both tho atmosphere and the stillation vessel. The residue after distillation is n off into a vessel which may be evacuated.
—J. S. G. T.

Concentrated solutions [*; Centrifugal apparatus for the*] *manufacture of* ——. B. Junquera. E.P. 144,240, 9.8.19. Conv., 30.5.19.

The basket of a centrifugal apparatus has a double wall and double bottom, the cylindrical wall of the inner basket being perforated. The solid to be extracted is placed in the inner basket, and the solvent supplied through an axial opening to the space between the double walls. The centrifugal head of the liquid in the jacket space causes it to flow inwards through the solid matter, after which it may be exhausted over the rim of the outer basket or collected by a scoop and returned to the axial inlet of the same or another apparatus. The solid material may be preheated in a furnace and the extraction apparatus contained in a casing through which the hot gases from the furnace are passed.
—B. M. V.

Centrifugal pulp-thickener. J. T. Jaeger. U.S.P. 1,374,377, 12.4.21. Appl., 14.7.19.

The rotating member is tubular and flares to a larger diameter at the discharge end, where there are a non-rotating central outlet for the liquid and a peripheral outlet for the pulp.—B. M. V.

Grinding, crushing, and dividing granular substances; Apparatus for ——. V. Antoine. E.P. 147,686, 8.7.20. Conv., 14.7.17.

In a disc grinder the driven disc or millstone is mounted on a ball and socket joint on the end of the shaft, the grinding pressure is applied by a weight and lever, and adjustable stops are provided to limit the maximum and minimum grinding space.
—B. M. V.

Mills for grinding and disintegrating materials [*; Classifying devices for conical* ——]. H. W. Hardinge. E.P. 150,997, 20.8.20. Conv., 11.9.19.

A conical mill is provided with an additional classifying device consisting of a truncated conical hood surrounding and rotating with the outlet end of the mill which is perforated to allow partly ground material to pass out. The undersize flows away from the classifying hood either over the edge or through perforations. If the mill is mounted on tyres and rollers instead of a journal bearing, the hood may be entirely supplied through the ordinary outlet end of the mill. Alternatively, a baffle may be provided inside the mill proper at about the end of the cylindrical portion, this baffle being perforated with one large central hole and thus acting as a weir, or with many smaller ones and acting as a screen. In all cases a spiral conduit is provided to lead back the oversize from the classification compartment to the main portion of the mill.
—B. M. V.

Grinding mill. A. E. Jacobson. U.S.P. 1,374,207, 12.4.21. Appl., 7.4.19.

In a grinding machine with revolving beaters the grinding surface is formed from a segmental plate with loops cut and pressed out of it, the loops remaining attached by their ends.—B. M. V.

Asbestos cloth, more especially for the dry separation of solid matter from blast furnace gases and the like. E. Danhardt. E.P. 153,558, 9.7.20. Conv., 31.10.19.

Asbestos cloth is made with the warp or the woof composed entirely or partly of threads of loosely spun asbestos; the other threads are of metallic wires or tightly spun asbestos or both. After weaving the cloth may be roughened on both sides.
—B. M. V.

Furnaces for heating crucibles employed for melting or heating metals and/or other materials. The Crosthwaite Engineering and Furnace Co., Ltd., and J. W. Crosthwaite. E.P. 161,386, 11.2.20.

The furnace is built up of a number of layers of refractory material which are each pierced with a large central round hole to accommodate the crucible and several other smaller holes (*e.g.*, one at each corner if the exterior shape is square). Each lamina has also fan-shaped recesses formed on each face so that when the laminæ are assembled with the outer or corner holes co-axial the pairs of fan-shaped recesses will form fan-shaped ports for the passage of air from the corner ducts to the central crucible chamber. The bottom of the crucible chamber is closed by a refractory hearth, and the whole rests on a hollow bed-plate through which air may be supplied to the vertical corner passages. The tops of the corner passages are closed by plugs so shaped that on rotating through part of a circle a flange will obstruct the upper fan-shaped ports.—B. M. V.

Fuller's earth; Method of preparing for transit insoluble materials such as ——. L. G. Hill. E.P. 161,419, 8.3.20.

Dusty material, such as fuller's earth, is mixed with a dilute solution of sodium silicate, and after drying the product is broken into lumps. The material can be recovered in its original finely divided state by treatment with water.—B. M. V.

Filters. W. J. Still. E.P. 161,639, 5.1.20.

A bag filter for large quantities of water carrying small quantities of solid has the framework for the bags constructed of strip metal on three sides and a cast base on the fourth, with coil springs stretched between the base and the further side. The cast base has outlet passages communicating with the interior of the springs, and several units may be clamped together to form a larger unit or block, the whole being enclosed in a pressure-tight casing to which the water is admitted under pressure. Two blocks of filters may be connected with a distributing valve which is automatically operated by rise of pressure (owing to clogging) to switch the liquid over to the other block of filters.—B. M. V.

Filtering material. E. Müller. U.S.P. 1,375,532, 19.4.21. Appl., 16.3.17.

The ashes from vegetable matter, after treatment with a soluble silicate, are washed, dried, and powdered, and a plastic mixture of the product with powdered clay and water is moulded, dried, and baked at a glowing heat.—L. A. C.

Filter; Automatic ——. A. and A. Sommer. G.P. 330,078, 30.10.18. Conv., 19.2.14.

The liquor flows upwards through a number of superimposed receivers separated by horizontal partitions. Each receiver is separated by the filter surface into an upper and lower chamber, and the inlet and outlet are situated respectively below and above the filter surface.—L. A. C.

Drying machine. T. Allsop and W. W. Sibson, Assrs. to The Philadelphia Drying Machinery Co. U.S.P. 1,374,709, 12.4.21. Appl., 18.12.19.

The drying chamber contains a conveyor, *e.g.*, a zig-zag continuous chain with carriers for the goods, and a fan, which are driven from the same source of power but can be started and stopped independently; the direction of rotation of the fan may also be reversed.—B. M. V.

Drying materials; Process and apparatus for ——. E. M. Bassler. U.S.P. 1,374,874, 12.4.21. Appl., 24.3.16. Renewed 16.6.19.

The material to be dried is carried forward on a suitable conveyor in a closed trunk, and meets a current of warmed air which is made to pass through the conveyor at intervals by baffle-plates.—B. V. S.

Drying liquids; Atomising process for ——. Chem. Verwertungsges. m.b.H. G.P. 332,000, 10.2.20.

The liquid is delivered by a pipe to a trough, whence it overflows on to a plate, on the upper side of which it is subjected to a preliminary dispersion by a jet of fluid under pressure directed downwards upon the plate, prior to being atomised into the drying chamber by a similar jet directed upwards from beneath the plate.—J. S. G. T.

Evaporator. J. T. Wann, Assr. to R. C. Newell and W. C. Murdoch, jun. U.S.P. 1,375,431, 19.4.21. Appl., 4.5.20.

An evaporator contains separate storing, heating, and exit chambers, and a drying chamber subdivided into a number of compartments in pairs for receiving the material on trays. Inlet flues on the one side of each of the compartments, and outlet flues on the other side, communicate with the heating and exit chambers respectively, and means are provided for deflecting the heat below each pair of compartments.—L. A. C.

Evaporation or concentration of solutions, emulsions, and suspensions, and for carrying out chemical reactions; Process and apparatus fo
——. G. A. Krause. G.P. 329,658, 2.5.16.

The liquid is delivered centrally to an atomisin
device consisting of a number of tubular arm
attached to a chamber rotating with high velocit
the arms being provided with small openings fo
efflux of the liquid. The atomiser is containe
within a chamber through which a current of ai
is induced, whereby the efficiency of its action i
increased.—J. S. G. T.

Mixing liquids with gases or liquids, or gases wi
gases; Process and apparatus for ——. A. Wach
G.P. 323,655, 3.8.19.

The respective fluids are forced under pressure fro
hollow members through fine jets tangentially in
a mixing chamber, the respective discharges bein
in parallel planes one above the other and in count
directions. The fluid discharged through the low
system of jets ascends spirally in the mixi
chamber and meets the oppositely directed strea
of the other fluid, discharged from the upper syste
of jets, at the narrowest section of the mixi
chamber, which tapers gradually.—J. S. G. T.

Filling material having the form of a truncat
cone for reaction columns etc.; Annular —
Stellawerk A.-G. G.P. 324,442, 14.11.17.

The filling material is built up of rings in su
manner that the inner and outer surfaces of t
resulting structure have the form of truncated co
tapering in opposite directions. This form
packing takes up only about 35% of the space of t
reaction chamber, compared with 40—60% tak
up by other kinds of filling material.—J. S. G. T

Saturated solutions; Apparatus for producing —
W. Otte. G.P. 328,218, 8.11.19.

The substance to be dissolved is supported in a se
of superposed rings of inverted frusto-conical sh
with their axes vertical, the diameter of success
rings increasing in the downward direction.
floor of the lowest ring upon which the substa
rests is perforated for the passage of solvent.
device rests upon a down pipe, and is contai
within a vessel holding the solvent, the top c
being above the level of the liquid.—J. S. G. T

Heating or cooling device with scrapers. F. Fiedler, Dampfkesselfabrik, Maschinen- u. Apparate-Bauanstalt, O. Kittel, and F. Hornung. G.P. 328,761, 26.4.19.

A series of cylindrical or hemi-cylindrical heating or cooling chambers is disposed with their axes parallel and adjacent to one another, and scrapers are arranged so as to remove any matter deposited upon the cylindrical surfaces, each scraper being effective over a half cylinder. A conveyor or similar device traversing the length of the apparatus and disposed above a channel serves for the removal and collection of material removed by the scrapers.
—J. S. G. T.

Steam boilers; Method of maintaining low pressure —— free from mud and scale. Maschinenbau-A.-G. Balcke. G.P. 331,279, 27.6.18.

Sufficient hydrochloric acid is added to the feed water to convert carbonates into soluble chlorides; these salts are not decomposed at the comparatively low temperature, so that the water can be evaporated to 15% concentration without formation of scale or damage to the shell from free acid.—C. I.

Gases; Method of separating and recovering —— and apparatus therefor. W. A. Patrick, B. F. Lovelace, and E. B. Miller. E.P. 137,284, 24.12.19. Conv., 28.12.18.

See U.S.P. 1,335,348 of 1920; J., 1920, 392 a.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Tar fog, dust, and water in producer gas; Determination of ——. E. Jenkner. Stahl u. Eisen, 1921, 41, 181—183.

It is essential to cool hot gas before filtering to separate suspended matter, otherwise a fractionation of any deposited tar may occur. The gas is drawn at the rate of 60 l. per hr. through a glass tube 30 cm. long, one portion of which 10 cm. long and 2 cm diam., with a nozzle of 6 mm. diam., is water-cooled, and projects into the gas main. The after portion of the tube, 20 cm. long and 4 cm. diam., is packed with Raschig rings of glass, 5 mm. diam. These retain all the dust and practically all the tar. The residue is retained by a weighed glass tube packed with cotton wool. This is followed by two weighed U-tubes containing calcium chloride to retain water. To separate the tar and dust in the first tube, the tar is extracted with warm benzene, and the weight of dust retained by the Raschig rings is obtained. The benzene solution is filtered through a tared filter to obtain the weight of dust lost in the washing. The weight of tar can then be deduced.—H. J. H.

Petroleum residues; Method of determining the density of ——. C. Predescu. Bul. Sci. Acad. Roumaine, 1920, 6, 148—150.

A sp. gr. bottle is weighed empty (p_1), a small piece of the petroleum residue is then pressed on the interior wall of the bottle and the latter again weighed (p_3); the bottle is then filled with water at 15° C. and again weighed (p_4). If p_2 is the weight of the bottle filled with water alone, then the sp. gr. (x) of the petroleum residue is given by the formula $x=(p_3-p_1)/\{p_2+p_3-(p_1+p_4)\}$.—W. P. S.

Petroleum; Refractive index of Roumanian ——. C. Predescu. Bul. Sci. Acad. Roumaine, 1920, 6, 150—156.

The refractive index of Roumanian petroleum increases with the boiling point of the fractions, the increase being greater than is the case with the specific gravity. The fraction, b.p. 50°—60° C., has $n^{15}_{D}=1{\cdot}384$ and sp. gr. 0·6830, whilst the fraction, b.p. 340°—350° C., has $n^{15}_{D}=1{\cdot}526$ and sp. gr. 0·9051.—W. P. S.

Petroleum; Optical rotation of Roumanian ——. C. Predescu. Bul. Sci. Acad. Roumaine, 1920, 6, 181—188.

Certain Roumanian petroleums, particularly the higher boiling fractions of these oils, contain optically active substances. As the colour of the fractions interferes with observation in the polariscope, even when the material is diluted with a solvent, the petroleum was filtered through fuller's earth under pressure before examination. Two oils examined in this way had $[\alpha]^{20}_{D}=+1{\cdot}19$ and $+1{\cdot}52$ respectively.—W. P. S.

Petroleum; Capillary constants of Roumanian ——. C. Predescu. Bul. Sci. Acad. Roumaine, 1920, 6, 188—196.

The capillary constant α, or the surface tension, is found from the formula $\alpha=d\times r(h+\frac{1}{3}r)/2$, where r is the radius of the capillary, d the sp. gr. of the petroleum, and h the height of the capillary column of oil. The value increases with the b.p. of the petroleum fraction; for the fraction, b.p. 50°—60° C., $\alpha=1{\cdot}92$, and for the fraction, b.p. 340°—350° C., $\alpha=3{\cdot}18$. The viscosity of the fractions increases more rapidly than does the capillary constant.
—W. P. S.

Light petroleum (pentane, hexane, heptane, octane); Narcotic action of ——. H. Fühner. Biochem. Zeits., 1921, 115, 235—261.

In contradistinction to ether and to chloroform, the hydrocarbons mentioned when inhaled (by mice and rats) often cause great excitement, and soon affect the respiration adversely; benzene is an even more powerful excitant. In molecular quantities benzene is a somewhat less powerful anæsthetic than chloroform; ether has only one-quarter of its activity. Hexane and ether, heptane and benzene, octane and chloroform have about the same degree of activity. The activity in the homologous series, pentane, hexane, heptane, octane, increases approximately in the ratio $1:3:3^2$...... . The solubility in water diminishes in the same ratio.—G. B.

Blast-furnace gas. Fowles. *See* X.

Patents.

Coking retort-oven. J. Becker, Assr. to The Koppers Co. U.S.P. 1,374,546, 12.4.21. Appl., 8.11.20.

The coking chambers have contiguous heating walls with vertical combustion flues. Tapered horizontal flues in each heating wall connect a number of the combustion flues of their respective heating walls, the horizontal flues also communicating with the corresponding horizontal flues of an adjacent heating wall. Reversible regenerators, which can be regulated individually, extend crosswise parallel with the coking chamber and the heating walls, and are connected in pairs with combustion flues of a single heating wall. Means are provided for controlling the individual flow through individual regenerators and their connected groups of combustion flues.—A. G.

Constituents of the distillation gas from fuel [e.g., ethylene]; Process for the separate recovery of ——. F. Bergius and P. Kalnin. E.P. 146,332, 2.7.20. Conv., 26.10.17.

The gas is freed from tar, ammonia, and benzene, and is then passed over adsorbent charcoal at 0° to −20° C. The adsorbed gas is then expelled and again subjected to the same treatment. By repeated adsorption the ethylene content can be greatly increased, *e.g.*, from 1—2% successively to 17, 36, and 59%.—A. G.

Purifying coal gas; Method of —— by means of ammonia. C. Still. E.P. 147,583, 8.7.20. Conv., 10.12.17.

The scrubber first traversed by the cooled crude gas is sprayed with the highly concentrated final product of the ammonia-recovery plant, and the subsequent scrubber is sprayed with the weaker ammonia solution from the reflux condenser of this plant. The gas flows in series through further scrubbers which are traversed in counter current, first by condensed liquor from the crude gas which contains little ammonia, and then by fresh water for the purpose of completely or partially washing out the ammonia. The residue of ammonia remaining in the gas after passing the ammonia scrubbers is recovered, together with the ammoniacal vapours arising from the ammonia recovery plant, and containing hydrogen sulphide and carbon dioxide, in a saturating plant in the form of ammonium sulphate, for which the necessary sulphuric acid is produced from the hydrogen sulphide remaining in the exhaust gases from the saturator. When the whole of the ammonia is removed in the scrubbing plant the gas that leaves the recovery plant is washed with the ammoniacal liquor condensed in the preliminary cooling of the original crude gas, so as to return the ammonia carried by the first-named gas to the ammonia-recovery plant. —A. G.

Soot-carbon, retort-graphite and other carbon products; Process for the production of —— from natural gas. Rütgerswerke A.-G. E.P. 137,065, 24.12.19. Conv., 12.6.18.

Natural gas is decomposed to the extent of 65% only in a retort, and the exit gases are used for firing the retort. The degree of decomposition is regulated by varying the speed of the gas, which may be preheated by the exhaust from the combustion chamber.—C. I.

Petroleum jelly; Process for making a substitute for ——. Rütgerswerke-A.-G. E.P. 134,528, 1.10.19. Conv., 26.10.18.

Powdered pitch of m.p. about 50°—60° C., containing 50% or more of aliphatic hydrocarbons, produced, *e.g.*, by distilling low-temperature coal-tar, or lignite tar, at about 300° C., under reduced pressure, is treated below its softening point with petroleum ether and/or benzene, and/or other solvents, in sufficient quantity to yield a homogeneous, viscous mixture. The solvent is expelled after separation of the insoluble matter, yielding a product which, after purification and decolorisation by the usual means, can be employed as a substitute for petroleum jelly.—L. A. C.

Petroleum and analogous distillates; Process of cleaning and refining ——. A. J. Paris, jun. E.P. 161,253, 2.1.20.

The distillates are compressed in the form of spray, vapour, or mist, in the presence of a permanent gas free from oxygen and a neutral purifying liquid, such as glycerin, Turkey-red oil, mineral lubricating oil, or castor oil, under such conditions of temperature and pressure (which may range from 25 to 350 lb. per sq. in.) that cracking of the distillates is avoided. A mixture of the gas with oil vapour, prepared by treating the distillates or crude oil with the gas at a suitable temperature, may be fed into the compression chamber, or the gas and oil may be fed in independently. After the treatment the gas and purifying liquid are separated from the oil vapour, which is subsequently condensed, and are returned to the apparatus for treating more oil. —L. A. C.

Crude oil; Process of recovering ——. I. S. Joseph. U.S.P. 1,362,105, 14.12.20. Appl., 29.4.19.

To recover crude oil from emulsions, such as "cut oil," "bottom settlings," etc., the emulsion is subjected to centrifugal action so as to cause the constituents of different specific gravity to move along different paths, and a liquid of approximately the same specific gravity as the heavier constituent is introduced into the separator and caused to move along the path of the heavier constituent with a velocity greater than that of the latter, so as to carry along solid impurities which would otherwise be deposited.

[Air condenser for use in] apparatus for treating hydrocarbons. J. W. Coast, jun., Assr. to The Process Co. U.S.P. 1,374,357, 12.4.21. Appl., 31.5.17.

A horizontal cylindrical vessel, fitted internally with horizontal tubes open at both ends, is separated into a number of chambers by baffles open alternately at the top and bottom to provide a sinuous path for the hydrocarbon vapours or the like which are led into the bottom of the vessel at a point near one end. A current of air, induced by connecting all the tubes, at the end near the inle for hydrocarbon vapours, with a common flue passes through the tubes and cools the vapours t progressively lower temperatures as they pas through the vessel, causing condensation o different fractions in the separate chambers, whenc they are withdrawn.—L. A. C.

etroleum-oils; Apparatus for distilling ——. A. D. Smith. U.S.P. 1,374,402, 12.4.21. Appl., 13.3.17.

still consists of a vessel with a sloping bottom nd a number of sloping tubes below the vessel conected at their ends with the bottom of the vessel, hich is also connected with a well. The circulation f oil induced by heating the tubes and the vessel iminishes the deposition of carbon in the pparatus.—L. A. C.

ydrocarbon oils; Process of converting higher-boiling-point —— into lower-boiling-point hydrocarbon oils. W. M. McComb. U.S.P. 1,374,858, 12.4.21. Appl., 3.7.20.

A. C.

ydrocarbons; Process of distilling ——. W. C. Averill, jun. U.S.P. 1,375,245, 19.4.21. Appl., 12.7.19.

distilling crude petroleum oil containing aterial quantities of asphalt-forming material and aving a high sulphur content, *e.g.*, Gulf Coast rude petroleum, to produce pale lubricating oil and istillates, including gasoline, a portion of the proucts of combustion employed for heating the still ottom is withdrawn from the flue, cooled, and assed through the oil in the still. The hydrocarbon apours are subsequently condensed from the mixure of gas and vapour issuing from the still. —L. A. C.

Mineral] oil; Apparatus for refining ——. S. F. Stephens, Assr. to W. J. Boyle, sen., and C. G. Grant. U.S.P. 1,375,427, 19.4.21. Appl., 14.11.18. Renewed 24.1.21.

he oil is fed on to a rotating, horizontal plate ithin a still and flows as a thin film towards the eriphery of the plate, whence it is discharged as fine spray on to the walls of the still.—L. A. C.

ineral oil hydrocarbons; Conversion of —— into low- and high-boiling products. Deutsche Erdöl A.-G., F. Seidenschnur, and C. Koettnitz. G.P. 302,585, 29.1.16.

he oil is treated by one of the known cracking ocesses, and the benzine produced is removed from e products, which are then distilled to obtain a oduct having a boiling point and specific gravity ar to that of the original oil. This is then put rough the cracking process again, either alone mixed with a proportion of the original oil. The ocess gives a larger yield of benzine which is e from the usual objectionable odour of benzine tained by a cracking process, while the residue om the distillation is a more valuable lubricant an the usual tarry residue that is obtained, and smaller quantity of gas is produced. The total s in the process is about 8%.—A. R. P.

bricating-oil. R. H. Brownlee. U.S.P. 1,374,277, 2.4.21. Appl., 23.11.18.

e oil produced as described in U.S.P. 1,309,432 , 1919, 621 a) has a flash point of 425°—450° F. 8°—232° C.), and a cold test of approximately ° F. (−20° C.) for a cut having a viscosity of 76 212° F. (100° C.).—L. A. C.

cous [lubricating] oils; Manufacture of ——. etralin G.m.b.H. G.P. 333,060, 28.7.18. Addn. o 319,799 (J., 1920, 623 a).

rmaldehyde, polymerisation products of formehyde, or substances capable of yielding formaldehyde, are allowed to react with hydronaphthalenes, with or without addition of condensing agents, but in absence of acids. By heating tetrahydronaphthalene with paraformaldehyde and phosphorus pentoxide a highly viscous oil (probably ditetrahydronaphthylmethane), b.p. 257°—258° C. at 15 mm., is formed, and also a brittle, light-coloured resin. If acids are used as condensing agents more resin is formed and the yield of oil is reduced. The viscous products may be used as lubricants, especially for refrigerating machines and aircraft engines. As the oils are easily sulphonated their sulphonic acid salts can be made use of for the manufacture of drilling oils and the like.—C. A. C.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Charcoal; Production of artificially dense —— [for gas-masks]. L. F. Hawley. J. Ind. Eng. Chem., 1921, **13**, 301—302.

As a substitute for coconut shell for the manufacture of charcoal for gas-masks, the residue, obtained by hydrolysing sawdust with dilute acid and then leaching out the sugar, has proved to be more satisfactory as regards yield, density, and activity of the charcoal than any untreated wood. For small-scale experiments, 2-in. briquettes compressed at 35,000 lb. per sq. in. from 20-mesh sawdust, to a density of 1·21, were distilled in a 2·5-in. pipe, enclosed in a 4-in. pipe, pressure being maintained during the operation by means of a screw and falling weight. At about 300 lb. per sq. in. and a maximum temperature of 450° C., a 40% yield was obtained, the charcoal having an apparent density of 0·62 and a chloropicrin absorption value of 700 mins., as compared with 0·63 and 900, respectively, for coconut shell charcoal. The product was hard and shiny, resembled anthracite coal, and had a conchoidal fracture. On a semi-commercial scale with a retort 10 ft. in length, the best results were obtained by slowly distilling 4-in. briquettes, made from 4- to 43-mesh dust, under pressures varying from 80 to 130 lb. per sq. in.; the product had an apparent density of 0·58 and a chloropicrin absorption value of 600. The less satisfactory results obtained on the large scale may be due to the vapours not escaping readily from the larger briquettes and to the coarser raw material used.—W. J. W.

Patents.

Retorts for the distillation of carbonaceous substances. Low Temperature Carbonisation, Ltd., M. Davidson, and H. L. Armstrong. E.P. 161,608, 14.10.19.

Coal or other carbonaceous substance is distilled at low temperature in relatively thin layers under such conditions that the gas and vapour evolved throughout the charge in the retort are rapidly drawn away from the hot retort walls, to which the heat is applied, into a central space or chamber, whence they are immediately withdrawn. This central space is capable of contraction to accommodate the expansion of the charge during distillation. In the case of vertical retorts, a collapsible casing or equivalent is used, and means are provided for permitting the inward movement of the plates constituting the collapsible casing. Steam may be admitted to the retort.—A. G.

Wood distillation. E. M. Sawtelle, Assr. to J. P. Carter and R. L. Squibb. U.S.P. 1,374,887, 12.4.21. Appl., 10.9.18.

Subdivided wood is fed continuously into a producer, air being blown in at the bottom, but no steam being injected. The products of distillation are led off into a condensation system from which the pyroligneous liquids are removed.—A. G.

Impregnated wood; Recovery of the preserving material from ——. H. Wiedemann. G.P. 334,307, 16.11.19.

Impregnated wood is subjected to fractional distillation whereby, in addition to the usual products of wood distillation, the substances, such as anthracene or creosote oils, or copper sulphate, which were used to preserve the wood, are also recovered. The distillation may be carried out in the usual way or, after addition of water, under increased pressure.—A. R. P.

Liquids of high organic content; Process of destructively decomposing —— *and product of such process.* A. H. White. U.S.P. 1,374,889, 12.4.21. Appl., 24.7.19.

An aqueous liquid, containing a large amount of organic matter and capable of yielding valuable carbon compounds upon destructive distillation, is intimately mixed, in a concentrated condition, with sufficient quicklime to heat the mass autogenously to a temperature at which destructive distillation occurs, and the volatile compounds are distilled off, at least the major portion of the heat required being supplied by the heat of the reaction. The residue is calcined to produce a fresh charge of lime. —A. G.

Electrodes for electric searchlights. Optische Anstalt C. P. Goerz A.-G. E.P. 148,450, 10.7.20. Conv., 24.9.18.

The formation of soot on electrodes used in searchlights which are operated on current overload is reduced by the addition of oxides or silicates, such as cerium oxide, silica, etc., to the electrodes. Alternatively, the electrodes may be surrounded with a casing of silicates.—J. S. G. T.

III.—TAR AND TAR PRODUCTS.

Phenoxides; Decomposition of —— *by heat.* F. Fischer and U. Ehrhardt. Ges. Abhandl. Kennt. Kohle, 1919, 4, 237—263. Chem. Zentr., 1921, 92, I., 762—763.

Investigation of the products obtained by the dry distillation of a number of normal and basic metal phenoxides and cresyl-oxides showed that sodium and potassium phenoxides yield solely gaseous products, chiefly hydrogen and a little methane, whereas the compounds with other metals yield varying proportions of liquid products in addition to the above and other gases.—L. A. C.

Naphthalene; Exhaustive sulphonation of ——. H. E. Fierz and F. Schmid. Helv. Chim. Acta, 1921, 4, 381—387.

According to the results of Armstrong and Wynne (1885—1895), who showed that sulpho-groups never enter the naphthalene nucleus in the ortho-, para, or peri-position to one another, exhaustive sulphonation of naphthalene can lead to only two products, namely, the 1.3.6-trisulphonic and 1.3.5.7-tetrasulphonic acids. The authors are, indeed, unable to confirm the statement (G.P. 79,054) that these two acids are accompanied by Senhofer's naphthalenetetrasulphonic acid (Monatsh., 1882, 3, 112) when naphthalene is heated at 260° with concentrated sulphuric acid and phosphorus pentoxide. The apparent losses attending the manufacture of H-acid are dependent on the formation of the tetrasulphonic acid and on oxidative destruction of naphthalene. Together with the tetrasulphonic acid, the 2.7- and the 1.6-disulphonic acids are often formed in small proportions, these acids evidently undergoing further sulphonation to the 1.3.6-trisulphonic acid only with difficulty. 1-Nitronaphthalene-3.6.8-trisulphonic acid is described. Tar-oils, especially from lignite; Process for refining —— *with aqueous alkalis.* Deutsche Erdöl A.-G. G.P. 333,061, 24.10.18.

The oil is intimately mixed with the alkali solution by passing a current of steam through the two liquids. The mixture is then distilled with steam at temperatures up to 300° C. and eventually under reduced pressure. No separation of tarry and asphalt-like components takes place, and the distillate obtained is very pure and practically odourless.—A. R. P.

Pyridine bases; Manufacture of ——. Farbw. vorm. Meister, Lucius, und Brüning. E.P. 147,101, 7.7.20. Conv., 23.12.18. Addn. to 146,869 (J., 1921, 5 A).

Formaldehyde or acetone is substituted for a part of the paraldehyde. Thus, when 15 pts. of formaldehyde (30%) is heated with 8·7 pts. of ammonia (25%) and 13·2 pts. of paraldehyde a mixture of bases is obtained consisting of about 50% of aldehyde-collidine and 50% of methylpyridines, chiefly α-picoline. Ammonia, paraldehyde, and acetone give a product consisting almost entirely of trimethylpyridine. —G. F. M.

1.4-Naphthylenediamine and its sulphonic acids; Manufacture of arylsulphonyl and arylenedisulphonyl derivatives of ——. G. T. Morgan, and The Imperial Trust for the Encouragement of Scientific and Industrial Research. E.P. 160,853, 6.8.19.

Arylsulphonyl - 1.4 - naphthylenediamines, and arylenedisulphonyl - *bis* - 1.4 - naphthylenediamines, and the sulphonic acids of these compounds can be prepared by the reduction in a not too strongly acid or alkaline reducing medium of the *p*-azo derivatives of the corresponding arylsulphonyl- or arylenedisulphonyl-naphthylamines or their sulphonic acids containing the sulphonic group in the 2, 6, 7, or 8 positions. The reduction can be carried out with such reagents as zinc dust and sodium hydroxido, zinc dust and ammonium chloride, iron borings and dilute acids, alkaline sodium hydrosulphite, stannous or titanous chloride, etc., provided the medium is not sufficiently acid or alkaline to effect hydrolysis of the arylsulphonyl groups. Thus, for example, toluene-*p*-sulphonyl-1.4-naphthylenediamine is obtained by condensing α-naphthylamine with *p*-toluenesulphonic chloride in presence of sodium acetate, dissolving the product in sodium hydroxide, and treating with benzenediazonium chloride, whereby sodium benzene-4-azotoluene-*p*-sulphonyl-α-naphthylamine separates; this is converted into the free azo compound, and the latter reduced with zinc and ammonium chloride in aqueous alcoholic solution. (*Cf.* J.C.S., June.)
—G. F. M.

Fluorene; Catalytic oxidation of ——. *Process of producing maleic acid. Process of producing anthraquinone. Catalytic oxidation of naphthalene.* (A) J. M. Weiss and C. R. Downs, (B, C, and D) C. R. Downs, Assrs. to The Barrett Co. U.S.P. 1,374,695, and 1,374,720–2, 12.4.21. Appl., (A) 21.11.19, (B and C) 3.7.20, and (D) 10.7.20.

A) **Fluorene** is oxidised to fluorenone by treatment at 300°—700° C. with a gas containing oxygen in the presence of a metallic oxide as catalyst. The use of mercury out of contact with the reaction mixture but in heat-transferring relationship thereto is claimed in the manufacture of (B) maleic acid and (C) anthraquinone by the partial oxidation of benzene and anthracene respectively by a gas containing oxygen in the presence of a catalyst. (D) Naphthalene vapour is partially oxidised by treatment with a gas containing oxygen in the presence of aluminium oxide as catalyst.—L. A. C.

β-Nitronaphthalene; Manufacture of ——. Tetralin G.m.b.H. G.P. 332,593, 7.10.19.

A **mixture** of mononitrotetrahydronaphthalenes btained according to G.P. 299,014 (J., 1920, 174 A) s subjected to fractional distillation; β-nitrotetraydronaphthalene is separated from the first fractions by freezing and is dibrominated and the prouct distilled. By a vacuum distillation of the hick, oily, brominated product hydrobromic acid is plit off at about 150° C. and β-nitronaphthalene, m.p. 76° C., distils over at 190°—200° C. at 0 mm. β-Nitronaphthalene cannot be obtained by irect nitration of naphthalene.—C. A. C.

4-Chloronitroanthraquinones; Manufacture of ——. F. Ullmann. G.P. 332,853, 17.8.16.

4-**Dinitro-1-hydroxyanthraquinone** is treated ith arylsulphochlorides in presence of substances apable of combining with acid. If the reaction is lowed to take place in presence of potash the ydroxyl group is replaced by chlorine and 1-chloro-4-dinitroanthraquinone is formed. If diethylniline is used a good yield of 1.2-dichloro-4-nitronthraquinone is obtained. 2.4-Dinitro-1-hydroxyanthraquinone, prepared from 1-hydroxyanthraquinone and nitric acid (sp. gr. 1·52) in sulphuric acid solution, forms yellow needles (from glacial acetic acid), m.p. 248° C.; it is slightly soluble in hot alcohol and hot glacial acetic acid, easily soluble in nitrobenzene. 1-Chloro-2.4-dinitroanthraquinone crystallises from glacial acetic acid in slightly yellow needles, m.p. 240° C., slightly soluble in hot alcohol, soluble in benzene, easily soluble in nitrobenzene; by heating with β-naphthylamine in amyl alcohol solution the purple compound 2.4-dinitro-1-β-naphthylaminoanthraquinone is obtained. 2.4-Dinitro-1-hydroxyanthraquinone heated with *p*-toluenesulphochloride and diethylaniline gives 1.2-dichloro-4-nitroanthraquinone, yellow needles from benzene, m.p. 246° C., slightly soluble in alcohol, soluble in benzene, easily soluble in nitrobenzene.—C. A. C.

Liquors containing phenoloid bodies; Purification of ——. The Koppers Co., Assees. of C. A. Basore. E.P. 139,168, 14.2.20. Conv., 15.2.19.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Wool; Harmful action of acids on ——. M. Becke. Textilber., 1921, 2, 194—195.

When treated with acids wool acquires an acidic character so that its resistance to treatment with alkalis is diminished. When samples of wool were steeped for 2 hrs. in solutions containing respectively hydrochloric, sulphuric, oxalic, formic, and acetic acids, 0·9, 0·4, 0·4, 0·225, and 0·1% of the wool dissolved. The same samples were washed, dried overnight, neutralised with a very dilute solution of sodium bicarbonate, and boiled for 2 hrs. in a 4% (on weight of wool) solution of Marseilles soap, whereby a further 1·8, 2·0, 1·35, 1·15, and 1·0% of the wool dissolved. When different samples of wool were immersed for 2 hrs. in solutions containing 0, 2, 4, 6, 8, and 10% respectively of sulphuric acid, whereby 0·35, 0·20, 0·45, 0·75, 1·10, and 1·50% of the wool dissolved, and were then washed, neutralised in a dilute solution of sodium bicarbonate, and heated for 2 hrs. at 95°—100° C. in a solution containing 2·5% of sodium carbonate, a further 1·2, 1·8, 3·0, 4·4, 5·2, and 7·6% of the wool dissolved. When samples of wool, after immersion in solutions containing 4% of sulphuric acid and 0, 10, 25, 50, 100, and 200% of Glauber's salt, whereby 0·45, 0·375, 0·35, 0·30, 0·275, and 0·20% of the wool dissolved, were treated with a 4% solution of soap at 95°—100° C., a further 2·0—1·9% of the wool dissolved. Under the same conditions, except that acetic acid (5% instead of 4%) and sodium acetate were used in place of sulphuric acid and Glauber salt, 0·10, 0·125, 0·20, 0·24, 0·25, and 0·25% of the wool dissolved, and in the subsequent soaping the amount of wool which dissolved was 1·20—1·30%.—A. J. H.

Retting; Investigations of the process of ——. E. Kayser and H. Delaval. Bull. Soc. d'Encour., 1920, **132**, 277—296.

THE conditions affecting the retting of fibrous materials such as flax, hemp, ramie, jute, and nettles by means of six different kinds of micro-organisms isolated from macerations of flax, hemp, jute, etc., have been investigated; all of the micro-organisms were aërobic except one, which was a facultative anaërobe. Sterilisation of the materials before retting was effected by means of alkali hypochlorite solution or preferably with carbon bisulphide vapour. The optimum temperature for four of the organisms used was 25°—30° C., and for the others 32°—35° C. Manganese salts hindered retting, and aeration of the retting liquors was beneficial in one instance and detrimental in another. In one experiment the gas liberated in the early stages of retting contained 65% of carbon dioxide and 35% of nitrogen, and in the later stages it contained 75% and 25% respectively, while the retting liquor contained alcohol and a much smaller amount of acetic acid. By the selection of suitable bacilli and conditions the retting process may be scientifically controlled so as to give uniform results.—A. J. H.

Reeds (Phragmites communis, Trin.); Composition of ——. F. Herig. Cellulosechem., 1921, **2**, 25—34. (*Cf.* Heuser, J., 1920, 744 A.)

IN an investigation of the composition of reeds (*Phragmites communis*), the cellulose content was determined by the chlorination method of Cross and Bevan (an improved form of apparatus is described), the pentosans by Tollens' furfural method, moisture by drying at 105° C., ash by carbonisation with ammonium nitrate, and the lignin content by difference. In different samples of air-dried reeds the stems (57·09—60·92% of the total), sheaths (16·35—16·38%), and leaves (26·56—22·70%) contained respectively: cellulose, 38·64—40·98, 24·96—31·06, and 21·45—21·35%; pentosan, 17·27—19·66, 15·75—17·59, and 15·21—10·52%; lignin, 32·42—30·36, 37·42—35·35, and 42·01—50·79%; ash, 2·20—2·00, 14·00—8·00, and 11·33—10·67%; moisture, 9·47—7·00, 7·87—8·00, and 10·00—6·67%.—A. J. H.

Swelling [of cellulose acetate]; Nature of the process of ——. E. Knoevenagel and O. Eberstadt. Kolloid-Chem. Beih., 1921, **13**, 194—212.

CELLULOSE acetate does not swell in pure water or in absolute alcohol, but it will swell readily in aqueous mixtures of alcohol, acetone, and acetic acid. In each case there is a definite mixture where the swelling is at a maximum. Unswollen cellulose acetate is only slowly dyed at 25° C. by a 0·05% aqueous solution of Methylene Blue, and the maximum coloration is reached only after several months. Under identical conditions swollen cellulose acetate is dyed to the maximum tint in a few minutes. Unswollen cellulose acetate is hydrolysed by aqueous alkali hydroxide solutions with the greatest difficulty, but the swollen material is completely hydrolysed in 30 mins. by a $N/2$ solution of potassium hydroxide at 25° C. (*Cf.* J.C.S., June.)
—J. F. S.

Sulphite liquors; Titration of ——. R. Sieber. Paper, Apr. 6, 1921, 24—27.

RESULTS are given of a comparative investigation of methods for analysing sulphite liquors, and the high values (5—15%) obtained for the free acid when determined by titration with standard alkalis are shown to be due to carbon dioxide. For works practice the total acid is most suitably determined by means of the iodometric method. Sander's new method (J., 1921, 256 A) which depends on the reaction between bisulphite compounds and an excess of mercuric chloride, whereby hydrochloric acid is liberated, gives correct results only when carefully carried out and is therefore more suitable for laboratory control and for exhaustive investigations. The free acid is most conveniently determined by Sander's older method or by Höhn's method. This latter gives more accurate results (maximum error 1—2%) if methyl orange or *p*-nitrophenol be used as an indicator, instead of phenolphthalein.—A. J. H.

Sulphite-pulp; Determination of the degree of digestion of ——. R. Sieber. Paper, Apr. 6, 1921, 17—22.

THE degree of digestion of sulphite pulp may be estimated by means of a solution of bleaching powder. 21 g. of moist pulp (5 g. of dry pulp) is placed in a brown glass bottle (light appreciably affects the reaction) with 150 c.c. of distilled water and is allowed to stand for ½ hr. in the case of a dry pulp. 100 c.c of a solution of bleaching powder containing 6% (on weight of pulp) of active chlorine is added, and after 1 hr. the mixture is filtered through a bronze sieve and the remaining chlorine is determined in 50 c.c. of the filtrate. The amount of chlorine absorbed by the pulp ("chlorine number") is proportional to its lignin content and is related to the quality of the pulp as judged by its physical properties. The results obtained by this method with hard and soft pulps are similar to those obtained by the methods of Klason (J., 1911, 79), Richter (J., 1912, 869), and Becker (J., 1920, 482 A). The chlorine numbers of 25 pulps varied from 2·7 to 8·5, but were found to be somewhat too high in the case of very completely digested pulps. The chlorine number is influenced by the poor washing of a pulp, but this may be avoided by washing the pulp with 150 c.c. of warm water for ½ hr.—A. J. H.

Paper pulp; Dyeing of ——. J. Huebner. J. Soc. Dyers and Col., 1921, **37**, 139—145.

IN the manufacture of paper pulp the degree of disintegration of the fibres produced by beating greatly influences the affinity of the pulp for dyestuffs. When samples of pulp produced from purified cotton yarn were immersed under comparable conditions in a solution of Night Blue the amount of dyestuff absorbed was inversely proportional to the average length of the fibres, and while unbeaten cotton yarn showed a constantly increasing absorption during 72 hrs., the absorption by the most highly disinegrated pulp was almost complete during the first our. The highly disintegrated pulp absorbed twice s much dyestuff as the unbeaten yarn, but had no reater depth of shade. In the case of pulp made om wool, increased disintegration augmented e rate of absorption but did not influence the mount of dyestuff absorbed. When immersed in a lution of Night Blue, jute, bleached poplar cellu- se, and unbleached sulphite-cellulose absorbed the ye more quickly than bleached esparto cellulose nd cotton half-stuff. Purification of sulphite- ellulose reduced its affinity for the dyestuff. The izing of paper greatly increases its affinity for dye- tuffs, and when resin size was added to a dye-bath ontaining Metanil Yellow or Scarlet R and alum, e pulp immersed therein rapidly absorbed 80— 0% of the dyestuff. For the production of cheaper nd faster shades, such mineral colours as Iron uff, Chrome Yellow, Manganese Bronze, and russian Blue should be precipitated within the ulp. Acid dyestuffs have small affinity for paper nless it is heavily sized. Fast shades are obtained y precipitating an acid dyestuff by means of a basic yestuff within paper pulp, and useful combinations re Auramine and Naphthol Yellow S; Chrysoidine, agenta, or Brilliant Green and Orange II.; Vic- oria Blue and Water Blue or Methylene Blue, hodamine and Eosin, etc. Direct dyes are espe- ially suitable for the production of mottled paper, nd the shades obtained are fast.—A. J. H.

traw pulp for the manufacture of cardboard; Colouring ——. H. Press. Papierfabr., 1921, **19**, 261—266, 365—368.

HE possible production of coloured cardboard by e direct addition of mineral or organic colouring atters to the straw pulp in the hollander was in- estigated. The dried straw pulp (after previous oiling with milk of lime under 4—5 atm. pressure) ontained cellulose 40·4%, pentosans 20·5%, lignin y diff.) 29·9%, and ash 9·2%. The mineral matter onsisted chiefly of calcium silicate, $CaSiO_3$, and his was not removed in the preparatory treatment f the pulp. A solution of the dyestuff was added a known weight of pulp, and after 20 mins. the xhausted dye solution was poured into a glass ylinder and its colour matched by the addition of a tandard solution of the dye to water (which had een poured off from undyed straw pulp) contained another cylinder. Straw pulp absorbed 95% (of e dyestuff added) of direct cotton dyes, 78—93% basic dyes, and 53—75% of acid dyestuffs. The bsorption of mineral colouring matters was deter- ined by means of ash estimations and varied from to 54%. For the production of a khaki-coloured rdboard a mixture of a mineral and an organic louring matter was found to be suitable.—A. J. H.

aper; Investigations of materials suggested for the manufacture of ——. Bull. Imp. Inst., 1920, **18**, 323—335.

EMS of *Cyperus Papyrus* from Egypt treated with ustic soda under conditions similar to those used r the preparation of paper pulp gave 34—42% of y pulp, which was difficult to bleach and was suitable for the production of white paper. mples of Bourdie grass (*Typha* sp.) from Egypt ve about 35% of dry pulp, which was difficult to each, and produced a harsh, stiff paper, which runk considerably in drying. The Kokerboom *loe dichotoma*) from South Africa is not a suit- le paper-making material, and is inferior to other uth African products. Vau stems (*Hibiscus tili- us*) from Fiji gave a good yield of pulp, but of erior quality. Matai wood (*Podocarpus spicatus*) m New Zealand gave a very low yield of p, which was not suitable as a paper-making terial. "Tabocca Brava," a bamboo from Brazil, nished, on rather drastic treatment, a good yield of pulp of fairly high quality, suitable for wrapping papers. Aninga (*Montrichardia arborescens*) stems from Brazil yielded a pulp furnishing a good brown paper, but the pulp could not be bleached sufficiently for the manufacture of paper suitable for writing or printing purposes.—J. C. K.

Patents.

Pressed [fibrous] material; Manufacture of articles from ——. Ottmar Reich, and H. Weiss. E.P., 133,952, 13.10.19. Conv., 23.3.17.

Dried straw and similar reed-like materials are disintegrated, treated with dilute solutions of alkalis (*e.g.*, 0·5% of caustic soda), acids (*e.g.*, 0·42% of nitric acid), or sulphites, whereby ligneous incrusting substances are removed, and are then bleached. Successive treatments of the raw material with caustic soda and a hypochlorite give better results than when both substances are used together. The moist pulp so obtained is "formed" under pressure in moulds made of porous material, which allow excess of water to be expressed.—A. J. H.

Balloon envelope material and process of manufacturing same. Ballonhüllen Ges. E.P. (a) 139,795 and (b) 139,807, 3.3 and 4.3.20. Conv., 3.3.16 and 22.9.17.

(a) Gas-tight balloon fabric is built up of a textile fabric united to an animal entrail skin, such as goldbeater's skin, by means of an adhesive layer containing glue and a substance to render it elastic. A suitable adhesive composition consists of 100 pts. of water, 10 pts. of gelatin, 10 pts. of Turkey-red oil, and 5 pts. of glycerin; 0·25 pt. (or 1%) of potassium bichromate or formaldehyde is added for waterproofing purposes. (b) The goldbeater's skin may be dispensed with if the textile fabric is coated with several layers of the adhesive composition. (Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 12,230 of 1890; J., 1891, 1016.) —A. J. H.

Degumming textile materials. Soc. Suisse de Ferments. E.P. 145,583, 29.6.20. Conv., 30.6.19. (*Cf.* Tagliani, J., 1921, 256 a.)

The rapid loss of diastatic power which occurs when a dilute solution of animal amylase (obtained from slaughterhouse waste) is heated at 55°—60° C., is greatly diminished by the addition of neutral salts (notably chlorides) of alkali or alkaline-earth metals. Sodium chloride and calcium chloride are suitable, 3—5 kg. being used per 1000 l. of solution. Textile materials are more easily penetrated by the solution of amylase if it contains a biliary salt such as is present in pancreatic juice and purified ox gall. —A. J. H.

[Textile] fibres; Process and apparatus for degumming and washing ——. R. L. Pritchard. E.P. 161,219, 7.11.19.

Fibres are packed in receptacles (7—15 cm. deep) having solid lateral walls and perforated bottoms, which are piled one above the other (the top one having a perforated cover) and secured so as to form a rigid column. This is fitted tightly within a vessel open at both ends and standing on a perforated shelf which rests on the bottom of a larger vessel containing the liquid used for treating the fibres. The liquid rises upwards through the fibre receptacles and is pumped back into the outer vessel. The fibres are thus subjected to a continuous unidirectional flow of liquor, whereby adhering matters are loosened. The pile of fibre receptacles is then removed and made to slide slowly down through a vessel containing pure water, whereby the fibres are washed free from the loosened impurities. —A. J. H.

Retting of fibrous straw; Method of and bath for ——. J. M. Masson. U.S.P. 1,374,941, 19.4.21. Appl., 12.1.20.

Straw is steeped and then boiled in a solution containing trisodium phosphate and sulphonated oils, and is then washed.—A. J. H.

Viscose silk; Manufacture of artificial ——. E. Bronnert. U.S.P. 1,374,718, 12.4.21. Appl., 8.9.20.

Artificial silk thread up to 1 denier in fineness is produced by spinning raw viscose, containing alkaline condensation products of phenols and aldehydes, in a bath containing a bisulphite, the concentration of which is inversely proportional to the fineness of the thread.—A. J. H.

Cellulose; Manufacture of ——. Badische Anilin- und Soda-Fabr. G.P. 331,950, 13.1.18.

Wood, straw, or the like is treated with alkali and carbon dioxide. The treatments may take place once or several times, and in any succession. If ammonia is used as alkali it can be recovered as well as the carbon dioxide. After the aqueous liquors have been separated from the cellulose they can be concentrated in order to convert them into a fodder which, like molasses, is mixed with bran, peat, and the like.—C. A. C.

Paper in pulp form; Sizing of ——. J. W. Zanders. G.P. 303,341, 20.9.16.

Montan wax is saponified with caustic alkali, especially with potassium hydroxide, and is converted into a stable emulsion. The emulsion is added to the pulp in the hollander, and the montan wax is precipitated by aluminium salts or the like and fixed in the paper fibre. By sizing further than to the standard hardness a dense watertight paper is obtained without special impregnation.—C. A. C.

Paper; Method for sizing —— with animal glue or proteins. F. Hassler. G.P. 331,350, 31.3.14.

The precipitation of the glue and proteins is effected by means of sulphonic acids of unsaturated hydrocarbons, especially of the higher hydrocarbons of coal tar, or by condensation products of the sulphonic acids obtained by heating a mixture of them, or by condensing them with formaldehyde or with phenolsulphonic acids. As the precipitates may be easily obtained pure white and are not coloured by iron salts, they may be applied to all pulp products. The pulp is treated either alternately with the glue or protein solutions (the latter from yeast or fish) and the solutions of the precipitating agents, or glue (protein) and precipitant are added together dissolved in sodium carbonate; precipitation takes place when acid or aluminium sulphate is added. For surface sizing the paper is passed first through a solution of the condensation product and then through a solution of glue and afterwards is dried as usual. Examples of the application of the condensation products prepared from naphthalenesulphonic acid alone or with formaldehyde or phenolsulphonic acid are given.—C. A. C.

Paper and pulp products; Method for sizing and impregnating ——. H. T. Böhme, A.-G. G.P. 331,742, 16.5.18.

Sulphite-cellulose waste lyes are applied together with emulsions of coumarone-resin and animal glue, or coumarone-resin and crude montan wax, or crude montan wax, or crude "montan wax colloid." Even when neutralised the sulphite lye acts as a precipitant for the above emulsions and participates in the sizing. For the precipitation of strongly alkaline emulsions acid sulphite-cellulose lye is used, or if the light-coloured neutral waste lye is used, other acid precipitants, as aluminium sulphate or dilute acids, are added. When precipitating emulsions of coumarone-resin and animal glue by sulphite lye the greater part of the glue is also precipitated. For the manufacture of waterproof paper or pulp products the dyed material is first treated with sulphite-cellulose lye, which may have to be acidified, and then is treated with the emulsions. The two-bath system may also be used with advantage for other textile products.—C. A. C.

Furnace plant for the recovery of salts, especially in sodium sulphate cellulose factories. W. Schacht. G.P. 317,082, 11.10.18.

A calcining and melting furnace mounted to rotate on wheels, rollers, or ball bearings, is movable parallel and perpendicular to the longitudinal axis of a rotary furnace, and the discharge outlet of the latter is faced with refractory material and adapted to fit into the inlet of the melting furnace, so as to make an almost air-tight junction for the transfer of material from the rotary furnace to the hearth of the melting furnace.—J. H. L.

Sulphate-cellulose plants; Treatment of gases and vapours from ——. A. E. Nielsen. G.P. 333,031, 6.3.19. Conv., 13.10 and 15.12.17.

The gases are treated with an absorption mass containing calcium carbonate. The green waste lime from the manufacture of sulphate-cellulose may be used with advantage. After the treatment with the gases the mass contains: sodium carbonate, sodium sulphide, sodium sulphate, sodium thiosulphate, hydrogen sulphide, thiocyanic acid esters, sodium thiocyanate, acetone, other ketones, aldehydes and mercaptans, calcium sulphite, calcium sulphate, calcium sulphide, calcium oxide, calcium tetrathionate, calcium carbide, etc., which can be converted into useful products. Calcium thiosulphate is converted into sodium thiosulphate.—C. A. C.

Fibres; Treating ——. J. H. Pickup and G. A. Wilson. E.P. 161,600, 15.9.19.

See U.S.P. 1,350,621 of 1920; J., 1920, 653 A.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Woollen fabrics; Two- and multi-coloured effects in ——. M. König. Textilber., 1921, 2, 178.

Coloured effects may be obtained in the piece-dyeing of woollen fabrics by suitably treating part of the yarn before weaving. Yarn which has been treated with chlorine or caustic soda has an increased affinity for acid, mordant, and direct cotton dyes, and yarn mordanted with tannic acid and tin or antimony salts loses its affinity for acid wool dyes but is strongly coloured by basic dyestuffs. After treatment with solutions of potassium, ammonium, or calcium thiocyanate, wool has a permanently increased affinity for acid, afterchrome, and mordant dyestuffs. Wool which has been immersed for 1—1½ hrs. at 50° C. in a solution containing 25% of sodium thiosulphate and 16% (on weight of wool) of hydrochloric acid of 22° B. (sp. gr. 1·18) has a diminished affinity for acid, substantive, and mordant dyes, and an increased affinity for basic and vat dyestuffs.—A. J. H.

Dyeing of wool; Direct ——. L. Guglialmelli and C. G. Estrella. Anal. Soc. Quím. Argentina, 1920, 8, 325—326.

Wool and silk can be dyed directly by diazotisation and subsequent treatment with certain polyphenols and phenolic glucosides. By the use of metallic salts, such as potassium bichromate and copper sulphate, variations in shade and greater fastness to light can be obtained.—G. W. R.

[Printing] reserves under Indigo; Function of manganese oxide in ——. R. Haller. Textilber., 1921, 2, 173—174.

The conditions under which manganese compounds may resist the fixation of vat dyestuffs on fabrics have been investigated by means of a Schleicher-Schull dialysing cell, the material of which has been considered as having the properties of a cotton ibre. The dialyser was filled with a solution of manganese chloride and placed in a 2% solution of austic soda. After 24 hrs. the inner liquid was lear and neutral, but a precipitate of manganese hydroxide had formed in the caustic soda solution. A cross-section of the thoroughly washed dialyser howed that a brown deposit of manganese hydroxide had formed on the outer half of the membrane, while the inner half was free from manganese. When a solution of indigo reduced by means of ydrosulphite was dialysed in the same dialyser, which was immersed in water, the indigo penetrated considerably into the deposit of manganese ydroxide. In another experiment, the dialyser mmersed in 2% caustic soda) contained a solution of 20 pts. of manganese chloride and 1 pt. of sodium ichromate, and after 24 hrs., no bichromate remained in the inner solution. A cross-section of the alyser showed (inside to outside), a brown deposit a manganese-chromium compound, a colourless yer, another brown manganese-chromium deposit, broad colourless layer, and a small deposit of anganese hydroxide. These facts are attributed the formation of a compound, $2MnO_2,Cr_2O_7$, hich has been prepared, and is regarded as an lsorption compound of a manganese chromate th manganite. When the same dialyser was used r the dialysis of a solution of indigo and hydrolphite, the indigo only penetrated as far as the st manganese-chromium deposit. It is concluded at indigo reserve pastes which contain manganese loride and sodium bichromate are effective beuse of the high oxidising power of the manganese romate which is formed, and that for this type of serve indigo vats prepared with zinc and lime are more suitable than those containing hydrosulphite, since the latter diffuse more quickly through the dialysing membrane.—A. J. H.

Ultramarine; Printing fabrics with ——. G. Stein. Textilber., 1921, 2, 176—177.

It is difficult to obtain effects which are fast to washing by means of printing pastes which contain starch and coarse varieties of ultramarine, since the affinity of ultramarine for cotton decreases with an increase in the size of the ultramarine particles. Moreover, in order to avoid "scumming," it is necessary to add to the printing paste such substances as dextrin, gums, and caustic soda, and these decrease the affinity of ultramarine for the fibre.—A. J. H.

Patents.

Bleaching of fabrics. J. Kershaw. E.P. 162,198, 19.5.20.

Wool, cotton, silk, and other fabrics in piece form are passed through a bath containing a cold 25% solution of hydrogen peroxide made slightly alkaline with ammonia, and after a period (16 hrs. for medium weight woollens) are washed with soap, and then passed through a cold 8½% solution of sodium hydrosulphite (a trace of sulphuric acid may sometimes be added), washed, and dried. The bleaching effect is permanent and the baths may be used continuously.—A. J. H.

Dyeing with acid sulpho-amino dyestuffs; Process for ——, *and manufacture of lakes.* Farbenfabr. vorm. F. Bayer und Co. E.P. 143,242, 12.5.20. Conv., 31.10.14.

Dyeings and lakes produced from acid dyestuffs which contain both sulpho- and amino-groups are rendered faster to light by treatment with a complex metatungstic acid or its salt. Phospho-tungstic, silico-tungstic, and antimony-tungstic acids are suitable. In wool dyeing, 1% of the tungstic acid is added to the dye-bath before or towards the end of the dyeing process. In the manufacture of lakes, the tungstic acid is added to a solution of the dyestuff, and barium chloride or other suitable precipitant is added.—A. J. H.

Dyeing tops, yarn and the like; Apparatus for ——. A. Ashworth. U.S.P. 1,374,628, 12.4.21. Appl., 15.10.20.

A perforated tube is mounted vertically within a dyeing vat, and means are provided for forcing a dye or mordant liquor through the tube and a series of collectively collapsible tubular yarn spools which are mounted upon it.—A. J. H.

Warp-dyeing machine. W. F. Haskell. U.S.P. 1,375,389, 19.4.21. Appl., 4.4.18. Renewed 15.9.20.

Warp yarn is drawn through a series of unit coils each having inlets for the dye liquor, which is supplied to the last unit. The overflow for exhausted liquor from the last unit is connected with the inlet of one of the preceding units.—A. J. H.

Silks; Process of treating [dyeing grege] ——. E. L. Maupai. E.P. 161,625, 10.12.19.

See U.S.P. 1,332,675 of 1920; J., 1920, 514 a.

Dyeing paper pulp. Huebner. *See* V.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Nitric acid; Concentration of ——. E. Galle. Z. angew. Chem., 1921, 34, 168—170, 173—175.

Nitric acid prepared by the oxidation of atmospheric nitrogen or of ammonia always has to be concentrated, the highest initial strength obtained being 50% HNO_3. The Pauling tower as improved by Hoenig is used for this purpose. The tower, about 8 m. high, is made of cast iron rings lined with acid-resistant material, and packed with Raschig rings carried on silicon-iron grids interposed between adjacent sections. The uppermost section, which is not packed, includes a stoneware acid distributor, a gas-exit pipe to the nitric acid cooler, acid-feed pipes, and thermometer. The bottom section is fitted with a manhole, steam-jet, and run-off pipe for dilute denitrated sulphuric acid. The nitric acid cooler is a worm of silicon-iron, and any uncondensed gases are drawn by a stoneware injector to an absorbing tower, the weak acid from which is returned to the process. The acids are elevated by silicon-iron pumps with chromium-steel shafts. The process is started by feeding with concentrated sulphuric acid and blowing in steam until the temperature at the top reaches 130° C. In normal working the temperature at the top of the tower stands at about 112° C. The quantity of sulphuric acid required depends on the dilution of the nitric acid. With the usual nitric acid of 1·26 sp. gr., 5 pts. of sulphuric acid to 1 pt. of nitric acid is required. The sulphuric acid may be replaced by an equivalent quantity of the same in the form of mixed waste-acid. In the case of nitric acid containing hydrochloric acid the consumption of sulphuric acid is greater. Laboratory experiments showed that, with an effective fractionating column, dilute nitric acid can be concentrated up to 65% HNO_3 without the use of sulphuric acid with no appreciable loss. To complete the concentration of this acid 2 pts. of sulphuric acid (monohydrate) is required for each 1 pt. of water present in the nitric acid. The large-scale application of this method would effect a great increase in the capacity of a given plant and saving in sulphuric acid. The addition of hydrochloric acid to the mixed acids greatly raises the boiling point, necessitating more sulphuric acid, and in addition the latter must be in excess to prevent formation of nitrosyl chloride. In the case of mixed waste acids about 50% of the N_2O_4 present is oxidised during distillation, but absorption in alkali is advisable to recover the remainder.—C. I.

Electrolytic cells; Marsh —— for chlorine, caustic soda, and hydrogen. C. W. Marsh. Trans. Amer. Electrochem. Soc., 1921, 297—306. [Advance copy.]

The Marsh electrolytic cell comprises a top of stoneware or other suitable material shaped like an inverted trough with ends extended downwards. The cell is suspended from this, or supported in a box, and from the top are also suspended the anodes, whilst the cathode is clamped to the top and ends. Openings are provided in the top for brine inlet, brine control device, brine level indicator, brine gauge glass, chlorine outlet, and for cleaning purposes. The anodes consist of graphite rods, 4·4 cm. diam. and 60 cm. long, arranged one above the other with spaces between, and are fixed to a rectangular graphite section. The cathode of perforated sheet steel is corrugated to conform to the surface of the horizontal graphite rods, and an asbestos paper diaphragm is tightly clamped to the edges of the cathode. The cathode with the ends and top forms the electrolytic compartment; it may be confined if the hydrogen gas is to be recovered. For small industrial plants and water and sewage purification, batteries of 100—300 amps. are suitable; the cells measure 25×72×80 cm. and a battery of 15 cells yields 5·5 kg. of chlorine, 6·1 kg. of caustic soda, and 0·15 kg. of hydrogen per hour. Normally, the life of the batteries is six months and of the anodes two years. The cost of chlorine from such a plant, taking into account the value of the caustic soda, is 4·5—5·0 cents per lb., as compared with liquid chlorine at 12 cents per lb. For large electrolytic alkali, bleach, and chlorine plants, batteries of 1250 to 5000 amps. are used. The cells measure 25×134 cm. and have a voltage of 3·35 and power efficiency of 63%. The batteries can be operated at double capacity, the current available then being 2500—10,000 amps. In this case the cells measure 25 cm.×5 m.; the voltage will be 4, and the power efficiency 50%. Over long periods the ampère efficiency amounts to approximately 90%; it may reach 95—97%. Features of the Marsh cell are the low average voltage resulting from the provision of a large electrode surface, regular distribution of deposits on the diaphragms preventing clogging of the passages, good circulation, and effective removal of chlorine bubbles. Small cells of large capacities operating at high efficiencies can thus be successfully employed.—W. J. W.

Ammonia synthesis equilibrium; Interpretations of ——. R. S. Tour. J. Ind. Eng. Chem., 1921, **13**, 298—300.

Equilibrium in the reaction $\frac{1}{2}N_2+\frac{3}{2}H_2 \rightleftarrows NH_3$ may be expressed by the formula $a/(1-a-c)^2 = KP(r^{3/2})/(1+r)^2$ where a=volume fraction of ammonia at equilibrium, c=volume fraction of inert gases at equilibrium, r=volume ratio of hydrogen to nitrogen at equilibrium, P=total pressure in atm., and K is a function of the absolute temperature. A set of curves shows the effect on the ammonia content at equilibrium of a variation of any one of the conditions when the others have the arbitrary values: $T=773°$ abs., $P=100$ atm., $r=3$, $c=0$. Both curves and equation show that effect of temperature is very marked; a reduction from 500° to 485° C. is as advantageous as a rise in pressure from 100 to 120 atm. Pressure increases the ammonia content at a decreasing rate with increasing ammonia content. Changes in the ratio of hydrogen to nitrogen have a small effect; a variation from the theoretical to the ratio $2N_2:3H_2$ or to $0·5N_2:3H_2$ involves a reduction of less than 10% of the equilibrium content. The effect of inert diluents is not only to lower the partial pressures of the reacting gases, but to dilute these as well. Each of the terms of the equation may be plotted as a separate curve for the sake of simplicity in computation, and a simple nomograph has been constructed for determining the equilibrium ammonia content when only temperature and pressure are variable, r has its theoretical value of 3·0, and $c=0$.—W. J. W.

Hydrogen for the synthesis of ammonia; Manufacture of ——. G. Claude. Comptes rend., 1921, **172**, 974—977.

The source of hydrogen suggested is water-gas, town gas, or coke-oven gas. In order to separate the hydrogen and the carbon monoxide the author suggests the use of solvents under pressure. By the use of ether under a pressure of 100 atm. and a temperature of about −50° C. it is easily possible to obtain hydrogen containing less than 0·2% of carbon monoxide. This pressure should not be greatly exceeded, as above this limit the solubility of hydrogen in the solvent increases very rapidly in proportion to that of the carbon monoxide.—W. G.

Potassium compounds; Application of the vapour pressures of —— to the study of the recovery of potash [from silicates] by volatilisation. D. D. Jackson and J. J. Morgan. J. Ind. Eng. Chem., 1921, **13**, 292—295.

The information gained from experiments on the vapour pressures of potassium compounds (J., 1921, 177 A) has been applied to an investigation of their volatilisation. If greensand is heated with lime to 1300° C., up to 90% of the potash is volatilised, whereas in the case of felspar not more than 20% is obtained, the explanation lying in the fact that the water liberated from the former silicate assists the formation of potassium hydroxide which has a high vapour pressure. The efficiency of calcium chloride, in admixture with lime, as a volatilising agent, was tested with glauconite and felspar, in such proportions as to give a residue having the composition of Portland cement. In the case of glauconite, volatilisation was practically complete, even at 1215° C.; with felspar it was less so. Contrary to Spackman and Cornwell's claims (U.S.P. 1,202,327; J., 1916, 1221), it was found that when sufficient chloride is present in the mixture to form potassium chloride, no advantage is gained by introducing water vapour. From mixtures of greensand with limestone in smaller proportions than required for Portland cement, without addition of a chloride, volatilisation is very small up to 1170° C., even in presence of water vapour; but if a chloride is added, mixtures containing only one-third of limestone, heated just below their fusing point, show a high volatilisation of the potassium compound. As a volatilising agent sodium chloride appears to be superior to calcium chloride.—W. J. W.

Potassium salts; Solubility of different —— in mixtures of water and alcohol. M. Pierrat. Comptes rend., 1921, **172**, 1041—1043.

The solubility at 14° C. in aqueous alcohol of varying concentrations and the electrical conductivity of aqueous solutions containing the same weight of salt in a volume of water equal to that of the aqueous alcohol have been determined for the bitartrate, perchlorate, platinichloride, fluosilicate, and cobaltinitrite of potassium. The solubilities, in g. per l., in alcohol of 94·7% concentration (by weight) at 14° C., of the different salts in the order given above are 0·05, 0·15, 0·02, 0·0096, 0·026.
—W. G.

Sodium sulphide; Action of —— on ferric oxide. J. C. Witt. J. Amer. Chem. Soc., 1921, **43**, 734—740.

An excess of sodium sulphide converts ferric oxide into a black amorphous substance, which after removal of most of the sodium sulphide dissolves in water to form a brilliant green solution. The solution is a reversible sol containing less than 0·07 g. of iron per litre. (*Cf.* J.C.S., June).—J. F. S.

Sodium silicate; Manufacture of ——. A. A. Perazzo. Anal. Soc. Quim. Argentina, 1920, 8, 404—409.

An improved plant for the preparation of sodium silicate by fusion is described. The furnace is rectingular in plan and is divided into two unequal portions by a bridge which is so constructed that only fused material can pass under it while floating unmelted material is held back. When a fresh charge is delivered into the larger compartment the used sodium silicate is forced under the bridge nto the smaller compartment of the furnace and verflows into a tank which is maintained full of old water. The sudden cooling of the fused silicate produces a fine granular product. The apparatus is ontinuous in working and the product obtained is more readily dissolved than that obtained by older methods involving the use of grinding machinery.
—G. W. R.

'luorides; Modification of Starck and Thorin's method for the determination of ——. E. D. Garcia. Anal. Soc. Quim. Argentina, 1920, 8, 321—324.

tarck and Thorin's method (J., 1912, 259) for the timation of fluorides in aqueous solution is odified, the excess of calcium in the filtrate from e mixed precipitate of calcium oxalate and uoride being estimated volumetrically. Knowing e amount of calcium required for the calcium oxalate, the amount of calcium fluoride and, hence, the percentage of fluorine in the original solution is obtained. Insoluble fluorides are first fused with silica and sodium carbonate. After treatment of the mass with water, silica is removed by ammonium carbonate and fluorine estimated as above.
—G. W. R.

Hypochlorous acid; Electrometric titration of ——. W. D. Treadwell. Helv. Chim. Acta, 1921, **4**, 396—405.

When hypochlorite is titrated with either arsenious acid or potassium iodide the end point may be determined accurately by electrometric means. The comparison electrode employed consists of a glass tube about 8 cm. in length, with its end drawn out to a capillary and turned up and the extremity of the capillary closed by a plug of filter paper or a drop of gelatin containing potassium sulphate. In this tube is placed potassium sulphate solution mixed with either a little hypochlorite solution already titrated or a drop of about *N*/100 iodine solution containing iodide. As electrodes use is made of two smooth platinum wires, one dipping into the hypochlorite solution and the other fairly deeply into the comparison electrode. These two electrodes communicate by way of either a high-resistance millivoltmeter or a galvanometer with suitable resistance. A sudden drop of the galvanometer deflection to zero marks the end point. When arsenious acid solution is used, the alkaline hypochlorite should be neutralised and at once titrated, but the loss due to premature formation of chlorate is inappreciable if the titration is carried out in dilute solution, at the room temperature, and within a few minutes of neutralisation. The end point becomes indistinct if a solution containing alkali carbonate or hydroxide is titrated with arsenious acid. The optimal hydrogen-ion concentration for the end point of the titration of a hypochlorite with potassium iodide, calculated from the equilibrium, $IO_3'+5I'+6H^{\cdot}\rightleftarrows 3H_2O+3I_2$, is 10^{-7}, which is that of the neutral point. The fundamental objection to this method is the pronounced sensitiveness of the end point to the reaction, and Pontius (J., 1904, 133), who devised the method, made use of a highly alkaline solution $[(H^{\cdot})=10^{-9}]$, which retards the end point. Good results are obtained with a solution alkaline with bicarbonate if the available chlorine amounts to about 0·1 equivalent per litre, but *N*/100 hypochlorite solution yields unreliable values under these conditions. When a very dilute solution is titrated, the final stages must be carried out very slowly, otherwise the blue coloration of the starch appears too late.
—T. H. P.

Hydrocyanic acid; Formation of —— in plants. P. Menaul. J. Biol. Chem., 1921, **46**, 297.

The formation of hydrocyanic acid was observed *in vitro* in sunlight, in a solution containing potassium nitrate and formaldehyde, but only if the reaction was acid to methyl orange. It is suggested that hydrocyanic acid may thus be formed in plants.—G. B.

Hydrofluosilicic acid; Equilibria of ——. L. J. Hudleston and H. Bassett. Chem. Soc. Trans., 1921, **119**, 403—416.

The standard "Analytical Reagent" methods for the detection of silica in hydrofluoric acid are inadequate. The proportion of hydrofluosilicic acid in mixtures with hydrofluoric acid can be determined by complete neutralisation with sodium hydroxide (*cf.* Wagner and Ross, J. Ind. Eng. Chem., 1917, **9**, 1116), according to the equation, $H_2SiF_6+6NaOH=6NaF+H_2SiO_3+3H_2O$. The estimation is carried out in conical flasks of wax or waxed glass, closed with rubber stoppers and containing measured quantities of sodium hydroxide coloured with phenolphthalein. Weighed quantities of the mixed acids are placed in wax test tubes inside the flasks and the contents of both mixed by shaking. When the colour has faded (the time being measured), further alkali is run in until permanent neutralisation is reached. If n c.c. of alkali were originally present and N c.c. were required for total neutralisation, $(N-n)/N \times 100$ is the percentage of total non-available hydrion (*i.e.*, the "complex" hydrofluosilicic acid) in the solution at the moment of fading. From the different values for this figure a value for the initial concentration of the complex, *i.e.*, the percentage of hydrofluosilicic acid initially present in the mixture, can be calculated. For concentrated solutions the measurement of $(N-n)/N \times 100$ is accurate to 0·25%, but for dilute solutions only to 1%. The time readings, due to the difficulty of bringing about complete mixing, and measurement of temperature due to heat of reaction, are also liable to error. The rate of dissociation of sodium silicofluoride into silicon tetrafluoride and sodium fluoride has been determined, together with the formula for the variation of the velocity constant with temperature. The equilibria set up when silicon tetrafluoride is passed into water are discussed. All four substances—hydrofluosilicic acid, hydrofluoric acid, silicic acid, and unchanged silicon tetrafluoride — are present, though in small concentration. Silicic acid is shown to exist in true solution to the extent of at least 0·003 mol. per litre at 15° C.—P. V. M.

Hydrogen peroxide; Kinetics of the decomposition of ——. F. Bürki and F. Schaaf. Helv. Chim. Acta, 1921, **4**, 418—425.

DECOMPOSITION of hydrogen peroxide in alkaline solution is a reaction of the first order, the velocity of the reaction being dependent on the concentration of the base but independent of its nature and conditioned apparently by the concentration of the hydroxyl ion alone.—T. H. P.

Carbon; Adsorption by ——. H. Herbst. Biochem. Zeits., 1921, **115**, 207—219.

THE adsorptive power of charcoal depends partly on the content of pure amorphous carbon, and can in some cases be increased by removing tarry impurities by means of a solvent or by distillation, or by destroying them by chemical means, as in the Aussig zinc chloride process. At about 1150° C. charcoal is fairly rapidly transformed into graphite and becomes a less powerful adsorbent. The author has prepared pure amorphous carbon of maximal adsorptive power, and expresses the "true" activity of technical samples as percentages of the former (comparison by CO_2 isotherm). Experiments with gaseous chloropicrin, benzyl chloride, and phosphorus tribromide, lead to the conclusion that in each case 1 mol. is fixed by 6 atoms of pure carbon, probably present as a C_6-ring.—G. B.

PATENTS.

Sulphuric acid, Concentration of —— in a vacuum. Badische Anilin- u. Soda-Fabr. G.P. 302,553, 12.1.17.

A HEATING chamber is provided with pipes of perforated sheet iron coated internally with lead which is connected homogeneously to the iron at the perforations. The exterior of the pipes may also be covered with lead. These pipes resist the chemical action of the boiling liquid and also the difference of pressure. The chamber is also lined with lead, and a continuous process is practicable.—C. I.

Ammonia oxidation; Process for the activation of contact masses for catalytic ——. Badische Anilin- u. Soda-Fabr. G.P. 304,232, 27.1.15.

THE activating material is applied to the catalyst in a state of fine division in the reaction chamber. This method may be applied to the revival of old contact masses without interference with the process. In the case of a contact mass containing bismuth, an acid solution of bismuth nitrate containing 10% Bi is injected into the reaction chamber.—C. I.

Sulphate kilns; Apparatus for the introduction of sulphuric acid into mechanical ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 332,954, 29.11.19. Addn. to 331,238 (J., 1921, 301A).

IN place of an acid feed vessel, a pipe secured to the rotating spindle and curved at the end is used. —C. I.

Sulphur dioxide; Obtaining and utilising —— from blast-furnace slag. L. H. Diehl. E.P. 139,172, 16.2.20. Conv., 16.1.17.

FOR the recovery of sulphur, existing as sulphide, from blast-furnace slag, a current of air, preferably heated, is blown through, or led over the slag, in sufficient amount to give a gas mixture containing not less than 2% SO_2, whilst at the same time avoiding solidification of the slag or further oxidation of its contained metallic oxides. The operation may be conducted in a slag pan with hood and gas outlet, or in a covered sump inserted in the slag run. In conjunction with the air oxidation, the introduction of oxidising compounds, such as calcium sulphate, is recommended, these being added in a highly heated or molten condition. The sulphur dioxide recovered is free from arsenic. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 11,544 of 1899 and 2405 of 1908; J., 1899, 444; 1908, 1209.)—W. J. W.

Percarbonates; Manufacture of ——. Deutsche Gold- u. Silber-Scheide Anstalt vorm. Rössler. E.P. 117,085, 24.6.18. Conv., 25.6.17.

ALKALI percarbonates mixed with carbonates are prepared by interaction of alkali peroxide and bicarbonate in presence of a limited amount of water. The percarbonate is separated from crystallised carbonate and salted out by addition of sodium chloride. Negative catalysts such as alkali silicates, stannic acid, or gums may be added to the percarbonate solution.—C. I.

Iron salt [for tanning]; Production of a solid non-hygroscopic ——. O. Röhm. E.P. 146,214, 26.6.20. Conv., 27.12.18.

BY the action of chlorine on ferrous sulphate, whether in the solid state or in solution, a non-hygroscopic compound of the composition $FeSO_4Cl$ is obtainable, which is specially suitable for tanning purposes.—D. F. T.

Ammonia; Method of and means for use in manufacture of [aqueous] ——. R. P. Douglas. E.P. 161,244, 31.12.19.

A PORTION of the vapours from the liming chamber of an ammonia still is passed through a reflux condenser to remove water, and thence to a finishing condenser, where strong aqueous ammonia is obtained.—C. I.

Ammonia; Process for the preparation of —— from nitrogen. H. Hampel and R. Steinau. G.P. 310,761, 24.8.17.

A METAL is treated at high temperature and pressure with hydrogen and with ammonium chloride or other ammonium compound or other substance which liberates nascent hydrogen. The ammonium or metallic salt used is recovered, as also is the metal, by reduction of the oxide or carbonate formed either directly or as a result of subsequent reactions.—C. I.

Ammonia and ammonium sulphate; Production of —— by the action of steam on cyanogen compounds formed in the distillation of organic nitrogen compounds. F. J. Collin, A.-G. zur Verwertung von Brennstoffen und Metallen. G.P. 328,829, 18.5.19.

A MIXTURE of gas containing cyanogen and steam, after removal of free ammonia, is treated with excess of sulphuric acid, with continual heating, *e.g.*, in a column apparatus, whereby the cyanogen is converted into ammonia, which combines with the acid to form ammonium sulphate. In the case of gases of low cyanogen content the cyanogen is absorbed in water or ammoniacal liquor, the resulting liquor is distilled, the ammonia absorbed, and the waste gases from the sulphate saturator treated as described. The reaction velocity is increased by the presence of hydrogen sulphide.—C. I.

Ammonium bicarbonate; Preparation of dry —— from wet precipitated salt. Badische Anilin- u. Soda-Fabr. G.P. 301,674, 12.1.16.

THE salt is thoroughly exposed to a counter current of warm, indifferent gases (air, carbon dioxide, or flue-gases) which have passed through a drying chamber.—C. I.

Sodium pyrophosphate; Manufacture of acid ——. A. Kelly. E.P. 161,273, 5.1.20.

THE calculated amount of acid, *e.g.*, hydrochloric acid, is added to a strong solution of sodium pyrophosphate, and the acid salt precipitated by saturating with sodium chloride.—C. I.

Phosphatic materials; Process of sintering ——. F. S. Washburn, Assr. to American Cyanamid Co. U.S.P. 1,373,471, 5.4.21. Appl., 23.7.20.

A MIXTURE of phosphatic and silicious materials is sintered to form a porous mass which is mixed with carbon and heated in an electric furnace, the evolved phosphorus being recovered.—W. J. W.

Aluminous compounds; Manufacture of ——. P. Spence and Sons, Ltd., H. Spence, and W. B. Llewellyn. E.P. 161,606, 11.10.19.

THE process in which iron is precipitated from aluminium sulphate solution by addition of a potassium salt and 5—10% excess of alumina (E.P. 9148 of 1914; J., 1915, 799) is made more rapid by adding to the solution a proportion of impalpable mud. This is prepared by grinding the silicious residues from the treatment of aluminous minerals, or native alunite may be used. The basic ferric potassium sulphate is then readily separated from the liquor. Part of it is used for a fresh operation, and the valuable constituents in the mud are thus gradually concentrated and may be recovered. —C. I.

Aluminium hydroxide; Manufacture of ——. M. Lindner. G.P. 333,388, 1.5.18.

STRONGLY cooled dilute solutions of aluminium salts are added to dilute and strongly cooled solutions of ammonia, which are kept vigorously stirred by means of a current of air saturated with ammonia. Aluminium hydroxide is thereby precipitated in a light gelatinous form (sp. gr. about 1) possessing a high adsorptive power.—A. R. P.

[*Aluminium sulphate;*] *Treatment of colloid-containing mediums* [*e.g., in ore flotation, and in manufacture of* ——]. W. A. Deane, Assr. to The Dorr Co. U.S.P. 1,359,037, 16.11.20. Appl., 13.1.20.

THE product obtained by the action of sulphuric acid on bauxite is treated with "packing-house stick" (an organic gel obtained as a by-product in the packing-house industry by boiling waste meat products etc. with water), whereby colloidal impurities (clay, silica, etc.) are coagulated and can be easily separated. Packing-house stick may also be used as a dispersing medium in ore flotation processes; the deflocculated colloids are separated from the ore pulp by decantation, and their interference in the subsequent flotation operation thus avoided.

Copper sulphate; Process of obtaining —— from metallic copper. P. A. Mackay. E.P. 161,656, 9.1.20.

REFINED or blister copper is dissolved in hot 70% sulphuric acid in presence of silver nitrate or other salt of a metal more electronegative than copper. Blister copper often contains enough silver for the purpose, and in this case only nitric acid is added. Excess of metal is used, and the silver etc. is deposited on the residual copper.—C. I.

Potassium carbonate; Method of making ——. E. P. Stevenson, Assr. to A. D. Little, Inc. U.S.P. 1,360,046, 23.11.20. Appl., 19.1.20.

A SOLUTION of potassium acetate in ethyl alcohol is treated with carbon dioxide, the potassium bicarbonate is separated, and the alcoholic solution is then treated with a reagent, *e.g.*, lime, to produce a salt (calcium acetate) of low solubility, which is used in making further quantities of potassium acetate.—W. J. W.

Potassium salts; Process for recovering —— from solutions carrying borates or carbonates or both. C. E. Dolbear, Assr. to D. C. Norcross, J. H. Miller, and G. J. Henry. U.S.P. 1,373,179, 29.3.21. Appl., 30.10.19.

SOLUTIONS of potassium salts containing boron compounds are treated with an aluminium compound, the insoluble aluminium borate is removed, and the potassium salt recovered from the residual solution. —W. J. W.

Alkali sulphides; Process of making ——. W. H. Landers, Assr. to H. S. Loud. U.S.P. 1,374,209, 12.4.21. Appl., 17.11.19.

AN alkali salt of a volatile mineral acid is intimately mixed with "sludge-acid" containing at least 5% of carbon, and the mixture heated to reduce the sulphate formed to sulphide.—C. I.

Carbides and derivatives thereof; Process and apparatus for manufacture of ——. F. E. Norton. U.S.P. 1,374,317, 12.4.21. Appl., 1.4.18.

IN a continuous process for the manufacture of carbides from a mixture of carbon and oxides or hydroxides, the necessary heat is supplied by combustion of part of the carbon with oxygen.—C. I.

Basic melts rich in lime; Process for the preparation of ——. L. H. Diehl. G.P. 307,190, 21.12.17.

A MIXTURE of about molecular equivalents of calcium oxide and sulphate is melted with an easily fusible compound, such as sodium chloride, calcium chloride, sodium hydroxide, or sodium sulphate. Limestone may be used in place of lime. The melt can be used for the decomposition of sulphides in furnace slags by agitating them with a current of air and adding the basic mixture, preferably in a molten state. Sulphur dioxide is evolved by the interaction of sulphide, sulphate, and air: the residual slag is granulated and the granular mass dried and powdered to the fineness of cement.—C. I.

Hydrogen peroxide; Process of obtaining solid compounds of ——. E. Merck. G.P. 331,111, 29.3.12. Addn. to 303,680 (J., 1918, 371 A).

Hydrogen peroxide solutions rendered stable by the methods described in G.P. 174,190, 203,019, and 216,263 (J., 1908, 1204; 1909, 1314) are evaporated with neutral organic or inorganic carriers. Hydrogen peroxide is thus obtained in combination with the substance used in a solid stable state. —C. I.

Hydrogen; Manufacture of —— by dissolving iron in sulphuric acid. R. Blum and M. Buchner. G.P. 303,281, 8.1.16.

Iron is treated with the equivalent quantity of sulphuric acid, with the application of heat or pressure, or both, for the production of hydrogen. The resulting ferrous sulphate is calcined in a current of air to ferric oxide with the evolution of sulphur trioxide, which is re-converted into sulphuric acid and used again in the process together with the iron resulting from the reduction of the ferric oxide.—A. R. P.

Silica gels and processes of making same. W. A. Patrick. E.P. 136,543, 6.12.19. Conv., 7.12.18.

See U.S.P. 1,297,724 of 1919; J., 1919, 363 A.

Alumina and its salts; Process for the extraction of —— from clay. H. G. Wildman. E.P. 161,310, 14.1.20.

See U.S.P. 1,326,384 of 1919; J., 1920, 191 A.

Cyanogen compounds; Process for recovering ——. E. V. Espenhahn. Reissue 15,090, 19.4.21, of U.S.P. 1,315,219, 9.9.19. Appl., 17.1.21.

See E.P. 109,254 of 1917; J., 1918, 570 A.

Zinc sulphide; Manufacture of ——. P. Comment. U.S.P. 1,374,435, 12.4.21. Appl., 23.4.19.

See E.P. 126,274 of 1919; J., 1919, 630 A.

Mixed acid. G.P. 303,892. *See* XXII.

VIII.—GLASS; CERAMICS.

Clays; Effect of time on the drying shrinkage of ——. R. F. Geller. J. Amer. Ceram. Soc., 1921, 4, 282—287.

The drying shrinkages of three shales, two ball-clays, and one fireclay were determined to ascertain how quickly different clays could be dried and to examine the influence of the time of drying on the total shrinkage. The volume shrinkages were determined in each case. It was concluded that the time required for drying depended largely on the water content, but that the structure of the clay was an important factor, fine-grained clays such as ball-clays not being dried at so rapid a rate as clays of coarser grain. The total shrinkage was proportional to the water content and was not influenced by the rapidity of drying.—H. S. H.

Kaolin; Formation and constitution of ——. V. J. Bernaola. Anal. Soc. Quim. Argentina, 1920, 8, 392—400.

A theoretical discussion of the origin of kaolin from felspars and the supposed occurrence in it of crystalline particles. (*Cf.* J.C.S., June.)—G. W. R.

Silica bricks from quartzite rock; Possibility of preparing high-grade ——. E. Lux. Stahl u. Eisen, 1921, 41, 258—264.

Silica bricks can be made from quartzite rock of a quality corresponding with those made from tertiary quartz. These bricks show under the microscope a high degree of transformation even of the large quartzite grains. Such a transformation is effected in the case of quartzite rock by a high burning temperature such as is employed in America. The degree of transformation of German silica bricks is usually of a much lower order, but microscopical examination of the better bricks shows that by arranging the method of manufacture to suit the raw material, a brick may be made which is not inferior to those prepared from tertiary quartz.—J. W. D.

Enamel pigment; Manufacture of a red —— from cadmium sulphide and selenium. S. Sugie. Kōgyō-Kwagaku Zasshi (J. Chem. Ind. Japan), 1921, 24, 252—258.

Red enamel pigments known as "fire-red" or "cadmium-red" are prepared from a mixture of 80—90% of cadmium sulphide and 20—10% of selenium, the dried and finely powdered components being well mixed and heated in a clay crucible in a muffle furnace at about 700° C. When the blue flame, which burns at the mouth of the crucible, is nearly extinguished, the crucible is removed from the furnace and the product is immediately cooled either by spreading it over a cold place or by pouring cold water over it. The product probably has the empirical formula Cd_2SeS_2.—K. K.

Enamelling oven; An electric vitreous ——. C. W. Mehling and J. W. Carpenter. J. Amer. Ceram. Soc., 1921, 4, 271—276.

An electric oven eliminates the risk of damaged ware which is always present with oil-, coal-, and gas-fired furnaces and permits the use of the entire heating space. Its initial cost is higher, as is also the power cost per hour compared with that of fuel, but the cost per pound of metal dealt with is actually in favour of the electric oven. Details of the construction are given. The oven, which is wound with nichrome ribbon, can be operated up to 1800° F. (980° C.). The finish of the ware is more satisfactory than with the older types of furnace.—H. S. H.

Patents.

Electric insulating material; Manufacture of ——. E. F. A. Bültemann. E.P. 137,326, 2.1.20. Conv., 29.1.18.

A fireproof, heat-resisting insulating material, insensitive to moisture, is prepared by mixing substances capable of setting hydraulically, such as cements, plaster, magnesium oxychloride, etc., with easily fusible insulating substances, such as resins, bitumens, asphalts, sulphur, etc., and vegetable or mineral fibrous filling material, such as cellulose, asbestos, peat, slag wool, glass wool, etc. The mixture is treated with water, preferably under pressure, allowed to harden, dried, and heated, whereby the fusible substances soften and fill up the pores of the mass.—J. S. G. T.

Refractory insulation. P. G. Willetts. U.S.P. 1,374,538, 12.4.21. Appl., 17.12.19.

A refractory heat-insulating material is prepared by burning a mixture of finely divided lignite and plastic fireclay having a high silica content. —J. S. G. T.

Ceramic pastes; Process and apparatus for dewatering ——. O. Frank. G.P. 330,224, 31.10.18.

In order to reduce the water content of ceramic pastes so as to leave a mass suitable for shaping, the paste is placed in an apparatus consisting of clay plates with narrow feet so arranged that there is a hollow cavity between them. By reducing the air pressure in this chamber the excess water is sucked through the top plate and is removed by passing a current of air through the chamber. —A. R. P.

Kiln, especially for enamelled ware. A. Sommer. G.P. 325,747, 15.12.18.

The kiln is heated indirectly by hot gases conveyed through channels of refractory brick running along the side walls and roof, but at a distance from the same.—L. A. C.

Refractory and insulating products; Manufacture of ——. G. L. Dimitri and J. E. Delaunay. U.S.P. 1,374,493, 12.4.21. Appl., 21.6.20.

See E.P. 142,513 of 1920; J., 1921, 348 a.

IX.—BUILDING MATERIALS.

Gypsum; Relation between the fineness and other properties of calcined ——. W. E. Emley and F. C. Welch. J. Amer. Ceram. Soc., 1921, 4, 301—305.

Calcined gypsum was screened to provide material of different sizes. Each size was tested for normal consistency (measured by the Southard viscosimeter), time of set (measured by a Vicat needle), tensile strength, combined water, and plasticity (measured by spreading a paste of normal consistency upon a porcelain plate of known absorptive capacity at a constant rate). The results indicated that the finer the calcined gypsum the more water was required to make a paste of normal consistency and the more quickly did it set. Within the limits of the specifications of the American Society for Testing Materials, increased fineness of the calcined gypsum was accompanied by increased strength of the set material, but any increase of fineness beyond this resulted in decreased strength. The finer the calcined gypsum the more sand would it carry. —H. S. H.

Blast-furnace slags; Experiments on ——. H. Burchartz. Stahl u. Eisen, 1921, 41, 193—200. (*Cf.* J., 1920, 573 a.)

Experiments on the suitability of blast-furnace slag for incorporation in concrete mixings have been extended to include ferroconcrete exposed to the action of sea water. Here the durability of the concrete depends largely on its density, and in this respect the concretes tried proved satisfactory and at least equal to those made with sand. The standard mixture consisted of 1 pt. (by vol.) of cement, 2 pts. of slag dust, and 3 pts. of slag particles of grade ranging from 7 mm. to 40 mm. Compression tests were made on specimens after various periods of hardening up to 3 years. Slag concretes were stronger at all periods than sand concretes. They were also sufficiently impervious to prevent percolation of sea water and rusting of the iron cores.—H. J. H.

Blast-furnace slags; Strength of ——. H. Burchartz. Stahl u. Eisen, 1921, 41, 472—475.

The view that the suitability of slag as building and road-making material can be correlated with its colour and composition has been examined by experiments on ten samples of blast-furnace slag. The samples were tested in compression, while resistance to wear was measured by noting loss in weight when the specimens were placed in a rotating drum for half an hour. The mean compressive strengths of the samples ranged from 768 to 2414 kg. per sq. cm. High mechanical strength appeared to be associated with dark colour and high content of iron and manganese. Resistance to wear was associated with compressive strength, but the connexion was not quantitatively rigid. The range of samples was, however, too restricted (seven being from one works) to allow of a wide generalisation.—H. J. H.

Patents.

Cement; Process of curing ——. G. L. Smith. U.S.P. 1,374,403, 12.4.21. Appl., 24.7.18.

Articles of cement, cement mortar, or cement concrete are heated in air or a gas under a pressure greater than that of saturated steam at the temperature of the moisture within the pores of the material.—L. A. C.

Fibrous material [*e.g., wood*]; *Method of treating* ——. W. Weimar. U.S.P. 1,375,125, 19.4.21. Appl., 5.2.20.

The material is rendered non-absorbent, and its insulating properties and texture are improved by successive immersion in a hot solution of sodium carbonate, a hot hydrocarbon liquid, and a solution of sulphur and resin at a temperature sufficiently high to keep the sulphur molten; the material is dried after the first two immersions, and after it has remained in the third solution for a sufficient period to fill the pores it is suddenly cooled. —L. A. C.

Heat insulators; Manufacture of moulded ——. P. Krause. G.P. 329,409, 29.3.19. Addn. to 317,170.

Moulded articles prepared as described in the chief patent from the waste sludge of iron oxide and silicates obtained in the manufacture of alumina are heated, with or without the addition of a flux or an alkali, until they are partially vitrified. The porosity of the articles may be increased by adding combustible material, such as sawdust or cork waste, to the mixture before heating.—L. A. C.

Impervious acid-resisting apparatus; Manufacture of —— *from cement.* Freskoschmelz- und Mosaikwerke G.m.b.H. G.P. 332,940, 29.7.17.

A mixture of cement with quartz or similar material and a flux is burnt, and the resulting mass, after grinding, is mixed with a further quantity of the flux and a binder, *e.g.*, Portland, Sorel, or zinc cements, water-glass, or a mixture of water-glass and an alkaline-earth oxide. The mixture is made into the required shape, which is then glazed and fired.—A. R. P.

Cement; Manufacture of ——. K. G. Wennerström. E.P. 143,243, 12.5.20. Conv., 10.2.19.

See U.S.P. 1,343,948 of 1920; J., 1920, 573 a.

Impregnated wood. G.P. 334,307. *See* IIb.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

[*Steel*] *process; Deoxidation processes in the basic Bessemer* ——. O. von Keil. Stahl u. Eisen, 1921, 41, 605—611.

A careful examination was made of two charges at each of nine steelworks. The oxygen was estimated by reduction at 950° C. An increase of oxygen was noticeable during the after-blow in two cases only; in other cases there was a diminution. The average limiting values of oxygen before deoxidation were 0·075 and 0·095%, and after deoxidation 0·030 and 0·040%. Percentages of oxygen determined by reduction at 950° and 1170° C. did not indicate any connexion between the progress of the smelting or the method of deoxidation and the percentage of oxygen. It was found that with less than 0·4% of manganese the oxygen value was high, and with over 0·5% the oxygen value was lower. On account of the uncertainty of determining the oxygen completely by the method used, co-ordination between the oxygen percentages and the stages of the process cannot be affirmed. Further work on synthetic charges of known oxygen content is also necessary to establish the exact influence of manganese.—J. W. D.

Basic slag; Influence of basicity of —— on the working results of the converter. L. Blum. Stahl u. Eisen, 1921, **41**, 69—74.

The basicity of basic slag is limited by the proportion of free lime remaining in excess of that required for the formation of tetracalcium phosphate and calcium monosilicate. From consideration of a large number of works analyses it is concluded that for an economical basic process in regard to efficient dephosphorisation and low manganese consumption as well as to effective high desulphurisation and low loss of iron, the excess lime calculated as above should be about 4%.—J. W. D.

Iron and steel; Roentgen spectrographic investigations of ——. A. Westgren. Iron and Steel Inst., May, 1921. [Advance proof.] 23 pages.

The results of the investigations show that α-iron has a cube-centred cubic lattice structure, thus verifying Hull's result (Phys. Rev., 1917, **9**, 84; **10**, 661). At 800°—830° C., within the so-called β-iron interval, the iron atoms are oriented similar to those of α-iron. Adopting the view that allotropy is synonymous with polymorphy for solid crystalline substances, this means that β-iron cannot be considered as a separate modification of iron. In austenite and in iron at 1000° C. the crystals have face-centred cubic lattices. This is a characteristic of γ-iron and a fundamental crystallographic difference between α- and γ-iron. In martensite iron is present as its α-modification. This is also the case in high-speed steel of ordinary composition hardened at 1275° C.—J.W. D.

Iron; "Slip-lines" and twinning in electro-deposited ——. W. E. Hughes. Iron and Steel Inst., May, 1921. [Advance proof.] 9 pages.

Etched sections of electro-deposited iron, deposited under various conditions, exhibited peculiar lines or markings that appeared sometimes, and especially at low magnifications, as wave-lines running through the mass of the metal, and sometimes, on individual grains, in herring-bone arrangement. It is suggested that these lines are "slip-lines" which are produced in the grains of which the deposit is composed by the forces of contraction that act during the deposition.—J. W. D.

Iron; Solid solution of oxygen in ——. J. E. Stead. Iron and Steel Inst., May, 1921. [Advance proof.] 5 pages.

When iron is heated in air or oxidising gases, the surface layers apparently absorb oxygen which passes into solid solution, and when the solution becomes supersaturated the oxide separates forming globules of free oxide. These globules become larger and larger as oxidation proceeds, eventually joining together to form continuous layers. Oxidising gases find their most facile passage into the steel between the crystals. The gradual changes from solid solution to free oxide can be clearly traced along the oxidised junctions. Sulphur in the gases, possibly as sulphur dioxide, penetrates into the body of the crystals, producing manganese sulphide, and possibly protoxide, which appear in globular form. —J. W. D.

Iron; Cupric etching effects produced by phosphorus and oxygen in ——. J. H. Whiteley. Iron and Steel Inst., May, 1921. [Advance proof.] 13 pages.

Differences in the phosphorus content of less than 0·02% in adjacent parts of otherwise pure iron can be readily discovered by means of cupric etching reagents. As the difference increases up to 0·15% the contrast becomes more and more pronounced. These differences were produced by first phosphorising strips of iron with phosphorus in hydrogen at 1000° C. and then welding, in hydrogen or other gas, a pile made up of alternate strips of phosphorised and unphosphorised material. Attempts to produce in a similar way an unequal distribution of oxygen which could be detected by cupric reagents failed. When oxygen was present white resist-lines were formed only at the weld junctions, but these lines were not formed where unoxidised iron was welded in dry hydrogen. Two methods of obtaining an unequal oxygen content were used: first by soaking pure iron in its own oxide at a high temperature and then welding it with the unoxidised material; second by reducing highly oxidised iron in hydrogen and then welding it with the original metal at a low temperature.—J. W. D.

Iron; Baumann sulphur test and the behaviour of phosphorus in ——. P. Oberhoffer and A. Knipping. Stahl u. Eisen, 1921, **41**, 253—258.

Investigations were carried out on iron containing from 0·045 to 0·139% of sulphur, iron containing from 0·67 to 1·33% of phosphorus, and iron containing small percentages of both phosphorus and sulphur. As regards the Baumann sulphur printing test, results indicate its usefulness under all circumstances. A side reaction which occurs in the alloys containing phosphorus, due to the formation of hydrogen phosphide, is so small that it does not affect the bromide paper to any marked extent. With pure iron-phosphorus alloys annealing temperatures from 1200° C. upwards and a short heating at 1300° C. remove the dendritic phosphorus structure. This is the case only with pure iron-phosphorus alloys since the presence of carbon or other elements in solid solution in technical irons, such as steel, renders the homogenising so difficult that up to the present no practical heat treatment has been found sufficient to remove the dendritic segregation.—J. W. D.

Sulphur in steel; Comparison of different methods of estimating ——. T. E. Rooney. Iron and Steel Inst., May, 1921. [Advance proof.] 13 pages.

In the great majority of cases drillings of ordinary commercial carbon steels need not be annealed before estimating sulphur by the evolution method unless incipient rusting has taken place or the presence of elements such as titanium is suspected. Annealing may be necessary with steel low in manganese and containing chromium and liable to contain oxides which may form an eutectic with the sulphide. No definite conclusions could be drawn from experiments carried out on nickel-chromium steels, including annealing in hydrogen, as only two of the samples were of the type yielding low results by the evolution method, and further work is necessary to determine the cause of this condition in nickel-chromium steels.—T. H. Br.

Pig iron containing manganese; Production of —— from low-manganese residues, especially Siegerland blast-furnace slag. H. Thaler. Stahl u. Eisen, 1921, **41**, 249—253, 338—343.

A series of experiments was carried out with Siegerland blast-furnace slag containing approximately 12·25% MnO. Different charges of this slag mixed with varying proportions of iron ores were reduced with carbon using calcium phosphate and limestone as a flux. The reductions were carried out in a small electric furnace, and pig irons containing manganese and ferro-manganese alloys were produced. Economical results were obtained both as regards the percentages of manganese reduced and also as regards cost.—J. W. D.

Quenching cracks [in steel]; Cause of ——. K. Honda, T. Matsushita, and S. Idei. Iron and Steel Inst., May, 1921. [Advance proof.] 16 pages. (*Cf.* J., 1919, 582 a.)

Owing to the presence of arrested austenite in martensite the periphery of quenched small pieces of steel is harder than, as hard as, or softer than the interior according as the quenching is soft, medium, or hard respectively. When the interior is much harder than the periphery, quenching cracks occur, due to the smaller specific volume of the austenite as compared with the martensite of the central portion, which exerts a tangential stress on the periphery. This difference in specific volumes increases as the temperature falls, and cracking usually takes place at room temperature. In the case of a large specimen cracking may take place either at room temperature or in the A1 range. In the latter case the stress is caused by the structural difference between the inner pearlitic and the outer austenitic structures. In a hard quenching, owing to a gradual transformation of the arrested austenite the hardness generally increases with lapse of time. —T. H. Bu.

Tungsten tool steel; Prevention of hardening cracks and the effect of controlling recalescence in a ——. S. N. Brayshaw. Iron and Steel Inst., May, 1921. [Advance proof.] 86 pages.

The changes Ac 1.2.3 and Ar 3.2.1 in a tool steel containing 1·1% C and 0·8—0·9% W take place in stages which may be separated from each other if sufficient time be allowed for the process. By annealing bars at temperatures corresponding to the completion of the stages of the change point and afterwards subjecting them to a standard hardening process, they were found to lengthen or shorten and respond under bending stress according to the heat treatment received. Milling cutter blanks were heat-treated along with the bars and the blanks machined to a design extremely difficult to harden. The cutters were then subjected to the standard hardening process and it was found that the resulting cracks occur in sequence with the treatment and with the results from the bars. Liability to crack in hardening was greatly reduced when sufficient time was allowed for the heat treatment. Within a certain range of temperature cutters which broke badly in hardening were generally made from blanks in which the ratio of the Brinell hardness number to the Shore figure was comparatively high. It was found that specific heat treatments can be given which ensure a minimum change in length after hardening. The modulus of elasticity of the hardened bars, which differed greatly in other respects, remained remarkably uniform. A standard hardening test is suggested which would give a recognised standard of hardening behaviour. —T. H. Bu.

Tungsten steels; Use of very slow cooling in the micrographic study of alloys and the structure of ——. A. Portevin. Comptes rend., 1921, 172, 964—967.

By very slow cooling it is possible to get an enlargement of the whole structural design in alloys in chemical equilibrium, thereby facilitating their micrographical examination; to realise a state of equilibrium or a state nearer to this latter in the case of alloys showing constituents of tempering; to obtain evidence of states not in equilibrium; which have hitherto only been indicated by new equilibrium structures. By the application of this method to tungsten steels containing 0·1—0·4% C and 5—7·5% W, after a reheating to 1300° C. and cooling to 200° C. in 75 hrs. it is possible to obtain a structure with four constituents comprising a ferrite with tungsten, a tungsten carbide, a troostite with tungsten, and a new constituent, a complex of ferrite+Fe_2W.—W. G.

Rusting experiments with sheet iron containing copper. O. Bauer. Stahl u. Eisen, 1921, 41, 37—45, 76—83.

Two series of experiments were carried out with iron sheets containing increasing percentages (0·09—0·46) of copper. In the first series large sheets were used with the annealing or rolling skin unbroken. The influence of the copper is only plainly marked in industrial districts where iron high in copper corrodes less readily than iron poor in copper. In pure air or in sea air slight additions of copper have in general little effect. This also applies to rusting tests carried out in sea water and on buried material. In the second series of experiments the sheets were small and were without an annealing or rolling skin. With sheets of this nature the results obtained in pure air were not distinct nor reliable, and in distilled water, tap water, or North Sea water the varying percentages of copper were without effect. In water containing much carbon dioxide in solution copper slightly reduced the rusting. Small copper additions also protected against attack by sulphuric acid, and partly counteracted the influence of high percentages of phosphorus.—J. W. D.

Iron and steel; Corrosion of ——. T. S. Fuller. Trans. Amer. Electrochem. Soc., 1921, 337—346. [Advance copy.]

Relative rates of corrosion of iron were determined by observing the formation of rust caused by a single drop of water placed on a roughly polished surface of the metal. Results of oxidation are perceptible in 1 min. and well marked in 15 mins. By applying successive drops on the same spot, after complete evaporation of a previous drop, the initial rate of corrosion was shown to be much greater than that of later action. Zinc inhibited corrosion in its immediate vicinity, but the zinc itself was attacked. Small quantities of aluminium and calcium did not change the initial rate of corrosion, but chromium produced a marked effect. Copper steels proved to be more resistant to corrosion than cold-rolled wrought iron.—C. A. K.

Iron; Protection of —— *with paint against atmospheric corrosion.* J. N. Friend. Iron and Steel Inst., May, 1921. [Advance proof.] 4 pages.

A continuation of previous work (J., 1918, 736 a). Plates of open-hearth steel, cold-rolled, charcoal annealed, and eventually polished, were painted, left exposed to the air for 5 years, cleaned, and the loss in weight determined. Ordinary boiled oils do not offer so good a protection as litho oils owing to the catalyst (drier) accelerating disintegration of the paint film. The best results are obtained by giving the iron first a coat of low pigment content followed by a coat of high pigment and low oil content. The first film then clings tenaciously to the surface of the metal, while the outer coat protects the inner owing to its lower permeability by moisture and greater resistance to mechanical erosion. —A. R. P.

Brasses containing tin; Quenching of ——. L. Guillet. Comptes rend., 1921, 172, 1038—1041.

The mechanical properties of brasses containing tin are considerably improved when the percentage of tin is sufficiently high for the formation of the special constituent, similar to the δ-constituent of bronzes (*cf.* J., 1906, 813), if the conditions of quenching are such that this constituent goes into solution. Thermal anomalies appear with this special constituent, which shows the same transformation as the δ-constituent of bronzes. This constituent dissolves at 350° C. in the β-constituent of brass. Quenching at 600° C. considerably improves alloys containing this constituent, there being a marked increase in their breaking strain, resilience, and hardness.—W. G.

Arsenic; Removal of —— from zinc electrolyte by means of hydrogen sulphide. H. R. Hanley. Chem. and Met. Eng., 1921, 24, 693—696.

A plant for the safe generation on a technical scale of hydrogen sulphide and its employment for the precipitation of arsenic from a solution of arsenical zinc fume in sulphuric acid is described, consisting of a rotating horizontal cylindrical generator, charged with a low-grade copper matte and about 75% (of the weight of matte) of sulphuric acid in 20% dilution, and connected through its end trunnions with the precipitating tank by pipes forming a completely closed circulatory system through which the gases are propelled by means of Roots blowers, the attenuated gas after passing through the arsenical solution being returned to the generator. The gas is delivered to the precipitating tank through a perforated coil situated midway up the tank, whilst a portion of the attenuated gas is injected into the bottom of the tank by a second blower in order to keep the liquid in agitation, and prevent the precipitation of zinc sulphide by a local excess of hydrogen sulphide. The last traces of arsenic are removed by precipitation as an iron arsenic compound, as complete removal by hydrogen sulphide would cause co-precipitation of zinc. The arsenic solution is given a preliminary treatment with sulphur dioxide to reduce arsenates if present, before the hydrogen sulphide treatment.—G. F. M.

Sintering process; Investigation of the ——. K. Endell. Metall u. Erz, 1921, 18, 163—177.

In the making of agglomerates for smelting from finely divided ores, flue dust, and other residues, the aim should be to produce a body which is porous and mechanically strong at 1000° C., has the greatest possible surface, and requires the minimum of fuel in the subsequent smelting process. Sintering of the mass is usually brought about either by an increase in the grain size of one or more of the constituents with consequent intercrystallisation of the particles, in most cases accompanied by an increase in the specific gravity, or by reactions between the solid constituents of the mass resulting in an evolution of heat and partial fusion of the particles, or in the formation throughout the mass of interlocked crystals of a new compound. The course of the changes that take place during sintering may be followed by the construction of a heating curve and by direct observation through a microscope in conjunction with a small electric heating furnace fitted with a thermo-couple. Such an instrument is described in the paper in detail, together with some results obtained by its use.
—A. R. P.

Blast-furnace and cupola slags. Their composition and graphic methods for determining their constitution. J. E. Fletcher. Iron and Steel Inst., May, 1921. [Advance proof.] 20 pages.

The author's investigations support the view that blast-furnace slags consist of a solvent silicate of $2RO,SiO_2$ type in which the remaining constituents are dissolved. A clear view of the theory is provided by means of graphic methods. Alumina lowers the fusion temperature, affects the viscosity of the silicate in which it is dissolved, and behaves as a neutral constituent. The free silica is the active agent in siliconising the hearth metal. The metasilicates when superheated above their melting point become orthosilicate in character, the amount of superheating needed being reduced in the presence of alumina and ferric oxide. The composition of the primary slags is of fundamental importance. Though the mineralogical character of cold slags affords useful information, it is necessary to ascertain the most probable composition of the liquid slags at the time the reactions are in progress. As the alumina content in blast-furnace slags increases, the silica activity decreases. As the lime content of cupola slags increases, their character approaches that of blast-furnace slags.—T. H. Bu.

Blast-furnace gas; Cleaning of ——. S. H. Fowles. Iron and Steel Inst., May, 1921. [Advance proof.] 21 pages.

The use of blast-furnace gas for boiler firing shows only 20% efficiency as compared with its use in large gas engines, and the problem of the most efficient use of blast-furnace gas (*i.e.*, in internal combustion engines) rests largely on a satisfactory gas cleaning process. Internal wet cooling of the gas is condemned because of the loss of potash, and because the dew point of the gas is raised, necessitating a higher degree of preheating of the gas before entering the bag chamber to avoid deposition of moisture. In a plant erected by Palmers' Shipbuilding and Iron Co. the crude gas passes through dry coolers through which pass four vertical annular tubes. Water sprays in the inner tubes effected a temperature fall of 40°—45° C., but good results are obtained by forced air cooling. The gas then passes through the preheaters and filter-bags, the whole of this system being under suction, as more rapid cooling and dust separation were effected under this condition than when the cleaning plant was under pressure. The temperature at the filter-bags should not be below the dew point of the gas. The ideal condition to be aimed at is to cool the gas externally, before cleaning, to a point approaching a dew point of 15°—25° C., as the cleaned gas would then be directly available for use in a gas engine. The electrostatic type of cleaner allows the sensible heat of the gas to be retained, but the gas is not sufficiently freed from dust for use in gas engines and the power costs are high. Operating details of the plant are given in an appendix.—C. A. K.

Patents.

Furnaces [; Reverberatory ——]. J. L. Gal. E.P. 122,395, 19.9.18. Conv., 12.1.18.

The roof of a reverberatory furnace is of parabolic or other suitable geometrical form and arranged so that the material to be heated receives the whole of the reflected heat rays from the fire-hearth or other source of heat. In contact with, or spaced from, the interior of the crown is a covering of trellis work coated with material of high absorptive and emissive power such as cerium oxide, and the exterior may be similarly covered with material of low emissive power, such as copper sheet. The trellis work may be heated directly by Bunsen burners.—B. M. V.

Furnaces; Heating device for —— particularly applicable to furnaces for the melting of steel and other metals. A. Festa. E.P. 147,190, 7.7.20. Conv., 7.12.18.

In a reversible furnace fired with liquid fuel, the fuel is ignited (and partially distilled) on trays in a chamber at the end of the furnace. Air required for the combustion of the fuel, after passing through a hot regenerator, is conveyed through a flue close to the chamber containing the fuel trays, and meets the products of partial combustion after entering the furnace chamber.—C. A. K.

Solder for aluminium and other metals. P. A. Agostini. E.P. 156,665, 6.1.21. Conv., 5.1.20.

A solder particularly suitable for soldering aluminium to copper or to another piece of aluminium contains at least 50% of zinc, together with tin, copper, and aluminium, preferably in the proportions, 30—35% Sn, 1—2% Cu, 12—15% Al, and 50—53% Zn.—A. R. P.

Pre-leaching apparatus for use in the treatment of calcined ore and the like. E. C. Vigeon and J. McConway. E.P. 161,375, 6.2.20.

Dry ore or the like on its way from the roaster is sprinkled with a liquid while in a conveyor, preferably of the screw type.—B. M. V.

Tin scrap; Method of obtaining iron and tin from ——. P. A. Mackay. E.P. 161,654, 9.1.20.

Tin is removed from tin scrap, leaving bright iron, by immersing the scrap in diluted oleum, the concentration of free sulphur trioxide being maintained at about 10%. The temperature is preferably kept at 45°—50° C.—C. A. K.

Gold-separator; Electrochemical ——. H. P. Ewell. U.S.P. 1,374,370, 12.4.21. Appl., 7.11.18.

The apparatus consists of an amalgamating chamber into which the ore is continually fed by mechanical means and a second chamber in which liquid sodium amalgam is formed, and from which it is fed continuously into the amalgamating chamber. The whole charge passes from the latter to a shaking pan, where the amalgam is drained off from the tailings and passed to a device where it is treated to remove the excess of mercury from the gold amalgam. The recovered mercury is returned to the chamber in which the sodium amalgam is made.—A. R. P.

Ore; Process of treating ——. C. G. Collins, Assr. to C. A. Stevens. U.S.P. 1,374,434, 12.4.21. Appl., 13.1.20.

Ore is heated to expel, and treated so as to prevent the re-entry of, air and moisture. The ore is then concentrated.—C. A. K.

Treating liquids with gases; Apparatus for ——. Flotation apparatus. W. E. Greenawalt. U.S.P. (a) 1,374,445, (b) 1,374,446, (c) 1,374,447, (d) 1,374,499, and (e) 1,374,500, 12.4.21. Appl., (a) 4.11.19, (b) 16.10.19, (c) 26.5.16, (d) 27.12.15, and (e) 30.10.15. Renewed (b) 25.5.20, (c) 22.3.20, (e) 12.2.20.

(a) A tank is fitted with a rotary atomiser mounted on a vertical shaft. Liquid in the tank is caused to flow to the centre of the atomiser, and the gas and liquid are mixed and ejected together through outlet holes arranged radially in the atomiser. (b) Gas is passed through a hollow shaft and rotary atomiser into the liquid in the tank. (c) A vertical shaft suspended in a tank is provided with a number of perforated discs which rotate between similar fixed discs. Gas is introduced into the bottom of the tank and is atomised by rising through the series of discs. (d) A hollow member on a vertical shaft rotates in close proximity to stationary baffles, and an electric current is passed from the rotating to the fixed parts. (e) Gas may be passed through a hollow shaft and into a hollow rotating member under the liquid. The drum is provided with radial outlets for the gas.—C. A. K.

Electrolytic process [for copper deposition]. F. S. Woodward. U.S.P. 1,374,541, 12.4.21. Appl., 25.7.19.

Copper is deposited from an acid bath, using an insoluble anode, and in restoring the bath to normal strength the resulting increase of acidity only is neutralised.—J. S. G. T.

Pickling process. J. Coulson, Assr. to Westinghouse Electric and Mfg. Co. U.S.P. 1,374,552, 12.4.21. Appl., 8.10.17.

A ferrous metal is pickled by subjecting it to the action of an electric current in the presence of an electrolyte containing sulphuric acid, the polarity of the metal being reversed during the process.
—A. G.

Electromagnetic separator. Maschinenbauanstalt Humboldt. G.P. 330,641, 7.8.19.

The separator consists of two magnets one above the other, with a magnetic roller in between. The lower magnet, between which and the roller the material to be separated is passed, is provided with one or more openings beneath the middle of the roller, through which the non-magnetic material falls, while the magnetic part is carried over the far end of the lower magnet by the action of the roller.—A. R. P.

Zinc and tin; Process for electro-plating metals with ——. Deutsche Metallveredlungs-G.m.b.H. G.P. 305,583, 22.4.17.

By depositing zinc or tin from baths of 4°—5° B. (sp. gr. 1·03—1·04) with a low current density (not greater than 2·5 amps. per sq. dm. of cathode area), very thin, strongly adherent, firm coatings of metal may be obtained.—A. R. P.

Alloys containing graphite; Manufacture of ——. G. H. Wichmann. G.P. 332,914, 16.5.20.

The granulated alloy is given a coating of graphite and then cast or pressed into the required shape. The graphite remains evenly distributed throughout the metal, which is suitable for use in stuffing-boxes or bearings.—A. R. P.

Precious metals; Recovery of —— from sea-water. Siemens und Halske A.-G. G.P. 333,758, 17.8.18.

Sea-water is passed through absorption filters, preferably of fine-grained charcoal, which are cathodically polarised by the use of small currents of a few milliampères.—A. R. P.

Steel. P. MacGregor and A. Balfour. U.S.P. 1,375,255, 19.4.21. Appl., 18.9.18.

See E.P. 129,330 of 1917; J., 1919, 685 a.

Metals; Process of separating and refining ——. G. Haglund. U.S.P. 1,375,631, 19.4.21. Appl., 5.12.18.

See E.P. 121,591 of 1918; J., 1919, 908 a.

Blast furnaces, gas generators, and the like; Automatic charging apparatus for ——. Eisenwerk Jagstfeld Ges. E.P. 145,539, 22.6.20. Conv., 22.4.18.

Ore sintering mechanisms. R. J. Tugwood. From Dwight and Lloyd Metallurgical Co. E.P. 161,491, 7.8.20.

XI.—ELECTRO-CHEMISTRY.

Water; Electrolysis of ——, and an oxyhydrogen gas element. E. Baur. Helv. Chim. Acta, 1921, 4, 325—333.

With the object of storing seasonal water-power, the author has devised an apparatus by means of which fused aqueous sodium hydroxide is subjected to electrolysis, sheet-iron electrodes being employed. When the electrolysis is interrupted, the cathodes generate hydrogen and undergo corrosion, but this does not occur when the apparatus is at work. The purity of the hydrogen and oxygen formed is about 99% and the current yield over 90%. Only the hydrogen is stored and is used subsequently in conjunction with air in an element in which electric current is produced by the union of the hydrogen and oxygen in contact with fused sodium hydroxide, iron electrodes in the form of grids being employed. —T. H. P.

XII.—FATS ; OILS ; WAXES.

Kapok seed ; Indian —— as a source of oil. Bull. Imp. Inst., 1920, 18, 335—337.

Indian kapok (*Bombax malabaricum*) yielded on extraction with petroleum ether 22·3% of a bright yellow oil, which deposited a quantity of "stearin" on standing, and had $n_D^{40}=1·461$. The yield of oil is higher than that generally obtained from other kapok seed, and the oil appears to be of better quality. The material left after the extraction of the oil contains about 36% of crude proteins. —J. C. K.

Oil from Cynara cardunculus. E. H. Ducloux. Anal. Soc. Quim. Argentina, 1920, 8, 410—412.

The oil extracted from the seeds of the "donkey thistle" (*Cynara cardunculus*), a troublesome weed in South America, is deep yellow in colour, tasteless, and aromatic in odour. It has sp. gr. 0·9213 at 15° C.; $n_D^{20}=1·4729$; $n_D^{15}=1·4712$; iodine value, 103·5; saponif. value, 197·4; insoluble fatty acids, 95·6%; acid value, 39·8; solidif. pt. of fatty acids 29° C. Its properties are similar in many respects to those of cottonseed oil.—G. W. R.

Acetyl value of fatty substances; Determination of the ——. É. André. Comptes rend., 1921, 172, 984—986.

The saponification value of the material is determined before and after acetylation. These values being S and S_1 respectively, then the acetyl value equals $S_1-S[1+\lambda S/(1-\lambda S)]$, where $\lambda=0·75$. The values obtained by this method are always slightly lower than those obtained by the method of Lewkowitsch (*cf.* J., 1890, 660; 1897, 503).—W. G.

Decolorising agents for the fat industries. J. Zifferer. Oel- u. Fettind., 1920, 2, 63—64, 87—88, 112—113, 134, 160, 183—184. Chem. Zentr., 1921, **92**, II., 861—862.

The only suitable carbons are those made from materials which do not fuse on charring; hence proteins, glue, etc. give the best products when carbonised with potassium carbonate or sodium potassium carbonate. Carbons containing nitrogen are more active than those containing none. In diminishing order of activity the chief carbons are: animal charcoal from ferrocyanide residues, blood charcoal, bone charcoal, glue charcoal, soot, wood charcoal, and sugar charcoal. Nodules of the size of peas should be used for aqueous solutions, but for oils finely ground carbon is best. For the fat industry bone char is of much less importance than charcoal from ferrocyanide manufacture; the latter cannot be revivified. Florida fuller's earth (*floridin*) is active in the air-dry state at 18° C., but more so at 120° C. or when dehydrated at 300°—400° C. The oil is treated with 2—5% and warmed. The earth can be revivified by various methods, but it recovers only two-thirds of its original activity. Salad oils decolorised by silicates often have a slight rancid flavour, and for this reason sodium bicarbonate is frequently added. An earthy flavour is eliminated by washing with 10% brine.—J. H. L.

Oxidised fatty acids in olive oils obtained by extraction with carbon bisulphide; Determination of ——. F. Goldschmidt and G. Weiss. Seifenfabr., 1920, **40**, 649. Chem. Zentr., 1921, **92**, II., 815—816.

Contrary to Stadlinger's results (J., 1920, 663 A), the authors obtained practically the same values for the oxidised fatty acids in three samples of olive oil high in oxidised acids obtained by extraction with carbon bisulphide, when using different samples of petroleum spirit, including one containing 4% of xylol.—A. de W.

Fats; Influence of light on animal and vegetable ——. H. Much and H. Schmidt. Z. Immunitätsforsch. Exp. Ther., 1920, 31, 169—200. Chem. Zentr., 1921, **92**, I., 645.

The colour of animal and vegetable fats is destroyed by the combined action of light and oxygen; light of short wave-length has the most effect. If the ats are dissolved in solvents, the effect of light is east in an ethereal solution and greatest in a carbon tetrachloride solution. It is possible that the colour of animal fats is derived from carotinike substances present in the food of the animals. —W. P. S.

$_{18}$ *fatty acids. I. Non-identity of elæostearic acid tetrabromide from tung oil with ordinary linolic acid tetrabromide.* B. H. Nicolet. J. Amer. Chem. Soc., 1921, 43, 938—940.

Contrary to the views of Kametaka (J., 1903, 138), it is shown that the tetrabromide obtained rom α-elæostearic acid isolated from tung oil is not dentical with linolic acid tetrabromide. It is dentical with β-elæostearic acid tetrabromide Morrell, J., 1912, 1189). (*Cf.* J.C.S., June.) —W. G.

Hydrogenation of oils; New catalyst for ——. G. Grote. Seifensieder-Zeit., 1920, 47, 713—714. Chem. Zentr., 1921, 92, II., 812.

A catalyst, with which the time of hydrogenation can be reduced to 10—15 mins. and the temperaure to 160° C., is prepared by treating an aqueous olution of a nickel salt with a solution of a magesium or aluminium salt so as to obtain a coloidal precipitate (double silicate) containing the whole of the nickel and magnesium or aluminium. The voluminous gelatinous precipitate is washed, dried, powdered, and heated in a stream of hydrogen, and the dark-grey reduction product stored in il.—A. de W.

Beeswax; Detection of very small quantities of —— *in admixture with mineral oil and colophony.* A. Jolles. Oel- u. Fettind., 1920, 2, 207, 231—232. Chem. Zentr., 1921, 92, II., 862.

Comparative experiments were made with mixtures f which one contained 70% of colophony and 30% f mineral oil and the other 67% of colophony, 30% f mineral oil, and 3% of yellow beeswax. The aponification values of the original mixtures proved useless for the detection of beeswax. By extraction with cold 70% alcohol, however, the olophony was removed, and the residue in the ase of the wax-free mixture gave saponification and acid values of practically 0, whilst in the other case he saponification value was 8·41, the acid value ·70, and the Hübl iodine value 3·94, the calculated alues being 8·46, 1·80, and 3·67 respectively. It was found possible to separate the wax from the mineral oil by means of petroleum ether, in which he former is insoluble.—J. H. L.

Carnauba wax palm; Utilisation of the ——. C. Grimme. Pharm. Zentralh., 1921, 62, 249—257.

The S. American carnauba wax palm (*Copernicia erifera* Mart.) yields an edible fruit containing about 10% of oil, the greater part of which is found n the seeds; the roots of the tree are stated to have ertain medicinal properties, the trunk consists of a very hard wood, and the leaves are useful for a variety of purposes (thatching, paper-making, hread making, etc.). The young green leaves are edible, and from them exudes the well-known carnauba wax.—W. P. S.

Hydrogenated phenols and their use in the soap industry. W. Schrauth. Seifenfabr., 1921, 41, 129—132. Chem. Zentr., 1921, 92, II., 814.

The mixture of cyclohexanol and the three isomeric methylcyclohexanols, known under the trade name of "hexalin," is used as a substitute for castor oil products hitherto used in technical soaps. In spite f its small solubility in water and its oily nature, hexalin yields clear permanent solutions with aqueous soaps, even when present in an amount substantially in excess of the soap. A suitable mixture consists of oleic acid, 500 kg., alkaline lye (50° B., sp. gr. 1·53) 200 kg., hexalin 600 kg., water 400 kg. Special advantages are claimed for hexalin soap mixtures in wool-scouring, chemical cleaning, emulsification, and in the preparation of cutting oils, shoe creams, plant sprays, etc.—A. de W.

Glycerin; Viscosity of distilled ——. J. Kellner. Z. deuts. Oel- u. Fettind., 1920, 40, 677—678. Chem. Zentr., 1921, 92, II., 834.

The viscosity of a crude glycerin distillate, with an ash content of 0·001% and sp. gr. 1·24 at 15° C., was reduced by the refining process from 35·5° Engler to only 16·75° at 24° C. The latter value corresponds with an almost chemically pure glycerin, according to tables given in the paper. Viscosity measurement is recommended therefore as a valuable test of the purity of glycerin.—B. V. S.

Wax-colophony mixtures. Jahn. *See* XIII.

Patents.

Oils and fats; Process of refining ——. K. Stiansen. E.P. 141,028, 9.3.20. Conv., 21.3.19.

Oil, *e.g.*, whale or herring oil, is agitated at 40°—50° C. with about 5% of its weight of powdered, calcined apatite or other mineral phosphate, and is subsequently allowed to stand at the same temperature, whereby the apatite settles to the bottom together with impurities present in the oil. Solid fats are treated at a temperature sufficiently high to render them fluid.—L. A. C.

Animal and vegetable oils; Refining and decolorising ——. A. S. Quick. E.P. 161,813, 20.3.20.

To every 20 galls. of the oil an equal quantity of water and 10 lb. of monazite sand or other radioactive material are added, the mixture is heated to a temperature below that at which it is chemically altered, *e.g.*, about 120° F. (49° C.), and stirred continuously for about 6 hrs., allowed to settle, and the oil separated.—A. de W.

Fatty acids and glycerides thereof; Process of treating [dehydrogenating] ——. H. A. Levey. U.S.P. 1,374,589, 12.4.21. Appl., 19.9.16.

Fatty oils are dehydrogenated by subjecting them to the action of a gas when mixed with catalytic material at a temperature in excess of that at which hydrogenation is effected under the same conditions by passage of hydrogen.—A. de W.

Sulphated oil. F. L. Randel. U.S.P. 1,374,607, 12.4.21. Appl., 11.12.19.

A fatty or oily material is mixed with sulphuric acid *in vacuo*.—A. de W.

Fats; Apparatus for the extraction of —— *from moist, granular, or powdery materials.* A. Lorenz. G.P. (a) 333,492 and (b) 333,493, 25.7.17.

(a) The cover of the extraction vessel slopes steeply from one side to the other and is pierced in the centre by the shaft of the agitator. The solvent containing the fats is withdrawn through the highest part of the cover, and the outlet is fixed on one side of the agitator, which is driven from the top. The pulley is attached on the low side of the cover. (b) The closed extraction vessel has a perforated bottom, beneath which the solvent is admitted. At the side of the vessel a box is attached containing a group of valves, arranged one above another, each of them being preceded by a filter. The valves are connected with the outlet, allowing the solvent to be withdrawn from the vessel, after the extraction is completed, without coming in contact with the atmosphere.—C. A. C.

Glycerin; Process for purifying ——. Elektro-Osmose A.-G. (Graf Schwerin Ges.). E.P. 146,865, 5.7.20. Conv., 17.1.19.

Crude glycerin is freed from electrically-active impurities, *e.g.*, inorganic salts, fatty acids, soaps, fat, protein, colouring matters, and the like, largely present in the colloidal state, by electro-osmosis, using diaphragms of marked electric potential and carrying a suitable charge to induce passage of the impurities through the diaphragms. Thus, crude glycerin is freed from accompanying acid (negatively charged) impurities by subjecting it, preferably at raised temperature, to an electric current when contained in the cathode chamber of a cell divided into two compartments by a positive diaphragm, such as leather, the acid impurities migrating to the anode chamber which contains water. Similarly, basic impurities migrate to the water contained in the cathode chamber of a cell divided into two compartments by a vegetable (viscose or parchment paper) diaphragm, when the crude glycerin is contained in the anode chamber. The crude glycerin may also be contained in the middle chamber of a three-part cell, the two separating diaphragms of which may be either of negative or of a positive character, or that bounding the cathode chamber of negative or indifferent character, while that bounding the anode chamber is of positive character, the electrodes being in the side cells which contain water.—A. de W.

Oil; Process for extraction and refining of ——. P. M. Heyerdahl. E.P. 137,514, 6.12.19. Conv., 9.1.19.

See U.S.P. 1,368,148 of 1921; J., 1921, 227 A.

Soaps; Deodorisation of ——. C. Stiepel. E.P. 145,502, 21.6.20. Conv., 10.8.16.

See G.P. 305,702 of 1916; J., 1918, 476 A.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Smalt; Constitution of ——. A. Duboin. Comptes rend., 1921, **172**, 972—974.

Using the method previously described (*cf.* Comptes rend., 1892, **114**, 1361) the author has produced two blue cobalt compounds of the type of smalt. One has the constitution K_2O, CoO, $3SiO_2$, and the other KCl,K_2O,CoO,$4SiO_2$.—W. G.

Turpentine; Composition of French ——. M. Vèzes. Comptes rend., 1921, **172**, 977—980.

The results obtained by the polarimetric method of Darmois (Thesis, Paris, 1911) for the estimation of the relative amounts of pinene and nopinene present in French turpentines can only be considered as first approximations. Further work is necessary to elucidate the discrepancies found. —W. G.

Turpentine oil; Determination of petroleum spirit in ——. J. Marcusson. Chem.-Zeit., 1921, **45**, 418.

Replying to recent criticism by Salvaterra (J., 1921, 186 A), the author maintains the accuracy of a method described previously by himself (J., 1912, 441) and depending on the conversion of the turpentine oil into soluble oxidation products by means of fuming nitric acid.—W. P. S.

Phenols of low-temperature coal tar [; *Resins from* ——]. W. Gluud and P. K. Breuer. Ges. Abhandl. Kennt. Kohle, 1919, **4**, 221—236. Chem. Zentr., 1921, **92**, II., 855—856.

An investigation was carried out to determine what proportion of the total phenols in low-temperature coal tar could be utilised in the production of "bakelite" and "novolac" by condensation with formaldehyde. The action of the latter in the presence of ammonium chloride as catalyst was tested on the following products: Crude tar from which the most viscous compounds had been removed, the fractions distilling between 150° and 250° C. and between 250° and 300° C., including the hydrocarbons that distil at these temperatures, the cresol fraction, and the phenols obtained from the lubricating oil and resinous fractions. The hydrocarbons present did not interfere with the reactions and could readily be removed from the products, which were solid, brittle resins having the properties of the "novolacs." Condensation of a crude tar-cresol mixture with benzaldehyde and paraldehyde yielded viscous semi-solid products which could be changed into solid resins by heating under pressure. The colour of the resins varied, according to the material from which they were produced, from light yellow to dark brown, and they could be made less brittle by leaving behind in the final product a certain amount of the hydrocarbons originally present in the raw material. Bakelites A (soluble), B (fusible), and C (infusible) were prepared by condensation in the presence of a basic catalyst such as ammonia, but variety A can only be made from the whole of the phenol fraction of the crude tar or from the whole of the crude tar itself. The bakelites are clear solid substances varying in colour from light yellow to very dark brown, and the A variety yields good varnishes in 50% alcoholic solution. Variety C may be made from A by the use of benzylamine as a catalyst, or it may be produced directly from the phenol fraction boiling below 230° C. or from that boiling between 230° and 260° C. if soda is used as a catalyst. —A. R. P.

Lead compounds of phenols; Use of —— [*in paints*]. F. Fischer and V. Ehrhardt. Ges. Abhandl. Kennt. Kohle, 1919, **4**, 264—279. Chem. Zentr., 1920, **92**, II., 854.

Lead oxide combines with phenol, cresol, *p*-hydroxydiphenyl, and naphthols in benzene solution to give products which are not very satisfactory as paints. If, however, instead of the pure phenols the crude phenol-rich fraction (middle oil) of low-temperature tar or coke-oven tar is used, the product is a useful paint for protecting iron-work from rust. The difference in the two products is ascribed to the action of the resinous substances produced from the easily oxidisable hydrocarbons in the crude oils by the action of the lead oxide. Oxidation of the crude tar oils and distillation with potassium permanganate or nitric acid yields varnish-like substances.—A. R. P.

Wax and colophony; Supersaturated solid solutions of ——. G. Jahn. Kolloid-Chem. Beih., 1921, **13**, 213—232.

Mixtures of beeswax and colophony can be divided into liquid mixtures, solid solutions, and mixtures in which solid solutions are in equilibrium with pure wax. Mixtures containing up to 75% of colophony can form solid solutions, and on melting and rapidly cooling, supersaturated solutions are formed which are more stable the longer the mixture has been kept in the liquid condition. (*Cf.* J. C. S., June.)—J. F. S.

Protection of iron. Friend. *See* X.

Patents.

Resin-like bodies; Production of ——. M. Melamid. E.P. (a) 133,712 and (b) 133,713, 11.10.19. Conv., 4.2.18.

(a) Resin-like substances are obtained by treating aromatic sulphochlorides with salts of resinic, humic, or lignoceric acids; *e.g.*, to a solution of 120 kg. of sodium colophonate in 100—200 kg. of water is added 100 kg. of α- or β-naphthalenesulphochloride with stirring, the solution being heated to 30° C. for 12 hrs. The liquid is allowed to cool, and the solid product separated by decantation or filtration, and dissolved for the purpose of purification in an organic solvent, *e.g.*, benzol, which is then evaporated off. (b) The resinates or the like are replaced by soft coal-tar pitch, anthracene oil distillates obtained in the production of hard pitch therefrom, or the alkali-soluble phenolic portion of soft pitch or anthracene oil, in the presence of alkali; *e.g.*, 100 kg. of soft pitch containing 20% of alkali-soluble matter, is heated with sufficient caustic soda lye to neutralise the acidity, allowed to cool while stirring constantly, and about 24 kg. of *o*- or *p*-toluenesulphochloride (or a commercial mixture of the same) in benzol added. After stirring for 12 hrs., the benzol solution is separated from the aqueous layer, washed with water until neutral, dried over, *e.g.*, calcium chloride, and the solvent distilled off *in vacuo*.—A. de W.

Anti-corrosive paint or composition. C. H. Ivinson and G. S. Roberts. E.P. 161,201, 12.7.19.

To a solution of asphaltum in a volatile solvent, *e.g.*, 6 lb. to 0·75 gall. of benzol or petrol, is added 2—5% of a solution of rubber in benzol or other solvent, of a strength of, *e.g.*, 2 oz. to 40 oz. of solvent; preferably a similar amount of a solution of 1 oz. of gum elemi in 2—6 oz. of solvent is also added. The mixture is treated with 1—4% of sulphur, sulphur monochloride, or sulphides such as antimony sulphide, and vulcanised by heating to about 95° F. (35° C.) for about 30 mins. The composition, when cooled, is ready for use, or suitable filling agents such as silica, asbestos, graphite or the like may be added. Metallic stearates, palmitates, oleates, or resinates dissolved in a volatile solvent may be employed in place of the solution of gum elemi. Alternatively, 0·5—1% of sulphur or a suitable sulphide may be added direct to the molten mixture of asphaltum and rubber, the vulcanised composition being then dissolved in a hot solvent.—A. de W.

Pigments; Process of making ——. L. R. Baker. E.P. 161,280, 6.1.20.

A solution of commercial zinc sulphate is heated by live steam and blown with compressed air, during which time about 1% by wt. of an alkaline-earth peroxide, *e.g.*, calcium or barium peroxide, and powdered zinc or lead oxide are added. After filter-pressing to remove precipitated iron oxide, the filtrate containing hydrated zinc oxide in suspension is again treated with steam and compressed air, and subjected to another filter-pressing operation. The filtrate is then mixed with a solution of barium sulphide in equivalent amount, the resulting precipitate being filter-pressed, washed, dried, calcined, etc.—A. de W.

Strontium and barium sulphates; Method of obtaining —— *from native sulphates.* P. A. Mackay. E.P. 161,655, 9.1.20.

Native strontium or barium sulphate ground to pass a 200-mesh sieve is dissolved in oleum and reprecipitated by dilution. The resulting *blanc-fixe* is superior in colour and fineness to that prepared by grinding and levigation.—C. I.

Coating composition and process of producing same. W. Alexander and J. E. Clegg. U.S.P. 1,358,914, 16.11.20. Appl., 25.9.17.

A liquid coating composition is composed of a cellulose ester (pyroxylin, celluloid) and a boron compound (dehydrated boric acid) dissolved in a common solvent, *e.g.*, methyl ethyl ketone, which is saturated with the boron compound.

Finely-divided material [carbon black]; Process of cleansing ——. J. C. Morrell. U.S.P. 1,359,091, 16.11.20. Appl., 22.3.19.

Volatile impurities, *e.g.*, adsorbed hydrocarbon oils, are removed from carbon black by heating it to 450°—600° C. in an iron crucible having a perforated false bottom and treating it with superheated steam introduced beneath the false bottom. The process is applicable to the purification of other finely divided materials, *e.g.*, kieselguhr.

Phenolic condensation product; Process of producing a ——. L. V. Redman, A. J. Weith, and F. P. Brock, Assrs. to Redmanol Chemical Products Co. U.S.P. 1,374,526, 12.4.21. Appl., 16.9.18.

Equal parts of 40% formaldehyde and phenol are boiled together in the absence of a catalyst until a viscous gummy lower layer and a supernatant aqueous layer containing approximately 10% of formaldehyde are formed. The aqueous layer is discarded and the mass shaped and subjected to a prolonged heat treatment below 100° C. until it becomes hard, substantially insoluble, and anhydrous throughout. The mass is then subjected to further heat treatment at a temperature exceeding 100° C. for a relatively short period.—A. de W.

Pitch, colophony, shellac, etc.; Process and apparatus for comminuting materials such as ——. R. Behr. G.P. 333,704, 13.2.18.

A stream of the hot liquefied material is conducted over heated distributing plates or discs from which it flows in very fine threads; the latter are cooled and solidified by falling through the air or by passing through an artificially cooled space. —J. H. L.

Siccatives and binding agents for lacquers and paints. P. Friesenhahn. G.P. 334,761, 25.7.19.

Metallic resinates or linoleates are dissolved in hydrogenised phenols, such as the cyclohexanols or their esters, or in cyclohexanone and its homologues, with or without the aid of other solvents. Solutions of resinates of aluminium, tin, zinc, manganese, and cobalt in cyclohexanyl formate constitute excellent siccatives. The solutions, with or without linseed oil or linseed oil varnish, can be used as vehicles in paints.—J. H. L.

Soot-carbon. E.P. 137,065. *See* IIa.

Lakes. E.P. 143,242. *See* VI.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Hevea rubber; Use of brackish water in the preparation of ——. W. Spoon. Comm. Central Rubber Stat., Buitenzorg, 1921, No. 25, 1—15.

On account of the more thorough washing to which it has been subjected, crêpe rubber is less affected than sheet rubber by the use of brackish water, *e.g.*, tidal river water, for the dilution of the latex. The presence of 12% of sea water in the brackish water is sufficient to produce an appreciable effect on sheet rubber, whereas in the production of crêpe rubber the limiting proportion is about 28%. —D. F. T.

Rubber; Changes in plantation —— after storage. O. de Vries. Comm. Central Rubber Stat., Buitenzorg, 1921, No. 25, 16—28.

STORAGE for 2—4 years in cupboards does not adversely affect the quality of first-grade rubber, and the tensile strength and slope remain unaltered; the rate of vulcanisation generally shows a small increase, but the viscosity frequently decreases considerably. Lower grades of rubber sometimes undergo marked deterioration on storage. Crêpe from "matured" rubber behaved similarly to first-quality crêpe, except that its rate of vulcanisation decreased. Storage therefore tends to lessen the variability in the rate of vulcanisation of plantation rubber.—D. F. T.

PATENTS.

Vulcanisation of rubber. G. Bruni. E.P. 140,387, 4.3.20. Conv., 15.3.19.

IN the presence of a salt of a divalent or trivalent metal with a dithiocarbamic acid derived from a primary or secondary aliphatic amine, *e.g.*, zinc pentamethylenedithiocarbamate, vulcanisation can be effected with as little as from 0·2 to 2% of sulphur.—D. F. T.

India-rubber products; Manufacture of ——. A. Helbronner. E.P. 142,083, 11.2.20. Conv., 19.4.19.

SURFACE resinification in rubber goods vulcanised in an atmosphere of hot air can be avoided by incorporating a reducing agent, such as quinol, pyrogallol, tannins and derivatives, *p*-aminophenol, formaldehyde derivatives, sulphites, or hydrosulphites. Litharge is commonly used for a similar purpose, but causes the development of a black colour which is avoided with the preceding substances.—D. F. T.

Rubber products; Manufacture of ——. H. Wade. From Goodyear Tire and Rubber Co. E.P. (A) 161,482 and (B) 161,483, 6.7.20.

(A) AIR-DRIED glue (containing 5—15% of moisture) is introduced into rubber by subjecting a mixture of it with unworked rubber to a milling action in a jacketed container; heat is developed, and the temperature is maintained below 300° F. (about 150° C.) by external cooling. After this operation the cooled mixture needs no further drying, and the remaining compounding ingredients are incorporated in the usual manner. (B) Instead of introducing fine powders, such as carbon black, directly into rubber, the powder is first mixed uniformly into an emulsion of an aqueous jelly or solution of glue with benzene; this mixture is then incorporated into rubber in the usual manner. —D. F. T.

Rubber, ebonite, vulcanite, and the like substances; Reforming or vulcanisation of ——. H. Gare. E.P. 161,648, 9.1.20.

THE heating necessary for the vulcanisation of rubber or the "reforming" of old vulcanised rubber is effected by a hot circulating solution of which the b.p. is a little above the necessary temperature. A solution of calcium chloride in water is convenient, the proportions for a vulcanising temperature being 3½ lb.:1¼ pints (b.p. 270° F., 132° C.), and for reforming, 6lb.:1½ pints (310° F., 151° C.).—D. F. T.

Rubber; Manufacture of products resembling ——. Badische Anilin und Soda Fabrik. G.P. 329,676, 4.5.18.

THE polymerisation of butadiene and its homologues is considerably expedited by the addition of the polymerisation products obtained in the manner described earlier (F.P. 459,005 of 1913, and Addition thereto; J., 1913, 1161).—D. F. T.

Rubber; Process of treating ——. J. Porzel, Assr. to Superior Rubber Co. U.S.P. 1,374,231, 12.4.21. Appl., 7.8.18. Renewed 9.10.20.

SEE E.P. 124,887 of 1918; J., 1919, 379 A. Oxygen is excluded during the mixing operation.

Rubber and the like; Methods of and apparatus for mixing or masticating ——. Farrel Foundry and Machine Co., Assees. of D. R. Bowen and C. F. Schnuck. E.P. 137,820 and 158,279, 9.1.20. Conv., 13.1.19.

XV.—LEATHER; BONE; HORN; GLUE.

PATENTS.

Tanning or impregnating materials; Process for ——. Elektro-Osmose A.-G. (Graf Schwerin Ges.). E.P. 143,921, 28.5.20. Conv., 30.11.18.

AFTER a preliminary tannage or impregnation by the electro-osmotic process described in E.P. 19,849 of 1914 (J., 1915, 1020) the hides or skins are completely tanned or impregnated in pits or casks without the aid of an electric current and preferably in strong liquors.—D. W.

Catechin and catechutannic acid; Manufacture of ——. E. H. Bray. From Indian Wood Products Co. E.P. 161,431, 24.3.20.

WOOD of the *Acacia catechu*, *A. sendra*, etc., is disintegrated and heated with water, preferably in closed vessels with a steam pressure up to 30 lb. per sq. in. The extract is evaporated, preferably under reduced pressure, to a sp. gr. of 1·05—1·10, when catechin separates on cooling. On further evaporation under reduced pressure the mother liquors yield catechutannic acid.—D. F. T.

Leather substitute; Process for preparation of a ——. G. Ruth and E. Asser. G.P. 332,866, 13.6.19.

CELLULOSE esters, alone or mixed with esters of naphthenic acids, are incorporated with insoluble metallic naphthenates, such as the aluminium, chromium, iron, and cobalt salts, particularly the aluminium-magnesium salt, and the mixture is treated in the usual way with loading material. —B. V. S.

Hides; Process for tanning —— by means of ferric salts. Chem. Fabr. vorm. Weiler-ter Meer. G.P. 334,004, 27.2.16.

IN the treatment of hides with solutions of ferric salts the formation of basic salts is avoided by the addition of an acid, such as formic acid, to increase the hydrogen ion concentration, or by employing double ferric ammonium salts, which do not readily hydrolyse, or by adding chromium salts which retard hydrolysis of the iron salts. By this means the hides may be rapidly and uniformly permeated by the iron solution. They are subsequently treated with a neutralising agent, such as sodium carbonate, to increase their durability. Good results are also produced by adding oxidation or decomposition products of glucose or other sugars, such as those obtained by treatment with chromium oxide or chromates, or by addition of vegetable tanning agents, to the solution of iron salts.—W. J. W.

Colouring of natural horn; Process for making the —— water-resisting. M. Lambeck. E.P. 154,200, 22.11.20. Conv., 26.9.19.

ARTICLES of natural horn are exposed either before or after polishing to the action of formaldehyde, its polymers, or substances capable of yielding formaldehyde.—D. W.

ixing or agitating lime in tannery pits; Apparatus for ——. F. J. Boys. E.P. 161,362, 28.1.20.

ron salt for tanning. E.P. 146,214. *See* VII.

XVI.—SOILS; FERTILISERS.

oils; Amount of unfree water in —— *at different moisture contents.* G. Bouyoucos. Soil Sci., 1921, **11**, 255—259.

URTHER experimental evidence is given in support f the view that the amount of water which soils re able to render unfree (*cf.* J., 1921, 231 A) does ot vary with the different moisture contents of the oils, but appears to remain constant. This is conrary to the mathematical deductions of Keen (*cf.* ., 1919, 956 A).—W. G.

oil; Lime requirement and reaction of lime materials with ——. C. J. Schollenberger. Soil Sci., 1921, **11**, 261—276.

XPERIMENTS were carried out with a nearly pure mestone of high calcium content, in five degrees f fineness, with calcite, magnesite, and dolomite, round to pass a 100-mesh sieve, with chemically repared oxides and carbonates of calcium and magesium, and with two slags, one a dicalcium silicate nd the other a blast-furnace slag. These materials ere mixed with soil in undrained pots kept at a uitable moisture content and without a crop. The mestone, calcite, and magnesite were similar in ehaviour, approximately one half of an application quivalent to 3·1 tons per acre being attacked in weeks and two-thirds in 28 weeks. The dolomite as 50% more resistant than the other materials. uicklime is more reactive than the precipitated arbonate, although the differences become less arked with time. Chemically prepared magnesium xide gradually became carbonated, but on the ther hand the disappearance of carbonate from an quivalent application of prepared magnesium arbonate was complete within one month. The icalcium silicate slag reacted with soil as readily s precipitated calcium carbonate, but blast-furnace lag was the least reactive of all the materials ested. Fineness of grinding is of importance, oarsely ground limestone being far less reactive han finely ground limestone. The quantitative elations between bases not residual as carbonate nd reductions in lime requirement were found to e reasonably close, a possible consumption of bases y nitrification being considered. Possible sources f error in determining lime requirements, such as nanner of preparation of the sample, the temperaure, and the time allowed for the determination re considered.—W. G.

oil; Comparison of the technique recommended by various authors for quantitative bacteriological analysis of ——. Z. N. Wyant. Soil Sci., 1921, **11**, 295—303.

HE author recommends the following procedure for he quantitative bacteriological examination of soils. Not less than 10 g. of soil should be used in naking the first dilution, which should be not less han 1:10. The weighed soil, 10 g., should be laced in a graduated flask and sufficient of the iluting liquid added to make up the volume to 00 c.c. If the soil contains a considerable amount f organic matter, it should be triturated in a nortar with a little of the diluting liquid. In makng further dilutions or plating, an aliquot portion f the soil must be transferred and subsequent diluions may well be 1:10. Numbers of micro-organsms (total or otherwise) should be estimated on the asis of soil dried to a constant weight at 100° C. —W. G.

Soils; Analysis of ——. K. A. Vesterberg. Svensk Kem. Tidskr., 1921, **33**, 12—22. Chem. Zentr., 1921, **92**, I., 752.

THE author questions statements to the effect that salts dissolved in the moisture in soils are absorbed by plants at the same rate as the water itself; the roots do not take up the salts etc. in the proportion in which they occur in the soil. As regards the concentration of plant foods in soil moisture which constitutes the minimum requirement of plants, the following quantities are suggested:—P_2O_5, 1—2; nitrogen, 2—5; K_2O, 10—20 mg. per litre. Climate would possibly have some effect on the efficiency of these amounts of foods.—W. P. S.

Soil fumigation experiments with p-dichlorobenzene for the control of the peach-tree borer, Sanninoidea exitiosa, Say. A. Peterson. Soil Sci., 1921, **11**, 305—319.

p-DICHLOROBENZENE gave satisfactory results when used as an insecticide for the control of the peach-tree borer. One ounce of the material is applied to the soil in a circular band round the tree and 2 in. from it, on a level with the highest point where gum is exuding from the tree, which is earthed up if necessary. The *p*-dichlorobenzene is then covered with soil which is packed down. This treatment it is claimed will kill 90—100% of the borers if the soil temperature is 55°—60° F. (13°—15·5° C.) or higher and the soil is not too wet. —W. G.

[Plant] growth and sap concentration. H. S. Reed. J. Agric. Res., 1921, **21**, 81—98.

OBSERVATIONS on apricot and orange trees show that growth and sap concentration tend to vary in opposite directions. As the season advances there is a gradual increase in sap concentration, this increase being noticeable for some time after active growth has ceased. Of the environmental factors examined, soil moisture was the only one having an obvious effect upon sap concentration, increase in soil moisture causing a diminution in the concentration of the plant sap. Lower concentrations of plant sap in the shoot as a whole appear to be associated with abundant water intake and rapid vegetative growth, higher concentrations with slow growth and fruit-bud formation.—W. G.

Nitrogen-fixing organism; Influence of uranium salts on a ——. E. Kayser. Comptes rend., 1921, **172**, 1133—1134.

THE influence of uranium salts on *Azotobacter agile* depends upon the nature of the salt used, its concentration, and the colour of the containing vessel. Uranium acetate gave an increased fixation of nitrogen and better utilisation of sugar at certain concentrations, but uranium phosphate in every case gave less satisfactory results than the control. —W. G.

Seeds; Effect of salt solutions having definite osmotic concentration values upon absorption by ——. W. Rudolfs. Soil Sci., 1921, **11**, 277—293.

SINGLE salt solutions of calcium nitrate, potassium carbonate, magnesium sulphate, potassium phosphate, sodium chloride, potassium chloride, and sodium nitrate, and one of Shive's three salt solutions R_5C_2 (*cf.* Shive and Martin, J., 1918, 598 A) were used, the osmotic concentration values of the solutions varying from 0·001 to 7·0 atm. The amounts of absorption from these solutions by different varieties of seeds were determined. The results indicate a marked variation in the absorbing power of seeds of different species, leguminous seeds showing the highest rate of absorption of the seeds examined. The rates of absorption are progressively retarded by increase in osmotic concentration values of the solutions, provided there is no chemical action on the seed coating, there being an approximately linear relation between these two factors. The retardation of absorption rates is apparently due to osmotic resistance offered to the entrance of water into the seed.—W. G.

Patents.

Phosphates; Manufacture of assimilable ——. J. J. Morel. E.P. 160,847, 14.8.20.

Mineral phosphates, consisting of mixtures of tricalcium phosphate and calcium carbonate, are treated in a rotary furnace at 1000° C. with a continuous current of sulphurous gas, air, and steam, the proportions being such as to give a mixture of mono- and dicalcium phosphate and calcium sulphate. The production of these phosphates is facilitated by adding about 1% of a chloride, *e.g.*, calcium chloride, to the phosphatic material. —W. J. W.

Organic matter; Treatment of —— *for fertiliser purposes.* A. J. Grinnell. E.P. 136,829, 16.12.19. Conv., 27.4.17.

See U.S.P. 1,268,563 of 1918; J., 1918, 522 a.

XVII.—SUGARS; STARCHES; GUMS.

[Sugar] juices which cannot be satisfactorily defecated. C. Muller. Bull. Assoc. Chim. Sucr., 1921, **20**, 239—247.

Difficulties in the defecation of juices from canes damaged by heat or frost are due to the presence of abnormal amounts of acetates and other organic salts which cannot be eliminated. As palliative measures the author recommends carbonatation of the juice from the third and fourth crushings, sulphitation of the juice after decantation, and perhaps imbibition with cold water. Cases occur also in which juices from sound canes resist defecation even by large amounts of lime. These are attributed by the author to the presence, in certain canes, of colloidal compounds containing organic and silicious matter not precipitable by lime, which are liberated from the cells ruptured by crushing. Sulphitation is no remedy, but the colloidal matters may be destroyed by superheating the juice at about 116° C. before liming; the organic matter is thereby coagulated and the silica is rendered precipitable by lime. The colour of the juice is also improved, defecation can be effected with about ⅓ of the usual amount of lime, and sulphitation is often unnecessary or it may be postponed to a later stage, *e.g.*, that of syrup.—J. H. L.

Honey; Valuation of artificial ——. V. Stanek and J. Vondrak. Z. Zuckerind. Czecho-Slov., 1921, **45**, 203—205.

For the determination of dry substance in artificial honey the authors recommend either the refractometric method, applied to the undiluted material, previously warmed if necessary to dissolve crystals, or the following saccharometric method:—The sp. gr. of a mixture of the sample with an equal weight of water, in degrees Balling, is corrected for temperature if necessary and then multiplied by 2, and from the product 0·7° is subtracted to allow for the effect of contraction on dilution. Both methods give results accurate to about 0·1%. —J. H. L.

Polysaccharides. VII. Constitution of cellobiose. P. Karrer and F. Widmer. Helv. Chim. Acta, 1921, **4**, 295—297.

Hydrolysis of heptamethyl-β-methylcelloside (J., 1921, 342 a) by 5% hydrochloric acid yields tetra- and tri-methylglucoses, and since heptamethyl-β-methylcelloside is obtained by methylation of cellobiose, the latter must, in accordance with the formulæ for tri- and tetra-methylglucoses, be 5-β-*d*-glucoside-*d*-glucose. This constitution has been given also by Haworth and Hirst (J., 1921, 234 a), but the heptamethyl-β-methylcelloside used by these authors contained an admixture of heptamethyl-α-methylcelloside.—T. H. P.

Starch; Gelatinisation of —— *in cold water in presence of alkalis or neutral salts.* A. Reychler. Bull. Soc. Chim. Belgique, 1920, **29**, 118—122.

Starch grains may be rapidly gelatinised at the ordinary temperature by solutions of potassium or sodium hydroxide, but not by ammonia; by using a 0·75% solution of potassium hydroxide the process may be made sufficiently slow for microscopical observation. Many neutral salts also produce gelatinisation. Among the least active are sodium and calcium chlorides, whilst ammonium chloride, stannous chloride, mercuric chloride, lead nitrate, and sodium benzoate are more active, but even in concentrated solutions they act more slowly than 0·75% potassium hydroxide solution. The following substances at the concentrations stated have the same gelatinising power as 0·75% potassium hydroxide solution:—Sodium hydroxide at 0·53%, potassium iodide at 26—28%, ammonium nitrate at 30—35%, silver nitrate at 29%, potassium thiocyanate at 12—15%, and chloral hydrate at 55%. The mechanism of the gelatinisation process is discussed from the botanical standpoint. —J. H. L.

Amylopectin; The fundamental organic substance of ——. Samec and A. Mayer. Comptes rend., 1921, **172**, 1079—1082.

A new classification is suggested for the products of hydrolysis of starch, namely, amyloses (without reducing power), dextrins (with reducing power), dextrinic acids (acid reaction), prefixing these names by amylo-, erythro-, or achroo-, according as the particular member gives a blue, red, or no colour with iodine. The carbohydrate derived from amylopectin would thus be termed an erythroamylose.—W. G.

Inulin; Application of the biochemical method of detection of dextrose to the study of the products of enzymic hydrolysis of ——. E. Bourquelot and M. Bridel. Comptes rend., 1921, **172**, 946—949.

Using the method previously described (J., 1920, 344 a), it is shown that the products of hydrolysis of inulin by the inulase of *Aspergillus niger* contain reducing sugars but no dextrose. Inulin is thus constituted by the condensation of lævulose molecules alone.—W. G.

Patents.

Centrifugal apparatus for straining liquids [sugar juices]. J. Y. Johnson. From F. W. Fischlein. E.P. 161,822, 26.3.20.

The apparatus, which is designed particularly for the straining of defecated sugar juices, consists of a casing within which is mounted on ball bearings a vertical shaft carrying one or more conical strainers. The shaft is rotated by means of a turbine at its upper end, to which the juice to be strained is delivered under pressure. After effecting the rotation of the turbine the juice falls from the latter into the top strainer, which preferably has the widest perforations, and passes in turn through the lower and finer ones. In each strainer is a deflector to direct the falling liquid against the conical walls, but a narrow annular opening near the bottom of each strainer permits solid matters retained by the latter to fall into the next strainer and eventually to escape from the lowest strainer into a special protected outlet at the bottom of the casing. The casing has a separate outlet for the liquid.—J. H. L.

Lactose or milk sugar; Manufacture of ——. J. Tavroges, J. W. Roche, and G. Martin. E.P. 161,887, 22.7.20.

The lactalbumin contained in whey from cheese manufacture is completely precipitated by means of a colloidal substance added to or produced in the whey. For example, the whey, heated to 70°—80° C., is treated with about 0·25% of sodium thiosulphate, which by reacting with the free acid of the whey produces a precipitate of colloidal sulphur; the latter, being negatively charged, precipitates the positively charged albumin. After removal of the precipitate the whey is concentrated for the recovery of lactose.—J. H. L.

Caramel; Substitute for ——. H. Thoms. G.P. 333,115, 1.4.20.

Vegetables which contain carbohydrates in any form, such as cellulose, lignocellulose, galactans, etc., are subjected to acid hydrolysis, *e.g.*, by heating with dilute hydrochloric acid under atmospheric or higher pressures, and the product is evaporated to dryness and heated to 200° C. to caramelise the sugars. Remaining traces of acid and other odourous substances may be removed by a current of air. The residual brown mass is extracted with water and the filtered extract is concentrated.—J. H. L.

Starch; Production of —— *from potatoes.* H. Wertheim; and Nyitraer Stärkeindustrie-A.-G. G.P. 331,378, 1.3.17. Conv., 3.2.17.

The pulped potatoes are freed from juice as far as possible by known methods and then treated with the minimum amount of water necessary to remove the remaining extractive matters, and finally the starch is washed out with water as usual. The process renders possible the complete recovery of all valuable constituents of the potatoes, and avoids the difficulties associated with the treatment of waste waters obtained by the usual methods.
—J. H. L.

Sugar-cane mills. C. McNeil. E.P. 161,726, 26.1.20.

XVIII.—FERMENTATION INDUSTRIES.

Fermentation; Researches on ——. *VII. Influence of additions (toluene, chloroform, thymol, and neutral salts) upon the fermentative decomposition of dipeptides by yeast extract.* E. Abderhalden and A. Fodor. Fermentforsch., 1920—1, 4, 191—208.

Experiments were carried out on the decomposition of glycyl-*l*-leucine by yeast extract, the course of the reaction being followed at intervals of 10 mins. by the formaldehyde titration method. Additions of toluene, chloroform, and thymol had no effect upon the decomposition, which is explained by the fact that these substances have no influence upon the colloidal state of the yeast enzymes. The addition of small amounts of sodium chloride caused a slight retardation in the reaction, which was increased by increasing the amount of salt added; whether the yeast extract were fresh or old made little material difference. With additions of potassium chloride, bromide, nitrate, and sulphate there was a slight acceleration of the reaction during the first interval of time, then a slight retardation, and then a rapid inhibition. This result was given by a concentration of two-thirds an equivalent of each salt per l.; with higher concentrations the inhibition began earlier. Potassium iodide and thiocyanate produced at once a marked diminution in the reaction. It is concluded that the influence of the salt added is of a complex nature and depends upon the change produced in the electric charge of the solution and upon the change in the colloidal state produced thereby. The addition of the salts has the effect of displacing the hydrogen ion concentration of the solution towards the acid side of the scale.—J. H. J.

Fermentation. VIII. Production of ferment sols from yeast phosphoprotein. Activity of the sols as a function of the colloidal state. A. Fodor. Fermentforsch., 1920—1, 4, 209—229.

Yeast maceration extract prepared in the usual manner was treated with dilute hydrochloric acid when the phosphoproteins were precipitated; these were then washed with water and triturated with water to form sols, which in the absence of traces of acid were stable and fermented solutions of polypeptides. The sols obtained were examined ultramicroscopically and various degrees of dispersion were noticed. It was found that the fermentative activity varied directly with the degree of dispersion of the sol. The addition of alkalis and of alkali phosphates increased the degree of dispersion and the fermentative activity of the sols. The addition of potassium chloride in small amounts increased the fermentative activity, but in large amounts caused flocculation. Yeast phosphoproteins which have become more or less inactive can be regenerated, preferably by the addition of alkali and potassium chloride, with a corresponding increase in degree of dispersion.—J. H. J.

Diastase; The co-enzyme (complement) of ——. W. Biedermann. Fermentforsch., 1920–1, 4, 258—300.

Animal and plant diastases consist of a thermolabile and by itself inactive component (zymogen) and a thermostable co-enzyme, such as an inorganic salt. Many experiments were carried out to determine the effect of salts on diastatic fermentation and also on the influence of the reaction of the solution. It was found difficult to obtain by dialysis a completely inactive diastase solution, as traces of salts were sufficient to activate the enzyme. The salts used as activators were the neutral salts of the alkali and alkaline-earth metals with inorganic and organic acids, phosphates, bicarbonates, and thiocyanates. The anion proved to be the active component. The most active salt was sodium chloride, closely followed by potassium thiocyanate; in the second rank were potassium chloride and bromide, sodium bromide, and ammonium chloride; in the third rank were the chlorides of calcium, magnesium, strontium, and barium. After these came nitrates, iodides, and sulphates. Of the cations sodium had the most influence, followed by potassium. All the salts form with diastase complex compounds of indefinite composition which are easily dissociated. The activity of these neutral salt-diastases is greater in strictly neutral solutions; the slightest addition of acid and alkali is enough to check fermentation at once, and with long contact the enzyme is destroyed. Alkaline and acid salts behave differently from neutral salts. Acid sodium phosphate and acid sodium citrate in solutions up to 0·3% strength activate salt-free diastase in spite of the acid reaction of the mixture; above this strength the reaction is checked. Disodium phosphate and sodium bicarbonate activate fermentation in concentrations in which the more acid salts would inhibit. There is a relative retardation produced by disodium phosphate which

can be removed at once by a trace of sodium chloride, the reaction remaining neutral. The diastatic power of this mixture exceeds that of all others. The high activating power of phosphate ions is shown by the fact that the activating power of a sodium chloride solution is not only unimpaired but is considerably increased by a slight addition of a diphosphate. Similarly sodium carbonate does not cause any checking of an active sodium chloride-diastase. Saliva yields a diastase solution which depends for its activity upon the composition of the co-enzyme, that is, the combination of inorganic salts, the most important of which are sodium chloride, potassium thiocyanate and phosphate, to which must be added bicarbonate and carbon dioxide, which play an important part in the diastatic fermentation of pancreatic juice.
—J. H. J.

Carboligase: an enzyme linking carbon chains. C. Neuberg and J. Hirsch. Biochem. Zeits., 1921, 115, 282—310.

By the fermentation of sucrose or dextrose by top yeast, bottom yeast, or maceration juice in the presence of benzaldehyde a hydroxy-ketone of the constitution, $C_6H_5.CO.CH(OH).CH_3$ or $C_6H_5.CH(OH).CO.CH_3$, is formed. Its production is attributed to the presence in yeast of a new enzyme, to which the name carboligase is given, which produces a condensation of the benzoïn type between one molecule of benzaldehyde and one either of acetaldehyde or of pyruvic acid, its precursor in alcoholic fermentation. The same compound is formed by the action of yeast upon a mixture of benzaldehyde and pyruvic acid, but the direct condensation of the two aldehydes cannot be effected. (*Cf.* J.C.S., June.)—E. S.

Amygdalinase and amygdalase; Curious modification of —— due to ageing. G. Bertrand and A. Compton. Bull. Soc. Chim., 1921, 29, 229—237.

Under the influence of time amygdalinase and amygdalase, as extracted from almonds, lose their activity very slowly, to the extent of about one-third in ten years, but they show a marked variation in the optimum hydrogen-ion concentration for the medium in which they act. Thus a sample of emulsin (amygdalinase+amygdalase) prepared in 1910 showed maximum activity in a medium slightly alkaline to phenolphthalein, but when examined in 1914 it showed maximum activity in a medium slightly acid to this indicator.—W. G.

Enzymes of B. coli communis. V.—(a) Anaërobic growth followed by anaërobic and aërobic fermentation. (b) The effects of aeration during the fermentation. E. C. Grey and E. G. Young. Proc. Roy. Soc., 1921, 92 B, 135—150.

Anaerobic fermentation of dextrose by an emulsion of *B. coli communis* proceeds differently according as the organisms have been grown previously with or without oxygen. When the immediate past history has been anaërobic the fermentation under anaërobic conditions yields little or no lactic acid and a greatly diminished quantity of succinic acid. In place of these acetic acid appears in large proportion. Admission of oxygen during the fermentation leads to lactic acid production, there being an increase in lactic, acetic, and succinic acids and a diminution in hydrogen, carbon dioxide, and formic acid, the alcohol remaining pactically constant. Under anaërobic conditions greater variations occur in the proportion of alcohol to acetic acid than under aërobic conditions, one of the effects of the introduction of oxygen during the fermentation being apparently to inhibit the mechanism of auto-reduction which is responsible for the variations in alcohol. Another effect of the introduction of oxygen is probably to diminish the part played by water in the reactions.
—W. G.

Bacteria; Influence of fats on the growth of ——. H. Much and H. Schmidt. Z. Immunitätsforsch. Exp. Ther., 1920, 31, 169—200. Chem. Zentr., 1921, 92, I., 645.

The addition of fats to nutrient media does not accelerate the growth of bacteria; with many species the growth is hindered, and chaulmoogra oil has a retarding effect on all bacterial growth. Staphylococci decompose the fats, and in a fatty medium the organisms themselves appear to be somewhat larger than usual and to a certain extent swollen, but their other properties remain unaltered, except when chaulmoogra oil is present.
—W. P. S.

Fruit [for wine making]; Influence of degree of ripeness of —— on the acceleration of fermentation by various nitrogenous compounds. Cellar experiments to secure pure fermentation and stability of fruit wines. Lactic acid malady appearing in fruit wines after complete fermentation of the sugar. Importance of blending for the stability of mild fruit wines. H. Müller-Thurgau and A. Osterwalder. Landw. Jahrb. der Schweiz, 1920. Chem. Zentr., 1921, 92, II., 748—750.

Expressed juices from unripe, ripe, and over-ripe pears of four kinds were fermented with and without addition of ammonium chloride or carbonate, and with and without the use of pure culture yeast. The effect of ammonium salts confirmed previous conclusions (J., 1919, 333 A); they accelerated the fermentation of juice from unripe pears less than that of juice from ripe pears, and it is concluded that the former already contain more assimilable nitrogen than the latter. Spontaneous fermentation was in all cases sluggish, but with addition of pure yeast the juices from unripe fruit fermented at least as rapidly as those from ripe fruit, the higher tannin-content of the former having no perceptible retarding influence. Most fruit wines, especially those of low acidity and tannin-content, require more careful treatment in the cellar than grape wines. A common malady is one in which lactic and acetic acids are formed, and unlike ordinary acetous fermentation this cannot be checked by exclusion of air. The best preventive measures are rapid fermentation, *i.e.*, use of pure yeast and ammonium salts, and avoidance of high temperatures. Treatment with sulphur dioxide or metabisulphite is desirable to prevent the development of the malady after fermentation. The malady is distinct from that in which mannitol and lactic and acetic acids are formed from sugar by *Bact. mannitopacum*; in the former the acids appear to be produced from glycerol and other unknown constituents, for it may develop after all the sugar has been fermented. In the case of juices of low acidity and tannin-content the malady may be warded off during fermentation by mixing such juices, before fermentation, with apple or pear juices rich in acid and tannin (pear juices rich in tannin alone are not so suitable). The mixed juice is fermented as rapidly as possible and afterwards sulphited.—J. H. L.

Maize silage. Fred and others. *See* XIXa.

Patents.

Acetone and higher alcohols, particularly butyl alcohol; Method and apparatus for the production by fermentation of ——. A. Fernbach. E.P. 109,969, 30.8.17. Conv., 31.8.16.

The method described in E.P. 15,203, 15,204, and 16,925 of 1911, and 21,073 of 1912 (J., 1913, 987), nay be carried out in apparatus of the kind lescribed in E.P. 15,561 of 1898 (J., 1898, 1066); his apparatus comprises fermentation vats each rovided with a feeding orifice, an agitator, a ystem of pipes for the introduction of air or inert as, communicating pipes, and a filter. A small ' leavening vat" is used in conjunction with the ermentation vats, and means are provided by vhich the reduced pressure resulting from the coolng of the sweet wort after sterilisation is utilised or introducing the culture.—W. P. S.

Vood and other cellulose-containing substances; Manufacture of sugar and furfural from ——. A. Classen. E.P. 142,480, 27.4.20. Conv., 18.3.19.

HE material is heated under a steam pressure of bout 7—8 atm. with sufficient dilute sulphuric or ydrochloric acid to effect conversion, but one or nore additional acids, or salts capable of yielding cids, are employed at the same time as catalysts. The action of the additional acids improves the ield and fermentable quality of the sugar proluced, and the yield of furfural can be increased by suitable choice of additional acids, *e.g.*, sulphuric nd sulphurous acids when hydrochloric acid is used or conversion, or hydrochloric and sulphurous cids when sulphuric acid is used for conversion. Besides acid catalysts metals or metallic oxides, specially those of the iron group, may be mployed.—J. H. L.

lucose [for fermentation] from wood; Process and apparatus for obtaining ——. H. Terrisse and M. Levy. E.P. 143,212, 6.5.20. Conv., 13.5.19.

RY sawdust is treated in a mixing cylinder with bout twice its weight of 33% hydrochloric acid nd is then conveyed through other mixing ylinders into each of which gaseous hydrochloric cid is introduced so as to increase the acid conentration to about 41%. During these operations he temperature is maintained at 0°—25° C. The mpregnated material is digested in a rotating essel at a slightly higher temperature for 10 hrs., nd the excess of hydrochloric acid is removed by aising the temperature to about 30° C. and reducng the pressure to 40 mm., the gaseous acid being bsorbed and collected. The residual mass is exracted with water, the extract filtered and disilled under reduced pressure to remove hydrohloric acid completely.—W. P. S.

ellulose-containing materials; Saccharification of ——. A. Wohl. E.P. 146,860, 5.7.20. Conv., 7.4.17.

HE material is intimately mixed with strong nineral acid, *e.g.*, 70—75% sulphuric or 39—40% ydrochloric acid, and subjected to powerful agitaion and compression. The amount of acid reuired is much less than when the material is not neaded and pressed, *e.g.*, 1·5 pt. of 75% sulphuric cid is sufficient for 1 pt. of wood waste.—J. H. L.

ellulose; Fermentation of ——. The Power-Gas Corporation, Ltd., and H. Langwell. E.P. 161,294, 8.1 and 18.3.20. Addn. to 134,265 (J., 1920, 38 a).

N the process described (*loc. cit.*) acetic acid is e chief product when the aeration is limited; if e rate of aeration is increased, alcohols, particurly ethyl alcohol, are the principal products of e fermentation.—W. P. S.

east; Manufacture of pressed —— from distillers' grains, oil-cake and the like. J. Effront. E.P. 160,496, 21.11.19.

ITROGENOUS material such as oil-cake, distillers' ains, etc., is digested with concentrated hydroloric or other mineral acid for 48 hrs. at 106°—8° C. The extract obtained, which is rich in amino-acids, is employed as yeast food, whereby the amount of sugar consumed by the yeast without production of alcohol is much reduced.—J. H. L.

Fermented liquors; [Use of sour whey solids in the] manufacture of ——. C. S. Townsend. E.P. 160,562, 23.12.19.

The solids obtained by the desiccation of sour whey from the manufacture of cheese are employed as a constituent of fermented beverages, *e.g.*, "stone ginger beer." They assist fermentation and give a distinctive flavour to the beverage. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 20,183 of 1912; J., 1913, 987.)—J. H. L.

Fermentation process. A. Römer, and Deutsch-Koloniale Gerb- u. Farbstoff-Ges. m.b.H. E.P. 161,870, 17.6.20.

In a continuous process for the fermentation of saccharine liquids, *e.g.*, molasses worts or sulphite-cellulose liquors, the liquid is passed through a series of "ferment filters," *i.e.*, cylindrical vessels containing yeast fixed in kieselguhr, sawdust, or the like. The liquid is passed upwards through each vessel, at a suitable temperature and at such a rate that after traversing the whole series, *e.g.*, 6 vessels, it is completely fermented. The order of the vessels may be changed at will so that the yeast in any one does not remain too long in contact with liquid poor or rich in sugar. Any vessel may be cut out of the series, re-charged with fresh yeast, and brought into operation again without arresting the working of the others. For the fermentation of liquids poor in sugar one filter may suffice. The process may be adapted to other types of fermentation, *e.g.*, to the production of butyl alcohol, glycerol, lactic, butyric, or citric acid, acetone, etc. —J. H. L.

Mashing process. H. E. Deckebach. U.S.P. 1,374,191, 12.4.21. Appl., 20.9.19.

Ground malt is mashed in a mash tun and raw grits are simultaneously heated with water in a converter, and the two vessels are so connected that the materials can be circulated from the tun into the converter and from the converter into the tun, until the starch is saccharified.—J. H. L.

Fermentation of beer and the like [by the Burton union system]; Apparatus for ——. J. F. Warwick. E.P. 161,496, 16.8.20.

Caramel substitute. G.P. 333,115. *See* XVII.

Foods. E.P. 161,885. *See* XIXa.

XIXa.—FOODS.

Milk; Relation between lactic acid production and bacterial growth in the souring of ——. J. C. Baker, J. D. Brew, and H. J. Conn. New York Agric. Expt. Stat. Bull. No. 74, 1919. 24 pages.

The rate of acid production per individual cell per hr. with different cultures of bacteria, varied considerably, being much lower in the case of an organism which multiplied arithmetically than with one which multiplied normally (geometrically); for a vigorous culture the rate was between 5×10^{-10} and 10×10^{-10} mg. of lactic acid per hr. The ratio of total acid produced to the number of organisms present proved to be fairly constant, and was directly proportional to the amount of acid produced per generation by each individual cell; the ratio increased as the curdling point was approached. There was a tendency for the acid present to increase geometrically until coagulation ensued and, to a certain extent, this was true even with the organisms which were multiplying arithmetically. At the curdling point, the multiplication of the bacteria appeared to cease and there was a noticeable decrease in the rate of acid production. The bacteria were, in all cases, counted individually under the microscope.—W. P. S.

Milk powders; Antiscorbutic potency of ——. E. B. Hart, H. Steenbock, and N. R. Ellis. J. Biol. Chem., 1921, **46**, 309—318.

Apart from the original content of vitamin, as influenced by fodder, the powders vary with the process of manufacture used; the spray processes are more destructive than the Just (heated rolls) process. With the possible exception of powders made by the Just process from summer milk (or even from winter milk obtained on a vitamin-rich diet of roots and tubers) these preparations must be supplemented in infant feeding by some potent source of antiscorbutic vitamin.—G. B.

Vitamin; Stability of the antiscorbutic ——, and its behaviour to various treatments. N. R. Ellis, H. Steenbock, and E. B. Hart. J. Biol. Chem., 1921, **46**, 367—380.

The antiscorbutic vitamin in cabbage is destroyed by desiccation at 65° C., even in an atmosphere of carbon dioxide, and also by the fermentation involved in the making of sauerkraut, and of silage from maize. It is not removed from orange juice by ether or by aeration, but is destroyed by oxidising agents. Blood charcoal and the Chamberland filter remove a measurable amount from orange juice.—G. B.

Fats; Special nutrition values of different ——. Accessory food factors. I. H. Aron and R. R. Gralka. Biochem. Zeits., 1921, **115**, 188—203.

Feeding experiments on rats are described which confirm the presence of vitamin A in cod-liver-oil, butter, and egg-yolk, and its absence in margarine. —E. S.

Alimentary ration and vitamins. A. Desgrez and H. Bierry. Comptes rend., 1921, **172**, 1068—1071.

On a ration, deprived of fats, containing only protein and carbohydrates, but rich in vitamins, the growth of young rats and the equilibrium of adult animals can be assured, but in the complete absence of vitamins, nitrogen equilibrium can only be maintained if the constituents of the ration are all present and in certain proportions.—W. G.

Egg preparations; Drying and preserving of ——. Briant and Harman. Nat. Assoc. Review, 1921, **38**, 247—251.

The baking value of eggs lies in their power of retaining gas produced by baking powders etc. in the dough, and the value is dependent on the amount of coagulable albumin present. In the case of dried eggs a portion of the albumin may be coagulated during the drying process, especially if the temperature exceeds 65° F. (19° C.), and the loss due to coagulation is increased by the presence of small quantities of boric acid.—W. P. S.

Lactic acid bacteria; Relation of —— to corn [maize] silage. E. B. Fred, W. H. Peterson, and J. A. Anderson. J. Biol. Chem., 1921, **46**, 319—327.

Lactobacillus pentoaceticus plays an important part in maize silage and increases the amount of alcohol and volatile acid, while the lactic acid is decreased. *Bacillus lactis acidi* persists only during the first days of fermentation.—G. B.

Pentosans; Destruction of —— in the formation of silage. W. H. Peterson, E. B. Fred, and J. H. Verhulst. J. Biol. Chem., 1921, **46**, 329—338.

Corn (maize) fodder contains 21·8% of pentosans and 0·34% of methylpentosans. After fermentation for 50 days the content of pentosans ranges from 17·6 to 20·9% according to the moisture present. Taking account of the loss of dry matter, at least 15—20% of the pentosans is destroyed during fermentation. Pentoses or other furfural-yielding substances soluble in water occur, probably as the result of bacterial action. A mixture of 2% of acetic and 5% of lactic acid did not appreciably hydrolyse pentosans in 20 days at 28° C. Immature maize contains 0·6% of free pentoses.—G. B.

Silage crops; Application of the Van Slyke method to hydrolysed protein extracts of ——. R. E. Neidig and R. S. Snyder. J. Amer. Chem. Soc., 1921, **43**, 951—959.

The proteins of forage crops, either before or after conversion into silage, cannot be successfully analysed by the Van Slyke method applied directly to the hydrolysed extract of the original material, because of the formation of considerable quantities of humin from the cellulose. The method of Eckstein and Grindley (J., 1919, 301 A) gives results which permit of a fair interpretation of the protein molecule when applied to concentrates which contain but little cellulose.—W. G.

Grape honeys and fruit syrups; Process and apparatus for the manufacture of ——. E. Barbet et Fils et Cie. E.P. 153,548, 21.1.20. Conv., 31.10.19. Addn. to 135,175 (J., 1921, 364 A).

The apparatus previously described (*loc. cit.*) has the disadvantage that the vapours given off from the first evaporation are sometimes charged with sulphurous acid, which slowly attacks the copper and may thereby contaminate the juice. This is obviated by subjecting the sulphited juice to a preliminary desulphitation in a tower used in conjunction with each of the evaporating groups of the earlier apparatus and made of ceramic ware or volvic lava. The desulphitation is effected by means of juice vapour introduced into the bottom of the tower through a regulating valve. The desulphited liquor passes from the bottom of the tower to the evaporator.—G. F. M.

Eggs; Method of preserving ——. G. Dreyer and G. F. Hanson. E.P. 161,110, 21.7.20.

Eggs are immersed in, or washed with, formaldehyde solution or with water containing chlorine and are then stored in a receptacle through which a current of moist sterilised air at 5° C. is passed The eggs are turned once every 24 hrs. during storage.—W. P. S.

Alimentary products containing water-solubl vitamines; Manufacture of ——. "Forget-me not-Flours," Ltd., and R. Hutchinson. E.P 161,238, 23.12.19.

Wheat bran, or the husk of other edible seeds, i dried at 100° F. (38° C.) under reduced pressure and ground; the powder may be used as such or a aqueous infusion may be prepared from it. Th infusion may be mixed with gelatin etc., an formed into tablets, or it may be evaporated unde reduced pressure to produce a dry powder. Filtration of the infusion is optional.—W. P. S.

Food preparation [from pine seeds]; Production o a ——. C. Farmachidis. E.P. 161,291, 8.1.20.

Shelled pine seeds are washed, dried, ground, an mixed with flour and gluten; other substances, such as baking powder, sugar, flavouring matter, etc., may be added. The mixture is formed into biscuits, which are baked at 130° C.—W. P. S.

Vegetable gelatin; Process of making [edible] —— and the product thereof. M. M. Malcolm and C. S. Townsend. E.P. 161,612, 10.11.19.

Vegetable gelatin is prepared from seaweed, especially from *Chondrus crispus* or carragheen, by soaking the material in water for some hours, washing to remove impurities and salts, bleaching the softened substance with "floridin," "norit," or albumin, disintegrating by boiling with 5 pts. of water containing acids or alkalis, preferably 0·5% acetic acid, with gentle agitation, and finally expressing the liquid from the undissolved residue. A preservative such as 0·5% of bisulphite, or 1·0% of sodium benzoate, is added to the liquor, and the gelatin may be dried by running the filtered material on to heated rollers, to produce sheets; by atomising the liquor after a preliminary concentration, into a chamber through which a current of hot air is passed, whereby a gelatin powder is produced, or by drying the concentrated liquor in trays in an oven to produce the material in block form.—G. F. M.

Foods: Process for the preservation of by-products of brewing, distillation and other processes for use as animal ——. A. Stouffs. E.P. 161,885, 19.7.20.

By-products suitable for feeding-stuffs, *e.g.*, brewers' grains, exhausted beet slices, etc., may be preserved from fermentation for about 10 months by moistening them with dilute hydrochloric acid at the rate of 1 kg. of 33% fuming acid diluted with 200 l. of water per 1000 kg. of material. The products may be compressed into cakes.—J. H. L.

Meat; Process of producing powdered ——. J. C. MacLachlan, Assr. to Standard Food Products Co. U.S.P. 1,372,527, 22.3.21. Appl., 26.5.19.

Finely-cut or ground meat is projected by centrifugal force into a hot drying medium, in which it is intercepted, beaten, and desiccated.—J. H. L.

Cheese; Process of sterilising ——. E. E. Eldredge. U.S.P. 1,374,141, 5.4.21. Appl., 24.9.19.

Cheese is mixed with 2% of its weight of sodium phosphate, and then heated at a suitable temperature.—W. P. S.

Sugar; Composition of —— and method of preparing the same. N. C. Fowler, jun.; F. A. Fowler, admintrix. U.S.P. 1,374,160, 5.4.21. Appl., 8.8.16. Renewed 16.4.18.

Dried fruit is ground with the addition of water and sugar, the mixture dried, and then re-ground. —W. P. S.

Milk; Production of dehydrated ——. S. M. Dick, Assr. to International Dry Milk Co. U.S.P. 1,374,555, 12.4.21. Appl., 31.1.20.

Milk is atomised without pressure in a suitable dehydrating cell, and is exposed to the action of compound currents of heated air. It is thereby dried without breaking or injuring the globules of butter fat, which become coated with casein, albumin, and other colloidal constituents of the milk. The product is readily soluble with the production of a liquid substantially the same as normal milk, on which the cream will rise in the usual way. —G. F. M.

Food product; Manufacture of a —— [from sugar residues or the like]. H. Stoltzenberg. G.P. 329,321, 24.4.19.

Residues from the desaccharification process, *e.g.*, osmose molasses, wash liquors, etc., are treated hot with an organic solvent, such as alcohol or a ketone or ester, and after the mixture has cooled and stood for some time, the upper layer, *i.e.*, the organic solvent, which contains the unwholesome constituents in solution, is separated. After the lower layer has stood for a further period, the amino-acid salts which settle out are removed, converted to the free acids, and returned to the solution, which has in the meantime been freed from the last traces of organic solvent by heat. The product can be employed as a food product or as fodder, or can be fermented to yield an alcoholic beverage or for the production of pressed yeast, or it can be utilised in the manufacture of sweetstuffs and the like. —L. A. C.

Rennet, rennet extracts and the like; Process for the preparation of ——. Gebr. Schubert. G.P. 333,458, 5.6.18.

The material is fractionally extracted with alcoholic calcium chloride solution and the united extracts evaporated. The use of calcium chloride allows of the concentration of weak extracts without precipitation of the salts or the enzyme.—A. de W.

Food from fish-flesh; Preparation of ——. M. Jewnin. G.P. 333,554, 8.4.19.

The comminuted flesh is extracted with aqueous alcohol of a strength not exceeding 70%, and is then mixed with amino-acids resulting from the acid hydrolysis of proteins and with flour. The product is free from the characteristic, disagreeable fishy flavour.—A. de W.

Fodder; Process for the conversion of the stomach-contents of animals into a dry ——. G. Beckstroem. G.P. 334,170, 17.6.19. Addn. to 300,063 (J., 1919, 960 a).

Fish or fish waste may be employed together with stomach-contents and cellulosic matter. The bacteria which develop attack fish bones, scales, and fins.—J. H. L.

Desiccating buttermilk, sour milk, and the like; Apparatus for ——. Collis Products Co., Assees. of N. P. Collis. E.P. 138,092, 20.1.20. Conv., 13.12.15.

XIXb.—WATER PURIFICATION; SANITATION.

Water; Determination of the hydrogen ion concentration of ——. I. M. Kolthoff. Z. Unters. Nahr. Genussm., 1921, 41, 112—122.

A colorimetric method for the determination of the hydrogen ion concentration of water consists in treating the water with Neutral Red solution and comparing the coloration with that of standardised acid and alkaline solutions of the same indicator contained in graduated wedge-shaped tubes. The carbon dioxide content of a water may be calculated from the hydrogen ion concentration and the bicarbonate content by the formula $[H_2CO_3]=[H^{\cdot}]\,[HCO'_3]\,/3{\cdot}04\times10^{-7}$.—W. P. S.

Water; Influence of minute quantities of metallic salts in —— on its bacteriological content. E. L. Atkinson and R. C. Frederick. J. Roy. Nav. Med. Service, April, 1921. [Reprint.] Pp. 5.

Natural waters of different types were treated with lead acetate, copper sulphate, ferric chloride, or zinc sulphate, equivalent to 0·5 and 0·25 pt. of metal per 100,000, and after inoculation with *B. typhosus* each sample was sub-cultured into ordinary nutrient broth tubes on four successive days. The results show that even 0·25 pt. of copper per 100,000 in the water markedly inhibited development in the cultures; zinc had a slight effect at 0·5 pt. per 100,000 but practically none at 0·25 pt., whilst lead and iron at 0·5 pt. per 100,000 were without any appreciable action. In further experiments an upland surface water and a mixture of shallow well and upland surface waters were treated with salts as above, and after standing for 48 hrs. were subjected to routine bacteriological analysis. Here again the results were seriously affected even by 0·1 pt. of copper per 100,000 of water, and lead and zinc at 0·5 pt. per 100,000 appeared to influence the results in some cases. The authors conclude that a chemical analysis of water is necessary for the interpretation of the results of bacteriological tests.—J. H. L.

Nitrogen; Conservation of —— with special reference to activated [sewage] sludge. G. J. Fowler. J. Indian Inst. Sci., 1920, 3, 227—279.

An extensive review is given of the existing data as to the nature and amount of the nitrogen in fæces and sewage and of the attempts which have been made to recover some of its value for agricultural purposes. In the activated sludge process of sewage purification there appears to be an increase of nitrogen in the end products over the quantity in the crude sewage treated. Laboratory experiments in which activated sludge and sewage were agitated together by means of an air diffuser, the clarified liquid being withdrawn daily for 5 days and fresh sewage added, showed that the sum of the total nitrogen in the original sludge and in the sewage added daily amounted to 1·793 g., and that in the effluent withdrawn daily and in the final sludge amounted to 1·865 g., an increase of about 4%. In experiments on the incubation of activated sludge with culture solutions favourable for the growth of nitrogen-fixing bacteria, there was found to be a gain of nitrogen of 25% in 4 weeks. For the purpose of studying the effect of activated sludge and the products of its decomposition on plant growth, a seedling was grown in sand partially immersed in activated sludge and water. Aeration was continued for 3 weeks when the liquid contained, per 100,000 pts., 0·03 pt. of ammonia and 0·2 pt. of nitrite, whereas a control experiment with sludge and air showed only 0·5 pt. of ammonia and 0·05 pt. of nitrite, and another with plant and sludge only 2·8 pts. of ammonia and no nitrite. The experimental plant grew well, whereas the control plant gradually died. It is suggested that the stimulating effect of activated sludge on plant growth may be due to the presence of auximones.
—J. H. J.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Caffeine in yerba maté, coffee, tea, kola nut, and guaraná; Determination of ——. T. Ugarte. Anal. Soc. Quim. Argentina, 1920, 8, 413—415.

Half a gram of the finely powdered substance is introduced into a 500 c.c. flask, and carbonised by heating with a small flame. Dense white vapours are evolved and the heating is so regulated that they do not reach to the upper part of the neck of the flask. After cooling, the contents of the flask are washed out with successive 5 c.c. portions of water and filtered. The united filtrate is evaporated to dryness on a water bath and the residue redissolved in 2 c.c. of water. A few drops of *N*/1 ammonia solution and 5 c.c. of chloroform are added. After agitating, the two liquids are filtered through filter paper impregnated with chloroform and washed with two 5 c.c. portions of chloroform. The filtrate and washings are evaporated to dryness. Caffeine is extracted from the residue with successive small quantities of water and weighed after drying at 100°—105° C.
—G. W. R.

acao; Determination of alkaloids in ——. A. Ceriotti. Anal. Soc. Quím. Argentina, 1920, **8**, 400—403.

EN grams of the fat-free material is boiled for at east 1 hr. with 150 c.c. of 5% sulphuric acid under reflux condenser. Colouring matters, tannins, nd resins are then precipitated by addition of 00 c.c. of 3% mercuric acetate, and the boiling is ontinued for another 10 mins. The filtrate after eutralisation with magnesia is evaporated to 0 c.c. on a water bath. After addition of 10 g. of and and excess of calcined magnesia the liquid is vaporated to dryness. The alkaloids are extracted rom the powdered residue in a Soxhlet apparatus y a mixture of benzene and chloroform (1:1) and, fter removal of the solvents, weighed in a tared ish. The weight of theobromine is obtained by ifference after three successive extractions with arbon tetrachloride to remove the caffeine.

—G. W. R.

lkaloids of valerian. A. Goris and C. Vischniac. Comptes rend., 1921, **172**, 1059—1061.

VALISZEWSKI's statement (Union Pharm., 1893, **34**, 51) as to the existence of the two alkaloids chatiine and valerine in valerian root is confirmed. rom 1 kg. of fresh root 0·1 g. of mixed alkaloids as obtained, the chatinine predominating. hatinine is soluble in ether, whereas valerine is nsoluble in ether but soluble in chloroform.—W. G.

lkaloids; Behaviour of phospho- and silico-tungstic acids towards ——. A. Heiduschka and L. Wolf. Schweiz. Apoth.-Zeit., 1920, **58**, 213—218, 229—233. Chem. Zentr., 1921, **92**, II., 840—841.

HE precipitates obtained by the addition of silicoungstic acid to alkaloidal solutions are colloidal vith the exception of the quinine and caffeine preipitates. The addition of electrolytes causes coaguation. An equilibrium exists between the neutral nd acid salts, depending on the concentration of he acid during precipitation and during washing. y using $N/100$ solutions of silicotungstic acid in resence of 1% hydrochloric acid, sparteine, uinine, cinchonine, and nicotine are precipitated s di-acid bases corresponding to the formula $iO_2,12WO_3,2H_2O,2Alkaloid,xH_2O$, whilst the comosition of the precipitates obtained with morphine, odeine, thebaine, and cocaine is represented by $iO_2,12WO_3,2H_2O,4Alkaloid,xH_2O$. In other cases he precipitate has no simple composition, and a uantitative determination is accordingly imposible in consequence of the alteration in composition y washing. Alkaloids forming silicotungstates vhich are only slightly altered by 0·1% sodium hloride solution can, in the absence of albumin, e determined by adding an excess of silicotungstic cid standardised with sodium hydroxide and nethyl red, followed by 1% sodium chloride, filtering nd washing the precipitate with 0·1% sodium hloride solution, and titrating back the excess acid n the filtrate and washings. Phosphotungstic acid ehaves in a similar manner towards alkaloids. In resence of less than 1% of hydrochloric acid, parteine, quinine, cinchonine, and nicotine give recipitates corresponding to the formula $[P(W_2O_7)_6]H_7,3Alkaloid,xH_2O$, in other cases the omposition is dependent on external conditions. he solubility of the alkaloidal silico- and phosphoungstates is affected to varying extents by the ddition of hydrochloric acid or sodium chloride, ut minute quantities of alkaloids can be deterined with some degree of exactitude by comparing he opalescence produced by silicotungstic acid ith that produced in a solution of known strength.

—G. F. M.

Hydrocyanic acid; Micro-crystalline reaction for the identification of —— in cyanogenetic glucosides. G. Denigès. Comptes rend. Soc. Biol., 1921, **84**, 309—310. Chem. Zentr., 1921, **92**, II., 623—624.

THE substance to be tested is ground with water and, after some time, a portion is placed in a short, narrow test-tube; the mouth of the latter is covered with a microscope slide carrying on its under side a drop of alloxan reagent which has been rendered ammoniacal previously. The alloxan reagent is prepared by dissolving 1 g. of uric acid in a mixture of 1 c.c. of nitric acid (sp. gr. 1·40) and 1 c.c. of water and diluting to 50 c.c. If hydrocyanic acid is present, star-shaped crystals of oxaluramide are formed in the drop of reagent, usually within a few minutes. The test is more sensitive when pyridine is used in place of ammonia; in this case the crystals are in the form of bundles. It frequently happens that the reagent mixture shows a red coloration due to the simultaneous formation of murexide.—W. P. S.

Quinic acid; Presence of —— in the leaves of some conifers. G. Tanret. Bull. Soc. Chim., 1921, **29**, 223—229.

THE author has isolated quinic acid from the leaves of cedar trees growing in the neighbourhood of Paris, finding 5 g. of the crystallised acid per kg. of leaves (dried at 100° C.) picked in July, but only 2 g. per kg. in leaves picked in December. Similar results were obtained with larch leaves, but the acid could not be isolated from leaves of yew, juniper, or fir trees. The addition of ammonium molybdate causes marked modifications in the rotatory power of quinic acid. With increasing quantities of ammonium molybdate the value of $[\alpha]_D$ ($-43·2°$) first increases to a maximum ($-63°$), then falls to a minimum ($-54·8°$), and finally increases again to a maximum limit value ($-71·7°$).—W. G.

Capsella bursa pastoris; Active constituents of ——. H. W. van Urk. Pharm. Weekblad, 1921, **58**, 553—556. (*Cf.* Boruttau and Cappenberg, J., 1921, 276 A.)

ALKALOIDS and allyl mustard oil are absent, and the presence of glucosides is very doubtful. (*Cf.* J.C.S., June.)—S. I. L.

Bromural. E. Yoshitomi and K. Watanabe. Yakugakuzasshi (J. Pharm. Soc. Japan), 1921, [468], 125—130.

PURE α-monobromoisovalerylurea (bromural) melts at 154° C., whilst commercial samples melted at 145°—157° C. The difference is due mainly to the presence of methylethylbromoacetylurea and isovalerylurea. The melting-point curve of mixtures of bromural and isovalerylurea has a minimum, and hence the same melting point may correspond to two different mixtures. To ascertain the purity of bromural, determination of the melting point is, therefore, of no value, and the bromine content should be determined.—K. K.

Hydrogenation; A catalytic method of ——. J. Nivière. Bull. Soc. Chim., 1921, **29**, 217—219.

THE material to be hydrogenated, dissolved in a suitable solvent, is placed in a stout-walled bottle. A small amount of a solution of palladium chloride or platinum chloride is added to act as a catalyst, and then the calculated amount of calcium hydride is added gradually, the flask being stoppered and well shaken. This method was used successfully for the reduction of benzaldehyde, nitrobenzene, and benzylidene-acetone.—W. G.

Phenylhydrazones; Catalytic hydrogenation of ——. A. Mailhe. Comptes rend., 1921, **172**, 1107—1110.

PHENYLHYDRAZONES are hydrogenated when passed in a rapid current of hydrogen over reduced nickel at 180°—190° C. If derived from aldehydes they give aniline and the corresponding nitrile, but if derived from ketones they yield aniline, the primary amine, and some secondary amine.—W. G.

Benzoic acid; Synthesis of chlorine-free —— from benzene. R. H. McKee and F. A. Strauss. Chem. and Met. Eng., 1921, 24, 638—644, 697—702.

The reactions involved in the conversion of sodium benzenesulphonate into benzoic acid were investigated with a view to their utilisation on a commercial scale. Experiments on the direct formate fusion method indicated that benzoate formation only takes place at a high temperature and is accompanied by much decomposition. Synthesis through benzonitrile gave greater promise of success on the technical scale. The main reaction in which benzonitrile is formed is accompanied by side reactions of two general types—reduction of the sodium benzenesulphonate by sodium cyanide, and decomposition of the cyanate formed, by water vapour, with formation of sodium carbonate, carbon dioxide and ammonia, and secondly pyrogenic decomposition of the benzenesulphonate with production of a large number of substances including thioethers, thiophenols, hydrogen sulphide, etc. The most favourable reaction conditions for the formation of the maximum yield of benzonitrile were shown to be: Temperature of the reaction mixture must be kept between the limits of 420°—430° C.; finely powdered cyanide and sulphonate intimately mixed in equimolecular proportions, or a slight excess of cyanide; addition to the mixture of sand or other inert material, an admixture of 70% of 40-mesh sand being the optimum. Under these conditions a nitrile formation efficiency of about 43% was obtained. Reducing the pressure did not improve this result, but rather favoured the formation of sulphur compounds and tar. Hydrolysis of benzonitrile by sulphuric acid (sp. gr. 1·6) was more rapid and efficient than alkali hydrolysis, and gave yields amounting to about 95% of the theory of practically pure benzoic acid. With a source of cheap cyanide the authors consider that the process proposed would produce benzoic acid of a higher degree of purity and at a lower price than the methods at present in use.—G. F. M.

p-Aminophenol; Electrolytic manufacture of ——. A. S. McDaniel, L. Schneider, and A. Ballard. Trans. Amer. Electrochem. Soc., 1921, 319—327. [Advance copy.]

Nitrobenzene was reduced electrolytically at 30° C. in strong sulphuric acid (90—91%), free from iron and heavy metals, using platinum electrodes, with a cathode current density of 6—8 amp. per 100 sq. cm., and anode density double. Glazed earthenware cells with porous diaphragms of thin, dense porcelain were used. Under these conditions minimum sulphonation was obtained. By washing the cell sludge with commercial hydrochloric acid, centrifuging, and treating with pure hydrochloric acid *p*-aminophenol hydrochloride was obtained, the yield being 40—50% on the nitrobenzene (exclusive of mother liquors which yield a further 10%). Apart from the cost of platinum, the most important economic factor is the necessity of providing for the cheap concentration of the spent acid. Cost of upkeep, owing to the excessive corrosive action of the materials on the apparatus, is also considerable.—P. V. M.

Phenoxarsine; Derivatives of ——. W. L. Lewis, C. D. Lowry, and F. H. Bergeim. J. Amer. Chem. Soc., 1921, 43, 891—896.

6-Chlorophenarsazine, m.p. 193° C., has a greater irritant action on the skin and mucous membrane and is more toxic than diphenylchloroarsine, m.p. 37°—38° C., b.p. 333° C., which in turn is more irritant and toxic than 6-chlorophenoxarsine, $O(C_6H_4)_2AsCl$, m.p. 124° C., or chlorophenyl-α-naphthylarsazine, m.p. 228° C. The chlorine in 6-chlorophenoxarsine may readily be replaced or displaced, and a number of new compounds have been prepared from it. (*Cf.* J.C.S., June.)—W. G.

Chlorovinylchloroarsines. S. J. Green and T. S. Price. Trans. Chem. Soc., 1921, **119**, 448—453.

Three products are formed when acetylene acts upon anhydrous arsenic trichloride in the presence of anhydrous aluminium chloride, either in the pure state or in solution in an anhydrous solvent, at 15° C. β-Chlorovinyldichloroarsine, $CHCl{:}CH.AsCl_2$, colourless, b.p. 93° C. at 26 mm., or 96° C. at 30 mm., possesses a powerful vesicant action. ββ′-Dichlorodivinylchloroarsine, $(CHCl{:}CH)_2AsCl$, b.p. 130°—133° C. at 26 mm., colourless, possesses less powerful vesicant action than the primary compound. ββ′β″-Trichlorotrivinylarsine, $(CHCl{:}CH)_3As$, colourless, b.p. 151°—155° C. at 28 mm., m.p. 3°—4° C. All are insoluble in water and dilute acids, but are soluble in organic solvents, with the exception of the tertiary compound which is insoluble in alcohol. Halogens are readily absorbed with the formation of definite characteristic solid compounds. The tendency is for the tertiary derivative to be formed largely at the expense of the others, but it is readily changed to a mixture of the primary and secondary compounds by heating with arsenic trichloride at 200°—250° C. —P. V. M.

ββ′-Dichlorodiethyl disulphide. G. M. Bennett. Trans. Chem. Soc., 1921, **119**, 418—425.

ββ′-Dichlorodiethyl disulphide is synthesised through dihydroxydiethyl disulphide from either monothioethyleneglycol by oxidation with potassium permanganate etc., or from ethylene chlorhydrin and sodium disulphide. Heating with concentrated hydrochloric acid converts the dihydroxy compound into ββ′-dichlorodiethyl disulphide, b.p. 15° C. at 30 mm., sp. gr. 1·3375 at 20°/4° C. The pure disulphide closely resembles the monosulphide in properties, but has only one-third its vesicant action. Oxidation with nitric acid gives quantitatively β-chloroethanesulphonic acid. In the light of his results the author discusses the condition of the system arising from the interaction of sulphur monochloride and ethylene, and concludes that the liquid produced at temperatures below 35° C. is a two-phase system in which the continuous phase is nearly pure dichlorodiethyl monosulphide and the disperse phase a liquid consisting chiefly of sulphur. —P. V. M.

Sulphur monochloride and substituted ethylenes; Interaction of ——. W. J. Pope and J. L. B. Smith. Trans. Chem. Soc., 1921, **119**, 396—400. (*Cf.* Gibson and Pope, J., 1920, 383 A.)

From an examination of the interaction of ethylene, propylene, and β-butylene with sulphur monochloride, it is shown that the formation of the corresponding β-chloro-substituted alkyl sulphide and sulphur is general for ethylenic hydrocarbons. β′-Dichlorodipropyl sulphide $(C_2H_4Cl.CH_3)_2S$ boils at 105°—106° at 11 mm., and ββ′-dichlorodi-*sec*-butyl sulphide $(CHCH_3Cl.CHCH_3)_2S$, at 121°—122° at 11 mm. The speed of absorption varies in each case, and of the three substances examined is greatest for β-butylene. Under comparable conditions the speed of absorption, *i.e.*, the rate of interaction, is represented by ethylene:propylene:β-butylene=1:1·33:4. No analogous reaction was obtained between sulphur monochloride and trichloroethylene, the sulphur monochloride acting merely as a chlorinating agent with the formation of pentachloroethane.—P. V. M.

Iercaptans; Catalytic preparation of ——. R. L. Kramer and E. E. Reid. J. Amer. Chem. Soc., 1921, **43**, 880—890.

3Y passing alcohol vapour and hydrogen sulphide n equimolecular proportions at the rate of 1 g.-mol. n 6 hrs. over pumice coated with thorium oxide at 80° C., the following percentage yields of mer-aptans were obtained: methyl 41%, ethyl 35%, ropyl 45%, butyl 52%, isobutyl 45%, isoamyl 47%. Propyl, butyl, and isoamyl mercaptans give constant oiling mixtures with the corresponding alcohols nd ternary mixtures with the alcohols and water. *Cf.* J.C.S., June.)—W. G.

crolein. C. Moureu, C. Dufraisse, A. Lepape, P. Robin, J. Pougnet, A. Boutaric, and E. Boismenu. Ann. Chim., 1921, **15**, 158—211.

MORE detailed account of work already published. *Cf.* J., 1920, 42 A, 82 A, 173 A.)—W. G.

ormaldehyde; Distillation of aqueous solutions of ——. J. A. Wilkinson and I. A. Gibson. J. Amer. Chem. Soc., 1921, **43**, 695—700.

HE distillate from dilute aqueous solutions of ormaldehyde (below 8%) is always stronger than he original solution, but with higher concentra-ions the distillate is always weaker. With low oncentrations the residue is always weaker than he last distillate, but with high concentrations the esidue is always stronger.—J. F. S.

yanamide; Passage from guanidine to —— *and from diguanidine to dicyanodiamide.* G. Pellizzari. Atti R. Accad. Lincei, 1921, [V], **30**, I., 171—175.

ARIOUS reactions similar to the conversion of *o*-henylenediguanide into *β*-cyano-*o*-phenyleneguani-ine by treatment with nitrous acid (Atti R. Accad. incei, 1921, [V], **30**, I., 39) have been discovered. hus, nitrous acid converts diguanide into cyano-uanidine or dicyanodiamide, and guanidine partly nto cyanamide. In the latter case, the formation f nitrosoguanidine as an intermediate compound as been detected and it is probable that in the ther instances analogous intermediate products re formed. (*Cf.* J.C.S., June.)—T. H. P.

yanogen bromide and iodide; Preparation of ——. V. Grignard and P. Crouzier. Bull. Soc. Chim., 1921, **29**, 214—217.

N aqueous solution of sodium cyanide is run slowly n to bromine covered with a small amount of rater, with constant stirring, the temperature not eing allowed to rise above 25° C., until the colour ue to the bromine has disappeared. Chlorine is hen bubbled through the liquid and, at the same ime, more sodium cyanide is run in, drop by drop, eeping the liberated bromine in slight excess, ntil the whole of the sodium bromide originally ormed is decomposed, when a very slight excess of he cyanide is added. The cyanogen bromide, which rystallises out, may be filtered off, or the contents f the flask may be distilled, the vapour being assed over anhydrous calcium chloride at 80° C. yield of 91% is obtained. Cyanogen iodide may e prepared in a similar manner, but it is best olated by extraction with ether. A yield of 89% obtained.—W. G.

ssential oil of hamagô. Y. Shinozaki. Kōgyō-Kwagaku Zasshi (J. Chem. Ind. Japan), 1921, **24**, 191-202.

Y the distillation of the leaves and twigs of *Vitex ifolia*, L. (*Vitex ovata*, Mak.?) (Jap., hamagô), rown in the Ogasawara Islands and Kanagawa refecture, 0·11—0·28% of an oil having a brown olour and characteristic odour was obtained. hree samples of the oil had the following characters:—Sp. gr. at 15° C., 0·8908—0·9141; n_D^{20}=1·4707—1·5010; optical rotation, −39° 6′ to −47° 20′; acid value, 0·0—1·75; saponif. value, 23·38—38·70; saponif. value after acetylation, 40·14—53·34. The chief constituents of the oil were *l*-α-pinene, which does not give solid nitrosochloride; camphene (percentage with pinene: 55%); terpinyl acetate (10%), b.p. 84°—86° C. at 15 mm., sp. gr. 0·9629 at 15° C., n_D^{20}=1·4670; a diterpene-alcohol ($C_{20}H_{32}O$ or $C_{20}H_{34}O$) (20%), b.p. 165°—167° C. at 4 mm., sp. gr. 0·9760 at 15° C., n_D^{20}=1·5143, optical rotation, −46° 39′, and saponif. value after acetylation 42·02. The oil is separated into its three chief constituents by fractional distillation, and the middle part is suitable for perfumes, as it is mainly composed of terpinyl acetate.—K. K

Essential oil of shimamuro. Y. Shinozaki. Kōgyō-Kwagaku Zasshi (J. Chem. Ind. Japan), 1921, **24**, 202—208.

BY distillation of the leaves and twigs of *Juniperus taxifolia*, Hook. et Arn. (Jap., shimamuro), a coniferous plant, indigenous to the Ogasawara Islands, 0·24% of a light green oil was obtained. Two specimens of the oil had the following characters:—Sp. gr. at 15° C., 0·8675, 0·8701; n_D^{20}=1·4702, 1·4718; optical rotation, —, −29°; acid value, 0·94, 0·0; saponif. value, 11·69, 10·37; saponif. value after acetylation, 19·60, 18·89. The oil contains α-pinene (above 50%, mainly *l*-α-pinene containing small quantity of *r*-α-isomer) and possibly a bicyclic terpene, a free alcohol ($C_{10}H_{18}O$), ester, sesquiterpene, and sesquiterpene alcohol.—K. K.

PATENTS.

Dichloroethylene; Manufacture of ——. A. Wacker, Ges. für Elektrochem. Industrie. E.P. 156,080, 22.10.20. Conv., 23.12.19.

DICHOROETHYLENE is obtained in 85—88% yield by passing the vapour of tetrachloroethane mixed with steam through a chamber charged with iron, aluminium turnings, or granulated zinc. The crude product issuing from the chambers is condensed and fractionally distilled, the fraction collected between 48° and 60° C. being a mixture of two stereo-isomeric dichloroethylenes. The small higher fraction of unchanged tetrachloroethane is returned to the process.—G. F. M.

Tubercle bacillus and other germs; Detoxication of —— *for the preparation of vaccines.* D. Thomson. E.P. 161,341, 23.1.20.

THE germ cultures are separated into a number of non-toxic fractions by successive extractions with either "antiformin" (15% sodium hydroxide plus 15% sodium hypochlorite solution) or *N*/1 sodium hydroxide, *N*/1 hydrochloric acid, absolute alcohol, and chloroform. The insoluble matter is separated after each extraction by centrifuging, and the clear solution is removed for further treatment. The portions extracted by the alkaline and acid solutions are again fractionated by precipitating a portion of the dissolved material with acid and alkali respectively, and subsequently adding absolute alcohol to the liquors to precipitate second fractions. The alcohol extract is precipitated by the addition of normal aqueous sodium chloride, and the final portion extracted with chloroform is recovered by evaporating the solvent. The precipitates are mixed together, with the exception in certain cases of the fractions precipitated by alcohol from the alkali and acid extracts, which possess provocative properties, and are emulsified with normal sodium chloride solution containing 0·5% of phenol, to yield a vaccine corresponding to ten thousand millions of germs per c.c.—L. A. C.

Allyl esters of p-aminobenzoic acid. R. Adams and E. H. Volwiler, Assrs. to The Abbott Laboratories. U.S.P. 1,360,994, 7.12.20. Appl., 10.5.20.

Allyl esters of amino derivatives of aromatic acids containing a benzene nucleus are prepared by reduction of the corresponding nitro derivatives. The allyl ester of *p*-nitrobenzoic acid, prepared from *p*-nitrobenzoyl chloride and allyl alcohol, boils at 178° C. at 19 mm., and on reduction yields the allyl ester of *p*-aminobenzoic acid, white crystals, m.p. 51°—52° C., of value as an anæsthetic. The dihydrochloride of the allyl ester of 3.5-diaminobenzoic acid is a yellowish solid, m.p. 224° C. (decomp.).

Phenylcinchonic acid salt. M. E. Wolvecamp, Assr. to The Abbott Laboratories. U.S.P. 1,361,128, 7.12.20. Appl., 15.9.17.

Acid sodium phenylcinchonate, $C_{16}H_{10}NO_2Na$, $C_{16}H_{11}NO_2$, prepared by the action of the calculated quantity of sodium hydroxide solution on the acid and dried below 100° C., forms citron-yellow crystals, freely soluble in water and exhibiting the same medicinal properties as the free acid.

Acetylation of hydrocarbons and subsequent recovery of the products of the reaction. G. T. Koch and A. L. Stallkamp, Assrs. to The Ohio Fuel Supply Co. U.S.P. 1,374,666, 12.4.21. Appl., 4.11.20.

Chlorohydrocarbons of the paraffin series are converted into acetates (*e.g.*, amyl acetate) by heating at 250°—450° F. (120°—230° C.) under a pressure of 200—225 lb. per sq. inch with an alkali acetate in presence of activated carbon or " batchite " as a catalyst. The product is fractionally distilled and the lower fractions returned to a subsequent operation.—G. F. M.

Organic compounds; Preparation of —— by chemical reactions promoted by light. Farbenfabr. vorm. F. Bayer und Co. G.P. 297,933, 25.6.15.

The light of the Osram half-watt lamp is used, which is nearly equivalent to sunlight in its chemical effect. Examples are the preparation of xylyl chloride from xylene, pinacone from acetone and isopropyl alcohol, etc.—C. I.

Cyanamide; Preparation of solutions rich in —— from calcium cyanamide. A.-G. für Stickstoffdünger. G.P. 302,515, 5.11.16.

Calcium cyanamide is extracted with water and the solution treated with carbon dioxide or absorbing materials, *e.g.*, earth or peat, to remove the lime. The resulting liquor containing 2—3% N is used to extract further quantities of calcium cyanamide. No polymerisation of the cyanamide in solution takes place during the operation.
—A. R. P.

Alkali cyanamides; Process for preparing ——. Preparation of alkali cyanamide solutions. E. Hene and A. van Haaren. G.P. (A) 306,315, 28.9.16, and (B) 307,011, 17.11.16.

(A) Calcium cyanamide and alkali sulphate are allowed to interact at temperatures below 100° C., preferably 25°—35° C., in water. Excess of alkali sulphate reduces the amount of calcium cyanamide left in solution, but a double sulphate is then formed. (B) Instead of alkali sulphate a double alkali-calcium sulphate may be used. To a weak solution of alkali cyanamide, calcium cyanamide and sufficient alkali sulphate to form mono-alkali cyanamide along with a double sulphate are added. The resulting mud is used with more calcium cyanamide and water to form fresh weak solution, and the mono-alkali cyanamide which still contains calcium is treated with fresh alkali sulphate.
—C. I.

Fatty acids and aldehydes; Process for the preparation of ——. C. Harries, R. Koetschau, and E. Albrecht. G.P. 332,594, 23.3.17. Addn. to 324,663 (J., 1920, 765 A).

Ozonides prepared from petroleum, shale oil, or tar oils or the compounds formed by their reaction with water vapour or alkali are treated with oxidising agents, *e.g.*, hydrogen peroxide and alkali, Caro's acid, halogens, chromic acid, glacial acetic acid and permanganate.—C. I.

5(4)-*Aralkylaminoalkyliminazoles; Manufacture of ——.* O. Gerngross. G.P. 332,955, 10.6.14. Addn. to 278,884 (J., 1915, 250).

Compounds of the general formula, iminazolyl. $(CH_2)_x$.NH.$(CH_2)_x$.aryl are prepared by the interaction of iminazolylalkyl chlorides and aralkylamines or aralkyl chlorides, Ar.$(CH_2)_x$.Cl and iminazolealkylamines, or the salts of the compounds respectively. By interaction of 4(5)-methyl-5(4)-chloromethyliminazole hydrochloride and *β*-phenylethylamine, a mixture of secondary 4(5)-methyl-5(4)-phenylethylaminomethyliminazole and tertiary di-5(4)-methyliminazolyl-4(5)-methyl-*β*-phenylethylamine is obtained. They are separated by fractional crystallisation of their picrates from acetone, the picrate of the tertiary base being more soluble. By heating *β*-*p*-hydroxyphenylethyl chloride with *β*-4(5)-iminazolylethylamine in dry methyl alcohol for 12 hrs. at 100° C. under pressure, 4(5).4′-hydroxyphenylethylaminoethyliminazole, $OH.C_6H_4(CH_2)_2.NH.(CH_2)_2C_3H_3N_2$, is formed. It melts at 156° C. and is slightly soluble in water. The compounds have a physiological effect similar to that of ergot.—C. A. C.

Formic acid esters; Preparation of ——. Elektrochem. Werke G.m.b.H., H. Bosshard, and D. Strauss. G.P. 334,298, 19.11.16.

Formic acid and alcohols of the highest concentration practicable are caused to react in the theoretical proportions in presence of calcium chloride without addition of mineral acids. The apparatus may be made of iron, and the calcium chloride recovered.—C. I.

Hexamethylenetetramine; Preparation of addition products of ——. J. D. Riedel A.-G. G.P. 334,709, 31.12.18.

If a mixture of hexamethylenetetramine and monohalogen-acetic acid, in an anhydrous solvent, is heated, the salt first formed is converted into a substance resembling betaine hydrochloride. The presence of a little water or the use of halogenated higher fatty acids leads to the formation of hexamethylenetetramine-halogen hydrate. The addition products from monochloro- and monobromoacetic acids are coarsely crystalline substances, easily soluble in water, slightly in alcohol, and insoluble in acetone and ether. On crystallisation from aqueous alcohol the halogen hydrate compound is formed. The aqueous solution, which tastes acid, evolves formaldehyde on heating. The substances are strong bactericides.—B. V. S.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic plate; Extinction by a blackened —— as function of wave-length, quantity of silver, and size of the grains. A. Deumens. Proc. Roy. Acad. Amsterdam, 1921, 23, 848—865.

Two series of plates were prepared, one set developed with varying times, or temperature, or developer strength, in a caustic quinol developer and the other set with similar variations in a glycin developer. All the plates were examined as to density, amount of silver, and grain size. The density value was found to vary with the wavelength of the light by which it was measured to an extent which varied with the conditions of development, this being one of the factors determining grain size. Plates developed in a normal glycin developer were practically neutral in colour in the yellow-green portion of the spectrum and suitable therefore for use as reducers of light intensity in photometric measurements etc. using yellow-green light. The relation between quantity of silver and density is shown to vary with grain size. It is suggested that the proportionality (photometric constant) previously found by Hurter and Driffield, Sheppard and Mees, and Eder was due to their use of silver images with grains of equal size. Some figures are also given for collargol.—B. V. S.

[*Photographic*] *red sensitiveness of silver iodide.* R. B. Archey. Phot. J., 1921, 61, 235—236.

In using various cinematograph positive films a considerable variation in the ease of fogging by the dark-room light was observed, both between different brands of film and between different emulsions of the same manufacture. Film was exposed 30 mins. to a 25 c.p. lamp behind a Wratten No. 1 safelight at a distance of 1 ft., and developed under constant, normal conditions. The resulting density measured on a König-Martens photometer was ound to be proportional, not to the speed of the plate, but to the contrast. In one case the same ilm was tested at intervals of 1 month for 9 months, he H. and D. speed, developing factor, and red ensitiveness being determined; changes in the two atter corresponded but not with changes in speed. The addition of excess iodide in the manufacture of an emulsion in one case led to a fog value f 2·72. Spectrograms of two films are given at either end of the spectrum in each case, the two pectra at the blue end being practically indistinguishable, while at the red end one film shows no mage and the other a very strong one.—B. V. S.

Patents.

Photographic] *toning-baths for silver-pictures, with tellurium or selenium as the toning agent.* Kraft und Steudel, Fabr. phot. Papiere, G.m.b.H. G.P. 334,172, 1.6.20.

In the preparation of toning baths containing a elenium or tellurium salt as toning agent, other known toning agents such as thiourea, hydrazine, or hydroxylamine may be added, along with a salt uch as a borate or phosphate, or preferably, acetate, citrate, tartrate, etc., which prevents precipitation of the selenium or tellurium. A bath prepared with tellurous acid and an alkali, such as ithium hydroxide, is preferably acidified. The tability of a toning bath may be increased by the addition of a protective colloid such as albumin or tarch. The developed, fixed, and washed print is oned for 3—15 mins. according to the tone required; chloride prints tone more quickly and require a weaker bath. Selenium gives redder tones than tellurium.—B. V. S.

Coloured [*photographic*] *pictures; Process for making* ——. A. Traube. E.P. 147,103, 7.7.20. Conv., 3.12.18. Addn. to 147,005.

Basic dyes of the thiobenzenyl, thiazine, pyronine, safranine, oxazine, and acridine classes give better results than the dyes mentioned in the chief patent (J., 1921, 325 A), by reason of their greater permanence in the toning processes, combined with easy staining and sufficient colour intensity.—B. V. S.

Photographic reproduction; Process of ——. R. John, Assr. to Iconochrome Co. of America, Inc. U.S.P. 1,374,853, 12.4.21. Appl., 25.7.19.

For the production of a transfer printing plate an emulsion is used containing in addition to the light-sensitive material a substance which reacts with the product of light action on the sensitive material to form a hardening agent, and a further substance having a neutralising effect on the hardening agent which is added in sufficient proportion to make the amount of hardening proportional to the amount of image.—B. V. S.

Photosensitising dye of the isocyanine type. Photosensitising dye effective for infra-red radiation. E. Q. Adams and H. L. Haller. U.S.P. (A) 1,374,871 and (B) 1,374,872, 12.4.21. Appl., 28.5 and 17.7.20.

(A) Photosensitising dyes are produced by the action of strong bases in alcoholic solution upon the alkyl halides of lepidine. (B) The dyes obtained from the higher alkyl halides of lepidine give sensitiveness in the infra-red. (*Cf.* J., 1921, 75 A.) —B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Corn [*maize*] *cob cellulose; Possible uses of* —— *in the explosives industry.* L. G. Marsh. J. Ind. Eng. Chem., 1921, 13, 296—298.

Cellulose extracted from maize cobs by treatment with 1% sodium hydroxide, and then 4% sulphuric acid, at 100° C., absorbs 150% of its own weight of nitroglycerin, and is therefore a suitable ingredient for dynamite. In preliminary tests of its absorptive capacity for water, with a view to employing it as a substitute for cotton in nitrocellulose manufacture, samples were totally submerged in less than 12 secs. after dropping on the surface of the water. Some difficulty was experienced in separating nitrated maize cob cellulose from the acid on account of its fineness; screening was ineffective, and it was finally separated by gravity, a mat of nitrated cotton being used. Washing and settling were carried out satisfactorily; pulping was unnecessary, but the usual purification system could be adopted. A yield of about 130% was obtained. The product gave a satisfactory heat test. The nitrogen content was only 12·3%, due to a high proportion of material insoluble in acetone; after removing this, the nitrogen figure was increased to 12·7%. Even by nitrating equal parts of cotton and maize cob cellulose, no material reduction was effected in the acetone-insoluble residue; its structure, consisting of fine, hard grains, militates against the use of maize cob cellulose for the manufacture of perforated powders.—W. J. W.

Trinitrotoluene poisoning; Nature, diagnosis, and prevention of ——. C. Voegtlin, C. W. Hooper, and J. M. Johnson. Hygienic Lab., U.S. Public Health Service. Bull. 126, 1920, 7—181.

Numerous tests were made on dogs, which are more sensitive than other animals, and develop the typical symptoms noted with human beings. The toxic action of TNT is essentially due to 2.4.6-trinitrotoluene, and not to impurities. As indicated by Moore (Causation and Prevention of Trinitrotoluene Poisoning, Medical Research Committee, London. 1917), TNT is not excreted as such, but is converted after absorption into a hydroxylamine compound. This compound may also undergo reduction to the mono- or diamino-derivative which do not give the Webster reaction but have the same pharmacological action as TNT. Differences in resistance of different individuals may be due to the fact that more resistant animals oxidise the methyl group of TNT more readily. Reliance on clinical symptoms alone in the diagnosis of TNT poisoning in munition workers is not sufficient, as marked blood changes may be present, even when the workers do not exhibit signs of cyanosis, pallor, or icterus; an examination of the blood is therefore essential. Sex has no influence on susceptibility to poisoning, and individual susceptibility, as with dogs, explains the absence of relation between time of exposure to the poison and contraction of anæmia. The authors do not concur with Moore's view that all TNT poisoning is caused by skin absorption, and that individual susceptibility is accounted for by difference in skin permeability. Preventive measures should include efficient ventilation and the use of induced draught for cleaning floors, etc. Overalls extending over the ankles and a head-dress should be worn; gloves are useless. A skin wash of 10% sodium sulphite solution has proved satisfactory. Workers' diet should include a fair proportion of meat, vegetables, bread, and fruit. Although to a certain extent intermittent employment reduces the health risk, it does not entirely prevent poisoning, as the system retains TNT for a long time. Workers should undergo a preliminary medical examination, and none suffering from anæmia or liver disease should be employed. —W. J. W.

Parazol (crude dichlordinitrobenzene); Toxicity of ——. C. Voegtlin, A. E. Livingston, and C. W. Hooper. Hygienic Lab., U.S. Public Health Service. Bull. 126, 1920, 183—202.

Parazol, which was extensively used as a high explosive during the war, is a mixture of three isomers: *m*-dinitro-*p*-dichlorobenzene, *o*-dinitro-*p*-dichlorobenzene, and *p*-dinitro-*p*-dichlorobenzene; in addition, a small fraction consisting of *p*-nitrochlorobenzene has been separated from it. The action on the skin of crude and recrystallised parazol, as well as of two of its isomers and of *p*-nitrochlorobenzene, was studied with rabbits, and confirmed in some cases with human skin. In each case dermatitis was produced. More severe lesions were caused by the crude product than by its isomers, and of these latter the *m*-dinitro compound proved more injurious than either the *o*-dinitro compound or *p*-nitrochlorobenzene. In regard to the action on the eyes, no effect was produced when the products were applied as a 1% solution in olive oil; on the other hand, the dry powder caused marked conjunctivitis; that this result was not due merely to mechanical irritation was proved by the varying effect produced by the different products, crude parazol being the most active. Crude parazol when injected subcutaneously caused extensive edema and induration, sometimes leading to the formation of an abscess. When introduced through the mouth it was absorbed without gastro-intestinal irritation. Relatively large amounts of parazol are required to produce anæmia, and it may therefore be regarded as a low grade poison. The active agents in causing anæmia are probably the nitro-groups, which, as with TNT, become reduced in the body. On the other hand, dermatitis and conjunctivitis depend on the presence of chlorine in the molecule. To protect parazol workers contamination of the air with the material should be prevented, and goggles should be worn. The provision of proper overalls is essential; skin varnishes are unreliable.—W. J. W.

Mercury fulminate; Skin irritation and systemic effects produced by ——. A. E. Livingston. Hygienic Lab., U.S. Public Health Service. Bull. 126, 1920, 203—211.

Application of mercury fulminate to the shaved skin of rabbits invariably caused a marked lesion after 2—3 hrs., and blanching of the skin took place, followed by endema; after a longer period a hemorrhagic condition replaced the blanching. Applications of fulminate to the human skin produced no effect whatever, but no conclusion can be drawn from this as to its effects on workers in factories, where friction, lack of cleanliness, etc., may cause the poison to enter the skin, and where individual susceptibility has an important bearing. In regard to the systemic effects of mercury fulminate, there is no evidence of fatal results brought about by absorption through the skin, nor could it be detected in the urine, after skin application. When administered as capsules through the mouth the minimum lethal dose for rabbits appears to be about 20 mg. per kg. As a preventive measure against fulminate poisoning, a shellac skin varnish has given good results. Sodium thiosulphate solution is beneficial if used as a wash; it is, however, useless for treatment after injury.—W. J. W.

Detonators and percussion caps; Examination of ——. A. Langhans. Z. ges. Schiess- u. Sprengstoffw., 1921, 16, 49—52, 57—59.

Microscopical examination of cap and detonator compositions affords a means of identifying their components. In a quantitative examination the risk involved in removing the composition from its metal container is avoided by submitting the whole detonator or cap to solution and analysis. The author describes a method of analysis. The composition of the caps was as follows: Mercury fulminate, 0·054 g. (mercury, 0·038 g.); antimony sulphide, 0·208 g.; potassium chlorate, 0·339 g.; powdered glass, 0·013 g.; potassium nitrate, 0·0684 g.; sulphur, 0·0081 g.; carbon, 0·0135 g.; copper, 0·79 g. Four caps were treated for 2 hrs. with a mixture of 50 c.c. of nitric acid and 25 c.c. of water. The solution was evaporated to dryness, and the residue boiled three times with dilute nitric acid, and filtered; powdered glass, together with some charcoal and sulphur, remained on the filter. After dilution of the filtrate to 500 c.c., 100 c.c. was treated with hydrogen sulphide; the precipitate was treated with sodium sulphide solution and potassium hydroxide and the solution filtered from the undissolved coppe sulphide, which was dissolved in acid and electrolysed. The filtrate containing sulphides of antimony and mercury in solution was acidified, and the precipitated sulphides filtered off and treated with ammonium sulphide for a prolonged period the antimony sulphide was precipitated with su phuric acid, whilst the undissolved mercury su phide was dissolved in nitric acid and electrolysed For the estimation of potassium chlorate an nitrate the filtrate from the original hydrogen su phide precipitation was evaporated to expel hydro gen sulphide, and the residue then treated wit water and sulphuric acid and again evaporated t dryness. From the potassium sulphate found th respective amounts of chlorate and nitrate we calculated. For the analysis of detonators a analogous method to the above may be employe For mercury fulminate and potassium chlorate con positions a method of estimating chlorate by th use of nitron is also applicable.—W. J. W.

Patents.

Explosives [for detonators]. A. G. Lowndes. E. 160,953, 6.1.20.

The sensitiveness of explosives, such as lead azi is said to be due more to the structure and cleava than to the size of the crystals. By adding a n colloidal solution, which has no action on lead azid to the liquid in which it is precipitated so as increase the density of the liquid, the azide m be obtained in the form of anhedra, flakes, or th plates, of less sensitiveness than the holohe usually formed. Thus, 200 c.c. of sodium az solution (40 g. per l.) is added to a mixture

200 c.c. of lead acetate solution (117 g. per l.) and 1000 c.c. of sodium nitrate solution (450 g. per l.), all at 15° C. Alternatively, equivalent solutions of sodium azide and lead acetate may be run into sodium nitrate solution. (*Cf.* E.P. 142,898; J., 1920, 529 a.)—W. J. W.

Explosive; High —— and process of making same. W. R. Swint, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,373,844, 5.4.21. Appl., 6.5.18.

An explosive composition consists of wet nitrocellulose of a high degree of nitration and a liquid nitro-derivative of a hydrocarbon.—W. J. W.

Explosive. G. Weber, Assr. to Soc. Les Petits Fils De Francois De Wendel et Cie. U.S.P. 1,375,243, 19.4.21. Appl., 27.9.19.

An explosive contains a combustible organic substance adapted to absorb liquid air, and blast-furnace dust.—L. A. C.

Detonators; Process for destroying waste —— and recovering copper and mercury from the same. W. Eschbach. G.P. 298,860, 29.11.16.

The detonators are placed in a rotary drum, provided with a suitable shock-absorbing device, and treated with a hot solution of sodium carbonate, which loosens the composition by dissolving its potassium chlorate or perchlorate, and converts the mercury fulminate into mercuric carbonate and sodium fulminate. After filtering and washing this mixture the mercury is recovered from it electrolytically. The empty shells are washed and introduced in small quantities into a furnace in which any remaining traces of explosive are decomposed. —W. J. W.

Mixed acid; Process for preparing ——. Chem. Fabr. Griesheim-Elektron. G.P. 303,892, 1.3.16.

Dilute nitric acid is absorbed, *e.g.*, in a tower, by a counter current of cooled concentrated sulphuric acid.—C. I.

Ammonium nitrate and carbon; Process of obtaining mixtures of —— which can be cast. Verein Chem. Fabr. in Mannhein. G.P. 309,288, 5.9.17.

Wood charcoal of a definite, not too low adsorptive power and water content, is mixed with ammonium nitrate. The melting point of the mixture is lowered by the addition of carbon or oxygen compounds; *e.g.*, 15 pts. of finely powdered wood charcoal is saturated with 25% of its weight of water, then mixed with 77 pts. of ammonium nitrate and 8 pts. of sodium nitrate, the mixture heated to 110° C., and cast in the desired shape.—C. I.

XXIII.—ANALYSIS.

Viscosimeter. R. Fischer. Z. angew. Chem., 1921, 34, 153—154.

The tube of a falling-sphere viscosimeter described previously by the author (Chem.-Zeit., 1920, 44, 622) may be widened so that the path of the sphere is not affected by the tubulus for the thermometer; the apparatus may be standardised with different sized spheres for use with liquids of low and high viscosities, and, when dealing with aqueous liquids, the electrical contacts at the bottom of the tube may be covered with a layer of carbon tetrachloride which is introduced before the liquid.—W. P. S.

Combustion analysis by means of tellurium dioxide. T. R. Glauser. Z. angew. Chem., 1921, 34, 154—155, 157—159, 162—163.

A record of further work on a method described previously (J., 1914, 223). Whilst the carbon in many substances (*e.g.*, iron, heavy metals, graphite) is oxidised readily to carbon dioxide by heating with tellurium dioxide, the reaction proceeds very slowly in the case of ferrosilicon, carborundum, etc., and for the determination of carbon in these it is better to use lead oxide or a mixture of lead oxide and tellurium dioxide as the oxidising agent. —W. P. S.

Refractive indices of liquids; Simple instrument for the determination of the ——. W. A. M. Smart and F. A. Hocking. Pharm. J., 1921, **106**, 286—288.

A vertical rod, fixed to a wooden base, carries a sliding device to which is attached an observation lens; a piece of hat-pin is also attached to the sliding device below the lens so that its end is vertically below the centre of the lens. A thin mirror is let into the base and a convex lens of +6D to +10D is laid on the mirror. The slider is raised or lowered until the pin and its image (as seen by reflection from the mirror and through the lens) are exactly coincident. The distance between the pin and the centre of the lens is then read off on a scale fixed to the vertical rod. A few drops of water are then placed between the mirror and the lens and the new focal position read off after adjusting the slider. This operation is repeated, using the liquid the refractive index of which is to be determined in place of the water. The refractive index, μ_2, of the liquid is then calculated by the formula, $\mu_2=\mu(f-F_2)F_1+(F_2-F_1)f/F_2(f-F_1)$, where μ is the refractive index of water, f the focal length of the lens when air is between it and the mirror, F_1 the focal length of the water-lens combination, and F_2 that of the liquid-lens combination, these lengths being read in mm. on the scale.—W. P. S.

Enamelled bombs; Use of —— in calorimetry. C. Matignon and G. Marchal. Comptes rend., 1921, **172**, 921—922.

Enamelled bombs of recent manufacture are likely to be attacked by the dilute nitric acid, such as is always formed under the ordinary conditions of calorimetric work. To obviate this source of error new bombs should be filled with $N/1$ nitric acid and submitted to its action for 4—5 hrs. before being used.—W. G.

Filtration in dry or indifferent gases; Apparatus for ——. A. Wolfram. Ber., 1920, 54, 857—859.

The apparatus permits the preparation, filtration, and desiccation of a hygroscopic substance in a single operation, with complete exclusion of moisture. The reaction vessel is a round-bottomed flask provided with a tubulus in one side by means of which a dropping funnel is attached, into which a dried gas can be passed as required. The accurately-ground neck of the flask presses a hardened filter paper against a perforated porcelain disc placed in a filter tube similar to those used with Gooch crucibles, the junction between tube and flask being made by a rubber ring. The narrow end of the filter tube is connected by a two-holed rubber stopper with a separating funnel, the other hole permitting attachment to an exhaust pump. The complete apparatus is mounted in a slightly inclined position and the reacting substances are mixed in the flask; it is subsequently brought into a vertical position, whereby the mixture flows on to the filter paper and the precipitate is filtered by suction. The filtrate is run off through the larger funnel and the precipitate is washed with liquid introduced through the smaller one. It is finally desiccated by aspirating a current of dry air or other suitable gas through it.—H. W.

Spot reactions in qualitative analysis. E. Hauser. Z. anal. Chem., 1921, 60, 88—89.

The advantages of spot reactions on filter paper for the identification of simple substances or of mixtures, as described recently by Feigl and Stern (J., 1921, 280 a), are confirmed.—W. P. S.

Metals of the second group; Separation of ——. G. G. Longinescu and G. P. Theodorescu. Bul. Sci. Acad. Roumaine, 1920, 6, 159—161.

The mixed sulphides are heated with ammonium carbonate solution, and filtered; the arsenic alone is dissolved. The precipitate is then dissolved in hydrochloric acid with the addition of potassium chlorate, the solution diluted, cooled, and filtered to remove the greater part of the lead chloride. The filtrate is neutralised with sodium carbonate, sodium hydroxide is added, the mixture boiled, and filtered. Mercury, bismuth, copper, and cadmium remain in the insoluble precipitate, whilst tin, antimony, and the remainder of the lead pass into the filtrate. The precipitate is dissolved in hydrochloric acid and the solution rendered ammoniacal; mercury and bismuth are precipitated and these two metals are then separated and identified by the usual methods and tests, as are also the lead, tin, and antimony.—W. P. S.

Mercury; Identification of —— as cuprous mercuric iodide. P. Artmann. Z. anal. Chem., 1921, 60, 81—88.

When precipitated cuprous iodide is treated with a drop of a mercury salt solution, a bright red coloration is obtained. The test may be made on a microscope slide, or better, on filter-paper, the cuprous iodide being applied to the latter and dried at a low temperature before the mercury solution is added. The reaction may be obtained with a drop of solution containing 2 mg. of mercury per litre. The acid concentration of the mercury solution must not be greater than $N/10$, and bismuth salts and substances which are reduced readily must not be present.—W. P. S.

Iron; Determination of —— by the cupferron method. G. E. F. Lundell. J. Amer. Chem. Soc., 1921, 43, 847—851.

Precipitation of iron by cupferron is quantitative in hydrochloric and sulphuric acid solutions containing as much as 20% by volume of either acid. The precipitate is not dissolved by washing with cold dilute hydrochloric acid (1:9). Ammoniacal wash waters, which need rarely be employed, may cause losses. These are always indicated by the formation of turbid filtrates. Perfectly clear filtrates and washings are absolutely essential in accurate determinations of iron by the cupferron method. The precipitates occasionally exhibit a tendency to creep through the filter, consequently when the filtrate or wash water is even opalescent the need for such corrective treatments as re-filtration or digestion in the cold followed by re-filtration is indicated.—J. F. S.

Electrometric titration; Determination of iodic acid and silver by ——. W. S. Hendrixson. J. Amer. Chem. Soc., 1921, 43, 858—866.

Iodate may be accurately determined by reducing it with a known excess of iodide in dilute sulphuric acid and titrating the excess with permanganate by the electrometric method previously described (J., 1921, 241 A). Iodides can be titrated directly with iodate in dilute sulphuric acid solution by the electrometric method. Hydrochloric acid may not be substituted for sulphuric acid except within very narrow limits of concentration in the determination of iodide with either permanganate or iodate. These estimations may be made in the presence of chloride not exceeding about $0{\cdot}1N$ or in the presence of nitric acid of higher concentrations if it contains only traces of nitrous acid. Silver may be accurately determined electrometrically with pure iodide and permanganate solution. Pure silver may be used as a standard in determining the values of both iodide and permanganate.—J. F. S.

Copper; Use of silver cathodes in the electro-deposition of ——. H. W. Doughty and B. Freeman. J. Amer. Chem. Soc., 1921, 43, 700—704.

Silver cathodes for use in the electro-deposition of copper are cleaned by placing them in contact with pure tin-foil in a boiling 10% sodium hydroxide solution until bright. They are then washed successively with dilute hydrochloric acid, dilute ammonia, and distilled water, rinsed with alcohol, and ignited to burn off the alcohol. The electrolysis is carried out as usual except that the electrode is not immersed in the solution until the current has been switched on. To remove the copper deposit, after the final weighing, the cathode is placed in a wide-mouthed stoppered bottle filled with a 10% solution of trichloro-acetic acid in aqueous ammonia (sp. gr. 0·90) to which an equal volume of water has been added. The copper is removed in 10 mins. and the silver electrode is not attacked. Chloroform or carbon tetrachloride may be substituted for trichloro-acetic acid, but in this case the ammonia solution is made from 1 pt. of ammonia of sp. gr. 0·90 and 1 pt. of alcohol. The reaction is slower and care must be taken that no sulphur compounds are present in the carbon tetrachloride. (*Cf.* J.C.S., June.)—J. F. S.

Gold; Electrolytic determination of —— and its separation from copper, palladium, and platinum. W. D. Treadwell. Helv. Chim. Acta, 1921, 4, 364—374.

Gold may be electrolytically deposited, rapidly and quantitatively, from solutions of the chloride containing acetate, this method admitting of the separation of gold from copper, palladium, and platinum. The readiness with which palladium is attacked in comparison with platinum, when subjected to anodic polarisation in hydrochloric acid solution, serves as a means for the approximate estimation of the palladium content of a precipitate composed of a large proportion of palladium and of little platinum. —T. H. P.

Hydrochloric acid; Detection of —— in the presence of hydrobromic and hydriodic acids. G. G. Longinescu and G. Chaborski. Bul. Sci. Acad. Roumaine, 1920, 6, 122—124.

The mixed salts are heated in a test-tube with a mixture of ethyl alcohol and concentrated sulphuric acid, an inverted funnel containing paper moistened with silver nitrate being placed over the mouth of the test-tube. The hydrochloric acid evolved together with a small amount of iodine is absorbed by the silver nitrate, and when the silver chloride is dissolved subsequently in ammonia the iodine remains insoluble. The hydrobromic acid is decomposed partially and bromoethanes are formed. If the heating is continued after all the hydrochloric acid has been expelled, the bromoethanes and iodine are evolved and may be collected by inverting a moistened beaker over the mouth of the test-tube. The beaker is then washed out with water and the solution treated with chlorine-water after the addition of carbon bisulphide; when sufficient chlorine has been added the violet coloration due to the iodine disappears and the brown coloration of the bromine remains.—W. P. S.

Nitric acid; Detection of ——. G. G. Longinescu and G. Chaborski. Bul. Sci. Acad. Roumaine 1920, 6, 176—178.

When a nitrate is heated with a small quantity of benzene and concentrated sulphuric acid, nitrobenzene is formed, and this may be detected readily by its characteristic odour. If bromides or iodides are also present, the odour of nitrobenzene cannot be noticed until after the mixture has been neutralised with sodium hydroxide.—W. P. S.

PATENTS.

Gas; [Laboratory] apparatus for the generation of —— formed by the action of liquids on solid reagents. F. Hirsch. E.P. 161,681, 14.1.20.

THE apparatus consists of a reservoir, containing the liquid reagent, connected through a tap with a long tapering generating tower with a perforated bottom constricted to a tube forming a tight connexion with a receiver placed beneath it, into which the spent liquor from the generating tower flows. The receiver is furnished with a gas outlet at the top and a spent liquor outlet at the base. The gas is thereby caused to pass through the mass of the solid reagent in the tower in order to reach the gas outlet, and when the latter and the reservoir tap are closed the further generation of gas ceases. —G. F. M.

Gas analysing apparatus. Svenska Aktiebolaget Mono. E.P. 138,355, 28.1.20. Conv., 29.1.19.

IN gas analysing apparatus operated as described in E.P. 16,561 of 1908 and provided with two or more measuring vessels, synchronous analyses may be carried out by arranging that the gas from only one of the measuring vessels passes through the remaining members of the apparatus, whilst the gas from the other measuring vessels escapes to the atmosphere.—J. S. G. T.

Analysing gases; Apparatus for ——. R. H. Davis and C. Rosling. E.P. 160,930, 30.12.19.

APPARATUS for analysing gases comprises a vessel containing an absorbent of the constituent to be determined, both ends of the vessel being in the form of diaphragms such as are employed in aneroid barometers. Gas is admitted to the vessel through a valved inlet and the change of pressure due to absorption of a constituent of the gas is transmitted by one of the diaphragms to a pointer moving over a scale. The second diaphragm controls the entry and exit of gas before and after analysis, and serves to retain the absorbent liquid for subsequent analyses.—J. S. G. T.

Gas-analysing apparatus. O. Rohde, and Svenska Aktiebolaget Mono. E.P. 160,854, 7.8.19.

IN apparatus in which two measuring vessels are employed for measuring the volume before and after absorption of various constituents, the first measuring vessel is cooled by liquid flowing into its interior, and the second by liquid flowing in a helical coil surrounding the vessel. The liquid is kept in circulation by means of a pump, and preferably a regulating vessel is inserted in the discharge pipe so that the flow of cooling water may be adjusted to about 3 to 5 drops per sec.—J. S. G. T.

Gas-analysing apparatus. O. Rohde, Assr. to Svenska Aktiebolaget Mono. U.S.P. 1,373,264, 29.3.21. Appl., 8.9.19.

SEE E.P. 160,854 of 1919; preceding.

Gas; Apparatus for analysing ——. O. Rohde, Assr. to Aktiebolaget Ingeniörsfirma F. Egnell. U.S.P. 1,374,391, 12.4.21. Appl., 29.1.17.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Caldwell. Crushing and grinding apparatus. 13,272. May 10.

Collins. Furnaces for steam-generators, kilns, etc. 13,842. May 17.

Cross. Compositions for preventing corrosion and removing incrustation in boilers etc. 13,636. May 13.

Ingersoll-Rand Co. Devaporising and cooling. 13,814. May 14. (U.S., 5.6.20.)

Lloyd and Miller. Grinding or crushing machines. 13,564. May 13.

Lodge Fume Co., and others. 14,230–1. *See* XI.

Nitrogen Corp. Catalyst, and method of preparing same. 13,161. May 9. (U.S., 8.5.20.)

Rigby. Heating or cooling liquids or admixed solids in evaporative etc. treatment. 13,206. May 10.

Techno-Chemical Laboratories, Ltd., and Boberg. Refrigeration. 13,253. May 10.

Wade (Union Trust Co.). Regenerative furnaces. 14,152. May 20.

Weddingen. Removing incrustation from boilers and softening feed-water therefor. 14,147. May 20.

COMPLETE SPECIFICATIONS ACCEPTED.

17,331 (1917). Krause. Evaporising or cooling solutions, emulsions, and suspensions, and production of chemical reactions. (162,678.) May 19.

28,244 (1919). Hall. Grinding, crushing, or disintegrating machines. (163,064.) May 25.

29,488 (1919). Cathcart. Method and apparatus for drying. (162,705.) May 19.

31,696 (1919). Soc. l'Air Liquide. Separation of constituents of gaseous mixtures. (136,837.) May 19.

32,639 (1919). Mitchell. Apparatus for making emulsions. (162,719.) May 19.

13,718 (1920). Sawtelle. Destructive distillation of wood. (143,545.) May 25.

16,539 (1920). Lotz. Burning pulverulent fuels. (162,958.) May 19.

III.—TAR AND TAR PRODUCTS.

Applications.

Adam, Galbraith, Shannon, and Siderfin. Manufacture of amines from phenolic compounds. 13,664. May 13.

Plauson's (Parent Co.), Ltd. (Plauson). 14,188. *See* XX.

Complete Specifications Accepted.

27,221 (1919). Sasa. Manufacture of phthalic anhydride. (140,051.) May 19.

79 (1920). Commin. Treating pitch. (162,727.) May 19.

10,924 (1920). Tindale. Distillation of tars and treatment of residual pitches. (163,199.) May 25.

IV.—COLOURING MATTERS AND DYES.

Applications.

Barritt. Azo dyestuffs and intermediates. 13,764. May 17.

Farbenfabr. vorm. F. Bayer u. Co. Manufacture of copper compounds of substituted azo dyestuffs. 13,624. May 13. (Ger., 14.6.20.)

Johnson (Badische Anilin- u. Soda-Fabr.). 14,161. *See* XIII.

Complete Specification Accepted.

23,799 (1919). Pope, and Scottish Dyes, Ltd. Production of colouring matters. (162,687.) May 19.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Boyer. Treatment of fabrics, paper, etc. 13,509. May 12.

Eyrich and Schreiber. Removing ink from print paper. 13,850. May 17.

Humphrys. Treating flax, straw, etc. 14,175. May 20.

Plauson's (Parent Co.), Ltd. (Plauson). Extraction of wood. 13,758. May 17.

Plauson's (Parent Co.), Ltd. (Plauson). 14,187. *See* XVII.

Schülke. Production of artificial multiple-filament threads from cellulose solution. 13,592. May 13. (Ger., 17.5.20.)

Schülke. Production of wool-like yarns from artificial threads. 14,033. May 19. (Ger., 20.5.20.)

Complete Specifications Accepted.

2120 (1920). Deuts. Celluloid Fabrik. Manufacture of cellulose compounds. (138,116.) May 19.

2995 (1920). Bouillon and Worms. Treatment of cellulose filaments, threads, or films. (162,759.) May 19.

3951 (1920). Courtaulds, Ltd., and Stokes. Washing or otherwise treating with liquids artificial filaments etc. (163,099.) May 25.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Ashworth. Dyeing-apparatus. 14,002. May 19.

Brandwood and Brandwood. Bleaching, dyeing, etc. yarns wound in cheese form. 13,571. May 13.

Britton and others. 13,871. *See* XIV.

Complete Specifications Accepted.

32,733 (1919). Kershaw and Cole. Machines for dyeing, mordanting, bleaching, etc. wool, slubbing, yarn, etc. (162,720.) May 19.

3537 (1920). Arent. Fireproofing and/or waterproofing treatment of materials. (138,641.) May 19.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Crosland. 13,676. *See* IX.

Gaillard. Manufacture of sulphuric acid. 13,210. May 10.

Harter and Oehlrich. Production of a contac mass for the catalytic synthesis of ammonia 13,656. May 13.

Minami Manshu Tetsudo Kabushiki Kaisha Manufacture of anhydrous chlorides of alkaline earth metals. 13,290. May 10. (Japan, 15.5.20.

Nitrogen Corp. 13,161. *See* I.

Nitrogen Corp. Preparation of gas mixture and ammonia. 13,162. May 9. (U.S., 8.5.20.)

Nitrogen Corp. Production of hydrogen an ammonia. 13,812. May 17. (U.S., 14.5.20.)

Nitrogen Corp. Production of hydrogen fro hydrocarbons. 13,813. May 17. (U.S., 25.5.20

Soc. Anon. de Prod. Chimiques Etabl. Malétra. Continuous production of sulphates. 14,035. May 19. (Fr., 25.5.20.)

Wilton and Wilton. Manufacture of sulphate of ammonia. 13,261. May 10.

Complete Specifications Accepted.

2838 (1920). Edwards. Manufacture of arsenical compounds. (162,747.) May 19.

6206 (1920). Ellis (Foundation Oven Corp.). Purification of ammonium salts. (163,162.) May 25.

13,579 (1920). McKee. Manufacture of hydrogen and zinc oxide. (163,210.) May 25.

17,453 (1920). Röhm. Production of a solid non-hygroscopic iron salt. (146,216.) May 19.

18,165 (1920). Collin A.-G. Discharging ammonium sulphate from saturator baths. (145,781.) May 19.

VIII.—GLASS; CERAMICS.

Applications.

Clark. Moulding and annealing glass. 13,346. May 11. (U.S., 11.5.20.)

Feldenheimer and Plowman. Treatment of clay. 13,172. May 9.

Plauson's (Parent Co.), Ltd. (Plauson). Refining china clay etc. 14,189. May 21.

Wolf. Cementing procelain. 13,413. May 11.

IX.—BUILDING MATERIALS.

Applications.

Crosland. Kilns for calcining lime, cement, plaster, ores, etc. 13,676. May 13.

Hildyard. Production of imitation wood. 13,504. May 12.

Rowse. Manufacture of roofing and building materials. 14,234. May 21.

Whitby. Imparting a highly-glazed surface to artificial stone. 13,251. May 10.

Complete Specifications Accepted.

20,130 (1919). Crawford. Manufacture of bricks. (162,683.) May 19.

34,876 (1920). Alletson. Kilns for burning blue or other bricks. (163,251.) May 25.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Ashcroft and Lacell. Treatment of ores etc. 13,605-6. May 13.

Ashcroft and Lacell. Production and purification of lead. 13,607. May 13.

Booer, and District Chemical Co. Flux for welding or depositing metals electrically. 13,181. May 9.

Brunskill. Treatment to obviate rusting or oxidation of iron or steel surfaces. 13,235. May 10.

Crosland. 13,676. *See* IX.

James, and Star Electric Accessories, Ltd. Casting metals of high melting-point. 13,783. May 17.

Jones. Coating metal plates. 13,268. May 10.

Marino. Removing rust, grease, paint, etc. from iron and steel. 14,164. May 20.

Minerals Separation, Ltd., and Vautin. Treatment of ores. 13,283. May 10.

Smaill. Production of an alloy. 13,158. May 9.

Soc. d'Electro-Chimie et d'Electro-Métallurgie. Obtaining deposits of iron by electrolysis. 13,621. May 13. (Fr., 9.6.20.)

Soc. d'Electro-Chimie et d'Electro-Métallurgie. Obtaining metallic electrolytic deposits easily detachable from the cathode. 13,622. May 13. (Fr., 13.6.20.)

Complete Specifications Accepted.

19,028 (1919). Browning. Extraction of metals from solutions or separation of metals. (162,682.) May 19.

25,116 (1919). Lane and Williams. *See* XII.

32,571 (1919). Storen and Johanson. Treatment of poor iron ores containing weakly magnetic or non-magnetic oxygen compounds of iron. (162,718.) May 19.

22 (1920). Wright. Smelting or reduction of iron ore. (162,725.) May 19.

3181 (1920). Eklund. Recovery of tin from stanniferous waste products. (138,622.) May 19.

3594 (1920). Heraeus Ges. Vacuum melting and refining of metals and alloys. (138,648.) May 19.

3672 (1920). Lang. Furnace for making iron and steel. (162,808.) May 19.

3731 (1920). Heraeus Ges. Purifying and refining iron. (138,651.) May 19.

4064 (1920). McCaffery. Bessemerising iron. (138,900.) May 19.

4100 (1920). Jackson (Forge Products Corp.). High-speed steel and process of forming and forging the same. (163,100.) May 25.

10,835 (1920). British Thomson-Houston Co. (General Electric Co.). Tungsten alloys especially for electric lamp filaments. (162,907.) May 19.

11,934 (1920). Electrolytic Zinc Co. of Australasia. Recovery of zinc by electrolysis. (155,792.) May 25.

12,432 (1920). Vos. Alloys. (162,917.) May 19.

13,831 (1920). Krupp A.-G. Manufacture of hard cast-iron articles. (143,554.) May 25.

15,645 (1920). Heraeus Ges. Treating metal used in the manufacture of parts of vacuum tubes. (144,690.) May 25.

26,768 (1920). Kilby and Bacon. Recarburising molten steel in an open-haarth furnace. (162,994.) May 19.

XI.—ELECTRO-CHEMISTRY.

Applications.

Booer and others. 13,181. *See* X.

Burgess Battery Co. Dry cell. 13,661–2. May 13. (U.S., 15.5.20.)

Coley and Frampton. Regeneration of spent dry cells. 14,149. May 20.

Garbutt. Electric accumulators. 13,398–9. May 11.

Hancock and Hancock. Electric furnaces. 13,497. May 12.

Lodge Fume Co., Ltd., Lodge, and Stallard. Electrical precipitation apparatus. 14,230–1. May 21.

Niblett. Apparatus for producing electrolytic compounds. 13,192. May 10.

Niblett. Primary and secondary batteries. 13,681. May 17.

Soc. d'Electro-Chimie et d'Electro-Métallurgie. 13,621–2. *See* X.

Complete Specifications Accepted.

11,934 (1920). Electrolytic Zinc Co. *See* X.

13,671 1920. Merrmann. Manufacture of material for use as electrical insulator. (153,884.) May 19.

XII.—FATS; OILS; WAXES.

Application.

Pineger. Detergent. 13,114. May 9.

Complete Specifications Accepted.

25,116 (1919). Lane and Williams. Treatment of waste grease from tin works and other works. (163,056.) May 25.

25,355 (1919). Williams and Moseley. Soaps, polishes, etc. (162,691.) May 19.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Applications.

Anderson and Maclaurin. Preparation of synthetic resins. 13,744. May 17.

Ivinson and Roberts. Enamel or varnish. 13,912. May 18.

Johnson (Badische Anilin u. Soda-Fabrik). Production of pigment colours. 14,161. May 20.

Lefebvre. Obtaining an oil having the chemical properties of oil of turpentine. 13,160. May 9.

Complete Specification Accepted.

18,900 (1920). Jerone. Waterproof paints. (146,986.) May 19.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Application.

Britton, and Griffiths Bros. and Co. Preparation of rubberised fabrics and rubber goods. 13,871. May 17.

Complete Specifications Accepted.

16,560 (1920). Farrell Foundry and Machine Co. Mixing or masticating rubber etc. (147,547.) May 25.

18,915 (1920). Goodyear Tire and Rubber Co. Manufacture of rubber products. (146,992.) May 19.

19,585 (1920). Waitz. Recovering caoutchouc and fabric from rubbered fabric. (147,628.) May 25.

XV.—LEATHER; BONE; HORN; GLUE.

Complete Specifications Accepted.

63 (1920). Melamid. Manufacture of artificial tanning substances. (137,323.) May 19.

4080 (1920). Marks (Chicago Process Co.). Liming and dehairing hides. (163,109.) May 25.

XVI.—SOILS; FERTILISERS.

Complete Specification Accepted.

5100 (1920). Silberrad. Artificial manures. (163,137.) May 25.

XVII.—SUGARS; STARCHES; GUMS.

Application.

Plauson's (Parent Co.), Ltd. (Plauson). Saccharification of wood and like cellulosic materials. 14,187. May 21.

Complete Specification Accepted.

19,707 (1920). Aumann. Preparation of sugar beets suitable for making marmalades, extracts, wines, beers, etc. (147,713.) May 19.

XVIII.—FERMENTATION INDUSTRIES.

Application.

Bryant. Aeration of brewers' wort etc. 13,924. May 18.

Complete Specifications Accepted.

2057 (1920). Goldschmid and Migeon. Treatment of peat, distillers' wash, etc. (162,738.) May 19.

19,707 (1920). Aumann. *See* XVII.

22,102 (1920). Bensley. Portable dry yeast. (162,978.) May 19.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Baker, and Fluorescent Materials, Ltd. Charging water etc. with radium emanation. 13,873. May 17.

Pennell. Filtration of turbid water etc. 13,411. May 11.

Prentice and Stevenson. Sterilisation of milk etc. 13,537. May 13.

Weddingen. 14,147. *See* I.

Complete Specifications Accepted.

2972 (1920). Koppers Co. Purification of liquids. (139,159.) May 25.

8229 and 8330 (1920). Wood. Food compositions. (140,462–3.) May 19.

19,707 (1920). Aumann. *See* XVII.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Chem. Fabr. vorm. Sandoz. Manufacture of a new preparation of hexamethylenetetramine. 13,981. May 18. (Switz., 12.6.20.)

Dreyfus. Manufacture of organic products. 13,472. May 12.

Hoffmann-La Roche u. Co. Manufacture of soluble double compounds of 1-allyl-3.7-dimethylxanthine. 13,674. May 13. (Switz., 2.7.20.)

Hoffmann-La Roche u. Co. Manufacture of 1-allyl-3.7-dimethylxanthine. 13,675. May 13. (Switz., 2.7.20.)

Lefebvre. 13,160. *See* XIII.

Mills. Blood coagulation mediums. 13,276. May 10. (U.S., 6.5.20.)

Plauson's (Parent Co.), Ltd. (Plauson). Manufacture of ichthyol oil and ichthyol preparations etc. 14,188. May 21.

Soc. Anon. de Prod. Chim. Etabl. Malétra. Production of acetaldehyde from acetylene. 14,049. May 19. (Fr., 15.6.20.)

Soc. Chim. des Usines du Rhône. Compressed vanillin. 14,244. May 21. (Fr., 17.2.21.)

Complete Specifications Accepted.

16,211 (1920). Badische Anilin- u. Soda-Fabrik. Manufacture of urea. (145,060.) May 25.

31,000 (1920). Penfold. Manufacture of serum from animals. (154,886.) May 25.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Applications.

Camiller and Hay. Manufacture of multicolour screens, films, etc. for natural colour kinematography etc. 13,637. May 13.

Christensen. Multicolour screens for photography. 13,524. May 12. (Denmark, 15.5.20.)

Lage. Production of coloured photographs. 14,031. May 19.

XXII.—EXPLOSIVES; MATCHES.

Complete Specification Accepted.

27,032 (1919). Brock and Butt. Pyrotechnics, matches, percussion caps, fuses, etc. (162,697.) May 19.

XXIII.—ANALYSIS.

Application.

Dale. Apparatus for analysis and recording of gases. 13,447. May 12.

Complete Specifications Accepted.

4228 (1920). Fairweather. Gas calorimeters (162,826.) May 19.

20,902 (1920). Arndt. Gas-analysing apparatus (148,998.) May 19.

I.—GENERAL; PLANT; MACHINERY.

Protective linings and coverings for chemical plant. F. Schüler. Chem.-Zeit., 1921, 45, 315—316.

Most of the coverings in use for protecting chemical plant present some disadvantages, and some have a very limited application. Metallic coatings applied galvanically have a short life owing to their thinness and porosity. Sheet metal linings cannot be used with vacuum plant, as the air between them and the walls of the vessel tends to loosen them; on the other hand, a homogeneous layer of lead is satisfactory in many cases. Coating vessels with paints or varnishes is not successful when these are subject to mechanical friction from stirrers etc. or to raised temperature. Enamelled apparatus has frequently considerable durability, but its liability to chip is a drawback. Earthenware linings have found an extensive use, especially with acids, and the sections are sometimes applied in double layers, or after previous coating with lead; objections to the use of this material are its thickness, which materially reduces the capacity of vessels, and the fact that it cannot be used for lining tank covers, or for such purposes as in heating coils, where it is liable to fracture. Thin glass plates have been found to be very resistant and in many ways superior to earthenware, inasmuch as they may be used for covering parts of apparatus and also for lining jacketed vessels, for which earthenware is unsuitable owing to its thickness. Glass linings are not liable to fracture by sudden changes of temperature.—W. J. W.

Humidity control by means of sulphuric acid solutions, with critical compilation of vapour pressure data. R. E. Wilson. J. Ind. Eng. Chem., 1921, 13, 326—331.

The use of sulphuric acid solutions of definite composition affords the most convenient means of obtaining atmospheres of known humidity; the air is bubbled through three successive vessels containing sulphuric acid of the necessary strength. The acid n the first vessel usually needs changing when its volume has altered by 3—4%. A graph is given howing the strength and gravity of sulphuric acid solutions which will give any desired humidity to air; for instance, reference to the graph shows that a relative humidity of 50% at 25° C. is obtained with 43·4% sulphuric acid (sp. gr. at 25° C., 1·329). Formulæ are also given for calculating the vapour pressures from one temperature to another when it s desired to employ other temperatures than those hown on the graph.—W. P. S.

Patents.

Cooling viscous liquids; Process for —— and apparatus therefor. Soc. des Condenseurs Delas. E.P. 142,454, 19.4.20. Conv., 30.4.19.

The viscous liquid (*e.g.* heavy oil) flows in the form f threads through suitable nozzles on to a vertical eries of water-cooled pipes, the oil spreading over he whole surface of the pipes but re-forming into rops or threads upon the underside and dropping pon the next pipe. In order to ensure that there hall be no mixing of the liquid and the cooling water as a result of leakage, the header plates supporting the tubes at each end may be double, with space between.—B. M. V.

Electrical gas purification. Metallbank u. Metallurgische Ges. A.-G., and J. E. Lilienfeld. E.P. 145,477, 21.6.20. Conv., 8.8.18.

The generation of ions in the electrical discharge is increased by the use of pulsating undamped irect current voltage, the frequency of pulsation ranging from 250 to 1500 cycles per sec., and the number of cycles being adapted to the capacity of the high tension circuit, so that the pulsations are not smoothed out by the capacity of the circuit. The pulsating direct current voltage is suitably obtained by superimposing upon a constant direct current voltage an oscillation of a considerably greater frequency than that of the usual technical alternating current.—J. S. G. T.

Disintegrators or pulverisers. J. Brey. E.P. 148,551, 10.7.20. Appl., 28.2.19.

In a Carr's disintegrator, to prevent accumulation of partly ground material in the fine grinding chamber, the faces of the outermost ring of percussion members are inclined to throw the material inwards, the faces of the next ring of percussion members being oppositely inclined. In addition to the screens in the grinding track others may be arranged at the side thereof and a current of air used to draw out the finely ground material.
—B. M. V.

Centrifugal machines. P. T. Sharples. E.P. 148,753, 3.7.20. Conv., 30.7.19.

The material is fed to, and solids discharged from, the bowl through an axial hole in a boss at the bottom. The boss and the bowl are steadied by a drag-bearing permitting slight radial movement and contained in a conical plug easily removable from the outer casing of the machine. The plug also contains means for lubrication of the bearing and a nozzle for introducing the material upwards through the bottom.—B. M. V.

Centrifugal separator. E. D. Gray, Assr. to Standard Oil Co. of California. U.S.P. 1,375,506, 19.4.21. Appl., 2.9.20.

The top of the bowl, forming a closed chamber, is provided with a peripheral pocket. An axial inlet pipe enters near the bottom of the chamber, and a substantially axial outlet pipe leads from a point above the pocket. An outlet from the top of the bowl near its outer edge leads to a chamber forming a casing around the bowl.—H. H.

Acid-gas or similar substance mains; Pipe connections for ——. P. L. Pfannenschmidt. E.P. 149,684, 31.7.20. Conv., 31.7.19.

To avoid destruction of the jointing-material of horizontal mains by condensed acid, one pipe end extends beyond the jointing material into an enlarged part of the other pipe from which the condensed acid may be removed. Two similar pipe ends may be symmetrically fitted within a connecting piece jointed to each and formed with an enlargment for collecting the condensed acid.
—H. H.

Filters. J. Miller, and G. Fletcher and Co., Ltd. E.P. 161,993, 5.5.19.

A filter as described in E.P. 158,387 (J., 1921, 203 a) is provided with a stop-cock at the bottom to remove sediment while the filter is in operation and with another cock, preferably leading to the outlet trunnion, through which the residual filtered liquor in the filter can be removed before opening the filter to change the filtering medium. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 23,585 of 1895.)—B. M. V.

Filters; Production of very fine [ultra-] ——. E. de Haën, Chem. Fabr. "List," G.m.b.H. G.P. 334,063, 27.1.20.

In the preparation of ultra-filters by deposition from a colloidal solution upon a supporting layer, which may contain a coagulating agent, the colloidal solution (collodion) is treated with a coagulating agent (water) before it is poured on the supporting layer (filter paper). The permeability of the filter will vary according to the amount of water added and according to the vapour pressure of the water; addition of hygroscopic substances such as calcium chloride or glycerin has a favourable influence on the quality of these ultra-filters.—J. H. L.

Filter pulp; Process and apparatus for washing ——. E. Steuer. G.P. 334,113, 17.6.19.

The pulp is subjected to the action of water which has been charged under pressure with air or gas. The gas in escaping from solution, loosens the fibres and carries them to the surface. The "gas emulsion" may be produced chemically, *e.g.*, by the action of acids on suitable substances below, in, or above the filter pulp. The apparatus comprises a vessel provided with a perforated false bottom and divided ducts below the latter connected with a pressure vessel in which the washing liquid is saturated with air or gas.—J. H. L.

Stills [; Entrainment separator for ——]. A. Philip. E.P. 162,000, 15.9.19 and 29.1.20.

A separator for entrained liquid consists of a number of frusto-conical plates placed close together, with their small ends downwards, in the vapour space of a still, so that any entrained liquid will be caught on the surface of the plates and run back into the distilling liquid. The separator is provided with a conical or domed roof so that any liquid which condenses after passing the separator will be led to a gutter and thence outside the still. The device is specially suitable for mineral oil stills.—B. M. V.

Liquids and gases; Apparatus for bringing —— into intimate contact. W. C. Holmes and Co., Ltd., D. M. Henshaw, and J. Whittell. E.P 162,166, 1.4.20.

In a scrubber consisting of a number of brush rings secured back to back in pairs to a series of discs rotating between other fixed discs and dipping into the washing liquid, the rotating discs are perforated between the brush rings and the shaft, and passages are formed through the fixed discs alternately within and without the brush rings. The gas current splits into two streams which pass through the brushes of each pair in the same direction and through adjacent pairs in opposite directions.
—B. M. V.

Separating floating and other impurities in suspension from liquids; Apparatus for ——. C. G. Petree. E.P. 162,206, 4.6.20.

The liquid to be treated, *e.g.*, defecated sugar juice, is delivered tangentially upon a gallery surrounding a central circular hole in the cover of a conical settling vessel and flows through the hole into a cylinder extending from the cover beneath the surface of the liquid in the vessel. This cylinder is provided with an opening near its upper end for the escape of liquid, which is thereupon directed by a volute wall along a path of considerable length to a scum deflector and an overflow for the clear liquid. The scum is intercepted by a plate extending above and below the surface of the liquid and is directed by mechanically-actuated blades to an outlet.—H. H.

Drying finely divided materials. H. F. Chappell U.S.P. 1,375,080, 19.4.21. Appl., 14.11.18.

The material to be dried is fed on to one end of a travelling platform which is enclosed in an outer chamber. Heating gases which pass through a flue under the platform provide the necessary heat for the drying operation.—C. A. K.

Dryer. E. B. Ayres, Assr. to Proctor and Schwartz, Inc. U.S.P. 1,376,244, 26.4.21. Appl., 27.5.20.

A casing is divided into a heating and two drying compartments, and a fan situated in one of the latter circulates air through all three compartments.—B. M. V.

Drying kiln. S. E. Cornish, Assr. to H. H. Plummer. U.S.P. 1,376,319, 26.4.21. Appl., 20.1.20.

A kiln is provided at one side with fans which direct air through flues to points on the opposite side of the kiln intermediate between the inlets to the fans, so as to create a continuous circuitous movement of air in the kiln.—B. M. V.

Dryer; Column —— consisting of separate cells. G. Zimmermann. G.P. 333,943, 5.7.17.

In a column dryer consisting of a number of cells each of which is connected with the one below it by a funnel-shaped constriction, the walls of the cells are provided with oblique openings for the current of air which traverses the cells. The descending material travels only very slowly in the cells themselves, and owing to the wide openings in their walls the transverse air currents have a relatively small velocity and encounter only small resistance.—J. H. L.

Fire-extinguishing composition. P. A. Crosby, R. R. Matthews, and R. B. High, Assrs. to Roxana Petroleum Co. U.S.P. 1,375,779, 26.4.21. Appl., 8.8.19.

The constituents of the composition are sodium bicarbonate, a phosphoprotein, and water.
—B. M. V.

Catalytic material [nickel]; Process of making ——. S. Drucker, and W. Sieck, jun. U.S.P. 1,375,368, 19.4.21. Appl., 7.11.19.

Nickel carbonate is precipitated from a nickel salt solution, washed, mixed with a powdered inert non-reducible material, and the mixture dried without calcining and reduced in an atmosphere of hydrogen.—H. H.

Alcohol and ether [vapours] from admixture with air; Process for the recovery of ——. E. Bindschedler. U.S.P. 1,376,069, 26.4.21. Appl., 2.8.20.

Alcohol is removed from the mixed vapours by intimate contact with water, and ether absorbed from the residue by means of concentrated sulphuric acid.—J. S. G. T.

Tube evaporator; Rotary ——. A.-G. der Chemischen Produkten-Fabrik Pommerensdorf. G.P. 333,304, 22.12.17.

To avoid vibration, and failure of the driving gear, a tube evaporator is placed eccentrically in its fire chamber, and is so arranged that its weight is equally distributed on both sides of the drive.
—W. J. W.

Separation of small quantities of materials from liquids and gases. H. Bechhold. G.P. 335,303 31.8.18.

Solid impurities are removed from a liquid or gas by adsorption on a suitable medium, such as charcoal or fuller's earth, provided with a coating o insolubble material which enters into combination with the impurities to be removed. For example air is freed from chlorine by filtration througl charcoal coated with 2% of mercury.—C. I.

Gas-mixtures; Separation of —— by means of a internally heated column. G. Petzel. G.P 335,115, 10.4.14.

The column is fitted with an internal heating coi he highly compressed gas mixture, *e.g.*, air, before ıtering the coil, is allowed to expand to the ressure suitable for operating the column, the cold roduced by the expansion serving to cover the sses through radiation etc.—C. I.

ulveriser mills. Fuller-Lehigh Co., Assces. of J. W. Fuller. E.P. 145,497, 21.6.20. Conv., 1.6.18.

EE U.S.P. 1,345,082 of 1920; J., 1920, 564 A.

eparation of gas mixtures; Process for the ——. G. Petzel. E.P. 148,302, 9.7.20. Conv., 9.4.14.

EE G.P. 335,115 of 1914; preceding.

parating suspended matter from liquids; Process and apparatus for ——. A. F. Meston. E.P. 162,390, 28.1.20.

EE U.S.P. 1,334,160 of 1920; J., 1920, 355 A.

rinding-mills [; Open-pan ——] for grinding flint, china stone, and other materials. W. F. Malkin. E.P. 162,481, 8.3.20.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

omplete gasification; Experiments in ——. F. H. Robinson. N. Eng. Gas Managers' Assoc., 6.5.21. Gas World, 1921, 74, 368—371.

XPERIMENTS were carried out at Harrogate on a ıttery of eight retorts, 14 ft. long by 22 in. by in., with a water-gas generator at one end, the hole installation being accommodated within the ch of the retort-bench. The ends of the retorts ı the charging side had the ascension pipes concted in the usual way, whilst the other ends rminated in a chamber above the generator. rimary and secondary air could be admitted or ut off simultaneously by means of a piston valve hich was also connected with the steam jet, the eam supply to the blowing engine, and the stack ılve, so that only one movement was necessary to ıange from "blow" to "run," or *vice versâ.* uring the run, the water-gas passed from the nerator into and through the retorts and away the ascension pipes, the heat of the hot gas being ıus utilised. The coke was discharged from the ırious retorts in turn to the generator. A thin r, sp. gr. 1·12, was obtained, which yielded water 2%, light oils to 170° C. 1·6%, 170°—230° 3·4%, 0°—270° 13·8%, 270°—300° C. 7·2%, and pitch ·8%. It was entirely free from separated ıphthalene even on standing overnight. The al used was a mixture of Yorkshire and Durham ntaining 2·87% of moisture, and (on a moistureee basis) 29·50% of volatile matter, 57·00% of ed carbon, and 13·50% of ash. The setting was nnected with the foul mains in the retort house that the hot water-gas could be enriched with e lighter hydrocarbons from the tar vapour erein. The gas produced contained, in one case, O_2 8·4%, O_2 0·2%, illuminants 1·4%, CO 18·9%, H_4 17·42%, H_2 39·26%, and N_2 14·42%, and had a lorific value of 396 B.Th.U. per cub. ft. (gross). ıe average CO content over a long period was ·3%, whilst the CO_2 content was 5·8% and the lorific value was 384 B.Th.U. per cub ft. The tal efficiency of the process as determined on ree occasions was 70·3%, 73·3%, and 82·6% reectively, values which are very close to the figures entioned in the Clerk-Smithells-Cobb report of 19.—A. G.

Producers for the gasification of natural fuels with recovery of the by-products. H. Koshmieder. Brennstoff-Chem., 1921, 2, 134—135, 150—152.

THREE separate zones may be distinguished in a producer using natural fuels such as wood and peat, viz., the upper zone in which moisture is driven off, the middle zone in which the fuel is destructively distilled, and the lowest zone where the coke is burned. The capacity and height of the producer for most efficient working depend upon the nature of the fuel, and the rate at which it passes through the producer. The variations in the size of the producer required with wood, peat, lignite, and coal are discussed with a view of showing the most efficient dimensions for each type of fuel. The advantages of carbonisation are also discussed for certain fuels. —W. P.

Gas purification. W. A. Dunkley and C. E. Barnes. Gas J., 1921, 154, 27—29, 148—150, 204—205, 266—268, 381—382.

IN a co-operative research carried out by the Illinois State Geological Survey Division, the Engineering Experiment Station of the University of Illinois, and the U.S. Bureau of Mines, sixteen gas plants, comprising nearly all the medium-sized plants of the State, including the suburban plants at Chicago, were inspected. Low-sulphur Eastern gas coals were being used in practically all the coal gas plants inspected. The average H_2S content of the gas entering the purifiers was 250 grains per 100 cub. ft. Six of the eight straight water-gas plants were using low-sulphur coals for generator fuel. The average H_2S content in the unpurified gas in these plants was 140 grains per 100 cub. ft. Tar was found in appreciable amounts in the gas entering the purifiers in nearly all the plants inspected, and the spent oxide from all the plants contained some tar (6·9% in that from water-gas plants and 3·6% in that from mixed gas plants). Tar seemed in some cases to be responsible for low sulphur absorption. The spent oxides from mixed gas plants contained, on the average, 37·4% of sulphur, whilst those from straight water-gas plants contained 21·7%. Revivification *in situ* was practised by most water-gas plants, but by few mixed gas plants, and only one plant revivified in the off box. Little trouble was reported in this plant, and the operating cost was low. Though several purifying installations are arranged for reversible gas flow, or for rotation of boxes, little effort seems to be made to realise the fullest advantage of such arrangements. In very few cases were records kept of the performance of particular batches of oxide, and there was a lack of systematic testing of the purifiers to determine the performance of a batch of oxide. Total purification costs for 1919 varied from 0·5 c. to 2·25 c. per 1000 cub. ft. of gas purified. The authors recommend the establishment of simple but regular testing routine, together with better purification records, and the analysis of fouled oxides for sulphur and tar. In several cases coals of higher sulphur content could be used if existing equipment were rearranged and made more flexible in operation.—A. G.

Benzene hydrocarbons; Determination of —— in coal gas and coke-oven gas. A. Krieger. Z. angew. Chem., 1921, 34, 192.

THE paraffin method for the absorption of benzene hydrocarbons still remains the best practical method for their determination in coal gas etc., and the bad results recorded by Berl and others (J., 1921, 289A) are due to incorrect methods of working, particularly the use of an insufficient amount of absorbent paraffin. Further improvements in this method are attained by removing the last traces of water from the gas by means of carbide, and by using a freezing mixture instead of ice. The new method using activated carbon offers no advantage over the paraffin method either in point of accuracy or time required.—G. F. M.

Petroleum; Determination of chlorides in ——. R. R. Matthews. J. Ind. Eng. Chem., 1921, 13, 325—326.

Five hundred c.c. of the oil is mixed in a cylinder with 125 c.c. of acetone, 1375 c.c. of water is added, and the mixture shaken carefully to avoid the formation of an emulsion. When the water-acetone layer has separated, about 400 c.c. is drawn off, filtered, and the chloride titrated with $N/20$ silver nitrate solution.—W. P. S.

Paraffin; New developments in the separation of —— from lignite tar and its distillates. F. Seidenschnur. Brennstoff-Chem., 1921, 2, 49—51, 73—76, 81—86.

The method in general use at present consists in distilling the tar with the use of steam or vacuum and chilling the dried distillate oils. The wax that crystallises is removed by filter-pressing and submitted to a process of "sweating." A final treatment with sulphuric acid and decolorising earth may be employed. The process is very expensive in labour and materials. So far the principal objects of the industry have been the production of wax, the expressed oil being used as fuel, but recently this oil has served as a source of lubricating oil, large amounts having been used during the war. One method that has been suggested for separating the wax consists in boiling the distillate oils with alcohol, the wax being preferentially soluble and crystallising from the alcoholic solution on cooling. The separation is, however, very imperfect, the wax containing much oily matter. A number of patents have been taken out for the application of the Edeleanu method, since liquid sulphur dioxide is a fairly good solvent for unsaturated and aromatic compounds, the paraffinoid components remaining undissolved. By the addition of aqueous pyridine or pyridine bases to lignite tar the paraffin is first precipitated, and subsequently other oils, the tar acids remaining dissolved in the aqueous pyridine, and being finally recovered by distillation. Erdmann has found that the addition of two volumes of acetone in conjunction with moderate chilling precipitates the paraffin almost completely. In all these cases the neutral oils, freed from paraffin, may be used as lubricating oils. The author has found that certain mixtures of alcohol and benzol are quite as effective as acetone in precipitating the wax, hard and soft paraffin being capable of preparation in one operation; the mixture is, moreover, sufficiently non-volatile to obviate the losses involved with acetone. A number of experiments at 0° and —20° C. with acetone and with alcohol-benzol show the solubility of paraffin wax in these liquids and the quality of the wax precipitated by them. The apparatus and method of procedure adopted for working up considerable quantities of lignite tars into wax and lubricating oils are described.—A. E. D.

Vaseline and paraffin; Action of oxidising agents on ——. A. Langer. Chem.-Zeit., 1921, 45, 466.

Investigations in regard to the conversion of hydrocarbons into fatty acids were made with vaseline oil, vaseline, and liquid and solid paraffin, using oxidising agents such as potassium permanganate in acid and alkaline solution, sodium hypochlorite and permanganate, manganese dioxide and hydrochloric acid, and nitric acid. When a mixture of yellow vaseline oil and concentrated sodium hydroxide solution was treated for a few days with permanganate, a supernatant oil was obtained and a residue which was dissolved in dilute sulphuric acid. The oil from this residue was only slightly soluble in sodium carbonate or hydroxide solution; when heated with concentrated sulphuric acid, it gave a black crystalline mass and evolved sulphur dioxide. It was insoluble in most solvents. Oxidation with permanganate and sodium hypochlorite solution gave no better results. Liquid paraffin behaved in a similar manner to vaseline oil, when treated with alkaline permanganate. When oxidised with acid permanganate solution, undissolved manganese hydroxide remained; the residue after filtration was dissolved in hydrochloric acid and yielded a soft resin. The oxidation product from solid paraffin is of the nature of a salve; with litharge it forms a lead salt which is soluble in ether. From vaseline a hard and a soft resin are produced, the latter containing no substances of an acid character; the yield of saponifiable matter is smaller than with vaseline oil, nor does the product form soluble lead salts as is the case with the product from solid paraffin.—W. J. W.

Patents.

Fuel and method of producing same. L. W. Bates. U.S.P. 1,375,811, 26.4.21. Appl., 22.1.20.

Asphalt and free-carbon particles in a liquid hydrocarbon are stabilised by mixing "coal distillate or an equivalent peptising substance" with the hydrocarbon and "blending the components and simultaneously peptising the particles with heat treatment between normal temperature and 95° C."
—L. A. C.

Peat and similar material; Manufacture of briquettes from ——. S. Henlein and A. Hopf G.P. 332,890, 27.11.19.

The material is first passed through an extrusio press to ensure mixing of its various layers, and i then subjected to a high pressure to remov mechanically combined water, after which it i ground and passed through a rolling mill at temperature of 200°C., by which means the moistur is reduced to a small percentage. The past material obtained may be again pulverised o briquetted without further treatment.—W. J. W.

Pulverulent fuels; Method of and means for burnin ——. R. S. Walker. E.P. 139,158, 28.1.2 Conv., 15.2.19.

The powdered fuel is fed into the combusti chamber in a thin vertical stream of curtain-li formation, and its combustion occurs as a reverti flame from which the ignition of the entering fu is maintained. The supply of air for combustion directed into the chamber from below, so that as in falling from the combustion zone, is cooled a slagging is thus avoided. The feed device for t fuel consists of a nozzle with a horizontal slot e tending transversely across the chamber.—A. G.

Coking plants. Gewerkschaft Emscher-Lippe, a H. Heyn. E.P. 153,313, 2.11.20. Conv., 3.11.

The glowing coke is cooled by the circulation inert gases through the mass, the gases imparti their heat to a heat-interchange system, *e.g.,* steam boiler and feed water heater. For examp the coke is loaded into travelling cars which connected with a blowing system by means of wh flue gas is blown through the hot coke, and the l gases are then passed through two feed wa heaters and a steam boiler, travelling on a which is capable of running along the discharge s of the coking plant.—A. G.

Coke ovens. J. Marr, and The Coke Oven C struction Co., Ltd. E.P. (a) 162,045 and 162,236, 16.1.20.

(a) In a coke oven of the type having two para horizontal heating flues side by side in each divid wall between the retorts, an inlet conduit for air is provided at the front end of one such flue.

gas inlet is connected with the conduit, and horizontal ports lead from the other end of that flue to the other flue in the same dividing wall, a second gas supply being connected with the ports, whilst a conduit at the front end of the second flue leads to a discharge conduit for the products of combustion. The flues have longitudinal horizontal partitions extending from the conduit at the front right to the back of each flue. Ports at the rear ends of the flues afford communication from each of the spaces between the partitions in one flue to the spaces at the same level in the return flue. Each space has a gas inlet at the rear end of the flue. Either of the two conduits at the front ends of the two flues acts as the inlet, as desired, and both the conduits are provided with gas inlets. The conduits at the front ends of the two flues, one on each side of each retort, are connected with a single sole channel running longitudinally below the retort for its whole length, with or without a preliminary gas admission at the rear end of the sole channel. B) The retorts have horizontal heating flues in the walls and regenerators below the retorts, each communicating with the adjacent ends of two flues, the next adjacent regenerator on each side communicating with the other end of one of the abovementioned two flues and also with the adjacent end of the next flue. Alternate regenerators are employed for the supply of the air and for the exhaust of the waste gases, two transverse main flues communicating one with one set of alternate regenera- or chambers and the other with the other set. Means are provided for establishing communication between either main flue and either the chimney or the atmosphere, so that the flow of the heated gases through the flues may be reversed. Recuperator passages are provided in which partially cooled burnt gases issuing from the regenerators are utilised for preheating the combustible gas by conduction of heat through the walls. One or more addi- ional compound flues are provided with passages or the gas to be heated and for the hot burnt pro- ucts, conduits affording communication between he passages for burnt products at one end of the aid compound flue and the chimney and between he other end of the compound flue and the main ransverse flues. In the compound flue, passages or gases extend longitudinally through the flue nd are built up of blocks, each containing one or more vertical ports which extend transversely to he direction of the passages and baffles to direct he gases passing through the ports to and fro across he longitudinal passages.—A. G.

as-producer. G. E. and G. M. Williams. E.P. 162,455, 21.2.20.

IR and steam are introduced as a circular blow hrough an annular hollow chamber, surmounted nd overhung by an annular water-cooled casing. his directs the blast into the centre of the pro- ucer, and the cooling prevents clinker adhering. —C. I.

olid and gaseous fuel; Process and plant for the continuous production of —— with by-product recovery. H. Nielsen and J. R. Garrow. E.P. 162,459, 23.2.20.

NE of a battery of gas producers is supplied with st sufficient fuel to produce such a quantity of s that the sensible heat of the gas is sufficient to rbonise the charge in a retort at a low tempera- re. The mixture of producer gas and gas from e retort is treated to separate the low-tempera- re volatile oils, and is then mixed with the remain- g producer gas from the other producers of the ttery and treated for the recovery of ammonia sulphate. The retort is of the revolving type, d is of such construction as to provide sufficient id fuel for use in all the producers, a measured quantity being fed to the producer which generates the gas employed for heating the material in the retort.—A. G.

Hydrocarbon vapours or gases; Process for generating and utilising ——. J. P. Kendall, Assr. to Kendalite Co., Inc. U.S.P. 1,376,100, 26.4.21. Appl., 14.3.18.

To prevent accumulation of carbon deposits in a hydrocarbon vapour generator for intermittently operated burners, barium oxide is heated in the generator in the presence of air until partially converted into barium peroxide. A hydrocarbon liquid containing an oxidising agent is then charged into the generator and the heating is continued to vaporise the liquid and convert a further portion of the barium oxide into peroxide. The vapour is burnt outside the generator to continue vaporisation and to convert the barium peroxide into oxide with simultaneous oxidation of any carbon deposits. As the apparatus cools, a portion of the barium oxide is reconverted to peroxide.—L. A. C.

Gas producers with inner distillation chamber; Packing for ——. F. Siemens. G.P. 330,278, 30.6.17.

In a gas producer provided with separate outlets for the products of distillation and gasification and with a rotating distillation chamber, loss of gas on the one hand or admixture of air with the gas on the other hand, in the event of defective packing, is prevented by enclosing the joint between the rotating and fixed parts of the apparatus in a chamber filled with the gases generated in the lower part of the apparatus. The gases from the upper part of the apparatus pass out through an annular space between the charging device and the rotating distillation chamber.—L. A. C.

Gas-producer. R. Bergmans. G.P. 330,728, 1.1.19.

The space below the hearth of a gas producer is divided into two compartments by means of a partition. Into one of these, below the combustion chamber, the air for combustion is introduced, whilst the gases from the combustion chamber are passed into the second compartment, which is beneath the gas exhaust chamber. Admixture of oxygen with the combustion gases is thus prevented. —W. J. W.

Gas and coke; Production of —— and recovery of by-products. W. Zimmermann. G.P. 334,002, 4.7.18.

Coal is heated by passing gas through it until low-temperature tar is formed, after which degasification is continued by means of external heating and a solid coke is obtained.—W. J. W.

Ammonia; Extraction of —— from gases. E. L. Pease. E.P. 162,314, 29.10.19.

Gas is passed through a pipe along which a dry material containing aluminium sulphate is conveyed in the reverse direction. The absorbent material is prepared by heating shale or clay with sulphur and coke in a gas producer and collecting the ash.—C. I.

Ammonia and tar recovery process. J. Van Ackeren, Assr. to The Koppers Co. U.S.P. (A) 1,375,475, (B) 1,375,476, (C) 1,375,477, and (D) 1,375,478, 19.4.21. Appl., (A and B) 21.8.19, (C and D) 25.8.19.

(A) Producer gas is freed from dust, washed while still hot with water, further cooled to remove tar, and washed with acid. (B) Steam is generated by the heat of the gas leaving the producer and used for blowing the producer after passing through a gas-fired superheater. (C) Gas at its saturation temperature is washed with acid and the dilute mother liquor concentrated with superheated air, which air, thus saturated with moisture, is used in the producer. (d) Hot gas free from dust is blown through condensed ammonia liquor to distil the ammonia, and the mixed still vapours and dust-free gas are freed from tar and moisture in an electrical precipitator and then washed with acid. —C. I.

Ammonia and tar recovery process. J. Becker, Assr. to The Koppers Co. U.S.P. (a) 1,375,483, (b) 1,375,484, and (c) 1,375,485, 19.4.21. Appl., 21, 22, and 25.8.19.

(a) Producer gas is cooled and freed from dust and tar, and the ammonia removed in an acid washer so operated that the gas effects the concentration of the ammonium sulphate liquor. (b) Gas is cooled and freed from tar by a counter current of air and the heated air used to concentrate ammonium sulphate liquor. (c) Superheated air is used to concentrate the sulphate liquor and the air after reheating supplied to the producer.—C. I.

Sulphur; Removal of —— from gases. N. E. Rambush. E.P. 162,554, 21.5.20.

In the removal of sulphur from a gas by washing with a suspension or solution of a metallic compound and revivifying the sludge produced with a current of air, a sensible loss of sulphur occurs in the latter stage. To reduce this loss to a minimum the air is circulated, with admission of enough fresh air to maintain the oxygen content at about 8%; or air may be drawn in slowly as the liquid flows down a tower, by chimney draught and by the injector action of the inflowing liquid.—C. I.

Oil; Recovery of —— from substances such as bitumen and shale in situ. D. Diver. E.P. 162,337, 23.12.19.

Two bore holes close together in the shale or the like contain metal cylindrical casings, one of which is closed and contains a series of electric heating coils, while the other is perforated for a portion of its length at the lower end, and is provided at the top with a cup and an outlet pipe for conveying vapours to a condenser and gas storage plant. The heat generated in the first casing heats the surrounding rock and decreases the viscosity of the oil therein, which flows through the perforations into the second casing, whence it is removed by pumping or other means, while the lighter fractions are volatilised and pass out through the pipe at the top.—L. A. C.

Liquid fuel; Process of treating ——. E. E. Wickersham. U.S.P. 1,376,180, 26.4.21. Appl., 26.9.20.

By passing electric sparks through liquid fuel, the final boiling point is reduced.—D. F. T.

Oil mixtures [e.g., shale oil]; Process for separating ——. K. Kubierschky. G.P. 333,294, 2.12.17.

Oil mixtures are dissolved in alcohol of a high strength and the solution is then washed in a counter-stream of water or aqueous alcohol. To separate shale oil (sp. gr. 0·900) into two fractions of sp. gr. 0·93 and 0·84 respectively, the crude oil is washed with an equal quantity of 90% alcohol, the resulting solution having a sp. gr. of 0·866. By introducing water into the upper end of the washing column, a mixture of 80% alcohol and the extract gradually forms at the bottom and can be drawn off, whilst the oil (sp. gr. 0·84) which separates from the extract passes out at the top. —W. J. W.

Lubricants; Production of ——. H. W. Klever. G.P. 331,504, 2.2.15.

Small amounts of fatty acid salts of alkaline-earth or heavy metals dissolved in coal-tar oils increase their viscosity appreciably and their power of adhesion to metallic surfaces.—W. J. W.

Lubricants; Manufacture of ——. P. Friesenhahn. G.P. 332,909, 25.7.19.

Hydrogenised phenols or their derivatives, such as cyclohexanone and its homologues, or cyclohexanol and its esters, may be used, either alone or mixed with other lubricants, as lubricating agents. Cyclohexanol has sp. gr. 0·945, b.p. 160° C., and viscosity 3·5° (Engler), and readily mixes with fats, oils, and hydrocarbons.—W. J. W.

Crude oil refining processes and apparatus. J. G. P. Evans. E.P. 162,873, 9.3.20.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Adsorbing power of charcoal; Determination of ——. I. M. Kolthoff. Pharm. Weekblad, 1921, 58, 630—656.

Freundlich's rule, that the order in which materials are adsorbed is almost independent of the nature of the solid phase, is found to hold for five kinds of charcoal tested with many different substances. The order of the adsorbing capacity is:—Blood charcoal (M)>vegetable carbon (M)= medicinal carbon (M)>bactanate >norite (M indicates Merck's preparation). A test of adsorptive power is the weight of mercuric cyanide o phenol adsorbed by 1 g. of charcoal from 100 c.c of $N/10$ solution. (*Cf.* J.C.S., June.)—S. I. L.

Patents.

Decolorising carbon; Method of making ——. C. S Hudson. E.P. 139,156, 20.1.20. Conv., 15.2.19

Carbonisable organic material is mixed with fusible acid, *e.g.*, phosphoric acid, in the proportio of not less than 0·5 pt. (*e.g.*, 2 pts.) of acid to 1 pt of organic material, and the mixture is carbonise at 375° C. or over.—A. G.

Decolorising charcoal; Process for the preparatio of ——. De Bruyn, Ltd., and C. Revis. E.P 162,117, 6.2.20.

Filter-press residues from the refining of edibl oils, such as cottonseed oil and the like, are carbor ised to produce a dry, porous carbonaceou material. The carbonisation takes place with th admission of a regulated quantity of air and th carbonised product is washed with a mineral aci in order to neutralise the alkaline salts. After neutralisation, the mixture is formed into cakes and again heated to expel moisture and excess acid. —A. G.

Distilling carbonaceous material; Apparatus for ——. W. P. Perry. E.P. 162,136, 25.2.20.

An apparatus for distilling carbonaceous material consists of one structure divided by vertical or slightly inclined partitions into three chambers, the middle one, the distilling chamber, having a number of openings into the gas distributing chamber and the collecting or condensing chamber on either side. The two latter chambers have each a capacity equal to or greater than that of the distilling chamber.—A. G.

Carbonising apparatus. H. N. McLeod. U.S.P. 1,375,714, 26.4.21. Appl., 18.12.20.

A number of chambers are so arranged that the discharge end of one chamber leads into the receiving end of the next chamber in the series. The chambers are divided into two series with separate heating circuits, the heating circuit of the second set of chambers comprising a primary source of heated gas and conduits receiving the heated gas, the walls of the conduits being in contact with the material in the chambers of the second set. The flow of the heated gas through the conduits is in counter-current to the passage of the material through the chambers of the second set. Condensing apparatus is connected with the last chamber of the second set. Conduits having walls in contact with the material in the chambers of the first set receive the heated cooling medium from the jackets of the condenser and convey it in counter-current to the material to be carbonised through the chambers of the first set. The material to be carbonised is conveyed mechanically through the chambers of the first set and then through the chambers of the second set.—A. G.

Distillation; Furnace system for dry ——. T. M. U. von Post. U.S.P. 1,375,943, 26.4.21. Appl., 16.10.19.

The retort proper is inserted in a closed chamber and is provided with a conduit communicating with an inlet at the bottom of the chamber, gases being conducted from the inlet into the top of the retort. The retort is also provided at the bottom with an outlet communicating with an outlet pipe opening into the bottom of the chamber, where means are provided by which the outlet and the inlet are separated from each other by a gas-tight joint. A condenser communicates with the inlet and the outlet.—A. G.

Distillation of wood, charcoal, or peat; Apparatus and process for continuous ——. Köln-Rottweil, A.-G. G.P. 326,227, 21.10.19.

In a process in which the material is distilled either at normal or elevated pressure or *in vacuo*, in horizontal retorts into which it is introduced in counter-current to the heating gas, the charge is first compressed in a suitable machine and then delivered to a screw-conveyor, the latter having a scraper which causes uniform amounts of the pressed material to be introduced into the retort. To ensure rapid and regular heating, the material is kept in motion in the retort; the products of distillation must be rapidly removed.—W. J. W.

Retort for distillation of carbonaceous materials. H. Graf. G.P. 328,821, 3.5.19.

The retort, in which the charge is carbonised from the top downwards, is surrounded by a cooling chamber which communicates with it by means of openings through which the products of distillation pass. A water pipe through the outer chamber serves to condense some of the products, which are drawn off through a pipe at the bottom, whilst the uncondensed gases escape through a pipe which passes centrally upwards through the retort. A high yield of condensed distillation products is thus obtained.—W. J. W.

III.—TAR AND TAR PRODUCTS.

Polycyclic phenols from sodium phenoxide fusions. F. Hofmann and M. Heyn. Brennstoff-Chem., 1921, 2, 147—150.

Sodium phenoxide was heated in a stream of hydrogen or nitrogen at 485°—490° C. Four of the six possible isomeric dihydroxydiphenyls were isolated from the residue. (*Cf.* J.C.S., July.) —W. P.

Diphenylamine; Melting point of ——. H. Rogers, W. C. Holmes, and W. L. Lindsay. J. Ind. Eng. Chem., 1921, 13, 314—316.

The m.p. of pure diphenylamine was found to be 53·0° C., which is 1° lower than the value given in the literature.—W. P. S.

Benzene hydrocarbons in gas. Krieger. *See* IIa.

Aniline bisulphate. Sabalitschka. *See* VII.

Patents.

Products [from tar] soluble in or forming emulsions with water; Process for the manufacture of ——. M. Melamid and L. Grötzinger. E.P. 134,223, 22.10.19. Conv., 31.10.17.

The solid or semi-solid resin-like substances, prepared from soft pitch, coal tar, lignite tar, or the like by extraction with sodium hydroxide solution with subsequent acidification of the extract, are distilled *in vacuo*; the portion distilling above 270° C. (20 mm.) is dissolved in cold sodium hydroxide solution, with or without previous sulphonation, and tar oil or mineral oil is added to the solution. The products are suitable for use as lubricants and as substitutes for soap and Turkey-red oil.—L. A. C.

Asphalt substitute; Manufacture of an ——. Verkaufsvereinigung f. Teererzeugnisse G.m.b.H. G.P. 332,888, 12.8.19. Addn. to 330,970 (J., 1921, 339 a).

Anthracene residues when treated with sulphur yield a product of high tenacity which is suitable for lacquers, briquettes, or road-making.—W. J. W.

Tar or tar residues, and filling material; Production of a homogeneous mass from ——. N. Reif. G.P. 332,941, 3.1.20.

Tar fog is caused to circulate and impinge on the periphery of a moving annular cloud of filling material so as to envelop and penetrate the latter. In order to obtain a product possessing hardness, elasticity, and resistance to heat, the tar, or a mixture of tar and oil, is first oxidised or treated with a halogen or sulphur and then incorporated with the filling material at a suitable temperature. —W. J. W.

Salts of sulpho-acids; Process for obtaining —— *from lignite tar oils.* Sudfeldt und Co. E.P. 148,763, 10.7.20. Conv., 14.3.19.

Lignite tar oils are treated with sufficient concentrated sulphuric acid to polymerise the acid resins, *i.e.*, 3 to 5% of their weight, and, after separation of the polymerisation products, with 10 to 20% of concentrated sulphuric acid to sulphonate the oil. After separation of the product into two layers, the oil layer is removed and agitated with an excess of $N/2$ sodium hydroxide solution to dissolve the sulphonic acids, which are then precipitated from solution by the addition of sodium chloride. The sulphuric acid layer is treated with a little water to remove excess sulphuric acid, the sulphonic acids are dissolved in water, and are precipitated from the filtered solution by the addition of sodium chloride. Sufficient saturated salt solution is first added to precipitate a small fraction of the product together with impurities, and, after separation of the precipitate, the remainder of the product is precipitated by the addition of more salt. The product is purified by treatment with oxidising agents, *e.g.*, permanganates, in aqueous solution. —L. A. C.

Naphthylamine sulphonic acids; Manufacture of ——. South Metropolitan Gas Co., and H. Stanier. E.P. 161,859, 25.5.20.

The separation of the 1.4.8- and 1.3.8-naphthylaminedisulphonic acids from the crude mixture obtained by the sulphonation of naphthylamine is effected by taking advantage of the differences in solubility of the barium salts of the acids. A suitably concentrated solution of the disodium salts is boiled with a quantity of barium chloride sufficient to convert all the acids into their barium salts. Barium 1.4.8-naphthylaminedisulphonate is precipitated, and the liquor is filtered hot. The filtrate and washings are acidified with hydrochloric acid, whereby the acid barium salt of the 1.3.8-disulphonic acid is precipitated, and filtered off hot to secure retention in solution of the corresponding salts of the 2.4.7- and 2.4.8-acids which may be present. Alternatively the barium salt may be added in proportion sufficient to convert only the 1.4.8- and 1.3.8-acids into barium salts, in which case the acid barium salts of the latter acid can be filtered off cold.—G. F. M.

Sulphur compounds of the thiophene series; Manufacture of ——. H. Scheibler. G.P. 331,793, 17.4.15. Addn. to 327,050 (J., 1921, 173 A).

The tar oil, after purification with soda-lime, is treated with sodamide or with ammonia and sodium below 120° C.—L. A. C.

Thionaphthene; Process of separating —— from coal-tar [*naphthalene*]. Ges. für Teerverwertung m.b.H. G.P. 333,156, 26.2.20. Addn. to 325,712 (J., 1920, 777 A).

The mixture of sulphonic acids, obtained as described in the chief patent, is distilled with steam at such a temperature that only a small proportion of the naphthalenesulphonic acid is hydrolysed. The distillate, m.p. 50°—60° C., containing 20 to 30% of thionaphthene, is treated with alkali for the removal of phenols, and is then purified by fractional distillation; the fraction 220°—225° C. gives a dark-red coloration on treatment in carbon bisulphide solution with sulphuric acid (sp. gr. 1·84). Steam distillation of the solution, after separation of the carbon bisulphide and dilution with water, yields pure thionaphthene.—L. A. C.

Anthranol; Manufacture of ——. A. G. Perkin, Assr. to British Dyestuffs Corp. U.S.P. 1,375,972, 26.4.21. Appl., 9.6.20.

See E.P. 151,707 of 1919; J., 1920, 743 A.

Lubricants. G.P. 331,504 and 332,909. *See* IIA.

IV.—COLOURING MATTERS AND DYES.

Nitroamines and their derivatives; Some properties of ——. F. M. Rowe. J. Soc. Dyers and Col., 1921, 37, 145—150.

A review of the author's published work on nitroamines (J., 1913, 417; 1917, 958; 1918, 119 A). The nitrogen analogues of Stilbene Yellow and Mikado Orange can be prepared from *p*-nitroaniline by similar condensations to those which occur in the stilbene series. In the latter case the reaction is facilitated by the presence of negative groups in the *o*-position, but in the former case, sulphonic or nitro groups in the *o*-position with respect to the basic nitrogen exert an impeding effect in condensation, probably owing to a tendency to ring formation. The oxidation of an alcoholic solution of *o*-nitroaniline with neutral sodium hypochlorite results in the formation of 2.2′-dinitroazobenzene, but in presence of alkalis benziso-oxadiazole oxide is formed in quantitative yield. The latter compound yields a dinitro-derivative which forms true salts and affords an example of hydrogen in the benzene ring possessed of acidic properties. Dinitrobenziso-oxadiazole oxide, treated with sodium sulphide and sulphur by the condenser method, yields a fine brown sulphide dye of good properties, and thus suggests an outlet for *o*-nitroaniline. —F. M. R.

1.8-*Dihydroxynaphthalene.* G. Heller and H. Kretzschmann. Ber., 1921, 54, 1098—1107.

1.8-Dihydroxynaphthalene, m.p. 140° C., is most conveniently prepared by heating 1.8-dihydroxynaphthalene-4-sulphonic acid with sulphuric acid and water at 150° C. It couples with an equimolecular quantity of benzenediazonium chloride in hydrochloric acid solution to 4-benzeneazo-1.8-dihydroxynaphthalene, which does not melt below 260° C.; the same substance is formed in acetic acid or alkaline solution but, in addition, about 10% and 7·5% respectively of products insoluble in alkali are produced. The use of an increased proportion of diazo-compound leads, in acetic acid but not in mineral acid solution, to the production of 4.5-dibenzeneazo-1.8-dihydroxynaphthalene, m.p. about 238° C.; in alkaline solution, an isomeric dibenzeneazo dye appears also to be formed. 4-*p*-Sulphobenzeneazo-1.8-dihydroxynaphthalene dyes unmordanted wool a dark cherry red, a paler shade being produced on aluminium-mordanted wool and dark brown shades on the chrome-mordanted fibre. (*Cf.* J.C.S. July.)—H. W.

Azo components; Aromatic acylamines as ——. W. König and K. Köhler. Ber., 1921, 54, 981—987.

Diazotised *p*-nitraniline couples with *p*-toluenesulphon-α- and -β-naphthylamides, giving compounds of the type

$$\mathrm{O\underset{\ddot{O}}{:}N.C_6H_4.N{:}N.C_{10}H_6.\underset{Na}{N}{:}\underset{\overset{|}{O}}{S}(:O).C_6H_4.CH_3};$$

since reaction does not occur under similar conditions with the corresponding methylnaphthylamides, it appears probable that the naphthylsulphonamide couples in its enolic form,

$$\mathrm{C_{10}H_7.N{:}S(:O)(OH).C_6H_4.CH_3}.$$

Carboxyamides can also couple with diazotised *p*-nitraniline but reaction occurs extremely slowly. The auxochromic power of the different groups under consideration diminishes in the order, $-\mathrm{OH}$, $-\mathrm{NH.SO_2.C_6H_4.CH_3}$, $-\mathrm{NH.CO.C_6H_5}$. $-\mathrm{NH.CO.CH_3}$. (*Cf.* J.C.S., July.)—H. W.

Isatins; Synthesis of ——. *Action of chloraloxime on aromatic amines.* T. Martinet and P. Coisset. Comptes rend., 1921, 172, 1234—1236.

In acid solution chloraloxime condenses with aniline to give isonitrosoacetanilide, which when warmed with sulphuric acid yields isatin. If the aniline is replaced by *p*-chloro-*o*-anisidine hydrochloride the products are in turn 2-methoxy-5-chloroisonitrosoacetanilide, m.p. 190° C., and 4-chloro-7-methoxyisatin. The latter gives the corresponding copper and barium isatates and when condensed with indoxyl yields 4-chloro-7-methoxyindirubin, which with hydrosulphite gives an unstable yellowish-green vat changing almost completely into ordinary indigo.—W. G.

Isocurcumin. III. G. Heller. Ber., 1921, 54, 1118—1119.

Examination of the action of acetylacetone on *p*-hydroxybenzaldehyde and thymolaldehyde in the presence of alcoholic hydrogen chloride has shown that the poor yield of β-isocurcumin obtained from vanillin under like conditions (J., 1914, 544) is due to the decomposition of acetylacetone by the alcoholic acid into acetone with which the aldehyde preferentially condenses.—H. W.

Patents.

Anthraquinone series; Manufacture of nitrogenous condensation products of the ——. Badische Anilin- u. Soda-Fabrik. G.P. 329,247, 16.6.14.

1-Halogenanthraquinones or derivatives containing a reactive substituent in *o*-position to the halogen atom are heated with *o*-aminodiarylamines or their nuclear substitution products, alone or in an inert solvent or suspension medium, and with or without addition of catalysts and substances capable of combining with acids. Anthraquinonylbenzohydroazines of the formula,

$$C_6H_4<\genfrac{}{}{0pt}{}{CO}{CO}>C_6H_2<\genfrac{}{}{0pt}{}{NR}{NH}>C_6H_4$$

similar to the products described in G.P. 329,246 (E.P. 3347 and 100,581 of 1915; J., 1916, 831), are formed. From 1-chloroanthraquinone, *o*-aminodiphenylamine hydrochloride, potassium acetate, and naphthalene, a product of the composition, $C_{26}H_{16}O_2N_2$, insoluble in dilute hydrochloric acid, and crystallising from acetone in needles with a coppery lustre, is obtained. The same substance is formed from 1.2-dichloroanthraquinone, m.p. 202°—204° C., and from 1-bromo-2-methoxyanthraquinone, whereas from 1.5- or 1.8-dichloroanthraquinone two isomeric monochloro-derivatives of the substance are formed. With 1.4-dichloroanthraquinone both chlorine atoms are replaced, and a blue condensation product, almost insoluble in acetone, is obtained.

Anthracene derivatives containing nitrogen; Preparation of ——. Preparation of nitrogenous condensation products of the anthraquinone series. Badische Anilin- und Soda-Fabr. G.P. (a) 330,572, 14.8.14, and (b) 332,013, 16.6.14. Addn. to 329,247 (*cf. supra*).

(a) Alizarin or a heteronuclear hydroxy-substitution derivative (with the exception of 1.2.5.8-tetrahydroxyanthraquinone) is heated with primary aromatic amines or their substitution products with or without addition of stannous chloride. On heating alizarin with aniline and stannous chloride to 170°—180° C., phenylaminocoeramidonine is formed, which, after freeing the melt from excess of aniline by hydrochloric acid, is extracted with acetone, from which it crystallises in glistening needles, m.p. 203°—205° C. (uncorr.), soluble in alcohol, nitrobenzene, and aniline with a red, and in concentrated sulphuric acid with a greenish blue colour. Other arylaminocoeramidonines from *p*-toluidine and alizarin (m.p. 198°—199° C.), 1.2.6-trihydroxyanthraquinone and *p*-toluidine (m.p. 284°—287° C.), 1.2.7-trihydroxyanthraquinone and *p*-toluidine, 1.2.5-trihydroxyanthraquinone and *p*-toluidine, and 1.2.5.6-tetrahydroxyanthraquinone and *p*-toluidine, are described. All these products can be used as dyestuffs or as raw materials for the preparation of dyestuffs. Their sulphonic acids dye unmordanted wool in red, violet, and blue shades. (b) Arylaminoanthraquinones, or their nuclear substitution products, containing a reactive substitution group in the ortho-position to the imino-group, are condensed with primary aromatic amines. Thus 1-phenylamino-2-methoxyanthraquinone is produced from 1-bromo-2-methoxyanthraquinone and aniline; it dissolves in sulphuric acid with a yellowish-red and in alcohol with a carmine-red colour. It gives a condensation product with aniline and caustic potash identical with that described in the principal patent.—A. R. P.

Diazo-azo-hydroxy compounds; Preparation of ——. O. Müller. G.P. 330,832, 7.4.16.

Sufficient alkali carbonate is added to render alkaline a solution containing equivalent quantities of (a) a diazohydroxynaphthalene, or derivatives of the same, such as 1-diazo-5 (or 7)-hydroxynaphthalene, or 2-diazo-8-hydroxy-6 (or 3.6-di)-sulphonic acid, and (b) a highly reactive mono-diazo compound containing a negatively substituted benzene nucleus, such as *p*-nitrodiazobenzene. Alternatively, a solution of (b) is added to a solution of (a) containing sufficient alkali carbonate to render the solution alkaline at the end of the reaction, which is marked by the disappearance of both diazo compounds from the solution. The products couple, *e.g.*, with *m*-toluylenediamine, 1-aminonaphthalene-6 (7)-sulphonic acid, or 1-amino-8-hydroxynaphthalene-4-sulphonic acid, yielding dark blue to black substantive cotton dyes. Diazo-1-hydroxynaphthalene compounds which are capable of reacting with a diazo compound in both alkaline and acid solution, produce in the two cases different diazo-azo compounds, which yield different dyestuffs on coupling. —L. A. C.

Azo dyestuffs dyeing on mordants. C. Jagerspacher, Assr. to Soc. of Chem. Ind. in Basle. U.S.P. 1,375,701, 26.4.21. Appl., 15.11.19.

See E.P. 149,553 of 1919; J., 1920, 816 a.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Plant colloids. VIII. Some cellulose dextrins. M. Samec and J. Matula. Kolloid-Chem. Beih., 1921, 11, 37—73.

Sulphite-cellulose is not completely dissolved by 50% sulphuric acid, whilst 86% sulphuric acid chars it. Solutions of cellulose in sulphuric acid (50—85%) are at first colourless, but on keeping they speedily become coloured. As the degradation of the cellulose becomes greater the coloration produced by iodine changes from blue to violet, then to various shades of brown, and finally disappears; the relative viscosity rises to a maximum and then falls as the swelling and solution increase. In the degradation, dextrins are produced, some of which are soluble in water whilst others are insoluble. The insoluble products are destroyed by sulphuric acid (60% and above) within the first half hour. As the degradation proceeds the following changes are observed successively:—the dextrin esters are gelatinised by alcohol and the dextrin is precipitated; the dextrin esters and the dextrins are both insoluble in alcohol; the dextrin esters are soluble, the dextrins are insoluble in alcohol; both dextrin esters and dextrins are soluble in alcohol. Phosphoric acid of a greater concentration than 75% at ordinary temperatures forms a colourless, very viscous jelly with cellulose which is only slowly changed at this temperature, but at higher temperatures a slow degradation occurs and eventually the solution becomes brown or black. The action of sulphuric acid on cellulose depends not only on the concentration of the acid but also on the relative quantities of acid and cellulose. With a sufficient excess of acid dialysable dextrins are produced in the first quarter of an hour and at the same time the molecular weight of the colloidal residue is reduced. The degradation of both dialysable and non-dialysable portions proceeds further by continued action of the acid until after 5 hours the mean molecular weight of the most coarsely disperse portion is 2400. At the same time the $-SO_4H$ group enters the molecule with the formation of esters. Diastase is capable of converting some of the dextrins produced into fermentable sugars. (*Cf.* J.C.S. June.) —J. F. S.

Colophenic acids. Aschan. *See* XIII.

Patents.

Wool-washing machines. J. F. and W. H. White. E.P. 162,313, 8.10.19.

The wool is carried forward over several consecutive hemi-cylindrical perforated surfaces by means of adjustable drums having projecting tangential beaks, whereby it is constantly immersed in the washing liquid. The tangential beaks are so shaped that there is no tendency for the wool to lap around them.—A. J. H.

Fireproofing material and heat- and cold-retaining coverings; Process of making —— and product thereof. C. S. Hathaway, Assr. to J. A. Locke. U.S.P. 1,374,885, 12.4.21. Appl., 24.3.20.

A fabric is impregnated with a composition containing a tar and an hydraulic cement.— H. S. H.

Sulphate pulp; Manufacture of ——. E. Olsson. U.S.P. 1,375,759, 26.4.21. Appl., 2.4.19.

A digestion liquor containing sodium hydroxide and a larger amount of sodium sulphide is used. —A. J. H.

Articles obtained from solutions [cellulose and the like]; Process for the production and simultaneous conversion of —— into their ultimate forms. B. Borzykowski. U.S.P. (a) 1,375,823 and (b) 1,375,824, 26.4.21. Appl., 29.5.17 and 19.6.20.

(a) Articles are produced from solutions of viscose by "forming" and "setting" in a non-acid salt solution and are immediately afterwards converted into the final cellulose product. (b) Articles are produced by passing solutions, capable of coagulation, directly into an alkaline bath and are immediately afterwards subjected to an ultimate chemical conversion; *e.g.*, cellulose thread is produced by spinning a solution of cellulose into an alkaline bath, withdrawing the thread and winding it under tension and simultaneously converting it into cellulose hydrate by treatment with sulphuric acid.—A. J. H.

Fibres; Process for making ——. R. Kron. U.S.P. 1,376,285, 26.4.21. Appl., 18.9.19.

Fibres which felt together not too densely and thereby produce an absorbent spongy sheet sufficiently strong and durable for application to the manufacture of rough pasteboard, which after saturation with tar or bitumen, is suitable for roofing, linings, etc., are produced (without the use of alkalis or acids) from wood in the form of logs and similar large pieces and from ligneous or strongly silicious plants. These materials are boiled with water or steamed, rolled out, crushed and ground so as to obtain the natural cellulose fibres without deterioration and not weakened by chemical reagents.—A. J. H.

Paper material coated with leaf metal. F. Tscheike, Assr. to The Chemical Foundation, Inc. U.S.P. 1,376,737, 3.5.21. Appl., 6.6.17.

See E.P. 113,297 of 1917; J., 1918, 179 a

Separating solid particles from suspension [e.g., fibres from paper mill waste waters]; Process for ——. N. Pedersen. U.S.P. 1,376,459, 3.5.21. Appl., 3.9.18.

See E.P. 119,028 of 1918; J., 1919, 760 a.

Chlorate explosives. G.P. 307,100. *See* XXII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Anilides of β-[hydr]oxynaphthoic acid [in production of ice colours]. E. R. Brunskill. J. Ind. Eng. Chem., 1921, 13, 309.

Although the colours obtained by substituting β-hydroxynaphthoic acid for β-naphthol in the ice process are brighter, they are not fast to washing; to overcome this defect amides of the acid have been used, the chief of which is the anilide (Naphthol AS). Dyeing experiments were made with the following substances as naphthols:—β-hydroxynaphthoic acid, the anilide, the toluidide, and the *p*-chloroanilide; each naphthol was coupled with aniline, *p*-nitroaniline, *p*-chloroaniline-*o*-sulphonic acid, *p*-toluidine, *m*-nitro-*p*-toluidine and *o*-chloro-*p*-toluidinesulphonic acid. All the colours made from β-hydroxynaphthoic acid washed out, but the anilides gave fairly fast colours, except in the case of the sulphonated amides. The latter, however, were rendered fast by immersing the dyed fabric for 30 mins. in 3% calcium chloride solution at 50° C.—W. P. S.

Patents.

Dyeing; Method of ——. A. Lendle, Assr. to Kuttroff, Pickhardt and Co. U.S.P. 1,375,919, 26.4.21. Appl., 9.9.20.

Fabric is dyed with a basic dyestuff and is subsequently treated with a complex acid containing phosphorus and tungsten. (*Cf.* E.P. 143,242; J., 1921, 385 a.)—A. J. H.

Decomposition products of proteins [protalbinic and lysalbinic acids]; Use of —— [in dyeing]. C. Bennert. G.P. (a) 331,484, 25.12.15, and (b) 332,476, 19.1.16. Addns. to 330,133 and 331,234 (J., 1921, 256 a, 297 a).

(a) The use of the decomposition products, prepared, *e.g.*, by heating casein or gluten with sodium hydroxide, is claimed in weakly alkaline, neutral, or weakly acid vats, but not in strongly alkaline vats. (b) In the case of sulphur dyes suitable for dyeing animal fibres, the vat is prepared by treating the dye with hydrosulphite and sodium hydroxide, and the alkali is neutralised by the addition of an acid or a neutral salt of a volatile alkali and an organic acid, *e.g.*, ammonium formate, together with the protalbinic and lysalbinic acids.—L. A. C.

Hosiery, gloves, and the like dyed with Aniline Black; Manufacture of ——. K. Schlatter. G.P. 332,675, 23.3.19. Conv., 21.11.18.

The goods are made from raw yarn of which a part has been treated with a substance which prevents the injurious effect of the Aniline Black process (such as a metal oxide which can be printed on to the yarn, or a compound capable of combining with an acid or acting as a reducing agent) or of which a part has not been aged. A suitable method of manufacture is to employ double threads, in which one has been dyed with Aniline Black, and the other has been dyed with another black dye, or has been treated as described above. —L. A. C.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Hydrochloric acid; New method of purification of ——. J. Lamquet. Bull. Soc. Chim. Belg., 1920, **29**, 309.

Commercial hydrochloric acid may be freed from arsenic, chlorine, and sulphur dioxide by the simple addition of hypophosphorous acid or one of its salts, the reactions being represented by the following equations:

$3H_3PO_2+4AsCl_3+6H_2O=3H_3PO_4+12HCl+4As.$
$H_3PO_2+2Cl_2+2H_2O=H_3PO_4+4HCl.$
$H_3PO_2+SO_2=H_3PO_4+S.$

By using the barium salt sulphuric acid is precipitated at the same time.—G. F. M.

Glauber's salt; Manufacture of ——. W. Hüttner. Chem.-Zeit., 1921, **45**, 313—315.

The waste product derived from the manufacture of potassium chloride and consisting chiefly of a mixture of rock salt and kieserite, may be utilised as raw material for the production of Glauber's salt. It contains approximately: KCl, 2·6%; $MgSO_4$, 10·5%; $CaSO_4$, 3·4%; NaCl, 54·3%; and Na_2SO_4, 6·9%. The waste heaps are sprinkled with water at 45°—50° C., until a solution is obtained of sp. gr. 1·27—1·29 and of the approximate composition: NaCl, 21·1%; $MgSO_4$, 9·1%; $MgCl_2$, 1·3%; H_2O, 68·4%. Formerly it was usual to crystallise this solution in winter at below 0° C., but artificial refrigeration is now adopted, the solution being placed in vats with cooling coils, and depositing fine crystals of Glauber's salt on cooling. The crystals are re-dissolved in steam-heated vessels and freed from iron by precipitation with lime; the solution is then allowed to crystallise again in such a manner as to yield either large crystals or a fine crystalline material, as required. To obtain a calcined product, suitable for glass works, the salt solution is evaporated in a vessel provided with copper heating coils, and the residue is dehydrated.—W. J. W.

Ammonia and carbonic acid; Compounds of —— *in equilibrium with their aqueous solutions.* E. Terres and H. Weiser. Z. Elektrochem., 1921, **27**, 177—193.

The conditions under which the different compounds of ammonia and carbonic acid are stable in contact with aqueous solutions of the components were studied between 0·1° and 60° C. Five different compounds can exist as solid phases, namely ammonium bicarbonate, the bicarbonate-carbonate double salt, $2NH_4HCO_3,(NH_4)_2CO_3,H_2O$, the normal carbonate, ammonium carbamate, and the carbamate-bicarbonate double salt, $NH_4CO_2NH_2,NH_4HCO_3$. All these have distinctive crystalline forms by which they can be identified microscopically. Previously only the bicarbonate and carbamate had been prepared in the pure state, but methods have now been devised for preparing the bicarbonate-carbonate doublo salt and the normal carbonate. The former salt crystallises from solutions containing NH_3 and CO_2 in the ratio 4:5. The normal carbonate is prepared by dissolving 395 g. of ammonium bicarbonate in 150 g. of water and 333 g. of 25% ammonia solution whilst passing in ammonia under a pressure of 0·2 atm. and warming to 40° C. until solution is complete. On cooling to 10° C. the normal carbonate crystallises out. Only the bicarbonate forms congruent solutions, in which the ratio of NH_3 to CO_2 is the same as in the solid phase. The other compounds form stable solid phases only in presence of excess of ammonia. The equilibrium diagram shows that the normal carbonate and the two double salts have a limited temperature range of stability, whilst the bicarbonate and carbamate can exist at all temperatures between 0° and 60° C. with the necessary ammonia concentration. Starting with bicarbonate and water, between 0° and 33° C., as the concentration of ammonia increases the solid phase changes consecutively to bicarbonate-carbonate, normal carbonate, and finally carbamate. At about 33° C. both the double salt and normal carbonate disappear and the new double salt bicarbonate-carbamate appears between the bicarbonate and carbamate. No further change takes place up to 60° C.
—E. H. R.

Potassium, sodium, ammonium, and aniline bisulphates, potassium binoxalate and tetroxalate; Decomposition of —— *by solvents.* T. Sabalitschka and H. Schrader. Ber. deuts. Pharm. Ges., 1921, **31**, 183—198.

The crystallisation of aqueous solutions of potassium, sodium, ammonium, and aniline bisulphates, results in the formation, to a greater or lesser degree, of the normal salt and the free acid. Thus pure potassium sulphate was deposited from a solution of pure potassium bisulphate, whilst a mixture of the normal and acid salts was obtained in the other cases. The addition of alcohol to an aqueous solution of sodium bisulphate caused the precipitation of the pure normal salt. The precipitate obtained in a similar way with ammonium bisulphate solution contained 60—70% of the normal salt. The prolonged extraction of the dry bisulphates with alcohol in a Soxhlet apparatus resulted in the removal of acid, leaving a residue of the normal sulphates in the case of the potassium and sodium salts, and a mixture in the case of the ammonium and aniline salts. The extraction of potassium tetroxalate with ether and alcohol resulted in a similar decomposition into free acid and potassium binoxalate, the latter being unchanged by further action of the solvents.—G. F. M.

Ammonium sulphate; Melting point of ——. J. Kendall and A. W. Davidson. J. Ind. Eng. Chem., 1921, **13**, 303—304.

Divergent figures for the melting point of ammonium sulphate must be ascribed to the instability of the normal salt (*cf.* Watson Smith, J., 1895, 629). Results obtained by many observers for the melting point of the acid salt are in close agreement with Kendall and Landon's figure, 146·9° C. (J. Amer. Chem. Soc., 1920, **42**, 2131), and a melting point of 251° C., given by Jänecke (J., 1920, 818 a), is explicable. The actual melting point of the normal salt can be determined only by heating it in a sealed tube, with no free air space, so as to avoid appreciable loss of ammonia. Under these conditions the salt softened at 490° C. and its melting point was found to be 513° C. ± 2°, under an ammonia pressure of considerably more than 1 atm.
—W. J. W.

Bleaching powder; Solution of ——. M. Champion. Bull. Soc. Chim. Belg., 1920, **29**, 24—28.

Mixtures of bleaching powder and water containing from 1 to 20% of the former were shaken for 3 hours, allowed to settle, and in the clear supernatant solution the active oxygen, total chlorine and calcium, and the density were determined. If the concentration exceeds 4% there is a risk of some of the active oxygen being retained in the residual sludge from the preparation. The figures on the whole show rather higher proportions of calcium and total chlorine to active oxygen than those required by the formula, Cl.CaOCl.—W. G.

Reaction $CaCO_3=CO_2+CaO$*; Reversibility of the* ——. P. Jolibois and Bouvier. Comptes rend., 1921, **172**, 1182—1183.

Using various forms of calcium carbonate, it was found that the reversal of the dissociation on cooling was never complete except when precipitated calcium carbonate was dissociated by heat in the presence of an excess of calcium oxide.—W. G.

Calcium carbide; Apparatus and method for estimation of ——, for calcium cyanamide manufacture. E. von Drathen. Chem.-Zeit., 1921, 45, 447.

Twenty grms. of carbide is placed in a stoppered separating funnel, the tap of which has a conical bore, varying in diameter from 1·5 mm. to 2·5 mm., so that when it becomes choked the particles are easily dislodged by turning through 180°. The funnel is fixed in a filter-flask containing a saturated solution of salt, and connected by tubing with a gas-measuring flask. This latter has a capacity of 5 l. and is graduated in 50 c.c. divisions; its lower end is continued as a long tube of 800 c.c. capacity graduated in 10 c.c. divisions, and this is in communication with a levelling flask. The volume of the acetylene generated by introduction of the carbide into the salt solution may be read to within 5 c.c.—W. J. W.

Chrome alum solutions; Action of sodium carbonate on ——. L. Meunier. J. Soc. Leather Trades' Chem., 1921, 5, 103—111.

As a result of Burton's experiments (J., 1921, 19 A) the author has carried out further work on the action of sodium carbonate in precipitating chrome alum solutions. The amount of sodium carbonate necessary to bring about the commencement of precipitation is less when the solution of chrome alum is more dilute, when the temperature is higher, when the solution is old, and when it is stirred vigorously. A reversible change takes place in chrome alum solutions which have been heated for some time at a constant temperature, but the change is irreversible if the heating has been prolonged or has taken place at 100° C. or above. Sodium carbonate precipitates a basic chromium sulphate from chrome alum solutions heated to 100° C. and chromium hydroxide from cold or freshly prepared solutions. Chrome alum solutions undergo hydrolysis and the basic chromic salts so formed polymerise under the action of heat and more slowly on keeping. Precipitation is due to the sodium carbonate acting as a neutralising agent and also as a coagulating agent on the chromium hydroxide or the polymerised basic chromium salts in colloidal solution.—D. W.

Phosgene; Solvents for ——. C. Baskerville and P. W. Cohen. J. Ind. Eng. Chem., 1921, 13, 333—334.

One part by weight of phosgene (carbonyl chloride) is dissolved by the following weights of different solvents at 20°—21° C.:—Carbon tetrachloride, 3·6; chloroform, 1·7; gasoline, 1·2; paraffin oil, not soluble; Russian mineral oil, 2·8; benzene, 1; toluene, 1·5; glacial acetic acid, 1·6; ethyl acetate, 1; chlorocosane, 3·2. The last substance is paraffin which has been melted and treated with chlorine. In the case of gasoline, chloroform, and glacial acetic acid reaction was evident by heat of solution and change in b.p. of the solvent; there was also a change in the b.p. of the toluene, but the other solvents appeared to be inert towards the gas. —W. P. S.

Oxidation of sulphur. MacIntire and others. *See* XVI.

Titration of boric acid. Boëseken and Couvert. *See* XVII.

Patents.

Nitric acid; Manufacture of concentrated ——. Bayerische A.-G. f. Chem. und Landwirtschaftl. Fabrikate, H. Hackl, and H. Bunzel. G.P. 307,601, 9.3.16.

Barium nitrate is heated with sulphuric acid in a vessel through which the mixture is conveyed by a screw device in order to allow of a continuous process.—W. J. W.

Protection of walls of enclosures in which reactions [e.g., synthesis of ammonia] take place under high temperatures and pressures. "L'Air Liquide," Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude. E.P. 140,083, 9.3.20. 18.12.18.

The chamber in which the reaction takes place, being incapable of resisting a very high pressure, is enclosed in a pressure-resisting outer vessel which must be protected from the reacting substances (*e.g.*, gaseous hydrogen). The vessel is therefore filled to a level above the zone of reaction with a liquid that is neutral to the reacting substances and a bad conductor of heat (*e.g.*, potash-soda mixture). To prevent loss of heat by convection the space between the reaction chamber and the outer walls is filled with overlapping rings made of a solid which is also a bad conductor of heat and preferably may be capable of removing any corrosive substance dissolved in the liquid (*e.g.*, rings of magnetic oxide of iron will absorb hydrogen with formation of water vapour, which in turn may be absorbed by metallic iron placed inside the vessel but above the zone of reaction and out of the intense heat).—B. M. V.

Aluminium chloride; Production of ——. M. Shoeld, Assr. to Armour Fertilizer Works. U.S.P. 1,375,116, 19.4.21. Appl., 5.11.20.

Alumina is heated to 1600°—2000° C. to render it anhydrous, and is then subjected to the action of chlorine, in presence of carbon.—W. J. W.

Perborates; Manufacture of ——. J. K. Langhard, Assr. to Frederikstad Elektrokem. Fabr. A./S. U.S.P. 1,375,596, 19.4.21. Appl., 6.2.20.

A solution of a borate is electrolysed in presence of a cyanogen compound.—C. I.

Per-salts and metallic peroxides; Process for rendering —— stable by coating them with gelatin or glue. H. E. Bergmann. G.P. 334,868, 1.5.19.

The gelatin or glue solution is first oxidised to destroy reducing impurities and thus avoid loss of active oxygen in the compound to be preserved. The stabiliser may be applied to the reagents before preparation of the peroxides etc., as it does not interfere with the reaction.—C. I.

Arsine, phosphine, and stibine; Process and apparatus for electrolytic generation of ——. H. Blumenberg, jun. U.S.P. 1,375,819, 26.4.21. Appl., 11.6.19.

A compound containing phosphorus, or other element of the phosphorus group (nitrogen and boron excepted), is electrolysed in conjunction with a reagent capable of forming nascent hydrogen at the cathode and oxygen at the anode, and the gases formed are collected.—A. J. H.

Basic zirconium sulphate; Process of making ——. E. J. Pugh, Assr. to Pennsylvania Salt Manufacturing Co. U.S.P. 1,376,161, 26.4.21. Appl., 30.1.19.

Chlorine is passed over the heated ore and the sublimate of zirconium chloride dissolved in water. Basic zirconium sulphate is precipitated from this solution by addition of sulphuric acid.—A. R. P.

Magnesium bisulphite solution and magnesium oxide; Process of making ——. P. and A. Frank and M. Lebram. G.P. 302,472, 8.9.15.

Magnesium sulphate is converted into oxide by heating with sawdust or other carbonaceous material, and half of the oxide is transformed into bisulphite by saturating with the sulphur dioxide evolved. Excess carbonaceous matter is burnt off. —C. I.

Alumina; Process for the preparation of —— suitable for the manufacture of aluminium. M. Buchner. G.P. 303,923, 10.9.16.

The crude ore is decomposed with sulphuric acid, freed from iron, and the purified aluminium salt treated with enough ammonia to precipitate basic sulphate. The precipitate is washed, dried, and ignited in a current of air, the sulphur trioxide and ammonia evolved being recovered. The alumina produced is granular and not powdery.—C. I.

Nitrogen; Process for the oxidation of ——. Gewerkschaft des Steinkohlenbergwerks Lothringen, and M. Kelting. G.P. (a) 329,846 and (b) 329,847, 17.12.19.

(a) In a process for the oxidation of nitrogen heated to over 1500° C., the mixture of oxides of nitrogen from the reaction vessel is passed at a high speed (at least 5 m. per sec.) through a preheater consisting of narrow tubes of zirconia. In the reaction vessel a contact body is arranged, the active surface of which is several times that of the catalytic preheater surface. (b) The entering gases are passed through a heating chamber with refractory lining connected with a number of pipes, the front portions of which are insulated. After undergoing the reaction the gases pass on through pipes constricted to a small diameter into a cooling chamber, which may itself be formed of pipes set at right angles to the direction of the current of gas.—C. I.

Titanium tetrachloride; Process for manufacturing ——. O. Priesz. G.P. (a) 334,248 and (b) 334,249, 10.10.17.

(a) In the manufacture of titanium tetrachloride by passing chlorine over a heated mixture of titanic acid and charcoal, the activity of the chlorine is increased, and the reaction temperature reduced to below 300° C., by adding a small amount of an oxide or chloride of a rare earth metal, or of a metal of the manganese group, *e.g.* cerium, zirconium, or manganese. (b) In the treatment of titanic acid by heating it with a mixture of carbon monoxide and chlorine, the addition of small amounts of carbon to the titanic acid increases the yield of titanium tetrachloride.—W. J. W.

Magnesium hypobromite; Preparation of insoluble basic ——. E. Merck and W. Pip. G.P. 334,654, 12.6.19. Addn. to 297,874.

A mixture of a solution of a magnesium salt and an alkali or alkaline-earth hydroxide is treated with an equivalent weight of hypobromous acid or the corresponding amount of liquid or gaseous bromine. The basic hypobromite is deposited in a gelatinous state and dries to a yellow powder almost insoluble in water.—C. I.

Sulphur; Treatment of mined ——. R. F. Bacon and H. S. Davis, Assrs. to Texas Gulf Sulphur Co. U.S.P. (a) 1,374,897 and (b) 1,374,898, 19.4.21. Appl., 6.10.19.

(a) The free burning quality of mined sulphur containing oil is improved by heating it to 400°—430° C. for a sufficient time to carbonise the oil. (b) Crude sulphur containing oil is refined by heating it to carbonise the oil, then allowing the mass to cool to a temperature above the melting point of sulphur and stand until the carbon has segregated. —A. R. P.

Sulphur; Process for recovering —— from sulphates, especially calcium sulphate. Metallbank und Metallurgische Ges. A.-G. G.P. 334,247, 23.12.16.

In calcining a mixture of sulphate and fuel, the depth of the layer of the material and the introduction of air are so regulated that the surface of the material retains a dark appearance during the process. By this means the greater part of the combined sulphur is recovered in the free state. —W. J. W.

Caustic soda or soda lye; Prduction of ——. Schweizerische Sodafabrik. E.P. 144,266, 17.5.20. Conv., 4.6.19.

See G.P. 332,003 of 1919; J., 1921, 301 a.

Ammonium sulphate; Method of discharging —— from saturator baths. F. J. Collin, A.-G. zur Verwertung von Brennstoffen und Metallen. E.P. 145,781, 2.7.20. Conv., 2.4.19.

See G.P. 316,596 of 1919; J., 1920, 405 a.

Aluminium hydroxide; Process for the production of ——. M. Buchner. E.P. 162,303, 28.11.17.

See U.S.P. 1,337,192 of 1920; J., 1920, 488 a.

Alkali aluminates; Preparation of pure ——. P. Miguet, Assr. to Rochette Frères. U.S.P. 1,376,563, 3.5.21. Appl., 3.11.19.

VIII.—GLASS; CERAMICS.

Glass; Dissolved gases in ——. E. W. Washburn, F. F. Footitt, and E. N. Bunting. Univ. Illinois Bull. 15, Vol. XVIII., 13.12.20. 32 pages.

The percentage of gases dissolved in various samples of glass was determined by melting the sample under atmospheric pressure in an electric resistance furnace connected by means of a valve with a large evacuated tank with an internal pressure of less than 1 cm. and sometimes 0·02 mm. of mercury. When the glass was at a suitable temperature the valve was opened quickly, thus causing a sudden drop of pressure in the furnace and causing the glass to effervesce vigorously and to expand rapidly to about six times its original volume. In a modified form of the apparatus, the furnace consisted of a porcelain tube 3 cm. diam. and 13 cm. high, wound with platinum wire, surrounded by a tightly fitting porcelain protection tube, then by a second porcelain tube, the whole being enclosed in glass. The sample weighing about 25 g. was heated *in vacuo* to 1400° C. until no more gas was evolved. A barium flint optical glass with a refractive index of 1·605 yielded 15·3 c.c. of gas per 50 g. of glass, or 110% by vol. Two other samples yielded 50% by vol. of gas; the gas contained 25% CO_2 and 75% O_2. A light flint bulb glass gave 20% by vol. of gas consisting of CO_2 58%, O_2 24%, and N_2 18%. A borosilicate glass gave 20% by vol. of gas consisting of CO_2 26%, O_2 37%, and N_2 37%. The amount and composition of the gas varied with the type of glass and the conditions of melting and plaining. The results obtained indicate that if glass were melted on an industrial scale in a vacuum furnace, the customary plaining would be eliminated, thus reducing the temperature necessary for finishing the glass, and the yield of perfect glass would be increased owing to the absence of all "seed." (*Cf.* J.C.S., June.)—A. B. S.

Patents.

Furnaces for melting glass. The E. W. Harvey Gas Co., and E. W. Harvey. E.P. 162,232, 16.9.20.

Heating of the glass near gathering or tapping openings of gas-fired glass-melting furnaces with one or more reversible flames is secured by providing supplementary flues in suitable positions near these openings. The flues, which are regulated by dampers, are connected directly with the chimney, and so have a stronger draught than that in the main ports or waste gas flues, these being only indirectly connected with the chimney through regenerators. The method may be applied to various types of tank and pot furnaces.—A. C.

Quartz glass; Process for making articles of ——. J. Scharl, Assr. to General Ceramics Co. U.S.P. 1,375,657, 19.4.21. Appl., 8.2.19.

Quartz glass is fused to a plastic mass in an electric furnace provided with a resistance core. The fused mass is removed from the furnace together with the hot core and blown into the desired shape. —J. S. G. T.

Dental cements; Manufacture of ——. S. Schiff. E.P. 161,868, 16.6.20. Addn. to 145,052.

In the manufacture of dental cements of the kind where a powder is mixed with a liquid to produce a composition which hardens to a solid cement, colloidal silica is added for the purpose of increasing the hardness and transparency of the product. —H. S. H.

Bricks, slabs, and the like; Method for treating clayey material for making ——. C. W. Wallace. E.P. 162,483, 11.3.20.

The bricks etc. are formed from the clayey material and passed directly into an ordinary working furnace, where they are well heated throughout by direct contact with the flames of the furnace. They are then withdrawn from the furnace and cooled suddenly by plunging them totally into water. A dense compact brick is thus formed from clayey materials (*e.g.*, certain African clayey materials similar to kaolin) which, if prepared and fired in the usual manner, give products which are too soft and porous to be of real service.—H. S. H.

Graphite crucibles; Method of making ——. *Method of making clay and graphite crucibles.* J. H. L. De Bats, Assr. to Lava Crucible Co. of Pittsburgh. U.S.P. (a) 1,374,909 and (b) 1,374,910, 19.4.21. Appl., 31.5.18. Renewed 5.8.20.

(a) Non-ferrous metal is mixed with the material, containing clay, from which the crucible is made, giving, in use, a surface coating of metallic silicate. (b) By mixing finely-divided metal of the aluminium-magnesium group with material containing clay used for making crucibles, the latter may be burned shortly after moulding.—A. C.

Highly-refractory article, and method of producing same. H. H. Buckman and G. A. Pritchard, Assrs. to Buckman and Pritchard, Inc. U.S.P. 1,375,077, 19.4.21. Appl., 9.10.19.

Zircon is added to the batch for making refractory material.—A. C.

Refractory material. M. L. Hartmann, Assr. to The Carborundum Co. U.S.P. 1,376,091, 26.4.21. Appl., 17.5.20.

A refractory article contains carborundum and a bonding material containing mixtures of zirconium and aluminium silicates.—H. S. H.

Brick-kiln. F. Munhollon. U.S.P. 1,375,719, 26.4.21. Appl., 29.12.19.

A brick kiln has a series of furnaces spaced about the outer wall. Transverse passages run beneath the floor of the kiln, and are connected by other passages with the furnaces. The openings into the transverse passages vary in size according to their distance from the furnaces.—H. S. H.

Annealing furnaces for glass-ware and the like. H. M. Thompson. E.P. 140,817, 26.3.20. Conv., 1.6.18.

See U.S.P. 1,281,713 of 1918; J., 1919, 16 a.

IX.—BUILDING MATERIALS.

Patents.

Porous cement or mortar products; Manufacture of ——. A. Sinding-Larsen. E.P. 146,172, 25.6.20. Conv., 3.7.19.

A substance (*e.g.*, aluminium powder), which is capable of reacting with water and alkaline solutions to form a non-volatile compound and hydrogen, is mixed with Portland cement or other mortar. The large volume of hydrogen evolved causes the product to be very porous. It is of advantage to mix the substances in a dry state and to use hot water or a solution of caustic alkali.—H. S. H.

Stone-like materials of foam-like structure; Method for manufacturing ——. E. C. Bayer. E.P. 162,318, 17.11.19.

Stone-like material permeated with air-filled pores is made by mixing together diatomaceous earth and powdered felspar or rocks containing felspar, forming the mixture into the desired shape with the addition of a little water, and heating to the fusing point of the mixture (about 1200°—1300° C.). The particles of air contained in the diatomaceous earth expand under this treatment and are surrounded by softened or fused solid matter which forms dense walls on cooling.—H. S. H.

Slag; Process for reducing fused —— *to granular form.* M. Maguet. E.P. 162,375, 26.1.20.

A jet of highly-heated basic slag from a blast furnace is divided into drops by means of an air blast directed against it. The temperature of the slag is thereby lowered to about 1300° C. On dropping into water the slag forms granules suitable for use in the manufacture of slag cements and bricks.—H. S. H.

Plastic composition for producing a jointless floor covering. M. Roberts. E.P. 162,514, 6.4.20.

A plastic composition is produced by incorporating sawdust, cork-dust, or wood pulp, a solution of magnesium chloride, magnesite, and French chalk, with or without colouring matter, and subsequently mixing with a solution of magnesium chloride in water until the desired plasticity is attained.—H. S. H.

Wood protection; Method of ——. P. Bartsch. U.S.P. 1,374,806, 12.4.21. Appl., 23.10.20.

Wood is protected from destructive organisms by removing the resin by means of a solvent, displacing the solvent by a chemical which in turn is displaced by an aqueous solution of arsenic and copper, then chemically dehydrating the wood to cause precipitation of poisonous substances, displacing the dehydrant by a paraffin solvent, and finally displacing the latter by poisoned paraffin.—H. S. H.

Asphalt substitute. G.P. 332,888. *See* III.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Electrolytic iron [; Hardness on quenching of ——]. O. Bauer and W. Schneider. Stahl u. Eisen, 1921, **41**, 647—648.

Test-pieces of electrolytic iron, previously annealed at 950° C. and cooled in air, were quenched from different temperatures varying from 650° to 1200° C. The Brinell hardness showed little variation as did also the ultimate breaking stress. Similar results were obtained with iron annealed at 950° C. *in vacuo* and quenched at temperatures varying from 620° to 1100° C. The different results recorded by Boynton (J., 1906, 538) are probably due to the different methods employed for determining hardness.—J. W. D.

Copper in molybdenum ores; Behaviour of ——. J. P. Bonardi and M. Shapiro. Chem. and Met. Eng., 1921, **24**, 847—850.

Molybdenum interferes in the usual iodometric copper assay as it also liberates iodine from potassium iodide. Previous precipitation of the copper by zinc or aluminium is incomplete in the presence of molybdenum, but the latter may be removed by prolonged boiling of the solution with caustic soda. Double precipitation is, however, necessary to eliminate all the molybdenum, and the following modification of the thiocyanate method is, therefore, recommended. 0·5—5·0 g of finely powdered ore is dissolved in 10—15 c.c. of nitric acid, 5—10 c.c. of hydrochloric acid is added, the mixture evaporated nearly to dryness, the mass treated with a little water, 10—15 c.c. of dilute sulphuric acid (1:1) added, and the whole evaporated till fumes appear. The mass is cooled, treated with water, and the solution filtered. The filtrate is diluted to 250 c.c., treated with ammonia till just alkaline, then with 2 c.c. of sulphuric acid (1:1) and 2—3 g. of anhydrous sodium sulphite. To the boiling solution is then added 10—25 c.c. of a 20% ammonium thiocyanate solution, and the resulting copper precipitate is filtered off and washed till free from the blue colour of the reduced molybdenum compounds. It is redissolved in nitric acid, the solution evaporated nearly to dryness, and the assay finished by the iodide method as usual. Alternatively, the precipitate of cuprous thiocyanate may be extracted with hot caustic soda, the cuprous hydroxide filtered off, and the filtrate acidified and titrated with permanganate. In this case a weighed amount of pure copper should be put through the whole process as a standard. The separation of copper minerals from those containng molybdenum is briefly discussed.—A. R. P.

Tin in cassiterite; Determination of ——. H. Corti. Anal. Asoc. Quím. Argentina, 1921, **9**, 44—53.

The method proposed is a modification of that of Fresenius. Half a gram of the powdered material s mixed with 5 g. of a mixture of sodium carbonate nd sulphur and placed in a crucible, in the bottom f which is about 2 g. of sodium carbonate. A coverng of the sodium carbonate-sulphur mixture is dded and the crucible placed in a cold muffle urnace. The muffle is heated to redness and mainained thereat for 2 hrs. After cooling, the melt is xtracted with water and the residue washed with eak ammonium sulphide. Filtrate and washings are united and stannic sulphide is precipitated by adding 25 c.c. of hydrochloric acid (1:4). The stannic sulphide is collected on a filter and washed with 1% hydrochloric acid. It is then dissolved in strong hydrochloric acid with gentle boiling, the last traces of hydrogen sulphide being removed by the addition of a few drops of bromine. Ammonia is added till the reaction is alkaline and the liquid raised to boiling. The precipitate of hydrated stannic oxide is washed by decantation, using 1% ammonium nitrate containing a little ammonia, collected, dried, ignited, and weighed as stannic oxide.—G. W. R.

Bismuth [; Determination of ——] in high-grade ores. G. Spurge. Chem. Age, 1921, **4**, 584.

The following colorimetric method is recommended as giving in 15 mins. results correct to 0·2—0·3% in ores containing up to 45% Bi. 0·05 g. of finely powdered ore is dissolved in 100 c.c. of nitric acid (1:3) and the solution diluted to 500 c.c. A portion is filtered through a dry paper and transferred to a 25 c.c. burette, while a second burette contains a standard solution of bismuth (1 c.c. = 0·00005 g. Bi). Two Nessler tubes are prepared, each containing 10 c.c. of a 10% potassium iodide solution and 3 drops of a solution of sulphur dioxide. 1 c.c. of the bismuth standard solution is added to one tube and the assay is run into the other until the colours match. Lead and copper in large quantities are the only interfering metals. The former is removed by addition of sulphuric acid before making up to bulk and the latter by filtering off any precipitated iodide before comparing the colours, or by precipitating the bismuth as basic nitrate prior to making up to bulk.—A. R. P.

Patents.

Steel; Process of making ——. E. T. Pelton. U.S.P. 1,376,160, 26.4.21. Appl., 6.7.20.

A charge of iron materials low in phosphorus and sulphur is melted in an acid-lined furnace, and the slag is removed from the surface of the molten metal, which is then treated with a quantity of iron ore. Ebullition is produced in the mixture and the charge poured.—A. R. P.

Gases derived from roasting ores; Removal of dust from ——. Manufactures de Prod. Chim. du Nord, Etablissements Kuhlmann. E.P. 147,020, 6.7.20. Conv., 6.5.14.

In a dust-settling chamber the gas stream is caused to meet a series of chain curtains. The curtains are formed of a number of parallel single chains, each of which is arranged in relation to the adjacent ones so as to divide the gas stream as finely as possible. The separate chains may be connected together by a wire which affords a means of shaking the curtains and causing the collected dust to fall. —C. A. K.

Slags containing iron; Process of separating —— from coke and other fuel residues. F. Krupp A.-G. Grusonwerk. E.P. 152,642, 23.8.20. Conv., 11.10.19. Addn. to 150,333.

Particles of coke remain attached to the iron after the magnetic separation of slags containing iron as described in the chief patent (J., 1921, 139 a). The magnetic material is therefore ground and subjected to a second magnetic treatment.—C. A. K.

Ores; Treatment of argentiferous lead-zinc sulphide ——. F. E. Elmore. E.P. 162,026, 18.12.19.

Finely ground ore or concentrate is mixed with alkali or alkaline-earth chlorides, with or without the addition of zinc chloride, and heated to 450°—500° C. in an oxidising atmosphere. Lead together with a proportion of the silver is obtained in solution by extracting the oxidised mixture with hot brine, and may be recovered by cooling the liquor. From the zinc sulphide which remains unattacked the remaining portion of the silver may be extracted by treatment with suitable solvents. (See also E.P. 129,773, 135,968, and 141,044; J., 1919, 685 A; 1920, 117 A.)—C. A. K.

Zinc solutions; Purification of ——. S. Field, and The Metals Extraction Corp., Ltd. E.P. 162,030, 19.12.19.

Zinc sulphate solutions acidulated, and at a temperature of 70°—100° C., are treated with either finely divided zinc or aluminium or an aluminium-zinc alloy in the form of powder or granules, in the presence of mercuric sulphate. These metals are more electro-positive than the metallic impurities present and cause the latter to be precipitated upon the mercury in the form of a sludge.—J. W. D.

Electro-deposition of metals upon iron and alloys of iron [; Cleaning process preliminary to ——]. R. J. Fletcher. E.P. 162,391, 28.1.20.

The iron or iron alloy is cleaned by being used alternately as cathode and anode in an acid bath containing copper sulphate, a current density of 150—500 amps. per sq. ft. being employed.

—J. S. G. T.

Aluminium alloys. T. F. Bradbury, and Rolls-Royce, Ltd. E.P. 162,467, 25.2.20.

Aluminium alloys containing 3—15 % Cu, or 5—20 % Zn, or 1—20 % Zn and 1—6 % Cu, show an increased fluidity when molten and reduced tendency to crack during solidification, and give sounder castings. Antimony, magnesium, and titanium may be added between the total limits of 0·5 and 3 %, the higher limits of the individual metals being 1·5 % Sb or Mg and 0·8 % Ti.—C. A. K.

Alloys; Method of treating light-metal ——. W. R. Veazey, Assr. to Dow Chemical Co. U.S.P. 1,374,968, 19.4.21. Appl., 21.1.20.

Alloys of high magnesium content are heated to 500°—700° F. (260°—370° C.) and then forged or similarly worked.—J. W. D.

(A) *Acid-resisting alloy.* (B, C) *Alloy.* A. W. Clement, Assr. to The Cleveland Brass Manufacturing Co. U.S.P. (A) 1,375,081, (B) 1,375,082, and (C) 1,375,083, 19.4.21. Appl., (A) 27.7.18, (B, C) 15.8.18.

(A) An acid-resting alloy contains approximately 40 % Cr and a metal having the properties of molybdenum, together with iron and carbon. (B) The principal components are molybdenum and a metal possessing the properties of nickel and cobalt, together with not more than 4 % Mn. (C) Iron not exceeding 10 % in quantity replaces the manganese in (B).—C. A. K.

Acid-resisting alloy. Acid-resisting article and method of making same. A. W. Clement, Assr. to The Cleveland Brass Manufacturing Co. U.S.P. (A) 1,375,672 and (B) 1,375,673, 26.4.21. Appl., 26.7.17.

(A) An alloy of 60 % Cr, 2—4 % Si, 2—5 % C as graphite, and the remainder iron. (B) Articles made of iron-chromium alloys free from carbon are made acid-resisting by treating the surfaces in a suitable manner with carbon and then cooling rapidly, whereby iron and chromium carbides are produced in the surface layer.—A. R. P.

Alloys; Electrical-resistance ——. F. F. Hansen, Assr. to Hansen-Halliburton Mfg. Co. U.S.P. (A) 1,375,454 and (B) 1,375,455, 19.4.21. Appl., 19.9.19.

(A) An alloy containing approximately equal amounts of chromium and copper and not less than 10 % of tungsten and molybdenum together, the tungsten being in excess of the molybdenum. (B) An alloy of chromium, tungsten, and aluminium, the chromium being in preponderating amount compared with the combined amount of tungsten and aluminium, and the tungsten being in excess of the aluminium.—J. W. D.

Alloy. C. D. Stovall. U.S.P. 1,375,804, 26.4.21. Appl., 14.7.20.

An alloy containing Au 72 pts., Ni 13½ pts., and Cu 16½ pts.—C. A. K.

Metal alloy. J. F. Wandersee, R. Peretto, and T. A. L. Albrecht, Assrs. to Ford Motor Co. U.S.P. (A) 1,376,056 and (B) 1,376,062, 26.4.21. Appl., 10.9.19 and 7.6.20.

(A) The alloy consists of 2—5 % C, 35—65 % Co, and the remainder chromium and tungsten. (B) An alloy of 20—35 % Cr, 5—20 % W, 1—15 % Fe, and the remainder cobalt and carbon.—A. R. P.

Ores; Treatment [chloridising] of ——. J. H. Hirt, Assr. to Alvarado Mining and Milling Co. U.S.P. 1,375,002, 19.4.21. Appl., 24.1.20.

Ores, metallurgical products, and the like are chloridised by heating in a closed multiple-hearth furnace and then introducing a chloridising agent in a gaseous or vapour form.—A. R. P.

Ores; Separation of mixed sulphide ——. C. Faul and H. Lavers, Assrs. to Minerals Separation North American Corp. U.S.P. 1,375,087, 19.4.21. Appl., 12.3.15.

A mixed sulphide ore is concentrated selectively by means of a froth flotation process in presence of a copper material and an alkali bichromate.

—C. A. K.

Ore concentration process. W. A. Scott, Assr. to Minerals Separation, North American Corp. U.S.P. 1,375,233, 19.4.21. Appl., 10.9.17. Renewed 15.9.20.

A gas is introduced into the ore pulp in the form of minute bubbles, the resulting mineral-carrying bubbles are treated to remove the gas from them before they reach the surface of the pulp, and the mineral carried by the bubbles is separated from the remainder of the ore.—A. R. P.

Sodium; Manufacture of metallic ——. A. W. Smith and W. R. Veazey. U.S.P. 1,375,330, 19.4.21. Appl., 16.7.17.

A fused mixture of sodium carbonate and another salt is electrolysed, the ingredients being proportioned so that the mixture has a lower melting point than any of its constituents.—J. W. D.

Metallurgical furnace. D. Baird, Assr. to Genera Chemical Co. U.S.P. 1,375,346, 19.4.21. Appl. 17.6.20.

A multiple-hearth roasting furnace is provide with means for causing the material to fall from on hearth to another, and with an air conduit situate behind the stream of falling ore, so that an ai blast may be directed into the stream.—A. R. P.

Furnace; Metallurgical ——. J. W. Griswold an H. O. Loebell. U.S.P. 1,375,754, 26.4.21 Appl., 24.7.18.

A closed melting chamber is surrounded by number of combustion channels in which a mixtu of gas and air is burnt. Products of combustion a passed through a detached heat exchanger, and t furnace is mounted on trunnions for pouring.

—C. A. K.

Converters; Gas-discharge conduit for rotary ——. W. H. Howard, Assr. to American Smelting and Refining Co. U.S.P. 1,375,965, 26.4.21. Appl., 4.12.19.

The waste gas discharge flue from the upper side of a horizontal cylindrical matte converter is brought to a position concentrically disposed to the axis of the converter by means of right-angled bends. A loose sleeve connecting the discharge end portion with the flue leading to the chimney permits of rotation of the converter.—C. A. K.

[Mineral] values; Process for the extraction of —— from highly dilute solutions. M. L. E. Baudin. U.S.P. 1,375,441, 19.4.21. Appl., 7.4.17.

Mineral compounds are extracted from very dilute solutions by bringing the latter into contact with a support coated with a colloidal absorbent material. —A. R. P.

Silver-solder. W. B. Bocchetti. U.S.P. 1,375,552, 19.4.21. Appl., 10.2.20.

A solder containing Ag 55—65%, Cu 20—30%, Zn 10—20%, and arsenic trioxide.—J. W. D.

Brass scrap; Process of treating ——. O. C. Ralston. U.S.P. 1,375,930, 26.4.21. Appl., 2.1.20.

The copper content of copper-bearing alloys is increased by treatment of the alloy with an aqueous solution containing a solvent for metals electropositive to copper.—C. A. K.

Bearing metal. J. G. Kelly, A. L. Pringle, and H. Hall. U.S.P. 1,376,339, 26.4.21. Appl., 7.5.20.

The alloy consists of 1 pt. of aluminium, slightly more than 1 pt. of zinc, 2 pts. of lead, and 4 pts. of tin.—A. R. P.

Ores or concentrates; Process of roasting ——. P. R. Middleton, Assr. to J. C. Lalor. U.S.P. 1,376,025, 26.4.21. Appl., 20.1.20.

Ore containing a metallic sulphide is heated in presence of air to a temperature below the ignition point of the sulphur, and maintained at this temperature until the maximum proportion of the metallic sulphide has been oxidised to sulphate. —W. J. W.

Iron; Bessemerising ——. R. S. McCaffery. E.P. 138,900, 10.2.20. Conv., 13.11.18.

See U.S.P. 1,338,655 of 1920; J., 1920, 455 a.

Alloys; Process of producing —— and alloys produced thereby. Rare Metals Reduction Co., Assees. of J. B. Grenagle. E.P. 138,348, 27.1.20. Conv., 7.12.15.

See U.S.P. 1,248,648 of 1917; J., 1918, 95 a.

XI.—ELECTRO-CHEMISTRY.

Fuel cells; Construction of high-temperature ——. E. Baur, W. D. Treadwell, and G. Trümpler. Z. Elektrochem., 1921, 27, 199—208.

In a former paper, fuel cells were described in which copper oxide was used as a cathode (J., 1916, 1266). A number of cells of varying construction have now been devised in which iron oxide is substituted for copper oxide. The cells described are of two types, carbon-oxygen and hydrogen-oxygen, and are all characterised by the use of a porous diaphragm in the form of a tube or crucible of magnesia, or better, of a specially-prepared magnesia-clay mixture suitably moulded and fired. One of the most satisfactory cells described had electrodes respectively of iron and magnetite packed in two channelled magnesia-composition tubes, air being passed through the Fe_3O_4 tube and hydrogen through the iron tube. The electrolyte, equal parts of fused caustic soda and potash, was contained in an iron vessel, and the surface of the electrolyte was covered with a considerable thickness of loose magnesia, in which the electrode tubes were embedded in a horizontal position. The porosity of the magnesia and of the tubes was sufficient to allow the electrolyte to make good contact with the electrodes. Such a cell gave an E.M.F. at 800° C. of 0·90 volt, and had an internal resistance of about 3 ohms. The opinion is expressed that such fuel cells are a technical possibility.—E. H. R.

Sodium-oxygen cell. E. Baur. Z. Elektrochem., 1921, 27, 194—199.

A method has been devised for measuring directly the sodium-oxygen potential in a caustic soda cell at temperatures between 300° and 600° C. A number of different types of electrode were first tested by measuring the hydrogen-oxygen potential in caustic soda between 300° and 400° C. Measurements of the sodium-oxygen potential were eventually made in three types of cell, viz., with an alloy of sodium and lead containing 40 mols. % Na against a silver-oxygen electrode, with pure sodium against the same oxygen electrode, and with pure sodium against an iron-oxygen electrode. The lead-sodium alloy gave results about 0·3 volt lower than pure sodium. The cells containing pure sodium gave a mean result of 2·2 volts at 340° C., which corresponds with the value found by Neumann and Bergve for the decomposition potential of sodium hydroxide (J., 1915, 1088). The temperature coefficient found was, however, smaller than theirs, namely, $-1·3\times10^{-3}$ instead of $-2·95\times10^{-3}$. Some experiments were also made on the behaviour of the cells when supplying current. As the current increases, polarisation sets in, but may be partly prevented by increasing the rate of the oxygen current.—E. H. R.

Patents.

Melting and other furnaces; [Packing for] electrically heated ——. The Morgan Crucible Co., and C. W. Speirs. E.P. 162,246, 7.10.19.

In using electrically heated crucibles etc. of the type described in E.P. 24,626 of 1912 (J., 1913, 1019), mounted in a metal or other casing from which they are insulated by refractory brick, access of air to the carbon resistors is avoided by using natural crystalline plumbago of a "platey" nature as a packing between the resistor and the refractory wall of the furnace. A layer of fine powder, such as sand, is placed at the bottom of the annular space between the resistor and the refractory wall.—J. S. G. T.

Electric furnace. W. K. Booth and W. L. Morris, Assrs. to The Booth Electric Furnace Co. U.S.P. 1,376,072, 26.4.21. Appl., 9.4.20.

An electric furnace having a refractory lining is provided with means for rotation about its axis. Electrodes, extending axially through the end walls of the furnace, are carried by adjustable supports mounted on the end walls and are provided with metal collars through which water may be circulated during rotation of the furnace.—J. S. G. T.

Electrolytic cell. H. I. Allen and K. R. Fox, Assrs. to Electron Chemical Co. U.S.P. 1,374,976, 19.4.21. Appl., 1.6.20.

An anode for use in the electrolysis of saline solutions consists of one or more flat carbon plates provided with spaced parallel ribs, the faces of the ribs and of the plates between the ribs being active. —J. S. G. T.

Battery electrode; Depolarising —— and process of making same. R. C. Benner and H. F. French, Assrs. to National Carbon Co. U.S.P. 1,375,647, 19.4.21. Appl., 22.8.18.

Cuprous oxide prepared electrolytically is oxidised to cupric oxide and then mixed with sulphur. —J. S. G. T.

Electrically preparing stencil plates, die plates and the like; Solution or bath for ——. G. E. Wertheimer. U.S.P. (a) 1,376,366, (b) 1,376,367, (c) 1,376,368, and (d) 1,376,369, 26.4.21. Appl., (a) 24.12.17, (b, c, d) 16.5.18.

A solution for the electrolytic treatment of metallic plates or blocks is composed of an aqueous solution of sulphuric acid and nitric acid together with (a) ammonium chloride, (b) ammonium chloride with a small proportion of copper nitrate, (c) ammonium chloride with a small proportion of acetic acid, (d) small proportions of iodine, copper nitrate, and acetic acid.—J. S. G. T.

XII.—FATS; OILS; WAXES.

Herring oil. T. Lexow. Chem. Umschau, 1921, **28**, 85—86, 110—113.

The following constituents are well established:—Myristic, palmitic, zoomaric, stearic, oleic, clupanodonic, gadoleic, and erucic acids, together with acids of formulæ $C_{20}H_{30}O_2$ and $C_{22}H_{34}O_2$, hydroxylated acids, and unsaponifiable matter. Oil from salted herrings also contains lactones, lipoids, and soaps. Formation of free fatty acids begins the moment the herring is dead; the quantity in ordinary good quality oil lies between 2 and 5%. The colour and flavour show no close relationship to the free fatty acid content, the former depending largely on the fishes' nourishment and the method of pickling. The author finds the saponification value unaffected by the season of the year or the size of the fish. There is, however, a considerable variation of this value according to the latitude in which the fish are caught, average values rising from 184 to 189 with an increase in latitude from 66° to 71°. The percentage of unsaponifiable matter varies in a similar way, but inversely with increase in latitude. About 120 determinations of the iodine value (Wijs) show that this varies markedly with the season of the year, in the same way as the yield of oil—the two latter figures being at their highest (149 and 13%) in July, August, and September and at their lowest (110 and 2%) in March.—H. C. R.

Critical temperatures of solution of fats in mixtures of ethyl and amyl alcohols. A. J. J. Vandevelde. Bull. Soc. Chim. Belg., 1921, **30**, 14—16, 58—62.

Experiments were undertaken to determine whether a mixture of 94% ethyl alcohol with isoamyl alcohol (*cf.* J., 1914, 1074), which gave critical solution temperatures similar to those of Crismer's ethyl alcohol, could advantageously replace the latter. A mixture which gave with light petroleum the same CST as Crismer's alcohol was found to give lower values with glycerides, and a mixture which gave with beef fat the same CST as Crismer's alcohol, gave, especially with cacao butter and light petroleum, higher values than those of Crismer's alcohol. The distances between the extreme critical solution temperatures of the substances examined are greater for Crismer's alcohol than for the amyl alcohol mixtures, which gives the former a greater sensitiveness. The divergences observed with the amyl alcohol mixtures seem to be due to the relative solubility of the fats in amyl alcohol.—G. F. M.

Sulp[on]ated oils; Improved formulæ for the calculation of inorganic impurities in ——. R. Hart. J. Amer. Leather Chem. Assoc., 1921, **16**, 159—161. (*Cf.* J., 1921, 226 a.)

The formula previously cited may be simplified when 2A is equal to or $<A_s$ since no carbonate can be present.

Inorganic impurities $=\text{Ash}-0{\cdot}0634(2A+A_s)$.

When $2A>A_s$ sodium carbonate will be found in the ash. By substituting A_s for 2A in the sulphate term the formula becomes

Inorganic impurities $=\text{Ash}-(0{\cdot}0795A_s+0{\cdot}0946A)$.

These new formulæ are simplified by substituting S (the percent. combined SO_3) for its equivalent A_s. They become in the absence of carbonate

Inorganic impurities $=\text{Ash}-0{\cdot}1268(7S+A)$,

and where carbonate is present

Inorganic impurities $=\text{Ash}-0{\cdot}0946(11{\cdot}77S+A)$.

The data required are:—ash, combined SO_3 (S), and fixed alkalinity (A) in mg. of KOH.—D. W.

Oxidation of vaseline and paraffin. Langen. *See* IIa.

Patents.

Oils and fats; Refining of ——. V. Schwarzkopf. E.P. 138,115, 22.1.20. Conv., 25.10.18.

The oil is mixed with 4—8% of bleaching earth, *e.g.*, fuller's earth, and heated *in vacuo* to 250° C. in a current of hydrogen until free fatty acids nc longer distil over.—H. C. R.

Hydrogenation of unsaturated oils and fats; Pro cess for the continuous ——. E. R. Bolton. E.P 162,370, 26.1.20.

The oil is hydrogenated in vessels fairly tightl packed with nickel wool which has been activate by treatment with nitric acid, roasting, and re ducing in a current of hydrogen. The activity o the catalyst may be restored *in situ* by washing wit hot oil to remove soaps, then with an oil solvent and finally re-heating in hydrogen.—H. C. R.

Hydrogenation of oils, fats, and the like Method of maintaining the activity of metalli catalysts during the ——. E. R. Bolton an E. J. Lush. E.P. 162,382, 27.1.20.

The poisoning of the nickel catalyst by soap form tion is avoided by the addition of a small quantit of mono- or diglycerides of fatty acids to the oil t be treated. This combines with any free fatt acids present or formed during hydrogenation an so prevents the attack of the nickel. Oils contai ing free fatty acids can be hydrogenated directly after adding enough mono- or diglycerides to combine with the free fatty acids.—H. C. R.

Oils, fats, and fatty acids; Process of extracting ——. R. H. McKee. U.S.P. 1,376,211, 26.4.21. Appl., 24.5.19.

The material containing oil is dehydrated and subjected to the solvent action of liquid sulphur dioxide.—B. M. V.

Fat; Stimulating the production of —— in microbes. Reichsausschuss für pflanzl. und tier. Oele und Fette, G.m.b.H. G.P. 332,411, 12.10.18.

The microbes are exposed in the form of a thin layer to the action of air containing alcohols or their derivatives, *e.g.*, air mixed with the gases derived from fermentation processes.—L. A. C.

Fats and oils; Process for neutralisation [and hydrogenation] of ——. H. Schlinck & Co. G.P. 334,659, 15.8.16. Addn. to 315,222 (J., 1920, 198 A).

Neutralisation and hydrogenation are effected simultaneously by adding glycol and a suitable catalyst to the fat or oil and then treating it, at a high temperature, with hydrogen, preferably in excess.—J. H. L.

Catalytic agents for reduction or hydrogenation purposes; Process for producing ——. A. Radisson (Assr. to Soc. de Stearinerie et Savonnerie de Lyon), and P. Berthon. U.S.P. 1,377,158, 3.5.21. Appl., 29.10.19.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Colophony; New constituents of ——, *colophenic acids and their analogues.* O. Aschan. Ber., 1921, 45, 867—886.

A new series of acids, $C_nH_{2n-10}O_4$, has been isolated rom the residues left after the preparation of inabietic acid from the "black liquor" of sulphate-ellulose factories (J., 1919, 646 A) and also from merican and Finnish colophony. These are rovisionally termed colophenic acids. They are onobasic acids which are differentiated from the esin acids by the ready solubility of their sodium alts in cold water and the stability of the solutions owards carbon dioxide. The lactone ring and the ldehydic group are not present. The presence of he ketonic group could not be definitely established ut one oxygen atom is present in a hydroxyl group. he acids are colourless or pale yellow, whereas olutions of their alkali salts are dark yellow or rownish-yellow. Hexadekacolophenic acid, $_{16}H_{22}O_4$, m.p 96°—105° C. (yellow granules, from ncentrated solution) or 86°—98° C. (almost lourless powder, from dilute solution), $[\alpha]_D^{17}=$ -22·33° (colourless form) or +21·66° (yellow form) benzene solution, heptadekacolophenic acid, p. 100°—105° C. after softening at 70°—75° C., todekacolophenic acid, and eikosicolophenic acid, hich softens at 80°—90° C. and is molten below 0° C. are described. Hexadekacolophenic acid prepared artificially by the oxidation of a slightly kaline solution of pinabietic acid with hydrogen roxide. (*Cf.* J.C.S., July.)—H. W.

Resin of maritime pine; Acid constituents of the ——. G. Dupont. Comptes rend., 1921, 172, 1184—1186. (*Cf.* J., 1921, 357 A.)

Pimaric acid as isolated from pine resin and purified by Vesterberg's method (*cf.* J., 1906, 82) consists of a mixture of 37% of *d*-pimaric acid and 63% of *l*-pimaric acid.—W. G.

Paint vehicle. Paint composition. Paint vehicle for anhydrous pigments. Paint composition. W. N. Blakeman, jun. U.S.P. (A) 1,375,352, (B) 1,375,353, (C) 1,375,354, and (D) 1,375,355, 19.4.21. Appl., 12.6.17.

A mixture of (A) hydrogenated oil, tung oil, and marine animal oil or (C) untreated commercial marine animal oil and tung oil is used as a paint vehicle. As a paint composition (D) a mixture of an anhydrous pigment with the vehicle described under (C), or (B) an anhydrous mixture of pigment with a fluid hydrogenated oil may be used.
—D. F. T.

Resinous condensation products [from hydrogenated naphthalene]; Manufacture of ——. A.-G. für Anilin-Fabr. G.P. 305,575, 19.4.17.

Hydrogenated naphthalene is treated with formaldehyde in the presence of acids, with or without the addition of a solvent or diluent. The products can be worked up with turpentine and linseed oil for the manufacture of varnishes.—L. A. C.

Wood; Process for impregnating —— before painting. H. Haarhaus and W. Hoffmann. G.P. 332,908, 3.3.20.

To accelerate the drying of oil paints when applied to wood, the latter is first impregnated with a neutral or slightly alkaline solution of alkali naphthenates, and then treated with salts of iron, aluminium, zinc, lead, manganese, or cobalt, to cause precipitation of metallic naphthenates.
—W. J. W.

Asphalt substitute. G.P. 332,888. *See* III.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Patents.

Vulcanising processes and apparatus for the manufacture of high pressure expanded vulcanised rubber and like substances. C. L. Marshall. E.P. 162,176, 15.4.20

For the manufacture of a semi-rigid expanded vulcanised rubber, ceresin wax or similar material is incorporated into the mixture so as to render it capable of retaining an inert gas under pressure. By enclosing the material before vulcanisation in a skin of rubber which will allow the diffusion of gas, the vulcanised foam is protected against subsequent mechanical disruption. Vulcanisation is effected in an externally heated chamber containing a removable inner chamber which is provided with inlet and outlet valves for the automatic control of the internal gaseous pressure transmitted from the compressed atmosphere of the larger vessel. The froth formation is developed by a rapid partial reduction of pressure at the completion of vulcanisation, whilst the rubber is still hot.—D. F. T.

Vulcanisation of caoutchouc; Process for the ——. S. J. Peachey. E.P. 162,429, 12.2.20. Addn. to 129,826 (J., 1919, 688 A).

In the vulcanisation of rubber by the action of hydrogen sulphide and sulphur dioxide, the process is accelerated by applying one or both of the gases under pressure.—D. F. T.

Vulcanised rubber goods; Methods for the preservation of ——. H. P. Stevens. E.P. 162,528, 16.4.20.

The rate of perishing of vulcanised rubber decreases with the proportion of moisture in the surrounding atmosphere. For the preservation of rubber goods, therefore, the atmosphere of the storage chamber is kept saturated with moisture, or nearly so. (*Cf.* J., 1920, 251 T.)—D. F. T.

Vulcanised-oil product. W. O. Snelling. U.S.P. (A) 1,376,172, (B) 1,376,173, and (C) 1,376,174, 26.4.21. Appl., (A, B) 8.8.19 and (C) 21.8.19.

(A) A vulcanised oil product is depolymerised in the presence of hydrogen chloride. (B) Various degrees of plasticity are imparted to different portions of vulcanised oil, and the products are mixed. (C) A liquid vulcanised oil product capable of being solidified by contact with water is claimed. (*Cf.* U.S.P. 1,315,246 of 1919; J., 1920, 697 A.)
—D. F. T.

Rubber; Drying —— *by means of indifferent gases.* A.-G. Metzeler und Co. G.P. 332,974, 21.2.19.

Flue gases freed from ashes, soot, sulphur dioxide, etc., and cooled or heated as the case may be, are employed.—J. H. L.

Rubber-like products; Hindering oxidation in synthetic ——. Badische Anilin- und Soda-Fabr. G.P. 332,305, 28.3.18. Addn. to 330,741 (J., 1921, 312 A).

The material is mixed with aromatic nitro-compounds, *e.g.*, 1% of nitronaphthalene, nitrobenzene, etc., instead of phenols or naphthols. The products can be vulcanised as usual.—J. H. L.

Rubber-like products; Preparation of ——. Badische Anilin- und Soda-Fabr. G.P. 333,496, 22.8.18. Addn. to 329,676 (J., 1921, 400 A).

The polymerisation is carried out in presence of aromatic hydroxy- or nitro-compounds, or other substances which hinder oxidation of synthetic rubber-like products (*cf.* preceding abstract). The added substances remain homogeneously distributed throughout the products and minimise oxidation during the working of the latter.
—J. H. L.

Rubber products; Manufacture of ——. Goodyear Tire and Rubber Co., Assees. of C. W. Bedford. E.P. 146,992, 6.7.20. Conv., 29.5.17.

See U.S.P. 1,323,951 of 1919; J., 1920, 123 A.

Vulcanising: Method and apparatus [*annular moulds heated by induced electric currents*] *for* ——. Goodyear Tire and Rubber Co., Assees. of C. W. Post. E.P. 145,425, 17.6.20. Conv., 22.5.19.

XV.—LEATHER; BONE; HORN; GLUE.

Tanning material; Yield of extract from ——. A. Harvey. J. Soc. Leather Trades' Chem., 1921, 5, 115—117.

In calculating the yield of extract from tanning materials an error is usually made by ignoring the decrease in weight sustained by the material due to loss of soluble matter. This loss, which may run as high as 20 , is only partly accounted for by the formation of sludge during cooling. In a case now being investigated a very considerable loss was sustained, although very little sludge was formed.
—D. W.

Tanning solutions; Filtration of ——. J. G. Parker and J. T. Terrell. J. Soc. Leather Trades' Chem., 1921, 5, 112—115.

Experiments are described showing the superiority of the Berkefeld filter candle to filter paper for the determination of soluble matter in tanning extracts. There is loss of soluble matter due to adsorption by the filter paper even when a considerable quantity (200 c.c.) of the filtrate is rejected before evaporating to dryness. Differences of 3·5% and 5·1 of total soluble matter were obtained with mimosa and quebracho extracts respectively. Filter candles are now obtainable, and their use should be made compulsory.—D. W.

Tannins; Action of —— *and the swelling of pelt.* G. Grasser. Collegium, 1921, 1—10, 58—67, 105—117. (*Cf.* J., 1921, 154 A.)

Tannins have very little repressing action on acid-swollen pelt. Neither sodium chloride nor gallic acid exerts any swelling action on pelt. Formaldehyde has an extraordinarily high repressing action on acid-swollen pelt and neither acids nor alkalis can modify it. Formaldehyde is the most astringent tanning agent known. From their action on swollen pelt, phenol and phenolsulphonic acids should prove good bating materials. Vegetable tannins do not reduce acid-swollen pelt, but the effect is different if the pelt is treated with tannin first and then with acid. Pieces of pelt were treated with different tannin solutions and then with acid and the increase in weight determined and compared with the increase in weight obtained by subjecting untreated pelt to the same acid treatment. From the figures obtained, the initial speed of tannage, C, was calculated. The maximum speed of tannage, J, was similarly obtained by making experiments over longer periods of time, and the intensity of tannage, E, was calculated by dividing the maximum speed of tannage by the time to attain that maximum. Tables are appended giving C, J, and E for a large variety of tanning materials. A comparison of these figures shows that there are tannins which have a comparatively high initial tanning velocity, C, but it is not maintained to the end of the tannage. The synthetic tannins are characteristic in this respect. They have the highest C value and are specially suitable for re-tanning. Tannins which resemble dyes (mangrove, cutch, and logwood) have a very low initial tanning velocity and intensity in spite of their ready solubility. This is due to their feeble tanning properties. Sulphite-cellulose, though a weak tanning agent, has a high tanning velocity The more favourable behaviour of basic chromic sulphate in comparison with basic ferric sulphate explains why chrome tannage has become of suc practical importance. Potash alum gives lov values. True tannins do not give high values fo C, J and E, but an average for J, 0·45—0·58, C 0·40—0·49 and E, 0·40—0·54. The values observe for various materials, including tannins and other are J, 0·36—0·97, C, 0·36—0·93, and E, 0·32—5·6
—D. W.

Hydrolysis and adsorption [*by hide*]. V. Kubelk Collegium, 1921, 135—141.

A criticism of Moeller's work (J., 1920, 730 A).
—D. W.

Synthetic tannins. C. Immerheiser. Collegiu 1921, 130—132.

A criticism of Moeller's views on synthetic tann (J., 1921, 154 A). Sulphonation is not the essenti principle involved in the preparation of synthet tannins, but only a means of rendering some them soluble, and *β*-naphthalenesulphonic ac which has none of the characteristics of a tanni cannot be compared with commercial synthe tannins which have a definite tanning action. Ordoval has no harmful action on leather even when used in excess. The synthetic tannins are valuable because of their easy penetrability, and because they dissolve difficultly soluble tannins in mixture with vegetable tanning materials. Ordoval, for dissolving solid quebracho extracts, has replaced sulphiting. In spite of all attacks, the synthetic tannins have gained a firm footing in the leather trade and have attained to great practical importance.—D. W.

Chrome [tanning] liquors; Acid titration of ——. A. W. Thomas and S. B. Foster. J. Amer. Leather Chem. Assoc., 1921, **16**, 61—63.

Dhavale and Das (J., 1920, 758 a) have shown that the maximum increase in acidity is obtained by adding 49 g. or more of sodium chloride to 400 c.c. of solution containing 0·1747 g. of chromium. With samples of chrome liquors diluted to 400 c.c. with distilled water and treated with 50 g. of sodium chloride, the amount of acid found by titrating the boiling solution with $N/10$ alkali was equal to that determined by the conductance method. The official method for titrating chrome liquors can be made to yield more correct results by adding 50 g. of sodium chloride to the solution before the titration is commenced.—D. W.

Chrome tanning; One-bath ——. E. Griliches. Collegium, 1921, 127—129. (*Cf.* J., 1920, 633 a.)

In reply to Stiasny's criticisms (J., 1921, 53 a) the author states that he used feebly pickled pelt for his experiments, equivalent to 2 c.c. of $N/10$ NaOH per litre, which would be insufficient to influence the figures as Stiasny suggests. It is not easy to show the influence of the acid content of the pelt on the acid taken up from the tanning liquor, and it is probable that Stiasny greatly over-estimates that influence. In Stiasny's suggested method of expressing the basicity of chrome liquors $Cr:SO_4 = 52·1:X$, the author considers that X should be termed the acidity.—D. W.

Aldehyde tannage. VII. W. Moeller. Collegium, 1921, 117—125.

Aldehyde tannage is differentiated from all other kinds of tannage both qualitatively and quantitatively. The peculiar structure of the hide and the energetic tanning action of formaldehyde prevent pelt from absorbing much formaldehyde. Freiberg hide powder has been treated with formaldehyde and all experiments done with it in determining the tanning action of formaldehyde are influenced thereby. Using stronger solutions of formaldehyde and very finely divided untreated hide powder, it is possible to get as much as 27% of formaldehyde taken up by the hide powder, which is almost the same as the amount absorbed by animal charcoal. Pieces of pelt treated with formaldehyde solutions of similar strength do not take up more than 4% of formaldehyde owing to their microscopic structure. The formaldehyde polymers choke the pores of the leather and prevent further penetration.—D. W.

Iron tannage. D. D. Jackson and T. P. Hou. J. Amer. Leather Chem. Assoc., 1921, **16**, 63—75, 139—159, 202—219, 229—259.

Iron is more basic than either chromium or aluminium. Ferric salts, particularly the sulphate, are very readily hydrolysed, and the ferric hydroxde thus formed seems to pass through the colloidal range so rapidly that it is soon precipitated and this causes hard and brittle leather. Another difficulty with iron tannage is that the ferrous iron in solution, though easily partially oxidised, is completely oxidised only with difficulty. It is necessary to convert the ferrous iron to the ferric state completely and then to keep it in the ferric state throughout the tanning operation under adverse conditions, and to prevent the separation of any hydrated ferric oxide by maintaining the proper acidity of the liquor employed. Chlorine, sodium nitrate and sulphuric acid, nitric and sulphuric acids, and sodium bichromate are the most suitable oxidising agents, and working details are given for their use in the manufacture of iron tanning liquors. Ferric chloride is more stable towards dilution than ferric sulphate for the same basicity and behaves like chromic chloride and other chromic salts. The oxidation of ferrous sulphate by chlorine is a ready means of securing one-third of acid radical in the form of a chloride. $Fe(OH)SO_4$ is very unstable whilst more basic ferric chlorides are quite stable. On treating pelt with basic iron liquors, the iron is absorbed by the skin very rapidly. The mineral acid is also taken up by the skin but in less proportion. The tannage is complete after drumming for 1½ hrs. Iron seems to yield a more permanent tannage than alum but the leather will not withstand the action of boiling water. An iron-tanned leather, properly tanned, is not brittle on the grain and does not deteriorate on storing. It is important to rinse the tanned stock, after neutralisation, to remove soluble salts. The harsh feel, due probably to the presence of a large amount of iron oxide in the leather, may be counteracted somewhat by heavy fat-liquoring, oiling, or the use of flour. Not less than 4% Fe_2O_3 should be present in the air-dried leather. Iron-tanned leather compares favourably with other mineral-tanned leathers but the colour is an undesirable feature for some purposes. The basicity ratio of the tanning liquor should vary between one OH equivalent to every 3—5 equivalents of mineral acid radical. The neutralisation should be gradual so that the iron may be uniformly fixed throughout the whole skin. Before dyeing, the leather should be dried out to minimise the chemical reactions between the iron in the skins and the substances employed. A procedure for the chemical analysis of iron-tanned leather is outlined, including the following determinations:—moisture, fat, ash, Fe_2O_3, Cr_2O_3, free mineral acid, P_2O_5, total SO_3, hide substance.
—D. W.

[Tannin analysis;] Shake method and the filter bell process [of ——]. G. Baldracco and S. Camilla. Collegium, 1921, 125—127. (*Cf.* J., 1920, 496 a.)

A reply to Lauffmann's criticism of the authors' modified shake method (Collegium, 1920, 430).
—D. W.

Free sulphuric acid in leather and animal hide; Determination and behaviour of ——. C. Immerheiser. Collegium, 1921, 132—135. (*Cf.* J., 1920, 731 a.)

Moeller's criticisms of the determination of free sulphuric acid in leather by the ether-sulphuric acid method (J., 1921, 53 a) are not based on experimental evidence. His claim that leather may contain a considerable amount of chloride is not borne out in practice even with mangrove-tanned leathers, and his assertion that organic matter combines with the sulphuric acid and causes a lower figure to be obtained than the actual amount of acid present is not supported by facts. The amount of sulphuric acid purposely added to a leather can be determined by this method with a fair degree of accuracy. When pelt is brought into contact with a tanning material which has an acid reaction, a process of neutralisation ensues, and this fact can be established experimentally. With increasing tannage the acid figure of the leather diminishes until a constant is obtained which is characteristic for each tannin. The "acid figure" of the finished leather is apparently dependent on the acidity of the tanning material, so that a leather tanned with a strongly acid tannin will require less acid to neutralise it than a leather tanned with a less acid tannin.—D. W.

Patents.

Tanning substances; Manufacture of artificial ——. M. Melamid. E.P. 137,323, 2.1.20. Conv., 24.12.18.

The alkali-soluble portion of anthracene oil or "soft pitch" is treated with aromatic sulphochlorides in alkaline solution, and the product is sulphonated.—D. W.

Tanning substances; Process for the manufacture of artificial ——. M. Melamid. E.P. (a) 148,268, 23.2.20, and (b) 148,738, 25.2.20. Conv., (a) 19.7.19 and (b) 21.7.19. Addn. to 137,323 (*cf. supra*).

(a) The alkali-soluble portion of anthracene oil boiling between 100° and 300° C. (12 mm.), or of soft pitch (100 kg.), is sulphonated at 30°—40° C. with an equal weight of 100% sulphuric acid until the mass is soluble in water, when the product is dissolved in water, neutralised with sodium hydroxide, and the bulk of the sodium sulphate removed by evaporation and crystallisation. A solution of 28 kg. of sodium hydroxide is added to the product, and the mixture is agitated with a solution of 100—110 kg. of *o*- and/or *p*-toluenesulphonyl chloride in 200 l. of benzene at normal temperature until the whole of the sulphonyl chloride has entered into reaction. The product is used for tanning without further treatment. (b) The product as obtained above, but omitting the treatment with sulphonyl chlorides, is used direct for tanning.—L. A. C.

Substances precipitating glue [*tanning agents*]; *Manufacture of* ——. A. Römer, Assr. to A. Kuttroff. U.S.P. 1,375,976, 26.4.21. Appl., 9.5.17. Renewed 29.6.20.

A naphthalenesulphone is sulphonated and the product is treated with formaldehyde, yielding a substance capable of precipitating glue from its solutions.—L. A. C.

Leather; Process for impregnating and loading ——. H. Burger. G.P. 303,204, 15.5.14.

The addition of naphthalene, alone or in combination with substances such as fat, paraffin, tallow, wax, resin, asphalt, or caoutchouc, to impregnating or filling agents for leather, improves their penetrating power. Sulphur may be utilised as an impregnating agent by dissolving it in naphthalene. The dried, heated leather is steeped in the solution at 100° C. for ½—1 min. The product may be readily dyed.—W. J. W.

Hides; Depilation of ——. W. Rautenstranch. G.P. 304,251, 8.4.17.

Barium hydroxide solution, of a concentration above *N*/10, forms a satisfactory depilatory agent for hides. The waste solution may be used again after addition of more barium hydroxide, and its efficiency is not affected by presence of albuminoid matter from the hides. After treatment the hides may be freed from barium hydroxide by washing with water containing a small amount of sulphuric, hydrochloric, lactic, or butyric acid, or of an acid salt.—W. J. W.

Hides; Process for unhairing —— *by the action of enzymes.* R. Hilgermann and M. Emmerich. G.P. 334,526, 26.10.18.

Cultures of *B. emycoides tumescens, megatherium,* and *mesentericus* are prepared using a mixture of beef, horse-flesh, eggs, and lactose, and of *Mucor* and *Aspergillus* using yeast, glucose, resin, and asparagin, whilst mixed cultures are prepared by means of glycerin and peptone. By suitable treatment enzyme preparations are obtained from these bacteria and moulds in 8—12 weeks. The hides, which have been previously softened with acid and alkali, are placed in water and treated with the enzyme preparation, in the proportion of 300—500 c.c. per 100 kg. of hide, for 24—96 hrs. at 22°—25° C. —W. J. W.

Substances precipitating glue [*tanning agents*]; *Manufacture of* ——. A. Römer, Assr. to A. Kuttroff. U.S.P. 1,375,975, 26.4.21. Appl., 28.11.14. Renewed 24.4.20.

See G.P. 293,042 of 1913; J., 1916, 1072.

Casein specially adapted for the production of imitation horn; Manufacture of ——. A. Bartels. E.P. 162,301, 16.1.17.

See U.S.P. 1,320,666 of 1919; J., 1919, 955 a.

XVI.—SOILS; FERTILISERS.

Soil organic matter and organic carbon; Dry combustion method for the simultaneous determination of ——. J. W. Read. J. Ind. Eng. Chem., 1921, **13**, 305—307.

A weighed portion of the soil is digested with dilute hydrochloric acid and hydrofluoric acid to remove carbonates and hydrated minerals, and the insoluble portion is collected on a layer of asbestos in a combustion boat having a perforated bottom (*cf.* Rather, J., 1918, 478 a). After drying, the boat is transferred to a silica combustion tube which is heated by a three-unit electric furnace; the tube is packed as follows:—oxidised copper gauze, combustion boat, asbestos and pumice coated with cerium dioxide, copper oxide, asbestos and pumice coated with cerium dioxide, and copper gauze filled with lead peroxide. The latter layer is maintained at 300°—320° C. The carbon dioxide is absorbed in bulbs filled with soda-lime.—W. P. S.

Humic acids. S. Odén. Kolloid-Chem. Beih., 1921, **11**, 75—260.

A comprehensive review of the humic acids. These acids are subdivided into humic acid, hymatomelanic acid and fulvic acid. Humic acid with ammonia yields salts and adsorption compounds. Humic acid has an equivalent of 340±10; it is tetrabasic, insoluble in water, but readily forms colloidal solutions. It has the composition $C_{60}H_{52}O_{24}(CO_2H)_4$ and the anion is almost black in colour. Hymatomelanic acid is yellowish-brown and has an equivalent weight of 200; its salts are insoluble in alcohol, but easily form highly dispersed suspensions. Humus colloids exert a protecting action on clays which is of the same order as that of other protective colloids, but is specific to certain varieties of clay and electrolytes. Limed samples of humoid soil bind more water than unlimed samples, but the difference in amount is not of practical importance. The limed humus gives up its water more readily than the unlimed humus. After liming the water appears to be a little more firmly held and consequently is less easily taken up by plants.—J. F. S.

Boron in relation to the fertiliser industry. J. E. Breckenridge. J. Ind. Eng. Chem., 1921, 13, 324—325.

During recent years potash has been obtained from many new sources and some of the raw materials used have contained boron; cases of injury to crops have been noticed where such fertilisers have been used. Maize and beans are injured by the application of 6 lb. of borax per acre; the growth of potatoes appears to be stimulated with 4—6 lb. of borax per acre, but with 10 lb. there is decrease in root formation. With plenty of moisture the plants recover gradually, but would probably die in a dry season.—W. P. S.

Sulphur; Non-biological oxidation of elementary —— in quartz media. W. H. MacIntire, F. J. Gray, and W. M. Shaw. J. Ind. Eng. Chem., 1921, 13, 310—313.

Sulphur is oxidised by moist quartz under sterile and non-sterile aërobic and anaërobic conditions. The oxidation is accelerated by the presence of limonite and is decreased by that of iron or magnesium carbonate.—W. P. S.

Cellulosic residue of leaves. A. J. J. Vandevelde. Bull. Soc. Chim. Belg., 1920, 29, 317-322.

The insoluble cellulose residue (residue remaining after an acid and alkali treatment of the dried and powdered substance) of various leaves, including the vine, lilac, gooseberry, raspberry, and lime, at various periods of growth, was determined. Very irregular variations were found at different periods, and in different years, for the same kind of leaf, and no general relationships were apparent similar to those previously found for the ash, water or starch content at different stages of development of the leaf. The acid residue and the alkaline residue of the dried leaf showed analogous variations.

Patents.

Fertilisers; Manufacture of ——. Badische Anilin u. Soda Fabrik. E.P. (a) 145,036 and (b) 145,037, 14.6.20. Conv., 29.7.16 and 26.3.17.

A) A non-deliquescent and non-explosive fertiliser s obtained by mixing ammonium nitrate and potassium chloride in the presence of a small quantity of water, or by mixing ammonium nitrate, containing a small percentage of moisture, with dry potassium chloride. Crude potassium chloride containing about 64% KCl may be used. (b) Ammonium nitrate in the dry state is mixed with potasium chloride or potassium sulphate in absence of water.—W. J. W.

Fertiliser, and process for making same. E. H. Sams. E.P. 161,777, 17.2.20.

Unground chalk is mixed with house refuse which has been pulverised and screened, or with the ashes f the same, and the mixture is then milled. The ddition of the house refuse facilitates the grinding f the chalk owing to absorption of its moisture.
—W. J. W.

Fertiliser; Process of producing ——. M. Sheeld, Assr. to Armour Fertilizer Works. U.S.P. 1,375,115, 19.4.21. Appl., 13.9.20.

A suitable material is added to wet precipitated hosphate to prevent the latter becoming dusty fter drying.—W. J. W.

Lime; Production of catalytic —— for fertilising. R. Mandelbaum. G.P. 333,484, 22.12.18.

The fertilising properties of lime are improved by the addition of small amounts of calcium sulphate, sulphite, or sulphide. By the action of water on calcium sulphate and sulphide in the soil, heat is generated.—W. J. W.

XVII.—SUGARS; STARCHES; GUMS.

Sucrose; Decomposition of —— during milling. J. N. S. Williams. Int. Sugar J., 1921, 23, 271—272.

It is believed that an appreciable loss of sucrose must occur during the operation of milling under present-day conditions, that is, when the cane is finely shredded, and when the filter-press washwaters and the thin juices from the last unit are used for maceration. It was observed in the case of Plantation A, applying a moderate crushing and maceration, that the extraction was 89·1%, the fibre content, 13·3, the polarisation of the first mill juice, 16·6, the purity of the first mill juice, 88·3, and the calculated sugar in the cane, 279·4 lb. per ton; while on Plantation B, in which the cane was subjected to the extreme degree of crushing and compound maceration, the extraction was 96·34, the fibre content, 13·76, the polarisation of the first mill juice, 17·5, the purity of the first mill juice, 87·55, and the calculated sugar in the cane, 268·2 lb. per ton. Thus, Plantation A dealing with an inferior cane showed 279·4 lb. of sugar per ton of cane compared with 268·2 lb. in the case of Plantation B with a much better cane.—J. P. O.

Sucrose; Neutral polarisation modification of the Clerget method of determining ——. C. A. Browne. Int. Sugar J., 1921, 23, 276—281.

Replying to Jackson and Gillis (J., 1921, 361 a), the author agrees that in the case of Method 2 prescribed in Bull. 375 (J., 1920, 634 a) the errors in determining the positive and negative constituents do to a considerable extent neutralise each other, though his experiments show that compensation is perfect only at a concentration of about 13 g. of sucrose per 100 c.c. However, he points out that in the case of Method 3 (*loc. cit.*) for the analysis of beet products, the errors remain uncompensated, since the ammonium chloride is present only when making the negative reading, none being added for the positive reading as in Method 2. In Method 3, therefore, the final error may be considerable.
—J. P. O.

Sucrose; Determination of —— by the inversion method. V. Sázavsky. Z. Zuckerind. Czechoslov., 1921, 45, 227—229, 235—238.

is completely precipitated by basic lead acetate and For the clarification of solutions of raw (beet) sugar products the author recommends tannin solution followed by basic lead acetate solution. Although commercial tannin is optically active it gives rise to no error. A solution containing the normal weight (26 g.) of molasses may be treated with 10—15 c.c. of a 6% tannin solution and then, after shaking round, with 10—12 c.c. of basic lead acetate solution; for twice the normal weight of raw sugar it is usually sufficient to employ 10—20 drops of the tannin solution, followed by 1—2 c.c. of basic lead acetate. Solutions thus treated require no further clarification after inversion. Determinations of the inversion constant under Clerget-Herzfeld conditions, for different concentrations of pure sucrose, practically confirmed Herzfeld's formula. The presence of 1 g. of molasses ash in the solution raised the constant by 0·2; and in inverting 6·5 g. of molasses it is therefore better to employ the factor 132·66 than the lower one corresponding to 6·5 % solution of pure sucrose. For the inversion of molasses 5 c.c. of acid is not always sufficient, and it is advisable to use 6·5 c.c. Stanek's method for eliminating the error due to optically active non-sugars (J., 1914, 705) is considered more convenient than those proposed by Saillard and Andrlik and Stanek (*cf.* J., 1911, 63).—J. H. L.

Dry substance of sugar products; Determination of —— by means of the refractometer in the presence of crystals. H. Kalshoven. Archief Suikerind. Nederl.-Indië, 1920, 28, 913—917. Int. Sugar J., 1921, 23, 289—290.

In determining the dry substance of sugar products containing crystals, the author no longer uses the lower prism of the refractometer, the massecuite or molasses being pressed with the aid of a small glass plate (reinforced with a piece of copper sheet) against the upper prism, and the reading taken at least 10 mins. after turning on the cooling water. —J. P. O.

Sugars; Configuration of some ——. [Use of invert sugar in titrating boric acid.] J. Boëseken and H. Couvert. Rec. Trav. Chim., 1921, **40**, 354—380.

The electrical conductivity and optical rotation, with and without the addition of boric acid, of a number of substances of the sugar group have been determined. Invert sugar, prepared by heating sucrose for 1 hr. at 100° C., with 0·25 times its weight of 0·1 % aqueous hydrochloric acid and neutralising the product, may with advantage be employed in titrating boric acid with barium hydroxide. Very accurate results are obtained in $N/10$ solution with phenolphthalein as indicator if sufficient invert sugar be used to provide 5 mols. of lævulose for every mol. of boric acid. (*Cf.* J.C.S., July.)—C. K. I.

Starch; Studies on ——. A. Reychler. Bull. Soc. Chim. Belg., 1920, **29**, 309—317.

The gelatinisation of starch can be conveniently followed microscopically at ordinary temperatures by using a solution containing about 0·135 mol. of alkali hydroxide per litre. A similar action is produced by $4N$ or $5N$ acids and by certain concentrated salt solutions, such as 30% ammonium nitrate, 15 % potassium thiocyanate, etc. The reverse action is produced if to 100 c.c. of a starch paste, 80 g. of sodium sulphate, 40 g. of ammonium or magnesium sulphate, etc., is added, a complete coagulation resulting in a few minutes regardless of the temperature. Under ordinary conditions this retrogradation takes 10 or 12 days, and is then only partial. The microscopical observations may be interpreted by postulating that the starch mucilage is a suspension of swollen and partially burst granules consisting of an internal substance and an envelope which is impenetrable by water unless at an elevated temperature or in presence of an alkali, etc., when it becomes hydrated and allows the internal material to form a voluminous gel or sol. The coagulum produced by sodium sulphate etc., is composed of amorphous granules, smaller in size than the swollen granules of the mucilage, and formed by the shrinking of the envelope and the consequent expulsion and coagulation of the internal sol. Starch solutions formed by heating the mucilage at 120°—150° C. exhibit a similar phenomenon of coagulation, and the precipitate formed may readily be isolated by taking advantage of its resistance to diastase. On drying it forms a hard, warty mass, resistant to all reagents except potash, but still showing under the microscope its constituent globules. It is dissolved by water at 150° C., and the solutions resemble those of the original starch, but are characterised by giving a deeper blue colour with iodine, and by yielding an almost theoretical quantity of maltose when treated with malt extract. It appears, therefore, to be composed exclusively of a polysaccharide (amylose), whilst the original starch contains in addition a more refractory substance originally designated by Maquenne amylopectin (*cf.* J., 1905, 630). Amylose may therefore be characterised as a solid, relatively soluble, in the starch granules; colloidally dissolved and coagulable in the internal fluid of the granules in the mucilage, in starch solutions, and in solutions of the coagulum; solid and attackable with difficulty in the coagulum. Amylopectin is met with as a solid, dense and resistant in the envelope of the starch granules; as solid, but swollen permeable by water and liquefiable by malt extract, in the granular envelopes of the mucilage; and also dissolved in the starch solutions. —G. F. M.

XVIII.—FERMENTATION INDUSTRIES.

Extract yield from raw grain (maize and rice): Determination of ——. W. Windisch and P. Kolbach. Woch. Brau., 1921, 38, 57—59, 63—64, 76—77.

A comparative study of various methods. In the one recommended 40 g. of the maize or rice is mixed with 150 c.c. of water and 100 c.c. of a filtered malt extract (made by digesting 1 pt. of malt with 4 pts. of water for 1 hr. at 30° C. with frequent stirring). Next morning the mash is heated rapidly to 70° C., then in 40 mins. to 80°, and then boiled for 5 mins. on a sand-bath. After cooling to 50° it is treated with a further 100 c.c. of malt extract and the temperature is maintained at 50° for ½ hr., raised to 70° in 20 mins., maintained at 70° for 25 mins., raised to 75° in 5 mins., and maintained at 75° for 30 mins. The cooled mash is made up to 450 g. before filtering. The method of calculation is explained fully.—J. H. L.

Malt analysis; Comparative experiments respecting the most convenient method of calculation and the accuracy attainable in the pyknometric determination of extract in ——. H. Keil. Woch. Brau., 1921, 38, 95—96.

In accurate determinations of wort gravities by the pyknometer, tedious corrections for air displacement under different conditions of barometric pressure may be avoided by the use of a "compensation pyknometer" (*i.e.*, a counterpoise such as a pyknometer suitably loaded with shot and hermetically sealed, having approximately the same weight and volume as the pyknometers in use when the latter are filled with water). The exact weight of the counterpoise is determined once for all, and the extra weights required in one pan or the other to balance a pyknometer filled with water or wort against the counterpoise are added to or subtracted from the weight of the latter. This method ha been adopted in the analytical laboratory of th Versuchs und Lehranstalt in Berlin.—J. H. L.

Enzymes; Actions between ——. H. Van Laer. Bull. Soc. Chim. Belg., 1919, **28**, 340—346.

The maceration juice, separated at the moment of autolysis from a mixture of dried yeast and water, contains an invertase, which is sensitive to both active and passive papaïn and to amylase. This sensitiveness is not shown by the juice separated after autolysis or by the limpid extracts from yeast killed by acetone. The liquids obtained by macerating yeast killed by acetone with active solutions of papaïn or amylase show a notable increase in inverting power, which is apparently due to the difference between the increase resulting from the liberation of invertase masked by the protoplasmic substances, and the diminution caused by a greater sensitiveness of the freshly liberated enzyme to the products of digestion of its cellular substrate.
—W. G.

Fruit wine; Preparation of —— from frozen or frost-bitten fruit, with special reference to changes in the juice corresponding to the severity of freezing. A. Widmer. Schweiz. Apoth.-Zeit., 1920, **58**, 339—344. Chem. Zentr., 1921, **92**, II., 878—879.

Expressed juice from frost-bitten fruit (apples and pears) has a low sp. gr. owing to its relatively large amount. Mere freezing of the fruit produces no perceptible change in the constituents of the juice, and does not preclude vinification provided the fruit is thawed without delay, at the lowest possible temperature, and the expressed juice is fermented at once. In frost-bitten fruit, on the other hand, there occurs a decrease in the acidity and tannin-content of the juice, part of the tannin being precipitated in combination with proteins; such fruit yields mild but unstable juices which sometimes have an unpleasant flavour and odour. Frost-bitten unripe fruit is only fit for vinification if free from the last-mentioned defects, and in any case it is advisable to employ pure yeast for the fermentation. All fruit wine made from frozen fruit should be consumed as soon as possible.—J. H. L.

Patents.

Alcoholic fermentation; Process for accelerating ——. Aktiebolaget Astra, Apotekarnes kemiska fabriker. G.P. 334,866, 7.5.14. Conv., 6.5.13.

The liquid to be fermented is treated with one or more salts of organic acids, other than ammonium salts, or with neutralised solutions containing organic acids produced biochemically. Alkali salts of acids of the formic and glycollic acid series are particularly active, producing an acceleration of 30—100%, with increased attenuation in many cases.—J. H. L.

Fat in microbes. G.P. 332,411. *See* XII.

Extracting ferments etc. G.P. 334,660. *See* XX.

XIXa.—FOODS.

Milk; Detection of the addition of sodium carbonate to ——. A. J. J. Vandevelde. Bull. Soc. Chim. Belg., 1920, **29**, 52—54.

The author relies on an ash analysis. The ash of milk normally contains Na 6·0%, K 20·4%, P_2O_5 26·3%. The addition of sodium carbonate will alter the ratio of Na+K to P_2O_5 as well as the ratio Na to K.—W. G.

Goat's milk; Detection of —— in cow's milk. W. Austen. Milchw. Zentr., 1921, **50**, 125—127.

The method depends on the insolubility of the casein of goat's milk in 25% ammonia, in which the casein of cow's milk is completely soluble. It is only applicable to fresh milk. Potassium bichromate should be used as a preservative, as formaldehyde affects the solubility of the casein. The cream should first be separated as completely as possible by centrifuging in a Gerber tube stoppered at both ends, and removing by means of a fine pipette. About 20 c.c. of the separated milk is thoroughly mixed with 2 c.c. of 25% ammonia in the Gerber tube and heated in a water bath for about ½ hr. The tube is then placed in a centrifuge with the graduated part outwards and rotated at about 1200 revs. for some minutes. Cow's milk gives little or no precipitate, whereas that from pure goat's milk about half fills the narrow graduated tube. Less than 20% of goat's milk in cow's milk can, however, not be detected with certainty. The method can be applied to approximate quantitative estimations.
—H. C. R.

Lard; Boehmer's method for detecting tallow in ——. Vitoux and C. F. Muttelet. Ann. Falsif., 1921, **14**, 86—92.

Further experiments with the method previously described (J., 1921, 126 a) confirm its usefulness. As little as 5% of beef or mutton fat can be detected in lard, the value (2G − A) falling below 68; even in the case of lard adulterated with beef or mutton fat together with fats rich in liquid glycerides, *e.g.*, horse fat, the method loses none of its sensitiveness. It is equally effective in detecting hydrogenated fish oils. Fats poor in solid glycerides, however, such as oleomargarines and horse tallow, escape detection unless present to the extent of more than 20—30%, but it appears possible that a modification of the method may overcome this difficulty.—J. H. L.

Phytase; Activity of —— as determined by the specific conductivity of phytin-phytase solutions. F. A. Collatz and C. H. Bailey. J. Ind. Eng. Chem., 1921, **13**, 317—318.

Changes in the specific conductivity of an aqueous solution of phytin and phytase indicate the progress of the hydrolysis of the phytin. In the case of phytase prepared from wheat bran, the most favourable temperature for complete hydrolysis appears to be about 55° C., although the hydrolysis proceeds more rapidly at 60° C. during the first 15 mins.
—W. P. S.

Wheat flour grades. Electrical conductivity of water extract. C. H. Bailey and F. A. Collatz. J. Ind. Eng. Chem., 1921, **13**, 319—321.

The specific conductivity of water extracts of wheat flour varies with the time and temperature of extraction; the highest values are obtained at about 60° C., and the conductivity is due chiefly to inorganic phosphates resulting from the hydrolysis of phytin by phytase. To compare different flours it is necessary to use a uniform procedure in the preparation of the extracts, and it is suggested that 10 g. of flour be heated at 25° C. for 30 mins. with 100 c.c. of conductivity water, the mixture then centrifuged, and the conductivity of the clear extract determined at 30° C. with a dip electrode. The specific conductivity of flour extracts runs parallel with the ash content and can be used as an index of the grade of the flour.—W. P. S.

Patents.

Cooked food products from wheat grain; Manufacture of ——, and apparatus therefor. C. V. Rowell. E.P. 140,457, 18.3.20. Conv., 18.3.19.

Whole wheat grains are heated at about 460°—

500° C. for about ½ min. in presence of highly superheated steam under a pressure of about 1000 lb. per sq. in., and the product is ejected from the horizontal, cylindrical heating chamber by a sudden release of the pressure.—H. H.

Blood-meal; Manufacture of ——. G. A. Krause. G.P. 332,434, 19.8.17.

Blood which has coagulated without heating, and in which the clots have been subsequently broken up into fine particles, is atomised and dried by a current of hot air, yielding a meal completely soluble in water with the exception of the fibrin. —L. A. C.

Plants; Process for improving the flavour and odour of food- or fodder-yielding —— of the Cruciferæ or related families. H. Brün. G.P. 334,274, 18.10.17.

The comminuted and partially or completely dried material is moistened with a very dilute solution of hydrogen peroxide, then tightly compressed for 48 hrs., and afterwards spread out and dried. Products thus obtained from beets and the like may be used as diluents or substitutes for flour or soup powders or may be employed in the manufacture of jam.—J. H. L.

Pickling brine; Process for recovering proteins contained in ——. G. Coblitz. G.P. 334,322, 10.12.16.

The proteins, separated from solution by fractional thermal coagulation, are cooled at once by means of water or otherwise, and the different fractions are subsequently mixed and dried as usual.—J. H. L.

Lupin seeds, horse chestnuts and the like; Removal of bitter substances from ——. P. Schmidt. G.P. 334,589, 5.12.18.

The seeds, freed from shells, are treated for 1 hr. at 95°—100° C. with a dilute solution (1:25) of the waste mother liquor from potash manufacture, and then twice more with similar solution, for 2 hrs., each time at 50° C., with continuous stirring, and finally the seeds are well washed with water, dried, and ground if necessary.—J. H. L.

Fodder from straw (e.g., from cereals or leguminous plants); Preparation of a —— by digestion of the comminuted material [with alkali solution]. Veredelungsges. für Nahrungs- und Füttermittel m.b.H. G.P. 335,155, 27.3.18. Addn. to 305,641 (J., 1919, 789 A).

The alkaline digestion liquors are used over and over again until they become acid, and each charge of straw is digested in stages with successive portions of liquor, each fresher than the preceding one. The alkali is thus completely utilised and digestion is accelerated.—J. H. L.

Cooling chocolate and other materials; Machine for ——. E. Savy. U.S.P. 1,375,734, 26.4.21. Appl., 1.3.19.

See E.P. 124,196 of 1919; J., 1920, 78 A.

XIXb.—WATER PURIFICATION; SANITATION.

Boiler feed water; Purification of ——. F. Blumenthal. Z. angew. Chem., 1921, **34**, 189—192.

A review of the lime-soda, baryta, Permutite, and Neckar processes for softening boiler feed water. The lime-soda process can only reduce the hardness to a limit of 2 or 3 degrees on account of the solubility of calcium and magnesium carbonates, and in addition soluble sodium salts and about 10—15 g. of sodium hydroxide per cub. m. are left in the water and pass into the boilers, which must therefore be blown out periodically. In the baryta and Permutite processes, on the other hand, smaller amounts of soluble salts are left in the feed water. In the Neckar process, heating the feed water to 80° C. cannot cause the precipitation of the calcium and magnesium carbonates; such precipitation must be due solely to the soda alkalinity of the boiler water which is returned to the purifier. Moreover, the statement that in this process the carbonic acid is entirely precipitated is quite incorrect, since it is all converted in the purifier into sodium bicarbonate, is fed into the boiler, and is there expelled with the steam, the residual normal carbonate being returned to the purifier and the above operation repeated. Magnesium salts are only completely precipitated when sufficient sodium hydroxide is formed in the boiler by hydrolysis of the carbonate unless additional hydroxide is supplied to the purifier, which materially increases the cost of the process.—G. F. M.

Cryptogamic diseases of plants; Use of coloured screens for combating ——. R. Lance. Comptes rend., 1921, **172**, 1201.

The spray is prepared by mixing 650 g. of ultramarine blue, 250 g. of ultramarine green, and 100 g. of ultramarine violet with several litres of water, adding 2 kg. of calcium sulphate and 1350—1400 g. of quicklime, and when the colouring is uniform, stirring in 1 kg. of aluminium sulphate or 1·5 kg. of alum. The precipitated alumina fixes the dye and the whole mixture is diluted to 400 litres and is ready for use. The deposit formed on the plants by the use of this spray acts as a colour screen, permitting only blue, violet, and ultra-violet rays to pass.—W. G.

Anticryptogamic product. R. Lance. Comptes rend., 1921, **172**, 1201—1202.

The material recommended is prepared by dissolving 1 kg. of zinc sulphate in 100 l. of water, adding 500 g. of lime to precipitate the zinc as hydroxide, and then 80—100 g. of an ultramarine colour. Finally 250 g. of aluminium sulphate is added and the whole is well shaken and after filtering is ready for use. This mixture, it is claimed, combines the antiseptic action of zinc with the microbicidal action of the blue, violet, and ultra-violet rays. —W. G.

Patent.

Water; Process and apparatus for removing dissolved oxygen from ——. L. and C. Steinmüller. G.P. 334,181, 28.3.17.

The water is passed slowly over an extensive surface of iron in a direction substantially parallel to the surface. Vessels or drums packed with a series of concentric sheet iron cylinders may be used. The process is more effective than the use of filters containing iron shavings, and the apparatus lasts longer and is more easily cleaned than the latter. —J. H. L.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Morphine; Chemico-toxicological detection of ——. D. Ganassini. Boll. Chim. Farm., 1921, **60**, 2—5.

In the test for morphine given by Denigès (J., 1911, 47), the copper sulphate and hydrogen peroxide may be replaced by potassium ferricyanide and ammonia; the reaction is then applicable to the detection of morphine in blood and in non-putrefied animal organs, but is not very sensitive. The copper sulphate may be replaced also by hæmatin, which readily catalyses hydogen peroxide, the hæmatin of human blood being far more active in this respect that that of the blood of animals. For the detection of morphine in blood, Denigès' test must be modified as follows: 0·25 c.c. of blood is diluted to 10 c.c. with water and the solution treated with nitric acid (about 10 drops) until a brown precipitate of globin and hæmatin is formed. The liquid is filtered and the colourless or almost colourless filtrate treated with 1 c.c. of ammoniacal cuprammonium sulphate solution, prepared by adding 10 drops of hydrogen peroxide solution (1 vol. perhydrol to 1 water) to a mixture of 20 c.c. of concentrated ammonia with 5 c.c. of 0·5% copper sulphate solution. With blood free from morphine, the liquid remains colourless, whereas the presence of a minute proportion of morphine rapidly produces a more or less intense pink coloration. This procedure serves also for the detection of morphine in milk or urine, addition of nitric acid being then unnecessary; in these cases, however, the reaction is less sensitive than with blood. The above reaction is given neither by hydroxydimorphine, nor by the alkaloids accompanying morphine in opium, nor by artificial derivatives of morphine such as dionine and peronine, but it is shown, contrary to the statement of Denigès, by heroine. The latter gives the following specific reactions, which serve to distinguish it from morphine: When heated with sulphuric acid it yields acetic acid, or in presence of alcohol, ethyl acetate; when treated with concentrated nitric acid it becomes successively yellow, greenish-blue, and yellow slowly in the cold, but rapidly when heated; when treated with 2 c.c. of a solution of urotropine (hexamethylenetetramine) in concentrated sulphuric acid it turns first golden-yellow, then orange, and finally dark blue.—T. H. P.

Iodotannic syrups; Preparation of ——. *Rapid determination of combined iodine.* T. Ugarte. Anal. Asoc. Quím. Argentina, 1921, 9, 5—16.

Methods are described for avoiding loss of iodine in the preparation of iodotannic syrups. Two rapid methods are described for the estimation of combined iodine in two different types of preparation. The second method, which is applicable in both cases, consists in titrating the syrup with $N/10$ mercuric chloride until a permanent opalescence is obtained; each molecule of mercuric chloride corresponds to three atoms of combined iodine. —G. W. R.

Humic acids; Synthetic and natural ——. W. Eller. Brennstoff-Chem., 1921, 2, 129—133.

Humic acids have been obtained by the oxidation of phenols in alkaline solution (J., 1920, 717 a). The chemical reactions of the products resemble those of the natural humic acids. (*Cf.* J.C.S., July.)—W. P.

3.4.6-*Trinitroresorcinol* (*styphnic acid*). H. Einbeck and L. Jablonski. Ber., 1921, 54, 1084—1089.

Styphnic acid, m.p. varying from 174° C. to 179°—180° C., is obtained by the oxidation of quebracho extract with nitric acid (sp. gr. 1·4). For its characterisation the mono- and di-potassium salts have been prepared by the regulated addition of alcoholic potassium acetate solution to styphnic acid dissolved in acohol, and the mono- and di-sodium salts by the use of alcoholic sodium hydroxide. All the salts, the mono-sodium compound n particular, explode violently when heated. *Cf.* J.C.S., July.)—H. W.

Tartaric acid and acid potassium tartrate; Manufacture of ——. H. Voss. Chem.-Zeit., 1921, 45, 309—313, 335—337, 360—364, 411—412.

The manufacture of acid potassium tartrate, with details of the necessary plant is described. An extensive survey of the manufacture of tartaric acid by both the neutral and the acid process has been made, for details of which the original paper should be consulted.—W. J. W.

ββ-Dichloroethyl sulphide. Delépine, Fleury, and Ville. Comptes rend., 1921, 172, 1238—1240.

ββ-Dichloroethyl sulphide when prepared from ethylene and sulphur chloride is never pure. It contains substances which are apparently isomeric with it, and on distillation under reduced pressure yields a small amount of hydrogen chloride. It cannot be used satisfactorily as a solvent for cryoscopic measurements.—W. G.

Cyanic acid and urea; Synthesis of —— *by oxidation of ketones, acids, and amines in presence of ammonia.* R. Fosse and G. Laude. Comptes rend., 1921, 172, 1240—1242.

Cyanic acid and subsequently urea, by tautomerisation, have been obtained by the oxidation in the presence of ammonia of ketones, mono- and dibasic acids, phenols, alcohols, and amines. The yield of urea varies considerably with the substance used, and in the case of amines, those capable of giving formaldehyde by oxidation give the highest yield.—W. G.

Chloroform; Manufacture of —— *from ethyl alcohol, and the mechanism of the reaction.* S. Ochi. Kogyo-Kwagaku Zasshi (J. Chem. Ind. Japan). 1921, 24, 209—228.

Chloroform was prepared by passing chlorine into a mixture of ethyl alcohol and milk of lime at 60° C., the concentration of alcohol being 10%, and the quantity of calcium hydroxide ca. 300 g. per litre of alcohol, and that of chlorine 0·75—0·87 mol. per mol. of calcium hydroxide; 63·5—65·5% of the chlorine and 54·4—54·9% of the alcohol were utilised. Magnesium oxide, barium oxide, sodium and potassium hydroxides gave poorer yields than calcium oxide, and ferric hydroxide had no catalytic action on the process. The products of the reaction were examined quantitatively, and it is concluded that reactions corresponding to the following equations take place: $2C_2H_5OH+8CaOCl_2=2CHCl_3+2Ca(OH)_2+5CaCl_2+Ca(HCO_2)_2+2H_2O$; $2C_2H_5OH+10CaOCl_2=2CHCl_3+2Ca(OH)_2+7CaOCl_2+CaCO_3+CO_2+3H_2O$; $C_2H_5OH+2CaOCl_2=CH_3COOH+2CaCl_2+H_2O$. 65—75% of the formic acid produced is decomposed into carbon dioxide and water by further oxidation and one-fourth of the acid remains unchanged in the residue. About two-thirds of the alcohol used is utilised in the formation of chloroform and the greater part of the remainder is converted into acetic acid. Carbon dioxide is not produced directly from the alcohol. The explosive reaction in manufacturing chloroform is due to violent evolution of oxygen by the decomposition of calcium hypochlorite at the high temperature produced during the oxidation of the alcohol. It can be avoided by operating at a lower temperature.—K. K.

Ethyl chloride; Rate of evaporation of —— *from oils.* C. Baskerville and M. Hirsh. J. Ind. Eng. Chem., 1921, 13, 322—323.

The rate of evaporation of ethyl chloride from oils (maize oil) quickly acquires a definite and fairly constant velocity when the mixture contains 13—14% by vol. of ethyl chloride. If a mixture originally containing 15% is used, the uniform speed of evaporation is established within 10 mins. for surface exposures.—W. P. S.

Acetic acid and anhydride. L. Crismer and J. Timmermans. Bull. Soc. Chim. Belg., 1920, 29, 46—52.

The rule of mixtures for critical temperatures of

solution does not apply to mixtures of acetic acid and its anhydride. By means of determinations of critical temperatures of solution with a Russian petroleum it is shown that phosphoric anhydride is a suitable reagent for dehydrating acetic acid.
—W. G.

Catalysts; Influencing of the activity of ——. *III. Oxidative catalytic dehydrogenation of alcohols. I.* K. W. Rosenmund and F. Zetzsche. Ber., 1921, **54**, 1092—1098. (*Cf.* J., 1921, 321 A, 368 A.)

The catalytic oxidation of a primary alcohol may lead to the production of aldehyde, acid, ether, and condensation products. The reaction has been studied in the case of benzyl alcohol under conditions which do not involve vaporisation and with the object of limiting the scope of the change to the production of benzaldehyde. Benzyl alcohol only gives about a 3% yield of the latter when oxidised by oxygen in boiling cumene solution and this yield is not very greatly increased in the presence of copper, silver, magnesium, platinum, nickel, aluminium, zinc, antimony, or carbon. Amongst these almost equivalent catalysts, selective action can be induced in the cases of copper, nickel, and silver by the suitable addition of quinoline, the production of benzaldehyde being favoured in the case of copper and the formation of ether and condensation products in the cases of nickel and silver, thus giving an example of the transformation of slightly active catalysts into powerful and specific substances. The dehydrogenating action of catalytically excited oxygen and of nitro-groups is additive, the latter being introduced preferably in the form of *m*-dinitrobenzene. The best yields of aldehydes from alcohols are obtained by the oxidation of an equimolecular mixture of alcohol, quinoline, and *m*-dinitrobenzene in cumene solution in the presence of copper.—H. W.

Alcohols; Catalytic dehydrogenation of ——. E. K. Rideal. Proc. Roy. Soc., 1921, **A99**, 153—162.

In confirmation of Sabatier's experiments the application of the Nernst approximation formula indicates that the variation of the dissociation constants of the equilibria, $CH_3CHO+H_2 \rightleftarrows C_2H_5OH$ and $CH_3COCH_3+H_2 \rightleftarrows CH_3.CH(OH).CH_3$, with the temperature are extremely large. The velocity of decomposition at the surface of a solid catalyst is much higher than the reverse reaction of hydrogenation. The variation of the values of the dissociation constants with the temperature was experimentally determined with a constant volume thermometer containing reduced copper as catalytic material, and at low pressures a fairly close approximation to reversibility was obtained. The value of ΔU_0 (heat of reaction) for the decomposition of ethyl alcohol was determined as 11,500 cals., whilst the mean value from the heats of combustion is 10,700. In the case of isopropyl alcohol the respective values are 21,300 and 11,800 cals., but an error of 1% in determining the heat of combustion of the alcohol would account for the discrepancy.
—G. F. M.

Verbenene (dehydro-α-pinene) and certain of its derivatives. A. Blumann and O. Zeitschel. Ber., 1921, **54**, 887—894.

Crude *l*-verbenene (J., 1913, 498) readily yields a crystalline dibromide, m.p. 70°—72° C., $[\alpha]_D^{15}=+297·65°$ in benzene solution, from which the parent substance is regenerated by reduction with zinc and acetic acid. Pure *l*-verbenene has sp. gr. 0·8866 at 15° C., $[\alpha]_D=-100·61°$, whilst the *d*-compound has sp. gr. 0·8867 at 15° C., $[\alpha]_D=+100·71°$, $n_D^{20}=1·49800$. The mode of formation, physical constants, and chemical behaviour of the compounds are in harmony with the view that verbenene is dehydro-α-pinene. Reduction with sodium and ethyl alcohol converts *l*-verbenene into dihydroverbenene (δ-pinene), b.p. 158°—159° C. at 762 mm., sp. gr. 0·865 at 15° C., 0·8625 at 20° C., $n_D^{20}=1·4662$, $[\alpha]_D=+36·52°$. (*Cf.* J.C.S., July.)—H. W.

Potassium oxalates. Sabalitschka. *See* VII.

Patents.

Lobelia inflata; Process for obtaining the active ingredient of ——. C. H. Boehringer Sohn. E.P. 145,622, 29.6.20. Conv., 2.9.14. Addn. to 145,621 (J., 1921, 195 A).

The active α-lobeline hydrochloride present in the aqueous solution after the crystallisation of the β-lobeline hydrochloride, can be extracted by other chlorinated solvents such as carbon tetrachloride, trichloroethylene, or tetrachloroethane, instead of chloroform.—D. F. T.

Butyl alcohol; Manufacture of secondary ——. C. Weizmann and D. A. Legg. E.P. 161,591, 24.2.16.

Liquefied β-butylene is mixed with 75% sulphuric acid, with phosphoric acid, or with benzenesulphonic acid, either at ordinary temperatures under pressure, or at −10° to −15° C. under atmospheric pressure, and when the hydrocarbon has completely dissolved the liquid is distilled with steam, pure secondary butyl alcohol passing over.
—G. F. M.

[Hydr]oxyaldehydes and their derivatives; Manufacture of ——. G. B. Ellis. From Soc. Chim. des Usines du Rhône. E.P. 161,679, 13.1.20.

Hydroxyaldehydes are produced by the action of formaldehyde on a phenol or a phenol derivative in presence of a nitroso-compound, such as nitrosobenzene or nitrosodimethylaniline, and, if necessary, a catalyst. For example, vanillin is obtained by treating for 1—2 hrs. a solution, in 50 pts. of methyl alcohol, of 4 pts. of guaiacol, the nitrosodimethylaniline derived from 8 pts. of dimethylaniline, and 8 pts. of 40% formaldehyde, hydrogen chloride being continuously bubbled through. The product is diluted with water, the methyl alcohol distilled off, and the vanillin extracted from the aqueous residue with ether or benzene. The nitrosodimethylaniline is mostly transformed into *p*-aminodimethylaniline. (Reference is directed, in pursuance of Sect. 8, Sub-sect. 2, of the Patents and Designs Acts, 1907 and 1919, to E.P. 139,153; J., 1920, 527 A.)—G. F. M.

Oxalic acid; Manufacture of —— *from carbohydrates.* Valentiner u. Schwarz, G.m.b.H. G.P. 329,591, 20.12.13.

Sugar (100 pts.) is treated below 70° C. with a mixture of, *e.g.*, 320 pts. of sulphuric acid, 300 pts. of nitric acid, and 380 pts. of water in the presence of salts of vanadium, molybdenum, or manganese, as catalysts, yielding 142 pts. of oxalic acid. The reaction is allowed to continue until the liquor is free from nitric acid, and the nitrous fumes evolved are absorbed by the mother liquor from a previous preparation.—L. A. C.

Alkyliminodisulphonic acids; Production of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 330,801, 4.8.18.

Basic salts of iminodisulphonic acid react with organic halogen compounds, such as methyl iodide, epichlorhydrin, or ethylene bromide, or inorganic acid esters, such as dimethyl sulphate, in accordance with the equation, $KN(SO_3K)_2+R.Cl=KCl+R.N(SO_3K)_2$. The salts of alkyliminodisulphonic acids hydrolyse in the presence of acid in two stages, with the production first of alkyliminomonosulphonic acids and then of alkylamines. Potassium dihydroxypropyliminosulphonate,

$$(SO_3K)_2N.CH_2.CH(OH).CH_2.OH,$$

is prepared by the prolonged action of epichlorhydrin on an aqueous solution of potassium iminodisulphonate at normal temperature in the presence of potassium hydroxide and subsequent evaporation of the solution; the product is stable in neutral or alkaline solution, but is decomposed by boiling with acids into sulphuric acid and dihydroxypropylamine. The preparation of potassium ethylenediaminetetrasulphonate, and of potassium methylaminomonosulphate and methylamine from potassium methyliminodisulphonate, are also described.—L. A. C.

Alcohols and amino-alcohols of the quinoline series; Preparation of ——. *Preparation of quinolyl ketones.* Vereinigte Chininfabr. Zimmer und Co., G.m.b.H. G.P. (A) 330,813, 8.3.18, and (B) 330,945, 11.6.18. (B) Addn. to 268,830 (J., 1914, 277).

(A) Quinolyl ketones and quinolyl aminoketones are reduced to secondary alcohols by treatment in alcoholic solution with a metal of which the hydroxide possesses weakly acid properties, such as zinc or aluminium, and with an alkali ethoxide. Quininone, $CH_3O.C_9H_5N.CO.C_9H_{14}N$, yields a mixture of quinine and quinidine; the former is isolated as the insoluble sulphate, and the latter is extracted with ether from the mother liquors after they have been made alkaline. Dihydrocinchoninone, $C_9H_6N.CO.C_9H_{16}N$, yields dihydrocinchonine and dihydrocinchonidine, both of which occur naturally together with quinine, and also the two other possible stereoisomers, of m.p. 126° C. and 106° C., and $[\alpha]_D^{14} = +88{\cdot}5°$ and $[\alpha]_D^{18} = +48°$ respectively, which up to the present have not been found in nature; the two latter are both converted to dihydrocinchotoxine by boiling with dilute acetic acid. Cinchotoxine, $C_9H_6N.CO.(CH_2)_2.C_7H_{12}N$, 6-methoxyquinolyl-4-methylketone, and 6-methoxyquinolyl-4-piperidylmethylketone, yield on reduction respectively cinchotoxol, a yellow oil, 6-methoxyquinolyl-4-methylcarbinol, m.p. 120°—121° C., and 6-methoxyquinolyl-4-piperidinomethylcarbinol,, m.p. 109° C. (B) The use is claimed of esters having the general formula $R'.CH_2COO.R''$, in which R' is an N-acylated basic residue instead of an alkyl group, as claimed in the chief patent. N-Benzoylhomocincholoipon ethyl ester condenses with quinoline-4-carboxylic acid ethyl ester at 80° C. in the presence of sodium ethoxide forming a β-ketone acid ester, which on boiling with hydrochloric acid yield a quinolyl ketone identical with dihydrocinchotoxine, the transformation product of dihydrocinchonine.
—L. A. C.

Morphine alkaloids and derivatives of barbituric acid; Preparation of compounds of ——. Ges. für Chem. Ind. in Basel. G.P. 330,814, 6.6.17. Addn. to 322,335 (E.P. 107,409; J., 1917, 979).

Anæsthetics for use in inducing "twilight sleep" are prepared by the action of arylalkylbarbituric acids on morphine alkaloids, as described in the chief patent. Morphinephenylethylbarbituric acid, ethylmorphinephenylethylbarbituric acid, and codeinephenylethylbarbituric acid melt respectively at 250°, 87°, and 80° C.—L. A. C.

Iron-albumin compounds; Preparation of water-soluble ——. Bauer und Co. G.P. 330,815, 11.4.19.

An aqueous solution of albumose is added to a solution containing ferric nucleate and a neutral salt of an organic acid, such as sodium nucleate, trisodium citrate, or potassium sodium tartrate, until a test portion gives with yellow ammonium sulphide no black precipitate of iron sulphide, even after several hours, but yields a clear bluish-green solution; the solution is then evaporated to dryness. Ferric nucleate is prepared as a flesh-coloured precipitate by the addition of ferric chloride to sodium nucleate in aqueous solution.—L. A. C.

Mercury sludge [obtained, e.g., in the manufacture of acetaldehyde from acetylene]; Recovery of mercury from ——. Consortium für Elektrochem. Ind. G.m.b.H. G.P. 332,202, 30.8.17.

The water is removed by heating the sludge below 155° C.—L. A. C.

Ferments, enzymes, alkaloids and other substances; Extraction of —— *from animal organs and plants.* Gebr. Schubert. G.P. 334,660, 23.12.17.

The fresh or dried material is mixed with sufficient water to form later with calcium chloride a solution which remains liquid well below 0° C. The moistened material is frozen and thoroughly comminuted, and calcium chloride is then added, whereupon liquefaction occurs. The calcium chloride solution formed, containing the substance required, is separated from the residual mass and worked up. The calcium chloride may be precipitated from this solution by an excess of salt, and after centrifuging, the liquid is concentrated to the required extent. The process ensures a very thorough disintegration of the tissues and a complete extraction of the substance required, *e.g.*, pepsin from sheep's stomach, active principles from various glands, etc.
—J. H. L.

Petroleum; Production of a preparation [embrocation] from crude ——. Chem. Werke Grenzach A.-G. G.P. 334,916, 4.2.19.

Crude petroleum, freed from its more volatile constituents, is treated with hypochlorous acid or salts thereof, and afterwards with feebly basic oxides, hydroxides, or basic salts. The hypochlorous acid combines with unsaturated constituents of the petroleum and prevents any irritating effect when the latter is employed as an embrocation in cases of horse scabies and similar affections. The added bases neutralise acid constituents and give the product the consistency of an emulsified salve readily liquefied on warming.—J. H. L.

Alcohol and ether vapours. U.S.P. 1,376,069. *See* I.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Patent.

Photomechanical designs, pictures, or printing surfaces; Process of producing ——. F. Hausleiter. E.P. 139,472, 23.2.20. Conv., 19.8.14.

A negative on a transparent support is developed with a developer which hardens the gelatin in the neighbourhood of the image. The unexposed parts are washed away, and the remaining image is stained with a suitable dye to increase its opacity to the light to which bitumen is sensitive, and is then coated with bitumen, exposed from the back and developed in the usual way.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Patents.

Explosive. B. F. Halvorsen. U.S.P. 1,375,588, 19.4.21. Appl., 4.12.19.

A nitro-derivatve of urea is utilised as an explosive.—W. J. W.

Explosive composition. Explosive. F. Olsen. U.S.P. (A) 1,376,029 and (B) 1,376,030, 26.4.21. Appl., 22.5.20 and 15.1.21.

(A) An explosive composition contains an inorganic perchlorate, a nitro-hydrocarbon, a propellent powder, a non-explosive combustible substance, a chlorine-fixing material, and a material for regulating the flame-temperature. (B) A nitro-starch explosive is mixed with a propellent powder. —W. J. W.

Potassium perchlorate explosives. Chem. Fabr. von Heyden A.-G. G.P. (A) 298,568, (B) 300,669, and (C) 303,330, 6.12.16.

(A) A MIXTURE of potassium perchlorate, liquid hydrocarbons, and finely-divided iron, without a nitro-compound, gives an explosive which can be readily detonated. (B) By the addition of ammonium perchlorate to potassium perchlorate explosives, not containing a nitro-compound, the proportion of hydrocarbons may be increased. (C) The use of nitroglycerin in potassium perchlorate explosives may be dispensed with and cheapness thereby increased, by adding an appreciable amount of chlorate, exceeding the 0·2% present in commercial pure potassium perchlorate. The resulting explosive has a high degree of safety.—W. J. W.

Guncotton; Process for stabilising ——. Riensberg. G.P. 299,039, 17.8.16.

THE water used for the purification of guncotton is heated in boilers which are separated from the stabilising vats, and is automatically supplied to, and drawn from, the vats.—W. J. W.

Smokeless powders; Manufacture of ——. Claessen. G.P. 299,760, 15.10.14.

GELATINISATION of smokeless powders, containing nitrocellulose and less than 30% of nitroglycerin or a nitro-compound, is effected, without the aid of a volatile solvent, by incorporating them at a temperature below 100° C., and raising the temperature of 100° C. after organic materials such as resin, diphenylamine, paraffin, etc., have been added. To prevent these substances permeating the powder and retarding its rate of combustion, a protecting film may be produced on the surface of the powder by adding substances such as starch, tragacanth, or gum arabic, which are insoluble in the nitroglycerin or nitro-compound, before introducing the other organic materials.—W. J. W.

Liquid air explosives; Manufacture of ——. Westfälische Berggewerkschaftskasse. G.P. 300,728, 7.1.16.

IN the preparation of liquid air explosives, cork meal constitutes a suitable ingredient, inasmuch as it can absorb 6·7—7 times its weight of liquid oxygen and does not consume much oxygen on detonation. Liquid air explosives containing cork meal retain their sensitiveness to detonation for a longer period than those in which the absorbent consists of wood meal.—W. J. W.

Liquid air explosives; Manufacture of ——. B. Diamand. G.P. 304,300, 1.6.17.

LIQUID hydrocarbons or their compounds are absorbed by, or crystallised in, moss or peat, which is then impregnated with liquid air or oxygen. Both moss and peat retain their elasticity even after absorption of the hydrocarbons, and are therefore readily formed into cartridges.—W. J. W.

Detonating compositions containing lead azide and nitro-compounds. W. Eschbach. G.P. 305,100, 1.1.18.

INFUSORIAL earth, or powdered asbestos, is added to lead azide compositions. Explosives obtained by this means are especially suitable for detonating cartridges which have been steeped in liquid oxygen.—W. J. W

Gunpowder and smokeless powder; Manufacture of an explosive consisting of a mixture of ——. Claessen. G.P. 308,538, 5.1.18.

A MIXTURE of gunpowder and smokeless powder consisting of nitroglycerin and nitrocellulose is less hygroscopic and leaves a smaller residue on combustion than ordinary gunpowder; such an addition to gunpowder therefore ensures more regular combustion.—W. J. W.

Chlorate explosives; Manufacture of granulated ——. Fürstlich Plessische Miedziankitfabrik. G.P. 307,100, 29.11.17.

SULPHITE-CELLULOSE waste liquors are added to the other ingredients of chlorate explosives, the moist mass being subsequently forced through sieves and dried. The granular explosive thus produced has a high efficiency.—W. J. W.

Signals; Mixtures for light and smoke ——. A. Lang. G.P. 307,610, 8.5.17. Addn. to 265,656 (J., 1913, 1169).

THE mixtures described in the original patent as suitable for exterminating plant pests may be adapted for use in signals by the addition of light- and smoke-producing substances, *e.g.*, metallic powders, such as lead or zinc, or compounds of cadmium and arsenic. Such mixtures will burn even in water.—W. J. W.

Explosive propellants. O. Silberrad. E.P. 150,002, 11.8.20. Conv., 21.8.19.

SEE U.S.P. 1,349,983 of 1920; J., 1920, 676 A.

XXIII.—ANALYSIS.

Zinc; Volumetric estimation of ——. I. M. Kolthoff and J. C. van Dijk. Pharm. Weekblad, 1921, 58, 538—553.

THE mercury double thiocyanate method is found to be best. The reagent is prepared by dissolving 1 mol. of mercuric nitrate in 4 mols. of potassium thiocyanate, and is added in excess to the zinc solution. The whole is made up to a known volume and filtered, and the excess of reagent titrated in an aliquot part of the filtrate by means of mercuric nitrate, using iron alum as indicator. (*Cf.* J.C.S., June.)—S. I. L.

Cobalt; Nitroso-R-salt, a new reagent for the detection of ——. H. S. van Klooster. J. Amer. Chem. Soc., 1921, 43, 746—749.

NITROSO-R-SALT gives an intense red coloration or precipitate with cobalt salts, by means of which 1 pt. of cobalt may be detected in presence of 200 pts. of nickel. The salt is prepared by the action of nitrous acid on sodium 2-naphthol-3.6-disulphonate. The test is carried out as follows: To 2 c.c. of a dilute solution of the salt to be tested (1·5—2·0 g. in 100 c.c. of water) is added 1 g. of sodium acetate and 2 c.c. of nitroso-R-salt solution (0·5 g. in 100 c.c. of water). The liquid is boiled over a small flame and after the gradual addition of 1 c.c. of nitric acid (sp. gr. 1·4) the boiling is continued for at least 1 min. A permanent change in colour towards red indicates the presence of cobalt. The colours produced by other metals are destroyed by the nitric acid. It is essential that the original solution should not be acid, for this retards and may prevent the formation of the red coloration. (*Cf.* J.C.S., June.)—J. F. S.

Arsenic reduction tube; Electrically heated ——. K. Zwicknagl. Chem.-Zeit., 1921, 45, 418.

THE tube of a Marsh apparatus is heated by means of a length of resistance wire wound round it and insulated with asbestos-paper. To ensure better contact of the gases with the heated wall of the tube the latter is flattened so that its cross section is about 2×14 mm.—W. P. S.

Hydrogen ion concentration; Colorimetric determination of —— in small quantities of fluid. L. D. Felton. J. Biol. Chem., 1921, **46**, 299—305.

DROPS of indicator solutions are mixed on a porcelain plate with drops of the solution to be examined and with drops of known buffer mixtures respectively. (*Cf.* J.C.S., June.)—G. B.

Protein analysis; Modification of the Van Slyke method of ——. P. Menaul. J. Biol. Chem., 1921, **46**, 351—352. (*Cf.* J., 1911, 1135.)

THE humin is precipitated with phosphotungstic acid instead of with calcium oxide. (*Cf.* J.C.S., June.)—G. B.

Chlorine, sulphur, and phosphorus in organic substances; Determination of ——. A. Grégoire and E. Carpiaux. Bull. Soc. Chim. Belg., 1919, **28**, 331—335.

THE method, which is designed for use with plant products, consists in digesting the material with concentrated nitric acid and a little potassium permanganate in a distillation flask, the exit tube from which passes through a short condenser. At its lower end the exit tube is connected with the absorption device, which consists of two inclined tubes, 18—22 mm. diam., and about 1 m. long, arranged crosswise and joined by a connecting tube. To improve the contact between the absorbent and the vapours, pieces of glass tubing are placed in the inclined tubes, each piece being drawn out at one end which projects into the end of the next higher piece of tubing. The sulphur and phosphorus remain in the distillation flask as sulphuric and phosphoric acids, whilst the chlorine distils off along with nitrous fumes, and is collected in water as hydrochloric acid. The three acids are then estimated in the usual way.—W. G.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Brettell (Soc. Anon. les Ateliers Réunis). Pulverisers and crushing-mills. 14,499. May 25.

Broadbent, Claughton, Hamilton, Jack, and Smith. Clarification of waste lubricants etc. 14,607. May 26.

Burden. Reducing or disintegrating machines. 14,848. May 28.

Gregory. Extinguishing-fluids. 15,127. May 31.

Minerals Separation, Ltd., and Williams. 14,812. *See* X.

Möller. Apparatus for separating suspended bodies from gaseous fluids etc. 15,118. May 31. (Ger., 31.7.14.)

Pohlmann. Method of operating refrigerating-plants. 15,200. June 1. (Ger., 4.6.20.)

Rhodes. Barrel filter. 14,486. May 25.

Rigby. Heating or cooling liquids or admixed solids and liquids in evaporative etc. treatment. 14,599. May 26.

Sturgeon. Centrifugal separators. 15,038. May 31.

Williams. Tunnel ovens. 15,120. May 31.

COMPLETE SPECIFICATIONS ACCEPTED.

2242 (1920). Conder and Vivian. Crushers with vibrating jaws. (163,750.) June 8.

2243 (1920). Conder and Vivian. Roller mills. (163,751.) June 8.

3895 (1920). Josse and Gensecke. Evaporation of liquors. (138,871.) June 1.

5558 (1920). Testrup, and Techno-Chemical Laboratories, Ltd. Evaporating or distilling apparatus. (163,793.) June 8.

5860 (1920). Fuller-Lehigh Co. Pulverising-mills. (139,511.) June 1.

7189 (1920). Soc. l'Air Liquide. Apparatus for carrying out exothermic chemical reactions under high temperatures and pressures. (140,089.) June 8.

8228 (1920). Ely. Rotary furnaces. (163,543.) June 1.

8247 (1920). Read. Pulverising-machines. (163,856.) June 8.

10,387 (1920). Vanneau. Grinding or crushing apparatus. (141,721.) June 1.

11,927 (1920). Grondal. Apparatus for lixiviating granular or pulverulent material. (142,493.) June 8.

18,646 (1920). Stumpf. Heating and purifying boiler feed-water. (146,522.) June 8.

23,317 (1920). Alexander (Best). *See* II.

31,616 (1920). Velten. Apparatus for separating materials of different specific gravity. (155,570.) June 1.

35,921 (1920). Soc. d'Utilisation des Combustibles Pulverisés. Rotary drying-apparatus. (163,653.) June 1.

6986 and 6988 (1921). Kennedy. Gyratory crushing-apparatus. (160,463 and 160,465.) June 1.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Beasley, Stenning, and Minerals Separation, Ltd. Production of coal briquettes. 15,066. May 31.

Benjamin and Treneer. Purification of hydrocarbons. 15,080. May 31. (U.S., 4.6.20.)

Clabaut and Coureyeur. Gas-generators. 15,248. June 1. (Fr., 11.6.20.)

Cunningham and Stern. Production of water-gas. 15,001. May 30.

Helps. Manufacture and distribution of gas. 14,605 and 14,725. May 26 and 27.

Illingworth. Coking coal. 14,676. May 26.

Klee. 15,458. *See* XXIII.

Maclaurin. Water-gas plant. 15,203. June 1.

Marshall. Retorts for treating carbonaceous etc. materials. 14,472. May 24.

O'Byrne. Recovery and preparation of peat, turf, etc. for fuel etc. 14,428. May 24.

Piron. Regenerative coke-ovens. 15,363. June 2.

Poore. Destructive distillation of wood etc. 14,820. May 27.

Rigby. Heat-regenerating systems of gas-producer plants etc. 14,598. May 26.

Shields (Mine Safety Appliance Co.). Gas-purifying compositions, and their production. 15,330. June 2.

Tully. Manufacture of gas for heating and lighting. 15,254. June 1.

Umpleby. Gas producers and/or retorts. 14,276. May 23.

Complete Specifications Accepted.

6426 (1919). McLeod. Apparatus for carbonising and distilling moist carbonaceous materials. (163,343.) June 1.

18,151 (1919). Dalley (Greenway). Distillation or cracking of hydrocarbon oils. (163,347.) June 1.

28,614 (1919). Illing and Kelly. Treatment of petroleum etc. (163,363.) June 1.

6235 (1920). Williams, Francis, and Bynea Steel Works, Ltd. Gas-producers. (163,513.) June 1.

6509 (1920). Fyleman. Separation of mineral oils etc. from sand or rock. (163,519.) June 1.

8955 (1920). International Coal Products Corp. Manufacture of carbonised fuel briquettes. (140,821.) June 8.

17,613 (1920). Nasspress Ges. Utilising coal slimes. (146,264.) June 8.

19,151 (1920). Meyer. Carbonising solid fuels in a circulating current of gas. (147,117.) June 8.

19,308 (1920). Otto u. Co. Coke-ovens. (147,229.) June 1.

19,310 (1920). Otto u. Co. Coke-ovens. (147,231.) June 8.

19,512 (1920). Collin A.-G. Recovery of by-products from fuel gases. (147,633.) June 1.

20,608 (1920). Riedel. Recovery of nitrogen contained in fuel. (148,784.) June 8.

23,317 (1920). Alexander (Best, Inc.). Oxidation of finely subdivided material, and combustion apparatus therefor. (162,623.) June 1.

2833 (1921). Illing and Kelly. Production of asphalt from petroleum etc. (163,656.) June 1.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Bowler. Decorticating-machine and chemical apparatus for treating palm fibres. 14,374. May 24.

Brodie. Treatment of esparto grass, fibrous material, etc., for manufacture of paper. 15,205. June 1.

Budde, and Hendon Paper Works Co. Manufacture of hydro-oxycellulose, a new xanthogenated compound therefrom, etc. 14,852. May 28.

Dreaper. Spinning filaments of artificial silk. 14,256. May 23.

Dreyfus. Coating or treating surfaces etc. 14,802. May 27.

Dreyfus. 14,861. *See* IX.

Complete Specifications Accepted.

999 (1920). Braun. Manufacture of cellulose. (137,831.) June 1.

3916 (1920). Fearnley. Manufacture of paper. (163,421.) June 1.

4693 (1920). Braun. Manufacture of cellulose. (139,171.) June 1.

4877 (1920). Bronnert. Manufacture of viscose silk. (163,466.) June 1.

5983 (1920). Bronnert. Manufacture of viscose silk. (163,817.) June 8.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Calico Printers' Assoc., Ltd. Printing variegated effects on fabrics etc. 15,414. June 3.

Charlesworth. Dyeing processes. 15,482. June 4.

Silbereisen. Apparatus for continuous scouring, dyeing, etc. of fabrics in the piece. 14,441. May 24. (Fr., 2.3.21.)

Complete Specifications Accepted.

5188 (1920). King and Haines. Bleaching and bleaching compounds. (146,078.) June 1.

14,820 (1920). Poulson. Sizing textile fabrics etc. (163,915.) June 8.

1343 (1921). Krantz. Dyeing yarn on bobbins in circulating dye liquor. (157,418.) June 8.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Casale and Leprestre. Apparatus for catalytic synthesis of ammonia. 14,459. May 24.

Elektrizitätswerk Lonza. Treatment of residuary ammonium chloride lyes. 14,900. May 28. (Switz., 29.5.20.)

Evershed and Gitsham. Manufacture of sulphate of lead. 15,078. May 31.

Griffith. Schlippe's salt etc. 14,920. May 30.

Heenan and Froude, Ltd., and Walker. Concentration of brine. 14,501. May 25.

Jourdan. Ammonia-soda process. 15,426. June 3. (Ital., 3.6.20.)

Wright and Wright. Production of ammonium salts and coloured pigments. 15,023. May 31.

Complete Specifications Accepted.

9994 (1920). Phillips. Manufacture of readily soluble alkali silicates. (163,877.) June 8.

15,458 (1920). Badische Anilin u. Soda Fabrik. *See* XVI.

20,566 (1920). Jaubert. Apparatus for purifying hydrogen or oxygen. (148,564.) June 1.

VIII.—GLASS; CERAMICS.

Applications.

Atkinson, and Stein and Atkinson. Drying china clay, etc. 15,304. June 2.

Deussing. Production of artificial meerschaum. 14,592. May 25. (Ger., 7.6.20.)

Techno-Chemical Laboratories, Ltd., and Testrup. Manufacture of china clay. 14,992. May 30.

Complete Specifications Accepted.

5597 (1919). Gowen. Manufacture of refractory materials. (124,208.) June 1.

25,262 (1920). Festa. *See* X.

IX.—BUILDING MATERIALS.

Applications.

Dreyfus. Treatment of wood, paper, etc. 14,861. May 28.

Hawes. Substitute for wood etc. 14,782. May 27.

Complete Specifications Accepted.

26,280 (1919). Dale. Concrete etc. (163,731.) June 8.

4337 (1920). Mattison. Manufacture of fibrous cement products. (138,921.) June 1.

4398 (1920). Lewis. Continuous kilns for burning bricks etc. (163,439.) June 1.

4890 (1920). Brothers. Manufacture of plaster of Paris. (163,468.) June 1.

10,302 (1920). Milner and Robinson. Manufacture of bricks, blocks, etc. from blast-furnace slag. (163,569.) June 1.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Alloy Welding Processes, Ltd., and Jones. Electrodes, welding rods, and soldering sticks. 15,435. June 3.

Aymard. Treatment of silica-bearing ores. 14,946. May 30.

Jones, and Sylvette, Ltd. Nickel alloys. 14,603. May 26.

Loke. Direct reduction of titanic-iron ores or slags. 14,813. May 27.

Marshall. Anticorrosive and antifouling composition for metals. 15,174. June 1.

Minerals Separation, Ltd., and Williams. Prevention of dusting of powdered minerals. 14,812. May 27.

Thompson (Aikens). Electrolytic refining of tin. 15,047. May 31.

Turner. Production of carbon-free ferromolybdenum. 15,179. June 1.

Wardall. Aluminium alloys. 14,544. May 25.

Complete Specifications Accepted.

19,015 (1919). Niiranen and Hibbert. Recovery or separation of metals. (163,348.) June 1.

7139 (1920) Irons. Manufacture of steel. (163,526.) June 1.

8468 (1920). Grondal. Apparatus for use in concentrating ores etc. (140,775.) June 1.

9136 (1920). Rustproofing Syndicate, Ltd., and Newman. Metal pickling or cleaning. (163,868.) June 8.

9250 (1920). Vermaes, and Syndicaat Electro-Staal. Manufacture of iron from iron ores. (163,561.) June 1.

10,302 (1920). Milner and Robinson. *See* IX.

17,393 (1920). Krupp A.-G. Production of low-carbon and low-silicon ferrochromium. (145,711.) June 8.

20,131 (1920). Zelewski. Zinc-extracting furnaces with vertical retorts. (148,210.) June 1.

20,181 and 20,200 (1920). Dagory. Removal of copper deposit from the bores of guns. (148,250 and 148,263.) June 8.

22,562 (1920). Lavandeyra. Aluminium alloys. (149,638.) June 8.

25,262 (1920). Festa. Furnaces for fusing steel and other metals, baking ceramic products, refractory materials, etc. (155,231.) June 1.

5614 (1921). Brown, Boveri & Co. *See* XI.

6417 (1921). Passalacqua. Soldering aluminium or aluminium alloys. (159,480.) June 1.

XI.—ELECTRO-CHEMISTRY.

Applications.

Alloy Welding Processes, Ltd., and Jones. 15,435. *See* X.

Boite, Edridge, and Lyto, Ltd. Galvanic batteries or cells. 14,302. May 23.

Chloride Electrical Storage Co., Ltd., and Heap. Secondary electric batteries. 14,571. May 25.

Loke. Electric etc. furnaces. 14,814. May 27.

Philippart. Electric accumulators. 14,543. May 25. (Fr., 31.5.20.)

Rennerfelt. Electric furnaces. 14,702. May 26. (Sweden, 2.6.20.)

Thompson (Aikens). 15,047. *See* X.

Complete Specification Accepted.

5614 (1921). A.-G. Brown, Boveri & Co. Electrically heated muffle furnaces. (159,195.) June 1.

XII.—FATS; OILS; WAXES.

Applications.

Bolton and Lush. Recovery of oil from and purification of fuller's earth, charcoal, etc. for re-use in oil refining. 14,413. May 24.

Krebitz. Separating saponaceous matter from lime sludge. 15,428. June 3.

COMPLETE SPECIFICATION ACCEPTED.

23,957 (1919). Bolton and Lush. Conversion of fatty acids or oils, or fats containing free fatty acids, into glycerides. (163,352.) June 1.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Clarke, and Cookson and Co. Manufacture of paints and enamels. 14,956. May 30.

Macpherson. Preparation of pigments from titaniferous laterites. 15,308. June 2.

Pearson. Treatment of acaroid resins. 14,753. May 27.

Wright and Wright. 15,023. *See* VII.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Abrey. Plastic material made from casein. 14,948. May 30.

Carmichael and Ockleston. Tanning. 14,943. May 30.

Glover and Martin. Preparation of chrome tanning agent. 14,654. May 26.

COMPLETE SPECIFICATIONS ACCEPTED.

20,665 (1919). Serle. Production of casein cements. (163,349.) June 1.

5690 (1920). Melamid. Manufacture of artificial tanning substances. (147,534.) June 8.

13,006 (1920). Bayerische Maschinenfabr. Regensburg. Rotary tanning and fulling drums. (143,228.) June 1.

19,964 (1920). Korn. Production of a substitute for leather etc. (147,910.) June 8.

XVI.—SOILS; FERTILISERS.

COMPLETE SPECIFICATIONS ACCEPTED.

28,304 (1919). Wolf and Fry. Manures. (163,359.) June 1.

3687 (1920). Sams. Manure and method of making same. (163,417.) June 1.

15,458 (1920). Badische Anilin u. Soda Fabrik. Transforming ammonia into a salt for use as a fertiliser. (144,659.) June 8.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATIONS.

Classen. Manufacture of sugar from wood etc. 15,249. June 1. (Ger., 4.6.20.)

Petree. Manufacture of sugar. 15,457. June 3.

COMPLETE SPECIFICATIONS ACCEPTED.

16,322 (1920). Patterson. Manufacture of syrups and sugar. (163,924.) June 8.

22,021 (1920). Tavroges, Roche, and Martin. Purification of crude lactose. (163,937.) June 8.

XVIII.—FERMENTATION INDUSTRIES.

COMPLETE SPECIFICATION ACCEPTED.

28,594 (1919). Meyer. Production of yeast. (144,244.) June 8.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Atkinson, and Stein and Atkinson. Destruction of refuse. 15,305. June 2.

Howles. Insecticides, fruit washes, etc. 15,413. June 3.

Nielsen. Sterilising milk. 15,136. May 31.

Torrance. Manufacture of chocolate or cocoa products. 15,514. June 4.

COMPLETE SPECIFICATIONS ACCEPTED.

5707 (1920). Haddan (Naaml. Vennoots. Algem. Norit Maatsch.). Treating large quantities of liquids with purifying reagents in a continuous manner. (163,505.) June 1.

8310 (1920). Horlick. Food compound. (140,472.) June 8.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Farbw. vorm. Meister, Lucius, u. Brüning. Manufacture of methylsulphites of secondary aromatic-aliphatic amines. 14,986. May 30. (Ger., 31.5.20.)

Goodyear Tire and Rubber Co. Process of making thioureas. 15,088. May 31. (U.S., 5.6.20.)

Peufaillit. Industrial preparation of derivatives of bornyle for preparing synthetic camphor. 15,441. June 3. (Belg., 10.1.21.)

COMPLETE SPECIFICATIONS ACCEPTED.

9667 (1920). Imray (Soc. Chem. Industry in Basle). Manufacture of mercury compounds of glucosides. (163,874.) June 8.

15,621 (1920). Du Pont de Nemours and Co. Production of tetra-substituted ureas. (144,681.) June 8.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Davies. Manufacture of photographic papers. 14,549. May 25.

Griffith. 14,920. *See* VII.

XXII.—EXPLOSIVES; MATCHES.

COMPLETE SPECIFICATION ACCEPTED.

25,486 (1920). Lundsgaard. Explosives. (163,946.) June 8.

XXIII.—ANALYSIS.

APPLICATIONS.

Hedley. Gas combustion furnaces for organic analysis. 14,262. May 23.

Kleo. Apparatus for determining flash points of oils etc. 15,458. June 3.

COMPLETE SPECIFICATION ACCEPTED.

14,621 (1920). Svenska Aktiebolaget Mono. Apparatus for use in analysing gas mixtures. (143,918.) June 8.

I.—GENERAL; PLANT; MACHINERY.

Evaporation of water and aqueous solutions; Use of the heat pump [steam compressor] in the ——. H. Claassen. Z. angew. Chem., 1921, 34, 233—235.

The compression of the steam, generated by the evaporation of solutions, so as to render it utilisable for heating the evaporators, demands considerable expenditure of power for driving the compressor, and an additional disadvantage lies in the fact that a large amount of exhaust steam from the compressor itself has to be disposed of. With weak solutions a saving of steam is effected only by linking the compressor to the first effect of a multiple-effect evaporator system; with more concentrated solutions and steam at higher pressure compression offers no advantage. A piston-compressor gives better results than a centrifugal compressor, but the oil which is carried over diminishes the transmission of heat. Steam jet compressors are preferable. Taking into account the high power-consumption of compressors, their use does not tend to economise the process of evaporation, unless a natural source of power, such as water, is available.—W. J. W.

Suspensions; Viscosity and flocculation of coarse ——. H. Egnér. Medd. K. Vetenskapsakad. Nobel-Inst., 1920, 4, [1], No. 4.

The viscosity formula of Arrhenius (Medd. Nobel-Inst., 1916, 3, No. 13) does not hold for suspensions of china clay and infusorial earth; it was not possible to test it with suspensions of graphite. The empirical formula of Bingham and Durham (Amer. Chem. J., 1911, 46, 278) holds good in some ases but not in others. The effect of electrolytes n the state of coarse suspensions is very large. Cations flocculate and increase the viscosity and edimentation height. Anions act in the opposite irection. The magnitude of the flocculating ower generally follows the valency rule, but ydroxide ions often act irregularly. The properies of suspensions are very similar to those of uspension colloids.—J. R. P.

afety device for electric installations. Grempe. *See* XI.

till-heads. Moore. *See* XXIII.

Patents.

vaporation of liquors; Method of effecting —— and apparatus therefor. E. Josse and W. Gensecke. E.P. 138,871, 9.2.20. Conv., 27.2.15.

HE liquor is evaporated *in vacuo*, and the vapour ising therefrom is compressed by means of a lower and then used for heating the liquor be evaporated. The residual mixture of heated apour and air is cooled to a low temperature by eans of a condenser, and uncondensable gases are moved by the vacuum pump in the installation. he process is made continuous by removing the quor at the bottom of the evaporator and using it an atomised state to heat the compressed and eated vapour.—H. R. D.

vaporators [; Heating element for ——]. G. Bonsignori. E.P. 162,877, 12.3.20.

a concentric twin-tube heating element for aporators, a conical plug, held in the header castg by a single nut, secures both the inner and the ter tubes, and provides communication to approiate passages in the header.—B. M. V.

Grinding or crushing apparatus. J. M. C. Vanneau. E.P. 141,721, 14.4.20. Conv., 9.11.17.

In a disc grinder the grooves in the plates are of "logarithmic" spiral form, and decrease in depth outwardly. Grooves of other form may run into the main grooves.—B. M. V.

Grinding, crushing, or disintegrating machines. C. E. V. Hall. E.P. 163,064, 25.6.20.

In a disintegrator of the type in which a number of swinging bars rotate inside a revolving cage, the circumferential bars of the cage are of non-circular section so that by partial rotation of each in its support the distances between the bars may be varied. The swinging motion of the beater bars is kept within limits by projections on the driving boss or by providing their pivoted ends with flat faces.—B. M. V.

Heterogeneous mixtures; Devices for separating the constituent parts of ——. A. Müller. E.P. 146,283, 28.6.20. Conv., 10.2.19.

The material is treated with a separating liquid, and the constituents which separate in the liquid at various levels are removed by two or more separate conveyors extending to different depths. —B. M. V.

Incrustation on the walls of steam boilers, feed water heaters and the like; Prevention or reduction of —— by electrical means. Siemens u. Halske A.-G. E.P. 147,528, 8.7.20. Conv., 2.1.19.

Alternating current or three-phase current derived from the transformation to low voltage of a supply at customary voltage is supplied to electrodes immersed in the water. The electrodes may be subdivided and the wall of the boiler connected with a neutral point of the supply circuit. —J. S. G. T.

Inflammable liquids; Method of protecting —— from fire. Martini und Hüneke Maschinenbau-A.-G. E.P. 147,622, 8.7.20. Conv., 23.9.16.

The inflammable liquid is placed under an atmosphere consisting of the exhaust gases from internal combustion engines, from which oxides of sulphur and nitrogen have been removed.—B. M. V.

Separating solid substances from gases and vapours, more especially furnace gases; Metallic filter for ——. E. Dänhardt. E.P. 148,795, 10.7.20. Conv., 26.10.18.

A metallic filter has a layer of uncompacted mineral fibre (*e.g.*, asbestos, slag wool) upon one side only, preferably on the inlet side.—B. M. V.

Emulsions; Apparatus for making ——. G. Mitchell. E.P. 162,719, 30.12.19.

The material to be emulsified, *e.g.*, castor seeds, is fed with water into a masticating chamber provided with a narrow discharge outlet at its outer edge and divided into compartments extending from the inlet to the discharge edge with gradually diminishing depth as the outlet is approached. The chamber comprises two plates, preferably conical, capable of relative movement, and the compartments are constituted by corrugations on the inner face of one or both plates disposed obliquely to the direction of the movement. The corrugations extend between volute ribs formed on one plate, and of a depth to contact with the other plate. The emulsion is discharged into an annular trough sloping to an outlet.—H. H.

Heating furnaces; Utilisation of combustible gases for —— and for other purposes. H. A. Williams. E.P. 162,802, 5.2.20.

The flue gases from a furnace are caused to pass

▲

through a liquid seal in the flue, whereby a higher temperature in the furnace is attainable. The liquid in the seal may be held at a constant level by automatic devices.—B. M. V.

Kilns; Rotary ——. S. J. Vermaes, and Syndicaat Electrostaal. E.P. 163,175, 15.3.20.

In a rotary kiln the heat is supplied by gases of combustion in helical passages in the walls of the kiln, and the air for combustion may be preheated by passing it through other passages exterior to the gas passages. The gas for combustion may sometimes be derived from the reacting materials in the kiln (*e.g.*, carbon monoxide from iron ore and carbon). In the latter case the inlet ends to the heating channels are at the charging end of the kiln, and any ore that may drop into the annular chamber connecting the heating channels and reaction chamber of the kiln is lifted out by cups formed in the annular channel and caused to drop back into the kiln. The joint between the fixed and rotating part may be water-cooled, and a fixed or rotating scraper may be provided inside the kiln to remove adhering material from the crown. —B. M. V.

Tunnel kilns; Means for cooling ——. J. B. Owens. U.S.P. 1,377,522, 10.5.21. Appl., 30.12.19.

Flues in which air is circulated are built in the walls at the level of the space below the conveyor for the material under treatment.—B. M. V.

Disintegrating fused materials; Apparatus for ——. A. Losey. E.P. 162,909, 20.4.20.

The molten material falls from a small aperture in the melting vessel, which may be provided with a reciprocating needle to cause the formation of drops, through a vertical tube and then on to a ball or plate, rotating upon a vertical axis, which scatters the material into a chamber containing water or other cooling liquid. The impact ball may be heated electrically, and the vertical tube may be kept full of a gas neutral to, or capable of reacting with, the material being granulated. —B. M. V.

Refrigerating machines. F. C. Stockel. E.P. 163,360, 17.11.19.

In refrigerating machines in which water is caused to boil at a low temperature by means of a high vacuum, and the vapour absorbed in a liquid, such as sulphuric acid, the refrigerating chamber, absorbing chamber, and pump cylinder all revolve together, the piston of the pump being prevented from rotating by straight grooves in the fixed stand and being reciprocated by cam grooves attached to the rotating part.—B. M. V.

Syphon apparatus [; Automatic restarting ——]. K. Hickman, and The Imperial Trust for the Encouragement of Scientific and Industrial Research. E.P. 163,381, 19.12.19.

A siphon for keeping the liquid, in, *e.g.*, a washing tank, at a constant level is kept primed either by by-passing a little of the incoming washing liquid down a narrow tube with a loop in it attached to the long leg of the main siphon, so that air is drawn in at the upper end of the tube from the highest point of the main siphon, or by passing the incoming washing liquid through an ejector drawing air from the same place. In either case a liquid sealing cup is provided at the bottom of the long leg.—B. M. V.

Liquids; Process and apparatus for treating large quantities of —— *with purifying agents in a continuous manner.* A. J. H. Haddan. From Naaml. Vennoots. Algem. Norit Maatschappij (General Norit Co.). E.P. 163,505, 25.2.20.

The liquid to be treated is passed continuously through a mixing cylinder or a series of mixing cylinders containing the finely-divided purifying material (decolorising carbon, kieselguhr, or the like). The liquid and purifying agent are thoroughly mixed, particles carried away mechanically are retained by a filter device within the apparatus, and the deposited material removed and brought back mechanically to where it is again mixed with the liquid under treatment. The purifying material can be used in relatively large quantities, and so exercise its absorptive properties on comparatively small amounts of liquid at a time, whereby a degree of exhaustion of the material can be reached, which otherwise would be practically impossible.—H. R. D.

Oxidation of finely sub-divided material and combustion apparatus therefor. A. E. Alexander. From W. N. Best, Inc. E.P. 163,623, 9.8.20.

Finely subdivided solid material, *e.g.*, coal-dust, culm, copper, falls by gravity through a fan-shaped flame of liquid fuel atomised by a gaseous medium into a combustion chamber, so that the solid material is highly heated and the combustible portion completely oxidised.—H. R. D.

Drying materials, especially leather, by means of gases; Apparatus for ——. J. L. Fairrie. U.S.P. 1,371,083, 8.3.21. Appl., 6.11.20.

A current of air heated to a definite temperature is passed through the drying chamber and by means of a wet-bulb thermometer connected with a relay which operates a D-slide valve, a portion of the moist air leaving the drying chamber is mixed with the atmospheric air entering the dryer in order to regulate the humidity of the drying air.—D. W.

Drying apparatus for wood-pulp and other matters. J. D. Ullgren. U.S.P. 1,376,659, 3.5.21. Appl., 25.9.18.

The material is caused to travel through a channel provided with end inlets for drying air and with intermediate outlets for the air. Oblique deflectors are provided at the inlets, and the air is exhausted through the outlets and then forced through the inlets.—H. H.

Dehydrator. H. B. Hartman, Assr. to Electric Water Sterilizer and Ozone Co. U.S.P. 1,376,691, 3.5.21. Appl., 24.1.20.

A dehydrator includes a tubular chamber divided by transverse partitions, each having a central opening. Moisture-absorbing material is arranged in spaced strata in the chamber, and a baffle extending close to the wall of the chamber is disposed between each stratum and the opening in the adjacent partition.—H. H.

Drying apparatus. H. B. Lowden. U.S.P. 1,377,896, 10.5.21. Appl., 7.1.20.

An apparatus for carrying out the process described in U.S.P. 1,339,771 (J., 1920, 476 A).—H. H.

Dryer. W. M. Schwartz, Assr. to The Philadelphia Textile Machinery Co. U.S.P. 1,377,793, 10.5.21. Appl., 20.10.19.

A drying chamber contains a series of rotating perforated cylinders within each of which is fitted a segmental guard. Suction is induced within each cylinder, and the material is fed to the surface of the first cylinder, on which it is held by the suction until this is cut off by the guard, whereupon it is transferred to the second cylinder, and so on until finally discharged.—H. H.

Drying compressed gases; Method of and apparatu for ——. W. Wilkinson, Assr. to Air Reductio Co. U.S.P. 1,376,985, 3.5.21. Appl., 15.10.20.

The greater part of the moisture is separated b cooling the gas by a counter-current of preceding portions of the gas, and the separated moisture is withdrawn while the gas is thus cooled. A current of additional cooling medium is used to compensate for heat derived from the atmosphere and from the condensation of the moisture.—H. H.

Furnace gases; Method of recovering water-soluble material from ——. F. S. Moon, Assr. to International Precipitation Co. U.S.P. 1,377,363, 10.5.21. Appl., 5.7.18.

Hot furnace gases are passed in contact with a flowing stream of liquid in which a suspended constituent of the gas is soluble, in such a manner as to collect in the liquid suspended constituents of the gases. A "retarder" is added to the liquid to prevent an incrustation forming on the surface over which the liquid flows. The insoluble matter is separated from the liquid, which is then returned to the flowing stream. The water-soluble matter is subsequently recovered from the liquid.—H. S. H.

Generating gases and treating solutions therewith; Apparatus for ——. H. R. Hanley. U.S.P. 1,377,478, 10.5.21. Appl., 13.11.19.

A partial vacuum is maintained in the gas generator of the system described in U.S.P. 1,360,524 (J., 1921, 72 a).—B. M. V.

Compounding of solids with gases or solids with solids and gases, including fertilisers, and apparatus therefor, and the products resulting therefrom; Electrical treatment in ——. J. E. Bloom. U.S.P. 1,377,553, 10.5.21. Appl., 6.2.20.

The solids are dried and powdered, and the resulting powder and the gases are charged respectively to different potentials with charges of opposite signs. The whole is then compounded in the absence of air while insulated, the solids being suspended and moving in the gases.—J. S. G. T.

Filling material for washing, absorption, and reaction towers and the like. R. Wussow and E. Schierholz. G.P. 332,388, 23.10.18.

The filling consists of triangular strips made into rolls of approximately conical shape, which are placed promiscuously in the absorption tower or the like.

Displacement of liquids in substances by other liquids; Process and apparatus for ——. Purification and concentration of aqueous colloidal solutions by means of the electric current. Elektro-Osmose A.-G. (Graf Schwerin Ges.). G.P. (a) 335,108, 20.6.18, and (b) 333,575, 12.9.19.

(a) The material is freed from the greater part of its liquid content by being submitted to suction, and if necessary to excess pressure when spread out in the form of a uniform layer of sludge on a permeable support, and is then compressed mechanically, pneumatically, or by means of hydraulic power into a form suitable for submitting it to a mechanical or electro-osmotic process for the displacement of the remaining fluid. (b) A suitable acid or base is added to the solution to be treated, according to the desired direction of transport of the water, prior to the solution being submitted to the action of the electric current between diaphragms. Alternatively, the solution may be rendered free of electrolyte prior to being so treated. The solution is passed from a storage tank into the middle compartment of a three-chamber electro-osmotic device wherein it is treated by electro-osmosis and submitted to the action of washing fluid. In general the acidity or alkalinity of the solution to be treated is adjusted so as to correspond to $N/10$ acid or alkaline solution respectively.
—J. S. G. T.

Separation of the constituents of gaseous mixtures liquefiable at very different temperatures. L'Air Liquide, Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude. E.P. 136,837, 17.12.19. Conv., 4.2.14.

See F.P. 475,297 of 1914; J., 1916, 31.

Pulverising mills. Fuller-Lehigh Co., Assees. of J. W. Fuller. E.P. 139,511, 26.2.20. Conv., 27.8.17.

See U.S.P. 1,358,837 of 1920; J., 1921, 2 a.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Transformation of —— into oils by hydrogenation. I. Hydrogenation of coal and other solid fuels by means of sodium formate. F. Fischer and H. Schrader. Brennstoff-Chem., 1921, 2, 161—173.

Coal is little affected by heating with molecular hydrogen under pressure. If heated with sodium formate, the nascent hydrogen liberated by the decomposition of the latter has a marked effect on coal, peat, and fresh plant substances. A portion of the product of hydrogenation consists of oils soluble in ether. The research was mainly carried out with a Rhine lignite (Union briquettes), but coal, peat, wood, and other substances were also tried with favourable results. The lignite gave on dry distillation at 400° C. about 7% of its weight of tar reckoned on the ash-free fuel. On repeating with a mixture of lignite with 4 times its weight of sodium formate the yield rose to 23—27%. The yield was still further increased by heating in an autoclave under the pressure of the steam and gases formed during heating; in this case, with double its weight of sodium formate the lignite yielded 45% of tar, and with 8 times its weight 48%. Added water had no effect on the yield. The best temperature appeared to be 400° C. With coal the yield of tar diminished with the age of the coal, varying from 39% with flaming gas coals to 1·61% with anthracite. Lignites gave 27%—45%, peat, wood, cellulose, and lignin 13%—24% of tar. Dry distillation of the coal after treatment with hydrogen gave a yield similar to that obtained by ether extraction.—W. P.

Lignite, peat, and bituminous shale; Separation of wax, resin, and bitumen from ——. A. Grün and E. Ulbrich. Seifenfabr., 1920, **40**, 773—775. Chem. Zentr., 1921, **92**, II., 998.

Finely divided lignite or the like which has been vigorously agitated as a paste for 1—2 hrs., with a mineral acid, such as waste hydrofluoric acid or sulphuric acid at 100°—120° C., then washed with water to remove the acid and dried, gives a better yield of wax, resin, etc., on subsequent extraction with an organic solvent, such as benzene, toluene, xylene, or a mixture of benzene and petroleum spirit, than untreated material.—L. A. C.

Sulphur in coal and gas; Control of ——. A. R. Powell. Gas World, 1921, **74**, Coking Sect., 63—64.

On carbonisation, the pyritic sulphur in coal divides into two parts, one half remaining in the coke and the other half entering the gas as hydrogen sulphide. As the temperature is increased to 1000° C., the pyritic sulphur disappears, as does also the sulphate sulphur, whilst the organic sulphur remains practically constant and the sulphide sulphur increases. In a sample of Tennessee coal the sulphide sulphur increased from 0 to 0·84%, the sulphur as hydrogen sulphide increased from 0 to 1·44% and that in the tar increased from nil to 0·16% Above 400° C. there is formed a very stable union of part of the organic sulphur with carbon, but it cannot be stated whether this union is chemical or physical. This particular combination of sulphur with carbon seems to be partly produced from the sulphide sulphur, as, with every coal carbonised, there has always been a disappearance of part of the sulphide sulphur above 400° C. The sulphur in the gas occurs as carbon bisulphide, thiophene, thio-ethers, and isothiocyanates. Carbon bisulphide is a secondary product formed by the action of red-hot coke on hydrogen sulphide. By passing purified coke-oven gas through a charge in the oven, the sulphur content of the coke has been reduced by 15%. (See also J., 1920, 145 A, 713 A, 811 A, and 1921, 110 A.)—A. G.

Tully gas plant; Principles of the —— *and its adaptation to modern gas works practice.* C. H. Chester. N. Eng. Gas Managers' Assoc., 6.5.21. Gas J., 1921, **154**, 323—326.

The plant consists essentially of a retort or retorts superimposed on a generator with outlet gas connexions, valves, etc. Steam can be admitted either at the top of the retort or chequerwork (or both) or below the fire-bars. The fuel is preferably fed in through a hopper at the top of the retort. Trouble was previously experienced in preventing the blast from passing up the sides, owing to the whole load of the fuel in the retort resting on the central portion of the generator charge, which consisted mainly of fines, the larger fuel falling to the sides. The plants are now fitted with flat grates and dead plates, the waste gas ports being situated in the lower end of the retort. The waste gases contain CO_2 17·2%, O_2 1·4%, and CO 0·8%, at the end of the second minute of blowing. The distillation of the coal is accomplished by the heat generated by the combustion of the waste gases and by the passage through the coal charge of the hot water-gas, and is essentially a process of low-temperature carbonisation in a protective atmosphere of water-gas. The temperature in the retort varies from 450° C. at the top to about 1200° C. immediately above the waste gas ports. For every ton of coal treated, there are produced 12,000 cub. ft. of gas of calorific value 500 B.Th.U. per cub. ft. and 48,000 cub. ft. of water-gas of calorific value 300 B.Th.U. per cub. ft., making a total of 60,000 cub. ft. with an average calorific value of 340 B.Th.U. per cub. ft. At a works of 70-million cub. ft. capacity in Scotland the cost of Tully gas worked out at 10·60d. per 1000 cub. ft. compared with 24·08d. for coal gas and 18·90d. for mixed gas. At Scunthorpe, the average make of mixed gas was 23,125 cub. ft. per ton of coal, with 10·88 cwt. of coke and 9·57 galls. of tar. The percentage of water-gas was 48·11. Details are given of results obtained on the Scunthorpe plant over the period of a year, with analyses of the tar obtained.—A. G.

Oils from shale; Study of the saturated and unsaturated ——. C. W. Botkin. Chem. and Met. Eng., 1921, **24**, 876—880.

A rough but satisfactory method of estimating the saturated and unsaturated content of shale oils is to agitate vigorously a sample of the oil with twice its volume of sulphuric acid (sp. gr. 1·84), and then centrifuge the mixture; the volume of undissolved oil represents the saturated portion of the sample. Analyses of a number of samples of American shale oils, both from plant and laboratory distillations, showed about 11 to 28% of saturated substances; one sample from Nevada, however, contained 41·2%, and a sample of Scottish oil contained 38·0%. It has been suggested that the presence of unsaturated compounds is partly due to cracking during distillation, but the author has found that although crude shale oil cracked to a considerable extent on distillation at atmospheric pressure, the distilled oil contained a higher percentage of saturated compounds than the original oil. Fractional distillation of the crude oil showed that the higher boiling fractions contained a higher content of unsaturated compounds than the lower boiling fractions, and decomposition, as shown by the formation of gas and coke, was also greater at higher temperatures. Distillation of Colorado shale in a laboratory retort at high and low temperatures and also at low temperatures with the passage of steam or hydrogen through the retort, yielded in no case an oil containing more than about 30% of saturated compounds. In experiments where steam was led through the retort the percentage of saturated compounds was considerably lower, viz. 15·6 to 17·6%, owing to more rapid removal of the oi and consequent reduction of cracking, but one distillation of the oil increased the value to 35·2% High-temperature distillation somewhat decreased the yield of oil, but the product showed a higher degree of saturation. These experiments show clearly that it is the low hydrogen content of th shale, and not the method of retorting, which accounts for the high content of unsaturated compounds in shale oils.—L. A. C.

Organic carbon in bituminous limestones. Sernagiotto. *See* VII.

Patents.

Pulverised fuel furnaces. Fuller Engineering Co., Assees. of H. R. Collins. E.P. 146,085, 29.3.20. Conv., 1.7.19.

The pulverised fuel is blown in at the top of the fire-box of the furnace in a downward direction by only a portion of the air necessary for complete combustion; the remainder of the air is admitted at the lower part of the fire-box, preferably through a grate, in the usual position for the fire-bars, but in this case used only for removal of ash. The freshly deposited granular ash is removed as it is formed (to prevent it fusing and forming a solid mass) by using a mechanically operated grate, preferably in the form of hollow shafts geared together and carrying triangular or other shaped castings meshing with each other. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 133,921; J., 1919, 890 a.)—B. M. V.

Burning pulverulent fuels; Method of and means for ——. C. W. Lotz. E.P. 162,958, 18.6.20.

The fuel is fed into the furnace in a curtain formation by means of an air blast feeder, and the angle of feed is controlled partly by a guide-plate capable of adjustment and partly by the injection of an air supply transversely beneath and about the burning fuel curtain, the air passing round the periphery of the fuel cloud.—A. G.

Motor fuel; Process for producing ——. J. R. McCabe. U.S.P. 1,376,713, 3.5.21. Appl., 27.10.19.

Hydrocarbon oils are heated and the vapours passed through metal tubes, in which they are subjected to the action of high frequency electric discharges which pass transversely through the tubes. —A. G.

Fuel; Process of producing ——. E. C. D'Yarmett. U.S.P. 1,376,925, 3.5.21. Appl., 24.3.16.

Natural gas is introduced under pressure into a ody of heated hydrocarbon liquid, and the vapours f the liquid and gas are allowed to mingle above he liquid at a pressure above that of the atmsphere. Any condensable portions of the blended ixture are cooled and condensed.—A. G.

uel; Solid —— for generating heat and light. P. Friesenhahn. G.P. 327,180, 28.6.19.

he addition of a small quantity of a solid soap, a aturated fatty acid, or a saponified or unsaponified ax to cyclohexanol, cyclohexanone, or their esters, ields a solid fuel which burns with a clear flame ithout formation of soot.—L. A. C.

oke ovens. C. Otto und Co., G.m.b.H. E.P. 147,229, 7.7.20. Conv., 14.7.16.

coke ovens which may be heated by either poor rich gas, a separate regenerator chamber is proided for each burner for preheating the air and a parate recuperator chamber for preheating the eating gas, both chambers lying between the soles the oven and the sub-structure.—A. G.

istillation gases; Arrangement for withdrawing —— in vertical retorts. J. Pieters. E.P. 163,230, 27.7.20.

he withdrawal of the gases takes place in two stinct directions. A first portion of the gases, mprising the water vapour and a small proportion combustible gas, is extracted as usual at the top the retort, whilst the second portion, comprising e greater part of the combustible gas, is collected rough openings in the vertical end walls of the retort at various levels. The gases from the top of the retort pass through a large number of openings arranged on both sides of the length of the retort and unite in two collecting mains, parallel to the centre line of the retort and resting upon the upper brickwork. The gases formed in the lower part of the retort pass through a number of openings in the unheated end walls of the retort and are collected in vertical mains. The separate collectors of the different retorts of the battery are connected with a common exhaust conduit leading to the by-product plant.—A. G.

Steam generators for producer gas plants. J. W. Parker and E. Goldsmid-Abrahams. E.P. 162,899, 8.4.20.

A single tongue or fin attached transversely to the firebars, projects downwards and passes through a longitudinal slot into a pipe, in which water is kept at a constant level. Alternatively, some or all of the firebars may be provided with fins adapted to project through apertures in a slotted pipe as described.—A. G.

Gas producers. D. Williams, W. E. Francis, and The Bynea Steel Works, Ltd. E.P. 163,513, 1.3.20.

The upper part of the shell is lined with brickwork and the lower part is provided with a jacket through which water is circulated. The water outlet pipe of the jacket is preferably connected with the feed water tank for the boilers.—A. G.

Fuel gases; Process of recovering by-products from ——. F. J. Collin A.-G. zur Verwertung von Brennstoffen und Metallen. E.P. 147,633, 8.7.20. Conv., 3.3.19.

Tar and ammonium sulphate are recovered in a plant comprising three circuits, partly overlapping, for the ammoniacal liquor separated from the gas, which liquor is used as sole agent for cooling and washing the gas. One of the circuits includes the ammoniacal liquor receptacle, the liquor cooler, and the washer in parallel with the gas cooler. The second circuit includes the gas washer, the free ammonia still, and the evaporating cooler for the hot liquor from the free ammonia still, whilst the third circuit includes the evaporating cooler and liquor cooler, a portion of the water being continuously or intermittently removed from the last circuit and taken to a regenerative cooler attached to the distilling apparatus, whence it passes with the vapours to the saturator. The distilled ammoniacal liquor is evaporated for the production of ammonium chloride.—A. G.

Gas producers; Recovery of by-products from ——. J. Pintsch, A.-G. G.P. 316,501, 20.9.17. Addn. to 316,500 (J., 1920, 358 a).

When fuel with a high content of water is used in the producer, it may be necessary to heat the ammoniacal water from the coolers before passing it to the air saturator.—W. J. W.

Hydrocarbon oils; Distillation or cracking of ——. C. Dalley. From T. J. Greenway. E.P. 163,347, 21.7.19.

A vertical retort, narrower in the lower half than in the upper, and tapering at the bottom to a water-sealed outlet, is provided at the top with an open feed-shoot which extends below the top of the retort for a short distance and thus provides an annular space between the shoot and the retort walls. Oil is sprayed on to the solid fuel as it is fed continuously or intermittently into the shoot. Admission of air under pressure through tuyères near the bottom of the retort causes combustion of the fuel therein, and the oil distils in the upward current of hot gases, the vapours passing out through an opening leading from the annular space at the top into condensers. The nature of the products obtained, *i.e.*, the extent to which the oil is cracked, is regulated by adjusting the supplies of oil and air.—L. A. C.

Petroleum or the like; Treatment of ——. Production of asphalt from petroleum or the like. V. C. Illing and J. Kelly. E.P. (A) 163,363 and (B) 163,656, 18.11.19.

(A) Oil is heated below 300° C. by electric or other means under a pressure of 40—60 lb. in a tubular heater, and is released into the upper end of a sloping distillation chamber maintained at the temperature of the oil and under reduced pressure. The chamber is provided with trays down which the oil flows in a thin film, and with residue and vapour outlets at the lower and upper ends respectively. The vapour is fractionated and the supply of oil to the heater is simultaneously preheated by passing the vapour under reduced pressure through a series of condensers cooled to successively lower temperatures by the passage of a counter-current of the oil through the cooling coils. (B) The residue from the distillation chamber, which should be solid or semi-solid at the normal temperature, is pumped through a heating coil into a second distillation chamber, similar to the first, maintained at 250°—300° C., in which it is oxidised and freed from remaining volatile oils by the passage of a current of air through the vessel. The vapours are condensed as in (A), the cooling oil joining the supply from the first set of condensers before entering the heating tube, and the residual asphalt is run off into storage vessels.—L. A. C.

Mineral oils or the like; Process for separating —— from sand or rock. M. E. Fyleman. E.P. 163,519, 3.3.20.

Rock or sand impregnated with bitumen or mineral oil, such as the tar sands or oil sands of Alberta and Utah, is agitated at 60°—80° C. with an aqueous solution of a froth former, *e.g.*, alkali soaps, Turkey-Red oil, saponin, or glue, or an alkali salt, hydroxide, or carbonate, or with a dilute acid; the aqueous solution is subsequently separated by decantation, and the mineral matter removed by lixiviation. Alternatively, a liquid miscible with the oil or bitumen but not with water, *e.g.*, paraffin oil, may be added together with the aqueous solution, and the mixture agitated at normal temperature, in which case a solution of the hydrocarbon material in the paraffin oil rises to the surface of the aqueous solution, and the mineral matter settles to the bottom.—L. A. C.

Still [; Oil ——]. D. L. Newton and N. H. Anderson. U.S.P. 1,376,631, 3.5.21. Appl., 30.6.19.

An inclined cylindrical still is provided with an oil inlet pipe at the lower end, and with an oil overflow pipe and vapour outlet pipe on the under and upper side respectively of the raised end. The lower portion of the still contains steam coils totally immersed in the oil.—L. A. C.

Petroleum and the like; Process for the purification of ——. Siemens-Schuckertwerke, G.m.b.H. G.P. 334,120, 12.5.18.

The product is subjected to the action of an electric current as it flows between electrodes, and the purified and crude portions are prevented from mixing at the exit by means of baffle plates. The action of the electric current may be augmented by centrifugal force by inserting the electrodes in a centrifuge.—F. M. R.

[Lubricating] greases; Process for the production of technical —— [from tar]. G. Blass und Sohn. G.P. 335,189, 22.10.18.

Tar, without preliminary treatment, is saponified with alkaline lye, calcium hydroxide, or magnesium hydroxide, and the required consistency attained by the addition of oil if necessary. The properties of the saponified tar may be modified by the addition of solutions of salts of calcium, magnesium, and aluminium. The product can be used as a lubricant for waggons, cylinders, machines, etc.
—F. M. R.

Waste [lubricating] grease from tin works and other works; Treatment of —— to obtain oils and other useful products. L. Lane and D. H. Williams. E.P. 163,056, 5.6.20.

Waste grease or pitch is heated in a primary still to free it from solid impurities, and the melted pitch is then strained through a perforated pipe into a second still in which it is subjected to gradually increasing heat. The second still is connected with an arrangement of condensing pipes whereby the volatile constituents of substantially the same class are separated and led into different receiving tanks.—J. W. D.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Gas quality and lighting efficiency. E. Terres and H. Straube. Gas u. Wasserfach, 1921, 64, 309—314, 329—336, 348—354.

An investigation of the lighting efficiencies of upright and inverted incandescence mantles used in conjunction with straight coal gas and mixtures of coal gas with 10, 20, 30, and 40% of water-gas, producer gas, gas derived from the treatment of lignite, waste gases constituted of 20% CO_2 and 80% N_2, and mixtures of coal gas with air at pressures of 30, 40, 50, and 60 mm. water column. Details of the composition of the various gases employed are given and particulars of the specific gravity and tne degree of primary aeration effected. A detailed examination was made of the degree of primary aeration as affected by the specific gravity of the gas and the supply pressure employed. Curves are given showing how the mean horizontal candle power of the upright burner depends upon the degree of primary aeration in the case of the various samples of gas employed. The principal conclusions reached are as follows: In general, in the case of the upright burner the lighting efficiency is reduced by admixture of the other gases with straight coal gas. Making the comparison on the basis of equal additions of diluent gas, water-gas is the best, followed by gas derived from lignite, so far as effect upon the lighting efficiency of the upright burner is concerned. The carbon dioxide content of the gas exercises more influence upon the lighting efficiency than does nitrogen, and in specification of the permissible degree of dilutiou of straight coal gas with gases of lower calorific power, it is important that the maximum permissible percentage of carbon dioxide should be stated. In the case of the inverted burner, the lighting efficiency depends principally upon the degree of primary aeration effected by the burner. Alterations of gas quality are of only secondary importance so far as lighting by the inverted burner is concerned. Contrary to what is experienced in the case of admixture of other diluting gases, with water-gas the candle power increases in proportion as the percentage admixture of water-gas increases, the same degree of primary aeration being presupposed in each case. So far as absolute candle power is concerned, the inverted burner showed much less change over the range of gases and pressures employed than did the upright burner. According to the degree of primary aeration effected and the gas pressure employed, the candle power varied between the limits 60—110 Hefner candles. The results obtained are interpreted in terms of the respective flame volumes as compared with the size of the mantle, and it is concluded that the degree of primary aeration is the criterion upon which depends the efficiency in use of gases within the limits of calorific values investigated (3400—5500 cals. per cub. m.). Flame temperatures alter so very little from one gas to another that they are of small consequence. It is the flame volume, dependent upon the degree of primary aeration, that determines the lighting efficiency of a gas mixture.—J. S. G. T.

Distillation of coal and similar carbonaceous substances. Low Temperature Carbonisation, Ltd., H. L. Armstrong, and T. M. Davidson. E.P. 162,684, 21.8. and 14.10.19.

The respective retorts are provided with separate water-jacketed cooling chambers, into which the charge may fall on discharge, the cooling chambers having each a curved end wall and an opposite vertical end wall, in which an outlet aperture is provided. The cooling chambers are so set as to provide intervening spaces to form flues for the waste gases.—A. G.

Carbonising sawdust and other finely divided material; Apparatus for —— and for treating gases and vapours with finely divided substances. P. Poore. E.P. 162,769, 2.2.20.

The apparatus consists of an outer cylindrical casing which can be rotated and an inner casing or flue, provided with a number of intercepting pockets of such form that whilst there is free communication for fluid to pass through the pockets, the solid matter in a finely divided condition within the outer casing is intercepted within the pockets and prevented from accumulating in the inner casing or flue. The walls of the pockets are provided with holes so placed that any finely divided material which may have passed into the pockets in the rotation of the outer casing returns to the outer casing, whilst any such material which may have passed into the inner casing or flue returns to the pockets. The inner and outer walls of the pockets are formed of an alternate ridge and furrow section, the furrow on the outer face of the inner wall being opposite to the ridge on the outer face of the outer wall. The holes are provided at the ridges of the outer and inner walls respectively. The pockets are formed of metal plates having peripheral parts and flat flanges, a circular series of rods being fitted by means of which the plates may be disposed in series to form the inner casing or flue.—A. G.

Vertical retort settings for the destructive distillation of coal and the like. S. Glover, J. West, and West's Gas Improvement Co., Ltd. E.P. 163,150, 24.2.20.

The setting is so arranged that the waste gases can be passed through a steam generator situated on the top of the setting, the steam from which may be used for steaming the retorts, or they can be by-passed direct to the stack. A steam superheater may also be connected with the same system.—A. G.

Charcoal; Impregnated —— [for case-hardening]. F. C. Atkinson. U.S.P. 1,361,131, 7.12.20. Appl., 8.8.19.

Wood or the like is impregnated with a soluble salt of an alkali or alkaline-earth metal, *e.g.*, barium acetate, and carbonised.

Distillation [of carbonaceous materials]; Method of ——. G. F. Rendall, Assr. to Carbon Products Co. U.S.P. 1,376,582, 3.5.21. Appl., 13.6.17.

The retort is charged with solid carbonaceous material, then hermetically sealed; superheated steam is blown in until all air is expelled from the retort, and the latter is then heated externally. The vapours are withdrawn from the retort by means of superheated steam and condensed, the residue in the retort being cooled prior to its removal by blowing in wet steam.—A. G.

Arc-light electrode with capillary passages. Planiawerke A.-G. für Kohlenfabrikation. E.P. 101,471, 14.4.16. Conv., 13.9.15. Addn. to 16,364 of 1915 (J., 1921, 292 a).

Faulty rekindling of the arc is prevented by disposing the capillary passages or the like in the upper electrode upon a circle or other figure of a diameter equal to or greater than the diameter of the lower electrode.—J. S. G. T.

Vacuum tubes; Treatment of metal used in the manufacture of parts of —— [*to remove gases*]. W. C. Heraeus Ges. E.P. 144,690, 9.6.20. Conv., 18.4.18. Addn. to 138,648 (p. 474 A).

The vacuum melting process described previously (*loc. cit.*) is applied to the manufacture of metals or alloys used in parts of vacuum tubes. Metals or alloys so prepared and rolled into sheets or drawn into wires or rendered incandescent in the presence of gases such as hydrogen, do not absorb noxious quantities of gases.—J. S. G. T.

Electric lamp filaments; Tungsten alloys particularly for ——. The British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 162,907, 19.4.20.

Electric lamp filaments characterised by long life and high efficiency, due to the prevention of offsetting, are produced by sintering together pure zirconium intimately mixed with tungsten containing a certain percentage of silica or the like, *i.e.*, the X metal described in E.P. 155,851 (J., 1921, 264 A).—J. S. G. T.

Electrodes for arc lamps using high current density, more especially for use in searchlights. Optische Anstalt C. P. Goerz A.-G. G.P. 333,491, 11.6.1[illegible].

Metal is incorporated in the electrode in such proportion that it vaporises in the arc without dropping away from the electrode; for example, a positive electrode provided with a thick metallic core may be used in conjunction with a graphite electrode in which no metal is incorporated, or alternatively a thin graphite negative electrode with metal may be used in conjunction with a positive electrode containing no metal.—J. S. G. T.

Electric discharge tube with incandescent cathode. W. North and H. Loosli. G.P. 334,463, 4.2.20.

The cathode wire is made of zirconium or an alloy thereof. At the same temperature the quantity of the discharge is greater than with cathodes of tungsten, tantalum, or molybdenum, and the wire is more durable.—C. I.

Wood; Destructive distillation of ——. E. M. Sawtelle. E.P. 143,545, 18.5.20. Conv., 10.9.18.

See U.S.P. 1,374,887 of 1921; J., 1921, 380 A.

Carbonisation and distillation of moist carbonaceous materials; Apparatus for ——. H. N. McLeod. E.P. 163,343, 14.3.19.

See U.S.P. 1,375,714; J., 1921, 427 A.

Fuel. G.P. 327,180. *See* IIA.

III.—TAR AND TAR PRODUCTS.

Tars; Composition of high and low temperature ——. J. Marcusson and M. Picard. Z. angew Chem., 1921, 34, 201—204.

The authors have made analyses of the tars obtained in the high and low temperature distillation of coal and lignite, and also of the tars obtained in wood distillation and in oil-gas and water-gas processes. The tars were first separated into saponifiable and unsaponifiable constituents, and each group examined separately. Lignite tars contain less saponifiable matter than coal tars. Both low and high temperature lignite tars contain appreciable quantities of solid and liquid ketones. Wood tars from coniferous and deciduous trees show appreciable differences in constitution. Oil-gas and water-gas tars resemble each other, but vary in composition according to the nature of the raw materials used.—W. P.

Benzol; Presence of a paraffin hydrocarbon in commercial ——. J. Timmermans. Bull. Soc. Chim. Belg., 1920, 29, 227—229.

A hydrocarbon, principally normal heptane mixed with a small quantity of a heptamethylene, was separated from commercial benzol; the hydrocarbon did not yield a sulphonic acid and the quantity present was less than 1/3000 of the weight of the benzol.—W. P. S.

Reduction of some nitrated benzene derivatives with ammonium sulphide. A. Korczynski and S. Piasecki. Anz. Akad. Wiss. Krakau, 1917, 176—183. Chem. Zentr., 1921, 92, I., 866—867.

When an aqueous or dilute alcoholic solution of *symm.*-trinitrobenzene is reduced as described by Bader (Ber., 1891, 24, 1654) 1-nitro-3.5-phenylenediamine, brown-red needles, m.p. 159° C., is obtained instead of dinitroaniline. The course of the reaction, therefore, is dependent on the nature of the solvent employed. The reaction is intimately connected with the formation of addition products of *symm.*-trinitrobenzene and 2 mols. of ammonia (*cf.* Korczynski, J. Chim. Phys., 1910, 7, 575), such products being also formed during the reduction with ammonium sulphide. In the reduction of 2.4.6-trinitrophenol, 2.6-diamino-4-nitrophenol is formed, so that both the nitro-groups, which exert the greatest influence in the formation of these abnormal salts, are reduced. The partial reduction of 2.4-dinitrobenzoic acid results in the reduction of the *p*-nitro group, which exerts the strongest action in forming abnormal salts, and not the *o*-nitro-group as is usually assumed; both nitro-groups are reduced by ammonium sulphide in aqueous solution. An attempt is made to explain the relationship between the formation of abnormal salts and the behaviour on reduction on the basis of a balance of residual affinity between the nitro-groups concerned, the acidic hydrogen, and the ammonia molecules.—F. M. R.

Diaminoanthraquinones. M. Battegay and J. Claudin. Bull. Soc. Ind. Mulhouse, 1921, 87, 71—72.

When 1.3-dibromoanthraquinone (*cf.* Battegay and Claudin, J., 1921, 340A) disssolved in nitrobenzene is treated with *p*-tolylsulphamide, potassium carbonate, and powdered copper, 1.3-anthraquinoneditolylsulphamide, m.p. 245° C., is obtained. When a solution of this in 96% sulphuric acid is heated for 1 hr. on the water-bath and poured into aqueous ammonia, 1.3-diaminoanthraquinone is precipitated, which crystallises from nitrobenzene as red crystals having a black reflex and m.p. 290° C. The 1.6- and 1.7-diaminoanthraquinones obtained by treating the corresponding nitroanthraquinonesulphonic acids (Clauss, Ber., 1882, 15, 1514) with ammonia under pressure, crystallise from anisol, the former in red spangles, m.p. 292° C., and the latter as red needles, m.p. 290° C. The 1.6- and 1.7-diaminoanthraquinones yield the corresponding dihydroxyanthraquinones when diazotised and boiled with water. (*Cf.* J.C.S., Aug.)—A. J. H.

Titration of weak acids and bases. Kolthoff. *See* XXIII.

Patents.

Pitch; Treating ——. F. J. Commin. E.P. 162,727, 2.1.20.

Pitch is reduced to a fine state of division suitable, *e.g.*, for adding to cellulose pulp for producing cellulose fibre compositions, by grinding with an equal weight of water and about 2% of a peptising agent such as rosin soap or an alkaline casein solution.—L. A. C.

Coal tar, blast furnace tar, and like tars; Distillation of —— and treatment of the residual pitches. H. Tindale. E.P. 163,199, 20.4.20.

The proportion of asphaltenes and petrolenes in pitch is regulated to yield products suitable, *e.g.*, for road making, by distilling tar in a fire-heated still provided with a swan-neck lagged to prevent the distilled oils flowing back into the still, and a perforated coil at the bottom of the still for introducing superheated steam. The temperature of the tar is maintained below 300° C., and when distillation is complete air is blown through the pitch for 2 to 24 hrs. according to the amount of asphaltenes in the pitch and the consistency required. The product may be softened by the addition of suitable oils.—L. A. C.

Tars, particularly tars from deciduous trees; Process of treating ——. Byk Guldenwerk Chem. Fabr. A.-G. G.P. 334,518, 5.10.18.

The tars or their crude fractions are treated with alkalis in an autoclave at temperatures above 240° C., and finally distilled with superheated steam diluted with air. Such a neutralised tar can be distilled up to 320° C. under diminished pres-ure, the distillate being the unsaponifiable oil. The residue is still liquid at these high tempera-ures and may be used for the preparation of in-ulating materials, rubber substitute, etc., or for he recovery of the fatty acids of the tar, whilst the distillate is used as a lubricant.—F. M. R.

Core-oils [from tar oils]; Process for the production of ——. M. Melamid. G.P. 335,323, 13.12.19.

Oxidised tar-oils are produced by treating tar-oils with air, oxygen, or other oxidising agents until iscous liquids or resinous substances are obtained. Other oils, particularly fatty oils, such as linseed, maize, and fish-oils which are more easily oxidised han tar-oils, may be added prior to the oxidation. These oxidised tar-oils give homogeneous mixtures with foundry-sand fully equal in quality to those btained with linseed oil. Their binding power is reater than that of unoxidised oils, and cores made with them are less likely to crack than those made with known substitutes for linseed oil.
—H. C. R.

hthalic anhydride; Manufacture of ——. H. Sasa. E.P. 140,051, 5.11.19. Conv., 7.3.19.

o 450 kg. of sulphuric acid (sp. gr. 1·82) heated o 150°—160° C., 35 kg. of α-nitronaphthalene is lded, and when the latter has melted 80—90 kg. iron borings or other reducing metal, such as nc dust, is stirred in. After the vigorous evolu-on of gas has ceased the temperature is raised to 00° C. to expel aqueous vapour etc., and the hthalic anhydride is then distilled off under dimin-hed pressure at about 300° C. Ordinary concen-ated sulphuric acid may, with advantage to the eld, be replaced by fuming sulphuric acid.
—G. F. M.

rinitroresorcine; Manufacture of ——. W. Friedrich. E.P. 162,578, 2.7.20.

RINITRORESORCINOL is obtained by nitrating sorcinoldisulphonic acid, suspended in concen-ated sulphuric acid, with 90—100% nitric acid a temperature between 30° and 80° C. For ex-nple, 44 kg. of powdered resorcinol is sulphonated ith 320 kg. of concentrated sulphuric acid at a mperature rising to 70° C. After cooling to 30° C., 120 kg. of concentrated nitric acid is slowly added in a thin spray. The addition requires 2½ hrs., and the temperature is maintained at 40°—50° C. After keeping for 1 hr. the product is separated from the waste acid by centrifuging, and washed with dilute nitric acid and water. It is a yellowish-brown substance, m.p. 173°—175° C.
—G. F. M.

Nitro-compounds of tetrahydronaphthalenes or alkyltetrahydronaphthalenes substituted with hydroxyl- or amino-groups in the aromatic or cyclohexene ring; Production of ——. Tetralin Ges.m.b.H. G.P. 326,486, 17.3.16. Addn. to 299,014 (J., 1920, 174 A).

Derivatives of tetrahydronaphthalene are nitrated as described in the chief patent to prevent oxidation and resinification. Nitration with mixed acid of *ar*-tetrahydro-β-naphthol and *ar*-tetrahydro-α-acetonaphthalide yields respectively a product of m.p. 93°—96° C., and a mixture of small quantities of 2- and 3- with 4-nitro-1-acetoaminotetrahydronaphthalene; the 4-nitro compound has m.p. 175°—176° C., yields aceto-*ar*-1.4-tetrahydrodiaminonaphthalene on reduction, and 1-amino-4-nitrotetrahydronaphthalene, m.p. 114°—117° C., by hydrolysis with hydrochloric acid. A mixture of 2- and 3-nitro-1-acetoaminotetrahydronaphthalene is precipitated by pouring the acid liquor, after separation of the 4-nitro compound by filtration, into water; the two are then separated by treatment with hydrochloric acid, whereby the 2-nitro compound is more readily hydrolysed than the 3-nitro compound; *ar*-1.2- and *ar*-1.3-diaminotetrahydronaphthalene melt respectively at 84°—85° C. and 79°—80° C., and the 1-amino-2-nitro compound has m.p. 78°—80° C. A solution of *ar*-tetrahydro-β-acetylaminonaphthalene in acetic acid on nitration below 40° C. with mixed acid and subsequent dilution of the nitration mixture with water yields a yellow precipitate which gives crystals of 2-acetoamino-3-nitrotetrahydronaphthalene, m.p. 135°—136° C., on crystallisation from alcohol, while the 2-acetoamino-1-nitro compound, m.p. 125°—126° C., remains in solution. From these compounds are obtained by hydrolysis and reduction: 1- and 3-nitro-2-aminotetrahydronaphthalene, m.p. 94°—96° C. and 124°—125° C. respectively, and *ar*-1.2- and *ar*-2.3-diaminotetrahydronaphthalene, m.p. 84°—85° C. and 135°—136° C. respectively. Nitration at 0° C. of a solution of *ar*-tetrahydro-β-acetylaminonaphthalene in sulphuric acid with mixed acid yields mainly 4-nitrotetrahydro-2-acetylaminonaphthalene, m.p. 194°—195° C.; this compound by reduction and subsequent hydrolysis yields *ar*-1.3-diaminotetrahydronaphthalene, m.p. 78°—80° C., which is also formed from 3-nitro-1-acetylaminotetrahydronaphthalene (see above).—L. A. C.

3-*Nitroquinoline and its derivatives; Manufacture of ——.* Badische Anilin- und Soda-Fabr. G.P. 335,197, 1.6.19.

Aromatic aldehydes or ketones containing an amino group in the *o*-position, or derivatives of the same, are condensed with methazonic acid, NOH:CH·CH:NOOH. *o*-Aminobenzaldehyde and a solution of methazonic acid, on prolonged standing at normal temperature, yield 3-nitroquinoline, m.p. 128° C. Methazonic acid and an alkaline solution of isatin, with subsequent acidification with hydrochloric acid, yield a mixture of 3-nitro-4-quinolinecarboxylic acid, m.p. 204° C., and β-isatinoxime, which is separated by treatment with sodium bicarbonate solution. *o*-Aminoacetophenoneoxime and 3-nitro-4-methylquinoline, m.p. 118° C., are prepared by the action of methazonic

acid on a solution of *o*-aminoacetophenone in hydrochloric acid, and the products are separated by treatment with cold, dilute aqueous sodium hydroxide, which dissolves only the oxime.
—L. A. C.

Erratum. J., June 30, 1921, p. 428 a, col. 1. *Manufacture of naphthylaminesulphonic acids* (E.P. 161,859). In the third line of the abstract, for "obtained by the sulphonation of naphthylamine," read "obtained as described in E.P. 4265 of 1888." (*Note*.—The acids mentioned are not produced in the sulphonation of naphthylamine.)

Lubricating greases. G.P. 335,189. *See* IIa.

IV.—COLOURING MATTERS AND DYES.

Indigotin; Estimation of ——. W. Thomson. J. Soc. Dyers and Col., 1921, 37, 166—168.

One g. of 20% Indigotin paste was dried on a watch glass, washed into a beaker with 30 c.c. of concentrated sulphuric acid, and heated at 50° C. for 3 hrs. After cooling the product was diluted to 1 l. The indigotinsuphonic acid was then estimated by diluting 200 c.c. of this solution to 1 l. in a porcelain basin and titrating with $N/50$ potassium permanganate solution till the liquor became golden yellow in colour and showed a rim faintly tinged with pink. With 1-g samples drying was unnecessary, but when 5 g. of undried Indigotin paste was sulphonated an error of −0·3% occurred. It is necessary to use the same kind of illumination during the titration, since titrations in daylight and in artificial light gave results differing by 0·87%. The presence of starch and glycerol (100% on weight of dry Indigotin) in the Indigotin paste does not seriously affect the estimation, except that when the sulphonation was carried out at 90° C. the solution obtained was discoloured and the end point could only be determined within 8—10 drops.
—A. J. H.

m-Xylene; Derivatives of ——. S. A. Pearman. Chem. Soc. Trans., 1921, 119, 717—721.

6-Nitro-*m*-xylene-4-azoresorcinol prepared from diazotised 6-nitro-*m*-4-xylidine and resorcinol formed light red tabular crystals, and dyed chromed wool full orange shades. 6-Nitro-*m*-xylene-4-azosalicylic acid similarly prepared is a brick-red amorphous substance giving deep yellow shades on chromed wool. Acetyl-4.6-diamino-*m*-xylene was obtained as colourless needles, m.p. 164°—166° C., by the reduction of acetyl-6-nitro-*m*-4-xylidine; it gave a scarlet azo derivative with *β*-naphthol. 6-Nitro-5-methylindazole obtained by Noelting's method (J., 1904, 781) was reduced by ferrous sulphate and ammonia to 6-amino-5-methylindazole, m.p. 241°—242° C. Its diazonium chloride gave a dark red insoluble azo-*β*-naphthol, and a violet azo-dye with J-acid. Di-*p*-toluenesulphonyl-4.6-diamino-*m*-xylene obtained in the usual way formed white needles, m.p. 221°—222° C. Formaldehyde gave a condensation product of undetermined constitution with diamino-*m*-xylene. It formed a crystalline sulphate of the molecular formula $(C_{10}H_{12}N_2)_2H_2SO_4$, a mono-acetyl derivative, and a nitrosamine.—G. F. M.

Arylsulphonylnaphthylenediamines and their sulphonic acids. G. T. Morgan and W. R. Grist. Chem. Soc. Trans., 1921, 119, 602—610.

The preparation of the arylsulphonyl-1.4-naphthylenediamines and their 6-, 7-, or 8-sulphonic acids has already been described (E.P. 160,853, J., 1921, 381 a). When the sulphonic group occupies position 4 or 5 in the original naphthylamine, 2-azo-compounds are obtained, which on reduction yield derivatives of 1.2-naphthylenediamine. Whilst the *para* (1.4)-series give yellow diazo derivatives coupling to form azo-compounds with phenols etc., the *ortho* (1.2)-series yield non-coupling *ortho*-diazoimides.—G. F. M.

Metallic compounds of Trypaflavine. Berliner. *See* XIXb.

Patents.

[*Indanthrene*] *colouring matters; Production of* ——. W. J. Pope, and Scottish Dyes, Ltd. E.P. 162,687, 27.9.19.

N-Dihydro-1.2.1′.2′-anthraquinoneazine or its derivatives are manufactured in improved yield and quality by fusing 2-aminoanthraquinone or its derivatives respectively with potassium hydroxide in the presence of a salt of an organic acid, such as potassium formate or acetate or a mixture of the two, which is miscible in a fused state with the alkali. Suitable oxidising agents, such as potassium chlorate, may be introduced into the melt to improve still further the yield and quality of the product.—F. M. R.

Wool dyestuffs; [*Azo*] *acid* ——. G. de Montmollin, Assr. to Soc. of Chem. Ind. in Basle. U.S.P. 1,359,969, 23.11.20. Appl., 13.12.19.

Diaminodiarylsulphones, especially 2.5- and 2.4-compounds, are converted into monoacidyl derivatives, diazotised, and coupled with 2-aminonaphthalene derivatives, especially 2-aminonaphthalenesulphonic acids and 2-aminonaphtholsulphonic acids, yielding dyestuffs which dye wool in an acid bath orange-red to blackish-violet shades fast to washing and to light.

Diazotisable [*azo*] *dyestuffs easily soluble in water.* H. Fritzsche, Assr. to Soc. of Chem. Ind. in Basle. U.S.P. 1,362,936, 21.12.20. Appl., 29.12.19.

Easily soluble azo dyestuffs are obtained by the action of formaldehyde-bisulphite on diazotisable azo dyes containing at least one external amino-group or by coupling aromatic diazo compounds with azo components containing an external N-methyl-ω-sulpho-group, *e.g.*, by combining a tetrazo derivative of a diamine such as 3.3′-diamino-4.4′-dimethyldiphenylmethane, with the N-methyl-ω-sulpho derivative of 2-amino-5-hydroxynaphthalene-7-sulphonic acid. They dye cotton directly yellow to claret shades, which become extraordinarily fast to washing when diazotised on the fibre and developed with a non-sulphonated azo component.

o-Aminoazo dyes; Manufacture of ——. C. Rudolph. G.P. 298,852, 22.10.16.

Diazotised *o*- or *p*-aminosalicylic acid, sulphoaminosalicylic acids, nitroaminosalicylic acids, or amino-*o*- or amino-*m*-cresotic acids are coupled with 1.8-aminonaphthol-4.6-disulphonic acid in acid solution at 30°—40° C. The products yield valuable dyes when coupled with diazotised amines or tetrazotised diamines.—F. M. R.

Vat dyes; Manufacture of ——. Chem. Fabr. vorm. Weiler-ter Meer. G.P. 300,094, 21.3.16

Benzidine is condensed with chloroacetic acid or its esters, with or without the addition of alkalis, and the products, after saponification if necessary, fused with caustic alkalis with addition of suitable condensing agents. The glycine obtained from benzidine and chloroacetic acid is a white powder, insoluble in water and most organic solvents, and forms water-soluble salts with alkalis and strong acids. The dye is a dark powder, soluble in sulphuric acid with a brown colour, and separates on dilution as the blue sulphate; it dyes cotton and wool from the vat in blue-green shades.—F. M. R.

Semiazoanthraquinones and their derivatives; Manufacture of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 335,160, 1.1.18.

Semiazoanthraquinones are formed by the action of bromine on α-aminoanthraquinone or its derivatives in presence of alkali. For example, 1.5-disemiazoanthraquinone, red-brown needles, soluble in sulphuric acid with a yellow colour and a green fluorescence, is formed by the action of a solution of sodium hypobromite on finely divided 1.5-diaminoanthraquinone at about 50°—80° C., whilst 1-semiazo-4-chloroanthraquinone, orange needles, soluble in sulphuric acid with a reddish-yellow colour, is formed similarly from 1-amino-4-chloroanthraquinone at 40°—100° C. The semiazoanthraquinones form violet to blue solutions when heated with aniline, and when dissolved in sulphuric acid and precipitated with water, the corresponding aminohydroxy-compounds are obtained. In the case of 1-semiazo- and 1.5-disemiazo-anthraquinones, the hydroxyl group enters the free *p*-position, forming 1-amino-4-hydroxy- and 1.5-di-amino-4.8-dihydroxyanthraquinone respectively. When the *p*-position is occupied, the hydroxyl group enters the *o*-position with respect to the amino-group. These products are to be used in the manufacture of dyes.—F. M. R.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Reeds; Silicic acid content of ——. F. Herig. Cellulosechem., 1921, 2, 44—47.

Reeds (*Phragmites communis*, Trin.) are distinguished from all other plants available for paper manufacture by their high ash and silicic acid content, which average 5·83% and 4·42% respectively. The silicic acid is present as an amorphous deposit in the cell membrane, and probably possesses physiological significance in the living plant as a strengthening material against the action of external influences. The greater portion (on an average about 70%) of the silicic acid is dissolved during the digestion process. The investigation of the effect of the silicic acid during bleaching is incomplete, but in view of the quality of the product, it appears to exert no detrimental action. In spite of the high silicic acid content, there appears to be no ground for the assumption that reeds are unsuitable as a source of cellulose for paper manufacture.—F. M. R.

Cellulose residue [*crude fibre*]; *Insoluble* ——. A. J. J. Vandevelde. Bull. Soc. Chim. Belg., 1920, 29, 258—284.

A synopsis of the literature relating to the composition, reactions, etc. of cellulose and cellulosic constituents of plants. The ordinary method of determining crude fibre by successive digestion with dilute acid and alkali solution yields approximately correct results, and modification of the time of treatment, concentration, etc., does not usually affect the results to an appreciable extent.
—W. P. S.

Cellulose of lichens and yeast: the concept "hemicellulose," and the autolysis of yeast. E. Salkowski. Z. physiol. Chem., 1921, 114, 31—38.

The cellulose of *Lichen islandicus* is more easily hydrolysed than ordinary cellulose and would correspond to Schulze's "hemicellulose." This term is, however, criticised and should at most be applied only to pure material, for the same specimen of yeast cellulose, prepared by the author, was hydrolysed at different rates according to its mechanical condition. Yeast cellulose, when heated or a long time with water under 2—2½ atm. ressure, is separated into achroocellulose, insoluble in water, and erythrocellulose, apparently identical with yeast glycogen.—G. B.

Lignin; Investigation of ——. K. H. A. Melander. Cellulosechem., 1921, 2, 41—43.

The waste lye of the sulphite-cellulose process contains at least two kinds of sulphur-containing lignin substances, for the addition of 21 g. of salt per 100 g. of lye at 65°—70° C. produces a precipitate of α-lignin, whilst β-lignin remains in solution. According to Klason the residue obtained by evaporating the waste lye to dryness contains 71% of lignin, and on this basis α-lignin represents 26·5% of the dry substance. α-Lignin was purified by repeated solution and precipitation by salting out; the product contained when dry 20—30% of sodium chloride. This product, which, apart from the sodium chloride, is a mixture of high molecular ligninsulphonic acids containing loosely-bound SO_2, is termed α-lignin-S-acid, and the proportion of C to S in it is by no means constant. In the waste lye α-lignin-S-acid is combined with calcium, but on salting out the product contains only a small proportion of calcium. The analysis of a number of preparations of free α-lignin-S-acid shows that the existence of a well-defined sulphonic acid cannot be assumed. Calculations for a sulphur-free substance, based on the assumption that during the sulphite process 1 mol. H_2SO_3 is united to a double bond in lignin, vary considerably, but in the majority of cases 34 atoms C and 11 atoms O per molecule are indicated. The principal difference between the products lies in the hydrogen content. The conclusion is drawn that the products contain relatively high proportions of loosely-bound SO_2. When α-lignin in relatively dilute solution is precipitated with hydrochloric acid the free α-lignin-S-acid is obtained, whereas in concentrated solution hydrochloric acid precipitates the sodium salt of α-lignin-S-acid.—F. M. R.

Alkali-content of straw pulp; Determination of the ——. E. Heuser and T. Blasweiler. Papierfabr., 1921, 19, 509—514.

Of the total alkali-content of straw pulp, only about 10% can be extracted by means of hot water. The following method for determining the alkali-content gives accurate results:—For total alkali, 10 g. of dry pulp is treated with $N/10$ sulphuric acid and the excess of acid titrated. For fixed alkali (portion not extracted by water), 10 g. of dry pulp is heated with 400 c.c. of water, pressed, treated for several hours with sulphuric acid, and the excess of acid titrated. Free alkali (portion extracted by water) is obtained by difference; it cannot be accurately estimated by direct methods. $N/10$ sulphuric acid is used, since $N/100$ acid gives slightly inaccurate results, and $N/1$ acid requires a large quantity of pulp.—A. J. H.

[*Paper manufacture;*] *Control of alum content of the tubsizing bath* [*in* ——]. P. W. Codwise. Pulp and Paper Mag., 1921, 19, 499—501.

For the volumetric estimation of alum in sizing baths, litmus is not a sufficiently sensitive indicator and tends to give low results. Bromothymol blue (dibromothymolsulphophthalein; *cf.* J., 1916, 980) possesses greater and more uniform sensitiveness; it is a yellow substance which, by the action of alkalis, undergoes colour changes to yellow-green, blue-green, and finally blue. It is most suitably used in the form of test-papers prepared by saturating filter-paper with a solution of 0·1 g. in 50 c.c. of alcohol, and the end point of the titration is denoted by a blue-green coloration. Owing to the error inherent to the use of indicators with aluminium sulphate, a correction factor must be applied, and it is also necessary to make a correction for the original alkalinity or acidity of the gelatin in the bath.—W. J. W.

Patents.

Fireproofing and/or waterproofing materials. A. Arent. E.P. 138,641, 5.2.20. Conv., 5.2.19.

Textile fabrics, paper, etc., are treated with a solution of an antimony or bismuth compound in amyl acetate, or with a mixture of a drying oil, such as linseed oil, and an antimony or bismuth compound, such as antimony trichloride, with or without the addition of a solvent such as amyl acetate. Plastic masses composed of a cellulose derivative, with which antimony trichloride is incorporated, merely char in direct contact with a flame.—F. M. R.

Felt; Stiffening and waterproofing ——. W. Esch. G.P. 335,060, 8.2.20.

A crystalline magma of basic lead carbonate, basic magnesium carbonate, or lead formate is deposited in the felt, which is then treated with a saturated solution of a chlorinated naphthalene derivative in a chlorinated hydrocarbon.—F. M. R.

Fibres; Production of separate —— from bundles of bast fibres, with simultaneous removal of woody material and incrustations. W. Gierisch, P. Krais, and P. Waentig. G.P. 328,034, 5.4.19.

The crude fibrous material, after it has been steeped in 1% sodium hydroxide solution, is treated with chlorine, washed, treated with dilute alkaline solution, washed, and dried.—L. A. C.

Fibres suitable for spinning; Method for producing —— from rice straw. S. Fricke. G.P. 331,514, 4.5.18.

Rice straw, after treatment in an alkaline or acid solution, is passed between rollers under high pressure, and boiled in alkali (sp. gr. 1·02) for a long time. The material is washed, boiled with water containing 1% of soap or emulsified oil on the weight of the dry straw, passed again between the rollers, and then treated in the normal manner for spinning fibres.—F. M. R.

Cellulose filaments, threads or films; Treatment of ——. E. Bouillon and M. Worms. E.P. 162,759, 31.1.20.

In the manufacture of threads, films, or filaments from viscose a coagulating bath containing aluminium sulphate, sodium sulphate, and an inorganic acid is used at 45°—50° C. The inorganic acid may be replaced by an equal proportion of sodium thiosulphate or bisulphite.—F. M. R.

Artificial [silk] filaments and the like; Washing or otherwise treating with liquid ——. Courtaulds, Ltd., and W. H. Stokes. E.P. 163,099, 9.2.20.

The non-perforated bobbins on which artificial filaments are wound after coagulation, are covered with a porous material, such as cotton or woollen fabric, which allows the ready passage of a liquid and the surface of which does not injure the filaments.—A. J. H.

Viscose silk; Manufacture of ——. E. Bronnert. U.S.P. 1,376,672, 3.5.21. Appl., 10.9.20.

Sulphuric and lactic acids are used in the spinning bath, the amount of sulphuric acid being in proportion to the fineness of the thread to be produced, and the amount of lactic acid being substantially in inverse proportion to the age of the viscose to be treated.—H. H.

Artificial silk; Process of recovering salts formed in the manufacture of ——. E. Bronnert. U.S.P. 1,376,671, 3.5.21. Appl., 7.9.20.

In the manufacture of artificial silk from viscose solutions the salts formed in the sulphate precipitation baths are recovered by lixiviating the threads in sulphuric acid solution to convert the sulphates into bisulphates.—H. H.

Nitrocellulose solutions; Process for spinning ——. A. Dryen. U.S.P. 1,377,761, 10.5.21. Appl., 23.9.19.

In the process of spinning solutions of nitrocellulose for the manufacture of artificial silk and the like, the filament is coagulated in a bath of sulphuric acid at the issue of the spinning orifice.—A. J. H.

Staple fibre; Process for the production of ——. A. Lauffs. G.P. 333,174, 26.11.18.

The bundles of incompletely set fibres are united in the manner usually employed for spinning artificial silk, except that they are carried forward at a diminished speed, so that a more loosely bound thread is formed, which is allowed to harden under slight pressure. The individual fibres are pressed in different directions, and as a result are curled, so that when cut into suitable lengths the fibre possesses a wool-like character.—F. M. R.

Plastic masses; Production of ——. G. Ruth and E. Asser. G.P. 334,983, 13.6.19.

Cellulose esters or solutions of cellulose esters are mixed or kneaded with esters of naphthenic acid; the greater the proportion of the latter, the more flexible and supple is the product. "Commercial pure" naphthenic acid is a mixture of hydroaromatic carboxylic acids and is esterified by the action of an alcohol and gaseous hydrogen chloride, or by the action of an alcohol on naphthenic acid chloride in presence of pyridine.—F. M. R.

Cellulose [half-stuff]; Manufacture of ——. C. A. Braun. E.P. (a) 137,831, 12.1.20, and (b) 139,171, 16.2.20. Conv., 5.8.16 and 29.5.18.

(a) For the production of half-stuff and fibres which can be spun, raw plants such as wood, jute, reed grass, Manila hemp, typha, nettles, etc., are boiled under pressure with a solution which contains, besides easily decomposable alkaline compounds such as sodium carbonate and soaps, varying quantities of alkali sulphites and sulphides. (b) When some plants have been treated as described under (a), the resulting half-stuff is coloured green with chlorophyll substances. This is overcome by the addition of caustic alkalis to the digestion liquor. A suitable liquor contains 25 pts. of sodium sulphite, 5½ pts. of sodium sulphide, and 2⅓ pts. of caustic soda.—A. J. H.

Paper; [Preventing frothing in] manufacture of ——. J. R. B. Fearnley. E.P. 163,421, 9.2.20.

Finished and diluted paper pulp, immediately before it flows on to the wire of the paper-making machine, is passed in the form of a film through a vacuum chamber, for the purpose of removing air and gas bubbles which would otherwise lead to froth formation.—A. J. H.

Wool; Process of washing or scouring ——. R. M Poole and H. F. Davis. U.S.P. 1,377,790, 10.5.21 Appl., 24.9.19.

See E.P. 152,513 of 1919; J., 1920, 779 a.

Cellulose compounds; Manufacture of ——. Deutsche Celluloid Fabrik. E.P. 138,116, 22.1.20. Conv., 9.1.18.

See G.P. 332,203 of 1918; J., 1921, 344 a.

Drying sheet material [paper etc.]; Methods and apparatus for ——. O. Minton. E.P. 142,810, 3.5.20. Conv., 6.10.14.

See U.S.P. 1,147,809 of 1915; J., 1915, 901.

See also pages (a) 456, *Drying apparatus for wood pulp* (U.S.P. 1,376,659). 462, *Treating pitch* (E.P. 162,727). 478, *Scouring and fulling agent* (G.P. 328,099). 479, *Protecting surfaces with wool-fat preparations* (E.P. 163,474); *Rubber fabric* (E.P. 147,628). 484, *Glucose from wood waste* (E.P. 154,170).

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Ingrain o.o′-dihydroxyazo dyestuffs. F. Blumer. Bull. Soc. Ind. Mulhouse, 1921, 87, 47—50.

When naphthol-prepared fabric is treated with faintly acid solutions of diazotised 2.3-dinitroaniline, 2.4-dinitroaniline, picramic acid, tribromoaniline, 1.6-dibromo-4-nitroaniline, 2.6-dinitro-*p*-toluidine, and 2-bromo-6-nitro-*p*-toluidine, orange to red shades are produced which are fast to acids, alkalis, and copper salts. If neutral or slightly alkaline diazo solutions (ammoniacal solutions at 60°—80° C.) are used, violet to blue shades are obtained which are turned red with acids. The shades are, however, rendered fast to acids by after-treatment with salts of copper and other divalent metals of the iron group (chromium excepted). This stabilisation is probably due to the formation of metal lakes of the violet to blue dyes, which are regarded as having the constitution, $R(OH).N_2.R(OH)$, with the hydroxyl groups ortho to the azo group.—A. J. H.

Fur dyeing. W. F. A. Ermen. J. Soc. Dyers and Col., 1921, 37, 168—170.

By the oxidation of *p*-phenylenediamine, dimethyl-*p*-phenylenediamine, *p*-amino-phenol and -cresol, o-aminophenol, amidol, diaminoanisol, diamino-anisol and phenylenediamine, and diphenylamine derivatives on fur, brown to bluish-black shades were obtained. The fur was wetted out in a cold solution of caustic soda (3° Tw., sp. gr. 1·015), sodium carbonate (9° Tw., sp. gr. 1·045), or ammonia, mordanted for about 12 hrs. in a cold bath containing 0·5% of acetic acid and 0·5% of either sodium bichromate, ferrous sulphate, or copper sulphate or a mixture of these, and was then entered (with or without previous drying) into a dye-bath which contained 0·1—0·5% of the amine. Towards the end of the dyeing, the bath was made slightly alkaline with ammonia and 20—80 c.c. of 12-vol. hydrogen peroxide was added per l. of dye liquor. The fur was allowed to remain n the dye liquor overnight, when the shade fully developed. The oxidation of pyrogallol produced hades lacking in depth.—A. J. H.

Crêpe effects on delaines. C. Favre. Sealed Note 1500, 1.10.04. Bull. Soc. Ind. Mulhouse, 1921, 87, 65. Report by A. Wolf. *Ibid.*, 66—67.

Unbleached delaine is passed through cold water nd is then steeped in a bath containing 20 g. of arium thiocyanate and 6 g. of sulphuric acid of 5° B. (sp. gr. 1·82) per l., the temperature of which raised during 15 mins. to 75° C. and maintained or 1 hr. The fabric is washed so as to develop rêpe effects, chlored, bleached by immersion for 5 mins., at 75° C., in a bath containing bisulphite f 30° B. (sp. gr. 1·265) diluted 15 times, printed, ashed, and finished. The crêpe effects develop fter 8 days. Wolf points out that the fabric must ot be under tension during the process and that e thiocyanate may be dispensed with, since dilute lphuric acid or even water alone produces similar fects.—A. J. H.

Printing] yellow effects on fabrics by means of perthiocyanogen. H. Schmid. Sealed Noto 928, 30.10.1896. Bull. Soc. Ind. Mulhouse, 1921, 87, 67—68. Report by A. Lipp. *Ibid.*, 68.

Fabric is padded with a solution of gum tragacanth hich contains 150—200 g. each of ammonium thio-anate and sodium chlorate per l., and is then eamed (as for Aniline Black), washed, soaped, and ied. Lemon-yellow to orange-yellow shades (due formation of perthiocyanogen) are obtained which t as mordants for basic dyestuffs. If vanadium salts be added to the padding liquor, the possible tendering of the fabric is avoided. Lipp states that the shades obtained are bright and fast.—A. J. H.

Nitrate discharge of Indigo; Freyberger's ——. C. Sunder. Bull. Soc. Ind. Mulhouse, 1921, 87, 51—54.

In carrying out Freyberger's process, difficulties are encountered in that the fabric becomes more or less gelatinised, the selvedges "break-out," and the squeezing rollers, one of which is made of rubber and the other of hardened rubber, wear rapidly. The discharges are not so sharp as when other "steaming" methods are used, although the addition of sodium nitrite to the nitrate leads to better results. Nitric acid accumulates in the acid bath, but its harmful action is reduced by the addition of ferrous sulphate. White discharges will be stained with yellow unless the fabric is completely freed from pectic substances. If the fabric is not immersed more than 9 secs., no tendering takes place. In practice, the cost of acid is considerable, since it is not always possible to use the dilute recovered waste acid liquors for bleaching and for neutralising mercerised fabrics, while a complete acid recovery plant involves large maintenance expenses.—A. J. H.

Discharges on fabrics dyed with diamine dyestuffs; Production of white and coloured —— by means of sodium hydrosulphite and barium tungstate. Scheurer, Lauth et Cie., and G. van Caulaert. Sealed Note 1447, 23.1.04. Bull. Soc. Ind. Mulhouse, 1921, 87, 69—70. Report by A. Lipp. *Ibid.*, 70.

Fabric dyed with diamine dyestuffs is printed with a discharge paste containing 250 pts. of sodium tungstate, 90 pts. of hydrosulphite NF.(M.L.B.), and 660 pts. of a solution of gum tragacanth (for coloured discharges lake dyes, *e.g.*, ultramarine blue, ultramarine violet, vermilion, Guignet's green, chrome yellow, acetylene black, etc. are added). It is then steamed for 3 mins., in a Mather-Platt, passed during ½ min., through a cold bath containing 50 g. of barium chloride per l., and is then washed and dried. The process is particularly suitable for mercerised cotton and silk. Lipp reports that fabrics dyed by this method have a more agreeable "handle" than is the case when hydrosulphite and zinc oxide, lithopone, or barium sulphate are used in conjunction with albumin and casein.—A. J. H.

Linen and cotton goods; Recent improvements in the finish of ——. M. Fort. J. Soc. Dyers and Col., 1921, 37, 161—166.

The presence of mere traces (0·1% is sufficient) of oil, fat, wax, or similar substances in cotton or linen fabrics prevents the production of a firm linen finish. The ordinary preparation of fabric is not a reliable means for removing these residual fats, but successful beetling is always obtained if the fabric is extracted at any previous stage by means of organic solvents. There is but little inducement to use solvent extraction as an aid to whitening cloth in bleaching.—A. J. H.

Patents.

Dyeing, mordanting, bleaching, scouring, or similarly treating wool, slubbing, yarn, and other fibrous material; Apparatus for ——. J. Kershaw and J. T. Cole. E.P. 162,720, 31.12.19. Addn. to 122,227 (J., 1919, 132 A).

In a machine of the type specified in the original patent, a removable carrier, *e.g.*, a perforated cage, is provided for receiving the material, either in bulk or in hanks. The treated material is removed through doors in the bottom of the cage. The cage is divided horizontally into two sections resting on the false bottom, and the top section is detachably secured to the lattice top. An open box-like truck provided with guides receives the cage on runners or antifriction rollers when it is removed from the machine.—F. M. R.

Dyeing fur, hair, feathers, and the like. Chem. Fabr. Griesheim-Elektron. G.P. 331,011, 14.12.16.

Fur, hair, and feathers are treated with a solution of a mixture of *m*-hydroxydiphenylamine and *o*-aminophenol or their derivatives, with addition of suitable oxidising agents. The addition of *o*-aminophenol to the *m*-hydroxydiphenylamine changes the shade towards greenish or blackish grey-brown, whereas *m*- and *p*-aminophenol do not produce such an alteration in the shade.—F. M. R.

Fast shades; Production of —— by dyeing or printing. Farbenfabr. vorm. F. Bayer und Co. G.P. 335,301, 22.12.16.

Fabrics are printed or dyed with α-hydroxynaphthoyl-*o*-benzoic acid or its derivatives, such as its halogen derivatives, and metallic mordants. Fast lemon-yellow shades, resistant to hydrosulphite, which are technically valuable as substitutes for shades produced with Persian berries, are produced in this manner by the use of chromium or aluminium acetate as mordant.—F. M. R.

Bleaching and bleaching compounds. J. F. King and H. B. Haines. E.P. 146,078, 20.2.20. Conv., 28.6.19.

See U.S.P. 1,321,643—4 of 1919; J., 1920, 17 A.

Textile goods in hank form; Apparatus for treatment of —— by means of circulating liquid. E. Nägelin. E.P. 152,299, 14.4.20. Conv., 4.10.19.

Foam-producing material. G.P. 328,631. *See* XII.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Alkali cyanides. J. Meyer. Z. anorg. Chem., 1921, **115**, 203—217.

Methods have been devised for preparing the hitherto unknown cyanides of lithium, rubidium, and cæsium in a pure state. They are all extremely soluble in water and the lithium salt is hygroscopic. All three salts form double cyanides with silver cyanide of the type $LiAg(CN)_2$. These salts are soluble in water and do not give the usual silver reactions except with hydrogen sulphide. Lithium ferrocyanide crystallises with $6H_2O$ and the ferricyanide with $4H_2O$; the salts are therefore not isohydric with the corresponding sodium salts. (*Cf.* J.C.S., July.)—E. H. R.

Alkali pyrophosphates; Volumetric estimation of ——. F. Lutz. Magyar Chemiai Folyóirat (Ungar. Chem. Zeits.), 1919, **25**, 96—98. Chem. Zentr., 1921, **92**, II., 949—950.

An excess of $N/10$ silver nitrate solution is added to a solution of water-soluble pyrophosphate, the mixed solution is diluted to a known volume, and the precipitate of silver pyrophosphate is separated by filtration; excess silver is estimated by Volhard's method, using $N/10$ ammonium thiocyanate with iron alum as indicator. As silver pyrophosphate is soluble in a concentrated solution of sodium pyrophosphate, owing to the formation of a double salt, which however dissociates on dilution, and is also soluble in dilute acids, it is essential to work with dilute solutions and, if necessary, to neutralise any free acid with $N/10$ sodium hydroxide.—L. A. C.

Arsenious acid; Oxidation of —— by nitric acid in presence of mercuric ions: the change of a negative catalyst into a positive. A. Klemenc and F. Pollak. Z. anorg. Chem., 1921, **115**, 131—140.

Mercuric nitrate may catalyse the oxidation of arsenious acid by nitric acid positively or negatively according to its concentration. At a concentration of $7{\cdot}7\times10^{-6}$ mols. per l., the reaction is completely inhibited. With diminishing concentration the inhibiting effect becomes smaller down to $7{\cdot}7\times10^{-8}$, and at $7{\cdot}7\times10^{-9}$ mols. per l. there is a positive catalytic effect, which becomes more marked at $7{\cdot}7\times10^{-11}$. The extraordinary sensitiveness of the reaction to mercury is such that, when a flask had once been used for a reaction in presence of mercury, the positive catalytic effect was shown when the flask was again used for a blank experiment, in spite of most careful cleaning. The smallest previously recorded effective concentration for catalysis was 7×10^{-6} mols. per l. of colloidal platinum in the decomposition of hydrogen peroxide. (*Cf.* J.C.S., July.)—E. H. R.

Organic carbon; Determination of —— in bituminous limestones. E. Sernagiotto. Giorn. Chim. Ind. Appl., 1921, **3**, 153—154.

Organic carbon in bituminous limestones may be conveniently and accurately estimated by the Corleis method for determining the total carbon in steel. On one side the Corleis flask, which is covered externally with asbestos and fitted with an internal condenser, is connected with a tower charged with lump potash, and on the other with a sulphuric acid drying tube, a short hard glass tube containing cupric oxide and lead chromate, a phosphoric anhydride tube, a soda-lime tube, and a phosphoric anhydride tube. Such an amount of the material as contains about 0·1 g. of organic carbon is introduced into the flask by means of a long, wide-necked funnel, which is washed down with 30 c.c. of syrupy phosphoric acid and then with water; the flask is then closed by a rubber stopper carrying two glass tubes. Expulsion of the carbon dioxide is effected by heating the flask gently and repeatedly evacuating it with a water-pump, the expelled gas being replaced each time by air which has passed through the potash tower. The condenser is then introduced, the sulphuric acid seal in the neck of the flask restored, and the absorption apparatus connected, the copper oxide tube being heated to redness. The chromic acid solution is prepared by dissolving the pure acid in its own weight of water and boiling 35 c.c. of this solution for half an hour with 200 c.c. of pure sulphuric acid (sp. gr. 1·84). This liquid, when cold, is placed in the flask and heated gently to boiling, which is maintained for about 4 hrs. The procedure is then identical with that followed in estimating carbon in cast iron. —T. H. P.

Oxalates; Decomposition of ——. M. Herschkowitsch. Z. anorg. Chem., 1921, **115**, 159—167.

When ferric oxide is prepared by ignition of ferrous oxalate, unless a sufficient supply of air is assured the product is contaminated with ferrous oxide and carbon, and is consequently unsuitable for glass polishing. When ferrous oxalate is ignited in absence of air, about half of the iron appears in the residue as ferrous oxide, the remainder as metal, a little carbon is formed, and a mixture of carbon monoxide and dioxide is evolved. The decomposition of oxalates of nickel, potassium, calcium, and lead in absence of air was also studied. The primary products are always metal and carbon dioxide; nickel oxalate gives almost pure nickel. The more readily oxidisable metals, such as potassium and calcium, reduce about half of the carbon dioxide to monoxide, eventually forming carbonate and carbon monoxide. In the case of lead oxalate, part of the carbon dioxide is reduced with formation of lead

suboxide. By a calorimetric examination of the residue from heating lead oxalate, the heat of formation of lead suboxide from its elements was found to be +49,190 cals. (*Cf.* J.C.S., July.)
—E. H. R.

Cyanogen chloride; Preparation of ——. E. Sernagiotto. Giorn. Chim. Ind. Appl., 1921, **3**, 153.

HYDROCYANIC acid, obtained by dropping water on to a mixture of sodium bisulphate and sodium cyanide, is passed together with chlorine through a bulb tube filled with animal charcoal and surrounded by a jacket through which water is circulated, the reaction occurring being expressed by the equation $Cl_2+HCN=HCl+CNCl$. In order that the cyanogen chloride may not undergo polymerisation the hydrogen chloride is completely removed by passing the mixed gases through a tower charged with moistened marble, the carbon dioxide thus liberated escaping when the cyanogen chloride is condensed by means of ice. The exhaust pipe should pass under a hood or into the air-pipe of a lighted gas blowpipe.
—T. H. P.

Chlorine; Formation of Julin's chloride [hexachlorobenzene] in the electrolytic preparation of ——. F. Bourion and C. Courtois. Comptes rend., 1921, **172**, 1365—1367.

THE white crystalline material, which collects in the pipes through which the chlorine passes from the electrolytic cells, is shown to consist for the most part of hexachlorobenzene with some less chlorinated derivatives of benzene. These compounds are probably formed from the tar used in the manufacture of the carbon anodes and not completely destroyed in the subsequent heating.—W. G.

Carbon formed by the action of mercury on carbon tetrachloride, tetrabromide, and tetra-iodide. G. Tammann. Z. anorg. Chem., 1921, **115**, 145—158.

BY the action of mercury vapour on carbon tetrachloride at 600°—700° C., mercurous chloride and carbon are formed. Under high pressure, 900—2760 kg. per sq. cm., the reaction starts at about 400° and is accompanied by a fall in pressure. Carbon tetrabromide and tetra-iodide react similarly. The carbon so formed has an abnormally high density, 2·32—2·51, that of graphite being 2·1 to 2·3. It absorbs water very readily, and is chemically more reactive than other forms of carbon, such as sugar carbon. The density of different forms of carbon is discussed, and its bearing on the condition diagram of carbon and the artificial and natural formation of graphite and diamond. (*Cf.* J.C.S., July.)—E. H. R.

Carbon; Behaviour of —— *towards silicon.* G. Tammann. Z. anorg. Chem., 1921, **115**, 141—144.

WHEN a loose mixture of equal weights of silicon and carbon is heated, an exothermic reaction starts at a temperature depending on the kind of carbon used. With carbon prepared by heating carbon tetrachloride with mercury at 450° C. the reaction started at 1220° C., with soot from turpentine at 1340°, with sugar charcoal at 1410°, and with graphite at 1390° C. The reaction product from the first kind of carbon, when freed from unchanged arbon and analysed, appeared to contain the compound SiC. It consisted of microscopic particles mixed with a small quantity of thin needles. The density of the particles varied between 2·4 and 2·8, nd after slow ignition that of the heavier particles ncreased to 3·0. The density of carborundum is ·12. Similar products were obtained by using a igher proportion of carbon and by heating carbon with silica in a carbon tube, but these had a composition varying between SiC and SiC_2.—E. H. R.

Carbon; Condition diagram of ——. J. A. M. van Liempt. Z. anorg. Chem., 1921, **115**, 218—224.

THE work of Lummer, Fajans, Van Laar, and others on the temperature of the crater of the carbon arc at low and high pressures is discussed. The supposed observation of liquid carbon at temperatures below 4700° C. is probably erroneous.
—E. H. R.

Arsenic acid. Kolthoff. *See* XXIII.

PATENTS.

Catalysts [for ammonia synthesis]; Process for production of ——. L. Duparc and C. Urfer. E.P. 140,061, 16.2.20. Conv., 13.3.19.

A REDUCING metal, such as aluminium or magnesium, is caused to react at normal pressure with at least one oxide of such metals as lithium, uranium, calcium, barium, strontium, titanium, glucinum, molybdenum, and vanadium, which when heated with nitrogen form pulverulent nitrides readily decomposed by hydrogen. A pulverulent mass is thus produced consisting of the reduced metal distributed in a very finely divided and pure state over the oxide of the reducing metal, which serves as a carrier. During the reduction of the metallic oxides nitrides of the metals may be formed and may therefore be present in the catalyst; as their presence renders the catalyst more active it is advantageous to assist their production by cooling the composition, after reduction of the oxide, in pure nitrogen or air. The catalysts produced by this process are characterised by high activity, and may be utilised for the synthesis of ammonia at atmospheric pressure and at temperatures between 250° and 600° C.—W. J. W.

Ammonia synthesis; Catalyst for —— *and process of preparing the same. Process of synthesising ammonia.* J. C. Clancy, Assr. to The Nitrogen Corporation. U.S.P. (A) 1,363,392 and (B) 1,363,393, 28.12.20. Appl., (A) 20.12.19, (B) 1.6.20.

(A) PURIFIED pumice, asbestos wool, or the like is impregnated with a concentrated solution of calcium ferrocyanide, dried at 100° C., and heated with exclusion of air, *e.g.*, in a mixture of nitrogen and hydrogen, for 10—12 hrs. at about 150° C., then gradually to 200° during 6 hrs., at 200° for 2 hrs., to 300° during 6 hrs., at 300° C. for 3 hrs., then gradually to 350° C. and at 350° C. for several hours. After cooling, the material is transferred to the contact chamber of an apparatus for the synthesis of ammonia, to which a mixture of nitrogen and hydrogen at 100 atm. pressure is supplied at the rate of 300 cub. ft. per hr. The contact material is heated gradually to 300° C., then gradually to 360° C., kept at 360° C. for 1 hr., and then the temperature is allowed to rise to about 450° C., at which temperature the catalyst is maintained by controlling the rate of flow and pressure of the gas, until hydrogen cyanide is no longer evolved. The pressure is then reduced to 1000 lb. per sq. in. and the rate of flow increased to 400 cub. ft. per hr., whereupon the temperature may rise suddenly to 600° C., but is caused to drop to 450° C. by adjusting the pressure and rate of the flow of the gas. The catalyst is then ready for use in the synthesis of ammonia at 450° C. and 100 atm. pressure with a gas flow of 400 cub. ft. per hr. (B) Ammonia is synthetised with the aid of a highly porous support and catalyst prepared as under (A).—W. J. W.

Ammonium salts; Purification of ——. G. B. Ellis. From Foundation Oven Corp. E.P. 163,162, 1.3.20.

CRUDE ammonia liquor is freed from organic impurities by treatment with a solvent such as benzene which is then removed, after which the liquor is filtered, if necessary, to separate solid impurities. The purified liquor is used to neutralise any free acid present in ammonium salts, such as the sulphate.—W. J. W.

Ammonium chloride and potassium nitrate; Manufacture of ——. Badische Anilin- und Soda-Fabrik. G.P. 307,112, 18.4.16. Addn. to 306,334 (J., 1921, 179 A).

The solution, after separating most of the potassium nitrate, is concentrated slightly, moderately cooled to deposit ammonium chloride, and filtered. To render the process continuous, limited quantities of potassium chloride, ammonium nitrate, and water are added to the residual liquor, and the latter is again subjected to the process. For example, to 72 pts. of a solution containing 16 pts. each of potassium nitrate and ammonium chloride and 40 pts. of water, there are added 28 pts. of water, 8 pts. of ammonium nitrate, and 7·5 pts. of potassium chloride. After dissolving the added salts by heating to 30°—40° C., potassium nitrate is separated by cooling to 0° C., then 27—28 pts. of water is evaporated from the mother liquor, and the residual solution cooled to 20° C., whereupon pure ammonium chloride separates.

Iron salt [for tanning]; Process for the production of a solid non-hygroscopic ——. O. Röhm. E.P. 146,218, 26.6.20. Conv., 11.4.19. Addn. to 146,214 (J., 1921, 388 A).

A solid non-hygroscopic iron salt, suitable for tanning purposes, is obtained by removing the liberated hydrochloric acid from a mixture of ferric chloride, sulphuric acid, and water in the molecular proportions, 1:1:6, or by allowing a mixture of ferric chloride, ferric sulphate, and water in the molecular proportions, 1:1:18, to react and solidify. A crystalline salt, $FeSO_4Cl,6H_2O$, is obtained.—D. W.

Carbon monoxide; Conversion of —— *into carbon dioxide.* J. C. Clancy, Assr. to The Nitrogen Corp. U.S.P. 1,376,514, 3.5.21. Appl., 7.2.20.

The preferential combustion of carbon monoxide in presence of hydrogen is effected by a catalyst which includes a cyanogen compound of copper.—C. I.

Lead oxide; Process and apparatus for the production of ——. H. S. Reed and H. L. Publow. U.S.P. 1,376,581, 3.5.21. Appl., 17.9.20.

Basic lead carbonate mixed with organic matter is heated with agitation in a revolving drum in an electric furnace to 315° C. until all the organic matter is oxidised. The material is then heated to about 600° C. in a closed electric furnace with an exit for carbon dioxide, yielding granular lead oxide.—C. I.

Sulphur dioxide; Process of recovering ——. *Process of obtaining a continuous supply of sulphur dioxide from white metal [copper matte].* W. H. Howard, Assr. to American Smelting and Refining Co. U.S.P. (A) 1,377,012 and (B) 1,377,013, 3.5.21. Appl., 10.5.18 and 10.3.20.

(A) Copper matte is blown or otherwise treated to yield gases having a comparatively low content of sulphur dioxide and then in portions at a time to yield gases high in sulphur dioxide. (B) Different batches of the matte are treated successively without intermission to yield a continuous supply of sulphur dioxide.—B. M. V.

Gelatinous precipitates; Purification of ——. M. Buchner. G.P. 303,312, 1.2.14.

Such compounds as the hydroxides of aluminium and iron are precipitated and extracted with water in an extraction apparatus, the precipitate being covered with a porous plate.—C. I.

Bituminous ores [e.g. alum shale]; Treatment of ——. R. Blum. G.P. (A) 305,656, 28.9.17, and (B) 312,382, 10.10.17.

(A) The bitumen of aluminous and similar ores is gasified by distillation with water-gas or hydrogen. The products of gasification, *e.g.*, power gas, tar, oil, sulphur, ammonia, and other valuable by-products are recovered and the residue of metal oxide or mixture of metal oxides is then treated. (B) Earthy bituminous matter containing several metal oxides is gasified and the residue treated to separate the metals or metal compounds. The residue may be treated with sulphuric acid or bisulphate, the filtrate drawn off from the insoluble portion and precipitated with ammonia and the precipitate treated by a suitable process to recover alumina and ferric oxide, whilst ammonium sulphate is obtained from the mother liquor. Alternatively, the filtrate drawn off from the insoluble portions is treated with hot saturated ammonium sulphate solution, ammonium alum is crystallised from the solution and decomposed with ammonia to recover the alumina, whilst ferric hydroxide is precipitated from the mother liquor by ammonia. The ammonium sulphate liquor remaining in both cases is either put back into the process or the solid salt recovered. Even in cases where the ash content is 50% or above and large amounts of silicic acid are present, the method is workable.—T. H. Bu.

Alkali thiosulphate; Preparation of ——. A. Clemm. G.P. 307,131, 24.3.18. Addn. to 305,194 (J., 1920, 406 A).

Half the alkali sulphide is replaced by the sulphide of an alkaline-earth, and the mixture is subjected to the action of carbon dioxide and air in presence of carbonaceous material. In this way the sulphur of gypsum etc. can be utilised.—C. I.

Hydrogen sulphide; Process for the removal of —— *from gases.* Badische Anilin- u. Soda-Fabrik. G.P. (A) 334,524, 20.2.16, and (B) 334,525, 15.3.16.

(A) Gas is washed with a suspension or solution of ferric hydroxide or carbonate in an alkaline solution, and the solution oxidised with air in the reaction vessel. The oxidised liquor should not be completely reduced in further use. The process can be worked continuously with circulation, or alternately with two vessels, and sulphur is recovered in the elementary state. (B) Suspensions of ferric hydroxide or carbonate in water or a solution of a neutral salt may also be used.—C. I.

Arsenical compounds [thioarsenates]; Manufacture of ——. K. B. Edwards. E.P. 162,747, 29.1.20.

Thioarsenates of the general formula, $RAsO_{3-x}S_x$ or $R_3AsO_{4-x}S_x$, are obtained by treating arsenious oxide or trisulphide with an alkali polysulphide, or by treating arsenic pentasulphide with an alkali monosulphide, or preferably by treating a solution of an arsenate with hydrogen sulphide. For example, if 100 pts. of a solution containing 420 g. of sodium arsenate per l. is treated with 3·5 pts. of hydrogen sulphide, the compound $Na_3AsO_3S,12H_2O$ is deposited in crystals on the addition of alcohol. Larger quantities of hydrogen sulphide give successively the compounds, $Na_3AsO_2S_2,10H_2O$, $Na_3AsOS_3,11H_2O$, and finally by saturating the solution with the gas at 60° C., $Na_3AsS_4,8H_2O$ is obtained. The potassium salts are obtained in a similar manner, and organic ammonium salts by double decomposition with the above. As an example of the alternative methods, 6·4 pts. of sulphur is dissolved in a solution of 72 pts. of sodium sulphide in 48 pts. of water, and 19·8 pts. of arsenious oxide is added to the cooled solution. A violent reaction occurs and the mixture is finally boiled until a clear solution is obtained which may be reduced to a dry powder, consisting of equimolecular quantities of $Na_3AsO_2S_2$ and Na_3AsOS_3, by evaporation in a vacuum ball mill.—G. F. M.

Hydrogen or oxygen; Apparatus for purification of ——. G. F. Jaubert. E.P. 148,564, 10.7.20. Conv., 12.10.18.

A perforated metallic basket containing a catalyst is surrounded by an electrical spiral for heating to start the reaction, and further by a heat-retaining sheath. The whole is enclosed in a casing connected below with a heat-recovering device comprising a number of parallel tubes enclosed by a jacket. The hydrogen (or oxygen) to be purified traverses the heat-recovering device on its way to the catalyst in one direction, whilst the purified gas passes around the tubes and loses its heat of reaction whilst passing out in the reverse direction. —H. R. D.

Fractionally distilling gaseous mixtures [*air*]; *Continual process of* ——. W. Lachmann. U.S.P. 1,363,659, 28.12.20. Appl., 3.3.16. Renewed 1.10.20.

A rectifying column (which may be heated) having inlets for the mixture (liquefied air) at the middle, and for the more volatile constituent (liquid nitrogen) at the top, and outlets for less volatile constituent (liquid oxygen) at the bottom and for the more volatile constituent (liquid nitrogen) at the top, is also provided with an additional or "fore" outlet near the top, but below the top outlet, for diverting part of the contents of the column to the top inlet in order to increase the ratio of falling liquid to rising gas in the upper part of the still. By suitable regulation it is possible to obtain either nitrogen or oxygen in a pure state from the column, but not both.—B. M. V.

Chlorine solution; Apparatus for production of a ——. M. G. Slocum. U.S.P. 1,376,471, 3.5.21. Appl., 29.11.19.

Sodium chloride solution is electrolysed in a cell in which the anode is enclosed in a vessel in which pressure can be developed.—C. I.

Bromine; Method for extracting —— [*from brines*] *and apparatus for use therein.* H. H. Dow, Assr. to The Dow Chemical Co. U.S.P. 1,376,610, 3.5.21. Appl., 7.6.16. Renewed 14.8.20.

rine is subjected to electrolysis, and the gases prouced and not absorbed by the brine are drawn off y means of air, after which the absorbed gases are ecovered from the brine.—W. J. W.

mmonia saturators. American Coke and Chemical Co., Assees. of A. Roberts. E.P. 138,129, 24.1.20. Conv., 17.4.15.

e U.S.P. 1,331,784 of 1920; J., 1920, 294 a.

ydrogen and zinc oxide; Process of making ——. R. H. McKee. E.P. 163,210, 17.5.20.

e U.S.P. 1,355,904 of 1920; J., 1920, 819 a.

rmanganates; Process for manufacture of ——. H. O. Jenkins and H. Woolner. U.S.P. 1,377,485, 0.5.21. Appl., 3.2.19.

Se E.P. 126,756 of 1918; J., 1919, 462 a.

Amonium sulphate; Process of neutralising and rying commercial ——. S. E. Linder and R. essing, Assrs. to Hydronyl Synd., Ltd. U.S.P. 377,493, 10.5.21. Appl., 2.6.19.

S E.P. 141,787 of 1919; J., 1920, 447 a.

Minerals and rocks containing potassium; Process of recovering useful substances [*potassium compounds*] *from* ——. O. Ravner, Assr. to Det Norske Aktieselskab for Elektrokem. Ind. U.S.P. 1,377,601, 10.5.21. Appl., 24.2.19.

VIII.—GLASS; CERAMICS.

Clays; Plasticity of ——. J. W. Mellor. Faraday Soc., 31.5.21. [Advance proof.]

The plasticity of a clay depends on the resistance it offers to change of shape and also on the amount of deformation which it can undergo without cracking. No method of measuring plasticity is satisfactory which does not take account of both these factors. As water is added progressively to a dry clay the plasticity increases until a maximum value is attained, after which any further addition of water results in decreased plasticity. The greater the moulding pressure applied to the clay the smaller is the proportion of water required to develop maximum plasticity. It is probable that, other things being equal, the distribution of grain sizes which permits the closest packing of the particles and exposes the maximum surface area will be most favourable to high plasticity. Agents which cause a clay slip to coagulate enhance the plasticity of clays, while those which deflocculate the clay diminish its plasticity. These effects can be explained by considering the various molecular forces between the clay and liquid molecules. Plasticising agents (*e.g.*, gum, tannins, etc.) probably act indirectly by adsorption, though the plasticity of china clays practically free from organic matter shows that adsorbed organic colloids are not the source of their plasticity. There is an intimate connexion between the plasticity of a clay and its past history with respect to contact with water, which suggests that the clay is slowly hydrated to form a colloid, though no difference can be detected in the plasticity of a clay after removing as much of its colloidal matter as possible. Clays gradually lose some of their so-called combined water at ordinary temperatures, but the water is regained on exposure to a moist atmosphere, showing that no drastic change has occurred in the structure of the clay molecule. This change is wholly different from that which occurs when water is expelled at a higher temperature. The re-absorption of the water is then so very slow that a long time is required to restore the original plasticity. The working qualities of certain troublesome clays can be modified by desiccation. —H. S. H.

Viscosity of suspensions. Egner. *See* I.

Patents.

Glass and its manufacture. L. E. Barton and H. A. Gardner, Assrs. to Titanium Pigment Co. U.S.P. 1,362,917, 21.12.20. Appl., 21.3.17.

Titanic oxide is incorporated with a glass batch in proportion not less than 25% of the total, and the mixture is fused at a temperature and for a time sufficient to ensure chemical combination of the titania. The fusibility and fluidity of the charge are increased, and a uniformly translucent or transparent, easily workable glass is obtained.

Bricks; Manufacture of ——. W. W. Crawford. E.P. 162,683, 1.12.19.

Any kind of earth, soil, or clay is burned in an oxidising atmosphere at about 1500° C. and then mixed with a relatively small quantity of previously dehydrated Portland or like cement. The mixture is moistened with water and pressed into moulds. The moulded bricks are immersed in cold water for several hours and finally air dried at a temperature only slightly above 0° C.—H. S. H.

Kilns for burning blue or other bricks. H. J. Alletson. E.P. 163,251, 10.12.20.

The firing chambers of the kilns communicate with each other by cross flue passages controlled by dampers. Each chamber has a flue outlet passage, controlled by a damper, leading to the main flue, and also a by-pass flue extending over or around the top of the chamber and also controlled by a damper. A chamber is heated to the "blueing" temperature and the dampers adjusted so as to change from an oxidising to a reducing atmosphere. The products of combustion from each chamber pass through or around the succeeding chamber in which bricks are being burnt and then into the next chamber made ready for firing.—H. S. H.

IX.—BUILDING MATERIALS.

Steel reinforcement in blast-furnace slag cement. R. Grün. Stahl u. Eisen, 1921, **41**, 577—579. (*Cf.* J., 1921, 260 A.)

Laboratory tests show that the rusting of steel in alkaline concretes to any great extent is excluded provided porosity and consequent entrance of air is prevented by working the material sufficiently in the usual manner. From the practical point of view observations made on ferro-concretes at various industrial centres show that the reinforcement remains permanently unaffected in concretes prepared from slag cement, Portland, and iron-Portland cement. Either iron-Portland cement or blast-furnace slag cement, provided it is prepared according to specification, can be used equally well in the manufacture of ferro-concrete.—J. W. D.

Patents.

Plastic composition and method of producing the same. G. M. Formby, Assr. to Formby Petrinite Corp. U.S.P. 1,376,523, 3.5.21. Appl., 11.5.20.

A plastic composition is produced by adding water and lime to calcium oxychloride, boiling the mixture thus produced and letting it set, and finally mixing with it Keene's cement.—H. S. H.

Lime-burning process. J. C. Schaffer. U.S.P. 1,377,367, 10.5.21. Appl., 19.1.17.

A rotary kiln having devices for supplying material at one end and for discharging the products at the other end into a cooler is combined with a furnace having a combustion chamber outside the kiln. The furnace is by-passed by the discharge to the cooler from the kiln. A controlled steam supply below the grate of the furnace enables the humidity to be modified and a "tempered combustion region" to be produced extending from the furnace into the kiln.—H. S. H.

Quicklime production. W. Crow and J. C. Schaffer. U.S.P. 1,377,401, 10.5.21. Appl., 13.11.17.

The method comprises decarbonating limestone, mingling with it a "lime hydrate," and passing the mixture through a region of gradually increasing temperature in order to produce porous nodules. —H. S. H.

Burning of watery material [cement slurry] in [rotary] kilns. A. Larsen. E.P. 144,255, 22.3.20. Conv., 4.6.19.

See U.S.P. 1,358,760–1 of 1920; J., 1921, 11 A.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron; Dephosphorisation of Ilseder basic —— in the basic converter and open-hearth furnace. A. Jung. Stahl u. Eisen, 1921, **41**, 687—692.

With the limitations due to a few trials only having been made and the use of a plant not designed to work hot metal, the dephosphorisation of Ilseder pig-iron (3% P) by the Hirsch process is described, also the recovery of the phosphoric acid, using both poor and rich ores in the primary furnace. The trials deal with dephosphorisation only, economy and output not being considered. The results given indicate that in the basic Bessemer process the phosphorus in the iron is utilised to greater advantage than in the open-hearth process.—J. W. D.

"Reversed chilled iron." P. Bardenheuer. Stahl u. Eisen, 1921, **41**, 569—575, 719—723.

The nature of and conditions giving rise to "reversed chilled irons" were investigated by the examination of various artificially prepared irons. These investigations show that if the iron is undercooled after casting it solidifies as a hard white iron, with an exterior wall which becomes grey iron, due to the production of temper carbon. The causes favourable to undercooling are a high sulphur content and a low casting temperature.—J. W. D.

Manganese; Determination of —— in cast iron. F. Graziani and L. Losana. Giorn. Chim. Ind. Appl., 1921, **3**, 148—152.

Gravimetric methods for estimating manganese in cast iron, although the most accurate, are tedious and for ordinary purposes the best method is Campredon's modification of the Volhard method (*Guide prat. du chim. métall. et de l'essayeur*, 1909, 511). This consists in treating the sample with hydrochloric acid, oxidising it with potassium chlorate, evaporating to dryness, re-dissolving in hydrochloric acid, diluting, precipitating the iron by boiling for 15—20 mins. with a slight excess of zinc oxide—which also neutralises the liquid—and titrating with permanganate solution until a persistent pink tint is obtained.—T. H. P.

Iron; Diffusion velocity of carbon in ——. I. Runge. Z. anorg. Chem., 1921, **115**, 293—311.

The velocity of diffusion of carbon into iron was determined by measuring the change of resistance of iron wire in a current of gaseous hydrocarbon at high temperatures. Illuminating gas diluted with hydrogen had little or no action. Toluene diluted with nitrogen reacted slowly, but more quickly when diluted with hydrogen, whilst a rapid action was shown by mixtures of benzene with nitrogen, petroleum ether (b.p. 90°—100° C.) with hydrogen, and hexane with nitrogen or hydrogen. The resistance-time curves were similar in character to the theoretical curve, assuming the diffusion of carbon to follow the diffusion law. At 900° C. the diffusion coefficient of carbon in iron is about 2×10^{-7} sq. cm. per sec. With an active gas, at 930° C., 0·6 mg. of carbon passes through 1 sq. cm of surface in the first 3 mins. The resistanc change due to 1% of carbon is 5·7% at 920° C., 7% at 830° C., and 40% at 18° C. of the resistance a the corresponding temperature. The velocity o cementation falls off rapidly with temperature an at 700° C. is inappreciable. About 900° C. γ-mixe crystals are formed, and the product consists o cementite and pearlite. At 800° C. the β-iron take up carbon to form an equilibrium mixture of γ-mixed crystals containing 0·3% C and β-iron. The experiments do not show conclusively whether diffusion takes place in the gaseous form or as carbon, but the marked influence of hydrogen on the rate of diffusion points to the former.—E. H. R.

Eutectic points and solubility limits in systems containing iron; Calculation of the positions of ——. K. Daeves. Z. anorg. Chem., 1921, **115**, 290—292.

It has been shown by Tammann that in mixed crystal series there are certain limiting compositions beyond which the mixed crystals are or are not attacked by certain chemical agents, and that these limits are found where the atomic proportion of one constituent is $\frac{1}{8}$ or a multiple of this fraction (Z. anorg. Chem., 1919, **107**, 1). In binary systems containing iron, for instance iron with carbon, titanium, phosphorus, arsenic, or boron, similar atomic or molecular fractions are of importance. For instance pearlite contains 0·89% C or $\frac{1}{8}$ mol. of Fe_3C; the solubility limit for carbon, 1·75%, corresponds with $\frac{2}{8}$ mol. of Fe_3C whilst the eutectic point, 4·29% C, corresponds with $\frac{3}{8}$ mol. Fe_3C. The molecular fraction $\frac{5}{8}$ frequently occurs at the eutectic point of an alloy. Such relations may throw light on the molecular structure of alloys.
—E. H. R.

Copper impurity in lead ores smelted at the Sulphide Corporation's works, Cockle Creek; Treatment of the ——. D. C. M'Gruer. Proc. Austral. Inst. Min. Met., 1920, 93—103.

In the refining of the lead bullion before putting it through the Parkes process, the copper impurity is removed by drossing in copper kettles. The "wet" dross obtained is sweated in a suitable furnace and the resulting dross, containing 60—70% Pb, 6·6% Cu, 2·2% Fe, 1·5% Zn, 4·5% Sb, 1·6% As, and 4·5% S, is smelted in a small blast furnace with the necessary fluxes to produce a low-grade matte containing about 23% each of lead and copper. This is worked up to a high-grade matte which is tapped when the iron content is 2%, the copper and lead then being about 47% and 24% respectively. This product is crushed, roasted at 600°—625° C., so as to obtain about 7·5% of sulphur as sulphate, and leached with hot dilute sulphuric acid at 70° C. until the solution contains 7—8% Cu and is nearly neutral. The residue is agitated with hot 5—10% sulphuric acid until no further quantities of copper are dissolved; it is then returned to the original lead blast furnace to recover its lead and precious metal contents. The opper liquors are purified by agitation with lime nd copper oxide (roasted matte or copper preipitate) by means of a stream of air and steam. he resulting liquors containing 80 g. Cu, 3·1 g. Zn, 15 g. Fe per litre, and traces of As, are concenrated in 750-gall. lead-lined vats fitted with steam oils, until the liquid attains a sp. gr. of 1·4, when t is run into a storage vat where it is further conentrated by waste steam to 1·42 sp. gr.; it is then assed to the crystallising vat. The mother liquor divided into two parts, one of which is treated ith scrap iron and the resulting copper precipitate asted and used as a source of copper oxide, and e other added to the liquor in the purifier. The ystals of copper sulphate obtained assay 99·23% $uSO_4,5H_2O$ and 0·09% Zn, with traces of nickel d iron, while the mother liquor contains 84 g. Cu d 11·0 g. Zn per l.—A. R. P.

inc; Recovery of —— *from lead blast-furnace slags.* G. Courtney. Proc. Austral. Inst. Min. Met., 1920, 75—84.

ARGES of ten tons of slag were heated in a reverratory furnace with limestone and coke, and it s found that 35—40% of the zinc was expelled in the fume, but only when the temperature was above 1600° C. Heating the slag in an electric resistance furnace without addition of reducing agents or fluxes expelled 60% of the zinc content in the fume, which assayed approximately 15% $PbSO_4$, 5% $PbCO_3$, and 63% ZnO. The best results were obtained in the blast furnace by running a charge consisting of 100 pts. of slag, 17 pts. of limestone, and 34 pts. of coke. The charge assayed 3·6% Pb and 7·8% Zn, and yielded 70% of its lead and 60% of its zinc content as fume, which assayed 63% ZnO, 25·4% PbO, and 8% SO_3. The tests showed that for economical recovery the slags should not contain much less than 15% Zn and that it is preferable to start with cold slag, as a considerable quantity of the zinc is evolved before melting and then hardly any more comes off until the temperature reaches 1600° C.—A. R. P.

Copper-zinc alloys; Specific heat of technical —— *at higher temperatures.* F. Doerinckel and M. Werner. Z. anorg. Chem., 1921, **115**, 1—48.

The specific heat of copper-zinc alloys containing 58%, 63%, 67%, 72%, and 85% Cu, and of pure copper increases with increasing temperature. In the case of tempered alloys (previously heated to 800° C.) the increase is linear, but the curves for untempered alloys, when the copper content is 72% or less, show a sudden increase of specific heat at about 470° C. This discontinuity may be due to a tempering effect, or more probably is connected with the transition from β-mixed crystals to α- and β-brass observed by Carpenter and Edwards at about 470° C. Experiments on the effect of tempering on the specific heat gave somewhat inconclusive results. It is probable that small amounts of impurity influence the behaviour of the alloys in an indeterminate manner. The true specific heat at temperature, T, is given by the equation $C = a + 2b(T - t)$ where a is the specific heat at $t = 20°$ and b is a constant. The true specific heats at different temperatures are given in the following table:—

% Cu.	20°C.	100° C.	232° C.	400° C.	600° C.	800° C.
99·82	0·0922	0·0941	0·0972	0·1010	0·1059	0·1106
84·80	0·0922	0·0944	0·0977	0·1021	0·1071	0·1125
70·96	0·0916	0·0942	0·0972	0·1032	0·1090	0·1159
66·42	0·0909	0·0937	0·0980	0·1034	0·1099	0·1168
62·96	0·0902	0·0940	0·0998	0·1070	0·1168	0·1254
57·28	0·0895	0·0951	0·1038	0·1145	0·1283	0·1418
53·50	0·0892	0·0955	0·1059	0·1191	0·1349	0·1506

The figures of the last line were obtained by extrapolation. With decreasing copper content the specific heat rises in a linear manner above 300° C., whilst below this temperature it falls slightly or remains practically constant. At about 65·8% Cu, however, there is a sudden change in the direction of the curve, in the sense of a much more rapid rise in specific heat with diminishing copper content at higher temperatures, and a more rapid fall at lower temperatures. Between 100° and 200° C., however, the specific heat remains practically constant for all compositions. The break in the curves at 65·8% Cu corresponds with the saturation limit for α-mixed crystals which has been previously found at 64% Cu. (*Cf.* J.C.S., July.)—E. H. R.

Aluminium and light metal alloys; Influence of cerium on the properties of ——. J. Schulte. Metall u. Erz, 1921, **18**, 236—240.

Addition of cerium (up to 0·77%) to aluminium and to alloys of aluminium with 3% Cu or 3·3% Mg does not appreciably affect the tenacity or conductivity but makes the metal more ductile and lowers its resistance to attack by acids. Aluminium alloys containing 4% Mg. or 10% Cu, or 25% Zn are unaffected by treatment with cerium. Contrary to previous statements, addition of cerium to commercial aluminium does not remove the silicon, but it considerably diminishes the nitrogen content, thus 0·2% Ce reduced the nitrogen from 0·028 to 0·014%; further addition, however, only lowered this very slightly. The presence of foreign metals in the aluminium tends to prevent the removal of nitrogen by cerium.—A. R. P.

Patents.

Metals and alloys; Vacuum melting and refining ——. W. C. Heraeus G.m.b.H. E.P. 138,648, 5.2.20. Conv., 11.1.18.

Metals or alloys are melted in a hermetically closed electric furnace under diminished pressure. A high vacuum is then produced and heating continued till no increase in pressure is observed. The pressure, temperature, and duration of treatment vary with the character of the material. High-grade alloys of exact composition are made by first purifying the ingredients by this method and subsequently melting them together by the same process. The process has been applied to the manufacture of very soft iron and pure nickel and nickel alloys. Pure amorphous metals or mixtures of metals may be converted into a homogeneous state without affecting their purity.—T. H. Bu.

Iron; Process of purifying and refining ——. W. C. Heraeus G.m.b.H. E.P. 138,651, 6.2.20. Conv., 18.4.18. Addn. to 138,648.

Commercial or other iron is treated by the process described in the chief patent (*cf. supra*) with the addition of oxidising and/or reducing agents, whereby gaseous and solid impurities are removed, and a soft iron with desirable magnetic and other properties is obtained.—T. H. Bu.

Cast iron articles; Manufacture of hard ——. F. Krupp A.-G. Grusonwerk. E.P. 143,554, 19.5.20. Conv., 20.5.19.

Articles of gray or mixed pig iron are cast in the usual way in sand, composition, or loam, and the like, dressed if necessary, then heated to the critical temperature, *i.e.*, the transition temperature of pearlite into martensite, and chilled in water or other liquid.—J. W. D.

Iron ore containing weakly magnetic or non-magnetic oxygen compounds of iron; Process and apparatus for treating ——. R. Stören and R. Johanson. E.P. 162,718, 29.12.19.

The material is reduced in a furnace consisting of a revolving cylinder having a central passage for the introduction of the heating agent, a refractory lining, and one or more reduction chambers arranged helically around the central heating passage. A magnetic separator consisting of a stationary and a movable system of magnets is arranged outside a belt of non-magnetic material in the furnace casing, the movable magnets effecting the delivery of magnetic material to a compartment of the furnace in which the reduction is continued. —J. W. D.

Iron ore; Smelting or reduction of ——. D. Wright. E.P. 162,725, 2.11.20.

A continuous process for the reduction of iron ores consists in blowing atomised liquid fuel into a furnace and burning it with an oxidising flame until a temperature of about 1500° C. is attained; diminishing the supply of air so that incomplete combustion of the fuel results and the furnace contains a continuously renewed superheated atmosphere of carbon monoxide; blowing into the furnace iron ore in an atomised or flour-like spray so that instantaneous chemical reaction takes place; and then, when the temperature of the furnace is reduced to about 1150° C., interrupting the admission of atomised ore and increasing the supply of air until the flame reassumes an oxidising character and the temperature of the furnace has risen again.—J. W. D.

Iron and steel; Furnace for the manufacture of ——. H. Lang. E.P. 162,808, 6.2.20.

A furnace for manufacturing iron and steel direct from the ore consists of a melting furnace of the open-hearth type in conjunction with a reducing furnace. Gas and hot air are admitted through inlets to the melting furnace, and the hot waste gases pass through a controlled opening to the reducing furnace and thence to a pair of regenerators used alternately.—T. H. Bu.

Steel; Recarburising molten —— in an open hearth furnace. J. N. Kilby and N. H. Bacon. E.P. 162,994, 20.9.20.

Carbonaceous material is introduced into the steel through the slag by means of a vessel provided with a hopper containing the carbonaceous material and having a downward extension passing through the slag. This extension is closed by a stopper of wood or other material readily consumed or melted, and the aperture between the hopper and the extension is closed by a similar material. The vessel is also provided with a vent to allow the escape of the gases generated by the reaction.—T. H. Bu.

Steel; High-speed —— and process of forming and forging the same. W. J. Mellersh-Jackson. From Forge Products Corp. E.P. 163,110, 10.2.20.

High-speed steels are forged at temperatures of 2000° F. (about 1090° C.) or under. The metal is thereby improved in quality, having greater homogeneity, density, and tensile strength, and may also be tempered within a greater range of temperature variation than hitherto possible.—J. W. D.

Iron; Manufacture of —— from iron ores. S. J. Vermaes, and Syndicaat "Electro-staal." E.P. 163,561, 30.3.20.

Finely-divided iron ore and fluxes are preheated together or separately at 1100° C., then discharged into a reduction furnace, heated indirectly through the walls, wherein they are mixed with finely grained solid carbonised or non-carbonised fuel and the mixture heated to a temperature above 1000° C., but below the melting point of iron. The mass is rapidly reduced, carbon monoxide being formed, and is then transferred to another furnace and melted by burning part of the gas produced in reduction, the remainder of the gas being used partly to heat the first furnace and partly to preheat the ore and fluxes. Rotary furnaces are preferably used.—J. W. D.

Alloy steel to carbon steel; Process of uniting ——. O. L. Mills. U.S.P. 1,376,963, 3.5.21. Appl., 10.10.19.

A tape is evenly coated on one side with a paste containing finely-divided alloying material mixed with linseed oil, and is wrapped round a low-carbon steel core with the coated side in contact with the core. This electrode is then dried and an electric current passed through it and the metal to be coated, thus uniting the fused alloy with the fused surface of the metal.—T. H. Bu.

Case-hardening; Process for controlling ——. W. H. Allen, Assr. to Parker Rust-Roof Co. U.S.P. 1,377,174, 10.5.21. Appl., 17.4.19. Renewed 17.1.21.

Selected areas of iron and steel articles are hardened by coating them with a material which is disintegrated by heat but is insoluble in dilute acids, converting the remaining areas into iron phosphates, and then subjecting the whole to case-hardening gases.—H. H.

Iron ores; Treatment of ——. F. A. Eustis, Assr. to C. P. Perin. U.S.P. 1,377,822, 10.5.21. Appl., 27.4.20.

Iron ore containing alumina is treated with a solvent which dissolves both the iron and alumina. After precipitation of the alumina by chemical means, metallic iron is obtained from the solution by electrolysis.—C. A. K.

Alloys of iron with molybdenum, vanadium, and tungsten; Process for making ——. P. Müller. G.P. 334,065, 16.2.18.

The alloys are made directly from the sulphide ores, molybendite, patronite, and tungsten sulphide, by melting together with the necessary amount of iron to give the desired concentration of metal, corresponding to $MoS_2+3Fe=FeMo+2FeS$ or a similar equation. For complete desulphurisation after removing the iron sulphide, silicon, aluminium, manganese, or a mixture of lime and carbon is added to the bath. When using ores containing copper, alloys free from copper are obtained and no loss of molybdenum by volatilisation of molybdic acid takes place.—T. H. Bu.

Zinc; Recovery of —— by electrolysis. Electrolytic Zinc Co. of Australasia Proprietary, Ltd. E.P. 155,792, 29.4.20. Conv., 24.12.19.

The presence of chlorine exceeding 50 mg. per l. in zinc-bearing solutions causes excessive deterioration of the lead anode and aluminium cathode used in the electrolytic process of zinc recovery. The chlorine content is reduced to the desired extent by an addition of silver sulphate to an acidified portion of the liquor. Coagulation of the silver chloride is accelerated by basic conditions, and the settled chlorine-free liquor is returned to the untreated portion. Silver is recovered by agitating the precipitated silver chloride with dilute sulphuric acid and zinc, with subsequent conversion of the metallic silver into silver sulphate by heating with sulphuric acid at 250°—300° C.—C. A. K.

Aluminium or aluminium alloys; Process for soldering ——. A. Passalacqua. E.P. 159,480, 25.2.21. Conv., 25.2.20.

A liquid prepared warm by adding to a paste comprising linseed oil, olive oil, resin, paraffin wax, and solid fat, a small amount of a mixture of an aqueous solution of nickel sulphate, ammonium chloride, and sodium pyrophosphate, and an aqueous solution of stannous chloride, sodium pyrophosphate, and citric acid is applied, prior to soldering, to the cleaned parts to be soldered. —J. W. D.

Metals; Process for the extraction of —— from solutions, or for the separation of metals. W. J. Browning. E.P. 162,682, 31.7.19.

One or more of the metals is precipitated in the form of a sulphide or sulphides by reaction with elementary sulphur or hydrogen sulphide produced by burning, calcining, or distilling pyrites or cupriferous pyrites in the presence of steam additional to that from the moisture of the material or n the air used. The residual gas from the precipitation operation contains sulphur dioxide and s passed through an incandescent carbonaceous zone while regulating the supply of oxygen and maintaining the carbonaceous matter at the optimum temperature, whereby sulphur and hydrogen sulphide are formed.—J. W. D.

Alloys. C. Vos. E.P. 162,917, 5.5.20.

An alloy for degasifying and deoxidising iron and steel is composed of 90 to 95% of aluminium, 1·5 to 9·5% of magnesium, 0·005 to 2·75% of uranium, 0·05 to 1·25% of ferrosilicon, and 1 to 1·80% of iron. In preparing the alloy 0·01 to 5% of sodium fluoride is used as a flux.—T. H. Bu.

Alloy. C. D. Stovall. U.S.P. 1,376,656, 3.5.21. Appl., 7.6.20.

An alloy consisting of gold, nickel, copper, and platinum.—T. H. Bu.

Alloy. F. Milliken, Assr. to F. Milliken, S. F. Weaver, and J. M. Repplier. U.S.P. 1,377,089, 3.5.21. Appl., 8.10.19.

The alloy consists of Cu 45—55%, Ni 29—35%, Pb 1—3%, Zn 5—9%, Fe 4—8%, and Si up to 0·30%. —T. H. Bu.

Manganese-magnesium alloy and method of making same. W. R. Veazey, Assr. to The Dow Chemical Co. U.S.P. 1,377,374, 10.5.21. Appl., 24.7.18.

An alloy of manganese with magnesium, in which the magnesium largely predominates.—J. W. D.

Molybdenum-tungsten alloy; Manufacture of ——. F. G. Keyes, Assr. to Cooper Hewitt Electric Co. U.S.P. 1,377,982, 10.5.21. Appl., 11.7.17.

A mixture of molybdenum and tungsten in the proportions required for the alloy (*cf.* U.S.P. 1,308,907; J., 1919, 643 a) is moulded in a moist condition into bar form, dried, and heated to 1200° C. in an atmosphere of hydrogen.—C. A. K.

Electroplating. T. A. Edison. U.S.P. 1,359,972, 23.11.20. Appl., 21.6.19.

A metal, *e.g.*, copper, nickel, iron, is provided with a surface coating of selenide by immersion in selenious acid. If the metal thus coated is electroplated with nickel, copper, iron, silver, etc., the plating can afterwards be easily stripped off without defacing the surface even when this is marked with delicate figures or designs.

Metallic substances; Smelting or fusing ——. B. Stoughton. U.S.P. 1,376,479, 3.5.21. Appl., 14.4.19.

The metallic substances are subjected in a furnace to the action of heat resulting from the combustion of fuel, and the temperature of the furnace is controlled by means of a heated air blast, the temperature of which can be rapidly regulated.—J. W. D.

Furnace; Metallurgical ——. F. C. Curtis. U.S.P. 1,376,680, 3.5.21. Appl., 12.8.18.

An elongated tilting furnace is mounted upon its shorter axis, and is provided with openings closed by doors at the ends of its longer axis, and with a burner for fluid fuel directed towards an inner surface of the roof.—J. W. D.

Slags; Process and apparatus for the electrical utilisation of molten ——. J. E. Bloom. U.S.P. 1,377,554, 10.5.21. Appl., 3.5.20.

Materials containing substances which may be profitably recovered are mixed with the molten slag, and the electrons of one sign emitted during the mixing process are neutralised under insulated conditions, the substances in question being thereafter recovered from the mixture and from the fumes, vapours, etc. (*Cf.* U.S.P. 1,334,590; J., 1920, 782 a.) —J. S. G. T.

Slag; Treatment of —— from the Thomas and Siemens-Martin [steel] processes, for the recovery of iron and a fertiliser. Eisen- und Stahlwerk Hoesch A.-G. G.P. 327,054, 28.6.19.

Hydrochloric acid vapour is led over the glowing slag to convert the iron into ferric chloride, which is subsequently leached out of the mass and converted into ferric oxide and hydrochloric acid by heating to 200°—230° C. The residual mixture of calcium phosphate and silica is suitable for use as a fertiliser.—L. A. C.

Metallic constituents; Recovery of —— from a mixture. G. W. Mullen, Assr. to H. B. Bishop. U.S.P. 1,377,217, 10.5.21. Appl., 14.1.20.

A mixture of metals, of which one is tin, is treated with a sulphate, such as nitre-cake, and a reducing agent to produce a mixture of metallic sulphides. The soluble sulphides are separated by extraction with water, converted into the oxides, and smelted with a reducing agent.—C. A. K.

Flotation process. C. Spearman. U.S.P. 1,377,937, 10.5.21. Appl., 22.7.18.

Ore is ground with water and a small quantity of oil to cause flotation of an ore concentrate. The adhesion of the coalesced particles is then destroyed and the material in powder form is separated from larger flakes by screening.—C. A. K.

Annealing; Chamber and process for bright ——. F. K. Meiser. G.P. 327,362, 23.3.18.

A combustible gas is admitted gradually into the chamber and burns therein without the production of an explosive mixture until all the oxygen has been consumed and the vessel is full of gas; when the heating process is complete and the vessel has cooled down, the gas is slowly burnt by the gradual admission of air.—L. A. C.

Metals; Extraction of —— from ores and residues. K. Schmidt and G. G. Reininger. G.P. 334,309, 23.3.20.

In the recovery of metals from ores and residues by adding them to a molten salt bath, a salt is employed which possesses reducing properties, for example, an alkali cyanide (which also has strong desulphurising properties), tartar, sodium formate, or alkali ferrocyanide. The bath may consist of a reducing salt used alone or a mixture of a neutral and a reducing salt.—T. H. Bu.

Copper; Process for separating —— from the remaining metals in copper matte and speiss. Rheinisch-Nassauische Bergwerks- und Hütten-A.-G., A. Wyporek, and H. Goldmann. G.P. 334,810, 6.3.20.

The materials are roasted first at about 400° C., and the temperature is raised further only in the later stages of the roasting. The roasted product from matte is crushed, and lixiviated with a strong (65%) solution of sulphuric acid, while that from speiss is first stirred with water and then lixiviated with dilute sulphuric acid solution. Copper goes into solution and is obtained by crystallisation as the pure sulphate. Lead, antimony, and silver remain in the insoluble residue.—T. H. Bu.

Steel; Manufacture of ——. R. H. Irons. E.P. 163,526, 9.3.20.

See U.S.P. 1,345,192 of 1920; J., 1920, 575 A.

Zinc extracting furnaces with vertical retorts. R. von Zelewski. E.P. 148,210, 9.7.20. Conv., 28.3.16.

See U.S.P. 1,250,071 of 1917; J., 1918, 95 A.

Nickel; Method of separating and recovering ——. A. McKechnie. U.S.P. 1,377,713, 10.5.21. Appl., 17.9.20.

See E.P. 142,310 of 1919; J., 1920, 456 A.

See also pages (A) 456, *Rotary kilns* (E.P. 163,175). 461, *Charcoal for case-hardening* (U.S.P. 1,361,131). 462, *Tungsten alloys* (E.P. 162,907). 463, *Core oils* (G.P. 325,323). 470, *Sulphur dioxide from copper matte* (U.S.P. 1,377,012—3).

XI.—ELECTRO-CHEMISTRY.

Electric installations; Safety device for ——. P. M. Grempe. Chem.-Zeit., 1921, 45, 506—507.

A device is described by which both liability of workers to injury from shock, and fire-risk, which are features of high-voltage installations, are avoided. It comprises a transformer for converting voltages of 110—220 to 10—20 volts. Passage of high-voltage current into the circuit is prevented by well-insulated primary and secondary coils, and a double-polar device protects both the transformer and the leads against effects of short-circuiting. The apparatus may be connected with any existing installation.—W. J. W.

Electrolytic chlorine. Bourion and Courtois. *See* VII.

Hydrogen electrode vessel. Hastings. *See* XXIII.

Patents.

Insulator for electrical purposes; Manufacture of a material suitable for use as an ——. H. Herrmann. E.P. 153,884, 18.5.20. Conv., 7.11.19.

A heated mixture of resin and a drying or other oil is mixed with a refractory earth, such as kaolin, and powdered zinc white, the resulting mixture is heated until it becomes liquid, and then incorporated with powdered mica.—J. S. G. T.

Insulating material for submarine telephone cables. Felten u. Guilleaume Carlswerk A.-G. G.P. 303,871, 15.4.16.

Gutta-percha which has been partly or completely freed from resin and then mixed with natural or synthetic rubber possesses certain advantages over untreated gutta-percha as an insulating material for submarine telephone cables.

Muffle furnaces; Electrically heated ——. A.-G. Brown, Boveri & Co. E.P. 159,195, 18.2.21. Conv., 18.2.20.

The furnace chamber into which the muffles project is heated simultaneously by electric arcs and by a bath of liquid molten material, maintained at the desired temperature by the heat of the arcs, which are formed between the molten bath and electrodes projecting into the furnace chamber.—H. R. D.

Electrolytic cell. J. M. Williams. U.S.P. 1,376,495, 3.5.21. Appl., 5.9.16. Renewed 22.7.20.

The perforated bottom of the cell serves as cathode, and the anode is composed of a number of slabs contained entirely within the cell and individually supported on shoulders on the side walls. An asbestos diaphragm through which the catholyte flows during operation of the cell is disposed above the cathode.—J. S. G. T.

Galvanic cell; Primary ——. C. Drucker. G.P. 333,443, 21.9.19.

The cell is constituted of a zinc electrode and a carbon electrode immersed respectively in an alkali solution and an acid chromate solution, the electrodes being separated by a diaphragm. The use of an acid chromate solution prevents clogging of the diaphragm and consequent increase of the resistance of the cell, and hence a rapid decline of the initially high E. M. F. of the cell is prevented. —J. S. G. T.

Photo-electric cells; Process of producing ——. Photo-electric cell. T. W. Case. U.S.P. (A) 1,376,604, (B) 1,376,605, and (C) 1,376,606, 3.5.21. Appl., 27.8.20.

(A) For the production of a photo-electric cell an electrode, capable of being heated, is coated with a suitable material, and is then enclosed, together with a second electrode, in a vacuum. The first electrode is then heated so as to volatilise its coating, and the two electrodes are subjected to the action of an electric current, by which means the coating, separated from the first, is deposited on the second electrode. The coating for the electrode may consist of (b) barium or (c) strontium.—W. J. W.

Electric accumulator. G. Marconi. U.S.P. 1,377,722, 10.5.21. Appl., 9.3.18.

See E.P. 151,293 of 1918; J., 1920, 754 a.

XII.—FATS; OILS; WAXES.

Fats and fatty acids; Apparatus for the routine determination of the melting points of ——. S. H. Blichfeldt and T. Thornley. Analyst, 1921, **46**, 180—182.

A glass tube 6·5 cm. long, 1 mm. bore, and 3 mm. diam., is dipped into the melted sample so that a column of 1 cm. of fat is obtained in the tube; the latter is placed between two blocks of ice for 2 hrs., and then fixed vertically in a water-bath so that the upper surface of the fat is 1 cm. below the surface of the water. The water is heated at the rate of 1° C. per min., and the temperature at which the fat begins to rise in the tube is taken as the m.p. The water-bath consists of a glass tank fitted with a cover, on the under side of which are mounted six 16 c.p. carbon filament lamps for heating the water; a vertical partition, which does not quite reach the ends of the tank, divides the latter into two compartments, one holding the lamps and the other the m.p. tubes and thermometer. A stirrer produces a steady flow of water through the two compartments.—W. P. S.

Oils from grape seeds. E. André. Comptes rend., 1921, **172**, 1296—1298.

The examination of eleven samples of oil obtained either by extraction or pressure from grape seeds from different sources confirms Lewkowitsch's statement (*cf.* Oils, Fats and Waxes, 1904, 639) as to the divergence shown by the physical and chemical characters of such oils. In these eleven samples the ranges of values obtained were: sp. gr. at 18°—20°/0° C., 0·9103—0·9334; $n_D^{18-20}=1·4708—1·4772$; saponification value, 171·0—191·1; iodine value (Hanus), 94·3—135·0; acetyl value 13·3—49·3.
—W. G.

Fats; Hydrolysis of —— by reagents made from cymene. R. H. McKee and L. J. Lewis. Chem. and Met. Eng., 1921, **24**, 969—975.

Cymene-stearosulphonic acid was investigated as a fat-splitting reagent of the Twitchell type. It was prepared by stirring together 140 g. of cymene with 280 g. of oleic acid, and gradually adding 300 g. of sulphuric acid (66° B., sp. gr. 1·84), the temperature being kept below 35° C. Sulphonation at 98° C. gave a darker product, which however was equally effective as a hydrolysing agent. The acid was purified before use by agitation first with 2% hydrochloric acid and afterwards with petroleum spirit. In comparative tests of the hydrolysis of cottonseed oil by a commercial reagent from a soap factory, cymenesulphonic acid, benzene-stearosulphonic acid, naphthalene-stearosulphonic acid, and cymene-stearosulphonic acid, great superiority was shown by the last reagent, about 60% of the oil being hydrolysed at the end of 18 hrs., using 1% of the reagent reckoned on the weight of oil, as compared with 25% with naphthalene-stearosulphonic acid and less than 10% with the other reagents. In the presence of 0·2% of sulphuric acid hydrolysis proceeds at satisfactory rates with only $\frac{1}{2}$% of the reagent. Comparative tests on coconut oil and tallow showed a slight superiority of cymene-stearosulphonic acid over the corresponding naphthalene derivative. The darkening effect produced on the fatty acids during hydrolysis is also much less with the new reagent than with all others investigated. The theory of the action of these fat-splitting agents is discussed and the conclusion arrived at that, for efficient action, a high degree of emulsification of the fat must be produced and the hydrogen ions must be greatly concentrated on the surface of the globules. The presence of free fatty acids up to 10% seems to aid the formation of a stable emulsion. The cost of the new reagent would be less than that of reagents at present in use.—H. C. R.

Fats; Hardening of ——. F. Ulzer. Oel- u. Fettind., 1920, 367. Chem. Zentr., 1921, **92**, II., 995.

Parts of a fat-hardening plant were cleaned with petroleum spirit and trichloroethylene, and traces of the solvent were inadvertently left in the plant. Very poor results were obtained in the subsequent hardening process. When the traces of solvent were removed normal results were obtained.—H. C. R.

Colloidal clay and the hydrolysis of oils and fats. F. E. Weston. Chem. Age, 1921, **4**, 604—605, 638—641.

The usual methods of hydrolysing fats all suffer from the disadvantages that high temperatures and excess of the catalyst must be used, and that an excessive length of time is required for complete hydrolysis. Hydrolysis is more completely and rapidly produced the more perfect an emulsion of the oil is obtained. Colloidal clay has marked emulsifying powers on mixtures of oil and water, and in all the cases examined the oils were more easily hydrolysed in the presence of this substance than without. In experiments with caustic soda as the hydrolysing agent large excess of alkali was found to be unnecessary. The actual rate of saponification varied considerably with the nature of the oil under investigation. The following oils were tried:—cottonseed, linseed, soya-bean, palm, whale, Japan fish, rapeseed, olive, arachis, and tung oils. The quantity of clay used in most cases was 10%, but that required for optimum hydrolysis is stated to be about 20% of the weight of oil taken. The most easily hydrolysed oils readily form emulsions with the colloidal clay used. A colloidal clay soap can thus be directly prepared with great saving in fuel and labour.—H. C. R.

Lipase; Action of ——. E. Abderhalden and A. Weil. Fermentforsch., 1920, **4**, 76—89.

Solutions of sodium bicarbonate are able to hydrolyse glycerides at 38° C., the velocity of hydrolysis increasing as the dilution of the fat and the concentration of the alkali solution increase. At equal molar concentrations, diacetin is hydrolysed more rapidly than triacetin, and the latter more rapidly than tributyrin, while tristearin undergoes scarcely appreciable hydrolysis in 22 hrs. In mixed fats the stearic acid residue in the β-position is hydrolysed more rapidly than that in the α-position; β-stearo-$\alpha\alpha$-dichlorohydrin is also readily hydrolysed in emulsions. The catalytic action of the fat-splitting enzyme of ox-pancreas is non-specific, that is, independent of the molecular structure and spacial isomerism of the fat. The velocity of hydrolysis of a fat in $M/30$ concentration by $N/10$ sodium bicarbonate solution is accelerated by the pancreas preparations employed to the following extents: 10% for αα-diacetin, 45% for triacetin; 100% for αβ-dibutyro-γ-dichlorohydrin; 300% for tributyrin; 220% and 73% respectively for the scission of the stearic acid from β-acetodistearoglycerol and β-stearodiacetoglycerol. The distinction of a special esterase from the lipase which resolves triglycerides is no longer possible, since the acceleration of the velocity of hydrolysis in sodium bicarbonate solution follows the same course with esters of ethyl alcohol, cholesterol, and glycerol. Ultrafiltration weakens the lipolytic action of glycerol extracts of ox-pancreas, the filtrate being re-activated by addition of the residue left on the filter.—T. H. P.

Oleic acid; Undecamethylenedicarboxylic acid, a degradation product of ——. I. Lifschütz. Z. physiol. Chem., 1921, **114**, 28—30.

The so-called "oily acid" from wool-fat (J., 1920, 697 A) is considered to be identical with a product obtained by the oxidation of oleic acid in glacial acetic acid solution by means of permanganate (J., 1908, 525). This wax-like oxidation product, purified by repeated precipitation from its calcium salt, and melting at 82°—85° C., is further considered to be identical with an undecamethylenedicarboxylic acid (m.p. 81°—82° C. after distillation and crystallisation) obtained by Komppa (Ber., 1901, **34**, 899) and differing from *n*-undecanecarboxylic (brassylic) acid.—G. B.

Patents.

Fatty acids or oils or fats containing free fatty acids; Conversion of —— into glycerides. E. R. Bolton and E. J. Lush. E.P. 163,352, 30.9.19.

Fatty acids or fatty oils containing free fatty acids are rapidly converted into glycerides by heating to 200°—250° C. and treatment with glycerin vapour. The oils are preferably heated *in vacuo* and the glycerin may be vaporised by heating with superheated steam. Catalysts may be used, but have not been found necessary.—H. C. R.

Oils; Process of clarifying and decolorising ——. R. W. Mumford, Assr. to Darco Corp. U.S.P. 1,377,021, 3.5.21. Appl., 11.7.17.

The oil is vigorously agitated at 100° C. with successive quantities of granular vegetable carbon of open texture, having open pores representing approximately the cellular structure of the original vegetable material from which it was made (*cf.* U.S.P. 1,314,204; J., 1919, 785 A), and is simultaneously subjected to the influence of oppositely charged electrical poles.

Soaps, polishes, dressings and other compositions containing saponaceous material. M. L. Williams and J. F. Moseley. E.P. 162,691, 16.10.19.

The colloidal product obtained by incorporating bentonite, a hydrous aluminium silicate, with water is added to soap, metal polish, floor polish, or the like.—L. A. C.

Soap or cleaning compound. E. D. Chaplin. U.S.P. 1,362,393, 14.12.20. Appl., 7.6.15. Renewed 20.2.20.

Cellulose in the form of fibres of short length, *e.g.*, the short lint obtained in the delinting of ginned cottonseed, is mixed with resin, allowed to harden, and then reduced mechanically to granules, which are incorporated with a soap containing a small excess of free alkali, preferably potash. In use the alkali of the soap combines with the resin and liberates the fibres, which exert a rubbing action.

Waxy material from wool fat; Production of ——. P. Beiersdorf und Co. G.P. 326,933, 15.12.18. Addn. to 286,244 (J., 1915, 1153).

The wool fat is saponified to form soaps of metals other than those of the alkali group, *e.g.*, magnesium, and the product is then treated as described in the chief patent. The saponification liquor is displaced by the addition of the wash liquor from a previous operation. The process yields a pure, crystalline fatty acid, and a soft, amorphous, unsaponifiable material.—L. A. C.

Scouring and fulling agent. Chem. Fabr. Stockhausen und Co. G.P. 328,099, 25.3.19.

A liquid giving a good lather is prepared by adding 2—3% of naphthol in alkaline or alcoholic solution to a solution of the alkali or alkaline-earth salts of amino-fatty acids, such as glycocoll or the mixture obtained by boiling glue with dilute mineral acid, with or without the addition of hydrocarbons or chlorinated hydrocarbons.—L. A. C.

Emulsions and foam; Material for forming ——. E. Gips. G.P. 328,631, 9.2.18.

A material suitable for use in washing, fulling, printing, mordanting, degumming, and other similar purposes, as well as for the production of a water-soluble drilling oil, is prepared by hydrolysing seaweed with acids and neutralising the product.—L. A. C.

Powdered metals and sub-oxides [for use as catalysts for hydrogenation of oils]; Production of ——. C. Ellis. E.P. 162,038, 14.1.20.

See U.S.P. 1,329,322 of 1920; J., 1920, 790 A.

Emulsions. E.P. 162,719. *See* I.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Resin of the maritime pine; Acid constituents of the ——. Isomerisation of the pimaric acids. G. Dupont. Comptes rend., 1921, **172**, 1373—1375. (*Cf.* J., 1921, 357 A, 439 A.)

l-Pimaric acid readily undergoes isomerisation o heating in the presence of acetic acid, or better stil hydrochloric acid, as catalyst. The change take place in two stages, α-pimarabietic acid being firs formed and then changing into β-pimarabietic acid *d*-Pimaric acid does not undergo isomerisation unde these conditions.—W. G.

Resinification; Connexion between —— and th constitution of chemical compounds. W. Herzog Oester. Chem.-Zeit., 1921, **24**, 76—79. (*Cf.* J. 1921, 187 A.)

The grouping—N:C:N—is characteristic of a whol class of substances which readily undergo poly merisation with the formation of resins, and ma therefore be regarded as a typical resinopho group. A general method for the preparation o such synthetic resins consists in heating *sym*-d substituted thioureas or ureas at temperatur above their melting point, either alone, or prefe ably in presence of a solvent, whereby hydroge sulphide, or water, is eliminated and the resultin carbo-di-imides are immediately transformed int resinous polymerides. Thus, for example, *sym* diphenylthiourea, dissolved in an equal quantity aniline, is converted by heating for 40 hrs. at th boiling point of the solution into a resin, the greate part of which can be distilled at 190°—240° C.

30—40 mm. pressure. The distillate, representing 67% of the theoretical yield, forms a clear amber-like resin, soluble in benzene, turpentine, and fatty oils. Similar resins were prepared from ditolylurea, allylphenylurea, etc., and also mixed resins from mixtures of substituted ureas. The latter, unlike the simple resins, show no tendency to depolymerisation and deposition of the crystalline carbimide, and should be of value as synthetic lacs. A phosphorus resin, containing the grouping—N:P:N— was similarly prepared from triphenylphosphamide. (*Cf.* J.C.S., July.)—G. F. M.

Patents.

Floor coverings [linoleum substitute]; Manufacture of ——. R. Jeschke. E.P. 146,367, 2.7.20. Conv., 17.12.18.

A mixture of viscose, prepared by treating sulphite-cellulose in alkaline solution for about 24 hrs. with carbon bisulphide vapour at 46° C., the rubber-like product obtained by heating carbohydrates or glue with glycerin, and saponified colophony, coumarone resin, or other resin, is boiled for about 1 hr. until a tough mass is obtained. Formaldehyde, chromium salts, alum, tannin, or the like, may be added towards the end of the boiling to harden the product, and an equal weight of cork meal is added together with colouring matter to the product, which is then kneaded and rolled.—L. A. C.

Protection of surfaces [by wool-fat preparations]. O. Reynard and E. Edser. E.P. 163,474, 18.2.20.

A solution of anhydrous wool fat in a non-inflammable solvent such as carbon tetrachloride or trichloroethylene or in a solvent rendered non-inflammable by the addition of such chlorinated compounds, is applied to metals for the prevention of rust. Instead of pure wool fat there may be used the crude "Yorkshire grease" obtained from wool-washing effluent, the free fatty acids being previously converted into calcium soaps by treatment with milk of lime or with calcium chloride. —D. F. T.

Chloronaphthalenes; Process for improving technical mixtures of —— for use as resin substitutes. Deutsche Conservierungs-Ges. m. b. H. G.P. 332,725, 11.4.20. Addn. to 327,704 (J., 1921, 188 a).

The addition of iron or other metals as catalyst in the process described in the chief patent diminishes the proportion of low-boiling, poisonous constituents in the product.—L. A. C.

Resinous condensation products; Manufacture of ——. A.-G. für Anilin-Fabr. G.P. 334,710, 5.10.18. Addn. to 332,391 (J., 1921, 358 a).

Resinous products soluble not only in benzene, chloroform, linseed oil, and turpentine, but also in alcohol, are prepared by the action of metal halides on a mixture of halogen addition products of naphthalene or its derivatives, or halogen derivatives of hydrogenated naphthalene, and phenols, in the presence or absence of solvents. Thus, phenol is heated to 90°—95° C. with a solution of naphthalene tetrachloride in tetrachloroethane in the presence of ferric chloride; *o*-cresol is heated to 100° C. with a solution of naphthalene tetrachloride in *o*-dichlorobenzene in the presence of ferric chloride or aluminium chloride; or a mixture of phenol, ferrous chloride, and the product obtained by chlorinating tetrahydronaphthalene at the ordinary temperature until 4 atoms have been absorbed, is heated to 100° C. The products are washed free from acid and dried at 140°—150° C. —L. A. C.

Polishes etc. E.P. 162,691. *See* XII.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Vulcanisation of rubber in sol and gel forms. H. P. Stevens. Indiarubber J., 1921, **61**, 1160—1161.

By heating an ordinary rubber-sulphur (90:10) mixture dispersed in benzene in a stoppered bottle at vulcanising temperatures a clear viscous sol is obtainable in which the rubber is combined with part of the sulphur. On cooling no separation of sulphur occurs, but by evaporation films are obtained which possess the ordinary characteristics of heat-vulcanised rubber; they "bloom" readily and the coefficient of vulcanisation may have any value up to 10; when immersed in a solvent the films merely swell in the normal manner. Similar sols were produced by treating a benzene solution of rubber with a 1% solution of sulphur chloride in the same solvent at the ordinary temperature; if the concentrations were too great gels were produced, the limit of concentration for the rubber for sol-formation being about 10%. The gels frequently shrink with exudation of solvent. Similar vulcanisation experiments to those with sulphur chloride were made with hydrogen persulphide.—D. F. T.

[Rubber] ageing tests; Ten years' experience with ——. W. C. Geer and W. W. Evans. India-rubber J., 1921, **61**, 1163—1170.

The method adopted is to submit a number of samples in the form of standard strips $\frac{3}{32}$ in. thick, to a continuous current of air at 160° F. (71° C.) in an electric oven; three samples are withdrawn daily over a period of two weeks, each set being tested as to tensile strength and elongation after 24 hrs. at the ordinary temperature; the data are then plotted to give a time-decay curve which gives an approximate representation of the tendency to depreciate under natural conditions; one day of the accelerated test is roughly equivalent to six months of natural ageing. The method is of value only for comparative purposes and comparisons should be confined to "compounds" of similar type, and the samples should possess an initial tensile strength of at least 1000 lb. per sq. in. The test is of great value in aiding a decision as to the correct degree of vulcanisation, rapid deterioration being almost invariably a result of faulty vulcanisation rather than the effect of any particular compounding ingredient.—D. F. T.

Butadiene; Cold autopolymerisation of ——. C. Harries. Gummi-Zeit., 1921, **35**, 898.

Butadiene enclosed in sealed tubes for five years solidified to a hard white granular mass which still contained a little of the parent substance; the product, which was practically insoluble and showed no tendency to swell in the customary organic solvents, vaporised to a considerable extent when heated, and then suddenly melted with intumescence and carbonisation.—D. F. T.

Patents.

Caoutchouc and textile material from rubber fabric; Process of recovering ——. F. Waitz. E.P. 147,628, 8.7.20. Conv., 5.7.17.

Old rubber fabric, *e.g.*, cycle tyres, in coarse fragments, is heated below 180° C. in a closed vessel under pressure with a solvent such as petroleum ether, benzene, toluene, ether, or the like, and is simultaneously subjected to mechanical treatment, such as kneading, rubbing, beating, or the like. Rubber is recovered from the solution by evaporating the solvent, and the textile material, after washing with more solvent, is suitable for, *e.g.*, paper making.—L. A. C.

Rubber or like plastic material; Method of and machine for mixing or masticating ——. Farrel Foundry and Machine Co., Assees. of C. F. Schnuck and D. R. Bowen. E.P. 147,547, 18.6.20. Conv., 11.7.19.

Insulating material. G.P. 303,871. *See* XI.

XV.—LEATHER; BONE; HORN; GLUE.

Tanning value of extracts; Determination of the true ——. G. W. Schultz and T. Blackadder. J. Amer. Leather Chem. Assoc., 1920, **15**, 654—664.

Wilson and Kern's assumptions (J., 1920, 522 A) are disputed. There is not a definite chemical compound formed between tannin and collagen. The same chemical compound is not formed throughout the whole of the hide powder used in the analysis. Tannin solutions were shaken with hide powder for 6 hrs. and tests with gelatin-salt solution showed that the tannin had been completely removed. Successive washings with water removed a considerable amount of tannin from the tanned hide powder. The finer particles of hide powder are tanned more completely than the coarser particles and a large percentage of these tannin-rich particles is lost in washing, thus yielding a low percentage of tannin by the Wilson-Kern method. —D. W.

Chromium in chrome [tanning] liquor; Rapid determination of —— by use of the immersion refractometer. A. W. Thomas and M. W. Kelly. J. Amer. Leather Chem. Assoc., 1920, **15**, 665—668.

A pure chrome liquor was prepared by reducing sodium bichromate solution with gaseous sulphur dioxide. The resulting liquor was washed free from excess of gas and analysed according to the official (American) methods. A table of refractometer readings was prepared from observations on this liquor at different dilutions, and it is suggested that this constitutes a cheap tannery control method for rapidly estimating the strengths of chrome liquors. —D. W.

[Tannery] lime liquors; Determination of alkaline sulphides in ——. F. G. A. Enna. J. Soc. Leather Trades' Chem., 1921, **5**, 131—137.

Calcium sulphydrate, present in lime liquors to which sulphides have been added, oxidises to calcium sulphide and thiosulphate. Strong acids liberate sulphur dioxide from thiosulphates, and this reacts with the hydrogen sulphide giving a low result in the determination of sulphides. To obviate this the hydrogen sulphide is liberated from its salts by boiling in an atmosphere of carbon dioxide. Carbon dioxide is passed through a flask containing a measured quantity of lime liquor, and the hydrogen sulphide collected in a measured volume of standard copper acetate solution. The precipitated cuprous sulphide is filtered off and the residual copper estimated iodometrically. A blank determination should be carried out with the copper acetate solution. Concordant results are obtained with this method.—D. W.

Patents.

Liming and dehairing hides; Process of ——. E. C. R. Marks. From Chicago Process Co. E.P. 163,109, 10.2.20.

Hides are soaked, left for one day in a used lime and sulphide liquor, then for one day in a used lime liquor to which has been added (for each hide) 0·5—1 lb. of sodium sulphide, washed in water to remove excess sulphide and passed through four lime liquors, remaining one day in each. The last lime liquor is a fresh liquor of about 18° Bkr. strength, and is subsequently used successively in the earlier stages of the process.—D. W.

Tannin; Process of producing a surrogate for ——. C. Graf, Assr. to The Chemical Foundation, Inc. U.S.P. 1,376,805, 3.5.21. Appl., 11.3.16.

Tar is treated with an aqueous solution of an alkali or its equivalent, the liquid obtained is separated and treated with copper or aluminium sulphate. —D. W.

Patent leather; Method of rendering harmless the ozone formed in the hardening of —— by means of ultra-violet rays. J. J. Stöckly. G.P. 331,005, 14.12.17.

Substances capable of combining with ozone to form ozonides, *e.g.*, oil of turpentine, are introduced, in the form of vapour, into the drying (hardening) chamber.

Leather waste; Utilisation of ——. H. E. Dietz. G.P. 326,941, 9.10.17.

Tanning compounds and dyestuffs are removed by treating the waste leather above 90° C. with an aqueous solution of alum and an acid which does not act chemically on the leather, and the product is then heated with a dilute acid, whereby it is converted into a viscous mass suitable for applying to leather goods, or which can be rendered insoluble by treatment with formaldehyde.—L. A. C.

Casein cements; Production of ——. P. H. W. Serle. E.P. 163,349, 22.8.19.

Salicylates, benzenesulphonates, or naphthalenesulphonates of alkali metals are added to the usual casein cements, to lower the surface tension and render the gelatin or glue soluble at low temperatures.—D. W.

Horn-like masses from casein; Apparatus for the manufacture of ——. A. Bartels. U.S.P. 1,375,623—4, 19.4.21. Appl., 16.2.16. Renewed 22.4.20.

See E.P. 10,049 and 13,203 of 1915; J., 1916, 935, 1125.

Drying leather. U.S.P. 1,371,083. *See* I.

Iron salt for tanning. E.P. 146,218. *See* VII.

XVI.—SOILS; FERTILISERS.

Acid soil studies. I. Study of the basic exchange between soil separates and salt solutions. R. H. Robinson. Soil Sci., 1921, **11**, 353—362.

For a given soil the different mechanical fractions liberate approximately the same amount of acid when treated with the same salt solution, but the mode of action of salts of mineral acids is different from that of salts of organic acids. In the former case the acidity is due mainly to aluminium and iron salts rendered soluble by base exchange, but in the latter case the organic acid is apparently actually liberated.—W. G.

Acid soil studies. II. Changes in calcium compounds added to acid soils. R. H. Robinson and D. E. Bullis. Soil Sci., 1921, **11**, 363—367.

When calcium carbonate or oxide was added to several acid soils in amounts equivalent to their lime requirements and the soils exposed to the weather for one year, the calcium was retained chiefly as humate and easily decomposable silicate. In the case of an acid soil, which from field observations did not respond to lime, most of the calcium was present as difficultly decomposable silicate, and the added calcium was combined chiefly as easily decomposable silicate.—W. G.

Sulphur for neutralising alkali soil. P. L. Hibbard. Soil Sci., 1921, **11**, 385—387.

Sulphur added to an alkali soil soon becomes oxidised, probably by bacterial activity, into sulphuric acid, which neutralises the alkali present. With very alkaline soils, it is preferable to leach out as much of the alkaline material and salts as possible first, before applying the sulphur.—W. G.

Potassium and ammonium [in soils]; New methods for the determination of ——. S. Arrhenius. Medd. K. Vetenskapsakad. Nobel-Inst., 1920, **4**, [1], No. 6.

Potassium is determined in soil analysis as follows: The material is freed from all metals except sodium and potassium, the solution is made up to 15 c.c., acidified with 5 c.c. of glacial acetic acid and cooled to 0° C. Five c.c. of freshly prepared 10% sodium cobaltinitrite solution prepared according to Biilmann's description (Z. anal. Chem., 1900, **39**, 284) is added, and the precipitate allowed to settle in the cold for about 12 hrs. Most of the clear solution is decanted off and the precipitate transferred to centrifuge tubes with capillary stems. The last traces of precipitate are washed into the tubes with a little mother liquor. The tubes are centrifuged until the height of precipitate in the capillaries becomes constant. The height is read off by a scale on a mirror and compared with standards. The estimation of 0·01—0·02 mg. of potassium in 20 c.c. of solution is possible. The results are not affected by relatively large amounts of sodium salts. The method of Folin and Macallum (J. Biol. Chem., 1912, **11**, 523) for the estimation of ammonia is not accurate unless a saturated salt solution is used to suspend the soil. A solution of 0·5 g. of sodium sulphate in 2 c.c. of water is prepared in a test-tube, the weighed sample of soil added and vigorously shaken. One to 2 c.c. of saturated sodium hydroxide solution and a few drops of petroleum are added. The tube is connected with an absorption flask containing standard acid, and air is aspirated through the solution to carry over the ammonia. A slow stream of air is used at first, but is increased later and continued for 15—20 mins. The sample should not contain more than 1 mg. of ammonia. Higher nitrogen compounds are not attacked, but absorbed ammonia is recovered. —J. R. P.

Soils partially sterilised by calcium sulphide; Increase in the number of Clostridium Pastorianum (Winogradski) in ——. G. Truffaut and N. Bezssonoff. Comptes rend., 1921, **172**, 1319—1322.

lostridium Pastorianum developed better on soils artially sterilised by calcium sulphide than on ntreated soils. A method is described for eliminatng facultative anaërobes without destroying *lostridium* in such tests.—W. G.

rganic nitrogenous compounds; Effect of —— *on the nitrate-forming organism.* E. B. Fred and A. Davenport. Soil Sci., 1921, **11**, 389—407.

He results obtained do not support Beijerinck's iew (Folio Microbiol., 1914, **3**, 91—113) that the itrate-forming organism when grown in the resence of certain organic substances loses its ower of oxidation. Contrary to this, it was found hat certain forms of organic matter benefit rather han injure these organisms.—W. G.

umus; Application of physico-chemical methods to the study of ——. S. Odén. Faraday Soc., 31.5.21. [Advance proof.] (*Cf.* J., 1920, 242 a, 667 a.)

y conductivity measurements on aqueous suspenons of humus to which increasing amounts of mmonia were added, the formation of humic ions as proved, and hence the acid nature of "humic id." It is considered that the usefulness of liming peaty soils depends on the formation of a rich supply of calcium humates, and its bearing on the xerophytic habit of bog vegetation is discussed. —W. G.

Fertilisers containing borax; Influence of —— *on the yield of potatoes and corn [maize], season 1920.* A. W. Blair and B. E. Brown. Soil Sci., 1921, **11**, 369—383.

Borax when applied at the rate of 50 lb. per acre or more along with a complete mixture of artificial fertilisers was injurious to the potato crop and to the corn (maize) crop. The rainfall during the season was above normal.—W. G.

Hydrogen-ion concentration relations in a three-salt solution. H. F. A. Meier and C. E. Halstead. Soil Sci., 1921, **11**, 325—351.

The experimental data indicate that the hydrogen-ion concentration of three-salt solutions in which wheat has been grown tends to become less than the initial reaction of the solution. All the cultures were acid at the beginning and tended to become neutral, this change being possibly due to selective adsorption of the ions by the plant. There was no direct correlation between the yield of the plants and the p value or its change in value.—W. G.

Colloidal sulphur spray. Kühl. *See* XIXb.

Calcium and magnesium arsenates. Patten. *See* XIXb.

Peat, distiller's wash, or like material; Process of treatment of —— *[to produce a fertiliser].* R. B. Goldschmidt and M. Migeon. E.P. 162,738, 22.1.20.

Peat is dried to about 60% of moisture and is then treated with distiller's wash, or similar material rich in sugar and bacteria. The mixture is allowed to ferment so as to decompose the ulmic acid, by which a considerable part of its moisture is evaporated and its physical condition is changed. The product is finally compressed and the moisture thus reduced to 15—20%. In this condition it may be used directly as a fertiliser, or it may be carbonised in a closed vessel, and the ash treated for recovery of potash.—W. J. W.

Manures; Artificial ——. O. Silberrad. E.P. 163,137, 19.2.20.

Sulphite-cellulose waste liquors are incorporated with fertilisers, such as "nitrolim," and the product is then granulated; formation of dust is by this means largely avoided.—W. J. W.

Acid-phosphate [superphosphate] apparatus. R. E. Forbis, Assr. to Chemical Construction Co. U.S.P. 1,376,612, 3.5.21. Appl., 14.6.20.

A stationary annular phosphate den is provided with a travelling device for charging, and another travelling device for discharging.—W. J. W.

Electrical treatment in production of fertilisers. U.S.P. 1,377,553. *See* I.

Slag. G.P. 327,054. *See* X.

XVII.—SUGARS; STARCHES; GUMS.

Cane sugar [sucrose]; Inversion and determination of ——. A. R. Rose. J. Biol. Chem., 1921, **46**, 529—535.

The sucrose is inverted by heating for 10 mins. at 100° C. with 2 vols. of saturated picric acid; then 1 vol. of 20% sodium carbonate is added, and after heating for a further 30 mins. the total dextrose+lævulose is estimated colorimetrically by the Lewis-

Benedict method (J., 1915, 200). The amount of reducing sugar originally present is estimated in a similar tube, in which the sodium carbonate was added before heating. The difference between the two tubes represents the sucrose in terms of invert sugar.—E. S.

Dextrose, invert sugar, and lævulose; Table for the determination of —— by the potassium thiocyanate-iodide method. G. Bruhns. Chem.-Zeit., 1921, 45, 486—487.

A TABLE is given showing the quantities of sugars corresponding with different volumes of thiosulphate solution; the sugar solution is treated as described previously (J., 1920, 829 A) and titrated with the thiosulphate solution. The same quantities of reagents, but without the sugar solution, are titrated at the same time, and the difference between the two titrations is a measure of the quantity of sugar present, this quantity being found by reference to the table, an abridgement of which is given below:—

Thiosulphate. c.c.	Dextrose. mg.	Invert sugar. mg.	Lævulose. mg.	Thiosulphate. c.c.	Dextrose. mg.	Invert sugar. mg.	Lævulose. mg
0·1	0·45	0·45	0·45	10·0	45·50	47·35	49·30

Sugars containing sulphur and selenium; Synthesis of ——. F. Wrede. Z. physiol. Chem., 1920, 112, 1—12.

THE synthesis of dicellosyl selenide, cellosyl-glucosyl sulphide, cellosyl-glucosyl selenide, and galactosyl-glucosyl selenide is described. (*Cf.* J.C.S., 1921, i., 161.)—S. S. Z.

Starch grains; Optical properties of —— in polarised light. J. Gillis. Bull. Soc. Chim. Belg., 1921, 30, 114—119.

A STARCH grain formed of superposed concentric layers which are distinctly visible produces a "depolarisation" of polarised light, except at the points where the tangent of each layer is parallel or perpendicular to the ray of light, and it is at these points that the black bars are observed. The bars intersect at the hilum, where the layers are smallest in size.—W. P. S.

Amylose. Biedermann. *See* XVIII.

PATENTS.

Sugar juices; Carbonatation of ——. C. Asselbergs. G.P. 325,940, 15.1.18. Conv., 9.8.17.

THE juice, after treatment with lime, is forced by means of carbon dioxide under pressure into the upturned branches of a number of U-tubes arranged one behind another, and portions of the juice are led back from one or more of the downflow tubes to the first downflow tube; the carbon dioxide is thus never brought into contact with the fresh juice, and undue frothing is avoided.—L. A. C.

Purifying liquids. E.P. 163,505. *See* I.

Glucose from wood waste. E.P. 154,170. *See* XVIII.

Lævulosemonophosphoric acid. G.P. 334,250. *See* XX.

XVIII.—FERMENTATION INDUSTRIES.

Diastatic enzymes; Formation of —— outside of living cells. W. Teschendorf. Fermentforsch., 1920, 4, 184—190.

LIKE those of Wohlgemuth (J., 1919, 508 A) and of Sallinger (Fermentforsch., 2, 449), the author's results fail to confirm the assertion of Biedermann (Fermentforsch., 1, 385, 474; J., 1917, 230; 1919, 958 A) that diastatic enzyme is formed when dilute solutions of starch are allowed to stand or when starch is brought into contact with the ash of saliva. Biedermann's results are ascribed to the intervention of bacterial action.—T. H. P.

Enzymic investigations on green algæ. K. Sjöberg. Fermentforsch., 1920, 4, 97—141.

THE enzyme contents of *Ulothrix zonata, Cladophora glomerata, Cladophora fracta,* and *Spirogyra* vary widely with the character of the nutrient solution in which the algæ are grown. In solutions containing sucrose, lactose, maltose, dextrose, or galactose the proportion of amylase diminishes, and after four days usually becomes very small. In starch solutions, however, the amylase increases in amount, and in solutions of calcium tartrate and lactate also a small increase occurs. The presence of potassium chloride and phosphate is without influence. Previous treatment of the algæ with 96% alcohol produces augmentation of the activity of the amylase, this effect reaching a maximum 3 hrs. after the treatment; chloroform exerts a similar action, but toluene and thymol have no influence. Under the experimental conditions employed sunlight has no effect on the formation of amylase, although after some hours the algæ form starch. For the optimal activity of the amylase in *Cladophora glomerata* in a phosphate mixture the value of p_H is 4—5. The activity of the amylase is diminished when the algæ are dried. Invertase is affected somewhat differently from amylase. In sucrose solutions the inverting power increases, as is the case with yeasts and moulds and certain bacteria; in dextrose and lactose solutions a similar result is obtained, but maltose and galactose lower the inverting power, and glycerol is without influence. The activity of the catalase is diminished by treating the algæ with alcohol, chloroform, or toluene, but is increased by drying the organisms. —T. H. P.

Enzymes; Action of hydrolysing ——. M. H. Van Laer. Bull. Soc. Chim. Belg., 1920, 29, 214—227.

THE action of hydrolysing enzymes is simply a form of catalysis by hydrogen ions. It appears tha the colloidal granule adsorbs hydrogen ions and th substratum on which it acts, and the velocity o the reaction is a function of the concentration of th substratum in the enzyme micelle and not of th concentration of the substance in solution; it increases proportionally to the concentration o hydrogen ions in the medium.—W. P. S.

Invertase preparations; Phosphorus content o highly active, dialysed —— and its determination. H. von Euler and O. Svanberg. Z. physiol Chem., 1921, 112, 282—294.

AFTER complete dialysis the organic "high molecular" combined phosphorus is proportional to th activity of the enzyme. It was approximately esti

mated, after wet ashing, by Neumann's method, and microtitration of the molybdate precipitate.
—G. B.

Enzymic reactions; Action of poisons on ——. II. Inactivation of invertase by organic compounds. H. von Euler and O. Svanberg. Fermentforsch., 1920, **4**, 29—63.

The most active organic poisons for invertase are aniline and *p*-toluidine, the former, in suitable proportion, causing almost instantaneous inactivation. The degree of the poisoning is independent of the concentration of the substrate (sucrose). The curve connecting the proportion of aniline present and the relative activity of the enzyme is a dissociation curve with the parameter $2{\cdot}5\times10^{-4}$. The dissociation constant is too large to allow of any certain conclusion regarding the molecular concentration of the enzyme. The inactivation produced by aniline may be partly eliminated by addition of benzaldehyde or acetone. The assumption is made that the aniline unites with the invertase by means of an aldehyde group and, consequently, that the aniline-invertase compound has the structure of a Schiff's base. Among aldehyde reagents other than aromatic amines, phenylhydrazine exhibits the greatest inactivating action on invertase, this action reaching its maximum after the lapse of a certain incubation period; less active are hydroxylamine, semicarbazide, hydrocyanic acid, and sodium sulphite. Of reagents for amines, formaldehyde exerts an inactivating action which gradually increases to a definite end-value, whilst diazonium chloride has an inactivating effect which is presumably irreversible. Quinine sulphate has but slight inactivating action on invertase, and cyclamin, which is an intense protoplasm poison, is absolutely without effect on the enzyme.
—T. H. P.

Enzymic reactions; Action of poisons on ——. III. Influence of copper sulphate on the autolysis of yeast. O. Svanberg and H. von Euler. Fermentforsch., 1920, **4**, 90—96.

Copper sulphate exerts only very slight inhibitory influence on the activity of invertase, and attempts were made to prepare highly active invertase preparations by adding this salt to pressed yeast. It was found, indeed, that autolysis of the yeast was prevented in this way, but the invertase passed into the juice to a far less extent than was the case with the untreated yeast.—T. H. P.

Enzyme reactions; Action of poisons on ——. IV. Electrometric measurements on the combination of silver and copper with invertase and other organic compounds. H. von Euler and O. Svanberg. Fermentforsch., 1920, **4**, 142—183.

A number of substances have been investigated electrometrically to ascertain if any of them exhibit an affinity for silver ions resembling that shown by invertase, with which silver forms complex compounds and at the same time becomes de-ionised. Such affinity is shown by egg-albumin, cysteine, and a nucleic acid, and the action of the invertase on the silver ions is assumed to be due to the presence in the enzyme of the SH group and of a nucleic acid residue; these are found to have considerably less affinity for the copper ion than for the silver ion, the lower toxicity of the Cu ion towards invertase being thus explained.—T. H. P.

Enzymes; Studies on ——. V. Enzyme formation by the action of ions. [Properties of amylose.] W. Biedermann. Fermentforsch., 1920, **4**, 1—28. (*Cf.* J., 1919, 958 A.)

The longer an amylose preparation is kept under alcohol the more highly opalescent is the aqueous solution prepared from it, and this change is accompanied by a diminution in its ability to undergo autolytic cleavage, which is evidently favoured by a degree of dispersion as high as possible. Only clear amylose solutions are, indeed, suitable for experiments on autolysis by means of simple salt solutions; such may be obtained by extracting wheaten starch with water at 80° C., the residue left after extraction being regarded as amylopectin. Amylose solutions prepared by boiling are always contaminated with substances from the stroma (starch residues). The extracted residues of wheaten and pea starches, when digested with filtered saliva, leave a residue which gives the reactions of cellulose. Highly disperse amylose exhibits a very marked capacity for adsorption. Thus, if pure filter paper is steeped in clear, undiluted amylose solution for some hours, the solution no longer gives a colour with iodine, whereas with the paper a deep blue coloration is obtained; the amylose has become firmly united with the cellulose of the paper and cannot be brought into solution again. Under the influence of certain ions or mixtures of ions water-soluble amylose yields a substance (an amylase) which acts as an enzyme and must be regarded as a complex compound of a constituent of the amylose with the ions in question.
—T. H. P.

Amylase solutions; Characterisation of ——. H. von Euler and O. Svanberg. Z. physiol. Chem., 1921, **112**, 193—230.

The authors measure the reaction constant of the first, unimolecular part of the reaction, with a 0·72—2·8% solution of Lintner's soluble starch, and such quantities of the enzyme that a constant between 0·004 and 0·08 is obtained. The constant for any one experiment, *K*, is multiplied by the maximum weight of maltose capable of being formed in that experiment, and the resulting product is divided by the weight of the enzyme preparation used. The value, *Sf*, thus obtained is fairly constant for experiments within the range given, and should be determined at 37° C. and optimum $p_H = 5$. By calculation it is found that 1000 Lintner units = 26*Sf* and 1000 units of the new scale of Sherman and others (J., 1910, 1173) = 38·5*Sf*. (*Cf.* J.C.S., July.)—G. B.

Amylase; Poisoning of —— by heavy metals and organic substances. U. Olsson. Z. physiol. Chem., 1921, **114**, 51—71.

The poisoning of amylase by silver nitrate is proportional to the amount of the poison; silver chloride and cyanide gave similar results. With silver salts the inhibition is instantaneous, with copper salts it occurs only after a time; in both cases there appears to be slight spontaneous regeneration. With the author's enzyme solutions $2{\cdot}1\times10^{-7}$ *N* $AgNO_3$ and 0·15*N* aniline both reduced the activity to one-half.—G. B.

Pancreatic enzymes; Effect of age on ——. F. Fenger and M. Hull. J. Biol. Chem., 1921, **46**, 431—435.

Pancreas preparations stored for one year show considerable loss in diastatic and lipolytic activities; the proteolytic activities, however, remain constant, indicating that trypsin is the most stable of the pancreatic enzymes.—E. S.

Vitamins-B (biocatalysts) and co-enzymes. H. von Euler and A. Pettersson. Z. physiol. Chem., 1921, **114**, 4—16.

The fermentation of living yeast was previously shown to be accelerated as much as 100% by an extract of dried yeast, in which Harden's so-called co-enzyme was the active constituent. Since it has appeared in recent years that there is a similarity between this co-enzyme and vitamin-B, the authors have investigated the effect of extracts of yeast, lemons, and wheat seedlings (all containing vitamin-B) on fermentation, and speak of the active substances as "biocatalysts." Again accelerations up to 100% in the rate of the fermentation were observed, although the increase in the number of cells may be only 10%.—G. B.

Yeast; "Bios" of Wildiers, and the cultivation of ——. M. Ide. J. Biol. Chem., 1921, 46, 521—523. M. B. MacDonald and E. W. McCollum. *Ibid.*, 525—527.

Further discussion of the question whether it is necessary to supply Wildiers' "bios" or the antineuritic (water-soluble B) vitamin to enable yeast to develop (*cf.* J., 1921, 363 A).—E. S.

Wines; Ebulliometric determination of alcohol in ——. U. Pratolongo. Giorn. Chim. Ind. Appl., 1921, 3, 143—147.

For concentrations of alcohol up to 3% by vol., almost normal ebullioscopic behaviour is shown by all the constituents of wine, the boiling point being raised by about 0·51° C. by the addition of 1 g.-mol. of solute to 1 l. of the solvent; the rise in the boiling point is compensated, although not entirely, by the dilution of the aqueous alcohol produced by the added solute. When the concentration of alcohol is 12—18%, tartaric acid and presumably also malic, succinic, and citric acids and their salts maintain their normal ebullioscopic behaviour, whereas dextrose, lævulose, acetic and lactic acids and their salts behave abnormally, the abnormality in the case of the two sugars increasing with the alcoholic strength; for any of these constituents the effect of the dilution of the aqueous alcohol caused by addition of solute not only annuls but changes in direction the rise in the boiling point. For intermediate alcoholic solutions, ranging from 3 to 12% in concentration, there is for each of the more important wine constituents a percentage of alcohol for which the two opposed influences compensate one another exactly. Thus, if an ebulliometer graduated by means of aqueous alcohol solutions is employed to determine the alcoholic content of tertiary or quaternary or even more complex mixtures, such as wine, the results obtained are low, almost exact, or high according as the percentage of alcohol is less than 3, between 3 and 12, or between 12 and 18.—T. H. P.

Wine containing cyanide. P. Malvezin. Ann. Chim. Analyt., 1921, 3, 154—155.

An Algerian wine yielded a blue coloration when mixed with another wine containing iron: the wine contained ferrocyanide and had evidently been treated with this substance for the purpose of clarification and for removing iron. Too much ferrocyanide had been used and, although ferrocyanides are considered to be relatively non-poisonous, the fact that the wine also contained free hydrocyanic acid due to the decomposition of ferrocyanide renders this method of purification dangerous to health.—W. P. S.

XIXa.—FOODS.

Butter; Detection of adulteration in —— *by means of the melting-point of the insoluble volatile acids.* G. Van B. Gilmour. Analyst, 1921, 46, 183—187.

The m.p. of the insoluble volatile acids from genuine butter lies between 15·8° and 25·6° C.; butters with high total and insoluble volatile acid values usually have low m.p. Genuine butters give a m.p. above 15·8° C., but if the total volatile acid value falls below 28, the m.p. should be above 28° C. The presence of either coconut oil or palm-kernel oil in the butter fat lowers the m.p. of the insoluble volatile acids, and 10% of these oils in butter fat can be readily detected.—W. P. S.

Butter; Detection of coconut oil in ——. R. Meurice. Ann. Chim. Analyt., 1921, 3, 143—145.

The saponif., Hehner, and Reichert-Meissl values are calculated to a common basis, *i.e.*, c.c. of $N/1$ sodium hydroxide solution per 100 g. of fat; for this purpose the saponif. value is multiplied by 1·782, the Hehner value by 3·71, and the Reichert-Meissl value by 2. If the sum of the Reichert-Meissl and Hehner values is subtracted from the saponif. value (all on the new basis) a difference value (Δ) is obtained which in the case of butter fats varies between 17 and 30, average 26·9. For coconut oil this difference value is 96. The ratio, Δ/Reichert-Meissl value, is 0·47 for butter fat and 7·4 for coconut oil. An alternative method consists in separating the fixed insoluble fatty acids as in the determination of the Hehner value, and titrating them in alcoholic solution, the result being expressed as c.c. of $N/1$ sodium hydroxide solution per 100 g. of fat; the value, F, thus obtained is 338 for butter fat and 417 for coconut oil. If the quantity of insoluble volatile acids is divided by that of the soluble volatile acids, a value R is obtained. In the case of butter fats $F \times R = 53{\cdot}2$ (maximum), whilst for coconut oil $F \times R = 1042{\cdot}5$.—W. P. S.

Hydrogenated vegetable oils (cottonseed, arachis, linseed, and sesamé oils); Physiological and pharmacological examination of —— and of unhardened sesamé oil. E. Rost. Arbb. Reichs-Gesundh.-Amt, 1920, **52**, 184—209. Chem. Zentr., 1921, **92**, II., 78.

The hardened oils are similar in their physiological action to the unhardened oils, and exhibit no harmful properties; they should contain practically no nickel and arsenic; the minute traces of nickel always present, and those of arsenic which occasionally occur, cannot be regarded as injurious. —L. A. C.

Cereal and meat products; Determination of water in ——. F. C. Cook. J. Assoc. Off. Agric. Chem., 1921, **4**, 347—351.

Malted cereal preparations having a low starch content and containing about 3% of moisture showed a greater loss when dried for 14 hrs. in a vacuum oven at 65° C. than when dried for 5 days in an ordinary vacuum desiccator over sulphuric acid, the difference being about 0·2%; the opposite was the case with samples of high starch content, *e.g.*, a sample losing 7·83% in the vacuum desiccator lost 6·81% in the vacuum oven at 65° C. With meat and fish identical results were obtained by the two methods, but meat extracts gave a higher result in the vacuum desiccator method.—W. P. S.

Carbohydrates; Determination of —— in vegetable foods. V. C. Myers and H. M. Croll. J. Biol. Chem., 1921, **46**, 537—551.

Soluble carbohydrates in the edible portions of vegetables and fruits are estimated by the Lewis-Benedict method as used by Rose (see page 481 a). For the estimation of the total available carbohydrate a weighed quantity of the ground vegetable is first boiled with water, then ground to a paste, and the starch hydrolysed by "taka-diastase." An aliquot part of the filtered solution is acidified with concentrated hydrochloric acid until about 0·6 *N*, and the hydrolysis completed by boiling. After nearly neutralising with strong sodium hydroxide solution, the estimation is completed by the method used for the soluble carbohydrates. A separate determination of the reducing sugar contained in the "taka-diastase" is made and a correction applied. The results of numerous estimations are given.—E. S.

Fruits and vegetables; Disinfection of —— by bleaching powder. M. Champion and E. Vandevelde. Bull. Soc. Chim. Belg., 1921, **30**, 124—129.

Fruits and vegetables may be sterilised by immersion for 30 mins. in a 0·2% solution of bleaching powder; *B. coli* and pathogenic organisms are destroyed, and in many cases the treated fruits are quite sterile. The treatment does not affect the taste or flavour of the fruits etc., especially if they are rinsed subsequently with boiled water. —W. P. S.

Cassava flour. C. Grimme. Z. Unters. Nahr. Genussm., 1921, **41**, 172—175.

Cassava flour is prepared from *Manihot utilissima* bitter cassava) or *M. palmata*, preferably from the ormer, as this loses the whole of its hydrocyanic acid when heated. The dry flour contains proteins, ·75; fat, 1·26; starch (tapioca), 88·8; crude fibre, ·81; ash, 1·12%. Tho ash contains about 33% K_2O and 20% P_2O_5.—W. P. S.

Crude fibre; Comparison of the natural and artificial digestion of ——. W. Thomann. Mitt. Lebensmittelunters. u. Hyg., 1920, **11**, 227—236. Chem. Zentr., 1921, **92**, I., 582.

Comparative feeding experiments on sheep and abbits, using ordinary straw and straw which had een treated with alkali, showed that the artificial digestion process proposed by Mach and Lederle (Landw. Vers.-Stat., **95**, 89) is equivalent to natural digestion as regards crude fibre. By digestion with alkali tho digestibility of the crude fibre of straw is increased from 40—50% to 70—75%. The crude fibre was determined by the methods of Weender and of Cross and Bevan. In the former method small quantities of cellulose are destroyed, and the crude fibre obtained contains pentosans and lignin, in addition to cellulose; its composition is not constant, but varies with the nature of the original material. Cross and Bevan's method gives higher results; the crude fibre is of more constant composition and contains very little lignin, but contains mineral matter and much pentosan.—W. P. S.

Patents.

Food compositions and processes of preparing the same. S. M. Wood. E.P. (a) 140,462 and (b) 140,463, 19.3.20. Conv., 19.3.19.

To an invert sugar syrup containing (a) 35—65% or (b) 65—85% of the total sugars as dextrose and lævulose, is added cocoa in proportion to form from 5 to 55% of the whole. The mixture is then boiled, with stirring, preferably for 40—60 mins., and cooled.—H. H.

Sugar-beets; Preparation of —— suitable for the manufacture of marmalades, extracts, wines, beers, and similar foods. A. Aumann. E.P. 147,713, 8.7.20. Conv., 13.12.17.

To purify and deodorise crushed sugar-beets, steam at 100°—104° C. is passed into a saccharified mash of the pulp.—H. H.

Beverages; Process for making ——. F. W. Graff and J. V. Oppel. U.S.P. 1,376,870, 3.5.21. Appl., 21.12.16.

The green beans of a vegetable beverage material, such as coffee or cocoa, are germinated and extracted. The malt extract thus produced is fermented and the product is desiccated, roasted, and again fermented.—H. H.

Dehydrating potatoes; Process of ——. A. E. Allen. U.S.P. 1,377,172, 10.5.21. Appl., 31.12.19.

Potatoes are cooked until soft and formed into elongated filaments. These are dried below 156° F. (69° C.), broken into short sections, and heated above 156° F. for a brief period.—H. H.

Dryer [for foodstuffs]. W. J. Warrington, Assr. to L. E. Tonglet, E. J. McGinnis, and C. G. Gaspard. U.S.P. 1,377,644, 10.5.21. Appl., 3.11.19.

Foon to be dried is conveyed down an inclined conduit from a receiving chamber to a discharge chamber. A moisture-extracting agent is supplied to the discharge chamber, and means are provided in the tops of the chambers to control the flow of this agent so that it may escape either direct from the discharge chamber or through the conduit and the receiving chamber.—H. H.

Spent grain; Process for extracting foodstuffs from ——. F. Pfeffermann, W. Jeroch, and Reichsausschuss für pflanzl. und tier. Oele und Fette G.m.b.H. G.P. 327,675, 3.1.18.

The fat and albumin are extracted successively from the grain, and the latter is decomposed to amino-acids, yielding a product suitable for flavouring soup. The residues are roasted to yield a substitute for, *e.g.*, coffee.—L. A. C.

XIXb.—WATER PURIFICATION; SANITATION.

Cresols and cresol soap substitutes. E. Hailer. Arbb. Reichs. Gesundh.-Amt, 1920, 52, 253—277. Chem. Zentr., 1921, 92, II., 87.

A neutral, aqueous solution of cresol, prepared by neutralising with acid an alkaline solution of cresol, is suitable for use a disinfectant. The presence of the salts formed by neutralising the alkali has no effect upon the disinfecting action of the solution. For general use a 1% solution of cresol is recommended, as an increase in the concentration does not materially improve the disinfecting action of the solution. The concentration of the cresol in solution diminishes with a rise of temperature (*e.g.*, to 0·6% at 30° C., 0·5% at 40° C., and 0·3% at 50° C.), but the solutions at these temperatures are as effective as a 1% solution at the ordinary temperature. Of the three isomers, *o*-cresol and *m*-cresol possess respectively the weakest and strongest disinfecting properties in aqueous solution. The best results with *Staphylococcus* were obtained with 1·0 to 1·25% aqueous solutions of crude cresol; stronger solutions were found in many cases to be less effective in their action. (*Cf.* J., 1920, 278 A.)—L. A. C.

Bacteria and bacterial toxins; Action of metals and metallic salts on ——. Utilisation of the oligodynamic action of metals. K. Laubenheimer. Z. Hyg. Infekt.-Krankh., 1921, 92, 78—114. Chem. Zentr., 1921, 92, I., 848.

Metallic silver can only be employed with safety for sterilising water comparatively free from germs. Unlike colloidal silver and metallic copper, it does not weaken tetanus toxin. The process of detoxication does not result in the destruction of the whole poison molecule, but affects only the toxophore group, and the product can be employed for cultivating an immunising agent in mice. The detoxicating action of copper towards tetanus toxin can be imparted to physiological salt solution or to distilled water; cupric chloride has the same action as metallic copper. Copper has a detoxicating action not only towards ectotoxins, such as those of diphtheria and tetanus, but also towards the endotoxin of the dysentry bacillus; thus dogs can be immunised against a quantity of the endotoxin several times the normal lethal dose by means of a copper-dysentry-endotoxin. The endotoxin of dysentry is not detoxicated by means of colloidal silver, but treatment with metallic silver, *e.g.*, by using glass vessels silvered on the interior, kills the typhus bacillis, yielding an active and only slightly poisonous typhus vaccine. A non-poisonous dysentry vaccine cannot be prepared by means of metallic silver, but copper is suitable for preparing a dysentry vaccine and a paratyphus-B-vaccine, both of which possess high immunising and only feebly poisonous properties.—L. A. C.

Trypaflavine; Bactericidal action of metallic compounds of ——. M. Berliner. Berl. klin. Wochschr, 1921, 58, 177—178. Chem. Zentr., 1921, 92, I., 875—876.

Trypaflavine-cadmium (25·4% Cd) possesses six times, and Trypaflavine-gold (2·5% Au) five times as strong a bactericidal action on streptococci as Argoflavin (diaminomethylacridinium chloride-silver). There is no distinguishable difference between the bactericidal action of Argoflavin and that of the methyl-free diaminoacridine-silver.
—F. M. R.

Sulphur; Colloidal fluid —— as a spray for plants. H. Kühl. Chem.-Zeit., 1921, 45, 479—481.

A sulphur preparation, termed colloidal liquid sulphur, recently placed on the market as a fungicide, consists of sulphur in such a fine state of division that the individual particles can scarcely be distinguished under the miscroscope. The preparation forms a uniform layer when dried on glass and the sulphur does not collect in lumps; in a dilution of 0·5 per 1000, the spray has no injurious action on foliage and the film adheres well even in wet weather.—W. P. S.

Calcium and magnesium arsenates; Solubility of —— in carbon dioxide, and its relation to foliage injury. A. J. Patten. J. Assoc. Off. Agric. Chem., 1921, 4, 404—406.

There is a considerable variation in the amount of arsenic dissolved from calcium arsenate by water saturated with carbon dioxide; the quantity dissolved varies from 23 to 86% of the amount present and bears no relation to the amount of free lime in the arsenate. Magnesium arsenate also dissolves readily in water containing carbon dioxide. Cases of injury to foliage when these arsenates have been used in place of lead arsenate for spraying purposes may be due to their greater solubility in the presence of carbon dioxide. Lead arsenate is only slightly soluble in water saturated with carbon dioxide.—W. P. S.

Patent.

Respirators; Apparatus for use with —— for the detection of small quantities of carbon monoxide. L. A. Levy and R. H. Davis. E.P. 163,102, 9.2.20.

Air, after passage through a compartment in a respirator for removing carbon monoxide, passes through another compartment containing successive layers of calcium chloride, a reagent such as a mixture of iodine pentoxide and fuming sulphuric acid (which on contact with carbon monoxide generates iodine or other irritating vapour and thus indicates to the wearer the approaching exhaustion of the respirator), cotton wool to absorb sulphur trioxide, and a material, *e.g.*, animal charcoal, capable of absorbing traces of iodine liberated by carbon monoxide which may accidentally pass the first compartment before it is exhausted.—L. A. C.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Strychnine; Determination of —— in scale preparations containing quinine and other cinchona alkaloids. T. F. Harvey and S. Back. Analyst, 1921, 46, 188—193.

The method proposed is a combination of those described by Harrison and Gair (J., 1903, 1019) and by Simmonds (J., 1914, 275). Ten g. of the sample is dissolved in 70 c.c. of water and 5 c.c. of *N*/1 sulphuric acid, and ammonia is added until the precipitated quinine only just re-dissolves; 30 g. of Rochelle salt is then added, the mixture nearly neutralised with ammonia, heated at 100° C. for 15 mins., cooled, diluted to 100 c.c., and filtered. Fifty c.c. of the filtrate is rendered ammoniacal and extracted with chloroform (30, 10, and 10 c.c.) and the chloroform solution is then extracted with 10% (weight/vol.) sulphuric acid (30, 10, and 10 c.c.); the acid solution is placed in a separator containing a plug of cotton-wool in the stem above the tap, 5 c.c. of 4% potassium ferrocyanide solution is added and the separator is filled with 10% sulphuric acid. After 2 hrs., the liquid is filtered through the plug of cotton-wool, the strychnine ferrocyanide washed with 6 c.c. of 10% sulphuric acid, and the strychnine recovered by shaking with ammonia and chloroform. The chloroform solution is evaporated, the residue washed three times with 1 c.c. of ether, dried at 100° C., and weighed. A correction of $-1{\cdot}7\%$ is made for the volume of the quinine tartrate precipitate. Quinidine and cinchonidine do not interfere, and small quantities of quinicine may be removed by washing the strychnine with 1 c.c. of acetone.—W. P. S.

Aconite; Colour reaction for ——. S. Mallannch. Analyst, 1921, **46**, 193—194.

A green coloration is obtained when a minute portion of aconitine or powdered aconite root and a small crystal of potassium ferricyanide are placed together and moistened with a drop of formic acid; the reaction is not given by morphine, strychnine, atropine, digitalin, eserine, or hyoscyamine. H. Finnemore pointed out that the reaction appears to be given by Indian aconite which contains pseudaconitine but not aconitine.—W. P. S.

4-β-Methylaminoethylglyoxaline. R. G. Fargher and F. L. Pyman. Chem. Soc. Trans., 1921, **119**, 734—740.

An N-alkyl derivative of 4-β-aminoethylglyoxaline, one of the active principles of ergot, was prepared in order to compare its physiological action with that of the naturally occurring base. The synthesis was effected from *dl*-α-chloro-β-glyoxaline-4-propionic acid, itself obtained from histidine, by treatment with 40% aqueous methylamine at 110° C. and subsequent decarboxylation of the resulting *dl*-α-methylamino-β-glyoxaline-4-propionic acid. The yields of 4-β-methylaminoethylglyoxaline were very poor, and its physiological activity was only about one-hundredth of that of the parent base.
—G. F. M.

Inositol hexaphosphoric acid; Synthesis of ——. S. Posternak. J. Biol. Chem., 1921, **46**, 453—457.

A reply to Anderson's criticisms (*cf.* J., 1921, 194 A).—E. S.

Catalytic action of certain metallic salts in reactions of organic compounds. A. Korczynski. Bull. Soc. Chim., 1921, **29**, 283—290.

In the preparation of *p*-nitrophenyl thiocyanate vith various metallic salts as catalysts, catalytic ictivity is at its maximum in the case of metals vith atomic weights between 55·84 and 63·57. Other elations between catalytic activity and atomic veight are suggested. (*Cf.* Willgerodt, J. prakt. Chem., **35**, 392.)—H. J. E.

alicylic acid; Bromometric determination of ——. I. M. Kolthoff. Pharm. Weekblad, 1921, **58**, 699—702.

o test the accuracy of the bromometric method for stimating salicylic acid, 25 c.c. of a 0·01 mol. soluion of salicylic acid was mixed with 25 c.c. of $N/10$ otassium bromate and 1 g. of sodium bromide, and arying quantities of $4N$ hydrochloric acid ere added. The mixture was allowed to stand in a oppered flask for 5—10 mins., and after addition 5 c.c. of $N/1$ potassium iodide the solution was trated with $N/10$ thiosulphate. Accurate results ere only obtained when the amount of hydroloric acid did not exceed 2—6 c.c. The excess of omine has little influence on the results. With wer concentrations of salicylic acid, *e.g.*, in foodtuffs, the amount of hydrochloric acid added is of sser importance. In this case 25 c.c. of a 0·008—012 mol. solution is mixed with 25 c.c. of $N/10$ tassium bromate and 1 g. of sodium bromide. ot more than 5 c.c. of $4N$ hydrochloric acid is then ded, the solution is kept in a closed flask for 5—10 mins., 5 c.c. of potassium iodide is rapidly introduced, and the mixture titrated with $N/10$ thiosulphate, starch being added only towards the end of the titration. (*Cf.* J.C.S., July.)—W. J. W.

Tartaric, oxalic, and formic acids; Simultaneous detection of —— *by resorcinol and sulphuric acid.* F. Krauss and H. Tampke. Chem.-Zeit., 1921, **45**, 521.

About 0·2 g. of resorcinol is dissolved in 5 c.c. of a solution of the three acids in dilute sulphuric acid, and 10 c.c. of concentrated sulphuric acid is added so as to form a layer under the solution. Formic acid is characterised by the evolution of carbon monoxide and the formation of an orange ring at the junction of the two liquids, and oxalic acid by a blue ring below the orange ring. If the mixture is heated gently without shaking, a red ring develops below the blue ring if tartaric acid is present. Carbonates, sulphides, iodides, bromides, and oxidising substances must not be present.—W. P. S.

Ethylene and sulphur monochloride; Interaction of ——. F. G. Mann, W. J. Pope, and R. H. Vernon. Chem. Soc. Trans., 1921, **119**, 634—646.

Pure sulphur monochloride is prepared by distilling the technical product with sulphur and about 1% of absorbent charcoal as a catalyst. The fraction distilling above 137° C. is redistilled with sulphur and charcoal *in vacuo*, whereupon the pure substance distils and condenses as a golden yellow liquid. At temperatures above 60° C. it darkens in colour owing to dissociation into the dichloride and sulphur, and in the absence of a catalyst the re-establishment of equilibrium proceeds very slowly after cooling. The interaction of ethylene with sulphur monochloride thus purified was studied, and it was shown that the same product, ββ-dichlorodiethyl sulphide, is formed at all temperatures between 30° and 100° C., and that a disulphide is not produced, but that the sulphur which is liberated during the reaction is retained at the lower temperatures in a state of pseudo-solution. Further, no intermediate compound of the type $CH_2Cl.CH_2.SCl$ is formed, as is stated by Conant (J., 1920, 348 A), but, on the contrary, dichlorodiethyl sulphide is present at all stages of the reaction, in amount strictly corresponding to the amount of ethylene absorbed. The varying yields obtained by different workers are shown to be due to the presence of alcohol vapour in the ethylene. With very pure materials the yield is about 80%, and a high-boiling by-product is formed which Conant considered to be a pentasulphide, but is now proved to be ββ-dichlorodiethyl trisulphide. The introduction of all other possible impurities but alcohol left the yield of mustard gas unaltered, but the 98% yields previously reported by Pope and Gibson (J., 1920, 383 A) were immediately obtained when alcohol vapour was introduced with the ethylene.—G. F. M.

Acrylic acid and acrylic esters. Halogenated propionic acids and esters. C. Moureu, M. Murat, and L. Tampier. Comptes rend., 1921, **172**, 1267—1269.

Acrolein is saturated with dry hydrogen chloride at −15° C., and the product is oxidised with nitric acid (sp. gr. 1·49). When the resulting β-chloropropionic acid is warmed with aqueous sodium hydroxide an excellent yield of acrylic acid is obtained. This acid or its esters are converted into the corresponding β-halogenated acids or esters by the action of the hydrogen halides. Acrylic esters may be prepared in some cases by direct esterification in the presence of sulphuric acid, or in general by warming the corresponding β-halogenated propionic ester with diethylaniline. (*Cf.* J.C.S., July.).—W. G.

Acetone; Iodometric determination of ——. P. H. Hermans. Chem. Weekblad, 1921, 18, 348.

The accuracy of the iodoform method for estimating acetone in aqueous solution depends on the amount of potassium hydroxide added. With either an excess or a deficiency of the hydroxide quantitative results are not obtainable even after standing. If the volume of the aqueous acetone is 20 c.c., 10—15 c.c. of 3*N*/2 potassium hydroxide must be taken, and the reaction is then complete in 1—2 mins. For 100 c.c. of acetone solution, 25—30 c.c. of the hydroxide must be added, and the time of reaction is 3—5 mins. In two experiments with absolute acetone in aqueous solution the results obtained were correct within 0·1 and 0·5% respectively.
—W. J. W.

Gurjun balsam; The Turner reaction for ——. J. B. Luther. J. Assoc. Off. Agric. Chem., 1921, 4, 422—424.

To avoid obscuration of the coloration by the charring action of concentrated sulphuric acid, the reaction described in the U.S. Pharmacopœia (known as the Turner reaction) for the identification of gurjun balsam in copaiba is modified as follows: A solution of 4 drops of the volatile oil in 1 c.c. of glacial acetic acid is treated with 1 drop of 10% sodium nitrite solution, and at once mixed with 2 c.c. of glacial acetic acid containing 5% of its vol. of concentrated sulphuric acid. The immediate formation of a violet colour denotes the presence of gurjun balsam; copaiba balsam itself gives a pink coloration after a short time (10 secs. or more).—W. P. S.

Oil of cade; Relation between the content of volatile oil and the yield of —— from the wood of Juniperus oxycedrus. R. Huerre. J. Pharm. Chim., 1921, 23, 441—449.

The oil produced by the dry distillation of the wood of *Juniperus oxycedrus* (oil of cade) is essentially a solution of the tarry substances, resulting from the action of heat on the ligneous elements of the wood, in the volatile oil of *J. oxycedrus*, the latter distilling over in its entirety and practically unchanged. The distillation of wood deprived of its volatile oil by steam distillation, and of its resins by extraction with solvents, yielded only a quantity of tar which was heavier than water, and it is therefore evident that the yield of oil of cade is largely conditioned by the content of volatile oil in the wood. The prolonged action of heat during the dry distillation only causes the transformation of 20—25% of the *l*-cadinene present in the volatile oil, the remainder distilling unchanged.—G. F. M.

Essential oil of Juniperus oxycedrus. Hydrochloride, hydrobromide, and hydroiodide of cadinene. R. Huerre. Bull. Soc. Chim. Biol., 1920, 2, 239—246.

The compounds mentioned are described, and appear to be identical with those obtained by Wallach. (*Cf.* J.C.S., 1921, i., 158.)—J. C. D.

Titration of weak acids and bases. Kolthoff. *See* XXIII.

Patents.

Urea; Manufacture of ——. Badische Anilin- und Soda-Fabr. E.P. 145,060, 15.6.20. Conv., 9.8.16.

In a continuous process for the manufacture of urea, a mixture of, *e.g.*, 2 vols. of ammonia and 1 vol. of carbon dioxide is forced into an autoclave and heated to 135°—150° C. for about 2 hrs. under a pressure of 50—100 atm. The product is slowly blown out through the bottom of the apparatus into a distillation column, whence the uncombined gases are returned, together with a fresh supply of the gases, to the autoclave.—L. A. C.

Maleic acid [and benzaldehyde and benzoic acid]; Production of ——. J. M. Weiss and C. R. Downs, Assrs. to The Barrett Co. U.S.P. 1,377,534, 10.5.21. Appl., 18.6.20.

Toluene in the vapour phase is oxidised with a gas containing oxygen, in presence of vanadium oxide as catalyst, at 400°—550° C.—W. J. W.

Carboxylic acids of carbocyclic and heterocyclic compounds; Manufacture of ——. K. W. Rosenmund and E. Struck. G.P. 327,049, 7.7.14.

Halogen derivatives of carbocyclic or heterocyclic compounds are treated with an alkali cyanide in the presence of copper or a copper compound and water or other suitable solvent; the presence of other substituents besides the halogen does not affect the reaction. Examples are given of the production of benzoic acid by treating chlorobenzene with potassium cyanide and copper cyanide in 25% alcohol at 210°. C., and of phthalic acid, anthranilic acid, thiophene-α-carboxylic acid, and naphthalene-1-carboxylic acid from 1.2-dibromobenzene, *o*-bromoaniline, α-bromothiophene, and α-bromonaphthalene respectively. In treating chloronitrobenzene, nitraniline was produced in addition to nitrobenzoic acid.—L. A. C.

Lignic acid and iron; Production of a compound containing ——. C. S. Fuchs. G.P. 327,087, 15.11.18.

A product of therapeutic value is prepared by treating soluble salts of lignic acid with ferric salts in aqueous solution; 75—80% of the lignic acid is precipitated as an iron compound which dissolves in a solution of sodium hydroxide. On neutralisation with hydrochloric acid the solution yields a gelatinous precipitate, which turns powdery on heating, and no iron can be detected in the filtrate after removal of the precipitate.
—L. A. C.

Bromonuclein; Production of ——. P. Bergell. G.P. 328,103, 2.8.18.

Nuclein is treated with bromine in an indifferent solvent, and the product is dried at a low temperature. Yeast nuclein and fish roe or fish milt nuclein absorb respectively about 14% and 10% of bromine; by prolonged boiling with sodium hydroxide the bromine is split off as sodium bromide. The products have therapeutic value in cases of neurosis and increased reflex irritation resulting from malnutrition.—L. A. C.

Lævulosemonophosphoric acid and salts of the same; Preparation of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 334,250, 11.5.18.

Lævulosediphosphoric acid, or, *e.g.*, its calcium salt, is heated with dilute acid until 1 mol. of phosphoric acid has split off, yielding, *e.g.*, calcium lævulosemonophosphate, $C_6H_{11}O_5,PO_4Ca,H_2O$. The free lævulosemonophosphoric acid forms with phenylhydrazine an osazone of m.p. 153° C.
—L. A. C.

N-Alkyl-acylhomopiperonylamines; Manufacture of ——. E. Merck Chem. Fabr. G.P. 334,788, 24.12.12. Addn. to 332,474 (J., 1921, 369 A).

The alkali salts of N-acyl derivatives of C-alkylhomopiperonylamines of the general formula, $CH_2O_2{:}C_6H_3.CHX.CHY.NH.CO.R'$, instead of N-acylhomopiperonylamines as described in the chief patent, are treated with alkylating agents. The product obtained by ethylating N-formyl-methyl-2(3.4-methylenedioxyphenyl)-ethylamine is a feebly coloured oil, b.p. 210° C. at 10 mm.—L. A. C.

Amino compounds of cinchona alkaloids and their derivatives; Preparation of ——. C. F. Boehringer und Soehne. G.P. 335,113, 9.6.18.

Cinchona alkaloids containing a free phenolhydroxyl group are coupled with diazonium salts, the azo compounds are reduced, and the phenolhydroxyl group is alkylated. Cupreine-azobenzenesulphonic acid, prepared by coupling cupreine with *p*-diazobenzenesulphonic acid in alkaline solution, m.p. (decomp.) 257° C., on reduction with sodium hydrosulphite in alkaline solution yields aminocupreine, m.p. (decomp.) 195° C., which by catalytic reduction yields aminohydrocupreine, and on treatment in alkaline solution with diethyl sulphate yields aminoquinethyline, $C_{21}H_{27}O_2N_3$, m.p. 213°—214° C. Catalytic hydrogenation of aminoquinethyline yields aminohydroquinethyline, identical with the product prepared by reduction of nitroethylhydrocupreine (*cf.* G.P. 283,537).—L. A. C.

Olefine hydrocarbons; Production of reactive acid liquor, alcohols, esters, and the like from ——. E. C. R. Marks. From New Jersey Testing Laboratories. E.P. 160,185, 22.4.19.

See U.S.P. 1,356,046, 1,356,048, and 1,356,050; J., 1921, 162 a.

Thioarsenates. E.P. 162,747. *See* VII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Autochromes; Desensitisation of ——. C. Adrien. Bull Soc. Franç. Phot., 1921, 8, 110—112.

The safranine desensitising process (*cf.* J., 1921, 99 a) is applicable to autochrome plates, as the dye is removed in the acid permanganate bath and the underlying colour-screen is not affected. There is a small retardation of development which is compensated by an increase of exposure by one-third. —B. V. S.

Patents.

Silver prints; Process for toning ——. B. Kobs. G.P. 319,268, 4.7.18.

Tones resembling those of gold-toned collodion prints are obtained by the use of a toning bath ontaining mercuric chloride and potassium bromide, along with cadmium and ammonium salts. ter toning the prints are treated with an alum-" hypo " fixing bath.—B. V. S.

Photo-electric cells. U.S.P. 1,376,604—6. *See* XI.

XXII.—EXPLOSIVES; MATCHES.

xplosives [tetryl]; Physico-chemical problems connected with the stability of ——. C. N. Hinshelwood. Chem. Soc. Trans., 1921, 119, 721—734.

the decomposition of molten tetryl between 140° d 150° C., evolution of gas ceases at approxi ately 2 g.-mols. per g.-mol. of tetryl, and the non seous residue amounts to 73%. The process is a uch less profound change than that which occurs detonation and does not involve complete dis tegration of the molecule; it constitutes a uni lecular, autocatalytic reaction. A large propor n of picric acid is found in the residue, and periments over the whole range of decomposition owed that autocatalysis is quantitatively ac unted for by its production. 2.4.6-Trinitro-3-droxyphenylmethylnitroamine behaves similarly tetryl, in that its rate of decomposition increases nsiderably on melting. Whilst it is unstable elf by virtue of its nitroamino-group, its instability is increased by its own hydroxyl group to about the same extent as that of tetryl is increased by picric acid. These relations suggest that this may be an instance of hydrogen-ion catalysis in a substance in the fused state. Farmer (J., 1921, 100 a) stated that the acceleration in the decomposition of solid tetryl in the early stages is largely due to progressive melting. It is found that this acceleration is quantitatively connected with the production of the liquid phase due to lowering of the melting point by decomposition products. A comparison of the ratio of the velocities of decomposition of solid and liquid tetryl at 120° C. with that deduced from the latent heat of fusion indicates that the decomposition of the solid is largely governed by traces of impurities which cannot be removed by recrystallisation.—W. J. W.

Patents.

Nitro-starch and the like; Method of making ——. G. R. Anchors. U.S.P. 1,376,598, 3.5.21. Appl., 19.3.18. Renewed 15.10.20.

For the nitration of starch the nitration acids are introduced at the bottom of the vessel containing the starch.—W. J. W.

Fuse for explosives; Manufacture of a ——. A. Kowastch and R. Mewes. G.P. 300,750, 11.3.17.

A case of suitable material, *e.g.*, metal, and provided with openings and with a pellet primer, is filled with liquid nitrogen-, halogen-, or sulphur oxides, or peroxides, with or without the addition of absorbents; the case is then put into the charge, and the whole is saturated with oil or other combustible material. Alternatively, the case may be filled with a solid combustible material, and the fuse, either alone or together with the cartridge, steeped in liquid nitrogen compounds.—L. A. C.

Fuse for projectiles. E. Nowak. G.P. 326,330, 4.5.15.

The fuse contains a catalyst, *e.g.*, a pellet of meerschaum coated with platinum black, and a readily oxidised material such as methyl alcohol, hydrogen, or coal-gas, contained in a case, *e.g.*, of lead, which is easily broken to bring the material and the catalyst in contact.—L. A. C.

Explosives; Apparatus for drying ——. C. Gielow and A. Faust. G.P. 326,760, 3.9.18. Addn. to 325,611 (J., 1921, 101 a).

In the apparatus described in the chief patent, the hot air inlet tube is connected with the conveyor for carrying forward the explosive material, and the air is conveyed out of the air chamber into the chamber containing the material through tubes at the sides.—L. A. C.

Pyrotechnics, matches, percussion caps, fuses, and the like [; Manufacture of compositions for ——]. A. Brock and R. M. Butt. E.P. 162,697, 3.11.19.

The consolidation, and preservation from atmospheric, chemical, and fermentative action, of pyrotechnic and similar compositions, may be effected by incorporating with them a small quantity (about 5%) of sodium silicate, or of potassium silicate, or both, or other soluble silicates such as those of calcium, magnesium, iron, lead, strontium, barium, and ammonium, or double salts of these with potassium or sodium.—W. J. W.

Coloured-smoke-producing composition. E. C. Weisgerber. U.S.P. 1,377,533, 10.5.21. Appl., 10.1.19.

A composition for producing coloured smoke consists of potassium chlorate, lactose, iodine, and *p*-nitraniline.—W. J. W.

Mixture for producing a luminous flame. Geka-Werke Offenbach G. Krebs. G.P. 326,761, 10.11.17.

An intimate mixture of powdered silicon or ferrosilicon and barium peroxide is employed.—L. A. C.

Trinitroresorcinol. E.P. 162,578. *See* III.

XXIII.—ANALYSIS.

Still-heads; Comparative study of fractionating ——. N. P. Moore. J. Phys. Chem., 1921, 25, 273—303.

A still-head made entirely of brass which will fractionate a mixture of 75% of chloroform and 25% of carbon tetrachloride with an efficiency of 82·7% is described. The maximum efficiency of the older forms of cylindrical still-head for the same mixture is 47·8%. The still-head consists of a bed plate, 36″ long, 6″ wide, and $\frac{1}{16}$″ thick and a cover plate of the same dimensions but only $\frac{1}{32}$″ thick. These plates are rounded at the ends. The bed plate carries 120 slotted angle strips made of 26-gauge metal and $\frac{1}{4}$″ apart. Each strip is 6″×$\frac{3}{16}$″ with $\frac{1}{8}$″ "turn-up." This "turn-up" is provided with slots $\frac{3}{32}$″ deep and $\frac{1}{32}$″ wide, so that it constitutes a dam $\frac{1}{32}$″ high completely across the bed plate. The slots serve as open sluices through which the overflow liquid can travel down the still-head. The number of slots increases from the top of the still-head to the bottom; the top 7 strips having 5 slots, the second 7 having 10 slots, and the number of slots increasing by 5 for each successive 7 strips until the bottom 7 has 90 slots. The bed plate and cover plate are joined together by a strip of $\frac{1}{8}$″ square brass rod which runs continuously round the plates and completely closes it in. At the lower end a brass tube $\frac{5}{8}$″ diam. is soldered, and this receives the vapour from the distilling flask; at the upper end a tube 6″ long and $\frac{1}{2}$″ diam. serves as the delivery tube. The still-head is usually set at an angle of 45° to the vertical, but this may be varied between 15° and 75° without any great change in the efficiency.—J. F. S.

Fermentation and food products; Determination of acidity in ——. L. Michaelis. Woch. Brau., 1921, 38, 107—108.

Determination of the hydrogen ion concentration is recommended in place of the usual titration methods. Standard indicator solutions are prepared as follows:—*m*-Nitrophenol, 0·3 g. per 100 c.c. of water; *p*-nitrophenol, 0·1 g. per 100 c.c. of water; γ-dinitrophenol, 0·1 g. per 400 c.c. of water; and α-dinitrophenol, 0·1 g. per 200 c.c. of water. Varying quantities (see table below) are measured into a series of test-tubes, and each is diluted to 7 c.c. with $N/10$ sodium carbonate solution. Six c.c. of the solution to be tested for acidity is then treated with 1 c.c. of one or other of the indicator solutions, the suitable indicator being the one which neither becomes quite colourless nor shows its maximum coloration, and the coloration obtained is compared with the test-series to obtain the corresponding p_H value. For $N/1$ acid $p_H = 1$, for $N/1$ sodium hydroxide solution $p_H = 14$.—W. P. S.

Hydrogen electrode vessel adapted for titrations. A. B. Hastings. J. Biol. Chem., 1921, 46, 463—466.

The main feature is an arrangement rendering possible the measurement of hydrogen ion concentrations and the making of electrometric titrations without allowing the escape of gases or volatile matter from the electrode vessel. (*Cf.* J.C.S., July.)—E. S.

Acidity of coloured solutions; Determination of the ——. J. L. Lizius. Analyst, 1921, 46, 194—195.

The liquid is titrated in the usual way, spot tests being made on a filter paper placed in a Buchner funnel and moistened with phenolphthalein solution; when a pink coloration is obtained, the whole of the liquid is filtered through the paper. The filtrate is then treated with 0·5 c.c. of $N/10$ acid and again filtered. If the filter-paper remains pink, more acid is added, and so on. It may be necessary to re-moisten the filter-paper with phenolphthalein solution from time to time.—W. P. S.

Bases combined with weak or moderately strong acids and of very weak bases with acids, and vice versâ; Determination of ——. I. M. Kolthoff. Z. anorg. Chem., 1921, 115, 168—180. (*Cf.* J., 1920, 706 A.)

Although tropäolin O and OO are comparatively insensitive indicators to acids and alkalis, they are valuable for certain titrations for which more sensitive indicators are unsuitable, for example, in the titration of an alkali acetate with hydrochloric acid. Solutions not weaker than $N/1$ should be used for the titration, since with $N/10$ or $N/100$ solutions the change of hydrogen ion concentration at the neutral point is too gradual. Dimethyl yellow gives an acid reaction when only 80% of the acetate is neutralised, but tropäolin O gives a good end-point with an error of only 0·3%. For determining the end-point, comparison is made with a standard consisting of $N/2$ acetic acid or 0·003 N hydrochloric acid. Salts of other weak acids such as lactic, formic, benzoic, or salicylic acid having a dissociation constant smaller than $1-2\times10^{-4}$ can be similarly titrated. Weak bases such as aniline, having a constant greater than 10^{-10} can be titrated with acids, using tropäolin O as indicator. Very weak acids, such as phenol, and salts of moderately strong bases, such as ammonium salts, can be titrated with caustic soda, using the same indicator.—E. H. R.

Phosphoric acid; Colorimetric determination of ——. A. Grégoire. Bull. Soc. Chim. Belg., 1920, 29, 253—258.

The reagent used is prepared by dissolving 1 g. of quinine sulphate in dilute nitric acid, adding barium hydroxide in quantity sufficient to precipi-

tate the sulphate, filtering the mixture and adding the filtrate to a solution of 40 g. of ammonium molybdate in 500 c.c. of nitric acid (sp. gr. 1·2); the solution is then diluted to 1 litre. The phosphoric acid solution, containing not more than 0·025 mg. P_2O_5, is treated with 2 c.c. of nitric acid (sp. gr. 1·2), diluted to 45 c.c., 2 c.c. of the reagent is added, the whole diluted to 50 c.c., and the coloration obtained compared with a standard prepared under similar conditions. Small quantities of silica do not interfere, but iron must be removed previously, preferably by means of "cupferron."
—W. P. S.

Phosphoric acid; Gravimetric determination of small quantities of ——. G. Embden. Z. physiol. Chem., 1921, **113**, 138—145.

A micro-method is described, depending on precipitation as strychnine phosphomolybdate (Pouget and Chouchak, J., 1909, 261), and weighing instead of estimating colorimetrically. From 1 mg. of P_2O_5 upwards can be estimated accurately. Since the precipitation is carried out in neutral or faintly acid solution, inorganic phosphoric acid can be estimated in the presence of easily hydrolysed organic derivatives of phosphoric acid. (*Cf.* Raper, J., 1915, 102.)—G. B.

Arsenic acid; Iodometric determination of ——. I. M. Kolthoff. Pharm. Weekblad, 1921, **58**, 727—728.

The author has obtained accurate results in the method of estimating arsenic acid by treating it in acid solution with potassium iodide and titrating the liberated iodine with thiosulphate. Liberation of iodine by the action of dissolved oxygen on the iodide (Fleury, J., 1920, 485 A) does not occur if the arsenate and hydrochloric acid are heated on the water-bath, to expel air, before adding the iodide. If, however, the iodide is added to the acid arsenate solution at room temperature and the mixture then heated, some oxidation does take place, but even then the error is slight, and the results are not much higher than those obtained by neutralising the solution with sodium bicarbonate, after removal of the iodine by thiosulphate, and titrating the arsenious acid with iodine solution. (*Cf.* J.C.S., July.)—W. J. W.

Iron and manganese; Method for rough estimation of —— *in qualitative analysis.* L. J. Curtman and N. H. Hecht. Chem. News, 1921, **122**, 254—255.

The method is based on the capacity of stannous chloride to bleach ferric thiocyanate, and on the conversion of manganese salts by sodium bismuthate nto permanganic acid, and bleaching of the latter by hydrogen peroxide. The precipitate obtained n Group III. (hydroxides of aluminium and chromium and sulphides of nickel, cobalt, iron, manganese, and zinc) is treated with hydrochloric cid, and the sulphides of nickel and cobalt are ltered off. The filtrate is evaporated to 2 c.c. to xpel hydrogen sulphide and excess of hydrochloric cid, and diluted to 50 c.c. For the determination f iron 25 c.c. of the solution is boiled with 10 c.c. f 6*N* sodium hydroxide and 1·5 g. of sodium perxide. The solution is diluted with twice its olume of water, and filtered. The precipitate and lter are treated with 50 c.c. of concentrated hydrochloric acid and immediately boiled, and the soluon is diluted and filtered, the filter being washed ith dilute hydrochloric acid; both solution and ashings are then evaporated to half the original olume to expel chlorine, and cooled. After addion of 5 c.c. of 5*N* potassium thiocyanate, the ixture is titrated with stannous chloride solution (5 mg. Sn per c.c.) until a pink colour is obtained which matches that of a solution of ferric chloride (0·05 mg. Fe) in 50 c.c. of hydrochloric acid (1:1) to which 5 c.c. of 5*N* potassium thiocyanate has been added. The stannous chloride solution should be standardised before each estimation. *Manganese.* To determine manganese the remaining 25 c.c. of the original solution is treated with sodium hydroxide and sodium peroxide to precipitate iron and manganese, and the mixture is boiled and diluted as before, after which the precipitate is washed till free from chlorides. Precipitate and filter are heated to boiling with 25 c.c. of concentrated nitric acid and 10 c.c. of 3% hydrogen peroxide, and the solution is diluted and filtered. The combined solution and washings are evaporated to half their volume, cooled, and diluted to 100 c.c., of which 20 c.c. is used for the estimation, the acidity being first adjusted by neutralising with ammonia, adding 10 c.c. of concentrated nitric acid and diluting to 200 c.c. 4 g. of sodium bismuthate is added, and after 5—10 mins. the solution is decanted through a fluted filter. The residue is washed with 5% nitric acid and the liquid again decanted. The solution is then titrated with 0·3% hydrogen peroxide until colourless. The hydrogen peroxide is standardised with standard permanganate solution containing one-fourth of its volume of nitric acid. The methods gave results accurate to approximately 1—2%.—W. J. W.

Sodium salicylate; Use of —— *as microchemical reagent for aluminium, iron, chromium, and manganese.* C. van Zijp. Pharm. Weekblad, 1921, **58**, 694—698.

With aluminium nitrate, sodium salicylate forms colourless needles which tend to unite into spherical masses. The reaction is improved by the addition of cæsium chloride and is rendered still more definite by exposing a drop of the mixed solutions to ammonia vapour, by which precipitation of aluminium hydroxide is prevented. Excess of the aluminium salt retards crystallisation, whilst in presence of excess of salicylic acid the crystals redissolve. In applying the above method for detecting aluminium, iron, and chromium, either separately or in a mixture, the solutions must be of such concentration as to avoid formation of crystals before treatment with ammonia. Iron salts produce no crystals, but under the action of ammonia, the violet coloration produced with sodium salicylate is changed to yellow; no hydroxide is precipitated. On the other hand, with chromium salts, chromium hydroxide is precipitated, but, as with iron, no crystals are formed. The presence of iron in solutions of aluminium salts is indicated by the brown coloration of the crystals produced; and of chromium by separation of hydroxide and crystals on evaporation of the drop, whilst the yellow colour of the hydroxide together with a brown coloration of the crystals indicates a mixture of aluminium, iron, and chromium. Manganese salts give no crystals with sodium salicylate, but when the mixed solutions are exposed to ammonia, there is immediate formation of light green, pointed crystals. With sufficient sodium salicylate, the reaction is very sensitive and is not affected by the presence of zinc.
—W. J. W.

Zinc; Gravimetric determination of ——. L. W. Winkler. Z. angew. Chem., 1921, **34**, 235—236.

For the estimation of zinc as zinc ammonium phosphate, 100 c.c. of an acid solution containing 0·01—0·1 g. is heated to boiling with 2 g. of ammonium chloride, and 10 c.c. of a 20% solution of diammonium phosphate (prepared by mixing

42 c.c. of 20% ammonia with 100 c.c. of 20% phosphoric acid, allowing to stand overnight, and filtering through cotton wool) is added in a thin stream. The zinc ammonium phosphate is precipitated first in an amorphous form, but rapidly becomes crystalline. After standing overnight it is separated by filtering through cotton wool, which has been previously treated with methyl alcohol and dried at 130° C., washed with 50 c.c. of a saturated aqueous solution of zinc ammonium phosphate, drained with the aid of the pump, washed with 2—3 c.c. of methyl alcohol, again drained, and finally dried at 130° C. for 1 hour. Heating the precipitate to redness and weighing it as $Zn_2P_2O_7$ is less accurate. The results are not affected by the presence of ammonium nitrate or sulphate, and only slightly by sodium chloride. On the other hand, potassium salts appreciably decrease the accuracy of the method; if present in considerable amount, they cause the precipitate to pass through the cotton wool filter, whilst in small quantities they are precipitated as $KZnPO_4$.—W. J. W.

Silicon, tin, titanium and zirconium; Separation of —— by sodium carbonate. P. Wenger and J. Morel. Ann. Chim. Analyt., 1921, 3, 139—142.

The mixed oxides are fused for 3 hrs. with 6 times their weight of sodium carbonate, the fused mass is boiled with water, and the solution filtered. The filtrate contains the silica and a portion of the tin, and these are weighed together after evaporation with nitric acid, the silica being separated subsequently by treatment with hydrofluoric acid. The insoluble portion contains the titanium, zirconium, and the remainder of the tin; it is ignited, fused with 18 times its weight of potassium bisulphate, and the mass boiled with water containing nitric acid. Tin remains insoluble and is separated by filtration; the filtrate is neutralised, treated with hydrogen peroxide, and the precipitated zirconium separated and weighed. The titanium is then precipitated by ammonia.—W. P. S.

Patent.

Gas analysing apparatus. M. Arndt. E.P. 148,998, 12.7.20. Conv., 30.11.15.

In an apparatus for the treatment of gas by a single absorbent, a definite volume of gas is trapped by a sealing device in a U-tube, and then forced into a bell-shaped container surrounding the U-tube and filled with the absorbent. The movement of a float in the reservoir of absorbing liquid indicates the volume of residual gas.—C. I.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

A.-G. Brown, Boveri, & Co. Mercury-vapour pumps for high vacua. 16,876 and 17,240. June 20 and 23. (Switz., 24.6. and 17.7.20.)

Blair, Campbell, and McLean, and Ferguson. Evaporators and distilling apparatus. 17,203. June 23.

Boberg, Testrup, and Techno-Chemical Laboratories, Ltd. Refrigeration. 15,701. June 7.

Buxton and Buxton. Rotary multiple drying cylinder. 15,884. June 9.

Buxton. Drying apparatus. 16,186. June 13.

Daniels and others. 17,249. *See* XVII.

Erickson. Furnaces. 16,401. June 14.

Hooper, Pratt, and Pratt. Mixing apparatus. 17,410. June 25.

Marchant. Drying-machines. 16,061. June 10.

Rigby. Heating or cooling liquids or admixed solids and liquids in evaporative etc. treatment. 16,547. June 16.

Scherhag. Drying-apparatus. 16,161. June 11. (Ger., 30.7.20.)

Thunholm. Apparatus for evaporating liquids. 16,802. June 18. (Sweden, 21.6.20.)

Complete Specifications Accepted.

11,088 (1915). Moller. Separating suspended bodies from electrically insulating fluids, particularly gaseous fluids. June 22.

28,364 (1919). Bomsel. Preventing incrustations or boiler scale. (164,382.) June 22.

698 (1920). Ellis. Distillation apparatus. (164,407.) June 22.

2637 (1920). Mumford. Apparatus for separating solids from liquids. (164,410.) June 22.

2837 (1920). Travers. Furnaces. (164,073.) June 15.

3474 (1920). Imray (Mauss). Centrifugal separators. (164,418.) June 22.

3851 and 27,965 (1920). Douglas. Condensers, dephlegmators, and column stills. (164,793.) June 29.

4800, 14,397, and 16,917 (1920). Feldenheimer and Plowman. Catalysts and catalytic reactions. (164,808.) June 29.

5971 (1920). Freeman. Distilling apparatus. (164,098.) June 15.

6102 (1920). Reynard and Edser. Lubricants. (164,107.) June 15.

7245 (1920). Zimmermann and Weyel. Drying-apparatus. (164,157.) June 15.

7265 (1920). Hoyle. Centrifugal dryers. (164,500.) June 22.

7778 (1920). Merz. Evaporation of liquid and recovery of vapours. (164,525.) June 22.

8091 (1920). Sturgeon. Centrifugal separating apparatus. (164,867.) June 29.

8573 (1920). Martin and Richards. *See* X.

18,319 (1920). Freytag. Washing gases and vapours. (146,356.) June 15.

18,379 (1920). Soc. l'Oxylithe. Washing or purifying and drying air and other gases. (146,397.) June 15.

18,521 (1920). Elektro-Osmose A.-G. Process for extracting materials. (146,453.) June 15.

20,081 (1920). Grenet. Heating or drying apparatus. (148,171.) June 29.

23,497 (1920). Thompson (Soc. Anon. Fours et Procédés Mathy). Regenerative furnaces. (164,991.) June 29.

36,644 (1920). Moulin. Apparatus for diffusion of essences or volatile liquids. (156,162.) June 15.

801 (1921). Krupp A.-G., and Fauth. Filter plates. (156,739.) June 29.

4059 (1921). Zimmermann and Weyel. Drying apparatus. (164,290.) June 15.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Akt.-Ges. f. Anilinfabr. Fuel for internal-combustion engines. 16,742. June 17. (Ger., 20.9.20.)

Aktiebol. Cellulosa. Furnace for dry distillation of waste liquors etc. 16,394. June 14. (Sweden, 29.6.20.)

Bauer, Kaeser, and Deutsche Petroleum A.-G. Retorts for distillation. 17,230. June 23. (Ger., 3.7.20.)

Bijleveldt and Verburgh. Manufacture of fuel briquettes etc. 15,711. June 7.

Bloxam (Sinclair). Fuel for internal-combustion engines. 16,261. June 13.

Bour. Storage of inflammable volatile liquid fuels. 15,918. June 9.

Climie. Plant for generating and treating gas. 16,469. June 15.

Helps. Gas manufacture. 16,183. June 13.

Hickman. Fuel oil for internal-combustion engines. 15,872. June 9.

Keillor. Combination plant for making coal gas, blue water-gas, and coal-tar or oil gas. 16,622. June 16.

Leadbeater. Obtaining carbon from peat for decolorising. 17,169. June 23.

Marlow. Gas-producer for firing or heating. 16,826. June 20.

Meguin A.-G., and Müller. Carbonsing bituminous shale etc. at low temperature. 17,352. June 24. (Ger., 4.9.20.)

Minerals Separation, Ltd., and Price. Treatment of coal. 16,913. June 20.

Nesfield. Desulphurising oils. 16,387. June 14.

Perry. Apparatus for treating peat etc. 17,100. June 22.

Poore. Destructive distillation of wood, woody fibres, etc. 16,069. June 10.

Standard Oil Co. of New York. Distilling petroleum etc. under pressure. 15,776. June 8. (U.S., 20.10.13.)

Turner. Gas-producers. 16,554. June 16.

Complete Specifications Accepted.

20,599 (1919). Low Temperature Carbonisation, Ltd., Armstrong, and Davidson. Retort settings. 164,372.) June 22.

2945 (1920). Ellis (Foundation Oven Corp.). Coke-ovens. (164,077.) June 15.

4370 (1920). Engelke. Obtaining volatile fractions from crude mineral oils etc. (164,800.) une 29.

6078 (1920). Illingworth. Coking of coal. 164,104.) June 15.

7994 (1920). Kormann. Distilling petroleum ils. (164,529.) June 22.

8593 (1920). Tulloch and Smith. Gas-producers. 64,548.) June 22.

8699 (1920). Carpenter. Purification of coal gas d like gases. (164,183.) June 15.

11,802 (1920). Woodall, Duckham, and Jones, d Duckham. Gasification of coal etc. (164,935.) ne 29.

21,847–8 (1920). Knöpflmacher and Adler. Puriation or washing of gases. (149,340–1.) June 29.

819 (1921). Halbergerhütte Ges. Treating or handling filter plants for filtering combustible gases. (156,753.) June 22.

3238 (1921). Halbergerhütte Ges. Purification of blast-furnace and like gases. (160,758.) June 22.

III.—TAR AND TAR PRODUCTS.

Application.

Morgan, Rider, and Thermal Industrial and Chemical Research Co. Distillation of tar. 15,726. June 7.

Complete Specifications Accepted.

862 (1920). British Dyestuffs Corp., Green, and Porter. Manufacture of phthalic acid and anhydride. (164,785.) June 29.

4461 (1920). Miersch. *See* VII.

IV.—COLOURING MATTERS AND DYES.

Applications.

Durand und Huguenin A.-G. Manufacture of halogen derivatives of basic acridine dyestuffs. 16,368. June 14. (Ger., 30.6.20.)

Hart. Production of dyes and pigments. 16,214. June 13.

Complete Specifications Accepted.

30,461 (1919). British Dyestuffs Corp., Baddiley, and Hill. Manufacture of scarlet lakes. (164,053.) June 15.

7028 (1920). Kane. Production of azo dyes. (164,488.) June 22.

8394 (1920). Tootal. Dye preparations. (164,178.) June 15.

12,526 (1920). Carpmael (Bayer und Co.). Manufacture of indigoid vat dyestuffs. (164,594.) June 22.

12,639 (1920). Carpmael (Bayer und Co.). Manufacture of azo dyes. (164,218.) June 15.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Aktiebol. Cellulosa. 16,394. *See* II.

Bouillon and Worms. Filters for producing cellulose filaments etc. 16,333. June 14.

Bouillon and Worms. Apparatus for producing threads etc. from viscose. 16,334. June 14.

Dreyfus. Treatment of products of cellulose derivatives. 15,931. June 9.

Dryepondt and Govaerts. Treatment of ramie, flax, hemp, etc. to produce fibre for spinning. 16,730. June 17.

MacLennan. Preparations for cleansing and sterilising textile fabrics etc. 15,959. June 9.

Steinhilber. Production of cellulose from reeds etc. 16,975. June 21. (Ger., 13.5.21.)

Weygang. Treating fibrous materials for papermaking etc. 16,582. June 16.

Williams. Open-width scouring of cotton piece-goods. 16,196. June 13.

Zdanowich. Manufacture of acetylated cellulose and artificial silk, films, etc. 16,850. June 20.

Complete Specifications Accepted.

20,852 (1919). Marks (Du Pont de Nemours and Co.). Production of pyroxylin bodies. (164,032.) June 15.

20,853 (1919). Marks (Du Pont de Nemours and Co.). Pyroxylin solvents and solutions. (164,033.) June 15.

21,474, 21,661, and 21,773 (1919). Dreyfus. Manufacture of cellulose derivatives. (164,374–5, 164,377.) June 22.

30,216–8 (1919). Dreyfus. Manufacture of products having a basis of cellulose derivatives. (164,384–6.) June 22.

1279 and 25,417 (1920). Jenkins. Apparatus for drying, cleansing, or carbonising wool etc. (164,064.) June 15.

6382 (1920). Le Tall (Soc. Franç. des Crins Artificiels). Production of moulded cellulose articles. (164,126.) June 15.

15,370 (1920). Sutherland. Manufacture of pulp board and other pulp articles. (164,620.) June 22.

16,908 (1920). Akt.-Ges. f. Anilinfabr. Manufacture of cellulose esters of organic acids. (145,524.) June 29.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Blicquy and Callebaut. Dye vats or machines. 17,080. June 22.

Bloxam (Akt.-Ges. f. Anilinfabr.). Dyeing furs, feathers, skins, etc. 15,727. June 7.

Bunney and Dunn. Dyeing knitted fabrics. 16,986. June 21.

Farbw. vorm. Meister, Lucius, u. Brüning. Manufacture of stable, dry, readily soluble vat preparations for dyeing. 16,491. June 15. (Ger., 1.11.20.)

Reichelt. Production of liquid washing-blue and bleaching substance. 16,223. June 13. (Ger., 8.3.21.)

Williams. 16,196. *See* V.

Complete Specifications Accepted.

9056 (1920). Soc. la Soie Artific. de la Voulte. Waterproofing and strengthening threads and fabrics. (158,851.) June 29.

19,042 (1920). Ornstein. Bleaching vegetable substances by means of hypochlorous acid. (147,069.) June 29.

20,390 (1920). Jackson and Bro., Gass, Hammond, and Fish. Apparatus for bleaching or washing fabrics etc. (164,980.) June 29.

1344 and 1346 (1921). Krantz. Dyeing yarn on bobbins in circulating dye liquor. (157,419 and 157,421.) June 22.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Chambers, Hammond, and Sowden. Treating waste etc. liquors containing ferrous chloride. 16,320. June 14.

Cougny, Girou, and Lefèvre. Extraction of iodine from seaweeds or ashes thereof. 15,969. June 9.

Courtaulds, Ltd., and Jones. Manufacture of caustic soda. 16,164. June 11.

Dutt, Godfrey, and Wilson. Extraction of titanium dioxide from titaniferous laterites. 16,063. June 10.

Johnson (Badische Anilin- u. Soda-Fabr.). Production of oxalic acid. 15,732. June 7.

Mau. Manufacture of concentrated hydrogen peroxide solution. 16,743. June 17. (Ger., 26.7.20.)

Officine Elettrochimiche Dr. Rossi, and Toniolo. Drying or eliminating water vapours and nitrous or nitric acid vapours from gases derived from oxidised ammonia. 16,248. June 13. (Ital., 12.6.20.)

Prideaux. Preparation of bismuth compounds from the metal. 17,068. June 22.

Tyrer. Manufacture of red oxide of iron. 15,813–4. June 8.

Volart y Jubany. Manufacture of hydrochloric acid. 16,265. June 13. (Spain, 11.6.20.)

Wilderman. Electrolytic decomposition of alkali salts. 16,619. June 16.

Wilderman. Production of hypochlorites and chlorates. 16,636. June 16.

Complete Specifications Accepted.

30,268 (1919). Williams and Haynes. Synthetic production of nitrogen compounds. (164,050.) June 15.

4461 (1920). Miersch. Obtaining hydrofluoric acid from the sulphonating mixtures of organic sulpho acids and calcium fluoride. (164,803.) June 29.

10,386 (1920). Dior. Construction of sulphuric acid chambers. (164,572.) June 22.

11,115 (1920). Wade (Lindsay Light Co.). Recovery of thorium. (164,581.) June 22.

16,534 (1920). Levinson and Martin. Utilisation of waste or spent lime sludge. (164,625.) June 22.

18,746 (1920). Unione Italiana fra Consum. e Fabr. di Concimi e Prod. Chemici, and Sonneck. Manufacture of sulphuric acid. (164,627.) June 22.

VIII.—GLASS; CERAMICS.

Applications.

Edwards. Producing porcelain effect on glass. 15,548. June 6.

Frohman. Refractory material. 16,048. June 10.

Levitt. Treatment of silicates. 15,894. June 9.

Lott. Manufacture of glass articles. 17,237. June 23.

Lott. Production of charges of molten glass. 17,238. June 23. (U.S., 7.1.20.)

Complete Specification Accepted.

21,666 (1919). Williamson. Continuous and intermittent ovens for firing pottery etc. (164,376.) June 22.

IX.—BUILDING MATERIALS.

Applications.

Ammon. Treating wood. 15,934. June 9. (Ger., 1.7.20.)

Imperial Trust, and Schryver. 17,026. *See* XIII.

Rönblom. Wood-like material for building. 16,750. June 17.

Scott and Scott. Compound for waterproofing and hardening cement. 15,921. June 9.

Complete Specification Accepted.

28,952 (1920). Curtis. Cementitious compositions for flooring, paving, etc. (164,666.) June 22.

X—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Akt. Svenska Kullagerfabr. Hardening of metal. 15,840. June 8. (U.S., 15.6.20.)

Allan, Middleton, Hague, and Cammell, Laird and Co. Cementation of iron, steel, and ferrous alloys. 15,655. June 7.

Ashcroft and Lacell. Treatment of metal-bearing ores etc. 16,165. June 11.

Bloxam (Aluminium Co. of America). Aluminium alloys. 16,263. June 13.

Brooke, Cooper, and Kerr. Soft solder for aluminium. 15,998. June 10.

Capdeville. Smelting tin ores. 17,257. June 23.

Chemical and Metallurgical Corp., Ltd., and Elmore. Treatment of argentiferous lead-zinc sulphide ores. 15,815. June 8.

Chemical and Metallurgical Corp., Ltd., and Elmore. Treatment of lead-bearing mattes etc. 16,163. June 11.

Collins. Treatment of ores. 16,157. June 11.

Craig, Pearson, and Durelco, Ltd. Electrolytic treatment of materials containing tungsten or molybdenum. 16,148. June 11.

Cross, and Zynkara, Ltd. Removing rust from iron or steel surfaces. 16,632. June 16.

Dent and Seddon. Alloys for repairing defective castings and machinery. 16,818. June 18.

Dutt and others. 16,063. *See* VII.

Fairweather (Hybinette and Peek). Refining copper-nickel matte. 16,489. June 15.

Harris. Apparatus for refining metals. 16,871. June 20.

Hilger, Ltd., and Twynam. Annealing. 17,049. June 21.

Hilton. Regenerative, liquid-fuel-fired melting furnaces. 16,723. June 17.

Le Maréchal, and Siemens Bros. and Co. Production of tungsten and tungsten filaments. 16,806. June 18.

Liebreich. Separation of chromium. 16,159. June 11. (Ger., 11.6.20.)

Metcalfe and Usher. Recovery of gold from pulverised material. 16,791. June 18.

Perkins, Picard, Sulman, and Taplin. Treatment of ores containing copper silicate. 15,968. June 9.

Silverberg, and Siemens Bros. and Co. Production of tungsten. 16,807. June 18.

Thompson (Thoumyre Fils). Lead alloys. 16,456. June 15.

White (National Lead Co.). 16,404. *See* XIII.

Complete Specifications Accepted.

29,761 (1919). Hadfield. Manufacture of alloy steel. (164,039.) June 15.

30,447 (1919). McKune. Open-hearth furnaces. (164,052.) June 15.

30,724 (1919) and 8103 (1920). Hadfield. Manufacture of alloy steel. (164,394.) June 22.

30,725 (1919). Hadfield. Manufacture of steel. (164,395.) June 22.

6390—1 (1920). Rondelli, Sestini, and Sestron Colour Oxidising Co. Oxidising and colouring metallic surfaces. (164,127—8.) June 15.

6392 (1920). Rondelli, Sestini, and Sestron Colour Oxidising Co. Preparation of ferrous surfaces for enamelling, varnishing, etc. (164,129.) June 15.

7190 (1920). Minerals Separation, Ltd. Ore concentration. (154,870.) June 22.

7260 (1920). Basset. Production of metals or metalloids, their alloys and combinations. (140,096.) June 22.

8573 (1920). Martin and Richards. Treatment of pulverulent or granular material with gases, particularly the roasting of ores etc. (164,547.) June 22.

8960 (1920). United Lead Co. Hard lead alloys. (140,824.) June 15.

8962 (1920). National Malleable Castings Co. Refining iron for castings. (140,826.) June 15.

9455 (1920). Talbot. Metallurgical furnaces. 164,901.) June 29.

11,115 (1920). Wade (Lindsay Light Co.). *See* VII.

13,849 (1920). Kroll. Producing alloys containng alkaline-earth metals. (164,608.) June 22.

14,698 (1920). Deutsche-Luxemburgische Bergverks- u. Hütten-A.G., and Klinkenberg. Manuacture of steel and alloys thereof. (143,934.) une 22.

15,007 (1920). Caspersson. Iron alloys. (164,960.) une 29.

27,032 (1920). Correa and Briolais. Alloy for se in soldering aluminium. (164,655.) June 22.

27,120 (1920). Griggs. Open-hearth furnaces. 65,002.) June 29.

3238 (1921). Halbergerhütte Ges. *See* II.

XI.—ELECTRO-CHEMISTRY.

Applications.

Craig and others. 16,148. *See* X.

Hancock and Hancock. Electric furnaces. ,324. June 24.

Svenska Ackumulator Akt. Jungner. Electric tteries. 16,966. June 21. (Sweden, 21.6.20.)

Tungsten Manuf. Co., Ltd., and Weston. Electric furnaces. 16,520. June 15.

Wilderman. 16,619. *See* VII.

Complete Specifications Accepted.

32,700 (1919). Bocker and Eichhoff. Manufacture of galvanic elements. (164,062.) June 15.

4117—4120 (1920). Pouchain. Negative electrodes for accumulators. (164,431—4.) June 22.

6222 (1920). Burgess Battery Co. Dry batteries. (140,065.) June 15.

13,262 (1920). Fuller's United Electric Works, and Fuller. Galvanic batteries. (164,221.) June 15.

3378 (1921). Pouchain. Negative electrode for accumulators. (164,685.) June 22.

XII.—FATS; OILS; WAXES.

Applications.

Bradley and Bradley. Fluid soaps. 16,823. June 20.

Davies. Manufacture of soap. 17,288. June 24.

Feeny (Title Guarantee and Trust Co.). Treating fish etc. oils. 16,239. June 13.

Goslings. Purification of oils and fats. 17,116—7, 17,239. June 22 and 23. (Holland, 3.8 and 14.12.20.)

Khorassany. Manufacture of soap. 17,137. June 22.

Maypole Margarine Works, and Michelson. 15,856. *See* XIX.

Complete Specifications Accepted.

23,644 (1919). Cocking and Lilly. *See* XVIII.

6207 (1920). Whiton and Bredlik. Extraction of fatty matter from garbage etc. (143,196.) June 15.

6226 (1920). Bollmann. Removal of fatty acids, resins, bitter and mucilaginous substances from fats and oils. (164,115.) June 15.

11,580 (1920). Hey. Clarifying oil or grease solvents. (164,931.) June 29.

16,114 (1920). Elektro-Osmose A.-G. Decolorising liquids containing glycerin or crude glycerin. (145,046.) June 22.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Applications.

Barton, and Lead Products Synd. Apparatus for making lead oxide. 17,058. June 22.

Dutt, Godfrey, and Wilson. Manufacture of pigments from titaniferous bauxites. 16,064. June 10.

Fitzgerald. 16,112. *See* XIV.

Hart. 16,214. *See* IV.

Imray (Soc. Chem. Industry in Basle). Manufacture of resins. 15,942. June 9.

Imperial Trust, and Schryver. Manufacture of coating compositions. 17,025. June 21.

Imperial Trust, and Schryver. Manufacture of plastic material for floorings etc. 17,026. June 21.

Low, and Low Engineering Co. Manufacture of lac. 17,141. June 22.

Pummerer. Production of artificial resins. 17,151. June 22. (Ger., 25.6.20.)

Rütgerswerke A.-G., and Teichmann. Manufacture of black printing-inks. 16,480. June 15. (Ger., 8.7.20.)

Tyrer. 15,813—4. *See* VII.

White (National Lead Co.) Corrosion of lead. 16,404. June 14.

Complete Specifications Accepted.

30,461 (1919). British Dyestuffs Corp., and others. *See* IV.

32,553—4, 32,559 (1919). Melamid. Manufacture of resin-like substances. (137,291—3.) June 15.

7564 (1920). Ivinson and Roberts. Anticorrosive paint or composition. (164,836.) June 29.

11,981 (1920). Titan Co. Akt. Titanic oxide pigments. (149,316.) June 22.

14,693 (1920). Scholz and Tiedemann. Working up scrap linoleum into new linoleum. (158,210.) June 22.

154 (1921). Chem. Fabr. Worms. Manufacture of printing and stamping colours. (156,212.) June 15.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Application.

Fitzgerald. Manufacture of substitute for vulcanite, horn, shellac, etc. from blood. 16,112. June 11.

Complete Specifications Accepted.

24,333 (1919) and 7 (1920). Stevens. Vulcanisation of rubber and treatment of vulcanised rubber. (164,770.) June 29.

30,469 (1919). Schauermann. Manufacture of ebonite and vulcanite substitutes. (164,392.) June 22.

7294 (1920). Crozier. Black rubber compound. (164,159.) June 15.

8117 (1920). Ricard Allenet et Cie. Vulcanising rubber. (157,050.) June 15.

29,501 (1920). Pheazey and Campbell. *See* XV.

XV.—LEATHER; BONE; HORN; GLUE.

Application.

Fitzgerald. 16,112. *See* XIV.

Complete Specifications Accepted.

13,561 (1920). Dunham. Casein solution. (164,604.) June 22.

29,501 (1920). Pheazey and Campbell. Manufacture of artificial leather and substitutes for rubber, guttapercha, etc. (165,007.) June 29.

XVI.—SOILS; FERTILISERS.

Applications.

Desmond and Tisdall. Fertilisers. 15,694. June 7.

Plauson's (Parent Co.), Ltd. (Plauson). Treatment of rock phosphate etc. 17,079. June 22.

XVII.—SUGARS; STARCHES; GUMS.

Applications.

Daniels, Kopke, and McKinlay. Apparatus for removing accumulation of sugar or cake from the filtering-walls of centrifugal machines. 17,249. June 23.

Knuepffer (Moser and Pezold). Manufacture of sugar from wood, peat, etc. 15,666. June 7.

Levy and Terrisse. Obtaining glucose from wood. 16,886. June 20.

Perry. Converting cellulosic and ligneous materials into sugar. 15,689. June 7.

Perry. Treatment of peat etc. 15,690–1. June 7.

Perry. Treatment of wood etc. 15,692. June 7.

Perry. Apparatus for treating wood etc. to obtain fermentable sugars etc. 15,693. June 7.

Complete Specification Accepted.

1247 (1920). Kowalski. Treatment of syrups in the manufacture of sugar. (137,849.) June 29.

XVIII.—FERMENTATION INDUSTRIES.

Applications.

Fitzgerald and Matthews. Aerobic fermentations. 16,630. June 16.

Hyde. Brewing malt liquors. 17,077. June 22.

Complete Specifications Accepted.

9181 (1916). Weizmann and Hamlyn. Fermentation processes for producing acetone and butyl alcohol. (164,023.) June 15.

9132 (1918). Weizmann and Spiers. Fermentation of cereals and other starchy materials. (164,366.) June 22.

9133 (1918). Weizmann and Spiers. Fermentation of starchy material to produce acetone and butyl alcohol. (164,762.) June 29.

23,644 (1919). Cocking and Lilly. Production of glycerin by fermentation. (164,034.) June 15.

9920 (1920). Scott. Skimming yeast from fermentation vessels and separating the liquid therefrom. (164,908.) June 29.

17,445 (1920). Huberty et Cie. Manufacture of milk vinegar. (146,216.) June 22.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Bateman, Chaplin, and Parkhouse. Treatment of tea. 16,087. June 10.

Maypole Margarine Works, and Michelson. Manufacture of margarine. 15,856. June 8.

Morison. De-aeration or de-oxidising of water. 17,149. June 22.

Complete Specifications Accepted.

7950 (1920). Baker and Sons, Ltd., Head, and Prescott. Treatment of cocoa and similar foodstuffs. (164,860.) June 29.

9242 and 12,493 (1920). Forget-me-not, Ltd., and Hutchinson. Ageing wheaten flour to improve its baking qualities. (164,557.) June 22.

17,445 (1920). Huberty et Cie. *See* XVIII.

18,947 (1920). Ebers. Obtaining dried egg constituents. (147,004.) June 22.

24,191 (1920.) Elektro-Osmose A.-G. Method of killing micro-organisms. (150,318.) June 22.

29,828 (1920). Bovy. Treatment of cream and preparation of butter etc. (152,690.) June 22.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Darrasse, Darrasse, and Dupont. Manufacture of synthetic camphor. 15,601. June 6. (Fr., 9.6.20.)

Imray (Soc Chem. Industry in Basle). Manufacture of dialkylamides of nicotinic acid. 15,730. June 7.

Maeder, Merck, and Wolfes. Preparation of tropinonemonocarboxylic acid esters. 16,526. June 15. (Ger., 16.5.20.)

Complete Specifications Accepted.

9181 (1916). Weizmann and Hamlyn. *See* XVIII.

9133 (1918). Weizmann and Spiers. *See* XVIII.

31,294 (1919). Dreyfus. Manufacture of acetic anhydride. (136,574.) June 22.

475 (1920). Bielouss. Production of amino-compounds from trinitrotoluol. (137,529.) June 22.

862 (1920). British Dyestuffs Corp., and others. *See* III.

9306 (1920). Moureu and Lepape. Manufacture of acrolein. (141,057.) June 15.

22,873 (1920). Kub. Production of neutral alkyl esters of sulphuric acid. (149,688.) June 29.

30,873 (1920. Fabr. de Prod. Chim. de Thann et de Mulhouse. Manufacture of borneol. (158,533.) June 22.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Application.

Batty and Whyte. Photographic processes. 16,626. June 16.

XXII.—EXPLOSIVES; MATCHES.

Complete Specifications Accepted.

6481 (1917). Rintoul, Thomas, and Nobel's Explosives Co. Explosives. (164,362.) June 22.

475 (1920). Bielouss. *See* XX.

17,605 (1920). Wohl. Explosives. (146,258.) June 15.

I.—GENERAL; PLANT; MACHINERY.

Drying of solid materials; Rate of ——. W. K. Lewis. J. Ind. Eng. Chem., 1921, 13, 427—432.

The author discusses the conditions governing the rate of drying of solid materials, and develops a number of differential equations (with graphs), showing, *inter alia*, the variation of the water content with the time of drying, and of the rate of drying with the amount of air used for drying and with the thickness of various sheet materials. The drying of a solid material appears to be a balance between a process of diffusion of moisture through the substance and of evaporation from its surface, and these processes can be quantitatively represented by the differential equation $-dw/d\theta = 8ARw/L(4A+R)$, where w is the weight of moisture per unit of surface, θ is the time, R is a coefficient depending on the rate of surface evaporation, L is the thickness of the material, and A is a coefficient depending on the rate of diffusion of moisture from the interior of the sheet. Formulæ for use in practice can be derived from this equation after modification dependent on the material being dried.—B. M. V.

Compartment dryers; Theory of atmospheric evaporation, with special reference to ——. W. H. Carrier. J. Ind. Eng. Chem., 1921, 13, 432—438.

Experimental results obtained by the author (Proc. Amer. Soc. Heat. Vent. Eng., 1912, 24, 25) and by Box (Treatise on Heat, 1870) show that the amount of water vapour, expressed in terms of B.Th.U. (H), given off from the surface of a liquid evaporating (not boiling) is given by $H=97(1+v/230)(e'-e)$, where v is velocity of air moving parallel to the horizontal surface of liquid, in ft. per minute, e' and e are vapour pressures of liquid and atmosphere respectively in inches of mercury. If the surface from which evaporation is taking place is vertical, and the atmosphere impacts upon it at right angles with velocity, v, the constant 97 above is nearly doubled. The factor $e'-e$ is practically proportional to the wet bulb depression, the relation being 95° F. for a difference of vapour pressures of 1 in. of mercury. A chart is given showing the relation between dry bulb temperature as abscissa, and as ordinates—grains of moisture per lb. of dry air; cub. ft. per lb. of dry air when dry and when saturated; B.Th.U. required to raise 1 lb. of dry air 1° when saturated; total heat above 0° contained in 1 lb. of dry air when saturated; vapour pressure in inches of mercury. The moisture curves are drawn for every 10% of humidity, and the wet bulb temperatures marked off by slanting ines.—B. M. V.

Dryer; The compartment ——. W. H. Carrier and A. E. Stacey, jun. J. Ind. Eng. Chem., 1921, 13, 438—447.

The construction and method of operation of a number of types of compartment dryer are described and the purposes for which they are suitble are given. They may be considered as disontinuous tunnel kilns, and if steam is used as eating medium, 2 or 2½ lb. will be necessary per . of water removed.—B. M. V.

rying; The spray process of ——. R. S. Fleming. J. Ind. Eng. Chem., 1921, 13, 447—449.

He spray process (*cf.* F.P. 369,337 and 372,581 and .S.P. 1,183,098; J., 1907, 110, 631; 1916, 822) is ot so efficient thermodynamically as some other ethods, needs rather more expensive apparatus, d causes some loss of material as dust, even with good dust collector, but it is very suitable for quids that would be damaged by other means of ying, as the actual temperature of the drying chamber may be many degrees above the scorching point of the liquid, the very small droplets being kept cool by rapid evaporation until they are dry and thus comparatively immune from damage by high temperature. The thermal efficiency of the process may be considerably increased by concentrating the liquid *in vacuo* before drying. —B. M. V.

Drying apparatus; Direct heat rotary ——. R. G. Merz. J. Ind. Eng. Chem., 1921, 13, 449—452.

The paper deals in a general way with the types, general mechanism, applications, advantages, disadvantages, and efficiency of rotary dryers. Even organic materials can often be safely dried by the direct contact of hot gases of combustion with the material, provided the hot gases enter with the wet material (parallel current system).—B. M. V.

Tunnel dryers. G. B. Ridley. J. Ind. Eng. Chem., 1921, 13, 453—460.

The paper covers most of the points (with equations and nomographs) necessary to lay out and operate a tunnel drying system, having given the characteristics of the material to be treated, which is the most important consideration of all, and upon which point there is probably least information available. Tunnel dryers are suitable for all materials that can be handled on trays, the direct method of heating being far and away the most efficient and the concurrent movement of material and gases likely to be the quickest method. The hot air should be used in large quantity, at high velocity, with re-circulation, and the air actually discharged should be as near saturation point as the material will permit.—B. M. V.

Rusting of boilers. G. Bruhns. Z. angew. Chem., 1921, 34, 231—232.

In a boiler which had been fed with water derived from peat soil both the scale and the deposit were of a deep red colour, and consisted chiefly of iron oxide with traces of calcium sulphate; the scale was free from carbonate. Inasmuch as the feed water contained only traces of iron, the rust was obviously derived from the boiler, and since no pitting or corrosion was apparent, the action was evidently of an oxidising nature, extending uniformly over the whole surface, even above the water line. The feed water showed low hardness, traces of bicarbonate, with slight excess of carbon dioxide, an appreciable amount of nitric and nitrous acids, humin, and other weak acids; ammonia was absent. In the boiler water weak acids were found; it contained less nitric acid than the feed water, but an increased amount of nitrous acid as well as iron, and an appreciable amount of ammonia. The condensed water contained traces of iron, nitrous acid, and ammonia, but no carbon dioxide. The results obtained supply an explanation of the formation of rust in the boiler. In a weak acid medium, produced by evolution of carbon dioxide from the bicarbonate, humic acid is liberated, and, under the influence of heat and pressure, attacks the iron. The effect is increased by nitric acid, liberated from the water by the combined action of carbon dioxide and humic acid, the nitric acid itself becoming reduced to nitrous acid and ammonia. The absence of carbonate in the boiler scale was due to its re-solution in the acid water; calcium sulphate, having a lower solubility in solutions of calcium salts, is deposited. The rusting of the steam pipes was due to traces of nitrous acid which were mechanically driven off with the steam. In localities where marsh water is employed, and where facilities for its previous treatment do not exist, the best preventive against boiler attack is the addition of milk of lime to the water; an alkaline reaction must be maintained, and the boiler scale will also constitute an efficient protection.—W. J. W.

Patents.

Lixiviating granular or pulverulent material. G. Gröndal. E.P. 142,493, 29.4.20. Addn. to 137,930 (J., 1920, 239 A).

The raking device of the apparatus described in the previous patent is modified to give a comparatively rapid stirring motion with only a slow advance of the material from vat to vat.—B. M. V.

Leaching apparatus [for light vegetable material]; Counter-current ——. Maschinen- u. Werkzeugfabrik A.-G. vorm. A. Paschen. G.P. 331,302, 13.12.17.

The leaching fluid flows downwards in a zigzag course through a series of chambers disposed at successively lower levels. The material to be treated is fed through a pipe into the lowest chamber, and is transferred upwards through the series of chambers by means of rotating scoops. The scoops are trough-shaped, and the direction of rotation is such that the steep closed end leads the open end, whereby the material slides backwards from the scoop upon the junction between adjacent chambers. In this manner harmful stirring of the material is prevented.—J. S. G. T.

Solution, lixiviation, washing, etc.; Drum for ——. Amme, Giesecke u. Konegen A.-G. G.P. 332,708, 28.12.18.

The interior of the drum is provided with a screw, the turns of which are furnished with openings at some little distance from the wall of the drum so that the liquid may pass from one division to the next in counter-current to the material to be treated. Collecting chambers furnished with lateral discharge openings alongside or near the wall of the drum are provided on the inlet side of the several openings of the screw, and means are provided for controlling the level of the liquid and its velocity through the drum. The material is fed into the drum at one end and discharged centrally from the other by means of scoops and a shaker. —J. S. G. T.

Solutions of constant density; Process for the continuous production of ——. W. Otte. G.P. 332,197, 15.11.19.

A stream of the solvent is divided into two parts by a flap capable of rotation. The one portion is delivered to a vessel wherein a saturated solution is produced and an equal volume of mother liquor delivered therefrom to a second vessel, into which the second portion of the stream is delivered direct, and whence the mixture overflows. The density of the mixture determines the depth of immersion of a float in the second vessel. The float is connected with the flap in such manner that the latter regulates the ratio of the respective volumes of solvent in the two streams.—J. S. G. T.

Extracting materials; Process for ——. Elektro-Osmose A.-G. (Graf Schwerin Ges.). E.P. 146,453, 3.7.20. Conv., 3.7.19.

The material while being subjected to continuous or periodic extraction is disposed between positive and negative electrodes carried by diaphragms which are impermeable to the extract. Applications referred to are the extraction of sugar, of tannin, and of bitter principles or poisons from plants. An apparatus of filter-press form, suitable for extracting sugar, is described, in which the anode diaphragm is made of bladder and the cathode diaphragm of cellulose.—H. H.

Filtration of liquids of every description; Method of and means for ——. E. F. Engelke. E.P. 163,105, 10.2.20.

In a filter-press of the plate and frame type the pulp to be filtered is fed to several points in the feed channel by interposing in the press any desired number of plates, each of which has one or more radial channels leading from the feed hole to the edge of the plate, the outer end of the channels being connected with the main feed pipe line by a connexion which can be easily broken.—B. M. V.

Refrigerating apparatus; Compression ——. A. S. Haslam. E.P. 163,769, 18.2.20.

In compression refrigerating apparatus with a multiple-effect receiver, a valve actuated by a diaphragm or Bourdon tube is fitted to the inlet from the condenser to the receiver, or to the outlet from the receiver to the evaporator, the movement of the diaphragm or Bourdon tube being controlled by the condenser pressure on one side and by the receiver or evaporator pressure on the other side. —H. H.

Evaporation or distilling apparatus. N. Testrup, and Techno-Chemical Laboratories, Ltd. E.P. 163,793, 24.2.20.

A moving surface, *e.g.*, a drum rotating and dipping into the liquid, is covered with a layer of the liquid to be evaporated or distilled, and is at the same time heated on the other side, *e.g.*, on the interior of the drum, by means of the compressed vapour of the liquid, the motion of the surface being variable and suited to the nature of the liquid. A scraper or the like may be provided for removing any scale formed.—B. M. V.

Distillation and sublimation; Apparatus for ——. Farbenfabriken vorm F. Bayer u. Co. G.P. 332,196, 8.8.19.

Condensation and choking up of the tubes by which the vapours pass from the distillation or sublimation chamber is prevented by disposing the tubes so that they extend longitudinally downwards through the chamber. The tubes are enlarged in the form of funnels where they pass out of the chamber. A plate arranged near the upper open end of each tube prevents solid matter falling into the tubes.—J. S. G. T.

Drying apparatus. O. Zimmermann and H. Weyel. E.P. (A) 164,157, (B) 164,290, 10.3.20.

(A) A drying chamber is divided into four compartments by a vertical partition and a perforated drying-floor. At one end is arranged an underground flue supplying hot air and at the other end a similar discharge flue, and each flue communicates through dampers with each of the lower compartments. A rotary valve in the upper part of the vertical partition allows communication between the two upper compartments, each of which communicates through a flap valve with a chimney. Provision is also made for supplying cooling air, when required, to the lower compartments. (B) Two drying chambers with perforated floors are disposed one on each side of two parallel flues either or both of which can be put into communication at one end with a hot-air supply and at the other end with a chimney, and the space beneath each floor communicates with the adjacent flue. A superstructure containing drying trays and in permanent communication with the drying chambers, is provided over the drying chamber and the flues, the space above the flues being partitioned off and communicating through damper with the spaces above the trays and with the chimney.—H. H.

Air and other gases; Process for washing or purification and drying of ——. Soc. L'Oxylithe. E.P. 146,397, 2.7.20. Conv., 22.1.19.

The operations of washing, purifying, removing carbon dioxide, and drying are effected under pressure. Solid caustic alkali is used for removing most of the moisture, and the conditions are so adjusted that the amount of alkaline liquor passing from the dryer is sufficient to remove the carbon dioxide in the washer; the gaseous pressure is utilised for circulating the washing liquid.—H. H.

Pulverising machines. A. M. Read. E.P. 163,856, 19.3.20.

A ball-mill is divided into several compartments by transverse perforated screens, which are inclined both to the vertical, and to the cylindrical or conical part of the mill, in such a way that the material in the lower part of the mill presses downwards upon them, and they may at the same time be so shaped (*e.g.*, conical) that the material which is lifted by the rotation of the mill, on falling back will be guided by the upper parts of the screens away from the lower parts, so that a space will be left below the lower parts of the screens to facilitate the passage of material through the screen from the next lower compartment.—B. M. V.

Separation of solid particles from gases; Apparatus for ——. O. Happel. G.P. 317,083, 13.7.18.

The apparatus comprises a casing within which vertical tubes provided with small openings in their walls are arranged in groups having parallel side faces and doubly inclined ends, the groups of tubes in each row being displaced laterally with reference to the groups in adjacent rows. The spaces between the parallel side faces of adjacent groups of tubes form passages or nozzles for the gas to be treated, which passes through these passages with high velocity and strikes against the openings in the tubes of the next group and is thereby deflected, so that it does not enter the tubes but passes through the spaces between the tubes to the next gas passage. Suspended solid particles are not deflected, but pass through the openings into the tubes, where they are deposited.

Gases and vapours; Process for washing ——. W. Freytag. E.P. 146,356, 2.7.20. Conv., 19.8.18.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

3rown coals and lignites. I. Heat treatment at temperatures below 400° C. as a possible method for enhancing their fuel values. W. A. Bone. Roy. Soc. Proc., 1921, **A 99**, 236—252.

T is possible to enhance the fuel value of a lignite y treatment at or below a temperature known as 1e "practicable upgrading limit" for the par- cular lignite in question. By heating to this mperature, steam and carbon dioxide are evolved 1d varying quantities of carbon monoxide are berated. With Morwell lignite from Victoria, a adual evolution of steam and carbon dioxide took ace, commencing at 130° C. but occurring prin- pally at 250°—375° C., no condensable oils or scous hydrocarbons being liberated. The gas nounted to 1427 cub. ft. per ton and was composed H_2S 1·5%, CO_2 88·5%, CO 4·1%, CH_4 1·1%, and , 4·8%. This quantity was equivalent to 6·6% by ight of the dry coal and the moisture liberated 1ounted to 5·5% by weight. The consequent loss weight experienced by the "dry ashless" substance up to the temperature limit in question may amount to anything between 8 and 15% of its original weight, and this loss in weight occurs principally at the expense of the oxygen content of the dry coal, which is diminished by between one quarter and one third of its original value. Practically the whole of the potential energy of the fuel may be correspondingly concentrated by suitable heat treatment in the resulting carbonaceous residue, which may therefore be burnt with greater calorific intensity than the original coal.—A. G.

Moisture in fuel; Influence of —— on gasification in producers. H. Koschmieder. Brennstoff-Chem., 1921, 2, 117—121.

The author divides the gas-producer into three zones, the upper zone being that in which the moisture is evaporated from the fuel, the middle zone being one of distillation, and the lower zone being the one in which gasification occurs. Taking a coal of which the dry substance contains 82% of organic matter and 18% of ash, the heat required for evaporation of 10% of moisture in the raw coal in the drying zone amounts to 64 cals. per kg., whilst with 30% it amounts to 192 cals., and with 50% to 333 cals. In the carbonisation zone, the heat required per kg. of raw coal containing 10% of moisture for carbonisation is 96 cals., with 30% of moisture it is 75 cals., and with 50% 53 cals., the total heat required, including that necessary to heat up the charge, being for 10% of moisture 273 cals., for 30% 355 cals., and for 50% of moisture 436 cals. The utilisable heat in the gas produced decreases from 652 cals. with 10% moisture to 362 cals. with 50% of moisture in the raw fuel. Fuel with 50% moisture cannot therefore be completely gasified, especially if the temperature is kept down to 1000° C. by means of a cooling medium, the available heat in the gas being thus reduced.—A. G.

Coal; Modifications in the Lewis Thompson apparatus for determining the calorific value of ——. D. Lodati. Giorn. Chim. Ind. Appl., 1921, 3, 105.

A spiral of chrome-nickel wire, in contact with the fuse of the Lewis Thompson calorimeter, is rendered incandescent electrically and thus ignites the fuse. Ordinary potassium nitrate fuse is uncertain in its action, but good results are obtained by immersing two or three threads of three-ply cotton in a paste made from water and a mixture of 95 parts of ordinary black powder and 5 parts of dextrin, and subsequently drying them.—T. H. P.

Ammonia in coal distillation; Increasing the yield of ——. F. Sommer. Stahl u. Eisen, 1921, **41**, 852—859. (*Cf.* J., 1919, 350 a.)

A small part of the nitrogen of coal appears in the distillation gases as hydrocyanic acid, and in the majority of carbonisation plants is not recovered. The experiments recorded deal with the recovery of this portion by hydrolysis of hydrocyanic acid to ammonia (*cf.* J., 1914, 953). Hydrocyanic acid in a current of hydrogen or carbon dioxide and water vapour was bubbled through sulphuric acid of 60° B. (sp. gr. 1·71), and usually at 100° C., in which hydrolysis occurred, while the resulting ammonia was absorbed. Under optimum conditions a recovery as ammonia equal to 98% of the hydrocyanic acid taken was possible. It is suggested that the exit gases from ammonia saturators, which are often rich in hydrocyanic acid, should leave by way of a superposed small column with bubbling trays containing sulphuric acid of 60° B. at 70° C. in order to hydrolyse the hydrocyanic acid and fix the resulting ammonia. On town gasworks the higher cyanogen content of the gas should make the process more advantageous. Side reactions with the production of hydrogen and methane may cause diminished yields. These seemed less pronounced when hydrogen sulphide was present and the yields correspondingly better. Gas liquor should be freshly treated, as the thiocyanates which are formed on standing are more difficult to convert into ammonia.—H. J. H.

Sarre coals; The coking of ——. Baille-Barrelle. Comptes rend., 1921, **172**, 1580—1582.

To obtain satisfactory coke from Sarre coals the oven should be kept at a temperature below 320° C. until the difference in temperature between the centre and the outside of the charge is small, and then the temperature of the oven is raised with a uniform velocity until the final temperature of about 750° C. is reached, which is maintained until the coal is entirely coked. With an oven 25 cm. wide and a capacity of 500 kg. the total period of heating was 50 hours, and the coke obtained was comparable with the best Ruhr cokes. The by-products included 22 kg. of ammonium sulphate per ton of coal with 7% ash.—W. G.

Tar from coal; Aluminium apparatus for determining yield of ——. H. Schrader. Brennstoff-Chem., 1921, **2**, 182—183.

For the estimation of the yield of tar from coal by means of the apparatus previously described (J., 1920, 566 A), steam used in the process may be superheated in the apparatus itself. For this purpose the supporting arm, walls, and base of the retort body are drilled in such a manner that steam introduced into the arm can pass vertically downwards through a side-wall, across the base in a V-shaped course, vertically upwards, and through the cover, into the interior of the retort. Screwed openings into the channels through the retort-walls facilitate cleaning if choking occurs, and provision must be made to remove condensed water. In order to prevent condensation in the retort, the steam should not be introduced till the temperature has reached 130° C., and mechanical loss of coal is avoided by careful regulation of the steam current. A condenser should be inserted between the delivery tube and the receiver.—W. J. W.

Fire-damp and after-damp; Determination of combustible gases in ——. L. Wein. Chem.-Zeit., 1921, **45**, 610—611.

The gases are first freed from unsaturated hydrocarbons, carbon dioxide, and sulphurous gases by passing through a small coil containing a few c.c. of bromine, followed by wash-bottles containing 30% potash solution and concentrated sulphuric acid respectively. Carbon monoxide is then determined in the purified gas by passing through a "duck" containing iodine pentoxide heated at 105°—110° C. in an oil bath, and iodine and carbon dioxide are absorbed in thiosulphate and baryta solutions respectively and determined volumetrically. The results obtained from the carbon dioxide titration are the most reliable, except in cases where less than 0·1% of carbon monoxide is present. This is due to the difficulty of driving all the liberated iodine over into the thiosulphate solution. The residual gas from the above operation then passes through a drying tower charged with sulphuric acid and calcium chloride, followed by a phosphorus pentoxide tube, and methane and hydrogen are then oxidised together in a combustion furnace charged with a layer of copper oxide at least 25 cm. long. The water and carbon dioxide produced are absorbed in calcium chloride tubes and baryta solution and are determined in the usual way, the methane being calculated from the carbon dioxide, and hydrogen from the water after deducting that due to the methane. The results obtained show good agreement with one another and with the known content of artificially prepared gas mixtures.

—G. F. M.

Benzol in coke-oven gas and scrubbing oil; Estimation of ——. L. Shuttleworth. Gas World, 1921, **75**, Coking Sect., 67.

The benzol is absorbed in pure petroleum oil having a viscosity of 35—40 secs. at 60° F. When sufficient gas has been passed at the rate of 1 cub. ft. per hour, the oil is distilled by wet steam, a wide 2-bulb fractionating column being used. For the estimation of benzol in scrubbing oil, 2500 c.c. is placed in a gallon can and heated by direct heat until the temperature at the head of the fractionating column is 80° C., when steam is injected and the distillation continued until no oils lighter than water pass over; the oil thus obtained is dehydrated with calcium chloride and distilled up to 190° C. in the same manner as in a crude benzol test. The quality of this final distillate approaches that of crude 65% benzol, and the quantity obtained is taken as the amount of recoverable products in the 2500 c.c. of oil. (*Cf.* J., 1920, 357 A.)—A. G.

Mineral oils; Improvement of the lubricating properties of —— *by addition of fatty oils and acids.* J. H. Hyde. Engineering, 1921, **111**, 708—709. (*Cf.* Wells and Southcombe, J., 1920, 51 T.)

A description is given of the Deeley testing machine, which consists of two opposing friction surfaces, the lower of which is a disc and the upper is formed of 3 pegs on the underside of a rotating carriage. The carriage is connected with a torque-measuring device consisting of a coiled spring with indicating mechanism. The pressure between the surfaces can be varied, and the disc is carried in a tray containing the lubricant under test. The disc is rotated, whereupon the friction between the disc and pegs causes rotation of the carriage against the action of the spring. The maximum value of the static friction is determined by continuing the rotation of the disc until slipping of the opposed surfaces begins. The spring is prevented from unwinding at this point by means of a pawl and ratchet arrangement. The frictional surfaces are prepared by lapping to a "dead smooth" condition and then immediately covered with the oil. Readings are taken at 20, 40, 60, 80, 100, and 120 lb. pressure. The frictional coefficient was in most cases constant over the range of loads used. It was considerably reduced by addition of even as little as 0·1% of fatty acid to the mineral oil. Rape oil fatty acids were most effective in reducing the coefficient. Thus to reduce from 0·132 to 0·087 required 0·2% of rape oil acids, but a similar reduction needed 40% of rape oil (acidity 1%), 2% of oleic acid, and 85% of neutral rape oil respectively. An apparent time effect was noted when neutral rape oil was used, *e.g.*, 0·114 at the start, 0·100 after 20 mins., and 0·100 after 12 hrs. On the Lanchester-Daimler worm gear testing machine corresponding results were given.

—A. E. D.

Sulphur [in oils]; Estimation of —— *by the lamp method.* F. Esling. J. Inst. Petrol. Tech. 1921, **7**, 83—94.

A few c.c. of lamp-oil, kerosene, or paraffin oil i introduced into a glass lamp of approximatel 10 c.c. capacity, having a central tube of 3 mm internal diameter carrying the wick, and a sid tube for introducing a solvent when necessary. Th whole is weighed, and the lamp is lit and place under a glass chimney attached to one branch of bulbed U-tube, the other branch of which is co nected through an anti-splash bulb to a filter pum or aspirator. The U-tube contains 20 c.c. of $N/16$ sodium carbonate, and the second limb is closely packed with glass wool which has been washed free from alkali. The wick and aspirator are adjusted to maintain a clear, non-smoking flame. After $\frac{1}{2}$—1 hr. the flame is extinguished, and the lamp is again weighed. The U-tube and anti-splash bulb are washed out with distilled water, and the solution is titrated with $N/16$ sulphuric acid, using methyl orange as indicator. In testing highly volatile oils such as petrol or benzol, 5 c.c. of the oil is diluted to 25 c.c. with ethyl or amyl alcohol, or amyl acetate, 5 c.c. of the mixture is burnt to dryness in the lamp, and the last traces are removed by adding 1—2 c.c. of the solvent to the lamp, again burning to dryness, and repeating the process. In the case of high flash-point oils, 0·2—1·0 g. is weighed out into the lamp, 5—6 c.c. of a solvent is added, and the mixture burnt to dryness and the lamp cleaned as before. The method is not applicable to oils containing asphaltic or similar constituents which clog the wick and are left behind together with a large portion of the sulphur after the burning is completed. Blank tests should be run on the solvents employed.—L. A. C.

Photochemical processes [oxidation of carbon monoxide]; Mechanism of ——. *A. Coehn and* H. Tramm. Ber., 1921, **54**, 1148—1151.

EXAMINATION of the influence of pressure and degree of desiccation on the explosibility of mixtures of carbon monoxide and oxygen ($2CO+O_2$) has shown (1) that a moist mixture can be exploded by a spark at any pressure, (2) that a mixture dried by short exposure to the action of solid carbon dioxide and alcohol cannot be exploded but ignites and burns quietly, and (3) that a mixture which has been cooled for a sufficient time cannot be ignited; a pale bluish zone forms round the spark gap and slight combination is indicated by a small diminution in pressure. Exposure of mixtures belonging to the three types to ultra-violet rays from a quartz-mercury vapour lamp leads to practically the same result in each case, combination occurring to the extent of 4—5% within an hour. The presence of moisture, therefore, does not play a part in the union of carbon monoxide and oxygen under the influence of radiant energy.—H. W.

Chlorination of natural gas. Jones and others. *See* XX.

Coal slimes; Utilising ——. Nasspress-Ges. m.b.H. E.P. 146,264, 28.6.20. Conv., 6.11.16.

THE fluid slimes from the coal washer are mixed with coke breeze before they have had time to settle and the moisture is then expressed from the mixture.—A. G.

Semi-colloidal fuel mixtures; Methods of and apparatus for conveying, storing, and facilitating the burning of suspended or ——. G. Calvert. E.P. 163,797, 24.2.20 and 14.10.20.

THE mixture of liquid and pulverised solid fuel is kept in circulation in a circulating system, connected with one or more reservoirs, where the fuel an be agitated to prevent settling by means of air, team, or an inert gas such as flue gas. The various urnaces are supplied by branch pipes from the irculating main, any fuel not used being returned long the main to the reservoir.—A. G.

oking of coal. S. R. Illingworth. E.P. 164,104, 28.2.20.

ON-CAKING bituminous coal may be made to prouce good coke by submitting it to a temperature ot exceeding 500° C. out of contact with air, so as o destroy the non-coke-producing substances in the oal but to leave 5% by weight of the resinic subances in the product. The coal may be heated for definite periods at gradually increasing temperatures. The product is charged directly into the carbonising oven. (*Cf.* J., 1920, 111 T, 133 T.) —A. G.

Coke ovens. G. B. Ellis. From Foundation Oven Corp. E.P. 164,077, 30.1.20.

THE combustion flues of each heating wall are arranged in two or more independent groups, and the regenerating system is divided into separate regenerators, arranged longitudinally to the coking chambers to correspond with the grouping of the combustion flues. Means are provided to admit a common supply of air to a number of the regenerator chambers. Longitudinal distributing passages communicate with alternate combustion flues of the several groups through the corresponding regenerator chambers. The combustion flues are arranged in groups, with a common air admission flue and a common exhaust flue for all combustion flues of each group, a pair of main flues having a continuously open communication respectively with the air admission and exhaust flues of the various groups of combustion flues. Air may be admitted to, or alternatively gases may be exhausted from the main flues. The regenerator chambers communicate directly with the corresponding combustion flues without intermediate flues in which longitudinal flow of the gases takes place. There is one regenerator chamber for each alternate combustion flue and in direct communication therewith.—A. G.

Coke-ovens. C. Otto und Co., G.m.b.H. E.P. 147,231, 7.7.20. Conv., 3.1.16.

IN a horizontal sub-heated coke-oven each individual heating flue receives at its lower end heating gas from a burner and preheated air for combustion from a corresponding individual chequer-work chamber. The amount of both gas and air can be regulated from the sub-ways under the oven.—A. G.

Carbonising solid fuels in a circulating current of gas; Process and device for ——. P. Meyer. E.P. 147,117, 7.7.20. Conv., 29.6.18.

THE fuel is fed into the upper part of a chamber constricted midway of its height, and a supply of heated inert gas is passed through the fuel in the upper compartment, withdrawn at the top, passed through a cooling device, and then passed through the lower part of the chamber into which the carbonised material is discharged. The gas is thus preheated and after passing through a heater is passed through the upper part of the chamber again. The gas produced by carbonisation may be withdrawn either at the top of the chamber or at the bottom together with the coked residue.—A. G.

Nitrogen contained in fuel; Recovery of —— [as ammonium chloride]. A. Riedel. E.P. 148,784, 10.7.20. Conv., 16.7.17.

THE fuel before carbonisation or combustion is treated with an alkaline-earth chloride, whereby all the nitrogen is evolved as ammonium chloride, which is absorbed by washing the gases with tar oil at a temperature between 100° and 450° C. —A. G.

Coal gas and like gases; Purification of ——. C. C. Carpenter. E.P. 164,183, 24.3.20.

THE spent contact substance (*e.g.*, iron or nickel or their compounds) used for removing carbon bisulphide from combustible gases is revivified by passing over it a mixture of waste furnace gases and air. The proportion of waste gases is diminished as the revivification proceeds, until finally air alone is passed. The plant is so arranged that the quantity of oxygen passing per unit of time is always constant, no matter what proportion of waste gases is being used.—A. G.

By-product gases [e.g., blast-furnace or coke-oven gas]; Process for enriching ——. P. Kühn. G.P. 335,717, 24.4.18.

The gases are enriched by injecting into the stream coal dust mixed with a finely ground fluxing agent, *e.g.*, sand, fluorspar or the like, in order to slag off the non-combustible dust particles. The enriched gases may be used for firing steel melting furnaces. —A. R. P.

Distilling apparatus [for oils etc.]. N. H. Freeman. E.P. 164,098, 27.2.20.

The material is treated in a number of separately heated stills, in each of which a different constant working temperature is maintained by controlling the supply of heat by means including a temperature-operated device in contact with the material under treatment. The distillate from certain of the stills is passed for treatment into other stills wherein a lower working temperature is maintained, whilst the residue is passed into stills wherein a higher working temperature is maintained. The temperature control device includes a holder which is placed in the still, and a conduit extending from the holder to one surface of a movable column, *e.g.*, a mercury column, which is exposed at another surface to atmospheric pressure and can move into and out of operative position to control the supply of heat. The still is provided with an internal horizontal partition, dividing it into two compartments which communicate with each other through a perforation in the partition towards the end of the still. A supply conduit for liquid communicates with the upper compartment and delivers on to the partition towards the other end of the still, and a delivery conduit for liquid communicates with the lower compartment. The upper surface of the partition is provided with baffles so arranged as to cause the liquid to traverse an extended path from its point of delivery on to the partition to the point at which it flows into the lower compartment. The liquid supply conduit, before delivering into the upper compartment, traverses the lower compartment in a sinuous path. The liquid is delivered from the upper compartment to the lower at such a point that it has to travel the length of the still in the lower compartment to reach its delivery conduit. —A. G.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Gas quality and lighting efficiency. E. Terres and H. Straube. Gas- u. Wasserfach, 1921, 64, 440—446.

In continuation of previous work (J., 1921, 461 A), the authors have investigated the dependence of flame volume upon gas supply pressure and the degree of primary aeration in the upright and inverted incandescence burners, and the dependence of primary aeration upon the supply pressure. Pressures of between 30 and 60 mm. water column were employed, and samples of the gaseous mixture were withdrawn from various zones of the flame and analysed. In the case of the upright burner burning straight coal gas, an increase of supply pressure is accompanied by an increase in the lighting efficiency, since as the pressure is increased, the volume of the flame, initially greater than that of the mantles, approximates more nearly to the latter. With water-gas mixtures, an increase of the supply pressure is accompanied by a decrease of flame volume, whereby the surface of the flame departs more and more from the mantle, with consequent decrease in the lighting efficiency. Lighting efficiency depends upon the temperature attained by the combustion at the surface of the mantle, which is determined by the relative degree of completion of the combustion thereat. Similar effects follow from increasing the degree of primary aeration. The degree of secondary aeration likewise affects the lighting efficiency. Secondary air diffuses inwards to a depth of 10 mm. inside the mantle. Free oxygen is present even outside the mantle, combustion being practically complete at a distance of about 1 mm. outside the mantle surface. Thereafter dilution of the products of combustion with secondary air occurs extremely rapidly. When the degree of primary aeration is low, the admixture of secondary air tends to increase the flame temperature, with consequent increase of lighting efficiency. When complete aeration is effected primarily, the admixture of secondary air reduces the lighting efficiency. The form of the flame of inverted burners is conditioned largely by the mantle, and here the effect of the degree of completion of combustion at the mantle surface is even more clearly seen. No relation was found between the lighting efficiencies of the various gas mixtures employed, and the respective velocities with which combustion was propagated therein.—J. S. G. T.

Searchlight; High candle power ——. Siemens u. Halske A.-G. G.P. 334,424, 2.2.18.

The arc is struck between a positive electrode of tungsten, or of a metal or carbon core coated with tungsten, and a negative electrode of some other suitable material, such as carbon, preferably disposed above the positive electrode. With a coated positive electrode an arc having a hemispherical crater may be obtained by properly proportioning the dimensions of the coating and core.—J. S. G. T

III.—TAR AND TAR PRODUCTS.

Naphthalene; Estimation of —— *in tar and tar-oil.* R. Mezger. Gas- und Wasserfach, 1921, 64, 413—416.

A current of purified coal gas is passed through a flask containing a suitable weight of the material, *i.e.*, 0·4—0·8 g. of tar-oil, 0·1—0·2 g. of crude naphthalene, or 0·5—1·0 g. of tar, and 5 c.c. of 15% phosphoric acid, and the issuing gas is led into a potash bulb half filled with potassium hydroxide solution (1:1). The flask and bulb are supported in a vessel of water heated to 65°—70° C. during the experiment. The naphthalene is collected in a

scrubber, consisting of a reservoir and a bulb tube sloping upwards from the bottom of the reservoir, containing 50 c.c. of saturated picric acid solution. The gas is led through the apparatus at a rate of about 25 l. per hr., and extraction is continued for 3½ hrs. The contents of the scrubber are filtered, the scrubber and filter are washed with water, the washings are added to the filtrate, and the whole is titrated with $N/10$ sodium hydroxide solution, using sodium alizarinsulphonate as indicator; a correction is made for the volume of filtrate adhering to the filter paper and precipitate.
—L. A. C.

β-Naphthylaminemonosulphonic acids; Separation of ——. G. R. Levi. Giorn. Chim. Ind. Appl., 1921, **3**, 97—101.

When the mixture of 35% of 2-naphthylamine-8-sulphonic acid with 65% of 2-naphthylamine-5-sulphonic acid (containing also the 2.6- and 2.7-acids), obtained by treating β-naphthylamine with 94% sulphuric acid, is converted into the mixed sodium salts and the solution treated slowly with the quantity of sulphuric acid just sufficient to precipitate the whole of the 2.8-acid present, the product separating consists of practically pure 2.8-acid. The 2.5-acid, which is also obtainable pure in this way, finds useful applications as such, besides being readily isomerised into the 2.6- and 2.7-acids, useful as intermediates.—T. H. P.

Tetrahydronaphthols. A. Brochet and R. Cornubert. Comptes rend., 1921, **172**, 1499—1500.

When hydrogenated in the presence of reduced nickel under a pressure of 15 atm., α- and β-naphthol each yield a mixture of the *ar-* and *ac*-tetrahydronaphthols, the alicyclic isomeride predominating in each case.—W. G.

Tar yield from coal. Schrader. *See* IIa.

Coumarone resins. Glaser. *See* XIII.

Phenoxides. Durand. *See* XX.

Patents.

Material for distillation, e.g., tar, petroleum oil, or the like; Apparatus for heating —— and for separating vapour and liquid from the distillate. E. Senger and W. Steinmann. G.P. 327,088, 6.4.19.

The vapours (water, light oil, and middle oil) from the still pass into the bottom of a column fitted inside with a number of superposed, hollow bodies connected by tubes through which a cooling liquid flows in the opposite direction to the vapour; the upper surface of the cooling bodies is inclined and conveys the condensed liquid to an outlet pipe in the centre of the vessel. The middle oil fraction is thus condensed in the column and serves to preheat and dehydrate the raw tar or the like, which s used as cooling liquid.—L. A. C.

β-Dibromotetrahydronaphthalene; Preparation of derivatives of —— containing oxygen. Preparation of derivatives of tetrahydro-β-naphthylamine. Tetralin G.m.b.H. G.P. (a) 335,477 and (b) 335,476, 7.10.19.

a) By treating *ac-αβ*-dibromotetrahydronaphthalene *cf.* G.P. 316,218, J., 1920, 360 a) with water, lcohols, or acids, with or without the addition of nactive solvents, the α-bromine atom is replaced by -OR or $-O·CO·R$ (R=hydrogen or a hydrocarbon esidue), while the β-bromine atom remains unhanged. Compounds in which the α-bromine atom s replaced by hydroxy- (m.p. 112° C.), methoxy- b.p., 17 mm., 159° C.), ethoxy- (b.p., 20 mm., 63°—165° C.), amyloxy- (b.p., 15 mm., 175°—180° C.), allyloxy- (b.p., 18 mm., 176°—178° C.), acetoxy- (m.p. 94° C.), and formyloxy- (b.p. 136°—138° C.) are described. α-Ethoxy-β-bromotetrahydronaphthalene in ethereal solution reacts with magnesium in a similar manner to alkyl bromides; by decomposition of the product with ice and dilute acetic acid, and subsequent fractional distillation of the ethereal layer, α-ethoxytetrahydronaphthalene mixed with Δ_1-dihydronaphthalene distils between 103° and 115° C. (19 mm.), and bis-α-ethoxytetrahydronaphthalene a thick oil, distils at about 255° C. Bis-α-ethoxytetrahydronaphthalene on treatment with dilute sulphuric acid is converted to bis-Δ_1-dihydronaphthalene, m.p. 158° C., which yields ββ-dinaphthyl on treatment with bromine. (b) Physiologically active compounds of therapeutic value are prepared by treating the β-bromotetrahydronaphthalene compounds, substituted in the α position by a group containing oxygen, described in (a) with ammonia or primary or secondary amines, with or without the addition of solvents. α-Hydroxy-β-bromotetrahydronaphthalene yields α-hydroxy-β-aminotetrahydronaphthalene, m.p. 112° C., the β-diethylamino compound, b.p. (10 mm.) 170° C., the β-methylamino compound, b.p. (10 mm.) 168°—169° C., and the β-dimethylamino compound, m.p. 40° C., b.p. (10 mm.) 157°—158° C., by suitable treatment. α-Ethoxy-β-dimethylaminotetrahydronaphthalene, b.p. (13 mm.) 152° C., and α-ethoxy-β-piperidotetrahydronaphthalene, b.p. (11 mm.) 170° C., are prepared from α-ethoxy-β-bromotetrahydronaphthalene by treatment with a solution of dimethylamine in benzene, and piperidine respectively. α-Acetoxy-β-dimethylaminotetrahydronaphthalene is converted by hydrolysis into α-hydroxy-β-dimethylaminotetrahydronaphthalene.—L. A. C.

ar-α-Tetrahydronaphthalenecarboxylic acid; Manufacture of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 335,602, 30.10.15.

Dry sodium *ar-α*-tetrahydronaphtholate is treated for about 1 hr. at 110° C. with dry carbon dioxide, and the temperature is then raised to 210° C. The free acid has m.p. 161°—162° C., yields an acetyl derivative of m.p. 159° C., and on coupling with diazotised nitranilines or their derivatives yields azo-dyestuffs fast to light and milling.—L. A. C.

Oxindols; Preparation of N-substituted ——. R. Stollé. G.P. 335,763, 14.6.14.

By heating N-monohalogenacetyl derivatives of secondary alkylarylamines, or of diarylamines, of the general formula, $N(R)(R_1).CO.CH_2.X$ (R=alkyl or aryl, R_1=aryl, X=halogen), in the presence of an aluminium halide, the halogen atom in the acetic acid residue combines with the hydrogen atom in the aromatic nucleus in the *o*-position to the amino group, liberating a hydrogen halide and yielding a N-oxindol derivative. Chloroacetylethylaniline, b.p. 165° C. (21 mm.) and m.p. about 35° C., prepared by the action of chloroacetyl chloride on monoethylaniline in ethereal solution, on heating for 4 hrs. at 160° C. with aluminium chloride yields N-ethyloxindol m.p. 97° C.; N-phenyloxindol, m.p. 121° C., and N-methyloxindol, m.p. 89° C., are prepared respectively from chloroacetyldiphenylamine and chloroacetylmethylaniline. N-Phenyloxindol on treatment with oxidising agents, such as nitrosodimethylaniline, yields diphenylisoindigotin, m.p. 315° C., and with bleaching powder yields N-phenyl-β-dichloro-oxindol, m.p. 118° C.; N-methyloxindol is converted to dimethylisoindigotin, m.p. 265° C., by treatment with nitrosodimethylaniline or sodium hypoiodite, and to isonitrosomethyloxindol by treatment with nitrous acid or amyl nitrite and sodium ethoxide.—L. A. C.

Artificial asphalt. G.P. 335,748. *See* IX.

IV.—COLOURING MATTERS AND DYES.

Melanin; Extraction of —— from skin with dilute alkali. W. J. Young. Biochem J., 1921, 15, 118—122.

The pigment of the skin of the Australian black is soluble in *N*/20 alkali hydroxide and acid; on boiling the alkaline solution, it gradually loses a little hydrogen and nitrogen and ceases to be soluble in acid. The carbon content is about 50% and there is no iron. The pigment resembles that obtained by Gortner (J., 1910, 1298) from the wool of black sheep.—G. B.

Fluorescein in water. Lombard. *See* XIXb.

Patents.

Azo dyes; Manufacture of ——. Farbenfabr. vorm. F. Bayer und Co. E.P. 164,218, 6.5.20.

A diazo-compound of 1-amino-4-nitrobenzene-2-sulphonamide in which one or two hydrogen atoms of the amido-group are substituted by alkyl, aryl, or aralkyl groups, is combined with a 2-naphthylaminesulphonic acid or a derivative thereof, or a 2-amino-8-naphtholsulphonic acid in acid solution. The products dye wool from an acid bath in blue shades fast to light and milling. The nitro-group in these dyes may be reduced in alkaline solution or mixture with sodium hydrosulphide, and the products obtained dye wool from an acid bath in bluish shades fast to milling and light, and possessing good equalising properties. The amines required for the manufacture of these azo dyes are obtained from 4-nitro-1-chlorobenzene-2-sulphonic chloride by treatment, for example, with monoethylaniline whereupon 4-nitro-1-chlorobenzene-2-sulphoethylphenylamide is formed, which is then treated with alcoholic ammonia.—F. M. R.

Scarlet lakes [from azo dyes]; Manufacture of ——. British Dyestuffs Corp., Ltd., J. Baddiley, and J. Hill. E.P. 164,053, 5.12.19.

The monoazo dye derived from *m*-xylidinesulphonic acid ($CH_3:CH_3:NH_2:SO_3H=1:3:4:5$) and R-salt gives with the lake-forming metallic bases yellowish-scarlet lakes of great beauty of shade and remarkable fastness to light, greatly excelling in this respect the colours of the Ponceau class which otherwise it resembles. The dyes derived from *m*-xylidinesulphonic acid and other common naphtholsulphonic acids give products which are not fast to light.—F. M. R.

Dye preparations. S. M. Tootal. E.P. 164,178, 22.3.20.

See U.S.P. 1,367,930 of 1921; J., 1921, 210 a.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Sulphite liquor [acid calcium bisulphite solution]. R. Schwarz and H. Müller-Clemm. Z. angew. Chem., 1921, 34, 272—275.

From a study of the conditions of equilibrium between sulphurous acid and calcium bisulphite in presence of an excess of calcium sulphite it is shown that in this system, at any temperature, and independent of the initial concentration of sulphurous acid up to 6·5% before the addition of the calcium sulphite, the quotient of the combined sulphurous acid by the free sulphurous acid is a constant, namely 2. At higher initial concentrations than 6·5% experimental difficulties occurred owing to the evolution of gas as soon as calcium sulphite was added to the solution, and the equilibrium was thereby disturbed. In the equilibrium solution the quantity of bisulphite formed and the free sulphurous acid increase with decreasing temperature, except that irregularities occur between 30° and 22° C. which result in an intermediate or local maximum solubility of calcium sulphite at 26° C., followed by a decline to 22° C., after which the regular increase once more sets in. If a solution in equilibrium at a particular temperature is saturated with sulphur dioxide an increase of combined sulphurous acid occurs, accompanied by a proportionately greater increase in free acid. —G. F. M.

Reagent for wood. Grüss. *See* XX.

Patents.

Wool and artificial wool; Process for increasing the durability of ——. M. Becke. G.P. 334,528, 17.2.20.

To prevent deleterious action on the fibres during carbonising, condensing agents such as formaldehyde, acetaldehyde, benzaldehyde, hydroxybenzaldehyde, acetone, and acetoacetic ester, are added to the usual carbonising agents.—W. J. W.

Drying, cleansing, or carbonising of wool and other fibres or materials; Machinery for ——. E. Jenkins. E.P. 164,064, 15.1 and 3.9.20.

The usual plant, in which wool is dried by passage through a chamber heated with hot air, is used, except that it is provided at each end with a vertical air chamber. The hot, moist, used air is continuously drawn into the front vertical chamber together with a regulated amount of fresh air (which is thereby warmed), and the mixture is then forced, by means of a fan, through a heater, into the rear vertical chamber, through the wool drying chamber and again into the front vertical chamber. When desired, hot moist air from the top of the wool-drying chamber may be led into the current of air which is passing to the heater.—A. J. H.

Fibre; Process for obtaining —— from the needles of conifers. A., E., P., and R. Hoering. G.P. 335,562, 6.2.17.

The needles are gently boiled in alkaline lye, and the fibre separated from the leafy matter by mechanical working in edge-runners, beating-engines, etc. before complete solution of the latter has taken place. The mechanical separation of the fibre from the leafy matter can be hastened by the use of a stirrer during the boiling. The needles may be treated for the partial or total removal of the resinous matter before being worked up for fibre.—H. C. R.

Textile fibres from agaves and yucca; Manufacture of ——. Chem. Fabr. Griesheim-Elektron, and G. Banzhaf. G.P. 335,612, 3.2.20.

Textile fibres are obtained by crushing the outer layers of the leaves of the agaves and *Yuccaceæ*, particularly *Y. filamentosa*, and subsequently treating them with a solution containing a hypochlorite and a carbonate or hydroxide.—A. J. H.

Elastic material [for cushions etc.]; Production of —— from pine needles. A. Sternberg. G.P. 334,527, 12.7.17.

Pine needles are freed from oil and resin by treatment with dilute solutions of alkali hydroxides or sulphides in such a manner as to preserve their fibrous structure.—W. J. W.

Silk; Process for the degumming of —— without using soap. G. Bonwitt and O. Goldschmidt. G.P. 335,777, 2.12.16.

The silk is treated with neutral or feebly alkaline solutions containing peroxides. Gelatinising substances may be added to the solutions. The process has special application to the degumming of wild or nest-silks which can only with difficulty be treated by existing processes.—H. C. R.

Waterproofing and strengthening threads and fabrics; Process for ——. L. G. R. Auzenat, Assr. to La Soie Artificelle de la Voulte. U.S.P. 1,377,110, 3.5.21. Appl., 25.3.20.

Threads and fabrics, the tensile strength of which decreases when wet, are subjected to the action of at least two substances, in a gaseous state, which react with one another to form compounds impermeable to water.—F. M. R.

Waterproofing and strengthening threads and fabrics; Process for ——. La Soc. La Soie Artificielle de la Voulte. E.P. 158,851, 27.3.20. Conv., 11.2.20.

See U.S.P. 1,377,110 of 1921; preceding. The threads may be treated with turpentine oil vapours, alone or mixed with acetic acid vapour, and then with ozonised air; or with phenol vapour and then with formaldehyde vapour.

Viscose silk; Manufacture of ——. E. Bronnert. E.P. (a) 163,466, 17.2.20, and (b) 163,817, 27.2.20.

The acidity of the precipitating bath largely affects the degree of fineness to which viscose threads can be drawn. Fine threads of 1—5 deniers can be obtained if the precipitating bath contains (a) a concentrated solution of ammonium chloride or sulphate together with a small amount of free acid (5% of sulphuric acid or 2% of hydrochloric acid) or (b) a solution of sodium sulphate or other soluble sulphate containing much free acid (17—19% of sulphuric acid), the concentration of acid being higher the finer the thread to be produced.
—A. J. H.

Cellulose acetate; Manufacture of solutions of ——. Badische Anilin- und Soda-Fabr. G.P. 334,871, 10.2.14. Addn. to 284,672 (E.P. 145,511; J., 1921, 144 a).

Homologues of cyclohexanone, such as pure methylcyclohexanones or mixtures of isomers prepared respectively from pure or mixed cresols, wholly or partially replace the cyclohexanone used as a solvent in the process described in the chief patent.
—L. A. C.

Cellulose esters [acetates]; Preparation of ——. Verein für Chem. Ind. in Mainz. G.P. 335,359, 11.11.13.

Cellulose or feebly nitrated cellulose is treated with acetic anhydride or the anhydride of any other fatty acid in the presence of a suitable catalyst or mixture of catalysts. The reaction is carried out without the addition of a solvent, at a temperature below 20° C., so that the mixture does not liquefy. The resulting gelatinous mass is dissolved in a suitable solvent and the solution treated in the usual way with water, and, if necessary, with substances which effect hydrolysis.—A. R. P.

Pyroxylin solvents and solutions of pyroxylin. E. C. R. Marks. From E. I. du Pont de Nemours and Co. E.P. (a) 164,032 and (b) 164,033, 25.8.19.

(b) A mixture of ethyl acetate, a liquid aliphatic ydrocarbon having a relatively low boiling point, nd an alcohol, has a high solvent power for pyroxyin. A suitable solution, which is non-hygroscopic, ontains 41 pts. of ethyl acetate, 25 pts. of benzine, pts. of ethyl or methyl alcohol, and $21\frac{3}{7}$ pts. of yroxylin. (a) Solutions of pyroxylin as described n (b) are evaporated.—A. J. H.

dhesive or finishing material; Manufacture of —— from waste sulphite-cellulose liquors. Berliner Dextrin-Fabrik Otto Kutzner. G.P. 334,870, 19.9.18.

ulphite-cellulose waste liquors are treated with rganic bases such as aniline, aldehydes, and acids, y which means solid or pasty products, suitable r finishing processes, are obtained.—W. J. W.

Paper; Process for regenerating waste ——. W. Abele. G.P. 335,268, 8.1.20.

The treatment of waste paper with decolorising and disintegrating agents is assisted by the introduction of air or other gases, preferably heated.
—W. J. W.

Sizing material for paper. G. Muth. G.P. 316,617, 23.4.19. Addn. to 301,926.

Coumarone and indene resins are emulsified with casein, albumin, animal or plant mucilages, or other similar colloids, and then incorporated with resin or fatty soaps, instead of being directly emulsified with the latter as described in the chief patent.
—A. J. H.

Paper or other material in sheet form; Method of and apparatus for drying ——. O. Minton. E.P. 164,187, 26.3.20.

The material is passed through a liquid seal (mercury or other suitable liquid) into a vacuum chamber, over a series of rollers, and out through another or the same liquid seal. Within the chamber the paper passes close to, but not in contact with, a number of electrically or otherwise heated surfaces. The process is specially suitable for use in making coloured and imitation "loft-dried" papers.—A. J. H.

Bricks etc. G.P. 335,185. *See* IX.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Wool; Harmful action of strong acids on ——. M. Becke. Textilber., 1921, 2, 213—215, 230—231.

The use of mineral acids in the preparation and dyeing of wool is strongly condemned. In the removal of burs and coarse plant particles from woollen fabrics carbonisation should be avoided whenever possible (*cf.* G.P. 317,725; J., 1920, 444 a), since in many cases the loss of weight of wool is 3% and the consequent decrease in durability of the fabric 30%. In dyeing by means of acid dyestuffs the bath should contain acetic acid and sodium acetate in preference to sulphuric acid and Glauber's salt, since the former causes but little deterioration of the wool even if excess be used or the dyeing be unduly prolonged. Moreover, sodium acetate increases the levelling and penetration of the dyestuff and gives shades which are fast to rubbing. These advantages must be weighed against the inferior power which sodium acetate has in exhausting the dye-liquor. Dyeings, excellent in every respect, are obtained by the after-treatment with copper sulphate of woollen fabrics dyed with Eosin, Alizarin Yellow GGW, Naphthazarin, Eriochromazurol B, Chromotrope 2R, Fast Acid Blue R, Rhodamine B extra, Diamine Brown, etc. in a bath containing sodium acetate and acetic acid (instead of sulphuric acid and Glauber's salt or acetic acid alone). In many cases this treatment gave dyeings which were superior (especially as regards fastness to light) to those obtained by after-chroming methods. In dyeing wool with vat dyes the presence of sodium acetate (the first addition should be 50—100% on the weight of wool, and further additions 5—10%) in the vat is less harmful than soap or Turkey Red oil. Further data (*cf.* J., 1921, 381 a) concerning the action of acids on wool are given.—A. J. H.

Dyed fabrics; Influence of gases on the fastness of ——. E. Ristenpart. Textilber., 1921, 2, 213.

Under the usual conditions of storage dyed fabrics are liable to be affected by impurities in the atmosphere. In one instance discoloration of brown dyed stockings packed in cardboard boxes was traced to the action of vapours from formaldehyde which had been used in the composition of the cardboard. The gases of combustion from a Bunsen burner caused a similar discoloration. The remedy is to use dyes which are fast to formaldehyde, and a convenient test is to spot a dyed fabric with a drop of formalin, dry, and observe the change of shade. Triazol Brown A is very fast to formaldehyde, but the brands G, S, and N are not.—A. J. H.

Patents.

Cotton; Treatment of —— before bleaching. O. Röhm. G.P. 316,995, 11.9.15. Addn. to 316,098 (E.P. 100,024; J., 1916, 1057).

Before treatment with enzymes the cotton is boiled with water, with or without addition of alkali. Cotton so treated is especially pure and absorbent so that it may be used in surgical work and in the preparation of nitrocellulose.

—A. J. H.

Dyeing [wool] yarn on bobbins in circulating dye liquor; Means for ——. H. Krantz. E.P. 157,418, 10.1.21. Conv., 3.10.13.

A dye-vat contains a perforated false bottom. Immediately over each hole is arranged a column of bobbins (each consisting of yarn wound on a perforated shell), which is maintained in position by means of three upright guiding rods. Discs having a slightly larger diameter than the bobbins, and with a central hole, are placed between adjacent bobbins. The disc over the top bobbin is weighted and is not perforated, but contains a recess by which the central bobbin shell is held in position. Dye-liquor is circulated through the false bottom, up the hollow columns formed by the bobbin shells, and through the yarn wound on the bobbins.

—A. J. H.

Textile fabrics or the like; Sizing of ——. A. Poulson. E.P. 163,915, 1.6.20.

A composition for sizing cotton, linen, and silk fabrics is prepared by mixing 3·25 pts. of china clay, 3·25 pts. of pipe clay, 1·00 pt. of gelatin, 2·00 pts. of soft soap, and 0·50 pt. of a saturated solution of alum with 160 pts. of water.—A. J. H.

Finishing material. G.P. 334,870. *See* V.

Iron-alkali lactates. G.P. 335,475. *See* VII.

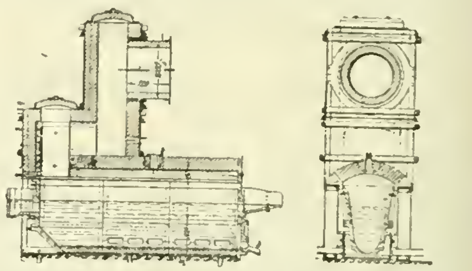
VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphur dioxide [and sulphur trioxide]; Determination of —— in burner gases. B. C. Stuer and W. Grob. Chem.-Zeit., 1921, 45, 553—554. A. Sander. *Ibid.*, 555.

The authors dispute Sander's contention that mercury has a strong catalytic action on mixtures of air and sulphur dioxide; the high percentage of sulphur trioxide found by him in burner gases is more probably due to oxidation when sulphur dioxide is absorbed by sodium hydroxide, as in his method (J., 1921, 256 A). In a determination of sulphur trioxide by difference, after estimating sulphur dioxide by Reich's method and total acidity by Lunge's method, 0·4% was found, whereas Sander's method gave 2·8 and 2·3%. The latter figures are regarded as erroneous. In a reply, Sander contends that if the sulphur dioxide is introduced into the alkali in a fine stream, and agitation is avoided, appreciable oxidation of the sodium bisulphite will not take place. He further maintains that his results for sulphur dioxide are in close agreement with those obtained by Reich's method, and that therefore the sulphur trioxide value, which is derived from the difference between total acidity and sulphur dioxide figures, must also be correct.—W. J. W.

Sulphur from blast-furnace slag; Recovery of —— [as sulphur dioxide]. L. H. Diehl. Stahl u. Eisen, 1921, 41, 845—852.

The author's process for recovering sulphur consists in blowing the slag, while still molten, with air. If calcium sulphate be added to the slag, some of its sulphur may also be given off as sulphur dioxide. The reactions are $CaS+\frac{3}{2}O_2+CaSiO_3=Ca_2SiO_4+SO_2$ and $CaS+3CaSO_4+4CaSiO_3=4Ca_2SiO_4+4SO_2$. The slag is run from the blast-furnace into a covered bath built up of water-cooled iron plates (see fig.); a wind-box runs along each side, and from these the air blast penetrates the liquid charge by horizontal slits in the side plates. The blast becomes enriched with sulphur dioxide, and leaves the bath by a flue system above for the vitriol or other plant. The sulphur is more readily given up by the hotter and more acidic slags, especially when calcium sulphate is used. The results given show a liberation of sulphur ranging from 0·46% to 1·38% on the slag treated. The gases produced contained up to 7% SO_2, 10% O_2, 1% CO_2, and the rest nitrogen. Arsenic, chlorine, fluorine, carbon monoxide, and objectionable dust are absent, so that the gas is suitable for the manufacture of pure vitriol, pure sulphites, and sulphur dioxide. A flue dust is collected which consists mainly of potassium and sodium compounds. The blown slag is run off from the bath, which is prepared for another charge, while the treated slag is still suitable for the production of slag wool, building materials, etc. It is estimated that from the German blast furnace plants with three or more furnaces, an annual production of 250,000 tons of sulphur would be possible.—H. J. H.



Nitric acid; Distillation of —— and of mixtures of sulphuric and nitric acids. P. Pascal and M. Garnier. Ann. Chim., 1921, 15, 253—290.

A more detailed account of work already published (*cf.* J., 1920, 780 A).—W. G.

Oxides of nitrogen; Absorption of —— by nitric and sulphuric acids. A. Sanfourche. Comptes rend., 1921, 172, 1573—1576.

When nitric oxide and nitrogen peroxide, mixed in equimolecular proportions, act on sulphuric acid they do not behave like a simple gaseous mixture, although the mixture contains the two gases for the most part as such. Although the proportion of nitrogen trioxide is small, its velocity of action is such that it serves as an intermediary in the solution, being re-formed as fast as it is absorbed, the two actions being $NO+NO_2=N_2O_3$ and $N_2O_3+2H_2SO_4=2NOHSO_4+H_2O$. The same occurs when the gases are absorbed by nitric acid, water, or alkalis.—W. G.

Hypochlorites; [Gasometric] determination of —— by hydrazine. A. K. Macbeth. Chem. News, 1921, 122, 268.

Hypochlorites may be determined by treating them in a Van Slyke nitrometer with an alkaline solution of hydrazine (5—10 g. of hydrazine sulphate and 10—15 g. of potassium hydroxide in 100 c.c. of water), and measuring the nitrogen evolved. In the absence of free chlorine reliable results are obtained. The method is applicable to the determination of available chlorine in bleaching powder. For the estimation of chlorates (*cf.* Hodgkinson, J., 1914, 815) the method proved unsatisfactory. —W. J. W.

Melting pot used for manufacture of nitrite from nitrate by means of lead; Deleterious action of potassium nitrate on a ——. A. Lottermoser. Chem.-Zeit., 1921, 45, 581.

During the operation of manufacturing nitrite by reduction of fused nitrate with molten lead, in a vessel provided with stirring gear, a hole was formed in the melting pot. Both from its nature, and from the fact that the melt near the hole was of a brown colour in contrast to the yellow colour of the remainder, it was concluded that the fault was caused by interaction of the ingredients with the metal of the vessel and not by fusion of the latter, especially as the temperature registered immediately before the accident did not exceed 450° C. It was found that when iron was heated with potassium nitrate, no effect at all was produced below 800° C.; at this temperature the melt assumed a greenish colour, but no loss in weight of the metal was detected. A mixture of potassium nitrate and lead heated to 400°—500° C., without stirring, produced no effect on either iron or steel; on the other hand at 800° C. a violent reaction occurred and both iron and steel were strongly attacked. The cause of the accident was explained by the fact that owing to too high a clearance of the stirring-gear, as also to a temporary interruption of its action, the molten lead by contact with the walls of the vessel had become heated to a emperature exceeding 800° C. To prevent such ccurrences, the stirring apparatus should operate ver the whole bottom surface of the vessel. —W. J. W.

alcium sulphide; Solubility of —— in presence of hydrogen sulphide. E. H. Riesenfeld and H. Feld. Z. anorg. Chem., 1921, **116**, 213—227.

HE solubility of calcium sulphide in pure water, in resence of the calcium sulphate and lime present n the crude material, is 0·212 g. per l. at 20° C. n presence of hydrogen sulphide at 760 mm. this increased to 206·5 g. per l. The solubility in- reases with the partial pressure of the hydrogen lphide. Determinations were made at 0°, 20°, nd 40° C. at pressures from 40 mm. to 760 mm. For essures above about 200 mm. the relation between lubility and pressure is linear. Pure calcium sul- hide can be prepared by extracting the crude aterial with aqueous hydrogen sulphide at a gher pressure and precipitating at a lower pres- re. (*Cf.* J.C.S., July.)—E. H. R.

rome alum; Action of sodium carbonate on solutions of ——. L. Meunier and P. Caste. Comptes rend., 1921, **172**, 1488—1490. (*Cf.* J., 1921, 432 a.)

MEDIATELY after chrome alum has been rapidly ssolved in water there is a short period during ich the volume of a given sodium carbonate solu- n required just to produce a permanent precipi- e increases with the time up to a maximum ich varies with the concentration of the alum ution and its temperature. This period is longer d more marked the more concentrated the solu- n and the lower the temperature. It is succeeded a relatively long second period, which may last eral mouths, during which the volume of sodium bonate required decreases slowly with the time. high temperatures, particularly at 100° C., the periods are of such short duration that the end their combined action is almost immediate. (*Cf.* J.S., Aug.)—W. G.

Photochemistry of lead compounds. C. Renz. Z. anorg. Chem., 1921, **116**, 62—70.

Lead chloride darkens when exposed for a long time to intense light, the sensitiveness depending on the method of preparation. The product is a "photochloride," since the colour is not removed by dilute nitric acid. The primary action of light on lead oxide exposed under water is a dissociation of the compound into metallic lead and free oxygen. The oxygen oxidises part of the monoxide into lead peroxide, which combines with more monoxide to form plumbate, whilst the metallic lead is reoxidised by atmospheric oxygen. (*Cf.* J.C.S., July.)—E. H. R.

Selenic acid; Preparation of ——. J. Meyer and H. Moldenhauer. Z. anorg. Chem., 1921, **116**, 193—200.

Selenic acid can be prepared by passing a current of chlorine through a cold solution of selenium dioxide in concentrated nitric acid containing lead nitrate, the selenic acid, as it is formed, being precipitated as lead selenate. For the preparation of free selenic acid in large quantities, the most convenient method consists in oxidising selenious acid with chloric acid. 100 g. of powdered selenium is stirred with 100 c.c. of water and oxidised to selenious acid by the slow addition of 150 c.c. of concentrated nitric acid, whilst warming on the water bath. When the selenium has all dissolved the solution is concentrated to 100 c.c. and further oxidised by gradual addition of an aqueous solution containing 50 g. of chloric acid (prepared from barium chlorate and sulphuric acid, avoiding excess of the latter). The solution is boiled to expel chlorine and oxides of chlorine, filtered from any sediment, and concentrated under low pressure (30—40 mm.). A yield of 190—200 g. of concentrated selenic acid (85—90% strength) is obtained. It can be further purified from traces of barium and chlorine compounds by again diluting, filtering, and concentrating. Concentrated selenic acid slowly decomposes into oxygen and selenium dioxide when heated above 160° C. (*Cf.* J.C.S., July.)—E. H. R.

New radioactive substance in uranium. O. Hahn. Ber., 1921, **54**, 1131—1142.

A new radioactive substance, designated Uranium Z until its parentage is definitely elucidated, and having the chemical properties of protactinium, is shown to be present in ordinary uranium salts. It emits β-radiations, and has a half-life period of 6·7 hours. Under the prescribed conditions the intensity of radiation of the new substance is only about 0·25% of that of UX (UX_1+UX_2) obtained from the same quantity of uranium. The parent substance can only be UX_1 or a new UX_1 isotope of similar life period.—H. W.

Hydrogen peroxide; Detection and determination of traces of ——. F. W. Horst. Chem.-Zeit., 1921, **45**, 572.

Traces of hydrogen peroxide may be determined qualitatively and quantitatively by reduction with ferrous sulphate, and colorimetric estimation of the ferric sulphate formed by means of ammonium thiocyanate. The ferrous sulphate solution must be freed from traces of ferric salt by passing hydrogen sulphide through it, first in the cold and then at the boiling point, and is cooled in a current of carbon dioxide. 20 c.c. of the sample to be tested is placed in a graduated tube, and a few c.c. of petroleum spirit is added as a protection against oxidation during the reaction. About 2 c.c. of the ferrous sulphate solution is added and agitated with the sample by means of a current of carbon dioxide. 5 c.c. of air-free ammonium thiocyanate solution is then introduced, and the colour is compared with that of a standard solution.—W. J. W.

Patents.

Nitric acid; Production of concentrated —— from dilute nitric acid obtained by the oxidation of ammonia. Farbw. vorm. Meister, Lucius, u. Brüning. G.P. 303,391, 30.3.17.

The sulphurous gases produced in the concentration of sulphuric acid are dissolved by a spraying process, and the solution is utilised for absorbing the nitrous gases derived from the oxidation of ammonia.—W. J. W.

Nitric acid; Process for evaporating ——. Badische Anilin- u. Soda-Fabrik. G.P. 335,762, 24.5.16.

Nitric acid is evaporated by passing it over heated metallic surfaces or bodies, at a temperature of 180°—250° C., in such a manner that the liquid is kept from contact with these by a layer of vapour.—W. J. W.

Nitrogen oxides; Process for oxidising lower —— Badische Anilin- u. Soda-Fabrik. G.P. 335,910, 9.4.18.

The conversion of the lower oxides into the higher oxides of nitrogen may be effected by passing them over contact material containing finely divided porous ferric hydroxide or antimony oxide, or a mixture of these, under pressure and at low temperature, if desired.—W. J. W.

Phosphoric acid; Manufacture of —— in a solid, non-hygroscopic form. Chem. Fabr. Marienfelde G.m.b.H. G.P. 335,474, 3.7.19.

Dilute phosphoric acid is stirred with starch paste at 15°—20° C., and the mixture is then dehydrated either *in vacuo* or in a current of air at 30° C. A product is obtained which may contain up to 25% of free phosphoric acid and is not hygroscopic. It may be used as a substitute for tartaric acid in baking powder etc.—W. J. W.

Nitrogen-hydrogen mixture in the synthetic production of ammonia; Manufacture of the ——. Badische Anilin- u. Soda-Fabrik. E.P. 145,058, 15.6.20. Conv., 2.7.15.

The necessary mixture of nitrogen and hydrogen for the synthetic manufacture of ammonia may be produced by subjecting to catalytic decomposition with water vapour a gas mixture containing nitrogen, carbon dioxide, and preferably hydrogen, of such composition as to give the required mixture after removal of carbon dioxide and other impurities. The carbon dioxide is removed by washing with water under a pressure of 10 atm., and traces of carbon monoxide by washing with cuprous solutions. The advantage of the process lies in the fact that the gasification periods may be considerably extended; if the water vapour be preheated the intercalation of the heating periods may even be entirely dispensed with. The gas mixture may be prepared by introducing air with the steam into a water-gas producer, or by mixing water-gas with Dowson gas in suitable proportions.
—W. J. W.

Ammonium sulphate; Manufacture of —— from ammoniacal gases. F. J. Collin, Akt.-Ges. z. Verwertung v. Brennstoffen u. Metallen. G.P. 335,305, 5.9.20.

In order to prevent choking of the gas delivery pipe by incrustations, it is caused to rotate in the saturator, and the absorbing liquid is introduced by a pipe bearing on the rim of the gas inlet pipe.
—W. J. W.

Ammonium sulphate; Conversion of ammonium carbonate into —— by means of calcium sulphate. C. Otto u. Co. G.m.b.H. G.P. 333,117, 19.6.17. Addn. to 299,621 (J., 1920, 448 A).

The process described in the original patent is carried out without introducing steam into the reaction column.—W. J. W.

Ammonium chloride; Production of pure—— from ammonia-soda mother-liquors. Deutsche Solvay-Werke Akt.-Ges. G.P. 335,532, 15.3.18.

Before cooling the mother-liquors from the ammonia-soda process, sufficient ammonia solution is added to convert all of the ammonium bicarbonate into normal ammonium carbonate.—W. J. W.

Sodium sulphate; Manufacture of —— from magnesium sulphate and sodium chloride. R. Bürstenbinder. G.P. 335,004, 25.4.20.

A solution containing magnesium sulphate and sodium chloride is decomposed at a suitable temperature by addition of alcohol.—W. J. W.

Alkali silicates; Manufacture of readily soluble ——. F. J. Phillips. E.P. 163,877, 9.4.20. (*Cf.* E.P. 151,339; J., 1920, 748 A.)

The process described in the original specification is modified by producing the silicic acid in a separate vessel and then adding it to, and agitating it with, the solution of silicates obtained from a mixture of silica and alkali. About 10% of silicic acid may be added with advantage.—W. J. W.

Calcium salt solutions; Process of emulsifying ——. H. Potratz. G.P. 334,766, 28.9.19.

Calcium salts and sugar dissolved in a little water are incorporated with a fatty oil at normal temperature; more sugar is then dissolved in the solution by the aid of heat, and the mixture is emulsified by agitation with carbon dioxide and addition of a gum solution.—W. J. W.

Magnesia [and hydrogen chloride]; Manufacture of —— from magnesium chloride liquors. F. Siemens. G.P. 335,062, 9.11.19.

Magnesium chloride liquors are evaporated and kept in motion by mechanical means during crystallisation. The crystalline product is continuously introduced into one end of a furnace, where it undergoes treatment with steam, and the magnesia is removed at the opposite end.—W. J. W.

Magnesium carbonate; Production of flocculent —— suitable for manufacture of tiles. Chem. Fabr. Buckau. G.P. 303,971, 10.4.15.

Basic magnesium carbonate, obtained in a crystalline condition by treating magnesium salts with carbon dioxide and excess of ammonia, is heated with water to a temperature exceeding 50° C.
—W. J. W.

Antimony sulphide; Preparation of yellow ——. Farbenfabriken vorm. F. Bayer u. Co. G.P. 335,600, 4.5.19.

Sodium thioantimonate is caused to react with sodium polythionate, whereby sodium thiosulphate is obtained as a by-product and the use of hydrogen sulphide is avoided.—W. J. W.

Iron-alkali lactates; Preparation of ——. K. A. Hofmann. G.P. 335,475, 28.11.19.

Crystalline compounds, insoluble in water at the normal temperature, having the general formula, $Fe(C_3H_4O_3)_2M+nH_2O$ (M=Li, Na, K, Rb, Cs, or NH_4), and suitable for use as iron mordants in tanning and dyeing, or for replacing ferric ammonium citrate in ferro-prussiate printing, are prepared by heating solutions of lactic acid with ferric compounds, *e.g.*, ferric oxide or chloride, and alkali compounds, *e.g.*, sodium carbonate. The solution should be feebly acid at the end of the reaction.—L. A. C.

Exothermic chemical reactions [e.g., synthesis of ammonia]; Apparatus for use in carrying out —— under high temperatures and pressures. L'Air Liquide, Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude. E.P. 140,089, 9.3.20. Conv., 24.12.18.

VIII.—GLASS; CERAMICS.

Glasses; Nomenclature of ——. C. J. Peddle. J. Soc. Glass Tech., 1921, 5, 3—11.

The following is suggested as a systematic terminology for the glass industry, based on the method of "qualifying constituents." No component oxide of less than 1% is to be included. The basic constituents (indicated by the metal, not the oxide) are to precede the acidic, the alkalis coming first, in order of atomic weights, other bases following in atomic weight order. Antimony and arsenic are to be counted as basic, but should be the last of these, with arsenic following antimony. Of acid radicles, silica should be indicated by "silicate," and, in the absence of silica, boric oxide by "borate" and phosphoric oxide by "phosphate." In presence of silica, boric oxide, phosphoric oxide, and fluorine are to be indicated by the respective prefixes, "boro-," "phospho-," and "fluo-," added to "silicate," and if present together are to be taken in this order. Example:—Sodium-potassium-zinc-barium-antimony-boro-silicate glass. For brevity sodium and potassium together are ermed "alkali," the word "silicate" is omitted where SiO_2 is the only acid, and the basic contituents are denoted by their chemical symbols *e.g.*, alkali-calcium glass, Na-Zn-boro-silicate lass). Optical glasses are divided into "flints" with lead) and "crowns" (without lead). There re seven main divisions, and these again are subivided by value of refractive index for the D line. The divisions are:—Ordinary crowns: Light n_D below 1·50), medium (1·50—1·52), and dense above 1·52). Zinc crowns (zinc for calcium) with o sub-division. Fluor crowns with no subivision. Phosphate crowns (with P_2O_5 as opposed o SiO_2) with no sub-division. Barium crowns: ight (below 1·56), medium (1·56 to 1·59), dense ·59 to 1·63), and extra dense (above 1·63). arium flints: Light (below 1·56), medium (1·56 o 1·59), dense (1·59 to 1·63), and extra dense above 1·63). Flints: Extra light (below 1·57), ght (1·57 to 1·60), dense (1·60 to 1·64), extra ense (1·64 to 1·70), and double extra dense above 1·70).—A. C.

lass; Development of various types of ——. C. J. Peddle. J. Soc. Glass Tech., 1921, 5, 72—106.

Comparison of the alkali-lime-silica and the kali-lead oxide-silica glasses previously examined (J., 1920, 545 a; 1921, 216 a). Up to 20% CaO or PbO the soda glasses of both types melt similarly; above this point there is evidence that lead glasses are easier to melt, but the devitrification tendencies of lime glasses prevent comparison. Density is largely increased by the molecular substitution of PbO for CaO (all comparisons are for cases where all the CaO has been replaced). Replacement of CaO by PbO, weight for weight, also causes a rise of density, the mean value for which is 0·01 for every 1% substituted. The refractive index for the D line in equimolecular series is higher for lead glasses, but, weight for weight, lime imparts to glasses a higher value of n_D than lead oxide, providing that the silica content of such glasses exceeds 60% and the alkali is less than 20%. The total dispersion of lead glasses is higher than that for glasses containing either equal weights or the same relative number of molecules of lime. Lead glasses spread the blue end of the spectrum relatively to the red more than do similar lime glasses of both equimolecular and equal weight series. In the series of similar molecular composition ν falls in both cases as n_D rises, but its fall with increase of PbO is much greater than with increase of CaO. Lime glasses, particularly those containing soda, are more liable to devitrification than lead glasses. If the former contain above 70% SiO_2 this tends to be deposited, but if they contain above 20% CaO the tendency is to deposit calcium silicate. There is a tendency to devitrification with lead glass even when the silica is as low as 60%, in which case silica is deposited. Lime glasses are less soluble than lead glasses of equimolecular series if the alkali content is above 15%, and with equal weights of the oxides present, lime glasses are again less soluble. Weathering is less with lead glasses when the alkali is less than 15%, but, weight for weight, up to 20% CaO or PbO, lime glasses weather better. Lead glasses, particularly those containing potash, are more brilliant than the corresponding lime glasses.
—A. C.

Glass; Influence of aluminium on properties of ——. V. Dimbleby, F. W. Hodkin, and W. E. S. Turner. J. Soc. Glass Tech., 1921, 5, 107—115.

A series of glasses of composition $6SiO_2$, xNa_2O, yAl_2O_3, where $x+y=2$, was prepared over a range $y=0·1$ to $0·6$ (it was found impossible to add more alumina). Viscosity was found to increase rapidly with increase of alumina (particularly above the glass with $y=0·2$), whilst toughness also increased. In working, especially glass with high Al_2O_3 content, the parison, on marvering, acquired a hard skin, but, when this was broken, tube could be drawn. Conductivity of heat diminished with increasing alumina content. The lower glasses of the series ($y=0·1$ to $0·4$) worked very readily in the blowpipe flame, the first resembling a lead glass, whilst devitrification was prevented. By replacing a small amount of the lime in a glass of type $6SiO_2$, $1·1\ Na_2O$, $0·9$ CaO by alumina, a more readily fusible glass was obtained. When the stage $6SiO_2$, $1·1\ Na_2O$, $0·6$ CaO, $0·3\ Al_2O_3$ was reached the glass fined only slowly at 1400°—1425° C., but it could be readily drawn, and in lamp-working it resisted devitrification very strongly.—A. C.

Annealing temperature of glass; Effect of aluminium on ——. S. English and W. E. S. Turner. J. Soc. Glass Tech., 1921, 5, 115—118.

The molecular replacement of soda by alumina in the glass $6SiO_2,2Na_2O$, has at first only a slight effect on the annealing temperature, raising it from 490° to 492° C. when 0·2 mol. Na_2O has been replaced. The rate of increase then becomes more rapid, the annealing temperature being 501° when 0·3 mol. Na_2O is replaced, and reaching 535° when

0·6 mol. Al_2O_3 is present. Comparing the effect of lime, magnesia, and alumina, when these replace one another molecularly, the annealing temperature of alumina glasses is found to be below that of lime or magnesia glasses up to nearly 7 mols. %, and is still below that of lime glasses at 8 mols. %. The curves indicate that alumina glass would have the highest annealing temperature below 9 mols. %, but such a glass would be difficult to melt. Where the oxides replace one another weight for weight alumina raises the annealing temperature least of all. In lime glasses of the type 6 SiO_2, 1·1 Na_2O, 0·9 CaO, replacement of 0·1 mol. CaO by Al_2O_3 causes a reduction of annealing temperature by 19° (581° to 562°), but further substitution up to 0·3 mol. Al_2O_3 has no effect. In general it can be said that annealing is rendered easier by presence of alumina.—A. C.

Glass; Re-annealing of ——. W. A. Whatmough. J. Soc. Glass Tech., 1921, 5, 44—54.

THE annealing of glass prevents the development of strain only, but re-annealing, by heating glass to its softening point, releases strains already present. High ring strain is produced in articles such as specimen tubes made from glass tubing by machines with high velocity burners, and to remove this the author constructed a re-annealing oven which is very successful. In its present form it consists of a tunnel lehr, 9 ins. square, shaped like an inverted siphon, the mouth of the short entrance limb being at a lower level than that of the longer exit limb. The central horizontal portion is a fireclay muffle, heated by two rows of burners which can be accurately adjusted. The bottom of the tunnel, on which an endless chain tray track runs, is of cast iron, and the lagging is of slag wool between metal plates. In both limbs are draw-off valves for hot gas, and nine pyrometers are inserted. The track can be drawn through at varying rates. To prevent the cracking of long tubes by "steaming" an oven is constructed over the hot end of the long limb to give articles a preliminary warming. The author follows the conditions of the critical annealing curve as worked out by English and Turner (J., 1918, 546 A).—A. C.

Glass annealing lehr; Electrically heated ——. E. F. Collins. J. Amer. Ceram. Soc., 1921, 4, 335—348.

TEMPERATURE gradients in the mass are the sole cause of strains in annealing, and they result from too rapid cooling or non-uniform heat distribution. Time of total relaxation of strain is dependent upon sensitiveness of heat control. Thus a glass which would be annealed in 2 hours at 476° C. with perfect control would take 5 hours with a temperature variation of ±10°, such as obtains with an average gas-heated lehr. The author claims that the introduction of electrically-heated lehrs with automatic control would reduce temperature variations to ±2·5°, and annealing time to 2—3 hrs. Suggested designs for electrically-heated box-type ovens for annealing optical glass and of vertical and horizontal lehrs are given. Vertical lehrs are claimed as superior to horizontal ones, the estimated output for the two (where goods enter at 370° C. and are not heated above 650° C.) being 10 lb. and 6 lb. per kw.-hour respectively. Advantages claimed for the vertical lehr are high thermal efficiency, uniform heat distribution, low temperature gradient, economy of floor space (18×21 feet) with convenience of situation, reduction of labour, abolition of "sulphuring" and of absorption of products of combustion, and delivery of ware perfectly sterilised and clean, ready for immediate use. Such a lehr would have a capacity of 500 lb. per kw.-hour. Actual tests show a saving of cost of 20% compared with gas-heated lehrs.—A. C.

Sodium-aluminium trisilicate glasses; Some optical properties of ——. J. R. Clarke and W. E. S. Turner. J. Soc. Glass Tech., 1921, 5, 119—120.

IN glasses of the series 6 SiO_2, 1·9 Na_2O, 0·1 Al_2O_3 to 6 SiO_2, 1·6 Na_2O, 0·4 Al_2O_3 density and refractive index decrease, whilst ν increases, with increase of alumina content.—A. C.

Thermal expansion of glasses; Effect of silica and sodium oxide on ——. S. English and W. E. S. Turner. J. Soc. Glass Tech., 1921, 5, 121—123.

THE linear coefficient of expansion of a series of seven simple sodium silicate glasses was found to vary regularly from 1346×10^{-8} for a glass with 66·91% SiO_2 to 755×10^{-8} for one with 82·83% SiO_2, indicating that silica reduces thermal expansion, whilst soda largely increases it. The Schott factors representing the change of cubical expansion per 1% Na_2O (10·0) and SiO_2 (0·80) are not in accord with the above results, values for Na_2O of 3×4·30 and for SiO_2 of 3×0·05 better fitting the facts. The Na_2O factor closely agrees with that deduced from values of this oxide in soda lime glasses, *i.e.*, 3×4·32.—A. C.

Glass tubing; Clouding of table-working —— *in the blowpipe flame.* M. W. Travers. J. Soc. Glass Tech., 1921, 5, 61—70.

IN articles made in the blowpipe flame from glass tubing a faint opalescent ring occasionally appears immediately adjacent to the glass actually melted. The effect was only obtained with coal gas when oxygen was in excess, and in the oxy-hydrogen flame when sulphur compounds were introduced. The amount of clouding varies with the time of heating. A glass jet heated externally by a hydrogen flame and conveying a current of sulphur dioxide clouded internally on cooling. From Nernst's equation the author calculates the dissociation pressure, in atmospheres, of the gases CO_2, SO_2, and SO_3 in contact with the solid phases Na_2CO_3, Na_2SO_3, and Na_2SO_4 to be $P_{CO_2}=40$, $P_{SO_2}=3{\cdot}0$, $P_{SO_3}=10^{-9}$ at 700°, and with the liquid phase, glass, present the values will be raised somewhat. Hence carbon dioxide will not attack glass, and sulphur dioxide at 1 atm. pressure will only attack at a temperature some distance below the softening point. As, however, the sulphur dioxide content of the burned gases at the edge of the flame varies from 2×10^{-5} atm. upwards, if at 700° only 0·01% of this were converted into sulphur trioxide, the pressure of the latter would be 2×10^{-9}. Thus it appears probable that there is, within the variation of the limits of the sulphur content of town gas, an amount which, if exceeded, would cause sufficient pressure of sulphur trioxide at the edge of the flame to give solid sodium sulphate (or less probably silica).
—A. C.

Fireclay and other refractory materials; Reversible thermal expansion of ——. H. S. Houldsworth and J. W. Cobb. J. Soc. Glass Tech., 1921, 5, 16—38.

EXPANSIONS between 15° and 1000° after a preliminary heating to 1280° C. have previously been given (J., 1920, 408 A). The following results have been obtained by extending his initial heating by 2 hours at 1410° and then by 2 hours at 1520°—1555° or by burning at the lower temperature of 980° C. Kaolin, bauxitic fireclay, magnesia brick carborundum, and alumina with 10% of ball clay have a regular reversible thermal expansion. Fireclays and glass-pot mixtures with fireclay basis showing irregularities after calcination at 980° or 1280°, lose these after firing to 1410° or 1530° C (unless much coarse quartz is present), and give linear expansion curves at incipient vitrification, the change being due to loss of quartz by interaction with clay and fluxes. The conclusion is reached that glass pots or crucibles will gain by keeping at a high temperature for some time before use, the red heat of the pot arch being useless for this. As distinct from silica itself, an intimate mixture of finely-divided kaolin and amorphous precipitated silica (containing 4% Na_2O) shows no irregularity after heating to 980° or 1280° C. Fireclay purified by osmosis behaves almost the same as a glass-pot mixture made from the fireclay, whilst the residue, after initially heating to 980° or 1280° C., gives curves similar to ganister. Increase of porosity of a fireclay up to 50% is accompanied by decrease of expansion between 15° and 1000° C., further porosity increase having little effect.—A. C.

Glass; Examination of —— by polarised light. S. Nakamura. J. Soc. Glass Tech., 1921, 5, 57—61.

The author describes a strain tester for optical glass slabs in which a sheet of black glass is used as polariser, and is so fixed that, with polariser and analyser set with crossed planes, the slab is in the "diagonal position" when laid horizontally between. The degree of strain is indicated by the amount of double refraction at the centre of the slab, and this is measured by trial, using a series of mica films of known retardation to obtain total extinction.—A. C.

Glass and crystal phases of silica; Stability relations of the ——. R. Wietzel. Z. anorg. Chem., 1921, 116, 71—95.

The heats of crystallisation of quartz, cristobalite, and chalcedony were determined, and also their mean specific heats from very low temperatures up to the melting-point. Variations in the transition temperatures of quartz and cristobalite were found to depend on the state of division of the material. With very finely divided quartz the transition oint could hardly be detected. Chalcedony is not distinct form of silica, but is microcrystalline uartz. The melting-point of cristobalite is 696° C. Quartz can be melted without conversion nto cristobalite; its melting-point is between 600° and 1670° C. (*Cf.* J.C.S., July.)—E. H. R.

lays; Water-smoking of ——. R. F. Geller, J. Amer. Ceram. Soc., 1921, 4, 375—389.

he behaviour during water-smoking of two plastic rick clays, one shale, and one fireclay was studied. he clays were ground to pass a 20-mesh sieve, ugged until stiff plastic, and moulded into 4-inch ubes. The cubes were either air-dried for 1—5 ays or dried to constant weight at 50° C., and en heated at varying rates in an electric oven 300° C. The temperatures of the top and bottom ces of the cubes and of the interior were taken y means of thermocouples. If the rate of heating too rapid the temperature of the clay lags behind at of the oven owing to the heat absorbed in pelling the water. The temperature range of ater-smoking lies between 100° and 240° C. for operly-dried material. To save time in water-oking the ware should be dried previously not r from 100° C. and good circulation should be ovided in the kiln. The temperature of the terior of the product should not lag appreciably hind that of the kiln. It should be possible to ter-smoke heavy clay products in 15 hours with heating rate of 20° C. per hr.—H. S. H.

fractories for oil-fired furnaces and boilers. W. H. Grant. J. Amer. Ceram. Soc., 1921, 4, 390—392.

E special causes of failure of firebricks in oil-ed furnaces have not been determined. Failures due to the spalling of the bricks in the side walls, the disintegration of bricks in the direct path of the flame, the production of a green glaze which penetrates and weakens the bricks, and the erosion due to the flame.—H. S. H.

Fireclay and stoneware bodies; Effects of firing temperatures on the strength of ——. H. G. Schurecht. J. Amer. Ceram. Soc., 1921, 4, 366—374.

The cross-breaking strengths, porosities, and shrinkages of fireclay and stoneware bodies were determined after firing to various temperatures up to cone 14. It was found that the firing temperatures had in general a greater influence on the cross-breaking strength than had the degree of vitrification. Maximum strength was developed by firing to cone 8 (except in the case of one clay), even when the porosity and shrinkage determinations showed that the bodies were over- or under-fired at that temperature. Possibly the formation of sillimanite caused the decrease in cross-breaking strength above cone 8. Bodies which exhibited maximum shrinkage and minimum porosity after firing at cone 8 were stronger than those which were over- or under-fired at that temperature. —H. S. H.

Enamelled cooking utensils; Acid-resistance of ——. B. T. Sweely. J. Amer. Ceram. Soc., 1921, 4, 407—412.

Experiments with trial pieces from poured samples, and with enamelled ware of various manufacturers showed that the surface of the layer of enamel which was uppermost during firing and cooling was readily attacked by acid, and this was taken to indicate that the more soluble materials tended to rise to the top of the melt. In the discussion, B. A. Rice said that he had repeated the experiments, using shallow cups, and had failed to find any difference in acid resistance in the top and bottom layers. It was suggested that the results with deep vessels were due more to the nature of the gases in contact with the enamel surface, or to the degree of volatilisation rather than to the segregation of the soluble constituents. Enamelled kitchen utensils should therefore be fired in an inverted position.—H. S. H.

Arsenic enamels for copper; Some data on ——. B. T. Sweely. J. Amer. Ceram. Soc., 1921, 4, 350—356.

The enamels were applied by the "dry" method, *i.e.*, after melting, quenching, and drying, they were ground so as just to pass 50-mesh, sifted over the clean copper surface, and fired in an electric furnace at about 850°—900° C. The following molecular limits of composition gave the best results:—KNaO 0·3 to 0·7, SiO_2 1·3 to 1·8, PbO 0·7 to 0·4, B_2O_3 0·0 to 0·2, As_2O_3 0·05 to 0·15. Increase of SiO_2 alone increased the tendency to fracture; increase of B_2O_3 alone, above 0·2, produced a matt effect, whilst increase of K_2O at the expense of PbO decreased opacity, improved fit and gloss, but increased solubility. High lead enamels flowed badly and attacked the copper excessively.—A. C.

Glazes; Nickel oxide in ——. J. D. Whitmer. J. Amer. Ceram. Soc., 1921, 4, 357—365.

A base glaze of the composition (0·25 K_2O, 0·45 BaO, 0·30 CaO); 0·35 Al_2O_3; 2·00 SiO_2; 0·025 NiO, was selected and the effect of varying the nature of the RO content noted. The dominant tendency of zinc oxide was to produce blue colours with nickel oxide, but it was not necessary in the production of greys, though it might be present in quantities not exceeding 0·30 equivalent. Barium monoxide with lime and potash gave browns, with zinc oxide, purples and reds. Barium monoxide was not necessary to produce greys, but it might be present in the formula, partly replacing the lime. Lime with zinc oxide produced blues, and must be present with magnesia to produce greys. Magnesia tended to produce greyish tints when used with other oxides. To produce neutral greys it should be used with lime or a combination of lime and barium monoxide. Bluish tones of grey were obtained when zinc oxide was present. The colouring influence of potash was slight, but its presence promoted maturity and good surfaces. (*Cf.* J., 1920, 628 A.)—H. S. H.

Patents.

[Glass] furnaces. M. W. Travers. E.P. 164,073, 29.1.20.

In gas-fired furnaces (particularly those for glass houses), the chamber beneath the eye is made of conical shape, tapering to the top, and gas enters it from below by a vertical co-axial duct of smaller diameter than the eye. Air is admitted through small orifices at the side of the chamber, where its diameter is greatest, and so air and gas rise in co-axial streams, with little mixing, until the eye is reached and combustion occurs. For glass furnaces a safety pocket is placed below the duct. —A. C.

Refractory materials; Manufacture of ——. A. V. Gowen, legal representative of N. Lecesne. E.P. 124,208, 6.3.19. Conv., 25.3.16. (*Cf.* F.P. 471,513; J., 1915, 356.)

A mixture of bauxite and anthracite is charged into the interior of a shaft furnace and separated from the walls of the furnace by an annular layer of bauxite or corundum, which protects the walls. The fuel is burned with the aid of an air blast. The top part of the furnace can be removed so that the block of corundum produced is readily reached. Hard compact corundum suitable for emery-grindstones or for use as an abrasive is produced by adding porous corundum to the mixture of bauxite and anthracite, a higher temperature being attained by the combustible gases burning in the pores.—H. S. H.

Furnaces, particularly for the fusion of steel and other metals, for the baking of ceramic products, refractory materials, and the like. A. Festa. E.P. 155,231, 1.9.20. Conv., 5.12.19. Addn. to 147,190.

The furnace described previously (J., 1921, 394 A) is adapted to the baking of ceramic products by making the hearth of the furnace flat and stationary. Traps or doors are provided for the charging and emptying of the furnace.—H. S. H.

[Ceramic] articles; Production of —— from ceramic materials by the casting process. G. Keppeler. G.P. 334,185, 1.6.19.

Part or all of the clay to be used is heated to 150°—500° C. and, with or without the addition of raw clay, non-plastic materials, fluxes, materials for increasing the strength of the ware, such as corundum, zircon, carborundum, etc., is converted into a slip by means of an alkaline solution of colloidal acids, such as humic, ulmic, boric, tannic, or fatty acids, or alumina, tannin, etc. The slip is cast in moulds in the usual manner.—A. B. S.

Articles readily permeable to gas and liquid; Production of fired ——. A. B. Schwarz. G.P. 335,747, 9.8.18.

Clay is mixed with combustible and incombustible threads and the stiff-plastic or dry mixture is made into the desired articles, which are then burned at so high a temperature that the mineral threads fuse. The articles are very permeable to gas and water and are very strong.—A. B. S.

Kilns; Construction of continuous —— for burning bricks and such like purposes. J. Lewis. E.P. 163,439, 13.2.20.

The kiln has a tubular brickwork body enveloped in an iron casing. In the sides of the kiln and near the level of the floor, orifices are situated, each of which serves in turn as stoking hole, chimney connexion, and for the loading and discharging of the goods of the part of the kiln to which it corresponds. The side walls of the tubular body are constructed with an outward slant for the purpose of increasing the capacity of the kiln where the intensity of the heat is usually greatest. —H. S. H.

IX.—BUILDING MATERIALS.

Wood; Relation of the moisture content of —— to its decay. W. H. Snell. Pulp and Paper Mag., 1921, **19**, 531—533.

In connexion with the suggestion to treat log piles with "artificial fog" to prevent fires, investigations were carried out to determine whether such treatment is influential in promoting conditions favourable to decay. The growth of wood-destroying fungi is dependent on both moisture and oxygen. The author's experiments were conducted with five fungi: *Lenzites sepiaria, Lenzites trabia, Trametes serialis, Fomes roseus,* and *Lentinus lepideus,* commonly found on pulp logs; loblolly pine sap wood and Sitka spruce were used, of which the densities are 27·5 and 22 lb. per cub. ft., and the sp. gr. 0·44 and 0·35, respectively. The results with the former agree with those found by Muench for Scotch pine. There was little decay when the moisture was below the fibre saturation point (25% calculated on the oven-dry weight of the wood). With increasing moisture, decay was more extensive up to a maximum between 33% and 42%. Above this, decay decreased; there was little at 50% and none at 60%. With Sitka spruce, different results were obtained. Penetration by the fungi took place when the moisture was slightly below the fibre saturation point. The greatest decay was found between 30% and 57%; but there was no penetration at 67%. Sitka spruce, on account of its lightness, is an extreme case, however; the figures obtained with loblolly pine sap may be taken to represent the other pulp woods. As spraying resulted in log piles taking up 52—60% of water in a short period, the experiments show that such treatment may be resorted to without risk of decay, although discoloration from external mould may arise.—W. J. W.

Cement; A new magnesian hydraulic ——. A. C. Vournazos. Comptes rend., 1921, **172**, 1578—1580.

The magnesium oxide is prepared from a deposit of magnesium carbonate ("leucolithe"), from the isle of Eubœa, the carbonate being heated sufficiently to drive off the carbon dioxide without melting the residue. The oxide is powdered and mixed with 30% by weight of powdered Santorin pumice and 35% of sand. The mixture is made into a paste with water, and compressed in moulds. The cement so obtained does not attain its maximum resistance at the end of one year. It attacks iron even less than does Portland cement and adheres equally well to it. Its coefficient of linear expansion is 0·0131 mm., that is almost equal to that of iron. If the pumice is replaced by artificially prepared amorphous silica a marble-white "leuco-cement" is obtained, but in this case 100 pts. of calcined leucolithe, 60 pts. of amorphous silica, and 70 pts. of sand should be used; it sets in 40 hrs., and is unaltered in air or under water. —W. G.

Patents.

Plaster of Paris; Manufacture of ——. W. M. Brothers. E.P. 163,468, 18.2.20.

Dry, powdered, or granulated hydrated calcium sulphate is fed continuously through a closed vessel under pressure without the addition of moisture or steam, at a temperature sufficiently high to generate from the material itself dry steam at 380°—420° F. (about 190°—215° C.), and to prevent any condensation of the steam generated and any consequent recrystallisation of the calcium sulphate.—H. S. H.

Bricks, blocks, and the like; Manufacture of —— *from blast furnace slag.* R. Milner and T. Robinson. E.P. 163,569, 13.4.20.

Slag from blast and other furnaces is ground and mixed with not more than 20% of clay and with a sufficient amount of ground carbon fuel to form a self-burning mixture, which is moulded into the required forms and fired in clamps or kilns.
—H. S. H.

Asphalt; Preparation of an artificial ——. A. Fürth and H. Japhé. G.P. 335,748, 30.1.20.

Low-temperature tar from coal or lignite or, in general, any tar that differs from coke-oven or gas-works tar and has not been overheated, is mixed with suitable mineral substances and the mixture treated, in the presence of an oxygen carrier, with air or oxygen at a temperature not higher than 110° C., whereby it is oxidised or polymerised, yielding a commercial asphalt powder.—A. R. P.

Bricks, building stones and other articles, such as slabs, pipes, etc.; Production of unfired —— *by means of waste sulphite liquor.* W. Philippsthal. G.P. 335,185, 5.2.20.

Loam, clay, or other building material is made into articles of the required shape which are allowed to dry in the air. They are then coated with sulphite liquor, again allowed to dry, and heated.
—A. B. S.

Artificial stones; Production of —— *from magnesia and filling materials.* G. Kassner. G.P. 334,858, 19.8.19.

The mixture is laid lightly in moulds permeable to ases and treated with moist carbon dioxide, or vith moist gases containing carbon dioxide. The noulds may be made of unglazed fired clay, perorated enamelled iron, or tinned or galvanised auze.—A. B. S.

nsulating roofing tiles of cement-sand mixtures. W. Bünte. G.P. 335,804, 30.7.20.

rushed kieselguhr is added to the mixture of ement and sand, and the dried tiles are soaked Kessler's " fluate " until saturated.—A. B. S.

ood; Artificial seasoning of ——. M. Kleinstück. G.P. 325,657, 12.4.19. Addn. to 323,973 (J., 1920, 785 a).

excess of ammonia is used, together with the oduct of the action of ammonia on formaldehyde; e wood is thereby coloured as well as seasoned.
—J. H. L.

gnesium carbonate for tiles etc. G.P. 303,971. *See* VII.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

iron; Synthetic manufacture of foundry —— *nd its properties.* J. Bronn. Stahl u. Eisen, 921, 26, 881—888.

ing to the war shortage, attempts were made at t Rombach works to obtain a foundry iron low in sulphur and phosphorus, by carbonising Thomas ingot iron, as a substitute for hæmatite, Swedish charcoal pig iron, and low-carbon foundry iron. Starting from a cold charge and adding electrode carbon in the electric furnace was found too expensive. Rolled scrap was next melted in a foundry cupola with the addition of ferrosilicon, but the method was abandoned owing to the high coke consumption, low resistance of furnace lining, and increase in sulphur in the iron. Fluid iron from the steel works was then charged into the cupola so as to relieve it of the melting down process. Although the phosphorus content slightly increased, the iron had a martensitic structure, and was exceptionally tough, due probably to being carbonised at a relatively low temperature. Only a very few tappings showed traces of mechanically included carbon. A series of experiments was made with increasing contents of Swedish and also Rombach iron in the charge. Bending, tensile, and ball tests, also quenching and piping tests cast in green and dry sand were made on the two sets of castings, and no differences were found in their properties. The analyses were also similar except that the Rombach iron castings were somewhat higher in silicon. The use of the substitute iron is recommended, but final judgment is reserved for its use in high quality castings, especially as Swedish pig iron has proved very uniform in quality. The Rombach pig iron has a porous appearance, and methods of manufacture are sought by which this is eliminated.—T. H. Bu.

Air in foundry plants; Condition of —— *and cheap production of dry air.* J. Bronn. Stahl u. Eisen, 1921, 41, 813—820.

At the Rombach foundry, the air at a height of 30 m. above the ground was found to contain over 20% less moisture than the air at a height of only 1·5 m. By erecting suction towers so that the air intake for the blowing machines and compressors is situated at a suitable height, blast furnaces may be supplied with about 35% dryer air without increase of working expenses. Diminution of the moisture content of air at comparatively small heights is not a general meteorological phenomenon, but depends on the radiation of heat from the foundry or other plant using a good deal of fuel, *e.g.*, coke oven installations and chemical works. For each grm. of water per cub. m. of air, 4 kg. of water is introduced into the blast-furnace hearth per ton of pig iron produced, so that by reducing the moisture content by 1 g. per cub. m. the following saving is effected per ton of pig iron produced: 6·5 kg. in the coal consumption, 1% in the blast capacity, and 15 cub. m. in the waste gas consumption for heating the Cowper stoves. The use of the suction towers described actually reduced the moisture content of the air several grms. per cub. m.—T. H. Bu.

Iron; Commercially pure —— *in the basic open-hearth furnace.* W. J. Beck. Chem. and Met. Eng., 1921, 24, 965—968.

The development of the process of manufacturing pure iron in the open-hearth steel furnace, *i.e.*, on a tonnage basis, is described. In early experiments the use of producer gas high in sulphur contaminated the metal. This was overcome by the use of natural gas. The chief difficulties encountered were the control of the high temperature necessary to obtain the desired composition of metal, and the proper degasification of the metal. The heats must be held longer in the furnace than ordinary steel heats, and the amount of aluminium needed to insure degasification is greater. The percentage of metal produced is lower than with steel heats, and owing to the high iron oxide content of the slag its " cutting " action is increased. Pure iron has a definite critical temperature range; the material must be rolled at a temperature above this range in the blooming mill, and below it in the bar mill. Special care must be taken in annealing, pickling, and galvanising sheets. Pure iron has a typical crystalline structure, essentially free from slag. It galvanises in a superior manner and goes into solution in spelter more slowly than steel. It is largely used for welding rods and wire. Pure iron has a low electrical resistance and has excellent vitreous enamelling properties. More than 200,000 tons of iron containing not over 0·014% of ordinary impurities was produced in the United States in 1920.—T. H. Bu.

[Steel] converter; Behaviour of sulphur in the basic ——. E. Herzog. Stahl u. Eisen, 1921, 41, 781—788.

The cooling of the metal bath in consequence of the addition of lime causes a considerable separation of the sulphur in the form of manganese sulphide. During the decarburisation period before the lime is thoroughly in solution in the slag, however, the manganese sulphide is again decomposed, and iron sulphide returns from the comparatively acid slag to the bath. Only at the moment during the after-blow when the lime is completely dissolved and the slag thoroughly basic is the manganese sulphide retained by the slag. At the same time the separation of sulphur as oxides attains increasing significance, due to the increased concentration of the calcium sulphide, the rapidly rising temperature, and the over-oxidation of the bath. A further separation of sulphur occurs at the end of the blow after the ferro-manganese additions, this reduction being similar to that during the after-blow. Lastly a return of sulphur to the metal takes place, due to the increasing acidity of the ladle slag caused by solution of the silicious ladle lining.—J. W. D.

Steel; Retarded solution and premature precipitation of iron carbide in —— and the influence of the initial state on these phenomena. A. Portevin and P. Chevenard. Comptes rend., 1921, 172, 1490—1493.

The differential curve of dilatation of an eutectic steel shows a period of marked dilatation on heating consecutive to the transformation Ac, and this anomaly has been interpreted as a manifestation of the retardation of solution of the cementite. It is less pronounced the slower the rise of temperature. Similarly when complete solution of the cementite is not realised there is observed, during cooling and a little before the commencement of the transformation Ar, a marked dilatation. The steel appears to be hypereutectoid, or in other words there is premature precipitation of the cementite. This is confirmed by a comparison of the two curves for a steel, obtained in the one case when the steel was "coalesced," the metal having been previously annealed in such a way that it contained the cementite in the globular state, whilst in the second case the steel was "regenerated" by several heatings followed by rapid cooling, resulting in a pearlitic structure. The premature precipitation was manifest in the first case, out did not appear in the second.—W. G.

Silicothermy and its practical application. R. Walter. Z. Metallk., 1921, 13, 225—233.

When soft iron and silicon or a high percentage ferrosilicon are heated together to 1250° C. a vigorous reaction takes place, the temperature rises rapidly to above 1800° C., and the mass melts. The product, according to the composition of the charge, consists of one or other of the iron silicides, FeSi (33% Si) and Fe_2Si (20% Si), or of a more or less saturated solid solution of one of these in iron. As the amount of carbon in the iron used increases, so the temperature produced by the reaction falls off; thus, while with electrolytic iron an almost explosive reaction takes place, with cast iron no appreciable increase of temperature is noticed when it is heated with silicon, but the latter slowly goes into solid solution in the iron and the carbon is thrown out as graphite. The alloys obtained by the silicothermic process are too hard and brittle to be used for making acid-resisting ware, but by the addition of a certain amount of carbon to the liquid alloy after cooling somewhat, and by treating it in such a manner that the carbon remains disseminated throughout the metal as finely divided graphite, a softer, less brittle, and machinable alloy is obtained which is well adapted for the manufacture of all varieties of acid-resisting ware. If the carbon addition is made when the metal is too hot, silicon carbide is formed and the alloy made harder than before. The structure of the finished metal consists of polygonal crystals of Fe_2Si distributed evenly throughout a ground mass of a solid solution of silicon in iron containing finely divided graphite particles.—A. R. P.

Carbon combustion train [for steel analysis]; Simplified ——. W. W. Boone. Chem. and Met. Eng., 1921, 24, 1068.

The author has designed a simplified combustion train in which a practically uniform pressure and flow of oxygen is obtained by the insertion of a water pressure tank. From the tank the oxygen flows through a bottle acting as a safeguard against sucking back, and another containing a saturated solution of potassium hydroxide. The oxygen is finally dried by means of calcium chloride, soda-lime, and sulphuric acid. After leaving the combustion tube the gas passes through a tube containing zinc to take up any sulphur gases, and 20-mesh calcium chloride and phosphoric anhydride, acting as drying agents, before entering the Fleming or similar absorption bulb packed in the usual way. Factor or half-factor weights of fine drillings are used to eliminate reference to tables or calculation. The method is accurate to 0·01%, and an estimation takes 5 to 6 minutes. For low-carbon steels it is sometimes necessary to preheat the sample for about 2 minutes to obtain perfect fusion.
—T. H. Bu.

Silicon; Determination of —— in cast iron. F. Graziani and L. Losana. Giorn. Chim. Ind. Appl., 1921, 3, 191—192. (*Cf.* J., 1921, 472 A.)

For estimating silicon in cast iron the most simple and rapid method consists in treating the metal with either hydrochloric acid or a mixture of nitric and sulphuric acids, weighing the residue and treating it with hydrofluoric acid to volatilise the silica. Blair's method, in which a current of chlorine is passed over the red hot metal to form silicon tetrachloride, gave rather low results. This method is, however, intended for the estimation of the free silicon in the metal, apart from that present in any included slag.—T. H. P.

Zinc dust; Nature of ——. O. Ravner. Tidskr Bergvaesen, 1919, [4], 138. Chem. and Met Eng., 1921, 24, 932—934. (*Cf.* J., 1920, 786 A.

Complete analyses of zinc dust from electri furnaces and retorts are given. The former i higher in sulphur and oxide. White crystal grains in sizes under 0·6 mm., were found, principall in the spelter dust. They are probably derive from the furnace lining, in which the presenc of fine hexagonal crystals of zinc oxide wa demonstrated. The dust from spelter furnace has sp. gr. 5·81, and that from refined zin 6·10. Under a load of 1500 kg. per sq. cm the dust from redistillation furnaces was r duced to 54·55% of its original volume, an dust from the spelter furnaces to 51·14%. Th latter briquette (density 4·35 g. per c.c.) was foun to be the stronger. By heating zinc dust unde mixtures of common salt and zinc chloride a goo

recovery of metallic zinc was obtained. With a mixture of 50% of calcium chloride and 50% of zinc chloride the recovery was as high as 91·6%. The higher the amount of oxide the greater must be the amount of zinc chloride in the melt.
—T. H Bu.

Red brass; Influence of lead on the properties of ——. J. Czochralski. Z. Metallk., 1921, **13**, 171—176.

Addition of lead up to 6% has no adverse influence on the mechanical properties of red brass (Cu 86%, Sn 9%, Zn 5%). It remains in solid solution in the α mixed-crystal phase, and does not segregate even if the alloy is quenched from above the transition point (700° C.) or kept for long periods above 480° C. The presence of lead in the alloy renders it more easily workable, and, when molten, less viscous, so that the resulting castings are more homogeneous and freer from flaws.—A. R. P.

Aluminium conductors; Use of —— [*in German electricity works*]. Wunder. Z. Metallk., 1921, **13**, 179—184.

The extent to which aluminium conductors have been used by 24 German electricity works during the last few years is given in a table together with notes from each of the works on the behaviour of the conductors under varied weather conditions. The results show that aluminium conductors if properly supported and insulated are, on the whole, satisfactory under weather conditions varying from those prevailing on the sea coast to wintry conditions in hilly country. In some cases there was a tendency for the wires to sag between the insulated supports, thus necessitating constant relaying, while in other cases there was disintegration or corrosion of the wires at the supports, probably due to electrolytic action, and at the welds or rivets between two sections. These difficulties were overcome by the application of several coats of insulating varnish.—A. R. P.

Hardening of metals; Slip interference theory of ——. Z. Jeffries and R. S. Archer. Chem. and Met. Eng., 1921, **24**, 1057—1067.

Mechanical failure in pure metals takes place long crystallographic planes of weakness before a tress corresponding to the inherent cohesion of the etals has been reached. Hardening and trengthening of metals may be considered as due rincipally to interference with slip. Grain refinement is the simplest source of increased hardness, s the propagation of slip along crystal planes is revented by the numerous grain boundaries. The morphous metal between grains is hard and strong ving to the absence of the planes of weakness aracteristic of crystals. By breaking the grains to fragments, cold working also introduces slip terference. On the obstruction principle the echanism of hardness is considered as the engthening of the matrix grains by the external pport of a stronger constituent, but metals may hardened to a greater degree by the presence of e particles of a substance uniformly distri- ted within the grains. It is not necessary for the d substance to possess great adhesion for the trix. The increase in strength of duralumin by a ing after quenching from 500° C. is probably d to a precipitation of $CuAl_2$ in particles of sub- n roscopic size. There appears to be a critical d persion of the hard constituent conducive to m ximum hardness, finer and coarser dispersion g ng softer metal. Atomic dispersion, as for ex- a ple in solid solutions, is too high, the maximum ha lness being probably caused by the smallest p ticles having the characteristic properties of the cr talline substance. The actual amounts of hard di ersed substances which produce useful results are from 2 to 15% by volume. The theory is applied to account for the properties of manganese steel in the "as quenched" and "as tempered" conditions. Martensite consists of α-iron in which the carbon is atomically dispersed. Its hardness is due to the super-refinement of the ferrite grains and the strengthening of the ferrite by carbon. On tempering, the cementite grains begin to be precipitated, producing hardening until the grains reach a critical size, after which softening is produced, and superimposed on this effect is the continuous increase in size of the ferrite grains producing a softening effect.—T. H. Bu.

Metals; Researches on —— *by means of X-rays.* S. Nishikawa and G. Asahara. Phys. Rev., 1920, [2], **15**, 38—45. Chem. Zentr., 1921, **92**, I., 986—987.

Test bars of the metals were cast 4 mm. thick, these were rolled down to 0·1—0·18 mm. (or 0·54 mm. in the case of aluminium), and their interference figures examined by means of X-rays. Aluminium, cadmium, copper, zinc, and brass gave ill-defined figures, symmetrical to the direction of rolling and characteristic for each metal. There was a distinct difference between the results obtained with pure copper and with copper containing 2% Zn, but no further difference was noticed until the zinc reached 40%. Silver and tin gave, immediately after rolling, similar results to the above metals, but after the specimens had been kept for 2—3 weeks the results were similar to those obtained with annealed metal, as also was the crystal growth. Lead and thallium showed a number of irregularly distributed interference points but no figures, and, in the case of thallium, these did not agree with those shown by the annealed metal. On heating the test-pieces the influence of the rolling disappeared, in the case of silver and tin at 80° C., but to produce the same result with copper required 2 hrs.' heating at 800° C. The transformation point of thallium at 227° C. is readily detected by X-rays, as a sudden alteration of the interference figures takes place, and the specimen has the appearance of a single crystal. The maximum crystal growth in tin is obtained by heating it to 80° C. for some time, after which no change in the figures takes place if the heating is continued at 160° C. Similar results are obtained by 30 mins.' heating at 220° C.—A. R. P.

Metals; Critical points of —— *due to hammer-hardening.* L. Guillet and M. Ballay. Comptes rend., 1921, **172**, 1576—1578.

Measurements of the variation of the electrical resistance with the temperature for a hammer-hardened and an annealed wire of the same alloy, the results being plotted on a differential curve, show for different alloys and particularly for brasses, clearly the variation of hardening as a function of the temperature. The apparatus as arranged for differential measurements permits of a study of the influence of the various factors which intervene in the hardening.—W. G.

Alloys; Dendritic crystallisation and its influence on the strength of ——. R. Vogel. Z. anorg. Chem., 1921, **116**, 21—44.

The principal factors conditioning the formation of dendritic crystals in metals and alloys are the rate of cooling and the rate of flow of heat from the surface of the polyhedral nuclear crystals which first form in the fluid phase. Dendritic forms result from the inhibition of growth at the faces of the crystal and acceleration at the edges and corners. By etching a section cut across the branches of a dendritic structure, it can be seen that the crystal particles are all similarly orientated; consequently the whole may be regarded as a single crystal. In the case of some metals, for example, copper, this phenomenon is not well revealed by etching. Etching with copper ammonium chloride reveals the apparent boundaries of the crystalline granules. By subjecting the specimen to pressure, however, and examining the specimen again after re-polishing, glide planes appear which establish the true boundaries of the different dendritic crystals and show that these are of much greater extent than the granules revealed by etching, many of the latter, in fact, belonging to the same dendritic crystal. It is therefore necessary to distinguish between the apparent and the real size of the particles in a structure. Dendritic structures, owing to the large size of the crystals, have low mechanical strength. The improvement brought about by recrystallisation or by working is due to the breaking up of the dendritic system and the formation of much smaller, differently orientated crystals.—E. H. R.

Patents.

Ferro-chromium; Producing low-carbon and low-silicon ——. F. Krupp A.-G. E.P. 145,711, 26.6.20. Conv., 11.1.18. Addn. to 145,709 (J., 1921, 307 A).

High-carbon ferro-chromium of medium silicon content produced in the blast furnace is transferred to an acid-lined converter and blown until the carbon and silicon are reduced to a point at which oxidation of the chromium would commence, whereupon steam is injected into the blast. The temperature of the charge and the blowing time are thus diminished, and a low-carbon low-silicon alloy obtained with considerably reduced oxidation losses.—T. H. Bu.

Iron castings; Manufacture of malleable ——. G. H. Wooby. E.P. 163,510, 28.2.20.

An iron alloy which is malleable as cast contains 79—86% Fe, 7—12% Ni, 4—10% Cu, and up to 10% Mn. When melting the iron, the carbon and silicon are burned out, and the nickel and copper are added as an alloy or separately, and then the manganese.—T. H. Bu.

Alloy steel and articles made therefrom; Manufacture of ——. R. A. Hadfield. E.P. 164,039, 28.11.19.

An alloy steel for permanent magnets, having magnetic qualities superior to those of ordinary tungsten steel and yet not of an expensive nature, contains 5—19% of cobalt. A steel containing C 0·52%, Mn 0·42%, Cr 2·20%, Ni 0·51%, W 8·0%, Co 8·89%, when magnetised in a field of 1200 C.G.S. units, gave a coercive force of 97 and a retentivity of 9900 C.G.S. units. A steel containing C 0·52%, Mn 0·57%, Cr 1·85%, Ni 0·62%, W 7·82%, Co 17·77%, similarly magnetised, had a coercive force of 130 and a retentivity of 10,150 C.G.S. units.
—T. H. Bu.

Metallic surfaces; Coloration of ——. *Oxidation and coloration of ferrous surfaces.* T. Rondelli, Q. Sestini, and Sestron Colour Oxidising Co., Ltd. E.P. (A) 164,127 and (B) 164,128, 2.3.20. Addns. to E.P. 106,774, 18.11.16 (J., 1917, 888).

(A) The surfaces of copper and iron articles are coloured by immersing them in an alkaline electrolyte of sp. gr. 1·3—1·5, consisting of a fixed alkali in which a compound of copper such as cupric oxide or hydroxide is dissolved, preferably to saturation, and subjecting them to anodic oxidation with application of heat. (B) The surfaces of iron articles are oxidised or coloured by subjecting them to anodic oxidation in a hot concentrated alkaline solution, such as caustic soda, to which an oxidising agent such as alkali nitrate or chlorate may be added. At a temperature of 145°—155° C. a violet-blue colour is obtained, while if the bath is heated to 160°—165° C. a bronze colour results.
—T. H. Bu.

Ferrous surfaces; Preparation of —— *for enamelling, varnishing, or like finish.* T. Rondelli, Q. Sestini, and Sestron Colour Oxidising Co., Ltd. E.P. 164,129, 2.3.20. Addn. to E.P. 106,774, 18.11.16 (J., 1917, 888).

Substantially non-oxidised iron is electrolytically deposited upon the ferrous surfaces at a temperature of about 120°—140° C. from an alkaline solution of sp. gr. 1·3—1·5 containing iron oxide either combined or in solution. Alternatively, the bath may be made by boiling sodium ferrate with excess of caustic soda at 125°—135° C. The article is made to serve alternately as anode and cathode, concluding as cathode. If necessary, hydrogen may be removed from the surface of the deposited metal by anodic oxidation or immersion at 140° C. in a solution of caustic soda containing 10—20% of sodium nitrate and having sp. gr. 1·4.—T. H. Bu.

Copper deposit; Automatic removal of —— *from bores of guns.* A. E. A. Dagory. E.P. (A) 148,250 and (B) 148,263, 9.7.20. Conv., 19.6 and 11.10.17.

(A) A layer of a fusible alloy consisting of Sn 55—60% and Pb 45—40% is placed upon the base of a number of projectiles. On firing the projectiles from the gun to be decoppered, the alloy is fused and projected in drops by centrifugal force upon the walls of the bore. The tin forms an easily fusible alloy with the copper, which is carried off by subsequent ordinary projectiles, the lead acting as a lubricant. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 20,438 of 1895.) (B) The lead-tin alloy may be placed on the cylindrical portions of the projectiles, to the rear of the driving band, or used in the form of powder, pastilles, ribbons, etc., in front of the firing charge or in the cartridge case.—T. H. Bu.

Metals; Recovery or separation of ——. W. J. Niiranen and A. Hibbert. E.P. 163,348, 31.7.19.

Copper is separated from its ores, which usually contain iron, by roasting the ore to convert all metals into their oxides, heating the mixture of oxides to 620°—700° C. and treating it with sulphur trioxide, the concentration of which is kept lower than the equilibrium gas pressure of iron sulphate but higher than that of copper sulphate at the above temperature. The copper oxide is thus converted into sulphate without the iron oxide being attacked, and is dissolved out after cooling. A similar method is applicable to other metals and other acid radicles.—T. H. Bu.

Metals and alloys; Manufacture of —— *by electrolysis of fused salts.* Metallbank und Metallurgische Ges. A.-G. G.P. 334,475, 29.5.19.

The anode consists wholly or partly of a metalli carbide, which is not readily decomposed by th volatile anion, and, on being attacked, yields a compound of the anion with the radicle of the carbid at the same time setting free an equivalent amoun of carbon. The decomposition voltage is als reduced to quite a small amount and, by the us of a metallic cathode and of an anode made from carbide formed by an endothermic reaction, ma even be made negative. Thus, lead-calcium allo may be made by electrolysis of fused calciu chloride, using a lead cathode and an anode calcium carbide and carbon, and aluminium fro

fused salts containing alumina in solution, using an anode of aluminium carbide and carbon.
—A. R. P.

Metal pickling or cleaning. The Rustproofing Synd., Ltd., and T. F. Newman. E.P. 163,868, 29.3.20.

A bath for pickling or cleaning ferrous metals, which attacks the scale portions only and has no detrimental effect on the metals, consists of 38 lb. of iron sulphate dissolved in about 300 galls. of water, to which is added 112 lb. of sulphuric acid of sp. gr. 1·84. To accelerate the scale-removing action 16 lb. of nitric acid may be added alone or 20 lb. of hydrochloric acid in conjunction with 12 lb. of nitric acid. The bath can be used cold.
—T. H. Bu.

Metallic articles; Process for improving the surfaces of ——. R. Walter. G.P. 335,039, 12.3.18. Addn. to 330,707 (J., 1921, 266 a).

Cast-iron articles are provided with an intermediate coating of malleable iron or steel or of a steel alloy either electrically or by autogenous welding. Articles of bronze or similar alloys are given an intermediate coating of nickel or cobalt or their alloys in a similar way.—A. R. P.

Metal coatings produced by the spraying process; Improving the adhesion of ——. Meurersche A.-G. für Spritzmetall-Veredlung. G.P. 334,998, 16.5.20.

The metal (*e.g.*, iron) to be coated is heated to a temperature higher than the m.p. of the metal (*e.g.*, zinc) used for producing a preliminary coating by the dipping method; the dipped metal is then cooled slightly and coated by the spraying process with a metal (*e.g.*, tin) of lower m.p. than that forming the first coat, so that the two metals weld together.—W. P. S.

Zinc; Autogenous welding of —— *and use of zinc as a solder for other metals.* E. Wilke. G.P. 335,178, 23.6.20.

Fused alkali hydroxides are used as a flux in soldering zinc. To solder other metals with zinc the flux may consist of alkali salts such as borates, phosphates, sulphates, carbonates, chromates, manganates, aluminates, stannates, and plumbates.
—W. P. S.

Iron; Method of refining —— *for castings.* National Malleable Castings Co., Assces. of W. G. Kranz. E.P. 140,826, 26.3.20. Conv., 17.11.15.

See U.S.P. 1,206,861 of 1916; J., 1917, 142.

XI.—ELECTRO-CHEMISTRY.

ry batteries. II. F. Kainz. Chem.-Zeit., 1921, **45**, 602—604. (*Cf.* J., 1921, 121 a.)

o appreciable improvement in the output or ngthening of the life of a dry battery appears acticable along the lines so far investigated. reshly prepared batteries of three elements will ow an initial potential of about 4·5 volts, decreasg gradually to a limit of about 3·85 volts in months, which remains constant until a sudden cline precedes the destruction of the battery ter 6 months or so. This alteration of the voltage probably to be ascribed to the changing equilibrium of the electrolytic solution pressure of zinc ions, as their removal from solution as complex zinc ammonium ions slows down. The potential is only increased by 0·2—0·3 volt above the aforementioned figures by using pure or synthetic manganese dioxide as depolariser, and other minor alterations, such as the addition of 1—3% of copper oxide, or the use of manganese chloride instead of ammonium chloride, have, on the contrary, an unfavourable influence. The life of the battery can be lengthened by using chemically pure zinc, but technically this is valueless owing to the cost. The current output can only be improved by improvements in the construction of the battery itself, and experiments are being undertaken in this direction with promising results.—G. F. M.

Aluminium conductors. Wunder. *See* X.

Patents.

Galvanic elements. F. Böcker and A. Eichhoff. E.P. 163,744, 30.12.19.

In cells employing an alkaline electrolyte in the form of a paste, permanganates, manganates, or manganic acid, with or without other depolarising agents and inert materials, are used as a depolariser for the positive electrode.—J. S. G. T.

Accumulators having an alkaline electrolyte; Electrode for ——. P. Gouin and E. Rossel. G.P. 335,370, 27.4.20. Conv., 10.9.19.

Increased capacity and conductivity together with a better distribution of current in the active mass of the electrode are secured by embedding a metal frame constituted of helices, a number of intertwined helices, or a mass of fine wires or coils of nickel, iron, steel, or nickel-plated wire in a mass of nickel or iron oxide and compressing the whole, so that the current may flow through all parts of the metal nucleus.—J. S. G. T.

Galvanic elements; Manufacture of [negative electrodes for] ——. F. Böcker and A. Eichhoff. E.P. 164,062, 30.12.19.

A negative electrode for use more especially in galvanic elements with an inspissated alkaline electrolyte consists of an amalgam of zinc or other metal with 3—40% of mercury. Prior to its amalgamation, the electrode may be heated to 150°—200° C., and after amalgamation to a temperature not higher than 100° C.—J. S. G. T.

High-tension electric discharge; Apparatus for subjecting substances or molecular matter to the electrostatic stress of a ——. F. G. Nieco and R. M. Leggett. E.P. 163,823, 28.2.20.

A high-tension discharge is derived from a Tesla coil supported within a treatment chamber containing two horizontal electrodes spaced apart vertically. An insulating tube, on which the secondary of the Tesla coil is wound, passes centrally through the upper electrode and communicates with the space between the electrodes, and serves as an outlet for gases and vapours therefrom, and also as a support for the upper electrode. A horizontal dielectric plate is arranged between and spaced from the electrodes, and means are provided for heating substances supplied to the treatment chamber. The apparatus may be used for the production of acetylene from carbon and hydrogen and its polymerisation to liquid or gaseous hydrocarbons, for the sterilisation of food products, etc.
—J. S. G. T.

Carbon electrodes; Manufacture of ——. Rheinische Elektrodenfabrik G.m.b.H., and L. Effertz. G.P. 335,246, 27.7.19.

By employing two carbon mixtures, the one having the ordinary composition, while a considerable amount of retort carbon or other carbon possessing high electrical conductivity is incorporated in the other mixture, an electrode is produced the conductivity of which in the region where current is fed to the electrode is greater than that of the remaining part of the electrode.—J. S. G. T.

Metals and alloys. G.P. 334,475. *See* X.

Colouring etc. metallic surfaces. Preparing ferrous surfaces. E.P. 164,127–9. *See* X.

XII.—FATS; OILS; WAXES.

Oil of oats. E. Paul. Analyst, 1921, **46**, 238—239.

Oats of the "Black Tartary" variety yielded 4·32% of petroleum spirit extract; this extract contained about 1% of its weight of lecithins, and when these had been removed by treatment with acetone the oil obtained had a yellow-green colour and an acrid taste; it became thick and granular at 10° C., and solidified completely in 24 hrs. at 3° C. The oil had the following characters:—Sp. gr. at 15°/15° C., 0·925; m.p. about 8° C.; free fatty acids (as oleic acid), 34·70%; saponif. value, 189·8; iodine value (Wijs), 114·2; unsaponif. matter, 1·30; n_D^{40}=1·4701; insoluble fatty acids, 93·6%; mean molecular weight of fatty acids, 284·8. At 99° C. the oil formed a hard varnish in 3 days, but at ordinary temperature gumming had only commenced after 2 months' exposure.—W. P. S.

Ergot oil. K. Gander and J. Zellner. Seife, 1921, **6**, 411—412. Chem. Zentr., 1921, **92**, I., 1021.

A freshly gathered sample of ergot from Obersteiermark on extraction with petroleum ether yielded only 21% of oil. The saponification value was 196·2, as compared with the only previously recorded figure of 180. The neutralisation value of the insoluble fatty acids (194·8) and the acetyl saponification value (248·7) were similar to those of a sample that had been kept for 10 years. The acetyl value (86·6) was, however, higher in the case of the fresh oil. The acetyl acid value was 162·1. The acetylation cannot, however, have been complete, since the fatty acids recovered by saponification had the same values as usual. The m.p. of the fatty acids was 39·5° C., solidif. pt. 38·5°—36·5° C. (capillary method).—H. C. R.

Oils of grape seeds. E. André. Comptes rend., 1921, **172**, 1413—1415. (*Cf.* J., 1921, 477 A.)

The fatty acids from a sample of the oil were separated into three fractions, in one of which the hydroxy-acids predominate, by fractional crystallisation of their lithium salts from 70% alcohol. From a particular sample of oil, which had an acetyl value 49·3, there were obtained 12·5% of solid acids, 62·5% of liquid acids, and 25% of viscous acids, the latter fraction containing the hydroxy-acids. The solid acids had m.p. 49°—50° C., mean molecular weight 281, iodine value 32, saturation value 199; the liquid acids had mean molecular weight 287, iodine value 131, saturation value 195; and the viscous acids had mean molecular weight 277, iodine value 110, saturation value 202.—W. G.

Illipé butter used as a substitute for cacao butter; Detection and determination of ——. F. G. H. Tate and J. W. Pooley. Analyst, 1921, **46**, 229—236.

The average chemical and physical characters of the two fats are as follows, the first value being that of cacao butter, the second that of illipé butter:—Sp. gr. at 60°/15·5° C., 0·8825, 0·8826; sp. gr. at 99°/15·5° C., 0·8575, 0·8577; viscosity (Redwood) at 60° C., 99·9, 103·7; m.p. 30·5°, 33·2° C.; iodine value, 39·8, 31·5; m.p. of fatty acids, 49·4°, 52·8° C.; n_D^{40}, 1·4569, 1·4568. If the sp. gr. at 60° C., the sp. gr. at 90° C., the viscosity, the m.p., the m.p. of the fatty acids, and the reciprocal of the iodine value are multiplied together the products or "factors" obtained for the two fats are:—Cacao butter, 3150; and illipé butter, 4403. The reciprocal is taken in the case of the iodine value, as this value is the lower for illipé butter and would have a nullifying effect. These "factors" afford a basis for the calculation of the proportions of the two fats in mixtures of the same, provided that the mathematical error involved is taken into account; the error has its maximum in a mixture composed of equal parts of the fats. If the amount of illipé butter found by calculation is 50%, 4·2% should be added; generally, an average addition of 2·1% (half the maximum error) may be added to all results obtained. If only small quantities of fat are available, a "short factor" may be obtained by multiplying together the m.p., the m.p. of the fatty acids, and the reciprocal of the iodine value; for cacao butter the "short factor" is 4166 and for illipé butter 5615, the correction for 50% of illipé butter being +3·9%.—W. P. S.

Iodine values; Abnormal —— *with special reference to the sterols and resins.* I. S. MacLean and E. M. Thomas. Biochem. J., 1921, **15**, 319—333.

The Hübl iodine value for phenol is greater than that given by Wijs' reagent, possibly because the latter reagent enolises and a change to ketodihydrobenzene is a necessary preliminary to the addition of halogen. Conversely the Wijs values are much higher than the Hübl values in the case of fatty aldehydes and ketones, phenanthrene hydrocarbons, sterols, and resins (abietic acid). In the case of carbonyl compounds, it is suggested that they are first enolised by the acid of Wijs' reagent. Abietic acid absorbs 4 atoms of iodine from the Hübl and 6 from the Wijs reagent; there are two double bonds in the molecule. Similarly the Hübl reagent gives correct values for sterols; those with the Wijs reagent are much too high. For a fat containing appreciable quantities of sterols, the Hübl value more accurately expresses the degree of unsaturation than the Wijs value.—G. B.

Fats; Higher terms of the series of saturated ——. A. Gascard. Ann. Chim., 1921, **15**, 332—389.

A more detailed account of work already published (*cf.* J., 1920, 376 A, 495 A).—W. G.

Brodie's hydrocarbon, melene, $C_{30}H_{60}$ [*from beeswax*]. Y. Funcke. Arch. Pharm., 1921, **259**, 93—101.

Beeswax was subjected to dry distillation from an iron retort and the distillate was separated into a volatile and a non-volatile portion by distillatio with steam, each portion being subsequently fractionally distilled. Mixtures of saturated and unsaturated hydrocarbons (with small amounts o oxygenated products) were obtained, the forme predominating in the distillates of higher, the latte in those of lower boiling point. The production o hydrocarbons of high molecular weight is favoure by rapid distillation. The solid residue left afte distillation could be separated by cold ether int two groups of hydrocarbons containing respectivel about 25 and 30 atoms of carbon, but these grou could not be subdivided further by physic methods. The only definite individual isolated w hentriacontane, $C_{31}H_{64}$, m.p. 68° C. Brodie hydrocarbon does not appear to have been isolat in a pure state up to the present.—H. W.

Linoxyn; The spontaneous decomposition of —— F. Ulzer. Oel- u. Fettind., 1920, 412. Che Zentr., 1921, **92**, II., 1092.

When extremely thin, dry boiled oil films are c posed for a short time in an atmosphere containing chlorine or bromine, bleaching, followed by the development of a red coloration takes place. After two months the solidity diminishes and stickiness begins to develop. In a further month the films change to an extremely viscous liquid. Absence of air and a high degree of atmospheric moisture accelerate the change. By omitting the preliminary treatment with halogens, the change to the liquid condition is much slower.—A. de W.

PATENTS.

Fats and oils; Removal of fatty acids, resins, bitter and mucilaginous substances from ——. H. Bollmann. E.P. 164,115, 1.3.20.

THE fat or oil is lixiviated with methyl, ethyl, or amyl alcohol, acetone, or acetic ester, which may be diluted, in a counter-current apparatus in successive stages, the solvent being separated from the fat or oil between each stage. The solvent may be recovered by evaporation and used again. By this process the formation of emulsions is prevented.
—H. C. R.

Lubricants [from wool grease]. O. Reynard and E. Edser. E.P. 164,107, 28.2.20.

CRUDE wool grease is melted and then treated with milk of lime to convert all the free fatty acids into their calcium soaps, and the product is dried. Crude wool-washing effluent may also be used after treatment with calcium chloride and filtering and drying the precipitate. In either case 5 to 50% of the anhydrous product is mixed with a mineral oil or grease to produce a lubricant, and graphite, talc, or soapstone may be added if desired.
—C. A. C.

Soaps; Manufacture of solid durable —— containing fat-solvents. A. Welter. G.P. 335,725, 25.9.19.

POWDERED soaps containing hydrocarbons or their halogen derivatives are subjected in moulds to so high a pressure that the powder fuses together to a homogeneous mass. The soaps so produced keep well and the fat-solvent contained in them is only lost from the outer surface, that contained in the interior being almost completely protected from evaporation.—H. C. R.

Soap powder; Manufacture of ——. A. Imhausen. G.P. 310,123, 28.6.18.

A MIXTURE of soap, soda, and other filling materials is blown into a foam in an autoclave. This is then allowed to break up under increased pressure and is blown through a nozzle or the like into a cooled space. The temperature is then increased and the mass removed by a conveyor. Formation of lumps and greasiness are in this way avoided.—H. C. R.

Washing powders containing volatile substances, especially fat-solvents; Manufacture of ——. A. Imhausen. G.P. 310,626, 27.8.18.

THE volatile substance is introduced into the mass of soap under agitation at a temperature as near 0° C. as possible or even lower. The volatile substances may be converted into a water-soluble form before adding them to the soap.—H. C. R.

Fatty matter; Extraction of —— from garbage and other fat-containing materials. L. C. Whiton, jun., and V. Bredlik. E.P. 143,196, 1.3.20. Conv., 15.5.19.

SEE U.S.P. 1,372,479 of 1921; J., 1921, 356 A.

Cholesterol. G.P. 335,603. *See* XX.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Turpentine; Composition of French ——, and α-pinene bromide. Pariselle. Comptes rend., 1921, 172, 1496—1499.

BY careful fractional distillation of 15 l. of French turpentine, α- and β-pinene were isolated. α-Pinene had b.p. 153·5°—154·5° C. at 760 mm., 62° C. at 32 mm.; sp. gr. 0·8748 at 0° C.; $n_D^{13}=1·4690$; $[\alpha]_D^{15}=-43·48°$; coefficient of viscosity $\eta=0·0141$. β-Pinene had b.p. 163°—164° C. at 760 mm., 71·5° C. at 34 mm.; sp. gr. 0·8848 at 0° C., 0·8728 at 15° C.; $n_D^{13}=1·479$; $[\alpha]_D^{15}=-19·80°$; coefficient of viscosity $\eta=0·0173$. With hydrogen bromide α-pinene gave a solid hydrobromide, m.p. 94° C.; b.p. 94° C. at 12 mm.; $[\alpha]_D^{15}=27·95°$, and a liquid isomeride. β-Pinene gave the same compounds. Bromine reacts with α-pinene in carbon tetrachloride at −10° C. to give a complex mixture of addition and substitution products.—W. G.

Resin; Action of air and moisture on powdered ——. F. Goldschmidt and G. Weiss. Z. Deuts. Oel u. Fettind., 1921, 41, 147—148. Chem. Zentr., 1921, 92, II., 1074.

IN control tests with the authors' stearine method (*cf.* J., 1919, 226 A) it was observed that samples of powdered resin almost always showed a smaller percentage of valuable resinous substances than the unpowdered material. Comparative experiments on lumps and powder showed that exposure to the air had an important effect on the powder, which was increased by the presence of water vapour. The percentage of useful resinous substance decreased, and the resin acids dissolved in the lower lye increased, together with the moisture content. No appreciable alteration of the lumps was observed. The stearine method, therefore, can only be considered reliable when the material to be tested is in the form of lumps. On powdered samples which have been lying by for some time, it may give rise to very misleading results.—H. C. R.

Coumarone resins. E. Glaser. Brennstoff-Chem., 1921, 2, 99—102, 113—117.

THE production of coumarone resin in Germany amounted in 1914 to 6000 tons, whilst in 1917 it had increased to 11,000 tons. The resin is produced from the residues remaining after the distillation of light benzol, heavy benzol, and carbolic oil, after these have been carefully freed from bases and phenols and washed with concentrated sulphuric acid. It is essential to obtain a thoroughly intimate admixture of the acid and the oil, and for this purpose mechanical agitation has largely displaced air agitation on account of the high benzol losses in the latter method. The washers are of wrought iron with a homogeneous lead lining. The acid is added in portions, as this has been found to give better results than adding all the acid in one charge. It is usual to add altogether about 5% by weight of sulphuric acid. The shrinkage in volume due to the absorption of unsaturated compounds may amount to 12% in inferior oils and is generally about 8%. Particulars are given of the properties and technical uses of coumarone resin. Indene was discovered by Kraemer and Spilker in 1890 in the crude benzol fraction, 176°—182° C. Sulphuric acid converts it into paraindene, three polymerides being known. With concentrated acid, a polymeride is obtained melting at 210° C. which is soluble with difficulty in ether. With weak acid, however, a polymeride is obtained melting below 100° C., which is easily soluble in ether. This last modification is the cause of the low melting point of many coumarone resins. Coumarone is a colourless liquid, boiling at 172° C. Its sp. gr. is 1·096, and it polymerises with certain reagents, *e.g.*, aluminium chloride, strong alkalis, or acids. Paracoumarone melts at 107°—108° C. and has an average molecular weight of 473 corresponding to $4C_8H_6O$. There are two modifications, one being soluble and the other insoluble in benzol.—A. G.

Abnormal iodine values. MacLean and Thomas. *See* XII.

Patents.

Lacquer paints; Preparation of quick-drying ——. Deutsch-Luxemburgische Bergwerks- und Hütten-A.-G., and S. Hilpert. G.P. 335,750, 16.5.17. Addn. to 324,722 (J., 1920, 792 A).

In the process described in the chief patent, tar oils of b.p. above 180° C. are also added either before or after addition of the pigments, or the pigments may be omitted, in which case the mixture forms a quick-drying varnish.—L. A. C.

Printing and stamping colours [inks]; Manufacture of ——. Chem. Fabr. Worms A.-G. E.P. 156,212, 3.1.21. Conv., 31.12.17.

Lactates, including lactates of colour bases, are employed with or without the addition of other solvents as hygroscopic media in place of, *e.g.*, glycerin, in the preparation of printing and stamping colours; thus 10 kg. of Crystal Violet is dissolved in 75 litres of water, 15 litres of methyl alcohol, and 25 kg. of potassium lactate solution (sp. gr. 1·45).—A. de W.

Resin; Extraction of crude —— from moist resinous material. A. Wenck. G.P. 335,154, 12.5.18.

The material is extracted with a mixture of amyl alcohol and hydrocarbons or halogenated hydrocarbons.—L. A. C.

Resin-like substances; Manufacture of ——. M. Melamid. E.P. (A) 137,291, (B) 137,292, and (C) 137,293, 29.12.19. Conv., (A) 27.12.18, (B) and (C) 28.12.18.

(A) Resin-like substances are produced in two stages, *i.e.*, a phenol and formaldehyde are caused to condense in known manner to produce a phenol-alcohol, which is subsequently esterified in caustic soda solution with a benzene solution of an aromatic sulphochloride; *e.g.* 100 kg. of cresol-alcohol produced from commercial cresol mixture and formaldehyde by known methods, is dissolved in 300 kg. of 10% caustic soda solution and stirred at a temperature not exceeding 30° C. with a solution of 137 kg. of a mixture of *o*- and *p*-toluene sulphochloride or one or other of these isomers in 500 kg. of benzene for several hours. The benzene layer is washed free from alkali, dried, and the residual resin obtained by evaporation. The initial phenol-alcohol may also be produced in the presence of the aromatic sulphochloride and the product further treated with sulphochloride. (B) Phosgene or (C) an organic acid anhydride, *e.g.*, acetic anhydride, is employed in place of the aromatic sulphochlorides claimed in (A).—A. de W.

Lakes. E.P. 164,053. *See* IV.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber; New process for cold vulcanisation of ——. G. Bruni. Giorn. Chim. Ind. Appl., 1921, 3, 196—197.

Articles of rubber or of rubber mixtures are vulcanised by the formation in the mass of the material of thiocarbanilide, or other disubstituted aromatic thioureas, by the action of vaporised or dissolved carbon bisulphide on an aromatic amine incorporated with the rubber in presence of zinc oxide or other metallic oxide. For instance, a mixture of 100 parts of rubber with 8 of sulphur, 20 of zinc oxide, and 6 of aniline is exposed at the ordinary temperature to the vapours of carbon bisulphide.
—T. H. P.

Rubber; Thiouram disulphides as vulcanising agents for ——. E. Romani. Giorn. Chim. Ind. Appl., 1921, 3, 197—199.

Tetra-alkylthiouram disulphides, for instance, tetramethylthiouram disulphide,

$$N(CH_3)_2.CS.S.S.CS.N(CH_3)_2,$$

and cyclopentamethylenethiouram disulphide,

$$C_5H_{10}:N.CS.S.S.CS.N:C_3H_{10},$$

are able to effect rapid vulcanisation of rubber without addition of free sulphur. The action is more energetic in presence of certain metallic oxides, *e.g.*, zinc oxide, a mixture of 100 parts of rubber, 5 of tetramethylthiouram disulphide, and 5 of zinc oxide undergoing vulcanisation in 15 minutes at 145° C. These disulphides are crystalline compounds and are obtained most readily by passing a current of chlorine through aqueous solutions of dithiocarbamates of imines, *e.g.*,

$$2N(CH_3)_2.CS.S.NH_2(CH_3)_2+2Cl \rightarrow N(CH_3)_2.CS.S.S.CS.N(CH_3)_2+2NH(CH_3)_2,HCl;$$

the imine hydrochloride may then be used for the preparation of fresh dithiocarbamate.—T. H. P.

Accelerators [of vulcanisation]; Detection of ——. D. F. Twiss and G. Martin. Indiarubber J., 1921, 61, 1283—1284.

Hevea rubber, which forms the bulk of the rubber used to-day, gives an acetone-extract containing approximately 0·03% of nitrogen calculated on the original weight. The organic accelerators of vulcanisation are nitrogenous substances, and their presence in rubber causes a distinct increase in the nitrogen content of the acetone extract. It is thus possible to obtain an indication of the presence of such an accelerator. An analytical scheme is outlined for the identification in rubber of the vulcanisation accelerators most commonly applied.
—D. F. T.

Vulcanisation; Experimental —— on the small scale. D. F. Twiss and S. A. Brazier. Indiarubber J., 1921, 62, 25—27.

A gas-heated oil bath as recommended by van Rossem (J., 1918, 215 A) is very convenient for small-scale vulcanisation experiments, permitting wide variations in the period and temperature with greater accuracy than is possible with vulcanisation by steam-heat. The advantages are most marked when it is desired to prepare samples vulcanised over a range of periods.—D. F. T.

Patent.

Rubber; Vulcanising ——. Ricard, Allenet et Cie. E.P. 157,050, 18.3.20. Conv., 15.1.20.

Rubber is vulcanised with the addition of a small quantity of furfuramide or other nitrogenous furfuryl compound (*cf.* Dubosc, J., 1920, 698 A).
—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Aldehyde tannage. VIII. W. Moeller. Collegium, 1921, 217—220.

Fine hide powder which had been passed through a sieve of 20 meshes per cm. was left in contact with a 30% solution of formaldehyde for a month. The hide powder increased in weight by 7·82% due to the absorption of formaldehyde polymers whilst 24·4% of the formaldehyde was lost from the solution. The difference must be due to formaldehyde retained by the hide powder in a gaseou form or in some other condition which was disturbed by drying the hide powder at 100° C. By treating pelt with a large quantity of 15% formaldehyde solution for two months, it was found to absorb 20·36% of formaldehyde, thus showing that the aldehyde tannage is like other tannages, and that hide substance is capable of taking up large amounts of formaldehyde given sufficient time. This time factor is the only difference between aldehyde and vegetable tannages. The first action of the formaldehyde solution is too energetic, and the hide fibre complexes become choked with formaldehyde polymers. The hide powder experiments are open to the criticism that concentrated formaldehyde solutions would yield a precipitate of polymers more readily, but this criticism cannot be applied to the experiment with the pelt, which shows that the formaldehyde tannage cannot be explained on a purely chemical basis but only by a colloid-chemical conception of the tanning process, viz., the peptisation theory.—D. W.

Synthetic tannins; The bating effect of free sulphonic groups in ——. W. Moeller. Collegium, 1921, 232—236.

Artificial tannins have a slight preliminary tanning effect, but they contain a large amount of free sulphonic acids, which exercise a bating action on the untanned portion of the hide; this action is a function of the concentration, time, and temperature. Different pure sulphonic acids were recommended 30 years ago for bating. Procter ("Principles of Leather Manufacture," pp. 163—164) describes "C. T. Bate," which consists chiefly of naphthalenesulphonic acids. Burns and Hull (J., 1892, 248) used mono- and di-sulphonic acids. Hauff (J., 1895, 130) patented the use of cresolsulphonic acids for bating. All these sulphonic acids are employed in the manufacture of synthetic tannins and are present in the finished products. Synthetic tannins are only weak colloids or "semi-colloids," and consequently only "semi-tannins." Free sulphonic acids are absorbed by the hide owder in tannin analysis, and thus a false idea of he tannin content of synthetic tannins or of mixtures of synthetic and other tannins results. Another method of analysis should be devised for hese synthetic products based on a differentiation etween the dispersed molecules of free sulphonic cids and the polymolecular colloidal tannin contituent. A 10% solution of a synthetic tannin issolved 11·27% of the hide powder with which it as in contact for one month.—D. W.

annins; Physiological importance of ——. F. Czapek. Collegium, 1921, 227—232.

CHLEIDEN suggested that tannins were formed by peculiar transformation of the cellulose in the cell alls. Strecker's discovery of the sugar content of any tannins led to the erroneous conception of nnins as "organised reserve matter." Von hroeder determined the amount of tannin in fferent parts of the tree at different times of the ar and concluded that tannin was the product some oxidation process which was taking place the plant. In 1884, Kraus and Westermaier und that increased illumination of the leaves creased their tannin content, and they thought at tannin was not an excretion or waste product It played a fundamental rôle in plant development. Moeller advanced the view that the tannins re necessary for the migration of carbohydrates a tannin glucosides. Kraus has shown that the c sation of the assimilation of carbohydrates interf es with the tannin formation, and that the f mation of tannins and of sugars in the plant are a ays interdependent. Büsgen has confirmed K us's work showing that leaves exposed to s light contain 3—4 times as much tannin as le es in the shade, and that the formation of ta nin in these shaded leaves can be stimulated by the artificial introduction of sugar. He looks upon tannins as "building material" as instanced in their disappearance from young cork cells. This disappearance may be due to the tannins having become insoluble. Some tannins are mobile in the plant, others are stationary. Tannins can be precipitated in the cells of a plant without injury to the plant. No tannin is formed in the absence of chlorides. Tannins are often formed in conjunction with dyes. The accumulation of tannins in living and dead peripheral tissues has led to the conception of tannins as a protection against animal attack. Microscopical research has shown that tannins are sometimes dissolved in the cell sap and sometimes present as oily drops. Tannin vacuoles are formed in the meristem tissue only; their contents are looked upon as excreta. A complete list of references is appended.—D. W.

Tannins and similar substances. VII. Stereoisomeric catechins. K. Freudenberg, O. Böhme, and A. Beckendorf. Ber., 1921, 54, 1205—1213.

Acacatechin can be converted into 2.4.6.3′.4′-pentamethoxy-αγ-diphenylpropane according to the method used previously for gambier catechin (J., 1920, 729 A). The optical activity of the catechins is generally so slight as to be readily overlooked; their derivatives, however, are much more active. Examination of the penta-acetates and pentabenzoates proves that Gambier catechin is to be regarded as homogeneous *d*-catechin whilst acacatechin is a mixture of the corresponding *r*- and *l*-forms. Probably the pure *l*-variety is present in acacia catechin and partial racemisation occurs during the necessarily rather drastic extraction of the substance. (*Cf.* J.C.S., Aug.)—H. W.

Leather chemistry analysis; Contributions to ——. G. Grasser. Collegium, 1921, 224—227.

I. *Chemical control of deliming.*—2 g. of pelt for deliming is placed in a beaker with 20 c.c. of distilled water and the amount of acid required for deliming is added together with increasing amounts of common salt (0·2, 0·3, 0·4 g. etc.). The specimens are allowed to stand 2—3 hrs. with frequent shaking, and the residual acid is titrated and the pelt drained and weighed. An increase in this weight indicates swelling, which is undesirable. The greater the loss in weight, the more suitable is the composition of the deliming liquor. If free acid remains the control should be repeated with less acid. II. *Qualitative tannin analysis.*—A moderate excess of bromine water precipitates even pyrogallol-tannins, forming oxidation products. A large excess renders the precipitate of bromine compounds of catechol-tannins soluble and thus prevents a distinction of these two classes of tannins by this test. Most tannins which do not yield insoluble methylene compounds with formaldehyde and hydrochloric acid, give a distinct turbidity owing to the formation of phlobaphenes by the action of the acid and heat. To distinguish a true precipitate excess of sodium hydroxide is added; this will dissolve the phlobaphenes but not the methylene compounds. Colour changes with lime water and tannin solutions only occur in presence of atmospheric oxygen; hence it is necessary for precipitation to occur near the surface of the liquor. The first green precipitate gradually changes to red-violet in the case of galls, cutch, knoppern, and mimosa, and to magenta-red with oakwood and chesnut wood tannins. The slow oxidation in the liquor gives misleading colour changes. The sulphuric acid reaction with mimosa and quebracho is given when a dilute solution of sulphited quebracho extract is evaporated in a porcelain dish without the addition of sulphuric acid. A violet colour appears round the edges. III. *Three-bath chrome tannage.*—The total chromium is determined as CrO_3 by oxidation with sodium peroxide and iodometric titration. The chromic acid is determined volumetrically with iron alum and bichromate. The free chromic acid is deducted from the total CrO_3 and the difference multiplied by 3·392 to convert it to chrome alum. IV. *Reduction baths* contain thiosulphate and sulphuric acid or bisulphites. The total sulphur dioxide (A) is determined iodometrically and the total acid (B) by titration and calculated as SO_2. If $A=B$ there is no unchanged thiosulphate present and no free sulphuric acid. If $B>A$ then free sulphuric acid is present and it can be calculated from (B—A). If $B<A$ then some unchanged thiosulphate is present and it can be calculated from (A—B). In the case of bisulphite reduction baths A only is required.—D. W.

Leather; Determination of sugary matter in ——. J. C. van der Hoeven. Collegium, 1921, 220—224.

The aqueous extract from 10 g. of leather is detannised and inverted as usual (see "Leather Chemists' Pocket Book," 1912) and a measured quantity of the solution is mixed with 10 c.c. of each of the components of Fehling's solution and made up to 50 c.c., boiled 3 mins. over a bare flame, 2 mins. over a wire gauze, and quickly cooled but not below 25° C. After adding 3 g. of potassium iodide in 10 c.c. of water and 10 c.c. of 25% sulphuric acid the mixture is shaken and titrated with *N*/10 sodium thiosulphate. The difference from a blank determination shows the amount of copper sulphate reduced by the glucose present and from this the amount of glucose can be obtained by reference to tables.—D. W.

Patents.

Artificial tanning substances; Manufacture of ——. M. Melamid. E.P. 147,534, 25.5.21. Conv., 15.7.19. Addn. to 137,323 (J., 1921, 442 A).

Anthracene oil boiling between 100° and 280° C. (12—15 mm.) is sulphonated with twice its weight of 100% sulphuric acid at 50°—60° C. until the mass is soluble in water, when the product is dissolved in water, neutralised with sodium hydroxide, and the bulk of the sodium sulphate removed by crystallisation; the acid mixture may be partly neutralised with lime and completely with sodium hydroxide. The tanning substances produced precipitate gelatin in the presence of acid. The use of aromatic sulphochlorides and the alkali treatment of the anthracene oil (*loc. cit.*) are avoided.—D. W.

Iron-alkali lactates. G.P. 335,475. *See* VII.

XVI.—SOILS; FERTILISERS.

Soil; Results of partial sterilisation of —— *by heat.* Elveden. J. Agric. Sci., 1921, **11**, 197—209.

An attempt was made to determine the depth to which it is necessary to heat soils, in order to produce maximum partial-sterilisation effects. Layers of soil from varying depths were removed and steamed, and crops of mustard subsequently grown in them. The depth showing maximum crop increase was 16—18 ins. in a rich garden soil and 8—10 ins. in a field soil. No accumulation of substances toxic to plants was apparent at any particular depth. The percentage crop increase brought about by steaming was greater for rich soils than for poor and also greatest at depths showing the largest accumulation of plant food. The benefits of steaming were apparent in several successive crops, but were of a gradually decreasing order. Successive heat treatments of the same soil continued to produce increase in crop. Dry heating by flame and by electricity was less successful than steaming. Russell's theory that the benefits of partial sterilisation are due merely to the destruction of protozoa is questioned. Admixture of untreated with steamed soil did not mask the effects of the heat treatment and crops grown in such mixed soils varied with the proportion of steamed soil present.—A. G. P.

Soil; Dephenolisation in ——. N. N. Sen-Gupta. J. Agric. Sci., 1921, **11**, 136—158.

The decomposition of phenol in soil is effected by three distinct processes, viz., by biological means, by a rapid chemical process, and by a slow chemical or physical action. Any or all of these processes may be operative, according to the type of soil. Two types of bacteria have been isolated which are able to decompose phenol in culture solutions. An organism capable of decomposing *m*-cresol has also been isolated. The effects of heat, moisture content, and partial sterilisation on the power of soils to decompose phenol are described. The rate of disappearance of phenol in soil can be considerably augmented by repeated treatment with phenol and still more by treatment with 50% sulphuric acid. The very rapid disappearance of phenol in contact with soil appears to vary with the clay content. The factor causing loss of phenol is destroyed by autoclaving the soil at 130° for ½ hr. or by steaming it at 100° C. for 1 hr. For the estimation of phenol, two colorimetric methods were used:—The first, which utilises the colour given by phenol with Millon's reagent and nitric acid, gives 98% accuracy for quantities down to 0·25 mg. of phenol in 35 c.c. of water. The second method, which consists in comparing colours produced by nitrating phenol and rendering alkaline with ammonia, is less accurate than the first and is used for quantities of phenol between 0·25 and 0·01 mg.—A. G. P.

Finely divided material; Effect of —— *on the freezing point of water, benzene, and nitrobenzene.* F. W. Parker. J. Amer. Chem. Soc., 1921, **43**, 1011—1018.

Finely divided material, such as ferric hydroxide, alumina, and silica, causes a depression of the freezing point of a liquid when the liquid exists in the film or capillary condition in the solid material. This effect adds itself to that produced by any dissolved substance in the liquid. The bearing of the results on the hypothesis of Bouyoucos as to the condition of the water in soil (J., 1921, 231 A) and on the determination of the concentration of soil solution by the freezing point method is discussed (*Cf.* J.C.S., July.)—J. F. S.

Calcium cyanamide; Increasing the efficiency o
crude ——. M. Popp. Deuts. Landw. Presse 1920, [90], 617. Bied. Zentr., 1921, **50**, 216—220

The fertilising effect of crude calcium cyanamide i
improved by admixture with the soil-disinfectan
known as "Humus-Carbolineum," prepared fro
lignite (Biedermann's Zentr., 1920, **49**, 88). Detail
of field-trials with oats and potatoes are given
—A. G. P.

Ammoniacal liquor; Use of —— *for producin*
fertilisers. C. Bongiovanni. Staz. sperim. agra
ital., 1919, **52**, 521—523. Chem. Zentr., 192
92, II., 956.

By treating superphosphate with ammoniac
liquor, cyanides and cyanates are volatilised, and a
odourless, non-hygroscopic fertiliser is produce
containing 12·48% of water, 12·58% of P_2O_5 solub
in water and citrate, and 3% of nitrogen.—W. J.

Patents.

Fertiliser; Process for converting ammonia into
salt [ammonium chloride] for use as a —
Badische Anilin- u. Soda-Fabrik. E.P. 144,6
8.6.20. Conv., 10.7.15.

In the ammonia-soda process, instead of employi the same ammonia continuously in a circulating system, synthetically produced ammonia is introduced. The ammonium chloride formed is extracted from the mother liquors, on separation of the sodium bicarbonate, by alternate concentrating and cooling, the sodium chloride being removed from the hot solution. It is advantageous to combine the synthetic ammonia and the ammonia-soda process still further, by oxidising part of the ammonia and absorbing the nitrogen oxides by the sodium bicarbonate.—W. J. W.

XVII.—SUGARS; STARCHES; GUMS.

Cane juice; Clarification of —— for the manufacture of white sugar, using magnesium acetate M. Ishida. Int. Sugar J., 1921, 23, 282—283.

Magnesium hydroxide is proposed as a reagent for the clarification of cane juice on the technical scale. In the laboratory 500 c.c. of raw cane juice heated at 80° C. was treated with 0·08 c.c. of 15% ammonia and 0·25 c.c. of 1·82% magnesium acetate, and the clear liquid obtained on the subsiding of the precipitate treated with 0·4% of milk of lime of 15° B. (sp. gr. 1·116). An increase of purity amounting to about 8°, and the removal of 80% of the gums and pectins, 25% of the nitrogenous substances, and about 30% of the mineral matter originally present, was effected by this treatment. It is stated that caramel is also removed by magnesium hydroxide when this precipitate is formed in the body of the juice.—J. P. O.

Leaf type filters compared with plate and frame presses [in the sugar cane factory]. L. W. Thurlow. Sugar News, 1920, 1, No. 15, 21—26.

Advantages claimed as the result of factory tests in a Philippine central for the leaf type in comparison with ordinary plate and frame presses for the filtration of the mud from the settling tanks are: The sugar in the cake may be washed out with less water, and more quickly; the difference between the purity of the unfiltered muddy liquid and the filtered juice is much less, and that between the filtered juice and the wash water is likewise less; one set of cloths may last the entire season; opening, closing, and cleaning can be done in about one-third the time; and lastly the capacity for equal filtering areas is about double. A foreman and three labourers are considered sufficient to handle the press and mud tanks of a 1000-ton factory.
—J. P. O.

Sugar; Loss of —— through the presence of fine grain in the final molasses. J. Dedêk. Listy cukrovarnické. Int. Sugar J., 1921, 23, 327—330.

If much water be used for the solution of the crystals, Kalshoven's method of determining fine grain in waste molasses and other sugar products (J., 1920, 126 a) yields results appreciably higher than the truth, owing to contraction occurring on dilution. Solution of the fine grain should be effected by heating the undiluted product in a sealed tube in a glycerin-bath at 110° C. for ½ hr., while mixing from time to time, the refractometer reading after cooling being compared with that of the unheated product. Beet final molasses was found to contain on an average 6·9% of fine grain by this method.—J. P. O.

Dextrose; Method of applying to plants the biochemical process for the detection of ——. M. Bridel and R. Arnold. Comptes rend., 1921, 172, 1434—1436. (*Cf.* J., 1920, 344 a.)

The sugars are extracted from the leaves or other plant material with boiling ethyl alcohol and the extract purified in the usual manner. The residue is finally dissolved in 50% methyl alcohol, emulsin is added, and the mixture is left to stand at 20° C. The amount of reducing sugars present in this mixture is estimated at the commencement and every ten days. A diminution in the amount is indicative of the presence of dextrose in the original plant material.—W. G.

Inulin. H. Pringsheim and A. Aronowsky. Ber., 1921, 54, 1281—1286.

Inulin is converted by a hot mixture of acetic anhydride and pyridine into triacetylinulin, m.p. 102°—103° C. after softening at 95°, $[\alpha]_D^{20°}=-42{\cdot}55°$ in glacial acetic acid solution. The mean molecular weight of the compound in naphthalene, glacial acetic acid, and phenol respectively is 2633, which corresponds most closely with the presence of nine lævulose residues in the molecule, and is thus in excellent agreement with the recent observations of Karrer and Land (Helv. Chim. Acta, 1921, 4, 249) on methylated inulins. When hydrolysed with ice-cold, alcoholic potassium hydroxide solution it regenerates inulin.—H. W.

Beetroots; The polyoses in rotten ——. E. Votocek. Bull. Soc. Chim., 1921, 29, 409—413.

The complex polyoses of rotted beetroots consist of lævulans with a small amount of glucosans (generally less than 10%), the relative proportions varying slightly with the source of the roots; pentosans and galactosan were absent.—W. G.

Autolysis of starch. Biedermann. *See* XVIII.

Patents.

Syrups and sugar; Manufacture of ——. F. Patterson. E.P. 163,924, 16.6.20.

Dates are subjected to the action of moist air at a temperature between 150° and 300° F. (65·5°—149° C.), just insufficient to cause caramel production, and, while still hot, are mixed with hot water. The mass is partially concentrated by evaporation, strained, and further concentrated.—H. H.

Lactose or milk sugar; Method for the purification of crude ——. J. Tavroges, J. W. Roche, and G. Martin. E.P. 163,937, 22.7.20.

A solution of the crude lactose is treated with a sulphite, a hydrosulphite, or sulphurous acid, heated to 80° C., filtered, and evaporated.—H. H.

Extracting materials. E.P. 146,453. *See* I.

Emulsifying calcium salt solutions. G.P. 334,766. *See* VII.

XVIII.—FERMENTATION INDUSTRIES.

Fermentation; Influence of electric potential upon the velocity of ——. M. C. Potter. Proc. Univ. Durham Phil. Soc., 1915-1920, 6, 16—21.

The fact that a rise of potential of 0·3—0·5 volt is produced by the growth of yeast in a fermentable liquid suggested that the electric potential of the medium might have some influence on the velocity of fermentation, but no difference in the rate of fermentation of dextrose, as measured by the rate of evolution of carbon dioxide, or polarimetrically by the rate of disappearance of the sugar, could be detected, either when the medium was earthed, or raised to a positive or negative potential of 210 volts.—G. F. M.

Fermentation; Studies in ——. VII. The organic component of diastase and the true nature of the autolysis of starch. W. Biedermann. Fermentforsch., 1921, 4, 359—396.

By extracting with dilute aqueous sodium chloride the precipitate produced by shaking saliva with alcohol, a solution with strong diastatic properties is obtained. Alcohol precipitates from this solution a substance, to which the name saliva-albumose is given, resembling partly a protein and partly an albumose. It is purified by repeated precipitation from aqueous or dilute salt solution. The author regards this substance as the organic component (zymogen) of diastase. In salt-free aqueous solution it is inactive, but by activating with 0·5—1% sodium chloride (co-enzyme) and diluting to the volume of the saliva from which it was derived, the diastatic power of the latter is reproduced or even slightly increased. Further, the diastatic power of saliva, which varies with the source, is directly proportional to the amount of saliva-albumose which it contains. Extracts of commercial maltase preparations, white of egg, and gum arabic give reactions which are characteristic of saliva-albumose; it is therefore considered that all amylases, independent of their source, are identical. The author abandons his former view that the new formation of diastase is the cause of the autolysis of starch, and now considers that the starch grains are contaminated with traces of enzyme. This is directly proved by extracting starch with dilute aqueous sodium chloride; the solution so obtained quickly brings an approximately equal volume of amylose solution to the achromic point. Further, the non-destruction of the enzyme by heat in the preparation of starch is explained by the properties of saliva-albumose. Thus, when an aqueous solution of this substance is heated to between 60° and 100° it is decomposed into two components, one of which is coagulated while the other separates on cooling. The diastatic power of the solution decreases as the coagulum increases; nevertheless even after continued heating it is not completely destroyed. Moreover, mucin, neutralised gelatin, and starch paste exercise a protective action against heat. Finally it is shown that salt solutions, when boiled, lose to a great extent and for some time their activating power.—E. S.

Yeast cells; Chemico-physiological study of ——. II. Application of experiments which serve generally to demonstrate the existence of vitamins to the physiological study of yeast-cells. K. Schweizer. Bull. Assoc. Chim. Sucr., 1921, 38, 304—315.

The action of various fractions of autolysed yeast upon living yeast suspended in pure sucrose solution was measured by the amount of carbon dioxide evolved. The fractions used in the first series of experiments were the alcohol-soluble and alcohol-insoluble portions, and in the second series the cell walls and the cell contents. In both series the separate action of the fractions was small compared with that of autolysed yeast itself. The action of the latter was, however, reproduced in each case by uniting the two fractions. The nutritive value of autolysed yeast is diminished by heating for 2 hrs. in an autoclave.—E. S.

Fermentation of glucose [dextrose] and fructose [lævulose] by yeast-juice and zymin in presence of phosphate and arsenate; Effect of acetaldehyde and Methylene Blue on ——. A. Harden and F. R. Henley. Biochem. J., 1921, 15, 175—185.

Acetaldehyde diminishes the time required by a lævulose and phosphate mixture to attain its maximum rate of fermentation in the presence of yeast-juice or zymin, but the maximum rate obtainable is not substantially increased; acetaldehyde is fifty times as effective as lævulose in accelerating the fermentation of a dextrose-phosphate mixture, and in its presence lævulose is fermented more rapidly than dextrose. Methylene Blue behaves like acetaldehyde. Arsenate does not affect the action of yeast-juice, but causes a considerable acceleration with zymin.—G. B.

Alcoholic fermentation; Salt effect in ——. A. Harden and F. R. Henley. Biochem. J., 1921, 15, 312—318.

As found by Meyerhof, chlorides and particularly sulphates of sodium and potassium depress the maximum rate of fermentation, and the rate of attainment of this maximum. Salts diminish the rate of action of hexosephosphatase, but have no effect on carboxylase. The depressing effects of potassium sulphate and of excess of phosphate differ in character, the latter being greatly diminished by addition of acetaldehyde, whereas the former is practically unaffected.—G. B.

Azotobacter; Influence of the nitrogenous material elaborated by —— on alcoholic fermentation. E. Kayser. Comptes rend., 1921, 172, 1539—1541.

The addition of a culture of *Azotobacter*, even in small proportion, to an alcoholic fermentation, checks, as a rule, the multiplication of the yeast, increases the decomposition of sugar, and may stimulate the zymase action and increase the yield of alcohol. The type of yeast, the age of the bacterial culture, and the manner in which it is used are important factors in determining the result.
—W. G.

Enzyme action; Influence of the structure and configuration of substrates (polypeptides) on ——. E. Abderhalden and H. Handovsky. Fermentforsch., 1921, 4, 316—326.

Yeast maceration juice hydrolyses glycyl-*l*-leucine and glycyl-*l*-leucylglycyl-*l*-leucine, but does not attack glycyl-*d*-leucine or glycyl-*d*-leucylglycyl-*l*-leucine. The two latter compounds contain the *d*-leucyl group, which does not occur naturally; it is therefore concluded that enzymes do not hydrolyse polypeptides which contain as one unit the enantiomorph of a naturally occurring amino-acid. Evidence was obtained of a combination between glycyl-*d*-leucylglycyl-*l*-leucine and the enzyme; hence it is not the combination substrate+enzyme, but the actual hydrolysis itself which is specific. (*Cf.* J.C.S., Aug.)—E. S.

Polypeptides; Cleavage of —— by enzymes. E. Abderhalden and H. Kürten. Fermentforsch., 1921, 4, 327—337.

d-*l*-α-Amino-*n*-valeric acid (norvaline) was prepared and resolved in the usual manner and converted into glycyl-*d*-norvaline and glycyl-*l*-norvaline. Of these two optical isomerides the former only is hydrolysed by yeast maceration juice. The possibility of the natural occurrence of the hitherto unknown *d*-norvalyl unit is therefore not excluded. (*Cf.* J.C.S., Aug.)—E. S.

Tyrosinase; Identification of ——. The tyrosinase reaction. H. Haehn. Fermentforsch., 1921, 4, 302—315.

The presence of tyrosinase is best proved by the action of α-tyrosinase, after separation and activation with different neutral salts, upon solutions of tyrosine; characteristic colour reactions are obtained which differ with the particular salt used. By this method the identity of the tyrosinase in potatoes, red-mushrooms, and meal-worms is established. The function of the salt is twofold: it first activates the α-tyrosinase and finally precipitates the colloidal melanin.—E. S.

Patent.

Fermentation processes for production of acetone and butyl alcohol. C. Weizmann and G. A. Hamlyn. E.P. 164,023, 29.6.16.

See U.S.P. 1,329,214 of 1920; J., 1920, 276 A.

XIXA.—FOODS.

Milk; Investigation of the antiscorbutic value of full cream sweetened condensed —— by experiments with monkeys. E. M. Hume. Biochem. J., 1921, **15**, 163—166.

In full-cream sweetened condensed milk prepared by concentration at a low temperature *in vacuo* there is no destruction of vitamin, so that if the condensed milk is diluted to its original volume by addition of three volumes of water the vitamin content may be said to be adequate. If, however, it is diluted eight times or more, according to instructions, its vitamin content may be inadequate, although, owing to its higher sugar content, it still gives an adequate supply of calories.—G. B.

Dried milk; Antiscorbutic value of ——. H. Jephcott and A. L. Bacharach. Biochem. J., 1921, **15**, 129—139.

The antiscorbutic value of summer and winter milks dried by the roller process were found to be about equal to one another and to those of the original raw milks. Milk neutralised with sodium bicarbonate before drying had a slightly inferior antiscorbutic value, and milk dried by the spray process was markedly deficient in antiscorbutic value. The dose required of reconstituted summer and winter dried milks was 26 c.c. per 100 g. of body weight. (*Cf.* Hart and others, J., 1921, 406 A.)
—G. B.

Milk; Distribution of saline and mineral substances in ——. C. Porcher and A. Chevallier. Comptes rend., 1921, **172**, 1605—1607.

s a first approximation based on the composition f an artificial milk in which all the chemical and hysico-chemical relations of the components of he milk correspond to an average milk, the disribution of the mineral ingredients of milk is iven as follows:—1 l. of milk contains 1·09 g. odium chloride, 0·92 g. potassium chloride, 1·78 g. alcium citrate, 0·76 g. magnesium citrate, 0·67 g. otassium citrate, 0·25 g. sodium bicarbonate, 0 g. monopotassium phosphate, 1·10 g. dipotasum phosphate, 1·06 g. dicalcium phosphate, ·16 g. dimagnesium phosphate, 0·18 g. potassium lphate, 0·61 g. calcium caseinate.—W. G.

roteins of cow and ox serum, cow's colostrum and cow's milk; Comparative investigation of the corresponding —— by the method of protein racemisation. H. E. Woodman. Biochem. J., 1921, **15**, 187—201.

y following the rate of partial racemisation by kali of proteins under definite conditions a racemisation curve" is obtained which permits the identity or non-identity of proteins being tablished more rapidly than by Dakin's method volving isolation of amino-acids. Lactalbumin d serum albumin are two distinct proteins, but globulin and pseudoglobulin from different rces are identical.—G. B.

ets consisting of natural foodstuffs; Comparison f the growth-promoting properties of —— for uinea pigs. E. M. Hume. Biochem. J., 1921, **5**, 30—48.

RMER experiments with guinea pigs on the antirbutic properties of foodstuffs are analysed with erence to the promotion of growth, ascribed here vitamin A, and guinea pigs are recommended a suitable substitute for rats in testing the amin A value of non-fatty foodstuffs. Growth k place with green cabbage and its juice, hay, l milk (raw, heated, or dried), but not with te cabbage juice, swede juice, orange juice, ons, or germinated peas.—G. B.

Citrus fruit juices; Determination of the minimum doses of some fresh —— which will protect a guinea pig from scurvy, together with some observations on the preservation of such juices. A. J. Davey. Biochem J., 1921, **15**, 83—103.

The minimum daily doses are for the juice of the lemon 1·5 c.c., of the orange 1·5 c.c., of the lime 5 c.c., confirming the inferiority of lime juice. Preservation with sulphite at 0° C. is satisfactory, at room temperature uncertain, at 37° C. useless. Orange and lemon juices lose but little in activity during two years at room temperature when preserved with the rind oil. Preservation at 37° C. has so far been unsuccessful in every case, but might possibly be attained by previous sterilisation at 100° C. for 1 hr., which process does not materially diminish the antiscorbutic potency. (*Cf.* J., 1921, 318 A.)—G. B.

Sun-dried vegetables; Antiscorbutic and antiberi-beri properties of certain ——. J. A. Shorten and C. B. Ray. Biochem. J., 1921, **15**, 274—285.

Tomatoes, potatoes, and cabbage dried in the sun (at Quetta) retain to a considerable extent the antiscorbutic properties of the fresh vegetable; sun-dried carrots, brinjal, spinach, turnips, and turnip-tops have little or no antiscorbutic properties; mixed factory-dried vegetables are entirely devoid of antiscorbutic properties. Six varieties of vegetables examined, in daily rations of 10 g., protected common fowls against neuritis.—G. B.

Carbohydrate content of the navy bean. W. H. Peterson and H. Churchill. J. Amer. Chem. Soc., 1921, **43**, 1180—1185.

A 1917 sample of navy beans contained 58·97% of nitrogen-free extractives, of which 35·2% was starch and 8·37% pentosans. A 1919 sample contained 61·80% of nitrogen-free extractives, of which 50·54% was total reducing substances calculated as starch. Alaska garden peas contained 60·26% of nitrogen-free extractives and 1·21% of starch, and Canadian field peas contained 54·47% of nitrogen-free extractives and 45·11% of starch. The completeness of digestion of legumes by malt diastase is greatly enhanced by grinding, but prolonging the digestion from 4 to 10 hrs. gave but a very slight increase in the percentage of starch found. The authors do not consider the iodine test for starch a satisfactory means of determining when to stop digestion.—W. G.

Agar-agar [in jams]; Detection of ——. A. E. Parkes. Analyst, 1921, **46**, 239—240.

To detect agar-agar in jams, 50 g. of the sample is mixed with 500 c.c. of water at 50° C., allowed to settle, and filtered; the insoluble matter is washed with water at 50° C., then transferred to a porcelain basin and boiled with 50 c.c. of water. The hot mixture is filtered and the filtrate cooled. If an appreciable amount of agar is present, the filtrate will set to a gel; if only a small quantity (*e.g.*, 0·1%) is present, the filtrate must be evaporated to a small bulk before cooling.
—W. P. S.

Higher plants; Nitrogenous metabolism of ——. I. Isolation of proteins from leaves. A. C. Chibnall and S. B. Schryver. Biochem. J., 1921, **15**, 60—75.

Green leaves were extracted with water saturated with ether; on warming the opalescent solution to 40° C. a colloidal precipitate containing 10% N was deposited, consisting of crude protein; methods of partial purification are described. The purified proteins from cabbage, spinach, and scarlet runners contained about 13% N. When freshly prepared the two former were soluble, whilst the last-named was insoluble in weak aqueous alkali.—G. B.

Rhizome of Phragmites communis, Trin., and, in particular, its sugar content. T. Sabalitschka. Arch. Pharm., 1921, 259, 102—110.

During the war the rhizome of *Phragmites communis* was used in Germany for the manufacture of fodder. Complete analysis of the powdered rhizome, harvested at the end of November, shows the presence of water 5·3%, nitrogenous compounds 5·2%, fat 0·9%, nitrogen-free extract 50·8%, crude fibre 32·0%, and ash 5·8% (containing 3·3% sand). Reducing sugars 1·056%, sucrose 5·08% and dextrins and similar compounds 0·5% are present in the nitrogen-free extract.—H. W.

Oil of oats. Paul. *See* XII.

Illipé butter and cacao butter. Tate and Pooley. *See* XII.

Patents.

Food compound and process of making same. W. Horlick, jun. E.P. 140,472, 20.3.20. Conv., 22.1.18.

A mash formed from barley malt and gelatinised potato pulp is added to a similar mash formed from barley malt and wheat or other cereal flour. The wort extracted from the mixture is added to milk, and the product is dried.—H. H.

Fish and the like; Process and apparatus for drying ——. E. C. Krebs. E.P. 163,549, 23.3.20.

The material (fish etc.) is conveyed through a chamber and is dried by a current of air passed through the chamber in the opposite direction. Before entering the chamber, the air is cooled to 0° C. to remove the greater part of its moisture, and is then heated to about 20° C., and its temperature is raised gradually to about 30° C. as it passes through the chamber. The same air may be used over again after it has been cooled and heated, and the material as it passes through the chamber may be subjected to the action of ultra-violet rays. —W. P. S.

Subjecting substances to an electric discharge. E.P. 163,823. *See* XI.

Syrups. E.P. 163,924. *See* XVII.

Lactose. E.P. 163,937. *See* XVII.

XIXb.—WATER PURIFICATION; SANITATION.

Hardness [of water]; Soap solution for determining the ——. A. Krieger. Chem.-Zeit., 1921, 45, 559—560.

The soap solution recommended by the author for use in hardness determinations (J., 1921, 236 A) is prepared by dissolving 20 g. of potassium soap (Merck) in 50 c.c. of water and diluting to 700 c.c. with 94% alcohol. The results obtained in comparative estimations with the above solution and Clark's solution were in close agreement; in both cases it is advisable to dilute the sample if the hardness exceeds 12°. The use of the stronger soap solution in conjunction with a special Mohr burette instead of a hydrotimeter has proved to be advantageous and effects a considerable economy in the consumption of alcohol.—W. J. W.

Lead in peaty waters [; Detection of ——]. T. Tickle. Analyst, 1921, 46, 240—231.

The brown colour of certain peaty waters interferes with the detection of traces of lead by the alkaline sulphide test. To eliminate the colour, the water is treated with a slight excess of permanganate, then rendered ammoniacal, and kept for 48 hrs.; the precipitate which forms contains the whole of the lead and may be collected on a filter, dissolved in hydrochloric acid (a colourless solution results), and the solution tested for lead in the usual way.—W. P. S.

Fluorescein; Detection of —— in very dilute solutions [water]. M. Lombard. Bull. Soc. Chim., 1921, 29, 462—464.

To 30 c.c. of the water under examination are added a few drops of dilute sulphuric or hydrochloric acid, free from chlorine, and the solution shaken with a small amount of ether. When the ethereal layer, which should be 3—4 mm. deep, has separated completely, a few drops of ammonia are added and the tube shaken round gently. The development of a green colour in the ethereal layer, gradually passing into the aqueous layer, indicates fluorescein in the original solution. The test is sensitive at a dilution of 1 in 200,000,000 and can be made sensitive at a dilution of 1 in 500,000,000, by using 200 c.c. of water and making a double extraction with ether.—W. G.

Permutite; Equilibria of bases in ——. A. Günther-Schulze. Z. anorg. Chem., 1921, 116, 16—20.

Experiments on basic exchange in permutites were made by shaking a known weight of pure sodium-, potassium-, or ammonium-permutite with a measured volume of a solution of a metallic salt of known concentration, and by analysis of the solution determining how much of the base was removed from the solution by the permutite. The bases examined were copper, magnesium, zinc, nickel, cobalt, manganese, chromium, aluminium, calcium, strontium, barium, lead, thallium, silver, rubidium, and uranyl. Generally the behaviour of the bases was in accordance with the degree of dissociation of the corresponding permutites. Silver and thallium, however, the permutites of which are dissociated similarly to those of the alkali metals, were almost entirely removed from solution, whilst nickel and cobalt, which, on account of the low dissociation of their permutites, would be expected to go into the permutite, remained almost entirely in solution. It is a fairly general rule that the higher the atomic weight of the metal, the more readily it is removed by the permutite from solution, but aluminium provides an exception to this rule.—E. H. R.

Permutites; Equilibria of ——. F. W. Hisschemöller. Rec. Trav. Chim., 1921, 40, 394—432.

The transformations sodium permutite $\rightleftarrows$ ammonium permutite show false equilibria (chemical hysteresis) which disappear after repeated transformations at the ordinary temperature. The position of the real line of equilibrium is displaced by repeated transformations with warm solutions. By keeping the permutite in the dry state the positions of both the false and true equilibria slowly change, the hysteresis diminishing but not disappearing. An industrial permutite behaves like a laboratory preparation which has been kept for some time, and in such cases a single transformation results in the almost complete disappearance of the hysteresis. The position of the false and true equilibria are independent of the dilution and the size of the particles in the transformation sodium permutite $\rightleftarrows$ ammonium permutite. The transformation sodium permutite $\rightleftarrows$ calcium permutite also show hysteresis which is not suppressed by a single transformation. The final states depend on the dilution but agree only qualitatively with the formula o Rothmund and Kornfeld (*cf.* J., 1918, 559 A). —W. G.

Carbon monoxide; Oxidation of —— by passage with oxygen or air through the silent discharge and over ozone-decomposing catalysts. A. B. Ray and F. O. Anderegg. J. Amer. Chem. Soc., 1921, **43**, 967—978.

Carbon monoxide is completely oxidised when passed with oxygen or air through a silent discharge. The oxidation is more readily effected by passing a mixture of air or oxygen with carbon monoxide and ozone over a catalyst, such as silver, which destroys the ozone. Lead and lead dioxide are less efficient catalysts, whilst manganese dioxide, unless specially prepared, is ineffective although it completely destroys the ozone. The best results are obtained, both with regard to time and energy, when the undried air-carbon monoxide mixture is passed through a very large silent discharge unit and then over silvered asbestos. (*Cf.* J.C.S., July.) —J. F. S.

Rusting of boilers. Bruhns. *See* I.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Scopoline. J. Gadamer and F. Hammer. Arch. Pharm., 1921, **259**, 110—135.

The formula for scopoline advanced by Hess (Ber., 1919, **52**, 1949) is adversely criticised. His work has therefore been repeated using, however, the optically active bases (King, Chem. Soc. Trans., 1919, **115**, 496) as initial products; the results are considered to be in harmony with a more symmetrical formula. (*Cf.* J.C.S., Aug.)—H. W.

Salvarsan and neosalvarsan; Action of mercuric chloride on ——. A. Binz and H. Bauer. Z. angew. Chem., 1921, **34**, 261—263.

Salvarsan and mercuric chloride form in alcoholic solution an orange-red addition product, but in an aqueous medium this rapidly becomes greenish-black owing to decomposition, colloidal mercury being formed and the salvarsan oxidised to 3-amino-4-hydroxyphenylarsine oxide, $(OH)(NH_2)C_6H_3.AsO$. Unless an excess of mercuric chloride is present the oxidation does not appear to proceed further, but with a sufficient excess the reaction products are aminophenol, mercurous chloride, and arsenious acid. With neosalvarsan the reaction with mercuric chloride is more complicated, and depends largely on the relative proportions of the two substances present. With an excess of neosalvarsan at least six reaction products were identified, namely, col-oidal mercury and neosalvarsanic acid,

$(NH_2)(OH)C_6H_3.As:As.C_6H_3(OH)(NH.CH_2OSOH)$

produced in predominating amount as the result of all the possible parallel reactions, together with esser quantities of formaldehyde-sulphurous acid, $CH_2(OH)OSO_2H$, 4.4′-dihydroxy-3-amino-3′-iminomethylenesulphurous-acid-arsenobenzene, hydroxy-minophenylarsine oxide, and hydroxyiminomethyl-nesulphurous acid-phenylarsine oxide,

$(OH)C_6H_3(AsO)(NH.CH_2.OSO_2H)$.

Certain of the latter substances are certainly oisonous.—G. F. M.

.5′-Mercuri-bis-3-nitro-4-hydroxyphenylarsonic acid; Preparation of ——. J. Stieglitz, M. Kharasch, and M. Hanke. J. Amer. Chem. Soc., 1921, **43**, 1185—1193.

When a suspension of 3-nitro-4-hydroxy-5-acetoxymercuriphenylarsonic acid (*cf.* Raiziss and others, . Biol. Chem., 1919, **40**, 533) in water is boiled with odium thiosulphate it yields 6.6′-mercuri-*bis*-2-itrophenol, but if the sodium thiosulphate is re-aced by sodium sulphide the final product is 5.5′-ercuri-*bis*-3-nitro-4-hydroxyphenylarsonic acid, hich gives a crystalline ammonium salt. Mercury compounds of the type R.Hg.R may be distinguished from those of the type R.HgX, where R is an aryl radical and X is inorganic, by the fact that the former do not react with alkaline sodium stannite, whereas the latter are decomposed and give a precipitate of metallic mercury.—W. G.

Glyoxal; Action of alkalis on ——. B. Homolka. Ber., 1921, **54**, 1393—1396.

An aqueous solution of glyoxal, or preferably of its compound with sodium bisulphite, is converted by atmospheric oxidation in the presence of sodium carbonate into the sodium salt of tetrahydroxy-*p*-benzoquinone. The same substance, together with rhodizonic, croconic, and much glycollic acid, is produced in the presence of sodium hydroxide. Rhodizonic acid is also produced by the action of normal sodium sulphite on an aqueous solution of glyoxal or, in poorer yield, on a solution of sodium dihydroxytartrate. (*Cf.* J.C.S., Aug.).—H. W.

Sweetening agents; Artificial ——. A. F. Holleman. Rec. Trav. Chim., 1921, **40**, 446—450.

Benzene-o-disulphonamide, described by Armstrong and Napper (Proc. Chem. Soc., 1900, **16**, 160), is shown to be the ammonium salt of the imide, $C_6H_4:(SO_2)_2:N.NH_4,H_2O$. The corresponding sodium and calcium salts and the free imide have been prepared. The latter has a sweet and acid taste with a bitter after-taste.—W. G.

Wood and vanillin; Reagent for ——. J. Grüss. Ber. deuts. Botan. Ges., 1921, **38**, 361—368. Chem. Zentr., 1921, **92**, II., 978—979.

A few grms. of vanadic acid is heated with water and phosphoric acid is added gradually until the vanadic acid is dissolved; a wood shaving placed in the solution thus obtained is coloured red-brown after a time, and the solution becomes green. When vanillin is treated with the vanadyl phosphate solution, bright reddish-brown needle-shaped crystals are formed.—W. P. S.

Mercaptans; Iodometric determination of ——. J. W. Kimball, R. L. Kramer, and E. E. Reid. J. Amer. Chem. Soc., 1921, **43**, 1199—1200.

A modification of the method of Klason and Carlson (*cf.* J., 1906, 287) which gives excellent results with both aliphatic and aromatic mercaptans. 35 c.c. of $N/10$ iodine in aqueous potassium iodide is measured into a stoppered bottle, and about 0·25 g. of the mercaptan weighed in either a stoppered weighing tube or a thin glass bulb is added. The bottle is shaken vigorously, and afterwards the excess iodine is tirated with $N/10$ thiosulphate.—W. G.

Local anæsthetics. E. Fourneau. Bull. Soc. Chim., 1921, **29**, 413—416.

Ethyl dichlorohydroxyisobutyrate reacts with dimethylamine hydrochloride to give ethyl tetramethyldiaminohydroxyisobutyrate, which yields a benzoyl derivative in the form of its hydrochloride, m.p., 155°. This compound has a local anæsthetic action, but unfortunately it is not quite neutral and has at the same time an irritant action. (*Cf.* J.C.S., Aug.)—W. G.

Alcohol and ether; Vapour pressures of mixtures of 95% ——. L. J. Olmer. Bull. Soc. Chim., 1921, **29**, 382—385.

Curves are given showing the vapour pressures of mixtures of 95% alcohol and ether containing 0, 10, 20, 40, 60, 80 or 100% of ether over the temperature range −20° C. to +20° C. The results are fairly well represented by the equation $P=a+(b-a)x^n$, where P is the pressure of the mixture, a and b the maximum pressures of alcohol and ether at the given temperature, x the percentage of ether in the mixture, and n a constant$=0·7$.—W. G.

Alcohol-ether mixtures; Composition of the gaseous phase of —— as a function of the liquid phase. L. J. Olmer. Bull. Soc. Chim., 1921, **29**, 385—389 (*cf. supra*).

Curves are given showing the composition of the gaseous phase as a function of the temperature, the pressure, and the liquid phase respectively for mixtures of alcohol and ether over the temperature range −20° to +30° C.—W. G.

Ethyl nitrite; Volatilisation of —— from sweet spirit of nitre. J. G. Roberts. Amer. J. Pharm., 1921, **93**, 320—324.

Ethyl nitrite is rapidly volatilised from an alcoholic solution, exposure to the atmosphere in an open dish of a 4·58% solution resulting, for example, in one instance, in a reduction in 1½ hrs. to 0·038%, and a similar, though slower, evaporation occurs in partially filled bottles. The action of direct sunlight is also very destructive to ethyl nitrite solutions in flint glass bottles, but in amber-coloured bottles very little change occurs. Tho best method of storing 'spirit of nitrous ether' is in small, completely filled amber bottles kept in a refrigerator or ice-box.—G. F. M.

Alkyloxides and phenoxides; Decomposition of some metallic —— by heat. J. F. Durand. Comptes renu., 1921, **172**, 1504—1506.

Sodium methoxide begins to decompose at 300° C., the action being

$$6CH_3.ONa = 9H_2 + Na_2C_2 + 2Na_2CO_3 + 2C,$$

there being a slight secondary action. Potassium mothoxide behaves similarly, but towards the end of the action there is liberation of some free potassium. Barium methoxide begins to decompose at 350° C., $2(CH_3.O)_2Ba = 6H_2 + BaO + BaCO_3 + 3C$. Sodium ethoxide decomposes according to the equations: $2C_2H_5.ONa = 2C_2H_4 + 2NaOH$ and $2C_2H_5.ONa = 4H_2 + 2NaOH + 4C$. Sodium phenoxide decomposes on heating as follows:

$$C_6H_5ONa = 2H_2 + NaOH + 6C.$$

—W. G.

Alcohols; Determination of volatile ——. A. Grün and T. Wirth. Z. deuts. Oel- u. Fettind., 1921, **41**, 145—147. Chem. Zentr., 1921, **92**, II., 978.

One g. of the alcohol is heated in a closed flask for 30 mins. at 60° C. with about 10 c.c. of chlorolauric acid (chlorostearic acid or chloropalmitic acid may also be used); the mixture is then boiled with 50 c.c. of water for 1 min. under a reflux condenser, rinsed into a separating funnel with 30 c.c. of ether, the aqueous layer is drawn off, the ethereal solution washed once with water, and, after the addition of alcohol, the ether-alcohol solution is neutralised and the saponif. value determined. To determine water in alcohols, a portion of the latter is treated with calcium hydride in an atmosphere of carbon dioxide, and the volume of the hydrogen evolved is measured; one-half of this hydrogen is derived from the water, the other half from the hydride.—W. P. S.

Natural gas; Chlorination of ——. G. W. Jones, V. C. Allison, and M. H. Meighan. U.S. Bureau of Mines, Tech. Paper 255, 1921. [44 pages.]

The influence of catalysts, temperature, and water vapour on the chlorination of natural gas was studied, using a gas containing CH_4, 89·5%; C_2H_6, 10·1%; and N, 0·4%. The gas and chlorine were passed through separate flow meters into a mixing tube and thence into an electrically-heated tube containing a catalyst; the products of the reaction were cooled, scrubbed with sodium hydroxide solution, and condensed in vessels cooled with an ice-salt mixture. Where methyl chloride was the desired product, the chlorinated gas, after passage through scrubbers and traps for condensable products, was collected in a sampling vessel for analysis. Reaction between the gases begins just below 250° C., but at this temperature the chlorine reacts with the ethane in preference to the methane and chlorination is incomplete; at about 400° C., the best temperature for the reaction, chlorination is nearly complete, and there is no deposition of carbon according to the equation:—$CH_4 + 2Cl_2 = C + 4HCl$, such as takes place, often explosively, above 500° C. The reaction is strongly exothermic, and particularly with certain catalysts, extreme care is required to prevent a rise in temperature to above 500° C. The presence of small amounts of water vapour in the gas appears to assist the reaction. Of the large number of catalysts tried, silica gels, porcelain, asbestos, glass wool, and pumice stone gave poor results, whereas with material of high absorptive capacity such as coke or charcoal, either alone or with traces of deposited metals, chlorination was nearly complete. The catalyst used had a marked effect upon the products obtained. Coke on which small quantities of platinum, nickel, zinc, or iron were deposited gave the highest yield of chloroform (45—50%) out of a total chlorination of 77—95%; whereas "war gas charcoal," "Batchite" (a carbon material made from anthracite), and steamed coal gave out of approximately the same total chlorination, less than 10% of chloroform but 60—80% of carbon tetrachloride. The highest yield of methyl chloride was about 31%, using nickel, tin, or lead, deposited on coke as catalyst, and a ratio of 2 vols. of chlorine to 1 vol. of the gas.—L. A. C.

α-Pinene bromide. Pariselle *See* XIII.

Patents.

Ureas; Production of tetra-substituted ——. E. I. du Pont de Nemours and Co., Assees. of A. P. Tanberg and H. Winkel. E.P. 144,681, 9.6.20. Conv., 11.9.18.

Tetra-substituted ureas are obtained by passing the requisite quantity of carbonyl chloride into a solution of a secondary aromatic amine, such as monomethylaniline, in a suitable inert solvent such as benzene, carbon tetrachloride, etc., heated to 70° C. When absorption ceases, the solvent is removed by distillation, and the residue freed from amine hydrochloride and traces of unchanged amine by washing with dilute hydrochloric acid. The crude tetra-substituted urea is purified by crystallisation. The preparation of dimethyldiphenylurea is described in detail.—G. F. M.

Formyl derivatives of secondary bases; Preparation of ——. E. Merck Chem. Fabr. G.P. 334,555, 8.7.19.

The free base is treated with chloral hydrate in the cold; thus N-methyl-α-methylhomopiperonylamine yields a compound which crystallises from chloroform in long, lustrous needles, m.p. 94°—95° C., and piperidine yields formylpiperidine as an oil. b.p. 106°—110° C.—A. R. P.

Cholesterol derivative; Preparation of an aqueou colloidal solution of a ——. I. Lifschütz. G.P 335,603, 17.2.17.

Metacholesterol, prepared according to G.P 318,900 (J., 1920, 576 A), is boiled for some tim with 100 times its volume of water or made int a paste with a water-soluble organic solvent, whic is then diluted with water and the organic solven removed by evaporation. An opalescent colloida solution results, which may be used as an emulsifying agent for other water-soluble materials such a fats and the higher alcohols in the production o medical and cosmetic preparations.—B. V. S.

Cholic acid derivatives; Preparation of ——. J. D. Riedel. G.P. 334,553, 30.5.16.

The esters of cholic acid are treated with dehydrating agents, and the resulting products, after saponification, are treated with acids to precipitate the corresponding acid. For example, methyl cholate is heated with glycollic acid and potassium bisulphate to 130° C., whereby a mixture of unsaturated acids is obtained, from which an acetic acid compound of apocholic acid,

$$C_{24}H_{38}O_4,CH_3.COOH,$$

may be isolated in needles which, after sintering, melt at 150°—160° C. By removal of the acetic acid, free apocholic acid is obtained, sparingly soluble in ether and benzene, but readily soluble in alcohol and practically tasteless. Other unsaturated bile acids may be recovered from the acetic acid mother liquor by precipitation with water; they are differentiated from apocholic acid by their ready solubility in most organic solvents, and aqueous solutions of their salts exert a strong solvent action on many insoluble substances.—A. R. P.

Proteins and silicic acid; Preparation of compounds of —— containing phosphorus. Lecinwerk Dr. E. Laves. G.P. 335,063, 1.11.19.

Proteins, or their derivatives or halogen substitution products, are treated with phosphoric acid and colloidal silicic acid or its salts; or metaphosphates of proteins or their compounds are treated with colloidal silicic acid or its salts; or compounds of proteins and silicic acid are treated with phosphoric acid or soluble phosphates. In each case the products may be separated by treatment with acids; they are insoluble in water aud organic solvents, and do not liberate silicic acid when digested with pepsin-hydrochloric acid; they are readily soluble in alkalis. Silicic acid-albumin-metaphosphate contains 5·8% SiO_2, 5·2% P_2O_5, and 10·2% N. Silicic acid-casein-metaphosphate contains 6·0—15·4% SiO_2, 3·2—5·2% P_2O_5, and 11·0—11·2% N. Silicic acid-iodine-casease-metaphosphate contains approximately 17·6% SiO_2, 2·0% P_2O_5, 7·4% I, and 9·1% N.—W. J. W.

Protein derivatives and gold; Preparation of compounds of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 335,159, 27.6.19.

Pharmaceutical products with disinfectant properties are obtained by treating aqueous solutions of protein derivatives with compounds of gold; the products may then be converted into soluble compounds by adding suitable amounts of proteins. Gold-albumose, prepared by precipitating albumose olution with gold chloride, is a light brown powder, ontaining 12% Au, insoluble in water, but soluble n alcohol and concentrated solution of albumose. Gold-peptone contains 28% Au. Other products re described.—W. J. W.

Pine-needle extract; Preparation of a soluble powder from ——. Chemisch-wissensch. Laboratorium, Dr. Fraenkel u. Dr. Landau. G.P. 334,841, 5.1.19.

By treatment of the syrupy extract obtained from ine needles with anhydrous, crystallisable salts, nd with salts which generate gases, such as carbon ioxide, oxygen, or hydrogen sulphide, when mixed ith water, a spongy material is produced which an be readily pulverised and is soluble in water. uitable mixtures of salts are sodium bisulphate ith sodium carbonate, bicarbonate, perborate, or ulphide. Instead of sodium bisulphate, sodium hosphate or organic acids, such as tartaric or xalic acid, may be used.—W. J. W.

acterial vaccines; Process of stabilising ——. J. D. Riedel A.-G. G.P. 335,321, 10.7.19.

sterile vaccine containing colloidal silver is repared by producing colloidal silver in bacterial cultures by means of feeble electric currents; the current is broken when the concentration of silver reaches 0·1%. Gonococcus protein may be used as a protective colloid.—W. J. W.

Tetrahydro - naphthalene and -naphthylamine derivatives. G.P. 335,476—7. *See* III.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Desensitisers; Experiments on ——. A. and L. Lumière and A. Seyewetz. Brit. J. Phot., 1921, 68, 351—354, 370—371.

Measurements were made of the desensitising action, in comparison with that of Phenosafranine, of a number of intermediate substances in the preparation of Safranine and of about 20 Safranine derivatives. It was found that in this class of substance the phenazine group and the amino groups were both necessary to desensitising power, removal of one amino group reducing it and removal of both destroying it. Diazotising one amino group or acetylating both groups also destroyed desensitising action, while Indazine M, in which two methyl groups are introduced into one amino group and $C_6H_4.N:(CH_3)_2$ into the other, is much less active than Phenosafranine. Evidence as to the effect of sulphonating is not given, as the only sulphonic acid mentioned has only one amino group. The dyes comparable with Phenosafranine are Toluylene Red, dimethylphenosafranine, tetramethylsafranine, tolusafranine, methyltolusafranine, dimethylbenzoxylylsafranine, tetraethylphenosafranine, naphthophenosafranine, ethyldimethylethosafranine, and cresosafranine, the last named having an advantage in easier removal from gelatin by washing than Phenosafranines. Nine indulines examined showed no desensitising action. The thiazines, thiazones, oxazines, and oxazones (in which one of the phenazine-nitrogen atoms is replaced by sulphur or oxygen) have only slight desensitising action. Of other dyes than those derived from quinone-imine or di-imine only picric acid, Aurantia, Indian Yellow, and Chrysoïdine were found to have appreciable desensitising power, and no well-defined relation between this and constitution was apparent. Oxidising substances, such as quinone, and reducing substances, other than those already reported on by Lüppo-Cramer, containing nitrogen, such as the alkaloids, were also examined, but only apomorphine hydrochloride was found to have an action comparable with that of amidol. Amongst the inorganic substances tested, only neutral chromates had any appreciable action. The safranines, Toluylene Red, the yellow dyes mentioned above, and potassium chromate were examined as to desensitising action on panchromatic plates, only the Safranines, Toluylene Red, and Aurantia giving good results. The actual amount of desensitising action throughout the spectrum was determined for some of these substances by comparison of the spectra obtained on panchromatic plates, treated and untreated; the extreme figures given are for Phenosafranine a reduction of blue sensitiveness to 1/750 and destruction of the sensitiveness to the rest of the spectrum, and, for potassium chromate, a reduction of sensitiveness to 1/40 throughout the spectrum. It is suggested that Aurantia may find a use with sensitive papers, from which it is easily removed by washing, while Phenosafranine gives a permanent red stain to paper.—B. V. S.

Developers; Preservation of —— by means of stannous salts. M. J. Desalme. Rev. Franç. de Phot., 1921, 2, 128—129, 130.

A solution of stannous tartrate is prepared by the addition of 5 g. of stannous chloride and 7 g. of tartaric acid in 30—40 c.c. of water to a solution of 30 g. of sodium carbonate cryst. in 30 c.c. of water, the total volume being brought to 100 c.c. Such a solution acts as a powerful preservative of developers, and has no action on the silver bromide or on the latent image. A concentrated hydramine (quinol-*p*-aminophenol) developer containing 10% of the above solution kept perfectly well in a partially filled flask for 8—9 years. Stannous tartrate solution is particularly suitable for use with diaminophenol, for which purpose it is first slightly acidified with acid sulphite.—B. V. S.

Combined developing and fixing. L. J. Bunel. Rev. Franç. de Phot., 1921, 2, 129.

The addition of acetone to a diaminophenol developer increases its activity considerably, and thus renders it suitable for the preparation of a combined developing-fixing solution. The formula recommended is diaminophenol hydrochloride 0·5%, anhydrous sodium sulphite 3%, acetone 8%, and sodium thiosulphate 5%.—B. V. S.

Amidol-quinol. Lüppo-Cramer. Der Phot., 1921, 109.

The addition of diaminophenol (5 c.c. of ½% solution) to a quinol developer (100 c.c. of 0·625% solution) produces a developer having greater activity than an ordinary metol-quinol developer, giving also more detail in the shadows but somewhat less density in the high lights, and with no tendency to veil. Since the effect of the amidol disappears (on standing in partly-filled or open vessels) the developer must be freshly prepared (*cf.* J., 1921, 280 A).—B. V. S.

Duplicate negatives; New process for the preparation of ——. Lüppo-Cramer. Der Phot., 1921, 118.

Renwick's iodide-thiosulphate-sulphite solution (1%, 2%, and 2% respectively; J., 1920, 156 T) is recommended for use in the preparation of duplicate negatives, pre-exposed plates being bathed in the solution, washed, dried, exposed behind a negative, and developed. The first exposure controls the density and gradation obtainable in the duplicate. —B. V. S.

Photochemistry of lead compounds. Renz. *See* VII.

Patents.

Pigment pictures without transfer; Preparation of right-sided ——. J. Halbach. G.P. 334,327, 29.1.20.

A transparent paper, such as Japan paper, is attached to the film side of the sensitised pigment paper; exposure is made through this paper, and the picture adheres to it, the original base being removed in the development process.—B. V. S.

Kinematograph films; Method and apparatus for treating ——. J. Mason. E.P. 143,230, 11.5.20. Conv., 14.3.19.

For treatment with a liquid on one side only, without taking special precautions for the protection of the other side, film is drawn through a trough provided with smooth, rounded horizontal supports and containing the treating liquid; this is at such a level, between certain limits, that the lower face of the film, once wetted, is able, by reason of surface tension, to maintain contact with it right along the trough without danger of the liquid reaching the upper surface of the film. The method is particularly adaptable to the staining of two-colour kinema film, with an image on each side, the film after the first treatment being carried over rollers through 180° to a second similar trough for treatment of the other side. The contact between the wet film and the supports in the trough is so light as not to scratch or injure the gelatin surface.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Nitro-compounds; Heat of combustion and formation of ——. *I. Benzene, toluene, phenol, and methylaniline series.* W. E. Garner and C. L. Abernethy. Proc. Roy. Soc., 1921, A 99, 213—215.

The heat of combustion of nitro-compounds is influenced strongly by the position of the nitro-group, and the value decreases with increasing number of these groups. The heats of formation reach a maximum with the second or third member of each series and then decrease. In the benzene series the maximum is reached with the fourth member. The sensitiveness of nitro-compounds to impact and their comparative instability run in line with their heats of formation; thus 2.3.4-trinitrotoluene, which has the lowest heat of formation, is most sensitive to impact. The stability of the unsymmetrical trinitro derivatives of toluene and benzene is less than that of the symmetrical compounds. The large heat of formation of the nitrophenols is a disadvantage to their employment as explosives, though this is to some extent balanced by their comparatively high oxygen content. Of the isomeric trinitrotoluenes, the 2.3.4-compound has the smallest heat of formation, whilst the 2.4.6-compound has the largest. If on detonation these two substances gave the same products of decomposition, the former would have an advantage over the latter of 54 cals. per grm. For the same reasons unsymmetrical trinitrobenzene would be a more powerful explosive than the symmetrical compound.—J. F. S.

Cellulose and its esters. II. Stability and viscosity of nitrocellulose. J. Duclaux. Bull. Soc. Chim., 1921, 29, 374—382. (*Cf.* J., 1920, 528 A.)

Fric's observation (J., 1912, 92) that when nitrocellulose is heated the viscosity of its solutions diminishes is shown to be quite general. There is a definite relationship between the diminution in viscosity and loss of weight of the nitrocellulose, and measurements of the variations in viscosity of a nitrocellulose during prolonged heating furnish a ready means of following the degradation of the nitrocellulose and determining its stability.—W. G.

Patents.

Explosives. C. J. S. Lungsgaard. E.P. 136,946, 3.9.20.

Explosives suitable for detonator compositions are prepared by the action of perchloric acid on organic, cyclic amines or amino-compounds. Thus, *p*-phenylenediamine perchlorate is produced by adding *p*-phenylenediamine to perchloric acid, evaporating, and crystallising; or, a hot solution of *p*-phenylenediamine hydrochloride may be mixed with sodium perchlorate solution, the sodium chloride removed, and the solution crystallised. The products are not hygroscopic, and may be used alone or mixed with other explosives or other ingredients.—W. J. W.

Explosives. Chem. Fabr. Kalk, G.m.b.H., and H. Oehme. G.P. 310,789, 18.1.18.

As substitutes for nitroglycerin, the nitration products of unsaturated gaseous hydrocarbons, such as ethylene, with or without absorption or gelatinising agents, are employed.—W. J. W.

Volatile solvents; Recovery of —— *from smokeless powders.* Köln-Rottweil Akt.-Ges. G.P. 334,958, 16.10.18.

The smokeless powder cords or strips are suspended in a chamber and subjected to the action of a current of dry air, which is drawn off at the bottom while fresh air is introduced in equal amount through lateral openings at the top of the chamber. —W. J. W.

Nitrocellulose; Process for preparation of ——. Verein. Köln-Rottweiler Pulverfabriken. G.P. 310,087, 10.3.18.

The nitrated cellulose is freed from the greater part of the adherent nitrosulphuric acid and treated with fresh cold nitrosulphuric acid, which is then removed by washing with cold water. This avoids the rise in temperature produced by direct dilution of the nitrating acid with water and the consequent alteration of the properties of the nitrocellulose.—B. V. S.

Nitrocellulose; Recovery of nitric acid from ——. R. Müller. G.P. 298,477, 15.2.16.

Nitric acid, remaining in nitrocellulose after nitration, is expelled by means of a current of air, previously dried and cooled, and the vapours are then absorbed in alkaline solutions or condensed by means of sulphuric acid.—W. J. W.

Explosives containing liquid air, liquid oxygen, etc. I. Kreidl. G.P. 300,636, 5.3.16. Conv., 1.4.15.

Inorganic colloids such as sulphur, phosphorus, carbon, or silicon, or mixtures of them with, *e.g.*, aluminium, are used as absorbents for the liquefied air or oxygen.—B. V. S.

Detonators, detonating caps, and the like; Method of manufacturing ——. E. von Herz. E.P. 142,823, 4.5.20. Conv., 13.7.14.

See G.P. 285,902 of 1914; J., 1915, 1169.

Pyroxylin solvents etc. E.P. 164,032—3. *See* V.

XXIII.—ANALYSIS.

pacity of liquids; Methods for measuring the ——. J. Holker. Biochem. J., 1921, 15, 216—225.

he liquid is slowly run out of a vertical flat-ottomed tube until a thin wire becomes visible hen viewed through the diminishing column of quid. The wire is fastened on the outside across e bottom of the tube, and is illuminated by an lectric lamp. The intensity of illumination makes ery little difference, both theoretically and experi-entally. With bacteria, blood corpuscles, and her particles of standard size, the number can deduced from the opacity and a constant, aracteristic of the particles.—G. B.

9050 (1920). Engelke. Distillation of hydrocarbon oils, tars, asphalt, etc. (165,230.) July 6.

9506 (1920). Barrett Co. Distillation of tar. (158,852.) July 6.

IV.—COLOURING MATTERS AND DYES.

Applications.

Baddiley, Bainbridge, Payman, and British Dyestuffs Corp. Production of direct-dyeing cotton colours. 17,630. June 28.

Gillson and Mills. Manufacture and packing of dyestuffs. 18,136. July 5.

Complete Specifications Accepted.

8920 (1920). Ges. f. Chem. Industrie in Basel. Manufacture of substantive *o*-oxyazo dyestuffs and their application in dyeing. (142,448.) July 13.

17,038 (1920). British Dyestuffs Corp., Perkin, and Clemo. Manufacture of triphenylmethane colouring matters. (165,658.) July 13.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Acheson. Graphitised vulcanised fibre and method of preparing same. 18,497, 18,503. July 7. (U.S., 14.12.20, 31.1.21.)

A.-G. der Maschinenfabr. Escher, Wyss, u. Co. Boiling fibrous materials. 18,119. July 4. (Switz., 21.8.20.)

Claessen. Manufacture of elastic flexible masses from nitrocellulose. 18,553. July 8. (Ger., 21.1.21.)

Schwarzkopf. Manufacture of raw alkali-cellulose for working into viscose. 17,810. June 30. (Ger., 30.6.20.)

Soc. du Feutre. Carrotting fur and hair. 18,462. July 7. (Fr., 12.8.20.)

Complete Specifications Accepted.

8880 (1920). British Cellulose and Chem. Manuf. Co., and Roy. Production of artificial filaments. (165,519.) July 13.

8910 (1920). Minton. Drying paper etc. (165,521.) July 13.

9503 (1920). Wade (Barrett Co.). Manufacture of fibrous material. (165,240.) July 6.

27,197 (1920). Poulson. Sizing textile fabrics etc. (165,365.) July 6.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Ellis and Williams. Dyeing or colouring acetyl cellulose. 17,661. June 29.

Frood. Impregnated fabrics and the manufac ture thereof. 17,885—6. July 1.

Complete Specifications Accepted.

8366 (1920). Lumsden, Mackenzie, Robinson, an Fort. Scouring and bleaching yarns and fabric composed of vegetable fibres containing dyed effec threads or fibres. (165,198.) July 6.

8920 (1920). Ges. f. Chem. Ind. in Basel. *See* IV

20,241 (1920). Ohligser Leinen- u. Baumwol weberei. Treatment of fabrics. (148,327.) July 1

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Carteret and Devaux. Preparation and purific tion of titanium compounds. 17,499. June 27.

Crosfield and Sons, and Wheaton. 18,188. XIX.

Duffield and Longbottom. Manufacture of dolomite. 18,110. July 4.

Fairweather (Air Reduction Co.). Manufacture of hydrocyanic acid and cyanides. 18,333—4. July 6.

Hormann, Kaufler, and Wacker Ges. Manufacture of acid anhydrides. 17,833. June 30. (Ger., 30.6.20.)

Howe, Picard, and Sulman. Production of zinc oxide or blown oxides from zinc ores or products. 17,619. June 28.

Hunt. Recovery of sulphur, metallic sulphides, etc. 17,574. June 28.

Manuf. de Prod. Chim. du Nord Etabl. Kuhlmann. Mechanically-operated furnaces for roasting pyrites etc. 17,514. June 27. (Ger., 5.8.20.)

Reid. 17,873. *See* II.

Complete Specifications Accepted.

10,809 (1914). De Brunn. *See* XIX.

11,185 (1919). Desachy. *See* XIII.

4723 (1920). Duparc and Urfer. Synthetic production of ammonia. (140,060.) July 6.

7922 (1920). Enderli. Manufacture of sodium formate. (165,163.) July 6.

14,466 (1920). Carpmael (Bayer u. Co.). Furnaces for making hydrochloric acid and sodium sulphate. (165,639.) July 13.

17,983 (1920). Wargöns Aktiebolag, and Liedholm. Production of cyanamide from calcium cyanamide. (151,583.) July 6.

20,706 (1920). Casale. Production of nitrogen or nitrogen and hydrogen mixtures. (148,885.) July 6.

VIII.—GLASS; CERAMICS.

Applications.

Coley. Preparation of glass for photographic etc. purposes. 17,599. June 28.

Dobson and Storr. Material for use in pottery industry. 17,872. July 1.

Complete Specifications Accepted.

17,253 (1918). Vergniaud. *See* I.

9685 (1920). Assie. Manufacture of an abrasive and refractory material. (141,351.) July 13.

13,677 (1920). Travers. Tank furnaces. (165,628.) July 13.

18,577 (1920). Rosenthal. Art of colouring glass. (146,473.) July 13.

IX.—BUILDING MATERIALS.

Applications.

Barrett Co. Manufacture of construction material. 18,501. July 7. (U.S., 22.7.20.)

Crossley. Manufacture of building materials etc. 18,234. July 6.

Ferguson. Manufacture of cement. 17,730. June 29.

Ronblöm. Manufacture of a wood substitute or mortar. 17,984. July 2.

Complete Specifications Accepted.

5705 (1920). Fraser. Manufacture of bituminous emulsions. (139,491.) July 13.

5706 (1920). Fraser. Cementitious bituminous mulsion. (139,492.) July 13.

20,103 (1920). Ges. f. Torf Isolation. Manufacure of thermally insulating bodies from peat. 48,190.) July 13.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Barron and Barron. Annealing etc. of metals. ,533. July 8.

Croft and Co., and Spicer. Treating bullets for separating their component parts. 17,655. June 29.

Etabl. Métallurgiques de la Gironde. Process for cleaning aluminium. 17,616. June 28. (Fr., 11.4.21.)

Ferguson. Treatment of refractory ores etc. 17,731. June 29.

Gillott. Alloy iron. 18,263. July 6.

Howe and others. 17,615. *See* VII.

Manuf. de Prod. Chim. du Nord. 17,514. *See* VII.

Penny. Crucible furnaces. 18,453. July 7.

Soc. Anon. Usines Métallurgiques de la Basse-Loire. Production of basic steel. 18,034. July 2.

Complete Specifications Accepted.

16,034 (1918). Basset. Manufacture of iron and steel directly from the ore. (158,523.) July 13.

17,745 (1919). Calvert. Use of fluorspar in steelmaking. (165,465.) July 13.

18,821 (1919). Basset. Manufacture of iron and steel from scrap etc. (130,610.) July 13.

7954 (1920). Haddan (Light Metals Co.). Metal scavenging alloy. (165,166.) July 6.

9149 (1920). Amalgamated Zinc (De Bavay's), Ltd. Recovery of lead and silver from ores and metallurgical products. (141,044.) July 13.

9251 (1920). Lovelock, and Try and Son. Electrolytic deposition of iron and treatment of the deposits. (165,535.) July 13.

9445 (1920). Electrolytic Zinc Co. of Australasia. Electrolytic treatment of ores containing zinc and other metals. (141,688.) July 13.

14,625 (1920). Elektro-Osmose A.-G. Flotation processes for concentrating ores. (143,920.) July 13.

26,822 (1920). Riccio. Chill casting of pure aluminium and its alloys. (165,362.) July 13.

XI.—ELECTRO-CHEMISTRY.

Applications.

Chloride Electrical Storage Co., and Dean. Electric accumulators. 18,458. July 7.

Cornelius. Electric rotating furnaces. 17,594. June 28.

Dinin. Electric accumulators. 18,589. July 8.

Kolkin. Arrangement of electrodes for electrolytic apparatus. 17,506. June 27.

Lodge Fume Co. (Metallbank u. Metallurgische Ges.). Cleaning discharge electrodes in apparatus for electric precipitation of suspended particles from gases. 18,126. July 4.

Sgadari. Electric furnaces. 17,822. June 30.

Voss. Electric accumulators. 17,784. June 30.

Webb. Cathodes for electrolysers. 18,109. July 4.

Complete Specifications Accepted.

7023–4 (1920). Philadelphia Storage Battery Co. Storage electric batteries. (150,985 and 143,493.) July 6.

9251 (1920). Lovelock and others. *See* X.

9445 (1920). Electrolytic Zinc Co. *See* X.

16,701 (1920). Skinningrove Iron Co., and Smith. *See* I.

36,449 (1920). Reed. Electric furnaces. (161,154.) July 13.

XII.—FATS; OILS; WAXES.

Application.

Pelly, and Technical Research Works. Increasing lubricating properties of oils. 18,441. July 7.

Complete Specifications Accepted.

8805 (1920). Arii. Apparatus for extracting oil or fat by volatile solvents. (165,226.) July 6.

9314 (1920). Erslev. Treatment of oil-containing vegetable material prior to extraction of oil. (141,341.) July 6.

13,970 (1920). Salomonson. Process for neutralising oils or fats. (165,635.) July 13.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Applications.

Drummond, and Lorival Manuf. Co. Manufacture of condensation products of phenolic bodies with aldehydic compounds. 18,479. July 7.

Dutt, Godfrey, and Wilson. Preparation of titaniferous pigments from bauxite. 18,647. July 4.

Howe and others. 17,619. *See* VII.

Complete Specifications Accepted.

11,185 (1919). Desachy. Manufacture of mixtures of barium sulphate and zinc sulphide. (126,626.) July 13.

15,774 (1920). Bloxam (Akt.-Ges. f. Anilinfabr.). Manufacture of resinous substances. (165,322.) July 6.

15,946 (1920). Arent. Treatment of waterproofing and like materials to reduce their inflammability. (146,099.) July 13.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Application.

Frost, and Frost and Co. Vulcanising compositions. 18,230. July 5.

Complete Specification Accepted.

18,919 (1920). Goodyear Tire and Rubber Co. Manufacture of rubber products. (146,993.) July 13.

XV.—LEATHER; BONE; HORN; GLUE.

Applications.

Claessen. Manufacture of artificial leather. 18,552. July 8. (Ger., 6.11.20.)

Margotton. Tanning hides and skins. 17,826. June 30.

Complete Specifications Accepted.

22,328 (1919). Fairrie. Pits for tanning. (165,469.) July 13.

8416 (1920). Knudsen. Process for tanning fish skins. (165,199.) July 6.

17,293 (1920). Renner and Moller. Manufacture of vegetable tanning agents. (146,165.) July 13.

XVI.—SOILS; FERTILISERS.

Application.

Niedenzu. Manufacture of artificial nitrogenous fertilisers. 18,582. July 8. (Ger., 23.7.20.)

Complete Specification Accepted.

12,507 (1920). Gonsalez, Sandchez, and Llanos. Chemical manure. (165,604.) July 13.

XVIII.—FERMENTATION INDUSTRIES.

Application.

Soc. Ricard, Allenet, et Cie. Manufacture of acetone and butyl alcohol by fermentation. 17,834. June 30. (Fr., 28.2.21.)

Complete Specification Accepted.

36,263 (1920). Nathan and Gille. Cooling and aerating beer wort and separating sludge. (165,378.) July 6.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Crosfield and Sons, and Wheaton. Manufacture of a base-exchanging compound. 18,188. July 5.

Prentice and Stevenson. Sterilisation of milk etc. 17,508. June 27.

Schull. 18,336. *See* I.

Complete Specifications Accepted.

10,809 (1914). De Brunn. Production of base-exchanging bodies. July 6.

6192 (1920). Werner. Treating and improving flour. (165,149.) July 6.

15,114 (1920). Shimizu, and Nihon Chasei Kabushiki Kwaisha. Manufacture of tea essence. (165,644.) July 13.

19,499 (1920). Wolff. Continuous production of germ-free air. (147,566.) July 13.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Elektrizitätswerk Lonza. Production of crotonic acid from crotonaldehyde. 17,527. June 27. (Switz., 2.7.20.)

Hoffmann-La Roche u. Co. Manufacture of allylarsinic acid. 17,710. June 29. (Switz., 26.7.20.)

Hormann and others. 17,833. *See* VII.

Napp (Hoffmann-La Roche u. Co.). Manufacture of isopropylallylbarbituric acid. 17,799. June 30.

Soc. Ricard, Allenet, et Cie. 17,834. *See* XVIII.

Complete Specifications Accepted.

3396 (1916). Weizmann and Legg. Manufacture of hydrocarbons. (165,452.) July 13.

2075 (1920). Byrnes. Manufacture of aldehyde fatty acids and aldehydes from mineral oils or their distillates. (138,113.) July 6.

24,302 and 24,351 (1920). Elektro-Osmose A.-G. Manufacture of specific vaccines. (150,328 and 150,331.) July 6.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Applications.

Coley. 17,599. *See* VIII.

Hatt. Photo process screen and method of preparing same. 18,346. July 6. (U.S., 14.10.20.)

Macdonald. Treatment of waste kinematograph films etc. for recovery of silver and gelatin. 18,090. July 4.

XXII.—EXPLOSIVES; MATCHES.

Applications.

Rathsburg. Initial primers and process for their manufacture. 17,519. June 27.

Rathsburg. Manufacture of explosives and primers. 17,622. June 28.

XXIII.—ANALYSIS.

Applications.

Davidson. Means for regulating gas flow to gas calorimeters. 17,545. June 28.

Withers (Lanphier). Measuring calorific value of gas. 18,379. July 6.

I.—GENERAL; PLANT; MACHINERY.

Water; Adsorption of —— by powdery substances. K. Scheringa. Pharm. Weekblad, 1921, 58, 937—942.

In determinations of the adsorption of water by various substances in a powdered condition, salts such as potassium bromide, chlorate, and sulphate gave no appreciable result in moderately dry air, and no surface condensation occurred below 60% humidity. Animal charcoal is very adsorbent; even with 30% of humidity, no visible surface condensation takes places. Similarly sand shows a high degree of adsorption, and is therefore not suitable for moisture estimations in foodstuffs. For this purpose powdered quartz is more suitable; both it and powdered marble are non-adsorbent in dry air. —W. J. W.

Patents.

Incrustations or boiler-scale; Process for preventing ——. W. Bomsel. E.P. 164,382, 15.11.19.

To prevent incrustation in water-heating apparatus in which the water is not actually boiled, a small quantity of a reagent such as sulphuric acid, aluminium sulphate, or sodium bisulphate is added to produce a small amount of carbon dioxide in solution.—H. H.

Dryers; Centrifugal ——. H. P. Hoyle. E.P. 164,500, 10.3.20.

A perforated vertical drum, carrying a screw adapted to feed the material downwards through it, is disposed within a vertical cylindrical screen, and the drum and screen are capable of rotation at different speeds. A fixed feed hopper, arranged above a trunk upstanding from the screen, carries a scraper depending within the trunk. Fans on the exterior of the screen and within the drum draw air through the material. A screen formed in segments and with wedge-section wires is preferred.—H. H.

Evaporation of liquids with the recovery of the vapours by condensation; Method of and apparatus for ——. F. Merz. E.P. 164,525, 16.3.20.

The supply of heat for the evaporation and its withdrawal for the condensation are obtained respec-ively by the condensation and the evaporation of n operating liquid which circulates in a closed cycle etween two chambers. In one chamber, which is nder pressure, are condensed, with liberation of eat, the vapours of the operating liquid given off ı the other chamber, which is under reduced ressure.—H. H.

istillation apparatus. G. W. Ellis. E.P. 164,407, 8.1.20.

HE apparatus consists of two concentric tubes,. the ner one surrounded by one or more coils of wire small pitch down which flows the liquid to be stilled. To prevent loss due to splashing, calyx-aped screens, preferably of wire, are attached to o inner tube. The condensed liquid flowing down e inner wall of the outer tube is collected parately from any distillation residue. If desired, additional concentric tube may be provided ound the outer tube, in which case the outer wall the latter may serve as the evaporating surface a liquid of lower b.p.

ll. N. Bologa. U.S.P. 1,379,520, 24.5.21. Appl., 6.1.20.

TE still consists of a case having at the bottom a inage channel terminated by a valved drainage e, and enclosing a porous receptacle supported y from the walls of the case. The receptacle is vided with a discharge opening in the bottom and a gravitational valve complementary thereto and having a stem guided by apertures in a bridge-loop and cross-bar detachably secured in the receptacle. Means are provided for enclosing the latter in the casing, for closing this, and for drawing off the vapours.—A. R. P.

Separators; Centrifugal ——. W. Mauss. E.P. 164,418, 4.2.20.

A separator for use with liquids such as prepared sugar juice consists of a separating drum made in several sections, the liquid being fed to the lowest section; the separator rotates at such a rate that the solids are completely separated in all but the uppermost section, which is discharged separately from the other sections into an open launder in which the liquid may be inspected. A continuously operated separator is described, in which the separation is stopped periodically by means of a time control drum, which also actuates levers which cause the various sections of the separator to be parted and discharged.

Separating solids from liquids; Apparatus for ——. G. Mumford. E.P. 164,410, 22.4.20.

Continuous centrifugal apparatus, more particularly for the treatment of activated sludge, has a central axial inlet for the liquor, radial tubular arms leading from the inlet and connecting it with a separating chamber provided with inclined or conical sides, exterior outlet ports for the separated solid, and a band and scraper to collect the solids. The liquid flows from the separating chamber through suitable ports or radial arms into an axial outlet at the bottom of the apparatus.—R. L. F. R.

Separating of suspended bodies from electrical insulating fluids, more particularly gaseous fluids; Process and apparatus for the ——. E. Möller. E.P. 11,088, 30.7.15. Conv., 31.7.14.

In apparatus comprising wire-like emitters arranged axially in tubular separating field surfaces, such surfaces are provided with longitudinal apertures forming segments between which the bulk of the fluid is passed in a substantially transverse direction with the object mainly of avoiding interference with the adjustment of the electric field and with the uniformity of the discharge by the accumulation and removal of the separated matter.—H. H.

Settling tanks. W. J. Mellersh-Jackson. From The Dorr Co. E.P. 164,645, 2.9.20.

A circular settling tank, *e.g.*, for use in the wet treatment of ores, is provided with a bottom outlet for solid matter which is diverted towards the outlet by a rotating scraper supported on a pedestal upstanding centrally from the floor of the tank. An arm secured to the scraper carries a motor driving a traction wheel on a circular track over the rim of the tank.—H. H.

Thickening process; Continuous ——. A. L. Genter, Assr. to General Engineering Co. U.S.P. 1,379,095, 24.5.21. Appl., 3.3.19. Renewed 22.3.21.

A series of hollow filtering elements is immersed in the mixture to be thickened in a common reservoir, and liquid is continuously removed from any desired portion of the filtering elements while, at the same time, a cleansing action is produced on any other desired portion of the elements.—A. R. P.

Conveyance of highly inflammable liquids. J. Muchka. E.P. 153,914, 16.11.20. Conv., 19.6.16.

Heating or drying apparatus. O. A. J.-B. Greuet. E.P. 148,171, 9.7.20. Conv., 11.2.19.

Furnaces; Direct-fired oil fuel ——. C. F. Priest. E.P. 164,837, 13.3.20.

Temperature controllers. C. J. Tagliabue Manuf. Co., Assees. of A. Roesch. E.P. 138,640, 4.2.20. Conv., 28.8.14.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Sulphur recovery and gas purification; New method of ——. Conversion of hydrogen sulphide into sulphur by means of activated charcoal. A. Engelhardt. Z. angew. Chem., 1921, 34, 293—295.

The activated charcoal is prepared from wood by dry-distillation in the presence of salts, in particular the chlorides of ammonium, zinc, aluminium, and iron, or by treatment with superheated steam at about 1000° C. It is a powerful absorbent, taking up, for example, twice its own weight of hydrogen sulphide from a gas containing 6 g. per cub. m. The absorptive power is increased by the use of cooling and pressure. The gas to be purified is passed, together with a little oxygen and ammonia, over the activated charcoal. Oxidation is rapid and sulphur is deposited in the pores of the charcoal. The sulphur is recovered by extraction with dichlorobenzene or other suitable solvent. The charcoal may be used over again after washing out the solvent. The reaction temperature is about 60° C.—W. P.

Benzene hydrocarbons; Determination of —— in coal gas and coke-oven gas. E. Berl and K. Andress. Z. angew. Chem., 1921, 34, 278—279.

Absorption of benzene hydrocarbons from gases by paraffin is essentially a case of solution, and the vapour pressure of the solutions has a high temperature coefficient. With a benzene content of 20 g. per cub. m. about 3·4% is absorbed at 0° C., whilst at 20° C. the amount is only 1·3%. Absorption is proportional to the concentration of the hydrocarbon. When activated charcoal is used, the process is one of actual adsorption. The temperature coefficient is low; at 0° C. only 1·2 times as much as at 20° C. is adsorbed. Both on account of the simplicity of the apparatus and method, and of the better results obtained, the charcoal method is recommended in preference to the paraffin method. —W. J. W.

Shale oil; Composition of Swedish ——. G. Hellsing. Ark. Kemi, Min., Geol., 1920, 7, No. 29, 1—23.

A sample of oil obtained by heating Swedish shale directly was poor in paraffin hydrocarbons and differed from Scottish and French shale oils principally in its relatively high content of aromatic hydrocarbons; toluene, *p*-xylene, ψ-cumene, another trimethylbenzene (? hemimellithene), and durene were identified, whilst naphthalene was present only in traces. These aromatic constituents are regarded as primary and not as secondary products of the distillation of the shale. The resistant hydrocarbons probably consist principally of naphthenes.—T. H. P.

Patents.

Furnace temperature; Method of controlling ——. G. F. Fuller. E.P. 164,605, 17.5.20.

The furnace is first heated to the desired temperature by passing into it gases of combustion produced from fuel burning outside the furnace. When the necessary temperature has been attained, it is maintained by the admission of hot gases of combustion together with cold gases in the necessary quantities. The cold gases may be inert gases, *e.g.*, steam, which may be admitted to the furnace in the form of a water spray. The temperature may be maintained by admitting a constant supply of high-temperature gases and intermittently admitting low-temperature gases, or *vice versâ*.—A. G.

Retort settings. Low Temperature Carbonisation, Ltd., H. L. Armstrong, and T. M. Davidson. E.P. 164,372, 21.8.19.

In the construction of vertical retort installations for carbonisation at low temperatures, the vertical interstitial spaces between the respective retorts serve as heating chambers, having waste gas flues formed in two parallel portions separated by a partition wall of small thickness. Flues for preheating the air supply are built in two parallel portions and are disposed parallel to and at the side of the waste gas flues. Communicating passages extend through the partition wall, the waste gases from the heating chambers being discharged into the waste gas flues and air to support combustion being received from the air flues. The vertical interstitial spaces between the respective retorts are divided by horizontal partitions into a number of communicating horizontal heating chambers, burners being provided alternately at opposite ends of adjacent horizontal heating chambers.—A. G.

Gas producers. T. G. Tulloch and D. J. Smith. E.P. 164,548, 23.3.20.

The exhaust pipe of an internal-combustion engine is connected with the ash-pan of the producer so that the exhaust gases may be passed through the charge without the admission of air. A throttle valve may be provided so as to utilise a part or the whole of the exhaust gases in this way, and another may be provided in the pipe between the vaporiser and the ash-pan. Both of these throttle valves may be connected with the throttle valve in the main exhaust pipe in order to obtain a constant proportion of air, steam, and exhaust gases. The valves may also be connected with a throttle valve in the gas supply pipe to the engine.—A. G.

Explosive gases; Process and apparatus for generating ——. H. Blumenberg, jun. U.S.P. 1,379,077, 24.5.21. Appl., 11.6.20.

A gaseous fuel mixture is produced by passing a mixture of hydrogen and oxygen, generated electrolytically, through heavy hydrocarbons.—W. J. W.

Water-gas; Process of manufacturing ——. W. W. Odell. U.S.P. 1,379,038, 24.5.21. Appl., 7.11.18.

After lighting the fire in the producer, the fuel bed is subjected to an up-draught of air with a small proportion of steam during the first portion of the blast period only. The bed is subsequently subjected to a blast of steam with a small proportion of air to prolong the period of the runs. Two up-runs are made for every down-run.—A. G.

Filtration of combustible gases; Method of treating or handling filter plants employed for the ——. Halbergerhütte G.m.b.H. E.P. 156,753, 7.1.21. Conv., 29.4.14.

To avoid explosions when cleaning or stopping the plant, the combustible gas is displaced by an indifferent gas, which is in turn displaced by air On starting up the plant the process is reversed the air being replaced by the indifferent gas, which is then displaced by the combustible gas. Combustion gases may be employed as the indifferent ga for scavenging the filter.—A. G.

Blast furnace and like gases; Purification of ——. Halbergerhütte G.m.b.H. E.P. 160,758, 26.1.21. Conv., 23.3.20.

Air is admitted to the crude gas before purification in order to oxidise the dust and so eliminate its liability to spontaneous combustion. The air admission device is interconnected with the gas exhauster so that no inadvertent admission of air may take place when the supply of combustible gas is being diminished, explosions being thus avoided. —A. G.

Oils; Treatment of heavy ——. A. E. Dunstan and F. B. Thole. E.P. 156,284, 8.7.19.

Heavy residual oils containing amorphous solid hydrocarbons are subjected to a process of heat treatment, *e.g.*, to a temperature of 400° C. at 200 lb. pressure, whereby the aforesaid hydrocarbons are decomposed and a limpid fuel oil remains.—A. E. D.

Petroleum; Treatment of ——. J. W. Lewis, Assr. to The Atlantic Refining Co. U.S.P. 1,364,443, 4.1.21. Appl., 19.4.17.

Oil is cracked at a pressure greater than atmospheric. The pressure of the vapours is lowered, but still exceeds atmospheric, and condensation is effected under this intermediate pressure.—A. E. D.

Hydrocarbons; Treatment of ——. (a) W. F. Rittman, (b—d) W. F. Rittman and C. B. Dutton. U.S.P. 1,365,602—5, 11.1.21. Appl., 5.2.17.

(a) Vapour phase cracking is carried out in a vertical retort, the temperature in the upper end of which is higher than the vaporising point of the oil. The oil is introduced through an inner tube and discharges against the upper part of the retort. The products are withdrawn from the annular space. (b) Continuous treatment of oil is achieved in an apparatus wherein heat is drawn from a common source suficient to crack oil vapours and also to preheat incoming oil. (c) An oil of high boiling point is vaporised, and cracked, the desired product of low .p. is freed from higher boiling constituents, and he latter are re-cracked. (d) Hydrocarbons are ubjected to heat and pressure to produce "predominant" quantities of hydrocarbons boiling elow 30° C., the naphtha is condensed, and the ncondensed vapours are scrubbed through the aphtha condensate.—A. E. D.

etroleum oils; Distilling ——. F. A. Kormann. E.P. 164,529, 17.3.20.

ee U.S.P. 1,332,849 of 1920; J., 1920, 326 a. ricks made from a mixture of clay and cork flour e preferably used as the porous material, and perheated steam may be used to assist the process.

ydrocarbons; Cracking ——. [*Removing residual matter from cracking stills.*] J. W. Coast, jun., Assr. to The Process Co. U.S.P. 1,379,333, 24,5.21. Appl., 22.5.17.

e liquid residue is removed from the cylindrical cking still and the wet residual coke is dried d simultaneously swept backwards and forwards oss the arcuate bottom of the still. The dry coke subsequently removed from the still.—L. A. C.

S le; Method of treating —— and recovering oil herefrom. W. W. Hoover and T. E. Ellis. E.P. 56,396, 10.12.19.

A eating medium is introduced into shale formati s and distillation *in situ* is achieved. Explosive cl rges may be similarly introduced.—A. E. D.

G -producer. A. H. Lymn, L. A. Riley, and N. E. ambush. U.S.P. 1,380,993, 7.6.21. Appl., .10.16.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Charcoal; Some factors governing the sorptive capacity of ——. *Sorption of ammonia by coconut charcoal.* J. B. Firth. Chem. Soc. Trans., 1921, 119, 926—931.

The sorptive capacity towards pure ammonia of coconut shell charcoal, prepared by carbonising at as low a temperature as possible and heating to 600°—900° C., was examined for varying periods of heating and at different temperatures. Prolonged heating causes a considerable activation; at 600° C. a great increase in sorptive capacity is observed without much change in density. At 900° a still greater increase coincident with increase in density occurs. Prolonged heating at 900° C. or rapid heating to higher temperatures (above 1000°) causes a further rise in density with diminished sorptive capacity, and converts a portion of the carbon into a denser form, the density then depending on the proportion of each form. The activity of carbon also deteriorates with time. The equilibrium pressures at 18°, 0°, and −20° C. are recorded; the curves show that great increase in the volume of gas sorbed makes only a small change in the equilibrium pressure at first, but after a certain point a small change in the volume of ammonia in the charcoal considerably increases the equilibrium pressure. —P. V. M.

Patents.

Destructive distillation [of wood;] Process [for ——]. O. F. Stafford. U.S.P. 1,380,262, 31.5.21. Appl., 29.8.19.

In the destructive distillation of wood, one stage comprises heating the wood, out of contact with air, by means of the heat produced in the exothermic wood carbonising reaction, the supply of wood during the operation being continuous. —W. J. W.

Distillation; Apparatus for ——. C. A. Nottingham and C. Tuhey, Assrs. to American Nottingham Process Co. U.S.P. 1,379,876, 31.5.21. Appl., 16.5.19.

A number of horizontal retorts are superposed and connected so that the material traverses them in a zig-zag path; means are provided for introducing fresh material and discharging the final product without allowing a current of gas to pass, and each retort is supplied with a conveyor. The whole set of retorts is heated in such a manner that the material is subjected to a gradually increasing temperature during its passage.

Electric incandescent lamps [; Leading-in wires for ——]. A. Woosnam. From N. V. Metaaldraadlampenfabriek "Holland." E.P. 164,415, 3.2.20.

Leading-in wires are composed of molybdenum or other metal having a coefficient of expansion less than that of the glass. The diameter of the wires is 0·12 mm. or less. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 13,295 of 1910; 12,753 and 27,669 of 1913.)—J. S. G. T.

III.—TAR AND TAR PRODUCTS.

Nitro-compounds; Reduction of emulsified ——. I. β-Phenylhydroxylamine from nitrobenzene. A. Lapworth and L. K. Pearson. Chem. Soc. Trans., 1921, **119**, 765—768.

High yields of β-phenylhydroxylamine are obtained by reducing nitrobenzene in aqueous emulsion by means of alkali sulphide. Thus a solution of sodium hydrosulphide and chloride, obtained by carefully adding 2·1 pts. of hydrochloric acid (sp. gr. 1·16) to a solution of 5·52 pts. of hydrated sodium sulphide in 4·36 pts. of water, is mixed at 15° C. in a stoppered vessel with 1 pt. of nitrobenzene and 1 pt. of calcium chloride dissolved in the minimum quantity of water (absorption of oxygen being prevented). Emulsification is attained by intermittent agitation, the temperature not being allowed to rise above 30° C. When the oil has completely disappeared (in about 1½ hours), ammonium chloride (1·2 pts.) is added, and the mixture shaken. Filtration gives a yield of 72—74% of nearly pure crystalline β-phenylhydroxylamine. The use of ammonium sulphide instead of the sodium salt leads to precipitation of sulphur with the product.—P. V. M.

Nitro-compounds; Reduction of emulsified ——. II. R. D. Haworth and A. Lapworth. Chem. Soc. Trans., 1921, **119**, 768—777.

The mode of reduction of nitrobenzene by emulsification with sodium hydrosulphide (*cf.* Lapworth and Pearson, *supra*) has been extended to *o*-nitrotoluene and to a number of solid aromatic nitro-compounds. The prepared sodium hydrosulphide solution in requisite quantity is emulsified with a solution or suspension of the nitro-compound in from 1½—2 times its volume of benzene. The addition of calcium chloride, and subsequently of ammonium chloride proceeds as before. The low solubility of most substituted hydroxylamines in benzene renders the method especially attractive where these are the main products. The process gives satisfactory results with *p*-chloronitrobenzene—yield of β-substituted hydroxylamine 67—71%; *p*-bromonitrobenzene—yield 65%; *p*-iodonitrobenzene—yield 65%; *p*-nitrotoluene—yield 49—50%; *m*-bromonitrobenzene—yield 55%; *m*-chloronitrobenzene—yield 57%; α-nitronaphthalene—yield 73%. In each case the β-substituted hydroxylamine is secured at once in solid form, a few units per cent. only remaining in the filtrate. *o*-Nitrotoluene and *o*-chloronitrobenzene, the former as such and the latter when dissolved in benzene, do not at once yield solid hydroxylamines but give oils containing about 15 and 62% respectively of the corresponding hydroxylamines. *m*-Dinitrobenzene and 2.4-dinitrotoluene give mainly the solid dinitro-azoxy compounds. *m*-Nitroaniline and *p*-nitroaniline are reduced to the corresponding diamines. The process is not applicable to *p*-nitrophenol.—P. V. M.

Naphthol-, naphthylamine-, and aminonaphthol-sulphonic acids; Nomenclature of the ——. E. de B. Barnett. Chem. News, 1921, **123**, 33.

It is proposed to denote the position of the sulphonic groups by the usual numbers 1—8, the amino groups by the letters *a*—*h*, and the hydroxyl groups by the Greek symbols, α, β, γ, δ, ε, ζ, η, and θ, and to omit any other wording; thus 2-naphthylamine-6-sulphonic acid is *b*.6 acid and 1.8-aminonaphthol-3.6-disulphonic acid is α.*h*.3.6 acid or *a*.θ.3.6 acid.

Benzene hydrocarbons in gas. Berl and Andress. *See* II A.

Patents.

Benzol; Process of nitrating ——. T. J. Brewster. U.S.P. 1,380,185, 31.5.21. Appl., 20.11.17.

Benzol is treated with nitric acid in presence of a mercury compound, and during the process portions of the liquid are continuously withdrawn from the nitrating vessel, cooled to induce crystallisation, and filtered, the filtered liquid being returned to the nitrator.

Nitrophenolic compounds [picric acid]; Process for the production of ——. T. J. Brewster. U.S.P. 1,380,186, 24.5.21. Appl., 2.10.18.

In the manufacture of picric acid, phenol is sulphonated, the product is cooled to 50° C., diluted, and nitrated to the mononitro-derivative by the addition of a slight excess of nitric acid at a temperature below 70° C. The further nitration is effected by the addition of more nitric acid and allowing the temperature to rise above 70° C.—F. M. R.

Amino-compounds from trinitrotoluol; Process for the production of ——. E. Bielouss. E.P. 137,529, 6.1.20. Conv., 6.1.19.

Trinitrotoluene in acetic acid solution is reduced by means of iron and hydrochloric acid at 60°—100° C. The reduction product, 6-nitro-2.4-diaminotoluene, is extracted with benzene and is obtained as orange-red crystals by evaporating the solvent. —F. M. R.

Phthalic acid and anhydride. E.P. 164,785. *See* XX.

IV.—COLOURING MATTERS AND DYES.

Colouring matters; Synthesis of basic —— by the condensation of acetylene with aromatic bases. F. Consonno and A. Cruto. Gaz. Chim. Ital., 1921, **51**, I., 177—183.

When a current of acetylene is passed into a solution of sulphur in aniline heated at 150° C., dithiooxanilide, $C_6H_5.NH.CS.CS.NH.C_6H_5$, is formed in a yield quantitative with respect to the aniline employed; thio-oxalic acid, $CS_2H.CS_2H$, is probably formed as an intermediate product. If the aniline is replaced by dimethylaniline, two compounds result: (1) $C_{20}H_{20}N_2S$, m.p. 153° C., probably formed by condensation of the dimethylaniline wit the thio-anhydride corresponding with thio-oxali acid, this being presumably formed as the initia product; (2) a compound which could not be crystal lised and undergoes ready oxidation in the ai yielding Methyl Violet; its constitution is probabl $C[C_6H_4.N(CH_3)_2]_3.C[C_6H_4.N(CH_3)_2]_3$. Similarly by the action of acetylene on sulphur and phenyl- naphthylamine, and condensation of the produc with excess of dimethylaniline, Victoria Blue i formed.—T. H. P.

Phenolphthalein; Use of aluminium chloride in th preparation of ——. C. F. Ward. Chem. So Trans., 1921, **119**, 850—853.

The use of anhydrous aluminium chloride as cat lyst gives an improved yield of phenolphthalein— to 40% of the theoretical—when the phthal anhydride and aluminium chloride are in molecul proportions, and the phenol in slight excess. T reaction is smooth and readily controlled, and t product easily purified. Anhydrous ferric chlori is not so satisfactory; the yields average about 3 and the presence of other condensation produ makes the purification of the product diffic Acetic anhydride has no action as a condensi agent in the preparation of phenolphthalein by t method. The optimum temperatures are w $AlCl_3$ 45°—100° in 1 hour; $FeCl_3$ 135°—150° 5 hours. Steam distillation of the product a extraction first with hydrochloric acid and then with dilute sodium hydroxide yields a solution from which the crude product can be precipitated by dilute acid. The product is fractionally crystallised from 70% methyl alcohol. The method is not so efficient nor so economical as that involving the use of zinc chloride and hydrochloric acid described by Copisarow (J., 1920, 360 A).—P. V. M.

Phenazonium; Nitro derivatives of ——. F. Kehrmann and J. Effront. Helv. Chim. Acta, 1921, **4**, 517—526.

Nitro derivatives of phenazonium are readily prepared by the action of ferric chloride or concentrated nitric acid on the nitro derivatives of alphyl- or aryl-dihydrophenazines. The nitrates and perchlorates crystallise well and vary from lemon-yellow to orange-red in colour. They are, in general, powerful oxidising agents. Certain nitro-derivatives of alkyldihydrophenazines are prepared from picryl chloride and monoalkylated *o*-diamines. The former can in some cases be replaced by 2.6-dinitrochlorobenzene, but ring closure has not been effected with 2.4-dinitrochlorobenzene. (*Cf.* J.C.S., August.) —H. W.

Tetraphenylmethane; Coloured derivatives of ——. III. New syntheses of carbazine dyes. F. Kehrmann, M. Ramm, and C. Schmajewski. Helv. Chim. Acta, 1921, **4**, 538—546.

The synthesis of carbazine dyes has been effected n certain instances in accordance with the scheme:

$$(NO_2)_3C_6H_2Cl+H_2N{\cdot}C_6H_4{\cdot}CHR_2=$$
$$(NO_2)_3C_6H_2.NH{\cdot}C_6H_4{\cdot}CHR_2\rightarrow$$

$$(NO_2)_3C_6H_2<\genfrac{}{}{0pt}{}{NH}{CR_2}>C_6H_4,$$

he essential condition being the aromatic nature of he group "R." Thus picryl chloride and *o*-amino-iphenylmethane give the product, $C_{25}H_{18}O_6N_4$, ie potassium derivative of which is converted into 4-dinitrodiphenylcarbazine when boiled in quino-ne solution.—H. W.

onstitution and colour. VII. Theory of quinoid organic onium salts. F. Kehrmann. Helv. Chim. Acta, 1921, **4**, 527—537.

guments are adduced and examples are given to ow that at present it is only possible to express e constitution of the majority of dye salts by ans of the quinoid formula and that this is the st satisfactory form of expression until it is pos-le to bring Werner's and the quinoid theories o better harmony.—H. W.

Patents.

A dyes; Production of ——. J. L. Kane. E.P. 64,488, 8.3.20.

I the production of azo dyes in substance, im-p ved results as regards purity, strength and d th of colour are obtained by diazotising the a ne in presence of a starch paste prepared, for e mple, by heating 25—30% of dry starch with w er at 70°—80° C.—F. M. R.

T gsten lakes; Process for the production of ——. Linz, Assr. to The Chemical Foundation Inc. S.P. 1,378,882, 24.5.21. Appl., 19.1.21.

A louring matter is precipitated with a soluble co ound of tungsten, a soluble compound of phos-ph us, and a suitable acid which will form a double sal of tungsten in the presence of a colouring ma er, without destroying the latter.—F. M. R.

Sc nt for dyestuffs. H. A. Folsom. U.S.P. 1 79,175, 24.5.21. Appl., 25.2.21.

Va nd sulphide colours are dissolved by mixing wit water, an alkali, and sulphite waste liquor. —F. M. R.

Indigoid vat dyestuffs; Manufacture of ——. W. Carpmael. From Farbenfabr. vorm. F. Bayer u. Co. E.P. 164,594, 5.5.20.

See G.P. 298,098 of 1916; J., 1921, 294 A.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Lignin from rye straw. E. Beckmann, O. Liesche, and F. Lehmann. Z. angew. Chem., 1921, **34**, 285—288.

The character of lignin extracted from straw is dependent on the method of treatment and of its separation from pentosan and hexosan in the extract. Digestion with 1·5% sodium hydroxide, neutralising the liquor, and subsequently heating the gelatinous precipitate with 25% hydrochloric acid to dissolve the pentosan and hexosan yields a dark brown product (about 9·5% on the weight of dry straw). The impurities may be removed by precipitation from the alkaline solution with alcohol, and the lignin then separated by acid treatment. The best method consists in digesting straw with a mixture of 600 c.c. of 96% alcohol and 400 c.c. of a 2% sodium hydroxide solution; after neutralisation with acid and distillation of the alcohol, the lignin is precipitated by means of hydrochloric acid and a good product is obtained. Considerable divergence exists in regard to the composition of lignin. From determinations of its molecular weight, and examination of its benzoyl, *p*-bromobenzoyl, and *p*-nitrobenzoyl derivatives and sodium salt, the authors conclude that the most appropriate formula is $C_{40}H_{44}O_{15}$.—W. J. W.

Cotton, wool, and silk; Hygroscopic properties of ——. A. Scheurer. Bull. Soc. Ind. Mulhouse, 1921, **87**, 129—135.

When bleached silk, bleached cotton, and scoured wool are exposed till saturated, in air saturated with moisture, they absorb 28·0—29·8%, 19·0—20·2%, and 33·3—35·3% of moisture respectively, it being considered that fibre is absolutely dry when it has attained a constant weight on being heated in air at 110°—120° C. The amount of absorption is independent of the temperature of the moist air; when silk is exposed to air saturated with moisture at 25° C., the absorption is almost complete within 24 hrs. When cotton, silk, and wool are exposed to air having the same moisture content, each absorbs moisture strictly in proportion to its maximum absorbing capacity. Some observations on the moisture absorption of linen and jute are not conclusive, but indicate that linen behaves like cotton, wool, and silk.—A. J. H.

Cotton cellulose; Hydrolysis of ——. G. W. Monier-Williams. Chem. Soc. Trans., 1921, **119**, 803—805.

Crystalline "glucose" representing 90·67% of the yield theoretically obtainable from the crude material (containing 6·93% moisture and 0·13% ash), was obtained by hydrolysing 10 g. of cotton-wool with 50 c.c. of 72% sulphuric acid for 1 week at room temperature, diluting with water to 5 l., and boiling under a reflux condenser for 15 hours. After filtering and evaporating to dryness at 40 mm., alkalinity being kept down by repeated addition of *N*/10 sulphuric acid, the residue was extracted with methyl alcohol free from acetone, and the extract filtered, decolorised with animal charcoal, and evaporated in a current of dry air at a low temperature. The product had m.p. 144°—145° C. (uncorr.) and yielded a phenylosazone m.p. 204°—206° C. (uncorr.). No other products of hydrolysis could be detected. (*Cf.* Ost and Wilkening, J., 1910, 688 A; Irvine and Soutar, J., 1921, 76 A.) —P. V. M.

Methylcelluloses; Distillation of —— under reduced pressure. J. Reilly. Helv. Chim. Acta, 1921, 4, 616—621.

A series of methylated celluloses (*cf.* Woodhouse and Denham, J., 1913, 974; 1914, 1084; 1921, 211 A) containing 25·3%, 28·1%, 33·4% and 43·7% of methoxyl (and thus corresponding approximately with di- and tri-methylcelluloses) were distilled under 10—15 mm. pressure. The most definite results were obtained with the second product, which yielded 50% of methylated derivatives, the most volatile portion of which, after suitable purification, had the composition of a dimethyl-lævoglucosan and was hydrolysed to a dimethylglucose. Pictet and Sarasin's conception of the existence of the *l*-glucosan group in the cellulose molecule (J., 1919, 49 A) thus receives further confirmation. (*Cf.* J.C.S., Aug.)—H. W.

Pulpwood; Grinding tests of average infected and sound ——. J. S. Bates. Pulp and Paper Mag., 1921, 19, 687—688.

Comparative tests were carried out with rotten balsam fir, discoloured brown to the extent of 40% but still fairly firm and "average wood"—a mixture of equal quantities of balsam fir and sound spruce wood. The average weight of bone-dry wood per cubic foot was found to be practically the same for infected and sound wood, while the yield of bone-dry wood pulp per 100 parts of bone-dry wood was the same in each case, 92%. The infected wood took less time to grind than sound spruce, and gave a brown pulp, which on microscopical examination was found to consist of a mixture of coarse fibres and large quantities of wood flour, whereas the sound spruce pulp was of good colour, and the fibres proved to be fairly uniform in size. Three practical paper-making tests, using 27% of sulphite pulp, were run with the following results. Sound spruce worked well without breaks and gave a paper of good colour. Balsam fir did not run so well and caused several breaks, though the resultant paper was as strong as the spruce paper. Infected pulp with an equal quantity of average wood ran badly, was slow and sticky, and caused many breaks, very little finished paper being obtained. The paper obtained, though brown in colour, gave good results on testing. It would appear, therefore, that rotten wood should only be used in very small proportions in conjunction with good pulp. As regards storage qualities under conditions favourable to decay, it was found that the infected wood became very weak and crumbly after six months' storage, and infected even the sound pulp with which it was in contact.—D. J. N.

Patents.

Fibrous fabrics or compositions for frictional and wearing purposes; Manufacture of ——. H. Frood. E.P. 164,772, 9.12.19.

A mixture of dolerite or pumice and a binding agent such as starch, is suitable for the preparation of fabrics or compositions for use in brake blocks and linings, friction clutches, floor coverings, etc.; *e.g.*, 15 pts. of starch and 50 pts. of finely-divided pumice are mixed with 45 pts. of a 1% solution of caustic soda with which 2—5 pts. of petroleum jelly or lanoline has previously been emulsified, 35 pts. of cotton or other fibre is added (or the mixture is incorporated between layers of fabric) and the product is placed in moulds, subjected to a pressure of 2—5 tons per sq. inch, and a temperature slightly over 80° C. (so as to gelatinise the starch), and is then allowed to cool and dry under pressure.—A. J. H.

Balloon envelope material and process of manufacturing same. Ballonhüllen Ges.m.b.H. E.P. 139,794, 3.3.20. Conv., 24.12.14.

Material derived from the entrails of horses, cattle, pigs, or sheep or the stomach skin of the ox is suitable as a substitute for goldbeater's skin in the manufacture of balloon envelopes (*cf.* E.P. 139,795, J., 1921, 383 A). The entrails are divided into strips, freed from particles of fat, mucous matter, and the like, and then fastened together by means of an agglutinant so that they overlap each other and thereby form a larger strip comprising one or more layers. The material is prevented from becoming brittle by a treatment with glycerin or an oil containing glycerin. The material may also be attached to a textile fabric and rendered water-tight by means of varnish.—A. J. H.

Graphitised vulcanised fibre; Method of preparing ——. E. G. Acheson. U.S.P. (A) 1,379,155, (B) 1,379,156, 24.5.21. Appl., 14.12.20, 31.1.21.

(A) The fibre is beaten with finely divided graphite and the resulting material formed into a web; this is treated with a gelatinising agent, and afterwards washed and seasoned. (B) A formed paper web is treated with colloidal graphite.—D. F. T.

Cellulose derivatives [ethers]; Manufacture of ——. H. Dreyfus. E.P. (A) 164,374, 1.9.19, (B) 164,375, 3.9.19, (C) 164,377, 4.9.19.

(A) Alkyl ethers of cellulose of high viscosity, suitable for the production of cinematograph films, celluloid-like masses, varnishes, etc., may be prepared by kneading a mixture of 1 mol. of cellulose ($C_6H_{10}O_5$), containing $\frac{1}{2}$—$1\frac{1}{2}$ times its weight of water and 12—16 molecules of powdered alkali, with 6—7 molecules of a dialkyl sulphate or alkyl halide, at a temperature of 40°—55° C., for about 7—8 hours. The presence of an inert diluent, *e.g.*, benzene, is an advantage, and it is preferable to add the alkali and alkylating agent in successive small quantities over a period of 4—5 hours; catalysts, such as copper powder, may also be used. By the use of this highly concentrated solution of alkali (75—95%) none of the reaction products, either intermediate or final, are soluble in hot or cold water, or are thrown out of alcoholic solution by alcoholic alkali, thus ensuring a practically theoretical yield of cellulose ether. (B) One or more of the hydroxylic hydrogen atoms of the cellulose molecule may be replaced by benzyl groups or analogous groups containing one or more side chains. The process is carried out as in (A) except that the reaction temperature is between 50° and 100° C., and in place of alkylating agents benzyl chloride or any analogous compound containing one or more chlorine atoms in a side chain is employed. (C) Mixed cellulose ethers may be obtained by using as an etherifying agent benzyl chloride and dimethyl sulphate or analogous compounds, as in (A) and (B), either successively or together.—D. J. N.

Products [films etc.] having a basis of cellulose derivatives; Manufacture of ——. H. Dreyfus. E.P. 164,381, 164,385, 164,386, 3.12.19.

The alkylated sulphonamide derivatives described in E.P. 132,283, 133,353, and 154,334 (J., 1919, 896 A; 1920, 14 A; 1921, 42 A) may be used as high-boiling solvents for the cellulose ethers described in E.P. 164,374, 164,375, and 164,377 (*cf. ante*) in the production of films, celluloid-like masses, etc., of low inflammability. The cellulose ether, dissolved in benzol, is mixed with 25% of the sulphonamide derivative and 12% of tricresyl phosphate or triphenyl phosphate, and worked up in the usual manner. By increasing the quantity of sulphonamide derivatives present softer products are obtained. For films and varnishes the cellulose ether mixed with 10% of sulphonamide derivative, with or without addition of triphenyl phosphate, is dissolved in about 10 times its weight of low-boiling solvent, *e.g.*, benzol. The sulphonamide derivatives above referred to may be used as high-boiling solvents for nitrocellulose, nitroacetylcellulose, and other cellulose esters, or mixtures of these with any of the cellulose ethers described in E.P. 164,374, 164,375, and 164,377.—D. J. N.

Cellulose [acetate] composition. W. T. Scheele, Assr. to H. M. Specht. U.S.P. 1,379,699, 31.5.21. Appl., 23.10.20.

Cellulose is treated with a solution containing hydrogen peroxide and an alkali hydroxide, washed free from alkali, and then acetylated.—A. J. H.

Cellulose-nitrate composition. P. C. Seel, Assr. to Eastman Kodak Co. U.S.P. 1,379,596, 24.5.21. Appl., 26.4.19.

The composition contains cellulose nitrate, triphenyl phosphate, and fusel oil.—A. J. H.

Cellulose-nitrate composition and sheet. P. C. Seel, H. Combs, and R. Kemp, Assrs. to Eastman Kodak Co. U.S.P. 1,380,258, 31.5.21. Appl., 10.5.20.

Nitrocellulose is mixed with aliphatic alcohols containing 4 to 5 carbon atoms, and a volatile common solvent, of which the b.p. is below 100° C. —W. J. W.

Pulp board and other pulp articles and method of making same. D. M. Sutherland. E.P. 164,620, 7.6.20.

The usual process for preparing board from wood or paper pulp and suitable binding materials is employed, except that the "formed" board, immediately before compacting by means of combined heat and pressure, is allowed to retain (or regain) its normal amount of moisture (ca. 5%). The board so obtained has an increased tensile strength and toughness (sometimes by 66%). To prevent the board from sticking to the press plates it is coated with wax or a suitable vegetable oil.—A. J. H.

Filling material or adhesive; Preparation of a —— from waste cellulose liquors. Berliner Dextrin-Fabr. O. Kutzner. G.P. 335,483, 19.9.18.

Waste cellulose liquor or the residue obtained on evaporating such liquor to dryness is mixed with burnt gypsum, and, in the former case, the mixture is evaporated, whereby a very viscous, gummy mass of great adhesive power is obtained. Addition of certain salts to the mass increases its adhesive properties.—A. R. P.

Cellulose xanthogenate solutions; Process of making ——. L. Lilienfeld, Assr. to The Chemical Foundation, Inc. U.S.P. 1,379,351, 24.5.21. Appl., 16.5.14. Renewed 24.9.19.

See E.P. 14,339 of 1914; J., 1915, 830.

Parchment or the like paper; Machinery for the manufacture of ——. J. Carradice. E.P. 164,478, 6.3.20.

Solvent for dyestuffs. U.S.P. 1,379,175. *See* IV.

Plating bath. U.S.P. 1,380,142. *See* X.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Mordanting fabrics; Electrolytic process for ——. F. Driessen. Bull. Soc. Ind. Mulhouse, 1921, 87, 140—152.

When cotton fabric is attached to the platinum cathode in the electrolysis of a 0·025% solution of alum, it becomes mordanted with alumina and can be dyed red with alizarin in the presence of calcium acetate. Iron and magnesium sulphates and calcium acetate may be used instead of alum, and an optimum E.M.F. exists for each. The application of an external E.M.F. is not necessary, for if a piece of moist silk be placed between magnesium and carbon or platinum plates which are externally connected by means of a strip of copper, magnesium oxide is deposited within the silk, and this gives a violet lake with alizarin. If the silk be moistened with a solution of alizarin, it is directly dyed with a magnesia-alizarin lake. When moist cotton is placed between platinum and plates of iron, cobalt, nickel, copper, zinc, cadmium, tin, or lead under an E.M.F. of 14 volts for 1 min., the cotton is mordanted and acquires an affinity for alizarin (in the absence of calcium salts), provided that the platinum serves as the cathode. Cotton is mordanted with alumina when an aluminium plate serves as anode or cathode, although the shades of the alizarin dyeings differ. When cobalt and nickel anodes are used the most suitable E.M.F. is 2 and 4 volts respectively. In these experiments, oiled Indian cotton is preferable to ordinary bleached cotton, but silk and wool are even more suitable. The tin-alizarin and tin-lime-alizarin lakes are orange and reddish-prune respectively, but the latter is decomposed by hydrochloric acid. Alizarin lakes containing magnesium, strontium, or barium instead of calcium lack depth of shade. In dyeing with alizarin, calcium formate and phosphate (but not chloride) may be used instead of calcium acetate. Bleached cotton is more easily mordanted by electrolytic methods after steeping in saliva. —A. J. H.

Maleic acid and fumaric acid, and their salts; Application of —— in the textile industry. J. H. Carpenter. J. Ind. Eng. Chem., 1921, 13, 410—413.

For bottom-chroming of wool both maleic and fumaric acids and their salts gave uniformly good fulling, rubbing, washing, and light-fastness tests as compared with the results obtained with lactic and tartaric acid compounds. The action of maleic acid most closely resembled that of lactic and tartaric acids, sodium acid maleate resembled cream of tartar, whilst fumaric acid closely resembled sulphuric or acetic acid in its action. For the top-chroming process, maleic and fumaric acids replace successfully larger percentages of acetic acid, but for the meta-chroming process neither of these can be substituted for twice as much acetic acid; their ammonium salts might, however, be more valuable than ammonium sulphate in meta-chroming shoddy. For dyeing silks with acid colours, maleic acid gives brighter colours than the same percentage of any other acid, and fumaric acid gives colours as intense as does formic acid. Maleic acid is a good substitute for tartaric acid for discharging in cotton printing when using certain colours, and for oxalic acid when used for discharging indigo. —W. P. S.

Alizarin Red and Pink; Printing unoiled fabrics with ——. H. Sunder. Sealed Notes 2087 and 2119, 15.5. and 8.9.11. Report by L. Diserens. Bull. Soc. Ind. Mulhouse, 1921, 87, 137—139.

The red and pink shades obtained by printing unoiled fabric with Alizarin and Lizarol (M.L.B.) are less bright and fast to soaping and rubbing than those produced on oiled fabric, and to overcome this not more than 15 g. of stannous sulphoricinoleate should be added to 1 kg. of the printing paste. For pure red shades, the yellow brands of Alizarin must be used. A paste for printing Alizarin Red contains per kg., 200 g. of a 10% solution of gum tragacanth, 30 g. of Lizarol, 5 g. of acetic acid of 7° B. (sp. gr. 1·05), 335 g. of feculose thickening, 75 g. of 40% Alizarin, 120 g. of aluminium thiocyanate of 13° B. (sp. gr. 1·10), 40 g. of aluminium acetate of 12° B. (sp. gr. 1·09), 40 g. of calcium acetate of 15° B. (sp. gr. 1·12), 80 g. of tin lactate of 15° B., 10—15 g. of stannous sulphoricinoleate, and 65—60 g. of thickening. The presence of tin lactate instead of the oxalate allows the fabric to be steamed under pressure without tendering, whereby bright, pleasing, and fast shades are obtained. Another satisfactory red printing paste contains per kg., 400 g. of starch and gum tragacanth, 40 g. of Lizarol, 25 g. of castor oil, 150 g. of 20% Alizarin for red, 130 g. of aluminium lactate of 19° B. (sp. gr. 1·15; Al_2O_3, 4%), 100 g. of tin lactate of 25° B. (sp. gr. 1·21; SnO, 4·1%), 25 g. of aluminium acetate of 13·5° B. (sp. gr. 1·10; Al_2O_3, 5·2%), and 50 g. of calcium thiocyanate of 15° B. (sp. gr. 1·12; CaO, 7·8%).—A. J. H.

White [chlorate-prussiate] discharge on blue cotton fabrics. C. Sunder. Report on Sealed Note 1039, 1.7.1898 (by V. Kallab). Bull. Soc. Ind. Mulhouse, 1921, 87, 135—136.

The chlorate-prussiate discharge of the blue "ground" produced by printing or padding cotton fabric with a solution containing ammonia, the blue dyestuff, and sulphoricinoleic acid, and then drying and steaming, is not satisfactory. A faster blue "ground" is obtained (Bleu d'Alsace) if the padding solution contains per kg., 50 g. of Alkali Blue, 500 g. of water, 25 g. of tin oxychloride (50° B., sp. gr. 1·53), 60 g. of 25% ammonia solution and 250 g. of 80% ammonium ricinoleate. The tin oxychloride is made by gradually adding 100 pts. of stannous chloride to 60 pts. of nitric acid of 32° B. (sp. gr. 1·28). A blue "ground" less bright but of superior fastness is obtained by printing a reserve on the fabric and then dyeing it by a continuous process with Indanthrene Blue.—A. J. H.

Bleaching or washing fabrics; Apparatus for ——. Jackson and Bro., Ltd., G. P. Gass, R. Hammond, and J. R. Fish. E.P. 164,980, 10.7.20.

The apparatus allows cloth in open width to be sprayed with washing or bleaching liquors while it is passing from one batch roller to another and under and over rollers which are so arranged that the fabric is always under a uniform tension. It can be applied to ordinary kiers and chemicking, souring, and washing machines.—A. J. H.

Dyeing yarn on bobbins in circulating dye liquor; Means for ——. H. Krantz. E.P. (A) 157,419, and (B) 157,421, 10.1.21. Conv., 12.11.13 and 17.1.17. Addns. to 157,418 (J., 1921, 506 A).

(A) The use of upright guiding rods as described in the chief patent is unnecessary if the caulking discs and covers of each column of bobbins are of such diameter (and especially if they are polygonal in shape) that they abut against adjacent ones and the walls of the dye-beck, so that they mutually hold each other in position. (B) The fragile caulking discs with enclosed hollow spaces as described in (A) are replaced by similar discs made of cork, papier mâché, etc., which are buoyant and therefore counterbalance the load on the covers.—A. J. H.

Bleaching vegetable substances by means of hypochlorous acid; Process for ——. G. Ornstein. E.P. 147,069, 6.7.20. Conv., 2.12.16.

See U.S.P. 1,298,552—3 of 1919; J., 1919, 410 A.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Ammonia; Rôle of gaseous impurities in the catalytic oxidation of ——. E. Decarrière. Comptes rend., 1921, 172, 1663—1666.

Small amounts of hydrogen (0·44% by volume of the gaseous mixture) slightly increase the activity of platinum as a catalyst in the oxidation of ammonia, but larger amounts (1·0—1·5%) slightly lower the activity. The presence of hydrogen sulphide lowers the activity of the catalyst, but the effect appears to depend more on the concentration of the impurity than upon the total amount which has passed over the catalyst.—W. G.

Cyanide; Use of precipitated catalysts in synthetic production of ——. R. Hara. Tech. Rep. Tôhoku Imp. Univ., 1912, 2 [1], 40 pp.

With the object of replacing a mechanically divided catalyst by a more effective one consisting of chemically precipitated metal, preliminary laboratory scale experiments to study the conditions for obtaining the best yields were carried out by Bucher's method (J., 1917, 451). The most favourable results were obtained with proportions of alkali carbonate, carbon, and iron of 1:6:2 mols., a nitrogen velocity of 0·187 cub. ft. in 90 mins., and a reaction temperature of 950° C. As regards the quality of the carbon, either wood-charcoal or lampblack proved satisfactory; with coke a greatly reduced yield of cyanide resulted. Small amounts of chlorine, sulphur, or phosphorus in the raw materials did not affect the catalytic action of the iron. Experiments along similar lines were conducted with catalysts containing chemically precipitated iron. In a first series, these were prepared by saturating charcoal with dilute iron chloride solution and drying. This "ironised charcoal" proved an efficient catalyst, and, in addition, the amount of iron required was about one-tenth of that of mechanically-divided iron. Charcoal containing iron either in the ferrous state, or in a mixture of ferrous and ferric states, was superior to that with the iron in the ferric state alone. In a second series of experiments, the charcoal after saturating with iron chloride was treated with steam so as to precipitate ferric oxide on the charcoal. This catalyst showed much greater activity. Comparative experiments with metallic iron, iron chloride, and iron oxide, in proportions of 105, 9, and 12 parts respectively per 100 parts of sodium carbonate, gave conversions of 79·8, 79·8, and 92·3% respectively of the sodium carbonate into cyanide.—W. J. W.

Iron salt; A new ——. O. Röhm. Collegium, 1921, 282—284.

A strong solution of ferrous sulphate crystals was oxidised with chlorine, and allowed to stand in the air so that the excess water might evaporate; after some time wart-like crystals formed, and in a few minutes the whole mass solidified, forming crystals of the composition $FeSO_4Cl,6H_2O$, soluble in alcohol and water, but insoluble in ether. On shaking the new salt with a quantity of 96% alcohol insufficient to dissolve the whole, a solution was obtained which contained Fe, SO_4, and Cl in the proportions corresponding to the formula $FeSO_4Cl$. The salt can also be prepared by heating 1 mol. of ferric chloride with 1 mol. of ferric sulphate and 18 mols. of water, or 1 mol. of ferric chloride, 1 mol. of sulphuric acid, and 6 mols. of water. It is non-deliquescent and quite stable in the air. It is much superior to ferric chloride as a commercial product, and is more valuable as a tanning agent, giving a better leather. (*Cf.* E.P. 146,214 and 146,218; J., 1921, 388 A, 470 A.)—D. W.

Sodium perborate; Velocity of decomposition and catalysis of ——. U. Sborgi and G. Necentini. Gaz. Chim. Ital., 1921, **51**, 1., 289—307.

The authors have investigated the decomposition of sodium perborate in aqueous solution at different temperatures, and find that at 10°, 20°, and especially 40° C., this decomposition does not obey any simple law, although it corresponds approximately with a unimolecular reaction, the values of K lying on a regular curve which passes through a maximum. The velocity of the reaction is influenced in one direction or the other by the decomposition products of the perborate and by a number of other substances. (*Cf.* J.C.S., Aug.)—T. H. P.

Sodium perborate; Composition and use of ——. F. Foerster. Z. angew. Chem., 1921, **34**, 354—355.

The composition of sodium perborate is considered to be $NaBO_2,H_2O_2,3H_2O$ in preference to $NaBO_3,4H_2O$. Its practical utility lies in its low solubility. (*Cf.* J.C.S., Aug.)—W. J. W.

Aluminium; Volumetric determination of —— in its salts. A. Tingle. J. Ind. Eng. Chem., 1921, **13**, 420—422.

Two methods were found to be trustworthy for the determination of combined aluminium in aluminium sulphate. *Method A.* The boiling aluminium sulphate solution is titrated with $N/2$ sodium hydroxide solution, using phenolphthalein as indicator; the end-point is reached when the pink coloration persists after boiling for 1 min. *Method B.* The boiling aluminium sulphate solution is treated with a slight excess of barium chloride before being titrated as described in Method A. The addition of barium chloride is particularly useful when iron salts are present, as the colour of the iron is masked completely by the precipitated barium sulphate. Modifications of these methods (titration in the cold, with or without the addition of barium chloride, use of barium hydroxide solution for the titration, etc.) are less reliable.—W. P. S.

Silicon compounds; Unsaturated ——. H. Kautsky. Z. anorg. Chem., 1921, **117**, 209—242.

By carefully treating calcium silicide with cold dilute alcoholic hydrochloric acid in the dark, a white solid substance was obtained which, after isolation, was found to have the composition Si_2H_2O, and has been called oxydisilin. It has powerful reducing properties, and is spontaneously inflammable in air. It can be quantitatively converted by bromine into a new compound, silical bromide, Si_2OHBr, which is hydrolysed by water to silical hydroxide, the term silical being used to denote the radical Si_2OH-. Silical hydroxide is red in colour and is a strong base, forming salts with hydrochloric, sulphuric, acetic, and formic acids. These salts are red to yellow in colour, and are hydrolysed by water. Oxydisilin reacts with halogenated hydrocarbons in presence of a trace of water in the light; for instance, with carbon tetrachloride silical chloride and phosgene are formed. The silical compounds are oxidised by alkalis to silica with evolution of hydrogen. (*Cf.* J.C.S., Aug.)—E. H. R.

Disperse substances in gaseous media; Preparation of ——. V. Kohlschütter and J. L. Tüscher. Z. Elektrochem., 1921, **27**, 225—256.

The preparation of a number of oxides in a highly disperse colloidal form is described, the object of the experiments being to obtain such colloidal substances without the use of a solvent. A metal or oxide was vaporised in an electric arc and the vapour carried by means of a current of air or other gas into a chamber where it was suddenly chilled. The precipitation of the resulting fume of oxide was then brought about by means of a high-tension electric field. Preparations were thus made of oxides of aluminium, antimony, arsenic, lead, cadmium, calcium, chromium, iron, copper, magnesium, manganese, nickel, silicon, silver, vanadium, bismuth, zinc, and tin. The properties of the products indicated that the dimensions of the particles corresponded with those characteristic of the upper limit of the colloidal state. Many could be readily brought into colloidal solution by small quantities of peptising substances.—E. H. R.

Patents.

Sulphuric acid; Manufacture of ——. Unione Italiana fra Consumatori e Fabbricani di Concimi e Prodotti Chemici, and A. Sonneck. E.P. 164,627, 5.7.20.

Leaden chambers of any desired shape are constructed of great height in proportion to their horizontal cross-section; the gas communication between adjacent chambers is at a low level, the inlet being preferably slightly above the level of the outlet.—H. R. D.

Sulphuric acid; Concentration of ——. E. Hansen. U.S.P. 1,379,260, 24.5.21. Appl., 4.9.18.

Sulphuric acid is brought into direct contact with hot gases containing nitric oxide, and the resultant gas condensed and passed through the usual type of absorber for nitrous gases.—H. R. D.

Hydrobromic acid; Manufacture of ——. E. Theimer, Assr. to Lowenstein Radio Co., Inc. U.S.P. 1,379,731, 31.5.21. Appl., 4.8.19.

A concentrated solution of a soluble bromide is distilled with a concentrated mineral acid to produce aqueous hydrobromic acid practically free from bromine.—W. J. W.

Ammonia-still. A. Roberts, Assr. to American Coke and Chemical Co. U.S.P. 1,379,939, 31.5.21. Appl., 6.7.20.

A tray for a vaporising unit has a series of elongated parallel openings, each of which is surrounded by an upstanding collar covered by a bell (one end of which is rounded) having a downward flange encircling the corresponding collar. Overflow openings are provided in the tray, each having an upstanding flange with its apex placed between the ends of adjacent bells.—H. R. D.

Ammonia from compound nitrides; Process of making ——. G. L. Williams, Assr. to H. W. Campbell. U.S.P. 1,379,668, 31.5.21. Appl., 26.6.18.

"Compound aluminium and silicon nitride" is exposed to the action of hydrogen at a suitable temperature and in equivalent proportion to yield aluminium and silicon.—H. R. D.

Nitrogen compounds; Process and apparatus for synthetic production of ——. W. M. Williams and T. H. Haynes. E.P. 164,050, 3.12.19.

In a process of nitrogen fixation the gas is brought into contact with a subdivided base, such as an alkaline-earth oxide, and free carbon at an elevated temperature produced by exploding carbon monoxide and oxygen in presence of the reaction mix-

ture. The oxygen may be introduced in the form of air constituting the source of nitrogen, and, if necessary, to accelerate the reaction, additional oxygen up to 3—5% by volume may be added. The carbon monoxide may be employed in the form of producer-gas. The gases may be introduced under pressure and pre-heated to about 700° C. prior to ignition. The apparatus comprises a vertical steel tube, 5—6 ft. long, lined with refractory material, and in two sections. The sides of the upper section, constituting the explosion chamber, are parallel for the greater portion of their length, but are contracted conically at both ends. The solid charge and the gases are introduced at the upper end of the explosion chamber, and a sparking plug is provided for ignition. The lower section of the apparatus is wider, and is constricted at the bottom to form an opening into a chamber where the reaction products collect; this chamber has a steam inlet and is connected with an ammonia absorption plant.
—W. J. W.

Nitrogen compounds [*cyanides*]; *Apparatus for forming* ——. A. Kaufman, Assr. to Air Reduction Co., Inc. U.S.P. 1,379,187, 24.5.21. Appl., 2.5.17.

Apparatus for making alkali cyanides consists of an elongated vertical retort arranged to receive material at the top, and discharge the treated material at the bottom. The retort is surrounded by a heating chamber about equidistant between the top and bottom, so arranged that a central reaction zone is provided, together with an upper preheating zone. Means are provided for regulating the passage of heating gases about the preheating area.
—H. R. D.

Potassium content of potassium-containing liquors; Process of separating the —— H. P. Bassett. U.S.P. 1,380,035, 31.5.21. Appl., 12.6.20.

Liquors containing potassium carbonate are treated with sodium sulphate in at least molecular proportions with respect to the potassium carbonate, the solution is evaporated, the sodium carbonate removed after crystallisation, and potassium sulphate is crystallised from the cooled solution.
—W. J. W.

Potash; Process of making ——. J. Endler. U.S.P. 1,380,195, 31.5.21. Appl., 5.2.19.

The ash from potash-bearing plants is lixiviated by treatment with steam.—L. A. C.

Glauber's salt, trisodium phosphate, and neutral sodium phosphate; Process of making ——. G. T. Walker, Assr. to Colonial Chemical Corp. U.S.P. 1,379,735, 31.5.21. Appl., 23.4.18.

Sodium bisulphate solution is mixed with ground phosphate rock in such proportions as to produce a solution of acid calcium phosphate and Glauber's salt. The solution is neutralised with soda ash, filtered, and crystallised.—W. J. W.

Chromate and bichromate of sodium or potassium; Process for the conversion of —— *to chromic sulphate.* F. M. Mooney, Assr. to Formation Syndicate. U.S.P. 1,379,578, 24.5.21. Appl., 22.5.20.

A solution containing chromium trioxide is cooled to crystallise Glauber's salt, and, after separation of the crystals, the solution is treated with a "reducing sulphur-containing gas" (sulphur dioxide). (*Cf.* J., 1919, 681 A.)—L. A. C.

Adhesives [*water-glass*]; *Manufacture of* ——. J. D. Malcolmson, Assr. to The Container Club. U.S.P. 1,379,639, 31.5.21. Appl., 14.3.18.

The volume of water-glass is increased without impairing its adhesive properties by adding brine, and subsequently re-dissolving the coagulated silica. (*Cf.* J., 1920, 293 A.)—L. A. C.

Cyanamide; Production of —— *from calcium cyanamide.* J. H. Lidholm. U.S.P. 1,380,223, 31.5.21. Appl., 12.6.20.

To obtain cyanamide free from dicyanodiamide, calcium cyanamide is added gradually to an aqueous solution, and the calcium is precipitated by carbon dioxide.—W. J. W.

Halogen from natural brines; Process of separating ——. *Electrolytic apparatus* [*for electrolysis of brine*]. H. Tobler, Assr. to American Bromine Co. U.S.P. (A) 1,380,851, (B) 1,380,852, and (C) 1,380,853, 7.6.21. Appl., (A) 14.8.18, (B) 19.6.18, (C) 8.11.20.

(A) The halogen is liberated from brine by an oxidation process and is extracted by a pure, saturated, light hydrocarbon oil having a distribution coefficient for the halogen with respect to the brine greater than about six. (B) An electrolytic apparatus comprises a series of metal containers adapted to serve as cathodes, an insulating fitting surmounting each container, and an insulating pipe for circulating brine from the lower part of one container into the insulating fitting surmounting the next container. Each container has a carbon anode, and means are provided for electrically connecting the various cells so formed in series and for electrolysing the brine as it passes through the series of containers. (C) In an electrolytic apparatus as described under (B), the metal containers serving as cathodes are maintained at different potentials, and each container is provided with an integral extension with an opening through which sediment deposited from the brine may be flushed out.
—J. S. G. T.

Lime sludge; Utilization of waste or spent ——. H. Levinson and G. Martin. E.P. 164,625, 18.6.20.

Quicklime is added to the sludge to produce calcium hydroxide and calcium carbonate. By passing furnace or other gases containing carbon dioxide through the mixture, it may be converted entirely into carbonate. The products are applicable to agriculture etc.—H. R. D.

Calcium carbonate; Treatment of ——. W. H. Alton. U.S.P. 1,379,157, 24.5.21. Appl., 8.5.20.

Calcium carbonate is subjected suddenly to an intense heat whereby it is disrupted into minute particles; the heating is continued for a sufficient time to effect a partial conversion of the calcium carbonate into calcium oxide.—D. F. T.

Hydrobromic acid from bromine and hydrogen; Process and apparatus for making ——. A. Tschudi. U.S.P. 1,380,084, 31.5.21. Appl., 22.12.19.

See E.P. 154,472 of 1920; J., 1921, 79 A.

Aluminium compounds from silicates; Manufacture of ——. V. M. Goldschmidt, Assr. to Det Norske Akt. for Elektrokem. Industri. U.S.P. 1,380,552, 7.6.21. Appl., 19.3.17.

See E.P. 112,948 of 1918; J., 1918, 466 A.

Metals or metalloids. E.P. 140,096. *See* X.

VIII.—GLASS ; CERAMICS.

Glass utensils; Determination of the alkalinity of ——. F. Mylius. Z. angew. Chem., 1921. 34, 281—284.

As a means of classifying glasses of various qualities, a hydrolytic test is employed in which the glass is subjected to water treatment at 18° C. for 7 days, and then at 80° C. for 3 hours, the solution being then titrated with N/100 hydrochloric acid and iodeosin, and the alkalinity calculated as mg. Na_2O per sq. m. A glass showing more than 62 mg. Na_2O is considered unsuitable for apparatus. An alternative method consists in subjecting the article to the action of an ethereal solution of iodeosin (0·5 g. in 1 l. aqueous ether) for 24 hours at 18° C. and noting the intensity of the coloration; this test only indicates surface alkalinity, and is not suitable for a quantitative estimation. For the latter purpose, a modification of the "minute reaction" is applied. Fragments of the glass are immersed for 1 minute at 18° in an ethereal iodeosin solution and then rinsed in pure ether. By a colorimetric estimation, using a standard solution containing 0·0106 g. of sodium iodeosin per l., the "natural alkalinity" is estimated. This should not exceed 40 mg. per sq. m. For the determination of "weathering alkalinity," the treatment with iodeosin solution must be preceded by exposure of the glass for 7 days at 18° C. to air saturated with moisture. To avoid the necessity for fracturing the glass, a modification of the above process is employed in which a portion of the glass is ground so as to expose a fresh surface analogous to that of broken fragments, and the iodeosin adsorption is then determined. This should not exceed 200 mg. per sq. m. (*Cf.* J., 1907, 1048; 1908, 899; 1910, 628, 818.)—W. J. W.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Ferrous oxide and carbon; Reaction between —— and between carbon monoxide and iron. IV. V. Falcke. Z. Elektrochem., 1921, 27, 268—278. (*Cf.* J., 1913, 365; 1915, 554; 1916, 118.)

The author's earlier work and that of Schenck (J., 1905, 803; 1907, 692) and other experimenters is reviewed and criticised. In a later paper (J., 1918, 624 A) Schenck throws doubt on the author's observation that ferrous oxide can be reduced with graphite at temperatures at which pure amorphous carbon is inactive. Fresh experiments have now shown that both ferrous and ferric oxides can be reduced completely by mixing with rather more than the theoretically necessary quantity of graphite, compressing into tablets, and heating to 900°—1000° C. whilst the gases evolved are pumped away. The product obtained was not pure iron, as was observed before, but contained combined carbon. To test further Schenck's theory that free carbon is an active constituent of the solid phase of the reaction between ferrous oxide and graphite and between carbon monoxide and iron, fresh determinations of the equilibrium constant were made for the two above reactions and for the reaction $C+CO_2 \rightleftarrows 2CO$, between 600° and 750° C., the equilibrium for the last reaction being measured in presence of metallic nickel. The values of the equilibrium constants did not correspond, and it is concluded that elementary carbon plays no part in the equilibrium of the two reactions above. The earlier opinion that carbides are formed and determine the equilibrium explains best the experimental results.—E. H. R.

Steels at high temperature; Comparative tests of ——. R. S. MacPherran. Amer. Soc. Testing Materials, 24.6.21. Chem. and Met. Eng., 1921, 24, 1153—1155.

Specimen pieces, approximately 0·5 in. diam., were heated in a tube 2 in. diam., formed of alundum cement, wrapped with chromel wire, and insulated with magnesia. Irregularities due to lack of uniformity in the alloy steels were found to be numerous, but the result of tensile tests shows that the maximum tensile strength for rolled carbon steel, annealed, and forged 3·25% nickel steel, annealed, occurs at 600°—650° F. (315°—345° C.). The maximum tensile strength is developed at a higher temperature than the minimum ductility and usually falls as the temperature exceeds 800° F. (427° C.). The presence of nickel in considerable quantity lowers the temperature of maximum tensile strength and also lessens the ductility at the higher temperatures. Chromium steels appear to be affected less by rise in temperature than carbon steels, and generally the results indicate that the introduction of carbide-forming metals tends to strengthen steels at high temperatures.—C. A. K.

Steel; Forging experiments with mild ——. P. Junkers. Stahl u. Eisen, 1921, 41, 677—687.

Tests were carried out on two steels containing 0·13 and 0·50% carbon respectively. With the first steel resistance to deformation diminished with rising forging temperatures. Two ranges of temperature were observed where work affected the mechanical properties differently. Below 750° C. with similar amounts of forging and falling finishing temperatures, the elastic limit and breaking stress increased largely while the elongation, contraction, and impact test diminished. Above 750° C., with similar amounts of forging and increasing finishing temperatures, the elastic limit and breaking stress diminished and the elongation increased largely and the contraction moderately. With reductions in section of 50—85%, with constant finishing temperatures, the elastic limit and breaking stress rose with increasing forging; the elongation, contraction, and impact tests diminished. With the 0·5% carbon steel different forging temperatures followed by annealing produced similar results with the exception that the impact values showed an improvement on increasing forging. The improvement in the material due to forging was considerably greater than in the lower carbon steel. Microscopical examination of both steels showed effect of cold work below 750° C., a disturbed recrystallisation of the ferrite between 750° C. and the A3 point, and a strong formation of solid solution above the A3 point. The annealed worked steels showed a finer grain.—J. W. D.

Iron rust; Microscopic forms of ——. A. Ackermann. Kolloid-Zeits., 1921, 28, 270—281.

The forms exhibited by rust depend in the first place on the formation of ferric hydroxide. This colloidal substance assumes forms and passes through formation processes which are very like the forms and processes which occur in organised nature. Non-rigid threads are formed which grow like organic fibres and which move and change their form when subjected to changes in the external conditions. Under certain conditions cell formation is exhibited, which, externally at least, is similar to organic cell formation. Drops of a solution of ferric hydroxide possess properties which are otherwise only found in organic cells. They exhibit a solid or semi-solid enclosing semi-permeable membrane or cell wall, an adhering colloidal layer, and a nucleus. Such drops grow, spread, and divide in exactly the same way as is observed in the division of organised cells.—J. F. S.

Iron; A colloid theory of the corrosion and passivity of —— and of the oxidation of ferrous salts. J. A. N. Friend. Chem. Soc. Trans., 1921, 119, 932—949.

It is suggested that (1) the rate of corrosion of iron depends upon sol formation; (2) iron is passive to distilled water in the absence of a catalyst, but passes very slowly into solution in the presence of traces of electrolytes; (3) the dissolved iron is present initially in the ionised ferrous state, but is rapidly converted into the sol of ferrous hydroxide;

(4) this sol is oxidised by dissolved oxygen to the sol of a higher hydroxide, viz., ferric hydroxide sol, if conditions are favourable, but probably sols of ferrous, ferroso-ferric, and ferric hydroxides take part; (5) this higher hydroxide sol acts catalytically by oxidising metallic iron, itself undergoing reduction only to be oxidised again by diffused oxygen. The corrosion of iron is shown to be inhibited by rapidly moving water, which may be supposed to sweep away from the metallic surface the catalyst, derived from the iron and believed to be the hydrosol of iron hydroxide, which assists corrosion. Further support for the author's theory is derived from the results of an examination of the influence upon the corrosion of the iron of such factors as affect the formation, stability, and precipitation of colloids, and in particular electro-positive colloids. Substances which cause precipitation of colloids, *e.g.* dissolved electrolytes, alkalis, salts of organic acids (barring a slight initial rise in corrosion at low concentrations due to increased solvent action), exert a marked retarding influence upon the corrosion of iron. Other substances which inhibit corrosion are:—poisons, *e.g.*, arsenious oxide, which is adsorbed to a high degree by ferric hydroxide gel; radium rays, which tend to coagulate ferric hydroxide solution; and ethyl alcohol. The corrosive action of electrolytes falls off with rise of temperature due to the coagulative action of heat on colloids in the presence of electrolytes. All solutions which render iron passive are found to contain anions of powerful precipitating activity towards positive colloids; hence it is suggested that the passivifying action of various liquids on iron lies in the destruction of the catalysing sol. It is also suggested that the oxidation of ferrous salts by air, under which conditions the rate of oxidation is enhanced by light and retarded by mineral acids, is analogous to the corrosion of iron being catalytically accelerated by an iron sol. This receives support from previous observations on the Tyndall effect given by iron salts in neutral solution, showing that a hydrosol is present, which effect is destroyed by acids, and on the reduction of the rate of oxidation by the addition of chemically neutral salts, *e.g.* sodium chloride. The author postulates an auto-colloid (or secondary) catalytic theory of chemical reaction, whereby the action of many chemically inert catalysts is due to the existence of a colloid catalysts formed from the reactants.—P. V. M.

Total carbon; Determination of —— and a new method of determining graphitic carbon in iron alloys. P. Wenger and A. Trampler. Helv. Chim. Acta, 1921, **4**, 547—581.

Comparative examination of the Corleis method and of the electric furnace process (combustion at 1150° C.) with iron containing 0·2—8·3% of carbon, in addition to considerable percentages of other metals, has shown that the results obtained by the latter method are more concordant among themselves than those of the Corleis process; that the furnace method is much more rapid, and is universally applicable; and, lastly, that it does not involve a preliminary treatment with chlorine, which invariably introduces a small error in the determination of carbon. Graphitic carbon can be determined as follows: Phosphoric acid of sp. gr. 1·7 is heated in a platinum capsule to at least 150° C., and the finely divided alloy is gradually introduced in the proportion of 1 g. to 100 c.c. of acid. A small residue generally remains unattacked, and the original acid is therefore decanted and replaced by a fresh portion (25 c.c.). The mixture is filtered without dilution through a Gooch crucible, the residue of graphitic carbon is washed with water (300 c.c.), and ultimately burnt in an electric furnace. The temperature should not exceed 250° C. The method is applicable to ferromanganese, ferrovanadium, ferrochrome, and ferrosilicon. Certain alloys are, however, incompletely attacked; the addition of sulphuric, hydrochloric, or nitric acid to the phosphoric acid offers no advantage. The presence of hydrofluoric acid allows the method to be applied satisfactorily to ferrosilicons containing not more than 60—65% Si; in this case a temperature of at least 230° C. is necessary. The addition of metallic catalysts, such as platinum or mercury, does not yield satisfactory results.—H. W.

Steel; Influence of rolling on the electrical resistance of ——. E. L. Dupuy. Comptes rend., 1921, **172**, 1660—1662.

When a bar of steel is drawn into wire the electrical resistance decreases as the section diminishes. If such wire is heated to 800° C. and then cooled at a suitable velocity, although the alinement of the grains of pearlite and ferrite has disappeared and the wire has a micrographic structure similar to that of the original bar, the variation in resistance, though lessened, still persists. It is shown that the wire, even after annealing, contains iron oxide in solution, and a part of the resistance of the metal is due to the presence of this oxide. —W. G.

Zinc alloys; Cast ——. E. H. Schulz. Z. Metallk., 1921, **13**, 177—178.

The physical and mechanical properties of alloys of zinc with small percentages of lead, tin, iron, copper, and aluminium were determined, and the results are tabulated. Iron and lead tend to segregate; zinc used for alloying, therefore, should contain less than 1·3% Pb and 0·2% Fe. Tin, like iron and lead, causes brittleness, while copper increases the tensile strength, but at the same time produces a certain brittleness. Aluminium up to 3% increases the toughness of zinc, but above 3% tends to the formation of pipes in cast ingots. This may be prevented by addition of copper to the alloy, the best results being obtained with 6% Cu and 3% Al. For the fuses of projectiles an alloy of zinc (with less than 1·3% Pb, 0·4% Fe, and 0·5% Sn) and 7—9% of aluminium and copper together (Cu 6—4%, Al 2—3·5%) is the most suitable.—A. R. P.

Zinc and zinc alloys; Pressed ——. Hanszel. Z. Metallk., 1921, **13**, 209—219.

The physical properties of a brass consisting of 57—61% Cu, 1—2·5% Pb, and the remainder Zn and impurities (up to 0·7% Sn, 0·7% Fe, and not more than 3·5% total impurities), were greatly improved by pressing it hot into rods. Thus the tensile strength, as compared with that of the same alloy cast into rods, was 40—54 kg. per sq. mm. against 33; elastic limit 28—34 kg. per sq. mm. against 17; elongation 21—47% against 12%. With pure zinc pressed rods have a much finer crystalline structure than the cast metal and a tensile strength of 20 kg. per sq. mm., with an elongation of 25%, is readily obtained by pressing rods up to 45 mm. diam. at 100°—160° C. The tensile strength of pressed rods falls with rising temperature, being at 125° C. only half that at 20° C. The elongation increases slowly to 180° C., then rapidly falls away. The reduction in area increases rapidly from −40° C. to 0° C., after which it steadily diminishes with rising temperature, and the resistance of a notched bar to impact slowly rises with the temperature. During the war alloys of zinc with 6% Cu and 3% Al were used for fuses as a substitute for brass; the alloys have a tensile strength of 6—9 kg. per sq. mm. and a dendritic structure. Substitution of iron for the copper gave a hard, brittle, and unsatisfactory alloy (*cf.* Schulz, *supra*). An alloy of 30% Al and 70% Zn was used to replace brass for certain purposes. It has a tensile strength of about 30 kg. per sq. mm., but a relatively low elongation and resistance to shock. Pressing the zinc alloys referred to above did not result in any appreciable improvement of their physical properties.—A. R. P.

Red brass; Influence of antimony in ——. J. Czochralski. Z. Metallkunde, 1921, **13**, 276—281.

The influence of antimony up to 3% on the mechanical properties of lead-free red brass (86% Cu, 9% Sn, and 5% Zn), and on that containing 2% or 5% Pb, was determined. Up to 0·3% antimony has no deleterious effect, but larger amounts tend to make the alloy porous, hard, and brittle, which defects may be partly remedied by the addition of 2—5% Pb. The maximum tensile strength, ductility, and resistance to shock in each series was obtained with 0·5% Sb; higher proportions caused a rapid fall in the values obtained for these properties. Less than 3% Sb cannot be detected in the microscopic structure of the alloy unless about 5% Pb is also present, when dark segregated patches are seen unevenly distributed throughout the ground mass.—A. R. P.

Tin; Electrolytic refining of —— *in sodium sulphide solution.* B. Neumann. Z. Elektrochem., 1921, **27**, 256—268.

Experiments on the electrolytic refining of tin by the sulphide process were made both with pure tin and with a number of alloys. The metal to be refined was cast in the form of plates 11×8 cm., and between two of these as anodes was placed a tin-plate cathode of the same dimensions. To obtain a smooth deposit of tin with maximum current efficiency, the following conditions must be observed. The concentration of sodium sulphide in the electrolyte must not be under 10%, and some sodium sulphostannate (about 0·6% Sn) must be present in the solution before starting. Excess of sulphur must not be present in solution, as polysulphides have a solvent action on the cathode tin. The current should not exceed 1 amp. per sq. dm.; with higher current intensities hydrogen is evolved at the cathode, and the tin deposit is spongy. The temperature must not be lower than 80° C. When these conditions are observed a current efficiency of practically 100%, calculated on stanni-ions, can be maintained. The efficiency falls off for a time if the process is interrupted in any way, and if the electrolyte contains caustic soda the efficiency is liable to drop suddenly through evolution of hydrogen starting at the cathode. Alloys of tin containing respectively 9·9% Pb, 5·13% Bi, 1·1% As, 5·09% Cu, 8·7% Fe, and 4·63% P were refined with complete success, the deposited tin being free from impurity. Separation was also complete from arsenic but not from antimony. To obtain a satisfactory separation from antimony a much lower current was found to be necessary. Lead alloys of different compositions were tested; those containing 30·78% and 61·2% Pb were successfully refined with high efficiency, but with 85·2% Pb the efficiency rapidly fell off, and after a time the cathode tin started to redissolve. South American tin containing 88·6% Sn was readily refined, but the product contained 2·05% Sb. The recovery of tin was also effected from the anode mud obtained after the electrolytic separation of copper from bell bronze. The theory of the process is discussed and a description is given of a technical cell for carrying it out.—E. H. R.

Aluminium alloys; Ternary ——. M. Waehlert. Metall u Erz, 1921, **18**, 298—307.

The effect on the physical and mechanical properties of commercial aluminium of additions up to 10% of copper, zinc, tin, and iron was first determined; 2% of Cu or Zn reduces the depth of the pipe in cast ingots, but larger quantities tend to increase it again. Copper in aluminium increases the hardness, tensile strength, and elastic limit, but reduces the elongation; with 10% Cu the hardness of the cast alloy may be reduced 40% by rolling without greatly reducing the tensile strength. Zinc increases the hardness and tensile strength less rapidly than copper, but the metal is less affected by rolling than the copper alloys. Tin alone has very little effect on the mechanical properties of aluminium. In the ternary system, copper-zinc-aluminium, the piping is less than in pure aluminium to an extent depending on the composition of the alloy and the temperature of casting; the hardness is not affected by less than 3% Zn; above this up to 7% it increases, and with more than 7% Zn it falls again. Approximately 6% Cu has the same hardening effect as 13% Zn. With more than 6% Cu the elastic limit becomes equal to the ultimate stress, and both decrease. Triangular diagrams are given showing lines of equal hardness and tensile strength in this series. Addition of tin to copper-aluminium alloys yields a dense casting free from pores and reduces piping, but has little or no effect on the grain size or hardness and tends to lower the tensile strength. In alloys containing less than 2% Cu tin lowers the elongation, but increases it in alloys containing 4—6% Cu, after which it has no effect. In determining the tensile strength of the alloys of this series, if the load is plotted against the elongation a sudden sharp angle appears in the curve as soon as the metal begins to give, and, with continued steady application of load, a second angle appears, and the elongation then increases more rapidly until the test piece breaks. Iron has a bad effect on zinc-aluminium alloys, causing difficulty in the melting and pouring and leading to the production of unsound castings.—A. R. P.

Metal coatings as rust protecting agents. Lead, tin, and aluminium. W. Lange. Z. Metallkunde, 1921, **13**, 267—275.

The author has investigated the resistance of sheet iron coated with lead, tin, and aluminium to corrosion in distilled and tap water and salt and acid solutions. Electro-deposited lead coatings from alkaline baths had a very poor protective action on iron, the test piece becoming covered with rust in each of the solutions in less than a month; but those deposited from phenolsulphonic acid or fluosilicic acid baths showed good resistance to corrosion in tap water and $\frac{1}{2}$% salt solution. Treating the sheet iron by the "boiling" process previous to electro-deposition did not improve the resistance of the coating. Spraying the iron with lead by Schoop's process gave less satisfactory results than the electro-deposition from acid solutions. Of the various methods used for obtaining tin coatings on sheet iron, that in which the iron is dipped in molten tin gives the most resistant coating, while electro-deposition from a phenolsulphonic acid bath is satisfactory for small articles. Of all the metals tested, aluminium was the only one which protected the iron from all traces of rust for three months; this was probably due to the formation of a highly resistant film of oxide on the surface of the aluminium coating which prevented any further action taking place.—A. R. P.

Alloying; Systematic review of the art of ——. W. Guertler. Z. Metallkunde, 1921, **13**, 257—266.

The periodic table may be divided into 5 parts, the elements in each of which are more or less similar in their action in alloys, viz., the light metals of the alkali, alkaline-earths, and rare earths groups; the difficultly fusible metals of the silicon, vanadium, and chromium sub-groups; the transitional and noble metals; the low-melting metals of the zinc, gallium, tin, and antimony groups; and, finally, the non-metals. Two diagrams are given illustrating the nature of the binary alloys of all the metals that have been studied and showing the probable nature of alloys that have not yet been investigated. The principles underlying the art of alloying are recapitulated with reference to the diagrams and several concrete examples.—A. R. P.

Solid solutions [of metals]; Hardness of ——. W. Rosenhain. Proc. Roy. Soc., 1921, A 99, 196—202.

Solid solutions of metals in one another are considered to be formed by the replacement of atoms of the solvent metal in its crystal lattice by atoms of the dissolved metal. This replacement involves a distortion of the crystal lattice, which is less the more similar the two metals. In the condition of complete equilibrium the dissolved atoms form a type of space lattice of their own inside the space lattice of the solvent, while at the same time occupying positions in the distorted space lattice of the solvent metal. The distortion serves as a hindrance to slipping on crystal planes, and consequently increases the hardness of the alloy. In general the hardening effect of one metal on another in the form of a solid solution is inversely proportional to its solid solubility.—J. F. S.

Patents.

Steel; Manufacture of alloy ——. Manufacture of steel. R. A. Hadfield. E.P. (a) 164,394, 8.12.19 and 18.3.20, and (b) 164,395, 8.12.19.

(a) Nickel-chrome steel scrap is remelted in a basic lined open-hearth furnace with carbonaceous material, lime, and optionally iron oxide; a proportion of phosphorus and chromium is oxidised and the metal carburised. After removal of the slag the sulphur content of the metal is reduced by a further addition of lime and iron oxide, heating being continued until the carbon value is less than 0·3%. A covering of lime is added after a second de-slagging operation, and the sulphur and phosphorus may be reduced to the order of 0·012% and 0·01% respectively. Pig or alloy metal may be added to bring the bath to any required composition. (b) A similar process is applied to ordinary or carbon steel scrap, excluding nickel-chromium steels.—C. A. K.

Ferrosilicon; Process of making ——. Metallurgical process. Process of reducing iron from ore. J. T. Jones, Assr. to T. J. Howells. U.S.P. (a) 1,379,022, (b) 1,379,023, and (c) 1,379,024, 24.5.21. Appl., (a and b) 26.10.17, (c) 20.12.17.

(a and b) A finely ground (20—100 mesh) mixture of ore with excess of coal is heated out of contact with air to coke the coal and reduce the ore to metal. The metal and coke are separated subsequently, *e.g.*, by burning out the coke and remelting the metal. (c) Iron may be reduced from ore, without flux, by a similar process. Separation of metallic iron is effected by crushing the coked mass and treating it magnetically.—C. A. K.

Wrought iron; Method of making ——. J. Aston, Assr. to A. M. Byers Co. U.S.P. 1,380,178, 31.5.21. Appl., 4.2.20. Renewed 7.9.20.

The comminuted product of a steel-making operation is preheated and added to a bath of iron silicate slag to form a ball therein.

Case-hardening preparation. C. A. Stewart. U.S.P. 1,379,319, 24.5.21. Appl., 9.8.18.

Charcoal granules are mixed with an aqueous solution of an alkali compound, the quantity of solution being rather less than would be capable of absorption by the charcoal. The mixture is subsequently heated until dry.—C. A. K.

Ferric articles for metallic [lead] baths; Preparation of ——. J. H. Maddy. U.S.P. 1,379,998, 31.5.21. Appl., 11.11.20.

An adherent coating of lead may be applied to iron and steel articles by dipping them in a bath of molten lead, having previously coated the surface of the iron with a film of mercury by an electroplating process.—C. A. K.

Ores or the like; Apparatus for treating ——. G. H. Clevenger, Assr. to Research Corp. U.S.P. 1,379,083, 24.5.21. Appl., 10.4.19.

Material to be treated is moved progressively through a furnace, the reaction zone of which is heated by the combustion of gaseous fuel in the zone.—C. A. K.

Revolving drum furnace for roasting, burning, sintering, etc., of ores or the like. R. Engler. G.P. 335,029, 10.7.13.

The furnace consists of a metallic drum built up of a number of separate ring sections, supported by means of an iron framework inside a second drum. The space between the two drums serves as a cooling chamber through which air or other cooling material may be passed. This design is claimed to prevent slagging during frequent interruptions of the process.—A. R. P.

Aluminium oxide; Process of reducing ——. L. Burgess, Assr. to Standard Oil Co. U.S.P. 1,379,523, 24.5.21. Appl., 15.8.19.

Finely divided material containing aluminium oxide is mixed with a coke-producing substance, and the mixture is coked and then heated to a high temperature by means of an electric arc embedded in the mass.—A. R. P.

Aluminium; Alloy for use in soldering ——. M. A. Correa and M. Briolais. E.P. 164,655, 22.9.20.

An alloy of 49% Sn, 49% Zn, and 2% Cu is claimed. —A. R. P.

Magnesium compounds; Process for reducing ——. L. Waldo. U.S.P. 1,379,886, 31.5.21. Appl., 31.7.20.

The finely ground magnesium compound is intimately mixed with finely divided aluminium powder, and the mixture, after being compressed, is intensely heated *in vacuo*, whereby metallic magnesium distils and is collected in a suitable apparatus.—A. R. P.

Magnesium and its alloys; Process for hardening ——. F. Meyer. G.P. 335,030, 24.7.17.

Magnesium or one of its alloys in the form of rod or wire is subjected cold to a treatment by which its cross-sectional area is slightly reduced with only a small increase in length, and then, preferably, to a further treatment in a hammering or reducing machine (swage), so that the metal is compressed without appreciably increasing its length. "Electron metal," after this treatment, shows an increase in tensile strength from 20—24 kg. per sq. mm. to 43 kg. per sq. mm., and a reduction in elongation from 16—20% to 1—3%. The metal has similar properties to, and is as elastic as, iron.—A. R. P.

Metals, metalloids, their alloys and combinations; Production of ——. L. P. Basset. E.P. 140,096, 10.3.20. Conv., 10.3.19.

Oxides or oxidised compounds of a metal or a mixture of metals are mixed with sufficient carbon to reduce them, and the mass is heated by means of a flame produced by mixing a finely divided fuel, *e.g.*, coal "flour" or fuel oil, with just sufficient highly superheated air to produce by the combustion only hydrogen, carbon monoxide, and nitrogen. The process is especially suitable for the production of zinc, chromium, manganese, silicon, titanium, tungsten, molybdenum, vanadium, nickel, or phosphorus, or compounds or alloys of these metals with each other or with iron or carbon, and for the reduction of alkali or alkaline-earth sulphates to sulphides, and of lime or silica to the corresponding carbide.—A. R. P.

Alloy. F. E. Carter, Assr. to Baker and Co. U.S.P. 1,378,996, 24.5.21. Appl., 17.7.20.

The alloy contains 0·5—5% Pd, 5—15% Au, and the remainder platinum.—A. R. P.

Pulverulent or granular materials; [*Furnace for*] *the treatment of —— with gases or for roasting ores.* R. Martin and J. I. Richards. E.P. 164,547, 23.3.20.

A multiple-hearth roasting furnace with superposed hearths has openings at alternate ends of the hearths for transferring the ore from one hearth to the next lower, and each hearth is provided with a mechanically-driven scraper or plough so as to turn over the ore continually and expose fresh surfaces to the action of the gases. The scraper is in the form of a blade extending right across the hearth, and is connected with brackets which carry sector-shaped ploughs pivotally connected with the means whereby they are drawn backwards and forwards through the furnace so that the friction with the surface of the hearth causes them to turn the material over or draw it towards the opening as required. The parts of the apparatus that are subjected to a high temperature are constructed of a suitable heat-resisting alloy, such as nichrome. —A. R. P.

Ore concentration [*flotation process*]. Minerals Separation, Ltd. E.P. 154,870, 9.6.20. Conv., 29.11.19.

Oxidised metallic ores, *e.g.*, those containing carbonates, silicates, or oxides of copper or lead, are ground wet to 80-mesh, during which process a small quantity of oleic or similar fatty acid (say, 3 lb. or less per ton of ore) is added. The pulp containing 1 part of ore to 4 or 5 parts of water is then treated with a small quantity (say, 2 lb. per ton of contained ore) of sodium silicate, carbonate, hydroxide, or other suitable alkali, and the mixture subjected to agitation and aeration by known processes. The first froths may be re-treated without further addition of the frothing agent, but with a further small quantity of alkali, if necessary.—A. R. P.

Metallic sheets or foil; Production of thin ——. T. A. Edison. U.S.P. 1,379,089, 24.5.21. Appl., 4.10.19.

Alternate layers of two different metals are electrodeposited from a solution containing salts of each of the metals by the use of two anodes, one of each metal. A current of less density than will deposit one metal is first passed between the cathode and the anode of the other metal; this is then broken and a current of comparatively high density is then passed between the cathode and the other anode.—A. R. P.

Plating-bath. H. H. Hanson and A. C. Walker, Assrs. to Eastern Manufacturing Co. U.S.P. 1,380,142, 31.5.21. Appl., 17.11.19.

An electroplating bath for metals contains, in addition to a salt of the metal to be deposited, a relatively small proportion of the soluble material from the waste liquors obtained from treating wood by the sulphite process.—A. R. P.

[*Flotation*] *process and apparatus for separating ore materials from one another.* R. S. Towne and F. B. Flinn, Assrs. to Pneumatic Process Flotation Co. U.S.P. 1,378,920, 24.5.21. Appl., 12.9.14. Renewed 5.1.20.

The apparatus consists of a pulp receptacle having a conical bottom with a discharge opening therein, and a porous plate mounted in its lower half in such a manner that a gap is left all round between the edge of the plate and the sides of the receptacle. Ore pulp is fed mechanically into the apparatus from the top, and a current of air under pressure is forced evenly through the porous plate so that the bubbles attach themselves to the metalliferous portions of the pulp and carry them over the top of the vessel, while the gangue falls down through the gap between the plate and the walls of the vessel, and may be removed through the discharge-opening.—A. R. P.

Rust-preventive agent. Chem. Fabr. Flörsheim H. Noerdlinger. G.P. 335,724, 22.3.19.

Oils and fats containing phosphoric acid, produced in accordance with G.P. 313,617 (J., 1920, 72 a), are employed in conjunction with volatile solvents, other oils or fats, or other rust-preventive agents. —J. H. L.

[*Alloy for use in manufacturing*] *apparatus for high-temperature uses.* F. A. Fahrenwald. U.S.P. 1,378,941, 24.5.21. Appl., 25.8.19. Renewed 4.10.20.

The iron alloy contains 10—20% Cr, 2—6% Si, and smaller quantities of C and Mn.—L. A. C.

Welding; Process of ——. Wilson Welder and Metals Co., Inc., Assees. of D. H. Wilson. E.P. 136,827, 16.12.19. Conv., 31.10.17.

See U.S.P. 1,306,295 of 1919; J., 1919, 641 a. It is proposed to use ferrite electrodes containing about 0·25—0·75% Cu, 0·2—0·25% C, and 0·5% Mn; during the welding, part of the manganese is burnt out, but sufficient remains to provide a tough joint.

Nickel-plating solution. L. Schulte. U.S.P. 1,379,050, 24.5.21. Appl., 24.7.18.

The solution contains sodium sulphate and single and double nickel salts.—H. C. R.

Steel and alloys thereof; Manufacture of —— in open hearth furnaces. Deutsch-Luxemburgische Bergwerks- u. Hütten-A.-G., and A. Klinkenberg. E.P. 143,934, 29.5.20. Conv., 3.7.18.

Furnace; Electric ——. W. E. Moore. U.S.P. 1,378,972, 24.5.21. Appl., 18.7.19.

In a tilting electric furnace having a crucible of cylindrical shape or circular section, with conducting walls and electrodes entering through the roof, means for varying the inclination of the electrodes to the plane of the roof are provided, so that the arc may be struck between the electrodes or between one or more of the electrodes and the conducting wall of the furnace. Means are also provided for varying the inclination of the tilting axis of the crucible.—J. S. G. T.

Furnace; Electric ——. C. H. Priestley. U.S.P. 1,380,248, 31.5.21. Appl., 24.4.19.

A CYLINDRICAL furnace body is lined with an insulating tube and is retained by means of a clamping cap screw within a frame. Insulator caps are placed upon each end of the cylinder. Electrodes are inserted within a groove provided in the insulator cap and pass across the bore of the furnace. —J. S. G. T.

Furnace; Electric ——. F. T. Snyder, Assr. to Industrial Electric Furnace Co. U.S.P. 1,379,942, 31.5.21. Appl., 23.10.13.

THE temperature of a furnace having refractory heat-insulating walls and provided with a resister having a negative temperature coefficient, is varied by subjecting the electric circuit to means which decreases the energy within the furnace with an increase of current through the resister.—H. R. D.

Standard [*electric*] *cell.* C. J. Rottmann, Assr. to Westinghouse Electric and Manuf. Co. U.S.P. 1,379,698, 31.5.21. Appl., 13.9.19.

THE containing vessel of a standard cell is made of hard glass, and the leading-in wires are of tungsten. —A. J. H.

Storage-battery plate and process of making same. R. N. Chamberlain, Assr. to Gould Storage Battery Co. U.S.P. 1,379,900, 31.5.21. Appl., 12.9.18.

THE plate comprises a grid on which is pasted active material with particles of wood containing relatively little organic acid distributed uniformly in such material. The particles of wood are mainly of a size just passing screens of from 25 to 40 meshes to the inch, and the volume of wood used is about one quarter of that of the dry active material. —H. H.

Electric accumulators; Negative electrode for —— and the manufacture thereof. A. Pouchain. E.P. (A—D) 164,431—4, (E) 164,485, 10.2.20.

(A) AN active layer is deposited electrolytically from a bath containing salts of zinc, mercury, and magnesium upon a thin plate of metal, such as brass coated with silver, which is a good electrical conductor and which is not attacked by the electrolyte on closed circuit. (B) Bands or threads of silver or other metal of high conductivity, the surface of which is not attacked by the electrolyte on closed circuit, are fixed or laced on a zinc plate. (C) A layer of celluloid, shellac, or other material in a plastic condition is pressed between two perforated plates of amalgamated zinc, so as to penetrate into the perforations, whereby the zinc plates adhere firmly to the supporting plate. (D) Chemical action at the edges of a zinc plate employed in an accumulator is reduced by coating the perforated edges with an insulating varnish such as a solution of celluloid in acetone. (E) A layer of zinc is electrolytically deposited upon a silver support. —J. S. G. T.

Storage-battery separators; Method of treating ——. *Storage-battery separator.* C. C. Carpenter, Assr. to U.S. Light and Heat Corp. U.S.P. (A) 1,380,353 and (B) 1,380,354, 7.6.21. Appl., (A) 26.8.18, (B) 19.7.19.

(A) FOR purposes of storage or shipment, finished separators are treated with sulphuric acid. (B) Wood used for the manufacture of storage-battery separators is treated by a process of fermentation. —J. S. G. T.

Carbon [*electrodes*]; *Electrolytic process for the treatment of* ——. A. R. Bullock. U.S.P. 1,378,834, 24.5.21. Appl., 29.8.19.

CARBON electrodes are employed as cathode and anode in an electrolytic bath of sodium sulphate, the current strength and voltage being adjusted so as to remove carbon from the anode to the electrolyte.—J. S. G. T.

Precipitating installations; Arrangement of the insulators of ——. E. C. R. Marks. From Siemens - Schuckertwerke, G.m.b.H. E.P 164,686, 11.2.21.

THE deposition of impurities upon the insulators of the high tension electrodes is prevented by fixing the insulators in a recess in the gas duct, forming a conducting body screening off the electric field. The entrance to the recess is restricted.—J. S. G. T.

Precipitator for hot gases. L. Bradley, Assr. to Research Corp. U.S.P. 1,379,897, 31.5.21. Appl., 16.10.17.

A CLOSED chamber containing a discharge electrode system for precipitation from hot gases is fitted with a conductor passing to the electrodes through an opening in its wall, and the opening is provided with a cover of transparent material which insulates both electrically and thermally.—H. H.

Micanite; Manufacture of ——. H. Herrmann. E.P. 151,962, 18.5.20. Conv., 29.9.19.

A LAYER of mica scales is caused to adhere by suction to the perforated bottom plate of a hood connected with an aspirator or other suction device. The hood can be turned about an approximately horizontal axis, so as to bring the layer of mica scales into an easily accessible position for purposes of levelling. The layer is then deposited in a suitable receptacle and sprinkled uniformly with binding material such as powdered shellac, resin, etc. The operations are repeated until the desired thickness is built up, the material being then hot pressed and finally cold pressed.—J. S. G. T.

Electrolysis of solutions of metal salts; Apparatus for the ——. J. K. Langhard, Assr. to Fredriksstad Elektrokem. Fabr. A./S. U.S.P. 1,379,453, 24.5.21. Appl., 6.2.20.

XII.—FATS; OILS; WAXES.

Oils obtained from the feet of oxen and sheep. A. Bruno. Ann. Falsif., 1921, 14, 137—139.

Specimens of the oils prepared by boiling the offal with water and heating the resulting oil with water had the following characters:—*Sheep foot oil:* Sp. gr. at 15° C., 0·917; $n_D^{22}=1·46805$; iodine value, 84; saponif. value, 194; free fatty acids (as oleic acid), 0·34%. *Ox foot oil:* Sp. gr. at 15° C., 0·9169; $n_D^{22}=1·4675$; iodine value, 75·3; saponif. value, 197; free fatty acids (as oleic acid), 0·67%. Both oils yielded a pink coloration with Bellier's resorcinol test.—W. P. S.

Maize oil; Hydrogenation of ——. F. Reichert and R. A. Trelles. Anal. Asoc. Quím. Argentina, 1921, 9, 86—88.

In the hydrogenation of maize oil, using nickel or platinum as catalyst, the oil should be free from water. Impurities in the naphtha used for extracting the oil may destroy the activity of the catalysts employed. Preliminary experiments showed that the optimum temperature for hydrogenation was 210°—230° C. The catalytic action of nickel and platinum was compared by passing a current of hydrogen through the oil and determining the iodine value from time to time. When nickel was used as catalyst, the iodine value even after four hours did not fall below 44·5, but with platinum after three hours the iodine value fell to 21, and a product was obtained which solidified on cooling and had m.p. 57° C.—G. W. R.

Turkey-red oils; Valuation of and methods of investigating ——. Collegium, 1921, 279—282.

A meeting of the "Society of German Turkey-red-oil Manufacturers" has decided that future offers of Turkey-red oil shall be described as "Turkey-red oil X% commercial." A 50% commercial Turkey-red oil is a product containing half its weight of sulphonated washed castor oil. The fat content of this sulphonated castor oil may vary between 72 and 76%, so that a 50% oil will show a fatty acid content of 36—38%. For the volumetric determination of the fatty acids, 10—20 g. of Turkey-red oil is warmed with 25 c.c. of water until it dissolves and transferred to a Büchner fatty acid-determination-flask holding about 200 c.c., and with the neck graduated in 1-10th c.c. 33 c.c. of concentrated hydrochloric acid is added, the flask heated for 20 mins. over a naked flame, and then filled up with strong salt solution at 100° C. The flask is placed in boiling water and the volume of fatty acids read off after 15 mins. and multiplied by the specific gravity of the fatty acids. In the gravimetric method 10 g. of Turkey-red oil is dissolved in 50 c.c. of water, allowed to stand for ½ hr. on a water bath with 15 c.c. of strong hydrochloric acid, 10 g. of wax added, and after another ½ hr. the layer of wax and acids allowed to solidify and then weighed. —D. W.

Patents.

Oils from nuts, seeds, etc.; Apparatus for use in the extraction of ——. F. Durden. E.P. 164,962, 11.6.20.

The available area of filtering surface in the extraction pot is increased by providing the cylinder with vertically disposed filtering media adjacent to end pockets or chambers for collecting the oil and solvent, in addition to the usual filtering media in the lower part of the cylinder. The ends of the extraction cylinder are domed to form the necessary collecting pockets. Alternatively the cylinder may be provided with an internal cylinder which is perforated over the greater part of its area, the outer cylinder in this case forming the pocket for the collection of oil and solvent. This increase in filtering area results in a considerable saving of time. —H. C. R.

Solvents; Method and apparatus for clarifying oil and grease ——. H. Hey. E.P. 164,931, 27.4.20.

The suspended matters are removed by intimately mixing with the impure solvent either one or more of the following alkaline solutions:—Strong alcoholic or aqueous solutions of caustic potash or soda or ammonia, strong aqueous solutions of potassium, sodium, or ammonium carbonate, or other alkaline salts, such as borax, sodium silicate, or sodium aluminate. The clarification is accelerated by the addition of alcohol (methylated spirit or wood spirit) formaldehyde solution, or, in the case of petroleum solvents, castor oil, liquid castor oil fatty acids, or liquid castor oil soaps. As much as 1000 galls. of impure solvent can be clarified by treatment with ½—1 gallon of the solutions.—H. C. R.

Oils; Process for reducing the acidity of ——. F. O. Ritter. U.S.P. 1,379,045, 24.5.21. Appl., 17.8.18.

The oil is treated with an alkaline solution so as to form an emulsion; the oil and soap are then salted out, and the oil freed from soap by washing. —H. C. R.

Glycerin; Process for decolorising liquids containing —— *or crude glycerin.* Elektro-Osmose A.-G. (Graf Schwerin Ges.). E.P. 145,046, 14.6.20. Conv., 1.4.19. Addn. to E.P. 144,727 (J., 1921, 227 A).

The bleaching action of oxalic acid on glycerin solutions is improved by adding finely-divided metallic iron to the solution before the addition of the oxalic acid. The dissolved iron compounds may be precipitated before the addition of the oxalic acid by means of barium carbonate or calcium hydroxide.—H. C. R.

Glycerin. E.P. 164,034. *See* XVIII.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Linseed oil; "Non-drying" ——. A. Eibner. Farben-Zeit., 1921, 26, 2397—2403.

The "non-drying" considered by the author is not of the same degree as that of olive and almond oils, but refers to linseed oils drying abnormally slowly. The causes of such abnormality are reviewed and investigated by consideration of increase in weight curves of the oils on exposure to the air. True non-drying oils primarily form peroxides on exposure to air, but these differ from linseed oil peroxides in not subsequently forming the oxyglycerides which characterise complete drying. The action of light during exposure does not appear to be necessary for peroxide formation, since a sample of linseed oil, obtained by expression in the dark and exposed under the same conditions, dried completely though slowly. Light thus functions as a catalyst to induce drying, exposure of the oil to light through the seed walls being sufficient to cause linseed oil to dry when exposed in darkness; hence the greater drying power of oil expressed from ripe seed. Although olein is generally understood to be non-drying, oils containing even a large proportion of oleic acid as a constituent dry by virtue of this grouping being present as a mixed glyceride in combination with linolic and/or linolenic acid. Even in the case of dioleolinolin, the intervening group of linolic acid would be sufficient to induce drying in the mixed glyceride. Such steric influence will to some extent even manifest itself from an undercoat to the overlying film, hence the need of qualifying statements in this regard when reporting the behaviour of paint etc. films on drying. The so-called non-drying of certain unsophisticated linseed oil samples is often to be attributed partly to the influence of negative catalysts, such as retarding pigments, and negative catalysts derived from the seed by extraction with carbon bisulphide. Apart from the well-known factor of varying content of linolenic acid as shown by the hexabromide value, slowness of drying in linseed oil may be attributed to the absence of light during storage of the oil, freshness of seed, and the presence of moisture and mucilage. The presence of the latter two have been known to cause a linseed oil film to dry into droplets and hence to delay the drying. The glass plate method of Lippert and others for determining increase in weight of an oil on exposure is recommended for the valuation of linseed oil. In the case of suspected sophistication the hexa- and tetrabromide values should be supplemented by the plate tests, whereby abnormalities of drying can be interpreted by the shape of the curve accordingly. Non-drying oils are recognised by the formation of steps in the curve, low increases in weight, and delayed drying, whilst high-boiling ethereal oils are recognisable by losses in weight. Adulterated linseed oil may be qualitatively distinguished from faulty oil (from young seed and untanked) by determination of the melting-point of the dry film. The film from pure linseed oil does not melt, but is carbonised at 240°—260° C., whilst films from oils of the poppy class melt between 120° and 140° C., accompanied by frothing. The presence of a small quantity of foreign matter, such as rosin, rosin oil, mineral oil, or slow drying oil causes linseed oil to behave similarly to poppy oil. The presence of 5% of rosin causes the skin to melt at 130° C. with considerable frothing, whilst the non-volatile residue derived from admixture with turpentine previous to drying would similarly be shown.—A. de W.

Varnish-making; Notes on ——. M. Ragg. Farben-Zeit., 1921, **26**, 2335—2336.

When resin and linseed oil are heated together to 300° C., the free acids in the resulting product do not contain a proportion of free fatty acids substantially in excess of that existing in the original fatty oil. Thus no glycerin-rosin ester is formed at the expense of the fatty acid glyceride. On dissolving 40 g. of crystallised lead acetate in 100 g. of rosin at 110° C., 133 g. of reaction product completely soluble in benzol is obtained. Since lead acetate is insoluble in benzol and the loss in weight accounts merely for loss of the water of crystallisation, the formation of a definite compound of "aceto-abietic acid" is suggested. The slow drying properties of linseed oil and rosin or linseed oil and soft gum-resin preparations may be explained by the formation of similar complexes of the fatty and resin acids having properties different from those of the constituents.—A. de W.

Phenolic condensation product; Fractional precipitation of an oily ——. S. Satow and Y. Sekine. Kōgyō-Kwagaku Zasshi (J. Chem. Ind. Japan), 1921, **24**, 332—336.

An oily phenolic condensation product, produced by heating 1 mol. of phenol and 1 mol. of formaldehyde at 90° C. for 1 hr., using 0·1 mol. of ammonia as a catalyst, was thoroughly washed with water and then mixed with excess of a saturated aqueous solution of copper sulphate, whereby a dark brownish-green viscous oil was obtained, from which a yellow substance was precipitated by adding 95% alcohol. The dark brown filtrate gave a yellowish-green precipitate when mixed with ether, and a white precipitate was produced by adding water to the ether-alcohol filtrate. The three precipitates after drying gave powders, which were converted into clear, transparent, viscous oils by treating with lactic acid. The products resembled the original product, but did not change to a spongy substance on heating.—K. K.

Condensation products of phenol and formaldehyde; Influence of catalysts upon ——. S. Satow and Y. Sekine. Kōgyō-Kwagaku Zasshi (J. Chem. Ind. Japan), 1921, **24**, 321—332.

The oily condensation products from phenol and formaldehyde give distinctive colour reactions with many metallic salts. Applying these colour reactions, it was found that the nature of the condensation product varies according to the catalyst (*e.g.*, acid, ammonia, and caustic alkali) used. Phenolic condensation products may be classified into three main divisions of increasing degrees of condensation, viz., soluble and fusible resin, produced from 1 mol. of phenol and 0·7 mol. of formaldehyde by employing acid as catalyst; insoluble and infusible resin, produced from 1 mol. of phenol and 0·9—1·0 mol. of formaldehyde by using ammonia as catalyst; and insoluble and infusible resin, produced from 1 mol. of phenol and 1·5—2·5 mol. of formaldehyde by using caustic soda or sodium sulphite as catalyst. Addition products of the condensation product with metallic salts are easily decomposed by lactic acid. The solubility, fusibility, and chemical and physical resistance of the condensation product are proportional to the degree of condensation.—K. K.

Patents.

Titanic oxide pigments and production of the same. Titan A./S. E.P. 149,316, 30.4.20. Conv., 1.8.19.

"Titanium hydrate," *i.e.*, hydrated titanium oxides in general (ortho- or metatitanic acid or titanium hydrates containing SO_3 obtained by precipitating hydrated titanium oxide from sulphate solutions), associated or not with barium or calcium sulphate, is mixed with phosphoric acid or calcium phosphate in the proportion of about 15 pts. of P_2O_5 per 100 pts. of TiO_2, and calcined at about 950° C. for 1 hr. or more to expel the water of hydration or wholly or partly convert the titanic oxide into the crystalline modification. In a titanium product containing sulphuric acid or a sulphate, an alkaline-earth carbonate which forms an insoluble sulphate is added previous to dehydration or calcination with phosphoric acid, or calcium phosphate may be added to neutralise any free sulphuric acid. Alternatively, the titanium hydrate or aforesaid mixture may be first heated to a temperature sufficient for dehydration, phosphoric acid or phosphate added, and the mixture then calcined.
—A. de W.

Paint; Anti-corrosive ——. C. H. Ivinson and G. S. Roberts. E.P. 164,836, 13.3.20.

Mercuric chloride or other salt of mercury is dissolved in methyl alcohol or ether in proportions of 1 part of the salt to 6 parts of the alcohol or ether. From one to two parts of the resulting solution is added to 1000 parts of a basic asphaltum paint solution in a volatile solvent, which may also contain asbestos, silica, or other inert substances, together with metallic oleates or stearates, rubber, etc.—H. C. R.

Writing materials; Process and apparatus for the manufacture of ——. C. J. F. Lafeuille. E.P. 164,439, 28.2.20.

A mixture of a fusible agglutinant substance, *e.g.* sulphur, and a writing substance, *e.g.* graphite, is heated on a liquid or vapour bath at a temperature above the melting-point of the agglutinant, *e.g.*

125°—140° C., the mixture kneaded whilst hot and pressed into previously heated and lubricated cylindro-conical moulds, and removed therefrom after cooling. A suitable apparatus is described and claimed.—A. de W.

Pigment carbon derived from vegetable pith. S. E. Seaman. U.S.P. 1,379,222, 24.5.21. Appl., 3.11.19.

A pigment carbon derived from vegetable pith is claimed.—A. de W.

Surface-coating composition. A. C. Holzapfel. U.S.P. (a) 1,379,018 and (b) 1,379,019, 24.5.21. Appl., (a) 25.5.20, (b) 29.11.20.

(a) The composition consists of approximately 30—40 pts. by wt. of pitch derived from the treatment of oils and fats, and 60—70 pts. by wt. of a hydrocarbon solvent. (b) The composition (a) further includes not more than 25 pts. of titanium oxide.—A. de W.

Waterproofing composition. T. Shibata and E. Oe. U.S.P. 1,380,428, 7.6.21. Appl., 6.5.18.

The active agents are the reaction products of aluminium acetate and saponified vegetable oil. —H. C. R.

Linoleum; Process of working up scrap —— into new linoleum. V. Scholz and C. Tiedemann. E.P. 158,210, 29.5.20. Conv., 24.1.20. Addn. to 143,561 (J., 1921, 122 a).

Scrap linoleum is introduced into the upper portion of a pressure vessel separated by a sieve from the lower portion containing a steam coil. Organic solvents for linoxyn and linoleum cement, having boiling-points above 140° C., are mixed with other solvents of lower boiling points in order that the latter may carry over the former at a temperature below that of the decomposition of cork, and introduced into the lower part of the vessel either by gravity, or by a pump if extraction be carried out under pressure, and volatilised by the steam coil. The upper portion of the vessel is provided with an outlet pipe and condenser and means for maintaining a circulation of recovered solvents. After softening by exposure to the organic vapours, the softened scrap is discharged, the jute and basic linoleum pulp separated mechanically, and the latter repolymerised to the tacky condition for further use as cement, at a temperature of 100°—120° C. —A. de W.

Tungsten lakes. U.S.P. 1,378,882. *See* IV.

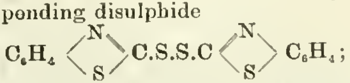
XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber; Presence of manganese in raw —— and the origin of tackiness. G. Bruni and C. Pelizzola. Indiarubber J., 1921, 62, 101—102.

Manganese dioxide, particularly in a colloidal conition, is a powerful agent in producing tackiness; ubber to which 1% had been added became very dhesive and almost fluid in a few weeks at the rdinary temperature. Examination of the ash of arious samples of rubber for manganese by the ersulphate-silver nitrate method revealed the fact hat the very tacky samples contained about 100 mes as much manganese as sound specimens, hilst in slightly tacky rubbers the proportion was bout 8 times as great as for sound rubber. The verage content of manganese in sound rubber was 00016%. Although tackiness may not invariably e due to the presence of manganese, this is condered the determining factor in the majority of ses. Tests for the presence of oxidising enzymes tacky rubbers gave negative results.— D. F. T.

Accelerators of vulcanisation; Mechanism of certain ——. G. Bruni and E. Romani. Indiarubber J., 1921, 62, 63—66.

Not only is the activity of organic accelerators dependent on their conversion into disulphides during vulcanisation (Scott and Bedford, J., 1920, 199 a; 1921, 228 a), but, as is now demonstrated, the organic disulphides derived from the "carbosulphydryl" class of accelerator are capable of yielding their own sulphur for vulcanisation. The dithiocarbamate accelerators derived from carbon bisulphide and a primary or secondary amine, during vulcanisation, undergo conversion into the corresponding zinc alkyldithiocarbamates, and these by the action of sulphur yield thiouramdisulphides (*cf.* J., 1921, 520 a). Similarly zinc ethylxanthate, although nitrogen-free, is a powerful accelerator, its effectiveness being due to its conversion by sulphur into a "dixanthogen" RO.CS.S.S.CS.OR. The activity of thiocarbanilide is dependent on its conversion through phenyl isothiocyanate into mercaptobenzothiazole  $C_6H_4\langle{}^{N}_{S}\rangle C.SH$, the zinc salt of which accelerates vulcanisation by yielding the corresponding disulphide



$$C_6H_4\langle{}^{N}_{S}\rangle C.S.S.C\langle{}^{N}_{S}\rangle C_6H_4;$$

the other substituted thiocarbamide accelerators act in an analogous manner. Anhydroformaldehydeaniline, when heated with sulphur, also gives rise to mercaptobenzothiazole, thus revealing its mode of action as an accelerator. The peculiar effectiveness of zinc oxide in increasing the activity of certain organic accelerators is dependent on the formation of salts possessing the necessary convertibility into the corresponding disulphides.—D. F. T.

Tetralin; Use of —— in the manufacture of rubber substitute. R. Ditmar. Z. angew. Chem., 1921, 34, 355.

If a hydronaphthalene derivative (tetralin etc.) is used as a solvent for drying oils before treating them with sulphur and sulphur chloride for the manufacture of rubber substitute, the violence of the reaction is considerably diminished.—W. J. W.

Patents.

Vulcanisation of rubber and treatment of vulcanised rubber. H. P. Stevens. E.P. 164,770, 6.10.19 and 2.1.20.

Vulcanisation by means of the usual vulcanising agents—sulphur, sulphur chloride, trinitrobenzene, etc.—at the appropriate temperatures can be effected with dissolved masticated rubber, and under suitable conditions it is possible to obtain solutions or doughs of vulcanised rubber. On removal of the solvent, a residue of vulcanised rubber is obtained which will not re-dissolve if treated afresh with a solvent. If the proportion of raw rubber in the solution is too high, vulcanisation will cause gelation, but it may be possible by mastication in the presence of additional solvent to convert the jelly into a workable dough; if the solution is too dilute, *e.g.*, 2·5—0·5%, the heating necessary for vulcanisation effects a degradation of the rubber. The residue obtained by evaporation is capable of re-dissolving in benzene: a suitable concentration of rubber is 10%; it is also desirable to restrict the proportion of sulphur to 1—4% calculated on the rubber. This method of preparing vulcanised solutions may be applied by (*a*) heating solutions of rubber and sulphur in a solvent, the b.p. of which is higher than normal vulcanising temperatures, (*b*) heating such solutions in more volatile solvents in a closed space under increased pressure, (*c*) heating a lightly vulcanised rubber with a suitable solvent, (*d*) treating a solution of raw rubber with a limited proportion of sulphur chloride, masticating the rubber either prior or subsequently to the vulcanisation process. Method (*b*) is the most promising of the three "hot" processes. Solutions of vulcanised rubber tend to become more viscous on keeping, and may even gelatinise, but the rate of change rapidly decreases and a solution which is mobile a few days after vulcanisation will remain so for long periods. Exposure to light increases the viscosity and may cause gelation, but in this case the gel gradually becomes fluid again if immediately transferred to a dark cupboard; these changes may be effected repeatedly with the same solution. Prolonged exposure to light may cause liquefaction of the jelly probably by a change analogous to "perishing."—D. F. T.

Rubber; Art of compounding ——. C. W. Bedford, Assr. to Goodyear Tire and Rubber Co. U.S.P. 1,380,765, 7.6.21. Appl., 12.7.19.

A solution of a vulcanisation accelerator is mixed with a compounding ingredient prior to incorporation in the rubber which is subsequently to be vulcanised.—D. F. T.

Ebonite and vulcanite substitutes; Manufacture of ——. F. L. Schauerman. E.P. 164,392, 24.3.20.

A mixture of rubber and sulphur is heated in a masticator for four hours at 270°—275° F. (132°—135° C.), and stearine pitch, shellac, lampblack, gelatin, and peat or other vegetable fibre are introduced. The mass is then heated to such a degree that it may be moulded, pressed, or cast into any desired form.—D. F. T.

Rubber-like material; Process of making —— *and resulting product.* J. C. Wichmann. U.S.P. (A) 1,379,149, 24.5.21. Appl., 3.9.20. (B) Assr. to L. J. Maescher. U.S.P. 1,379,150, 24.5.21. Appl., 22.12.20.

(A) The juice from the maceration of the fleshy parts of members of the cactus family is first mixed with a catalyst containing a mineral acid radicle, and then, after concentration, with a solution of rubber, linseed oil, asphaltum, and sulphur. The mixture is boiled, dried, and oxidised. (B) The yucca plant is treated as described, the catalyst being sodium tungstate.—D. F. T.

Rubber; Separation of —— *from raw or vulcanised rubber waste.* P. Friesenhahn. G.P. 336,146, 25.7.19.

The material is treated with hydrogenated phenols or derivatives of these, such as cyclohexanone and its homologues, cyclohexanols and their esters, either alone or mixed with other solvents. The cyclohexanols relative to the customary rubber solvents are characterised by low inflammability, high solvent power, and pleasant odour.—D. F. T.

Rubber and like materials; Machines for mixing or masticating ——. Farrel Foundry and Machine Co., Assees. of D. R. Bowen and C. F. Schnuck. E.P. 151,551, 26.11.20. Conv., 28.11.19.

Rubber; Manufacture of ——. *Treatment of rubber latex.* S. C. Davidson. U.S.P. 1,380,640, 7.6.21, and 1,381,455, 14.6.21. Appl., 24.2.20.

Substitutes for rubber etc. E.P. 165,007. *See* XV.

XV.—LEATHER; BONE; HORN; GLUE.

Hide and pelt; The relation of ammonia to ——. W. Moeller. Collegium, 1921, 265—279.

Some tannery chemists dispute the claim that ammonia is formed by oxidation or fermentation of hide substance. Few know that it contains ammonia present either as ammonium salts, acid amides, hydroxy-acids, or amino-hydroxy acids. The part played by this ammonia becomes very important in view of the chemical theory of tanning. The whole of the ammonia split off by alkalis is probably not in the form of ammonium salts of some acid but probably partly as an acid amide. It is impossible to determine this since hydroxy-acids and amino-hydroxy-acids are formed in the hydrolysis of hide substance and these tend to change to acid amides. The action of ammonia differs from that of other alkalis in the absence of swelling, which is probably due to some chemical change in the swelling ions. Hide powder gives up 1·56% of ammonia when distilled with potash; it contains 0·75% of hydrolysed protein matter, which in turn contains 3·05% of ammonia. The action of $N/10$—$8N$ solutions of ammonia on hide powder was determined, and it was found that the ammonia hydrolysed pelt, but to a lesser extent than calcium or sodium hydroxides. Maximum hydrolytic action was obtained with $4N$ ammonia solutions. The unhydrolysed portion of the hide powder absorbs large quantities of gaseous ammonia, and the absorption is in accordance with the usual adsorption laws. There is no chemical action between the ammonia and the unhydrolysed hide powder, but only with the soluble or hydrolysed protein matter. The chemical combination of the ammonia with the acid groups in the hydrolysed portion is quite independent of the amount of the latter, and varies only with the concentration of the hydroxyl ions. The hydrolysis is proportional to the time and concentration of the ammonia; this points to some reaction between the new compounds formed and the intact portion of the hide. The irregularities in the swelling of hide powder with ammonia are due to the proteolytic processes.—D. W.

Gelatins; Setting and melting points of ——. S. E. Sheppard and S. Sweet. J. Ind. Eng. Chem., 1921, 13, 423—426.

An intermittent stream of air bubbles, under constant pressure, is passed through the gelatin solution which is cooled with ice-water; a thermometer is immersed in the solution with its bulb adjacent to the air inlet, and the temperature at which bubbles cease to pass is taken as the setting point. After sufficient under-cooling, the set jelly is heated gradually, and the point at which air bubbles again pass through is taken as the melting point. In the apparatus used, compressed air is passed through a manometer and a manostat tube, and thence to a U-tube containing mercury, which is used as a valve to produce intermittence in the air supply; a solenoid, the current through which is made and broken every 15 secs. by a timing device, operates an iron plunger in the U-tube. The air is then conducted to a second U-tube acting as a compensator, and from this passes to the vessel containing the gelatin solution. Another melting-point apparatus, useful in certain cases, is described. The jelly is set in a test-tube with a thermometer embedded with the bulb just below the surface; a small test-piece, slipped round the thermometer, rests on the jelly by three equidistant wedge-shaped feet. The jelly is heated slowly and the melting point is taken as the temperature at which the test-piece has sunk just below the feet.—W. P. S.

Iron salt. Röhm. *See* VII.

Patents.

Artificial leather and substitutes for rubber, gutta-percha and the like; Manufacture of ——. A. J. Pheazey and J. S. Campbell. E.P. 165,007, 19.10.20.

Seaweed, preferably *Laminariaceæ*, *Naiadaceæ*, or *Fucaceæ*, is heated with a dilute aqueous alkaline solution below the b.p., with continuous stirring until a thick jelly is obtained; a jelly is also obtained by heating the skivings of untanned hides with aqueous caustic alkali, this jelly being subsequently treated with tanning agents, such as pyrogallol or catechol materials, or with chromium salts, about 1% of lime being finally added. The two jellies are then mixed and maintained at 120° F. (50° C.), with constant stirring, any desired filling or colouring materials being added meanwhile, until the mixture is dry. The dry mass is then mixed with a solution of an elastic binding agent such as rubber, and with a vulcanising agent, being stirred until a homogeneous dough is obtained. The raw product can be applied to the manufacture of leather substitutes, floor coverings, etc., either in the unvulcanised or vulcanised condition.—D. F. T.

Casein solution and process of making same. H. V. Dunham. E.P. 164,604, 17.5.20.

See U.S.P. 1,347,845 of 1920; J., 1920, 633 a.

XVI.—SOILS; FERTILISERS.

Clay; Chemical nature of —— as obtained by Atterberg's method. E. Blanck and F. Preiss. J. Landw., 1921, **69**, 73—78.

The crude clay fraction as obtained in the mechanical analysis of soil was still further divided into 26 sub-fractions by elutriation methods. Chemical analysis of the individual sub-fractions showed that about 80% of the total clay had a fairly constant composition, closely approximating to the theoretical clay-complex $Al_2O_3,2SiO_2,2H_2O$. The remaining sub-fractions, consisting of the coarser grades, showed a gradually increasing silica content. From this point the proportion of silica steadily increases through the fine silt, coarse silt, and fine sand fractions where the molecular ratio $Al_2O_3:SiO_2:H_2O$ was practically 1:8:2·8. It is concluded that the mechanical analysis of soils on the Atterberg basis effects a satisfactory separation of a true clay fraction.—A. G. P.

Soils; Variation of the soluble salts in —— and in the sedimentation-curve during the growth of turnips. W. Geilmann and A. van Hauten. J. Landw., 1921, **69**, 105—130.

Soil samples were taken simultaneously from a series of differently manured plots throughout the period of growth of the roots. Sedimentation-curves were obtained for all samples, and the amounts of total nitrogen, sulphates, lime, magnesia, soda, and potash in aqueous extracts were determined. Numerous tables show the variation of each of these quantities with season and with the type of manuring. Both the quantity of soluble salts and the sedimentation-curves are largely influenced by manuring and by the changes in soil-moisture content. Sedimentation-curves for individual plots vary considerably during the period of growth of the roots.—A. G. P.

Soil acidity; The iodine method for estimating ——. O. Lemmermann and L. Fresenius. J. Landw., 1921, **69**, 97—104.

The method developed by Stutzer and Haupt (J., 1915, 1064) is criticised adversely. The uncertainty of the method, due to absorption of iodine by soils, possible interaction with the organic matter, and variations in the time of contact of the reagents, s pointed out. The value of the method is thereby much depreciated.—A. G. P.

Plants; Behaviour of organic substances in ——. XIII. G. Ciamician and C. Ravenna. Gaz. Chim. Ital., 1921, **51**, I., 200—223. (*Cf.* J., 1920, 344 a.)

Further experiments have been made with a number of compounds of different chemical types (*cf.* J.C.S., i., 483).—T. H. P.

Patent.

Lime sludge. E.P. 164,625. *See* VII.

XVII.—SUGARS; STARCHES; GUMS.

Sugars and polyatomic alcohols; Reactions of —— in boric acid and borate solutions, with some analytical applications. G. Van B. Gilmour. Analyst, 1921, **46**, 3—10.

In the abstract of the above paper (J., 1921, 125 a), mention should have been made of the author's recommendation to use invert sugar in the volumetric determination of boric acid, in place of glycerol or mannitol (*cf.* Boëseken and Couvert, J., 1921, 444 a).

Lactose; Determination of —— in the presence of other reducing sugars. L. Le Grand. Ann. Falsif., 1921, **14**, 132—136.

The amount of lactose in a mixture of sugars may be determined by an application of a method described previously (J., 1921, 272 a), in which Barfoed's reagent is used; this reagent is reduced by monoses (dextrose, lævulose, galactose) but not by bioses (lactose, maltose). The lactose is the difference between the sum of the monoses and bioses as determined by Fehling's solution and the quantity of monose found by means of Barfoed's reagent. The method may be used for the determination of unaltered lactose in milk preserved with bichromate and of invert sugar which is sometimes present in sweetened condensed milk.
—W. P. S.

Lævulosan. A. Pictet and J. Reilly. Helv. Chim. Acta, 1921, **4**, 613—616.

Lævulosan is prepared by heating dried lævulose under 15—20 mm. pressure at 115°—120° C. during 2—3 hours. It is a white, very hygroscopic powder, m.p. about 100° C., $[\alpha]^{20}_{D}=+18{\cdot}6^\circ$ in aqueous, $+19{\cdot}5^\circ$ in methyl alcoholic solution. It is not fermented by brewers' yeast. Its reducing power towards Fehling's solution is exactly one-third of that of lævulose. It is readily converted into the latter by boiling water. With phenylhydrazine it gives phenylglucosazone. The presence of three hydroxyl groups is demonstrated by the preparation of the trinitrate, m.p. 139°—140° C.; triacetate, m.p. 85° C.; and tribenzoate, m.p. 125°—126° C.
—H. W.

Methylcelluloses. Reilly. *See* V.

Patents.

Sugar beets; Production of beet juice and valuable slices from ——. H. Mathis. G.P. 334,652, 24.5.19.

The sliced beets introduced into the diffusion vessel are treated with steam at or slightly above 100° C., after which the juice from the preceding vessel, as hot as possible, is introduced and the charge is further heated. The juice from the diffusion battery is concentrated as usual. The pulpy residues from the diffusers are stored in suitable receptacles, *e.g.*, deep trenches, in contact with the liquid contained in them, and allowed to undergo spontaneous lactic fermentation. The liquid is only drained off from the trenches near the close of the storage period in order to obtain a sufficiently dry fodder.—J. H. L.

Separators. E.P. 164,418. *See* I.

Glycerin [from sugar]. E.P. 164,034. *See* XVIII.

XVIII.—FERMENTATION INDUSTRIES.

Hops; Rapid polarimetric method of determining tannin in ——. A. R. Ling and D. R. Nanji. J. Inst. Brew., 1921, **27**, 310—313.

A modification of Chapman's method (J., 1908, 135) is proposed, in which the amount of cinchonine tannate precipitate is calculated from the decrease in the optical rotatory power of the cinchonine sulphate solution as the result of the precipitation. Ten g. of hops is extracted for 2 hrs. on a water bath and made up to 508 c.c. as described by Chapman, and 100 c.c. of the filtered liquid is evaporated to somewhat less than one-half and treated with 50 c.c. of an approximately 1% cinchonine sulphate solution, the exact titre of which has been determined from its rotatory power by use of Landolt's value $[\alpha]_D=170{\cdot}3°$. A quartz compensation polarimeter with Ventzke scale may be used, with the factor 0·3459 for conversion to angular degrees and sodium light. A strictly 1% solution of cinchonine sulphate, corresponding to 0·8145 g. of cinchonine base per 100 c.c., should read 4·92° V. in a 100-mm. tube. By subtracting the corresponding value for the solution after precipitation, the amount of base precipitated, and therefore of tannin present, may be calculated. The results cited agree satisfactorily with those obtained gravimetrically.—J. H. L.

Beets; Inhibitive action of saponin from —— on alcoholic fermentation. J. Satava. Chemické Listy, 1920, **14**, 1—6. Chem. Zentr., 1921, **92**, I., 914.

Fermentation by yeast is entirely prevented by the presence of 0·02—0·03 g. of beet saponin per 100 c.c. of liquid, but bacterial action is not affected. *S. ellipsoideus* is 2—3 times as sensitive as brewery and distillery yeasts towards the saponin. The sensitiveness may be diminished to some extent by acclimatisation. The inhibitive action of beet saponin may be annulled by addition of acids. —J. H. L.

Enzymes; Chemical nature of ——. T. Bokorny. Allg. Brauer- u. Hopfenzeit., 1921, 121—122, 129—130, 133—134. Chem. Zentr., 1921, **92**, I., 911—912.

Measurements of the volumes of nitrogen evolved by the action of nitrous acid on various enzymes (*cf.* J., 1921, 273 a) indicated the following percentages of amide nitrogen in the preparations employed: pepsin 3·16%, emulsin 4·17%, rennet powder 3·05%, and egg albumin 3·28%. Trypsin in neutral solutions is completely adsorbed by kaolin and by alumina; it is accordingly amphoteric, and is capable of fixing 3% of ammonia and 2—5% of sulphuric acid. Pepsin in neutral solutions is adsorbed incompletely by kaolin but completely by alumina; it is thus amphoteric but rather more acid than basic. Invertase is acid in character, being adsorbed incompletely by alumina and not at all by kaolin.—J. H. L.

Amylases of the cereal grains. Rye. J. L. Baker and H. F. E. Hulton. Chem. Soc. Trans., 1921, **119**, 805—809.

Ungerminated rye amylase, when allowed to act on potato-starch paste at 50° C., readily liquefies the paste and yields α-amylodextrin ($R=1{\cdot}5$; $[\alpha]_D=+184{\cdot}1°$) and maltose, which can be obtained crystalline after one fractionation with alcohol. Compared with ungerminated barley amylase, that of rye, though yielding identical products, possesses a greater enzymic activity towards starch paste. The amylase of germinated rye under the same conditions yields a product, the constants of which resemble those resulting from the action of malt amylase on starch, but alcoholic fractionation yields crystalline maltose with much greater ease. The final products are crystalline maltose and a non-hygroscopic, unfermentable reducing dextrin ($R=10{\cdot}8$; $[\alpha]_D=+181{\cdot}9°$) the apparent maltose in which is in a state of combination. The whole of this contained maltose is fermentable by yeast, and the intermediate alcoholic fractions are undegradable by malt amylase, hence there is no formation of the intermediate degradable maltodextrins formed by the action of malt amylase on starch. —P. V. M.

Enzyme; Auto-regeneration of an —— after poisoning by metals. H. von Euler and O. Svanberg. Ark. Kemi, Min., Geol., 1920, **7**, No. 27, 1—30.

After the reversible inactivation of invertase by very small proportions of mercuric chloride or silver nitrate, which proceeds in accordance with stoichiometrical relations, a spontaneous, partial auto-regeneration of the enzyme gradually occurs. This effect, which is readily reproducible, is comparable in many ways with the Danysz effect in immunochemistry. (*Cf.* J.C.S., 1920, i, 690.)—T. H. P.

Saccharase (invertase); Sensitiveness of —— towards ultra-violet light and oxidising agents. O. Svanberg. Ark. Kemi, Min., Geol., 1921, **8**, No. 6, 1—17.

The destruction of invertase by the action of the radiation from a mercury lamp on its solution may be prevented by passing hydrogen through the liquid while the light is acting on it, so that this action of ultra-violet light appears to be mostly a secondary photochemical effect. The enzyme is insensitive towards hydrogen peroxide and not sufficiently sensitive towards ozone for the latter to produce the effect of the ultra-violet light Amylase is far more profoundly affected by these oxidising agents than invertase. (*Cf.* J.C.S., Aug.)—T. H. P.

Wine; Analysis of ——. W. Fresenius and L. Grünhut. Z. anal. Chem., 1921, **60**, 168—187.

Detection of foreign dextro-rotatory substances, especially impure starch syrup, by polarisation. To detect the unfermentable constituents of impure starch syrup in a dry wine, 210 c.c. of the sample is evaporated to 70 c.c., diluted to 100 c.c., sterilised at 100° C., cooled, and fermented at 30° C. with pure wine yeast or washed brewers' yeast. When fermentation is complete, the solution is treated with 1·5 c.c of 20% potassium acetate solution, and evaporated to a syrup; 200 c.c. of 90% alcohol is added to the syrup, the mixture stirred, filtered, and the insoluble portion washed with alcohol. The insoluble portion is then heated on a water-bath to remove alcohol, dissolved in 10 c.c. of water, the solution treated with 3 g. of animal charcoal, filtered, and the charcoal washed with hot water until the filtrate measures 30 c.c. If the polarisation of this filtrate in a 200-mm. tube is more than +0·5°, the wine contains the unfermentable constituents of starch syrup. The method is not applicable to sweet wines. *Detection of gum arabic and dextrins.* Wines containing gum arabic or dextrins yield a sticky, granular precipitate when 4 c.c. of the sample is treated with 10 c.c. of 96% alcohol. In the case of dry wines, a more sensitive test consists in evaporating 100 c.c. to a volume of 10 c.c., adding 90 c.c. of absolute alcohol, collecting the precipitate after 2 hrs. and washing it with alcohol; the precipitate is then dissolved in 50 c.c. of water, 5 c.c. of hydrochloric acid (sp. gr. 1·12) is added, the solution heated on a steam-bath under a reflux condenser for 2·5 hrs., cooled, neutralised, diluted to 100 c.c., and filtered. The cupric-reducing power of the filtrate is determined and the results expressed as dextrose. This sugar is derived from the dextrins or gum arabic present, or from the latter alone if the test for unfermentable substances described above has given a negative result.—W. P. S.

Wine; Determination of glycerol in —— by conversion into acrolein by means of boric acid. A. Heiduschka and F. Englert. Z. anal. Chem., 1921, **60**, 161—166.

The extract from 100 c.c. of wine is rinsed into a small retort with 5 c.c. of water and evaporated to a volume of 2—3 c.c.; 1 g. of boric acid is added and the mixture is heated by a fusible-metal bath (Pb 8, Sn 3, Bi 8 parts) until all water has been expelled. The retort is then connected with receivers containing ammonia and cooled with an ice and salt mixture, and a slow current of air is introduced into the tubulus of the retort while the latter is heated gradually to 320° C. After heating for 45 mins. at this temperature, the receivers are disconnected, their contents mixed, treated with 5 c.c. of $N/10$ silver nitrate solution, and heated on a steam-bath for about 20 mins.; the mixture is then filtered and the excess of silver nitrate titrated in the filtrate. Reference to a table gives the amount of glycerol corresponding with the volume of silver nitrate solution reduced.—W. P. S.

Wines obtained from grapes attacked by insects [vendanges eudemisées]. E. Hugues. Ann. Falsif., 1921, **14**, 139—141.

As compared with wine obtained from sound grapes, that from grapes attacked by insects (*eudemisés*) has a harsh, bitter taste and contains more alcohol and nearly three times as much total acids and extractives; in one case 3·12 g. per litre of free tartaric acid was found against 0·31 g. in the sound wine.—W. P. S.

Oxalic acid; Determination of ——. A. Bau. Woch. Brau., 1921, **38**, 113—115, 122—124. (*Cf.* J., 1920, 349 a, 381 a, 613 a.)

Application of the calcium acetate method (*loc. cit.*) to the determination of oxalic acid in plant materials etc. showed that the barley plant contained 0·027; hops 0·567—0·647; pine needles 0·44; beer wort 0·004% of oxalic acid. The first three results are expressed as percentages of the dry substance.—W. P. S.

Jerusalem artichokes; Production of alcohol from ——. M. Rüdiger. Z. Spiritusind., 1921, **44**, 222—223. (*Cf.* J., 1920, 608 a.)

Artichokes in the fresh, hard state contain 15—16% of sugar or readily saccharifiable carbohydrates. They are not adapted to storage and are better left in the ground until required. For the production of alcohol the pulped or thinly-sliced tubers are mashed with ½—1 pt. by weight of luke-warm water, and if possible saccharified for 1—2 hrs. at, but not above, 55°—56° C. The cooled mash is fermented with ½ l. of liquid beer or wine yeast per hl. at a temperature not exceeding 30° C. As the fermentation occupies 4—5 days it is best conducted in covered vats to avoid infection. Some frothing is liable to occur during distillation. The average yield of alcohol in the author's experiments was 7—8 l. per 100 kg. of fresh tubers containing about 80% of water. The dry substance of the distillation residue contained 17·3% of nitrogenous matter, 2% of fat, 13·6% of raw fibre, and 6·9% of mineral matter.—J. H. L.

Patents.

Yeast; Process for production of ——. A. Meyer. E.P. 144,244, 18.11.19. Conv., 31.5.19.

In the manufacture of baker's yeast, with production of alcohol as by-product, the yeast is grown in absence of air, in closed vats which are maintained under reduced pressure for the withdrawal of the carbon dioxide and a part of the alcohol, the contents of the vats being preferably agitated meanwhile. The process may if desired be applied only to the preparation of the seed yeast or mother yeast, the subsequent growth being then carried out in open vats.—J. H. L.

Glycerin; Production of —— by fermentation. A. T. Cocking and C. H. Lilly. E.P. 164,034, 25.9.19.

Sugar solutions containing mixtures of normal and acid sulphites in such proportions as to be approximately neutral to litmus are fermented by yeast. Mixtures of normal and acid sulphites, preferably dissolved in water, may be added in successive quantities in the course of fermentation. If necessary aqueous solutions of bisulphites may be added, or the proportion of bisulphite in the added mixtures may be increased, in order to maintain approximate neutrality to litmus in the fermenting liquid. Yields of glycerol equivalent to nearly 50% of the sugar decomposed are attainable by prolonged fermentation and the use of 80 pts. of sulphite mixture per 100 pts. of sugar.—J. H. L.

XIXa.—FOODS.

Potatoes and potato flour; Mineral constituents of ——. Effect of process of manufacture on the composition of the ash of potato flour. C. E. Mangels. J. Ind. Eng. Chem., 1921, **13**, 418—419.

Although potato flour contains a smaller relative amount of total ash and a slightly smaller percentage of potassium than does the fresh potato, the ash of bolted flour from peeled potatoes does not differ appreciably from that of unbolted flour from unpeeled potatoes. Potatoes yield: ash, 4·31—5·70; CaO, trace—0·161; MgO, 0·235—0·290; K_2O, 2·12—2·60; P_2O_5, 0·570—0·730; S, 0·108—0·164; Cl, 0·076—0·260%. Potato flours yield: ash, 3·51—5·36; CaO, trace—0·145; MgO, 0·198—0·279; K_2O, 1·82—2·51; P_2O_5, 0·438—0·655; S, 0·105—0·155; Cl, 0·066—0·197%; all the results are calculated on the dry substance.—W. P. S.

Meat extracts and meat extract substitutes; Nitrogenous constituents of ——. K. Beck and E. Merres. Arb. Reichsgesundheitsamte, 1920, 52, 223. Chem.-Zeit., 1921, 45, Rep., 109.

Meat extracts contain total nitrogen, 7·8—9·8% (of which 66—75% is precipitated by phosphotungstic acid); ammonia-nitrogen, 0·33—0·41; amino-acid nitrogen, 1·0—1·5; total creatinine nitrogen, 3·0—6·7%; ash, 17—25; sodium chloride, 2—10; and water, 16·0—26·0%. Vegetable extracts and bone extracts contain considerably less total nitrogen, more amino-acids, and large quantities of ash and sodium chloride. Determinations of the total creatinine, amino-acids, and the proportion of nitrogenous constituents precipitated by phosphotungstic acid yield the most useful data for distinguishing between the different extracts.—W. P. S.

White-of-egg; Lime content of ——. H. Kreis and J. Studinger. Ann. Falsif., 1921, **14**, 148—151.

The ash of fresh white-of-egg contains 0·59—4·25% CaO; owing to this wide variation and to the fact that the quantity of CaO does not sensibly increase when eggs are immersed for many months in lime-water, the lime content does not afford any evidence as to whether eggs have been preserved in lime-water. The membrane enclosing the yolk is, however, rendered very fragile when the eggs are kept in lime-water for even a short time.—W. P. S.

Meat; Curing of ——. F. W. Kurk. U.S.P. (A—C) 1,380,068—1,380,070, 31.5.21. Appl. (A), 31.1.21; (B, C), 21.2.21.

(A) The meat is immersed in a pickling solution containing salt and saltpetre, and the fresh solution is inoculated with a virile culture of the non-putrefactive, non-pathogenic, nitrate-reducing micrococcus. (B) Sausage meat is inoculated with the culture described in (A). (C) The curing materials containing nitrates and the culture are applied superficially to the meats.—H. C. R.

Wheaten flour; Process for ageing —— *to improve its baking qualities.* Forget-me-not-Flours, Ltd., and R. Hutchinson. E.P. 164,557, 30.3. and 5.5.20.

Wheat, wheaten stock, flour, or dough may be rapidly "strengthened" by heating in vacuum vessels, and the effect controlled by varying the hydrostatic pressure. The material may be first heated under atmospheric pressure or in a low vacuum until the gluten has reached the desired degree of coagulation, and the coagulation then arrested by subjecting the material to a high vacuum. Or the material may first be heated in a sufficiently high vacuum to prevent coagulation of the gluten and then subjected to a low vacuum or atmospheric pressure to produce the desired coagulation. Moisture lost during the process may be added before treatment or restored afterwards. "Improvers" or yeast foods may be incorporated with the added water. Temperatures of not more than 80° C. can be safely employed.—H. C. R.

Meal or flour and milling products; Process for treating ——. E. C. Sutherland. U.S.P. 1,381,079, 7.6.21. Appl., 25.3.18.

The material is subjected to the action of chlorine in amount sufficient to react with the enzymes present, and then treated with a peroxide compound, and the mass finally subjected to conditions capable of decomposing the peroxide compound.—H. C. R.

Pectin; Process for producing ——. R. H. McKee. U.S.P. 1,380,572, 7.6.21. Appl., 29.3.19.

Fruit is heated with an equal quantity of water to 125° C. for several minutes, the fibrous matter is separated from the product, and finely-divided absorbent carbon is added to the solution. The solution is evaporated at less than atmospheric pressure and the concentrated solution separated from the absorbent carbon.—H. C. R.

Blood; Manufacture of a food preparation from fresh ——. F. Sgalitzer. U.S.P. 1,380,427, 7.6.21. Appl., 22.6.20.

Blood corpuscles from which the fibrin has been separated are disrupted and then dried *in vacuo* on surfaces heated to a temperature above the coagulating temperatures of the albumins, the degree of vacuum being such that the liquid is evaporated at about 30° C., the dry substance not being heated above 40° C. An easily digestible, durable and soluble preparation is obtained.
—H. C. R.

Syrups and the like; Evaporating and concentrating apparatus for ——. A. Rambaud. E.P. 144,631, 2.6.20. Conv., 10.6.19.

Vertical cloth drums are suspended from a number of concentric rings connected to a central ball-bearing hub; the whole is mounted above a tank containing the syrup, which is pumped through nozzles on to the upper parts of the cloths, the stream of liquid causing the cloth drums to rotate. The liquid is concentrated by evaporation as it flows down the cloths and drips from the bottom of the latter on to a cloth or metal baffle and thence into the tank. Certain of the nozzles may deliver the syrup on to the cloths in an opposite direction, so as to retard the rotation of the apparatus. If desired, the cloths may be stationary and the delivery nozzles caused to rotate. Fan blades may be provided between the vertical cloth drums to accelerate evaporation.—W. P. S.

Grape-juice; Concentration of ——. E. Monti. U.S.P. 1,379,470, 24.5.21. Appl., 28.3.19.

Part of the grape-juice is concentrated to sp. gr. 1·38 at a temperature not exceeding 40° C., and a further quantity is concentrated to sp. gr. 1·20 by freezing it in contact with the air. The first portion is then added to the second, which is still subjected to a low temperature, and the whole mixed and allowed to set. A product having the consistency of honey and the flavour of grape-juice may be obtained by concentrating one portion to 90% dry extract at a temperature not exceeding 40° C. and mixing the syrup obtained by freezing with this so as to produce a mixture containing 75—80% of dry extract.—H. C. R.

Meal or flour and milling products; Process for treating ——. E. C. Sutherland, Assr. to Naaml. Vennoots. Indus. Maatsch. voor. Noury & Van der Lande. U.S.P. 1,380,334, 31.5.21. Appl., 12.12.16.

XIXb.—WATER PURIFICATION; SANITATION.

[Ammonia;] Adsorption [of——*] in sand filters.* J. Don. Inst. Water Eng., 5.6.21. Engineering, 1921, 111, 759—760.

The adsorption of ammonia from water during filtration through sand was investigated in three filters consisting of glass tubes, 66 in. × 1 in., filled with fine sand to a depth of 32 in. Water containing 1 part per million of an ammonium salt was passed through the filters at the rate of 20, 12, and 2 in. per hour, respectively, and samples were drawn after columns of water 20 in. deep had passed through. Adsorption was little affected by rate of filtration. At the beginning it was almost complete, 90% or more of the ammonia being removed from the first five samples; it gradually diminished and was almost negligible when 400 in. had been filtered. At this stage 58% of the total ammonia had been adsorbed, equivalent to 7 g. by 1 cub. m. of sand. In estimating the adsorption of albuminoid ammonia, a solution of urea in water was used of such strength as to yield 2 parts of ammonia per million on decomposition. As the sand had previously been dried and was not immediately wetted, the first samples showed low adsorption. The total amount adsorbed represented 2 g. of organic ammonia per cub. m. of sand.—W. J. W.

Hardness of water; Modification of Wartha's method for determination of ——. G. Bruhns. Z. angew. Chem., 1921, **34**, 279.

In a modification of Wartha's method, 150 c.c. of the sample is treated with $N/10$ hydrochloric acid, using methyl orange as indicator, till a red coloration persists, free carbon dioxide being removed. About 0·03—0·05 g. of precipitated calcium carbonate is added, then 25, 50, or 75 c.c., dependent on the hardness, of Wartha's solution, and the sample is diluted to 250 c.c. It is then allowed to stand until at least two-thirds of the volume has become clear, which occurs in ½—1 hr. A clear sample is then withdrawn by means of a pipette and its alkalinity estimated. (*Cf.* Winkler, J., 1921, 365 a.)—W. J. W.

Phenols in water; Detection of ——. R. D. Scott. J. Ind. Eng. Chem., 1921, **13**, 422.

The reagent used is prepared by boiling together sodium tungstate 100 g., molybdic acid 18 g., 85% phosphoric acid 50 c.c., and water 750 c.c. for 2 hrs. under a reflux condenser; the mixture is then cooled and diluted to 1 litre. To test a water for phenol, 500 c.c. of the sample is acidified with 10 c.c. of dilute sulphuric acid (1:1), 100 c.c. is distilled, and the distillate is treated with 1 c.c. of the reagent and 5 c.c. of saturated sodium carbonate solution. The distillate from a water containing as little as 0·1 part per million of phenol gives a distinct blue coloration.—W. P. S.

Sewage purification; Straw filters for ——. E. H. Richards and M. G. Weekes. Inst. Civil Eng., 29.6.21. Engineering, 1921, **112**, 86.

Laboratory experiments on the filtration of a dilute solution of ammonium carbonate through a wheat-straw filter at the rate of 250 galls. per cub. yd. per day showed that the nitrogen was gradually retained in the filter, until after the twentieth day only 1% of it passed through. This continued until the straw was saturated and contained 7 parts of nitrogen per 1000 parts of dry straw; 86% of the nitrogen applied was found in the straw, and only 3·4% was unaccounted for. Similar results were obtained with sewage. Relying on these experiments, a straw filter was erected at Wainfleet Camp for the treatment of the sewage from 300 men, comprising urine and cookhouse and ablution water only. The filter was built in three tiers, each tier being formed of pipes placed 4 in. apart on which the straw was laid. The sewage was supplied from a large storage tank through notched V-shaped troughs at the rate of 96 galls. per cub. yd. per day. When the straw on the bottom layer became saturated it was removed, the straw in the other two tiers brought a tier lower down, and new straw put on the top tier. Analyses showed that the dissolved oxygen taken up in 5 days was reduced from 80 parts in the sewage to 15 parts in the effluent, but the effluent was putrescible after incubation. The nitrogen retained in the straw was 1·12% of the dry straw. The straw was insufficient n quantity and was not renewed sufficiently frequently to remove all the nitrogen. On storing the removed straw for 6 months, the nitrogen in t increased about 0·5%, and the straw was in good condition for applying to land.—J. H. J.

Sludge; Activated ——. J. Haworth. Inst. Civil Eng., 29.6.21. Engineering, 1921, **112**, 86—87.

The treatment of sewage by the activated sludge process was tried at Sheffield with successful results, but difficulties arose from the choking of the perorated pipes and porous diffusers used for the air upply. It was found that by suitably agitating he sewage in tanks open to the atmosphere similar esults as with compressed air could be obtained. Since November, 1920, a large tank divided in gridiron fashion to form a continuous channel 3544 ft. long has been worked on the continuous-flow principle. Circulation and agitation are obtained by 18 paddle wheels arranged on two shafts across the centre of the tank. The effluent is settled in Dortmund tanks. Strong sewage, up to 600,000 galls. per day, is being satisfactorily dealt with. The de-watering of the sludge has been dealt with experimentally only. One method tried was the use of a vacuum box and a travelling gauze band; this reduced the water from 98 to 75%. Another method comprised a gauze-covered revolving vacuum drum dipping into the sludge; the thin layer of sludge is dried on the drum and is removed by a steel roller and a fixed scraper.—J. H. J.

Sludge; De-watering ——. J. D. Watson. Inst. Civil Eng., 29.6.21. Engineering, 1921, **112**, 87.

The treatment of sewage sludge at Birmingham has been carried out since 1912 as follows:—Sludge is transferred from the sedimentation tank whose turn it is to be emptied into one or more of the digestion tanks, and some of the ripest sludge from a previously used digestion tank is added in the proportion of 1:4. In cold weather the temperature is raised by the introduction of steam, but in summer neither steam nor inoculation is required. Fermentation proceeds, and the sludge is buoyed up with gas. The sludge is stored for four months, and is then pumped on to drying-beds where the liquid readily drains away, and the solids are left exposed to the air for a month or more to dry. The dried sludge has a calorific value of 4000—5000 B.Th.U., and 1 lb. of the sludge will raise 1 lb. of steam. Many experiments were tried for the de-watering of the humus from percolating filters, but they all failed.—J. H. J.

Sewage sludge; Rôle of acidity in the dehydration of ——. J. A. Wilson and H. M. Heisig. J. Ind. Eng. Chem., 1921, **13**, 406—410.

Change of acidity has a considerable effect on the rate of filtration in the process of dehydrating sewage sludge in a filter-press; the maximum rate occurs at a p_H value of about 3. After a sample of sludge has been acidified with sulphuric acid, its acidity decreases during a period of hours owing to the slow absorption of acid by the substances of fibres and other organised jellies present; these effects may be overcome by suitably adjusting the concentration of the sludge before bringing to the desired acidity. A proper dilution of sludge which is to be dehydrated by means of filter-presses is essential; under certain conditions a dilute sludge can be dehydrated more quickly and efficiently than a more concentrated one containing the same amount of solid matter. The effect of acidity is also of importance in dehydrating sewage sludge by centrifugal action.—W. P. S.

Sewage; Purification of —— from bacteria and B. coli in the activated sludge process. P. Courmont, A. Rochaix, and F. Laupin. Comptes rend., 1921, **172**, 1696—1698. (*Cf.* J., 1920, 171 a.)

Under the normal procedure for the purification of sewage by the activated sludge process, the action being stopped when the ammonia has disappeared, the results for bacterial purification are very irregular, the diminution in count being seldom more than 50%. Similarly the diminution in the number of *B. coli* is very variable and generally small. Prolonged aeration is necessary if bacterial purification is to be satisfactory.—W. G.

Settling tanks [*; Sludge-ejecting means for* ——]. W. and W. V. Boby. E.P. 161,879, 24.3.20.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Mitragynine and mitraversine, two new alkaloids from species of Mitragyne. E. Field. Chem. Soc. Trans., 1921, **119**, 887—891.

The residue obtained by evaporating the alcoholic extract of the leaves of *Mitragyne speciosa* (N. O. *Rubiaceæ*) when dissolved in glacial acetic acid, freed from chlorophyll and resin by addition of water, and made alkaline with ammonia, yields an amorphous precipitate which when dissolved in 20% acetic acid and treated with a hot aqueous solution of picric acid yields a crude picrate, $C_{22}H_{31}O_5N.C_6H_3O_7N_3$, orange-red needles from methyl alcohol, m.p. 223°—224° C., representing 0·3% of the initial weight of the leaves. The free alkaloid is obtained by dissolving the picrate in boiling glacial acetic acid and pouring into dilute ammonia, filtering while hot. The new alkaloid, for which the name mitragynine is suggested, is a colourless amorphous solid, m.p. 102°—106° C., distilling unchanged at 230°—240° (5 mm.); it contains three methoxy groups, but no N-methyl groups, and is probably $C_{17}H_{22}N(OCH_3)(CO_2CH_3)_2$. Hydrolysis with sodium ethoxide gives a dicarboxylic acid, m.p. 280°. Both this acid and the alkaloid give the indole reaction with hydrochloric acid and vanillin. The acetate, mono- and trichloro-acetates, and the hydrochloride are described. Similar treatment of the leaves of *M. diversifolia* gives an alkaloid, for which the name mitraversine is suggested, having m.p. 237° C., molecular weight 328, and containing 2 methoxy groups. The hydrochloride melts at 208°—210°. It is probably $C_{22}H_{26}O_4N_2$.—P. V. M.

Eugenol and isoeugenol benzoates; Determination of the composition of —— by means of melting points. P. V. McKie. Chem. Soc. Trans., 1921, **119**, 777—779.

By conversion into the solid benzoates, the composition of mixtures of eugenol and isoeugenol can be accurately determined by the melting point of the benzoate mixture. The melting point curve has a well-marked eutectic point at 56·5° C., corresponding to 25·5% of isoeugenol benzoate, but shows divergence, the range of the disturbance of the curve being very small in the neighbourhood of the 50% mixture. The benzoates are prepared by the usual benzoyl chloride-pyridine method, ether extraction being used to secure the last traces of benzoate. Since the crude oil can be used without the preliminary drying and fractionation *in vacuo* necessary in the use of viscosity or density methods, this method ensures greater accuracy and simplicity of manipulation.—P. V. M.

Piperitone; Occurrence, isolation, and characterisation of ——. J. Read and H. G. Smith. Chem. Soc. Trans., 1921, **119**, 779—789.

The unsaturated ketone piperitone, $C_{10}H_{16}O$, associated generally with *l*-*α*-phellandrene and the secondary alcohol piperitol, occurs in various species of eucalypts and principally—up to 4%—in *E. dives*. Isolation is best effected by fractional distillation of the leaves and twigs under atmospheric pressure, followed by treatment with normal sodium sulphite. The product is characterised by feeble optical activity ($[\alpha]_D = -0·27°$), and has $n_D^{20} = 1·4843$, b.p. 128·5° (25 mm.). The most characteristic derivative, best adapted for the recognition and differentiation of piperitone from related ketones, is benzylidene-*dl*-piperitone, formed by the interaction of piperitone with benzaldehyde in absolute alcohol, in presence of sodium ethoxide; after 3—4 days the mixture is poured into cold, very dilute sulphuric acid and extracted with ether. Distillation of the residue gives a yellow, highly refractive oil, b.p. 245°—258° (25 mm.), crystalline on inoculation, m.p. (crystals from methyl alcohol) 61° C. The crystalline structure of benzylidene-*dl*-piperitone is discussed. Other derivatives are:—*dl*-Piperitone-hydroxylamino-oxime, m.p. 169°—170°; piperitone-oxime, m.p. 110°—111°; *dl*-piperitone semicarbazone, m.p. 219°—220°; benzylidene-*dl*-piperitone-oxime, m.p. 130°—131·5° C.——P. V. M.

Glycerol and polyhydric alcohols; Action of boric acid on ——. Application of a new physico-chemical volumetric method. R. Dubrisay. Comptes rend., 1921, **172**, 1658—1660.

Using the temperatures of miscibility with phenol to detect the formation of compounds (*cf.* J., 1920, 542 A), it is shown that boric acid and glycerol do not apparently form a compound. Mannitol and boric acid apparently form a compound, which is, however, dissociated. Similarly glycerol, boric acid, and sodium hydroxide form a compound which is certainly dissociated.—W. G.

Vanilla extracts; Determination of the lead number of ——. H. J. Wichmann. J. Ind. Eng. Chem., 1921, **13**, 414—418.

The following procedure is recommended to obtain a maximum precipitation and to combine determinations of the lead value and alcohol content of vanilla extracts. A mixture of water, 175, 8% normal lead acetate solution, 25, and vanilla extract, 50 c.c., is distilled; 200 c.c. of distillate is collected and the alcohol content is calculated from the sp. gr. of the distillate. The residue in the distillation flask is diluted to 100 c.c. with water free from carbon dioxide, filtered, and 10 c.c. of the filtrate is mixed with 25 c.c. of water, 10 c.c. of dilute sulphuric acid and 100 c.c. of alcohol are added; the precipitated lead sulphate is collected and weighed. A control determination is made at the same time, using water containing 5 drops of glacial acetic acid in place of the vanilla extract. The quantity of lead precipitated by the extract and expressed as g. per 100 c.c. is the lead value; for genuine undiluted extracts it is not less than 0·55. Sugar, glycerol, and coumarin do not interfere with the determination; if added vanillin is present it must be removed by extracting 50 c.c. of the sample with three successive quantities of 50 c.c. of a mixture of equal vols. of ether and petroleum spirit; the extracted aqueous solution is then used for the determination.—W. P. S.

Essential oil of Dokudame. Y. Shinozaki. Kōgyō-Kwagaku Zasshi (J. Chem. Ind., Japan), 1921, **24**, 557—562.

By steam distillation of the herb, *Houttuynia cordata*, Thunb., known as Dokudame in Japan 0·0049% of a light brown oil was obtained; it had a strong, somewhat disagreeable odour, and the following characters:—Sp. gr. at 15° C. 0·8744; $n_D^{20} = 1·4685$; $[\alpha]_D = -5°$; acid value, 16·65; saponif. value, 28·40. On treatment with sodium bisulphite methyl *n*-nonyl ketone (semicarbazone, m.p. 122°—123° C.) was isolated. Repeated distillation of the residual oil yielded a terpene fraction, b.p. 60°—61° C. (14 mm.), 167°—168° C. (766 mm.), as the principal product; this consisted of an aliphatic terpene (probably myrcene) and a small quantity of a cyclic terpene. The oil also appears to contain a solid acid.—K. K.

Essential oil of Kokusagi. Y. Shinozaki. Kōgyō-Kwagaku Zasshi (J. Chem. Ind., Japan), 1921, **24**, 563—566.

By steam distillation of the leaves and twigs of Kokusagi (*Oriza Japonica*, Thunb.), about 0·01% of light brown oil was obtained, having a characteristic odour recalling that of the oil of *Lindera sericea*; its characteristics were:—Sp. gr. at 15° C. 0·8974; $n_D^{20} = 1·4750$; $[\alpha]_D = -4·5°$; acid value, nil; saponif. value, 37·27; saponif. value after acetylation, 100·3. The oil is soluble in two vols. of 80% alcohol. Its principal constituents are camphene, linalool, a terpene alcohol and its ester.—K. K.

Patents.

Acetaldehyde and acetic acid; Preparation of —— from acetylene. Farbenfabr. vorm. F. Bayer und Co. G.P. 305,182, 5.3.16.

Oxygen or air is passed continuously or intermittently through the reacting liquid containing sulphuric acid and mercury compounds, either simultaneously or alternately with the current of acetylene, so that at least one equivalent of sulphuric acid reacts with one equivalent of mercury sulphate. By this means reduction of the mercury salt is avoided.—A. R. P.

[Paraffin] hydrocarbons; Method of chlorinating ——. G. T. Koch and A. L. Stallkamp, Assrs. to The Ohio Fuel Supply Co. U.S.P. 1,380,067, 31.5.21. Appl., 6.12.19.

A finely-divided catalyst is suspended in a paraffin hydrocarbon in the liquid phase, and chlorine is passed into the liquid below the catalyst. —L. A. C.

Alkyl esters of sulphuric acid; Production of neutral ——. E. Kuh. E.P. 149,688, 3.8.20. Conv., 8.8.19.

Alkylsulphuric acids are distilled *in vacuo* in the presence of suitable compounds capable of combining with the sulphuric acid formed. For example, ethylsulphuric acid (126 pts.) is distilled under a pressure of 10—15 mm. in the presence of 71 pts. of anhydrous sodium sulphate, or 148 pts. of dry sodium ethyl sulphate, yielding diethyl sulphate. —L. A. C.

Diethyl sulphoxide; Preparation of a substitution product of ——. Farbw. vorm. Meister, Lucius, und Brüning. G.P. 335,601, 29.7.19.

Thiodiglycol chloride is treated with nitrogen peroxide in an indifferent medium to produce thionyldiglycol chloride (dichloroethyl sulphoxide), $SO(CH_2.CH_2.Cl)_2$, m.p. 112° C., which is soluble in warm water, alcohol, ether, and benzene, and may be used as an intermediate in the preparation of dyes and pharmaceutical products.—A. R. P.

Phthalic acid and anhydride; Manufacture of ——. British Dyestuffs Corp., Ltd., A. G. Green, and J. W. Porter. E.P. 164,785, 10.1.20.

Naphthalene, or other suitable volatile hydrocarbons, such as α- or β-methylnaphthalene, tetrahydronaphthalene, α-naphthol or *o*-xylene, is oxidised to phthalic acid or phthalic anhydride by treatment with air at 300°—650° C. in the presence of, *e.g.*, 1 g. of vanadyl chloride per 100 l. of air.—L. A. C.

o-Cresol; Catalytic oxidation of ——. J. M. Weiss and C. R. Downs, Assrs. to The Barrett Co. U.S.P. 1,380,277, 31.5.21. Appl., 12.12.19.

Salicyl aldehyde and salicylic acid are obtained by the oxidation of *o*-cresol in the vapour phase with a gas containing oxygen in the presence of a metallic oxide as catalyst.—F. M. R.

Hexamethylenetetramine; Preparation of a derivative of ——. O. Matter and R. Bunge. G.P. 334,757, 7.9.16.

The hexamethylenetetramine salt of 2-methylpyridine-4.6-dicarboxylic acid, formed by the usual methods, is a colourless substance very easily soluble in water and slowly decomposing at 50° C. with evolution of formaldehyde. It is suitable for obtaining a strong formaldehyde action on blood-vessels. —B. V. S.

Terpenes; Process of securing certain derivatives of ——. W. B. Pratt, Assr. to E. H. Clapp Rubber Co. U.S.P. 1,380,414, 7.6.21. Appl., 22.4.18.

A mixture of spirits of turpentine and hydrated oxalic acid is digested at or above 140° C., and the acid is separated from the product.—L. A. C.

Borneol; Manufacture of ——. Fabr. de Prod. Chim de Thann et de Mulhouse. E.P. 158,533, 1.11.20. Conv., 4.2.20. Addn. to 144,604.

In the process described in the chief patent (J., 1921, 369 a), the yield of bornyl tetrachlorophthalate is increased by heating turpentine or pinene with tetrachlorophthalic acid in the presence of an organic solvent, such as an ether, ketone, or aromatic ester, either under atmospheric or increased pressure. Thus, 60 kg. of pinene mixed with 50 kg. of anisol on treatment with 20 kg. of tetrachlorophthalic acid yields 17 kg. of crude borneol, *i.e.*, the yield obtained from 100 kg. of pinene without the addition of a solvent. —L. A. C.

Thymol; Process of making —— from nitrocymene. R. M. Cole. U.S.P. 1,378,939, 24.5.21. Appl., 3.12.19.

1-methyl-2-amino-4-isopropyl-5-hydroxybenzene, prepared by the electrolytic reduction of nitrocymene, is diazotised and reduced.—L. A. C.

Wood alcohol; Process of making —— from methane. E. H. Riesenfeld, Assr. to The Chemical Foundation, Inc. U.S.P. 1,379,362, 24.5.21. Appl., 4.10.18.

Methyl chloride in anhydrous alcoholic solution is converted into dimethyl ether by heating with an alkali hydroxide under pressure, and the dimethyl ether is subsequently hydrolysed under pressure, the hydrolysis being accelerated by the presence of a free acid.—L. A. C.

Serums; Manufacture of —— from animals, excluding man. W. J. Penfold. U.S.P. 1,378,896, 24.5.21. Appl., 14.9.20.

Blood from an animal is passed into vessels containing an anti-clotting agent, such as an oxalate solution, and is allowed to stand until the red cells settle. After separation from the red cells, the plasma is treated with a clotting agent, such as a calcium salt, and the serum is separated from the plasma. The red cells are filtered off and returned to the blood vessels of the animal.—L. A. C.

Oxygen baths. R. Wright and W. Armstrong. E.P. 164,811, 4.3.20.

Sodium perborate (*e.g.*, 10 oz.) is added to the bath, followed by powdered talc (1 oz.) and either a mixture of copper sulphate (½ oz.) and ammonium chloride (½ oz.) or a double salt of copper and ammonium, sodium, or potassium.—L. A. C.

Acetic anhydride; Manufacture of ——. H. Dreyfus. E.P. 136,574, 13.12.19. Conv., 30.6.14.

See F.P. 478,951 of 1914; J., 1916, 1179.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photo-chlorides and colloidal silver; Colour of ——. K. Schaum and H. Lang. Kolloid-Zeits., 1921, 28, 243—249.

Silver sols of different colours can be prepared by treating a nucleus sol in gelatin with varying amounts of a solution consisting of 2 g. of sodium thiosulphate and 2 g. of *p*-phenylenediamine in 100 c.c. of water and adding very slowly definite quantities of a solution consisting of 18 g. of sodium thiosulphate and 0·75 g. of silver nitrate in 100 c.c. of water. The diameter of the particles of the sols of different transmitted colours has the following values: orange-yellow, $60\mu\mu$; orange-red, $90\mu\mu$; purple $120\mu\mu$; violet $150\mu\mu$; and bluish-green, $180\mu\mu$. (*Cf.* J.C.S., Aug.)—J. F. S.

Patents.

Selenium [*photographic*] *toning baths.* Chem. Fabr. auf Aktien (vorm. E. Schering). G.P. 335,627, 13.2.17.

A solution of selenium or its compounds in alkali sulphide solution containing also a sulphite is used for toning silver prints. The solution is odourless and stable and has only a slight action on the hands. (*Cf.* U.S.P. 1,064,379; J., 1913, 712.)—B. V. S.

Diapositives; Preparation of monochrome or multi-coloured ——. B. Lincke and R. Kaufhold. G.P. 336,041, 20.4.20.

A diapositive in relief, obtained in the usual way by means of a bleaching-hardening bath and removal of the residual soluble gelatin, is used as a printing plate for the transfer of dye to gelatin-coated paper. Multi-colour prints are obtained by superposing impressions from diapositives obtained from colour-selection negatives.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Explosives; Quantitative test of the thermal stability of nitroglycerin ——. M. Taliani. Gaz. Chim. Ital., 1921, 51, I., 184—193.

The author describes an apparatus and method for following the gradual increase in pressure developed when an explosive is maintained in a closed space at a constant temperature. A glass tube to contain the explosive is closed by a ground cap furnished with a tap and surmounted by a siphon tube, the siphon being half-filled with paraffin wax and connected with a mercury manometer. The apparatus is enclosed in a double-walled copper oven closed by a double glass door, the jacket being filled with a calcium chloride solution, the boiling point of which is 120° C. for nitroglycerin and explosives derived therefrom, or 135° C. for the nitrocelluloses. Of the explosive, grated so as to pass through a mesh of 0·6 mm. and remain on one of 0·4 mm., 1·3 g. is introduced into the tube, the apparatus being left open for 30 minutes in order to allow the moisture of the explosive to escape. Curves connecting pressure developed with the time have been traced for various different explosives, the results showing that such curves suffice to characterise explosives having bases of nitric esters.—T. H. P.

Patents.

Explosives; Process of manufacturing ——. A. Wohl. E.P. 146,258, 28.6.20. Conv., 14.1.19.

Solid, high molecular polymerisation products of acetylene, such as those prepared by treating cuprous oxide at 260° C. with acetylene, are used in place of kieselguhr in the manufacture of dynamite, or as an absorbent for liquid air, or as an ingredient of other explosives.—W. J. W.

Propellent powder; Process of making ——. R. G. Woodbridge, jun., Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,379,073, 24.5.21. Appl., 8.8.19.

The surface of granular explosives insoluble in water is impregnated with a deterrent material, also insoluble in water and having a m.p. above 100° C., by subjecting a mixture of the explosive and deterrent material to treatment with hot water. —W. J. W.

Matches; Manufacture of igniting compositions for ——. O. J. Mellgren. U.S.P. 1,379,355, 24.5.21. Appl., 11.11.19.

See E.P. 140,026 of 1919; J., 1920, 350 A.

Nitrophenolic compounds. U.S.P. 1,380,186. *See* III.

Cellulose-nitrate compositions. U.S.P. 1,380,258. *See* V.

XXIII.—ANALYSIS.

Phosphoric acid; Determination of —— *as magnesium pyrophosphate. VI.* D. Balareff. Z. anorg. Chem., 1921, 117, 91—102. (*Cf.* J., 1919, 743 A.)

A critical review of previous work on the estimation of phosphoric acid or magnesium by precipitation as magnesium ammonium phosphate and subsequent ignition of the precipitate. Neubauer's method and the use of a single precipitation at a low temperature are not to be recommended, as accurate results are obtained only under special conditions. The double precipitation method gives good results provided that the first precipitate is dissolved in not too little hydrochloric acid, that only Cl′ and NO_3′ anions and no large quantity of alkali cations are present during precipitation, and that the second precipitation is carried out by rapid addition of 10% ammonia solution. Schmitz's method is the only one which under special conditions, gives a pure magnesium pyrophosphate, and which gives accurate results under widely varying conditions (*cf.* J., 1918, 638 A).—E. H. R.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Boberg, Testrup, and Techno-Chemical Laboratories, Ltd. Evaporation, concentration, drying, etc. 19,442. July 19.

Corbould. Dissolving and washing tanks. 19,432. July 19.

Fabry. 19,804. *See* II.

Goskar. Drying coal, sand, etc. in granular etc. mass. 19,362. July 18.

Marks (Natural Air Dryers, Inc.). Drying-apparatus. 19,742. July 22.

Paterson. Filtering-apparatus. 19,848. July 23.

Plauson's (Parent Co.), Ltd. (Plauson). Preparation of colloids and colloidal solutions. 19,114. July 15.

Raper and Sutcliffe. Recovery of gases or vapours. 19,240. July 16.

Complete Specifications Accepted.

19,733 (1913). Möller. Electrically separating suspended bodies from non-conducting gaseous fluids. July 27.

2005 (1916). Lachmann. Continuous separation of gas mixtures. (100,085.) July 27.

10,611 and 11,766 (1917). Theisen. *See* II.

21,322 (1918). Francart. Operating furnaces, kilns, ovens, etc. (165,812.) July 20.

21,325–6 (1918). Francart. Tunnel furnaces, kilns, ovens, etc. (166,198–9.) July 27.

4428 (1919). Davies. Separation of gases. (165,816.) July 20.

15,605 (1919). Sauer. Filtering, decolorising, or purifying processes, and decolorising carbons therefor. (166,229.) July 27.

21,667 (1919). Legg and Adam. Copper catalysts. (166,249.) July 27.

24,709 (1919). Lambert. Absorbents for gases. (166,275.) July 27.

575 (1920). Scalione and Frazer. Catalysts and processes of making them. (166,285.) July 27.

3809 and 31,242 (1920). Hatfield, and Imperial Trust. Electrostatic separation of materials. (165,892.) July 20.

6761 (1920). Jagger. Grinding and mixing and agitating machines etc. (165,912.) July 20.

9385 (1920). Schmiedel. Device for bringing gases or vapours and liquids into intimate contact. (149,647.) July 20.

12,454 (1920). Merz. Evaporation of liquids. (166,004.) July 20.

15,577 (1920). Sharples. *See* II.

15,868 (1920). Soc. Gén. d'Evaporation. Continuous and systematic lixiviation. (144,721.) July 27.

19,620 (1920). Kamp. Filtering plates for filter-presses. (147,652.) July 27.

19,919 (1920). Fairlie. Filling-material for reaction spaces. (147,867.) July 20.

7027 (1921.) Lumpp. Centrifugal drying-machines. (159,839.) July 27.

7903 (1921). Hildesheim. Grinding or crushing. (160,142.) July 27.

15,118 (1921). Möller. Apparatus for separating suspended bodies from electrically insulating gaseous fluids. (164,014.) July 27.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Bargate and Walkey. Desulphurising petroleum oils. 19,289. July 18.

Blake. Alcohol fuels. 19,463. July 19.

Duckham, Kent, and Woodall, Duckham, and Jones. Total gasification of fuel. 19,537. July 20.

Fabry. Centrifugal drying-machines for coal etc. 19,804. July 23.

Giles (Field). Fuel for internal-combustion engines. 19,327. July 18.

Gluud. Extraction of sulphuretted hydrogen from gases. 19,669. July 21.

Goskar. 19,362. *See* I.

Hale and Ridout. Lubricating oil etc. 19,483. July 20.

Illingworth. Production of smokeless fuel and oke. 19,355. July 18.

James. Lubricants. 19,553. July 20.

Lentz. Oven for semi-coking of fuels. 19,158. July 15. (Ger., 15.7.20.)

Maclaren. Utilisation of wet carbonaceous material. 18,837. July 12.

Maclaurin. Plant for oil washing. 19,267. July 16.

Penhale. Alcohol fuel. 19,452. July 19.

Roberts. Carbonisation of coal. 19,525. July 20.

Warden. Coking retort ovens. 19,402. July 19.

Webster. Retorts or furnaces. 19,498. July 20.

Webster. Distillation of shale etc. 19,499. July 20.

Complete Specifications Accepted.

5583 (1917). Sutcliffe, and Pure Coal Briquettes, Ltd. Destructive distillation of carbonaceous substances. (166,161.) July 27.

10,450 (1917). Theisen. Gas purifiers and coolers. (108,163.) July 20.

10,611 (1917). Theisen. Apparatus for drying, purifying, and cooling gases etc. (108,319.) July 27.

11,434 (1917). Hill and Cook. *See* III.

11,766 (1917). Theisen. Centrifugal machines for purifying, cooling, and mixing gases. (165,802.) July 20.

6371 (1918). Wellington. Distillation of coal etc. (165,805.) July 20.

16,599 (1918). Barbet et Fils et Cie. Treating volatile products of distillation of wood. (120,560.) July 27.

2595 (1919). Sutcliffe. Production of activated carbonaceous substances. (166,202.) July 27.

2864 (1919). Everett, and Carboil Synd., Ltd. Treatment of carbonaceous material. (165,815.) July 20.

6956 (1919). Helps. Manufacture, utilisation, and combustion of fuel. (166,212.) July 27.

11,959 (1919). Davies. Distillation of coal, shale, peat, wood, etc. (165,825.) July 20.

15,605 (1919). Sauer. *See* I.

23,515 (1919). Knibbs. Distilling and cracking mineral oils etc. (165,863.) July 20.

24,665 (1919). Akker. Process for solidifying purified mineral oil. (166,274.) July 27.

5913 (1920). Southcombe and Wells. Lubricating oils and the manufacture thereof. (165,897.) July 20.

7191 (1920). Terneden and Kummel. Manufacture of ammonia and gas from fuel. (140,090.) July 27.

10,572 (1920). Trent. Method of cleaning coal. (146,931.) July 27.

12,802 (1920). Perry. Apparatus for distilling and briquetting carbonaceous material. (166,398.) July 27.

15,577 (1920). Sharples. Separation of substances from solutions, particularly paraffin wax from petroleum. (166,031.) July 20.

27,425 (1920). Barber Asphalt Paving Co. *See* XIII.

8164–9 and 8171 (1921). Bates. Fuel. (165,418–165,423, and 165,425.) July 20.

8170 (1921). Bates. Production of a grease. (165,424.) July 20.

8631 (1921). Helps. Gas manufacture. (166,497.) July 27.

III.—TAR AND TAR PRODUCTS.

Applications.

Maclaurin. 19,267. *See* II.

Wilton and Wilton. De-emulsifying crude oil, tar, etc. 19,088. July 14.

Complete Specifications Accepted.

11,434 (1917). Hill and Cook. Recovery of benzol, toluol, and light oils from coal gas. (165,801.) July 20.

17,963 (1919). Moore. *See* IV.

32,351 (1919). Legg and Adam. Reduction of nitro-compounds. (166,283.) July 27.

IV.—COLOURING MATTERS AND DYES.

Applications.

British Dyestuffs Corp., Perkin, and Spence. Manufacture of benzanthrone derivatives. 18,892. July 12.

Davies, Thomas, Thomson, and Scottish Dyes, Ltd. Colouring matters of the anthraquinone series. 19,064 and 19,850. July 14 and 23.

Davies, Thomas, Thomson, and Scottish Dyes, Ltd. Colouring matters of the naphthalene series. 19,849. July 23.

Durand et Huguenin Soc. Anon. Manufacture of mordant-dyeing colouring matters. 18,732. July 11. (Fr., 15.7.20.)

Complete Specifications Accepted.

18,292 (1914). Ransford (Cassella u. Co.). Manufacture of substances containing sulphur and of vat dyestuffs. July 27.

17,963 (1919). Moore. Reduction of azo and nitro compounds. (165,838.) July 20.

4166 (1920). Atack and Anderson. Manufacture of vat dyestuffs. (166,297.) July 27.

15,637 (1920). Bloxam (Akt.-Ges. f. Anilinfabr.). Manufacture of azo dyestuffs for wool. (166,023.) July 20.

16,198, 16,201–2 (1920). Akt.-Ges. f. Anilinfabr. Manufacture of ortho-oxydisazo dyestuffs. (145,053, 145,056–7.) July 27.

18,761 (1920). Meister, Lucius, u. Brüning. Manufacture of substantive azo dyestuffs. (146,872.) July 27.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Baxter. Fireproofing fibrous material. 19,480. July 19.

Dreyfus. Manufacture of solutions, compositions, preparations, or articles of cellulose derivatives. 19,531. July 20.

Tootal Broadhurst Lee Co., Ltd., and Willows. Treatment of yarn and fabrics of cotton etc. 19,286. July 18.

Complete Specifications Accepted.

2365 (1918). Lumsden, Mackenzie, Robinson, and Fort. Treatment of scrap fabrics of aeroplanes etc. (165,804.) July 20

3585 (1920). Bronnert. Manufacture of viscose silk. (166,294.) July 27.

7730 (1920). Martin. Machines for coating or impregnating paper, fabrics, etc. (166,313.) July 27.

17,435 (1920). British Cellulose and Chem. Manuf. Co. Cellulose-ester compositions. (146,212.) July 27.

18,526 (1920). Wohl. *See* XVII.

18,876 (1920). Claviez. Treatment of bast fibres. (166,044.) July 27.

22,971 (1920). Radcliffe Paper Mill Co., Lord, and White. Manufacture of paper etc. (166,459.) July 27.

27,443 (1920). Ringer. Manufacture of a hard, workable substance from animal or vegetable fibres. (151,641.) July 20.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Baxter. 19,480. *See* V.

Fernley, Spencer, Wilde, and Marple Printing Co. Dyeing textile fabrics, yarns, etc. 19,793. July 23.

Gott and Wallis. Dyeing or bleaching textile materials. 18,817. July 12.

Complete Specifications Accepted.

24,269 (1919). Drey. Production of discharge and resist effects on pile fabrics. (166,271.) July 27.

10,130 (1920). Calico Printers' Assoc., and Rouse. Printing cotton fabrics. (166,337.) July 27.

10,286 (1920). Calico Printers' Assoc., and Warr. Production of patterns or ornamental effects on fabrics. (166,346.) July 27.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Adam, Cooper, and Holmes and Co. Manufacture of sulphate of ammonia. 19,217. July 16.

Coke Oven Construction Co., and Marr. Manufacture of neutral ammonium sulphate. 19,220. July 16.

Corbould. 18,722. *See* X.

Deuts. Glühfadenfabrik. Purifying hydrogen. 18,976. July 13. (Ger., 13.7.20.)

Harter and Oehlrich. Synthetic production of nitrogen-hydrogen compounds. 19,237. July 16.

Johnson (Badische Anilin- u. Soda-Fabrik). Manufacture of finely-divided sulphur. 18,730. July 11.

Jubany. Manufacture of nitric acid. 18,981. July 13. (Spain, 27.7.20.)

Kelly. Treatment of mineral phosphates. 19,142. July 15.

Klencke and Schmiedel. Production of sulphuric acid. 18,806. July 12.

McElroy. Process of fixing nitrogen. 19,025. July 14.

Plauson's (Parent Co.), Ltd. (Plauson). Extraction of alkali from felspar etc. 19,113. July 15.

Schmiedel. Manufacture of sulphuric acid. 18,805. July 12.

Waldo. Reduction of magnesium compounds. 19,363. July 18. (U.S., 31.7.20.)

Complete Specifications Accepted.

26,078 (1913.) De Brünn. *See* XIX.

10,321 (1915). Beindl. Production of hydrocyanic acid. July 27.

14,942 (1919). Griggs. Apparatus for producing hydrogen. (165,829.) July 20.

16,001 (1919). Nitrogen Corp. Synthesising ammonia. (128,939.) July 20.

15,323 (1919). Marks (Catlin Shale Products Co.). Recovery of fluorine as hydrofluoric acid. (166,228.) July 27.

17,186 (1919). Fairweather. Treatment of ammoniacal liquor. (165,833.) July 20.

1346 (1920). Head. Manufacture of chromic oxide and sodium sulphide from sodium chromate. (166,289.) July 27.

7191 (1920). Terneden and Kummel. *See* II.

12,701 (1920). Fairweather (Fredriksstad Elektrokem. Fabr.). Manufacture of perborates by electrolysis. (166,396.) July 27.

16,529 (1920). Heisch. Ammonium sulphate saturators. (166,036.) July 20.

VIII.—GLASS, CERAMICS.

Applications.

Bailey. Kilns for firing pottery etc. 19,812. July 23.

Duncan, Parsons, and Peddle. Manufacture of optical glass. 19,149 and 19,851. July 15 and 23.

Ges. f. Tuff- u. Ton-Technik. Manufacture of ceramic masses. 19,329. July 18. (Ger., 20.7.20.)

Salerni. Abrading-materials. 18,884. July 12.

Sandison. Mineral product for use as an abrasive etc. 19,229. July 16.

Complete Specifications Accepted.

29,370 (1920). Friedrich. Production by the cold way of glaze-like coatings for iron. (152,651.) July 27.

136 (1921). Muth. Manufacture of spun glass. (156,202.) July 20.

IX.—BUILDING MATERIALS.

Applications.

Dehn (Studebaker Corp.). Treatment of wood. 18,844. July 12.

Soc. de Recherches et de Perfect. Industriels. Impregnation of wood. 19,446. July 19. (Fr., 20.8.20.)

Complete Specifications Accepted.

7424 (1920). Sanders Production of artificial coloured stone. (166,307.) July 27.

9995 (1920). Phillips. Heat-insulating materials. (166,327.) July 27.

16,196 (1920). Schiff. Manufacture of dental cements. (145,052.) July 27.

19,553 (1920) Lichty. Manufacture of non-explosive preparations especially for use in preserving wood. (147,608.) July 27.

20,039 (1920). Lichty. Preservation of wood. (148,137.) July 20.

27,425 (1920). Barber Asphalt Paving Co. *See* XIII.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Aitchison. Manufacture of unstainable steel and iron or alloys thereof. 19,052. July 14.

Aitchison and Dyson. Purification of chromium ores and residues containing chromium oxides. 19,053. July 14.

British Thomson-Houston Co. (General Electric Co.). Alloys and manufacture of same. 19,474. July 19.

British and Foreign Chemical Producers (Vogel). Pickling iron or iron alloys. 18,857. July 12.

Chemical Treatment Co., Jackson, Pratt, and Sears. Desulphurising iron ore, iron, and steel, and oke used in metallurgy of iron. 18,891. July 12. (U.S., 13.7.20.)

Chemical and Metallurgical Corp., Ltd., and Elmore. Production of lead from lead sulphate. 9,082. July 14.

Classen. Production of glossy metallic coatings n metals. 19,090. July 14.

Coles. Producing metallic objects and coating one etal with another by electrodeposition. 19,700. uly 22.

Corbould. Production of oxides of copper, nickel, inc, or cobalt from their ores. 18,722. July 11.

Corbould. Bath for electrolytic deposition of opper. 18,723. July 11.

Fierz and Prager. Production of nickel from ickel carbonyl. 19,074–5. July 14.

Franchot and McElroy. Blast furnaces. 19,024. uly 14.

Le Maréchal, and Siemens Bros. and Co. Production of tungsten and tungsten filaments. 19,040. uly 14.

Marino. Electrodeposition of metals on uminium or its alloys. 18,970. July 13.

Nevill and Soanes. Extraction of copper from its es. 19,538. July 20. (Australia, 13.12.20.)

Perkins, Picard, Sulman, and Taplin. Treatment ores containing oxidised copper compounds. 9,249. July 16.

Smith. Treatment and concentration of ores etc. ,748. July 11. (U.S., 26.7.20.)

Tagliaferri. Process for obtaining steel from furnaces. 19,253. July 16.

Waldo. 19,363. *See* VII.

Complete Specifications Accepted.

7848 (1919). Mordey. Electromagnetic separation or concentration of minerals. (165,822.) July 20.

12,293 (1919). Keller. Manufacture of cast iron. (126,971.) July 27.

21,667 (1919). Legg and Adam. *See* I.

21,677 (1919). Basset. Direct production of iron or steel or cast iron. (132,262.) July 20.

8728 (1920). Mathys (U.S. High Speed Steel and Tool Corp.). Production of high-speed tool steel. (165,919.) July 20.

9483 (1920). Dean. *See* XI.

11,250 (1920). Torbock. Means for granulating slag. (166,370.) July 27.

13,775 (1920). Langer. Electrolytic separation of metals. (166,409.) July 27.

20,156 (1920). Mond (Metallbank- u. Metallurgische Ges.). Furnace plant for annealing metals without tarnishing. (148,232.) July 20.

22,005 (1920). Wade (Byers Co.). Manufacture of wrought iron. (166,452.) July 27.

29,370 (1920). Friedrich. *See* VIII.

XI.—ELECTRO-CHEMISTRY.

Applications.

Archer. Electric batteries or accumulators. 19,065. July 14.

Brasse. Coating for electric wires or cables. 19,326. July 18.

Coles. 19,700. *See* X.

Corbould. 18,723. *See* X.

Hooker Electrochemical Co. Electrolysis of solutions. 19,744. July 22. (U.S., 5.8.20.)

Marino. 18,970. *See* X.

Pouchain. Electric accumulators. 19,665. July 21.

Complete Specifications Accepted.

19,733 (1913). Möller. *See* I.

17,047 (1918) and 8338 (1919). Quain. Apparatus for producing ozone. (166,197.) July 27.

6738 (1919). Pattison (General Research Laboratories). Process and apparatus for ozonising substances. (166,211.) July 27.

24,027 (1919). Marks (Koehler Manuf. Co.). Electric storage batteries. (166,267.) July 27.

3809 and 31,242 (1920). Hatfield and others. *See* I.

9483 (1920). Dean. Compound anode for electroplating. (141,073.) July 27.

12,701 (1920). Fairweather. *See* VII.

13,775 (1920). Langer. *See* X.

30,267 (1920). Dean, and Chloride Electrical Storage Co. Secondary batteries. (166,478.) July 27.

XII.—FATS; OILS; WAXES.

Applications.

Schou. Oleaginous emulsifying-materials. 18,805. July 12.

Schou. Manufacture of emulsions or emulsifying ingredients etc. 18,882. July 12.

Complete Specifications Accepted.

18,541 (1919). Nordiske Fabriker De-No-Fa Akt. Polymerisation of unsaturated fatty acids. (166,236.) July 27.

10,335 (1920). Bennecke. Conversion of fatty acids with several double linkages or their glycerides into oleic acid-like fatty acids or their soaps. (141,720.) July 27.

10,337 (1920). Mason. Separation of grease and oil from liquids. (166,349.) July 27.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Applications.

Allsebrook and Hetherington. Manufacture of lead chromate pigments. 18,949. July 13.

British Thomson-Houston Co. (General Electric Co.). Coating-materials and methods of forming same. 19,340. July 18.

Godfrey and Wilson. Preparation of white pigment bases from titaniferous bauxites. 19,422. July 19.

Schiffmann. Stamping-ink. 19,754. July 22.

Complete Specifications Accepted.

18,789 (1919). Resan Kunstharzerzeugungsges. Manufacture of artificial resin. (130,608.) July 27.

32,718 (1919). Koppers Co. Manufacture of paints or varnishes. (138,068.) July 20.

890 and 1211 (1920). Melamid. Manufacture of resin-like substances. (143,185 and 143,187.) July 27.

11,495 (1920). Bruyn. Manufacture of paste distemper or colour-wash. (166,372.) July 27.

27,425 (1920). Barber Asphalt Paving Co. Bituminous lining for surfaces exposed to corrosive action. (151,639.) July 27.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Applications.

Marshall. Vulcanising rubber etc. 18,683. July 11.

Reid. Treatment of rubber etc. juices. 19,548. July 20.

Complete Specifications Accepted.

1592 (1919). Nixon. Indiarubber compositions. (166,201.) July 27.

11,743 (1919). Nixon. Filler for caoutchouc etc. (166,218.) July 27.

10,555 (1920). Gray. Purification of indiarubber, gutta-percha, etc. (166,359.) July 27.

16,288 (1920). Kilburn (Fish). Apparatus for testing rubber latex. (166,431.) July 27.

XV.—LEATHER; BONE; HORN; GLUE.

Application.

Collard. Extraction of osseine. 19,841. July 23. (Fr., 24.7.20.)

Complete Specifications Accepted.

7215 (1920). Tannage Rationnel Meurant Soc. Anon. Tanning leather. (140,092.) July 27.

5677 (1921). Manvers. Preparing hides for tanning. (166,495.) July 27.

XVI.—SOILS; FERTILISERS.

Complete Specification Accepted.

22,747 (1913). Chem. Fabr. Rhenania, and Messerschmitt. Manufacture of manure from minerals. July 27.

XVII.—SUGARS; STARCHES; GUMS.

Complete Specifications Accepted.

18,526 (1920). Wohl. Conversion of cellulose-containing materials into soluble carbohydrates. (146,455.) July 20.

11,561 (1921). Tiemann. Purification of sugar juices by filtration and decantation. (161,987.) July 20.

XVIII.—FERMENTATION INDUSTRIES.

Application.

Ruymbeke. Production of alcohol. 19,177. July 15.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Activated Sludge, Ltd., and Coombs. Purification of sewage etc. 19,140. July 15.

Dunham. Food compounds. 19,552. July 20.

Henneberg. Separating micro-organisms from liquids. 19,265. July 16.

Hottinger. Sterilising liquids and solids. 19,673. July 21. (Switz., 1.6.21.)

O'Donnell. Disinfecting and deodorising. 19,511. July 20.

Paterson. Apparatus for purifying water, sewage, etc. 19,847. July 23.

Complete Specification Accepted.

26,078 (1913). De Brünn. Manufacture of base-exchanging bodies. July 20.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Imray (Soc. Chem. Industry in Basle). Manufacture of amino-ketones and amino-alcohols of the quinoline series. 19,536. July 20.

Johnson (Badische Anilin- u. Soda-Fabrik). Manufacture of urea. 18,731. July 11.

Johnson (Badische Anilin- u. Soda-Fabrik). Production of thymol. 19,376. July 18.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Complete Specifications Accepted.

14,344 (1914). Werthen. Sensitised metallic films or supports. July 27.

26,522 (1920). Rheinberg. Light-sensitive collodion coating mixtures and films. (166,063.) July 20.

XXII.—EXPLOSIVES; MATCHES.

Applications.

Deutsche Sprengstoff A.-G. Production of plastic masses etc. from smokeless powder. 19,753. July 22. (Ger., 2.11.20.)

Herz. Manufacture of detonating-compositions. 18,747. July 11.

Nobel's Explosives Co., Ltd., Nolan, Rintoul, and Stickland. Explosives. 18,729. July 11.

Complete Specifications Accepted.

24,841 (1919). Rintoul, Nolan, Stickland, and Nobel's Explosives Co. Explosives. (166,277.) July 27.

18,729 (1921). Rintoul, Nolan, Stickland, and Nobel's Explosives Co. Explosives. (166,502.) July 27.

XXIII.—ANALYSIS.

Complete Specifications Accepted.

24,005 (1919). Williams and Williams. Determining the composition of gases. (166,266.) July 27.

20,579 (1920). Ubbelohde. Continuous determination of the specific gravity of gases. (148,575.) July 27.

I.—GENERAL; PLANT; MACHINERY.

Volatile substances; Removal of —— from gases not readily absorbed [*air*]. *I. Use of activated carbon.* E. Berl and K. Andress. Z. angew. Chem., 1921, 34, 369—371, 377—382.

The capacity of active carbon prepared by the zinc chloride process (F.P. 471,295; J., 1915, 216) and dried at 120° C. *in vacuo* for adsorbing water vapour and the vapours of ether, alcohol, methyl alcohol, benzene, carbon tetrachloride, and acetone from dilute mixtures with air has been determined and adsorption isothermals constructed showing the relation between the amount of the vapour adsorbed and the partial pressure of the vapour in the gas-mixture. The nature of the curves obtained for the organic vapours tested was very similar for all, although each vapour has its own characteristic curve, but that obtained for water vapour was entirely different, being convex while the others were concave to the axis of the partial pressure. The amount of vapour adsorbed by the carbon depends on the temperature, the thickness of the layer, the rate of passage, and the degree of saturation of the air, and is greater the higher the molecular weight and boiling-point of the substance to be adsorbed. The carbon is suitable for removing the vapours of organic substances from air, coal gas, and the like, but not for removing small quantities of water vapour from gases.
—A. R. P.

Patents.

Evaporating apparatus; Means for preventing deposits and incrustations in ——. Soc. d'Exploit. de Proc. Evaporatoires Système Prache et Bouillon. E.P. 137,052, 22.12.19. Conv., 24.12.18.

A powder that acts purely mechanically (*e.g.*, sand) is introduced into the liquid, which is circulated sufficiently rapidly to keep the solid matter in suspension. The concentrated liquor is withdrawn through a "capacity" where the motion is not so rapid in order to ensure separation of the sand.—B. M. V.

Treatment [*evaporating, distilling, or concentrating*] *of liquid substances.* The By-Products Recovery Co., Assees. of C. R. Mabee. E.P. 138,118, 23.1.20. Conv., 19.7.15.

The liquid, *e.g.* milk, is caused to travel constantly n a thin film over the inner surface of a steam-acketed cylinder by devices which, under centri-ugal action, clean, brush, or polish the surface f the cylinder to prevent adherence thereto. A orizontal cylinder may be used, the vapours being withdrawn horizontally.—H. H.

Agitating or mixing of liquids. N. D. Nielsen. E.P. 147,492, 8.7.20. Conv., 25.9.16.

To expose the liquid contents of a tank, during gitation or mixing, more effectively to the heating r cooling action of the walls, *e.g.*, in the pasteuri-ation of milk, the tank is provided with curved des and bottom, and the liquid is thrown, *e.g.*, by propeller, in a vertical plane in all directions from point close to a junction of the sides and bottom. he liquid thus impinging on the curved surfaces deflected therefrom in a forward direction.
—H. H.

Cleaning gases and vapours, more especially blast-furnace gases; Apparatus for ——. Deutsche Maschinenfabrik A.-G. E.P. 149,232, 12.7.20. Conv., 12.5.19.

He gas is passed through a combined preheater nd filter, provided with a jacket through which the heating medium circulates to prevent radiation losses. The dust collects in a receptacle having a resilient cover to absorb the strains due to the vertical expansion and contraction of the whole apparatus.—H. H.

Purification or washing of gases; Process and apparatus for ——. A. Knöpflmacher and R. Adler. E.P. 149,340, 21.7.20. Conv., 12.4.19.

The gas is passed upwards through a tube, the top of which forms a mixing chamber in which it meets a spray of washing liquid, directed vertically upwards in such a manner that the liquid and gas are projected in the form of a spreading cone into the superposed purifying chamber, where the mixture meets a conical spray of washing liquid. To separate heavy particles from the gas before submitting to the above process, a screen of washing liquid may be formed in the gas inlet tube by means of jets arranged in the wall of the tube.—R. L. F. R.

Purification or washing of gases. A. Knöpflmacher and R. Adler. E.P. 149,341, 21.7.20. Conv., 8.8.19. Addn. to 149,340 (*supra*).

The gases are passed through two or more chambers arranged in series, in which they are washed as described in the chief patent, the temperature in each successive chamber being lower than that in the preceding chamber, so that a fractional separation of the condensates is obtained.—R. L. F. R.

Washing and cooling gases; Apparatus for —— with a multiple-stage disintegrator. F. Trappmann. G.P. 327,690, 28.5.19. Addn. to 327,047 (J., 1921, 204 a).

The efficiency of the disintegrating and mixing processes in a multiple-stage disintegrator of the type described in G.P. 327,047, and in which moreover the drums may rotate in the same direction, is increased by disposing the disintegrating drums concentrically with the axle, while the transverse plates dividing the chamber into compartments are arranged eccentrically thereto.—J. S. G. T.

Gas cleaning apparatus; Centrifugal ——. F. R. McGee and A. F. Nesbit. U.S.P. 1,381,719, 14.6.21. Appl., 10.12.20.

A device is inserted in the gas conduit which gives a rotary motion to the bulk of the gas by means of helical vanes, a small portion of the gas being allowed to flow straight through centrally. The apparatus may be combined with an electrical precipitator, the gas conduit forming the collecting electrode, and the discharge electrode being arranged centrally in the path of the straight-flowing portion of the gas. A number of dust traps may be arranged along the collecting electrode.
—B. M. V.

Depositing dust and particles from gases; Electrostatic plant for ——. The Skinningrove Iron Co., Ltd., and T. R. Smith. E.P. 165,655, 21.6.20.

A negative electrode for electrostatic deposition of dust is formed of chain-mail or of metal rods interlaced by wires, and is suspended from a fixed rail at its upper edge. A jerking motion is imparted to the electrode by mechanism whereby a heavy rail attached to the lower edge of the electrode is lifted at intervals and allowed to fall.—H. H.

Electrical precipitation of particles from fluid streams. C. W. Girvin. U.S.P. 1,378,224, 17.5.21. Appl., 16.2.18.

The opposing electrode systems are movable relative to each other and means are provided for isolating a space of predetermined cross-sectional area from the electric field activity, and for removing deposits collected on a face of one of the electrode systems while free from activity.—J. W. D.

Removing solids suspended in moving gases; Method of ——. R. B. Rathbun. U.S.P. 1,381,660, 14.6.21. Appl., 31.10.18.

The gas is passed through a series of electrostatic fields, all portions of the gas being made to pass through more than one field. The lines of force of each field extend in the general direction of the flow of gas, and are convergent, whereby the potential gradient and the zone of ionisation are increased.—H. H.

Dust; Removal of —— from tubular electrodes. H. Thein. G.P. 334,786, 28.11.19. Addn. to 331,590 (J., 1921, 248 A).

Tubular electrodes, as described in the chief patent, are freed from deposited dust by forcing clean gas through them under pressure, whereby a vibratory motion is imparted to the tubes, and the individual windings of which the tubes are composed are alternately brought closer together and separated. The cutting-off of the supply of unpurified gas, prior to the removal of dust, is effected automatically.—A. B. S.

Filter plates. F. Krupp A.-G. Grusonwerk, and P. L. Fauth. E.P. 156,739, 7.1.21. Conv., 3.9.19.

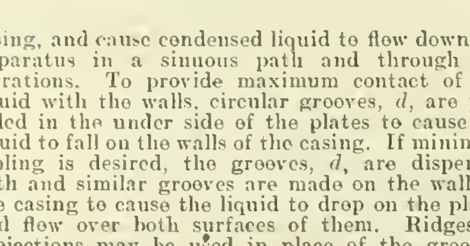
To reduce the tendency to clogging, the openings in the filter plates for the passage of the expressed liquid are provided with baffles in the form of ledges or projections.—H. H.

Heat; Mechanical production of ——. E. Scheitlin. E.P. 157,903, 10.1.21. Conv., 17.5.19.

Mechanical power is converted into a useful form of heat (*e.g.* steam) by means of a pump drawing a liquid from and discharging it into a boiler, the discharge (pressure) pipe being provided with at least one throttling device where the heat will be generated.—B. M. V.

Condensers, dephlegmators, and column stills. R. P. Douglas. E.P. 164,793, 9.2 and 2.10.20.

The condenser (see fig.) is provided with plates, *b*, which taper from the centre to the edges, and have serrated edges; these plates rest on the walls of the casing, and cause condensed liquid to flow down the apparatus in a sinuous path and through the serrations. To provide maximum contact of the liquid with the walls, circular grooves, *d*, are provided in the under side of the plates to cause the liquid to fall on the walls of the casing. If minimum cooling is desired, the grooves, *d*, are dispensed with and similar grooves are made on the walls of the casing to cause the liquid to drop on the plates and flow over both surfaces of them. Ridges or projections may be used in place of the grooves. Various modifications of the invention are described.



Re-run still. D. Pyzel. U.S.P. 1,383,024, 28.6.21. Appl., 4.9.19.

An inclined cylindrical shell with closed ends is provided with two heads spaced from the ends. The space between the heads forms a distilling chamber, the upper part of which is divided by partitions. A series of tubes extends through the lower part of the distilling chamber. Hot residuum is delivered to the end space at the higher end of the shell and flows through the tubes, and steam is introduced at the bottom of the distilling chamber to which also the liquid to be distilled is supplied. Vapours are withdrawn separately from the compartments bounded by the partitions.—R. L. F. R.

Distillation and sublimation; Apparatus for ——. Farbenfabriken vorm. F. Bayer u. Co. G.P. 334,669, 8.8.19. Addn. to 332,196 (J., 1921, 498 A).

Loss of heat from the liquid being distilled is prevented by making the tube for leading off the vapour doubled-walled, the space between the walls being filled with insulating material.—J. S. G. T.

Catalysts and catalytic reactions. W. Feldenheimer and W. W. Plowden. E.P. 164,808, 17.2, 26.5, and 22.6.20.

Colloidal clay prepared by peptisation with ammonia, sodium hydroxide, or sodium carbonate according to E.P. 106,890 or 121,191 (J., 1917, 879; 1919, 41 A) has marked catalytic effects both when used alone and in conjunction with known catalysts such as reduced nickel in reactions of oxidation (*e.g.*, oxidation of alcohols to aldehydes) and reduction (hydrogenation) and in the synthetic production of ammonia.—H. C. R.

Catalysts; Production of ——. C. B. Cluff, Assr. to The American Cotton Oil Co. U.S.P. 1,381,969, 21.6.21. Appl., 5.11.20.

A mixture of a reducible nickel compound and melted tallow is reduced with hydrogen at 240°—245° C.—R. L. F. R.

Oven furnaces; Gas-fired ——. E. E. Lucas. E.P. 164,833, 13.3.20.

At its front or door end the oven chamber has in its floor a damper-controlled opening leading to a down flue, which communicates through horizontal conduits with the base of the usual flue outlet. The air for combustion is preheated by passing it around these conduits. The lower end of the down flue is sealed by liquid in a quenching tank.—H. H.

Furnaces; Regenerative ——. W. P. Thompson. From Soc. Anon. Fours et Procédés Mathy. E.P. 164,991, 11.8.20.

At each side of the combustion chamber are two regenerators above which are arranged three passages. One passage, forming a flue for the products of combustion, is in constant communication with the combustion chamber, and can be placed in communication with one or other or both of the regenerators. The other two passages, conveying air and gas to the burners, may each be placed in communication with one of the regenerators. The furnace may be operated in three ways, viz., with flames extending across the chamber from the burners at one side and the products of combustion escaping by the flue passages at the other side; with flames extending into the chamber from the burners at one side and the products of combustion escaping by the flue passages at the same side; or with flames extending into the chamber from the burners at both sides, and the products of combustion escaping by the flue passages at both sides. —H. H.

Centrifugal separating apparatus. R. A. Sturgeon. E.P. 164,867, 18.3.20.

The centrifuging chamber is provided with an end wall or cover which is normally maintained closed by the pressure produced by centrifugal force in a renewable mass of liquid. The cover is opened by the pressure within the chamber when this liquid is drained away, whereupon the deposited solids may be flushed out of the chamber without stopping the rotation. Separate sets of outlets may be provided for clarified liquors of different specific gravities, *e.g.*, in the application of the apparatus to grease recovery or cream separation.—H. H.

Centrifugal apparatus. J. W. Phillips, Assr. to C. P. Landreth. U.S.P. 1,382,930, 28.6.21. Appl., 17.6.20.

The apparatus comprises two co-axial rotating drums, and means to feed the material and to move it forward between the drums. The separated materials are discharged, one through an outlet in the outer drum, and the other through an outlet leading from the interior of the inner drum.
—R. L. F. R.

Drying sugar, grain and other materials; Means for ——. M. and W. Blake. E.P. 164,897, 31.3.20.

A vertical casing is provided with a heating jacket, a central tubular shaft, and a series of conical surfaces, plain, louvred, or stepped, one above another, each alternate one being inverted, so that by the co-operation of suitably disposed fingers, combs, or brushes adapted to move over the conical surfaces the material is tumbled over the successive cones alternately from centre to periphery and from periphery to centre. The cones may be rotated with the central shaft, and the scraping devices fixed to the casing, or *vice versâ*. The casing has an inlet for the material at the top, a hot air inlet at the bottom, and additional hot-air inlets controlled by sleeves at various heights. Means are provided for admitting steam to the casing for cleaning.—J. H. L.

Drying apparatus for granular materials. H. Winde. G.P. 336,138, 18.4.20.

In a drying apparatus for granular materials comprising prismatic or conical, upright or inclined air cells and drying columns arranged alternately, the middle columns have a thicker layer of material to be dried than the columns on either side, which have progressively thinner layers of material. By this means more uniform drying is attained.
—A. B. S.

Trough-dryer. Maschinenfabrik Imperial G.m.b.H. G.P. 336,451, 17.7.19.

A trough-dryer is connected with the casing of a bucket-wheel discharging device. Two suction tubes open into this casing, one on either side of the connexion between the casing and the drying hamber. Each bucket is thus placed under suction before connexion is made with the drying chamber, which is operated under diminished pressure, and hen, after the bucket is filled and moved forward, it is again placed under suction to remove air.
—A. B. S.

Thermic process of any kind; Process and apparatus for performing a ——. K. A. F. Hiorth. E.P. 164,989, 4.8.20.

Fuel and raw material (solid or gaseous) are passed ownwards through a furnace in separate columns, orming between them a reaction surface which is eparated by a layer of fuel from the hottest zone of he furnace, and the discharge is arranged at a vel above this hottest zone. The invention is pplicable to heating, calcining, reducing, drying, and like operations, to the catalytic combination of gases or of gases and solids, to the production of lime from limestone, and to the hardening of metal articles.—H. H.

Crystallising pans. F. Peters. E.P. 165,195, 20.3.20.

A crystallising pan is formed of flexible material for the easy detachment of crystals, and is provided with internal ribs or shelves, or formed with a series of steps at the sides, to lessen the formation of crystals on the bottom.—B. M. V.

Washing sand or other granular material; Apparatus for ——. H., N. H., and C. G. Crowther. E.P. 165,257, 12.4.20.

An apparatus for washing sand comprises a conical drum with horizontal axis, to which the sand is admitted at the small and the wash water at the large end. The sand is conveyed by means of a helical baffle to the large end, where it drops into a still larger cylindrical portion of the drum provided with troughs or buckets which lift the material on to a discharge shoot; the lifting buckets may be inclined towards and stop short of the end of the drum in order to permit water to drain away from the sand before discharge.
—B. M. V.

Vacuum; Process for producing —— by means of charcoal as an air absorbing agent. H. Wade. From Sprengluft Ges. m. b. H. E.P. 165,675, 15.7.20.

For producing a vacuum in the jackets of storage tanks, charcoal prepared by heating wood which has been impregnated with salts such as zinc chloride or with substances having a similar absorbent action is used.—H. H.

Solvent recovery; Process for ——. A. S. O'Neil. U.S.P. 1,381,002, 7.6.21. Appl., 3.3.19.

Material containing solvent is brought in contact with a current of hot gas lighter than the solvent vapour, and the mixture of gas and solvent vapour is allowed to travel down a tortuous passage in contact with refrigerated solvent; the gas freed from solvent is used again. Circulation of gas and vapour is effected solely by the gas-heating and refrigerating operations.—R. F. L. R.

Refrigerating apparatus. Absorbent material for use in ice-machines. C. M. Smith and H. Weigand. U.S.P. (a) 1,383,246 and (b) 1,383,247, 28.6.21. Appl., (a) 16.1.19, (b) 5.3.20.

(a) Within a chamber provided with means for heating and cooling are containers each comprising an outer tube and a perforated inner tube, the latter being connected with a pipe for ammonia gas. The space between the tubes is filled with absorbent material. (b) An absorbent material for use in ice machines consists of anhydrous calcium chloride with charcoal distributed throughout the mass.
—R. L. F. R.

Decolorising liquids containing electrolytes. Elektro-Osmose A.-G. (Graf Schwerin Ges.). G.P. 335,816, 22.7.19.

The liquid is freed from electrolytes by dialysis or electro-osmosis, prior to treatment with a decolorising agent.—A. B. S.

Electro-osmotic dehydration [of peat]; Apparatus for ——. Elektro-Osmoso A.-G. (Graf Schwerin Ges.). G.P. 336,333, 26.2.18.

An apparatus to be used more especially in the disintegration of peat *in situ* and its subsequent electro-osmotic dehydration comprises a syringe pipe opening into a chest whereby the syringe may be shut off from its surroundings, and which can be raised and lowered along with the end of the syringe. The chest is connected with the suction pipe of the electro-osmotic machine, whereby the disintegrated peat may be transferred to the latter. The syringe pipe is disposed within the suction pipe in such manner that the ends of both pipes can be raised and lowered together.—J. S. G. T.

Filling material for absorption-, reaction-, or washing-towers and the like. A. Navratiel. G.P. 335,817, 15.1.20.

The material is made gable- or tunnel-shaped and provided with a rounded or projecting shoulder and smooth walls, with or without openings cut in the lower walls and edges.—A. B. S.

Dispersoids; Process for producing —— from solid colloidal masses. Plausons Forschungsinstitut G.m.b.H. G.P. 337,429, 30.8.18.

Colloids such as glue, gelatin, agar-agar, gum arabic, tragacanth, dextrin, starch, albumin, casein, hæmoglobin, yeast, cellulose esters, etc., in the form of a thoroughly dried, very finely-divided powder, are pressed into the desired shape either alone or mixed with filling material. Slightly soluble colloids are rendered insoluble by addition of formaldehyde etc., either during or subsequently to treatment in the colloid mill (J., 1921, 169 A), the resulting material being then worked up after removing excess of dispersing medium.—J. S. G. T.

Furnaces; Method of increasing the rate of transmission of heat in ——. A. Pfoser. E.P. 11,286, 7.5.14. Conv., 7.5.13.

See U.S.P. 1,257,524 of 1918; J., 1918, 248 A. The method described may be applied to all types of furnaces.

Lining for kilns. A. F. Meyerhofer, Assr. to Dynamidon Ges. U.S.P. 1,378,710, 17.5.21. Appl., 16.6.14. Renewed 23.10.20.

See F.P. 472,033 of 1914; J., 1915, 426.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Mineral oil and coal; New method of treatment [hydrogenation] of ——. F. Bergius. Z. angew. Chem., 1921, 34, 341—347.

Heavy mineral oils may be transformed into low-boiling products by treatment with hydrogen at 400° C. under a pressure of about 100 atm. A rotating autoclave of 5 l. capacity and heated by gas was used for the preliminary experiments. A continuous method is also described. The products and yields are compared with those from cracking processes; there is no formation of coke and the amount of uncondensable gases formed is much less than in the cracking process. Coal can be treated in the same manner with advantage in order to obtain greatly increased yields of oil. (*Cf.* Fischer and Schrader, J., 1921, 457 A.)—W. P.

Bituminous lignite; Constituents of —— from which tar is derived. E. Erdmann. Z. angew. Chem., 1921, 34, 309—314.

The author divides the constituents of coal other than moisture into four classes: bitumen, soluble in benzol; humic acids, soluble in hot soda; organic constituents insoluble in the usual solvents, termed "Restkohle"; and inorganic constituents. 100 g. of the bituminous lignite investigated contained 18·1 g. of bitumen, 43·3 g. of humic acid, and 38·6 g. of "Restkohle," and these constituents yielded 11·96, 3·55, and 12·80 g. of tar respectively. The bitumen was mainly responsible for the paraffins in the tar. The author agrees with Fischer (J., 1921, 172 A) that the humic acids in lignite are derived from lignin, but criticises his assumption that the cellulose of the original plant matter has had no influence in the formation of coal.—W. P.

Fossil resins; Constitution of ——. C. Engler and J. Tausz. Z. angew. Chem., 1921, 34, 308—309.

The authors describe the formation of fossil resins (amber, copal, dammar, coal bitumen, oil shale) as a long chemical process accompanied by polymerisation. Extraction of oil shale with benzol under pressure at 270° C. gives a much larger yield of extract than that obtained with boiling benzol at ordinary pressures. This is shown to be due to the increase in temperature, since shale previously heated to this temperature gives an equally large yield of extract when boiled with benzol at atmospheric pressure. The reason given is that the shales undergo depolymerisation when heated to 270° C.—W. P.

Acid in soot and other carbonaceous matter; Estimation of ——. *Fifty-seventh annual report* (1920) *on alkali etc. works by the Chief Inspector,* 51—57.

The wetting of soot or lampblack with strong alcohol prior to extraction with dilute alkali fails to inhibit the interaction of free acid with the constituents of the soot. Immediate neutralisation of free acid with minimum disturbance of the bases present in the soot, is obtained by evacuating occluded gases through dilute alkaline solution and then extracting the soot *in vacuo* with the same solution. A tap water containing bicarbonate may be used as an alkali with or without hydrogen peroxide.—H. Hg.

Carbonisation of coal at low temperature. J. Roberts. N.E. Inst. Min. Eng., 6.8.21. [Advance proof.]

The expansion of coals during heating is due to the decomposition of any binding material in excess of that required for cementing the mass; there is a secondary contraction above 750° C. Either coke or semi-coke may be made of greater uniformity, density, toughness, and hardness by mixing coke breeze with the coal prior to heating, whereby the initial expansion is prevented. The thermal conductivity of the mixture of coal and coke is higher than that of coal alone, so that coking is effected more rapidly. The optimum proportion of breeze to be added to any coal must be determined in the laboratory with reference to the strength of the product; the quantities used in the author's experiments varied from 20% to 50%. Hard semi-cokes which ignite readily have been prepared on a laboratory scale from such mixtures at a temperature of 750° C.—H. Hg.

Hydrogen sulphide; Burnt oxide and wood charcoal as catalysts in removing —— from gas. Fifty-seventh annual report (1920) *on alkali etc. works by the Chief Inspector*, 25—39.

Burnt oxide, "activated" by mixing with lime and burning with 10% of coal, was exposed to mixtures of hydrogen sulphide and oxygen at various temperatures in a laboratory apparatus which allowed the contraction in gas volume to be noted. With fresh material a rapid initial reaction occurred at ordinary temperatures, but after this it was necessary to treat the oxide with carbon bisulphide to restore its activity. It was then possible to increase the sulphur content of the material to 40%. There was little formation of oxidised sulphur compounds, 94% of the hydrogen sulphide being recovered as free sulphur. Using wood charcoal at 25°—57° C. there was a marked formation of acid products; the activity of the material rapidly decreased and could not be restored.—H. Hg.

Paraffin [oil] in coal gas; Vaporisation of ——. N. Swindin. Gas J., 1921, 155, 266—269.

The vapour pressure of commercial paraffin oil ranged from 0·97 in. of mercury at 15° C. to 1·72 in. at 65° C. The presence of water vapour, however, hinders the vaporisation. Dry coal gas can absorb 18 galls. of oil per million cub. ft. without subsequent deposition; undried gas absorbs 4 galls. at 60° F. (15·5° C.). The rate of vaporisation of oil in still air (in kg. per sq. m. per hr.) was 0·09 at 39° and 5·77 at 115° C. A vaporisation apparatus (*cf.* J., 1917, 998) in which large surfaces of oil were exposed to coal gas was found to be an efficient cooler and to permit of simultaneous condensation of water vapour.—H. Hg.

Colorado shale oils. A. J. Franks. Chem. and Met. Eng., 1921, 25, 49—53.

Colorado shale oils and their distillation fractions (*cf.* J., 1921, 336 a) were examined particularly in relation to the distribution of sulphur and nitrogen. Usual technical methods for the estimation of sulphur in oils were found to be unreliable. A modified method using sodium peroxide and potassium chlorate, together with a small quantity of benzoic acid, in a Parr bomb is preferred, whilst in the absence of a bomb, Waters' nitric acid method (J., 1920, 438 a) is recommended. For all the oils examined there were only slight differences between the amounts of sulphur present in the various 10% fractions. The amount was less in the light and heavy fractions than in the middle oils, in which the constancy of the sulphur content indicates the presence of a series of isomers, and it is probable that different series of sulphur compounds exist in the light and heavier fractions respectively. Colorado shale oils contain more nitrogen than is found in most petroleums, and in the process of cracking, only about 60% of the total nitrogen is recovered in the distillates. The heavy loss points to the existence of unstable nitrogenous compounds in the natural oil, and the high percentage of nitrogen in the fractions boiling above 225° C. is evidence of the presence of more stable compounds. It is suggested that the saturated and more stable oils formed during distillation are the decomposition products of unsaturated compounds of high molecular weight containing both nitrogen and sulphur.—C. A. K.

Removal of volatile substances. Berl and Andress. *See* I.

Oxidation of ammoniacal liquor. See VII.

Montan wax. Pschorr and others. *See* XII.

Patents.

Fuel. L. W. Bates. E.P. 149,306, 22.12.19. Conv., 5.8.19.

The fuel is composed of fuel oil and added solid carbonaceous substance in the form of a stabilised coarse suspension, and is heavier than water, bulk for bulk. The suspension is obtained by means of two or more of the following measures:—Use of a protective agent, use of a peptiser, use of a buoyant solid, use of an immiscible or only slightly miscible liquid, adjustment of viscosity, or pulverisation of the solid matter in the presence of the oil. Approximately 85% of the solid matter will pass a 200-mesh screen. The viscosity of the dispersion medium is adjusted by raising or lowering the same, adding a protective agent, *e.g.*, lime rosin grease, and peptising agent, *e.g.*, creosote, and blending the components. Agitation and heat treatment are employed.—A. G.

Carbonaceous matter; Flotation treatment of ——. F. B. Jones, E. Bury, and Minerals Separation, Ltd. E.P. 165,144, 18.2.20.

The liquor obtained by scrubbing coal gas is mixed with carbonaceous material and subjected to froth flotation, by which means the solid matter and organic materials in the froth are recovered together. Alternatively, carbonaceous materials may be separated from the gangue by froth flotation with the liquor from the scrubbing of coal gas, which liquor may be obtained by scrubbing with seawater. For the recovery of "bone-coal," a small quantity of paraffin oil is added to the liquor, *e.g.*, 1/5—1/10 lb. per ton of crude coal treated.—A. G.

Lignite for fuel; Process for preparing ——. S. M. Darling. U.S.P. 1,382,629, 28.6.21. Appl., 1.12.19.

Lignite, 80 to 82 pts., is mixed with pitch, 8 to 10 pts., briquetted, and carbonised, the briquettes being afterwards cooled in the presence of the gas evolved.—H. Hg.

Burning solid fuels; Method of and apparatus for ——. J. Martin. E.P. 164,914, 14.4.20.

In burning inferior fuels, the large is separated from the small fuel on an ignition grate arranged within the heating range of the main grate. The finer particles pass through on to the main grate, whilst the coarser particles are exposed to the igniting effect of the main grate for a longer period than the finer particles, and then pass on to the top of the finer particles on the main grate. The burning mass then travels over a step grate by gravity and mechanical action and the ash is discharged mechanically into slag bogies placed under the grate. The air supply is preheated by passage over the red-hot ashes. The ash is prevented from slagging by the mechanical agitation and the cooling effect of the air (*cf. infra*), and the ash discharge is substantially air-tight. The ignition grate is composed of overhanging grate bars, the amount of overhang being adjustable. Additional fuel of better quality may be fed in between the ignition grate and the main grate. The furnace is furnished with air-cooled side "strings" combined with the grate boxes to form a U-shaped hollow body, the free ends of the side "strings" being connected with air-supply boxes. The slag, by its own weight, pushes open a self-closing curtain, fitting against the back of the furnace.—A. G.

Pulverised fuel feed system. L. H. Bergman. E.P. 165,379, 4.1.21.

The powdered fuel is supplied to a main conduit, from which it is tapped off as required to the various furnaces. Any unused fuel is separated from the unused mixture of fuel and air and returned to the main. Additional fuel is drawn from a storage bin as required, and the supply is automatically regulated by means combined with the blower. Heated air, which has already made a cycle or cycles through the system, is passed again to the blower in order to utilise its heat, and a device is also provided for the admission of cool air to the blower.—A. G.

Pulverised fuel; Handling, storing and controlling ——. G. Calvert. E.P. 165,524, 26.3.20.

The fuel is suspended in a liquid carrier, and the suspension is continuously agitated. Wire drawing or filtration (separation) is prevented by ensuring that none of the orifices through which the fuel has to pass is of smaller size than the largest particle of fuel in the suspension. The rate of feed of the fuel is controlled by varying the pressure of gas in the feed tank, or by varying the head of fuel maintained, by deflecting the excess by a by-pass, by blowing off a variable amount of fuel from a weir, by feeding the fuel with a variable-speed pump, or by using a counter-flow of air to check the flow of fuel. The solid fuel is filtered off from the liquid carrier just prior to its injection into the furnace. —A. G.

Burning fuel in furnaces; Method of and apparatus for ——. J. E. Muhlfeld. E.P. 166,073, 24.2.19.

A preliminary combustion chamber is attached to a furnace for the combustion of pulverised or liquid fuel so that it is in free communication therewith. A stream of fuel and air passes downwards into the preliminary chamber and is deflected by an inclined base into the main furnace wherein it is deflected upwards. A horizontal stream of air is admitted to the preliminary chamber and impinges upon the downward and upward streams of burning fuel. —H. Hg.

Burning pulverised fuel. H. G. Barnhurst. Assr. to Fuller Engineering Co. U.S.P. 1,382,712, 28.6.21. Appl., 26.6.18.

Pulverised fuel and air are supplied to a furnace at such a rate that the velocity of travel through the zone of highest temperature is only 7 ft. per second. This ensures complete combustion and avoids erosion of furnace walls.—H. Hg.

Coke ovens; Regenerative ——. A. Klönne. E.P. 159,849, 25.5.20. Conv., 27.2.20.

The walls and flues are made of a rammed refractory material, thus forming a jointless structure. Alternatively, the surfaces of the walls and partitions are formed of a layer of rammed fine refractory material which ensures a higher refractoriness and facilitates the movement or forcing out of the finished coke.—A. G.

Ovens; Regenerative —— for production of gas and coke. O. Hellman. G.P. 334,740, 30.7.19.

The air-, gas-, and waste gas flues of the divided regenerator, corresponding to one-half of each oven, and the corresponding oven heating flues lead to a common draught-reversing device extending longitudinally at the side of the battery of ovens, and are connected through this with a common gas main or a common waste gas flue.—W. J. W.

Gas generators. La Soc. Française de Travaux et Construction de Fours (anc. Auburtin et Cie.), and J. E. Auburtin. E.P. 146,124, 23.6.20. Conv., 23.6.19.

A cylindrical producer for material other than coal has outlet openings for the gases in its periphery about midway up the wall and a central grate having an inlet for the admission of air. The ash and slag are removed by a rotating annular shell underneath the producer. In this way a constant bed of fuel of uniform composition is maintained between the grate and the outlet openings, and gas of uniform composition is obtained.—A. G.

Coal or other carbonaceous material; Plants and processes for the gasification of ——. Woodall, Duckham and Jones (1920), Ltd., and A. McD. Duckham. E.P. 164,935, 28.4.20.

In plants for the complete gasification of fuel, arrangements are made whereby any desired portion of the water-gas made by steaming the residue from carbonisation may be used for the external heating of the retort portion of the plant. The upper portion of the carbonisation chamber is heated more strongly than any other portion. —A. G.

Fuel; Plants for gasifying ——. Woodall, Duckham and Jones (1920), Ltd., and A. McD. Duckham. E.P. 164,949, 14.5.20.

In a plant for the complete gasification of fuel, the relationship between the pressure at the top of the retort and that at the top of the generator is kept constant by hydraulically sealing the outlet pipe from the retort and making the depth of the seal depend on the pressure of gas at the top of the generator. The water-seal pot is divided into equal compartments having free communication for passage of water between them, the outlet pipe of the retort being sealed in one compartment, from which the volatile products escape, whilst the other compartment communicates above the water level with the top of the generator.—A. G.

Gasification of fuel. Woodall, Duckham and Jones (1920), Ltd., and A. M. Duckham. E.P. 165,616, 10.5.20.

In a combined retort and water-gas generator forming a complete gasification plant, air is passed downwards through the generator in the reverse direction to the steam in order to reduce the formation of clinker.—H. Hg.

Gasification of fuel, and apparatus therefor. T. Twynam. E.P. 165,290, 7.5.20.

In a two-stage process of complete gasification a number of small retorts, heated externally to

600°—650° C. by the sensible heat of the producer gas, are used in conjunction with one producer. —H. Hg.

Gas manufacture. G. Helps. E.P. 165,456, 30.3.18.

In a self-contained plant for the manufacture of straight coal gas, water-gas, and producer gas, a retort is superimposed on a producer, being separated therefrom by a sliding valve. Coke may be passed through this valve into the producer or may be withdrawn through a door at the base of the retort. Around the valve are ports for the separate withdrawal of the gas made in the producer and for passing it to the exterior of the retort for heating purposes.—H. Hg.

Coal gas; Manufacture of ——. A. Meade. E.P. 165,581, 20.4.20.

The level of liquid in a hydraulic main is controlled by connecting the main with a pressure box in such a way that a U-tube system is formed. Gas under a controlled pressure is led into the box and by adjusting this pressure the liquid level within the hydraulic main may be varied without altering the gas suction within the foul main. Tar and liquor flow through the pressure box into a separator where they are separated whilst still hot.—H. Hg.

Carbonaceous materials; Treatment of —— *for the manufacture of power gas with recovery of hydrocarbon oils.* S. Everett, and Carboil Synd., Ltd., E.P. 165,815, 5.2.19.

Condensation members of inverted V-section and with perforated walls are placed transversely within a retort. The material being distilled is thus divided into sections, and the condensation members being inclined, oils condensing on or within the members at any level within the retort are separately removed by drainage.—H. Hg.

Explosive gases; Means for storing ——. Svenska Aktiebolaget Gasaccumalator. E.P. 160,158, 10.2.21. Conv., 11.3.20.

Porous material, such as charcoal, used for storing acetylene and other explosive gases is mixed with a powdered incombustible substance in order to minimise disintegration of the porous granules during transport and diminish the free space within the receiver.—H. Hg.

Benzol, toluol and light oils from coal gas; Recovery of ——. W. Hill and T. Cook. E.P. 165,801, 9.8.17.

The gas is washed with tar oil in a washer, and the benzolised oil flows into a tank at a lower level, and is then pumped into another receiver at a higher level fitted with an overflow pipe connected with the first tank. From the second tank the oil flows to a distillation apparatus where the benzene is distilled from the oil. The debenzolised oil flows to a third receiver which is at a lower level than the second receiver, but at a higher level than the washer to which it is conducted for re-use. With this arrangement of apparatus only one pump is required instead of the three commonly employed. —C. A. C.

Gas washer. W. Steinmann. G.P. 336,828. 20.8.18.

The apparatus comprises a vessel in which perforated discs rotate slowly and are sprayed by means of a device which does not close the perforations. The liquid is then removed by other revolving discs operating in conjunction with fixed scrapers, and the gas is freed from liquid by passing it through a series of nozzles into a chamber and through the latter in two paths, the second at right angles to the first. The apparatus is suitable for removing tar from gases.—W. J. W.

Mineral oils and the like; Process and apparatus for obtaining volatile fractions from crude ——. E. F. Engelke. E.P. 164,800, 12.2.20.

Crude mineral oil, coal tar, or similar hydrocarbon material, is subjected to a distillation treatment involving the action in three stages of heated gases containing free hydrogen, with or without superheated steam. The heated gases are first used to inject the preheated oil or the like into an expansion vessel from which the evaporated portions are conveyed to condensers, and the liquid remaining in the expansion vessel is subjected in two further stages to the action of more of the heated gases. The residues may be subjected to similar treatments in other apparatus at successively higher temperatures.—H. H.

Mineral oils and other hydrocarbon-containing material; Distillation and cracking of ——. N. V. S. Knibbs. E.P. 165,863, 24.9.19.

Distillation and cracking are effected by bringing the material into direct contact with a current of hot gas produced by the combustion of the residual carbonaceous matter resulting from the operation. The oil is sprayed into the top of a vertical metal cylinder containing a layer of refractory material. By allowing complete combustion of a limited supply of oil, air being introduced at the same time, the refractory material is heated. By gradually increasing the supply of oil only the residual part of it will reach the bottom of the chamber, the remainder, the volatile part, being distilled or cracked by the current of hot combustion gases. The temperature is regulated by the supply of air, or by the introduction of steam or water. For cracking, a pressure of 50—500 lb. is maintained in the chamber.—C. A. C.

Lubricating oils and the manufacture thereof. J. E. Southcombe and H. M. Wells. E.P. 165,897, 27.2.20.

Crude hydrocarbon oil, refined in the usual manner with sulphuric acid or the like, instead of being treated with alkali, is washed with water to such an extent that 1 to 3% of organic acids (sulphonic acids in particular) remain. The process may be modified by treating an oil containing 1 to 3% of glycerides with steam to hydrolyse the glycerides and produce a limited quantity of fatty acids. (*Cf.* J., 1920, 51 t.)—C. A. C.

Petroleum; Process of distilling ——. E. O. Hicks. U.S.P. 1,378,229, 17.5.21. Appl., 17.4.20.

The liquid portions of the paraffin series of petroleum distillates of b.p. above 500° F. (260° C.) are treated in a still at a temperature of 650°—850° F. (340°—450° C.), the vapour is condensed, then re-vaporised in receptacles in the still which maintain separation of the condensates from the liquid portions of the petroleum throughout the process and thereby preserve the viscous nature of the latter. The re-vaporised fractions are re-condensed and a pressure of 4—5 atm. is maintained on the vapours throughout their course and while undergoing condensation. The accumulation of gas from the products of condensation is released from time to time.—J. W. D.

Petroleum; Treatment of crude —— *for purification.* J. W. Bostick and C. H. Homer. U.S.P. 1,380,863, 7.6.21. Appl., 29.7.19.

Oil flows slowly through a series of shallow tanks in which the upper layer of oil is heated to a higher temperature than the lower layer, and only the surface layer in each tank flows into the succeeding tank. Impurities settling to the bottom of the oil are removed separately from each tank, and the vapour generated is withdrawn and condensed. —L. A. C.

Petroleum oils; Dehydrator for ——. H. R. Quinby, Assr. to Petroleum Rectifying Co. U.S.P. 1,382,234, 21.6.21. Appl., 25.2.20.

The apparatus comprises an outer electrode formed by a pair of concentric metallic walls and an inner cylindrical electrode arranged in the annular space of the outer electrode, into which also the oil is passed for treatment. The electrodes can be moved relatively to each other.—C. A. C.

Petroleum; Method of and apparatus for treating ——. D. W. Hoge. U.S.P. 1,382,727, 28.6.21. Appl., 25.8.16.

Petroleum from which gasoline has been removed is evaporated in a still, the vapours are forced into a cracking apparatus, and the hot cracked vapours are passed through a bath of petroleum containing gasoline. The gasoline is distilled and is withdrawn together with the cracked vapours and led to a condenser. The petroleum remaining in the bath is transferred to the still.—C. A. C.

Bone charcoal [for mineral oil refining]; Manufacture of a substitute for ——. Rekord-Zement-Ind., G.m.b.H. G.P. 337,060, 2.10.17.

Bituminous shale or the residue from its distillation is heated and subsequently cooled in the absence of air, yielding a product suitable, *e.g.*, for decolorising mineral oil.—L. A. C.

Decarbonising agents for internal combustion engines and the like. H. H. Cuthbert. E.P. 165,376, 14.12.20.

An alkaline-earth nitrate is mixed with, or dissolved in methyl or ethyl alcohol, and benzol, petrol, or chloroform is added for the purpose of softening the deposit. The proportions of the various constituents may be, 25 vols. of calcium nitrate, 71 vols. of methyl or ethyl alcohol or methylated spirit, and 4 vols. of benzol.—A. G.

Montan wax; Production from raw —— *of preparations capable of yielding persistent emulsions with water.* H. T. Böhme A.-G. Chem. Fabr. G.P. 335,996, 3.10.17.

Raw montan wax is heated under pressure with a dilute solution contain 3—8% of caustic alkali, until a sample is completely miscible with cold water; small quantities of protective colloids such as starch, glue, or soap may be introduced, as well as such substances as mineral oil or wax capable of modifying the character of the montan wax. —D. F. T.

Coking-oven; Horizontal ——. O. Piette, Assr. to Soc. Anon. des Fours à Coke Semet-Solvay et Piette. U.S.P. 1,378,129, 17.5.21. Appl., 28.1.18.

See E.P. 113,779 of 1917; J., 1918, 362 A.

Gas-generator; Suction ——. J. Franklin, Assr. to The Efficient Gas Power Co., Ltd. U.S.P. 1,382,074, 21.6.21. Appl., 12.6.19.

See E.P. 151,329 of 1919; J., 1920, 741 A.

Paraffin wax from petroleum; Process for separating substances from solutions, and especially ——. P. T. Sharples. E.P. 166,031, 9.6.20.

See U.S.P. 1,351,265 of 1920; J., 1920, 682 A.

Gas retorts; Apparatus for charging and discharging ——. A. D. Cresler. E.P. 165,111, 30.7.18.

See also pages (A) 568, *Still* (U.S.P. 1,383,024). 569, *Electro-osmotic dehydration of peat* (G.P. 336,333). 575, *Producer-gas tar* (G.P. 334,658), *Lubricating oils* (G.P. 335,610). 582, *Ammoniacal liquor* (E.P. 165,833). 606, *Gas calorimeter* (U.S.P. 1,381,714).

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Patents.

Carbonising fuels; Method of and apparatus for ——. Underfeed Stoker Co., Ltd., and S. McEwen. E.P. 165,154, 13.3.20.

Low-temperature carbonisation is conducted in a tube mill which is heated internally by gas introduced through one trunnion. Means are provided for the separate withdrawal of solid and volatile products. The process may be worked in conjunction with those described in E.P. 154,253 and 154,458 (*cf.* J., 1921, 37 A).—H. Hg.

Distillation of coal and other carbonaceous substances. S. N. Wellington. E.P. 165,805, 20.4.18.

The retorts are heated by means of pitch of high boiling point circulated through a heater, the supply of hot pitch to the exterior of different zones of the retorts being controlled according to the temperature desired.—H. Hg.

Distillation of coal, shale, peat, wood, and other bituminous or organic materials, and apparatus therefor. W. E. Davies. E.P. 165,825, 13.5.19.

A vertical retort is provided with lateral heating flues and central gas withdrawal ducts; the flues may be arranged in sections in order to obtain zones of different temperature within the retort. Part of the waste combustion gases is withdrawn into other lateral flues, mixed with extraneous gases and drawn transversely through the mass being carbonised into the central gas duct. Distribution of the gases within the retort is obtained by means of perforations in the flues and in the gas duct. The gases entering the retort may be electrically treated as described in E.P. 131,105 (J., 1919, 711 A). The extraneous gases suitable for mixing with the waste gases include blast-furnace, water-, or coal-gas, hydrocarbons, air, steam, hydrogen, and oil vapours. The choice of these, and of the temperature and pressure conditions within the retort, depend upon the result desired, *e.g.*, reduction of carbon dioxide to monoxide, complete gasification of the charge, ammonia synthesis, production of high quality coke, or formation of benzene, toluene, or high temperature by-products. (*Cf.* E.P. 136,880 and 128,660; J., 1920, 148 A; 1919, 621 A.)—H. Hg.

Kerogen shale; Apparatus for distilling ——. E. E. Hedges. U.S.P. 1,383,205, 28.6.21. Appl., 10.11.20.

The apparatus consists of an inclined rotating retort with an internal volute feeding conduit, receiving the material at the axis and discharging it at the periphery.—H. Hg.

Leading-in wires in quartz-glass vessels; Production of tight joints with ——. W. C. Heraeus G.m.b.h. G.P. 336,014, 24.9.18.

Wires of iron or other metal having a temperature coefficient of expansion considerably greater than that of quartz are used as leading-in wires in conjunction with vessels of quartz-glass. The diameter of the wire is such that the joint remains vacuum-tight at the highest anticipated temperature; the joint is reinforced by cements which melt at such temperature. Thus it is found that an iron wire of 0·5 mm. diameter affords a vacuum-tight joint in quartz-glass at a dull red heat, while wires of 0·9 mm. diameter may be heated to 360° C. without the joint leaking.—J. S. G. T.

Mercury vapour lamp. P. Bachmann. G.P. 336,570, 11.5.20.

The defect in the mercury vapour lamp arising from evaporation of the mercury is eliminated by the use of an anode of metal or alloy, the surface of which is amalgamated anew from time to time by means of mercury supplied from near the electrode. —J. S. G. T.

Gas- or vapour-[filled] electric lamp with arc discharge. J. Pintsch A.-G. G.P. 336,571, 26.1.18.

Thallium to which other metals such as lead, tin, calcium, cadmium, zinc, etc., may be added, but not an alkali metal, is used as cathode in a gas- or vapour-filled electric lamp, more especially those filled with a rare gas.—J. S. G. T.

Distillation-oven [for carbonaceous materials]. L. F. Schrader, W. E. Roberts, and V. Bredlik, Assrs. to Foundation Oven Corp. U.S.P. 1,382,746, 28.6.21. Appl., 24.2.19.

See E.P. 154,819 of 1920; J., 1921, 40 A.

III.—TAR AND TAR PRODUCTS.

Liquefied carbolic acid. C. T. Bennett. Brit. Pharm. Conf., June, 1921. Pharm. J., 1921, **106**, 472—473.

The m.p. of mixtures of phenol with varying quantities of water were as follows:—Water content 13·1%, m.p., 8·5° C.; 16·7%, 6·5° C.; 21·9%, 2·5°—3·0° C. The phenol itself had m.p. 40·5° C. —W. P. S.

Alkylarylmethanes; Synthesis of —— from ketones and phenols. A. Müller. Chem.-Zeit., 1921, **45**, 632.

The condensation of ketones with phenols is best effected by using hydrochloric acid containing a small quantity of ferric chloride as catalyst; other catalysts, such as sulphuric acid, phosphoric acid, acetic acid, zinc chloride, and thorium oxide are useless for this particular purpose. With acetone or monochloroacetone and phenol, resorcinol, or quinol, the yields are over 90%.—W. P. S.

Patents.

Tar; Distillation of ——. The Barrett Co., Assees. of J. M. Weiss. E.P. 158,852, 1.4.20. Conv., 7.2.20.

The process consists in circulating repeatedly through hot tar at the rate of from 1 to 20 cub. ft. per 100 galls. of tar per minute, a body of gas which does not condense at 0° C. and atmospheric pressure, and which is inert to and insoluble in the tar. Suitable gases are carbon dioxide, carbon monoxide, and nitrogen. On account of the relatively small formation of "free carbon," the distillation may be carried to such an extent that a pitch of a much higher melting point may be produced without endangering the apparatus, and consequently a much greater yield of oil may be obtained than is usually the case. Pitches of m.p. 350°—600° F. (about 180°—200° C.) can be obtained, and these can be removed from the stills without difficulty or undue coking on the shell of the still.—F. M. R.

Tar; Process for dehydrating producer-gas ——. Badische Anilin u. Soda-Fabrik. G.P. 334,658, 15.4.17.

The tar is agitated at a high temperature with an acid or an acid solution by means of a stirrer of which both the upper and lower parts, or the lower part only, can be rotated. After thorough admixture, the upper part of the stirrer is brought to rest, but agitation of the lower aqueous acid layer is continued until complete separation of the tar is effected; the upper layer of tar free from water can then be run off after a short period of settling. —W. J. W.

Lubricating oils; Production of neutral —— from tar oils. M. Melamid. G.P. 335,610, 12.3.19.

Tar oils are heated to 350°—450° C. with anhydrous sulphonic acids, *e.g.*, 10% of β-naphthalenesulphonic acid, in presence of alcohol. The neutral oil obtained is then washed.—W. J. W.

Naphthols; Manufacture of ——. L. F. Chebotaref, Assr. to National Aniline and Chemical Co., Inc. U.S.P. 1,381,280, 14.6.21. Appl., 23.11.16.

A mixture of 15 pts. of sodium naphthalene-β-sulphonate and 11 pts. of caustic soda is fused at a temperature between 280° and 350° C., and the upper layer of sodium naphtholate which is formed on prolonged heating is removed.—F. M. R.

Tetrahydronaphthalenesulphonic acids; Preparation of ar-1- and ar-2- —— and derivatives from their sulphonyl chlorides. Tetralin G.m.b.H. G.P. 336,615, 16.2.19.

Chlorosulphonic acid is added, drop by drop, to tetrahydronaphthalene maintained below 5° C. until the theoretical quantity of hydrogen chloride has split off; the product is poured into water, and the yellowish-white precipitate, which consists of nearly equal parts of 1- and 2-tetrahydronaphthalenesulphonyl chlorides, is separated by filtration. After purification by vacuum distillation, hydrolysis by steam, and evaporation to dryness of the solution, the mixture of sulphonic acids obtained is dissolved in hot chloroform; 1-tetrahydronaphthalenesulphonic acid, which crystallises from water with 1 mol. of water of crystallisation, m.p. 105°—110° C., crystallises on cooling, while the 2-acid remains in solution. The mixture of sulphonyl chlorides on treatment with ammonia yields a mixture of the corresponding sulphonamides, which are separated by solution in hot $N/1$ sodium hydroxide solution; on cooling the solution, the sodium salt of 2-tetrahydronaphthalenesulphonamide crystallises, and is converted to the free amide, m.p. 137° C., by treatment with acid, and the corresponding 1-compound is precipitated by acidification of the mother liquor, and on crystallisation from alcohol has m.p. 137°—140° C. 1-Tetrahydronaphthalenesulphonyl chloride, m.p. 70°—72° C., yields an anilide of m.p. 148°—149° C. The mixture of sulphonyl chlorides in aqueous suspension yields the sulphinic acids on treatment with zinc dust, and with zinc and hydrochloric acid is reduced to a mixture of 1- and 2-tetrahydronaphthylthiol, b.p. (15 mm.) 143°—147° C., which on treatment in alcoholic ammonia solution with air is converted to the corresponding disulphides. On addition of monochloroacetic acid to a solution of a mixture of 1- and 2-mercaptotetrahydronaphthalene in $2N$ sodium hydroxide solution, with subsequent heating and addition of concentrated aqueous ammonium chloride to the cooled solution, ammonium 2-tetrahydronaphthylthioacetate crystallises out (m.p. of free acid, 69°—70° C.), and acidification of the mother liquor yields the corresponding 1-acid, m.p. 133°—135° C. Both thioglycollic acids are readily converted to tetrahydronaphthalenethioindigo.—L. A. C.

Volatile fractions from mineral oils etc. E.P. 164,800. *See* IIa.

Benzol etc. from coal gas. E.P. 165,801. *See* IIa.

Obtaining hydrofluoric acid from sulphonating mixtures. E.P. 164,803. *See* VII.

IV.—COLOURING MATTERS AND DYE .

Patents.

Triphenylmethane colouring matters; Manufacture of new ——. British Dyestuffs Corp., Ltd., W. H. Perkin, and G. R. Clemo. E.P. 165,658, 23.6.20.

A monoalkyl-o-toluidine, such as monomethyl-o-toluidine, is condensed with 2.4-dichloro-5-nitrobenzaldehyde or the corresponding 2.4.5-trichlorobenzaldehyde by heating with ethyl alcohol and a little sulphuric acid, and the leuco-compound obtained is oxidised. The new colouring matters are pure greenish-blue basic dyes which are superior in fastness to light to known dyes of similar shade.—F. M. R.

Acid colours; Method of precipitating ——. A. Lendle, Assr. to Kuttroff, Pickhardt and Co. U.S.P. 1,378,418, 17.5.21. Appl., 9.9.20.

Acid colours are treated with a precipitating agent and a complex acid containing tungsten.—F. M. R.

Indigoid dyestuffs; Manufacture of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 336,211, 29.10.19. Addn. to 298,098 (J., 1921, 294 A).

Halogenated derivatives of isatin or naphthisatin capable of reacting in the α-position are condensed with 1.6-dihydroxynaphthalene, or derivatives of the same not substituted in the o-position to the α-hydroxyl group. The products are alkylated, and may be further halogenated, yielding dyestuffs identical with those described in the chief patent.—L. A. C.

Dyestuffs; Manufacture of yellow ——. Badische Anilin- und Soda-Fabr. G.P. 336,629, 24.6.19.

Ethylenediamine is condensed with o-nitrohalogenbenzene-p-sulphonic (or carboxylic) acids, or derivatives of the same, yielding dyestuffs having the formula

$$(1)X.C_6H_3.(3)NO_2.(4)NH.CH_2.CH_2.NH(4).NO_2(3).C_6H_3.X(1) \quad (X = -SO_3H \text{ or } -COOH),$$

in which the benzene nuclei may be further substituted. By boiling an aqueous solution of sodium 2-nitro-1-chlorobenzene-4-sulphonate with ethylenediamine and sodium carbonate for 48 hrs., and subsequently cooling the filtered solution, the condensation product crystallises, yielding a dyestuff which levels well and dyes wool yellow shades fast to light, and which is also suitable for producing colour lakes. The dyestuff from 2-nitro-1-chlorobenzene-4-carboxylic acid dyes paper yellow shades fast to light.—L. A. C.

Ortho-[hydr]oxy-azo-dyestuffs; Manufacture of substantive —— *and their application in dyeing.* Ges. für Chem. Ind. in Basel. E.P. 142,448, 26.3.20. Conv., 1.5.19.

See U.S.P. 1,338,414 of 1920; J., 1920, 443 A.

Azo dyestuffs dyeing on mordants. C. Jagerspacher, Assr. to Society of Chemical Ind. in Basle. U.S.P. 1,382,196, 21.6.21. Appl., 14.5.19.

See E.P. 137,733 of 1919; J., 1920, 262 A.

Phthaleins; Process of producing ——. A. L. Rispler, Assr. to Monsanto Chemical Works. U.S.P. 1,381,503, 14.6.21. Appl., 10.5.20.

See E.P. 157,030 of 1920; J., 1921, 171 A.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Hemp wood; Composition of ——. B. Rassow and A. Zschenderlein. Z. angew. Chem., 1921, 34, 204—206.

The content of pure cellulose (51·70%) in hemp wood, as given by Schwalbe and Becker (*cf.* J., 1919, 408 A), is too high, probably owing to their "pure cellulose" containing lignin. Analyses of two different samples of hemp wood shavings, carried out according to Schwalbe's scheme but using the chlorination method of Cross and Bevan as modified by Heuser (J., 1918, 685 A; 1919, 407 A) for determining the cellulose, gave, on a water-free basis: ash 1·28%, 1·51%; fat and resin, 2·85%, 4·26%; furfural, 14·18%, 14·37%; pentosans, 24·16%, 24·47%; cellulose corrected for pentosans, 40·57%, 40·43%; and lignin, 23·34%, 22·08%. To obtain a cellulose free from lignin the crude cellulose should be treated with chlorine at the rate of 1—2 bubbles per sec., during four ½-hr. periods, and the product washed each time with a 1% solution of caustic soda in preference to a solution of sodium sulphite. Hemp wood yields a pulp of good appearance and containing 93—94% of crude cellulose and 10% of pentosans, by heating it for 12—13 hrs., at 140°—150° C. with a 4% sulphite liquor (stronger liquors are less satisfactory). Other methods yield a product containing a higher proportion of pentosans. While coniferous woods have high lignin and low pentosan contents, the reverse is true for dicotyledonous woods, and it is suggested that pentosans are intermediate products in the natural synthesis of lignin.—A. J. H.

Decay of pulp wood and its effect in the soda process. E. Sutermeister. Pulp and Paper Mag., 1921, 19, 733—736.

The experimental work was carried out on samples of sound and rotten poplar and white birch. The conditions of boiling were: digestion for 5 hrs. at 110 lb. pressure with 25% of caustic soda (30% was used in two cases) in 7% solution, allowance being made for the moisture in the wood. The following table summarises the results obtained:—

	Poplar.		White birch.	
	Sound.	Rotten.	Sound.	Rotten.
Wt. per cb. ft. of bone-dry wood (lb.)	25	16·9	36·1	20·4
Soda consumption on bone-dry wood, %	21·7	23·5	21·1	27·5
Yield of good fibre on bone-dry wood, %	42·4	30·6	41·4	13·9
Yield per 100 cb. ft. of original wood, lb.	977·0	468·0	1464·0	262·0
Bleach consumption of air-dry fibre, %	7·9	15–24	14·7	over 25

The drop in weight per cubic foot, low yield of fibre, and high bleach consumption are significant indications of the disastrous effect of decay on wood. The bleached fibre from the rotten samples became disintegrated when beaten and could not be made up into sheets. When examined under the microscope it had all the characteristics of a fibre that had been beaten for a prolonged period, fragmentary pieces of all sizes and shapes being present. A mixture of 85% of sound wood with 15% of rotten wood gave 37·3% of good fibre with a bleach consumption of 23%. The colour of the fibre was much darker than that from sound wood, and the product contained many shives which showed up in the bleached material. The cost of production is shown to increase by 0·6—1·6% for each 1% of rotten wood used in the boilers, without any allowance being made for consequent reduced output.—D. J. N.

Pulp and pulp wood; Preservation of ——. Paper, July 20, 1921, 20—23.

A preliminary report by the American Paper and Pulp Association of an investigation undertaken in conjunction with the U.S. Forest Products Laboratory. Attempts to find an efficient antiseptic to prevent the decay of wood pulp in storage showed that of the chemicals so far examined only borax, sodium fluoride, and sodium dinitrophenolate were of any commercial value, compounds such as sodium carbonate and bichromate, otherwise suitable, being found to discolour the pulp. The wet laps containing 30% of dry pulp were made to absorb a definite weight of the chemical in aqueous solution, after which they were inoculated, some with mould spores, others with pulp-decaying fungi, and stored in a humid atmosphere at 72°—75° F. (22°—24° C.). Borax, applied in 5% solution in such quantity that the wet pulp contained 1% of chemical, kept the pulp in good condition for 8 months, and at the expiration of 15 months only small amounts of mould were present. Sodium fluoride when present to the extent of 0·6—0·9% only permitted slight moulding and slight decay after 12 months. Sodium dinitrophenolate—0·25%—kept the pulp nearly clean for 12—13 months, but has the disadvantage of staining the pulp yellow, which however is easily removed by washing. In mill practice the chemical, in fairly concentrated solution, would have to be sprayed on to the pulp as it leaves the press roll. —D. J. N.

Sulphite liquor. Gröger. *See* VII.

Cellobiose. Bergmann and Schotte. *See* XVII.

Polysaccharides. Bergmann and Beck. *See* XVII.

Patents.

Vaterproofing and like materials; Treatment of —— to reduce their inflammability and application of such materials. A. Arent. E.P. 146,099, 12.6.20. Conv., 26.6.19.

NFLAMMABLE materials, such as tar, creosote, sphalt, and the like, or non-drying oils, used for vaterproofing cloth, wood, paper, etc., are rendered ireproof by the addition of 5—20% of bismuth trihloride or antimony trichloride, preferably the atter, with or without organic solvents, *e.g.*, amyl cetate. The most favourable proportions are 1 gall. f creosote to 2 lb. of antimony trichloride, or —5 pts. of tar or asphalt to 1 pt. of antimony trihloride.—D. J. N.

crap fabrics of aeroplanes or other aerial machines; Treatment of —— and recovery and utilisation of products therefrom. J. Lumsden, R. W. R. MacKenzie, E. Robinson, and M. Fort. E.P. 165,804, 9.2.18.

HE coating on scrap aeroplane fabric is removed y extraction with pure or commercial acetone or hlorinated hydrocarbons, *e.g.*, tetrachloroethane, ith or without diluents. Fractional extraction ay be employed, *e.g.*, boiled oils, varnish, camhor, etc., may be extracted with benzol or petroum spirit, cellulose derivatives being subsequently issolved out with acetone. Alternatively, the cellulse derivatives may be precipitated from the etone solution of the coating by cautious addition water or weak alcohol. When pigments are prent partial extraction is employed, enough of the ating being left to hold back the pigment. The dope" solution is concentrated and used again, while the fabric serves as raw material for textile work or papermaking.—D. J. N.

Bast fibres; Treatment of ——. E. Claviez. E.P. 166,044, 6.7.20.

Fibres of a soft and woolly nature, suitable for textiles, are obtained from reed or bast fibres by subjecting the raw fibre, prepared by alkaline digestion or other methods, to a freezing treatment at about −20° C., whereby the natural agglutinant left on the fibre after boiling is destroyed. The fibres are then thawed and dried immediately or after rinsing with water.—D. J. N.

Cellulose esters of organic acids; Manufacture of ——. Akt.-Ges. für Anilinfabr. E.P. 145,524, 22.6.20. Conv., 11.7.14.

Before treatment by the usual methods of esterification for the production of cellulose esters (*cf.* E.P. 10,706 of 1912 and 1156 of 1914; J., 1913, 482; 1914, 688), cellulose is treated with nitric acid in the presence of nitrobenzene. For example, 10 pts. of cellulose is treated during 20 mins. at 25° C., with a mixture of equal quantities of 85% nitric acid and nitrobenzene. The product, which contains 2·6% N, is dissolved during 12 hrs. at 40°—45° C. in a mixture containing 40 pts. of glacial acetic acid, 40 pts. of acetic anhydride, and 1 pt. of bromine or other catalyst, and the cellulose acetate is then separated in the usual manner. —A. J. H.

Artificial [silk] filaments; Process and apparatus for production of ——. British Cellulose and Chemical Manufacturing (Parent) Co., Ltd., and H. B. Roy. E.P. 165,519, 26.3.20.

In the production of artificial threads and filaments by spinning solutions of cellulose acetate, nitrocellulose, or other cellulose derivatives in volatile solvents, downwards through a hollow casing in a current of warm air to remove the solvent, the finished thread is passed through a small hole in the side of the casing and wound up by apparatus placed outside the casing. A travel of 2—3 seconds in a current of air at 30°—50° C. removes the solvent efficiently.—D. J. N.

Alkali-cellulose; Production of —— from cellulose. E. Schülke. G.P. 335,563, 15.6.20.

The material, in the form of millboard, is conducted through a vessel containing sodium hydroxide solution, by means of an endless band conveyor, the speed of the conveyor and the quantity of solution being such that the material is uniformly impregnated and the whole of the solution is absorbed. No liquid is subsequently expressed from the material. Constituents soluble in alkali, *e.g.*, the so-called wood-gum, remain in the alkali-cellulose; their presence is not detrimental to the production of viscose.—J. H. L.

Plastic masses. Farbenfabr. vorm. F. Bayer und Co. G.P. 336,476, 15.2.18.

Cellulose ethers and their derivatives are mixed with oils or resinous substances obtained by the condensation of halogenated alkybenzenes, *e.g.*, benzyl chloride, benzylidene chloride, xylyl chloride, or *p*-xylylene chloride, with naphthalene or other constituents of coal-tar oil such as phenanthrene, anthracene, the xylenes, toluene, benzene, cymene, solvent naphtha, or derivatives of these. The resulting products possess high insulating power, great resistance to penetration, low permeability to gases, and marked stability towards water and alkalis. They are suited to the manufacture of waterproof materials.—D. F. T.

Calcium bisulphite; Process of making ——. Method of making calcium bisulphite cooking liquor. G. A. Richter, Assr. to Brown Co. U.S.P. (A) 1,378,616 and (B) 1,378,617, 17.5.21. Appl., 10.6. and 5.9.19.

(A) Water is treated with sulphur dioxide in one absorption chamber and the acid solution is then allowed to react with lime in another chamber. (B) Powdered limestone, containing calcium and magnesium carbonates, is allowed to react with sulphur dioxide in the presence of water.—A. J. H.

Wood cellulose; Conversion of —— into wood fibre for spinning. G. Elkeles. G.P. 336,200, 23.10.18.

The wood cellulose, after treatment with water or steam, is digested with dilute hydrochloric acid, the fluids and resulting chlorides being then removed by suitable means. The original material should be in the form of thin strips, *e.g.*, wood wool, capable of supplying the desired length to the final fibre.—D. F. T.

Paper, or other material in sheet form; Method of and apparatus for drying ——. O. Minton. E.P. 165,521, 26.3.20.

Paper, or other material in sheet form, is dried in a short time, at moderate temperatures, and under a low tension by causing it to travel, preferably in loop form, through a vacuum chamber, heated in such a manner that the paper does not come into actual contact with the heating surface. The material is led into and out of the vacuum chamber through seals of mercury or other suitable liquid, which has no deleterious effect on the wet or dry sheet. This method of drying under a low tension gives papers which are almost as strong in the cross direction as in the machine direction, and makes it possible to give tub-sized papers the characteristic "cockled" appearance of loft-dried papers. The lower temperature results in more uniform sizing and, in the case of tinted papers, brighter colours. —D. J. N.

Adhesive; Production of a cold ——. W. Kling, Chem. Fabr. G.P. 335,918, 3.6.19.

Paper is dissolved in water-glass and the product is conveniently mixed with an absorbent powder such as chalk. The resulting material possesses adhesive power comparable with that of ordinary glue but has the additional advantage of being applicable without previous warming.—D. F. T.

Adhesives from sulphite waste liquor; Production of ——. Cappenberg u. Co. G.P. 336,630, 21.12.18.

Purified acid-free sulphite waste liquor of sp. gr. at least 1·285 is bleached with 2—4% of sodium hydrosulphite at the ordinary temperature or with 1—2% at 90°—100° C., and is then mixed with magnesium oxide, clay, or similar white powders; the resulting adhesive is light coloured, dries quickly, and is not very hygroscopic.—D. F. T.

Paper stock; Rotary screens for ——. Bird Machine Co., Assees. of C. S. Bird. E.P. 146,890, 6.7.20. Conv., 16.9.18.

[Paper] pulp screens. Bird Machine Co., Assees. of R. S. Clarke. E.P. 146,892, 6.7.20. Conv., 26.6.16.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Bleach liquor; Method and apparatus for determining available chlorine in ——. M. Schrero. J. Ind. Eng. Chem., 1921, 13, 559—560.

The method depends on measurement of the pressure exerted by the oxygen generated when hydrogen peroxide reacts with hypochlorites in alkaline solution. The apparatus consists of two bulbs connected by means of a stop-cock and by a by-pass; the lower bulb has a lateral opening at an angle of 45° and the upper one terminates in a neck for conveniently clamping the apparatus. A manometer to which is attached a sliding scale is fixed through a stopper in the top bulb, and the scale is graduated from a determination of the number of mm. corresponding to 0·1 lb. of 35% bleach per gallon. Ten c.c. of bleach liquor is placed in the lower bulb and 10 c.c. of hydrogen peroxide in the upper one. The opening in the lower bulb is stoppered and the manometer is attached to the apparatus. The stopcock is opened and reaction between the liquids, which is assisted by shaking, is complete in 40—50 secs. After adjusting the zero of the scale, the number of lb. of 35% bleach per gallon is read off. The results by this method in actual practice agreed closely with those obtained by titration with sodium thiosulphate.—W. J. W.

Cotton; Effect of prolonged bleaching on ——. P. Heermann and H. Frederking. Textilber., 1921, 2, 249—251, 277—278.

Evenly bleached cotton fabric was immersed fifty times, for 15 mins. each time, in fifteen times its weight of a clear neutral solution of calcium hypochlorite containing 0·5 g. of active chlorine per l. at 20° C. A fresh solution was used for each immersion, and after each immersion the fabric was thoroughly washed in cold water, treated with a dilute solution of sodium thiosulphate to remove residual chlorine, washed, gently pressed by hand, dried at the ordinary temperature, and then wetted-out in preparation for the next immersion. The change of strength, elasticity, and weight of the fabric was measured after 5, 10, 15, etc., immersions. After fifty treatments the strength of the fabric had decreased 9%, its elasticity had increased 1·2%, and its weight had decreased 2·5%. The decrease in strength was almost directly proportional to the duration of bleaching, and only slightly greater than that produced when cotton was treated with soap and sodium carbonate solutions. On the other hand, cotton which was treated with solutions of soap and oxygen-liberating substances (*e.g.*, sodium perborate) suffered a much greater decrease in strength. After fifty bleaching treatments the cotton fabric contained very little oxycellulose.—A. J. H.

Tin-phosphate weighting of silk. H. Ley. Chem.-Zeit., 1921, 45, 645—646, 676—678.

Further evidence is given in support of the author's view (*cf.* J., 1913, 81; 1916, 303) as opposed to that of Heermann (J., 1914, 72) that the chemical reactions which occur when silk is weighted with tin phosphate, take place in the phosphate bath and not during the subsequent washing. After "pinking," silk strongly retains its acidity. It required 18 hrs.' washing in water to remove the acidity of silk which had been "pinked" once, and after "pinking" five times, the corresponding time was 44 hrs. Hence in investigations of the change of basicity of the phosphate bath during silk weighting, it is essential that the "pinked" silk be thoroughly washed. If the "pinked" silk be merely neutralised with alkalis, these, being easily soluble, may mask any increase of acidity in the

phosphate bath. It is again shown by laboratory experiments that the phosphate bath becomes acid, and in an example quoted from works practice a phosphate bath, to which 15 kg. of calcined sodium carbonate had been added, became acid when 75 kg. of "pinked" silk was immersed in it. Moreover the increase of acidity of the phosphate bath is correspondingly much greater than its increase in chlorine-content, so that Heermann's contention that this increase of acidity is due to the acid which is carried over by the silk is without support. Examination of the liquors used for washing silk after treatment in the phosphate bath showed that their alkalinity is much below that required by Heermann's theory, and that this, as well as their tendency to foam, is partly due to the presence of an organic substance derived from the silk, which is precipitated by the addition of excess of acid. In the estimation of disodium phosphate in the phosphate bath, the liquor was titrated with $N/10$ sulphuric acid, using methyl orange as indicator, and then back-titrated with $N/10$ sodium hydroxide using phenolphthalein as indicator (1 c.c. of $N/10$ $NaOH = 0{\cdot}03583$ g. $Na_2HPO_4,12H_2O$), and the alkalinity or acidity of the liquor was measured by the difference between the amounts of $N/10$ acid and $N/10$ alkali used. The results agreed very closely with those obtained by gravimetric methods.
—A. J. H.

Red dyestuff [*ice-colour*]; *Preparation and method of application of a new* ——. W. Kielbasinski and C. Benedek. Note deposited in Archiv des Int. Vereins der Chem.-Koloristen, 12.9.13. Textilber., 1921, 2, 281.

Naphthol AS couples with diazotised m-nitro-o-nisidine to give a brilliant bluish-red pigment "Meta Red") which is brighter than that proluced from β-naphthol and diazotised p-nitro-o-nisidine. A series of bright and fast pigments can e obtained from diazotised m-nitro-o-anisidine and ixtures of β-naphthol and Naphthol AS. For rinting with Meta Red, fabrics should be prepared ith a solution containing per kg. 20 g. of Naphthol S, 24 g. of caustic soda of 35° B. (sp. gr. 1·32), and 0 g. of Turkey-red oil. A suitable printing paste ontains per kg. 400 g. of the diazo solution, 550 g. f an 8% solution of gum tragacanth and 35 g. of ry sodium acetate. The diazo solution is prepared y adding 8 g. of sodium nitrite dissolved in 50 g. of ater to a mixture containing 17 g. of m-nitro-o-nisidine, 38 g. of hydrochloric acid of 20° B. (sp. r. 1·16), 212 g. of water, and 75 g. of ice. Naphthol S is imperfectly removed from printed fabrics by eans of a simple soaping. If, however, the fabrics washed with a soap solution which contains —10 c.c. of caustic soda of 35° B. per lb., the whites not yellow after subsequent "chloring." Both eta Red and the orange pigment produced from aphthol AS and diazotised p-nitro-o-anisidine are ry fast to alkalis and can be used in the presence caustic soda of 40°—45° B. (sp. gr. 1·38—1·45) for imped fabrics. Reserves with sulphur dyestuffs n be obtained.—A. J. H.

danthrene dyestuffs; Padding with ——. W. Kielbasinski and C. Benedek. Note deposited in Archiv des Int. Vereins der Chem.-Koloristen, 8.11.13. Textilber., 1921, 2, 281.

dyeing light shades by means of Indanthrene estuffs by the padding process, using a sulphoxyl-e-formaldehyde compound as reducing agent, it not necessary to dry the fabric before steaming. ight even dyeings are obtained if fabric is padded th a mixture containing 8 g. of Indanthrene ue ICD 10%, 6 g. of Indanthrene Grey B extra, g. of 50% gum Senegal solution (for blue), or g. of Indanthrene Blue ICD 10%, 1 g. of Indanrene Yellow R extra, 50 g. of 50% gum Senegal solution (for olive), and 936 g. or 931 g. respectively of a solution containing per kg., 50 g. of potassium carbonate, 10 g. of Rongalite, and 50 g. of 50% gum Senegal solution, and is then steamed in absence of air for 5 mins., rinsed, and soaped.
—A. J. H.

Printing [*fabrics*] *with vat dyestuffs; Production of two-coloured effects in* ——. W. Kielbasinski and W. Napalkow. Note deposited in Archiv des Int. Vereins der Chem.-Koloristen, 2.4.14. Textilber., 1921, 2, 281—282.

Two-coloured effects in the form of light and heavy shades are obtained when fabric is printed with a solution containing a vat-dyestuff and insufficient alkali and reducing agents, and is then overprinted with an alkaline solution of a reducing agent, steamed for 5—7 mins. in a Mather-Platt, washed, and strongly soaped. Suitable printing pastes contain per kg., 50 g. of Brilliant Indigo 4B paste (for blue) or 50 g. of Indanthrene Violet RR paste (for violet), 15 g. of Hydrosulphite NF, 100 g. of sodium carbonate and 835 g. of 50% British gum and gum Senegal solution; or 75 g. of Helindone Grey BB paste (for grey), 15 g. of Hydrosulphite NF, 100 g. of sodium carbonate, 25 g. of "dissolving salt" (sodium benzylsulphanilate), and 785 g. of gum tragacanth and starch thickening. The overprinting paste contains per kg., 150 g. of sodium carbonate, 100 g. of glycerin, 400 g. of 50% gum Senegal solution, and 100 g. of Hydrosulphite NF.—A. J. H.

Patents.

Yarns and fabrics composed of vegetable fibres containing dyed effect threads or fibres; Scouring and bleaching of ——. J. D. Lumsden, R. W. R. Mackenzie, E. H. Robinson, and M. Fort. E.P. 165,198, 20.3.20.

The fatty and other impurities present in grey cotton and linen fabrics are removed by extraction with benzol, naphtha, or benzine (alcohol and chlorinated hydrocarbons are less satisfactory), so that the subsequent bleaching operations may be less drastic than usual. Bleeding of the coloured effect threads is thereby avoided.—A. J. H.

Bleaching vegetable fibres; Process of ——. G. G. Taylor, Assr. to American Writing Paper Co. U.S.P. 1,381,440, 14.6.21. Appl., 18.12.20.

Vegetable fibres are bleached by treatment with a hypochlorite in the presence of less than its molecular equivalent of free boric acid.—A. J. H.

Bleaching, dyeing, etc.; Apparatus for ——. M. Poetzsch. U.S.P. 1,383,021, 28.6.21. Appl., 6.11.19.

Cloth is fed continuously through a vat containing the bleaching or dye liquor, and is re-folded longitudinally each time it passes over the feeding device before entering the vat.—R. L. F. R.

Dyeing, cellulose-acetate; Process for ——. R. Clavel. U.S.P. 1,378,443, 17.5.21. Appl., 5.1.21.

Dyeing is effected with a dye liquor containing a weak acid and at least one soluble chloride.
—A. J. H.

Dyeing; Apparatus for ——. C. H. Robbins, Assr. to C. A. Claflin Co. U.S.P. 1,378,618, 17.5.21. Appl., 28.4.20.

A dye-vat having a perforated false bottom is provided with a circulating pipe to a branch of which, extending downwards into the vat, is attached a rotating spraying device. Dye-liquor is withdrawn below the false bottom and re-introduced into the vat by spraying vertically downwards or at an angle.—A. J. H.

Textile fabrics and the like; Sizing of ——. A. Poulson. E.P. 165,365, 21.9.20.

A composition suitable for sizing textiles, and which avoids the use of foodstuffs, is prepared by mixing equal quantities of a 2% solution of gum tragasol or gum tragacanth and a 7½% solution of neutral sodium silicate. For transport the composition may be dried and ground to a powder. Before bleaching fabrics sized with this composition, it is merely necessary to wash them with boiling water.—A. J. H.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Nitric acid from the air; Manufacture of —— by the explosion method. F. Haüsser. Stahl u. Eisen, 1921, **41**, 956—962, 999—1003.

The synthesis of nitric acid by the explosion of combustible gas with an excess of air in a cast iron bomb avoids the series of steps necessary in the Haber and cyanamide processes, and is mechanically simpler than the electric arc method. The yield of nitric oxide for a given temperature and pressure calculated on the basis of experiments of Nernst was not obtained by experiment, yields being obtained increasing with the size of the bomb and far above those calculated. The yield is not affected at the higher temperatures obtained by reducing heat losses, or at greater oxygen concentration. As nitric oxide remaining in the bomb reduces the yield, it is necessary to sweep out the bomb with a blast of air after each explosion. Carbon monoxide due to incomplete combustion is also injurious. After preliminary experiments with a 100 l. bomb fed with town gas which, when operated at 6—10 explosions per minute, supplied an exit gas containing 8—9 g. HNO_3 per cub. m., an experimental plant was erected in connexion with a Westphalian coke oven installation shortly before the war. This consumed 5000, later 7000 cub. m. of coke-oven gas per day. The gas freed from sulphur and air was preheated to 300° C. by the exhaust and compressed to 5·5—6·0 kg. per sq. cm. A Linde oxygen plant was provided to enrich the air but its use was afterwards discontinued. The gas and air were mixed as they entered the two 100 l. bombs, and pre-ignitions, at first troublesome, were prevented by perforated metal sheets. The explosion pressure was 22—25 atm.; the air blast followed at an interval of 0·15 sec. and 44—45 explosions per minute were made in each bomb. The exhaust was cooled to 250° C. in an iron heat exchanger, then in an aluminium coil, the water containing 0·5 g. HNO_3 per l. which separated being run away. This trifling loss is due to the rapidity of the cooling, most of the combined nitrogen being still present as nitric oxide. The gas still under high pressure passed to an oxidation vessel of Krupp's V2a metal. As the speed of formation of nitrogen peroxide increases with the pressure this vessel need not be large. The gas was then absorbed in 4, afterwards 7 towers, the last two fed with soda solution. With both bombs working, 75% of the nitric oxide formed was obtained as 27—28% nitric acid and the balance as 24% sodium nitrite solution. In 1918 a 300 l. bomb commenced work and has run satisfactorily for 6 months with no corrosion of the water-cooled exit valve which had been a source of trouble with the smaller bombs. This apparatus gave a 50% increase of efficiency in formation of nitric oxide, yielding 96—107 g. HNO_3 per cub. m. of coke-oven gas, though part of this advantage was lost by the lower efficiency of the absorption plant for the richer gas. With the 300 l. bomb the heat lost in the cooling water was 22% of that generated in the bomb. The author considers bombs of 1000 l. and upwards to be practical. Calculations of the dimensions of the bombs necessary for stability and of the necessary capacity of the oxidation vessel based on Bodenstein's figure for the velocity of formation of nitrogen peroxide are given.—C. I.

Ammonia; Rôle of gaseous impurities in the catalytic oxidation of ——. E. Decarrière. Comptes rend., 1921, **173**, 148—151. (*Cf.* J., 1921, 542 A.)

Acetylene in small amounts exerts an effect more marked than and somewhat different from that of hydrogen sulphide in the catalytic oxidation of ammonia. During the first few minutes there is a slight rise in the yield but this is speedily followed by a decided drop, which is proportional to the absolute amount of the impurity which has passed rather than to its concentration, and continues even when the proportion passing is decreased or removed. The presence of hydrogen sulphide along with the acetylene in the proportion of 1:9 by volume apparently counteracts the injurious action of the latter. The initial rise is obtained but is not followed by the marked drop.—W. G.

Sulphur dioxide; Determination of —— in burner gases. E. Berl. Chem.-Zeit., 1921, **45**, 693. (*Cf.* J., 1921, 256 A, 506 A.)

The absorption of sulphur dioxide from gas mixtures containing it in the presence of oxygen, by means of caustic soda, yields low results, especially if the liquid is shaken vigorously or contains positive catalysts, such as copper sulphate. Good results are obtained, on the other hand, by the addition of small quantities of negative catalysts, especially stannous chloride. It is recommended to add to each assay 10 c.c. of a 1/1000 molar solution of stannous chloride (0·23 g. $SnCl_2,2H_2O$ per l.) before absorption. The gases are passed through the liquid, which is then acidified and titrated with iodine in the usual way. It is unnecessary to make allowance for the stannous chloride added.
—A. R. P.

Sulphite liquor [acid calcium bisulphite solution]. M. Gröger. Z. angew. Chem., 1921, **34**, 383.

The author has re-calculated from the figures given by Schwarz and Müller-Clemm (J., 1921, 504 A) the ratio between the combined sulphurous acid and the free sulphurous acid in equilibrium in the system sulphurous acid—calcium sulphite, and shows that it is 2·36:1 and not 2:1 as found by the latter authors.—A. R. P.

Hydrocyanic acid; The officiol [B.P.] method for the determination of ——. C. E. Corfield and C. J. Eastland. Brit. Pharm. Conf., June, 1921. Pharm. J., 1921, **106**, 482—483.

Excess of ammonia interferes with the accuracy of the results obtained by the B.P. method for the determination of hydrocyanic acid; the error increases with increased concentration of ammonia but it is not appreciable if the quantity of ammonia used is limited to 20 c.c. Increase in the quantity of potassium iodide is without influence unless the volume of potassium iodide solution used is more than 10 c.c.—W. P. S.

Arsenic acid and arsenates; Volumetric determination of ——. R. L. Morris. Brit. Pharm Conf., June, 1921. Pharm. J., 1921, **106**, 486-488.

To obtain satisfactory results with the method prescribed in the British Pharmacopœia, the conditions suggested by Gooch and Morris (Amer. J. Sci , 1900, **10**, 151; Chem. News, 1901, **83**, 15) should be adopted; the arsenate solution is treated with potassium iodide and hydrochloric acid and the titration with thiosulphate solution is commenced at once, the solution being added drop by drop with constant stirring. The time occupied by the titration should be 5 mins.; 0·0040 g. is deducted from the amount of arsenate indicated by the titration and the percentage is then calculated. Traces of nitrate in the arsenate do not interfere, but the method fails when considerable amounts of nitrate are present.—W. P. S.

Sodium arsenate; Quantitative determination of ——. C. E. Corfield and E. Woodward. Brit. Pharm. Conf., June, 1921. Pharm. J., 1921, **106**, 473—475.

Comparison of a number of published methods showed that the most trustworthy are those of Gooch and Morris (Amer. J. Sci., 1900, **10**, 151) and Williamson (J., 1896, 474). To obtain accurate results with the latter method the calculation should be made from the iodine titration; if the thiosulphate titration is utilised it must be corrected by a blank determination made under exactly similar conditions. The B.P. method gives results inaccurate to the extent of about 1% and would be improved by a titration with iodine following the thiosulphate titration.

Ammoniacal liquor; Oxidation of —— *by air. Fifty-seventh annual report* (1920) *on alkali etc., works by the Chief Inspector*, 20—24.

Part of the air normally admitted to the oxide purifiers of a gas works was admitted at the inlet of the ammonia washer in an attempt to oxidise ammonium sulphide and form thiocyanate. The total oxygen in the crude gas was 9·1 cub. ft. per 750 cub. ft. of gas; of this only 0·03 cub. ft. was removed by sulphur compounds oxidised. The thiocyanate content of the liquor was increased from 0·0775 to 0·0899% and the thiosulphate from 0·1347 to 0·1491% during its passage through the washer. —H. Hg.

Ammonia; New reaction of ——. C. D. Zenghelis. Comptes rend., 1921, **173**, 153—155.

The reagent is a 20% solution of silver nitrate containing 3% of commercial formalin (33—37%) and should be prepared immediately before use. When a drop of the reagent is exposed to an atmosphere containing ammonia a thin metallic mirror of silver s formed. The reagent is sensitive to 0·00000034 g. of ammonia.—W. G.

Bromide; Detection and determination of minute quantities of —— *in saline residues and in a mixture of the halogens.* A. J. Jones. Brit. Pharm. Conf., June, 1921. Pharm. J., 1921, **106**, 475—477.

A quantity of the saline residue containing not more than 0·5 g. of sodium chloride, and free from mmonium salts and organic matter, is dissolved in c.c. of water, and a drop of dilute " thymol blue " solution is added, followed by a few drops of $N/1$ ulphuric acid or just sufficient to give a rose-pink coloration; the solution is then treated with 0·3 c.c. f permanganate solution ($KMnO_4$, 5 g., H_3PO_4, p. gr., 1·75, 6·25 c.c., water, 100 c.c.) diluted to c.c., transferred to a small distillation flask, heated to 85° C. and a current of air bubbled hrough the mixture, the vapours and air escaping rom the side-tube of the flask being passed through small U-tube containing magenta reagent. After mins., the coloration obtained is compared with hat produced by known amounts of bromide. romine equivalent to 1·0 c.c. of $N/1000$ potassium romide solution yields a distinct coloration; the tter is rendered more distinct when the contents the U-tube are shaken with 7 c.c. of chloroform. iodides are present in the residue they must be moved previously by treating the solution with dium nitrite and phosphoric acid and extracting th chloroform. The magenta reagent is prepared mixing 100 c.c. of 0·1% magenta solution with a cold mixture of water, 60, and sulphuric acid, 40 c.c., and, after 24 hrs., diluting the solution to 200 c.c.; for use, it is mixed with an equal volume of glacial acetic acid.—W. P. S.

Iodides; Potentiometric titration of —— *with permanganate.* I. M. Kolthoff. Rec. Trav. Chim., 1921, **40**, 532—538.

Hendrixson's results (J., 1921, 241 a, 416 a) are confirmed. Potassium iodide can be titrated potentiometrically with permanganate in the presence of sulphuric acid, even in dilute solutions, provided that the strength of the acid is not less than 0·13 N. The presence of chlorides or bromides considerably lowers the jump in potential at the end-point, but accurate results are obtained even in the presence of twice the equivalent amount of bromide or twenty times of chloride.—W. G.

Nitrates in bismuth salts; Determination of —— *by means of titanium trichloride and Devarda's alloy.* T. McLachlan. Brit. Pharm. Conf., June, 1921. Pharm J., 1921, **106**, 477—478.

Reduction of the nitrate by means of titanium trichloride as described by Knecht (J., 1915, 126) and subsequent determination of the resulting ammonia by distillation is trustworthy provided that the reduction is made in approximately neutral solution. Consistent and reliable results may also be obtained by treating 5 g. of the bismuth salt (*e.g.*, carbonate) with 150 c.c. of water, 5 c.c. of alcohol, 50 c.c. of 33% sodium hydroxide solution, and 8 g. of Devarda's alloy (Cu 50, Al 45, Zn 5%), steam-distilling the mixture, and collecting the ammonia in a known volume of standard acid.—W. P. S.

Lead arsenate; Dry method of preparing ——. O. W. Brown, C. R. Voris, and C. O. Henke. J. Ind. Eng. Chem., 1921, **13**, 531—533.

In the preparation of lead arsenate by roasting a mixture of litharge and white arsenic, time and temperature are important factors. Between 300° and 400° C. the rate of oxidation is very slow; at 400°—450° C. the greater part of the oxidation takes place in the first 5 mins., but the rate is very slow after the first hour and the last traces of arsenious oxide are very difficult to oxidise, probably owing to their becoming covered by the pentoxide. The most suitable temperature for roasting is 450° C. The possibility of the litharge acting as a catalyst in the process is discussed. —W. J. W.

Calcium and barium; The highest oxides of ——. W. Traube and W. Schulze. Ber., 1921, **54**, 1626—1644.

Calcium peroxide octahydrate is converted by warm hydrogen peroxide into a yellow substance, which, under the most favourable circumstances, may contain 8·7% of calcium tetroxide, CaO_4. The products may be heated to 130° C. without undergoing change. They dissolve in dilute acid with immediate evolution of inactive oxygen which does not liberate bromine or iodine from acidified solutions of potassium bromide or potassium iodide. The corresponding barium tetroxide is much less stable. (*Cf.* J.C.S., Sept.)—H. W.

Calcium carbide; Preparation of —— *from calcium ammonium and acetylene.* L. Hackspill and E. Botolfsen. Comptes rend., 1921, **173**, 151—153.

Moissan's method of preparing calcium carbide from acetylene and calcium ammonium (J., 1899, 180) does not give a pure carbide. The product when decomposed by water gives a gas containing 25% of hydrogen and 4% of ammonia, and when heated to 500° C. gives a gas containing 5% of ammonia, 20% of acetylene, and 75% of hydrogen. —W. G.

Sodium cuprite. E. Müller. Z. angew. Chem., 1921, 34, 371—373. (*Cf.* J., 1921, 44 A.)

The blue solution of copper hydroxide in caustic soda deposits, on standing, a brown precipitate containing a variable amount of water, which is probably a solid solution of copper oxide in cupric hydroxide in equilibrium with the solution. The solubility of copper hydroxide in caustic soda rises to a maximum at 15·8 *N* NaOH (63 g. per 100 c.c.), after which it suddenly falls and the solution deposits a blue precipitate which after heating in the mother liquor crystallises on cooling and probably consists of sodium cuprite. It decomposes in the presence of an excess of water yielding cupric oxide, which is the stable solid phase in equilibrium with sodium hydroxide of concentrations below 15·8 *N*. Solubility diagrams of the systems copper hydroxide, copper oxide, caustic soda, sodium cuprite are given, and the subject is discussed from the point of view of the phase rule. (*Cf.* J.C.S., Sept.)—A. R. P.

Xanthates. Whitby and Beardwood. *See* X.

Patents.

Sulphuric acid chambers; Construction of ——. R. E. Dior. E.P. 164,572, 14.4.20.

Chambers for sulphuric acid manufacture are formed of two frusto-conical portions, the sides of the lower portion being more inclined to the vertical than those of the upper, and the whole chamber thus having approximately the shape of an inverted funnel. In a series of such chambers there is a gradual decrease in height to compensate for diminution of gaseous volume by condensation. A central tube, open at both ends, passes vertically through the chamber and controls or damps the eddies set up; as an alternative arrangement, jets for steam, atomised water, or dilute sulphuric acid may be fixed in the top of the chamber. An inlet pipe near the bottom and an outlet pipe near the top, arranged tangentially to the chamber walls, cause the gas to circulate spirally against the walls, and the latter are cooled externally by a flow of water.—W. J. W.

Sulphuric acid and hydraulic cement; Process for the manufacture of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. (A) 297,922, 2.10.15, (B) 299,033, 23.8.16.

(A) A mixture of gypsum with clay, kaolin, etc., with or without addition of silica, is burnt to a clinker. The gases evolved are converted into sulphuric acid and the residue ground and used as cement. (B) The conversion is carried out in a shaft furnace into which producer gas and air are forced and more air preheated by passing it through the burnt material.—C. I.

Sulphuric acid from sodium bisulphate; Production of ——. F. A. Weber. G.P. 336,560, 16.6.18.

A mixture of sulphuric acid and hydrochloric acid is produced by the interaction of sodium bisulphate and excess of hydrochloric acid solution. Sulphuric acid and hydrochloric acid are separated from the product in any known manner.
—J. S. G. T.

Hydrofluoric acid; Method of obtaining —— *from sulphonating mixtures of organic sulpho acids and calcium fluoride.* W. Miersch. E.P. 164,803, 13.2.20.

A part of the acid of sulphonating mixtures of organic sulphonic acids may be utilised by adding calcium fluoride and heating, whereby hydrofluoric acid is produced.—W. J. W.

Sulphurous acid from magnesium sulphate and double salts thereof; Production of ——. F. Siemens. G.P. 336,283, 10.10.19.

Magnesium sulphate is heated with excess of carbon or similar reducing agent, the reduced mass mixed with magnesium chloride and transferred to another part of the furnace wherein it is heated in an oxidising or chlorinating atmosphere. The process can be operated continuously.—J. S. G. T.

Hydrogen chloride; Manufacture of —— *from chlorine, water-gas, and steam.* Farbenfabr. vorm. F. Bayer und Co. G.P. 337,098, 4.3.19.

Hydrogen chloride free from chlorine is prepared by treating chlorine with water-gas saturated with water vapour.—L. A. C.

Phosphoric acid; Process for the preparation of —— *from calcium phosphate and acid.* Badische Anilin- u. Soda-Fabr. G.P. 337,154, 20.5.19.

Calcium phosphate is treated with nitric acid of 80% strength or above, at first with its equivalent to effect decomposition. Excess of nitric acid is then added, almost completely precipitating the calcium nitrate, and the acid liquid is filtered.
—C. I.

Base-exchanging bodies; Manufacture of ——. P. de Brünn. E. P. 26,078, 13.11.13.

A solution of 16½ lb. of sodium aluminate containing 50% Al_2O_3 in 255 galls. of water is mixed with a solution of 57¾ lb. of sodium silicate of 40° B. (sp. gr. 1·384) containing about 25% SiO_2. The liquor containing the precipitate is filtered, the cake residue washed free from alkali, and dried at about 110° F. (43° C.). The dried product is washed in hot water whereby hard, glass-like grains are produced, having a high capacity for exchange of bases.—H. R. D.

Base-exchanging bodies; Process for producing ——. P. de Brünn. E.P. 10,809, 1.5.14.

In a process for producing base-exchanging substances, *e.g.* by reaction between sodium aluminate and sodium silicate, the precipitate is washed to such a degree that it retains an amount of free alkali. The quality of the product obtained either by drying the precipitate itself or after pressing it into a cake, is thereby improved.—W. J. W.

Ammonia; Process for synthetic production of ——. L. Duparc and C. Urfer. E.P. 140,060, 16.2.20. Conv., 13.3.19.

A mixture of nitrogen and hydrogen, previously purified, is passed at atmospheric pressure, and at temperatures between 250° and 600° C., over a catalyst consisting of lithium, calcium, strontium, cerium, thorium, didymium, lanthanum, glucinum, or zirconium, and a carrier of magnesia or alumina. The catalytic metals may be used in the free state, or as their nitrides, or as a mixture of at least one pure metal and a nitride of such metal. (*Cf.* E.P. 140,061; J., 1921, 469 A.)—W. J. W.

Ammoniacal liquor; Treatment of ——. J. H. Fairweather. E.P. 165,833, 9.7.19.

The liquor is concentrated in a Kestner or other evaporator, driving off most of the free ammonia which is absorbed as usual. The residual liquor passes through a heat exchanger back to the gas-works circuit, and circulation is continued until fixed ammonia has accumulated sufficiently to necessitate a complete distillation. By this method the fuel consumption is reduced to 7 cwt. per ton of sulphate made.—C. I.

Ammonium sulphate saturators. G. P. Heisch. E.P. 166,036, 18.6.20.

Ammonia gas is introduced into the saturator by tangential jets in an annular pipe. A vortex motion is thus set up in the liquid, and the precipitated salt collects at the centre, whence a trough conveys it to an external ejector box, accumulation of solids in the main saturator being thus avoided. —C. I.

Ammonium sulphate; Manufacture of —— from calcium sulphate, ammonia, and carbon dioxide. Badische Anilin- und Soda-Fabr. G.P. 336,767, 29.9.17.

Calcium sulphate is treated with ammonia and carbon dioxide in such quantities that there is an excess of ammonia at the end of the reaction, when it is expelled from the mixture, or neutralised with sulphuric acid.—L. A. C.

(a) *Ammonia; Recovery of ——.* (b) *Method for the production of barium chloride.* (c) *Method of producing carbonates of the alkaline-earth metals.* J. H. MacMahon, Assr. to The Mathieson Alkali Works, Inc. U.S.P. (a) 1,378,593, (b) 1,378,594, and (c) 1,378,595, 17.5.21. Appl., (a) 3.9.19, (b) 20.1.20, (c) 19.2.20.

(a) Ammonium chloride present in the feeder liquor of the ammonia-soda process is treated with an alkaline-earth sulphide, and the resulting ammonium sulphide after separation of the alkaline-earth chloride is treated with an alkaline oxide. (b) Ammonium chloride is separated from the feeder liquor of the ammonia-soda process and barium sulphide added to a solution thereof. Barium chloride is separated from the resulting liquor by crystallisation. (c) Ammonium bicarbonate present in the feeder liquor of the ammonia-soda process is treated with barium chloride, barium carbonate is separated from the resulting solution, and the residual solution is treated with barium sulphide to form barium chloride which is used for the conversion of additional ammonium bicarbonate into barium carbonate.—J. S. G. T.

Ammonia; Process for oxidation of ——. J. R. Partington. U.S.P. 1,378,271, 17.5.21. Appl., 10.10.19.

Ammonia and steam are mixed in presence of oxygen, and the preheated mixture is passed over a heated catalyst.—W. J. W.

Ammonia; Process for the oxidation of ——. A. R. Frank and N. Caro. G.P. (a) 303,822, 18.10.14, (b) 303,823, 8.12.14.

(a) The gas mixture is cooled immediately before entering the catalyst chamber, thus enabling air enriched with oxygen to be used, and the reaction accelerated. (b) Oxygen derived from the Linde apparatus of a calcium cyanamide plant is used for oxidation of the ammonia prepared from the calcium cyanamide with cooling as above. The catalyst maintains its temperature without external heating.—C. I.

Ammonia; Catalyst for the oxidation of —— to nitric oxide. Badische Anilin- u. Soda-Fabr. G.P. (a) 334,975, 24.12.15, (b) 337,568. 1.9.16.

(a) A platinum contact mass, preferably flexible, rests upon a granular layer of oxides of base metals resistant to heat. With this arrangement it is possible to work with large contact chambers without irregularities in the gas flow resulting. (b) The contact mass is wholly or partly separated from the granular layer by an intervening space, and its durability so increased.—C. I.

Thorium; Recovery of —— [from monazite]. H. Wade. From Lindsay Light Co. E.P. 164,581, 21.4.20.

Monazite sand is digested with 96% sulphuric acid at about 500° F. (260° C.), by which means thorium, together with titanium, zirconium, and iron, is rendered soluble; the sand is then washed with water. A sufficient amount of 30% hydrofluoric acid or of a soluble fluoride is added to the acid solution to ensure selective precipitation of the thorium up to about 85%; the remainder may be precipitated by separating and diluting the solution and adding more hydrofluoric acid. The thorium fluoride obtained is practically pure, but may be further purified by conversion into hydroxide, which is then dissolved in dilute sulphuric acid and precipitated with a fluoride as before. (Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 127,555; J., 1919, 862 a.)—W. J. W.

Sodium formate; Manufacture of ——. M. Enderli. E.P. 165,163, 17.3.20.

In the manufacture of sodium formate by treatment of sodium sulphate with carbon monoxide in presence of milk of lime, the dilution of the sodium sulphate has considerable influence on the reaction. By using solid basic sodium calcium sulphate $Na_4Ca_3(SO_4)_4(OH)_2$, caustic lime, and calcium sulphate as reaction products, the concentration of the sodium sulphate is kept below 7% and the production of sodium formate is rapid. Alternatively, when sodium sulphate and milk of lime are employed, fresh sodium sulphate or basic sodium calcium sulphate may be introduced during the reaction to maintain the concentration. The basic double sulphate is prepared by heating together, in presence of water, sodium and calcium sulphates, or substances capable of forming these compounds, and calcium hydroxide or sodium hydroxide.—W. J. W.

Zinc chloride; Method for producing ——. P. Danckwardt, Assr. to Danckwardt Process Co. U.S.P. 1,378,219, 17.5.21. Appl., 23.6.19.

A solution of aluminium chloride is treated with zinc oxide, the precipitated aluminium oxide separated from the zinc chloride solution by filtration, the filtrate evaporated, and the residue fused. —J. W. D.

Potash; Recovery of —— from potash-bearing brines. G. Hecker, Assr. to Pacific Coast Borax Co. U.S.P. 1,378,410, 17.5.21. Appl., 21.9.18.

Concentrated hot liquors which contain potassium salts in solution, in association with borax, are agitated and cooled rapidly until the potassium salts are precipitated as uniform coarse crystals of good white colour, whilst the borax remains in solution.—F. M. R.

Potassium salts; Recovery of —— from solutions containing the same as well as other salts. J. W. Hornsey. U.S.P. 1,380,383, 7.6.21. Appl., 21.6.18.

By evaporation of the solution under pressure at a temperature above the normal boiling point, the contaminating salts are largely separated; the residual solution is then cooled to precipitate potassium salts.—W. J. W.

[Cement] furnace fumes; Process and apparatus for recovering soluble constituents [potassium salts] from ——. H. V. Welch, Assr. to International Precipitation Co. U.S.P. 1,382,037, 21.6.21. Appl., 11.8.17. Renewed 2.5.21.

The suspended matter of cement kiln flue gases is treated with water to produce a saturated solution; the resulting sludge is heated to render the potassium salts present therein soluble, and the solution then filtered from insoluble matter. —H. R. D.

Borax; Separation of —— from potassium salts. C. E. Dolbear, Assr. to Industrial Research Co. U.S.P. 1,382,825, 28.6.21. Appl., 26.10.20.

A mixture of potassium salts and borax is heated in a moist condition and the liquor subsequently separated from the undissolved salts.—H. R. D.

Crystallising tower for the crystallisation of hot concentrated solutions of potassium salts. C. Hermann. G.P. 337,389, 21.1.20.

The saturated solution trickles over a series of plates arranged step-wise and supported on adjustable angle irons placed within a passage way for air in the vertical upper part of a tower. The plates are disposed either horizontally or at a slight inclination to the horizontal. Crystals deposited upon the plates are removed by means of scrapers etc. and transported through a channel alongside the tower. Owing to the small height of the tower, there is, in general, no necessity for pumping the solution.—J. S. G. T.

Zinc oxide; Manufacture of —— direct from oxidised zinc ores. J. Allingham. U.S.P. (A) 1,380,514 and (B) 1,380,515, 7.6.21. Appl., 4.11. and 12.11.19.

(A) Oxidised zinc ore is treated with a solution of sulphuric acid and sodium chloride, the solution is separated and freed from compounds of other metals than zinc, and the latter is precipitated with calcium hydroxide; the zinc hydroxide, in presence of the solution, is subjected to the action of carbon dioxide, and the zinc carbonate is separated, dried, and ignited. (B) In the solution obtained as above and freed from other metals, zinc carbonate is precipitated by means of trona (sodium carbonate), dried, and ignited. The solution after removal of zinc carbonate is treated to recover sodium sulphate, part of which is added to the solution produced in cyclic operation of the process by solvent action on the ore, to remove lime.—W. J. W.

Fluorides; Process of making ——. H. B. Bishop. U.S.P. 1,382,165, 21.6.21. Appl., 30.8.19.

A mixture of an alkali fluoride and a gelatinous silicious compound is treated to render the latter soluble, and the soluble silicious compound is then separated from the fluoride.—H. R. D.

Selenium oxychloride; Manufacture of ——. V. Lenher. U.S.P. 1,382,920—2, 28.6.21. Appl., 15.5.20.

(A) Selenium and selenium dioxide are treated with chlorine. (B) A selenium compound is treated with water in presence of a solvent for selenium oxychloride. (C) Selenium dioxide is treated with hydrochloric acid and a dehydrating agent.—C. I.

Sodium hypochlorite; Process of making ——. J. R. MacMillan, Assr. to Niagara Alkali Co. U.S.P. 1,383,224, 28.6.21. Appl., 29.7.20.

Chlorine is passed into a solution of lime and sodium carbonate, and the resulting hypochlorite solution separated from the calcium carbonate.—H. R. D.

Alkaline-earth sulphates; Process for the decomposition of ——. Metallbank u. Metallurgische Ges. A.-G. G.P. 307,101, 1.7.16. Addn. to 227,175 (J., 1910, 1306).

In the production of sulphur dioxide from alkaline-earth sulphates, especially calcium sulphate, a finely powdered mixture of the sulphate and combustible material, in the form of angular or spherical fragments, is treated with an air blast. Alternatively a finely powdered mixture of the sulphate and a flux or reacting material is formed into angular or spherical fragments, mixed with combustible material, and treated with the blast.—J. S. G. T.

Copper sulphate from rich copper dross; Production of ——. Hirsch, Kupfer- u. Messingwerke, A.-G. G.P. 336,020, 13.3.18.

Rich copper dross is calcined and treated with sulphuric acid or liquor containing sulphuric acid.—J. S. G. T.

Mercuric chloride from mercury and chlorine; Manufacture of ——. E. Schultz. G.P. 336,614, 4.11.19.

Mercury is allowed to fall through an atmosphere of chlorine into water or a solution of a chloride, the operation being carried out in a closed rotating vessel wherein the chlorine is maintained at slight excess pressure. The mercury is kept in continuous circulation.—J. S. G. T.

[Sodium] metaborate; Manufacture of ——. Manufacture of [sodium] perborate. Aschkenasi. G.P. (A) 337,322 and (B) 337,058, 6.1.20.

(A) Powdered crystalline borax is added to concentrated sodium hydroxide solution, and the solid product is dried *in vacuo* at a moderate temperature. (B) Powdered crystalline borax is added to hot concentrated sodium hydroxide solution, the syrupy reaction product is mixed when cold with concentrated hydrogen peroxide, and either allowed to solidify and dry in the air, or treated with a current of warm air, or dried *in vacuo* at a moderate temperature.—L. A. C.

Nitrogen or nitrogen and hydrogen mixtures; Process for preparing ——. L. Casale. E.P. 148,885, 10.7.20. Conv., 12.7.19.

Air is burnt in a confined space in which an atmosphere of hydrogen is maintained. By regulation of the supplies of air and hydrogen the proportions of nitrogen and hydrogen in the issuing gases may be adjusted to those necessary for the production of synthetic ammonia or other nitrogen products.—A. R. P.

Hydrogen; Apparatus for the production of ——. A. R. Griggs. E.P. 165,829, 13.6.19.

Retorts in which iron is alternately oxidised and reduced are made of relatively large size and are so arranged in two groups that the gases from the reduction phase may be utilised continuously for heating the retorts externally and also intermittently for combustion within the retorts. The gases thus used within the retorts may be partially burnt and then passed to the exterior of the retort for completion of the combustion.—H. Hg.

Sulphur; Refining ——. R. F. Bacon and C. N. Wenrich, Assrs. to Texas Gulf Sulphur Co. U.S.P. 1,378,084, 17.5.21. Appl., 6.10.19.

Crude sulphur is heated to 115°—130° C. and then added, drop by drop, to a volume of a cooling liquid at such a rate, depending on the volume and b.p. of the liquid, that the drops will coagulate into pellet form.—A. R. P.

Sulphur from porous charcoal containing it; Recovery of ——. Farbenfabr. vorm. F. Bayer u. Co. G.P. 337,059, 4.10.18.

The sulphur is dissolved by treatment of the charcoal at 100° C. with aromatic halogenated hydrocarbons such as mono- or di-chlorobenzene. On cooling, sulphur is deposited from the solution. Solvent adhering to the charcoal is removed by steaming and the charcoal thus regenerated for use in extracting sulphur from gases.—J. S. G. T.

Graphite and carbon; Process for purifying ——. C. W. Woodruff and R. H. Pausch. U.S.P. 1,380,458, 7.6.21. Appl., 25.5.20.

The material is treated with gaseous hydrogen fluoride and the soluble compounds so formed are removed by washing.—A. G.

Hydrochloric acid and sodium sulphate; Furnaces for manufacture of ——. W. Carpmael. From Farbenfabr. vorm. F. Bayer und Co. E.P. 165,639, 27.5.20.

See G.P. 331,238 and 332,954 of 1919; J., 1921, 301 A, 388 A.

Ammonia; Process of synthesising ——. The Nitrogen Corp., Assees. of J. C. Clancy. E.P. 128,939, 25.6.19. Conv., 25.6.18.

See U.S.P. 1,352,177 of 1920; J., 1921, 300 A.

Base-exchange compound and process of making the same. H. J. Wheaton, Assr. to J. Crosfield and Sons, Ltd. U.S.P. 1,381,777, 14.6.21. Appl., 6.11.19.

See E.P. 142,974 of 1919; J , 1920, 525 A.

Iron salt [for tanning etc.]; Solid non-hygroscopic —— and preparation thereof. O. Röhm. U.S.P. 1,383,264, 28.6.21. Appl., 16.7.20.

See E.P. 146,214 of 1920; J. 1921, 388 A.

Catalysts. E.P. 164,808. *See* I.

Calcium bisulphite. U.S.P. 1,378,616—7. *See* V.

VIII.—GLASS; CERAMICS.

Glass; Thermal expansion and annealing temperature of ——. W. B. Pietenpol. Glass Ind., 1921, 2, 162—165.

Glass strips, 16 cm. long (the large size in order to reduce errors due to non-homogeneity), resting on sbestos, were heated in an electric furnace 100 cm. ong and 6 cm. diameter, the expansion being measured by means of microscopes focused on iamond scratches or on small platinum particles esting on the glass. The expansion of wellnnealed samples of optical and other glass was measured from room temperature to about 750° C., nd the rate of expansion was found to be almost near to 450°—550° C., depending on the comosition of the glass. There followed, then, a large ncrease of rate of expansion through a range 60°—00° C., where, for a temperature interval of about 00° C., the glass was distinctly plastic, whilst eyond this, near to the softening point, the rate expansion again decreased to a value generally ightly greater than that at low temperatures. he results do not bear out the observations of eters and Cragoe (J., 1920, 572 A), who found a ntraction just beyond the range of rapid expanon, which they stated to be due to surface tenon, but which the author attributes to deformaon through strain, caused by a quartz plate which ey rested on the sample. With unannealed glass, e rate of expansion generally decreased at 50°—0° C. below the temperature of rapid expansion, ilst strain quite disappeared when the point of pid expansion was reached, the interval of low pansion being the annealing range.—A. C.

fractory materials; Apparatus for determining the hardness of —— at high temperature. E. Rengade and E. Desvignes. Comptes rend., 921, 173, 134—137.

SIMPLE arrangement is described for testing the dness of refractory materials at temperatures to 1500° C. or higher. Ludwick's modification of the method of Le Chatelier and Bogitch (J., 1918, 373 A) is employed, using a cone for making the impress in the material and an electric furnace for heating. The results for eight clay bricks and one bauxite brick together with their analysis are given. Progressive softening with rise in temperature is indicated, and is similar in all cases except for a difference in the temperatures. The aluminium content does not appear to have any marked effect on the variations, but the presence of alkalis exercises a very injurious effect. With silica bricks the specimen shows no impress up to about 1600° C., beyond which the adherence of the grains diminishes suddenly and the cone penetrates, immediately cracking the brick.—W. G.

Enamels; Cause of flaws in pottery ——. J. Barlot and J. Martinet. Chim. et Ind., 1921, 5, 651—652.

The more frequent defects in enamels are attributed either to fragments of impurities (*e.g.*, iron oxide, copper oxide, dust from the furnace, etc.) which give rise to coloured spots, or to large grains in the body in contact with the enamel. These large grains are often calcareous and decompose on heating, giving rise to irregular hollows in the ware. Another defect, attributed to the decompostion of iron pyrites, takes the form of conical depressions containing a small black fragment at the bottom. In slabs to which definite amounts of ground pyrites were added, conical excavations of 2 to 3 mm. diam. and about 1 mm. depth were observed. The larger the size of the grains of pyrites and the more rapid the heating, the larger will be the conical depressions produced. It is shown that under ordinary pressure iron pyrites decomposes rapidly at 850° C.—H. S. H.

Patents.

[Glass] tank furnaces. M. W. Travers. E.P. 165,628, 18.5.20.

At each side of the melting end of a tank furnace is attached an underfed gas producer, with a short lead into the melting end, whereby heat losses are reduced. Waste gases pass from the working end of the tank into recuperators, situated against the producers, where secondary air is heated before being delivered into the leads from producers to tank.—A. C.

Ovens suitable for the firing of pottery and for other purposes; Continuous and intermittent ——. J. Williamson. E.P. 164,376, 3.9.19.

An oven suitable for the firing of pottery and for other purposes comprises a vaulted heating chamber for holding the goods to be heated, one or more combustion chambers or burner arrangements, a system of flues comprising a tunnel which is arranged longitudinally in the oven structure below the oven space and which communicates at the top with the lower portion of the oven space through a central longitudinal opening and at the bottom with the lower portion of the oven space through lateral longitudinal passages extending upwards. A longitudinal flue or heating chamber is arranged in the tunnel and communicates with the combustion chamber or burner arrangement and with a fan, chimney, or other exhausting means.—H. S. H.

Furnaces, kilns, ovens and the like [for ceramic ware]; Method of operating ——. H. Francart. E.P. 165,812, 19.12.18.

Bricks, terra-cotta and the like are fired in kilns of the Hoffman type, provided with drop-arches, by placing the articles in such a manner that a series of combustion chambers and non-combustion chambers, arranged alternately, is formed, and the ascensional force of the hot gases is utilised to produce a helical circulation of the gases through the kiln. The partitions which form the two kinds of chambers may be arranged either longitudinally or transversely.—A. B. S.

Clay wares; Burning —— in zigzag kilns. C. Runge. G.P. 333,698, 21.8.19.

The partition walls in a zigzag kiln have openings at both ends for the passage of the hot gases, so that part of these gases may take the shortest path, and thus heat the "dead space" which exists in zigzag kilns without the additional openings. These openings may be closed by dampers of paper or other material which will burn away when a definite temperature is reached.—A. B. S.

Kilns; Connected ——. M. and C. Simons, and P. Ramrath. G.P. 334,046, 8.2.20.

Kilns are arranged at an angle to a common main flue and with the outlet from each chamber leading directly beneath the grate of the next kiln in the series, so that the kilns may be worked independently or in series.—A. B. S.

Refractory material and process of making the same. C. H. Breerwood. U.S.P. 1,380,700, 7.6.21. Appl., 11.3.18.

A refractory product suitable for the walls of furnaces, crucibles, etc. is made from material adapted to form a "sinter" by introducing it in a finely-divided state into a furnace, mixing with it small pieces of material to which the finely-divided substance is adapted to adhere in its passage through the furnace to form balls, and subjecting it in such form to such a temperature and for a sufficient length of time to make the substance refractory.—H. S. H.

Dolomite bricks; Process for making ——. C. H. Breerwood, Assr. to Coplay Cement Manuf. Co. U.S.P. 1,380,701, 7.6.21. Appl., 5.7.19.

Dolomite containing a small amount of iron is finely ground and the mixture burned at a sufficiently high temperature to amalgamate or vitrify it. The burnt mixture is re-ground, compressed under great pressure into the desired shape, and burned at a temperature sufficiently high to amalgamate and vitrify the brick.—H. S. H.

Filter cloth for dewatering fluid ceramic materials. Porzellanfabrik P. Rosenthal und Co. A.-G. G.P. 335,662, 16.11.18.

Filter-cloth is impregnated with zinc chloride or fluoride, which makes the exterior of the fibres more horny and smooth, and so enables the filter-cakes to be removed more readily than when the cloth is impregnated with ammoniacal copper oxide. — A. B. S.

Casting; Production of material for —— from clay and non-plastic materials. A. Walter and E. Weber. G.P. 336,661, 14.8.17.

A slip suitable for casting is made by adding vegetable extracts of a neutral or alkaline character (such as saponin, cellulose waste lyes, or "cell pitch") to the customary mixture of argillaceous and non-plastic materials and alkalis. —A. B. S.

Fired [ceramic] ware; Production of ——. O. H. Gerach. G.P. 337,558, 18.6.20.

Instead of the usual binding agents such as clay, cement, plaster, etc., a mixture of quicklime and a hydraulic material such as zeolitic sand, brick-dust, or the like is used. The shrinkage of the ware during burning is thereby avoided.—A. B. S.

Glass; Art of colouring ——. H. Rosenthal. E.P. 146,473, 5.7.20. Conv., 21.1.14.

See U.S.P. 1,169,571 of 1916; J., 1916, 310.

Glass; Production of bores in ——. J. Kent. U.S.P. 1,382,650, 28.6.21. Appl., 1.4.20.

See E.P. 153,824 of 1920; J., 1921, 10 A.

Agglomerates [electrodes etc.] of various materials; Manufacture of —— and their utilisation. T. Rouse. U.S.P. 1,381,748, 14.6.21. Appl., 12.9.19.

See E.P. 124,262 of 1918; J., 1919, 324 A.

Glass; Methods of and apparatus for feeding molten ——. Hartford-Fairmont Co., Assees. of K. E. Peiler. E.P. 142,785, 15.1.20. Conv., 5.5.19.

IX.—BUILDING MATERIALS.

Cement and cement mortars; Volume changes of —— due to setting. O. Graf. Beton u. Eisen, 1921, 20, 49—52, 72—74. Chem. Zentr., 1921, 92, IV., 109—110.

The volume changes of mortars during the first nine hours of setting are largely dependent upon the water content of the mortars. Soft mortars undergo considerable changes of volume during the first six hours of setting, while the changes in the case of merely damp mortars are scarcely measurable. The volume changes occurring during the third to ninth hours of setting are largely dependent upon the cement content of the mortar. No clearly perceptible effect due to infiltration of iron was detected during the initial period of setting, notwithstanding the change of length occurring. The change of length due to saturation with moisture was less, and was produced more slowly in the case of limestone than in the case of sandstone. —J. S. G. T.

Patents.

Wood; Preserving ——. W. Lichty. E.P. 148,137, 9.7.20. Conv., 20.2.14.

Wood is preserved against dry rot and the like by immersing it in a solution containing 6·5 pts. of a 0·6% solution of mercuric chloride and 9, 12, 18 or more pts. of a 0·6% solution of sodium fluoride or other fluorine salt, or in a solution containing 20 pts. of a 0·6% solution of sodium fluoride, 5 pts. of a 0·6% solution of sodium silicofluoride, and 5 pts. of a 0·6% solution of mercuric chloride. The added solutions prevent the mercuric chloride from coagulating albumin, and so increase its antiseptic power.—A. B. S.

Wood; Process of treating ——. L. N. Lyon. U.S.P. 1,382,103, 21.6.21. Appl., 3.11.19.

The liquid used for permeating and sealing th wood is heated to a temperature above the boilin point of water, but below the flaming point o the liquid; the wood is immersed in the liquid unti the moisture in the wood escapes as steam, afte which the wood is removed, its pores being seale by the liquid.—A. B. S.

Cementitious compositions suitable for flooring paving, and so forth. C. F. Curtis. E.P 164,666, 13.10.20.

Wood dust (3 bushels) and plaster of Paris or similar setting composition (1 bushel) are tho oughly mixed together in a dry condition. Cok breeze (3 bushels), sand (2 bushels), and Portlan cement (6 bushels) are similarly mixed, and th two mixtures themselves are thoroughly mixe together in the dry state. Water, containing an required colouring matter, is added in nearl sufficient quantity for setting, and then 5 oz. of alum dissolved in water is added and the whole well mixed.—H. S. H.

Cement products; Process for controlling the setting of ——. C. L. Norton, Assr. to Asbestos Shingle Co. U.S.P. 1,379,204, 24.5.21. Appl., 4.12.17.

A flat, relatively thin, stone-like body of hydraulic cement of uniform exterior appearance and water-absorptive capacity is produced by confining it during the setting operation between two opposite restraining surfaces and maintaining an atmosphere of approximately 90% humidity about the edges.—H. S. H.

Cementitious composition; Process of making a ——. G. M. Formby, Assr. to Formby Petrinite Corp. U.S.P. 1,379,680, 31.5.21. Appl., 10.3.20.

A mixture of calcium and magnesium hydroxides is treated with hydrochloric acid, and the resulting product added to a cementitious composition. —H. S. H.

Cements; Process of and apparatus for burning ——. W. E. Snyder. U.S.P. 1,381,026, 7.6.21. Appl., 25.5.20.

To economise fuel, preheated air is supplied at an intermediate point in the length of the kiln to a chamber about the kiln, the chamber being in communication with one end of the kiln. The gases discharged at the opposite end of the kiln are conducted through a chamber about the kiln to a discharge located adjacent to the first-named point. —H. S. H.

Cementitious bituminous emulsion. W. M. Fraser. E.P. 139,492, 25.2.20. Conv., 25.10.17.

See U.S.P. 1,259,223 of 1918; J., 1918, 294 a.

Wood; Treatment of —— *for seasoning.* M. P. Otto. U.S.P. 1,381,656, 14.6.21. Appl., 22.5.19.

See E.P. 133,263 of 1919; J., 1919, 863 a.

Cement furnace fumes. U.S.P. 1,382,037. *See* VII.

Sulphuric acid and cement. G.P. 297,922 and 299,033. *See* VII.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Dolomite-tar mixture; Preparation of —— *for steel converter linings.* M. Backheuer. Stahl u. Eisen, 1921, 41, 954—956.

TAR is absorbed best by dolomite which has not been oo strongly heated. A loss in weight of 2—4% is ufficient. Silica reduces the power of absorbing ar especially if the silica and bases have fused nto lumps, as takes place if a silicious dolomite is oo strongly heated. The production of satisfactory nings depends largely on the fineness of grinding f the burnt dolomite and its uniform admixture ith the tar. The latter operation is carried out at 0° C. For converter sides a dolomite powder absorbing 8—10% of tar and for the bottoms a finer owder taking up 12% of tar is used. A detailed escription of methods of preparing the different arts of the lining is given.—C. I.

Cobalt and nickel in cobalt steels; Determination of ——. G. E. F. Lundell and J. I. Hoffman. J. Ind. Eng. Chem., 1921, 13, 540—543.

n the electrolytic determination of cobalt and ckel, the presence of vanadium does not affect e deposition of either nickel or cobalt alone, but es interfere when both are deposited simulneously; tungsten interferes in depositions of cobalt, or cobalt and nickel, but not of nickel alone. Ferrous salts, chromates, tartrates, and molybdenum exert a marked interference, but sulphates of potassium, manganese, and chromium, small amounts of platinum, and chlorides are without influence. The effects of interfering elements are overcome in the method described. The steel is dissolved in hydrochloric and nitric acids; tungstic and silicic acids are filtered off and treated with sodium hydroxide, and any insoluble matter is dissolved in hydrochloric acid and added to the main solution which is then treated with ether to remove most of the iron and molybdenum. The acid extract is heated with sulphuric acid till fumes are evolved, chromium, vanadium, and manganese are then oxidised by potassium persulphate, and the solution is poured into sodium hydroxide solution, whereby chromium, vanadium, and any residual tungsten and molybdenum are separated, and filtered. The precipitate is dissolved in sulphuric acid, with addition of sodium bisulphite, and freed from copper by treatment with hydrogen sulphide. After expulsion of the latter, the solution is precipitated with ammonia to remove iron, and the filtrate is electrolysed, nickel being separated from the deposit by treatment with dimethylglyoxime. When desired, determinations of chromium and vanadium may be made in the filtrate from the sodium hydroxide separation. Manganese is estimated in the nitric acid solution by the bismuthate method, and copper in the hydrogen sulphide precipitate.—W. J. W.

Tin-plate; Quality of —— *and its influence on the quality of tinned foods etc.* H. Serger. Z. öffentl. Chem., 1921, 27, 133—139.

During the last few years the quality of the tin-plate used for making containers for preserved foods, etc., has deteriorated considerably; the coating of tin on the plate is often less than 0·1 g. per sq. cm. and "pinholes" are numerous. Where the latter exist there is more or less rapid attack of the iron plate and the contents of the tin are spoilt. It is suggested that each side of a tin-plate should have a coating of not less than 0·2 g. of tin per sq. cm. The presence of "pinholes" in the coating is readily detected by means of potassium ferricyanide-gelatin reagent.—W. P. S.

Lead in brass; Determination of small amounts of ——. F. W. Glaze. J. Ind. Eng. Chem., 1921, 13, 553—554.

In the electrolytic determination of small amounts, *e.g.*, less than 0·06%, of lead in brass, current density and acid concentration are the most important variables. 8·643 g. of the sample is treated with 30 c.c. of nitric acid (1:1) and dissolved after further addition of 10—15 c.c. of nitric acid (sp. gr. 1·42). The solution is evaporated till copper nitrate begins to crystallise out, and cooled; 5 c.c. of nitric acid and a small amount of water are added, the solution is heated till the crystallised salt dissolves, diluted to volume, and electrolysed with a current of $N.D._{100}$ 1·5 amps. and 2·9—3·1 volts. The lead is all deposited in 1 hr. but the current should be continued for 10 mins. longer. The anode is washed with water and alcohol, dried at 200°—230° C. for ½ hr., weighed, cleaned, and again weighed; the difference, representing lead dioxide, multiplied by 10 gives the percentage of lead in the brass.—W. J. W.

Gas atmospheres in aluminium-alloy melting furnaces; Constitution of ——. R. J. Anderson and J. H. Capps. Chem. and Met. Eng., 1921, 25, 54—60.

A large number of gas samples representing the atmosphere over aluminium alloys during the process of refining were examined. In gas- and oil-fired open flame furnaces, the atmosphere was generally non-oxidising, the waste gases containing appreciable quantities of carbon monoxide, hydrogen, and methane. A marked difference was observed between natural and forced draught coke fires. Under natural draught the gases in contact with the liquid metal were fairly uniform in composition, but the carbon dioxide content was low, and the metal was subjected to both oxidising and nitridising conditions. This influence was reduced greatly when the draught on the furnace was raised by mechanical means. In a stationary cylindrical furnace of the Schwartz type, heated by oil, the atmosphere was more regular and approached neutrality as regards oxidising conditions. Gas samples taken from an indirect arc rocking furnace of the Detroit type showed a distinct change during the progress of the heating. Carbon dioxide formed by combustion of the electrode carbon was reduced to carbon monoxide which varied from 21 to 39·3% in a short melting period. Over a longer melting period carbon monoxide and hydrogen generally became less, possibly by interaction with the molten bath of aluminium, and although low in carbon dioxide and oxygen the atmosphere appeared to be of an oxidising character. In common with other furnaces of a closed type, the atmosphere of a granular resistance furnace was low in oxygen, and hydrogen and methane were ordinarily present in small amounts.—C. A. K.

Antimonial lead; Properties of ——. L. J. Gurevich and J. S. Hromatko. Chem. and Met. Eng., 1921, 25, 62—63.

Melting point determinations are not conclusive as to the quantitative amount of antimony in lead as no definite melting point exists for these alloys. The hardness (Brinell) of the alloy increases gradually, with increasing antimony, to the eutectic alloy containing 10% Sb; an alloy containing 2·76% Sb shows a hardness of 5·8, and the eutectic a hardness of 7·3. The tensile strength increases to a maximum when the alloy contains 10% Sb, while a 4·5% Sb alloy is the most ductile.—C. A. K.

[*Nickel and cobalt; Separation of* ——.] *Some reactions of the xanthates.* A. Whitby and J. P. Beardwood. J. Chem. Met. Soc. S. Africa, 1921, 21, 199—200.

Nickel and cobalt may be determined in ores containing arsenic and iron as follows: 1—3 g. of ore is dissolved in *aqua regia*, 2—3 g. of citric acid added, the solution filtered and rendered ammoniacal. The liquid is treated with 1—2 g. of sodium or potassium xanthate and made slightly acid with acetic acid. The precipitated xanthates of nickel, cobalt, and copper (if present) are filtered off, washed with warm water, rinsed back into the original beaker and digested with warm ammonia (1:1) to dissolve the nickel compound. The residual cobalt and copper xanthates are filtered off, washed with ammonia, ignited at a bright red heat, and the residue weighed as Co_3O_4+CuO. After solution of the oxides in hydrochloric acid, the copper is separated by hydrogen sulphide. The nickel in the original filtrate is re-precipitated by acidification with acetic acid, the precipitate is filtered off, washed with warm water, ignited, and weighed as NiO. The bulk of the arsenic and iron is in the first xanthate filtrate, the remainder is found in the filtrate from the nickel xanthate. (*Cf.* J.C.S., Sept.)—A. R. P.

Mercury; Rapid determination of —— *in its ores* A. Heinzelmann. Chem.-Zeit., 1921, 45, 657—658.

A mixture of the ore and quicklime is heated in a tube closed at one end and held almost horizontal. The portion of the tube in which the mercury has sublimed is separated from the remainder, the end sealed, and the mercury dissolved in about 1 c.c. of nitric acid (sp. gr. 1·48—1·50); a few drops of $N/10$ permanganate are added to oxidise mercurous salts, and the solution after neutralisation is titrated with $N/20$ potassium thiocyanate.

—W. J. W.

Mercury; Purification of —— [*in the laboratory*]. C. Harries. Z. angew. Chem., 1921, 34, 359.

Mercury containing tin or lead cannot be freed from these elements by the chromic acid method or by distillation *in vacuo*. The purification is best carried out by passing a stream of air through the metal heated to 150° C. for several hours in order to oxidise the impurities. They collect as a scum on the top of the metal and may be filtered off. Very little mercury is oxidised at this temperature, but a certain amount is held up in the form of fine globules in the oxide coating; this is recovered by digestion with hydrochloric acid. The final purification is effected by distillation *in vacuo* from an ordinary round fractionating flask fitted with cork stoppers rendered gas-tight with a mixture of glue and chalk or sulphite-cellulose tar and chalk. (*Cf.* J.C.S., Sept.)—A. R. P.

Tellurium; Alloying —— *with some white metals.* J. H. Ransom and C. O. Thieme. Chem. and Met. Eng., 1921, 25, 102—103.

When tellurium and lead are heated together, the former glows and appears to combine with the lead, forming a hard but somewhat malleable alloy which does not alloy with the excess of lead; the latter, however, takes up about 0·2% Te. Tellurium alloys with tin and slightly increases the hardness and tensile strength of the metal, but reduces its elongation. The behaviour of tellurium on heating with a 50:50 tin-lead solder was similar to that with lead; it also partly removed the copper present in the solder. No tellurium could be found in zinc or aluminium after similar treatment to the above, but in both cases the tensile strength was slightly increased, while the hardness was unaffected. The elongation of aluminium after treatment with tellurium was increased from 18·5 to 28·5%.—A. R. P.

Interpenetration of solids [*metals*]. H. Weiss and P. Lafitte. Comptes rend., 1921, 173, 146—148. (*Cf.* J., 1920, 575 a.)

There is no discontinuity for the penetration of zinc into copper when the temperature is raised to the melting-point of zinc. Penetration occurs at temperatures far below the melting-point of either metal, *e.g.*, at 100° C. for zinc-copper or tin-copper couples, providing sufficient time is allowed. The phenomenon is quite general, as is shown by experiments with a whole series of couples in which copper was always one metal, the couples used representing almost all the varieties of fusibility curves. Negative results were obtained where aluminium was the second metal, but this was due to lack of proper contact between the two metals.—W. G.

Patents.

Iron and steel; Manufacture of —— *from scrap and the like.* L. P. Basset. E.P. 130,610, 2.10.18. Conv., 29.1.18. Addn. to 158,523 (see U.S.P. 1,360,711 of 1920; J., 1921, 48 a).

The process described in the original patent is applied to the treatment of scrap iron or scrap steel with or without admixture of new spongy iron. The molten metal is subsequently refined by varying the proportion of air and fuel so as to obtain an excess of air at the end of the melting period whereby impurities are oxidised and eliminated. By the use of crude petroleum as fuel the products of combustion contain hydrogen in addition to carbon monoxide. The improved process is of particular advantage in the treatment of iron and steel turnings, as the metal is not carburised or burnt. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 112,275; J., 1920, 269 A.)—T. H. Bu.

Iron or steel; Process of and revolving furnace for the direct production of ——, or for the production of cast iron. L. P. Basset. E.P. 132,262, 3.9.19. Conv., 3.9.18.

A mixture of iron ore, carbon, and fluxes is introduced at the upper extremity of a rotary furnace having an enlarged zone at the lower extremity into which finely divided combustible and preheated air are injected in such proportions that combustion produces practically only an atmosphere of carbon monoxide for reducing purposes. Means are supplied for continuously drawing off slag from the enlarged zone.—J. W. D.

Iron alloys. K. A. Caspersson. E.P. 164,960, 2.6.20.

Alloys for use in making sheet iron resistant to projectiles contain 0·10—0·35% C, 1·0—10·0% Cr, 0·75—7·0 Si, 0·5—2·0% Mn, and other constituents usually contained in alloys of this kind other than nickel, but even the latter may be present in negligible quantities.—J. W. D.

Fluorspar; Use of —— in steel making. F. Calvert. E.P. 165,465, 16.7.19.

In the production of steel in an acid open-hearth furnace a total quantity of fluorspar at least sufficient to neutralise the silicon content of the furnace charge is added as follows:—25% in the melting down stage after melting has started, 25% during the boiling stage, and the remainder—in at least two stages—when the carbon in the charge is about 0·3% above that required in the final steel. The steel is cleaned and the bath kept in a working condition till ready for tapping. The highest-class steel can be made without pig iron or with only small quantities.—T. H. Bu.

Iron; Electrolytic deposition of —— and treatment of the deposits. H. Lovelock, and T. Try and Son, Ltd. E.P. 165,535, 30.3.20.

The iron or steel article on which the deposit is to be made is cleaned thoroughly by means of alkali or acid, after which it is made the anode in a cell containing, for example, 25% sulphuric acid, for a short time, using a heavy current. The acid is drained off, and replaced by a solution of ferrous ammonium sulphate, the current is reversed and maintained at about 8 amps. per sq. ft. of cathode surface at 0·75 volt until the deposit is sufficiently thick. The article is then annealed at a temperature above 925° C. for 2 hrs., whereby the deposit is caused to be incorporated thoroughly with, or welded on to the body of the article, which may, if required, then be case-hardened in the usual way.
—A. R. P.

Steel; Production of high-speed tool —— and the manufacture of tools therefrom. A. W. Mathys. From U.S. High Speed Steel and Tool Corp. E.P. 165,919, 24.3.20.

High-speed steel tools may be cast directly in the pproximate tool form from a melt prepared by ubjecting iron with ferrotungsten, ferrochromium, errovanadium, ferromanganese, and an alloy nown as S.A.M. Lion brand metal in specified proortions to an intense heat in a graphite crucible nd adding ferrotitanium as the liquefying stage is pproached.—J. W. D.

Ferrous metals; Coating ——. C. Baskerville. U.S.P. 1,378,439, 17.5.21. Appl., 25.6.14.

The ferrous metal is first coated with substantially pure antimony and afterwards with a material containing metallic lead.—T. H. Bu.

Steel sheets; Process of coating —— with aluminium. S. Peacock, Assr. to Wheeling Steel and Iron Co. U.S.P. 1,378,052, 17.5.21. Appl., 9.11.20.

The sheets are first passed through a molten bath of a double aluminium alkali chloride and then through a bath of molten aluminium.—J. W. D.

Steel; Method of heat-treating ——. W. C. Peterson. U.S.P. 1,380,676, 7.6.21. Appl., 19.5.21.

The article is heated to a temperature above its critical point and then quenched, the temperature and rate of heating being such that the article after quenching assumes the same dimensions as previous to heating.—J. W. D.

Iron-silicon alloy; Manufacture of a dense, highly acid-resisting ——. J. Römheld. G.P. 336,561, 4.6.18.

The molten alloy after leaving the cupola is heated without agitation with combustible material for sufficient time to allow occluded gases and kish graphite to separate from the mass.—L. A. C.

Iron and lead ores; Reduction of ——. R. J. Anderson, Assr. to International Fuel Conservation Co. U.S.P. 1,381,689, 14.6.21. Appl., 5.11.19.

Two combustion processes are maintained independently, one of complete and the other of partial combustion, and the combustion products from the two processes are delivered independently to the ore, the carbon produced by the partial combustion being utilised in the reduction of the ore.—J. W. D.

Lead and silver; Recovery of —— from ores and metallurgical products. Amalagamated Zinc (De Bavay's), Ltd. E.P. 141,044, 29.3.20. Conv., 29.3.19.

Ores and metallurgical products containing lead and silver in the form of chlorides are leached with hot brine containing ferric chloride, cupric chloride, or other substance capable of yielding chlorine, or alternatively the chloridising agent is formed *in situ* by the action of hydrochloric acid added to the brine solution. The solvent is separated from the material before there is any appreciable reversion of the silver chloride by reaction with sulphides, by carrying out the process in a moving belt filter or on filter beds having shallow layers of ore through which the solution is caused to pass rapidly by suction or pressure, or in a centrifugal machine. After leaching, the solution is allowed to cool, the lead chloride separated, and the silver recovered from the cold brine. Ores are chloridised preparatory to the process by mixing with zinc chloride and heating in a closed furnace.
—T. H. Bu.

[Cadmium and copper; Recovery of —— from residues obtained during] electrolytic treatment of ores containing zinc and other metals. Electrolytic Zinc Co. of Australasia Proprietary, Ltd. E.P. 141,688, 1.4.20. Conv., 4.4.19.

The solution of crude zinc sulphate obtained by leaching roasted zinc ores with sulphuric acid is purified, prior to electrolysis, by treatment with zinc dust or "blue powder." The precipitate produced contains copper, cadmium, and cobalt, if present, together with an excess of zinc. Cobalt-free precipitates are oxidised or roasted and then digested with sufficient dilute sulphuric acid to give a maximum zinc and cadmium extraction while leaving practically all the copper in the residue, from which it may be recovered by smelting. The solution containing the zinc and cadmium is treated in an agitating vat, in the absence of air, with "blue powder" or zinc dust sufficient to precipitate all the cadmium except for about 0·5 g. per l. The precipitate, which contains very little zinc, is roasted, treated with dilute sulphuric acid or spent electrolyte from cadmium cells, the solution is purified by agitation with excess of cadmium precipitate to remove copper, and the clear liquid electrolysed for the production of metallic cadmium. The filtrate from the bulk of the cadmium is treated with a slight excess of zinc dust to precipitate the remainder of the cadmium, an operation which is facilitated by the previous addition of about 0·5 g. of copper per l. of solution. This precipitate is worked up with further quantities of the original precipitate. Zinc may also be removed from a solution containing cadmium by agitating it at 60° C. with zinc oxide or hydroxide and then cooling to 35° C. to precipitate the zinc as basic sulphate. Blue-powder precipitates containing cobalt are oxidised and treated with dilute sulphuric acid to dissolve out the greater part of the cadmium and all the cobalt, leaving the copper and the bulk of the zinc undissolved. The bulk of the cadmium is precipitated from the solution by zinc dust as described above and the filtrate is worked up into a green cobalt-zinc oxide pigment.—A. R. P.

Zinc; Electrolytic production of ——. A. E. Hall, Assr. to American Smelting and Refining Co. U.S.P. 1,380,711, 7.6.21. Appl., 15.7.15.

Metallic zinc is deposited electrolytically from a neutral solution of a zinc salt containing chlorine, using lead anodes and successively higher current densities, whereby the acid of the zinc salt is liberated and lead peroxide and chloric acid are produced. The lead peroxide is removed from the solution, which is then used to treat the residue left from the previous treatment of an excess of zinc-bearing material, whereby the zinc of the residue is dissolved and the solution left acidic, fresh zinc-bearing material being treated with this solution, thereby neutralising it. Iron and similar impurities are precipitated from this solution, which is then transferred to the cells for deposition of the zinc, the residue being subjected to the above treatment.—J. W. D.

Zinc-bearing solutions; Purification of ——. A. E. Hall, Assr. to American Smelting and Refining Co. U.S.P. 1,380,712, 7.6.21. Appl., 7.1.16.

A zinc salt solution is electrolysed to deposit metallic zinc and liberate the acid with which it is combined; iron in amount equal to 0·044 lb. of ferric sulphate is added to each gallon of the solution, which is then treated with excess of a zinc-bearing material, whereby the zinc is dissolved, the acid neutralised, and any antimony precipitated, the neutral and antimony-free solution being then electrolysed.—J. W. D.

[Zinc] ores; Process of treating —— preparatory to smelting. J. W. Hegeler. U.S.P. 1,378,411, 17.5.21. Appl., 9.4.20.

Zinc ore, prior to smelting, is intimately mixed with coking coal or other coking material, and the mixture subjected to a coking process.—F. M. R.

[Zinc] ores; Method of treating ——. R. L. Lloyd, Assr. to Dwight and Lloyd Metallurgical Co. U.S.P. 1,378,699, 17.5.21. Appl., 22.8.19.

Zinc-bearing ore or material containing a negligible quantity of sulphur is mixed with a reducing agent and heated to a temperature below that at which zinc is reduced and volatilised, and then treated with a solvent which dissolves out the zinc component.—T. H. Bu.

Zinc; Treatment of lixiviation-residue ——. R. L. Lloyd, Assr. to Dwight and Lloyd Metallurgical Co. U.S.P. 1,378,822, 17.5.21. Appl., 10.10.19.

Ores containing zinc sulphide and other forms of zinc are roasted with the formation of soluble zinc compounds which are dissolved out with a solvent, the solid residue being then mixed with a reducing agent, heated to a temperature below that at which zinc is reduced and volatilised, and then subjected to the action of a solvent to dissolve out the remainder of the zinc.—J. W. D.

Furnace plant for annealing metals without tarnishing. A. Mond. From Metallbank und Metallurgische Ges. A.-G. E.P. 148,232, 9.7.20.

The plant consists of working and cooling chambers in communication with one or more annealing furnaces filled with inert gases under slight excess pressure. An air lock filled with inert gases permits of the working and cooling chambers being entered at any time during working without notable alteration of the inert furnace atmosphere.—J. W. D.

Furnace; Metallurgical ——. B. Talbot. E.P. 164,901, 1.4.20.

A tilting furnace is provided with two or more hearths arranged side by side with fluid-cooled passages between contiguous walls, a duct or ducts connecting the hearths below the level of the bath, and roofs for the respective hearths. The fuel gas inlet and the waste gas outlet are at opposite sides of the axis of oscillation of the furnace structure, being connected by joints (the elements of which are relatively movable) with stationary passages, including regenerator chambers, which are traversed alternately by waste gases and air. The tap-hole is adjacent to the waste gas passage with a cooling passage between.—J. W. D.

Furnaces; Open-hearth ——. J. O. Griggs. E.P. 165,002, 23.9.20.

An open-hearth furnace has a portable, removable, and replaceable back wall built of one or more rigid sections extending behind buck stays arranged to extend over an opening in the furnace which extends lengthwise of its back wall. The section or sections can be put in place or removed by means of a detachable counterweighted movable arm, each section having upper and lower apertured webs at the outer faces for that purpose.—J. W. D.

Furnace [; Galvanising ——]. C. J. Lane, and The Galvanizing Equipment Co., Ltd. E.P. 165,176, 18.3.20.

The furnace consists of a long, narrow, horizontal, cylindrical combustion chamber with a removable cover, having tuyères disposed along the lowermost part, and a rotatable drum on half bearings disposed eccentrically in the upper portion of the chamber and removable upwards when the cover is removed. Driving gear for rotating the drum also drives a fan for supplying air to the tuyères. —J. W. D.

Furnace; Ore-roasting ——. H. A. Clark, J. F. Hill, and A. G. McGregor. U.S.P. 1,380,529, 7.6.21. Appl., 19.7.20.

A roasting furnace with a central hollow rotating shaft has a burner which opens into the chamber of the furnace and is mounted to rotate with the shaft. Oil and air supply pipes, both rotating and stationary, with packed joints between, are arranged within the shaft.—J. W. D.

Furnace for heating metals. E. A. Leslie and H. M. Brigham. U.S.P. 1,382,002, 21.6.21. Appl., 18.11.18.

The heating chamber of the furnace is surrounded by an annular chamber into which the gaseous products of combustion from a combustion chamber are discharged, and whence they are distributed by means of ports into the heating chamber. Means are provided for supplying fluid fuel, air, and a diluent gas to the combustion chamber and for varying the proportions of the air and diluent gas so supplied.—J. W. D.

Melting or open-hearth furnace. F. Zimmermann. G.P. 336,982, 30.12.19.

The crown of the furnace is divided into a combustion chamber and an outlet flue for the gases, which pass through slag chambers after leaving the hearth, whereby their speed is reduced and particles of dust and slag contained in them are deposited. The purified gases are much less destructive to the walls of the outlet flue. —A. R. P.

Ores; Flotation processes for concentrating ——. Elektro-Osmose A.-G. (Graf Schwerin Ges.). E.P. 143,920, 28.5.20. Conv., 29.7.18.

To the finely comminuted ore in aqueous suspension an electrolyte is added having a charge of the same kind as the particles to be separated, so as to bring a part or parts of the gangue into the sol condition. It is generally advantageous to separate the parts in suspension and subject the residue to the flotation process with further addition, if necessary, of the sol-forming substance. As floating agent a substance is used which does not prevent or destroy the sol condition. Substances which would prevent sol formation are separated before treating the ore, *e.g.*, by a washing operation. (Reference is directed, in pursuance of Sect. 7, Sub-sect 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 107,401, 105,627, 8253 and 5454 of 1915, 17,327 of 1914, 26,262 of 1910, 2359 of 1909, 6148 of 1908, 7803 of 1905, and 18,660 of 1904; J., 1917, 968, 654; 1916, 895; 1915, 910; 1912, 31; 1910, 496; 1909, 839; 1906, 184; 1905, 1019.)—T. H. Bu.

Minerals; Flotation of ——. R. E. Sayre, Assr. to Metals Recovery Co. U.S.P. 1,378,562, 17.5.21. Appl., 25.1.21.

A small amount of an aldehyde condensation product is added to the mineral pulp and the mixture subjected to a flotation operation. —T. H. Bu.

Alloy; Metal scavenging —— and process of making and using the same. R. Haddan. From Light Metals Co. E.P. 165,166, 17.3.20.

An alloy of aluminium containing 10% of uranium is prepared and added in proportion of 150 pts. to a molten bath containing together about 47,170 pts. of aluminium and magnesium (*e.g.*, 44,000 pts. Al and 3170 pts. Mg). The alloy is suitable for scavenging iron and steel.—J. W. D.

Aluminium and its alloys; Chill casting of pure ——. A. Riccio. E.P. 165,362, 20.9.20.

A hollow core of common foundry sand thin enough to yield or collapse as the casting contracts is used on account of the high contractibility of the alloys on solidifying.—J. W. D.

Heat exchanging bodies; Manufacture of —— [by electrodeposition]. H. F. B. Jorgensen. E.P. 165,691, 2.9.20.

For the manufacture of radiators and other hollow heat-exchanging bodies a copper coating is deposited from a neutral bath on a matrix of easily fusible metal. When a firm deposit has been obtained the matrix is removed from the bath, thoroughly washed and immersed in the depositing bath proper until the copper deposit has attained the requisite thickness. The matrix is then removed by immersion in melted metal of the same kind as that of which it is made.—A. R. P.

[*Electroplating.*] *Electrolytic apparatus and process. Electrolytic process, product, and apparatus.* M. M. Merritt, Assr. to Copper Products Co. U.S.P. (a) 1,381,882 and (b) 1,381,883, 14.6.21. Appl., (a) 2.11.17 and (b) 2.8.18.

(a) A coating of metal of uniform thickness is produced on a revolving cylindrical drum by partly immersing it, as cathode, in an electrolyte and using, as anode, a mass of relatively small pieces of metal so disposed that their general surface is radially equidistant from the surface of the drum. (b) An electrolytic apparatus for use in depositing metal on a flexible cathode consists of a reel on which the cathode is wound and to which the ends are secured, and bars for supporting the intermediate portions of the cathode. By means of a differential driving gear the bars and the portions of the reel to which the ends of the cathode are secured may be driven at different speeds, whereby the points of contact of the flexible cathode on the bars may be varied.—A. R. P.

Electro-magnetic separation or concentration of minerals. W. M. Mordey. E.P. 165,822, 28.3.19.

A stream of the finely divided mineral is caused to pass longitudinally over a relatively long and narrow path arranged adjacent to the parallel poles of an alternate current multiphase system, the stream thereby being subjected to the action of the multiphase moving magnetic field in such a way that magnetic material becomes separated from inert material and is gradually swept in a lateral direction to one side of the path, while the inert material is caused to move in the opposite lateral direction to the opposite side of the path. The separated magnetic and inert matter may either travel along opposite side portions of the longitudinal path and be discharged from one end, or the magnetic matter may be discharged over the side or sides of the path, while the inert matter travels along one side or the centre of the path and is discharged at one end.—J. W. D.

Electrostatic separation of materials [e.g., ores]; Process and apparatus for the ——. H. S. Hatfield, and The Imperial Trust for the Encouragement of Scientific and Industrial Research. E.P. 165,892, 7.2. and 4.11.20.

The mixture of finely divided substances, such as an ore mixture, is suspended in a liquid or mixture of liquids such that the dielectric capacity of the liquid lies between that of the substances to be separated, so that on producing an electrostatic field between electrodes connected with a current supply of high potential and immersed in the liquid, one constituent of the mixture is attracted into the field while the other is repelled. Aniline is a suitable liquid for separating cassiterite from tin ores; the conductors are 0·25—1 mm. apart and are charged with an alternating current of 200 volts. With fine suspensions about 1% of neat's foot oil is added as a deflocculating agent. Blende and galena may be separated from a suspension in equal parts of paraffin oil and aniline or nitrobenzene. The process is carried out in a vessel provided with two limbs, one of which consists of a tube in which are arranged two parallel plates covered with fine metallic points and suitably insulated. The liquid flows down this tube while the current is on and the valuable ore constituent is attracted to, and collects on, the points, from which it is removed from time to time by means of a current of pure liquid. Another method of carrying out the process is to pass the sus-

pension over a series of parallel conductors, alternately oppositely charged, arranged on a flat plate of non-conducting material. A third apparatus consists of a vessel divided by a number of metal gratings, alternately oppositely charged, through which the suspension flows. One of the conducting boundaries of the electric field may consist of a conducting liquid which is immiscible with that used for the suspension, and water or other suitable liquid may serve as electrodes.
—A. R. P.

Converter-slag; Granulating ——. S. R. Garr, Assr. to American Smelting and Refining Co. U.S.P. 1,378,223, 17.5.21. Appl., 18.10.19.

A molten charge of slag is poured in a stream into a reverberatory ore smelting furnace and a stream of steam under relatively high pressure projected against the falling slag stream causing disintegration of the slag and spreading it over a large portion of the charge in the furnace.
—J. W. D.

Vanadium; Method for recovering ——. L. S. Copelin. U.S.P. 1,381,802, 14.6.21. Appl., 28.5.20.

Vanadium ores and compounds are heated with sodium sulphide solution.—J. W. D.

Alloy. C. Vos. U.S.P. 1,382,147, 21.6.21. Appl., 4.9.20.

An alloy possessing degasifying and deoxidising properties consists of aluminium with a smaller proportion of magnesium and still smaller proportions of ferrosilicon and zirconium.

Copper-aluminium compound [alloy]: Manufacture of a ——. A. Uhlmann. G.P. 335,888, 1.2.18.

A hard, tenacious alloy, thermo-electric power −20·8 microvolts, containing 36·43% Cu and 63·57% Al, corresponding to the formula $CuAl_4$, is prepared by melting together copper and aluminium in quantities proportional to their atomic weights, and subsequently adding a quantity of aluminium corresponding to three atoms, and heating to 1050° C.—L. A. C.

Alloys; Manufacture of ——. H. C. Grosspeter and W. Schuen. G.P. 336,519, 10.6.15.

In the manufacture of alloys from metals which tend to separate by liquation a portion of the chief metal is melted, sodium and then the other metals to be alloyed with the chief metal are added, and finally the remainder of the chief metal is added. The sodium is separated from the alloy by electrolytic means during the alloying and reducing processes.—L. A. C.

Metals; Process and apparatus for melting ——. Wolfram Ind. A.-G. G.P. 336,727, 21.3.18.

The metal is melted in a horizontal crucible constructed of the same metal, cooled on the exterior and fitted with an outlet tube at the bottom closed by the wall of the crucible itself or by a special stopper. The stopper or the bottom of the crucible is melted at the end of the process to allow the molten metal to flow away through the outlet tube, or the whole crucible may be melted. For successful operation of the process, the cross-section of the material conducting the electric current must change uniformly as the contents of the crucible melt.—L. A. C.

Briquetting turnings and scrap of metals and alloys. R. Walter. G.P. 337,296, 19.10.20.

Metal scraps or turnings are treated either before or during the briquetting with solutions of substances which dissolve the impurities and oxides adhering to the surfaces and which tend to cause agglomeration of the mass. If the metal is to be briquetted by the hot process, it is first treated with the necessary solutions and pressed cold, then put through the hot process.—A. R. P.

Copper sulphate. G.P. 336,020. *See* VII.

XI.—ELECTRO-CHEMISTRY.

Electrolytic cell; New type of ——. H. S. Lukens. J. Ind. Eng. Chem., 1921, **13**, 562—563.

An electrolytic cell of the two-compartment type comprises an outer metal vessel, constituting one electrode, and an inner porous vessel in which is placed the other electrode of special construction. This is formed from a rectangular sheet of metal of such size that when rolled it fits loosely into the porous vessel and is several mm. shorter. On its surface are marked series of rectangles which are cut through the metal along three of their sides, and of which alternate ones are bent outwards at an angle of 30° on opposite sides of the sheet. This electrode is attached to a circular lead plate, fitted in a rubber collar, and forming the cover of the porous cell. In an opening in the cover is fixed a cork with glass tube as gas-vent, and through a mercury seal in the cover a glass stirrer can operate in the porous vessel. The cell is suitable for electrolysis of suspensions of nitrobenzene, benzene and toluene, or anthracene, in dilute sulphuric acid, as well as for electrolysis of electrolytes in which all the constituents are in complete solution. Its advantages are ready assembling and dismantling, elimination of gas loss by diffusion through the porous cell, reduction of voltage drop owing to the electrodes being close together, and convenience in studying the efficiency of reaction by observation of the amount of gas escaping through the vent.
—W. J. W.

Patents.

Melting oxides etc. without contamination: Method and apparatus for —— *[by means of a high frequency electric current].* E. F. Northrup, Assr. to Ajax Electrothermic Corp. U.S.P. 1,378,189, 17.5.21. Appl., 30.7.19.

Metallic oxides and similar substances are melted

in a crucible composed of a metallic oxide having a melting point higher than the intended temperature of the melt and containing a molten layer of the metal the oxide of which is being melted.
—J. S. G. T.

Furnace; [Electric] melting ——. E. F. Collins, Assr. to General Electric Co. U.S.P. 1,378,526, 17.5.21. Appl., 10.1.20.

An electric heating device is disposed within a chamber adapted to contain a pool of molten metal, the chamber being connected by a conduit with a second chamber adapted to receive charges of unfused material. Means are provided for causing currents of molten material to be interchanged between the chambers through the conduit, whereby unfused material is subjected to the washing action of molten material while solid impurities are retained in the charging chamber.—J. S. G. T.

[Carbon] electrodes; Process and apparatus for making ——. W. G. Michel. U.S.P. 1,378,599, 17.5.21. Appl., 17.12.19.

A carbon electrode is composed of pulverised dry carbon mixed with a fluid hydrocarbon, and baked to a solid mass, the heating and mixing being effected under vacuum and pressure.—J. S. G. T.

Carbon electrodes; Process of manufacturing ——. A. Bergström. G.P. 336,877, 30.4.19.

To obtain electrodes of greater durability and conductivity, raw materials of different nature and origin are finely ground and mixed with material which has been similarly prepared, briquetted, treated to remove gas, and ground to different degrees of fineness. The whole is then mixed with tar or the like and pressed into the form of electrodes.—J. S. G. T.

Electrodes; Process for preventing the passage of carbon from —— *into the surrounding electrolyte.* Elektro-Osmose A.-G. (Graf Schwerin Ges.). G.P. 336,559, 16.1.19.

A neutral colloidal material dispersed in a solid or liquid medium is introduced between the carbon electrode and the electrolyte. Thus a sheath or layer composed of a mixture of a neutral substance such as clay, kaolin, graphite, etc., and an insoluble acid-resisting binding material, such as celluloid etc., may surround the carbon electrode. Electrodes so constituted may then be placed within a cell surrounded by a diaphragm and containing a colloidal suspension of a neutral substance.
—J. S. G. T.

Ozone; Apparatus for producing ——. R. Goedicke. G.P. 336,943, 6.7.19.

The yield of ozone is increased by using a number of concentric, tubular electrodes, constructed of wire-gauze or of wire spirals, and cooled on both the inner and outer sides by a current of air.—L. A. C.

Electric furnaces. R. R. Reed. E.P. 161,154, 30.12.20. Conv., 27.3.20.

XII.—FATS; OILS; WAXES.

Montan wax and a new method of determining the acid and saponification values of dark-coloured oils, fats, and waxes. R. Pschorr, J. K. Pfaff, and W. Berndt. Z. angew. Chem., 1921, 34, 334—336.

Methods of determining acid and saponification values are given for substances which are easily soluble in alcohol and are free from resin, and for substances which are soluble with difficulty in alcohol or contain resin. For montan wax an acid value between 22·6 and 23·1 and a saponification value of about 77 were found. The method depends upon the fact that acids present in the oils, fats, and waxes examined, with the exception of resin acids, can be converted into calcium salts only slightly soluble in alcohol and in water by boiling their alcoholic solution with sodium acetate and calcium chloride. The coloured substances are precipitated on cooling and diluting with water, and are removed, together with the calcium salts, by filtration; the liberated acetic acid can be titrated using phenolphthalein as indicator.—W. P.

Saponification value, iodine-bromine value, and bromine-substitution value; Determination of the ——. E. Schulek. Pharm. Zentralh., 1921, 62, 391—395.

Saponification is completed in a very short time when propyl alcohol is used as solvent in the determination of the saponif. value of fats and waxes (*cf.* Winkler, J., 1911, 556). In the case of linseed oil, croton oil, and lanolin, the iodine-bromine value increases with increased time of contact of the oil with the reagent; with lanolin, the value increases by 19 units when the time of contact is increased from 2 hrs. to 24 hrs. In the determination of the bromine substitution value, the reaction is practically complete with most oils and fats after 2 hrs.
—W. P. S.

Turkey-red oils; Analysis of ——. J. F. L. Reudler. Chem. Weekblad, 1921, 18, 419.

Ten g. of Turkey-red oil, mixed with five times its volume of water, is heated to 90° C. with excess of sulphuric acid. After cooling, the volume of the fatty acids is read off in a graduated tube. The results agree to within 1% with the amount of castor oil originally used, and the colour of the fatty acids gives a clue to the quality of the raw material. An indefinite separation implies presence of albumin in the castor oil.—W. J. W.

Fat-soluble vitamin. Steenbock and others. *See* XIX A.

Patents.

Oil-containing vegetable materials; Treatment of —— *prior to the extraction of the oil therefrom.* K. Erslev. E.P. 141,341, 31.3.20. Conv., 9.4.19.

The oil-containing material is treated with dry steam of 1⅓—3 atm. pressure for ½—2 hrs. and then hot air or an indifferent gas is blown through until the material has attained the desired degree of dryness (for at least 1 hr.). Owing to the destruction of all enzymes decomposition can no longer take place, and the taste of the product is favourably influenced.—H. C. R.

Extracting oil or fat by means of volatile solvents; Apparatus for ——. J. Arii. E.P. 165,226, 25.3.20.

The extraction vessel is jacketed and is heated by the vapour of the boiling solvent passing through the jacket and also by a steam coil, and is traversed by lateral pipes which increase the heating surface and also prevent conglomeration of the material being extracted. The distillation vessel below the extraction vessel is heated by a steam jacket and coil. The lower part of the extraction vessel communicates with the distillation vessel by way of a siphon.—H. C. R.

Oils and fats; Process for neutralising ——. H. W. Salomonson. E.P. 165,635, 20.5.20.

A solution of the oil or fat in a volatile solvent of low sp. gr., such as benzine or ether, is treated with a solution of alkali, or sodium silicate, of such concentration that the soap stock formed separates easily from the solution of fatty matter in a solid and compact state.—H. C. R.

Catalysers; Art of making ——. *Catalyser and method of producing same. Catalyser for oil-hardening and process for making.* C. Ellis. U.S.P. 1,378,336—8, 17.6.21. Appl., (A) 8.2.16, (B) 24.11.16, (C) 30.12.19.

(A) An organic salt of a catalytic metal, *e.g.*, nickel, is incorporated in an oily vehicle and heated at a pressure below atmospheric, until the major portion of the organic radicle is volatilised. A current of hydrogen may be passed through during the heating. (B) A catalyst is made by reducing nickel from nickel oleate as described under (A), but in the absence of reducing gases. An inert gas may be passed through the oily mixture during heating. (C) A finely divided, highly active mixed metal catalyst may be made by reducing a mixture of metallic salts of nickel, copper, and cobalt in an oily vehicle.—H. C. R.

Catalyst masses; Utilisation of —— [*after use in hydrogenation*]. W. Hoskins. U.S.P. 1,381,558, 14.6.21. Appl., 31.1.21.

The catalyst mass left after hydrogenation of a fat is mixed with a solvent acid at a temperature sufficiently high to liquefy the fat. The mixture is then filtered, and the catalyst carrier thereby separated.—H. C. R.

Oleo and stearine; Separation of —— *from fats.* C. H. Hapgood, Assr. to The De Laval Separator Co. U.S.P. 1,381,705, 14.6.21. Appl., 20.5.20.

The fat is mixed with a liquid which is heavier than the oleo, and subjected to centrifugal force. The oleo is discharged separately from the heavier liquid and the stearine. The two latter are then again subjected to centrifugal force to separate the stearine.—H. C. R.

Oils from foots; Process of separating ——. C. H. Hapgood, Assr. to The De Laval Separator Co. U.S.P. 1,381,706, 14.6.21. Appl., 24.5.20.

After separating the coarser particles by filtration, the material is mixed with a heated liquid of greater sp. gr. than the oil, the mixture is subjected to centrifugal force, and the oil separately discharged, whereby the other liquid carries off the solid particles not removed by the filtration. The heated liquid can be purified and used again. —H. C. R.

Bay berry fat; Production of an edible fat from ——. K. Paal. G.P. 309,145, 18.7.17.

The bay berry fat is treated with steam and, before or after decolorisation, freed from bitter flavour by means of boiling ethyl or methyl alcohol, the fat being maintained at 40°—50° C. meanwhile by cooling. The product is edible at this stage, but its consistency and stability may be improved by subjecting it to a slight hardening process and then heating it at 130° C. to remove volatile substances formed during the hardening process, which affect its flavour and odour. The product is innocuous, readily assimilable, and superior to coconut oil and palm oil owing to its higher content of glycerides of unsaturated fatty acids of high molecular weight.—J. H. L.

Soap powder; Production of ——. *Production of crystallised substances, especially soap powder.* A. Imhausen. G.P. (A) 310,122, 29.3.18, and (B) 310,625, 11.6.18.

(A) A liquefied soap is strongly cooled, if necessary below the freezing point, and then slowly warmed to the ordinary temperature. Crystallisation is thereby accelerated. If the cooled mass is kept in motion a fine crystalline meal is formed, so that grinding becomes unnecessary. (B) Liquefied gases, *e.g.*, liquid air, are mixed with the liquefied soap. This avoids the use of refrigerating machines and also bleaches the soap powder.—J. H. L.

Fatty acids [*for soap production*]; *Substitute for* ——. R. Willstätter. G.P. 336,212, 19.3.19.

Alkali salts of hydrogenised derivatives of phenylnaphthylmethane-*o*-carboxylic acid, $C_{10}H_7.CH_2.C_6H_4.COOH$, may be used as soaps.—J. H. L.

Hydrogenating oils; Process and apparatus for ——. A. J. MacDougall, Assr. to National Electro Products, Ltd. U.S.P. 1,381,319, 14.6.21. Appl., 22.5.19.

See E.P. 150,802 of 1919; J., 1920, 727 A.

Catalysts. E.P. 164,808 and U.S.P. 1,381,969. *See* I.

Resin oil. G.P. 336,253. *See* XIII.

XIII.—PAINTS ; PIGMENTS ; VARNISHES ; RESINS.

Pinabietic acid, a definite resin acid. I. Isolation and purification. O. Aschan. Annalen., 1921, 424, 117—133.

By methods fully described in the original a well-characterised crystalline acid, $C_{20}H_{30}O_2$, can be separated from the less volatile fractions obtained on distilling pine oil in a current of superheated steam. It melts at 182°—183° C., and forms the following sodium salts:—$C_{20}H_{29}O_2Na$; $C_{20}H_{29}O_2Na,2C_{20}H_{30}O_2$; $C_{20}H_{29}O_2Na,3C_{20}H_{30}O_2$. (*Cf.* J.C.S., Sept.)—C. K. I.

Pinabietic acid, a definite resin acid. II. Molecular weight and rotatory power. O. Aschan and K. E. Ekholm. Annalen, 1921, 424, 133—150.

Pinabietic acid (*cf. supra*) has the normal molecular weight in boiling ether. Its rotatory power is affected to a remarkable degree by the nature of the solvent employed, the general tendency being to exhibit strong dextro-rotations in benzenoid solvents and lævo-rotations of a similar magnitude in aliphatic solvents. (*Cf.* J.C.S., Sept.)—C. K. I.

Pinabietic acid, a definite resin acid. III. Constitution. A. I. Virtanen. Annalen, 1921, 424, 150—215.

As a result of a fairly extensive examination of the properties and reactions of pinabietic acid (*cf. supra*) a formula for this substance is suggested. (*Cf.* J.C.S., Sept.)—C. K. I.

Fossil resins. Engler and Tausz. *See* IIa.

Patents.

Resin oil; Conversion of light —— into heavy resin oil, a substance resembling fat, and pitch suitable for use in varnish manufacture. G. Ruth and E. Asser. G.P. 336,253, 9.5.20.

Resin oil of b.p. 200° C. or higher is treated under a reflux condenser with a current of air containing 10—15% of highly-superheated steam until it becomes solid or nearly solid. The product on distillation yields 20—30% of unchanged oil, 30—40% of heavy resin oil or a substance resembling fat, and 30—40% of black pitch.—L. A. C.

Binding material for paints; Preparation of ——. J. Uhr. G.P. 337,063, 19.11.19.

A hot aqueous solution of caustic soda (1:7) is added in a fine stream, with constant stirring, to a cold, thick paste of rye meal and water until a pasty mass is obtained which may be mixed in any required proportion with the colour paste in place of size. The mixture is suitable for covering walls and ceilings, and does not become mouldy or lead to the formation of efflorescences of saltpetre.
—A. R. P.

Paint; Water-resistant ——. Plönnis und Co. G.P. 337,189, 13.11.18. Addn. to 301,783 (J., 1921, 311 A).

Petroleum tar oil is added to the mixture specified in the chief patent. The resulting paint gives brighter tones and is suitable for use in optical signals.—A. R. P.

Paints or varnishes; Manufacture of ——. The Koppers Co., Assees. of M. Darrin. E.P. 138,068, 30.12.19. Conv., 18.1.19.

See U.S.P. 1,315,658 of 1919; J., 1919, 834 A. The mixing is effected at a temperature of 350°—570° F. (about 180°—300° C.). (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 17,378 of 1900 and 21,667 of 1911; J., 1901, 1123; 1912, 81.)

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Patents.

Rubber products; Manufacture of ——. Goodyear Tire and Rubber Co., Assees. of R. C. Hartong. E.P. 146,993, 6.7.20. Conv., 25.10.18.

Finely-divided "dusty" compounding ingredients, such as carbon black, instead of being directly introduced into the rubber, are first mixed with a gel or solution of any colloid such as glue, together with a small percentage of non-aqueous liquid, such as pine oil, asphaltic oil, or glycerin; the mixture is then incorporated with the rubber in the usual way. The modified procedure enhances the homogeneity of the final mixture.—D. F. T.

Indiarubber goods; Method of producing decorative surfaces on ——. C. E. Leheup. E.P. 165,200, 22.3.20.

The vulcanised rubber article is coated with a rubber enamel solution, dried, again coated by dipping in a second enamel solution of any colour and dried; the enamel coating is then treated with a vulcanising liquid or vapour, and the article is finally immersed in naphtha for the development of the desired matt surface; the outer layer of "enamel" rises from the under coating in the form of lines giving the appearance of irregularly woven filaments.—D. F. T.

Rubber boot and shoe soles; Solution or adhesive for uniting —— to leather soles and the like. A. A. Crozier. E.P. (A) 165,572, 15.4.20, and (B) 165,606, 6.5.20.

A solution of deresinised gutta or balata in (A) carbon bisulphide (1:3) or (B) in carbon tetrachloride (1:3) with the possible addition of 10% of cobbler's wax is used.—D. F. T.

Rubber; Process of reclaiming ——. E. Muschewski and W. W. Wood. U.S.P. 1,381,654, 14.6.21. Appl., 13.12.20.

Old rubber is finely divided, then moulded under heavy pressure with simultaneous application of heat, and finally, after being cooled in the air, subjected to a temperature of about 300° F. (150° C.) for 60 mins.—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Quebracho; Identification of —— in tanning materials. L. Jablonski and H. Einbeck. Ledertechn. Runds., 1921, 13, 41—43. Chem.-Zentr., 1921, 92, IV., 75—76.

By fusion of quebracho tannin with potassium hydroxide, protocatechuic acid and resorcinol are formed, but no phloroglucinol. Oxidation with nitric acid gives rise to formation of styphnic acid (trinitroresorcinol) in addition to oxalic acid and other products. The detection of quebracho tannin in presence of other tanning agents may be effected by first extracting the quebracho-tannin with ethyl acetate. Fat-free leather, for example, is extracted with alcohol, the alcoholic extract distilled, and the aqueous solution of the distillation residue extracted with ethyl acetate. After distilling off the ethyl acetate the residue is fused with phthalic anhydride and a little zinc chloride, when, if quebracho tannin was present, fluorescein is formed.
—W. J. W.

Patents.

Leather for linings, especially from inferior portions of hides; Process for increasing the durability of ——. H. Hoffmeister and J. Paessler. G.P. 335,484, 25.9.19. Addn. to 324,495 (J., 1920, 793 A).

In the process described in the chief patent, the wood-tar is dissolved in a mixture of benzene and a mineral oil, and addition of an organic acid is omitted. Vegetable-tanned leather is washed with a solution of formalin, an organic acid (*e.g.*, formic acid), and ferrous sulphate in water, and mineral-tanned leather is steeped in a strong solution of a tanning agent, or in purified, concentrated sulphite-cellulose waste liquor containing formalin, and an organic acid or ferrous sulphate, before impregnation with the wood-tar solution.

Leather; Dyeing alum-dressed —— with coal-tar dyes. Badische Anilin- und Sodafabr. G.P. 335,907, 17.5.18.

Uniform, full shades are produced by treating the leather before dyeing with a solution of a synthetic tanning agent.—L. A. C.

Catgut; Sterilisation of ——. Hageda, Handelsges. Deutscher Apotheker m.b.H. G.P. 336,799, 10.3.20.

Catgut which has been treated by the Claudius iodine-potassium iodide process is treated with sodium thiosulphate, washed with water and alcohol, and finally heated to 100° C. in sealed glass tubes in the presence of alcohol. The resulting catgut is sterilised, stable, and elastic.
—B. V. S.

XVI.—SOILS; FERTILISERS.

Patents.

Manure; Chemical ——. F. A. Gonzalez, V. V. Sanchez, and E. D. y F. do Llanos. E.P. 165,604, 5.5.20.

The fertiliser consists essentially of a graphitic mineral mixed with lime or chalk, the graphite being 14—16% of the whole. The graphite promotes nitrification in the soil.—A. G. P.

Fertiliser; Process of preparing a ——. P. Schmidt, Assr. to Landwirtschaftliche Handelsges. m.b.H. U.S.P. 1,378,284, 17.5.21. Appl., 20.4.20.

The fertiliser consists of a mixture of magnesium hydroxide and lime, prepared by treating lime with a solution of a pure magnesium salt.—A. G. P.

Ammonium nitrate mixture; Production of a non-explosive ——. Badische Anilin- u. Soda-Fabrik. G.P. 336,876, 11.6.18.

Solid ammonium nitrate is mixed with the residue resulting from the treatment of gypsum with ammonia and carbon dioxide. Such a mixture does not evolve any appreciable quantity of ammonia when brought into contact with limestone or chalk. —J. S. G. T.

Insecticide. U.S.P. 1,381,586. *See* XIXb.

XVII.—SUGARS; STARCHES; GUMS.

Sugar; The question of loss of —— *by "atomisation" during evaporation.* W. D. Helderman and C. Sijlmans. Arch. Suikerind. Nederl.-Indië, 1921, **29**, 495—500. Int. Sugar J., 1921, **23**, 403—405.

In order to test Schweizer's theory (J., 1921, 55 A) of the decomposition of sucrose during evaporation, owing to the "atomisation" of the entrained spray, by the rush of vapour through the pipes connecting the units of the multiple effect, laboratory experiments were made in which solutions containing 6—10% of sucrose and 0·1—3·2% of reducing sugars were sprayed while hot in the form of a fine cloud through a distance of about 40 cm. (16 in.), each lot of liquid being submitted to this "atomising" action 5 or 10 times. It was concluded from these experiments that no detectable amount of sucrose is decomposed, either by atomisation in a current of air at atmospheric pressure, or by atomisation in a space under reduced pressure, and further, that the presence of reducing sugars or salts, *e.g.*, potassium chloride, exerts no influence. (*Cf.* Abelous and Aloy, J., 1919, 475 A.) —J. P. O.

Molasses; Kalshoven's method of determining grain (fine crystal) in ——. W. D. Helderman and C. Sijlmans. Arch. Suikerind. Nederl.-Indië, 1921, **29**, 253—255.

Experiments are described showing that good results are obtained by Kalshoven's method (J., 1920, 126 A) when not more than 10 g. of water is used to dissolve the fine grain present in 100 g. of molasses. (*Cf.* Dedek, J., 1921, 523 A.)—J. P. O.

Sugar solutions; Refractive indices and dispersions of ——. H. Schulz. Z. Ver. deuts. Zuckerind., 1921, 347—359.

It is considered doubtful whether the values for the refractive indices of sugar solutions at 20° C. compiled by Krüss (J., 1921, 124 A) from the tables of Matthiessen, Main, and Schönrock (and based on a smoothed-out curve) can really be regarded as the most trustworthy. Schönrock pointed out that the error in his determinations was only about 1 unit in the 5th decimal place of the refractive index, whereas these new values of Krüss, as compared with those of Schönrock, show differences amounting to 4 units in the 4th place.—J. P. O.

Dextrose, lævulose, sucrose, and dextrin; Determination of —— *in the presence of each other.* A. Behre. Z. Unters. Nahr. Genussm., 1921, **41**, 226—230.

The dextrose is determined by oxidation with iodine in alkaline solution as described by Willstätter and Schudel (J., 1918, 556 A); if the determination is repeated after the sample has been inverted by heating with hydrochloric acid, the additional quantity of dextrose found is that derived from the sucrose, and is a measure of the amount of this sugar. To determine the lævulose, the solution remaining after oxidation of the dextrose is treated with lead acetate to remove iodide and gluconic acid, and the cupric-reducing power of the solution then gives the amount of lævulose present. The iodometric method may also be used for the determination of dextrose and dextrin in commercial starch syrup, the increased amount of dextrose found after the sample has been hydrolysed for 3 hrs. with hydrochloric acid being a measure of the dextrin; if lævulose is also present, it is decomposed to a certain extent by the prolonged acid treatment, but the products of the decomposition can be removed by treatment with lead acetate before the dextrose is determined.—W. P. S.

Galactose; Preparation of ——. E. P. Clark. J. Biol. Chem., 1921, **47**, 1—2.

A solution of lactose in 2½ times its weight of 2% sulphuric acid is boiled for two hours, then neutralised with barium carbonate, and the solution decanted through a layer of active carbon. The filtrate is concentrated under diminished pressure until its weight is 1·1 times that of the lactose taken. Galactose slowly crystallises on addition of ethyl and methyl alcohol to the warm syrup and seeding. The crude product is purified by adding a few c.c. of glacial acetic acid to a 25% aqueous solution, concentrating, and then saturating with 95% alcohol.—E. S.

Sugars; Unsaturated reduction products of the —— *and their transformations. II. New anhydrosugars. Synthesis of a glucosidomannose. Structure of cellobiose.* M. Bergmann and H. Schotte. Ber., 1921, **54**, 1564—1574.

Glucal is oxidised by perbenzoic acid to mannose with intermediate formation of anhydromannose (J., 1921, 315 A); the latter is converted by water into mannose and by methyl alcohol into methylmannoside. Rhamnal and cellobial similarly yield methyl derivatives and a new method of obtaining glucosides appears to be opened up, which, so far, has only led to the production of α-forms. Additional evidence in favour of the constitution assigned to cellobiose by Haworth and Leitch (J., 1919, 691A) is brought forward. (*Cf.* J.C.S., Sept.) —H. W.

Polysaccharides; Acetolysis of ——. M. Bergmann and F. Beck. Ber., 1921, **54**, 1574—1578.

By the use of a mixture of acetyl bromide, acetic acid, and much hydrogen bromide, acetylation, hydrolysis, and bromination are effected, the latter frequently occurring in such a manner as to throw considerable light on the structure of the parent polysaccharide. Under these conditions rice starch gives acetylbromoglucose in 85% yield, whereas cellulose is far less readily attacked and ultimately yields penta-acetylglucose (40%). Triacetyl-γ-methylrhamnoside gives acetylbromorhamnose. (*Cf.* J.C.S., Sept.)—H. W.

Glucosans; Polymerisation of ——. A. and J. Pictet. Comptes rend., 1921, 173, 158—160.

Glucosan when heated with zinc chloride at 135° C. undergoes polymerisation, giving diglucosan under a pressure of 15mm., and tetraglucosan at atmospheric pressure. Lævoglucosan at 155° C. in an open vessel gives tetralævoglucosan. These polymerides do not react with phenylhydrazine, and are only very feeble reducing agents. They are readily hydrolysed by dilute acids with formation of dextrose.—W. G.

Mannitol; Polarimetric determination of ——. J. Badreau. J. Pharm. Chim., 1921, 24, 12—19.

In the presence of arsenious acid, the rotatory power of mannitol is increased, especially in alkaline solution; and if the ratio of carbohydrate-alcohol to As_2O_3 is at least 1:17·5, the $[\alpha]_D$ becomes constant at +46·53°. On mixing 20 c.c. of a solution of mannitol (containing not more than 0·34 g.) with 30 c.c. of a solution containing 198 g. of arsenious acid and 132·5 g. of sodium carbonate in 1000 c.c., filtering, and polarising, the content x of mannitol is found from the equation $[\alpha]_D = \alpha V/lx$, in which α is the observed reading, V=50, and l is 2 or 5 according to the length of the tube used. It is stated that in general the rotation of pentoses, hexoses, ketohexoses, disaccharides, and polysaccharides is unaffected by the alkaline reagent; and that thus by a double polarisation mannitol may readily be determined in admixture with one or more of these. Cyclic polyalcohols (as the quercitols and inositols) vitiate the determination, as does also ethyl alcohol and glycerol.—J. P. O.

XVIII.—FERMENTATION INDUSTRIES.

Malt; Determination of the diastatic power of ——. W. Windisch and P. Kolbach. Woch. Brau., 1921, 38, 149—151.

A modification of Baker and Hulton's method (J., 1921, 272 A) is recommended. 25 g. of the finely-ground malt is digested with 500 c.c. of water for ½ hr. at 50° C. with constant stirring, and the mash is then cooled, made up to 525 g., and filtered. Of the filtrate 5 or 10 c.c., according to the character of the malt, is mixed with 100 c.c. of a freshly-prepared 2% solution of soluble starch, and the mixture is kept at 20° C. for exactly 30 mins., and then treated with 10 c.c. of $N/10$ sodium hydroxide solution and made up to 200 c.c. 30 c.c. of this, transferred to a flask, is treated with 20 c.c. of $N/20$ iodine solution and 30 c.c. of $N/10$ sodium hydroxide, and after 10 mins. 4 c.c. of $N/1$ sulphuric acid is added and the free iodine is titrated with thiosulphate solution. 1 c.c. of $N/20$ iodine consumed corresponds to 8·55 mg. of maltose. A correction is made for the iodine absorbed by the malt extract, which is determined in a separate titration. The diastatic power is expressed as g. of maltose produced per 100 g. of malt.—J. H. L.

Malt analysis; Application of the Zeiss immersion refractometer to ——. K. Geys. Z. ges. Brauw., 1921, 106—110.

Experiments extending over several years showed that in determining the extract in malt (by the German Congress method), where worts ranging from 8° to 8·8° Balling are obtained, the extract-content of the worts may be determined with sufficient accuracy by means of the Zeiss immersion refractometer. The refractometer reading at 17·5 C. (corrected for the water reading at the same temperature) is divided by a factor which varies from 3·945 for a corrected refractometer reading of 32 scale divisions, to 3·960 for a reading of 35 divisions. Over this range the variation of the factor with the corrected refractometer readings is practically linear. The extract-contents of worts found in this way agree closely with the values determined pycnometrically; differences of 0·03°—0·04° Balling are very rare. The adjustment of the wort temperature to 17·5° C. for the refractometric reading must be made with great care, and the room temperature should not differ by more than 1° C. from this standard. (*Cf.* Mohr, J., 1906, 395.)—J. H. L.

Brewers' spent grains; Examination of ——. F. Eckhardt. Z. ges. Brauw., 1921, 81—84, 89—92, 97—101, 103—106, 111—115.

The analysis of spent grains is of great value in brewery control, and where the worts produced are of low gravity it affords more accurate information as to the degree of extraction of the malt than can be obtained by the usual method of determining the brew-house yield. A representative sample of the grains may be obtained by mixing a number of small samples taken from the outlet of the grains screw conveyor. The percentage of soluble extract in the grains may most conveniently be found by calculation from the moisture-content of the sample and the sp. gr. of the liquid expressed therefrom by means of a hand press. It is best to use the last runnings from the press for the determination of sp. gr., since they have a slightly lower gravity than the first runnings and probably represent more nearly the average for the whole of the liquid contained in the sample. If the soluble extract has to be determined on a dried sample, the author recommends mixing 25 g. of the finely-ground material with water (200 c.c.) at 70° C., allowing the mixture to digest until cold, and then making up to 300 g., mixing well, filtering, and determining the sp. gr. of the filtrate; this method, however, gives higher results than the former one. For the determination of undissolved extract in grains a standard method is badly needed. The author suggests one in which 25 g. of the dried and finely-ground sample is boiled with water, mashed with 100 c.c. of malt extract (1:4), made up to 300 g., and filtered. The sp. gr. of the filtrate is corrected for that of the malt extract, and also for the soluble extract in the grains unless this has been removed previously by washing. The author describes a screening test applicable to grains samples, under water, for obtaining information concerning the character of the parent malt grist. Reference is made to the methods for determining starch in spent grains, described by Kreuzer and by Wieninger (J., 1911, 826; 1916, 377).—J. H. L.

Saccharin; Detection of —— in wine. C. von der Heide and W. Lobmann. Z. Unters. Nahr. Genussm., 1921, **41**, 230—236.

Five hundred c.c. of wine is evaporated to about 250 c.c., the liquor thus dealcoholised is cooled, treated with 5—10 c.c. of dilute sulphuric acid, and extracted with 100 c.c. of ether in the apparatus described by Ledent (J., 1913, 879). The ethereal solution is washed with water, the greater part of the ether removed by distillation, and the remainder by evaporation in a porcelain basin. The dry residue is dissolved in very dilute sodium hydroxide solution, heated on a water-bath, and 5% potassium permanganate added in small quantities at a time until a persistent red coloration is obtained; sulphuric acid is then added, and the mixture again oxidised with permanganate. After the excess of permanganate has been destroyed by the addition of sulphurous acid, the solution is evaporated to about 20 c.c., cooled and extracted three times with ether, using 10 c.c. each time; the ethereal solution is washed with water, evaporated, the residue treated with 3 c.c. of water and again evaporated. This treatment is repeated frequently so that the heating on the water-bath is prolonged for 1 hr. All benzoic acid is thus removed. If the residue then has a sweet taste, the presence of saccharin is indicated, and may be confirmed by fusing the residue with sodium hydroxide and testing for salicylic acid in the usual way.
—W. P. S.

Methyl alcohol and ethyl alcohol; Determination of —— in spirits, medicines, cosmetics, etc., by means of the Zeiss immersion refractometer. W. Lange and G. Reif. Z. Unters. Nahr. Genussm., 1921, **41**, 216—226.

The sample is rendered slightly alkaline and distilled, using an efficient fractionating column. The distillation is stopped when the temperature reaches 90° C., the volume of the distillate is noted and the sp. gr. is determined; the approximate alcoholic strength is found by reference to tables, and water is added to the distillate in quantity sufficient to make the alcoholic strength 50% by vol. At this concentration the sp. gr. of methyl alcohol is the same as that of ethyl alcohol, namely, 0·9346 at 15° C. The solution is then examined in the immersion refractometer; a 50% aqueous solution of methyl alcohol gives a scale reading of 40·2, whilst a 50% solution of ethyl alcohol gives a reading of 85·6. A table is given showing the percentages of methyl alcohol (in differences of 1%) corresponding with readings lying between these limits. (*Cf.* Simmonds, "Alcohol," pp. 182 *seq.*)
—W. P. S.

Patents.

Fermentation of cereals and other starchy materials [for the production of butyric and acetic acids]. C. Weizmann and H. M. Spiers. E.P. 164,366, 3.6.18.

A modification of the process of fermentation by means of heat-resisting bacteria, described in E.P. 4845 of 1915 (J., 1919, 301 A) and 9181 of 1916 (U.S.P. 1,329,214; J., 1920, 276 A), is claimed in which the mashes, prepared from cereals, acorns, horse-chestnuts, or other starchy materials, are maintained practically neutral or slightly alkaline during fermentation by the previous addition of substances such as calcium carbonate, sodium carbonate (subsequently converted into bicarbonate), or ammonia. By this means the yield of butyric and acetic acids is increased and the yield of acetone and butyl alcohol minimised. For example, a 6% mash made by cooking maize and 20—25% of its weight of calcium carbonate may be fermented as described in E.P. 4845 of 1915, the mash being kept agitated meanwhile. Under these conditions 240 pts. of maize yields 33 pts. of butyric acid, 19 pts. of acetic acid, 4 pts. of acetone, and 8 pts. of butyl alcohol, besides hydrogen and carbon dioxide.—J. H. L.

Acetone and butyl alcohol; Fermentation of starchy material for the production of ——. C. Weizmann and H. M. Spiers. E.P. 164,762, 3.6.18.

In using horse-chestnuts (*cf.* E.P. 150,360; J., 1920, 732 A) the saponins are first removed by grinding the dried material, freed from husks if necessary, and extracting with cold water. The solid residue, to which the coagulum produced on boiling the extract may be added, is cooked and fermented in accordance with E.P. 4845 of 1915 (J., 1919, 301 A) or 9181 of 1916 (U.S.P. 1.329,214; J., 1920, 276 A).
—J. H. L.

Yeast; Method of and apparatus for skimming —— from fermentation vessels and separating the fluid therefrom. W. Scott. E.P. 164,908, 9.4.20. (*Cf.* E.P. 21,925 of 1913; J., 1914, 978.)

The yeast is carried by suction through a pipe to a closed vessel in which a partial vacuum is maintained, air being admitted into the suction pipe with the yeast to prevent the pipe from becoming blocked. From the closed vessel the yeast may be transferred by suction or pressure to a yeast press.
—J. H. L.

Yeast propagation and fermentation; Preparatio of media for ——. R. Wahl. U.S.P. 1,379,294 24.5.21. Appl., 18.2.20.

A mash containing malt is kept at a temperatur favourable to peptonisation and continually sup plied meanwhile with lactic acid in amounts suc that no free lactic acid remains in the mash. Th peptonised mash is afterwards saccharified.
—J. H. L.

Aeration of liquids, especially the fermentatio liquid in the manufacture of pressed yeast. I Peter. G.P. 336,246, 25.9.17.

The air is distributed from the supply pipe, i fine bubbles, close to the floor of the fermentatio vessel, and a horizontal motion is imparted to th liquid by an independent stirring mechanism. Th branches of the air supply pipe may be fitted wit nozzles which cause a circulation of the liquid i the same direction as that produced by the stirrin mechanism. The rise of the air bubbles throug the liquid is thus retarded and the absorption air increased.—J. H. L.

Carrots and the like; Process for rendering comminuted —— odourless [for production of alcoholic beverages]. L. Kübler. G.P. 336,149, 1.10.19.

Mashes or juices prepared from the fresh or dried slices are treated at 60°—70° C. with an indifferent gas, such as air or carbon dioxide, and preferably agitated continuously meanwhile, or they are treated at 60°—70° C. with low-pressure steam without their temperature rising above 70° C. Juices suitable for the production of alcoholic beverages are thus obtained.—J. H. L.

XIXa.—FOODS.

Fat-soluble vitamin. VII. Fat-soluble vitamin and yellow pigmentation in animal fats with some observations on its stability to saponification. H. Steenbock, M. T. Sell, and M. V. Buell. J. Biol. Chem., 1921, 47, 89—109.

Further evidence is advanced showing that the occurrence of vitamin A does not run parallel to that of yellow pigments; nevertheless more vitamin is usually contained in butters rich in pigments than in those poor in pigments. A similar relation holds in the case of beef fats. Vitamin A resists saponification; hence it is neither a fat nor an ester.—E. S.

Sweetening agents. Paul. *See* XX.

Patents.

Flour; Method of treating and improving ——. E. E. Werner. E.P. 165,149, 1.3.20.

Flour is treated in an agitator with undiluted chlorine, in such quantity that all the gas is absorbed by the flour and none escapes to the atmosphere. About 100 lb. of chlorine is used for 1000 barrels of flour. It is claimed that in addition to bleaching the quality of the flour for baking purposes is improved.—A. G. P.

Heating liquids; Apparatus for —— especially applicable for use in pasteurising milk. T. E. Nunn and W. C. Froggatt. E.P. 165,329, 22.6.20.

The apparatus consists of an externally-jacketed conical vessel, with corrugated walls. For cooling, after pasteurisation, a similar vessel internally jacketed is employed.—A. G. P.

Soluble albumen; Process of extracting —— from whey. A. C. Weimar. U.S.P. 1,381,605, 14.6.21. Appl., 18.3.20.

Neutralised whey is concentrated at a temperature below the precipitation point of the albumin and, after removal of the crystallised lactose, is dialysed and finally dried at a temperature below precipitation point. The product contains the lbumin, a small amount of lactose, and some of the salts of the milk.—A. G. P.

Tea-essence; Process of manufacturing ——. S. Shimizu, and Nihon Chasei Kabushiki Kwaisha. E.P. 165,644, 3.6.20.

Juice obtained by steaming and pressing tea leaves s concentrated first in a vacuum evaporator at ow temperature (50° C.), then in an open pan just elow scorching temperature (*e.g.*, at 80° C.), and nally brought to the required consistency, or dried ompletely, in a vacuum evaporator at 60° C. —A. G. P.

Grape-juice syrup, and process of treating same. S. Avis, Assr. to A. Y. Ameer, J. Yonan, and J. N. Baboo. U.S.P. 1,381,613, 14.6.21. Appl., 18.9.19.

The syrup is shaken with whiting, allowed to settle, decanted, and concentrated.—A. G. P.

Cereal food and process of making same. C. Ellis. U.S.P. 1,382,963, 28.6.21. Appl., 16.5.19.

Bran is soaked in a liquid containing a smaller amount of sugary material, and the product is dried at a temperature high enough to produce a curling of the flakes without destroying the structure of the bran.—H. H.

Lupins; Removal of bitter substances from ——. P. Bergell. G.P. 335,646, 24.5.19.

The seeds, which may or may not have been freed from husks, are extracted at 55°—60° C. several times alternately with water and sodium chloride solution of at least 2% concentration, and then dried. A very rapid and thorough extraction of the bitter constituents is effected, with only a small loss of protein.—J. H. L.

Meat extract; Manufacture of products resembling ——. C. F. Hildebrandt and B. Rewald. G.P. 335,986, 3.8.18.

Materials containing protein or keratin are boiled with acid until hydrolysis to the amino-acid stage is complete; the solutions are then neutralised, and at the same time purified and rendered free from unpleasant odour or flavour by treatment with alkali silicates and removal of the precipitated silica.—J. H. L.

Fodder from straw and the like; Production of a ——. Veredelungsges. für Nahrungs- und Futtermittel m.b.H. G.P. (a) 336,017, 24.8.18, and (b) 336,484, 10.8.18. Addns. to 305,641 (J., 1919, 789 a).

(a) The alkaline liquor is artificially warmed, but not beyond 80° C. (b) The alkaline digestion of the comminuted material is arrested as soon as no further appreciable consumption of alkali or dissolution of constituents of the material occurs. The duration of the process is thereby shortened, and the yield is slightly increased without any decrease in the digestibility of the product.—J. H. L.

Baking powders; Production of stable ——. M. Lange. G.P. 336,665, 26.11.18.

The particles of one or both of the ingredients are coated with a film of solid cellulose acetate or formate. Premature evolution of gas resulting from absorption of moisture during storage is thus prevented, but at the baking temperature the cellulose esters are decomposed and the ingredients of the baking powder can interact.—J. H. L.

XIXb.—WATER PURIFICATION; SANITATION.

Water; Determination of the hydrogen-ion concentration of ——. I. M. Kolthoff. Pharm. Weekblad, 1921, 58, 1005—1020.

The use of the hydrogen electrode for determining the hydrogen-ion concentration of water is not recommended. A colorimetric method is described, in which the water after treatment with "neutral red" is compared with standardised acid and alkaline solutions of this indicator contained in wedge-shaped tubes attached to each other by Canada balsam. The value of p_H for a given tint can be read directly by means of a movable scale. From the hydrogen-ion concentration and the bicarbonate content the carbon dioxide content is found from the equation:

$$[CO_2]=[H^{\cdot}][HCO_3]/3\times10^{-7}.$$

(*Cf.* J., 1921, 407 A.)—W. J. W.

Sewage; Disappearance of pathogenic germs during the purification of —— by activated sludge. P. Courmont, A. Rochaix, and F. Laupin. Comptes rend., 1921, **173**, 181—184.

At the end of chemical purification, always attained in 6 hrs. in the authors' experiments, the pathogenic organisms of the typhus-paratyphus group were invariably present in the effluent, but the cholera vibrion had disappeared. The tardy disappearance of these organisms does not appear to be influenced by aeration or the presence of activated sludge, but requires as an essential factor the vital concurrence of other organisms, for whilst in raw sewage they never survived more than four days, and in raw sewage plus activated sludge, never more than three days, they survived for much longer periods in sterilised aerated sewage even after addition of activated sludge.—W. G.

Activated [sewage] sludges. F. Diénert. Comptes rend., 1921, **173**, 184—186.

Phenol at a concentration of 0·5% inhibits the formation of nitrous acid by activated sewage sludge, although the ammonia slowly disappears. It does not inhibit the conversion of nitrite to nitrate. The process of purification by activated manganese dioxide (prepared in an analogous manner to activated sludge) is bacterial and similar in character to that due to activated sludge. The loss of ammonia, which is not found as nitrite, nitrate, or ammonia in the sludge or the liquid, is not due to adsorption but to some form of bacterial action. —W. G.

Carbon monoxide diluted and carried along by a current of air; Fixation of ——. Desgrez, Guillemard, and Hemmerdinger. Comptes rend., 1921, **173**, 186—188.

The only satisfactory reagent found by the authors was 85 g. of granulated pumice impregnated with 18 c.c. of sulphuric acid (66° B., sp. gr. 1·84) and mixed with 70 g. of iodic anhydride. This absorbed carbon monoxide at a concentration of 8 pts. per 1000 of air, the mixture passing at the rate of 7 l. per min. at 35° C.—W. G.

Patents.

Insecticide and fumigation process. J. D. Neuls, Assr. to The Pacific R. and H. Chemical Corp. U.S.P. 1,381,586, 14.6.21. Appl., 15.4.18.

Insects are destroyed by treating trees etc. with a mixture of hydrocyanic acid gas mixed with an irritant such as mustard oil.—A. G. P.

Disinfecting liquids; Preparation of ——. M. Sarason. G.P. 336,798, 7.12.16.

Cresols are mixed with sulphite-cellulose waste lye in which about 1% of sodium chloride has been dissolved, this addition increasing the proportion of cresol which can be incorporated.—B. V. S.

Germs, ferments, and toxins; Destruction of ——. H. Bechhold. G.P. 336,989, 27.3.18.

Mixtures of different colloidal solutions of metals such as copper, silver, and mercury are used as germ-destroying agents, with or without addition of apparently inert substances. The germicidal action of mixtures of colloidal solutions of metals is greater than the sum of the actions of the component solutions, and the action is still further increased by addition of colloidal manganese dioxide or the like.—B. V. S.

Respirators; Material for renewing the air in ——. Ges. für Verwertung Chemischer Produkte m.b.H. Kom.-Ges. G.P. 337,644, 26.3.16.

Anhydrous peroxides are mixed with hydrous crystalline salts or compounds, such as sodium sulphate, carbonate, or peroxide hydrate. The mixture evolves oxygen immediately, whereas anhydrous sodium peroxide only does so after some time.—A. B. S.

Germ-free air; Continuous production of ——. A. Wolff. E.P. 147,566, 8.7.20. Conv., 12.9.17.

See G.P. 316,516 of 1917; J., 1920, 500 A.

Mercury compounds. G.P. 337,061. *See* XX.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Alkaloids; Titration of certain ——. N. Evers. Brit. Pharm. Conf., June, 1921. Pharm. J., 1921, **106**, 470—472.

Bromophenol blue is the best indicator to use in the titration of morphine, atropine, and neutral quinine salts; for acid quinine salts, methyl red is the most suitable indicator.—W. P. S.

Lecithin; Determination of ——. J. L. B. Van der Marck. Pharm. Weekblad, 1921, **58**, 989—992.

The molybdate method of estimating phosphorus in lecithin is tedious and not very reliable; in calculating mg. P_2O_5 from excess of $N/2$ alkali used the factor 1·365 should be employed instead of 1·268. A more convenient method consists in precipitating the phosphorus as magnesium ammonium phosphate in the residue after removal of organic matter by nitric and sulphuric acids. Estimation of the percentage of lecithin in samples from the amount of P_2O_5 found is not feasible, as the formula $C_{42}H_{84}NPO_9$ is open to question.—W. J. W.

Mercuration of aromatic compounds. O. Dimroth. Ber., 1921, **54**, 1504—1510.

The mercurated phenol ethers described by Manchot (Annalen, 1920, **421**, 331) have been found to be mixtures of mono- and di-mercury compounds. Their constitution is simply explained by regarding them as substituted phenolic ethers (*cf.* Dimroth, Ber., 1902, **35**, 2052, 2853). The additive formulæ advanced by Manchot are devoid of experimental basis. (*Cf.* J.C.S., Sept.)—H. W.

Pyramidone; Determination of —— in presence of antipyrine and aspirin. E. Oliveri-Mandalà and E. Calderaro. Gaz. Chim. Ital., 1921, **51**, I., 324—328.

When boiled with concentrated potassium hydroxide solution (1:1), pyramidone but not antipyrine yields dimethylamine. To estimate pyramidone in presence of antipyrine, with or without aspirin, about 2 g. of the mixture is boiled in an air- or oil-bath with 50 c.c. of the potassium hydroxide solution, through which hydrogen is passed to maintain regular boiling. The dimethylamine evolved is passed through a condenser into a known volume of $N/2$ sulphuric acid, the distillation being interrupted when the volume of the liquid in the flask has been reduced by one-half.

The excess of acid remaining is then determined by titration in presence of methyl orange: 1 g. of pyramidone is found to correspond with 8·50 c.c. of $N/2$ acid, the calculated volume being 8·64 c.c. When antipyrine only has been added to the pyramidone, the latter may be estimated by titration, using methyl orange as indicator: 0·5 g. of pyramidone corresponds with 21·6 c.c. of $N/10$ sulphuric acid. When pyramidone and aspirin only are present, 2 g. of the mixture is dissolved in the cold in the minimum quantity of alcohol and the solution diluted to about 200 c.c. with water and titrated with $N/2$ hydrochloric acid in presence of methyl orange; 16 c.c. of the acid corresponds with 2 g. of pyramidone and 1 c.c. of the acid corresponds with 0·9 g. of aspirin; hence the percentage of aspirin present $=9(16{\cdot}6-x)$, where x c.c. of the acid is required to neutralise 2 g. of the substance.—T. H. P.

Sweetening agents; Definitions and units in the chemistry of ——. T. Paul. Chem.-Zeit., 1921, **45**, 705—706.

THE "degree of sweetness," SG (*Süssungsgrad*), of a substance is defined as the number of g. of pure sucrose which, in a given volume of water, has the same sweetening effect as 1 g. of the substance. The degree of sweetness of dextrose was found to be 0·52, that of lævulose 1·03, lactose 0·28, mannitol 0·42, and that of a starch syrup containing 78% of solids 0·26; these values appear to be independent of the concentration, at least for sucrose concentrations between 20 and 100 g. per l. For saccharin and dulcin, SG diminishes with increasing concentration, the values corresponding to sucrose concentrations of 20, 60, and 100 g. per l. being 667, 316, and 187 in the case of saccharin, and 364, 90, and 70 respectively in the case of dulcin. The degree of sweetness of a mixture of saccharin and dulcin is greater than that calculated from the values for the ingredients; *e.g.*, 280 mg. of saccharin and 120 mg. of dulcin, in a litre of water, have the same sweetness as 535 mg. of saccharin alone in the same volume. The "sweetening unit," SE (*Süssungseinheit*), of a substance is defined as the number of g. required to produce the same effect as 1 kg. of sucrose, in a given volume of water.—J. H. L.

Glycerophosphates; Determination of small quantities of phosphates in ——. J. L. Lizius. Brit. Pharm. Conf., June, 1921. Pharm. J., 1921, **106**, 478—479.

ONE grm. of the glycerophosphate is dissolved in 50 c.c. of water and the solution is added from a burette to a mixture of 10 c.c. of 25% nitric acid and 10 c.c. of 10% ammonium molybdate solution until the coloration obtained is equal to that produced by a known amount (*e.g.*, 0·0002 g.), of phosphoric acid in the same amounts of reagents. If 10 c.c. of the glycerophosphate solution is required, the sample will contain 0·1% of phosphoric acid in inorganic combination. To apply the method to ferric glycerophosphate, the sample is dissolved in dilute nitric acid, heated, treated with sodium hydroxide, the ferric hydroxide separated by filtration, the filtrate diluted to 50 c.c. and used for the determination.—W. P. S.

Citric acid; Manufacture of —— from lemons. C. P. Wilson. J. Ind. Eng. Chem., 1921, **13**, 554—558.

CITRIC acid in lemons is contained entirely in the juice. The expressed juice is allowed to ferment for 4—5 days, filtered, and the filtered juice, containing about 4% of citric acid, is pumped into wooden tanks, provided with copper heating coils and mechanical agitators, and treated with sufficient hydrated lime to precipitate 90% of the total acid; calcium carbonate is then added in excess of the amount required to neutralise the remaining 10%. The precipitated citrate after filtration, washing with hot water, and air drying, is suspended in dilute wash liquor from a previous operation and treated with sulphuric acid (66° B.; sp. gr. 1·84) for 3 hrs.; the acid liquor (5—6° B.; sp. gr. 1·036—1·043), separated from the precipitated calcium sulphate, contains 12—15% of citric acid, about 0·2% of sulphuric acid, and is of 95—98% purity. This liquor is concentrated to 20°—25° B. (sp. gr. 1·16—1·21) in lead-lined evaporators, then to 37°—38° B. (sp. gr. 1·345—1·357) in lead-lined vacuum pans, and crystallised. The crude crystals are dissolved in water and the solution is freed from organic colouring matters, lead, copper, tin, antimony, iron, nickel, sulphuric acid, and calcium sulphate by suitable treatment. It is finally filtered and crystallised in wooden tanks lined with Monel metal.—W. J. W.

Methyl ethyl ketone; Catalytic manufacture of ——. J. Toussaint. J. Pharm. Belg., 1921, **3**, 221—224. Chem. Zentr., 1921, **92**, IV., 123.

BUTYLENE, prepared by passing *n*-butyl alcohol, a by-product from the fermentation of maize, over aluminium at 360° C., is converted by vigorous agitation with sulphuric acid into butylsulphuric acid; this on boiling with water yields isobutyl alcohol, which by passage over finely divided copper at 250° C. is converted into methyl ethyl ketone.
—L. A. C.

Formaldehyde and paraformaldehyde; Determination of —— in tablets. N. Evers and C. M. Caines. Brit. Pharm. Conf., June, 1921. Pharm. J., 1921, **106**, 470.

A TABLET is weighed, boiled with 200 c.c. of water for 30 mins. under a reflux condenser, the solution cooled, diluted to 500 c.c., and filtered. Ten c.c. of the filtrate is placed in a test-tube and a series of standards is prepared in 10 test-tubes, these containing, respectively, quantities of 0·1 to 1·0 c.c. of 0·0038% formaldehyde solution, and each diluted to a volume of 10 c.c. To each tube is added 2 c.c. of Schiff's reagent and the colorations obtained are compared after the lapse of 3 mins. The presence of lactose, sucrose, and menthol does not interfere.—W. P. S.

Terpenes; Optical investigations in the chemistry of the ——. A. Müller. Ber., 1921, **54**, 1466—1471.

INVESTIGATION of the absorption in the ultraviolet of citronellol, geraniol, and reuniol, their acetates, cyclo-products, and cyclo-esters show reuniol to be a mixture of citronellol and geraniol containing at least 60% of the latter. (*Cf.* J.C.S., Sept.)
—H. W.

Methyl and ethyl alcohols. Lange and Reif. *See* XVIII.

PATENTS.

Hydantoins; Preparation of ——. Chem. Fabr. von Heyden, A.-G. G.P. (A) 335,994, 28.6.16, and (B) 335,993, 2.2.16. Addns. to 309,508 and 310,426–7 (J., 1919, 389 A and 440 A).

(A) ARYLALKYLMALONITRILES, prepared by distilling arylalkylcyanoacetamides with phosphorus pentachloride *in vacuo*, are treated with hypochlorite or hypobromite solutions. Phenylethyl-, phenylisopropyl- (m.p. 210°—212° C.), and phenylbenzylhydantoin (m.p. 209°—210° C.) are prepared from the corresponding malonitriles which have b.p. (10 mm.) 130°—133° C.; b.p. (13 mm.) 143° C.; and

b.p. (11 mm.) 194° C., m.p. 97° C. respectively. (B) Urethanoarylalkylacetic acid esters of the general formula,
$(R).(R_1).C(NH.CO_2R).CO_2R(R=\text{alkyl}, R_1=\text{aryl})$
are treated with ammonia or monoalkylamines. The methyl ester of α-phenyl-α-aminopropionic acid on shaking with chloroformic methyl ester and sodium carbonate solution yields α-phenyl-α-urethanopropionic acid methyl ester, m.p. 45° C., which on treatment with alcoholic ammonia for 8—10 hrs. at 140°—150° C., with subsequent removal of ammonia and alcohol by distillation, solution of the residue in dilute aqueous sodium hydroxide and acidification of the solution, yields γγ-phenylmethylhydantoin, m.p. 193° C. 3-Ethyl-5, 5-phenylethylhydantoin, m.p. 88° C., is prepared by heating 35% monoethylamine solution with urethano-α-phenylbutyric acid ester for 10 hrs. at 140° C. The preparation of γγ-piperonylmethylhydantoin, m.p. 192—193° C. and γγ-chlorophenylethylhydantoin, m.p. 212° C., is also described.—L. A. C.

Hydrastinine; Preparation of derivatives of ——. K. W. Rosenmund. G.P. 336,153, 14.6.14. Addn. to 320,480 (J., 1920, 675 A).

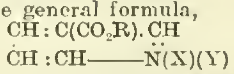
Instead of the process described in the chief patent, compounds of general formula,
$CH_2.O_2.C_6H_3.CH_2.CH(R).N(R_1).CH_2OH$
($R=H$ or methyl, $R_1=H$ or alkyl),
are treated with catalysts. Methylenedioxyphenylisopropylaminomethanol, prepared by the action of chloromethyl alcohol on the corresponding base, on treatment with 10% hydrochloric acid for ½ hr. at 100° C. yields 3-methyldihydronorhydrastinine, the hydrochloride and hydriodide of which have m.p. 232° C. and 217° C. respectively. The preparation of dihydrohydrastinine, N-ethyldihydronorhydrastinine, and 3-methyldihydrohydrastinine, m.p. 230°—232° C., is also described.
—L. A. C.

Betaine of hexamethylenetetramine; Preparation of a ——. J. D. Riedel A.-G. G.P. 336,154, 28.12.18.

A betaine of the formula $C_6H_{12}N_4.(OH).CH_2.CO_2H$, m.p. about 190° C. (decomp.), and suitable for use as a bactericide in preventing the spread of infectious diseases, is prepared by treating the hexamethylenetetramine addition products of α-halogenated acetic acid or esters of the same with silver oxide in aqueous solution. Esters, *e.g.*, monochloroacetic acid ethyl ester, are hydrolysed, yielding the corresponding carboxylic acids. The solution is concentrated *in vacuo*, and allowed to crystallise.—L. A. C.

Hexahydro derivatives of N-methylpyridine-3-carboxylic acid ester (N-methylnicotinic acid ester); Preparation of ——. E. Merck, Chem. Fabr., E. Kuhtz, and K. Roth. G.P. 336,414, 21.6.19 .

Alkylpyridinium salts of pyridine-3-carboxylic acid esters of the general formula,



$$\begin{array}{l}\dot{C}H:C(CO_2R).CH \\ \dot{C}H:CH\text{———}\ddot{N}(X)(Y)\end{array}$$

(R=alkyl or aralkyl, X=alkyl, Y=an acid residue), *e.g.*, the chloromethylate of pyridine-3-carboxylic acid ester, are treated in aqueous solution with hydrogen in the presence of platinum black until the calculated weight of hydrogen has been absorbed.—L. A. C.

Glucosides from Cascara sagrada bark; Preparing —— free from bitter constituents. F. Fritsche und Co., Chem. Fabr. G.P. 336,732, 20.6.19.

The cold extract from the bark is treated with lead oxide (Pb_3O_4) until all bitter constituents are removed, the lead oxide is separated, and the glucosides in solution are purified and dried by the usual method without application of heat.
—L. A. C.

Mercury compounds with formaldehyde-phenol condensation products; Preparation of ——. Holzverkohlungs-Ind. A.-G. G.P. 337,061, 13.3.19.

A phenol-formaldehyde condensation product, prepared by alkaline condensation (resole) or by acid condensation (novolac), is heated with a mercuric salt and with or without a solvent or diluent until caustic alkali no longer precipitates the yellow oxide from the product. The resulting mercury compounds are yellowish-white substances, soluble in caustic alkalis, but insoluble in alkali carbonates or in water and in the usual solvents; they can be used for disinfecting seeds, for destroying plant pests, and as antiseptics in the form of a fine powder or ointment for dermatological purposes.—B. V. S.

Liquid [crude methyl acetate]; Process for the manufacture of a —— exerting a vigorous dissolving action upon numerous substances. A. Helbronner and G. E. Criquebeuf. E.P. 1262, 16.1.14. Conv., 18.1.13.

See F.P. 464,646 of 1913; J., 1914, 502.

Cyanamide; Method of producing —— from calcium cyanamide. Wargöns Aktiebolag, and J. H. Lidholm. E.P. 151,583, 30.6.20. Conv., 19.9.19.

See U.S.P. 1,380,223 of 1921; J., 1921, 544 A.

Cinchona alkaloids and 2-phenylquinoline-4-carboxylic acid; Compounds of ——. A. B. Davis, Assr. to The E. Lilly and Co. Reissue 15,127, 21.6.21, of U.S.P. 1,213,464, 23.1.17. Appl., 5.5.21.

See E.P. 106,430 of 1916; J., 1917, 943.

Pyrophosphate casein compounds colloidally soluble in dilute alkaline solutions; Process for the manufacture of metal ——. A. Frey, Assr. to The Hoffmann-La Roche Chemical Works. U.S.P. 1,381,295, 14.6.21. Appl., 20.3.20.

See E.P. 154,112 of 1920; J., 1921, 61 A.

Catalysts. E.P. 164,808. *See* I.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Patents.

Cinematograph films; Preparation of —— and the subsequent projection of motion pictures in colour therefrom. W. Friese-Greene, and Colour Photography, Ltd. E.P. 165,826, 4.6.19.

A cinematograph film, colour-sensitised, preferably by the method described in E.P. 134,238 (J., 1919, 963 A), is exposed by the aid of a special shutter, alternately to white light and to yellow light, preferably that passed by a screen stained with Flavazine. The exposure ratio, white to yellow, is about 1:5, the difference in sharpness of the images tending to reduce flicker in projection. A positive is made from this negative and alternate exposures either coloured, or projected through coloured screens, blue-green for the white light exposures and orange-pink for the yellow exposures.
—B. V. S.

Photographic negatives for colour printing, colour photography or the like; Production of —— and apparatus therefor. A. B. Klein. E.P. 166,028, 4.6.20.

Negatives for colour processes are produced by using, to illuminate the subject, definite non-overlapping, spectrum bands of coloured light obtained by means of a spectroscope with adjustable selecting slit and recombining lens.—B. V. S.

Light sensitive collodion coating mixtures and films. J. Rheinberg. E.P. 166,063, 16.9.20.

Light-sensitive films are obtained by coating with a solution of collodion in, chiefly, methyl alcohol to which has been added a solution of an organic iron salt, preferably ferric ammonium citrate, in methyl alcohol. The addition of a salt of silver, gold, platinum, or palladium, preferably in ethyl alcohol solution, increases the sensitiveness, ethyl alcohol, up to a proportion of 1/3 or 1/4 of the methyl alcohol, increasing the density and clearness of the collodion film.—B. V. S.

Photographic developers. J. Hauff und Co., G.m.b.H. G.P. 333,687, 18.4.20. Addn. to 328,167 (J., 1921, 371 a).

The *o*- and *p*-amino- and diaminocresol-sulphonic acids in causic alkali solution give soft-working developers with no tendency to veil.—B. V. S.

X-ray plates free from halation. H. Engelken. G.P. 334,878, 11.7.16.

X-ray plates, provided either in the film or between the film and the support with a substance such as a yellow dye, which is transparent to X-rays, but less transparent to actinic rays, and has no sensitising action on silver bromide, give clearer negatives when used with an intensifying screen.

—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Fulminates. [*Action of mercury fulminate on various metals and alloys.*] A. Langhans. Z. ges. Schiess- u. Sprengstoffw., 1921, 16, 105—107.

In one series of experiments strips of the metals or alloys were exposed for 8 days to the action of both grey and white fulminate in suspension in water at normal temperature; in a second series the strips were in contact with dry fulminate exposed to a damp atmosphere. There was no appreciable difference in the effects produced by the two varieties of fulminate. With aluminium in the first series of tests, alumina was extensively produced. Magnesium was affected to an almost similar extent. Copper and zinc were appreciably attacked, other metals less so, and nickel not at all. Corresponding to their resistance to the action of fulminate the metals and alloys are arranged in the following order: nickel, silver, tin, bismuth, fusible alloy, cadmium, iron, white metal, lead, copper, zinc, brass, magnesium, and aluminium. In the second series of tests the effects were more slowly developed, but they tended to confirm the first results. A brief outline is given of the properties and preparation of fulminates other than those of mercury and silver.—W. J. W.

Patents.

Detonators and fuses for detonators [*containing lead trinitroresorcinate*]; *Method of making* ——. P. Wangemann. E.P. 139,811, 5.3.20. Conv., 30.4.18.

Lead trinitroresorcinate constitutes a suitable primer for shells, blasting charges, etc., without admixture of other initial explosives, if used in sufficiently large amount. It is less sensitive than mercury fulminate, and is without action on metals. Either alone or mixed with other explosive materials it may be used in detonating fuse; in this case a "phlegmatising" medium may be incorporated with it. (*Cf.* G.P. 285,902; J., 1915, 1169; and E.P. 138,083 and 156,429; J., 1921, 100 a and 164 a.)—W. J. W.

Detonating fuse cord; Process for the manufacture of ——. W. Friederich. E.P. 165,325, 16.6.20.

Detonating fuse cords contain the nitro-compound of hexamethylenetetramine, nitroanhydroenneaheptite, or mixtures of these, with or without other detonating explosives, together with phlegmatising agents, if desired, the composition being enclosed in a spun covering such as hemp, jute, cotton, etc. The cords are waterproofed by coating with any suitable material. To obtain slow-burning fuses, black powder or similar inflammable mixture is added to the above composition. The fuses are characterised by cheapness, as compared with those having metal coverings, and by ease of manipulation.—W. J. W.

Explosives. W. Rintoul, J. Thomas, and Nobel's Explosives Co., Ltd. E.P. 164,362, 7.5.17.

Colloid explosives consisting of nitroglycerin and nitrocellulose in proportions between those of blasting gelatin and of the propellant class, *e.g.*, cordite, are utilised in shells, mines, or grenades as contributory elements in the detonating train; they may be substituted for the usual crystalline trinitrotoluene in high explosive shells. Typical proportions of the two chief ingredients of such compositions are:—Nitroglycerin about 88%, and nitrocellulose about 12%, or nitroglycerin about 60%, and nitrocellulose about 40%, and a small amount of a stabiliser is added. Explosives containing not less than 10%, and not more than 50%, of nitrocellulose, may further be used for the bursting charges of shells.—W. J. W.

[*Nitrocellulose manufacture;*] *Producing nitrating liquor* [*for* ——]. I. Kitsee. U.S.P. 1,380,392, 7.6.21. Appl., 7.2.19.

The nitrating mixture is prepared by generating, in the nitric acid, sulphuric acid in the required amount to give the desired proportions of the respective acids.—W. J. W.

Nitrocellulose; Manufacture of ——. Deutsche Gasglühlicht A.-G. (Auerges.). G.P. 303,919, 25.2.17.

The nitrated material, after removal of the bulk of the nitration acid, is treated with previously cooled acid of gradually decreasing nitric acid content (*e.g.*, waste acid), and finally with cooled sulphuric acid. This prevents denitration, or "firing" of the nitrocellulose in the centrifuge.

—W. J. W.

Nitrocellulose; Process for continuous manufacture of ——. R. Müller. G.P. 306,377, 1.3.18.

After nitrating cellulose the mixture of nitrocellulose and acids is separated by means of a perforated, lead-lined wooden drum, which rotates in the vessel containing the mixture and is in communication with an air-pump.—W. J. W.

Nitrocellulose; Process for stabilising ——. Claessen. G.P. 306,400, 20.2.18.

Unstable impurities remaining in nitrocellulose after the waste acid has been removed by washing are eliminated by treatment with formic acid, acetic acid, alcohols, or ketones. By this process partial degradation of the nitrocellulose, which may occur when it is boiled with water, is avoided.

—W. J. W.

Nitrocellulose; Process for stabilising ——. Vereinigte Köln-Rottweiler Pulverfabr. G.P. 336,054, 14.8.18.

In the stabilisation of nitrocellulose, a short boiling with steam is followed by treatment under a reflux condenser with suitable solvents for the unstable components, *e.g.*, alcohol, with or without addition of nitrobenzene, acetone, etc.—W. J. W.

[Explosive] bursting charge; Process of forming an ——. C. A. Woodbury, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,382,260, 21.6.21. Appl., 4.4.18.

Explosive containers are filled with a mixture of a compound having a picryloxy group and a material comprising molten trinitrotoluene to dissolve and hold the first substance in suspension. —W. J. W.

Explosive [for primers]. W. O. Snelling, Assr. to Trojan Powder Co. U.S.P. 1,382,563, 21.6.21. Appl., 3.11.20.

The composition consists of nitrostarch desensitised by means of a hydrocarbon, and consolidated by means of a waxy substance.—W. J. W.

Smokeless powder; Process for manufacture of ——. Westfälisch-Anhaltische Sprengstoff A.-G. G.P. 301,659, 26.4.17.

Elimination of muzzle flame, without increase of smoke production or diminution of ballistic effect, is secured by the addition to smokeless powders of 0·5—5% of potassium chloride.—W. J. W.

Smokeless powder; Manufacture of ——. Westfälisch-Anhaltische Sprengstoff A.-G. G.P. 301,670, 16.3.13.

The stability and plasticity of smokeless powders are increased by the addition of esters of carbamic acid in which both hydrogen atoms are replaced by radicles, *e.g.*, diphenylurethane and methylphenylurethane. The ballistics of the powders are not adversely affected by adding even 5—8% of such substances.—W. J. W.

Ammonium nitrate explosives; Manufacture of ——. Sprengstoff A.-G. Carbonit. G.P. 303,880, 22.6.17.

Explosives having high detonating power, and safe to handle, are prepared by melting ammonium salts, such as the nitrate, with halogen compounds, such as sodium chloride. The mixtures may be used alone or combined with other ingredients. —W. J. W.

Vegetable meal; Preparation of —— for use in explosives. C. G. Schwalbe. G.P. 335,976, 25.1.18.

Vegetable raw materials, before grinding, are treated with acids or acid salts and heated to effect disintegration of the cell membranes; the residual acid is then neutralised with basic substances and any salts present are washed out. The product is a more energetic absorbent for liquid explosives than the materials usually employed, such as woodflour, ground peat, etc.—W. J. W.

Incendiary mixtures. W. T. Scheele, Assr. to the Government of the United States. U.S.P. 1,382,804–7, 28.6.21. Appl., 12.9.19.

An incendiary mixture consists of (a) hexamethylenetetramine and sodium peroxide. (b) Paraffin or (c) another oil may be be added to the mixture. (d) Suitable proportions for the composition described under (a) are hexamethylenetetramine, 22·5%, and sodium peroxide, 77·5%. —W. J. W.

Flashlight powders; Production of smokeless and odourless ——. Geka-Werke Offenbach G. Krebs. G.P. 336,004, 20.1.20. Addn. to 293,998 (J., 1916, 1180).

Instead of nitrates or perchlorates of the rare earth metals, mentioned in the original patent, permanganates, manganates, nitrates, peroxides, chlorates, perchlorates, sulphates, or persulphates of the alkaline-earth metals may be used, and greater stability thereby ensured.—W. J. W.

Smoke; Process for the production of —— on the stage by means of ammonium compounds of volatile acids. Schwabe und Co. E.P. 148,392, 9.7.20. Conv., 28.4.15.

An ammonium compound of a volatile acid is heated above its decomposition temperature, and the products of dissociation are allowed to recombine. Oxidisable substances such as coal, aluminium, or magnesium, alone or mixed with oxidising substances, such as ammonium perchlorate, may be mixed with the ammonium compound in order to supply part of the heat required for its decomposition.—W. J. W.

XXIII.—ANALYSIS.

Nephelometer-colorimeter; Further improvements in the ——. P. A. Kober and R. E. Klett. J. Biol. Chem., 1921, **47**, 19—25. (*Cf.* J., 1917, 571.)

The improvements, which are mainly designed to eliminate fatigue during the use of the instrument, are:—The removal of the milled heads which operate the cups from the top to the bottom of the instrument; the provision of a 50 mm. auxiliary scale which can be read from the top of the instrument through an eye-piece of the same focal distance as the telescope; and the presence of a micrometer arrangement for setting the zero point which can be locked in any position.—E. S.

Turbidimetry; Substitution of —— for nephelometry in certain biochemical methods of analysis. W. Denis. J. Biol. Chem., 1921, **47**, 27—31.

The author recommends the use of the turbidimeter in place of the nephelometer on the grounds that the former gives accurate results with fairly wide differences (50%) between the strengths of the standard and unknown solutions. It was tested in the estimation of calcium in blood by Lyman's method (J., 1917, 561), of fat in blood and milk by Bloor's method (J. Biol. Chem., 1914, **17**, 377), and of inorganic phosphates in blood plasma.—E. S.

Indicator papers; Use of —— for determining hydrogen-ion concentration. I. M. Kolthoff. Pharm. Weekblad, 1921, **58**, 961—970.

A number of indicator papers have been examined; their method of preparation, applicability, and the values of p_H between which they are effective, are given. In presence of a buffer mixture these papers give results agreeing with those obtained with indicator solutions. (*Cf.* J.C.S., 1921, ii., 515.)—W. J. W.

Iodometric estimations by Stortenbeker's method. D. do Miranda and A. E. R. van Limburg. Chem. Weekblad, 1921, **18**, 419—420.

To avoid loss in determining the end point at which chlorine ceases to be evolved, the retort is provided with a branch in the delivery tube, having a tap, and connected by a ground glass joint with a small vessel containing iodide-starch solution. The gas is periodically tested with this solution, and the latter may be returned to the retort.—W. J. W.

Zinc; Determination of —— as ammonium zinc phosphate. G. Luff. Chem.-Zeit., 1921, 45, 613—614.

Ammonium zinc phosphate is appreciably soluble in ammonium chloride solution and in monoammonium phosphate solution. Diammonium phosphate should be used for the precipitation, and before use should be rendered just alkaline to phenolphthalein by the addition of ammonia; the neutral zinc solution should be heated nearly to boiling before the diammonium phosphate is added, the mixture then cooled, neutralised (to litmus) if necessary by the addition of ammonia, the precipitate collected, washed with cold water, dried at 110° C., and weighed, or ignited to pyrophosphate and then weighed. Under these conditions the results obtained are trustworthy.—W. P. S.

Manganese; Determination of —— in hydrofluoric acid solution. J. Holluta and J. Obrist. Monatsh., 1921, 41, 555—571.

Manganese can be estimated in accordance with the equation, $MnO_4'+4Mn^{\cdot\cdot}+8H^{\cdot}=5Mn^{\cdot\cdot\cdot}+4H_2O$, under the following conditions. The neutral or faintly acid solution of the manganous salt, which must not contain more than 0·2 g. Mn, is diluted to 300 c.c.; after addition of 5—10 c.c. of 1:7 sulphuric acid and 5 g. of ammonium fluoride, the cold solution is titrated with $N/10$ permanganate. The first portions of the latter are decolorised immediately but, sooner or later, in accordance with the amount of manganese present, the liquid becomes reddish-yellow. The end-point is determined by observation of the absorption spectrum of the solution with a pocket spectroscope, a Watt 50-c.p. metallic filament lamp being used as source of illumination. The titration is considered to be finished when the bands at 547·3 and 525·6 $\mu\mu$ persist for more than five minutes. An excess of fluorine ions, low hydrogen-ion concentration, low temperature, and considerable dilution are essential. The presence of ferric iron in large amount, and of chlorine and nitrate ions does not interfere. If the titre of the permanganate is estimated by the fluoride method, the results are as accurate as those of the best volumetric methods described hitherto.—H. W.

Silver; Determination of —— and its separation from lead and other metals by means of hypophosphorous acid. L. Möser and T. Kittl. Z. anal. Chem., 1921, 60, 145—161.

A dilute solution of the silver salt is heated on a steam-bath and treated with an excess of hypophosphorous acid; the heating is continued until the precipitated silver is coagulated, the precipitate is then collected on a filter, washed with hot water, ignited, and weighed. The separation of silver from lead, zinc, cadmium, etc., depends on the solubility of the hypophosphites of these metals in hot water.—W. P. S.

Zinc and cadmium; Reductions with —— in volumetric analyses. W. D. Treadwell. Helv. Chim. Acta, 1921, 4, 551—565.

The disadvantages attendant on the use of finely-divided zinc as a reducing agent for ferric solutions are avoided by the employment of cadmium, which can be prepared in a sufficiently finely-divided state by the electrolysis of concentrated cadmium sulphate solution acidified with dilute sulphuric acid between platinum electrodes; the size of the particles is controlled by regulating the current density. Reduction of ferric sulphate solution occurs very rapidly and without noticeable evolution of hydrogen. The degree of acidity of the solution has no effect on the reaction. The method is well adapted to the estimation of very small quantities of iron. [*With A. Rheiner*]. Quadrivalent titanium is also reduced quantitatively by finely-divided cadmium; titanium and iron may be estimated simultaneously by complete reduction followed by titration with potassium permanganate; the end-points are conveniently determined electrometrically or, if this method is not available, by the use of potassium thiocyanate as outside indicator. In like manner, molybdenum trioxide is reduced quantitatively to the sesquioxide. Ammonium vanadate is uniformly reduced to the stage $V_2O_{2\cdot046}$; possibly the slight discrepancy from the divalent stage is due to back oxidation. The experiments are best performed by running the reduced solution directly into an excess of standard permanganate and back titration with oxalic acid. Uranyl sulphate is likewise smoothly reduced, probably to the uranous stage.—H. W.

Cadmium; Gravimetric determination of ——. L. W. Winkler. Z. angew. Chem., 1921, 34, 383—384.

A gravimetric method for the determination of cadmium is based on the fact that on treatment of a hot, strongly-acid solution of cadmium sulphate containing a very small amount of hydrochloric acid with hydrogen sulphide, a heavy-red crystalline precipitate of sulphide containing 1·01% SO_4 is obtained. The solution should contain 0·25—0·01 g. of cadmium sulphate, 3 c.c. of strong sulphuric acid, and 1 drop of $N/1$ hydrochloric acid in a bulk of 100 c.c. The gas is passed first through the boiling solution for ¼ hr., then through the cold solution for the same time. The precipitate is filtered off on a wad of cotton wool, washed with water containing hydrogen sulphide and a few drops of acetic acid, then with methyl alcohol, dried at 130° C., and weighed, 1 mg. being added to correct for the small amount of cadmium not precipitated. The result ×0·9806 gives the corresponding weight of pure CdS. Zinc is partly co-precipitated, and in its presence the first precipitate should be re-dissolved and re-precipitated. Chlorides must be removed by evaporation with sulphuric acid. Sulphates of the alkalis, magnesium, manganese, iron, cobalt, nickel, aluminium, and chromium do not interfere. (*Cf.* J.C.S., Sept.) —A. R. P.

Zirconium; Use of cupferron in the separation of —— from uranium. A. Angeletti. Gaz. Chim. Ital., 1921, 51, I., 285—288.

When zirconium and uranium present together are to be estimated, the former may be precipitated by means of cupferron in an acid medium, the uranium being afterwards precipitated by excess of ammonia solution as ammonium uranate, which is calcined in a current of hydrogen and weighed as UO_2; the small proportion of cupferron left in the filtrate does not interfere with the precipitation of the uranium.—T. H. P.

Arsenic, antimony, and tin; Quantitative separation of ——. F. L. Hahn and P. Philippi. Z. anorg. Chem., 1921, 116, 201—205.

The three elements can be separated quantitatively by oxidising an alkaline solution of their sulphides in sodium sulphide with hydrogen peroxide, when sodium pyroantimonate is precipitated. This is filtered off and the tin is precipitated from the filtrate as stannic acid by addition of ammonium nitrate. The mixed sulphides are dissolved in as little alkaline sodium sulphide as possible, mixed with an equal vol. of 20% caustic soda solution, and diluted to 50—100 c.c. Strong hydrogen peroxide is added until a colourless solution is obtained and oxygen is evolved. If the solution becomes brown instead of yellow during the oxidation, more alkali is needed. The solution is boiled for a short time, and 80% alcohol equal to ⅓ of its volume added. After standing for 24 hrs., the solution is filtered and the sodium pyroantimonate, part of which adheres firmly to the vessel in which it was precipitated, is washed with alcohol of increasing strength containing a little soda. The precipitate is then dissolved in the original vessel in dilute hydrochloric acid containing tartaric acid, and the antimony in the solution precipitated as sulphide. The filtrate from the pyroantimonate is evaporated to remove alcohol, diluted to 300 c.c., and as much 50% ammonium nitrate solution added as 20% caustic soda originally used. After boiling to expel ammonia the stannic acid is filtered off, washed with ammonium nitrate, ignited, and weighed as tin dioxide. From the filtrate the arsenic is precipitated as magnesium ammonium arsenate in the usual way, re-solution and re-precipitation being advisable.—E. H. R.

Nitrates; Determination of nitrogen in —— by Arnd's method. O. Nolte. Z. anal. Chem., 1921, **60**, 167—168.

The nitrate solution, measuring about 250 c.c. and containing up to 0·1 g. of nitric nitrogen, is treated with 2 c.c. of 20% magnesium chloride solution and 5 g. of a powdered 60:40 copper-magnesium alloy and distilled, the distillate is collected in a receiver containing a definite quantity of standard acid, and when 250 c.c. has distilled over, the excess of acid is titrated. The method yields trustworthy results. —W. P. S.

Iodide; Volumetric determination of —— with silver nitrate. I. M. Kolthoff. Pharm. Weekblad, 1921, **58**, 917—920.

Difficulty in determining the end-point, owing to precipitation of silver iodide, is avoided by adding a colloid to hold the precipitate in suspension. A 5% gum solution used for this purpose is apt to retain traces of iodine; starch solution used as indicator is found to be suitable if added in sufficient amount. If 10 c.c. of 0·00008—0·0001 *N* iodine solution and 20 c.c. of 2% starch solution are added to 25 c.c. of *N*/10 iodide solution, and the mixture is titrated with *N*/10 silver nitrate, the blue colour changes to green and then light-green, and ultimately, with excess of reagent, to yellow, the colour change being easily discernible. Bromide and chloride do not affect the reaction if present in amounts not exceeding 3% and 20%, respectively. Either acid or neutral solutions, of low or high concentrations, may be employed. As indicators, palladium salts offer no advantages over starch. (*Cf.* Schneider, J. Amer. Chem. Soc., 1918, **40**, 583—593.)—W. J. W.

Nitrogen; Microchemical determination of —— by Kjeldahl's method. V. Stanek. Z. Zuckerind. Czechoslov., 1921, **45**, 323—326, 335—338, 347—349.

A modification of Pregl's method (*Die quantitative Mikroanalyse*, Berlin, 1917) is described in which steam distillation is avoided. The amount of material taken may be as little as a few mgrms. For weighing out small quantities of solutions a form of weighing bottle having a small ground-in pipette as stopper is described. The material, according to its amount, is digested with 1—10 c.c. of sulphuric acid in a 25—30 c.c. conical flask loosely closed by a glass bulb having a tail-piece which extends downwards into the acid to prevent condensed drops falling suddenly into the latter. Digestion may occupy from 10 mins. to more than 1 hr. Distillation is carried out from a flask of about 160 c.c. capacity surmounted by a bulbed trap of about 100 c.c. capacity. The top of the trap is connected with the bent-over end of the condenser tube, which is of steel, about 5 mm. in diam. An electrical device to prevent irregular boiling is described. Connected with the lower end of the condenser tube is a glass tube dipping into the acid in the absorption flask, the latter being covered with a bored vulcanite plate. No loss of ammonia occurs, although the flask is purposely provided with less than the equivalent amount of *N*/70 acid in order to avoid back-titration with alkali. The acid titration is carried out with methyl red as indicator. The author has used the method for a considerable time for sugar-factory products, and has obtained results as accurate as by ordinary macro-determinations, and with a great saving of time and reagents.—J. H. L.

Patents.

Calorimeter [; Gas ——]. W. G. Laird, Assr. to H. L. Doherty. U.S.P. 1,381,714, 14.6.21. Appl., 24.6.19.

A gas calorimeter comprises a gas tank and a straight annular container having cylindrical walls spaced a short distance apart. The container is open at the bottom for the direct admission of air, and has an outlet at the top for direct passage of combustion products to the atmosphere. A burner, which can be connected with the gas tank, is enclosed by the inner wall of the container. Water is passed through the annular container and through a conduit leading from the container to the tank, and means are provided for measuring the rise in temperature of the water passing through the container.—H. C. R.

Photometric apparatus [for temperature measurement]. Siemens u. Halske A.-G. E.P. 147,146, 7.7.20. Conv., 8.7.19. Addn. to 112,614 (J. 1918, 353 A).
