Amongst others, one is certainly worthy of a place in history, as showing the ingenuity of the doctor, and the intelligence of the feathered tribe.

We were discussing the effects of anæsthetics, and the doctor informed us that, owing to the impossibility of administering chloroform to birds, he had been put to some considerable trouble in getting over the difficulty. It appears that he was suddeuly called by telegram to Northampton, where a friend of his had a raven suffering from cataract in the right eye. This raven was a great pet of the family, haviug lived with them for fifteen years, but was rather ferocious to strangers. The problem that presented itself was how to operate on the bird without the loss of an eye aud a finger or two. But the doctor, nothing daunted, devised a most cunning clamp for the bird's beak, and fetters for its legs; but a further difficulty presented itself. A bird has an extra eyelid of a horny substance, but, by a most ingenious effort of imagination, he constructed a hook of special design with which to hold the horny eyelid during the operation. The whole of these desigus were worked out and the instruments made while the telegraph-boy waited for the prepaid reply, which was sent off as follows: "Will come next train. Fee, fifteen guineas." All these beautiful instruments were, however, unnecessary, for the bird, being of a very intelligent nature, stood quite quietly during the operation, and, putting its head on one side, turned its eye at exactly the required angle, which made the operator's task comparatively easy. A perfect cure was the result. "But," said a sceptic, "how about spectacles?" "Quite so," said the doctor, "the owner insisted that these should be gold-rimmed, and pebbles had to be used in lieu of glass, as, from their greater hardness, they were less liable to be damaged when, in a moment of abstraction, the bird scratched its head with its claw."

Fifteen guineas certainly seemed cheap for so much ingenuity and skill, and we thought that the story alone was worth the money. Another very interesting story concerned two girls, cousins of the doctor, who had trained a pet monkey to such a marvellous degree that it was able to perform all the offices of a handmaiden, and several which do not usually fall to her lot.

The doctor was a great bather, but had a quite original way of eutering the water. Instead of taking a header like ordinary mortals, he leapt into the air with arms aud legs outstretched in front of him, and the first part of his anatomy to strike the water was that part which nature has generously provided for the chastisement of small boys. At his particular request, he was photographed by several members of the party with hand-cameras, and the resulting pictures will probably be exceedingly interesting to students of graceful motion.

From Acle we sailed by Ludham to Barton, and moored the wherry at Barton Staithe ; but, finding that we had a manure heap on one side, and a heap of weeds from the Broads on the other, we soon shifted our quarters. The doctor, who spent a somewhat restless night, and wandered about the cabin like a disturbed spirit, left early the next morning, accompanied in the dingey as far as Stalham by three of the party. On their return, we sailed in the dingey on Barton Broad, and on to Irstead Staithe, a very picturesque spot, which afforded much study for the would-be artists of the party.

On Friday morning we moved the wherry to the western part of the Broad, and moored to a post some considerable distance from the land, which we found much more pleasant than being close to the bank. We then sailed in the small boats to Irstead. On the way a somewhat amusing incident occurred. Signor Grogerino was rowing by himself in the jolly boat, and approached rather too closely a lot of cygnets ; the irate swan, resenting this behaviour, gave chase to the Signor, who pulled for dear life ; but the swan, with head thrown back and breast distended, continued the pursuit, and, in spite of the frantic efforts of the Signor, gained rapidly on the boat, when the Signor raised one of the sculls to defend himself, but in his excitement dropped the other scull, and was left to the tender mercies of the ferocious bird ; but the swan, satisfied with its victory, contented itself with flying on to the stern of the boat, and making for the focussing cloth, which was lying on the seat of the boat, which made the poor Signor think that his last hour had come. But the life of the good man was spared, and the swan, with cries of triumph and exulting pæans of joy, left the affrighted Signor to pick up his scull and pursue his way in peace. A photograph of this chase suggests a quite new idea for a picture of (Leader) Leda and the Swan.

Arrived at Irstead, we paddled up a narrow dyke much choked with weeds to Neatishead, a most charming little village beautifully situated at the entrance to Beeston Park. Here we had lunch at the White Horse, where the proprietor, Mr. Haylock, and his wife and charming daughters, make visitors so comfortable that when once they arrive they never wish to leave.

After lunch, the Professor and Signor Grogerino took some views in Beeston Park, while Buffalo Bill and the Major took things easy, and persuaded Mr. Haylock and his daughters to come for a row, and to have tea on the wherry. On the return of the others we set off, and, owing to the narrowness of the dyke, the Professor and the Major, instead of rowing, stood up, using their oars as paddles. In their efforts to catch the other boat they ran on to a stake, and the Professor took a header into the bottom of the boat, to the great delight of Miss Nellie, who enjoyed the joke more than the poor Professor, who was sadly shaken.

However, no bones were broken, so we started off again, soon catching the other boat, and, on reaching the Broad, hoisted our sail and took the other boat in tow, and were again pursued by the irate swan. The breeze was light, and our progress rather slow till we had nearly reached the wherry, when the wind suddenly increased, and we were going well through the water, when we quietly undid the towing-rope and left the other boat. The Signor Grogerino was the first to discover this, and the look of astonishment on his face when he found himself left was a study. After tea on the wherry, we took our visitors back to Irstead in the dingey, and had to row most of the way back, as the wind had dropped.

On Saturday some of the party went to Stalham for letters and telegrams, and in the afternoon we paid another visit to Irstead to try and induce the ladies to come for a sail in the wherry ; but this they were unable to do, as they had made other arrangements. We returned to our wherry in time for dinner, after which we sailed in the dingey—the Signor Grogerino in command—who, with a recklessness natural to his warm Southern blood, sailed gaily over mud banks and shallows, through reeds and sedges, and was with difficulty restrained from attempting to sail over the island. We got back in safety about midnight, and promoted the Signor to the rank of vice-commodore for his daring display of seamanship.

Sunday will probably be looked upon as the red-letter day the trip by those who were fortunate enough to take part in it. We sailed early for Irstead, walked to Neatishead, and brought back the ladies and their brother, and landed on the island, where the party were photographed in a series of artistic groups by the Professor. After lunch on board, we sailed all over the broad in the wherry, having tied our boats to a stake ; but the sail of the dingey was left up, and the wind, which had been very light, increased very considerably and broke the painter, and with the two boats in tow the dingey went gaily for a cruise on her own account. The Professor gallantly offered to plunge overboard to bring them back, but was restrained from the rash effort by the entreaties of the ladies, who implored him not to risk his life in such a dangerous enterprise. Luckily, another boat was sighted, with three men on board, who went in pursuit of the boats, and enjoyed a cruise on their own account.

The wind, which had been increasing, was now blowing half a gale, and we returned to our moorings. Soon after, we saw several men in a small boat, which was caught by the squall, and was in considerable danger of being overturned by the force of the gale. They attempted to lower their sail, but the block refused to run, and for some time they were in serious difficulties ; but, during a temporary lull, one of the men climbed the mast and cut the halyard with his knife, and let the sail come down with a run.

Our intention had been to dine in the middle of the day, but the man from whom we had ordered some ducks arrived minus the birds, and informed us that he had not yet killed them ; so we were compelled to put off dinner till the evening, and all hands were told off to shell peas whilst the unfortunate birds were suffering martyrdom. In the art of shelling peas the Professor greatly distinguished himself, and provided good ground bait for the fish by the number he dropped overboard.

After dinner on board, we took our visitors home in the dingey, after a day which we shall all long remember with very pleasurable recollections. The charms of the ladies, the excitement of the sail in the stormy gusts which constantly swept over the broad, the ever-changing effects of light and shade, the beauty of the scene, and marvellous cloud effects, all helping to make us all feel that it was a day to be jotted down in the tablets of our memories as one never to be forgotten.

Next morning we made an early start, sailing from our moorings to Barton Staithe at five in the morning, and after breakfast driving to Wroxham, through Neatishead, where Miss Dolly was seen, with her usual sweet smile, waiting at the door to bid us all good-bye ; and so ended a week's thorough enjoyment. A good boat, good company, and perfect weather, combined to make our happiness complete. And I may safely prophesy that we shall revisit the scene of our trip on the very earliest opportunity.—*Proceedings of the Camera Club.*

---

The National Gallery in Danger.—The perennial danger of the National Gallery from fire is a dread fact which the officials of the Board of Works should not be allowed to burke. The facts are simply these. The walls of the National Gallery absolutely touch, through a thin party wall, the highly inflammable buildings of the barracks behind. Such buildings, we all know, are a constant source of danger, and are often the scene of small conflagrations ; so that it is criminally careless to leave these priceless collections, which no wealth could replace, to the chance of destruction. Yet Mr. Plunket, in the full knowledge that within a few yards there stand as well the equally inflammable warehouses of Hamptons, the upholsterers, replies to questions asked in the House of Commons that he is willing to lay on a water-pipe with which to put out possible fires. Could anything be more short-sighted ? As regards this water-pipe, we can positively assert that the National Gallery authorities prefer to do without it. They are sufficiently burdened with the responsibility this danger of fire thrusts upon them, without incurring the further risks of damage by water. What should be done—and that at once—is perfectly clear : the barracks should be razed and the Gallery isolated. If, in accordance with Wilkins' original recommendation, the ground beyond, then occupied by dilapidated buildings, had been acquired, the proximity of the warehouses hard by would have been avoided.—*Magazine of Art.*

## THE PROGRESS OF PHOTOGRAPHY.*

BY ARTHUR H. ELLIOTT, PH.D.

Beginning with the apparatus of the professional photographer, we do not find any important advances. The cameras that were used a year ago hold their places in the estimation of the practical man. In the matter of hand-cameras, we note some quite unique improvements. In this respect the new film-carrier called the "Kamaret" is undoubtedly a marked advance in the utilisation of the space within the box to secure the most compact disposition of the parts. The roll is so arranged that it occupies the space between the cone of rays from the lens and the side of the box. By this method of disposition space hitherto not used has been made available. Coming to the use of plates in hand-cameras, the new magazine camera of Anthony embodies several new devices that are quite ingenious. First, the plates are made to come into focus automatically by means of a spring, and, after exposure, a single push on a button takes the exposed plate out of the way into a well, leaving another plate in place for further use. Second, after all the plates in the magazine of the camera have been exposed, the camera may be loaded up again by attaching a reservoir box to it containing a new lot of plates, which are readily transferred to the body of the camera by the use of a couple of slides. The empty box can now be used to hold the exposed plates in the camera, and these are removed by attaching it to the bottom of the camera, and, with the movement of two slides, the plates fall out to give place to those that are to be exposed afterwards. When we remember that all these transfers are accomplished in open daylight, we must confess that this is a decided advance in the construction of hand-cameras.

Yet another hand-camera is the "Hetherington." Here we have a camera using plates that are arranged pretty much as the leaves of a book. As each plate is exposed it is turned down out of the range of the lens, just as you would turn down the leaf of a book if it were placed upon its back closed. As each plate is turned down a spring brings a new one into place. This is a most ingenious piece of apparatus, but as soon as the plates are all exposed, you have to resort to a dark room to refill the plate-holder.

In the matter of lenses, by far the most important step has been taken by Carl Zeiss in the adaptation of the Jena glass to photographic lenses, and the construction of a lens in which the chemical and visual rays come to one and the same focus. Yet another improvement is the use of lenses so corrected that they may be used at very short focus and wide angle without the distortion hitherto encountered in lenses of this character. There is no doubt that this Jena glass, which has done such wonders in field microscopy, is destined to teach us some new things in the world of photography.

While on the subject of lenses, we must not forget to speak of the efforts of the English lens-makers to come to some understanding in the matter of threads and flanges of the lens-mounts. Although nothing definite has yet been accomplished, a report on the subject has been approved by the principal English lens-makers, and, with a little further modification, there is no doubt that a uniform screw-thread for the lenses of the same size, also a uniform thread for tripod screws, and a uniform system of marking the diaphragms of lenses, will be adopted by all the English makers, and probably by those of America, France, and Germany. If this can be accomplished, the photographer will be in the same position as the microscopist, in having all his lenses of the same size fit into the flanges on his cameras, or into adapters that also are uniform for all makes of lenses.

* Abstract of report presented at the American Convention.

While we are noting the novelties in photographic apparatus, a word about the new rival photographic operator is worth our attention; we mean the automatic photographing machines, where you put the nickel in the slot and get your picture taken, framed and all; but they are at present not worth more than a word, for all we have seen are easily distanced by the poorest tintype artist that visits the smallest country town. Nevertheless, these machines are the beginning of a series of inventions that will take the likeness of a sitter in front of them, and purely by mechanical motions as certain in their action as those of a clock. At present they are more of a curiosity than an innovation in photographic work.

Since we last met, quite a *furore* has been seen in the matter of "colour photography." Prof. Lippmann, of France, startled the world with the announcement that he had discovered the secret of taking photographs in their natural colours. After-developments proved that he had repeated the experiments of Edmond Becquerel—made twenty-five years before—except that he had used glass plates with greater success. Practically, his work is of little value, but it is interesting as a development of the theory of interference in light. The pictures he obtained are of the same character as the colours of the soap-bubble in the sunbeam, or the film of oil on water.

Working in the same field of research, Carey Lea has shown us some new wonders in the properties of silver chloride. Indeed, he has discovered that the basis of modern photography, the metal silver, is capable of existing in several distinct coloured modifications.

The Austrian photographer Verescz, who also experimented in the field of colour by photography, did work that is but a modification of the work of Carey Lea.

Some means of determining the actinic value of light in its relation to photography has long been a desideratum, and the English experimenters, Messrs. Hurter and Driffield, together with Capt. Abney, have arrived at some interesting results, showing that the exposure determines the gradation of the lights and shades in the negative. Incorrect exposure will not give an harmoniously graded negative, and furthermore, this incorrect exposure cannot be improved by a change of development. They have devised a method of determining the proper time of exposure, but at present the apparatus is more scientific than practical.

A much more convenient apparatus for the purpose of determining the time of exposure is the neat little actinometer of Ballard, which depends upon the measurement of the actinic power of the light on a subject by finding out how long the photographic—that is, the blue and violet—rays take to fade from a phosphorescent tablet that has been exposed to their influence. Its mode of operation is very simple. A small tube, blackened inside, has at one end a tablet of luminous paint so arranged that it hangs by a hinge, which allows it to be exposed on the subject for half a minute. The tablet is then closed over the tube, and by looking into the latter the time of fading to a standard tint, also in the tube, gives a figure that is a measure of the photographic power of the light reflected by the subject.

This same actinic power is modified by our use of the diaphragm in the lens. But here, also, some experiments of the past year have given us some new light. Dr. Michelke, of Germany, has shown that if we reduce the size of the opening in the lens to one-fourth, we shall have to increase the time of exposure not four times, as would be expected, but twenty per cent. more, or nearly five times. By using yet smaller openings we must add still more to the time, and with one thirty-sixth of the opening the time will have to be forty-eight times as long, or an increase of one-third the calculated time for correct exposures with a corresponding larger stop. In a word, if the time of exposure is correct with a stop of one inch, and it is desired to use a stop of one-quarter of an inch, we must increase the time of exposure not four times, but nearly five times.

Flash-light photography has many workers, and it is constantly being put to good use and its manner of application being improved. Various devices have been employed to overcome the hard shadows that were to be found in the first pictures made by its use. The methods of doing this are in the division of the magnesium powder into a number of small charges, rather than using it in one large flash. These charges are fired simultaneously by the use of a number of gas-jets that are made to impinge on pieces of gun-cotton on which is placed the magnesium, the projection of the many flames at the same instant being controlled by some device that regulates the pressure of the gas and increases it at the same moment at every jet. Pictures made by these methods are very hard to distinguish from those made by daylight.

The colour of the magnesium light is capable of much modification, and in this respect may be a most useful adjunct to the orthochromatic plates. Two German experimenters have applied this in photo-micrography, using a mixture of perchlorate of potash with magnesium, chloride of sodium, and tartrate of barium, with some excellent results.

The development of the photographic plate has received a good deal of attention during the past year. In the matter of developers there is not very much to report, but quite recently paramidophenol, a substance related somewhat to eikonogen, has been proposed as a new agent. Like eikonogen, it is not very soluble, and it is also rather expensive, but if it is found to have any decided advantage the chemist will soon find a way to make it cheaply. At the present time it is said to possess good developing powers, and its use gives no stains on the films. Compared with eikonogen and hydrokinone, it oxidises more rapidly than either. It is consequently more active than these developing agents. But its most important advantage is the fact that it will not colour the film, and can be used for a large number of plates in succession. It is said that as many as twenty plates may be developed in the same bath without causing the least stain on the negative. From these indications it would appear to be as rapid as pyro without its staining defects.

In connection with the subject of developers, the interesting experiments of Colonel Waterhouse deserve a moment's attention. He has found that, by the addition of a very small quantity of thiocarbamide to the developer of eikonogen, it is possible to produce a positive image instead of a negative one. This is a matter of small importance to the ordinary photographer, but to those who have to work the photo-mechanical processes it is a saving in the steps to be taken for the production of the final printing plate, for it saves the production of a positive from the usual negative.

Coming now to the printing processes, we must record the revival of the use of gelatine as a substitute for albumen, with more improvements than it has seen in many years. Aristotype paper has made some very important advances during the past year.

Platinum printing still holds its own with amateurs, and it would be a source of profit to the professional photographer in the better class of work if he would but take time to overcome some of the earlier difficulties. In Europe they are far ahead of us in this matter.

A new printing process was presented to the photographer by two English chemists some months ago, which depended for its action upon the change made by light in the chemical structure of a dye-stuff made from the colouring matter known as primuline. This substance has the curious property of uniting with different organic matters, and producing with each one a coloured print. If, therefore, we print in diazo primuline from a star-shaped negative, we can make each of the star rays of a different colour, by the use of different organic matters put on as developers in the form of paste.

The application of photography to astronomy continues to give the most wonderful results. Stars unseen by the human eye are detected by the photographic dry plate. And some recent photographs made in Sydney, Australia, show that the stars of the Milky Way are really larger than they appear to the eye through the telescope. This is due to the fact that they emit many blue rays which are invisible to our sight, but whose light affects the photographic plate.

Photo-mechanical printing processes have made important advances in colour printing, in which they are now producing some of the most beautiful work ever attempted by the aid of light and the printing press, and without the aid of the human hand.

Such is a very rapid survey of the advances of our art since we last met. In the brief space that could be given in such a report as this, many really important steps of progress have received but a word of mention.

---

The Eastman Company have issued, in connection with the late Buffalo convention, a very neat "Kodak Souvenir," which takes the form of an artistically got up pamphlet comprising a number of specimen prints on the three different grades of bromide paper issued by this enterprising firm. The pictures are of various dimensions, and have been printed by gas-light. They are designed to show the different sizes in which the kodak camera is now issued. The subjects chosen for illustration consist of various views of the Convention buildings at Buffalo, some capital instantaneous Niagara views, and last, but by no means least in interest, the Eastman Company's new works at Rochester, N. Y. With regard to these latter, we are informed that "the new plant consists of fifteen acres, on which four buildings are already in operation. The largest of these buildings is devoted exclusively to the manufacture of the 'Eastman Transparent Film'; the dimensions of the building are 300 by 100 feet, which will give some idea of the capacity for turning out this product alone. The other buildings consist of laboratories, emulsion rooms, carpenter and machine shops, boiler and engine rooms. The power house contains a 75 horse power compound engine, which runs two Eickemeyer dynamos—electricity being used throughout the factories for light as well as power to run all the machinery—and a 50-ton De La Vergne ice machine, which is employed to keep the emulsion and film rooms at a cool, even temperature. Space is left for other engines, as several other buildings are under consideration, which, when finished, will undoubtedly make this the most complete plant of its kind in the world."

## Notes.

However convenient the electric light may be for general domestic use, and valuable as many know it to be in the photographic studio and experimental laboratory, it has serious disadvantages when employed for lighthouses. During certain conditions of hazy atmosphere the electric light is not half so efficient as the gas and oil lamps which it has to a certain extent superseded, and in clear weather its light is so blinding as to be positively misleading to those for whose protection it is designed. Murmurs to this effect have long been heard, and at last the Shipmasters' Society has made complaints direct to the Trinity House authorities. They say that the glare of the light—that at the South Foreland is specially indicated—casts intense shadows, and produces a phantom-like appearance of hulls, masts, and sails, and it is suggested that its brilliance should be tempered by the use of coloured glasses. Another suggestion is that instead of the direct ray for the guidance of mariners, the beam of light should be cast upwards towards the clouds, making a veritable "pillar of fire," by which ships could easily be guided on their way. Lieut. Wells has recently been trying the effect of this method of projection at the Royal Naval Exhibition.

The hand-camera seems to be ousting to a great extent the ordinary quarter-plate from the market, and, while we regret that this should be the case, we cannot help seeing that for a time, at least, a rush in favour of the newer contrivance was inevitable. Many persons take up photography because it happens to be just now a fashionable craze, and, as the hand-camera seems to be the easiest form of the art, they purchase that description of apparatus in preference to that which apparently requires a little brain-work before its intricacies can be mastered. The better class of photographers—by which we mean those who pursue the art for the love of it—whether amateur or professional workers, know full well the far greater value of the old-fashioned camera, reserving the hand apparatus for special work.

In the meantime, the hand-camera mania is such a real boon to the plate-makers that they ought to erect a statue to those who originated the idea. More especially are they beholden to the devisers of those hand-cameras with rapid-changing contrivances, for it is the bearers of these things who use up—and we may truthfully say *spoil*—the greatest number of plates. When a man has to change his double back, and go through all the various motions necessary to taking a photograph with an ordinary camera, and when, moreover, he has the means of only carrying with him six plates, he treasures them up and takes care not to throw them away too liberally. Often he will, after focussing a view, decide that after all it is not worth spending a plate upon. Not so the gentleman who fingers his hand-camera. He presses the button—too often leaving others to "do the rest"—and hopes that each time he does so a picture is born to him. The temptation of firing away until all the ammunition is exhausted is a characteristic of inexperienced photographers, as it is of youthful soldiers.

A very cheap and efficient form of flash-lamp is described in a letter from Dr. Powell to *The Beacon*. To make it, one must procure a common flower-pot saucer, and perforate it with a hole at one side large enough to accommodate the stem of a "churchwarden" tobacco-pipe. The pipe is inserted into this hole from the inside of the saucer, and its bowl is cemented with plaster-of-Paris to the centre of the receptacle. A piece of cotton-wick, or asbestos fibre, is wound loosely around the bowl of the pipe, soaked in methylated spirit, and ignited. In the meantime the pipe has been charged with magnesium powder, and a length of india-rubber tube with a bulb at the end attached to its stem. Pressure on the bulb sends a puff of magnesium through the flame, and an intense flash results. The tobacco-pipe has before been utilised for flash-light purposes, but not so perfectly as in this case.

The chairman of the meeting of the shareholders in the Automatic Photograph Company, which was held a few days ago, had a very doleful tale to tell. We do not allude to the financial condition of the Company so much as to the working of the machine itself. It is useless now to disguise the fact that, as at present constructed, the apparatus will not work automatically. Each machine requires the services of an attendant, who, of course, must be paid, thus adding considerably to the expenses; but, even with the assistance of an official, the results were extremely unsatisfactory. As to the cause of this, we can say nothing, as one of the peculiarities of the prospectus was that the opinions of experts were carefully excluded. We may, however, mention that the chairman stated that there were at the present time no less than 150,000 bad plaques at the Company's office, so that the fault may not be altogether the machine's. Despite the miserable outlook, some of the shareholders think there is "something" in the apparatus, and are averse from winding up the Company. A committee has been appointed, and perhaps they may discover what the "secret process," of which so much has been made, is worth.

Admiral Gervais, who will shortly be the lion of Portsmouth, is giving a great deal of trouble just now. He has never faced a camera, nor has he ever allowed his features to be transferred to canvas. No doubt the difficulty will be overcome by our journalistic artists when they get a chance of sketching him; but this will not satisfy his admiring countrymen. In Paris enthusiasm always breaks out in shoals of the photographs of the idol of the hour being exhibited in the shop windows, and to find these barren of the portraits of the hero of Cronstadt and Portsmouth is a great privation.

There is an engaging simplicity about the following record in the official organ of the Manchester Amateur Photographic Society:—"The dark room has received some attention in the way of furnishing and completing since our last reference to it. A number of respectable-looking bent-wood chairs have been purchased, which help to give the room a more comfortable appearance." Photographers might take a hint from this. Why should one always stand in order to develop a plate? Providing the sink be of the right height, developing—especially in the case of dry plates—can be performed just as well by the operator sitting, while there is no doubt about the comfort. We have seen photographers fairly worn out after a long day's work, simply from the fact that they have never once sat down. Yet, as a sixth or so of the time was passed in the dark room, this proportion of rest might easily have been obtained.

## PHOTOGRAPHERS' AND ARTISTS' PERSPECTIVE.

BY ANTON M. HASCHEK.

Drawing and colouring combine to form an harmonious pictorial effect. They are the means by which the artist arrests the eye of the spectator, and they owe their origin and cultivation to the study of nature and the desire to imitate natural surroundings. When drawing according to definite rules was first introduced, a new factor entered into the perfection of the art—namely, science.

Not colouring, but delineation, and also the effects of light and shade, form the characteristics of photography. The absence of colouring shows, at the first glance, that photography, under ordinary conditions, remains very much behind painting. Its history also proves that it has arisen from the endeavour to reproduce natural objects—above all, the forms of human beings—and herein exists its principal application in portraiture. So far as it is a question of reproducing objects by drawing or by photography, the effect of each method is the same; but, as soon as either endeavours to work artistically, the distinction is manifest. The artist idealises, while the photographer only reproduces. It is not to be disputed that in the reproduction of nature, under favourable circumstances, a picturesque effect can be produced, and that by genius and taste the same may be essentially promoted. It shall now be our task to consider those rules which further the success of photography in an artistic sense. We have two means of doing this before us—the laws of perspective, and the study of the pictures of good masters. The principal aim in composing a picture is that the drawing, or rather the photograph, shall produce on the spectator an impression recalling nature itself.

In order to attain this end, it is necessary for the artist to study, on the basis of simple problems, the foreshortening and reducing of the lines consequent on the position of the objects on the plane. To the photographer this is not necessary, for his apparatus, supposing that it is an optically faultless one, delineates the perspective rightly automatically. We only need to put the eye into the same position as the lens in order that it may receive exactly the same impression from the objective point of view; but we are not accustomed to seeing from the objective, but from the subjective point of view. As we know from experience the real size of any object, we apply to them, when looking at them, other proportions of size than those which correspond to the actual appearance. Only one example of this assertion need be brought forward. As we know that the moon has enormous dimensions, it appears to us large—larger than all the other heavenly bodies. If different people are asked how large they see the moon, and are requested to give a comparison with some other object, very different answers will be received. One person will say, "I see the moon as large as a penny"; another compares it to a loaf of bread, and so forth. Therefore, the eye, in drawing, sees from a subjective point of view, and not from an objective one.

The following diagrams will illustrate this. The two towers in fig. 1 possess constructively the same dimensions, only one is drawn for the normal eye at a distance of twenty-five centimetres; the other for half that distance. If we look at them side by side, the first seems to be normal in appearance, while the other appears to be all out of drawing. This appearance is effected by the lines falling obliquely across the horizon; but if we take the precaution to look at the second tower through an eye-hole at a distance of twelve centimeters, we shall receive the same impression as the first drawing produces. Now, we generally look at pictures and drawings from a distance which is quite as great as or greater than this. Therefore, if we wish to produce the effect of nature through a picture or drawing, we must make the distance from the eye to be not smaller than twenty-four centimeters.

But there is still another thing which we must pay attention to: our eyes are only able to cover a limited space at one glance. Let us imagine the line of sight drawn from one edge of the picture to one eye; the size of the picture which is at once distinctly seen is thereby determined. But we must not let that hinder us from making larger pictures which we cannot see over at one glance, so that we are obliged to let the eye wander as we do in the contemplation of nature. But we have a second means of obtaining a general view in one glance; we choose a distant position—that is, we increase the distance of the picture from the eye. If we allow the eye to wander over the picture, and to contemplate part by part, and consequently see the picture with varying lines of sight, we shall fix now on places in the foreground, now on some in the middle distance, and now on others in the background, as in nature. Now arises the question, How shall we proceed as regards the sharpness of the picture? Shall we draw the foreground distinct, and the background misty and indistinct, because, in looking at

*Fig.* 1.

the foreground, we see the background indistinctly, and *vice versâ?* Or shall we make it all similarly indistinct? Neither. If we return to the contemplation of nature, we must grant to ourselves, after careful self-observance, that we see hardly anything indistinctly, but distinctly, and even very distinctly; for we do not see over a landscape with one glance, but contemplate part by part, and unconsciously accommodate the eye so that we see every part distinctly. This accommodation of the eye takes place so quickly that we are hardly aware of it, but get the same impression as when we are able to look over a large picture. But the fact that we are no longer in a position to recognise details has its reason, not in indistinct sight, but in the angle at which we see the object, and in the manner the light touches it.

If we look at the disc on a target, the circles and rings will appear continually smaller the farther we are from the target, and we shall even at last be able to attain a distance from which the target appears to us to be like a small white plate. Why? Because the thickness of the black rings makes with the eye an angle so small that we are no longer in a position to recognize details. If the eye could obviate this, telescopes and magnifying lenses would be superfluous; they serve not to enlarge the surroundings, but to enlarge the angle at which they appear. On the other hand, details are sometimes lost through bad light. The reproach that it makes objects too distinct is often made to photography; no painter would produce an object so distinctly as photography. This appears partly conscious and partly unconscious self-delusion. In a small photographic picture the details are lost, and even when they exist we do not see them at the proper distance of looking at a picture. It may happen even that large-leafed plants are found in the foreground so that in the picture the leaf-veins show—of course, with exaggerated clearness. The picture is not meant to be looked at with a magnifying glass, and with a proper choice of eye distance the details—which people are so fond of calling photographic clearness—vanish very rapidly. It is unfair to compare photographic pictures with paintings. The painter paints just as clearly, but with fewer details, because the picture is intended to be looked at from a greater distance, and thereby the whole effect is rectified. Not so photographs. We are not accustomed to hang the latter in frames on our walls, high above our heads, but to arrange them in albums, and to ornament the writing table with them, altogether to arrange them so that they can be looked at closely; and therefore they must be distinct, that is, full of detail.

There are, therefore, two universal rules for the photographer. To regulate his pictures for the proper angle of sight—that is, to avoid as much as possible taking the photograph at an angle—and not to work at too short a focal distance, is the one; and the other obliges him to produce pictures rich in detail. Distinctness and indistinctness, as long as the details are not blotted out, do not come at all into notice.

Let us now turn to the means which are at the disposal of the photographer in adjusting these difficulties. They are soon enumerated—choice of subject, its position, and retouching. These are all, except the purely mechanical means, such as the use of orthochromatic plates, ready-made developers, &c. With them may be ranked also the choice of printing process, which has important influence on the effect of the picture. Choice of subject and its position is possessed in common with painters in making a sketch. But how small are the other means compared with those of the painter. Apart from the fact that the painter can leave out what seems to him undesirable, and insert into his work figures, in order to heighten the effect—which last may be attained by skilful combination of negatives—he has, over photography, the invaluable aid of colour effects.

But to return to perspective. Unity of perspective is the primary condition of a picture; just proportion of size must be present; but a painter can obtain very beautiful effects by ignoring mathematical perspective, and practising what we may call artistic licence. One example shall explain this. When we wish to draw an archway symmetrically with other arches seen through it so that the right and left sides are identical, we must place ourselves exactly before the middle line of the opening, so that we see all the following arches in the background of the picture equally symmetrically. In fig. 2 the arches are symmetrically drawn. The point of sight, therefore, ought to be placed on the middle-line. If, however, you try to find the vanishing point on it, you discover that it has been removed to the side. Why has the designer turned aside from mathematical perspective? In order to avoid too complete symmetry, which would have an inartistic effect. More variety enters, in consequence, into the composition. This shifting of the vanishing point we often find in the pictures of the great masters.

Let us look, to select one out of a great many, at Raphael's famous cartoon, "Paul Preaching." Paul stands here on the Areopagus of Athens on a kind of public staircase, which occupies quite three-quarters of the space on the left hand of the picture. Statues, temples, palaces, &c., fill the background, but they are, like the figures, freely grouped; there is nowhere symmetrical calm, but life and movement, and the point of sight is placed somewhat to the right. This may be recognized by the vanishing point of the steps of the staircase, and has been purposely done by the artist to avoid the unpleasant fan-shaped arrangement of the steps, which would otherwise intrude itself.

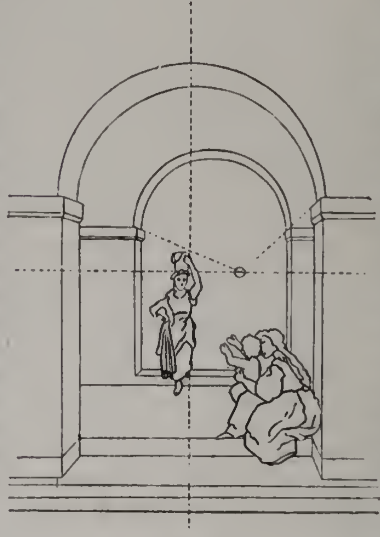

*Fig.* 2.

Further, we sometimes find two points of sight in a picture. In the "Decameron," by Winterhalder, in the left-hand corner of the picture a pavilion is seen over the summits of the trees. The lines of the sills and other horizontal lines vanish to a point which is different to that of the rest of the picture. But if the artist had taken the point of sight as the vanishing point of the picture, and held to the full view, the parts of the building lying in shade would have been visible, and the effect of the light architecture against the dark foliage would have been lost. Artistic licence with regard to perspective is made use of in a large measure where human figures enliven the picture. If perspective measurements are taken, we can often convince ourselves of the elongation of figures, as in the picture of Leonardo di Vinci, "The Last Supper;" the room here is hardly more than twice the height of

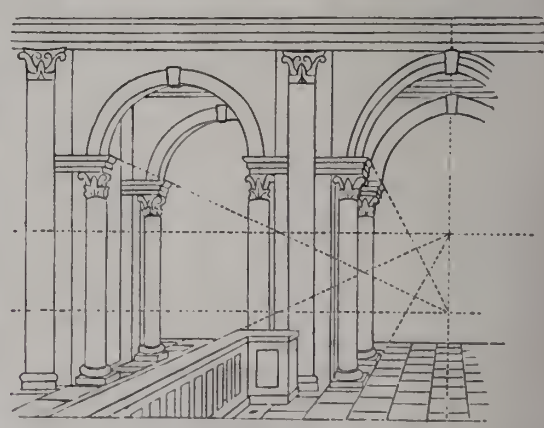

*Fig.* 3.

a man, while it is quite three times that amount in width. Nevertheless, the room makes a satisfactory impression, and does not appear oppressive. Again, Paul Veronese, in his picture of "Christ at the Publican's Supper," has brought a double archway into the middle line, and thereby obtained a perfectly symmetrical arrangement.

In the next example (fig. 3), we must imagine the drawing to the right transferred symmetrically to the left above the middle line. The weight of the arrangement in the original is softened by buildings strewn in the background. For the heads of the pillars and the arches above them and the shelves, the vanishing point is lowered to a considerable extent. The symmetry has thereby remained undisturbed; the pillars became thereby higher in appearance, and, as their bases are nearly covered by figures, the existence of the double point of sight is hardly discernible. Such cases of setting aside of the rigid laws of real perspective are not infrequent in painting. The artist will always exert a certain amount of licence if he thereby attains a more picturesque effect.

The photographer is, by his apparatus, bound to mathematical perspective. He cannot make use of the tricks of the painters, and is, therefore, inferior to them in resources. When, therefore, photography enters into competition with art in the shape of drawing and painting, it can only attain success by unusual skill.

It will be seen that I have endeavoured to show that photography is not only behind painting because of the absence of effects due to colour, but that its boasted absolutely correct lines, instead of representing an advantage, may often be looked upon in the opposite light. The photographer is far more dependent upon the perfection of his models, whether landscape or figures, than the painter can ever be.—Abstract translated from *Photographische Rundschau.*

## LONG DISTANCE TELEPHONING.

BY LUKE SHARP.

This is a story of the Camera Club.

The Camera Club in London, as everybody may not know, has now fine new premises near Charing Cross, ever so many stories high, of red brick outside, and filled with dark rooms and all sorts of luxuries inside. Among other things which the new building has which the old has not, is a telephone, which stands in the lower hall for the use of the members.

When a London club attains the luxury of a telephone, it at once takes rank among the leading institutions of the kind in the metropolis.

This story is the narrative of the fraudulent use of that telephone by one of the members, Mr. Pyrogallic H. Kinone, and as I have brought the matter to the attention of the committee, and as they have done nothing to punish Mr. Kinone, I think it only right to make the whole thing public. I do not think that a telephone is put in a club hall for deceiving an innocent New Yorker.

Pyro, as we call him for short, is a very popular member of the Camera Club. Perhaps that is why they do not deal with him as he deserves. He was over in America a year or so ago, and the Camera Club of New York treated him very nicely indeed. It seemed, however, that Mr. Hiram Waddell, of New York, played some sort of a joke on Kinone, a sell of some kind, and so Kinone swore to be even with him.

Not long ago he met Waddell in the Strand, and took him up to the club, where they had a long talk over New York matters and things in general, and he invited Waddell to lunch with him at the club the next day at a certain hour. Mr. Kinone asked about all the photographic boys in New York, and, among others, of John L. Vain. Pyro had liked Vain very much, and he asked Waddell if there was any chance of his being over this summer.

Waddell said there was'nt the slightest. John V. was interested in some big thing out west; he had seen him just before sailing, and Vain had said he wished he could get over to London this summer, but could'nt.

Shortly after this conversation Pyro was down at the Hotel Metropôle, when who should he run against but John L. Vain.

"Bless my soul!" he said; "London is full of Americans. I was just talking about you yesterday. I met Waddell on the Strand and took him up to the club, and I was asking if there was any chance of you coming over, and he said there wasn't; that you were going out west."

"Oh," said Vain jauntily, "I fixed that out west business all right, and I've come over to syndicate it if I can. Just got in to-day. Where's Waddell staying, do you know?"

"He is staying down at the Royal," answered Pyro.

"Well, I must call in and see him. I saw him just before he sailed."

"So he said. Look here, Vain, I want to fix up a sell on Waddell. You remember the one he got off on me in New York. We are going to have a lunch at the Camera Club to-morrow. Couldn't you join us?"

"I will be most happy," said Vain.

"Well, then, I'll get him up there about one o'clock. Can you be at the telephone here at the Metropôle at one o'clock to-morrow?"

"Certainly."

"Well, I'll call you up and turn you on to Waddell, and make him believe we have got a telephone line from here to New York. Do you understand? You think over it and fill him up. It will be a good story to tell the boys when you get back."

"I'll do it," said Vain heartily, and he did.

Kinone was to meet Waddell at Low's exchange, and they walked together to the club.

"I've just been telephoning over to Paris," said Kinone. "Have you seen about the Paris telephone?"

"Oh, yes, I read about it. Still, we do longer distance telephoning than that in America, you know."

"Ah, yes, but this Paris line, you understand, goes under the Channel."

"Well, I don't see that that matters much, does it? I believe that we telephone from New York to Chicago sometimes."

"Yes, I presume you do. Still, of course, that's all nothing to the Atlantic telephone from here to New York."

"Telephone? Cable, you mean."

"No, I mean telephone."

"Thunder! I never heard of a telephone under the ocean."

"Oh, you're behind the age. You've been out of America for a week. You are not up to the latest snap in electricity. Didn't you hear anything of Edison's new telephone before you left America."

"Oh, Edison's new telephone is an old thing, but I never heard of any attempt to telephone across the Atlantic."

"Attempt! Great heavens! You are not so far behind the lighthouse as all that, are you, Waddell? Why, bless me, you can ring up New York from any telephone in the city."

"Oh, you can't expect me to believe that," said Waddell.

"Believe it or not, as you like. I suppose if seeing is believing, hearing is believing as well. Here we are at the club. I will ring up New York, and you can tell me the names of any of your friends you want to communicate with."

"Oh, this is ridiculous," said Waddell.

Pyro made no answer, but he rung up the telephone. "Give me No. 15768." That was given him.

"Hello, switch me on New York, will you? Using the line? Well I'll wait a moment—Yes—yes—all right—give me New York—New York City. Is that New York?—I say, is that New York? All right."

"Now, then, whom shall I call up?" he said turning to Waddell.

Waddell was speechless.

"Tell me any of your friends; where's—who's your partner, by the way?"

Waddell gave the name of his partner. And then he shouted: "Give me Waddell & Co., Waddell & Co. Is Martin there? * * Oh, uot come down yet, all right."

"Not come down, nousense," said Waddell; this is after one o'clock."

"Ah, but you must remember it is a great deal earlier in New York. Say, what is Vain's address? Where's his place of business?"

"On Broadway. Harrison & Vain, you know."

"Say, give me Harrison & Vain * * * Harrison & Vain, Broadway—I don't know the number—Yes, is that Harrison & Vain? * * * This is London. * * * Yes. * * * England, of course. * * * Is Mr. Vain there?—Well, would you just ask him to step to the telephone for a moment? * * * Well, tell him Mr. Waddell, in London, wants to speak with him. * * * Tell him he'll only keep him a moment. * * * At his letters? Well, uever miud that. You tell him that we can't hold the line here all day. Ask him to come to the phone. * * * Oh! is that you, Mr. Vaiu? This is Pyro Kinone, of London. * * * Yes, Waddell's here. * * * Will you speak to him? * * * Certainly.

"Here you are, Mr. Waddell," and the astonished Waddell put the receiver to his ear.

"Hello, Waddell, is that you?" said the voice over the wire. "How did you get over? Have a nice passage?"

"Great heavens, Vain!" he said, "You don't mean to tell me that that's you?"

"Yes, can't you recoguize the voice?"

"Yes, by Jove I do. Say, I wouldn't believe this was possible."

"Oh, we've had this going for a week. Just started it after you left. Didn't you hear about it?"

"No, I heard nothing about it. How did that western speculatiou of yours turu out?"

"Oh, all right. I was out west just after you left and fixed things up most satisfactorily. Going to make some money out of that."

"Why, I can hear you as plainly as if I were talking from your office on Wall Street."

"Yes, it seems to work first-rate—that invention of Edison's is a great thiug. I met Edison this morning—he was in town early—and he tells me that he believes he is going to knock out telegraphing altogether."

"Well, I believe he will, if it's as successful as all this comes to."

Then Vain pumped him full to his horror about a great number of failures in New York, of men that he knew, and men that he was in intimate associatiou with. His jaw dropped as he listened.

"By gosh!" he said to Pyro, "New York's going to smash. I'll have to get back."

"Well, not before lunch, anyhow. Ring 'em off aud we'll come up and have lunch."

So they went up together into the dining room.

"Well, I can't get over that," said Waddell, "that beats the old Harry."

"Oh, American invention is a wonderful thing, you know," answered Pyro.

Just at that moment the waiter said: "There is a geutleman here asking for Mr. Kinone."

"Oh, yes, ask him to come in," said Pyro—and in walked John L. Vain.

"Hello, Waddell," he said, "how about transatlantic telephoning? I guess I rather set you up on failures, didu't I?"

"You two villians!" cried Waddell; "but haug it, I'm relieved to find that things are not as bad as I thought. I guess, Kinone, this is my treat. It's an English invention that is the wonderful thing this time."—*Detroit Free Press.*

---

Mr. W. England has called our attention to the fact that at the late photographic exhibition at Brussels he was the juror appoiuted to look after Euglish interests. We may add that his abilities as well as his name fitted him for the distiuguished positiou.

## CONVENTION OF THE PHOTOGRAPHERS' ASSOCIATION OF AMERICA.

The proceedings were opened by President Hastings in Buffalo, N.Y., on July 14th.

The address of welcome was given by Mr. McMichael, who, in the course of his remarks, said:—

Our art is not an attempt to reproduce nature, but to exemplify all that nature suggests aud teaches as possible to humau effort. Nature needs no helpmate, but does welcome co-operation in enlistiug man's admiration and man's enjoyment of existing things. And so anything which helps to keep alive the features of departed frieuds helps also to contiuue to revive the best influeuces of their lives, and must consequently be beneficeut in its effects. The work of the photographer makes this beneficence universal, for in all homes, from the most luxurious to the most humble, it may be availed of at will. Though this is only oue of its values, it alone is a reason why everything that may contribute to the improvement and perfection of our work should be sought. And if in other callings the workers find help by association for their mutual improvement, certainly our patrons and the public have a right to claim aud expect that photographers should seek to learn, by association with each other, the best methods and the surest means to the best results in the pictures we produce for their approval.

The report of the Committee on the Daguerre Memorial followed, with a statement of accounts in connection therewith. Other routine business was succeeded by the delivery of the President's Annual Report, from which extracts are appended:—

The art principles we are trying to inculcate into our Association by the awarding of special prizes, which will draw out latent talent, embraciug the ideal, the poetic, and the art of composition, will be seeu by coutinued competitions, and I think the public will appreciate and acknowledge it iu au approving manner. Do not give up the idea that, if we are not able to conceive and execute in a manner which will give us a standiug approaching a Meissonier, or any that might be named; we surely do not want to be simply machines, controlled by our patrons' whims, but to rise higher and higher, and be accorded the praise and credit belonging to us. Many are in the work without any love for the art aside from getting a living, and too often those who are trying to reach the high standard desired are baffled thereby by lack of patronage, because the scum of the profession are working at an inconsistent remuneration. Merit will demand recognition, eveu though it may come slowly. Persevere, and the goal will be reached.

In our profession we are unjustly taxed for fire insurance. The rate established when, we will allow, the risk was more hazardous, has not beeu decreased in proper proportion, and I think this Association ought to raise its voice against such exorbitant rates, and act in accordance with the proper authorities.

The second day's proceedings included communications and congratulations, various reports and discussions, and remarks by Mr. C. Gentile, of the Committee on the World's Fair, in which, suggesting the appointment of an advisory council, he stated that the Association had a large list of distinguished photographers throughout the world. and that it would not be difficult to name the committee. It was agreed, after discussion, that a committee of five be appointed as an advisory council to confer with the World's Fair authorities.

On the third day, Mr. Scandlin presented and read the "Report on the Progress of Photography" (see page 574) on behalf of Dr. Elliott.

The opinion has been generally expressed that, although the number of exhibits was smaller than usual, the standard of excellence was higher.

[The foregoing particulars are gleaned from *Wilson's Photographic Magazine.*]

## PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

The annual exhibition of the Society will open at the Gallery of the Royal Society of Painters in Water Colours, 5a, Pall Mall East, on Monday, September 28th, and will close on Thursday, November 12th. It will be inaugurated by a *conversazione*, open to members and their friends, at 8 p.m. on Saturday evening, the 26th of September, and will remain open daily (Sundays excepted) from 10 a.m. till 5 p.m. It will also be open on Monday, Wednesday, Thursday, and Saturday evenings, on which lantern slides will be shown from 7 to 10 p.m. Admission to the day exhibition will be one shilling, and to the evening exhibition sixpence. Members have free admission at any time, and will be supplied with as many tickets as they may require to admit their friends to the day exhibition, and with not more than twelve tickets for the evening exhibition.

Medals will be placed at the disposal of the judges (Messrs. J. E. Austin, F. Hollyer, P. H. Newman, F. M. Sutcliffe, and J. B. B. Wellington) for artistic, scientific, and technical excellence of photographs, for lantern transparencies, and for apparatus.

The following are the regulations:—

*Photographs.*—Each exhibitor must fill up the entry form supplied by the Society, and send it to "The Secretary, Photographic Society of Great Britain, 50, Great Russell Street, London, W.C." At the back of each frame must be written the name and address of the exhibitor, with the title or description of the photograph, and the number (if there be more than one) to which it refers in the entry form. Each frame or picture may have the exhibitor's name, and the title of the picture, neatly inscribed, and this only. Oxford frames and photographs already publicly exhibited within the London Postal District will not be admitted. Negatives and transparencies, photo-mechanical prints, photographs of purely scientific interest, and photographs coloured by scientific or mechanical means, will be admitted. Photographs coloured by hand will not be admitted. Lantern transparencies should be fitted in a frame to stand upon the table; if not removable, duplicates should be sent for exhibition in the optical lantern. Lantern slides will be eligible for award only when both the negatives and slides are the work of the exhibitor. With any work produced by a special process of the exhibitor, information as to particulars should be communicated.

*Photographic Apparatus.*—Each exhibitor must fill up the entry form supplied by the Society, and write a concise description of each piece of apparatus. A removable card must be attached to the exhibit containing the name of the exhibitor and the number to which it refers in the entry form. Attention is requested to this regulation, as, without it, the description of the apparatus may not appear in the catalogue. The exhibitor should fasten on each exhibit a small adhesive label, containing his name only. Apparatus and appliances that have been already shown at London exhibitions may be refused, and also those that do not contain some points of special interest (to be mentioned by the exhibitor on the entry form).

*Charge for Wall Space.*—No charge will be made to members of this Society; but to non-members a charge of one shilling per square foot will be made for wall space, the minimum charge being five shillings. Postal orders to pay for the wall space required by non-members must accompany the entry form. Should any of the photographs not be hung, the due proportion of the amount will be returned. The charge for wall space to those exhibitors who may be proposed as members of the Society at the November or December meetings will be remitted, and the amount paid credited to their entrance fee and subscription for 1892.

*Charge for Exhibiting Apparatus.*—As the apparatus will be under the personal supervision of a competent attendant, who will be ready to furnish explanations to visitors during the whole time the exhibition is open, a fixed charge will be made of five shillings to members, and ten shillings to non-members, which must be enclosed with the entry form, or the exhibit will not be received.

*Price Catalogue.*—A list containing the prices of pictures and apparatus to be disposed of will be laid on the table. It is desirable that exhibitors should state the price of their pictures on the entry form, as frequent enquiries are made respecting the prices of framed and unframed copies. Ten per cent. commission will be deducted on sales.

*Foreign Exhibitors.*—Foreign exhibitors are specially invited to contribute. The Society will pay the carriage of photographs one way, and provide frames during the exhibition for photographs approved by the judges. There will be no charge for wall space.

*Reception of Exhibits.*—Exhibits sent in packing-cases must be carriage paid, and addressed to "The Photographic Society of Great Britain, c/o Mr. James Bourlet, 17, Nassau Street, Middlesex Hospital, London." Packing-cases must arrive not later than Monday, September 14th; they will not be received after that date. No packing-cases can be received at the Gallery. Exhibits, including pictures, negatives, transparencies, lantern slides, apparatus, and appliances, sent by hand will be received at the Gallery, 5a, Pall Mall East, only on Wednesday, September 16th, until 9 p.m.

*Removal of Exhibits.*—Exhibits received in packing-cases will be re-packed and despatched directly after the close of the exhibition. Exhibits left at the Gallery by hand must be fetched away on the day appointed, due notice of which will be sent to the exhibitors. Particular attention is requested to the removal of exhibits on the day appointed. If not taken away then, considerable expense will be incurred in removing them from the Gallery to be warehoused. This expense will be charged to the exhibitor. Exhibitors can, by giving instructions to the assistant-secretary, and paying the cost, have their pictures packed in a case and sent to destination by carrier.

*Conditions.*—It is to be distinctly understood that the sending of exhibits signifies acceptance by the exhibitor of the decision of the council, upon all matters connected with the exhibition, as absolute and final. The council do not hold themselves responsible for any damage that may happen to the exhibits whilst in their custody, but every precaution will be taken to ensure their safety and prompt return to the owners at the close of the exhibition. To avoid damage to other frames, it is requested that all frames have sunken backboards, with the fastening nails not projecting, and the back covered with thick brown paper.

*Optical Lantern.*—Photographic lantern slides will be shown by means of the Society's optical lantern during the exhibition. The loan of slides for this purpose is invited; they must not exceed $3\frac{1}{4}$ inches in height, and, to enable the committee to select and arrange them, must be delivered at the Gallery not less than one week before the evening of their being shown in the lantern.

Blank entry forms and any further information respecting the exhibition, apparatus, and lantern slides, also nomination forms for membership, can be obtained from the assistant-secretary, P. S. G. B., 50, Great Russell Street, London, W.C.

An Improved Photographic Car.—The Pennsylvania Railroad Company is now having made, on a most elaborate scale, a photographic survey of their great system. The work is being done by Mr. William H. Rau, of this city, whose wide experience in every branch of photographic work, and in almost every part of the work, especially fits him for the undertaking. The railroad company has built for Mr. Rau a "photographic car," in which he will this summer travel from point to point, as the requirements of the work dictate. The car is not only thoroughly equipped as to dark room, water supply, and all the other photographic necessities, but with sleeping and dining conveniences as well. The "survey" will be mainly in the line of the picturesque, and the appliance which Mr. Rau is enabled to bring to bear upon the work will make the results especially valuable. Mr. Rau has already begun operations on the Pittsburgh division of the main line.—*Philadelphia Public Ledger.*

## HAVE NEGATIVES ANY VALUE?

Under the above title the well-known photographer, Mr. A. Bogardus, writes the following in *The St. Louis and Canadian Photographer*.

There seems to be but one opinion on this subject from the men in the fraternity who are capable of forming an opinion; but one opinion from the man whose position enables him to decide it intelligently—they are valuable. In establishments where they are registered regularly a large income is derived from them. They are valuable as an investment, and add much to the value of a gallery. They are also valuable to the family desiring duplicates, and doubly so after the death of the party represented. At one period of my business career, the income from duplicates averaged one hundred and twenty-five dollars per month, not counting publics. I am well aware that the orders for duplicates are much larger from the recently executed negatives (if the picture is satisfactory), yet the older the collection, the more valuable it becomes. As time passes, more of the persons represented are dead, and duplicates are in demand. Of course, in a large collection there are many from which orders are never received. Yet the fact of these being in place ready to fill any demand, and liable to be in demand any hour, renders the collection more valuable. They are a good investment pecuniarily if one dozen is ordered from each hundred negatives in the course of one year.

Rip-rap operators who, after getting a man's money, give him anything that happens to come up, may well say negatives have no value. They guess it the first time. Such men never receive orders for duplicates, and never expect to. The first dozen gives the man his "fill." The creature who goes on the witness stand and swears that negatives have no value, does so to injure his successful rival, or is destitute of brains, and it would be a good investment if he should go to the nearest drug store and try to buy ten cents worth of that commodity. If he succeeds in making a purchase, the amount named will be sufficient to keep him in stock for his lifetime.

As to insurance. Have a specified value for negatives stated on your insurance policy. In my insurance the value of each registered 8 by 10 negative was fixed at one dollar over and above its value as glass. This rating continued several years, and when the register numbered upwards of sixty thousand, a conference was held with the company's agent, and fifty cents. for each negative was agreed upon over and above its value as glass. During my long career I had but one fire, and that did not reach the negative rooms, the sky-light and a small work room receiving the principal damage. The few negatives in the work room were valued and paid for as per the amount stated on policy. It is not worth while to say the negatives of publics are valuable. It is a self-evident fact. When the lamented President Garfield died, it was impossible to supply the demand. I had orders for ten where I could only print and finish one. Each day's printing was sold before they passed through the burnisher.

A properly registered and well preserved line of negatives is your stock-in-trade, and in many instances all the photographer has to show for his years of care and trouble. The knowledge that you register and preserve your negatives tends to give a stability to your establishment. Your patrons appreciate it, especially when the death of some loved one makes duplicates desirable.

It seems a waste of time to argue this matter; you might as well debate as to whether water is wet, or whether fire will burn your fingers, as to discuss such a self-evident fact.

Carefully number each sitting, place a corresponding number on the negative, enter the names on an index book alphabetically for reference, and at the end of five years judge whether they are valuable. They are doubly so at the end of ten years.

13,449. Louis Gandolfi, 186, Fleet Street, London, "Improvements in Mounting the Front of a Photographic Camera on its Vase."—*August 8th.*

### Specifications Published.

3,571. *March 6th*, 1890.—"Shutter for Flash-Lamps." R. Slingsby, 168, High Street, Lincoln.

An arrangement is provided by which the camera shutter is actuated simultaneously with the flash-lamp or lamps, so that the shutter will be open for any interval during the flash, or the shutter may be actuated immediately before the flash.

3,718. *March 8th*, 1890.—"Studio." R. W. Thomas, 121, Cheapside, London.

The studio may or may not be portable. The sides are made preferably of canvas mounted on metal frames, and can be set at the best angles for reflecting light on the sitter.

3,730. *March 8th*, 1890.—"Film Apparatus." M. Evans, Savile Club, Piccadilly, London.

This relates to improvements on the invention described in Specification No. 10,131, 1889, consisting of means for intermittently actuating the film of the roller slide, and, at the same time, controlling the movements of the instantaneous shutter. The camera is intended to produce a rapid succession of pictures of moving objects to be afterwards combined by zoetropic apparatus. In one form of the roller slide, the film is drawn off the store reel, over a guide pulley, between two rollers (one of which is turned by a handle), and finally on to another store reel. To give the intermittent stoppages to the film necessary for exposure, a pin on the driving roller presses a brake block for a moment against the strip, and, at the same time, pushes the roller out of contact with the driving roller. To keep the film stretched, one of the store reels is driven by frictional contact through one of the gear wheels. Other modifications are described, in which the stoppage of the film is produced by withdrawing the actuating force without applying any special brake.

3,736. *March 10th*, 1890.—"Stands for Enlarging or Copying Photographs." J. C. Shenstone, 13, High Street, Colchester.

A board to receive the image slides on a graduated bar which slides in a platform adapted to support the lamp and camera. The platform is provided with a supplementary platform for the camera.

3,743. *March 10th*, 1890.—"Cameras and Dark Slides." W. Scorer, North Street, Havant, Hants.

A reversing frame at the back of the camera is provided with a sliding catch, which, when the dark slide is pushed into place, is slid under a catch on the latter, which is thus secured to the reversing frame. At the same time the catch is withdrawn from a notch in the dark slide shutter, which can thus be withdrawn only when the dark slide is secured to the camera. The camera back is provided with stops along one side and the bottom to ensure a light-tight joint with the dark slide. Also a shutter hinged to the reversing frame springs out at right-angles to the frame wheu the slide is withdrawn, and thus serves to exclude light. The two parts of the dark slide are fastened by a screw, which takes iuto sockets in both. The screw is fitted with a collar, which preveuts the screw being completely withdrawn. The base of the camera is provided with a slide which moves betweeu hooks, which arrangement is an improvement on the invention described in Specification No. 12,573, A.D. 1888. The Provisional Specificatiou also describes a modification of baseboard adapted for taking panoramic views.

*Stands.*—The legs consist of narrow strips of wood, which are jointed to parts to which the tip is adjustably secured by a thumbscrew. There are also supports for jointed stretchers, which take into notches iu the narrow strips of wood. The top ends of the latter are adapted for engaging with the base of the camera or portable dark tent, &c.

## Correspondence.

### "NOTES ON PERSPECTIVE DRAWING AND VISION."

Sir,—I notice that Dr. Emerson and Mr. Goodall have seut some observations on an article of mine to several photographic publications. I shall be glad if you will allow me to state that, as I have not a copying clerk at hand, I have sent what I have to say on the matter only to the journal in which my article appeared. Chapman Jones.

### THE "HOROPTER."

Sir,—In your issue of the 31st ult., I am not satisfied with the report as conveying exactly all I had to say. I gave a description of the "Horopter," gathered from authorities such as Helmholtz, Le Conte, and others, and referred those present to the works themselves, rather than occupy space by a suggestion that what I had said ou this matter need not be fully reported. I showed that no photographic method could reproduce the "Horopter." I considered Emerson and Goodall's paper a very important contribution, but was uncertaiu as to the full bearing of all the experiments on photographic perspective.

Briefly, the drawiug by a rectilinear lens and monocular perspective are absolutely identical when taken from the same point of sight and viewed from the same point. What I learnt from Emerson and Goodall to observe and express was, that neither monocular perspective nor its true parallel, the drawing of a photographic lens, really convey the sensuous impressious of vision, and that they become more and more unsatisfactory and unlike the sensuous impressions the wider the angle included, particularly with a lens of short focus, when not viewed at the distance of the focal length of the lens.

I found it was not a subject to be discussed and dismissed in a few words that had refereuce to measurement. That part has been self-evident from the first; but the bearing of work and observations such as that recently brought forward by Emerson and Goodall are uot those of measurement, but of individual impressions to be arrived at by individuals, in the maiu similar, though incapable of measurement. They have expressed for us what we have felt, and "balanced the egg" in this subject.

New laws are not given, as they cannot yet be reduced to measurement, if they ever will be. Photographic drawing and monocular perspective are, and always have been, capable of reduction to measurement, and in this difference lays the contention these gentlemen support, that photographic drawing is unsatisfactory and "small" in its rendering of sensuous impressions. Thos. R. Dallmeyer.

P.S.—I have read Mr. Burton's contributiou in the same issue of your paper, and will send you a few comments thereon on my return to town.

25, *Newman Street, W., August 12th.*

### EXHIBITION AT THE CAMERA CLUB.

Sir,—Will you kindly allow me to draw the attention of those interested to the exhibition which is now proceeding at the Camera Club. In addition to the photographs by the Countess Loredaua and the Marquis Dr. Vianna, we now have a collection of photographs by Prince Chotek, Prince Ruffo, and Herr Dreeseu, all of which are of such interest that every photographer should seize the opportunity of seeing them together.

The exhibitiou is open ou the usual conditions, namely, admission from 10 a.m. to 4 p.m. by tickets from members or from the hon. sec. G. Davison, *Hon. Sec.*

*Charing Cross Road, W.C., Aug. 10th.*

### GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

Sir,—The announcement that we have extended the time for entry till August 20th has brought me a number of enquiries as to the latest date for sending in pictures. I regret that we cannot make any chauge, and the last day must be August 22nd, as per prospectus.

William Goodwin, *Hon. Secretary.*

*Glasgow, Aug. 10th.*

### THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

Sir,—In justice to Mr. H. P. Robinson and to the Photographic Convention, I think it ought to be explained that Mr. Robinson, though he felt compelled to decline the presidency of the Convention at Edinburgh next year, did so on the sole ground that he feels physically incapable of undergoing the necessary exertion. It was certainly from no disinclinatiou to accept the invitation of the council that Mr. Robinson decliued the office. William Bedford, *President.*

*August 8th.*

### REDUCTION OF RAILWAY FARES FOR PHOTOGRAPHERS.

Sir,—With reference to the memorial initiated by my Society with a view to obtaining a reduction of fares for photographers and photographic societies, I regret to inform you that, at a meeting of superintendents held at the Railway Clearing House ou the 29th May last, it was resolved that the application could not be granted.

H. Selby, *Hon. Sec., West London Photo. Soc.*

42, *Ladbroke Grove Road, London, W., August 6th.*

### THE SOCIETY OF AMATEUR PHOTOGRAPHERS OF NEW YORK.

Sir,—A communication signed by "A Member of the Camera Club," in your issue of July 24th, reflecting somewhat on our New York Exhibition management, calls for an explanation. The reader would be led to infer that out of thirteen photographs sold, the value of which was £3 10s., only 7s. was returned after expenses were deducted. In reality, but seveu of the thirteen photographs were sold, amounting to £2, from which 4s. were deducted for commissions, 8s. duty, and 17s. for expressage and Custom House brokerage, leaving a nett result for the exhibitor of 11s., and six photographs (returned) valued at 30s., or an equivalent of £2 1s.

My communication in your same issue further explains the delay we experience in getting photographs through the Custom House.

Had the exhibitor notified the committee by mail of the date and the express company by which the pictures were shipped, probably they could have been gotten through the Custom House earlier, as was the case with Mr. Sawyer's exhibits.

That the exhibits were unusually delayed is certainly not the fault of the committee, but of the carrier, and upon the latter should rest the blame. F. C. Beach.

*Chairman, Committee of Arrangements.*

*New York, August 3rd.*

## Proceedings of Societies.

North Middlesex Photographic Society.

*August 10th.*—Mr. H. Staveley in the chair. Formal business having been taken and a new member nominated, objects of interest were called for.

Mr. Gill showed some hand-shutters and an exceedingly cheap half-plate camera made by Mr. Farrow, of Hornsey Road.

Messrs. Adams & Co. sent one of their "lightning" tripods, a Gilmes lens adapter, a "holiday" lamp, and a metal developing dish with cover, all of which were thoroughly examined and approved of.

Mr. Stewart reported that he had tested Mr. Barry's printing meter, and believed that, carefully worked, it would prove useful in carbon and opal printing.

Mr. Taylor then gave his demonstration on "Development," and explained the action of the various constituents of the developer—tho reducing agent, the restrainer, the accelerator, and the preservative; and, having brought six plates—two fairly-exposed, two under-exposed, and two over-exposed—proceeded to treat one of each with a normal developer, and then to develop the remaining under and over-exposed plates with such modifications of the developer as to make the best of them.

The usual competition of prints taken at field-day took place, Mr. Ainsley receiving the vote of merit for Kingsbury, and Mr. Walker for Beddington.

Sydenham Amateur Camera Club.

The usual fortnightly meeting took place on August 4th at the "Greyhound," the President in the chair.

In place of a discussion, Mr. Zimmer gave a demonstratiou of alpha printing and toning.

On Saturday, 8th inst., Mr. Piggott conducted an outing from Reigate to Betchworth, where the members had the opportunity of photographing wind aud water mills, sheep-folds, cornfields, &c., from which several satisfactory pictures have resulted.

Photographic Club.—Subject for Aug. 19th, "The Diazotype (Primuliue) Process"; 26th, "Films." Outing, Aug. 15th, West Drayton; train from Paddingtou at 2.35.

Richmond Camera Club.—At the meeting on the 7th inst. (Mr. Carolin presiding), Mr. Cembrano's report as delegate to the Photographic Couvention was unavoidably postponed till next Friday, and the subject "Home Portraiture" was discussed.

Diazotype Company. — Our attention has been called by this Company to an omission which lately occurred in our description of their process, which is based on the joint invention of Messrs. A. G. Greeu, C. F. Cross, and E. J. Bevau, and not on that of the first-named gentleman alone.

Automatic Photography. — The case of the Automatic Photograph (Foreigu and Colonial) Compauy came before Mr. Justice Chitty on Saturday. This was a petition by the Company for its winding up. It was formed for the purpose of supplying photographs, which Mr Whitehorn said people were supposed to get by dropping a penny in a slot and standiug in front of a lens. A petition had been presented to wind up a company for supplyiug England with the machines, but it was to stand over. With regard to the present Company, it was asked that it might be similarly dealt with, as a meeting of shareholders had appointed a committee to iuvestigate its affairs, aud it was desired that the petition should not be heard till the report was made. The postponement was opposed by Mr. Byrne, Q.C., on behalf of some of the shareholders. He submitted that the Company could not carry on business at a profit, and to let the matter stand over would be merely to waste the shareholders' money. Mr. Justice Chitty made a compulsory winding-up order.

## Answers to Correspondents.

Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.

E. B. B.—*Reversed Portrait.* Except from the title of the newspaper reading backwards, it would be impossible for a stranger to tell that the portrait *was* actually reversed; but you, having taken the picture, know that the old mau's left cheek and ear were illumiuated, aud the right side cast iu shadow, at the time of the sitting. Now, your letter of advice says: "The plate was put in the right way, or the print would not appear so sharp." So you believe; but, with all due deference, we beg to doubt this. The plate must have been put into the carrier for once with its sensitive side up, and the picture taken through the glass would give exactly such a result, as is well-knowu to all workers of the photo-mechanical processes. The difference in the length of focus might not be enough to interfere with sharp definition, especially with the splendid lens which you fortunately happen to possess.

W. T. W.—1. The letter announcing your change of address came to hand just in time to enable us to convey the information to our correspondent. 2. Leave the other matter in our hands uutil we find an opportunity of consulting with the person named, who is at present out of town. A cheap process is a desideratum.

H. G. (Brockley).—*Silver in Spent Developers.* The quantity is so small that it would hardly be worth while attempting to treat these separately; they should be put into the waste hypo residues, and then worked all together for silver.

M. P. (Redhill).—*Preservation of Sensitised Papers.* Twelve mouths is a loug time to keep any kind of ready-sensitised paper, and we doubt the policy of eadeavouring to push the conditions of permanence to this extraordinary leugth. Citric acid in the nitrate bath is the best kuown means of preserving the silvered surface, several formulæ for which you will find, as in chapter xxi. of Mr. Heighway's "Photographic Printers' Assistant"; Captain Abney's "Iustruction in Photography," page 268; aud others at the end of the Year-Book, pp. 232 and 233. *Blisters in Albumenised Prints.* Besides those you have enumerated, a fertile cause of this defect is the over-dryness of the paper at the time of albumenising; or bubbles happeuiug at this stage aud not quickly enough dispersed, which would lead to imperfect adhesion, ultimately resulting in blisters when the prints are being toued and fixed.

Blocks.—*Instruction.* Mr. W. T. Wilkinson, of 17, Henry Street, Derby, undertakes to give practical lesssons in photo-mechanical work generally, aud we have no doubt but that he would be able to instruct you iu the details of the process mentioned.

Constant Reader.—*Selection.* Most amateurs would prefer to use 3 or 4, aud pay the difference of cost for a superior article; but if money is an object, make do with No. 2, or even No. 1. Outside these we have no suggestion to offer.

G. Y. (Gourock).—*Platinum Compounds.* The salt uamed, besides all the other compounds of platiuum, can be procured from Messrs. Hopkin and Williams, 16, Cross Street, Hatton Garden; or, failing theui, from Messrs. Johnson and Matthey, Hatton Gardeu, who only supply in larger quantities.

Confused.—*Apparatus.* The camera mentioned is oue of the best made and most reliable in the market, and, together with the *first* of the lenses named, would constitute a thoroughly satisfactory outfit.

C. B.—*The Copyright Question.* We have read Mrs. Earnshaw's letter of August 5th, whereiu she distinguishes between "colour copyright" aud "copyright iu mouochrome." Until theu we always supposed that possession of the picture covered all kinds of copyright, but it appears that, in this case, the lady artist specially reserved the right of reproduction in monochrome, being already in treaty, as she believed, with the proprietors of the *Queen* newspaper for its appearance as one of their ordinary illustrations. For full text of the letter see the *Daily News* of 6th instant.

# THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV. No. 1720.—*August* 21, 1891.

CONTENTS.

## PHOTOGRAPHY IN STARLAND.

As might be expected, Dr. Huggins, in his presidential address to the British Association assembled at Cardiff, devoted a great deal of attention to the important work which has been done, and which is yet in progress, in which the photographic plate is being employed for the portraiture of the heavens. He called to mind the noteworthy circumstance that, at the very beginning of the history of photography, on the occasion of the announcement of the discovery of Niepce and Daguerre to the French Academy by Arago, that savant held out the hope that the wondrous new method of picture-making would be applicable to a more perfect delineation of the sun and of the moon than had before been dreamt of, and we all know that the prophecy came true, for such pictures were among the first which were successfully accomplished by the new art. These pictures, in fact, are still pleasant to look upon, so well are they executed, in spite of the many disadvantages under which they were produced, and with which photographic processes at that time were necessarily associated.

Even after the wet collodion method came into vogue, the difficulties of photography, although lessened, had not by any means been removed, and astronomical photography—except so far as it related to picturing the orbs of day and night—was still unheard of. And this, as the president of the British Association was careful to point out, was not for lack of instruments, but simply because of the shortcomings of the chemical process employed. The young photographer of to-day, why buys his plates ready prepared for his camera, has little notion of the anxiety and trouble which practice of the art involved under the old order of things. It would be beneficial to him in other ways, as it certainly would be as an item of photographic education, were he to learn in a practical manner how to clean a glass plate, how to collodionise it, and how to prepare a silver bath in which to sensitise it. He would soon see that the workers of old had many difficulties to cope with of which before he was ignorant, and possibly he would, after this experience, be the more ready to acknowledge the debt which he owes to the pioneer workers, and to the makers of commercial dry plates. If a candid man, he might even go so far as to acknowledge that, if photography were still to involve all the worry and mess that it was once credited with, he would never have bothered himself with a camera and its belongings.

The modern astronomer is in much the same position as the hypothetical being whose position we have just reviewed. He, too, can say that if photography still involved the use of a wet plate he would have none of it, not for the reason of its troublesomeness, but simply because it was not adapted to his work. For the sun and moon the old process was, as we have seen, good enough, for the flood of light given forth by the former was sufficient to impress a plate with its image in a very small fraction of a second, while the reflected light of the latter afforded sufficient radiance to perform the work in less than a minute; but when the more remote bodies in space came to be considered, it was found that their light was insufficient to impress the plate while the latter remained in a sensitive state. The collodion surface broke down, or rather, it became insensitive as the moisture evaporated from it, and therefore it required to be used fresh from the bath, or not at all. It is true that, by certain treatment with honey, &c., the evaporation could be delayed for a long time, but still not long enough to suit the purpose of the astronomer.

Then came the sudden revelation that, in the gelatine dry plate, we had a new agent which could do things which never had been accomplished before; a plate which was so sensitive to feeble rays of light that the utmost precautions had to be taken in all the necessary manipulations. The old brilliant yellow light, in which the photographer was wont to work, had to be discarded in favour of a deep red, which seemed just enough to make darkness visible. But beyond their wondrous sensitiveness, the new plates had other merits of an equally noteworthy kind. The chief of these was that they preserved their properties for an almost indefinite time, and development of the image could be put off for days, weeks, or months, to suit the convenience of the operator. Photography had, by the introduction of these dry plates, suddenly found itself in a state of revolution, and the new took the place of the old with astonishing rapidity.

But while the general public were busying themselves with the wonderful pictures obtainable by aid of the gelatine plate, the astronomer was not slow to see that this plate was the very thing that he had been waiting for so long. It answered all his requirements in responding to very feeble gleams of light, in remaining sensitive for any time required during exposure, and keeping well after exposure and before development; for the pictures which he dreamed of taking, wheth er they were of planets, distant stars, or nebulæ would require an exposure reckoned by hours rather than by seconds. The new agent was found to be fully equal to the call made upon it, and for the first time star charts were printed by their own feeble light.

But the dry plate is something more than a mere registrar of stars; it is, in a manner, a discoverer as well. Who does not remember the story of the discovery of the nebula attached to Maia, one of the stars in the Pleiades, and how it was found first of all in a photograph, its existence not having before been suspected? Then we have the totally unlooked-for result that the dry plate registers stars so distant that they have never yet been seen by human eye, even when aided by the most powerful telescope; for the action of the plate is cumulative, and these distant bodies, giving forth a light too feeble to excite the retina of the eye, by mere persistence of shining impress the sensitive plate.

But while taking credit to photography for so much, should we not say a word for the wonderful precision of the instruments employed? Who among us has not, in an idle moment, looked at Jupiter through the telescope of some itinerant astronomer, and has seen how the bright globe of light and its attendant satellites are plainly delineated on the dark blue of the sky? But, as we gaze, they are fast travelling out of the field of the telescope, and its owner has to give the instrument a jerk to one side in order that the image of the distant planet may once more run its course over the limited space. This motion, as we all know, is not due to Jupiter and his moons, but is an illusion caused by the movement of the earth itself. In our observatories this movement is counteracted by a clock, which controls the telescope and keeps the objects in the same places in the field of view. How beautifully made and delicate this apparatus must be when it is found possible to keep the image in exactly the same place on a sensitive plate for several hours. Nay, it is possible to do more than this. The same plate can be exposed for several evenings in succession, the work broken off by clouds or other obstructions on one night being taken up on succeeding nights. This power of executing the portraiture of the stars by instalments is one of the many benefits brought to astronomical research by the modern photographic dry plate.

## PHOTOGRAPHY IN FRANCE.

BY LEON VIDAL.

French Photographic Society—Meeting of August 7, 1891—Retouching Negatives from the Back—Apparatus for the Measurement of the Field of Vision and of the Focal Length of the Lens—Apparatus for Preparing Concentrated Solutions—Trial of Sensitive Plates—Celluloid Dishes—The "Mignon" Instantaneous Shutter—Oil for Lubricating Shutters—Self-Stretched Films with a Metallic Border—Oxy-hydrogen Lamp—The Ether Light—Photography in Colours.

At the French Photographic Society's meeting on August 7th the atteudance was but meagre, for the excursion season is at its height, and many members are at this time of year sojourning in the country. The process of retouching suggested by M. Poex seems difficult to realise in its normal couditions. He proposes to print a preliminary proof on paper, and to attach this by gum to the glass side of the negative. It would take too long to fully discuss this method, the weak points of which are immediately apparent.

The method brought forward by M. Sébert is based upon a plan which has already been indicated by Monckhoven. Its object is to measure the field of vision and the focal leugths of lenses. Two lines are traced ou the focussing screen of the camera at a certain distance from one another, aud the same distant point is alternately focussed. The same gentlemau brought forward a method by which concentrated solutions can be conveniently prepared.

Several manufacturers of dry plates were invited to send in specimen packages of their plates. M. Gravier stated that these plates had been submitted to trial in the presence of a few members of the Society. A small strip was cut from each of the different brands of plates, and these were placed side by side beneath a graduated screen, such as that employed in Warnerke's sensitometer. The whole were then exposed to the light of a taper for a determined time, and afterwards developed. The scale of tints thus obtained readily showed the relative sensitiveness of the plates. From the firm of Block, some celluloid dishes for developing purposes, as transparent as those of glass, were brought forward by M. Gravier.*

A new instantaneous shutter called the "Mignon" has been introduced, which has the merits of being cheap, easily manipulated, and capable of being used for instantaneous or time exposures. This shutter is small and compact, and is made entirely of metal. It is always set ready for action, and its mechanism is of such a character that it cannot readily get out of order.

The firm of Dehors and Deslandres present some printing frames in hardened cardboard. They are light, and not so easily broken as those made of wood. The same firm also bring forward au oil made specially for lubricating shutters and other apparatus having moving parts.

An automatically stretched film is brought forward by M. Planchon. In this case the emulsion is run upon a thin metallic frame which serves to keep the film, when dry, perfectly flat, and this permits it to be placed in the dark slide without any additional support. After development the frame is cut away and discarded, its work having been done. It remains to be seen whether this method will have any practical value.

* These dishes are sold in London by Mr. Gotz, of Buckingham Street.

The oxy-hydrogen lamp presented by M. Pellier has not given the expected light, no doubt because the pressure on his gas cylinders is insufficient.

As will be seen, the meeting did not result in anything very important being brought forward. We must, however, say a few words about M. de Saint-Florent's communication relative to photography in colours. He showed various proofs printed on celloidin paper. The images show analogous colours to those of Mr. Veress, of Klaussenbourg. M. de Saint-Florent thinks that the colourations are formed in the same manner as those produced by M. Lippmann, and he looks to this direction for a solution of the problem of photography in colours. The author of this communication has found means to fix these multi-coloured images, and the method by which he works will presently be published.

## DEVELOPING.

BY E. DECKER.

"There is a great deal of difference between seeing and observing." There is a mountain of truth in a molehill of words in that quotation, which will apply to developing as well as many other things.

It is merely putting in "brains Q. S." with the other constituents of the developer, but that makes all the difference (except that through pure luck) between a negative that will make a photograph that is a joy to look at, and a piece of paper with a blotch of silver over it. New developers and new developing agents can be obtained from nearly every one of our photographic journals. They are probably all good, only some may be better than others. It is not so much the formula, but the way it is used, that gives the result. There are probably no two persons, using the same plates and developer, that will produce the same quality of negative. One will only see that the image makes its appearance in due course of time, will see that it continues to develop, and when he sees that it is sufficiently dense will remove it from the developer. Another will not only see when the image appears, but will observe whether it is too slow or too quick, and will add a little force or apply the brakes as it may need. He will observe the exact time when it should be removed from the developer, and whether it should be washed very quickly before applying the fixing, or whether a longer washing would be better.

Whether pyrogallic acid, eikonogen, hydrochinon, iron, or any of the very latest developers should be used, should depend upon the observation of each one using them. Each one may be better for some special purposes than any or all the others. For general use, however, each person should adopt some special developing agent, learn to use it, and stick to it. Have also a standard developer; but, as there are many exceptions to most rules, so remember that you must look out for these exceptions in the way of different plates, different exposures, and different subjects, and strengthen or weaken your developing agent or your alkali, or add a retarder.

Among all the old or new developing agents "pyro" still holds the lead, and, from all appearances, will continue to do so. So far as my own observation goes it gives better strength, better detail, better printing qualities, and, for an over-timed or under-timed plate, a better negative than any of the others. It may not make so handsome a negative as some of the others, but it is not the beauty of the negative itself that is wanted, but the beauty of the print to be made from the negative. It is true it may stain the hands, but that can be remedied by using a pair of rubber gloves. The staining of the negative itself, where it goes so far as to be a detriment to its printing qualities, can be easily remedied; but in most cases, particularly where it only leaves a slight olive colour, it is much preferable to what is called "a wet plate effect."

You can make with "pyro" a negative as "thick as a board," or one as delicate as the bloom on a young lady's cheek, with the same kind of plate and the same exposure.

With the quickest plate a line drawing can be copied that will leave the lines pure black and the whites white paper, or all the detail in lights and deepest shadows in the portrait of the fairest blonde dressed in her bridal robes. To develop a first-class negative presupposes a correct, or nearly correct, exposure of the plate. Perfectly correct exposures are, and must be, extremely rare. It would take a long mathematical calculation and very sensitive instruments to give the exact strength of light with its shade of colour, and more exact shutters to our lens than we now have, with an operator at the shutter capable of taking advantage of all the mathematical and scientific points, to "touch the button" at the exact instant of time to get that exact exposure.

Such being the case, a "standard developer," while being "handy to have in the house," can be very seldom used without some change if the very best effects are truly sought for.

Have your sulphite of soda and your alkali of a standard strength; add the pyro only when you are about to use the developer; make a little stronger solution of pyro for emergencies, and have your bromide ready for use; then use all with discretion, not only seeing, but observing.

Have you ever thought how much developing a plate is like creation? Do you ever think that you are creating a little world every plate you develop? The developer is poured over the plate, and soon the tops of the highest mountains appear in the shape of the highest lights, then the lower hills as the lighter shadows, then the rolling and flat earth as it graduates into the deep shadows represented by the seas. Usually we so develop our plates that we can say, when finished, "Behold, it is good!"—*Buffalo Convention.*

Hints about Varnishes.—In making varnishes of all kinds, care should be taken in every case to see that the spirit is of full strength, the resins free from moisture and all foreign matter; and where the finer sorts of varnishes are to be made to see also that the resins are all fine picked. The resins should be small, and, if possible, granulated, as, if they are in large pieces, their solution is protracted, while, on the contrary, if they are too small and powdery they get into a cohesive mass, in which state it is almost impossible to effect solution. To effect speedy solution of the resins various plans are resorted to, such as constant agitation, with occasional immersion in hot water—if the varnish is being made in small quantity—in a glass bottle, or by rolling jars or tins on muffled rollers where the varnish is being made in quantities of two or three gallons, or in casks turned by mechanical means where the varnish is required in quantities larger still. It may be convenient, in the case of turpentine varnishes, which do not evaporate so quickly, to make them in wide-mouthed jars, and simply stir them frequently with a stick. If the stirrer in this case is provided with cross bars, the mass is more effectively broken up, and a solution consequently hastened. It is almost unnecessary to add that the utmost care and cleanliness should be exercised in the making of varnishes, as the least dust or moisture will affect their quality.—*Paint, Oil, and Drug Review.*

## THE ZOOLOGIST'S DEBT TO PHOTOGRAPHY.

BY G. A. B.

Photography has so often been styled the "handmaid of science" that the remark, although most true, has become, like the proverb quoted by Hamlet, "somewhat musty." But there is one branch of science which, I think, owes a debt to photography which has remained, as yet, almost unacknowledged. I allude to the great help which the art of sun painting has brought to the zoologist, in giving him far more perfect pictures of animal life than he could possibly command before its advent. Many of the representations of animal life with which our forefathers were obliged to content themselves were perfectly ludicrous in character, and were as unlike the animals that they were intended for as it was possible for them to be.

The earliest representations of animals are those found inscribed on bones and pieces of slate and stone which have been found in certain caves in France. These are supposed to be pre-historic, and owe their origin to the work of those early hunters who found their homes in these caves. One well-known one is supposed to be the only authentic portrait, if it can be called so, of the mammoth, or extinct elephant, and it has been executed with a sharpened stone on a piece of mammoth ivory. Another drawing of the same period gives a very fair representation of a battle between stags, in which the antlers are intermingled in a singularly truthful manner. But perhaps the best of these early drawings is one scratched on bone representing an animal with the lower jaw slightly displaced, so as to indicate the act of chewing the cud.

Now, strange as it may seem, these very early attempts at art are really more satisfactory as pictures, and more correct in their drawing, than numbers of works which have been used for illustrating books at, of course, a far later period. For some years it has been a hobby with the writer to collect books of a bygone age, especially those containing cuts of an extraordinary character, and interspersed among these are several books of travel containing representations of natural objects of a very marvellous kind. Travellers' tales used to be looked upon with grave suspicion, for men were not able to believe in anything outside their own environment; but if the tales were no truer than the pictures which illustrated them, the readers were certainly justified in hesitating to swallow them without a little mature consideration.

One of these books I recently took down from its shelf, and I have copied, for reproduction by the zincographic process, a few of the curious cuts which adorn its pages. These cuts were executed long before the revival of wood-engraving in this country, under the fostering care of Bewick, and the plate-mark, which is still visible round the margins of the original pictures, at once discloses the manner in which they were produced. They are copper-plate engravings, like all illustrations of the period, and had to be printed by a separate operation from the printing of the text which they illustrate, at great expenditure of time and labour.

The volume is still in its original leather covers, and bears date 1634. Whether the work is rare I have not had the opportunity of finding out; perhaps some reader of the Photographic News may be able to give some information on this point.

The title-page is a far more voluminous document than would be tolerated in these go-a-head days, and, as a curiosity, is worth quotation at length: "A relation of some yeares' travaile begunne *Anno* 1626 into *Afrique* and the greater *Asia*, especially the Territories of the *Persian* Monarchie: and some parts of the Oriental *Indies*, and Iles adiacent. Of their Religion, Language, Habit, Discent, Ceremonies, and other matters concerning them. Together with the proceedings and death of the three late Ambassadors: Sir D.C., Sir R.S., and the *Persian* NOGDI-BEG: As also the two great monarchs, the King of Persia and the Great Mogol. By T. H. Esquier. London. Printed by William Stansby, and Jacob Bloome, 1634."

The book begins with an account of the Canary Islands, illustrated with some pictures which are certainly like nothing in nature. Then we have an account of a tornado which overtook the ship in which the narrator of the story was journeying, which leads us to the first picture which I have selected for reproduction. But let me quote the original:—

"Yet in my judgment this (the tornado) is most unhappy to the sailors, who in those raines handing in their sailes and standing on the deckes, after the action, commonly goe to sleepe (the weather being terrible hot) in their wet clothes, which stinke very much of that ill-digested showre, and thereby beget long diseases and mortall, as the Calenture, Scorbute or Scurvie, Feavers, Fluxes, Aches, and the like: which (did they but forbeare *Arack* or strong liquours, and shift themselves out of those nasty infectious wet clothes, when they take their rest) might be prevented."

"And besides these, they should be wary, where, and when they wash themselves. Many heretofore have been devoured by ravenous fishes, such as justly we call sharkes, whose cruel appetite encourage them to devoure men alive, they are always directed by a little speckled fish, called a pilot fish, by guiding their monster-masters to a prey. Such attendants Lions have, like little Dogges called Jackalls, and here the adventurous ship-boyes were in peril of those sharkes, swimming so without heed, that some were in apparant danger. The shape of which fish

I have here (though unskilfully) pourtrayed for your better satisfaction."

Let us hope that the reader of two and a-half centuries ago received this portrayal with the wished-for satisfaction. It was certainly out of his power to check the correctness of the drawing by any standard work on natural history, for, even had there been such a book of reference at hand, its illustrations, if any, would have probably been as faulty as the one in question. People are better educated in these things now, and they know well enough that a shark does not possess a head like a rat, and that its mouth is quite on the underside of that head. The distinctive tail of the shark tribe, in which the upper lobe is double the length of the lower, is altogether missed by the artist, who has given his creation a tail like that of a herring. Very probably he had never seen a shark at all, and had made up the drawing from description, and by the help of any inhabitant of the deep which happened to be procurable. It is impossible to know what is intended by the spiral arrangement descending from the clouds, but perhaps it is a waterspout thrown in to add to the horrors of the situation.

Now, it is quite clear that the faulty nature of this and most of the other drawings is due to the fact that the artist had to work from mere description. This is evident from the circumstance that on the next page to that bearing the "sharke fish" there is a well-executed drawing of an inhabitant of Angola. This gentleman is "black but comely," his unclothed muscles are well developed and correctly drawn; the only objection to the work being that neither face nor figure has any marked characteristic about it, unless it be that of an inhabitant of England. The presumption is that the figure was drawn from a white model; but, apart from the fault named, there is nothing to take exception to.

The drawing of another biped—an inhabitant of Madagascar—cannot be spoken of in the same category, for it is as incorrect as it possibly can be. Luckily, however, the artist or author has been good enough, as in the former case, to give it a name. It is a flamingo, and about it we read that:—

"Here are many rare sorts of Birds; many we saw sold, one only I have drawne, which, though unworthy the labour, yet in that with us they are not, and the colour of their feathers so excellent crimson and white, with other colours, that they may compare with birds of Paradise."

The flamingo, as most of my readers will know, belongs to the important order of *Anseres*, or the goose tribe of birds, and the artist may have had this in his mind when he made the creature so much more like a goose than a flamingo. The head is not unlike that of a flamingo, but the neck has only a third of the length which it ought to have, and it is twice as thick as it should be. The attachment of the graceful neck to the body should not be marked by the protuberance shown, which the artist probably means for the crop of the creature. The bird is not humpbacked as shown, and its legs in the drawing are, like its neck, deprived of two-thirds of their length. An artist, whose chief work at the time consisted of drawings on wood blocks—which blocks he had to pay for himself—told me that it was always economical to draw giraffes, ostriches, and other creatures with long necks and legs in a stooping position. He generally made them in the act of drinking, so that just one-half the quantity of wood was occupied that would be required if they were standing bolt upright. The gentleman who drew this flamingo may have been guided by considerations of space in the same manner. Perhaps he had to pay for the copper-plate upon which it was engraved.

It is only fair that we should find as many excuses for the unfortunate artist as we possibly can. The author of the book probably made a rough and faulty sketch of the original creature—possibly the dead body of one—and from this the artist would be directed to make a presentable picture. He had no friendly Zoo to fly to as we have to-day, and was obliged to fill in details from his imagination.

The next example of inventive zoology which I have selected is even less veracious in character than the last. It is a picture of the penguin, and again I quote with it the original description of the bird:—

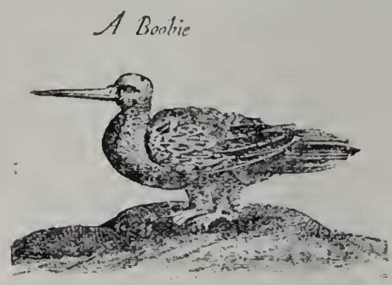
"Nearer the road (is another small Ile), seven leagues at most distant from the Bay; 'tis now and hath time out of mind beene called *Penguin* Ile, so called from a number of birds, white-headed and blacke intermixt, which bird is rather participant with the water than land, yet uses both; her diet is at sea, where she feeds and dives rarely; her nest ashore, where she breeds and rests; they have wings, but flie not; they are better to satisfie the curious than to feed the stomacke, except Oyle be delightful to it."

Penguins are familiar enough to the general reader to enable him to quickly appreciate the fact that the drawing which is here reproduced is most hopelessly wrong. Nature never yet produced such a bird as that figured here, which must, I should think, have been evolved half from mere hearsay, and the other half from the inner consciousness of the artist, helped, perhaps, by preconceived notions of what a bird's appendages ought to be like. The tail, it will be seen, is that of the sparrow, while the penguin, in reality, has no tail worthy of the name—a little pointed prolongation of the body rather than a complete organ. The artist has, too, entirely missed the most noticeable and interesting feature of this peculiar bird, which is that the wings are used as paddles in the water, and that this is almost their sole use. It is true that, when pressed by pursuers, the penguin will employ its wings as forelegs, and is able to run along at a good speed by their help, but they may be described generally as paddles, for this is their main use. There are many different species of penguins, but that most familiar to the public, and made familiar through the Zoological Gardens and the museums, is the king penguin. It is this bird which has furnished Mr. Stacy Marks with a model for his humorous picture now hung in the Birmingham Corporation Art Gallery, "Dominicans in Council." Here we see a group of these creatures on a sandy shore, and looking far more like a family of jolly fat friars than birds.

In my concluding example I give a representation of

"A Booby," and here again we have a most faulty drawing. There is less excuse for faults in this case, for the author admits that he had every opportunity of seeing the bird at close quarters—at least, this may be gathered from what he writes concerning it:—

"The foure and twentieth of *May*, we were under nineteene degrees and thirty-one minutes of south latitude, where one of the saylers, espying a bird fitly called a *Booby*, hee mounted to the top-mast and tooke her. The foolish quality of which bird is to sit still, not valuing danger, which bird I have here simply depicted as you see."



These examples of the sort of drawings that seventeenth century folks had to content themselves with are to me very interesting, and I hope that they may prove so to others. It is, of course, unnecessary to say that these crude productions were greatly improved upon in later years, but the best of them all cannot hold a candle to the beautiful work done within recent years by the camera. In connection with modern animal photography, I fancy that the earlier workers in this field are sometimes apt to be forgotten by the rising generation of photographers. But it will do no harm to remind them that certain pictures which have never yet been surpassed were taken long before the modern dry plate became an article of commerce. I may specially note the names of Mr. Haes, Mr. York, and Mr. Dixon. Any one of these gentlemen can point to pictures, taken under great disadvantages, from which the aspirant of to-day can get many valuable hints. There were then but few who attempted such work; now the camera bearers at the Zoological Gardens are almost as numerous as the animals of a lower grade. This phase of photography certainly has much fascination about it, and is most useful in giving truthful representations of some of the most beautiful of nature's works. That our forefathers laboured under some disadvantages in their endeavours to realise the appearance of creatures not indigenous to their own country, the examples which I have sent to the editor for reproduction will sufficiently attest.

---

A Novel Idea in Photography.— Ernest Marks, a young Plainfield photographer, who has made a name in connection with instantaneous photography, especially of racing events, has invented a method of photographing the finish of close races. In order to secure the exposure at exactly the right moment, he has his camera accurately placed beneath the wire on a pivot in such a way that, by first viewing the horses as they approach the last sixteenth of a mile, and following them up with his finder, the exposure is automatically made when the camera has reached its proper position under the wire just as the winning horse's nose passes under. Mr. Marks proposes to affix an electric arrangment by which he may secure a still more accurate exposure, there then being no chances of the shrinkage or expansion of the operating string. The camera will not lie, however heavy the bets may be on a losing horse, and there is no chance to declare a "dead heat" when a photographic negative plainly shows one horse to be a half head or more in advance of the other.—*Lithographic Art Journal.*

## PRACTICAL DIRECTIONS FOR THE RETOUCHING OF POSITIVES.

BY A. CHEVALIER.

### Retouching on Carbon Tissue.

The retouching of these proofs presents difficulties which are peculiar to the process, but, once well understood, it will permit one greatly to improve prints, although they may be originally of a very second-rate description. The resources at the disposal of the retoucher in this process are very many. A proof may be positively covered with blemishes, and to all appearance useless, but by following a methodical plan of retouching it is possible not only to save it, but to completely restore it. In the first place, you must attend to the groundwork in order to give to the picture its relative values. If the proof is afflicted with dark spots—which is frequently the case—you must scrape them until the blemishes are changed from black to white, and they can then be made to harmonise with the rest of the ground by the judicious use of the pencil or brush, but it is difficult to so adjust the work of the scraper and of the pencil as to obtain the required equalisation of tint.

If, on the contrary, the blemishes should be light rather than dark, the use of the brush is at once indicated. For this work you employ four colours, the mixture of which in certain proportions will give you the exact tone of the photograph. These colours are ivory black, carmine, emerald green, and blue. It is indispensable to add to the water employed in mixing these colours a sensible proportion of gum arabic, so as to give the necessary force to the shadows. Besides the gum must be added a very small quantity of prepared ox-gall, so as to make the colour flow well, and to counteract any grease which may be present.

### Stumping in a Background in Chalk (Pastel) on (say) Aristotype Paper.

In this case the background of the picture should be perfectly white. In order that the chalk may leave its mark on the paper without inequality, but with a regular grain, you must commence by abrading the paper by means of a fine linen sprinkled with finely-powdered pumice. Care should be taken to encroach as little as possible on the lines of the image, and also to avoid leaving any spaces uncovered by the pastel. You can then employ the stump, and obtain a background graduated, or of any other description.

The background thus made is mat, and by no means in harmony with the rest of the photograph. Moreover, it is so delicate that the slightest movement will cause it to rub off; so that it is advisable to fix it, and, at the same time, cause it to harmonise with the rest of the image. This can be brought about by using certain fixatives to be obtained commercially, and which are used for this purpose by pastel painters. These are applied by means of a spray producer, after care has been taken to protect the rest of the picture by means of parchment paper. This precaution is indispensable, for otherwise the wax dissolved in the fixative would interfere with further operations which might be required with pencil or scraper.

### Retouching on Eastman (Bromide) Paper.

This paper will take chalk or pencil. For the shadows it is best to employ a dark crayon, while the lights are treated with one which is very hard. In treating the background, the same method is advised as that recommended for carbon paper. It is probably more easy to make a background on bromide than on any other description of paper, because of the facility with which the chalk can be applied to it.

Platinum Paper.

This paper can be retouched in the same manner as the last. Some have tried to treat it with water-colours; but before this can be done satisfactorily the paper must be steeped in a solution of arrowroot—a proceeding which is applicable to neither bromide nor carbon paper.

Such are the means, stated in a condensed form, by which the methods are available for retouching on several kinds of photographic paper. The operator must not be afraid of retouching by any of these methods. At first they may appear to be difficult; but, with care and perseverance, all fancied obstacles in the work are easily surmounted, and the results obtained are worth striving for.—Abstracted from *Revue de Photographie.*

## PHOTOGRAPHIC EXHIBITION IN GLASGOW.

Glasgow, says the *North British Daily Mail*, is to have an international photographic exhibition on a scale never yet approached by any other city in the kingdom. In 1883 a small coterie of gentlemen formed themselves into the Glasgow and West of Scotland Amateur Photographic Association, and it was soon obvious that the movement was to be attended with more than ordinary success. The roll of members steadily increased year by year; a large and well ventilated suite of rooms was eventually engaged, where members could develop their plates, hold business meetings, read technical papers, and give practical demonstrations; and so popular did the movement become that ere long the executive found it necessary to extend not only their premises, but also the time of such meetings from a limited portion of the year to all the year round. Informal meetings of the members are now held almost nightly, whilst during the winter season lime-light entertainments form an attractive feature of the Association's programme. The outcome of all this has been an ever-increasing number of members to the roll, until, from about a dozen or so in 1883, the list has increased to over two hundred, amongst whom will be found the names of many of the most prominent merchants and manufacturers in the West of Scotland.

For some time there has been a strong desire on the part of several of the leading members that Glasgow should not be behind other photographic centres in the way of affording the public ample opportunities of seeing on a large scale the class of work that amateurs from all parts of the world can turn out, alongside that of well-recognised professional workers; and the thanks of the public are due to the indefatigable exertions of Mr. John Morison, junr., the president of the Association, and the enterprising council who are at present directing the Association, for their endeavours to organise in Glasgow an exhibition which will exceed in importance any such exhibition hitherto held. A large guarantee fund has been subscribed, chiefly among the two hundred members of the Association, and the executive have wisely called to their aid the services of several of the most experienced professional workers in the district, the result being that the movement has assumed dimensions of no ordinary character, and will embrace several novelties not previously seen at similar undertakings.

The entire suite of rooms forming the Fine Art Institute has been engaged for the whole of the month of September, and the exhibition of work will not only be of a truly international character, but will embrace some special features in the way of photo-mechanical exhibits. Among other numerous interesting exhibits will be found a series of photographs taken by Surgeon Newlands during the recent Manipur expedition.

Arrangements have also been concluded with well-known lecturers, who will give nightly lime-light entertainments in the large hall; and, to ensure the success of this branch of the Exhibition, a special twenty-feet opaque screen has been erected at the west end of the room for the projection of photographic transparencies. The list of lectures, both amateur and professional, will be found to contain the names of Mr. Andrew Pringle (with his "Life and Songs of Robert Burns"), Mr. Thos. N. Armstrong (with an entirely new lecture-set of a "Caravan Tour through the Trossachs"), Mr. Ralph Elder (with the outcome of this year's holidays, spent on the Continent), Mr. Paul Lange (with his popular "Tour in Iceland"), Mr. Geo. Napier, Mr. Wm. Lang, Mr. John Morison, junr., Mr. Wm. Scotland (the originator of caravan touring in the West of Scotland), and Mr. Charles Reid, of Wishaw (with his admirable animal studies).

Kindred photographic associations are lending a helping hand, and all are working with a zeal that must ensure an exhibition of more than ordinary interest, not only in pictures, but likewise in the latest novelties in the way of apparatus, ample space for which has been provided by the executive.

The Exhibition will open on the 1st of September with a full-dress evening *conversazione*, at which the Lord Provost will preside, and invitations to a very large number of professional and leading citizens of the West of Scotland have been issued. Musical promenades will be given at intervals, and Messrs. Ferguson and Forrester will take charge of the refreshment stalls. Altogether, the month of September should be a very attractive time for those desirous of spending a profitable and pleasant day or evening at the Fine Art Institute.

Mr. Wm. Gordon, the secretary of the Association, will readily furnish information regarding the undertaking on application to him at 3, Lynedoch Street. Intending exhibitors should note that the last date for receiving entry forms is the 20th inst., and the last day for sending in exhibits is the 22nd inst.

Loosening Glass Stoppers. — *The Pottery and Glassware Reporter* states that some one of the following methods is certain to prove effective:—(1) Hold the bottle or decanter firmly in the hand or between the knees, and gently tap the stopper on alternate sides, using for the purpose a small piece of wood, and directing the strokes upward. (2) Plunge the neck of the vessel in hot water, taking care that the water is not hot enough to split the glass. If the stopper is still fixed, use the first method. (3) Pass a piece of lint around the neck of the bottle, which must be held fast while two persons draw the lint backward and forward. (4) Warm the neck of the vessel before the fire, and when it is nearly hot the stopper can be removed. (5) Put a few drops of oil around the stopper where it enters the glass vessel, which may then be warmed before the fire; then apply process No. 1. If the stopper still continues immovable, repeat the above process until it gives way, which it is almost sure to do in the end. (6) Take a steel pin or needle and run it round the top of the stopper in the angle formed by it and the bottle. Then hold the vessel in your left hand and give it a steady twist towards you with the right, and it will very soon be effectual. If this does not succeed, try process No. 5, which will be facilitated by it.

# Notes.

The art of tattooing is a universal oue, being practised by savages as well as civilised beings. Mauy boys at school have undergone the process with the help of a needle to make the pricks, and a little gunpowder rubbed in to afford the necessary colouring. In some of our sea-ports tattooing is a regular trade, the tattooist being an artist who will, for a certain sum, depict any kind of device on the brawny breast or arm of the jolly tar. It may be that during the process, which is by uo means destitute of pain, the tar may lose his jollity, and we have the authority of the late Maddison Morton, the author of "Box and Cox" and a hundred other farces, that the aspect of the jolly tar when he is not jolly is a picture of misery which it is indeed hard to beat.

But the tar need no longer suffer the pains of the tattooing needle, for an iugenious gentleman who hails from Chicago has found out how to impress indelible pictures on the human skin by the aid of photography. We do uot know the particular process by which he works, but there are several ways in which the pictures might be printed on the skin. As to their permanence when compared with tattooing, we have our doubts, for, in the older process, the pigment is actually urged beneath the cuticle, and the photograph can hardly be anythiug more than a surface discolouration. It is said that the young men of Chicago are setting the fashion of having their sweethearts' portraits printed on their arms in this fashion, aud to the fickle the want of permanence will not be regarded as a disadvantage. This new method of photographic vaccination could certainly be turned to good account in an action for breach of promise, and we can imagine the scorn with which the counsel for the plaintiff would direct the defendant to bare his arm.

A writer in *Tit-Bits*, in the course of a paper which describes the manner in which the nobility increase their iucomes, alleges that there is a certain noble lord who fiuds in amateur photography not only a pleasurable hobby, but a source of profit. "Armed with an instantaneous camera fitted with all the latest improvements, he secures portraits of all his friends and acquaintances, and puts them away for future use." The future use is iudicated when one of these persons dies "or in any other way acquires notoriety." The noble lord then betakes himself to an eminent firm of photographers in London, and sells the negative of his friend, for which he is paid a sum of money varying from twenty to one hundred pounds. In a recent divorce case in which one of his friends was implicated he received as much as one hundred and fifty ponnds. Were the story true, the noble lord would certainly represent the meanest and most contemptible of mortals; but, as any practical man must kuow, it is a barefaced fabrication from begiuning to end.

A correspondent recently called the attention of our readers to the absence of titles on photographic views purchased on the Continent, and also in this country. In some cases the titles were there, but were clearly wrong and belonged not to the scenes to which they were attached, but in most others they were absent altogether. We quite agree with him that such pictures should bear their title on their face; but this should certainly be done in an unconspicuous manner. We have seen several pictures which, in our opinion, are spoilt by the glaring words in white letters which blot out part of the foreground, and when a lantern-slide has a title upon it of this nature the effect, when projected upon the screen, is equally deplorable. The illusion is spoilt by the presence of these white disfigurements, and photographers would do well to adopt some better plan. A painter, in signing a picture, does so in an unobtrusive manner in one corner, and the signature has to be songht for; it is not at once apparent. Cannot photographers take a hint from this laudable custom?

We suppose the public take an interest in the rough portraits of notorieties which appear in some of the evening and weekly newspapers, or proprietors would not go to the expense of having them prepared. From an artistic point of view they are deplorable, and one is often tempted to regret that photography puts it in the power of artists to commit such atrocities. We are, of course, aware of the difficulties which surround newspaper portraiture: the coarse paper, the rapid printing, the cheap ink, all are obstacles to which the artist must accommodate himself as best he may; but all these drawbacks in no way excuse the results, or render them less depressing to look upon.

Iu America newspaper portrait atrocities have reached even a lower depth, and we are quite in accord with the *Chicago Inland Printer*, which, in its anguish, writes as follows:—"From the advent of the first portrait of Lydia Pinkham to the distorted caricatures of the late Canadian Premier, the deadly newspaper cut has struck its paralysing force into the brains of old and young. No one can take up a paper without meetiug the ghost of an abortive attempt at a portrait of some kind in infinite variety. From the president down to the man as he looked 'before and after taking,' they tend to breed an anarchism of sensation sufficient to demoralise the strongest intellect." Accompanying this outburst are two portraits, one as it was originally drawn, and the other as it appeared after engraving and printing. As the *Inland Printer* is exquisitely printed on superb paper, every chance is given to the abortion. What it must have looked like in an ordinary newspaper imagination can scarcely picture.

The director of the Astronomical Observatory of Harvard College calls attention, in his annual report, to the need of a fire-proof building for the storage of photographic plates. The Observatory has received iu the last year about nine thousand such plates—some taken in Peru, some in California, and some in Cambridge—aud it has in all about twenty-seven thousand of them. They represent the entire sky from the North to the South Pole, the greater portion of it being covered several times, and they show the spectra as well as the position of the stars. A large part of the charts and nearly all the spectra are unique, not having been photographed elsewhere. It is very certain that such a collectiou must be exceedingly valuable. There is also also this to be remembered, that a photograph once destroyed can never be replaced. Even two photographs taken at the same time, and nuder similar circumstances, can possess points of difference. A fire-proof building as recommended is of the highest importance.

## INTERNATIONAL PHOTOGRAPHIC EXHIBITION AT CARDIFF.

[BY OUR SPECIAL COMMISSIONER.]

My first impression on reaching Cardiff was, that it was such a prosperous town, and its inhabitants so busily engaged in making money, that they had little or no time to devote to art matters. For the sake of the energetic men who form the committee of the Cardiff Photographic Society it is to be hoped that I am wrong. The visit of the British Association to this rapidly growing Welch seaport must bring a large number of people specially interested in all matters, both scientific and artistic, and the occasion is, therefore, a fit one to bring together as large a collection as possible to illustrate one of the most wonderful scientific developments of the Victorian era, and is quite in harmony, therefore, with the efforts of this celebrated migratory scientific association, and should be a great success.

Cardiff is famed for its arcades, which have somewhat of a Parisian aspect. In their construction the people have shown great wisdom, for so much rain falls in this corner of the British Isles, and it is of such a fine, penetrating character, if I may judge by the sample supplied for my discomfort, that I was glad to make use of the one which led to the hall devoted to the Photographic Exhibition.

So much work has to be done in a short space of time that it is no reproach to the Society to say that it was impossible to get a catalogue on the opening day. Through the courtesy of the energetic secretary, Mr. Faulks, I was enabled to have the use of the rough proof just hot from the printers, and should by chance, therefore, any of the names be wrong, this must be my excuse. The hall is a lofty one with arched roof and glass along its centre, and the pictures on the walls show extremely well. Some of those on the screens are not quite so fortunate, for the light is too directly overhead to do full justice to them.

On walking round the room, old friends met the eye at every turn—I mean pictures that had become so by long acquaintance. Of course this is inevitable in a country exhibition, for prize winners will send pictures likely to win prizes, and a very thin exhibition would result from restrictions like those practised at Pall Mall. There was no formal opening, and I was glad of it, for it gave me an opportunity of hearing Mr. Paul Lange's second lecture. The one on Norway was quite equal to the one on Iceland I had the pleasure of hearing at Gloucester a few months ago, and the slides to illustrate it, if not more interesting, were certainly more attractive. After hearing the lecture, which was full of interest from beginning to end, I felt sure that shoals of hand-cameras would be found careering up and down the beautiful fiords next summer.

The splitting the pictures into so many classes has one very serious evil: it makes medals too cheap. Pictures in no way worthy of recognition take rank with the productions of the best workers in the country simply because they happen to come into some out-of-the-way class, or into one with very few entries. It thus happens that the accidental shots of some hand-camera, as far as the awards are concerned, take precedence of the well thought-out, artistic work of the most distinguished artist. It certainly makes one wish that awards were done away with altogether.

The entries for professional portraits are very few. Mr. W. W. Winter is well to the front with his powerful work, and Prince Ruffo (only think of it, a prince among the professionals, and we in England can only boast of one baronet!) has distinguished himself by two or three of the most perfect heads possible. One of these is evidently a Doge of Venice, and, if this were not a serious journal, and the remark might be taken as an attempt at a very obvious joke, I would like to ask what dodge he employed to give such life and reality to this "grave and reverend segnior" as to bring him before us in the habit of the time in which he lived, which must be some 300 years past and gone. The time-furrowed and care-worn face of the abbess is not quite so striking, but equally fine.

The work of Mr. J. H. Hogg scarcely comes under the head of portraits, for there are successful attempts at picture-making in several of them. In one called "The Young Owl," a delightfully crummy young lady is stretching out her hand slightly above her reach to tempt the learned-looking inmate of the cage. She has something in the hand for the bird, but it is such a beautiful little dumpling of a hand that I am surprised such a wise looking creature did not seize hold of it instead of deliberating whether it should or should not take the offered food.

Mr. H. P. Robinson's "What is it?" might be called landscape with figure. A bull, with forelegs firmly planted, and head erect, is watching with indignant surprise the audacious attempt of the artist—fortunately for him on the other side of the stream—to produce his portrait without permission, and without any attempt to regulate the question of copyright. No wonder he looks so angry. The landscape is well selected, but the bull makes the picture. There are several more equally good, but they have been described before.

There are some capital interiors by Mr. Court Cole, and those by Mr. T. H. Faulks must not be passed over, for he has successfully dealt with very difficult subjects.

Mr. Robert Terras has very cleverly concealed his art in his two Astade-like, homely interiors, and he is deserving of the highest praise. I know the work of this gentleman pretty well, but am compelled to say that he has surpassed himself.

Mr. Bernard Alfieri is most successful with his pictures of animals. All are good, and the cattle in the shallow stream, evidently enjoying its cooling influence, would delight the eye of the veteran Sydney Cooper.

Looking over the catalogue, I saw the title of a picture that I felt sure would interest me. It was called "A Gutter Race," and I immediately looked for a picture which I felt certain only Rejlander could have successfully dealt with, but I looked in vain. A reference to the number in the catalogue took me to a very different kind of subject, a yacht race on a cloudy, uncertain day—a capital picture, one of the best of its kind in the room. It was simply a misprint, and should have been "cutter" instead of "gutter." Mr. W. H. Kitchin deserves praise for this clever little picture, for it is low in tone, and well expresses the feeling of the scene. The Champion Class is filled by old favourites, but they have all been described before, and do not call for further mention.

Mr. Horsley Hinton has followed in the steps of Mr. Davison, and has produced several *fuzzy* pictures, the best of which is "By Reedy Ways," for it is a very harmonious and artistic bit of light and shade, particularly when the beholder gets far enough away that he does not see the *modus operandi*.

"Evening at Cannes" is a very artistic little picture by H. Haughton. A break in the sky just before sunset reveals the town and distant hills, but all the rest of the picture is gloom. An inch off the forground, which is uninteresting, would convert this picture into a perfect little gem.

"Brotherly Attention" must not be passed over, though it is only two little nigger boys sitting on a boat. An old kettle and a worn-out tin pan are at their feet, and the elder one is carefully removing superabundant secretion at the tip of the younger one's nose with not the very cleanest of pocket-handkerchiefs. This picture is deliciously comic, but not at all vulgar.

Mr. J. E. Dumont has told his story with great boldness in his picture called "A Good Hand." A jolly priest, with skull cap to cover his shaven crown, is busy with his hand at whist or cribbage, and quite disregards the Chianti flask and very nearly empty glass by his side. The triumphant look on his face shows that he holds the winning card.

Mr. G. Tagliaferro's accessories are decidedly too much *en evidence* in his circus pictures; but he is most fortunate in his model who enacts the clown, for the love-struck expression when looking at the trim ankles of the *première danseuse* is extremely comic, though very true to life. The lady is apparently unconscious of the effect she is producing, for she has one of her feet on the drum and is busily occupied in fastening up her sandal.

Space does not permit much more, but the geological pictures by Mr. W. L. Howie must not be passed over. They illustrate the errosive action of rain on the softer parts of some strata, and the formation thereby of sharply pointed pyramids. A clear but concise description is attached to each frame.

A large series of pictures illustrating the district, and forming an extensive contribution to the county survey now on hand, are arranged in an outer gallery, and are most interesting. The wheeled Runic crosses that are unearthed from time to time deserve particular attention.

List of Awards.*

*Class* 1.—Portraiture. (8) W. W. Winter, silver medal; (24) Prince Ruffo, bronze medal; (17) J. H. Hogg, certificate.

*Class* 2.—Landscape. (49) J. P. Gibson, silver; (59) H. P. Robinson, bronze; (44) T. Birtles, certificate.

*Class* 3.—Architecture. (117) C. Court Cole, silver; (107) T. H. Faulks, bronze; (102) A. J. Loughton, certificate.

*Class* 4.—Genre. (135) Robert Terras, silver; (130) J. E. Austin, bronze; (138) Shapoor N. Bhedwar, certificate.

*Class* 5.—Enlargements. (179) West and Son, silver; (173) W. H. Kitchin, bronze; (154) T. B. Sutton, certificate.

*Class* 6.—Hand-Camera Work. (212) Percy Morris, silver; (220) J. D. Lysaght, bronze; (203) W. D. Welford, certificate.

*Class* 7.—Animals. (226) Bernard Alfieri, silver; (230) W. D. Welford, bronze; (228) Mrs. Pollard, certificate.

*Class* 8.—Instantaneous. (250) Henry Symonds, silver; (247) W. H. Kitchin, bronze; (242) A. R. Dresser, certificate.

*Class* 9.—Lantern Slides. John E. Austin, silver; Mr. and Mrs. Auckorn (No. 2 set), bronze; J. D. Lysaght, certificate.

*Class* 9a.—Lantern Slides. E. G. Lee, silver; Jas. Dore, bronze; A. Pringle, certificate.

*Class* 9b.—Lantern Slides. A. Pringle, silver; E. Beck, bronze; T. H. Faulks, certificate.

*Class* 9c.—Lantern Slides. Priestley and Sons, silver; West and Sons, bronze; James Dore, certificate.

*Class* 10.—Champion Class. Shapoor N. Bhedwar, gold medal for series "Feast of Roses."

*Class* 11.—Portraiture. (375) Miss Rose Collier, silver; (382) W. J. Jenkins, bronze; (362) Clarence B. Moore, certificate.

*Class* 12.—Landscape. (409) A. Horsley Hinton, silver; (446) Hamilton Emmons, silver; (399) A. R. Dresser, bronze; (405) Henry Holt, certificate.

*Class* 13.—Genre. (466) J. E. Austin, silver; (493) J. E. Dumont, bronze; (506) T. M. Brownrigg, certificate.

*Class* 14.—Landscape—Six ¼-plates. (516) W. L. Howie, silver; (515) W. H. Kitchin, bronze; (513) John E. Austin, certificate.

*Class* 15.—Society Competition, Lantern Slides. No competition.

*Class* 16.—President's Prize. (532) W. H. Kitchin, (537) C. H. Murrell, equal first.

Special Award. W. L. Howie, bronze medal for Geological Photographs—Nos. 543, 544, 545.

The Judges were Valentine Blanchard, Gambier Bolton, F.Z.S., and Paul Lange.

The Survey Competitions.

Classes competing for the medals offered by the committee of the Free Library and Museum in reference to the Photographic Survey of Glamorganshire and part of Monmouthshire.

*Class* 1.— Collection illustrating Glamorganshire past and present:— Gold medal, T. M. Franklin; silver medal, W. Booth; bronze medal, A. M'Kinnon.

Mr. Franklin's collection, both for number and selection of subjects and excellence of workmanship, is a model of what such survey work should be.

Mr. Booth's collection falls short of the standard in technical excellence, but the examples include so many subjects necessary for the survey that it is considered to stand second, but with a long interval. Mr. M'Kinnon's collection is only lacking in number of subjects in the more distant parts of the county.

*Class* 2.— Collections illustrating Monmouthshire, within twelve miles of Cardiff:—Silver medal, W. Herbert; bronze medal, N. R. Corfield.

Mr. Herbert's collection presents an interesting series, but does not include any important object or view in Newport or Carleon; but the more inaccessible subjects count as of higher value to the survey.

Mr. Corfield presents a few interesting examples, but is too restricted in number to be a representative collection.

*Class* 3. — Collections of photographs of churches and chapels of Glamorganshire:— Silver medal withheld; bronze medal, W. Booth.

The adjudicators take the view that these medals are offered for collections not of ancient churches exclusively, but as representing the buildings used for religious worship at present in the county. No collection offered does this satisfactorily; the chief medal is, therefore, withheld.

Mr. Booth presents a few examples, and the bronze medal was therefore adjudged to him.

*Class* 4.— Collection of photographs of Cardiff, past and present:— Silver medal, G. Wills; bronze medal, F. W. Simpson.

The collection of Mr. Wills is of the greatest merit, judged from the point of view of the survey, while the artistic excellence is not less. The few remaining nooks of old Cardiff have been carefully searched out and photographed.

Mr. Simpson's collection represents the more obvious points of interest in the town, in a series of photographs of striking merit.

*Class* 5.— Collections of photographs of Glamorganshire castles, mansions, religious houses, and crosses:—Silver medal, T. M. Franklin; bronze medal, T. H. Faulks.

Mr. Franklin's exhibit, comprising so many subjects inaccessible to most photographers, and his examples of Celtic crosses, represented with such remarkable success on so large a scale, forms a collection of high value.

Mr. Faulks' small collection is varied and well selected in subject, and is adjudged the bronze medal.

The adjudicators look upon the collections exhibited as satisfactory considering the short time during which the survey has been going on, and the unfavourable weather of the past and present seasons. The number of views of the same object taken by members of the Society is to be regretted as a waste

* Class 1 to 10, amateur and professional; class 11 to 14, amateur.

of energy, while many subjects within the purlieus of the survey remain unrepresented.

The western portion of the county, too, is quite unworked. Sufficient, however, is shown to indicate that great energy and skill have been devoted to the task, and to promote the completion of the survey in a satisfactory manner.

It has occurred to the adjudicators whether it would be thought advisable by the committee to award the silver medal withheld to the best selection of views illustrating the castles immediately round Cardiff, viz., Cardiff, St. Fagan's, and Castell Coch.

In such case they would recommend the five series exhibited by Mr. Dighton, which, being confined to the castles named, does not conform to either of the clauses described in the schedule. (Signed per pro.) W. H. Johnston.
T. H. Thomas.

## MEETING OF THE BRITISH ASSOCIATION AT CARDIFF.

In his inaugural address as President of the British Association, which is now meeting at Cardiff, Dr. Wm. Huggins, the astronomer, said:—

The new power which modern photography has put into the hands of the astronomer is great, and has led already, within the last few years, to new acquisitions of knowledge of vast importance, and the recent great successes in astronomical photography are not due to greater skill, nor, to any great extent, to superior instruments, but to the very great advantages which the modern gelatine dry plate possesses for use in the observatory over the methods of Daguerre, and even over the wet collodion film on glass, which, though a great advance on the silver plate, went but a little way towards putting into the hands of the astronomer a photographic surface adapted fully to his wants.

The modern silver-bromide gelatine plate, except for its grained texture, meets the needs of the astronomer at all points. It possesses extreme sensitiveness; it is always ready for use; it can be placed in any position; it can be exposed for hours; lastly, it does not need immediate development, and for this reason can be exposed again to the same object on succeeding nights, so as to make up by several instalments, as the weather may permit, the total time of exposure which is deemed necessary.

Without the assistance of photography, however greatly the resources of genius might overcome the optical and mechanical difficulties of constructing large telescopes, the astronomer would have to depend in the last resource upon his eye. Now, we cannot by the force of continued looking bring into view an object too feebly luminous to be seen at the first and keenest moment of vision; but the feeblest light which falls upon the plate is not lost, but is taken in and stored up continuously. Each hour the plate gathers up 3,600 times the light-energy which it received during the first second. It is by this power of accumulation that the photographic plate may be said to increase, almost without limit, though not in separating power, the optical means at the disposal of the astronomer for the discovery or the observation of faint objects.

Two principal directions may be pointed out in which photography is of great service to the astronomer. It enables him, within the comparatively short time of a single exposure, to secure permanently with great exactness the relative positions of hundreds or even of thousands of stars; or the minute features of nebulæ or other objects; or the phenomena of a passing eclipse, a task which, by means of the eye and hand, could only be accomplished, if done at all, after a very great expenditure of time and labour. Photography puts it in the power of the astronomer to accomplish in the short span of his own life, and so enter into their fruition, great works which otherwise must have been passed on by him as an heritage of labour to succeeding generations.

The second great service which photography renders is not simply an aid to the powers the astronomer already possesses. On the contrary, the plate, by recording light-waves which are both too small and too large to excite vision in the eye, brings him into a new region of knowledge, such as the infra-red and the ultra-violet parts of the spectrum, which must have remained for ever unknown but for artificial help.

The present year will be memorable in astronomical history for the practical beginning of the photographic chart and catalogue of the heavens, which took their origin in an international conference which met in Paris in 1887, by the invitation of M. l'Admiral Mouchez, Director of the Paris Observatory. The decisions of the Conference in their final form provide for the construction of a great photographic chart of the heavens, with exposures corresponding to forty minutes' exposure at Paris, which, it is expected, will reach down to stars of about the fourteenth magnitude. As each plate is to be limited to four square degrees, and as each star, to avoid possible errors, is to appear on two plates, over 22,000 photographs will be required.

With an exposure sufficiently long for the faintest stars to impress themselves upon the plate, the accumulating action still goes on for the brighter stars, producing a great enlargement of their images from optical and photographic causes.

The remarkable successes of astronomical photography, which depend upon the plate's power of accumulation of a very feeble light acting continuously through an exposure of several hours, are worthy to be regarded as a new revelation. The first chapter opened when, in 1880, Dr. Henry Draper obtained a picture of the nebula of Orion; but a more important advance was made in 1883, when Dr. Common, by his photographs, brought to our knowledge details and extensions of this nebula hitherto unknown. A further disclosure took place in 1885, when the Brothers Henry showed for the first time, in great detail, the spiral nebulosity issuing from the bright star Maia, of the Pleiades, and, shortly afterwards, nebulous streams about the other stars of this group. In 1886 Mr. Roberts, by means of a photograph to which three hours' exposure had been given, showed the whole background of this group to be nebulous. In the following year Mr. Roberts more than doubled for us the great extension of the nebula region which surrounds the trapezium in the constellation of Orion. By his photographs of the great nebula in Andromeda he has shown the true significance of the dark canals which had been seen by the eye. They are, in reality, spaces between successive rings of bright matter, which appeared nearly straight owing to the inclination in which they lie relatively to us. These bright rings surround an undefined central luminous mass. Some recent photographs by Mr. Russell show that the great rift in the Milky Way in Argus, which to the eye is void of stars, is, in reality, uniformly covered with them.

The heavens are richly, but very irregularly, inwrought with stars. The brighter stars cluster into well-known groups upon a background formed of an enlacement of streams and convoluted windings and intertwined spirals of fainter stars, which become richer and more intricate in the irregularly rifted zone of the Milky Way. We, who form part of the emblazoury, can only see the design distorted and confused—here crowded, there scattered, at another place superposed. The groupings due to our position are mixed up with those which are real. Can we suppose that each luminous point has no closer relation to the others near it than the accidental neighbourship of grains of sand upon the shore, or of particles of the wind-blown dust of the desert? Surely every star, from Sirius and Vega down to each grain of the light-dust of the Milky Way, has its present place in the heavenly pattern from the slow evolving of its past. We see a system of systems, for the broad features of clusters and streams and spiral windings which mark the general design are reproduced in every part. The whole is in motion, each point shifting its position by miles every second, though, from the august magnitude of their distances from us and from each other, it is only by the accumulated movements of years or of generations that some small changes of relative position reveal themselves.

The deciphering of this wonderfully intricate constitution of the heavens will be undoubtedly one of the chief astronomical works of the coming century. The primary task of the sun's motion in space, together with the motions of the brighter stars, has been already put well within our reach by the spectroscopic method of the measurement of star-motions in the line of sight.

Many other problems of the newer side of astronomy would claim attention if time permitted. The researches of the Earl of Rosse on lunar radiation, and the work on the same subject and on the sun by Langley. Observations of lunar heat with an instrument of his own invention by Mr. Boys, and observations of the variation of the moon's heat with its phase by Mr. Frank Very. The discovery of the ultra-violet part of the hydrogen spectrum, not in the laboratory, but from the stars. The confirmation of this spectrum by terrestrial hydrogen in part by H. W. Vogel, and in its all but complete form by Cornu, who found similar series in the ultra-violet spectra of aluminium and thallium. The discovery of a simple formula for the hydrogen series by Balmer. The important question as to the numerical spectral relationship of different substances, especially in connection with their chemical properties; and the further question as to the origin of the harmonic and other relations between the lines and the groupings of lines of spectra. On these points contributions during the past year have been made by Rudolf v. Kövesligothy, Ames, Hartley, Deslandres, Rydberg, Grünwald, Kayser and Runge, Johnstone Stoney, and others. The remarkable employment of interference phenomena by Professor Michelson for the determination of the size, and distribution of light within them, of the images of objects which, when viewed in a telescope, subtend an angle less than that subtended by the light-wave at a distance equal to the diameter of the objective—a method applicable not alone to celestial objects, but also to spectral lines and other questions of molecular physics.

Photographic Club.—Subject for August 26th, "Films"; September 2nd, "Testing Lenses." Outing Saturday next, August 22nd, Cobham (Surrey). Train from Waterloo at 2.27.

Photographic Society of Great Britain. — Technical meeting at 8 p.m. on August 25th; subject for discussion, "Printing Processes."

## THE DECOMPOSITION OF SILVER CHLORIDE BY LIGHT.

BY A. RICHARDSON, PH.D.

Although the fact that silver chloride darkens on exposure to light has long been known, the composition of the product formed has not yet been satisfactorily determined; the observation of Schelle, however, that the darkening process is accompanied by an evolution of chlorine, leads to the conclusion that the substance formed is either a subchloride or an oxychloride of silver, whilst its sparing solubility in dilute nitric acid seems to preclude the possibility of the reduction of the chloride to metallic silver.

Fischer, in 1814, assumed that the darkened product was a subchloride, and this idea has been generally accepted until recent years. When, however, doubt was cast on the existence of Wöhler's silver suboxide by the experiments of Muthman (*Ber.*, 1887, 20, 983), and of Bailey and Fowler (Trans. 1887, 51, 416), and the existence of the suboxide of Pfordten (*Ber.*, 1887, 20, 1458, 3375; 1888, 21, 2288) was disproved by Freidheim (*Ber.*, 1887, 20, 2554), the evidence in favour of the subchloride theory was somewhat shaken. Quite recently, however, Güntz (*Compt. Rend.*, 112, 861) claims to have obtained silver subchloride by the action of gaseous hydrogen chloride on silver subfluoride, as also the suboxide and other similar compounds; the subchloride so obtained has not, however, been identified with the darkened product formed by the action of light on silver chloride.

The other view, namely, that the compound formed is an oxychloride of silver, has lately been received with considerable favour, and seems to be supported by some experiments of Dr. Hodgkinson, in which the presence of the oxychloride appears to have been detected in the darkened compound (Meldola, "Chemistry of Photography," p. 856). As, however, the evidence in favour either of the subchloride or oxychloride theory is far from conclusive, it was thought desirable to examine the darkened silver chloride in order to determine whether it contained oxygen, and further, to study the decomposition of the chloride when exposed to light under water.

The silver chloride used in all the experiments was obtained by adding hydrochloric acid to a solution of pure silver nitrate, the precipitate being washed by decantation till free from acid.

*Action of Silver Chloride on Water when Exposed to Light.*—In the early experiments, the chloride was exposed to light in sealed tubes containing water, the space above being occupied by air. When opened after long exposure (about six months), it was found that a considerable quantity of gas had been formed, and that it contained sufficient oxygen to rekindle a glowing match (8 grams of the chloride gave 7 c.c. of gas). The evolution of oxygen under these conditions was confirmed by later experiments, and was studied more closely in conjunction with the other changes which occur.

An experiment is recorded by Robert Hunt ("Researches on Light," p. 81), in which absorption of gas was observed to take place when the chloride was darkened, leading him to the conclusion that the product contained oxygen; the conditions, however, were somewhat different, and this may account for the want of agreement between our results.*

During the exposure of the chloride under water, it

* It does not appear that in Hunt's experiment a large volume of water was present.

had been frequently observed that the volume of liquid present exercised a considerable influence on the rate at which the substance darkened; this point was, therefore, further investigated. The exposure of the chloride was made in tubes closed at one end, and so arranged that any gas which might be evolved would expel a portion of the water by an exit tube terminating in a bulb, in which it was collected. Four tubes of this form, having a capacity varying from 57 c.c. to 350 c.c., were filled completely with water containing equal quantities (5 grams) of silver chloride in suspension. After half an hour's exposure to bright sunlight, bubbles of gas collected in the tube, and continued to be evolved till the end of the experiment. The gas was measured after eight days' exposure (April 10-17), and the liquid was examined for free* chlorine by the addition of potassium iodide and titration with N/10 sodium thiosulphate in the usual way. The total chlorine was also estimated, the combined chlorine being found by difference. In determining the total chlorine, the method adopted in all cases was to add sulphur dioxide to a known volume of the liquid, the excess being removed by potassium chromate; sodium hydrate was next added, and the solution boiled; the precipitated chromic hydrate was filtered off, and the liquid and washings made up to known volume; the chlorine was then estimated with N/10 silver nitrate solution, the liquid having been previously acidified with dilute nitric acid, and neutralised with sodium carbonate.

This method was found to give good results provided the reagents used were free from chlorine. The results are given in the following table:—

Table I.

| 1. $H_2O$. | 2. O at 0° and 760 mm. | 3. Total Cl. | 4. Combined Cl. | 5. Free Cl. | 6. HCl in 100 parts of solution. |
|---|---|---|---|---|---|
| c.c. | c.c. | gram | gram | gram | gram |
| 57 | 4·02 | 0·097 | 0·092 | 0·005 | 0·162 |
| 121 | 5·74 | 0·124 | 0·122 | 0.0017 | 0·101 |
| 152 | 5·94 | 0·127 | 0·126 | 0·0010 | 0·083 |
| 356 | 6·61 | 0·142 | 0·142 | 0·0000 | 0·039 |

It will be seen that the effect of an increasing volume of water is to increase the total quantity of chlorine in solution, and therefore the amount of silver chloride decomposed; also to increase the total amount of hydrochloric acid formed and of oxygen liberated;† there is, however, a diminution in the amount of free chlorine present. Further, it is seen, on calculating the strength of acid per 100 parts of water (Column 6), that the strongest acid is found in the tube containing the smallest quantity of water, and it is here also that the largest quantity of free chlorine is present. The strength of acid and the amount of free chlorine therefore decrease as the volume of water increases.

As the decomposition of silver chloride by light is to a large extent dependent on the proportion of free chlorine present, the conditions which regulate its conversion into hydrochloric acid in the solution were studied.

*(To be continued.)*

The Royal Cornwall Polytechnic's exhibition opens on Tuesday next at Falmouth, lasting four days.

* The "free" chlorine is not necessarily present entirely as such, but may exist partly in the form of oxygen acids of chlorine.

† This only represents a portion of the oxygen formed, as the amount of gas dissolved in the water was not determined.

## LUNAR AND TERRESTRIAL VOLCANOES.

The following article by the Rev. H. N. Hutchinson, B.A., F.G.S., appears in the current number of our contemporary *Knowledge*. It will be interesting to our readers because the writer's conclusions are drawn from photographs of the moon. Excellent collographic reproductions of the original photographs appeared in a former number:—

Readers of *Knowledge* will not have forgotten the Editor's interesting paper in the May number of last year on "The Great, Bright Streaks which Radiate from some of the larger Lunar Craters." It has been suggested to me that the question of the origin of these remarkable streaks might be discussed from the geological point of view, and that I should present some facts with regard to the lines of fracture and displacement among the stratified rocks of the earth's crust which are known amongst geologists as "faults." Geological science has received valuable aid from astronomers, and possibly there are questions in astronomy on which geologists might throw some light; at all events, it is a good thing occasionally that students of one science should endeavour to throw light on another. I only regret that the subject is not handled by one more deeply versed in lunar questions.

In my previous paper on "The Cause of Volcanic Action," I mentioned the connection between volcanoes, mountain-chains, and lines of weakness in the earth's crust, which are closely connected with lines of fracture; and this would seem a fitting opportunity for turning our thoughts to those remarkable outbursts of volcanic action on a prodigious scale of which the moon's numerous craters stand as silent yet speaking witnesses, and to inquire how far the cracks radiating from some of them may be compared with terrestrial cracks.

In Mr. Ranyard's paper we find a summary of the opinions put forward by different authorities on the subject of lunar streaks. "There are certainly seven such ray systems," he says, "all with craters at their centres, namely: Tycho, Copernicus, Kepler, Byrgius, Anaxagoras, Aristarchus, and Olbers." Of these, Tycho is the most conspicuous example; its radiating streaks come out well in lunar photographs. The radiating streaks from Copernicus are well seen in the second photo in the December number of 1890. Two of the longest from Tycho extend to a distance of over one thousand miles from the crater. Nichol thought, as Mr. Ranyard tells us, that they were composed of matter shot up from the interior of the moon; and compares them to mineral veins or to "trap-dykes" (of basalt or other igneous rock), such as are known to pierce the sedimentary strata upon earth.

Nasmyth's opinion was that the radiations "are cracks divergent from a central region of explosion, and filled up with molten matter from beneath." His experiment with a glass globe to illustrate this is described in the above paper (p. 130), also in Nasmyth and Carpenter's book on the moon (1874, p. 134). "Proctor seems to have favoured the trap-dyke theory. Neison, after carefully setting out the observed facts, refrains from advancing any theory." Young hesitates between this theory and the idea that they may be mere surface markings. Mr. Ranyard himself thinks "that they correspond to a series of radiating cracks, or faults, from which comparatively warm air issues charged with aqueous vapour, which is deposited as hoar-frost on either side of the vent."

Thus there seems to be a consensus of opinion that, in some way or other, the radiating streaks are due to cracks, and we can only conceive of such fractures as being due to a disruptive action, originated by the reaction of the interior of the moon upon its outer crust. Taking so much for granted, we may pass on to the question of the nature of the disruptive force. Was it due—as Messrs. Nasmyth and Carpenter say—to the expansion of molten rocky matter below the moon's surface on nearing the point of solidification? Or was it originated by the cooling and consequent contraction of the body of the moon, which would leave the outer crust here and there unsupported, and hence this crust, in settling down and endeavouring to adapt itself to a smaller surface below, would undergo tangential strains and thrusts which, it is easy to conceive, might result in a certain amount of fracturing? A simple illustration of this is afforded by the wrinkling of the skin of an apple as it dries. The soft pericarp below shrinks as it loses water, and so the skin has to settle down and accommodate itself to a smaller surface, and in doing so it must inevitably be wrinkled, or thrown into folds. This is a view which might, perhaps, commend itself to a geologist, for it is on a similar theory that geologists explain the great foldings which have produced terrestrial mountain chains, which latter are clearly connected with lines of weakness or fracture such as they suppose allowed rocky matter from below (charged with steam) to well up to the surface and so give rise to volcanic action. Volcanoes, as we pointed out in our last paper, have a striking connection with mountain chains. On this view the folding, contortion, and fracturing of strata, so conspicuous in mountains, is a secondary result of the secular refrigeration of our planet. Nothing short of this seems, at present, equal to the Titanic work of upheaval. At the same time the theory is not proved, and some authorities refuse to accept it.

Let us now turn to the earth and see what geology tells us about terrestrial cracks. These are of two kinds: first, there are the "faults," to which we have already referred; secondly, the "trap-dykes," which are very numerous in Scotland and northern England.

It may easily be conceived that the force which was sufficient to raise vast masses of solid rock of immense thickness from the bottom of the sea, where they were deposited, high into the air in order to form dry land, and, moreover, to bend them into great folds and contortions of all sizes, might also be sufficient to crack and break them through. Accordingly, we find in the stratified series very frequent instances of cracks running through great thicknesses of rock, and obviously caused by disturbing force; sometimes they are mere fissures, but more frequently there is not only a severance but a displacement of the rocks that have been severed. Strata once continuous are left at very different levels on opposite sides of the fissure. Hence the term "fault." Some of the "faults" known to geologists are not only of great horizontal length as traced along the surface, but of very considerable depth, and have produced enormous displacements. Thus, the great Pennine "fault" of the north of England is known to be at least fifty-five miles long, and has a "throw" of 6,000 to 7,000 feet—*i.e.*, the rocks on either side have been displaced to that extent. It was probably formed at some time during the upheaval of the Pennine range of hills, which runs north and south, as the "fault" also does. The Tyndale "fault" has a throw of nearly 3,000 feet, and it runs eastwards for about fifty miles. Fractures not unfrequently occur along the axes of great folds, such as we find in mountain chains, the strata having snapped under the great tension to which they were subjected during upheaval. Thus, we find "faults" running parallel with some of the great mountain chains of the world—the Alps and Himalayas are cases in point.

This connection between great terrestrial cracks and important mountain ranges is only what might have been expected. The Unita Mountains of Wyoming and Utah consist of one broad, flattened fold, with a displacement, in places where the uplift has been greatest, of 20,000 feet! If the lunar streaks under consideration are due to "faults," it is difficult to understand how the level on each side should be so little disturbed. As a general rule, the brightness of the lunar surface corresponds to the altitude of the ground. Mr. Ranyard says the rays do not correspond to lofty ridges, or even to ridges a few hundred feet in altitude, for no ridges casting shadows as the sun rises and sets can be detected as coincident with the streaks. It seems generally admitted that they do not correspond to lava-streams, for the rays run across mountains and plains, and even through the rings and cavities of old craters.

(*To be continued.*)

Wayzegoose and Presentation.—On Saturday, Aug. 15th, the employées of Messrs. Percy Lund and Co. held their annual wayzegoose at Morecambe. Two saloon carriages were engaged, and the railway journey from Bradford was enlivened with songs and recitations. On reaching Morecambe the party divided into small companies to seek amusement in different ways, but in the afternoon they reassembled at the Regent's Park Gardens, which was the headquarters for the day. There a couple of hours were spent in various amusements, to which the wayzegoose ticket provided admission. After tea, which was served in a marquee in the gardens, short speeches were made by Messrs. Percy Lund, F. Rodger, E. Cullingford, H. Snowden Ward, W. Ethelbert Henry, and Wm. Ward; and Mr. F. Rodger and Mr. E. Cullingford, on behalf of their fellow-workers, presented to Mr. H. Snowden Ward a handsome inscribed travelling writing-desk, on the occasion of his leaving Bradford to take the management of the London branch of the business.

Glass Plates in Place of Lithographic Stones, &c.—Mr. Fred. Winterhoff, of Cologne, Germany, has invented and patented a process of preparing glass plates, which can be used in the place of lithographic stones and zinc plates, not only for printing directly or for preserving originals, but also for the preparation of impressions which can be transferred upon stone, zinc, glass, or other material. The preparation of the glass plates is simple, and may be executed by any intelligent workman. The plates occupy much less space than the lithographic stones, are cheaper, may be made of any size and quality desired, and their use requires less work and, therefore, less expense. The process consists in the covering of the glass plate with some sensitive substance—for instance, asphaltum or gelatine combined with chromate of potassium. This must be done evenly, and is allowed to dry, after which an impression taken from another plate is transferred upon the glass plate covered with the sensitive matter. The transfer paper is removed, the transfer appearing upon the plate covered with some metallic powder, like bronze or leaf metal; the space upon which the transfer has been made is now exposed to the sun for half an hour, and then washed with mineral oil. The spots which were protected from the impressions during the transfer will wash off, while the others have hardened and will adhere to the plate. After this the plate is etched very deep with hydrofluoric acid, washed off and cleaned, and is then ready for use as a printing plate. From it may be taken impressions for transfers at any time; and any number of impressions may be taken directly without wearing it out.—*Lithographic Art Journal.*

## Patent Intelligence.

### Applications for Letters Patent.

13,466. Travis Burton, 106, Cowhill, Chadderton, Oldham, "Improved Walking Stick Tripod Stand for Photographic Surveying or other purposes."—*August 10th.*

13,467. Edward Dunmore, 83, Corinne Road, Tufnell Park, London, "A Repeat Photographic Dark Slide and Improved Camera Back."—*August 10th.*

13,538. Adolphe Paul Auguste Beau, 23, Southampton Buildings, London, "Improvements in Means or Apparatus employed in Photography."—*August 12th.*

13,674. Alfred Charles Jackson, 33, Chancery Lane, London, "Improvements in or connected with Photographic Shutters."—*August 13th.*

13,686. Archibald Campbell, Southwell House, Southwell Gardens, London, "An Improved Portable Photographic Camera and Stand Combined."—*August 14th.*

13,720. Joseph Sewell, Edward Holliday, and Alfred Ernest Willey, 12, Lawrence Lane, Cheapside, London, "A Method of Producing on Veneer any Picture or Design in any Requisite Number of Colours."—*August 14th.*

### Specifications Published.

4,037. *March 14th*, 1890.—"Pressure-Gauge." A. T. Clarkson, 28, Bartlett's Buildings, Holborn Circus, E.C., and J. B. Spurge, 11, Reede Villas, North Street, Romford, Essex.

"Bourdon" and other gauges are filled with a liquid or jelly, which is separated from the gas under pressure by a diaphragm or piston, and a valve that closes to prevent leakage of the gas when the diaphragm breaks.

4,094. *March 15th*, 1890.—"Lamps." J. Walsh, 27, Chatto Road, Clapham Common, S.W.

*Lamp Lenses, &c.*—Relates to the construction of liquid and other lenses, and to their application to lamp globes and chimneys; and to railway carriage roof, street, and other lamps. The figure illustrates a liquid lens having flanges, which are heated and covered with cement. The lens, after immersion in water of the same temperature as the cement, is taken out and filled with water under pressure. It is then allowed to cool, and is hermetically sealed.

4,095. *March 15th*, 1890.—"Cyanides." E. Bergmann, 31, Johannisbollwerk, Hamburg.

Consists in producing cyanide of silver or copper by heating a ferrocyanide in neutral or acid solution with a silver or a copper salt. When cupric salts are used, reducing agents, such as sulphurous acids, sulphites, finely divided metals, or organic substances, must be added. Instead of soluble ferrocyanides, Prussian blue and other insoluble cyanides, raw cyanides from gas making, or ferricyanides, together with reducing agents, may be employed. Double cyanides are obtained by treating cyanide of copper with an alkaline or alkaline earthy sulphide, or with an alkaline ferrocyanide. Double salts are also obtained by treating barium-copper cyanide, obtained as above, with a sulphate or carbonate in aqueous solution.

4,178. *March 17th*, 1890.—"Photo-Mechanical Printing." G. Balagny, Paris.

The sensitive substance is spread on a flexible support, such as gelatine, collodion, celluloid, india-rubber, &c. It may be composed of bichromated gelatine, or gelatino-bromide treated with bichromate of potash, or the like. These flexible photo-type plates can be employed instead of the bichromated slab ordinarily employed in photo-mechanical processes; they are developed in a water bath, and stretched, and fixed to a rigid printing block of steel, stone, &c., by an adhesive substance, such as gelatine, dextrine, albumen, or the like. The plate is then inked and printed from in the usual way. A double impression is obtained when both silver and bichromate is used.

4,207. *March 18th*, 1890.—"Advertising and Magic Lanterns." S. J. Porter, 181, Strand, London.

*Magic Lanterns.*—The advertisement slides are carried on a revolving perforated disc which is actuated by clockwork, the advertisements being cast on a white screen of opal, &c., which carries an accumulator for an electric lamp, but gas or other light may be used.

## Correspondence.

PERSPECTIVE DRAWING AND VISION.

Sir,—It may save some discussion on a merely verbal matter if you will allow me to specify more precisely the meaning of an expression contained in the fourth paragraph of my communication in your last issue. The words "vertical measure, as before stated, does not enter into the question of binocular perspective," are intended to apply to anything that may be stated of binocular perspective or vision as differing from the monocular. That this was the intention will probably be evident to anyone who reads the paragraph from the commencement.

W. E. Debenham.

## Proceedings of Societies.

Enfield Camera Club.

The ordinary meeting of this Club was held on the 12th inst., eleven members being present. The subject for the evening was "A Discussion on Negatives," and about one hundred negatives were brought by various members for mutual criticism. A couple of hours were very profitably spent in comparing notes with reference to exposures given, developers, &c. The president (Mr. D. G. Pinkney) brought with him the latest pattern of the Beck-Newman time and instantaneous shutter, and said he had used it during a recent holiday, and that it gave great satisfaction, exposures of a fractional part of a second being made with absolute certainty, and without any vibration.

Photographers' Benevolent Association.

Meeting held at 55, Chancery Lane on the 14th inst., Mr. Jno. Spiller chairman. Present, Messrs. Berry, Freshwater, Atkinson, and Hon. Sec. Four applications for assistance considered and granted. Mr. W. J. Tabrum, solicitor, was elected assistant hon. sec. Miss Walker and Mr. Jas. Sharp, 16 and 17, Poultry, were elected subscribers.

Note.—All subscriptions are now due, and will be gladly received, as the funds are very low.

Richmond Camera Club.

At the ordinary meeting on the 14th inst., Mr. Faulkner in the chair, Mr. Cembrano, as delegate of the Club at the late meeting of the Photographic Convention at Bath, read a concise but comprehensive report of the proceedings of the Convention, calling special attention to the recommendation made by the lens standard committee with a view to securing uniformity in the matter of lenses, diaphragms, screws, and fittings of cameras, and winding up with expressions of warm appreciation of the kind reception which had been accorded to the Convention at Bath. The presentation of the report had been deferred for a fortnight to enable Mr. Cembrano to prepare his illustrations in the shape of lantern slides, with the result that no less than 120 pictures were thrown upon the screen, the slides being for the most part the work of Mr. Cembrano himself, and the rest by Mr. H. M. Hastings. They covered the whole ground of the Convention's rambles—Bath, Clifton, Bristol, Tintern, Chepstow, Salisbury, Glastonbury, Wells—and comprised architecture and landscape, shipping, cattle, and figure subjects, including in the last sundry unconventional groups of members of the Convention. The whole were of the highest interest, and Mr. Cembrano was warmly thanked by the meeting for his "illustrated report."

### Hackney Photographic Society.

The ordinary meeting was held last Thursday, Dr. Roland Smith, the president, being in the chair. The Secretary announced that the exhibition will be held in the Morley Hall (large hall) on October 21st and 22nd, and that there would be open classes, trade exhibits, lantern shows, organ recitals, concerts, &c., and that Mr. Traill Taylor and another gentleman—possibly Mr. Pringle—would act as judges. *Photography* has placed two medals at the Society's disposal, and Mr. Crouch has kindly offered a pair of stereoscopic lenses for competition.

Mr. A. Barker and Mr. Harvetson then passed round work executed by them during their holidays. Mr. B. Foulkes-Winks was nominated for membership.

The Hon. Secretary apologised for the absence of Mr. Adams, who was to have dealt with "Hand-Cameras" from a manufacturer's point of view, owing to business matters. A good show of hand-cameras was, however, made by Mr. Roberts, who showed his, the changing being effected by the dropping of plate through a slot. It could be used on a stand and focussed as an ordinary camera; no sheaths. Messrs. Phillip, Harris, and Co., of Birmingham, showed the "Cylox," a very neat and cheap camera. Dr. Roland Smith showed the one he had patented, which set the shutter and changed the plate with one movement. Messrs. Mercer, of Birmingham, sent the "Alert" (a rough model). This was a very nicely arranged and compact camera, very small, but taking quarter-plates, and on the magazine principle. Messrs. Harling sent the Cusworth repeater, which set the shutter and changed the plate with the one movement. The Hon. Sec. showed Adams's "Ideal," fitted with self-setting Newman shutter, with Iris diaphragm. The president handed round a new hand-camera lens, made by Mr. Crouch, having a focal length of 5 inches, and working at $f/5$. It was made from the Abbe-Schott glass, and gave splendid results. He showed his results of work done with lens. The "Dresser" shutter was also shown, which could be made to give any exposure.

---

From Jena another novelty is also to be expected soon. The technical institution, where the celebrated optical glasses are made, has offered to make a red normal glass for photographic dark rooms. Considering the fact that, from twenty red lights tested by me lately, I found only a few pieces which admitted the passage of red light only, and that of the other lights there could only be used some very small parts, the furnishing of a pure red glass can be only hailed with pleasure, particularly for the colour sensitive plates, which indiscriminately will all fog under a bad red light. While we have optical glasses in Germany, we are accustomed to get the cheaper glass for plates from Belgium, although the duties are pretty high.—*Dr. Vogel in Anthony's Bulletin.*

Fluorgraphy.—Fluorgraphy is a process of lithography or phototypy (collotypy) transfer to glass, by means of a fluoric ink, which, in contact with fuming sulphuric acid, disengages fluorhydric acid, which acts on the glass. The collotypes are inked with:

| | | |
|---|---|---|
| Soap ... ... ... ... ... | 50 | grammes |
| Glycerine ... ... ... ... | 200 | ,, |
| Talc ... ... ... ... ... | 50 | ,, |
| Water ... ... ... ... ... | 100 | ,, |
| Borax ... ... ... ... ... | 34 | ,, |
| Fluor-spar ... ... ... ... | 90 | ,, |
| Lampblack ... ... ... ... | 15 | ,, |

A negative is transferred to a plate. This is surrounded with a border of wax and covered with sulphuric acid at 64° or 65° Beaumé. After from fifteen to twenty minutes the acid is poured off, the plate washed in abundant water, then cleaned with a solution of potash, and, finally, well washed in water and dried with a rag.—*Wilson's Photographic Magazine.*

## Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.

M. A. S.—*Hot Development.* An enamelled iron basin or pie-dish heated over a well-diffused gas flame, such as given by Fletcher's No. 15 standard burner turned quite low, would give you quite as much heat as you require; and the contents of the dish should be frequently agitated, so that the temperature may become tolerably uniform throughout.

M. P. (Redhill).—*Ready Sensitised Papers.* 1. In confirmation of our remark last week to the effect that twelve months was too long a period to keep untainted a stock of ready-sensitised papers, we have just come upon some practical evidences of the fact by finding a small parcel, dated Monday, June 9th, 1890, which has remained in our possession closely wrapped up in non-actinic papers, and put away in a perfectly dark place for that length of time—fourteen months. Upon opening the packet we found the silvered papers blackened round the edges, and considerably stained all over—in fact, perfectly useless. Another parcel from a well-known manufacturer, dated February 14th last, has also become quite brown, although kept only six months in perfect darkness. Tin boxes are said to be the best mode of packing, being both air-tight and light-tight. 2. In answer to your second letter, just received, we may reply that the sensitising bath does *not* easily get out of order, for the citric acid tends to preserve it, but the silver being gradually withdrawn, will require to be compensated by addition of fresh solutions of even increased strength.

F. H.—*Photo-Mechanical Processes.* The best epitome is, perhaps, Mr. W. T. Wilkinson's book entitled, "Photo-Engraving, Photo-Litho, and Collotype" (London: Hampton, Judd, and Co.), or England Brothers. The later processes have not escaped notice in our columns. See page 190 of March 6th for Mr. Warnerke's "Collotype Printing without Machinery"; the News of April 17th and 24th for Sutton's "Process for Producing a Printing Block"; "The Russian Simplified Process," page 360 of May 8th; and the "Hoke Engraving Process," about which you are enquiring, described in the News of May 22nd, with sundry illustrations on pages 387, 417, and 513. The "Sir Paul Pindar" and "Hastings Caves" were, we believe, both reproduced by this process, and are the work of the editor.

L. P. G.—*Rapid Filtration.* A good sample of white filter paper immersed for a few moments in strong nitric acid (sp. gr. 1·42), and then rapidly washed in water, is found to filter both faster and more efficiently than the same paper in its original state. Being thus converted into pyroxylin (nitro-cellulose), it does not reduce chromic acid or silver solutions when filtered through it, and in the event of a precipitate having to be collected and burnt, of course the incineration is more easily accomplished.

Tyro (Burnham).—*Warnerke's Sensitometer.* You will find the instrument figured and described in the News of Oct. 19th, 1888, page 662.

A. B.—*Salts to Silver: Atomic Weights.* Having written out the formulæ:—

$$Ag\,NO_3 + Na\,Cl = Ag\,Cl + Na\,No_3;$$
$$Ag\,No_3 + K\,Br = Ag\,Br + KNO_3.$$

By reference to the table at the end of the Year-Book, the atomic weights are shown to be for NaCl 58·5; KBr, 118·8; $AgNo_3$, 169·5; so that these are the proportions required in order to get absolute results with pure materials. It is usual to employ a slight excess of potassium bromide in making emulsions.

Received: "Justus Von Leibig: an Autobiographical Sketch," translated by Dr. J. Campbell Brown; and "Outlines of a New Atomic Theory," by Dr. T. L. Phipson.

# THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV. No. 1721.—*August* 28, 1891.

CONTENTS.

## PHOTOGRAPHIC CIRCULARS.

Among the advantages of the past, the "good old times"—which, in one respect at least, deserved their laudatory epithet—was that negative bliss, the absence of discomfort too frequently occasioned in the present by the arrival of the everlasting circular. How often have wild words wandered from the mouth of Jones, who has long languished, expectant of that little cheque, and anxiously attending its arrival by every post, when he discovers—brought to him by the careful postman—now a list of the marvellous cures of a new medicine, and now a description of the advantages to be derived from becoming at once a member of the Company (Limited) for importing asses into Spain! To our ancestors these multiplied copies of exposition of mercantile interest called circulars, as addressed to a circle or number of persons, were happily unknown. Dr. Johnson, in his Dictionary, though in addition to the ordinary meaning of geometrical form, he treats of circular lines and circular sailing, is altogether dumb about the circular, the business circular of modern time.

The photographer who wishes to add to the heap of gold which he keeps at his bankers, it behoves to be wary exceedingly in the composition of circulars. What is the advantage now, in this brazen age of scepticism and incredulity, to chatter about "high finish" or "artistic skill"? Of what profit is it now to prattle in print in the page consecrated to advertisements of the "finest studio" in Stockwell? What boots it to talk of the "best portraits" in our modern Babylon? Of what avail to add that these same portraits are the "most economic" in all England? Or of what service to challenge to competition the world at large? People are no longer like those Bereans, more noble than the Jews of Thessalonica—the Bereans who received the word with all readiness of mind. Incredulity is in the air. We have learned to doubt the genuineness of such circulars, and to distribute them is but to sow the sand, to preach to the wind, to beat the waves, to bay the moon, to whistle a waltz to a milestone. The public is as careless of the "finest studio," the "best portraits," the "cheapest cartes," as the neighbouring rustics were in the old fable of the plaintive voice of the shepherd lad who beguiled his leisure moments by ejaculating "Wolf! wolf! wolf!" when there was no wolf. The public is all too wise to be caught by this venerable bait. Too often have the "best portraits" been weighed in the scale of family censure and been found wanting. Too often has the "finest studio" proved to be a small, ill-lighted, dilapidated, and draughty attic. Circulars conceived in this style serve less to attract than to repel. They have come to be synonymous, to the experienced understanding, of those weird words which Dante imagined written over the portals of Hell. What, then, is wanted in a photographic circular, when such incitements as these have been proved to be insufficient, and even our "own particular process" has been discovered to be totally inadequate to fulfil the design for which its ingenious parent brought it into being? The answer to this question is contained in one word—novelty. Nay, the successful circular must be like the latest comedy, not only new but also original.

The Athenians and strangers which were in Athens in the days of Paul were not, probably, the only people in the world of his period who spent their time in nothing else but either to tell or to hear some new thing. The saint, for his own purpose, singled them out especially, but the desire of novelty is as strong and universal in our metropolis in the time of our most gracious sovereign lady Queen Victoria, as it was in Athens in the days of the heathen Emperor Nero. The yearning avidity for something fresh, which is the chief principle of attraction in the crowd unable to fill its heart with gazing at the *kyrielle* of a street quack, or the gew-gaws used in the coronation of a queen, may be censured by ministers of the Gospel as arguing a worldly, shallow, or unsettled mind; but it is, nevertheless—by reason, perhaps, of our corrupt nature—so strangely prevalent that even these ministers themselves have been known to read, mark, learn, and inwardly digest the story of some ephemeral scandal in the *Daily Telegraph* with far more eagerness, interest, and concern than they show in the varying accounts of the appearances after the Resurrection, as given by the four evangelists of the New Testament. Nay, according to the witness of one of themselves, uttered with but little charity and, it is to be hoped, with still less truth, these "persons, forgetful not only of their calling, but of the very spirit of the Gospel, read the account of a battle with the most violent emotions; and, provided the victory falls to their favourite side, they exalt and triumph in proportion to the number of thousands that have been slain."

The advertisement which contains the element of the novel, the strange, the unexpected, is the advertisement which pays. Arrangements should be made artistically to excite curiosity and surprise. This is not easily managed, but it may be done; and if a *soupçon* of the comic is added to the mixture by some photographic Busch or Cruikshank, that is all that is required for a first-class and effective advertisement.

Some of the circulars of the past were in a high degree meritorious, and obtained, doubtless, for their inventors that fame and profit which was the end of their production. Many years ago a crafty gentleman, well aware that the liberal mind of the public is distinguished by nothing more than a large amount of curiosity, scattered abroad, on what he held to be suitable soil, certain seeds in the form of circulars full of the merits of novel pictures, which he called "winking photographs." This mysterious advertisement, with its weird and uncanny title, held the careless reader as securely as the ancient mariner with his glittering eye held the hurrying wedding guest.

But the photographs turned out to be a very ordinary device after all. Two negatives were taken of the same person; if a person conspicuous for extreme ugliness or extreme beauty, so much the better for the advertiser. One of these negatives was taken with the eyes open, the other with the eyes closed. They were fastened on opposite sides of a piece of transparent paper, and applied so as to correspond exactly, as Euclid says, each to each. The double picture thus formed, when held before any light of uncertain intensity—say, for instance, one of the lamps provided for the discipline, by its capricious flicker, of the patience of persons disposed to read on the Underground Railway—produced, by the combination of its negatives, the strange effect of a deliberate wink. A photographic circular which, in its bold originality, deserved if it did not meet reward, consisted of a card with the photographer's name and address, and nothing more; but then there was this peculiarity—it is a peculiarity no longer now—the whole legend was set diagonally. It did what every circular should do; it compelled attention. Like the mask of the highwayman, it remained imprinted on the tablets of the mind, and the address of that enterprising photographer was as little likely to be forgotten as the "Stand and deliver!" by him who had once heard these words of evil omen. The very conciseness of this photographer's story added to its effect. It avoided all expression of political or religious opinion; it appealed to no prejudices; it flattered no vices; it was not puffed up; it praised not its own wares; it offered quality for quantity; it produced no fatigue.

Persistence of vision has brought about some interesting photographic circulars. They are, perhaps, almost too well known to need description; but, for the information of such as have not seen them, it may be said that they consisted of two circular spots, one red, the other white. Underneath were directions to gaze on the red spot for some twenty seconds, and then turn the eyes upon the white, which would at once appear to be coloured with green. This blend of photography with optics depended, of course, for its effect on the simple law of complementary colour. But where does the advertisement come in? In the centre of the red spot. There, printed legibly in white, stood out the name and address of the craving artist, and this name was declared by the advertiser to be equally visible, though not equally existent, on both spots. Some excellent persons, whose vision was possibly of an exceptional order, were found unable to discover these marvels. It may be that they were professional rivals, and that the foul fiend of jealousy bleared their eyeballs. Anyhow, the public was solemnly assured that there was no trickery or fraud or vain conceit of any kind in the circular, and that the phenomena would be as stated to the normal sight. No idle jest was this advertisement, like that illusion attributed to Mr. Toole in the matter of the slimy dungeon. The comedian is said to have produced an empty box, in which, he averred, such dungeon was situated and clearly visible. People gazed expectant into this box, but no slimy dungeon was discoverable. "Then," said the comedian, airily, "if you cannot behold the dungeon, this much at least is clear, that the box contains a perfect cell!"

Brown had a fine high time of it with his coupons. He agreed to take a dozen portraits of the bearer of a coupon for half-a-crown. The coupon was only available for one month from date. This last touch did the business. People came in flocks to Brown's studio, and there was Brown hard at work, exposing, developing, and what-not, from dewy morn to dusky eve, and picking up gold and silver, as it were, from a veritable Tom Tiddler's ground. But in due course this trick of the coupons became stale, and, therefore, unprofitable.

Robinson still makes a pretty penny out of his portraits of celebrities advertised by his circular. The celebrities will commonly sit for the asking; if not, why, as Sir Horace Walpole was wont to observe, "Every man has his price"—an observation which may be equally true of woman. And celebrities never fail. In London there is the latest murderer, the fashionable ballet-girl, or the newly consecrated bishop; in small hamlets there are the local parsons, who little think—good, honest men—that they are helping a trade advertisement, or the editors of the local newspapers. Pictures of the former secure nine-tenths of the female flock, and pictures of the latter are well paid for by "pars" about a certain accomplished artist and his admirably arranged studio.

Circulars displaying phosphorescent photographs, or pictures of people luminous in the dark—people who have never been known to shine, like the above-mentioned celebrities, in the light—have doubtless had their day, and equally without doubt produced a comfortable income for their originators.

Circulars arousing interest by their crafty commencement are not, perhaps, far distant from a photographic fraud. They begin by setting forth the advantages, mental and bodily, of a trip (say) to Rosherville, and conclude with the delight and profit of taking a snap-shot at everything on the way by the "Rattlesnake" camera, only to be procured of the sole manufacturers and patentees, &c. Photographic circulars of this nature are already too numerous; but it is difficult to refrain from mentioning expressly the device of an ingenious gentleman who sold several pictures of a crowned head by the following announcement:—"On the 18th inst., about twelve hours before midnight, a man was seen to level a double-barrelled camera at His Majesty, who, finding all resistance in vain, at once surrendered, and was borne in triumph to ——, where he is now on sale in the shape of an exquisitely mounted carte at eighteenpence the dozen."

Though originality is pleasing in a circular, originality in some of its multiform varieties is hardly likely to effect its purpose of a ready sale. Of such a kind was the originality in a circular which cautioned mothers not to bring their young children—called, somewhat impolitely and contemptuously, "brats," though this word is used, certainly with no want of respect, by the old poet Gascoigne:—

"O Israel! O household of the Lord!
O Abraham's brats! O blood of blessed seed!"

as pictures of the said brats would on no account be taken. Of such a kind was the originality of a document which adjured ladies not to come for their portraits with their back hair done in the present hideous fashion. Of such a kind was the originality, dictated not by the charity which thinketh no evil, advising the public not to be misled by the specious pretensions of a rival who had "hired for a studio a second-hand stable."

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Transferring Albumen Prints to Wood, Metal, &c.—Orthochromatic Collodio-Bromide Emulsion—Increasing the Sensitiveness of Asphaltum.

*To Transfer Ordinary Albumen Prints to Wood, Metal, Glass, or Porcelain,* it is, according to *Photographie,* sufficient to thoroughly clean the surface to which the image is to be transferred, if it is a polished or a glossy one, and to smooth it if it is a rough one. It is then coated with a thin layer of copal varnish, and the toned and fixed albumen print is placed upon it whilst still wet. All the air-bubbles and the excessive varnish should be pressed out by means of a squeegee or an india-rubber roller, and then the whole allowed to dry for about four hours. After this time the back of the print is moistened by means of a sponge, when it may be lifted off its support, whilst the albumen film, together with the picture, remains on it. The image is then coated once more with copal varnish in order to protect it and to render it more brilliant. A reversed transfer is obtained in this way. If, however, gelatine negatives which can be stripped from their glass support, or transparent films, are used, a reversed print may be made on albumen paper, and this one transferred in the manner described above.

*Orthochromatic Collodio-Bromide Emulsion.*—At the suggestion of Professor Eder, Dr. A. Jonas has worked out a method for making orthochromatic collodio-bromide emulsion similar to that introduced some years ago by Dr. E. Albert. The results of this important work have been published by Dr. Jonas *in extenso* in No. 370 of the *Photo. Correspondenz.* The following two solutions are prepared:

*Solution No.* I.

| | |
|---|---|
| Bromide of ammonium ... ... | 64 grammes |
| Distilled water ... ... ... | 80 c.c. |
| Alcohol (absolute) ... ... ... | 800 ,, |
| Thick 4 per cent. collodion... ... | 1,500 ,, |
| Acetic acid ... ... ... ... | 65 grammes |

*Solution No.* II.

| | |
|---|---|
| Nitrate of silver (crystal) ... ... | 80 grammes |
| Distilled water ... ... ... | 50 c.c. |

The silver nitrate is dissolved by heat, and an aqueous concentrated solution of ammonia (spec. grav. 0·91) is carefully added in small portions, until the brown precipitate first formed is again just dissolved. About 75 c.c. of ammonia will be required for this purpose. Finally, 800 c.c. of warm alcohol (113° F.) are added. Both solutions may be prepared by daylight. In the dark room, which should be illuminated by orange light, solution No. II. is poured into solution No. I. in a thin stream, shaking violently all the time. The temperature of solution No. II. should be kept at from 104° to 122° F., because otherwise ammonio-nitrate of silver will crystallise out. A drop of the emulsion thus prepared is then brought into contact with litmus paper, and if it be alkaline, acetic acid should be added drop by drop until the emulsion gives a slightly acid reaction. It is then shaken for a quarter of an hour, allowed to stand for an hour, and then poured into five or six times the quantity of water. The precipitated emulsion is collected on a clean linen cloth, and the latter hung in running water for one or two hours. Finally, the superfluous water is gently pressed out, the emulsion washed several times with distilled water, pressed out once more, and spread out on thick blotting-paper to dry. For use, dissolve—

| | |
|---|---|
| Dry collodio-bromide ... ... ... | 6 grammes |
| Alcohol ... ... ... ... | 40 c.c. |
| Ether ... ... ... ... ... | 60 ,, |

To render the emulsion colour-sensitive, a certain quantity of picrate of ammonia and glycerine, and the solution of the dye, is added to it. In the case of cyanin, the following mixture should be prepared:—

| | |
|---|---|
| Collodio-bromide emulsion ... ... | 100 c.c. |
| Solution of cyanin, 1 : 150 ... ... | 10 ,, |
| Glycerine ... ... ... ... | 1 ,, |

The action of excess of silver nitrate in the dyed emulsion is very remarkable also in the collodion process. If 51 milligrammes of silver nitrate are added to each 100 c.c. of the emulsion, the sensitiveness of it will be increased at least two times. To obtain a highly colour-sensitive emulsion dyed with eoside of silver, proceed as follows. A raw emulsion is at first prepared by dissolving 6 c.c. of collodio-bromide in 40 c.c. of absolute alcohol and 66 c.c.

of ether by frequent agitation. Then the following three solutions are prepared :—

*Solution No.* I.

| | |
|---|---|
| Crystallised eosin ... ... ... | 4 grammes |
| Distilled water ... ... ... | 50 c.c. |
| Alcohol (96 per cent.)... ... ... | 450 ,, |

*Solution No.* II.

| | |
|---|---|
| Silver nitrate ... ... ... ... | 3·4 grammes |
| Distilled water ... ... ... | 50 c.c. |
| Alcohol (96 per cent.)... ... ... | 150 ,, |

Ammonia, concentrated solution, until the first formed precipitate is again dissolved.

*Solution No.* III.

| | |
|---|---|
| Picric acid ... ... ... ... | 3 grammes |
| Distilled water ... ... ... | 10 c.c. |
| Ammonia to neutralise the solution | |
| Alcohol (96 per cent.) up to ... ... | 300 c.c. |

Just before use, mix—

| | |
|---|---|
| Solution No. I. ... ... ... | 75 c.c. |
| Solution No. II. ... ... ... | 30 ,, |
| Solution No. III. ... ... ... | 30 ,, |
| Glycerine, chem. pure... ... ... | 20 ,, |
| Alcohol (96 per cent.)... ... ... | 45 ,, |

This eoside of silver solution is allowed to stand for one or two days and filtered, and 20 c.c. of it are mixed with each 100 c.c. of the raw emulsion. This dyed emulsiou requires only about one-third of the exposure of wet collodion, but it keeps ouly one or two days. The glass plates, before being coated with the emulsion, are provided with the following substratum: 5 grammes of white gelatine are dissolved in 500 c.c. of distilled water, and to this solution are added 15 c.c. of acetic acid and 10 c.c. of alcohol. The solution is filtered at a temperature of 100° to 110° F., and, whilst still warm, poured twice upon the plate. After being coated with emulsion, the plates are placed directly, without washing, into the dark slide, and can be at once exposed; they will, however, keep damp for thirty to forty minutes iu not too hot a room. When exposed, the plates are washed by dark red light until all greasiness has disappeared, and allowed to drain in an upright position for some time. This draining must continue the longer the larger the plates are ; if they are not sufficiently drained, streaks will be produced on the film during development. Development takes place by copiously pouring the developer over the plate, as in the case of the wet collodion process. The following concentrated hydroquinone developer is recommended as the best for this purpose :—

*Solution* A.

| | |
|---|---|
| Distilled water ... ... ... | 500 c.c. |
| Sodium sulphite ... ... ... | 200 grammes |
| Potash ... ... ... ... | 200 ,, |

*Solution* B.

| | |
|---|---|
| Hydroquinone ... ... ... | 25 grammes |
| Alcohol (96 per cent.) ... ... | 100 c.c. |

*Solution* C.

| | |
|---|---|
| Bromide of ammonium ... ... | 25 grammes |
| Distilled water ... ... ... | 100 c.c. |

The concentrated developing solution consists of—

| | |
|---|---|
| Solution A ... ... ... ... | 100 c.c. |
| Solution B ... ... ... ... | 5 ,, |
| Solution C ... ... ... ... | 7 ,, |

In the case of hard negatives, solutiou B is increased to from 6 to 7 c.c. The actual developer is prepared by mixing—

| | |
|---|---|
| Concentrated developer ... ... | 150 c.c. |
| Water ... ... ... ... | 1,000 ,, |

The plates can be intensified with pyrogallic acid and silver by preparing the following two solutions :—

*Solution* A.

| | |
|---|---|
| Pyrogallic acid ... ... ... | 7 grammes |
| Citric acid ... ... ... ... | 7 ,, |
| Distilled water ... ... ... | 1,500 c.c. |

When dissolved, add—

| | |
|---|---|
| Acetic acid ... ... ... ... | 25 drops |

*Solution* B.

| | |
|---|---|
| Nitrate of silver ... ... ... | 10 grammes |
| Distilled water ... ... ... | 100 c.c. |

Just before use, 100 c.c. of solution A are mixed with 5 c.c. of solution B. If it is desired to intensify the plates after fixing, the same pyro and silver intensifier may be used, but the hydroquinone and silver intensifier also answers very well. For reducing the negatives, the hypo and ferricyanide of potassium reducer, as used for gelatine plates, may be used.

*Increasing the Sensitiveness of Asphaltum.*—E. Valenta has found that the sensitiveness of asphaltum may be materially increased if it is incorporated with sulphur. He dissolves from 7 to 10 grammes of sulphur in a sufficient quantity of bi-sulphuret of carbon, and adds 100 grammes of Syrian asphaltum. The solution is then freed from the bi-sulpuret of carbon, and for about one hour heated up to 100° C. ; it is then transferred to an air-bath, and gradually heated up to about 180° C., until sulphuretted hydrogen is escaping. At this temperature it is kept for about five hours. The asphaltum forms, after this treatment, a black and shining mass, which does not dissolve in alcohol, and only to a small degree in ether, whilst it dissolves perfectly in turpentine, benzole, chloroform, and bi-sulphide of carbon. Four parts of this preparation are then dissolved in 100 parts of benzole, and the solution is applied in the usual manner to a polished zinc plate. It forms a light yellow, thin film of comparatively high sensitiveness to light, and gives, therefore, beneath a negative of good density clear and sharp impressions after the development with turpentine, even with comparatively short exposures.

## THE DECOMPOSITION OF SILVER CHLORIDE BY LIGHT.*

BY A. RICHARDSON, PH.D.

It is known that the presence of hydrochloric acid exercisesa retarding influence on the decomposition of chlorine-water by light, aud a series of experiments have been made (*B. A. Report*, 1888) in order to determine the influence of different quantities of acid ou its stability. The results given in Table II. show that even minute quantities of the acid exercise a very decided influence on the rate at which free chlorine is converted into hydrochloric acid under the influence of sunlight (exposure seven days, August 17—24).

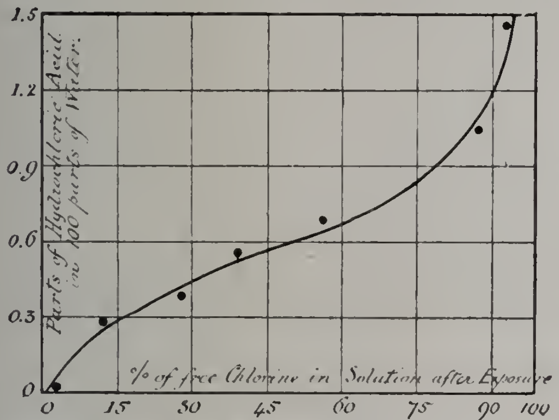
Table II.

| Parts of Cl per 100 $H_2O$. | Parts of HCl per 100 $H_2O$ added. | Per cent. free Cl found. | Per cent. combined Cl found—HCl added. |
|---|---|---|---|
| 0·284 | 0·029 | 2·34 | 97·66 |
| 0·270 | 0·289 | 12·61 | 87·38 |
| 0·260 | 0·400 | 28·57 | 71·42 |
| 0·290 | 0·587 | 39·25 | 60·95 |
| 0·290 | 0·724 | 58·71 | 41·29 |
| 0·282 | 1·158 | 87·82 | 12·18 |
| 0·291 | 1·447 | 95·47 | 4·53 |

Iu the case of silver chloride in water, the chlorine evolved during exposure to light is at first speedily con-

* Continued from page 597.

verted into hydrochloric acid, but as the strength of acid increases its rate of formation diminishes. Free chlorine, therefore, accumulates in the solution until (the intensity of light remaining constant) a maximum is reached, at which stage further decomposition of silver chloride is balanced by recombination of chlorine with the darkened product. The formation of free chlorine is still more marked where silver chloride is exposed under a solution of hydrochloric acid in the first instance, as is shown by the following experiment, in which equal quantities of silver chloride were exposed to light in solutions of hydrochloric acid of varying strengths. After an exposure of seven days (April 20—27) the free chlorine and oxygen liberated were determined. During exposure it was observed that the liquid in the tubes containing acid was of a distinctly green tint (especially when seen through



the entire length of the tube), the chlorine liberated from the silver salt remaining in solution in the water. In the night, however, rechlorination of the darkened silver compound had occurred to such an extent that the colour had almost entirely disappeared from the solution. The estimation of the free chlorine was therefore made immediately after exposure to bright sunshine, and again after the liquid had been left in contact with the darkened product for fourteen hours in the dark.

The results obtained are given in the following table:—

Table III.

| 1. HCl added per 100 c.c. solution. | 2. c.c. O set free. | 3. Free Cl found. | 4. Free Cl found after 14 hours in the dark. |
|---|---|---|---|
| 4·0 | minute bubble | 0·042 | 0·014 |
| 1·97 | 0·5 | 0·035 | 0·019 |
| 0·38 | 1·9 | 0·024 | 0·003 |
| 0·19 | 1·7 | 0·007 | 0·0008 |
| 0·00 | 4·2 | 0 0017 | 0·0003 |

In another experiment, made to determine how far the total amount of chlorine evolved from silver chloride during exposure was influenced by the presence of hydrochloric acid, the following results were obtained. A comparative experiment was made with silver chloride in pure water:—

Table IV.

| HCl per 100 pts. $H_2O$ taken. | Total Cl found (—HCl added). | Combined Cl found. | Free Cl found. | Per cent. free Cl. |
|---|---|---|---|---|
| 0·909 gram | 0·201 gram | 0·173 | 0·027 | 13·7 |
| 0·0 ,, | 0·276 ,, | 0·273 | 0·002 | 0·94 |

Here it is seen that, although the presence of hydrochloric acid increases the amount of free chlorine in the solution, yet the total chlorine set free—and, therefore, the amount of decomposition of the silver salt—is decreased. In order, then, to obtain the maximum amount of surface decomposition of silver chloride, it is necessary that the volume of water present should be relatively large, and that the solution of acid formed should be often replaced by pure water during the exposure.

The explanation of the retarding influence of haloïd salts and of oxidising agents on the darkening of silver chloride appears to be found in a study of the action of these substances on solutions of chlorine-water under the influence of light.

The condition of the free chlorine in the solution is one of some interest, and was next studied. The examination of the liquid for oxy-acids of chlorine was, however, hampered by the fact that a part of the oxygen liberated was present as ozone, the smell of this substance being distinctly recognised, especially during the first periods of exposure of silver chloride, when large quantities of water were present. To further prove the presence of this substance, air was drawn through water containing silver chloride in suspension during exposure to sunlight, and was then passed through two bulbs containing solutions of silver nitrate, and finally into a solution of potassium iodide which was protected from the light; the liquid in the first bulb became milky, that in the second remained perfectly clear, whilst iodine was set free in the solution of potassium iodide. No hydrogen peroxide was detected in the liquid containing silver chloride during any period of exposure.

The observations of Popper (*Annalen*, 227, 161) and of Pedler (Trans., 1890, 57, 613) show that hypochlorous and other oxy-acids of chlorine are formed during the decomposition of solutions of chlorine-water by light, and it seemed probable that a part of the chlorine evolved by the decomposition of silver chloride by light should, in presence of water, form similar products, and statements to this effect have repeatedly been made (*B. A. Report*, 1859, 107). An experiment was, therefore, made in which silver chloride, in contact with a small quantity of water (20 c.c.), was exposed to bright sunlight for six hours. The liquid was then tested for hypochlorous acid by agitation with mercury, and subsequent treatment with hydrochloric acid, as suggested by Wolters (*J. pr. Chem.*, 74, 68). The formation of hypochlorous acid was noted by the fact that mercury was present in the solution. Although this test could not be applied quantitatively in the presence of ozone, yet the comparatively large quantity of mercury in the solution could only be ascribed to the presence of hypochlorous or similar acids in the liquid, together with free chlorine. It was noticed, however, that a strong solution of hypochlorous acid was decomposed by contact with normal silver chloride, even in the dark, a green gas containing free oxygen and chlorine being evolved; the silver chloride appeared to be unaltered. How far dilute solutions of the acid are decomposed is yet to be determined.

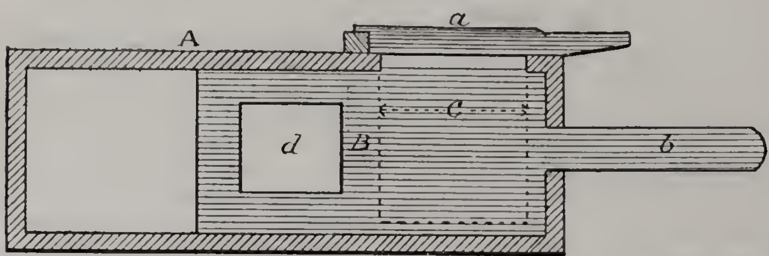
*(To be continued).*

We clip the following note regarding Mr. Robinson's pictures at the recent Buffalo Convention from *The Express* (New York):—"Strolling about the gallery, one is attracted by many handsome pictures. Mr. H. P. Robinson, considered the peer of landscape artists with the camera, makes a splendid exhibit, which never tires the eye. Sunlight and shadow are blended so perfectly that it is not difficult for the spectator to imagine himself surrounded by the charms of a summer idyl."

## PHOTOGRAPHING THE THROAT.

BY DR. MUSEHOLD, BERLIN.

In my experiments in attempting to produce a serviceable photographic picture of the throat, I started, in the first place (in the early part of 1890), with the idea of inserting a photographic apparatus between the mirror which is lighting the throat, and the eye of the researcher, in order to observe the throat picture on a focussing-screen just as it is seen by means of a laryngoscope. It is known that in previous experiments of this kind the results have been hardly satisfactory. This is shown by the last meritorious communication of Dr. Wagner (*Berlin Klin. Weekly Gazette*, 1890, No. 50); and the same failure had been already distinctly mentioned, and with justice, by Dr. Riesenfeld (*Photographic News*, Berlin, 1891, March, Part I). In my apparatus (which I constructed for the purpose), as soon as the picture of the throat thrown on to the ground glass shows the necessary sharpness and the desired position for photographing, the sensitive plate is rapidly made to take the place of the focussing-screen, and then the picture is taken by means of a magnesium flash-light. The changing of plates takes place by the help of the petroleum or gas light used in laryngoscoping, while the magnesium flash-light (Dr. Meithe) is so fastened on to the arm which joins the reflector and its lamp that the magnesium light, when produced, and the lamp flame are nearly concentric.



Half size of case. Back wall has been removed.

A. Case. *a*. Slit closed by a shutter. B. Back of slide. *b*. Bar for moving. *c*. Place for sensitive plates. *d*. Ground glass fastened on to front side.

The camera with the reflector, which is held by the universal jointed arm of Tobodd's laryngoscope, is fastened to the base of an ordinary strong head-rest by means of a screw, so that an approach to the object and a horizontal movement is possible. The apparatus permits in this way of being placed between the patient and the physician without trouble. As lens, I have hitherto used (in order to obtain pictures as large as possible), first a Hartnack-Anastigmat of 11 cm. focal distance and 11 mm. aperture, and latterly a Steinheil-Antiplanet of 12·5 cm. focal distance and 21 mm. aperture. The reflector is the one customarily used in laryngoscoping, of about 20 cm. focal distance, and with a central hole of 20 mm. The principal part of this on the whole very simple apparatus is the case. While at other times the lens is found in the camera, I have for this above-mentioned purpose placed it in the case. The latter is erected for plates 4 by 4 cm. in size, and consists of a box which is 15·5 cm. in length, 5 cm. in breadth, and 1·5 cm. in thickness; it has an opening 3 by 3 cm. in diameter in the centre of each of its sides. One of these openings, namely, that in the front side of case, has around it a ledge with sloping inner edges; this is to form a groove for corresponding ledges, which are arranged dove-tail fashion round a central opening of the same size in the back wall of the camera, which remains shut.

In the inside of the case is a slide, occupying its whole breadth, but only two-thirds of its length, which consists essentially of a board, with a bar fastened on the side. The latter projects 5·5 cm. from the right-hand short side of the case, according to the position which the case takes on the camera.

In this position the slide fills up the two-thirds of the case lying to the right. The left half has an opening measuring 3 by 3 cm., which, in the just mentioned position, therefore, is concentric with the two openings of the case, by reason of the handle being drawn out. This opening in the slide towards the front—that is, towards the camera—is covered with a ground glass; the right half of the slide has, on the front side, a support closed at the sides and underneath by ledges, and open at the top, which serves for the reception of the photographic plate. The sliding board which forms the back wall of the support, and also the velvet straps which are laid on the edges of it, prevent the plate being exposed to unnecessary light. The latter is pushed into the support through a closable slit, which is in the upper narrow long side, and which is made light-proof by means of a shutter.

As soon as the picture is clearly projected on the ground glass, the slide is pushed, by means of the bar or handle, to the left to the end of the case, and consequently moves the sensitive plate, which is on the same level, behind the front opening of the case—that is, where the ground glass was standing before. The same hand which pushes the slide immediately turns on the flash-light, and pulls the slide back again to the right by the handle, which still sticks out. The light which falls on the sensitive plate from the gas or petroleum flame during the pushing backwards and forwards of the slide has no influence on the sharpness of the picture; this has been proved with this case by some very successful portraits of children. After the operation is finished, the case must be taken into the dark room, and the plate removed and developed.

Naturally, the photograph can be done only in a room from which the daylight is quite excluded, or in the evening. But this disadvantage can be set aside by placing an instantaneous shutter on the slide itself in front of the sensitive plate, which should be put in motion as soon as the slide has been pushed right up to the other side of the case. Then, with the help of a magnesium light, the photographing can take place at any time of day.

The results at which I have arrived at hitherto are certainly encouraging to the continuance of experiments in this line. The size of the picture of the throat is from $\frac{4}{5}$ to $\frac{5}{6}$ of the natural size.

Although my experiments are not yet terminated, I have thought it advisable to describe the above arrangement, and especially the case, in order to facilitate the troublesome work to all those who occupy themselves with this subject, or to stimulate them a little to successful improvements of the simple apparatus described.

I hope before a very long time to be able to go more deeply into this subject in these columns.—Abstracted and translated from *Photographisches Wochenblatt*.

## SUNSPOTS.

The following interesting notes are extracted from a letter by Sir Robert Ball, Astronomer-Royal for Ireland, which recently appeared in the *Daily Graphic*:—

First let me say that no extensive or elaborate apparatus is necessary for the simple observations that I am suggesting: any fairly good telescope will answer for the purpose. I daresay this paper will be read by many who are enjoying their seaside holiday, and the same telescope that is used for observing a yacht race will often be quite sufficient for observing the sun. Of course, the eye must be protected by the interposition of a piece of dark glass, or in some other manner. If a convenient arrangement for this be not at hand, then a sheet of white paper held near the eyepiece can be so placed as to receive a picture of the sun, whereupon the interesting features on the surface of the great luminary that are now attracting so much attention will be distinctly visible. At the present time it happens that the sun is diversified with an exceptionally large number of spots; in fact, it seems that the number and extent of the spots has been largely augmented during the last six months, nor does it yet appear to have reached its maximum. This increase has not been, however, quite uniform. The surface covered by spots in February was in excess of that in January. There was, however, a falling-off in March; but in both April and May the area covered was about double that in January, while in June the spotted regions were nearly three times as great as at the beginning of the year. Anyone who is desirous of seeing the exact figures may refer to the current number of *Nature*, where will be found the particulars of an interesting series of observations made by M. Marchand, at Lyons Observatory, during the first six months of this year. It appears that since the end of March not a single day has passed without a spot having been visible on the sun. There are also indications of activity exhibited by the brilliant solar objects known as faculæ. Indeed, the area of the sun's surface covered by faculæ during the first six months of the present year was in excess of the total amount of faculæ seen in 1890. These circumstances will naturally lead to an increased amount of attention being devoted to the sun during the autumnal months.

The sunspots are well known to be openings through the glowing luminous exterior by which the somewhat darker interior is exposed. The aspect of the spots is constantly changing. This is partly due to the circumstance that the sun is turning round on its axis, so that the objects now visible on that side of the sun which is directed towards us will, in a fortnight, have passed to the other side of the luminary, and will again have returned to the same position from which they were first observed after the lapse of about twenty-five days. But this is on the supposition that the spots last as long as twenty-five days, and such is not always the case. Sometimes a group of spots will only live for a few days; generally, however, they last for a month or two, and in exceptional instances they endure for a year, or even longer. The rapid changes which these objects undergo become all the more significant when we bear in mind the enormous dimensions that are concerned. There are spots so large that the whole earth would not be too great to pass through the opening which they indicate. By far the most interesting point in connection with sunspots is that of their periodicity. It is now about fifty years since the patient observer, Schwabe, announced his important discovery. He had for forty-three years diligently studied the face of the sun, and recorded the spots which it presented. At first he seems merely to have aimed at patiently obtaining a record of celestial phenomena. He never could have foreseen the interesting result that he was to obtain when his long and patiently accumulated series of observations came to be discussed. They pointed, however, to a distinct recurrence of a maximum exhibition of sunspots at every period of about eleven years. These maxima are, however, not a little irregular both as to the time of their occurrences and the amount of the solar disturbance that they indicate. The last sunspot maximum occurred about 1883; but this was somewhat later than was expected, so that it seems as if we were now again approaching a sunspot maximum.

There is, however, a wide distinction between the predictions as to the recurrence of sunspots, and the prediction of ordinary astronomical phenomena, such as eclipses or the like. The latter we can foretell with absolute certainty, inasmuch as the causes which produce them are known to us; but with respect to the sunspot cycle of eleven years, all we can say is that we may expect it to continue because it has been observed in the past, but we know not the reason why. It might naturally be expected that changes in the sunspots should affect in some way the power of the sun for radiating heat, and thus influence the weather. He would indeed be rash who asserted that there was no connection of this nature. It is, however, certain that we have not yet, at all events, been able to trace the slightest connection between sunspots and the practical consideration of weather changes. Many attempts have, however, been made, and some have even gone so far as to search for a relation between sunspots and the price of wheat. It is impossible to trace any reliable connection of this kind, nor have the attempts to identify commercial crises with periods of sunspot maxima proved more successful. If any relation could be ascertained between sunspots and such terrestrial phenomena there would be every possible inducement to discover it. These have been happily suggested by Prof. S. P. Langley (of the Smithsonian Institution) in a passage with which I conclude this letter:—

"Would it be of any practical interest to a merchant in bread stuffs to have private information of a reliable character that crops the world over would be fine in 1888 and fail in 1894? The exclusive possession of such knowledge might plainly bring 'wealth beyond the dreams of avarice' to the user; or, to ascend from the lower ground of personal interest to the higher aims of philanthropy and science, could we predict the harvests, we should be armed with a knowledge that might provide against coming years of famine, and make life distinctly happier and easier to hundreds of millions of toilers on the earth's surface."

This may be possible in the future; but we seem a long way from it as yet.

---

We understand that Messrs. George Houghton & Son's portable tent studios are meeting with favourable comments in many quarters. One of these has been in use by Messrs. Barrauds for the past few weeks, first during the cricket week at Canterbury, and afterwards at Burlington House in connection with the Hygienic Congress there. This tent has been used at both places for taking many hundreds of portraits for composition pictures, illustrative of both events. As an instance of the portability of the apparatus, it may be mentioned that the tent was in use up to four o'clock on Friday at Canterbury, but was in working order in London at noon on Saturday.

## Notes.

We learn that there is every prospect of the coming exhibition by the parent society at Pall Mall proving a success. The demand for entry forms is three times as great as usual, and already a large number of these have been duly filled up and returned to the secretary. We may, therefore, reasonably look forward to an improvement in the standard of works exhibited, for it is evident that the hanging committee will have more pictures than they want, and will be in a position to pick and choose. We also learn that the Affiliation Scheme is gaining support, many of the provincial societies, including some of the largest, having signified their intention of joining it.

Photographers know well how nervousness, or self-consciousness, or some other quality ending in "ness," will make many of their clients assume an expression which, to the beholder, might suggest a visit to the dentist's, if not to the scaffold; and various are the methods by which they will endeavour to counteract this tendency on the part of their customers. "Now please look pleasant!" is a very common, though rather ineffectual, appeal, for when persons are commanded to smile, the attempt to obey is generally productive of a rather ghastly result. It is akin to requesting a humourist to say something funny. Perhaps the most original formula for bringing a nervous sitter to his senses is that which was lately recorded at the Convention in Buffalo, as a specimen of photographic procedure in the old days out West. The photographer of whom the story is told simply levelled a pistol at his client and said, "Look right square in the muzzle o' this yer revolver, my man, and remember that I hain't agoin' to hev this picture spoiled with any o' your foolin'!"

The unfortunate shareholders in the Automatic Photograph Company have suffered so severely that probably no one among them will again invest in any photographic concern on the strength of what they read in non-technical journals. It seems curious that, although there are so many photographic journals, it struck none of these shareholders to ask one of them the question whether this company was likely to fulfil its wonderful promises before they contributed their money to it. The general public is ready to swallow any statements with regard to the possibilities which may be achieved by either photography or electricity, and they are even gullible enough to believe in perpetual motion; but they do not care to take the simple precaution of seeking the advice of those who know more than themselves before investing their money.

It is doubtful whether the question of automatic photography will be revived for some time to come, simply because of the impossibility of getting persons to subscribe to a scheme which has already proved to be abortive; but if it ever be again attempted, it must be on fresh lines altogether. As we have already had occasion to point out, the machines are wonderfully ingenious, but, except under certain conditions, cannot fairly be described as automatic. Skilled attention is constantly necessary; but even with this attention, such machines cannot, from their very nature, be made to work for more than a very limited time, unless their customers are content to receive such terrible things as they have lately been doing.

But the work can easily be put to experimental proof if we attempt to produce a few pictures under the same conditions as these machines work. Take three basins. In No. 1 place the developing solution, in No. 2 the fixing bath, and let No. 3 contain clean water. Now take a photograph in the ordinary manner in the camera, and dip the plate for twelve seconds in each of these basins in their numerical order. Supposing that the light and time of exposure are in harmony, we may get a passable result at first, but what manner of chemical solutions must these be which will stand the constant admixture which must take place through the same unwashed hand or plate-holder dipping into them for successive pictures? No practical photographer would look for anything but failure under such conditions, and failure must be still more certain when unskilled labour comes in to complicate matters.

In an interesting article on Mr. Muybridge's later work, *La Nature* draws attention to his astonishing industry. The American photographer has now accumulated no less than 781 series of instantaneous studies, comprising more than 20,000 photographs. When Mr. Muybridge started in 1878 his ambition was very modest; but he soon became convinced that with improved appliances the work was almost without limit, and so, indeed, it has proved. The expense, however, was at first a great obstacle, and, but for the assistance rendered by the Pennsylvania University, might have been insurmountable. The 20,000 photographs alluded to comprise pictures of men, women, children, animals, and birds, walking, galloping, flying, working, dancing, &c. All these photographs are reproduced in photogravure without any retouching, and form an altogether unapproachable and unique work. *La Nature* gives four reproductions of different studies—viz., the jumping of a horse over a hedge, the walk of the monkey, that of the elephant, and of the movements of a child picking up her doll. The exposures were a thousandth part of a second.

*Apropos* of what may be called the science of instantaneous photography, the latest application is that of M. Demeney, an assistant of Mr. Muybridge's rival in France, M. Marey. M. Demeney has recorded, by means of the camera, the movements of the lips in speaking, and the results are said to be very curious. One captious critic remarks that "*Ich liebe Dich*" looks like a masticating process, while "*Io t'amo*" is suggestive of a desire on the part of the singer to swallow his beloved one. If singers who make grimaces when vocalising were subjected to this minute photographic process, we should fancy they would be effectually cured.

Manufacturers of the better kinds of sensitised papers are frequently handicapped by the difficulty of obtaining English paper equal to that made in Germany, when the supply of the German make falls short, as it sometimes does. As the "Paper Makers' Directory of all Nations" remarks, Germany leads the world in the making of paper, and it is a very interesting question to know why. There are 1,443 paper mills as against 270 in England and Wales, and 68 in Scotland; while in the matter of the very best qualities the German market is supreme. One would think that England should be able to hold its own, but it does not appear to be so.

## PHOTOGRAPHY AND THE BRITISH ASSOCIATION.

Photography continues to assert itself in many of the papers read before the British Association at Cardiff in such a marked manner that it would almost seem as if the president's address had given others the cue to give the art recognition. First of all, in connection with the Geological Section, a large number of photographs were displayed in an adjoining class-room, and the second report of the committee appointed to arrange for their collection, preservation, and registration was submitted by Mr. O. W. Jeffs. The report showed that during the past year the work of collecting photographs illustrating the geological features of the country had been continued, with the result that 278 additional photographs had been received and registered, making a total up to the month of July of 552. At the Leeds meeting of the Association upwards of 200 photographs were arranged for exhibition in the room appointed for the use of Section C, many of which illustrated sections of strata and other geological features of considerable scientific interest. The collection attracted much attention; and it was proposed to continue the exhibition at Cardiff if convenient arrangements could be made.

In Section A, which is devoted to mechanical and physical science, Professor Liveing, F.R.S., read a communication from Professor Piazzi Smyth relating to a comparison of some photographic representations of the solar spectrum made by eye some years ago (1884), and registered at the time by means of drawings. The eye is able to detect many details in the spectrum which are not reproduced by photographic processes, especially the separation of densely-crowded lines. The drawings made by Professor Piazzi Smyth were greatly admired, both for their accuracy and the artistic manner in which they were executed.

In the Geographical Section, Mr. John Thomson (London) read a paper on "Photography Applied to Exploration." He said:—My object in this paper is twofold—first, to show the growing importance of photography and its application to science, and secondly, to urge explorers to avail themselves more fully of the advantages it affords. The camera is an instrument of the highest scientific value, portraying as it does all visible objects with mathematical accuracy, the practical outcome of which may be seen in the reproduction to scale of maps, charts, plans, &c., by a single operation in the camera. The saving of time and labour thus effected is incalculable. Photogrammetry, or survey by photography, is now in use among engineers on the Continent and in America, but up to the present time this new departure has made little headway in this country. To the pioneer, whose object it is to map out a new route, picture new scenes, and provide the scientific world with perfectly accurate and trustworthy information, photography is of inestimable value. He has only to refer to the photographs he has taken *en route* to banish doubt, disarm the captious critic, and afford enduring evidence of work faithfully performed. Astronomical observations made abroad may be verified at home, and positions set down for guidance in map making. Such observations and registering of altitudes above sea level are matters requiring a separate scientific training, but beyond that there is much important work to be done in connection with the topography of a region, and such work, I maintain, lies within the scope of photography. Among other services which photography may render to the explorer, that of making observations depending upon proportional measurement is not the least. [The author then explained the details of a method of his own, whereby a perfectly reliable basis of measurement could be obtained.] He continued: The more general scientific use of photography may be indicated in taking evidence of the effect of erosion in drainage of mountain chains, the building up of delta by the detritus of rivers, the hydraulic force of streams in undermining and altering formations, in botany, for military purposes, and many other applications, commercial and scientific. Travellers, through the mistaken notion that the art can be picked up in the course of an afternoon, too often leave the photographic part of their training to the last moment. This is a fatal error, which I have been combating for years. Personally, I have studied and practised the art for over a quarter of a century, and still I have to study to keep pace with its progress. The author reverted to the subject of surveying by photography, suggesting that the surveying of the future will be performed by a captive balloon specially constructed and fitted for the purpose. This balloon may carry the camera, only to be worked from the ground by an electric current. It should be anchored by three cords from the corners of an equilateral triangular space, and its movements over the section of the space to be surveyed watched by means of an artificial horizon until the camera is over the centre of the section. The photograph should then be taken. A series of photographs, say, of a city in sections taken from a balloon could be joined together and photographed on one plate to form a complete map of the city. This plate, without touch of graver or pencil, could then be transferred to the printing press. (Numerous photographs taken by the author during his travels in the East were shown.)

Colonel Tanner, of the Indian Survey, said he had been advocating the adaptibility of photography to such work as the survey of portions of the Himalayas, which Europeans were not allowed to visit, and which the authorities in India had to map out as accurately as might be from a distance of one hundred miles. Photography in the hands of surveyors would greatly facilitate the mapping of the Himalayas, and would very considerably shorten the work. For ten years he had been endeavouring to make a map of Nepaul, no portion of which state had he been permitted to visit. All they had to go by was a representation of the chief mountain ranges, and they did not know the gaps in the ranges through which the rivers of Nepaul flowed. Photography would also greatly facilitate the survey of the highlands, covered with ice and snow, where his assistants were employed. One of his assistants was taking observations of a range of mountains 20,400 feet high, and he had to devote the whole of his time to recording observations in his note-book. He had not a moment to spare in order to take an outline of the great masses of snow mountains around him. He trusted that Mr. Thomson's observations would reach the Government of India, and that the system he advocated would be introduced in the Indian Service.

Mr. J. Coles thought that the question of the application of photography was in its infancy. He had applied photographs towards correcting the maps of the Russian Government of the region of the Caucasus. As to the application of photography to geographical discovery generally, he did not think that anyone could obtain so good an idea from a word picture as from a photograph, and it was of the utmost assistance in the making of maps. Photography in its application to the art of the cartographer would free us from the great liability of making errors.

The President pointed out that the Jungfrau had been surveyed and its contour outlined by means of photography. The photographic process of survey had been tested, and had been found most efficient, particularly where the ordinary surveyor had to deal with places which were inaccessible.

## LUNAR AND TERRESTRIAL VOLCANOES.*

Believing the trap-dyke theory to be the most plausible explanation, we would like to ask whether, in spite of no shadows having yet been detected, the rays may not be due after all to *slight ridges* of igneous rock welling out in a viscous state from long cracks, and so catching a little more light than the surrounding parts of the lunar surface. Such ridges might be no more than 100 or 200 feet in height, and if their sides slope gradually it might be impossible to detect their shadows. We may also suppose they consist of some light-coloured trap-rock, such as felstone, and to be "weathered" by the lunar atmosphere, thus presenting a somewhat whitened surface. It is quite possible that the lunar trap-rocks may be of a highly siliceous nature, like "volcanic glass," also that they may have been considerably weathered and whitened by the action of great quantities of steam, now absorbed by the moon, emitted in the last phases of lunar volcanic action. We know that steam can act chemically on glass, and turn it white. The lunar photograph in Mr. Ranyard's paper shows that the streaks are not nearly so bright as some mountains and craters, but this would easily be accounted for by the very great difference in height. Our idea is that the lunar mountain ranges are composed of volcanic rocks thrown up in some way from lines of fissure, and that the streaks are, as it were, attempts at lunar mountain ranges, which failed because, for some reason, the lava was not forced up in sufficient quantity. We rebel, for several reasons, against the idea of the lunar mountains being covered with snow. For instance, there is a great difference in the whiteness of different lunar mountains, which would be impossible if snow were the cause of the whiteness. But if they are composed of different kinds of trap-rock, it is extremely likely that they would weather differently, so that some might be whiter than others. Those, like basalt, of a more basic character (*i.e.*, with more lime and magnesia) would be of a darker colour, while others, like felstone (which is acidic and contains much free silica), would be of a lighter hue.

In looking over the beautiful pictures in Messrs. Nasmyth and Carpenter's book, we notice another point which seems to favour this idea—namely, that short lines of mountains are so often seen in connection with lunar craters, sometimes roughly radiating from them, sometimes all more or less in one direction. We observe this especially in the pictures of Gassendi (the frontispiece), Copernicus, Archimedes, Aristotle and Eudoxus, Trisnecker, Plato, Mercator, and Campanus, and also very plainly in the photo of Aristarchus and Herodotus. Again, the occurrence of craters in lines, in some cases, is another important fact tending to confirm this idea. (It will be remembered that terrestrial volcanoes run very markedly in lines.) It may be well here to quote the authors above referred to. They say (p. 98): "We have upon the moon evidence of volcanic eruptions being the final result of most extensive dislocations of surface, such as could only be produced by some widely diffused, uplifting force. We allude to the frequent occurrence of chains and craters lying in a nearly straight line, and of craters situated at the converging point of visible lines of surface disturbance. Our map will exhibit many examples of both cases. An examination of the upper portion (the southern hemisphere of the moon) will reveal abundant instances of the linear arrangement. Three, four, five, or even more crateral circles will be found to lie with their centres upon the same great-circle track; proving almost undoubtedly a connection between them, as far as the original disturbing force which produced them is concerned. Again, in the craters Tycho, Copernicus, Kepler, and Proclus, we see instances of the situation of a volcanic outburst at an obvious focus of disturbance."

On this theory, the dark linear markings on the moon, known as "hills" or "clefts," are probably cracks up which, for some reason, the molten matter only welled-up to some point below the surface. Perhaps they formed later than other terrestrial features, after the volcanic fires had died out, and when the linear surface was losing its old heat rapidly, and therefore cracking as it contracted on cooling.

It must be confessed that there is little to be said in favour of the view that the lunar streaks have been produced in a similar way to terrestrial "faults," for several reasons: First—the mountains of the moon, as far as we can see, are different to terrestrial mountains, and seem to be entirely volcanic, whereas our mountains are mostly due to the upheaving and folding of sedimentary strata; their present outlines being the result of long-continued atmospheric denudation. Secondly—it seems to me impossible, in the present state of our knowledge, to say whether stratified rocks are present on the lunar surface. If at one time there were seas, and an atmosphere at all like ours, "denudation" must certainly have taken place, and that would involve the accumulation of marine sedimentary deposits. Many believe that there is evidence of stratification, and even of tilted strata, in the lunar Apennines; but if this is the case, I should prefer to consider such strata as purely volcanic, viz., lava and ashes. Thirdly—terrestrial "faults" are very sharp lines of division, like the cracks which form in a sheet of ice after continued skating, so that we could not expect to see them.

One word in conclusion about "trap-dykes." These are veins of eruptive rock (basalt, &c.) filling up vertical or highly inclined fissures, and are so named on account of their resemblance to walls (*Scottice*, dykes). When the surrounding rock has decayed, the dykes may be seen projecting above ground exactly like walls. Sometimes the eruptive rock has followed the course of a "fault"; but in Scotland, at least, the vast majority of dykes rise along ordinary fissures which, having caused no displacement, cannot be considered as "faults." On the contrary, the dykes may be traced undeflected across some of the largest "faults." Dykes differ from veins in the greater parallelism of their sides, their verticality, and greater general regularity. Usually a dyke cannot be traced far, but the well-known Cleveland Dyke, in the north of England, runs for at least 60 miles, cutting through various "formations" till it reaches the Yorkshire coast,

* Concluded from page 598.

200 miles or more from the sheets of Miocene trap-rock with which it is probably connected. The south-western half of Scotland, and the northern parts of England, are ribbed across with thousands of dykes, which seem to be connected with the volcanic chain of the inner Hebrides (of Tertiary age). The fissures through which such dykes forced their way were not made by the molten matter itself, but more probably were the result of violent explosions and earthquakes proceeding from a region of volcanic action.

I must now conclude this paper, leaving the reader to judge if I am warranted in applying the trap-dyke theory to the lunar streaks. It certainly harmonises lunar and terrestrial phenomena, and suggests a close connection between radiating streaks, chains of lunar volcanoes, mountain ranges, and ridges or lines of hills near the volcanoes.

### Remarks by A. C. Ranyard.

If the reader will turn to the photographs of the moon, published in *Knowledge* for May, 1890, and October, 1889, he will see that the rays or streaks have not sharply defined edges, as they presumably would have if they were trap-dykes. The rays vary in breadth, many being from twenty to thirty miles broad, with very soft, nebulous edges. The whiteness of the rays in some cases may be seen to degrade gradually from a narrow, sinuous, bright band which runs along their centres—see, for example, the two rays from Tycho that run across the Mare Nubium, shown in the plate published in the May number for 1890. The rays seem in no way to interfere with the forms of the craters and irregularities of the lunar surface, as we should expect to find them interfering if they corresponded to a wall of injected rock either harder or softer than the surrounding material. A good instance of a broad ray passing over craters and rough ground without affecting the forms of the craters and mountains is shown in photograph No. 1, plate No. 1, in the October number for 1889, where a strikingly bright ray radiating from Tycho passes across the rough ground to the south of the Mare Nectaris, and then across the plain and onward.

Lava streams and volcanic regions on the earth are generally dark as compared with the surrounding rocks, but the light-reflecting character of these rays cannot be accounted for unless they are capable of reflecting more light than light sandstone, or even than chalk; for the light-reflecting power of the moon, taken as a whole, about corresponds to that of light sandstone. See the often-quoted observation of Sir John Herschel, who compared the light of the nearly full moon with that reflected from Table Mountain at the Cape. Everyone is familiar with the whitish appearance of the moon as seen in the daytime. It appears like a small, whitish cloud.

There are many large, dark areas upon the moon; consequently, the brighter parts must be relatively white as compared with light sandstone. It is true that the summits of lunar mountains and craters differ greatly as to their whiteness, but few terrestrial mountains are wholly covered with snow, and, as seen from a distance, their whiteness would depend upon the amount of rock surface and shadow intermixed with the snow. The moon, as a whole, reflects a little less than a quarter of the light reflected by fresh fallen snow. My argument is that the brighter patches and rays are so bright as compared with the rest of the moon's surface that their whiteness cannot differ greatly from the whiteness of snow.

---

Mr. E. J. Browne, of Liverpool, has hit upon the happy idea of making rubber stamps from half-tone photographs, and has sent us a specimen of his work in the shape of a profile portrait impressed at the head of his note-paper. This stamp appears to owe its origin to a coarse-screen process block. Such a stamp may be useful in lieu of signature for ephemeral documents—love letters for instance—and a still more practical use for it is indicated as a means of identifying a payee in a note payable to an individual.

## PHOTOGRAPHY AND THE SPECTRUM.

The following remarks were included in Dr. Huggins' address before the British Association at Cardiff last week:—

A very great advance has been made in our knowledge of the constitution of the sun by the recent work at the Johns Hopkins University by means of photography and concave gratings, in comparing the solar spectrum, under great resolving power, directly with the spectra of the terrestrial elements. Prof. Rowland has shown that the lines of 36 terrestrial elements at least are certainly present in the solar spectrum, while 8 others are doubtful. Fifteen elements, including nitrogen as it shows itself under an electric discharge in a vacuum tube, have not been found in the solar spectrum. Some 10 other elements, inclusive of oxygen, have not yet been compared with the sun's spectrum. Rowland remarks that of the 15 elements named as not found in the sun, many are so classed because they have few strong lines, or none at all, in the limit of the solar spectrum as compared by him with the arc. Boron has only two strong lines; the lines of bismuth are compound and too diffuse. Therefore, even in the case of these 15 elements, there is little evidence that they are really absent from the sun. It follows that if the whole earth were heated to the temperature of the sun, its spectrum would resemble very closely the solar spectrum. Rowland has not found any lines common to several elements, and, in the case of some accidental coincidences, more accurate investigation reveals some slight difference of wave-length or a common impurity. Further, the relative strength of the lines in the solar spectrum is generally, with a few exceptions, the same as that in the electric arc, so that Rowland considers that his experiments show "very little evidence" of the breaking-up of the terrestrial elements in the sun. Stas, in a recent paper, gives the final results of eleven years of research on the chemical elements in a state of purity, and on the possibility of decomposing them by the physical and chemical forces at our disposal. His experiments on calcium, strontium, lithium, magnesium, silver, sodium, and thallium, show that these substances retain their individuality under all conditions, and are unalterable by any forces that we can bring to bear upon them. Prof. Rowland looks to the solar lines which are unaccounted for as a means of enabling him to discover such new terrestrial elements as still lurk in rare minerals and earths, by confronting their spectra directly with that of the sun. He has already resolved yttrium spectroscopically into three components, and actually into two. The comparison of the results of this independent analytical method with the remarkable but different conclusions to which M. Lecoq de Boisbaudran and Mr. Crookes have been led respectively, from spectroscopic observation of these bodies when glowing under molecular bombardment in a vacuum tube, will be awaited with much interest. It is worthy of remark that, as our knowledge of the spectrum of hydrogen in its complete form came to us from the stars, it is now from the sun that chemistry is probably about to be enriched by the discovery of new elements.

Of the physical and the chemical nature of the coronal matter we know very little. Schuster concludes, from an examination of the eclipses of 1882, 1883, and 1886, that the continuous spectrum of the corona has the maximum of actinic intensity displaced considerably towards the red when compared with the spectrum of the sun, which shows that it can only be due in small part to solar light scattered by small particles. The lines of calcium and of hydrogen do not appear to form part of the normal spectrum of the corona. The green coronal line has no known representative in terrestrial substances, nor has Schuster been able to recognise any of our elements in the other lines of the corona. The spectra of the stars are almost infinitely diversified, yet they can be arranged, with some exceptions, in a series in which the adjacent spectra, especially in the photographic region, are scarcely distinguishable, passing from the bluish-white stars, like Sirius, through stars more or less solar in character, to stars with banded spectra, which divide themselves into two apparently independent groups, according as the stronger edge of the bands is towards the red or the blue. In such an arraugement the sun's place is towards the middle of the series. At present a difference of opiniou exists as to the direction in the series in which evolution is proceeding, whether by further condensation white stars pass into the orange and red stages, or whether these more coloured stars are younger, aud will become white by increasing age. The latter view was suggested by Johnstone Stoney in 1867. About ten years ago Ritter, in a series of papers, discussed the behaviour of gaseous masses during condensation, aud the probable resulting constitutiou of the heavenly bodies. According to him, a star passes through the orange and red stages twice, first during a comparatively short period of increasing temperature which culminates in the white stage, and a second time during a more prolonged stage of gradual cooling. He suggested that the two groups of banded stars may correspond to these differeut periods—the young stars beiug those in which the stronger edge of the dark band is towards the blue ; the other banded stars, which are relatively less luminous aud few in number, being those which are approachiug extinction through age. In the spectra of the white stars the dark metallic lines are relatively inconspicuous, and occasionally absent, at the same time that the dark lines of the hydrogen are usually strong and more or less broad upon a continuous spectrum, which is remarkable for its brilliancy at the blue end. In some of these stars the hydrogen and some other lines are bright, and sometimes variable. As the greater or less prominence of the hydrogen lines, dark or bright, is characteristic of the white stars as a class, and diminishes gradually with the incoming and increase in streugth of the other lines, we are probably justified in regarding it as due to some couditions which occur naturally during the progress of stellar life, and not to a peculiarity of original constitution.

To produce a strong absorption-spectrum, a substance must be at the particular temperature at which it is uotably absorptive ; aud further, this temperature must be sufficiently below that of the region behind from which the light comes for the gas to appear, so far as its special rays are coucerned, as darkness upon it. Consideriug the high temperature to which hydrogen must be raised before it can show its characteristic emission and absorption, we shall probably be right in attributing the relative feebleness or absence of the other lines, not to the paucity of the metallic vapours, but rather to their being so hot relatively to the substances behind them as to show feebly, if at all, by reversion. Such a state of things would more probably be fouud, it seems to me, in conditions anterior to the solar stage. A cousiderable cooling of the sun would probably give rise to bauded spectra due to compounds, or to more complex molecules which might form near the condensing points of the vapours. The sun and stars are geuerally regarded as consisting of glowing vapours surrounded by a photosphere where condensation is taking place, the temperature of the photospheric layer, from which the greater part of the radiation comes, being constantly renewed from the hotter matter withiu. At the surface the convection currents would be strong, produciug a considerable commotion, by which the different gases would be mixed and not allowed to retain the iuequality of proportious at different levels due to their vapour densities. Now the conditions of the radiating photosphere and those of the gases above it, on which the character of the spectrum of a star depends, will be determined, not alone by temperature, but also by the force of gravity iu these regions ; this force will be fixed by the star's mass and its stage of condensation, and will become greater as the star continues to condense. In the case of the sun, the force of gravity has already become so great at the surface that the decrease of the density of the gases must be extremely rapid, passing in the space of a few miles from atmospheric pressure to a density infiuitesimally small ; consequently, the temperature-gradient at the surface, if determined solely by expansion, must be expremely rapid. The gases here, however, are exposed to the fierce radiatiou of the sun, and uulcss wholly trausparent would take up heat, especially if auy solid or liquid particles were present from condensation or convection curreuts. From these causes, within a very small extent of space at the surface of the sun, all bodies with which we are acquainted should fall to a condition in which the extremely tenuous gas could no longer give a visible spectrum. The insignificance of the angle subtended by this space, as seen from the earth, should cause the boundary of the solar atmosphere to appear defined. If the boundary which we see be that of the sun proper, the matter above it will have to be regarded as in an essentially dynamical condition—an assemblage, so to speak, of gaseous projectiles for the most part falling back upon the sun, after a greater or less range of flight. But in any case, it is within a space of relatively small extent in the sun, and probably in the other solar stars, that the reversion, which is manifested by dark lines, is to be regarded as taking place.

## THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.*

### Abstract of Report of the Delegates of the Photographic Club.

The sixth Photographic Conventiou of the United Kingdom was opeued by the Mayor of Bath in the Guildhall of that city. After a speech of welcome from him, Mr. Bothamley, the retiring president, retuΓued thanks, and alluded to the fact that that city was iutimately associated with the early history of science and photography by the names of Fox Talbot and Herschel. He then vacated the chair in favour of his successor, Mr. William Bedford. The President, who was received very cordially, delivered his presidential address. He referred to Bath as of special iuterest to photographers, owing to its vicinity to Lacock Abbey, the first spot in the kingdom depicted by means of photography by Fox Talbot. After a remark on the increasing number of societies, the spread of literature aud journalism, and the success of recent exhibitions, he alluded to the scheme for the formation of a Photographic Institute somewhat similar to those already existing at Berliu and Vienna. He also spoke of the new premises of the Camera Club, and in connection therewith of their annual conference and one-man exhibitions, and of the photographic survey now being carried out by the Birmingham societies. He called attention to the investigations by Messrs. Hurter and Driffield on the effect of developmeut on the ratio of densities of negatives ; to the report of M. Lippmann's discovery of a means of reproduciug and fixing the colours of the spectrum ; and to Colonel Waterhouse's process for obtainiug a reversal of the image by the addition of thiocarbamides to the eikonogen developer. In optics the latest novelty was the lenses recently introduced by Zeiss, upon which Dr. Eder had so favourably commented. The primuline process of Messrs. Grecu, Cross, and Bevan, and the diazotype process of Feer were then dwelt upon, as well as Mr. Carey Lea's further experiments with allotropic forms of silver. After treating most exhaustively of the scientific discoveries and processes connected with photography, he dealt with the advance made in the artistic direction, not forgetting to comment on the new school, which, notwithstanding the renunciation of its former master, is still living, and, what is more, reaping due recognition of its merits. Eveu automatic photography was included in the address of our President.

On the following day, Tuesday, the excursion to Tiutern and Chepstow took place. On the Wednesday, after the general meeting and the meeting of the geueral committee, the group of members was takeu by Mr. Ashman, and, notwithstanding the rain, resulted in a most satisfactory picture. The afternoon and the eveniug of that day were devoted to papers, of which we will give but the briefest outline, the full text haviug been published in all the journals.

The subjects which occupied the council and geueral committee meetings were, priucipally, the place of meeting for next year's convention, and the affiliation scheme. Regarding the former, of the various iuvitatious sent for the 1892 gathering, the one for Edinburgh was accepted. As to the affiliation scheme, it having been brought forward ouly then, it was thought that the members were scarcely in a position to

* Read at a meeting of the Photographic Club, August 12th, 1891.

grasp its provisions, and it was therefore resolved that the matter be referred to the coucil for cousideratiou.

The first paper read was one by Mr. William Lang, upon "The Photographic Work of Herschel and Talbot." In it he mentions Fox Talbot's and Herschel's connection with Bath, and a contribution of the latter to the *Edinburgh Philosophical Journal* ou "Hyposulphurous Acid aud its Compounds." These experiments, which were the result of an accident, led Herschel to the production of other hyposulphites thau those of lime. Referring to the soda salt, he there stated that muriate of silver (now known as chloride of silver), newly precipitated, dissolved in this salt when in a somewhat couceutrated solution in large quantity. He further showed that zinc could separate metallic silver on being immersed in the hyposulphite solution. Several other experiments and papers by Herschel and Talbot are here quoted, but it would lengtheu so much this report that we refer you to the paper itself, which was printed *in extenso* in the photographic jouruals. It is worthy of notice that Mr. C. H. Talbot, son of the late Mr. Fox Talbot, was present at the reading of the above paper, and that he made some interesting remarks on his father's work in connection with photography. A selection of lantern slides from calotype negatives, and portraits of Herschel, Fox Talbot, and interesting scenes connected with them, were then shown on the screen.

Mr. Bothamley's paper on "Recent Developments in Printing Processes" then followed. The processes described are the kallitype, which is based upon Hunt's and Herschel's observations, that when a ferric salt is exposed to light, aud thus reduced to a ferrous salt, aud the ferrous salt is treated with a solution of nitrate of silver, metallic silver is precipitated in quantity dependent on the quantity of ferrous salt that has been formed on each part of the surface ; the Feertype or diazotype, and the primuline process, both of which are based on the use of coal-tar colours.

In the absence of Mr. Debenham, Mr. Traill Taylor read this gentleman's paper on "The Cult of Indistinctness," which attacks the tenets of the school which has produced such pictures as "The Poacher," "A Breezy Corner," and "Dedham Bridge." Perhaps, through not having been officially announced in the programme, this paper caused no discussiou between the lovers of softness iu pictures aud the admirers of a superabuudance of microscopical detail in photographic prints.

The eveniug was devoted to a most interesting lecture, given by Mr. Albert Taylor in the abseuce of Mr. A. A. Common, on "Recent Astronomical Photography," illustrated most profusely with a large series of lantern slides of astronomical photographic apparatus and reproductions of stellar photographs. Among the latter were some wouderful slides of the nebulæ in Orion, and of the moou.

Thursday was a busy day. Two excursions duriug the day, and report aud discussions on "Standards" in the evening.

The committe appointed to consider the adoptiou of the staudard lens fitttings recommended by the Photographic Society of Great Britain, or to suggest alterations in that system, preseuted their report.

Mr. Warnerke opened afterwards the discussiou on proposed international standards, and advocated very strongly the adoption of the decimal system, and also of internatioual staudards. He particularly emphasised the fact that any photographic standard suggested would not coufer complete benefit uuless it were universally adopted ; aud he therefore urged that this couutry be strongly represented at the forthcoming Congress iu Brussels.

Friday was a fine photographic day, aud the excursions to Wells, Glastonbury, and Lacock Abbey were, consequently, well patronised.

The annual dinner took place in the eveuing, the chair being occupied by the President, at whose right sat the Mayor of Bath. After the usual toasts followed a most enjoyable smoking concert.

The last day of the Convention, Saturday, nothing outside the council meeting was on the programme, but many of the members were busy during the greater part of the day photographing the many remarkable architectural subjects in the town.

Before we come to the second part of our report, we should like to state our deep gratitude to all those gentlemen who, by their kindness and hospitality, made our sojourn in Bath a most enjoyable one ; to the Mayor, Mr. Murch, for his courteous reception ; to the local committees for their untiring energy, which resulted in every arrangement being found perfect ; and to the deans, bishops, and other gentlemen for the permissions grauted. (Signed) H. M. Hastings.

F. P. Cembrano, jun.

The above report was illustrated by 114 slides made from negatives taken by the delegates during the Convention. The lantern was kindly lent by Mr. C. Lees Curtis. It is the same instrument as was used at the Bath meeting, and looked as perfect as when first made ; yet all it has had done to it since the Convention is the placing of a piece of sheet asbestos packing at the back between the woodwork aud metal lining, to prevent a repetition of the "yaller light" incident. The condenser is quadruple, and was made by Mr. C. Baker from calculations by Mr. E. M. Nelson. F. A. Bridge.

*Hon. Sec. Photographic Club.*

Photographic Club.—Subject for Sept. 2nd, "On Testing Lenses" ; Sept. 9th, "Printing by Development." Outing, Saturday, 29th inst., Hampton Court ; train from Waterloo, 2.10 p.m.

London and Provincial Photographic Association.—September 3rd, "Dark Room Appliances" ; September 5th, outing to Greenwich Hospital, conducted by Mr. A. Haddon ; September 10th, "Keeping Qualities of Dry Plates." Visitors cordially invited.

The Camera must go with the Ticket.—Some years ago the director-general was the great man of a world's fair, but considering au extraordinary liue of special artistic development since that time, the most important functionary now must be acknowledged to be the official photographer. The boss of this department for Chicago will be Mr. Camera Dryplate Arnold. Mr. Arnold's special work will be to take the buildings as they are built. Who shall officially photograph the Fair at its height for the purchases of the general public is for later selection. Another and much more important question relates to the general right of photography wheu Chicago shall open the show gates. The number of cameras of the amateur automatic persuasion is increasing in far greater ratio than the population. The adaptation of larger and more satisfactory sizes to the portable button-pressiug forms has progressed of late so successfully that the next few years may expect an enlargement of camera-carrying class, such as the already marvellous exteusion of the photographic fancy could scarcely suggest. The spirit of enterprise that animates the use of the camera is so vigorous, aud the number of its devotees will be so great by 1893, that not only will thousands of photographers be among the visitors of the Chicago Fair, but thousands will visit the Fair for the simple reason that they are photographers, and know that they will find in such an aggregation of men and things a memorable opportunity for the creation of interesting negatives. We disseut, therefore, from the proposition of our esteemed contemporary, *The Photographic Times*, that in Chicago, as in Paris, the privilege of photography should be sold to applicauts at sums fixed for amateurs and professionals. This branch of the artistic public is so large, and its work so desirable, that subjection to such discrimininátion from the rest of the population becomes an injustice. What more magnificent monument could be erected to the memory of Columbus than the recognition of the right of free photography? It is an indispensable feature of the scientifically progressive society that enjoys the other time-honoured blessiugs of the United States. At the great Columbian event a tax on cameras is not to be thought of. Let us all take views, if we desire, upon no other condition than the legal entrance iuto the grounds by the customary surrender of a ticket.—*New York Sun.*

## DOUBLES.

BY G. R. CROMWELL.

The making of double pictures has been a hobby with me for some time—in fact, several years. But I find I have kept the secret too long to be of any material value to me, or to receive any benefit from my patent application, having paid second money and received nothing; for, as you may know, I have experimented with pictures and the lantern since I was a boy. I remember when I was a child I threw the house into confusion with a tiny lantern. But it was always a passion with me, and what I am about to show you is one of my old tricks. I tried various methods of producing these doubles, with more or less success, as you will see. I finally hit upon a little box, a common cigar box with flaps or doors. With this little box attached to the hood of the lens, the door or flap opened on the side toward the subject, the first exposure is made, viz., with uncapped lens (doors closed); open first half (exposure), close again; and after the subject has changed position the other side, or double exposure, is made. This method is an attachment to the lens, and the doors being opened, first on one side and then the other, the cap cannot be used. But I do this same doubling without the box on any apparatus. This is it: A plain cigar box, blackened on the inside, is placed in front of the lens, covering one-half of the subject. It is as if the lens were an eye; the same as if I placed something in front of my eye. With the box cutting off one side it takes only what it sees; what the eye does not see it cannot take. This is a great aid to carry out Mr. Champney's instructions in reference to composing your foregrounds. When I went view shooting in Europe, and when I went to make a picture, I got down crouching behind the camera, and what I could not see I knew I should not get on the plate; I had no need to use a finder. So you have the same principle in taking double pictures.

I also make curious pictures with the guillotine shutter. Open the slide of plate, pull up the shutter, close, cover plate as if finished, change to opposite shutter, pull open the slide of plate again, pull up the shutter, close over plate, and develop. The result will be one background, but one or more figures repeated as placed on either side at the time of the exposure of the plate.

The best plan to double images on the plate, maintaining an undisturbed background, is as follows: To use a cap for the lens, also a box (cigar box will answer), black on the inside and edges at its opening. Place the box in front of the camera on a small stand, at the distance that the plate is from the lens when the focus is obtained. Make a mark on the table at the end of the box, so as to know, in changing its position, that the precise opposite is secured. Now to operate: Box in place, figure to be seen by open half of lens; expose, replace cap, change box and figure, uncap, close, and develop. Result, two figures—one and the same—one background, and no line of demarcation in its taking. Many lantern slides were exhibited to fully illustrate the successful use of the box with doors, the guillotine shutter, and the plain box. The simplicity of the process is at once evident.—*Phot. Amer. Review.*

---

Regarding the Convention at Buffalo, *Wilson's Magazine* has the following:—"A large number of amateurs availed themselves of the opportunity extended them to visit the Exhibition, and they generally found there were several things about photographing that their elders could teach them."

# Patent Intelligence.

### Applications for Letters Patent.

13,887. Arthur Kempson Penn and William Wallace Beasley, Claremont House, Claremont Road, Handsworth, "An Adjustable Vignetting Frame for Use in Photographic Printing."—*August 18th.*

13,950. Joseph Sedgwick, 37, Chancery Lane, London, "Improvements in Photographic Bags used for Changing Sensitised Plates."—*August 18th.*

13,964. Henry Foster, St. Wilfrid's House, Blake Street, York, "The Opaque-Negative Photo-Printer."—*August 19th.*

14,231. Herbert Weld-Blundell, 53, Chancery Lane, London, "Improvements in and connected with Photographic Apparatus for Surveying and Field-Sketching Purposes."—*August 19th.*

### Specifications Published.

4,704. *March 26th,* 1890.—"Magic Lanterns." F. H. Varley, Newington Green Road, London.

Relates to zoetropic cameras, which may be also used as magic lanterns. A sensitive film is wound on drums, one being the winding-on drum, and pass over guide rollers. The drums are actuated by springs in opposite directions, and are also in gear with one another, so that the tension of the spring of one drum serves to wind the spring in the other drum, thus serving to keep taut the sensitive film. The film is intermittently fed, in lengths equal to the part exposed between the rollers, by an oscillating lever terminating in a roller. The movement of the lever in withdrawing a length of film from the drum winds the spring of that drum, and as this winds the spring of the other, the latter winds on the film. Detents are used to prevent a reverse movement of the film. The shutter, which consists of a perforated disc revolving in front of a fixed perforated piece, is actuated by cams on a shaft. In a modification, the roller slides are differently actuated, and sliding shutters are used. Also the camera is provided at the back with a slide, which permits focussing, and also enables the camera to be fitted to serve for reproducing the zoetropic representations on a screen. [*Patent opposed. Case not yet decided.*]

## PERSPECTIVE DRAWING AND VISION.

Reply to Mr. Wheeler by Dr. P. H. Emerson.

Sir,—I do not know what Mr. Wheeler's theory of the visual perception is, but I feel sure Mr. Wheeler has but sipped at the spring of psychology—that is, to judge by his remarks. Mr. Wheeler ought to know that the "ignoring of well-accepted theory" is nothing against original experiment, whereas, for "the confusion of thought," that may be subjective and not objective.

Mr. Wheeler says, "the accepted mental theory, according to which distance can never be directly seen as such—that is, *it can never be apprehended as simple sensation.*" Now Mr. Wheeler shows by this remark that he knows nothing of the will of the "sensationalist," by whom the third dimension is considered to be a pure sensation. Such is the accepted theory of the sensationalists, and I am altogether with them, our researches being in their favour, and against the Berkleyans *et in genus omne.* Wundt's life has been spent in constructing a space theory, to my mind valueless, and I can say again, with one of the profoundest living psychologists, who emphatically calls "Wundt's 'theory' the flimsiest in the world."

So much for Mr. Wheeler's only accepted theory. I have shown the sensationalists have another theory.

Finally, all I have to say is, that since Mr. Wheeler seems to be innocent of the literature written against Wundt, Helmholtz, and Co., it is useless to open a disoussion. It only remains to state our observations are in no sense "judgments," but *pure sensuous impressions.*

Finally, I would recommend Mr. Wheeler to the works of Stumpf, Schön, Volkmann, Hering, and others.

P. H. Emerson.

## Proceedings of Societies.

Photographic Society of Great Britain.

At the technical meeting of this Society held on the 25th inst. the chair was occupied by Mr. W. E. Debenham.

The subject arranged for the discussion of the evening was "Photographic Printing Processes," and it was opened by Mr. Chapman Jones, who said that he took interest in two printing processes only, the carbon and the platinum processes. Photography was a recording process, and as such permanency was of the first importance. In the matter of colour, we ought to be prepared to give up a little for the sake of permanency. With the carbon process, however, any colour could be obtained, and if in time the colour did change somewhat, the print could not be said to fade. Silver prints did not always fade, but there could be no guarantee that they would not do so. Silver prints that he had made himself he had not found to fade except when he had experimentally prepared them with a view to fading. Bromide prints had been called permanent, but here again they had been found to fade, and, therefore, the title was not justified.

Mr. F. Ince had found carbon tissue to stick to the negative and spoil it.

Mr. Chapman Jones asked whether Mr. Ince's negatives had been varnished.

Mr. Ince said they had not.

Mr. Chapman Jones said that the object of varnishing the negative was not to preserve it when put by, but to enable it to withstand injury whilst printing.

Mr. Holiday wished to know if a silver print fixed without being toned was as permanent as a toned print. He considered the colour of the untoned print was so much more beautiful and artistic than the cold tone of the ordinary photograph.

Mr. W. England said that thorough toning was conducive to permanency, and so was a thorough washing.

Mr. A. Mackie said that a thorough fixing was also necessary to permanence. He advised the use of two fixing baths in succession.

Mr. Chapman Jones said that long washing was not necessary. He believed that, by proper treatment, a print might be thoroughly washed in half-an-hour. He washed for a few minutes, then immersed in a dilute solution of iodine until the print showed blue on the black, and it was then washed again and dried.

The Chairman said that Mr. W. K. Burton had found that such a heavy deposit of gold might be given to a silver print that it would withstand the action of a solution of bichloride of mercury. This solution entirely bleached an untoned silver print. A print containing so much gold would have greater probability of permanency.

Mr. T. Samuel had made prints thirty years since that were still unchanged. He also had some that were made by Mr. Melhuish twenty-five years since. These prints were as fresh as ever. They were toned by a process published at the time by Mr. Melhuish, as one giving black tones.

The Chairman observed that Mr. Chapman Jones had said that we ought to be prepared to give up something in the way of colour for the sake of permanency. No doubt, for purposes of record, that was true, but if it was found that in some particulars we could get a better print by silver than with carbon or platinum, he would say let us have the better print as well as the permanent one. The point in which he considered an albumen print to be better than one in carbon or platinum was in the matter of gradation. A carbon print was generally somewhat deficient in rendering gradation in the lights, and a platinum print similarly deficient in the shadows. As to the matter of colour, he considered that, as well as the condition of surface, whether matt or glossy, to be matters of indifference compared with a truthful rendering of the gradation of the negative. For colour, however, the public had decided in favour of that of a successfully toned print on albumen paper.

Mr. T. Bolas enquired of Mr. Holiday whether he found the colour that pleased him at one time did so at another.

Mr. Holiday replied in the affirmative.

Mr. Bolas thought it would have been the other way, and that the appreciation of colour was a shifting quantity.

Mr. Chapman Jones said that an infinitesimal amount of silver served to give a strong colouration. If this colour changed by fading, there was not enough of the metal to have the image brought out again. He thought that this was a fact which had been overlooked in a recent article on the subject in one of the journals.

Mr. A. Mackie asked whether anything more had been heard of the iron printing process, specimens of which were shown by Professor Meldola at a lecture at the Society of Arts.

It was replied that Professor Meldola's lectures were shortly to be published, and that occasiou might be utilised to obtain further information on the subject.

Mr. A. Glasse said that the character of a print depended much upou that of the negative from which it was made. With the strong negatives of former days it was easier to get a vigorous print such as might be expected to withstand the influence of fading, than with the thinner negatives now prevalent. Then he thought that the large amount of albumen now spread on the paper was conducive to fading. Formerly the coating of albumen was very dilute. A silver print was the richest in colour and most vigorous, and the best that could be given to the public or to the art world.

The Chairman thought that two statements that were frequently made concerning differences between the prints of the present day and those of thirty years or so since were mistaken. It was asserted that negatives were made much more intense then than now, and that the albumen coating was much lighter than at present. With regard to density, although it might be that the tendency of the inexperienced was to get too great density with pyro-developed collodion negatives, and to get too little density with gelatine negatives, he believed that the standard of experienced workers was about the same now as formerly. The time of the exhibition of 1862 was a convenient epoch for reference, and as one set of examples he mentioned the work of Mr. England, taken at the exhibition of that year. He would ask whether the negatives then takeu were not of about the same density as what would now be considered right. As to the albumeu coating, it was considerably earlier than that that the practice was to use albumen with as little water as was just necessary to dissolve the salt used.

Mr. England said that the negatives referred to by the Chairmau were of about the density of those of the present day, and that as strong an albumen coating as could be given was applied to the paper.

It was asked whether sulphur was not a constituent of albumen, and Mr. Bolas replied that that was a moot point. Sulphuretted hydrogen was formed wheu sulphates were present in company with organic matter. Wheu casks of spring water were sent to sea, it was found that the sulphate when present became decomposed, and so much sulphuretted hydrogen set free as to cause the water to smell and give the idea of some dangerous putrefaction having set in. The water was, therefore, left open for a time to allow of escape by evaporation and re-oxidatiou into sulphate.

Northern Tasmanian Camera Club.

The second annual meeting of the above Club was held at Mr. R. L. Parker's rooms, St. John's Street, Launceston. Mr. R. L. Parker occupied the chair. After the minutes of the previous meeting had been confirmed, and some correspondence read—

The Secretary read his report, in which he stated that during the year the number of members had increased from twenty-eight to thirty-six. The meetings had been fairly attended, considering so many members reside in the country, those meetings especially being in favour at which lantern work or practical developing formed the principal feature. A field-day was held at Westbury in January, when a goodly number of members attended; and a second excursion, covering two days, took place in March; the scene of operations on the first day being Latrobe, the second day Devonport. Through the kindness of the president (Dr. H. A. Roome), Messrs. William Aikenhead, P. C. Maxwell, John Sykes, and others, these excursions were most enjoyable, and the hearty thanks of the Club are due to these gentlemen, whose kindness and thoughtfulness made the excursion so successful. As a means of improvement in practical work these field-days are most useful. Two prize competitions have been held during the year, the first in "Indoor Portraiture," in which Mr. William Aikenhead took first certificate, Mr. F. Styant Browne second, and Mr. R. L. Parker third. The second competition was in "Objects in Motion," in which Mr. William Gibson, jun., secured first certificate, and Mr. F. Styant Browne second. Mr. S. Spurling acted as judge in both these competitions. The circulating albums have been most successful, members contributing freely and regularly, and the change in the rules permitting the member obtaining the most votes to retain the album has met with universal approval. During the year, albums have been awarded to Messrs. William Aikenhead, P. C. Maxwell, and F. Styant Browne. The exhibitions of lantern slides, made by members from their own negatives, have been most interesting, and were much appreciated. Recently His Excellency the Governor has kindly consented to accept the position of patron to the Club. The returns of income and expenditure were submitted in the treasurer's statement, and, although the expenses had been heavy, the report was very satisfactory, as when some outstanding subscriptions have been collected, a credit balance will remain. The journals subscribed to by the Club had been in good demand, and books, &c., were kindly donated from time to time by the president and other members.

At the conclusion of the reading of the secretary's and treasurer's report, office-bearers were elected for the ensuing year, with the following result:—*President*—Mr. R. L. Parker; *Vice-Presidents*—Mr. P. C. Maxwell, Mr. A. C. Bonner; *Committee*—Rev. A. H. Champion, Mr. R. Kermode, Mr. F. W. Stewart; *Secretary, Treasurer, and Librarian*—Mr. F. Styant Browne. Hearty votes of thanks were accorded to the retiring president (Dr. Roome) and to the secretary (Mr. F. Styant Browne) for their services during the past year.

It was decided that a club exhibit should be prepared for the forthcoming Tasmanian Exhibition; that the date of meeting in future should be the third Wednesday in the month, instead of the second, as heretofore; and that each member should be entitled to bring two ladies to the lantern evenings. An exhibition of members' slides closed the evening.

The Camera Club have reason to be pleased with their continued prosperity, and, taking into consideration the growing taste for the artistic and fascinating pursuit of amateur photography, there is every prospect of the Club growing much larger before the next annual meeting.

---

Messrs. York and Son, of Notting Hill, have just issued their twenty-second annual supplemental catalogue, which contains many novelties in the way of the ever-popular lantern slide. The new subjects include: "One Thousand Miles up the River Congo," with a series of fifty slides from direct negatives of the scenes portrayed; a new temperance story, "Ten Nights in a Bar Room," from life models; scenes from the life of John Wesley; "An Hour with the Church of England"; "The Riviera"; "A Visit to Madeira"; and many other items of a very interesting character. The excellent quality of Messrs. York's lantern slides is well-known, for they are to be found in all the civilised, and in a large proportion of the uncivilised countries throughout the globe.

# Answers to Correspondents.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.

Colourist.—*The Blind Spot in the Eye.* Professor Huxley devotes twenty-four pages (Lesson IX.) in his "Elementary Physiology" to the organ of sight, and at page 244 gives a diagram by which it may be proved that you have a "blind spot," which coincides with the position where the bundle of fibres constituting the optic nerve enters the eye. It is a simple experiment that anyone can try for himself: On a white card draw a cross on the left, and a round black spot to the right of it, about two inches apart; now, closing the left eyelid, look intently at the cross with the right eye about a foot off; on bringing the card nearer to the face, the black spot will then alternately disappear and reappear; blindness, or total loss of image, will occur at about six inches distance.

A. P. S.—*Automatic Photography.* We have no information beyond that already published in the daily papers. The general working and construction of the machines were described in the News of May 22nd and 29th last.

Edgbaston.—*Retoucher.* Advertise or consult the advertisement columns; for a short time ago there was something like a strong demand for services such as you could render. Watering places, rather than metropolitan establishments, want help just at this time of year.

Executor.—*Scientific Books and Periodicals.* If you let us see a list, we might be able to advise you; so much depends upon the class of literature which you have to offer. Each department of science seems to have its special mart or channel, and very often secretaries of societies will make a bid for their own official publications in order to complete their sets.

M. A. B.—*Hand Camera.* We should like to have a brief report when you can find time to favour us with a few lines. The inventor gave us a practical hint last week that may be of service to you. It is that at the time of changing each plate the front of the camera should be tilted up, just as in charging the magazine.

J. S. B. (Norwich).—*Celluloid.* A compound of a low-nitrated cellulose (pyroxylin) with camphor, obtained by thorough incorporation of the two ingredients at a temperature barely sufficient to melt the camphor, the material being afterwards flattened out between hot plates or rollers. Some of the camphor evaporates off on exposure to air, but the films always retain the aromatic odour of that substance. It is soluble in alcohol, glacial acetic acid, and other solvents, forming with the first-named a very good varnish. There are two large producers in America, whose rival claims formed the subject of a law-suit (see report in the News of March 21st, 1890). Mr. H. Walker, of the Eastman Company, gave an early account of it and demonstrated its use at the Camera Club, and Col. Waterhouse mentions its adaptability to drawing and printing purposes. See the News of February 7th and May 6th, 1890, respectively. *Second Letter.*—You might be able to get them from the Xylonite Company, Homerton, London, N.E.

Quadragesimus.—*Aluminium Castings.* Flat plates, bindings, and racks may be stamped out and shaped with dies from the aluminium sheet, but the metal does not work well under the file. With the bronze alloy there is no difficulty. Apply to the Aluminium Company, Birmingham, for the castings.

T. H.—*British Association.* Except in regard to the weather, which seemed to affect the attendance, the Cardiff meeting was a decided success. Photography came well to the front, both by mention and specimens, and the exhibition of the local society (550 frames) was very well worth seeing, especially the Welsh antiquities shown by the Glamorganshire Survey.

**THE PHOTOGRAPHIC NEWS.**

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV. No. 1722.—*September* 4, 1891.

CONTENTS.

## WILL PHOTOGRAPHY KILL WOOD-ENGRAVING?

This question must have often occurred to thoughtful persons as they turn over the pages of our numerous—perhaps too numerous—illustrated publications; for the trail of the serpent, in the shape of impressions from "process" blocks, is over them all. A large proportion of these publications, indeed, would never have come into existence at all had not photography pointed the way to produce cuts without the necessity of cutting, and imitated the wood-engravers' work so well that none but the initiated were able to detect the innovation.

So far as convenience of production and economy are concerned, there is no question that a process block has many advantages over a wood-cut. In the old days, the artist drew direct upon the wood-block, and in the process of engraving the original was of necessity destroyed. In this way thousands upon thousands of drawings of the highest class, which have illustrated books without number, have perished in the process which made them available for public use. It is not so now. An artist of to-day is commissioned (say) by a firm of publishers to illustrate a book, and the pictures are duly sent in to them drawn with pencil or brush upon Bristol board—pictures in black-and-white. Many of our readers must be familiar with the appearance of these beautiful drawings, for they have often had an exhibition all to themselves. Some are most elaborately finished in pencil, others are roughly painted-in with india-ink and Chinese white, the wood-engraver being depended upon to translate these shades into proper "tints" with his graver. The drawing, having been approved, is photographed on to the wood-block—being generally reduced to the size required by the camera—and the drawing, having now served its purpose, is put away. But is it done with? By no means; for if the artist have a name, it is a thing of value which can be sold, very often for a larger price than that paid originally to the artist for its production. In a recent exhibition of such works we noticed that the price asked for them varied from half a sovereign to twenty pounds or more, and some of them were remarkably cheap at the price. This exhibition is an annual affair, and is promoted by one of our largest publishing houses to get rid of their constantly-accumulating collection of works in black-and-white.

It will thus be seen that one of the first advantages in making use of photography is in saving the valuable original drawing from destruction. But in this case we are considering the use of photography only so far as it is required in transferring the reversed image of that drawing to the wood-block. The engraver has still his work to do in translating the photograph into a combination of lines and dots, which will afford a resting place to the printing ink so soon as the engraving has in its turn been translated into an electrotype.

But the real economy comes in when the drawing is translated direct into a metal printing block by what is known as "process work." In this work the wood-engraver is left entirely out in the cold; his skilled hand and unerring eye are not required, both being replaced by the work of the camera. In simple line work, there is no question that the simple zinco process gives results equal to the best wood-engraving; every line is most faithfully reproduced in the finished block, so that the artist is able to rely upon an absolute *fac simile* of his design. But when we come to consider the process which reproduces drawings in half-tone, the case is somewhat different. We do not mean that the copy is not as faithful a one as in the other case, but there are certain difficulties in the after-process of printing which must often make both printers and readers wish that the wood-engraver had had the work to do instead of his optical rival.

To the American publications we must look for the most perfect development of this art of printing from process blocks. Their paper, with its finished glaze, is well adapted for the work, and there is no doubt that they excel in their methods of printing. In such careful hands, and provided that the printing operation is not hurried, process blocks give very wonderful results. But when such blocks have to be used for illustrated papers of which tens of thousands of copies have to be issued weekly, the time and care which it is necessary to give to these fine-grained, shallow blocks becomes an impossibility, and a blurred and generally faulty reproduction is too often the result. Of course there are exceptions, and we can point to many admirably printed pictures from such process blocks in our own leading illustrated journals; but, as a whole, they are not so satisfactory as the wood-cuts they have so much superseded.

To answer the question which forms the title of this article. We do not think that photography will kill wood-engraving, and much as we have the interests of the former at heart, we most sincerely hope that wood-engraving will always keep a forward position. It is certain that it will continue to hold its own with regard to sketches "from our special correspondent at the seat of war"; for such sketches are necessarily rough in their character, and invariably pass through the hands of a capable artist at home, who, from their somewhat vague outlines, draws a finished picture on the wood, which is afterwards engraved. In certain cases where the original drawing is of a more finished character, and is in line, the original is reproduced by process. Such a picture has always an additional interest attached to it, from being a *fac simile* of what the artist drew on the spot.

## PRICES OF RARE METALS.

As some of the rare metals of the platinum group are attracting more or less attention for photographic purposes, the following list, with prices attached, will prove of interest.

The rarest metal—and it is so rare that recent discoveries have thrown doubt on its elemental character—is didymium, and its present market price, if anyone may thus term the quotation of an article that never appears on the market, is 4,500 dollars per pound. The next costliest metal is barium, an element belonging to the alkaline earth group; its value is 3,750 dollars. Beryllium, or glucinum, a metallic substance found in the beautiful beryl, is quoted at 3,275 dollars. Yttrium, a rare metal of the boron-aluminium group, so called because first noticed at Ytterby, in Sweden, is stated to be worth at present 2,250 dollars per pound. Niobium, or columbium, a name suggestive of the American origin of the metal, it having been first discovered in Connecticut, is valued to-day at 2,000 dollars per pound. The price of rhodium, an extremely hard and brittle substance, which owes its name to the rose-red colour of certain of its solutions, is also 2,000 dollars. Vanadium, deriving its title from one of the appellations of the Scandinavian goddess, Freya, and at one time considered the rarest of metallic elements, has been reduced in price to 1,775 dollars, at which value there will, no doubt, be many eager buyers. Iridium, a very heavy metal of the platinum group, so named from the iridescence of some of its solutions, and well known in connection with its use for the points of gold pens, may be bought to-day at approximately 700 dollars per pound. Osmium, another metallic element of the platinum group, is hard, infusible, and the heaviest substance known; its present value is 625 dollars per pound. Palladium, a silver-white, fusible metal used in the manufacture of certain parts of time-pieces, and occasionally applied in dentistry, is worth 500 dollars per pound. The present price of platinum, the better-known tin-white, ductile, but very infusible metal, is on a par with that of gold—viz., about 350 dollars per pound.—*American Journal of Photography.*

## PERSPECTIVE IN VISION, AND IN PHOTOGRAPHY.

BY W. H. WHEELER.

### Some Effects of Plane Projection—Resources of Photography Greater than Artists suppose.

In endeavouring to compare the perspective of natural vision with that of photography, we are met at the outset by the difference between the necessary conditions of a view depicted on a plane surface, such as a sensitive plate, from: First, the depth and solidity of nature; and secondly, the conditions of our visual sense and perception of it. We ought to know each of these sets of conditions before attempting really to compare them, and yet it is by comparison that their distinctive features become most striking. We will endeavour to point out those most important as we go on. Perhaps the process of copying from a rectangular original, which needs to be reproduced without distortion, to another true rectangle, is the one with whose conditions photographers are most generally familiar in this connection, and with which we propose to begin.

We all know that for a straight and true reproduction of this kind, it is necessary—and, with a rectilinear lens, nothing else is absolutely necessary—that the *planes* of both the original and the copy be truly parallel to one another. For good optical definition it is well, too, if the line of sight, which should then also be the axis of the lens, is placed in a position perpendicular to both these planes, and also so as to join their centres; though small differences are unimportant even for definition, and, as regards distortion, neither of these conditions are essential at all, whether with a lens or with a pinhole. But that the planes of original and copy be truly parallel to one another is *absolutely* essential; for then, and only then, all the lines from points in the original, passing through stop or pinhole to their corresponding points in the copy, bear strictly the same proportion to one another. The scale of reproduction is then the same all over, and the copy (provided the stop or pinhole be sufficiently small for good optical definition) will accurately reproduce the original in shape as well as in detail.

Just so it is if we set up our camera exactly in front of a building. Provided our lens is rectilinear, and the plane of our picture parallel to the face of the building, both vertically and horizontally, we may tilt our camera until it points obliquely towards both the building and the sensitive plate; yet, provided the back is kept vertically and horizontally to this true parallelism, both vertical and horizontal lines will be parallel on the plate, just as they actually are on the building itself. Such a picture, it is true, will probably be too stiff and symmetrical to be either artistic or pleasing—that is another matter altogether—but it will be an accurate reproduction in form of the original, and the face of it will be *true to scale*. In such a case, photographic methods of measurement will certainly not be fallacious, nor will they mislead if, instead of tilting our camera and adjusting by the swing-back, we move a sliding front vertically or horizontally so as to bring our lens opposite a margin of the plate instead of its centre. Neither a central position for our lens, nor perpendicularity of the line of sight to the plane of the plate or of the building, are conditions that affect anything beyond accuracy of optical definition. The lines of any surface in the object which is parallel to the plane of the sensitive plate will always be reproduced in their true proportions.

We may thus see that Anton M. Haschek, in the generally excellent article printed in the Photographic News of August 14th, has failed to do full justice to the means actually at the command of a skilful photographer. For, in fact, both figs. 2 and 3 of that article might have been photographed direct from buildings such as they represent by appliances readily attainable, although they are introduced as examples of a free-hand in perspective, impossible to photography. It is really an error to suppose that, to photograph an archway so as to be symmetrical with other arches seen through it, it is absolutely necessary "to place ourselves exactly before the middle line of the opening," always provided we have the needful appliances to attain our end otherwise.

It is sufficient that the *plane* of the sensitive plate be perpendicular to such an imaginary line of sight, and so made parallel to the face of the building. The *actual* line of sight may be different, and if the camera were placed opposite the point of sight indicated in the figure as on one side, and the front carrying the lens then moved horizontally, so as to be away from the centre, and also on one side (but the opposite side to the indicated point of sight), the perspective effect obtained might be precisely that of fig. 2. The desired symmetry in the drawing of the arches will follow from the plane of the sensitive plate being made parallel to the plane of the building. The desired want of symmetry in the different foreshortening of the two side walls will also follow at the same time from the actual position of the lens, opposite to the indicated point of sight on one side of the archway. It must be noted that this necessary position of the lens is its place relative to the *object*—not as relative to the sensitive plate. The effect is as though the lens were fixed, and the plate moved to one side sufficiently to take in the required extent of subject, obtained as though on part of a larger plate. Of course the covering power of the lens must be sufficient for that larger plate—larger than the one actually used—and the result might have been more simply, but less conveniently, obtained by taking a larger wide-angle photograph on the same scale, and cutting away part of it. Fig. 3, indeed, is so obviously like part of a larger wide-angle view that we can plainly see it would be quite simple in execution. When so many professional photographers, accustomed, perhaps, to a rising-front, but not to one laterally adjustable, are unaware of the full resources of their art, no wonder if artists fail to do justice to those resources. Let us hope that, when recognised, photographers will more often avail themselves of means they had overlooked, and secure the advantages described by M. Haschek, though he thought them denied to us. An artistic use may thus be found for the wide-angle lenses and small stops so much decried by artists who do not understand the means and resources of photography so well as they know their own art.

The special present purpose, however, of our example of straight and symmetrical reproduction is not so much this latent artistic value, as the nature and reason of its harmony with our ordinary visual perception, though there it results from different causes, and is arrived at through entirely different means.

We trust to explain these means as the result of mental action combining and interpreting our crude visual sensations, and transforming them into such intelligent visual perception as can not only satisfy our curiosity in the recognition of objects, inform and guide us by a quick and general perception of the world around (which we could otherwise only know through the slow, tentative processes of touch or smell), but also kindle our emotions with a sense of beauty. Now it is axiomatic that the very idea of beauty implies a perceiving mind; it is not even conceivable apart from such a mind, and though, doubtless, we may say that a mind implies a brain, because always united with it in our experience, yet we know that the brain cannot be *thought*, any more than the eye is *sight*. They are the organs by which we think and see; they do not think or see for us. As Addison said long ago, and the most modern science can go no further, it is the *whole soul* (not the separate faculties into which we divide it for convenience sake) that remembers, understands, wills, or imagines. And "what we call the faculties of the soul are only the different ways or modes in which the soul can exert herself."* This soul, he also remarks, "can understand, will, imagine, *see*, and hear."†

To demonstrate the necessity of this mental action, and to show its nature through the visual processes involved, we will return to our camera, set up exactly in front of a building, and suppose an observer to place himself where the camera stands, opposite its base, looking upwards to see its summit line, and on each side to observe its horizontal prolongations. Now, it is easy to perceive that the image on the concave surface of the observer's retina cannot correspond with the true proportions of the building as the photograph does, because that concave surface cannot possibly be parallel to the *plane* of the building, and no image on a concave surface can ever truly represent that plane as one on a plane surface may, and, if also parallel with it, actually does.

We may put the case also from another point of view, that of persons who imagine our visual perception to correspond precisely with apparent form and dimensions, such as result from the angles subtended by the different parts of an object, according to their differing distances from the eye. We shall see, however, that neither will the varying scales of such apparent results accord with the ordinary visual perception, for, as the summit line of the building between any two perpendiculars is more distant from an observer standing at its base than the base line would be, it *must* subtend a smaller angle at the eye than the base line does. Consequently, these two perpendiculars could not appear parallel‡; and if our visual perception really corresponded with the apparent angles subtended, the necessary result would be just such a distortion as when we tilt our camera upwards, neglecting to use the swing-back, by which these longer lines of sight from the summit of the building to the lens are balanced in their effect on the scale of the picture, its use lengthening the same lines between the stop and the bottom of the plate in exactly the same proportion. Of course, nothing even resembling this balance can take place when the image is received on a concave surface, such as the retina. The result of a direct consciousness of the retinal image would necessarily be that lines which should be straight would be seen as curved, both vertically and horizontally, thus

* *Spectator*, No. 600.

† Of course we understand by the "whole soul" the whole living being. I have elsewhere contrasted the mental with the physical *side of our nature*.

‡ I am aware that this discrepancy was pointed out many years ago, though, perhaps, generally lost sight of. It was then contended that, for this reason, painters ought commonly to represent such vertical lines, not as strictly parallel, but as converging upwards. Sound common-sense and sound artistic feeling prevented the general acceptation of this idea—except, perhaps, to a small extent, in extreme cases; but I am not aware that any serious attempt was then made to show how and why, in our ordinary visual perceptions, we do actually see vertical lines as parallel.

producing a distortion similar in kind, but far greater in degree, than the barrel-shaped distortion of the image made by an ordinary single lens when used with the stop in front. Whichever way we regard the case, it is simply impossible that a plane surface, whether of a picture to be copied, or of a building to be photographed, can be truly reproduced by an image received on a surface which is not also plane* and parallel.

As nothing, perhaps, in the whole theory of vision is more certain than the fact that we are not conscious of the whole image on the retina *as such*, seeing, as we always do, the upright object—not the inverted image—the lines of a building as rectilineal, and not as curved, like the image formed on the retina: that fact scarcely needs the proof afforded, really, though not formally, a mathematical demonstration; that our visual perception, though necessarily based on sensation, *does not necessarily coincide with it.* As we shall endeavour to show, the visual image owes its form—perhaps even more than its structure—rather to the mental processes of a combining memory, and an intellectual interpretation of the signs presented to us through sensation, than immediately to the sensation itself.

We have seen that the image of a plane surface will always be correctly represented as to form when depicted on another plane surface parallel to it; and that vertical lines are then parallel in the photograph as in the building itself. Painters also represent them as parallel in their pictures, and architects draw them so in their plans. I may too, I think, safely appeal to our common experience, that we always see them so in natural vision, and expect so to see them in any pictorial representation. But how does it come about that we *do* so see them, such vision not agreeing with the apparent angles subtended, nor with the image on the retina? The answer may properly be, because it *does* correspond very precisely with the *true form* of the object, and is a striking example of the fact that *it is true form*, rather than apparent form, which habitually dominates our visual perceptions. Though, however, we thus speak of the form that actually exists—the tangible form—as true form, it is right we should bear in mind that neither visual nor photographic perspective are properly matters of truth or of falsehood. The actual (or tangible) form of an object is one true fact; the (so-called) apparent form, corresponding to the angles subtended, and necessarily varying with varying distance and position, is another true fact. The two are quite incompatible in any single physical representation; but in the mental image which is the true visual perception, their differences tend to melt into one another, according to the varying strength of dominant preconceptions; and as the eye "wanders" over the whole, running along vertical lines, and recognising their true verticality; along horizontal lines, and recognising them as actually horizontal; and recognising also the actual parallelism of successive pairs of lines, our mental image of the whole scene is gradually built up. It is thus that a compromise is arrived at between our judgments of apparent magnitude and our estimates of real magnitude, as well as of our perceptions of apparent form, and our knowledge of true form. It is thus also that we apprehend *distance*, inferring it from the various signs presented to us in sensation, and uniting with it such conception of magnitude in distant objects as invests our perception of them with a dignity which would not otherwise be associated with the small angle under which they are seen. And it is thus—our gaze dwelling and lingering on the most interesting objects, while passing more rapidly over others—that the whole scene gathers order and purpose. Selection and emphasis arise in the mind, and we gradually learn to make pictures for ourselves. Finally, it is thus that a just sense of perspective is, to a perceiving mind, the latest resultant of its intellectual and emotional forces, modifying, as they interpret, the visual sensations.

The mental process above-described may seem long and complex, quite absurdly long for an "impression"; but "thought is quick." This is not all, however. Our practical results are probably, in general, far less those of direct present inferences than of an association of ideas resulting from previous inferences, and thus the general result may be hastened and simplified. These mental processes, too, being rarely accompanied by any consciousness, we—thinking of the objects we are looking at, and not at all of the process by which we recognise them—are not apt to realise that process. Still, the common forms of speech, "Cast your eye over it," "Run your eye along it," do seem an evidence of some general practical recognition of the means by which we habitually judge of form and magnitude.

Perhaps I ought here to remark that it is necessary, in dealing with this subject, to distinguish more carefully between the strict meanings of the words "sensation" and "perception" than is at all necessary in their common use. "Sense-perception" is a not-unfrequent phrase, and the similar one "sensuous impression," may serve very well to express the effect of a hasty glance, in which feeling is supposed to predominate over the results of an intellectual process, though whether feeling or emotion be not itself a product rather of the mind than of the body—rather of perception than of mere sensation—may well be doubted.* Perhaps, like a chemical combination, it should rather be looked on as a new product. I am not clear, however, as to what is the idea generally associated with the word "impression." Of course an impression on the eye really means an impression on the brain, which is to us a mental impression.

Professor Max Muller remarks that M. Flourens proved by experiments that "if the roots of the optic nerve are removed, the retina in the eye of a bird ceases to be excitable, the iris is no longer movable; the animal is blind, because it has lost the organ of *sensation*. If, on the contrary, the cerebral lobes are removed, the eye remains pure and sound, the retina excitable, the iris movable. The eye is preserved, yet the animal cannot see, because it has lost the organs of *perception*.†

I see that I have left myself no space for the wide difference between the relations of visual and photographic perspective when taking a straight and symmetrical view of a building, from those which exist when, on the other hand, we direct our gaze and our camera *obliquely*—especially if from so near a point of view as to necessitate the use of a wide-angle lens—and must postpone that to another opportunity, if space can be found for me. I may say, however, that the same sense of real form which corrects the distortion shown necessarily to characterise crude sensation in the straight and symmetrical view—could

* We of course leave out of consideration the unpractical case of a distorted image received on a distorting surface so contrived, as by opposing action, to correct one another. That would be only a toy.

* Hartmann explains feeling as resulting from affections of the will in combination with conscious and unconscious ideas.—Ueberweg. Hist. Phil., vol. ii., p. 336.

† *Science of Language*, vol. i., page 389.

such crude sensation be apprehended by the mind—will now act somewhat similarly in reducing the violent photographic perspective which, save for the effect of plane projection, would resemble such crude perception very closely.

But this will not help us much when, instead of looking at the object, we look at its photograph; for such a sense of reality as we justly have when observing nature itself, is greatly wanting when viewing only its pictorial image. The larger the photograph, however, and the more accurate its details, the better is our sense of reality, for then we find more material for our inferences. But binocular vision, which aids this sense of reality in nature by continually suggesting a stereoscopic solidity, not only fails us with the photograph, but acts most energetically by forcing on us the fact that it is *merely* a plane surface we are looking at, not the depth and solidity of nature. Therefore we are now really helped by shutting one eye that we may fall under the illusion of perspective; and if, at the same time, we can adjust our monocular point of view to the true point of sight—the place of the lens which formed the image—a more pleasing perspective will commonly result, despite the forced and artificial mode of observation.

Since the above was written, I have seen Dr. Emerson's reply to my "Remarks." I will now only say that Dr. Emerson evidently did not notice that the completion of the sentence which he partially quotes—"that (distance) can never be apprehended as simple sensation *in the way that differences of colour, brightness, &c., are apprehended*"—shows that on the question of physiological or psychological theories of our sense or perception of *contrast*, I have followed Hering rather than Helmholtz. I understand him to admit the ignoring of what is—in England, certainly—a well-accepted theory, on the ground that he prefers the accepted theory of the sensationalists, though, at the same time, he attributes my apparent ignoring of their theory to innocence of their literature. I dare say Dr. Emerson has drunk deeper of their waters than I—individual preferences will influence our choice of reading. I wish also to seize this opportunity of saying at once, concerning the sentence which I said seemed "very like confusion of thought," that it has since occurred to me that it meant simply that photographic or camera-obscura measurements may prove fallacious to an artist, because not necessarily according with his visual perception. In that case I entirely agree. It is several years since I ever thought their identity could be relied on, and for that reason probably such a meaning did not at once occur to me.

---

The only difference between the professional and amateur, according to the *Fliegende Blätter*, is that "an amateur photographs people as they *are*, a professional as they would like to be."

Guard Against Light.—It can never be too urgently insisted that the greatest care should be taken in the dark room as to the light and the exposure of plates thereto. It is not, however, so much the quality of the light, but as to quantity, and its proximity or otherwise to the plate. It is infinitely easier to work with a fairly light yellow or ruby screen, and keep your plate and developing dish at a distance from it, than to have a very dark screen, and have to hold your dish close to and strain your eyes to gauge progress. In every instance where the negative is to be held to the light, it should first be well rinsed so that none of the developer remains on the plate during examination.—*Photographic Scraps.*

## ILLUSTRATION OF POEMS BY PHOTOGRAPHY.*

BY MISS CATHARINE WEED BARNES.

Delegates to political conventions are often said to be "instructed," and so I conceive myself to have been in receiving a notification that my paper for this Convention need not be long, and should be instructive. I shall endeavour to carry out these instructions.

Let me put myself on record, to begin with, as decidedly and understandingly taking ground that the words "art" and "artistic" are no longer the private property of painters and sculptors. After several years' training in painters studios I have largely laid aside the brush for the lens, and in so doing it appeared to me as if I was only stepping from one room into another, working with different tools and under different conditions, but imbued with the same reverence for art, and feeling the same inspiration. It is an undeniable fact that painters and photographers are apt to put on very defective glasses in judging each others' work, and a course of mental optics would benefit both in correcting far more serious aberrations than any to be met with in a photographic lens. Where one's attention is almost entirely given to portraiture, pure and simple, much of what might be called art in photography is not required, and would not be appreciated; but photographers justify the reproach that theirs is machine work when they allow themselves to sink into such a deep groove as only to see along the narrow path before them, while experience in painters' studios ought to liberalise one's judgment of a picture, whether made by brush or lens. There is often, however, great bigotry in much so-called liberality, and it needs a steady hand to hold an even balance in judging camera work now that it is worthily claiming a higher place in the judgment of the world than any heretofore given it. Neither the scientific nor artistic qualities should be exalted beyond their proper places. The lens has limits, and it is not a brush; yet, when those limits are fully understood, it will be seen that they embrace wonderful possibilities of their own. But as always, when one departs from the beaten track, this means hard work, a great deal of trouble, endless patience, severe art training, and a thorough understanding of what is meant by illustrating. I conceive this last to be a pictorial translation of an author's meaning, and that anything and everything which will tend to elucidate that meaning is justifiable. This remark is intended, as will be seen, to cover a wide field. The faintest conception of the true art spirit ought to keep one from making his pictures the stilted, ordinary, not-to-be-mistaken photographs. Push photographic limits as far as possible, refusing to be bound by the traditions of the portrait studio, and cutting loose from whatever can suggest it. Start with the intention to have all your accessories what they claim to be and where it is obligatory to use imitations, have them as perfect as can be made. Do not adopt the penny wise and pound foolish policy, or think it always needful to go to great expense in the studio, for a little ingenuity often goes a long way in devising useful contrivances. In many cases where I have been credited with expensive appliances the same have been made with my own hands, and, where unable to actually make the desired articles, I have designed them after long and careful thought. It is well to settle in one's mind, before taking up illustrative work, whether the object or the manner of realising it is the main point to be considered. If the latter, then, like the Irishman, stop before you

* Read at the Buffalo Convention.

begin, for you will not have enough enthusiasm to carry you over the inevitable discouragements ahead of you. Believe in and respect the dignity and beauty of the work; count no detail of the work as beneath your notice; use all the resources your taste and experience can suggest, and make everything give way to the definite purpose of obtaining a picture which will tell a story. Do not try to show the extreme limit of what can be done by a lens, but study simplicity, and avoid using more figures than are absolutely necessary. An artist with whom I once studied cautioned me against introducing figures into my paintings of interiors. "No matter how good everything else may be," he said, "people will pass it by and criticise the figure." Photography and portraiture have for so long been understood as synonymous terms that it seems difficult to believe the figure is not the first thing to consider, even in illustration. But such is not always the case, for, however effective the figure may be, the picture as a whole may often be ruined by some petty detail or incongruity. This is one reason why illustrations by photography are expensive to make when they call for correct rendering of historical costumes and surroundings. It is generally wiser to select subjects which allow simple and easily procured scenery, and which, in many cases, allow the work to be done out of doors even better than in the studio. Illustrations of out-door scenes ought to be made out of doors, and the light be subdued, if needful, by thin screens. As plenty of distance can be gained by this method, beautiful effects are often secured.

It is a great help to make a sketch of the intended picture, and decide where the figures will be placed, as well as all the accessories, before making an exposure, and study the effect of different colours and materials. Another good plan is to arrange everything except the figures, and make a preparatory exposure on the size and kind of plate, and with the same lighting you expect to use. I have known otherwise fine negatives lost by neglecting this precaution, finding after development that the plate was an old one, or was slower than ordinarily used in the studio. In this connection I should mention that professionals have told me they were often tempted to return to wet plates, as the dry plates, however good when fresh, could not always be relied upon, and were apt to fail when it was impossible to duplicate a negative. Looking at the picture from a painter's standpoint, it must be remembered whether you are supposed to take it indoors or out, by full daylight, or in the evening. Do not, if the scene to be represented would naturally appear dark in certain parts, seek to light it evenly, but think how a painter would treat it. This may lay you open to criticism from a merely photographic point of view, but you are not making a portrait. In the great paintings of such men as Rembrandt, parts of a picture are often in dense shadow, and in a painting that would not be criticised, but the same thing in a photographic picture would, nine times out of ten, be sharply condemned. This is unjust, for lens or brush would be useless if not inspired by a skilful brain, and it does not follow that a man can arrogate to himself the name of artist simply becauses he uses a brush, or deny it to one who recognises the future possible for camera work. It is always hard to live down a prejudice or a preconceived opinion, but there is a great deal of that to be done before art in photography is fairly recognised. As in a battle, the flag must be raised high over men's heads to enable it to be always in their sight, so the ideal in any line of human endeavour ought to be kept plainly before men, so that they shall continually grow and improve, and never feel that there are no more worlds to conquer; and the best thing about illustrative work is that one can never learn it all, for every victory makes a further one possible. Perhaps, and rightly enough, there is no quality more demanded in artistic photography than originality, though it is often supposed not to co-exist with technical excellence. Photographic training by itself is apt to form a stiff and artificial style, but it is not necessary, therefore, to assume that originality consists mainly of a violation of the rules of technique. The height of art is to conceal art, and to do this requires a thorough knowledge of technique. Photography has only begun to show what it can do in illustrative work, and its progress should not be made any more difficult than is inevitable from the unavoidable obstacles in its path. Demand always creates supply, and these obstacles will be gradually removed; but the attempts already made in this line of work should be judged by what has been done heretofore, and not by what we hope to eventually accomplish. Wiseacres the world over may shake their heads and declare that art is being lowered by the camera seeking to displace the brush, but the inexorable logic of events is an overwhelming force, and there is no use in fighting the inevitable.

It is not the part of wisdom to ignore difficulties, but to meet and overcome them, and the greatest genius must, in this work, be governed by certain fixed rules, labouring, so to speak, in harness. The poem selected for illustration should be almost learned by heart, thought of, brooded over, and dreamed about, until the fitting lines force themselves on one's consciousness. The famous painter, Da Vinci, was blamed by the prior of the monastery for which he painted that wonderful fresco of "The Last Supper," because he spent days in sitting before his work without touching it. But the figures and surroundings were, meanwhile, being evolved from his inner consciousness, and when he finally took up his brush no part of the picture needed correction. Let your mental vision see the picture as a complete whole before you even think of actually making an exposure. I believe, also, in testing my models in an ordinary portrait before posing them for the illustration, as sometimes an apparently good subject will prove a very poor sitter.

The exposure ought to be so nicely calculated as to leave but little work for the retoucher, but this depends largely on the sitter. It cannot be too often repeated that the retoucher should have some knowledge of facial anatomy, and realise that he is to labour over an intricate network of muscles and nerves, each affecting the expression, and not over a flat surface with nothing beneath it. It might be well to have a school for training models, as it is very discouraging, after securing an effective pose or a fine printing negative, to find your sitter has moved. It is almost impossible to use head-rests in work of this kind, and where 11 by 14 plates, or larger, are used, expense is something to be considered. It is incomprehensible to me, this utter inability of some people to face a lens, and where their nervousness or constant questions as to how they shall sit causes the loss of a good negative, it requires genuine Christian charity to "think no evil." My first unregenerate impulse is to decline the sitter's further service when, for instance, a pathetic scene is to be represented, and he or she seems possessed by an insane desire to be humorous. Painters are more fortunate in this respect than photographers, as their models are usually trained, and are not apt to offer advice as to how they take best, as if that had anything to do with the parts you intend them to portray. The operator who conscientiously tries to bring out the thoughts of a writer is under a keener nervous strain than the sitter can understand, unless he or she is a camerist.

I have learned to have the warmest sympathy for professionals, and when I hear people say "it is so tiresome to sit for a picture," always wish to say "yon don't begin to endure what the operator has to, and your work is over with the sitting; he is the oue to be pitied, and not you."

The possession or lack of the true histrionic instiuct of forgettiug self in an assumed character is at once revealed by the model when the operator disappears under the mysterious cloth. When only the keen-eyed lens confronts the sitter, it seems, to nervous persons, as a friend once said to me, as if the aforesaid eye was gazing iuto one's very conscience. The average sittter, whether willing to acknowledge it or not, is intensely self-conscious, which is the true name for what they like to call nervousness. They should, for the time being, merge Miss A or Mr. B in an assumed character, aud it is a discouragiug truth that if they cannot do this the picture will be a failure, no matter how fine the conception. Sitter and operator ought to be in perfect accord, and I do not find that there is much to choose as between men and women in sharing the above blame; oue is no more self-conscious than the other. Sometimes, indeed, models are so williug to please that they wish you to arrange every finger joint, or suggest to them the exact shade of expression needed, generally at the very moment you are placing the holder in the camera, or drawing the slide. I do not know which is the more difficult to manage.

The operator who poses the figures and designs the pictures should have nothing to do with the petty details of filling holders, placing them, drawing slides, aud moving things into position. The mere physical fatigue dampens one's enthusiasm, and it is absolutely important to have the nerves under control, and not be couscious of one's body.

I have said little about technical details or studio appliances, deeming that that would, indeed, be bringing coals to Newcastle, but would like to speak of a few points which have proved practically useful to me. No illustrative work should be undertaken with any but the best lens. A rapid rectilinear is, generally, preferable, but a wide-angle is often absolutely required, and I believe in either case in having it able to cover a larger plate than the one used, cutting sharp with full aperture. The studio scenery ought to be, as far as possible, in real, not simulated, relief; plastic, not painted. This allows the figures to be more naturally posed, and not so apparently on a line. Most of my scenery can be taken apart and re-adjusted, so that wheu used with different draperies, carpets, and furniture, it will form a number of combinations. With regard to the skylight, I have continuous sheets of ribbed glass, a little over an eighth of an inch thick. This is covered by five sets of white shades, divided into half-yard pieces running on wires from side to side. Over these are three sets of black shades divided and run the same way. The shades on the vertical light slide up and down. I use an ordinary view camera, as, with double holders, it permits more plates being ready before commencing work, and this is likely to save much time and trouble. Competition and exchange of ideas such as this present Convention, when used for the purpose of self-improvement and not mere display, ought to be of incalculable benefit, and the inspiration gained by the attrition of different minds constautly raises the staudard of photographic progress. In illustrative work amateurs and professionals can labour side by side, and each gain from the other. The former will learn to appreciate the almost infinite tact, patience, and hard work demanded of a professional, who, on his part, will learn that the intelligent amateur helps to elevate the work to which he himself has perhaps given the best part of his life, and thus, by mutually disseminating a wider and clearer knowledge of photography, gain for it more thorough appreciation and admiration.

## GLASGOW INTERNATIONAL PHOTOGRAPHIC EXHIBITION.

### List of Awards.

Gold medal for special excellence, H. Van der Weyde.

*Professional.*—Class 1—Portraits (whole-plate and over), silver medal, W. M. Warnerke; bronze medal, W. W. Winter; extra bronze medal, G. Greül. Class 2—Portraits (under whole-plate), silver medal, H. Baker; bronze medal, W. J. Byrne. Class 3—Enlargement (portraits only), silver medal, H. Van der Weyde; bronze medal, T. and R. Annan and Sons. Class 4—Enlargement (other than portrait), silver medal, Alexander Brothers; bronze medal, T. and R. Annan and Sons. Class 5—Lantern slides, silver medal, G. W. Wilson and Co.; bronze medal, West and Son.

*Amateur.*—Class 6—Portraits (whole-plate and over), silver medal, Prince Ruffo; bronze medal, C. B. Moore. Class 7—Portraits (under whole-plate), silver medal, no award; bronze medal, W. J. Jenkins. Class 8—Enlargement (portrait only), silver medal, no award; bronze medal, W. H. Kitchin. Class 9—Enlargement (other than portrait), silver medal, R. H. Elder; bronze medal, W. S. Anderson. Class 10—Lantern slides, silver medal, J. E. Austin; bronze medal, A. Watson, A. Pringle. Class 11—Landscape (whole-plate and over), gold medal, D. R. Clark; silver medal, H. P. Robinson, A. H. Hinton; bronze medal, J. G. Pratt. Class 12—Landscape (under whole-plate), bronze medals, J. A. C. Ruthven and Mrs. Janie N. Hignett. Class 13—Marine and clouds, silver medal, no award; bronze medal, C. Millard. Class 14—Animals, silver medal, J. Catto; bronze medal, C. Reid. Class 15—Out-door groups, silver medal, Karl Gregor; bronze medal, F. Bremner. Class 16—Architecture, silver medal, no award; bronze medal, C. V. Shadbolt. Class 17—Interiors, silver medal, C. Court Cole; bronze medal, W. J. Byrne. Class 18—Still life, no award. Class 19—Flash-light, silver medal, John Stuart. Class 20—Instantaneous, silver medal, W. S. Anderson; bronze medal, H. Symonds. Class 21—Hand-camera (seaside and marine), silver medal, J. W. Wade; bronze medal, A. Watson. Class 22—Hand-camera (other subjects), silver medal, W. S. Anderson; bronze medal, R. H. Elder. Class 23—Stereoscopic transparencies, silver medal, W. S. Anderson; bronze medal, F. McKenzie; Class 24—Genre, silver medal, H. P. Robinson; bronze medal, J. Terras. Class 25—Scientific, silver medal, R. Kidston; bronze medal, W. H. Howie.

Champion class.—Portraits—Gold medal, W. Crooke; other than portraits—Gold medal, L. Sawyer.

Lady amateurs' class, silver medal, Mrs. B. G. Bennetto; bronze medal, Mrs. J. N. Hignett.

Silver medals awarded for exhibits of special merit—R. W. Robinson, Countess Loredana da Porto.

Photo-mechanical section—Silver medal, Boussod, Valadon, and Co.; bronze medals, Richard Paulussen, T. and R. Annan and Sons, Photo-chrome Engraving Co. of New York, S. B. Bolas and Co.

Apparatus—Bronze medals, W. Middlemiss, George Mason and Co., James More and Co., J. Lizars, W. Watson and Sons.

A Photographic Actress.—Mr. Henry Irving and Miss Ellen Terry, says the *Echo*, are now staying at North Deal. Miss Terry, it is not generally known, has mastered the art and mystery of photography, and, fortified with a camera, the most popular of actresses relieves the monotony of her professional "rest" by turning her lens upon every agreeable object within view. While Mr. Irving strolls along Deal Beach, Miss Terry is taking the likenesses of Deal boatmen. She manages her plates and black bag like an old photographic hand.

## Notes.

A large number of cameras are to be seen this year at every seaside resort, and although the greater proportion of these are in the hands of amateurs, a professional worker can often be detected amusing himself in this way. Few photographers, we fancy, go out of town without the means of taking a picture or two whenever they may feel inclined to do so, and many a time have we come upon some veteran in the art whiling away his holiday time in this manner.

One whom we lately met was intent upon photographing that which he enthusiastically called "one of the most beautiful things in the whole realm of nature." He alluded to a seagull in flight, and in searching for his quarry he adopted a device which he had, with the greatest disgust, seen practised by a cockney sportsman. This unworthy individual had gone out in a boat with a gun and several huge hunks of bread as bait. The bread he cast upon the waters in a literal sense, and as soon as the poor birds collected and hovered over it he blazed away at the beautiful creatures, apparently for the mere pleasure of killing, for the birds are useless for edible or any other purposes. Our friend, as we say, took a hint from this wanton practice, and fired at the birds with his hand-camera. The results he obtained were very beautiful, and, we venture to say, gave him far more pleasure than could ever be felt by the cruel sportsman from whom he borrowed the idea.

But the dismal weather which has been the remarkable feature of the present year has interfered sadly with the operation of photographing seabirds, or any other thing outside the studio, and the saving in unused plates must in the aggregate represent a great loss to the makers and dealers. The continuance of dull weather, which culminated the other day in London in a real November fog, has also been disastrous to photographic pursuits by making printing operations a very weariness of the flesh. It is said that September is to be a sunny month, but weather prophets are seldom to be believed in, and never seem to take heed of the American humourist's axiom which advises all men not to prophesy unless they *know*.

A new use has been found for portraiture, and, as it is in connection with industrial strikes, photographers may hope for an increase of business, for strikes seem to increase in number as the years roll by. The fact came out during certain proceedings at the County of London Sessions the other day which had for their origin the practice of picketing in connection with the carpenters' strike. It was stated that the picketing had not ceased, and in order to further its ends, a photograph of one of the witnesses for the prosecution was being circulated among the picketers so that he should be a marked man. In times gone by a man was marked by branding, having his ears slit, or in some other uncomfortable fashion. The photograph is far more effectual, for it is not attached to his body, and therefore cannot be hidden, while the mutilation can be more conveniently carried out subsequently.

Mr. Harry Furniss has not escaped the interviewer. Through the medium of the latter, we are told that Mr. Furniss thinks a caricature a much better likeness of a person than a photograph, as a photograph loses everything a caricaturist seizes and catches. For this Mr. Furniss blames the sitter quite as much as the artist or the photographer. They claim and are content with a mere conventional presentment of themselves with all the characteristics left out. This argument, at first sight, seems to be convincing, but is it really tenable? Mr. Furniss is a photographer as well as a caricaturist, and we shall be much surprised if he seriously contends that it is possible for a photograph to possess the essential quality of a caricature—namely, exaggeration. A caricaturist has an advantage over a photographer in being able to pick and choose his subject, and we may be sure he will never pick one which has no points he can seize upon. Gladstone with his collars, Harcourt's double chin, Randolph Churchill's moustache (when it existed), Sir Richard Temple's extraordinary nose, Sir Robert Peel's wonderful hat, with its curly brim, and his facial adornments—how easy to caricature such material! How difficult with the expressionless visages of Mr. John Morley, Mr. Parnell, or Sir Charles Dilke! The comparison between photography and caricature is not a fair one.

The *Daily News* and the *Court Journal* have each quoted the note which appeared a fortnight ago in these columns referring to the low standard of art represented by the portraits published by the evening and weekly newspapers. The *Court Journal* has, however, made us say that we are "not aware of the difficulties which surround newspaper portraiture," which is rather an unfortunate mistake, as what we did say was exactly the reverse.

We have not yet heard of the Holy Coat of Trèves being photographed, but it would not be surprising if some enterprising amateur tried his hand at it. As a business speculation it would pay handsomely, for photographs of relics of this nature find a ready sale among devotees. Unfortunately these relics are not, as a rule, exposed to the searching light of the sun, but are kept in such a dim religious seclusion that snap shots with a hand-camera are out of the question. The clergy of Trèves, according to the newspaper reports, do not disdain to turn an honest penny in the way of selling rosaries, tracts, and pictures of the Holy Coat, much to the disgust of the shopkeepers, who complain bitterly of the competition. Anyone who could offer photographs would, consequently, be largely patronised.

Despite the enormous increase in the consumption, and consequently price, of platinum, the source of supply remains exactly where it has been for many years past—the Ural Mountains in Russia. Platinum is to be found in other parts of the world—for instance, in California and Southern Oregon—but, according to the *Mining and Scientific Press*, of San Francisco, it has not hitherto paid to extract. At present prices, however, it should yield a profit. Platinum is chiefly found in connection with what is called gold placer mines, that is to say, where the gold is found in conjunction with gravel, and is obtained by hydraulic operations. The *Press* says, "At the advanced price now ruling, miners who are engaged in surface workings should look after their platinum closely, and save all they can." An increase in the supply would no doubt reduce the price slightly, but not so much as to affect materially the advice given by our San Francisco contemporary.

## PHOTOGRAPHY AT THE THEATRE.

THE *Photo Gazette* publishes in its last number an unusually fine collotype reproduction of a flash-light picture taken at one of the Paris theatres by M. Roger, of Nancy, who used a flash-lamp constructed by M. Boyer. The picture includes about seventy figures grouped on the stage during the performance of the successful play entitled *Le Régiment*.

In the course of an article which accompanies this illustration, the writer (J. Mareschal) points out that the apparatus sold for the purpose of producing the magnesium flash is of endless variety, but, as in most other things, the simplest of them are the best. He also asserts that magnesium powder is often adulterated with foreign material, notably with zinc, which, of course, burns with far less brilliance than the metal which it supplants. It is recommended that buyers should prepare the magnesium powder for use by passing it through a sieve made of silk tammy, rejecting the coarser particles, and employing only those which resemble very fine dust. Above all things, it should be used as pure as it can be obtained, and certainly not mixed with chlorate of potash. This mixture, which possibly gives a more brilliant light, is dangerous to handle, and may cause serious accidents. Moreover, there is produced during its use a far greater body of noxious vapour than when the metal is employed alone. With the ordinary flash-lamp sold for amateurs' use it is not advisable to cover too large a plate. The sizes 9 by 12, or, at the outside, 13 by 18 (centimetres), should not be exceeded. The mode of operation is very simple. The picture may be focussed with a taper, which, when moved from side to side, will show on the ground glass screen the limits of the picture to be taken. When all is ready, the shutter of the dark slide may be withdrawn. In the meantime, the gas or other lights of the place may be left burning, provided

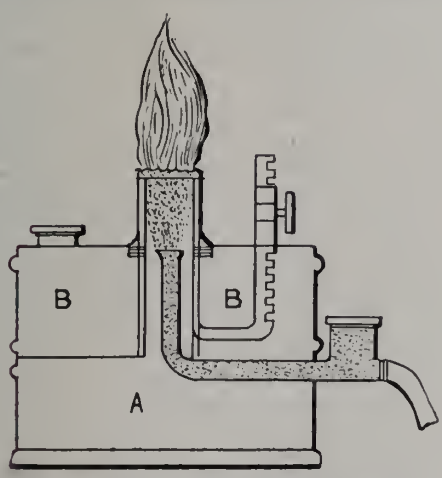

*Fig.* 1.—A, air chamber; B B, reservoir for alcohol.

none of them is in the field covered by the lens. The lens cap is not removed until the moment is at hand for firing the magnesium charge, and the lens should be covered again immediately after that operation.

If a picture of greater dimensions than those stated is required, a battery of lamps must be employed instead of a single one, and with this object M. Boyer has adopted a system the effectiveness of which is proved by the excellent results shown in the picture to which we have already called attention. It must not be thought that this picture is a mere fluke, a happy accident, for this is not the case, several theatrical pictures having been taken which, we are told, are quite as good. These pictures will presently be published by the firm of Dentu in the form of a highly interesting album.

The operator places his camera either in the middle of the orchestra stalls, or in the dress circle, according to

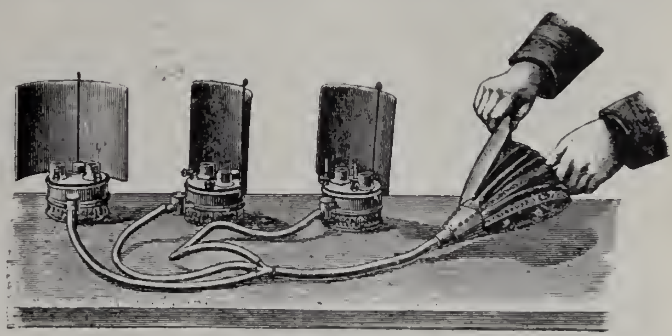

*Fig.* 2.

the size of the proscenium opening and the auditorium. The flash-lamps are placed close to the scene in front of the first tier boxes, right and left.

The lamp is one which burns alcohol with annular wicks, in the middle of each of which protrudes the pipe through which the magnesium dust is urged into the flame. The annexed cut (fig. 1) will sufficiently explain its construction. But this sectional cut shows only one wick, its object being to give relation of parts only. In fig. 2 it will be seen that each lamp has two wicks, and each of these has its separate supply of magnesium dust, although only fed by one air supply pipe. It will be seen that any number of these lamps may be joined together by india-rubber tubes, and these again by means of a main pipe connected with a pair of ordinary household bellows. The india-rubber tubes should be of a uniform length, in order that ignition may be simultaneous in all the lamps, producing one great flash. It is also necessary that the subjects to be photographed should be motionless, for although the flash is as rapid as possible, it is not absolutely instantaneous. Indeed, the light may occupy half, and in some cases a whole second of time. The art of the operator consists in the judicious disposal of his lamps so that few shadows are cast, and in exercising his judgment in making the light stronger on one side of the composition than on the other.

---

MANCHESTER AMATEUR PHOTOGRAPHIC SOCIETY.—The next meeting will be held on Tuesday, September 8th, when papers on "Printing Processes" will be read, and demonstrations given by the following members:—Dr. A. Hamilton, "Platinotype"; Mr. J. T. Lees, "Alpha Paper"; Mr. J. Drinkwater, "Chloride Paper."

THE following advertisement recently appeared in a German photographic paper:—"A born gentleman, 38 years old, of medium stature, heretofore an independent office-holder, but not altogether satisfied with his situation, amateur photographer and crayon portrait sketcher, seeks, from pure love of the art, a pleasant, wealthy lady (widows not excluded, nor is age material) who is in possession of a large photographic establishment, for the purpose of marrying the same. Honest proposals, including photograph, to be sent to 'A. B. C.,' 3149, care publication office, Düsseldorf, Germany."

## THE DECOMPOSITION OF SILVER CHLORIDE BY LIGHT.*

BY A. RICHARDSON, PH.D.

*Examination of the Darkened Chloride for Oxygen.*—The question whether the darkened compound is an oxychloride or a subchloride of silver appeared to be best decided by a careful examination of the compound for oxygen. The first experiments made in this direction consisted in heating the dry, darkened product in a vacuum, and collecting any gas which might be given off. 26 grams of pure silver chloride, which had been exposed to light under water until it had lost 8 per cent. of its total chlorine, was dried at 110°, and placed in a hard glass tube closed at one end, and connected at the other with a Sprengel pump; after the tube was exhausted, a graduated tube containing mercury was inverted over the turned-up end of the fall tube of the pump, in order to collect any gas which might be given off on heating. On gently warming the tube containing the chloride, it was found that just at first small quantities of gas were carried over; when gas ceased to come off, the temperature was raised and kept at the melting point of the chloride for about half an hour, during which period no further gas was evolved. The total volume of gas collected = 0·6 c.c.; this was proved to be air contained in the powder and on the glass, for, on shaking with alkaline pyrogallol, only a minute contraction of about 0·1 c.c. took place.

In a second experiment, 20 grams of the darkened chloride, from which 7 per cent. of the total chlorine had been removed by exposure to light, was heated as in the previous experiment; in this case, also, a minute quantity of gas was given off, which measured 0·4 c.c. at 0° and 760 mm.

It appears from these results that if oxygen is present in combination with the darkened chloride, it is not given off at the melting point of the silver chloride with which it is associated.

The next experiments were made to determine whether water was formed when the darkened product was heated in pure hydrogen. The gas, which was prepared by the action of steam on metallic sodium, was first dried by passing it through tubes containing sulphuric acid, then led over metallic copper heated to redness, and, finally, the last traces of moisture were removed by means of phosphorus pentoxide. The gas so obtained was passed into a combustion tube, in which the darkened chloride was to be heated. This tube was drawn out at one end and terminated inside a bulb, which was connected with a weighed phosphorus pentoxide tube, the escaping gas then passing through a second drying tube, and finally into a bulb containing water, in which the hydrochloric acid was absorbed.

That phosphorus pentoxide does not absorb dry hydrogen chloride to any appreciable extent (when exposed to the gas for a few hours only) was proved by the fact that the gain in weight of such a drying tube, after being exposed to the action of hydrogen chloride for 3½ hours, was only 0·003 gram, and that, on again passing the gas for two hours, no further increase in weight could be detected.† Tubes which had been exposed to the action of the gas till the weight remained constant were used in the subsequent experiments. Before heating the darkened silver chloride in hydrogen, the combustion tube was exhausted and gently heated until the air adhering to the glass and pulverised chloride had been removed; the tube was then heated in the current of hydrogen, the temperature being gradually raised till the chloride began to show signs of fusing. It was important, however, that the temperature should not rise too high, as the hydrogen chloride formed was found to act on the glass, carrying over small quantities of calcium chloride, which possibly (in one case) reached the weighed phosphorus pentoxide tube. The reduction, which lasted from seven to eight hours, was found to be complete when the escaping gas failed to give any turbidity with silver nitrate.

The results are given of four experiments made in the manner described. In the first three the darkened chloride was obtained from silver chloride from which 8 per cent. of chlorine had been removed by the action of light. In the last experiment, pure silver chloride was reduced in order to determine how far the gain in weight in the phosphorus pentoxide tube was due to experimental error. In the second experiment the tube had been strongly heated, and it was most probable that a trace of calcium chloride was carried over.

TABLE V.

| Weight of darkened chloride taken. | Gain in weight of $P_2O_5$ tube. |
|---|---|
| (1) 24·64 grams | 0·00375 gram |
| (2) 22·35 ,, | 0·00475 ,, (very strongly heated) |
| (3) 24·24 ,, | 0·00325 gram |
| (4) 13·0 ,, (normal chloride) | 0·00250 ,, |

From these experiments, it will be seen that the increase in weight in the phosphorus pentoxide tubes is so small as to preclude the possibility of the presence of an oxygen compound of silver in the darkened chloride.

In conclusion, it may be mentioned that, as a further proof of the absence of oxygen in this substance, an experiment, which is a modification of one described by Carey Lea (*Amer. J. Sci.* 38, 356-361), was made. Silver chloride was dried with extreme care and placed in a tube containing pure, dry carbon tetrachloride, from which all air was expelled by boiling. On exposure to light the chloride rapidly darkened, although it was certain that no oxygen was present.

* Continued from page 605.

† Dry air was drawn through the tubes before weighing.

CHAMOIS SKINS.—Considering what a useful thing a chamois skin is, it is astonishing that there is so much ignorance as to the proper way of keeping it in order and lengthening its term of service. Chamois skins should never be left in water after being used, but should be wrung out and hung up to dry, being spread out carefully so as to leave no wrinkles. They should not be used to wipe off colours, as paint stains form hard spots, and make the skin wear out sooner. Chamois was never intended to wipe the face and hands with, which makes the skin become greasy. Never put a chamois skin into warm water; anything above lukewarm water will curl it up, making it become thick, tough, and useless. To bring back chamois that has been injured by grease and paint, or used as a towel until it resembles a dirty old rag, the following is recommended: Take a bucket of clean water which has been made fairly but not too strong with ammonia; soak the skin in it over night, and the next morning rinse it out in pure water, after which use pure white Castile soap and water freely. The whole operation, aside from the soaking, need take no longer than a quarter of an hour, and it makes the skin in reality better than it was before, having freed it from all impurities.—*The Optician.*

THE September issue of *Die Photographie*, in an appreciative notice, announces the death of Emanuel Mariot (Schielhabl), at the age of sixty-six.

## ROYAL CORNWALL POLYTECHNIC EXHIBITION.

The fifty-ninth annual exhibition of the above Society was opened on Tuesday, August 25th, at Falmouth, by the Right Hon. Leonard Courtney, M.P., the President, whose three years' term of office expires this year. There was a large attendance of residents and visitors, but owing to the rain many who would have attended were kept away. The address of the President was listened to with great attention. He referred to all the departments—viz., mechanics, mining, fine arts, photography, &c.

Lectures, concerts, and addresses were given during the week, but the rain, which prevailed for the greater part of the time, very much thinned the attendance in the hall.

On Thursday evening Mr. W. Brooks, of Reigate, gave a lantern entertainment, the subject being "The Tower of London," with lecture, followed by a few pictures of the State apartments of Windsor Castle, taken during the Jubilee, and concluding with some statuary. The lecture was ably given by Mr. J. F. Peasgood, of London; and although the evening was so wet, the hall was packed. The lenses used were made by Messrs. Taylor, Taylor, and Hobson, of Leicester, for the occasion, and did their work well, giving an exceedingly sharp picture. The chair was taken by Mr. W. N. Carne.

The Art Union Drawing took place on Friday at 9 p.m. Notwithstanding the bad weather, the attendance was a little in advance of last year.

### Judges' Report—Photographic Department.

The Judges have pleasure in making the following report to the Society:—

Whilst the number of general exhibits is not quite equal to last year, there is no falling-off in the excellence of the work shown. In the professional section, landscapes are again, as last year, few in number. Portraiture, however, is exceedingly well represented, especially by our old exhibitors, whose names are well known by this time. By far the greater number of pictures are printed in platinum. The amateur section is well represented in the several classes, and in many cases show a distinct advance upon former attainments. There are also several exhibits of importance in the photographic appliance and lantern section.

*Professional Section.*—For interior work Mr. F. W. Edwards, of Peckham, takes first silver medal for his view of the nave of Westminster Abbey, which shows high technical excellence. Mr. and Mrs. Anckorn have two genre pictures, which are gems in their way. Mr. Gulliver Speight sends two skating scenes. Mr. Lyd. Sawyer, of Newcastle, is again well represented, but he had evidently overlooked the fact that some of his pictures had been previously shown here. For his humorous picture, "Two's Company," he has been awarded a second silver medal. Messrs. Green, Cross, and Bevan send some curious examples of photographic printing on silk, and also some transparencies on celluloid and glass, the latter being very poor. Mr. J. Milman Brown shows some landscapes, chiefly in the Isle of Wight. Mr. Clarence James has a frame of studies of dog and child, which are clever in arrangement, and tell their own tales. Mr. W. Rooke sends an enlargement, which would have been better if it had been taken direct. Mr. Henry Reeves is represented by three examples of interior work, which are soft and delicate. Mr. Bradshaw sends two portraits of the same child. Mr. W. D. Welford has been awarded a second bronze medal for transparencies. Mr. R. W. Robinson, of Redhill, shows good work in several classes, and his late pupil, Mr. S. N. Bhedwar, sends portraits of a luxurious type. Mr. J. P. Gibson, of Wrexham, takes the award for landscape with his small picture "When the Day Burns Low," viz., first bronze medal. Mr. S. J. Barrett, of Manchester, has a case of half-a-dozen portraits printed in silver. Landscapes are also treated by Mr. Hendry and Mr. Joseph Smith, which show careful work. In portraiture, the judges had some difficulty in making their award between Mr. W. W. Winter, of Derby, and Mr. W. J Byrne, of Richmond, as each seemed to have attained the highest point of excellence, the one in his well-known sepia tones (platinum), and the other in silver printing. They therefore in justice have been obliged to award a first silver medal to each. These two exhibitors have also various other works well worthy of inspection. Mr. Westley J. Fry this year enters in the professional section for enlargements, instead of as last year in the amateur section.

*Amateur Section.*—Mr. H. Tonkin, of Penzance, carries off the first bronze medal for an enlargement of "Mousehole Pier and Boats," which is a highly creditable work. The Rev. H. B. Hare is awarded a second silver medal for his meritorious picture "The Taker Taken." Mr. Ernest Beck, of Sheffield, sends a series of landscapes and river scenes, in platinum, which are decidedly artistic. Mr. A. K. Gillespie exhibits a small series. "The Stepping Stones" of Mr. T. B. Sutton, of Liverpool, is a picture of careful treatment. For genre work Mr. A. G. Tagliaferro takes first bronze medal, and his six pictures form a highly interesting collection. A view of the interior of Christ Church, Oxford, secures a first bronze medal for Mr. C. Court Cole. Mr. A. R. Dresser is represented by several enlargements. Mr. E. Austin secures first bronze medal for his picture denominated "Chaff," a work of instantaneous character. Mr. G. Soltau Symons sends specimens of divers methods of printing from the same negative. For "The Tomb," the Rev. G. E. Hermon receives a second bronze medal. Mr. H. Dudley Arnott exhibits a frame of interesting subjects. Six quarter-plate prints are shown by Mr. Victor J. Hatfield, printed in silver. Four transparencies are shown by a beginner, Miss Rachel Barclay; and some similar work by Mr. J. Richards, of Newlyn, Penzance. Dr. Campbell shows some instantaneous studies, but owing to their not being framed they are disqualified. It would not be right to omit to mention the splendid series of enlargements from the negatives of Mr. Sherring of botanical subjects, which, though growing in the neighbourhood of Falmouth, are of a tropical character, and the series cannot fail to be of great value to the student; they show great skill on the part of Mr. Sherring.

### List of Awards.

*First Silver Medals.*—F. W. Edwards, W. W. Winter, W. J. Byrne.

*Second Silver.*—Lyd. Sawyer, Rev. H. B. Hare.

*First Bronze.*—H. Tonkin, A. G. Tagliaferro, C. C. Cole, J. P. Gibson, E. Austin.

*Second Bronze.*—W. D. Welford, Rev. G. E. Hermon.

In the photographic appliance section, the awards are deferred until after trial.

## PHOTOGRAPHIC CHEMISTRY.*

BY PROFESSOR R. MELDOLA, F.R.S.

Apart from the popularity of photography as an inexpensive amusement, enabling the amateur to obtain, with comparatively simple appliances, permanent records of places visited, or representations, more or less faithful, of the features of those whose individuality it is wished to bear in remembrance, the subject is becoming of daily increasing importance, on account of the numerous applications which photographic processes have found, both in art and in science. For this reason, it is desirable that the claims of photography to be considered a distinct branch of applied science or technology should be urged upon all those who are in any way interested in the advancement of technical education. Some progress has already been made in this direction in certain schools and colleges in this country, but when our efforts are compared with the keen appreciation of the subject which is borne witness to by the splendidly equipped photo-chemical laboratories of the technical high schools of Berlin and Vienna, it will be admitted that in this, as in other departments of chemical technology, we have allowed ourselves to sink into a secondary position. It is certainly remarkable that the land of Fox Talbot and Herschel—the country which has given to the photographic world all the most important processes discovered since the foundation of the art by Niepce and Daguerre†—should nowhere possess a school of photo-chemistry where the subject can be taught from a scientific platform, or where original investigators can find the requisite appliances and the skilled assistance necessary for the prosecution of research.

Setting out from the admission that photography must, sooner or later, become incorporated in all schemes of systematic instruction in applied science, I propose, in the present course of lectures, to show how this subject may be dealt with from a chemical point of view. From this it must not be inferred that photography is to be regarded purely as a branch of chemical technology, for it has also its physical side, and the highly trained photographer should be well grounded in the theory and construction of lenses, spectrum analysis, and, in short, in the general principles of optics. Assuming this knowledge to have been acquired, we may proceed to ask how the subject is to be taught, and the consideration of this question is of considerable importance—it is, in fact, of far greater importance than may appear at first sight, for photography is most admirably adapted to bring out into prominence the principles of technical instruction in a subject which is very largely of a chemical nature. The consideration of this question may help to dispel some of the haze with which the much-abused term "technical training" has been surrounded, and it will certainly lead to a clear conception of the object and scope of these lectures.

There are many who identify technical instruction with the teaching of some handicraft, a notion which has, no doubt, arisen from the identification of technical skill with manual dexterity in some mechanical industry. By the adoption, either tacitly or openly, of this narrow definition, the chemical industries have suffered to a very large extent in this country, because their progress is more dependent on a knowledge of scientific principles, and much less dependent on manual dexterity, than any of the other subjects dealt with in schemes of technical instruction. Now, in order to give technical instruction in a subject like photography, which is so intimately connected with chemistry, we may adopt one of two courses: The student may become a practical photographer in the first place, and may then be led on to the science of his practice by an appeal to the purely chemical principles brought into operation. This may be called the analytical method. The other method is to give the student a training in general chemistry first, and then to specialise his knowledge in the direction of photography. This may be regarded as a synthetical method.

In other departments of technology, and especially in those where the underlying principles are of a mechanical nature, the analytical method may be, and has been, adopted with success. It is possible to lead an intelligent mechanic from his every-day occupations to a knowledge of the higher principles of mechanical science by making use of his experience of phenomena which are constantly coming under his notice. From this it is sometimes argued by those who are in the habit of regarding technical instruction from its purely analytical side, that technical chemistry can be taught by the same method. Some teachers may possibly succeed in this process, but my own experience, both as a technologist and a teacher, has led me to the conclusion that, for chemical subjects, the analytical method is both too cumbersome and circuitous to be of any real practical use. No person engaged in chemical industry in any capacity—whether workman, foreman, manager, or proprietor—can be taught the principles of chemical science out of his own industry, unless he has some considerable knowledge of general principles to start with. No person who is not grounded in such broad principles can properly appreciate the explanation of the phenomena with which his daily experience brings him into contact, and if his previous training is insufficient to enable him to understand the nature of the changes which occur in the course of his operations, he cannot derive any advantage from technical instruction. These remarks will, I hope, serve to emphasise a distinction which exists between technical chemistry and other technical subjects, and I have thought it desirable to avail myself of the present opportunity of calling particular attention to this point, because it is one which is generally ignored in all discussions on technical education.

The reason for this difference in the mode of treatment of chemical subjects is not difficult to find. The chemical technologist—the man who is engaged in the manufacture of useful products out of certain raw materials—is, so far as the purely scientific principles are concerned, already at a very advanced stage, although he may not realise this to be the case. The chemistry of manufacturing operations, even when these are of an apparently simple kind, is of a very high order of complexity. There are many branches of chemical industry in which the nature of the chemical changes undergone by the materials is very imperfectly understood; there is no branch of chemical industry of which the pure science can be said to be thoroughly known. For these reasons I believe that I am justified in stating that the chemical technologist

* Cantor lectures, delivered at the Society of Arts Theatre.

† This is no vain boast. Taking the discoveries in order, we have the silver print and chromatised gelatine emanating from Fox Talbot; the cyanotype due to Sir John Herschel; the collodion process introduced by Scott Archer and Fry; collodion dry plates by Russell; printing with pigmented gelatine worked out by Swan; gelatino-bromide emulsion introduced by Maddox; and the platinotype process of Willis; to say nothing of the photo-mechanical printing processes, such as Woodburytype, to which English investigators have contributed so largely.

is working at a high level, so far as the science of his subject is concerned, and this explains why he cannot be dealt with by the analytical method.

*(To be continued.)*

## ART IN PHOTOGRAPHY.*

BY G. HANMER CROUGHTON.

Many years ago (it was during the carte-de-visite rage) I was painting for a firm of photographers in Dublin, Ireland. Being in the reception-room one morning, I heard the principal of the establishment arguing with a sitter who did not like her portraits; he was trying to convince her that the portrait must be right, because the instruments he used being the very best, it was like standing before a looking-glass, and there would be as much sense in complaining about the reflection she saw in her mirror as in doing so with her portrait. The sitter answered the photographer by a question which completely silenced him. She said: "If that is true, what makes the difference between good and bad photographers?"

This is my text: "What is it that makes the difference now more than then?" I answer emphatically, the presence or absence of art. The presence or absence of art-knowledge or taste in the photographer makes the difference in the photographs made in his studio—makes the difference we see in the productions exhibited year after year at the exhibition of the Photographic Association of America.

In the early days, when little or no art was practised by photographers, the public were not so exacting, because, being ignorant themselves, they did not look for it. The difference consisted mostly in the chemical manipulations. Keeping the silver bath in order, keeping that and the collodion and developer in harmony, that each should work at its best in relation to each other, kept the operator busy, and left little time for the artistic. How many times has it happened that, while the operator was trying to get his sitter nicely arranged, his plate would dry, and so spoil his chemical effect? Is it much wonder, then, that the artistic gave way to the chemical? All honour to those photographers who in the wet plate days produced artistic photographs as well as good chemical effects.

Whatever the dry plate may be blamed for—and you cannot read a photographic journal without finding almost all the sins in the calendar attributed to it—there is one thing it has done for photographers, and that is, it has given them time to study for artistic effects of lighting and pose without the fear of spoiling their chemical effect, and by rapidity of exposure has enabled them to aim for expression, the soul of portraiture.

Some croakers claim that the glue plate—as the late Mr. Gregg, of this city, called them—has reduced photographic manipulations to a dead level, and that any "duffer" can now produce good negatives; if this is so—and I confess there is some truth in it—there is but one way to excel, and that is in the artistic.

Photographers have got to learn about art both inside and outside their studios. What I mean by that is, that photographers as a rule, even those who are known as artistic photographers, are too apt to study art through the one eye of their cameras, instead of studying it through the two eyes in their heads. They get so used to the photographic rendering of certain effects of colour, light, and shade, that they forget to look at them with the eyes of an outsider, and get to regard the photographic rendering as right because the lens and camera produced it so. It would be well for every photographer who wishes to keep ahead to join some art class or school, and study art independently of photography, as well as studying those books which are devoted exclusively to art photography, and to learn to look at it from an outsider's point of view.

This advice will, I know, be particularly irksome to Americans, who always want to go the quickest way to work, and who, unless they see some immediate advantage in it, will not care to try it. But, although the saying may be a chestnut, it is a sound and good one, that there is no short or royal road to knowledge, and experience must be gained by long and often irksome effort.

To see nature with the eyes of an artist who has been trained to see her as she is, is very different to seeing it through the lens in a photographic skylight. I have often heard photographers laugh at the efforts of artists to light a sitter in a photographic skylight, and their sneers at the failures made by them is natural enough, but it should cause thought on the part of the photographer as to the WHY ——?

The light in an ordinary photographic skylight is a very trying one to almost every sitter, and is the cause in nine cases out of ten of a strained or painted expression. An artist, when sitting a model to paint from, uses very little light, and the effect upon the sitter is better in many ways; the pupils of the eyes are larger, and the expression in repose. Let the photographer watch the lighting of the faces of his friends in an ordinary room, and if he has any discernment he will see at once the difference in the quality of the light and its influence upon the faces and expressions; he will also note that in an ordinary room the roughness of the textures is not noticed. But get those same faces under the photographic skylight, and on account of the volume of light the pupils of the eyes contract and the eyelids close together, which causes the constant complaint that the eyes in a photograph always look smaller than in nature. Seeing this effect in all their sitters, photographers have come to believe it is right, and treat with disdain the objections of the sitters and their friends, who miss the every-day expression, and see only a new one, which they cannot account for.

Another thing which has become so familiar to photographers that they have ceased to think it a defect is the exaggeration of the skin texture. When I was a student, the instructor of the life-class called our attention to the fine, short down all over the face of the model; then, taking us far enough away to lose the details of the skin texture, he pointed out how that down which we could not see gave a general soft blending of tints and shadows without getting any of the roughness of texture. He concluded by saying: "At best a microscopical study of the human mask would be an unpleasing curiosity." Now, it would appear as if some photographers thought this unpleasant curiosity was the right thing to get, and they will not only use a rectilinear form of lens for large portraits, but will stop down till the texture of the skin in the negatives is much more like what is seen through a microscope than the human skin seen at a moderate distance. Another cause of exaggeration of texture is in the lighting. The so-called Rembrandt or edge lighting will exaggerate texture out of all truth, and when to that is added microscopic sharpness, then truth and art are shut out. Do not think I am an advocate of out-of-focus fuzziness. I am opposed to extreme sharpness where that sharpness is at the sacrifice of truth to nature.

At the Convention at Boston there was an exhibit which

* Read at the Buffalo Convention.

attracted the attention of all; I think it was from Germany. They were portraits about 11 by 14, mostly heads, printed upon matt surface paper of some kind. I saw a great deal of them, and studied them with the greatest interest and profit. They were admired by all the best photographers who attended the Convention, not one of whom but gave them unqualified praise. They were certainly not sharply focussed according to the usual photographic standard, yet they were sharp enough for pictorial standards, and their great beauty was their truthfulness to nature. The retouching upon them was only just enough to remove the spots and blemishes due to the false rendering of colour by photography.

This is another abuse which has done much to bring photography under condemnation from artists: over-retouching. You must do it when you make such extremely sharp negatives, particularly when you make large heads. The photographic texture is an exaggeration of the natural texture, and the pencil of the retoucher must be used; and in getting rid of this exaggerated texture, the retoucher makes with his pencil another which is more unreal in its mechanical smoothness than the exaggeration of extreme sharpness. If you will use a portrait combination and do not stop down too closely, and use a diffused, subdued light, these exaggerations will not be seen, the retoucher's work will be much lighter, and you will have a consequent gain in truth.

From what I have seen of the new isochromatic plates, they are going to make quite a revolution in both lighting and retouching. I have not used many of them, but I am quite charmed with what I have. The breaks in the gradations of the shadows, caused by the false rendering of colour, are absent entirely, and the retouching reduced to a minimum. The texture of the skin is softer and more truthful, and the general effect so superior, that before long they must take the place of all others. One of the best firms in the city is using them exclusively, and speaks in high terms of them.

I have confined my remarks to suggestions; to write exhaustively would be out of place where there are so many other things to attract your attention. But I would like to impress upon all young photographers the importance of studying art apart from photography, to be able to detect the untruthfulness of photography, for with untruthfulness there can be no true art.

Remember you are catering for a public which every day is getting more critical as art education spreads, and to keep your place you must head the procession, not follow behind.

## THE RUSSIAN PLATINUM MINES.

All the the platinum of Russia comes from one district, the government of Perm. In 1885 the output amounted to 110,635 ounces, and in 1886 to 184,336 ounces. Hitherto it has only been found in alluvial deposits, and is always associated with gold. The proportion of the two materials varies greatly, the platinum sometimes being in greater quantity than the gold, in other places not constituting above one per cent. The former deposits are the more profitable to work. The most important of these distinctly platiniferous deposits occur in the district of Nijni-Taguil, near the watershed of the Urals.

All the platinum-bearing streams of this locality descend from Mount Solovskaia, which is composed of a serpentine rock. The rivers have greatly exceeded their present size in former times, or else—which is more probable—have shifted their course; for the wide valleys in which they flow contain alluvial deposits of considerable extent, which are exploited for platinum, and to a less extent for gold. Between Mount Solovskaia and the diorite mass of Mount Blanche the surface is covered with rounded boulders of serpentine and peridotite rock. As these boulders decompose under the action of the air, they form a sand or gravel from which the metal can be profitably extracted. This is similar to what takes place in the weathering of the diamond-bearing peridotite rock of Kimberley, which is exposed to the disintegrating action of the atmosphere before being washed for diamonds. The platinum of the alluvial deposits occurs in grains, or pound of 10 Kgm. weight. The gravel often contains ½ ounce per ton of platinum, but can be profitably worked for $\frac{1}{7}$ ounce. The deposit near the banks of the river Martiane consists of a serpentine conglomerate, and is from 4 to 5 metres in thickness. Above is a thickness of 23 to 24 metres of barren ground, chiefly clay. Most of the alluvial auriferous deposits in which platinum is found are in the neighbourhood of peridotite rock, or of serpentine rock formed by the partial alteration of the peridotite. Thus, the River Mioss takes its source from a mountainous district mainly composed of serpentine rock, and accordingly the auriferous deposits near the head of the river are rich in platinum; but further down stream, as the serpentine formation is left behind, the gold becomes less platiniferous. Small nuggets of platinum are sometimes found embedded in pieces of serpentine, of peridote, and of chrome iron ore, all constituent minerals of the peridotite rock, which there is good reason, therefore, to regard as the true mother rock of the platinum. The richest deposit of the Nijni-Taguil district is that of Avrarinski, extending for a length of 2 Km., 20 to 60 metres wide, and of a thickness of 4 to 5 metres. Here the platinum is found to the amount of 4½, 5, and sometimes even 9 ounces per ton. The metal contains a small proportion of gold, about 0·26 Gm. per kilo, which is separated by amalgamation. The crude platinum left contains about 90 per cent. of pure platinum. From October, 1886, to August, 1887, the production at Avrarinski was 40,475 ounces. The working of these deposits is to a large extent sublet by the proprietors to the peasants of the district, who are paid by the weight of metal obtained. They construct their own washing and other machinery, which is made of wood, and is of a very crude description. The conditions with regard to cost of living, wages, and so forth are, of course, very different from those obtaining in new countries, such as South Africa, where the precious metals are exploited.

Sometimes the present beds of the rivers contain sufficient platinum to pay for working, in which case the course of the river is diverted, and the water power used for driving the machinery. A large part of the gold mining of the Urals is likewise carried on under the system of subletting, but where the mother rock—generally quartz or diorite—is worked, more expensive plant is required, and the work is carried on by the proprietors of the soil or by companies. — *American Druggist.*

## TRANSFERRING PRINTS TO GLASS.

The *Lithographer and Printer* gives the following method whereby any chromo print, or even clipping from newspapers, any engraving, no matter in how many colours, or on what kind of paper, may be transferred to glass by different treatment of the various kinds of paper.

Place the object to be transferred, face downwards, upon a larger sheet of Manilla paper; prepare a solution of from 1 to 3 per cent. of nitric acid in water, according to thickness and strength of paper, and how strong it was sized; ordinary newspapers, and printings and engravings on unsized glazed paper, require even less than 1 per cent. nitric acid. One of the purposes of adding nitric acid is to remove the sizing out of the paper. This solution apply with a sponge to the back of your object to be transferred. Be careful not to overdo it; you only want to render the paper soft, but not wet. Continue sponging with this solution until you see the printing plainly—that is, until the paper becomes quite transparent.

Laying down the paper, first adjust the upper right-hand corner to the mark on the plate, hold it there with the tip of your finger, and adjust the left-hand lower corner, but be careful to avoid air-bubbles. The practical printer and lithographer, of course, does not need this advice, but to the amateur it is very valuable.

To prepare the glass for trausferring, proceed as follows :— Clean the glass plate thoroughly with alcohol by means of a ball of clean cotton ; dry it well ; wash it with turpentine ; dry it off again ; place the glass or plate upon a smooth elastic layer (such as flannel), aud with this elastic layer upon a table, or, better yet, upon a rubber blanket in the lithographic hand press. Now coat the cleaned surface with a thiu coat of half turpentine and half dammar varnish ; let it dry from ten minutes to one day, according to temperature and thickness of dammar varnish. The coating should not be allowed to dry entirely ; it should be a trifle sticky. Lay the impression face downward upon the glass plate ; it is important that neither water nor acid touch the surface during the entire process. To properly lay down the impression, take it up with both hands by holdiug the left-hand under-coruer and the right-haud upper-corner. Be careful not to get any air-bubbles under the sheet. This is best accomplished by marking upon the plate the exact position and size of the sheet.

Press the sheet to the adhesive dammar coat ; this may be done iu many different manners. It does uot require a very strong pressure, but it should be observed that *each and every spot* has to be pressed repeatedly agaiust the plate. We advise the use of a small rubber ruler, or a blotter ruler, or any similar instrument. You may also use the hand, but, of course, not with much safety ; or a dabber of cotton or rags, or an ivory paper folder. When the paper sticks quite smoothly to the plate, fan it perfectly dry, and then, with *wet* finger tips, slowly rub off the paper, and the print, of whatever colour or nature it may be, will remain on the glass plate. Upon this apply another coat of dammar varnish containing veiy little turpentine (with too much turpentine you run the risk of washing the entire picture from the plate again). If all our rules are followed, a splendid picture will be obtaiued, which can be washed and cleansed with water the same as a window, as often as desired, aud the transfer will not be injured thereby. Such a picture will be visible from outside of the glass, day and night, the saue as auy glass painting.

## Patent Intelligence.

### Applications for Letters Patent.

14,278. L. M. Kords, 18, Buckingham Street, Strand, London, "Improvements in or relating to Shutters for Photographic Cameras."—*August 24th.*

14,336. Charles Walker Clarke, 32, Market Place, Devizes. "Improvements in Photographic Apparatus."—*August 25th.*

14,536. Benjamin Joseph Edwards, 45, Southampton Buildings, London, "Improvements relating to Photographic Cameras and to Apparatus for use in connection therewith." *August 28th.*

14,556. Leon Berteau and Henri Roussel, 55, Chancery Lane, London, "Improvements in Shutter Apparatus for Regulating the Admission of Light for Photographic Purposes."—*August 28th.*

14,648. Arthur Rayment and George Lyons, 34, Southampton Buildings, Chaucery Lane, Loudou, "Improvements in Photographic Cameras."—*August 29th.*

### Specifications Published.

4,956. *March 29th*, 1890.—"Rapid Printing Apparatus." W. F. Greene, 92, Piccadilly, and F. H. Varley, 82, Newington Green Road, both in London.

The film is fed from the sensitisiug tank or direct from a sensitised roll betweeu the rollers, and under a guide roller through the printing frame. In this is fitted au under negative and au upper movable negative, through which the film is simultaneously exposed on both sides. The upper negative is actuated by toggle-levers, which are worked from eccentrics on a shaft, being thus intermittently lifted to permit the film to be fed forward. The film next passes over rollers, between which works a roller on oscillating spring levers, by which the film is withdrawn from the printing frame and held taut. The film then passes through developing, toning, fixing, and washing tauks, provided with suitable feeding or squeegeeing rollers. These, with the correspouding rollers, are actuated through suitable gearing by an oscillating sector lever. The film is finally wound on a roll mounted on a frictional hub driven from the last of squeegeeing, &c., rollers. The exposure in the printing frame is effected by perforated shutters, which slide over apertures in the ends of the frame, being actuated by a crank disc.

5,046. *April 1st*, 1890.—"Cameras aud Change-Boxes and Lens Fittings." W. B. Luce, Boston, Massachusetts, U.S.A.

The camera has internal grooves at the sides to receive the plates, which are held in opaque holders. In the lower part of the camera slides the lens tube, which is of such length that a plate placed immediately behind the open inuer end will be exactly in focus. The plates are, before exposure, held in the upper part of the camera, beiug supported by the lens tube, which, to expose the plates, is moved outwards to allow the plates to drop in succession. The lens tube may be threaded, or it may slide in a stuffing box, or it may be surrounded on the outside by a light-tight bellows.

"Sheaths."— The holders are preferably of sheet metal having flanges at the top and bottom.

5,158. *April 2nd*, 1890.—"Change-Boxes and Dark Slides." C. H. Stanbury, 91, Fleet Street, London.

The change-box cousists of a case fitted with a number of slides between which the sensitive plates are placed. The slides are fitted with numbered tabs to indicate the number of plates exposed. To transfer the plates into the dark slide, the box and dark slide are put into position, and the lower slide of the box aud the upper one of the dark slide are withdrawn. The plates, when exposed, are returned in a similar way to the top of the box. The dark slide is provided with a slide or shutter for exposure. In a modification the plates are placed in sheaths with V ends, in which case only top and bottom slides are used, and they are provided with V ends to facilitate insertion between the sheaths.

5,193. *April 3rd*, 1890.—"Cameras and Change-Boxes." G. Dickinson, 144, Morley Avenue, Noel Park, London, N.

The plates are inserted through the back of the camera into grooves formed in the top aud bottom. From thence they are withdrawn into position for exposure by inclining the camera so as to drop them in succession into a groove in a turntable, which is then rotated so as to bring the plate into a transverse position. The handle by which the turntable is rotated works in connection with a uotch indicator, which serves also to secure the handle. A spring clip, actuated by a milled thumb-piece, serves to retain the plate iu the slot. The plate registers against inclined, velvet-covered strips, which serve to shut out the light from the remaining plates. Corresponding with the groove is a vertical plate, which may be provided with a focussing screen. The distance of the object being known, it is focussed by turning a poiuter to a certain number in the graduated arc.

5,215. *April 3rd*, 1890.—"Shutter." F. Beauchamp, The Poplars, Chadwell Heath, Essex.

The shutter consists of a slide, which is worked up and down by a crank-pin fixed on a crank disc in a slit between the lenses. The shutter is attached to the lens by means of a split ring, which is clamped on the lens tube by a screw. The crank, which is actuated by a coiled spring, is released by lifting a detent lever, which is lifted clear of the crank for rapid exposures, but only partly—so as to catch the crank and hold open the lens—for slow exposure. The time of exposure is regulated either by forciug a brake disc against the face of the crank disc by a regulating screw, or by connecting the crank to the axis of a rotary air-pump, the outlet of which is regulated by a valve. To give several exposures with one winding of the actuating spring, an escapement is used for releasing and stopping the crank at each revolution, aud the range of the spring may be increased by toothed gear.

Hackney Photographic Society.—Arrangements for September :—10th, "A Holiday in Isle of Man and Ireland," W. Fenton Jones ; 13th, Excursion ; 24th, Members' lantern night ; 26th, Excursion to Wanstead Park—meet at Leytonstone Station at 2.45 p.m.

## Proceedings of Societies.

Hackney Photographic Society.

A meeting was held on Thursday, 27th Aug., Mr. C. F. Hodge presiding. Work was shown by Messrs. Gosling, Barton, Roder, &c., and duly criticised.

A question as to silver papers led to statements by several members of their experience with various papers in the market.

The Secretary presented the Society with a guide-book to the North of Ireland.

Mr. J. O. Evans then gave his paper and demonstration on "Bromide Enlarging," devoting the greater part of the time to demonstration, as being more interesting. With the aid of a powerful oil light he proceeded to expose a negative of some cattle on Ilford rapid bromide paper, giving an exposure of twelve minutes. Blocking the landscape out, he, by double exposure, printed in some clouds. The resulting picture was exceedingly good. He did not use a clearing bath, but merely washed the print with cotton-wool.

---

Birmingham Photographic Society.

A meeting was held at the Midland Institute on the 27th August, Mr. W. Jerome Harrison, F.G.S., in the chair.

Favourable reports were read of the Leicester and Arley and Fillongley excursions. Letters were read from Mr. Geo. Bankart (judge of the Leicester excursion competition), and Mr. Harold Baker (judge of the Arley and Fillongley excursion competition), announcing their awards as follows: Leicester prize, Mr. William Rooke; Arley and Fillongley prize, Mr. A. J. Leeson.

The business of the evening was the exhibition of the negatives sent in for the developing competition. Forty-eight sets, of three plates each, had been exposed by a Birmingham professional, each set consisting of one plate each over and under-exposed, and the other about right exposure. Forty-four sets were applied for, the prize being awarded by the judge (Mr. Harold Baker) to Mr. J. T. Mousley for a very even set.

Mr. Thomason said that he should have preferred to have had the plates exposed on some landscape than, as they had evidently been, in a photographic studio.

Mr. Middleton thought it impossible to expose forty-eight plates out-of-doors in a constant light. He also mentioned the case of a lens not covering a plate so large as it was advertised to cover.

The Chairman mentioned the fact that the Kew Observatory now undertook to test lenses and grant certificates on payment of a small fee.

Mr. J. H. Pickard was the recipient, on the 21st of August, of a testimonial in the form of a lock-up stationery cabinet and secretaire, given by members of the council on his retirement from the secretarial duties.

The president, Mr. J. B. Stone—who has just returned from a visit to Japan—in making the presentation, remarked that it was not given with the idea of making any award, but as a bond of friendship.

Mr. Pickard thanked the council for their unexpected gift, and briefly traced the progress of the Club from its inauguration in 1885 to its present position.

---

London and Provincial Photographic Association.—The outing on Sept. 5th will be to Greenwich Hospital. Members and friends meet at the West Gate, Royal Naval College, at 2.30 p.m.

Photographic Club.—Subject for Sept. 9th, "Printing by Development"; Sept. 16th, "Intensifying and Reducing." Saturday outing to Greenwich; rendezvous at West Gate, R. N. College, at 2.30 p.m.

Formaldehyde.—It has recently been discovered that formaldehyde, or a combination of that with bisulphite salts, has a remarkable effect on negatives, inasmuch as its application, either as an ingredient of the coating solution, or by bathing the plate either before or after exposure, tends to the same result as would be had with a long exposure. It is said to work well, and to be free from all tendency to turn yellow.—*Anthony's Bulletin.*

## Answers to Correspondents.

**All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.**

**All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.**

**Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.**

J. B. and Co. — *Methylated Spirit.* In addition to the ten gallons of crude wood naphtha contained in every 100 gallons of methylated spirit, the Board of Inland Revenue now directs that there shall be further added twelve gills (three pints) of mineral naphtha of not less than ·80 specific gravity. Whilst contributing to the nauseous character of the mixture, it is believed that this small extra addition will not prejudice the use of the spirit in making varnishes; and, from experiments both with petroleum oil and common benzol, we feel disposed to agree in this opinion, the quantity prescribed being so very small—three parts in eight hundred.

G. J. S.—*Weather Forecasts.* The prediction for August 20th, "changeable, some showers," was hardly a correct forecast for the greatest deluge of the year, when the southern counties were flooded, and the rainfall in London amounted to 1·33 inches. The total rain for August (4·66 in.) was just double the Greenwich average.

A. Mackie.—*Iron Printing Process.* We noted your enquiry at the last technical meeting, but heard recently that Professor Meldola had not yet been furnished with the particulars of the process upon which you desired information. You will not, however, have long to wait in doubt, for the official report of the second Cantor lecture (at which this experiment was performed) will probably appear in to-day's *Journal of the Society of Arts.*

Executor.—*Scientific Books.* You might send on the list, and offer them to Mr. Wm. F. Clay, 2, Teviot Place, Edinburgh; or put them up to auction sale through Messrs. Sotheby, Wilkinson, and Hodge, Wellington Street, Strand.

Rev. W. F. C.—*Camera Details, &c.* 1. Your surmise is correct; we *are* contemporaries. 2. You hardly do justice to the Cardiff programme, which included many matters of photographic interest besides those alluded to in the President's address. Geological, geographical, archæological, and meteorological applications were uncommonly well represented. (See notice on page 609 of last week.) Mr. Mark Stirrup's Languedoc series were shown as a lantern display at the first soirée, and the local society got together a very creditable photographic exhibition, to which all members and associates were freely invited. 3. Without seeing drawings we can hardly advise you as to the camera improvements. Do you remember Mr. Stillman's clamping arrangement shown to the Photographic Society in January, 1872?

Cantab.—*Colour Troubles.* The use of isochromatic plates ought to help you in overcoming many of the difficulties referred to in your letter.

H. E. Ross. —*Pall Mall Exhibition.* The receiving day is Monday, Sept. 14th, for packing cases sent through Mr. Bourlet, 17, Nassau Street, Middlesex Hospital; or Wednesday, 16th inst., if delivered by hand at the Gallery. For further particulars, see the Assistant-Secretary's letter in the News of last week, page 614.

Quadragesimus.—*Alloys.* Probably equal parts of aluminium and tin would give a suitable alloy; but before making this, try zinc and tin in the same proportions, which would be much cheaper, easy to make, and sufficiently light for your purpose. It is a non-corrodible alloy, remarkably stiff, and easily workable.

Vero.—*Discoloured Emulsion.* It is possible that the india-rubber joint, by giving off sulphurous emanations, may have affected your silver emulsion. As a test, lay a piece of white filter paper moistened with silver nitrate in contact with the suspected rubber, and see whether it becomes blackened in consequence.

# THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

VOL. XXXV. No. 1723.—*September* 11, 1891.

CONTENTS.

## A NEW METHOD OF PHOTOGRAPHING FLOWERS.

THE average photographer, like most other ambitious persons, is constantly sighing after fresh worlds to conquer, and, after the fashion of human nature, is prone to forget or overlook the opportunities for study which are within reach of his hand. Some will be constantly complaining that they have not time or means to get to foreign climes, and that this country does not afford scope enough for their talents. On this plea many will settle down into the common rut of every-day bread-and-butter existence, and will never attempt to produce a picture which is not of the common second-class studio type. Others never seem to care to picture anything which is not brought to them, and which they are obliged to do simply because they do not like to throw an order away. Some of them will actually refuse work for their camera if it entail a little extra trouble, or a slight deviation from the beaten track. This neglect to encourage business is not so rampant as it was before the inroad of the amateur. That indefatigable gentleman—who can do anything, from making a transparency to enlarging a head to life size—has at least taught the profession that they must not rest upon their oars, but must pull hard unless they would be left quite behind in the race.

It is, then, to the interest of the modern photographer that he should do his best to strike out into fresh lines, and should look around him and think in what new direction he can work. If he have the opportunity of visiting one or two of the numerous exhibitions of photographs which are now so common, he will do well to study the various kinds of pictures there shown, and he will generally be able to learn what to avoid rather than what to follow. But in one sense he will do well to avoid that which is technically good. What we mean is that at all these exhibitions there is a plethora of simple landscape, portrait, and latterly a large number of "instantaneous studies," as they are called, added to which will be a goodly number of snap-shots due to hand-cameras. These subjects are getting tiresome by reason of their monotony. Can we not look around and find some description of subject which is not photographed quite so often? Our search will not be a very protracted one, for we soon see that flowers have been almost wholly neglected by photographers, while at the same time they offer a wide field for successful work.

It may at once be conceded that flowers, although coming under the head of still life, are not easy things to photograph. First we have the colour difficulty. This has been surmounted to a great extent by using colour-sensitive plates; and even when such plates are not procurable, the colour difficulty can be made to disappear almost entirely by use of a yellow screen and ordinary plates, taking care to stop down the lens and to give a very liberal exposure. Another difficulty, and a serious one, is the impossibility of getting the flowers into one plane, particularly when the subject photographed is actually growing. There are sure to be some vagrant stems which will insist upon thrusting themselves too near to or too far from the lens. Such wanderers from the right path can often be secured by black threads, which are quite invisible in the picture. Indeed, in photographing such flowers as orchids *in situ* in their glass house, it becomes absolutely necessary to be armed with black thread, hammer, and tacks, so that the long stems of the plants may be brought under some kind of subjection.

Cut flowers in vases make most beautiful pictures, as Mr. Stevens, who has won so many medals for such studies, has long ago proved to everybody. But in this case the flowers are, of course, under the control of the photographer, and he can get contrast of light and shade, as well as of position, without any hindrance. The same remark applies to bouquets, when the photographer is occasionally asked to take a picture of a bride's bouquet after he has photographed a wedding party. Such a bunch of flowers can be presented towards the lens, and the subject will be comparatively in the same plane.

If it is wished to arrange cut flowers otherwise than in a bouquet, or a vase, there is some difficulty in supporting them in a manner which is effective. An American writer some time ago suggested that they should be laid on a flat surface—upon a suitable background—and photographed from above. We consider that this method gives a somewhat unnatural result, for there is some difficulty in preventing the shadows cast by the leaves being unduly heavy. Some time ago we devised a plan of arranging flowers for photography by which excellent results may be achieved, but it involves some little trouble in the arrangement of the apparatus. It permits of the most delicate forms being supported without casting any shadows whatever, and the effects produced are extremely graceful and fairy-like. The necessary stand for the camera can be knocked together by anyone who can handle a hammer, and the expense is trifling.

The stand referred to was made of an old camera tripod, with the head removed, and a triangular piece of pine with a two-inch hole bored in its centre, substituted for it. Upon this board, the camera is placed face downwards, with its lens projecting through the hole. The legs of the tripod are conveniently shortened, so that the image of the flowers can be focussed without using a pair of steps. Midway between the floor and the camera, a sheet of window glass is supported by means of cords stretching from leg to leg, or the glass may be made to rest upon screws temporarily placed upon the legs. Upon this sheet of glass the flowers are arranged in whatever manner the taste of the operator may suggest. A plain background of any description may be placed a couple of feet below, simply resting on the floor. Its condition and general appearance is not a matter of much moment, for it will be out of focus. The lens which we used in the experiment was a portable symmetrical—stopped down—and, with the help of a yellow screen, and a very long exposure, we were able to get some very fine results.

It may be mentioned that this method of supporting objects during exposure is most useful for other objects besides flowers. When a number of small articles—such as coins, geological specimens, or shells—have to be photographed it is most convenient. They have simply to be laid in position, and there they remain, without any aid from cement, pins, or any of the supports which have to be called into requisition when such objects are photographed against a vertical background. We trust that those of our readers who will care to construct the very simple appliance here described will derive as much benefit from it as we have. As far as we know, the idea is original with us; but, in these days of universal photography, it is quite possible that we may have been forestalled.

Mr. Lowes Dickinson, who was associated with Charles Kingsley, F. D. Maurice, Rosetti, Mr. Ruskin, and Dr. Furnivall in the conduct of the Working Men's College in its early days, has an an extraordinary faculty for painting the portraits of deceased persons, even if he has never seen them, from photographs, the descriptions of friends, and from the study and observation of surviving relatives. His portrait of Gordon was a remarkable example.—*Star.*

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Mignon Paper—Intensifying Process for Prints—Enamelling Albumen Prints—Reactions of Developers—Printing with Flat Negatives.

*Mignon Paper.*—A new gelatino-chloride printing-out paper, known as "Miguon Paper," which is manufactured by a firm in South Germany, has found a great number of adherents within the comparatively short time of its existence. It gives prints very similar to platinotypes, of a very fine velvet-black tone, and the paper is, therefore, recommeuded by some practicians as a substitute for platinotype paper. It is, perhaps, a little more sensitive than albumen paper, but its treatment during printing is the same as with the latter. After printing, the paper is washed for about ten to fifteen minutes iu two or three changes of water, aud then toned in a specially prepared sulpho-cyanide of gold bath containing one gramme of gold chloride to each 100 c.c. of the liquid. This toning bath is furnished in two separate solutions (No. 1 and No. 2), of which equal parts are mixed, and diluted with distilled water. To toue twenty cabinets, 10 c.c. of Solution 1 are mixed with 10 c.c. of Solution 2, and the mixture diluted with 1,000 c.c. of water. The prints are toned until the half tones appear ash-grey, and the deepest shadows will no longer show a reddish colour by transmitted light. In this bath sulpho-cyanide of silver is formed by substitution, which adheres to the prints in the form of a slight veil; the latter is, however, quickly and completely removed in the subsequent fixiug bath, consisting of a ten per cent. solution of hypo. After about ten minutes the prints are removed, and thoroughly washed in clean water. Finally, they are placed in a bath consisting of 5 grammes of ammouia alum iu 100 c.c. of hot water, which bath should be cooled before use. After this hardening process the prints are again well washed, and then dried. In order to impart to them a fine matt surface, they should be squeezed on to a finely-ground glass plate. The whole process is very similar to the ordinary gelatino-chloride printing-out process, and, in my experience, quite the same beautiful platinotype-like effects may be obtained with Liesegang's aristo paper if treated in the same way.

*Intensifying Process for Prints.*—The new printing process which has been used by Max Lautner in his book, "Who is Rembrandt?" in order to increase the contrasts of the shades in the photographs of old oil paintings, has already been described in these pages on a previous occasion. As will be remembered, it consisted essentially in printing one and the same thin film negative twice on gelatino-chloride paper, firstly as usual, and then inversely from the back of the paper. Referring to this process, Dr. Stolze recommends another method, by which the contrasts or the intensity of the picture may not only be doubled, but increased about five times. It consists in the following: The negative is printed with short exposure on bromide paper, and developed with eikonogen as hard as possible, so that the lights remain quite clear. The print is then fixed and very thoroughly washed, and then bleached in a solutiou of bromide of copper. Finally, it is again washed very thoroughly and re-developed with eikonogen.

*Enamelling Albumen Prints.*—According to the *Photographische Archiv*, a highly glossy surface may be imparted to albumen prints without the use of gelatine in the following way. Equal parts of ox-gall and of alcohol are mixed, and the mixture is allowed to stand for several days with occasional violent shaking. A glass plate is coated with it evenly, and the albumen print, as it comes off the washing water, is placed on it, and allowed to remain on it for about one hour under pressure. As soon as it is dry, it will come off with a beautifully glossy surface.

*Reactions of some of the Photographic Developers.*—In the same journal, Dr. Schnauss publishes a series of experiments he has made in order to analyse the ready-prepared solutions of hydroquinone, eikonogen, pyrogallic acid, and hydroxylamine. The author states that the most characteristic reactions took place with iodine, bromine, and acetate of copper. If a few drops of the latter are added to a solution of eikonogen, its blue colour is converted into green; if added to hydroquinone solution, the cupric solution acquires a yellow colour, both remaining clear; whilst, if added to hydroxylamine, the cupric solution discolours. Very curious is the reaction in the case of a solution of pyrogallic acid, which at once produces a greyish-black precipitate by the addition of the cupric solution. With iodine, as well as with bromine, the hydroquinone and the eikonogen solution combines to a beautiful crystallising body. Iodo- and bromo-hydroquinone are constant and will keep, whilst the crystals of eikonogen melt in the air and are decomposed. If to a strong solution of hydroquinone a few drops of strong bromine water are added with shaking, the colour and the odour of the latter disappear, apparently black, metallic shining crystal needles being deposited. If the alcoholic solution of this combination is left to spontaneous evaporation in a flat dish, magnificent golden shining needles of more than one centimetre in length are produced, which appear brownish-red by transmitted light. The combination of iodine with hydroquinone shows quite an analogous behaviour; in water the two combinations are hardly soluble. If to a strong solution of eikonogen a small quantity of iodine tincture is added, a precipitate of white crystalline needles is soon produced, which are badly soluble, even in boiling water and in alcohol, and which soon decompose in the air, as mentioned above. The combination of eikonogen with bromine is more readily soluble in water, but it also decomposes soon. The author then describes the action of these combinations upon the exposed gelatino-bromide film. Bromo-hydroquinone and bromo-eikonogen darkened the film not at all, nor was a discolouring of the film to be observed in the case of pyrogallic acid, to which bromine was added. Hydroxylamine mixed with bromine darkened the film very slightly, with considerable deliverance of ammonia, which probably caused the discolouration. If a strong solution of pyrogallic acid was mixed with bromine water, the mixture acquired at first a dark yellow colour, and its odour disappeared, and finally its colour also disappeared almost entirely. For the above-described experiments pure hydroquinone was used; but the so-colled permanent hydroquinone manufactured by Dr. Byk showed the same behaviour. The eikonogen used was that manufactured by Dr. Andresen, in the powdery state.

*Printing with Flat Negatives.*—In order to obtain vigorous prints from thin and flat negatives, Wilh. Schleifer, a distinguished amateur photographer, proceeds as follows. During printing, a light green coloured glass plate is placed over the printing frame, in which, beneath the thin negative, a gelatine plate of low sensitiveness has been placed. The plate is exposed by candle-light for about five minutes at a distance of forty inches, and developed in an already-used solution of the following developer:—

| | |
|---|---|
| Hydroquinone ... ... ... ... | 1 gramme |
| Soda ... ... ... ... ... | 4 grammes |
| Sodium sulphite ... ... ... ... | 5 „ |
| Water ... ... ... ... ... | 200 c.c. |
| Salicylic acid ... ... ... ... | 0·5 gramme |

The first traces of the image should come out after from fifty to sixty seconds; if they come out sooner, the developer was too energetic, and it must be diluted. After the lapse of one minute, the plate is placed in a more concentrated developer—

| | |
|---|---|
| Hydroquinone ... ... ... ... | 1 gramme |
| Soda ... ... ... ... .. | 4 grammes |
| Sodium sulphite ... ... ... ... | 5 „ |
| Water ... ... ... ... ... | 100 c.c. |
| Salicylic acid ... ... ... ... | 0·5 gramme |

in which the plate will gain contrasts and density. The plate is developed until the image is faintly visible from the back of the plate, when it should be carefully washed, placed for five minutes in an alum bath 1 : 10, and fixed in a solution of hypo 1 : 8. After the diapositive has been washed thoroughly, a negative is taken from it in the same way, only with longer exposure, about from five to eight minutes being given this time, according to the density of the diapositive. From the negative thus obtained a print is taken on gelatino-chloride paper, using again a light green glass plate during printing. The print, which should be printed very deeply, is washed, toned, treated with alum solution, and fixed in a freshly-prepared fixing solution. If a suitable green glass plate cannot be obtained, it may be prepared by coating a clean glass plate with a warm gelatine solution 1 : 10, allowing it to set, hardening it with alum solution, and placing it in a solution of methyl-green 1 : 10. After drying, the colour should be removed from the non-prepared side of the plate with hot water.

## HAND-CAMERA WORK.

BY XANTHUS SMITH.

Just at this season, when so much use is being made of the small hand or so-called detective cameras, a few hints in regard to their use may not be out of place.

A good detective-camera worker should be like a good soldier or sportsman—always cool and deliberate. He should not throw away his ammunition. I am inclined to think that there are full as many failures of the mark in hand-camera shooting, taking it collectively, as there are in a battle where the majority engaged are raw recruits —that is, if the mark aimed at in working with the camera is the securing of fairly good pictures.

It should be the first business of the aspirant to success with a hand-camera to consider carefully what is really his aim in its use. Of course, in its first form, as a nearly entirely concealed instrument, and when used—as its name implies—solely for detective purposes, it makes little or no difference whether the results of the exposures are pictures or not, so that a good, clear likeness is obtained of the parties sought; but, as the amount of genuine detective work is small indeed compared with that of viewing generally, and as more than half the hand-cameras used do not conceal the object for which they are used, it should be a matter of importance that the user classify the work to be done under different heads, and be prepared with some knowledge of what constitutes an attractive photograph.

After objects in motion, which constitute the most important work of the hand-camera, comes the getting of picturesque or interesting subjects which are so situated that the setting up of a tripod and making a time exposure is inadmissible—such being buildings and character groups in towns and cities, and water views. Of course the former are much the most difficult subjects to manage, for, in addition to the necessary perfection of the instrument, there is the always troublesome matter of choosing a point which will give the best background, the best lighting, the right distance, and, above all, the instant when the best movement is to be had. All those views that come under the head of sporting views—such as the race-course and athletic ground furnish—should be relegated to those familiar with what is sought, as they will in every way be the best qualified to secure what will be the best understood and most acceptable to those interested in such matters.

To the large class—chiefly travellers—who are anxious to make the most agreeable pictures, we would chiefly address our remarks. Their aim should be to look out for the most characteristic living groups, buildings of historical interest or remarkable for their beauty or picturesqueness, and picturesque and agreeable water scenes and landscapes. Do not shoot away indiscriminately at anything and everything. It is an absolute waste of time and material.

In the landscape and architectural views, choose a good lighting, if you can, or let them alone, not only for your own credit, but for the credit of the scene. The light falling directly as you look will not give sufficient contrast and effect; and, as instantaneous views are likely always to be under-timed in the shadows at best, do not look towards the light, or you will have a black, patchy, heavy picture.

In taking groups, especially of figures and animals, always think of what is back of them. It is the most difficult thing under the sun to get good, quiet backgrounds, especially in street scenes; and we are generally so absorbed in what we are immediately aiming at that we seldom ever think of what is back of it until our picture reveals the whole to us as a confused jumble, often absurd in its queer light and dark spots. If we perceive that a fine group is going to be swallowed up in this way by patches of black shadow in doors and windows, and streaks of white in walls and facings and awnings and awning posts, we had better let it alone.

In landscape and river work for shipping, especially the latter, it will be found of advantage to work where there is a great deal of atmosphere (murkiness or fogginess), as we will secure better perspective in the former, and quieter backgrounds for our groups of vessels in the latter. When you find that objects along a shore a half mile off are going to be stuck fast to your boats, let the whole business alone. In the real scene, the eye easily separates the distance from what is in the foreground, but cannot in the little photograph, the eyes necessarily being focussed for all on the same plane.

For a great deal of hand-camera work there is no reason why as much care in selection of subjects, and in securing proper effects of light and shadow, should not be given as in taking views with a camera set upon a tripod; and if such care were bestowed there would be far less waste of films and plates, and a much greater proportion of amateur photographers whose work would be a genuine gratification when shown to their friends, and a source of happiness to themselves.—*American Journal of Photography.*

## THE ALBUMEN PROCESS.

BY P. C. DUCHOCHOIS.

| | |
|---|---|
| Honey ... | 2 grams |
| Ammonium iodide ... | 0·8 gram |
| Ammonium bromide ... | 0·6 ,, |
| Iodine ... | 0·1 ,, |
| Albumen (whites of eggs) ... | 100 c.c. |
| Water (distilled) ... | 10 ,, |

Grind together the honey, iodide, bromide, and iodine with the water, add the albumen, and beat the whole to a solid froth. Let settle for ten or twelve hours, then decant the clear liquid for use.

Honey is added not to increase the sensitiveness of the photo-film, on which it has little action, but to prevent the crystallisation of the haloid salts resulting from the desiccation of the albumen, which retains no water, becomes hard and without elasticity, and then cracks, forming a multitude of small fissures. Even, for this reason, we often added two drops of glycerine to the above quantity of albumen.

The glass plates should be cleaned with extra care and well dusted before coating. It may seem strange that such a direction should be given to the readers of the *Bulletin*, for clean plates and no dust is a *sine quâ non* in all the photographic processes, but in this one it has still a greater importance on account of the thinness of the film and the purposes for which the process is now occasionally employed. In fact, to effectually exclude dust, the operating room should be swept, dusted, then sprinkled at least one hour before albumenising and gelatinising.

To coat the plates, procure a pneumatic holder, or, in lieu, a round wooden stem about 20 cm. long by 5 or 6 cm. in diameter, cut at one end in the form of a cup 2 cm. deep with a rim about 1 cm. broad. On the rim gutta-percha is melted and spread, which, for use, is softened over an alcohol lamp in order to fix the plate upon it.

The plate, being firmly fixed on one of these holders, is wetted under the tap, drained, and when still damp, it is coated twice over, in opposite directions, with the albumen solution. This done, drain well off the excess of albumen by one corner, tilt the plate to bring the albumen to the opposite corner, and back without a stop to the middle of the plate, then gently roll the stem between the hands to equalise the liquid on the whole surface, and the liquid accumulated at the edges being wiped off, let the plate dry spontaneously in a box made *ad hoc*, into which it is placed on levelled shelves. The plate can also be dried on an iron level stand by heating it with an alcohol lamp, care being taken not to coagulate the albumen. Some authors advise for the same purpose an iron plate heated to not over 50° to 55° C., upon which a number of plates can be dried at a time. At 65° C. albumen commences to coagulate.

We compound the silver bath thus :—

| | |
|---|---|
| Silver nitrate ... | 8 grams |
| Zinc nitrate ... | 3 ,, |
| Glacial acetic acid ... | 2 c.c. |
| Water ... | 100 ,, |

To sensitise, pour in a porcelain tray longer than the albumenised plate a certain quantity of silver solution, raise it to bring all the liquid at one end, place the plate on the upper end, then, in one move, lower the dish so that the whole plate be flooded at once. In this manner, stains from scums and transparent lines from stops when the plate is sensitised by dipping, are avoided. From twenty to thirty seconds are sufficient to coagulate the albumen, and transform the iodide and bromide of ammonium into silver compounds.

On their removal from the silver solution, the plates are washed moderately, in order not to entirely eliminate the silver nitrate in excess from the photo-film; a wash in water twice renewed, then rinsing rapidly, is sufficient. In that state the sensitive film keeps for about a week. If wanted to keep for a longer period, the washing should be done more thoroughly, and a preservative flowed over the albumen just after washing and draining. The preservative known as gum-gallic used in the collodion dry process answers well. We compound it as follows:—

| | |
|---|---|
| Gallic acid ... ... ... ... ... | 5 parts |
| Ammonium bromide... ... ... ... | 0·1 part |
| Gum arabic (best) ... ... ... ... | 5 parts |
| White sugar ... ... ... ... ... | 2 „ |
| Water ... ... ... ... ... ... | 480 „ |

Dissolve and filter before use.

The albumen photo-film is little sensitive to light, and therefore one should expose for a long time to obtain a developable image. The cause of this, which, in the old time, we thought due to the influence of the vehicle, is now easily explained by that which produces the various degrees of sensitiveness of silver bromide, that is, the different states of agglomeration into grains of the molecules of the silver haloid, which, of course, can occur only in a liquid and in certain circumstances, such, for example, as the cooking in the preparation of gelatine emulsions.

In a collodion film, the granulation is hardly apparent, but exists nevertheless; while in an albumen film, the transformation of the alkaline haloid into a silver salt taking place in a solid substance, the molecules of the new compound remain in a state of extreme division, and little sensitive to the luminous influence, as shown by Stas. No granulation is visible in an albumen photo-film examined by the microscope. This explains the incomparable sharpness of the images photographed by the process, and, as above said, the necessity of very long exposures.*

The development is effected by a physical or a chemical (alkaline) developer. The latter permits, as usual, to reduce by half at least the time of exposure, but, owing to the thinness of the silver film, and specially to the silver iodide, on which the alkaline reagent has but little action, the image remains weak, and one must, consequently, continue the development with the physical developer to obtain intensity.

The chemical developer consists of—

| | |
|---|---|
| A.—Sodium sulphite cryst. ... ... ... | 20 parts |
| Pyrogallol ... ... ... ... ... | 5 „ |
| Potassium bromide ... ... ... | 0·5 part |
| Water ... ... ... ... ... | 480 parts |
| B.—Sodium carbonate... ... ... ... | 20 parts |
| Water ... ... ... ... ... | 480 „ |
| or— | |
| Ammonium sesquicarbonate ... ... | 10 parts |
| Water ... ... ... ... ... | 480 „ |

For use, equal volumes, adding B gradually.

When the image is visible in all its parts, the film is rinsed under the tap, then flowed with the following solution:—

| | |
|---|---|
| Pyrogallol ... ... ... ... ... | 1½ part |
| Citric acid ... ... ... ... ... | 1 „ |
| Water ... ... ... ... ... ... | 480 parts |

which first neutralises the alkalinity of the film, and when a few drops of a 5 per 100 solution of silver nitrate are added, progressively develops the image to the proper general intensity.

* Compared to gelatine plate, sens. 20, the time of exposure is about as 120 to 1.

The diapositives are printed by contact, and developed as ordinarily, the negatives by a physical developer, compounded with gallic acid, pyrogallol, or a mixture of these two reagents. Gallic acid gives a greenish reduction, excellent for negatives, and not very objectionable for diapositives used for projections. Pyrogallol gives ordinarily a red reduction, or occasionally a red purple reduction. The developing solution should be acidified by citric or tartaric acid. A mixture of gallic acid and pyrogallol gives generally a brown reduction. These different allotropic forms of metallic silver are very curious. The red reduction is toned with difficulty by gold, platinum, or palladium chlorides.

Gallic Acid Developer.

| | |
|---|---|
| Calcium acetate* ... ... ... ... | 3 parts |
| Water ... ... ... ... ... ... | 480 „ |
| Gallic acid ... ... ... | To saturation (C. Laborde) |

This developer is employed at the temperature of 60° C.

Pyrogallol Developer.

| | |
|---|---|
| Pyrogallol ... ... ... ... ... | 3 parts |
| Citric acid ... ... ... ... ... | 1 part |
| Water ... ... ... ... ... ... | 480 parts |

Employed at the temperature of 35° to 40° C.

Mixed Developer.

| | |
|---|---|
| Gallic acid ... ... ... ... ... | 3 parts |
| Pyrogallol ... ... ... ... ... | 1 part |
| Acetic acid No. 8 ... ... ... .. | 30 parts |
| Water ... ... ... ... ... ... | 480 „ |

Employed at the temperature of 50° C.

Heating the developer has for its object the accelerating of development in order to force the details out. It is not necessary when developing diapositives.

To develop, the plate is flowed with the selected developer, which is allowed to act for a minute or so, then a little of a solution of silver nitrate (5.100) is added, when the development proceeds regularly. The silver nitrate should be added by degrees, and not much of it must be employed, for then the blacks would intensify too rapidly, and a harsh picture obtained.

The proofs are fixed in a solution of sodium thiosulphate (hyposulphite) at 8 or 10 per 100 of water. The toning presents some difficulties. The process by which were toned the admirable diapositives of Ferrier, Soulé, and recently those of Mr. Lévy, is a secret which has been well kept since nearly forty years. Some operators tone by sulphuration, either by fixing in an acid bath, or treating the proofs with a very diluted solution of ammonium sulphide. These processes, which succeed well with collodion diapositives, generally tinge yellow those on albumen films.

In our practice we operated in the following manner:—The diapositive, developed and well washed, is treated by a weak solution of mercuric chloride until uniformly blackened, stopping the chemical action when the reduction commences to bleach. The plate is then washed and fixed in the following solution, where the colour generally assumes a bluish black:—

| | |
|---|---|
| A.—Sodium thiosulphate ... ... | 8 parts |
| Water ... ... ... ... | 360 „ |
| B.—Auric chloride ... ... ... | 0·5 part |
| Water ... ... ... ... | 120 parts |

Mix, little by little, B to A, *not the reverse.*

We have now at our disposal many processes to tone before and after fixing. They are too well known by the readers of the *Bulletin* to be mentioned in this paper.

* Calcium acetate acts as an accelerator. It can be discarded when developing diapositives.

## PHOTOGRAPHIC CHEMISTRY.*

BY PROFESSOR R. MELDOLA, F.R.S.

The general considerations which have been offered apply to the special subject of photography with full force. A person may become an adept as an operator without knowing anything of physics or chemistry; there are thousands of photographers all over the country, who can manipulate a camera and develop and print pictures with admirable dexterity, who are in this position. If we adopt the narrow definition of technical instruction, we should appoint such experts in our colleges, and through them impart the art of taking pictures to thousands of others. But would our position as a photographing nation be improved by this process? I venture to think not. We might be carrying out the ideas of certain technical educators by adopting this method, but I do not imagine that in the long run the subject itself would be much advanced; our position in the scale of industry would not be materially raised by the wholesale manufacture of skilful operators. And so with all other branches of applied chemistry; it is technologists whose knowledge is based on a broad foundation that are wanted for the improvement of our industries. These are the men which are raised in the technical high schools of the Continent, and whose training the continental industries have had the wisdom to avail themselves of.

To become a photographic technologist, as distinguished from a photographer, it is desirable, therefore, that the student should have received instruction in the general elementary principles of physics and inorganic and organic chemistry. When thus prepared, he may begin to specialise his studies, and the real technical training will be commenced. The application of chemistry to photography will naturally divide itself into two branches; the chemistry of the materials used in the art, and the theory of the chemical changes occurring in photographic processes. With respect to the chemistry of photographic materials, time will not admit of any attempt to draw up a complete code of instruction. Nor is this necessary on the present occasion, for the requirements will be met by the simple statement that this branch of the subject should be an extension of the ordinary chemical training, with special reference to the preparation, properties, and reactions of the compounds which the student is most likely to have to deal with in photography.

Since the compounds of silver are by far the most important of photographic chemicals, it will be advisable to commence with these. After the study of the ordinary qualitative reactions of this metal, the student should be well practised in the quantitative estimation, both gravimetrically and volumetrically, so that the value of commercial silver nitrate may be ascertained with precision. The reducing action of fused sodium carbonate, of zinc and acid, and of alkaline solutions of glucoses on the silver haloids, can be made the basis of practical exercises in the recovery of silver from residues. It is desirable also to point out, and to illustrate by experiment, that silver is displaced from the solution of its salts by the more electro-positive elements—hydrogen, copper, mercury, iron, zinc, lead, and so forth. It is important also to demonstrate that silver is more electro-positive than gold and platinum, and displaces these metals from solutions of their salts.

In illustrating such points in the chemical history of silver as those referred to, and, in fact, in all practical work leading from ordinary chemistry to photographic chemistry, it will be found advantageous to adopt the general principle of performing the experiments, whenever practicable, both in glass vessels and on films. This method is admirably adapted to lead the student from the general science to its special application to his subject. For example, having shown that the salts of silver are reduced by such reducing agents as alkaline pyrogallol, ferrous sulphate, &c., in test tubes, and having allowed the experimenter to convince himself that the precipitate in these cases is really metallic silver, the production of a film of the metal may be shown by taking a sheet of paper coated with silver nitrate, and, when dry, painting stripes of ferrous sulphate solution on the coated surface. On washing out the excess of nitrate from the unreduced portions, it will then be realised that the dark stripes consist of finely-divided silver on a paper surface. With these silver films many instructive demonstrations can be given. Thus, the fact that silver displaces gold and platinum from solutions of the salts of these metals may be shown by passing the paper through a bath of platinic or auric chloride, when the silver stripe undergoes a change of colour, indicating the replacement of that metal by gold or platinum. A comparison of the strip thus treated with a portion of the original strip—by treating both with nitric acid—clearly proves that the platinised stripe has lost its solubility in that acid. The application of this principle to toning and intensification will naturally follow when photographic processes are being dealt with.

While demonstrating the reducibility of silver salts by such reagents as ferrous salts, &c., it must be strongly urged that reduction of the silver salt is accompanied by a corresponding oxidation of the reducing agent. This fact will be made apparent by the chemical equations; but it is important that the student should verify it experimentally. Many ways of doing this will suggest themselves, but it will be sufficient if I give one appropriate example. Every student may be assumed to be familiar with the different behaviour of ferrous and ferric salts towards potassium ferrocyanide. Now, on adding a solution of ferrous sulphate to a solution of silver nitrate we get a precipitate of silver, indicating the reduction of a silver salt. That a simultaneous oxidation of the ferrous salt takes place is proved by filtering off the silver and adding ferrocyanide to the solution, when Prussian blue is at once formed.

The precipitation of finely-divided silver may be made use of to illustrate some of the more obscure phenomena with which the photographic chemist is frequently confronted. It may be well at this stage to broach the idea that photographic chemistry, like all other branches of applied chemistry, does not begin and end with a series of reactions which can be written down in the form of equations. This mode of treating the subject may be academic, but it is not technical. It is believed by many experimenters that silver is capable of existing in several different conditions of physical aggregation according to the manner in which it is precipitated from its solutions. Thus the deposit obtained by adding ferrous sulphate to a solution of silver nitrate is grey; the product obtained by reducing silver solutions with organic ferrous salts is darker in colour.* It is possible that the difference of colour in these cases may be due, as suggested, to the differences of molecular aggregation. The rate of reduction may have something to do with it, and the well-known coloured forms of precipitated gold, studied by Faraday, may be referred to in this connection.

But, on the other hand, there is another possibility which must be borne in mind, and well emphasised in dealing with photographic chemistry. I allude to the tendency which silver and its compounds possess, in common with many other metals, of bringing down and retaining traces of foreign substances, in whose presence the metal or its compounds may be precipitated. This kind of combination is not sufficiently recognised by orthodox chemistry, because it does not take place in definite proportions, but there are many branches of applied chemistry where this so-called molecular combination plays a very important part. The practical outcome of these considerations is that the student of photographic chemistry cannot be too early prepared for the occurrence of indefinite combination, and he must not be allowed to suppose that, because a distinct formula cannot be ascribed to such compounds, that they are outside the pale of chemical science. I have thought it necessary to utter this caution, because in the present state of knowledge we must not commit ourselves to dogmatic assertions about allotropic modifications of silver. It may be that the different colours of reduced silver are due to the retention of "traces" of some foreign substance.

The haloid salts of silver will, of course, demand a considerable share of attention from the photographic chemist. The preparation and properties of these compounds should be

* Abstract of Cantor Lectures, continued from page 629.

* Pyrogallol will reduce silver nitrate in neutral or slightly acid solutions. It is not necessary to add alkali to show this reduction; the solution may be distinctly acid with acetic acid.

studied in detail; their solubility in well-known reagents, such as ammonia, potassium cyanide, and sodium thiosulphate, should be made the subject of practical exercises, and the chemical changes undergone can be made readily intelligible to the student whose elementary training has reached the necessary stage of efficiency. It will add to the thoroughness of the instruction if the student is made to realise that the statement that the silver haloid is soluble or insoluble in such or such a reagent is by itself inadequate; he must understand that solubility means the formation of a new compound which is more soluble than the original haloid. Thus, the absorption of ammonia by silver chloride can readily be shown by putting some of the dry haloid into a tube, weighing, and then passing dry ammonia gas till there is no further increase in weight. Then, again, silver chloride may be dissolved in strong ammonia, and the solution allowed to stand till the crystals of the ammonio-silver chloride separate. The preparation of the soluble silver sodium thiosulphate, by the method of Lenz,* is a good practical exercise, and the study of the salt will help to make clear why the silver haloids are dissolved by the thiosulphate. It is necessary to point out that by the same reagent three† distinct products may be obtained:—

1. Silver thiosulphate, $Ag_2S_2O_3$, by adding a solution of sodium thiosulphate to a solution of a silver salt, keeping the latter in excess. This is a white insoluble salt, which soon darkens by the formation of the sulphide:—$Ag_2S_2O_3 + H_2O = Ag_2S + H_2SO_4$.

2. The insoluble double salt $Ag_2Na_2(S_2O_3)_2$, formed by adding silver nitrate solution to a solution of sodium thiosulphate till a permanent precipitate is formed. The product is dark-coloured, and probably contains sulphide; it gradually becomes darker on standing, owing to decomposition with the production of sulphide.

3. The soluble double salt $Ag_2Na_4(S_2O_3)_3$, formed by the action of excess of sodium thiosulphate upon the last salt, or by adding a silver salt to a strong solution of the thiosulphate, keeping the latter in excess. In the solid condition this is a white crystalline salt, readily soluble in water, and much less prone to decompose into sulphide than the preceding salt.

Among other properties of the silver haloids to which attention may be directed are their decompositions by various haloid acids and salts. This information cannot but be of the greatest use in practical photography. I have summarised the facts in the form of a table.‡

The haloid salts of the alkaline metals and of ammonia, especially when in concentrated solutions, dissolve more or less of the silver haloid, with or without decomposition. The silver haloid is thrown out again either in an unaltered state, or transformed into another haloid by decomposition on diluting the solution with water. The solubility of the silver haloids in solutions of other salts is a feature in their chemical history which the photographic chemist will find it useful to be put in possession of. Thus, these haloids are to some extent soluble, and especially the iodide, in strong solutions of silver nitrate. It must be pointed out that in all cases where a silver haloid is dissolved by another salt, a double salt is probably formed.

The study of the forms of reduced silver will have prepared the way far taking into consideration the state of molecular aggregation of a substance as influencing its characters. The silver haloids should be dealt with from this point of view, both on account of the importance of bringing into prominence the factor of physical condition, and because of the possible practical bearing of the subject in connection with the preparation of sensitive emulsions. According to the mode of preparation of the haloid, such important characters as solubility, reducibility, optical absorption and colour, and photographic sensitiveness, are capable of being influenced. Thus, the state of concentration of a solution of silver nitrate, from which the chloride is precipitated by hydrochloric acid, appears to influence the solubility of the chloride in the acid. It is possible that this is due to the different forms of the chloride under these conditions. By dropping a solution of silver nitrate into strong hydrochloric acid, a considerable quantity of the chloride is dissolved. The chloride, prepared in the ordinary way, by precipitation from silver nitrate and a soluble chloride, after being washed and dried, is certainly not soluble in hydrochloric acid to the same extent. Here, again, it is possible that precipitation in the presence of strong hydrochloric acid gives no time for the molecular condensation of $(AgCl)$ to $(AgCl)_{nx}$, and that the former of these aggregates is more soluble than the latter.

I have called attention to this feature in the chemical history of the silver haloids because, in the present condition of practical photography, no student should be allowed to neglect this all-important subject. How far Stas's classification of the forms of silver bromide and chloride will stand the test of further investigation is at present doubtful. Some experimenters recognise only two modifications, and others three; while Stas himself recognises four, viz.:—

1. Flocculent, white or yellow. Produced by the addition of a solution of a soluble bromide or hydrobromic acid to a solution of silver nitrate in the cold. Both solutions must be dilute (0·5 to 1 per cent.); if the silver is in excess, the bromide is white; if the soluble bromide is in excess, the precipitate is yellow.

2. Pulverulent; obtained from the preceding modification by brisk agitation with water. This form is produced more rapidly in neutral than in alkaline solutions. It is described as a yellowish-white powder, which, when dry, becomes intensely yellow on heating.

3. Granular; produced by adding a very dilute boiling solution of ammonium bromide to a boiling solution of silver nitrate containing $\frac{1}{10}$ per cent. of this salt. Obtained also by the action of boiling water on the preceding modifications, the first (flocculent) giving a dull yellowish white, and the second (pulverulent) giving a bright, yellowish-white powder. By prolonged boiling with water, the granular modification gradually becomes sub-divided, and, after several days' boiling, forms a kind of milky emulsion, from which the bromide settles out very slowly. The precipitate which then subsides is pearly white, becoming intensely yellow on agitation with a strong solution of ammonium bromide.

4. Crystalline, or fused; obtained by fusing any of the other forms. This modification is never employed in photographic operations.

Among other points in the chemical history of the silver haloids which are of photographic importance, the relative reducibility claims special notice. In the earlier part of his practical work, the student will have obtained metallic silver from the haloids by reduction, but he must now be made to realise that this reduction is more readily effected in the case of the chloride than the bromide, and more readily in the case of the latter than with the iodide. And first of all, in order that the true chemical significance of reduction may be made intelligible, let a simple demonstration be given showing that, by the action of reducing agents, such as ammonium pyrogallate, potassio-ferrous oxalate, &c., the halogen is actually withdrawn from the silver, and is to be found in the solution by the usual tests. Then, in order to show that the chloride is more reducible than the bromide or iodide, a solution of potassio-ferrous oxalate may be diluted till it becomes just too feeble to reduce the bromide. Some of the same solution will be found to reduce the chloride readily. Adopting the usual course, and passing from test-tubes to films, sheets of paper coated with the three silver haloids may be streaked with the same solution of ferrous oxalate or ammonium pyrogallate, when the order of reducibility will be shown by the fact that the chloride gives a darker stripe than the bromide, and the latter a darker stripe than the iodide.

*(To be continued.)*

* A solution of silver nitrate is added, drop by drop, to a strong solution of sodium thiosulphate till a permanent precipitate (the insoluble double salt) just begins to appear. The solution is filtered, and alcohol added till the white crystalline (soluble) double salt separates out.

† There are probably many more double thiosulphates of silver and sodium, and even this series of salts requires further investigation. Thus, Mr. C. H. Bothamley informs me that by mixing 4 $AgNO_3$ with 5 $Na_2S_2O_3$ and adding alcohol, he obtained a white precipitate in which the ratio Ag : S was 1 : 1·961. The ratio calculated for $AgNaS_2O_3$ is 1 : 1·683. This salt is *soluble* and stable. By the action of 3 $Na_2S_2O_3$ on Ag Br and fractional crystallisation, he has isolated two crops of crystals corresponding with the formula $Ag_2S_2O_3, 3\,Na_2S_2O_3 = Ag_2Na_6(S_2O_3)_4$.

‡ See Photographic News, p. 213.

## Notes.

When writers who are not photographers give advice upon matters photographic, it is astonishing into what absurdities they are apt to lead their unfortunate readers. In a New York paper we find the suggestion that photographers who have a difficulty in determining how a view will look when photographed should carry with them a number of ferrotype plates, so as to use one in such a case and thus save weight of glass for trial plates. We fancy that for the average photographer the working of one process is quite sufficient, without the encumbrance involved in the necessary impedimenta for two. The writer in question has evidently never heard of films or roll-holders, else he would know that the ferrotype is not the lightest thing which a photographer can carry.

---

It is a curious but useful feature of photographic literature that the old processes are now and again trotted out and their virtues extolled, presumably for the benefit of those who came in with gelatine. We have lately noted several enquiries and notes with regard to the old collodio-albumen process, not, of course, for negative work, but for the production of lantern slides. We are not sorry to see this, for the old process is one of the best that can be adopted for that particular purpose. Any amount of density can be obtained, the lights are as clear as the clearest glass, and the image in so hard and permanent that no varnishing is necessary, and hardly anything can injure it. Its one disadvantage is that the slides must be made by contact, for it is far too slow for camera work. There are one or two professional workers—and we believe only one or two—who still hold to this method of producing slides, and they always are busy.

---

A contemporary gives a long list of methods by which a glass stopper which has become fixed in the neck of a bottle may be loosened, but strangely enough the best way of all—at least, so we have found it in our own practice—is omitted. The plan we refer to is to wet a cloth in very hot water, hastily wring it, and to wind it quickly round the neck of the bottle. After allowing the heat sufficient time to expand the glass, the stopper is quickly wrenched round, and will generally come away with ease. Every laboratory should possess a block of hard wood in which are slots of varying size to fit stoppers of different gauge, such block to be used as a wrench. But all trouble with stoppers is obviated by taking care that each is lightly touched with a little vaseline when its bottle is first brought into use.

---

According to the *Photographic Times*, a certain ingenious worker at Chicago keeps in his studio a supply of beautifully proportioned dummy feet for the use of those ladies whose pedal attachments are not by nature of the Chinese pattern. He anticipates a brisk business by this innovation, but we sincerely trust that he will be disappointed, for we have no wish to see photographic falsehood encouraged.

---

At the late Buffalo Convention there was exhibited in the apparatus section a tubular revolving show-case, which, we are told, consists of a narrow, tall glass frame, divided into panels for holding photographs, the entire arrangement being cylindrical and driven by clockwork. The object of the contrivance is to show the entire contents of the frame at one revolution. A quick printing machine for emulsion paper was also shown. By the motion of a crank the paper is unreeled from a spool, exposed, and cut off ready for development. It will be remembered that this is no new idea, for Messrs. Marion were showing a machine of the same kind about six years ago.

---

The art critic of a Sunday paper, in contending that artists who produce big pictures have a difficulty in selling them because they are beyond the capacity of the middle-class home, uses a curious argument. He says: "To this neglect of the conditions of the home of all but the wealthy few, is greatly to be attributed the preference for line engravings and for photographs, which artists agree to deplore." Is this really the reason why engravings and photographs are purchased, and do artists "agree to deplore" the "preference" in this direction? We fancy any print publisher will say that persons buy copies, rather than original pictures, simply because the latter are utterly beyond their means. The "conditions of the home" have nothing to do with the matter. It is the condition of the purse which determines whether a man can buy an original or a copy. As for the agreement of artists to "deplore" the preference for engravings or photographs, we doubt whether an artist is to be found who will agree with this supposed argument, seeing that the sale of the copyright for purposes of reproduction is a material gain to his pocket, and adds to the value of his picture by making it popular. The only persons who "deplore" the "preference" of photographs are—or used to be—for some occult reasons of their own, the publishers of engravings.

---

But photography has, in these days, run engraving so closely that publishers have found themselves compelled to adapt the former to the manners and customers of the latter. A notice attached to photographic copies of pictures, to the effect that only a certain number will be printed, and the negative will then be destroyed, is now occasionally to be seen in the shops of the print-sellers and picture-dealers.

---

The scientific traveller is now expected to be a skilled photographer. Nothing in the present day is taken on trust. In the course of Mr. Fawcett's description of prehistoric remains in South India given at the Congress of Orientalists, he mentioned that near Bellary he found "pictures" incised upon the rock. These pictures, says the *Standard*, seem likely to prove of inestimable value, but, adds our contemporary, "no photographs were shown apparently, and the Congress has decided to appoint a small committee, which shall make a thorough investigation." That photographs were anticipated is very clear.

---

The artificial asphalt described by *Industrie* seems worthy of investigation at the hands of scientific photographers. It is formed by heating resin with sulphur to about 250° C., when sulphuretted hydrogen is given off, leading to the formation of a black, pitchy substance, resembling Syrian asphalt in appearance and properties. It is insoluble in alcohol, but dissolves readily in chloroform, benzine, and other liquids. More important than all, it is sensitive to light.

## THE INTERNATIONAL PHOTOGRAPHIC EXHIBITION AT GLASGOW.

[By our Special Commissioner.]

The splendid collection of photographic pictures now to be seen in the suite of rooms known as the Institute of the Fine Arts, in Glasgow, only proves still further a fact that, after all, needs no proof—viz., that the Scot is thorough in all he undertakes; and it is only fair, therefore, to say at the outset that it is the finest assemblage of really good photographic productions that it has ever been my good fortune to see. How much hard work it has entailed only those who have laboured in a similar direction can justly estimate; and when it is known that Messrs. Annan and Miller pulled down the pictures from the principal wall of the large gallery, and made an entirely different arrangement in order to get a more striking *coup d'œil*, one need not be surprised that a great success has been the reward of their zeal. As an old photographer accustomed to look with pride at the annual show in Pall Mall, I could not help longing for just such a splendid home for the pictures brought together year after year by the Photographic Society of Great Britain. All the galleries (and there are six of them) are lit in the most perfect manner; and, in consequence, many pictures that I have seen before in Pall Mall in the corners of the room on a dull November day gain so much by the stronger light that they almost seem new productions. Of course, many of the photographic works are old friends, but there is an unusual amount of entirely new work, and for this result great praise is due to the energy that must have been displayed by the Glasgow Society's committee of management. The exhibition was open to the members of the press on Tuesday about mid-day, and later on I saw a fine subject for a picture. While the guests were partaking of the liberal luncheon spread at one end of the gallery, the judges were evidently desperately struggling to complete their labours, for they were seen frantically rushing from room to room to verify the awards, or to settle some debatable point; but evidently a moment came when they could work no longer, for they were now to be seen eagerly clutching chairs that they might sit down and rest during the luncheon so well earned. When they had settled down to serious work with knife and fork, the famished workers were surrounded by a little crowd, who looked on with almost wolfish eagerness. This seemed most unaccountable, for full opportunity had been given them to satisfy their hunger. I soon found out, however, that it was not cooked meats that they craved, but "copy." It was a race between the evening and morning papers to get first publication of awards. One hour more and it would be too late for the evening publications. An inspection of the long list published last week will show that it could not be replicated in a minute—hence the assemblage of the materials for this epic picture, which, unfortunately, *was not produced* by the graphic art of photography. In the evening the principal gallery was well filled with a brilliant audience, notwithstanding the torrents of rain that had fallen all day. The fair dames of Glasgow also do nothing in a half-hearted manner, if I may judge by the full evening costume adopted by most of them, and the consequent life and brilliance given to the opening ceremony.

The Lord Provost, in a commendably short speech, commenced the proceedings, and the president, Mr. J. Morison, called upon Mr. Valentine Blanchard for a few remarks on the Exhibition from the judges' point of view. Mr. C. W. Hastings and Mr. J. D. Welford also briefly spoke in its praise, and, after a vote of thanks to the Lord Provost, the gay throng moved about the rooms to inspect the pictures, whilst a capital orchestra went through a well-selected programme of music. When the principal room had sufficiently thinned, an impromptu ball terminated the proceedings.

An examination of the list of awards will show a large number of well-known names, but, whilst very naturally many pictures already distinguished by medals at other exhibitions are to be found on these walls, I am extremely pleased to see a large quantity of new work of the highest quality.

Of course, it is needless to speak of pictures already described in these pages. I shall therefore, as far as possible, pick out work new to me for notice. I am pleased to be able to say that pictures that stand out in consequence of vile taste in mounting or framing are very few and far between, and therefore the general effect is very good indeed. Great taste has been displayed in draping the room with material of harmonious colour, to give effect to the pictures, and all unavoidable spaces have been filled with drapery of the same colour. There is, in consequence, a unity and completeness rarely seen out of London.

Mr. Warneuke, of Glasgow, has produced some striking portraits of large size. "Ethel," a sweet, sunny-faced child, combines boldness of light and shade with delicacy in the details. "Desdemona," by the same gentleman, is the portrait of Mr. Herman Vezin's accomplished pupil. It is an oblong picture, and the figure is extended on a couch with hand on chin. The expression is well done, and the light drapery very delicately treated. There is also a very powerful portrait of Mr. Herman Vezin as Othello. The facial expression, as might be expected, is very fine, and the whole picture shows great skill on the part of the artist, with a slight exception: the lens employed was too short in focus, and the folded arms are, in consequence, out of drawing and unduly magnified; they show capacity, however, to strangle, and so far there is fitness.

Chancellor and Sons exhibit a very beautiful profile head called "Juliet." The lighting is unusually fine.

Tunny and Co. distinguish themselves by a series of portraits, also of large size. The most striking is of a lady most graceful in pose, but spoiled by a mass of dark, which runs through the picture in such a manner as to rob the figure of its necessary support. This is a great pity, for it is an unusually beautiful picture, and so little was needed to make it all right.

Mr. Van der Weyde has gained a gold medal for a group which is certainly one of the most perfect ever produced by the aid of the camera. Four beautiful girls in white are, apparently, watching from a balcony some interesting scene. Simple and unaffected is the pose of all four, and there is, apparently, the grace of unconsciousness; and yet, when it is known that the sitters are the beautiful Dorothy Dene and her sisters, it only shows what may be accomplished by an artist, assisted by accomplished sitters. The varied textures of the white dresses are rendered with consummate skill.

Mr. Harold Baker is again to the front with well-dressed models. Dorothy Dene, in classical dress, is one of the best. All the pictures show great skill in the management of pose and arrangement of drapery on the figure.

Mr. Swan Watson shows some female heads powerful in treatment, and one or two are very Rembrandtesque. Perhaps the contrast of light and shade is a little too marked to suit all tastes.

A very original effect has been produced by Messrs. Annan and Sons in an enlargement from a hand-camera picture. By means of a very blue tone, the cold of dawn on the mountain side is admirably expressed. The "Dusty Miller" is a powerful bit of light and shade, but the window spoils all; when the window panes are darker than the sash bars, one is inclined to think there is something wrong somewhere. The bromide enlargements are unusually good, and one of a lugger, with the shadows luminous by aid of the very transparent water—an effect so successfully painted by Mr. W. Bartlett—is wonderful when it is remembered that the effect is produced by monochrome only. Mr. Snell Anderson is to be complimented on this achievement, and also for a landscape where the ripple caused by a boat carries the shadows, broken up into long lines of light and shade, right down to the front of the picture.

Mr. H. P. Robinson has sent four of his best landscapes with figures, and no one will be surprised that he has taken a silver medal for them. They have been already described in these pages, however.

The Countess Loredana da Porto exhibits, in addition to the flash-light pictures which were so much admired at Liverpool, some peasant groups which add still further to her reputation as an artist. Perhaps the best is in the *genre* class. Two peasant girls are near a rude wayside cross, and one is kneeling at its foot, whilst the other is clinging to its stem. The back of the kneeling figure is shown, and the face is in profile. The subject is a hackneyed one, but it has been carried out with simplicity, and the peasant costumes are so natural that there is a great air of reality about the whole picture. A little more tone in the sky would have made it much better.

Mr. David R. Clark's four landscapes are a little unequal in quality; one of them is of such high artistic excellence that a gold medal has been awarded to it. The materials of the picture are extremely simple. Some trees in the foreground, one of which, a slender, graceful one, has fallen out of the upright, and sends its branches obliquely into the picture, whilst an expectant maiden leans against its base, furnish the principal features. The picture is full of light and atmosphere, and the chiaroscuro unusually fine. The title of the picture is the "Trysting Tree," and it is more like one of Leader's landscapes than a photograph.

Mr. Horsley Hinton's "Where Swaying Reeds Eternal Music Make" is a picture treated in the same manner as the one sent to Cardiff, and described in these pages a few weeks ago. No sharpness anywhere, and the rough paper gives a tone value which is certainly very artistic when the beholder is far enough away to get the mystery of effect imparted by distance. When close to the picture, it presents the appearance of a powerful sketch executed by bold washes of sepia, and, when sufficiently far away to lose the texture of the paper, it might be mistaken for an etching. The title sufficiently explains the subject. I certainly like it better than the one sent to Cardiff.

Mr. James Patrick's "Lowland Shieling," whatever that may be, for I had not time to ask, is a very charming little landscape. Only a little hollow on the hill-side, with sheep placidly browsing here and there, and a cottage in the distance—that is all the material employed; but the result is a picture the author may well be proud of.

Mr. J. G. Pratt shows some pictures so red in colour that their otherwise artistic quality might easily be overlooked, for the atmospheric effects are very beautiful in all. The one of Greenock from the old quay is perhaps the best of all. Landscapes in Bartolozzi red will not do.

Mr. C. Reid's cattle subjects are good, and his poultry better, but the best of all is a beautiful collie dog. The texture of the dog's coat is quite a study for animal painters. "Rats!" and also "Rats Again!" are most successful pictures. Expectant dogs are climbing up a stable door, and eagerly look for its rapid opening. The shadows thrown by the figures of the dogs are most transparent. There is a blaze of sunshine, but no hardness anywhere. Mr. J. Catto has taken a silver medal for this achievement..

Karl Greger still keeps to his red colour, but his groups are highly artistic; "Wood Gatherers" and "Gipsy Encampment" are perhaps the best.

Mr. W. J. Byrne's interiors are very fine, and I would much like to see them printed in platinum, for the glazed surface makes them look so very brilliant and out of harmony with the pictures near them. Mr. Court Cole's interiors are now so well known that they do not demand any special mention. Total absence of black shadows, and not a trace of halation anywhere, are their most striking points.

Mr. John Stuart has produced the very best flash-light pictures I have yet seen. Large interiors are perfectly illuminated into the remotest corners, and children are occupied in the most unconscious manner; in fact, there is not the slightest evidence of the powerful light employed. I asked Mr. Stuart if he had any new arrangement of light for the purpose, and he answered that he just used as much light as he wanted, that was all.

Mr. J. W. Wade's hand-camera pictures are very varied, and the chiaroscuro of several of them very fine. Mr. Archibald Watson's marine studies are full of light and yet not at all weak; and one or two of Mr. W. D. Welford's little pictures unusually good. There is one with the sunshine breaking out from behind a dark cloud that is one of the most perfect marine studies I have ever seen. The entries in this class, however, are not nearly so numerous as might have been expected.

Mr. Ralph H. Elder's "Snap-shots on Italian Lakes" are capital little pictures quite spoiled by the bad taste displayed in their framing. Indeed, it is almost impossible to look at them in consequence of the vividness of their surroundings.

The *genre* class is most disappointing. Apart from several well-known subjects—Robinson's "Primrose Time" being among the number—there is very little new work that calls for special notice. "A Duet," by Mr. Alex. M. Morrison, is certainly an exception. In the foreground a rustic lad is piping away on a whistle, and immediately opposite a bird on a twig is apparently trying to split his pipe in emulation. The pose of the boy is original, and the whole picture well carried out, but the selection of focus has given such sharpness to the foreground that the distance looks painfully blurred. Just a little more diffusion of focus would have made the little scene perfect.

Mr. F. Bremner has been unusually successful with several difficult Eastern subjects. The best is one called "Nature—Blasting Rocks." Detail is carried into the deepest recesses of the rocks, and yet there is perfect detail in the white dresses of the Eastern workers. Surely this is a difficult achievement!

Mr. J. E. Austin has not been quite so happy as usual in the picture he calls "She Won't Go to School." The grouping is very natural, but either it is under-printed or the negative over-exposed. At any rate, it is not so striking as usual with this gentleman's work.

The pictures in the Champion Class are, of course, well-known. Mr. W. Crooke has taken the gold medal for his remarkable series of distinguished Scotch Law Lords, shown at the Crystal Palace in the spring. They are natural in pose, and most effective in lighting. Strong individuality is shown in each, and any of them might easily be mistaken for a mezzotint by Sir Joshua Reynolds. Praise cannot easily go further. To Mr. Lyd. Sawyer has been given the second gold medal for his series of now well-known subjects, one of the Tyne series being selected for the honour.

A special silver medal has been given to Mr. Ralph Robinson for his fine series of "Artists at Home." These have, however, been well described in this journal, and do not need further mention.

Mrs. B. G. Benetto's pretty little portrait studies have taken the silver medal in the lady amateur class, and Mrs. Janie Hignet the bronze for some well-lit landscapes.

Prince Ruffo is most masterly in his treatment of rugged, time-worn faces, and Mr. W. J. Jenkins has made distinct advance in his "Young Heads." To the first has been awarded a silver medal, and to the latter a bronze.

I have endeavoured, within the limits available for this article, to notice a few of the most striking of the pictures new to the readers of this journal. When it is remembered that, besides the new work, a very large proportion of the most distinguished pictures executed during the past few years is to be found in this Exhibition, some idea may be formed of its completeness and importance. Several of the leading photographers have fitted up special exhibits for trade purposes, and, of course, not entered for competition. These will attract great attention, for most of them have been fitted up with great taste. There is, besides, a very good show of apparatus. There are a few novelties. One of the simplest and best is a camera clip exhibited by George Mason and Co. By means of three slotted brass pieces hooked at one end, so as to grip the stretching bar of the tripod legs, and held in position by a screw that travels at will along the three slots, the camera stand can be made rigid in a moment, and the anxious photographer will no longer dread the slipping of his stand on marble pavements. Surely this is a good thing. A capital lamp is shown by J. Lizars. Direct light is not used, but only the light reflected from the back of the lamp, which is painted yellow of the most non-actinic kind. Mr. W. Middlemiss is the maker of two useful instruments. One is for slide making, and is so simple that a girl with scarcely any knowledge could work it; and the other, the invention of Professor Barr, of the Glasgow University, is designed to make the lecturer's demonstration much easier. By an arrangement of mirrors, the lecturer can point on the slide itself, instead of doing so on the screen. It is difficult without a diagram to describe either of these inventions, but they struck me as specially useful. Doubtless there are many other things worthy of notice, but space will not permit it.

Mr. Paul Lange was the first lecturer, and his now well-known lecture on Iceland was attentively listened to by a crowded audience; and Mr. T. N. Armstrong followed on Thursday with "A Tour in the Trossachs with a Caravan," and, of course, illustrated on the screen with pictures taken during the journey. It is intended to have a popular lantern entertainment every night during the Exhibition.

All praise should be given to the Glasgow Society for its enterprise. They deserve success, for they have earned it.

## PHOTOGRAPHY AS AN AID TO ILLUSTRATIVE AND PICTORIAL ART.

BY W. H. JOBBINS, SUPERINTENDENT OF THE SCHOOL OF ART, CALCUTTA.

We will first consider photography as applied to the practical purpose of illustration. Many are probably ignorant of the ordinary mode of procedure in the production of every-day illustration—technically called event work. Suppose, for example, some event of public interest is to take place, and the special artist of an illustrated periodical is called upon to produce an illustration, which possibly may have to appear the following morning. The event is over in a few minutes, yet in that short time the illustrator may have to collect sufficient material which will enable him to produce the required illustration. He proceeds usually by scaling his figures, determining their relative sizes and positions, and makes notes of the background and details of costume. When the background is elaborate, this takes time, and then the practical character of photography as an aid asserts itself. One shot with a hand-camera, and the illustrator goes away comparatively happy, having thus secured his essential details. Without the aid of photography, the every-day production of illustrations—as in the *Daily Graphic*, for example—would be impossible. The illustrations may be drawn during the day, photographed by electric light at night, reproduced on metal, printed, and in circulation by six o'clock the next morning. The results of photography are apparent in the numerous processes employed in every illustrated periodical. In the old days, when the drawings were made directly upon the wood, the artist was entirely at the mercy of the engraver; and the agony and heart-burning of the illustrator, when he too frequently saw his work ploughed up, may be imagined. The drawings were mostly in *facsimile*, line for line upon the wood, to facilitate matters for the engraver; the block was well or badly cut, and the original drawing irretrievably lost. Photography has changed this, and the artist may choose his own method. In wood-engraving, the drawing is now made upon paper or other material, and in most instances photographed upon the block, and the original is thus saved. One interested in such matters can readily see how much is due to a process which has been the means of preserving so many original works, by inspecting the black and white drawings at the office of any first-class illustrated paper, as the *Graphic* or *Illustrated London News*, and the regret one feels that original work by such men as Millais, Rosetti, Holman Hunt, Sandys, F. Walker, Tenniel, Pinwell, Houghton Fildes, E. J. Gregory, and many others now famous, has been irretrievably lost. Imagine what an incentive to good work, and ultimate joy, it must be to the artist to feel assured that his work, reproduced by one of the many processes now in vogue, will be as near a *facsimile* to the original as it is possible to make it, so that it is pretty clearly demonstrated what the art of illustration owes to photography.

The phases of art iu which photography can be of material help covers the whole range—classical, historical, *genre*, laudscape, animal, marine, or architectural. In classical painting the artist in search of material may go to Pompeii, for example, make his studies and notes, and then supplement those by photographs. Imagine the advantage he has over one who has visited the place, say, fifty years ago. The photographs give him the minutest detail, texture, and every quality, except colour; and if a practical knowledge of photography has been acquired, he may select the special objects, or particular points of view, best suited to his purpose. He can thus collect details of costume, accessories, and backgrounds with the greatest facility, knowing, at the same time, that they cannot be otherwise thau absolutely true. In *genre*, the painter can arrange his figures, and get a pretty good idea of their composition and value. In landscape, he can study an infinite vatiety of effect and detail. The same in marine, and what can be more beautiful than some of the photographs of water with the varied movements and reflections? I know that old-fashioned painters of the couservative school will condemn this as rank heresy. There is a sort of impression that the aid of photography in art implies—at least, in painting—something which is incompatible with its dignity, and that the man who uses it, and is fouud out, loses caste among his *confrères*. But the fact remains that photography is extensively used, though paiuters will not admit it. The very fact of being accused of having had recourse to photography is libellous, and Van Beers brought an action in Paris some years since, and won his case, because a journalist asserted that photography has been used in his picture of "The Siren." The journalist was misled by the photographic look of the picture; it was as near the realisation of photography in colour as anything could be, and technically it was extraordinary work.

This is eminently a realistic age, especially in art matters, and the public have discovered a great deal as to appearances and facts in nature from photography. In every expedition now-a-days a camera is looked upon more or less as a necessity. It is remarkable the resemblance between the work of some eminent painters, when reproduced by photography, and photographs direct from nature. This is, perhaps, most noticeable in the work of the modern French school, of that portion who work out-of-doors. The subject is not generally so much thought of as the absolute truth of the rendering; but the "values" or proper relation of parts must be true. One can readily see this by glancing through any of the numbers of the *Figaro Salon*, and noticing the work by such men as Daguan-Bouveret, Dupré, Pasini, Ridgway-Knight, Muenier, Haquette, Tattegrain, &c.

In the use of photography as an aid to illustrative and pictorial art, it is pre-supposed the artist should, if possible, be his own photographer, so that the result should be that of his own labours, and I cannot see what possible objectiou there can be to a camera supplementing a sketch book. By the aid of both, he certainly will be able to obtain results which he could not if one or the other were alone used.

One does not wish to exalt photography at the expense of art, and in the great essentials photography has no place; but it may become, in judicious hands, a most valuable aid. One has been accustomed to cant phrases generally applied to painting, also applied to photography, especially that of "Impressionism"—subduing detail for effect—in which Mr. Emerson made himself so conspicuous. I do not wish to reopen the question, but some of the finest photographs I know in portraiture were of this character. I remember years since seeing portraits by Mrs. Cameron—notably of Darwin and Tennyson—which, to my mind, as portrait photography, were unsurpassed. They gave the character, and not merely the surface quality; you saw the individual behind the frame, and not thrust in front of it; the lines on the face were there, but not obtrusively so; and the faces had not been retouched until the surface was that of porcelain. It is vain for the photographer to try to infuse into his work the undefinable charm of great artists like Millet or Corot. Millet only gave the esseutials, religiously keeping out what was unnecessary; his hard-worked and uncomplaining peasants were the embodiment of the silent toil of centuries. Photography at its best can only give you facts; they may be subdued by being out of focus, but still they are there. Nor can photography give you the poetry of an evening as Corot did, where you saw the gentle ripple ou the water, the breeze shaking the leaves on the trees, and the feeling of peace and repose.

The majority rush into photography without even a rudimentary art knowledge, the result being that our æsthetic sense has many a rude shock; as it so frequently happens that, while the technique is all that could be desired, the choice of subject and composition are execrable. By a rudimentary art knowledge it is not implied that a knowledge of drawing eveu is essential, but some idea of selection, composition, and beauty of line. This can, iu a measure, be attained by carefully considering wherein consists the beauty of one picture, when compared to another of equal merit, technically remembering the maxim that "art is to conceal art."

It is a curious fact that in painting, as in photography, the results are in a way the reflex of the idiosyncracies of the individual. A common photographer makes his sitters look common; one only has to take the average work of the cheap photographer and see how vulgar his sitters appear, and the way in which any objectionable peculiarity seems to be intensified.

Even Mr. Pennell, in his recent tirade against photography, generally admits the aid it is to the illustrator. If I mistake not, practical proof of this is to be found iu some of his illustrations; only two examples ueed be mentioned. In the article on "Venetian Boats" in *Harper's Magazine* for March, 1890, pp. 541 and 553, the two illustrations look as if drawn from photographs well known in Venice, that used to be sold at a shop in the Piazza, on the left-hand side, between San Marco and the Caffé Floriau. The illustratiou on p. 541, called "An Afternoon Call," is practically a *facsimile* of the original; the other, called "Passenger Boats from the Islands," only partially so. The principal boat with figures appears to be drawn from a photograph taken some twelve years since at the Murano side of the city ou the Foudamenta Nuova, where these boats laud; they are never seen near the Custom House, where Mr. Pennell has drawn them.

The London and Provincial Photographic Association.—September 17th, The Lantern Microscope Demonstration, by Mr. T. E. Freshwater.

The Photographic Club.—Subject for September 16th, "Reducing and Intensifying"; September 23rd, "Enlarging." Saturday outing to Ockley; train leaves London Bridge 12.50.

## ON SOME CONDITIONS AFFECTING REVERSAL OF THE PHOTOGRAPHIC IMAGE.

BY HENRY SUTTON.

In drawing to a conclusion the discussion on Professor Minchin's paper at the last Conference of the Camera Club, Captain Abney remarked that the blue rays have a reducing and the red rays an oxidising effect. Of course Captain Abney taught us these facts many years ago, but I mention their expression at the Conference because it immediately occurred to me—though why I cannot say, for Professor Minchin's entirely different subject was distinctly before my mind—that reversal of the photographic image must be a result of an over-balance of the two effects, by the exposure being continued for such a time as to allow the reducing action of the blue rays to act all over the plate ; in short, to produce fog, even in the protected parts, it would allow the red and yellow-red rays time to re-oxidise such parts as are more or less unprotected.

It occurred to me that, by exposing a plate to ordinary light, so that the blue rays may exert their power of reduction, and then subsequently exposing such reduced (or fogged) plate, in contact with a negative or positive, to red rays, by interposition of a red screen, the result on development should be reversal.

On putting the matter to the test, I found such apparently to be the case. Captain Abney, Colonel Waterhouse, and Fox Talbot have noted the advantage of a preliminary exposure in assisting the reversal of image, but I have not noticed attention drawn to the connection between the preliminary and subsequent exposures, or the manner in which such a reversal is possibly produced by the relative action of the reducing and oxidising rays. So that in this paper no claim is set up how to produce reversal, nor yet to the effect that the red and yellow are the active rays in so doing (for, in the language of the patent office, "I am aware all this has been done before"), but what I desire to call attention to is how they probably act, and that in producing reversal a proper relation should exist between the reducing and oxidising rays. By a consideration of the subject from these points, an every-day method of producing reversed negatives suitable for collotype and carbon work may result. From the influence fog seems to have in producing the results, I am afraid it will be impossible to produce reversed negatives suited to ordinary relief block processes, in which clear glass is of more importance than density. In the following experiments very powerful exposures are used, and the results, except where otherwise stated, developed with Wood's hydrokinone developer used in strength as directed on the label, and therefore normally developed. It is interesting to note that development required about the same time as a normally exposed plate, and hence contrasts very markedly with the results obtained by Mr. Humphery when using hydrokinone, as stated in his paper read at the Club last October. In my experiments, judging a plate by its colour, I note such as appear to contain iodide produce the best results; this, I believe, is in agreement with the experiments of Captain Abney and others.

The theory of reduction and re-oxidisation suggested by the following experiments, it will be noticed, explains the alternate reversal, such as negative, positive, negative, positive, sometimes mentioned in the journals. These alternate reversals have not come under my notice experimentally.

*Experiment* 1.—Expose an Edwards' landscape plate to white light for one minute, then, still in light, placed in printing frame in contact with a negative, but separating them by a tissue of red stained gelatine. This was exposed to direct sunlight (July) for five minutes. On examination in the dark room by ruby light, it showed a delicately printed-out positive. It was then developed with Wood's hydrokinone developer, to which a small portion of same firm's eikonogen solution was added.

*Result.*—The plate developed in the ordinary manner, except that the positive print-out image disappeared shortly after immersion in the developer, and in less than one minute the reversed negative had begun to appear, rapidly gained density, and for ordinary work little inferior to the original.

*Experiment* 2.—Edwards' transparency plate, preliminary exposure to white light, then in contact with positive exposed for twenty minutes to diffused sunlight through red gelatine tissue.

*Result.*—Fog all over ; no reversal.

*Experiment* 3.—Same conditions and result as Experiment 2.

*Experiment* 4.—Preliminary exposed Edwards' landscape plate to direct sunlight half minute ; then exposed to direct sun through red tissue for five minutes.

*Result.*—Good reversal.

*Note.*—Unless otherwise stated, Edwards' landscape plates are used.

*Experiment* 5.—As Experiment 4, but exposed ten minutes through red tissue.

*Result.*—Reversal, but rather thin.

*Experiment* 6.—No preliminary exposure ; then exposed through red tissue five minutes' direct sun.

*Result.*—Developed thin negative, which gradually reversed to thin positive on front surface, and remained thin negative on back surface of film. On fixing, the result is barely visible. This experiment should be compared with Experiment 4, being under similar conditions, except that Experiment 4 had half a minute preliminary sunning, and produced a good reversal.

*Experiment* 7.—In order to have some idea of the developing value of the preliminary exposure, each side of a plate was exposed to candle-light at 6 in. for ten seconds; total exposure, twenty seconds; then exposed with red tissue to sun (haze) for four minutes.

*Result.*—Very good reversal, and would indicate that the preliminary exposure should be such as to produce, if developed, a good density. In this experiment an extra minute of exposure to sun would have produced clearer glass.

*Experiment* 8.—Preliminary exposed plate to candle-light, as in Experiment 7; then exposed ten minutes to diffused sunlight without red tissue.

*Result.*—Reversal, but not so good as 1, 4, 5, 7.

*Experiment* 9.—Preliminary exposed Edwards' transparency plate, as in Experiment 8; then exposed, without red tissue, to ten minutes' diffused sunlight.

*Result.*—Exceedingly weak reversal.

*Note.*—Where transparency plates are used, they are given an increased exposure, on account of the lower sensitiveness. They are not suited for reversal, but the landscape plates are particularly well adapted for it.

*Experiment* 10.—Preliminary exposed landscape plate to candle-light; then covered half with red tissue, and exposed to 12 in. of magnesium at 12 in. distance.

*Result.*—No reversal under tissue, but reversal where uncovered. Evidently the exposure under red was insufficient. At the same time, this experiment indicates that a good relative proportion of the two classes of rays may exist in the magnesium light, such as would produce sufficient fog all over the plate through all parts of the superposed image, and at the same time be sufficiently active in oxidising rays to undo the work of the reducing rays where the plate is least protected.

*Experiment* 11.—Preliminary exposed plate, as in Experiment 10, and exposed, without red tissue, to 8 in. of magnesium.

*Result.*—Thin reversal.

*Experiment* 12.—Same conditions and result as in Experiment 11.

*Experiment* 13.—Preliminary exposed plate for thirty seconds to candle at 6 in.; then covered half the plate with blue tissue, and exposed to 12 in. of magnesium at 6 in.

*Result.*—Partial reversal under the blue, but full reversal under the uncovered part. In this experiment the print-out image appeared as strong under the blue as under the uncovered part, yet, on development, a full reversal only occurred where uncovered. It is well to note here that a similar print-out image under red tissue reverses perfectly. It will be noticed in this experiment the advantage gained by increasing the power of the light, compared with Experiments 11 and 12.

*Experiment* 14.—As Experiment 13, except that a green tissue was used to part cover the plate and the magnesium burnt at 8 in. This experiment shows the result of reversal on the front surface and non-reversal on back surface of film very distinctly; the effect only took place on the uncovered portion of plate, the tissue covered part being insufficiently exposed. Experiment 13 shows, had the magnesium been burnt 2 in. nearer, a full reversal would have occurred. It is interesting that this plate has caught the transition stage nicely, as the result would disappear on fixing. The plate was not placed in hypo.

*Experiment* 15.—No preliminary exposure and no coloured tissue. Exposed to 12 in. of magnesium at 4 in.

*Result.*—Very good reversal.

*Experiment* 16.—As Experiment 15, but preliminary exposed for thirty seconds to candle-light at 6 in.

*Result.*—Reversal as in Experiment 15.

*Experiment* 17.—No preliminary exposure, then exposed to 18 in. magnesium but at 4 in.

*Result.*—Very good reversal.

*Note.*—Experiments 15, 16, and 17 show the improvement in results by stronger exposure.

*Experiment* 18.—Edwards' slow isochromatic plate. No preliminary exposure; no coloured tissue. Exposed to 12 in. of magnesium at 4 in.

*Result.*—Good reversal.

*Experiment* 19.—Edwards' transparency plate. No preliminary exposure. Exposed to 12 in. of magnesium at 4 in.

*Result.*—Very weak reversal.

*Note.*—Edwards' landscape plates, exposed to from 12 to 18 in. of magnesium weighing 4 gr. to the foot, and burnt at 4 in. distance, produces the best results, no preliminary exposure being required, sufficient fog being produced to develop to full density where the plate is protected, and at the same time the oxidising rays do their work on the unprotected parts.

*Experiment* 20.—Strips of red, blue, and green tissue were cut and laid on a negative so as to divide it into four sections, one of which was uncovered. No preliminary exposure being made, a landscape plate was exposed in contact with the sectional negative for five minutes to direct sunlight.

*Result.*—Under the blue and uncovered sections a very strong print-out positive appeared, and under the red and green a delicate print-out positive. The blue and uncovered sections developed decidedly positive, which gradually fogged away and left very thin reversals, mere ghosts. The red and green sections developed strong and vigorous reversals in a very decided manner, without any strengthening of the print-out positive. The development was the same as met in every-day procedure, but under the blue and uncovered sections there was an increase of strength in the print-out image, then a gradual fog, and finally a thin reversal. The green section is slightly more dense in deposit than the red.

*Experiment* 21.—Preliminary exposed plate one minute to candle-light at 6 in., then proceeded as in Experiment 20.

*Result.*—As in Experiment 20, but rather more deposit under the blue and uncovered sections, and more general fog. These experiments, I think, tend to show that a reduction is to some extent requisite in order that a subsequent oxidisation may occur, but that a total reduction is not desirable, and that this reduction may be obtained either by a preliminary exposure, or by the concurrent action of the reducing and oxidising rays in one exposure; in the latter case, the oxidising rays require so much time for their work that the reducing rays have ample time to exert their influence on even the most protected portions of the plate; evidently the best conditions being those under which a full-timed exposure or fog is made to balance a full effect of the oxidising rays, so that when the latter produce as nearly as possible clear glass, the former may develop to full density.—*Journal of the Camera Club.*

## ROYAL CORNWALL POLYTECHNIC EXHIBITION: PHOTOGRAPHIC DEPARTMENT.

Completion of Awards.

Messrs. Taylor, Taylor, and Hobson, of Leicester, send a pair of nine-inch lantern objectives, which the judges put to a practical test, and Mr. Brooks used them at his lantern entertainment; their performance left nothing to be desired, and the judges have awarded them a first silver medal. Mr. R. R. Beard exhibits a pair of his gas governors, with special packing to prevent straining and bursting of the pressure gauge, which seems to be very efficient; to these have been awarded a first bronze medal. He also sends a carrier for dissolving effects with a single lantern, which is a very clever arrangement, and is highly commended. The same exhibitor shows a compact little optical lantern, which packs into a very small compass, and will recommend itself to those who admire portability.

Mr. C. A. Rudowsky writes that as the price of platinum is lower, the manufacturers of the Pizzighelli paper, Dr. Adolf Hesekiel and Co., Berlin, have reduced their prices 25 per cent.

Carl Suck.—The *Photographisches Wochenblatt* of the 3rd inst. appears with two black-bordered pages in memory of Carl Suck, who died on September 2nd, after protracted illness, at the age of fifty-eight. The deceased, though engaged in business-management, devoted much time to original research, to the advantage of photograghy. The *Zusammenkunft Praktischer Photographen Berlins* pays its tribute in the record that they have lost a beloved colleague, a true friend, and a zealous promoter of the art.

## Patent Intelligence.

### Applications for Letters Patent.

14,689. Arthur Richard Wormald, Sutton, Surrey, "A Photographic Lantern Slide and Transparency Printing Frame."—*August 31st.*

14,695. Henry Edward Colville, 24, Chapel Street, Belgrave Square, London, "Improved Photographic Dark Slide for use with Celluloid Films."—*August 31st.*

15,032. Edmond Lambert Coninck, 53, Chancery Lane, London, "Improvements in Photographic Shutters."—*September 5th.*

### Specifications Published.

5,227. *April 3rd*, 1890.—"Camera with Roller Slide and Shutter." C. Whitney, Chicago, Illinois, U.S.A.

The camera belongs to the instantaneous or detective type, and is made in the form of an opera glass, book, or other like article. When in use, the front of the camera is drawn out and held by spring catches. A sensitive ribbon mounted on a roller slide is preferably used, or the sensitive paper may be cut in sheets and fed into position by rollers. In the roller slide the roll of sensitised paper is placed in a tube, through a slit in one side of which the end of the ribbon is drawn, passed round the back of the exposure chamber, and connected by a fastener to strap attached to the receiving roller. In some forms of the roller slide there is a knife actuated by a roller, which cuts the ribbon into lengths as it enters a receiving chamber. In another form the film is stored in sheets, and transferred to the receiving chamber by rollers. One form of the shutter consists of two slides, one of which slides above the other; the lower slide has an exposure aperture which passes in front of the lens aperture, and is then covered by the upper slide. A spring catch is fitted for holding the shutter open for slow exposures. The shutter is preferably fitted between the lenses, and actuated by spiral springs. In another form of the shutter a rotary disc, with several apertures to give a succession of exposures, is used.

5,458. *April 10th*, 1890.—"Cameras and Change-Boxes." H. R. Hume, 6, Allen Terrace, Kensington High Street, and E. W. Parfitt, 18, Gatcombe Road, Tufnell Park, both in London.

In a detective or hand-camera, plates, enclosed in sheaths having side projections at one end, are placed in a receptacle at the top of the camera, the plates being pressed towards the bottom by a spring. Within the camera, and below the receptacle, slides a carriage having racks on the top, on to which the projections drop in succession. The carriage is slid towards the back by a lever at the base of the camera, which lever actuates a sliding plate provided with a spring pin, which engages with recesses in the sliding carriage. When the lever is moved towards the front of the camera, the pin is withdrawn from the recess. The lever also works a ratchet indicator. As the front ends of the plates drop in succession from the ledge, they are held by a spring in a vertical position for exposure.

Leeds Photographic Society.—The hon. sec. of the above Society, Mr. S. A. Warburton, informs us that, in connection with the Photographic Exhibition which is to be held in the Municipal Art Galleries during the coming winter, in addition to the medals offered by the Fine Art Gallery Committee, the Committee of the Leeds Photographic Society have decided to offer the following special medals for competition amongst its own members:—One silver medal to be awarded to the exhibit which the judges may deem most worthy of the distinction; six bronze medals to be awarded as follows:—(1) Landscape; (2) figure subjects, including portraits; (3) architecture (exteriors and interiors); (4) instantaneous; (5) lantern slides; (6) enlargements. No special form of entry is required for the competition beyond advising the secretary that it is intended to exhibit, when all pictures coming within the above classification sent in to the Exhibition, by members of the Leeds Photographic Society, will be deemed eligible to compete for the above awards, which will be made quite independently of and in addition to any honours gained in the open Exhibition.

## Proceedings of Societies.

### Holborn Camera Club.

*September 4th.*—Mr. E. H. Bayston presiding. The subject for discussion was "Architecture (Exterior and Interior)."

Mr. Fred. Brocas opened the discussion on exterior architecture, which, he said, might mean a doorway, or a gateway, a house, or Westminister Abbey. It did not appear difficult, but there were certain rules to be observed, among the chief being, "never get directly opposite the subject." He then showed various photographs demonstrating this axiom. Another was that the camera should be perfectly level. He also gave some excellent hints which experience had taught him during his life as a camera-man.

Mr. Golding then gave his experience in taking interiors, which he characterised as the most difficult branch of photography. One of the chief difficulties was the exposure, which would differ in every interior taken. Experience alone would enable one to gauge the right exposure. Slow and thickly coated plates were best. The plate must be backed, or halation would certainly be present in the resulting image. Backing does not do away with halation altogether, but it does certainly lessen the evil. A good backing was a piece of insensitive carbon tissue, preferably black, soaked in weak glycerine, and then squeegeed on the back of the plate. It could easily be stripped off before development and used over and over again. He thought it was a mistake to get the whole of the interior of a church on the plate. A mass of detail is lost in this way, which is, perhaps, the most interesting part of an interior. With regard to exposure, the rule is to expose for the shadows, and not to make it too short. He had found Watkins' actinometer of some use to him in arriving at the right exposure. Another important matter was judicious and cautious development. He used pyro and ammonia, and commenced with the following:—$\frac{1}{2}$ grain of pyro, 1 grain bromide, and $\frac{1}{2}$ grain ammonia to every ounce of developer. When the high-lights begin to show, coax detail out with ammonia, then add pyro, and obtain sufficient density. He showed an excellent 12 by 10 interior, illustrating various points in his remarks.

### Lewes Photographic Society.

The annual meeting was held at the Fitzroy Institute on Tuesday evening. Mr. J. G. Braden occupied the chair, and the attendance included Alderman White, Councillor Wightman, Mr. E. J. Bedford (hon. sec.), Mr. C. A. Wells, Mr. J. Farncombe, jun., Mr. E. H. Fuller, &c.

Mr. George Carpenter was elected a member of the Society.

Mr. Bedford then read the annual report of the council, which expressed pleasure at the continued prosperity of the Society, and went on to say that four new members had been elected during the year, and three had resigned, leaving forty on the books. Ten ordinary meetings had been held during the year, at which interesting papers were read, and demonstrations given. The council called attention to the quarterly competitions, which have been established to promote friendly competition and criticism of members' work, and which the council also venture to think would tend to individual progress and improvement. The excursions, taking into consideration the unfavourable weather experienced during the season, had been very well attended. The exhibition of members' work held on January 28th brought together a very interesting collection of photographs, &c., and was a success, although, owing to the weather, there was a financial deficit. A bookcase having now been purchased, the council hoped that a library might soon be formed, and would be glad to receive books or pamphlets from members or others towards its formation. The treasurer's report was satisfactory, showing a balance in hand of £1 19s. 4½d., notwithstanding a deficit of £3 9s. 9d. in connection with the exhibition, and also several heavy items in the expenditure, which would not occur another year.

The election of officers was then proceeded with as follows:—*President*—Mr. J. G. Braden; *Hon. Secretary* and *Treasurer*—Mr. E. J. Bedford; *Vice-President*—Mr. Tunks; *Committee*—

Messrs. W. B. Funnell, E. Miller, P. Morris, G. J. Wightman, and H. B. Constable, the last-named gentleman being appointed in the place of Mr. C. R. Wells (resigned).

The set of hand-camera pictures by Mr. Percy Morris, which gained a silver medal at the Cardiff Photographic Exhibition, were on view in the room, and were much admired.

During the evening certificates were presented to Mr. W. Young for enlargements, and Mr. J. Tunks for lantern slides.

---

Richmond Camera Club.

*September 4th.*—Mr. Hunter presided. Mr. Richardson showed an actinometer of his own make for timing the printing of platinotype and carbon prints, &c.

The subject for discussion was "Testing Lenses." Mr. Ardaseer explained the mode of testing for faults in mounting and grinding, and the colour of the glass, and for iridescence, bubbles, flare-spots, "ghosts," spherical aberration, non-coincidence of visual and actinic foci, curvilinear distortion, astigmatism, flatness of field, and covering power.

Mr. Cembrano added some remarks on polish and striation, and the importance of accurately measuring the focal length of the lens and the apertures of the stops, and showed some plates which he had exposed to test covering power.

Outings took place on the 22nd ult. to Cobham, and on the 5th inst. to Pinner, with fine weather on each occasion.

---

Leeds Photographic Society.

The first meeting after the summer vacation was held on the 1st. inst., Dr. Jacob in the chair.

The evening was devoted to an exhibition of negatives, prints, &c., taken during the holidays. Amongst the exhibits the following may be mentioned: Mr. Robert Bownas, aristotype prints ; Mr. T. Butterworth, a fine collection of 12 by 10 prints in silver and Obernetter paper ; Mr. A. R. Dayson, hand-camera views ; Mr. Herbert Denison, 7½ by 5 and hand-camera prints on Obernetter and platinotype ; Mr. E. Kinsley, half and whole-plate Obernetter prints ; Mr. A. A. Pearson, a large collection of hand-camera views of Whitby and neighbourhood ; Mr. R. W. Savage, Obernetter and matt surface prints ; Mr. H. S. Walker, negatives of Derwentwater, &c. ; Mr. S. A. Warburton, pictures mounted in optical contact with the glass. A very agreeable evening was spent in discussing the various exhibits and processes involved.

The next meeting will be held on the 21st instant in the Society's room, Mechanics' Institution, when Mr. G. H. Rodwell will give a demonstration of "Lantern Slide Making."

---

Errata.—In Mr. P. H. Emerson's letter on "Perspective Drawing and Vision," in our issue of 28th ult., there are a few printer's errors, which escaped correction by mislay of copy :— 1st line, omit "the"; line 12, for "will," read "theory"; line 16, for "*in*," read "*id*"; line 18, for "say again," read "only agree"; omit comma.

The Hackney Photographic Society's Exhibition is to be held at Morley Hall, Triangle, Hackney, on the 21st and 22nd of October. There is to be an open competition in lantern slides, for the best six of which a silver medal will be awarded ; and there will be also an open class, for any picture by any process, except opals or transparencies, in which the award will be made of a gold, silver, and bronze medal for the three best pictures. The judges will be Messrs. J. Traill Taylor and A. Pringle. Sir Charles Russell, Q.C., M.P., has consented to perform the opening ceremony. In addition to the usual display of pictures for competition, the committee have arranged for popular entertainments, which will include concert and organ recitals, working trade exhibits, optical lantern displays, exhibition of photographic apparatus, &c. The prize distribution will be held on Thursday evening, when four gold, eight silver, and three bronze medals, besides other valuable prizes, will be awarded. Admission each day, one shilling. Further particulars and conditions of exhibition can be obtained of W. Fenton Jones, Hon. Sec., 6, Victoria Street, King Edward Road, N.E.

## Answers to Correspondents.

**All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.**

**All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.**

J. C. (Northwich).—*Gelatine Plates and Collodion.* 1. Thin, soft negatives with proper exposure should be sufficiently developed in five minutes, but for vigorous subjects requiring greater contrasts, ten minutes might be better. Alum bath, if used at all, need be but a short operation, say one to two minutes. Remember to wash before fixing, and leave the plate in the hypo until all the yellow bromide has been dissolved out. 2. Ten grains of pyroxyline, and five grains each of cadmium bromide and iodide, might be the right proportions for two ounces of collodion, but here again there is room for the exercise of judgment, the composition being varied according to the requirements of the case, and no two samples of gun-cotton are alike, those prepared at low temperatures giving a thicker collodion.

H. D. (Surbiton).—*Pall Mall Exhibition.* See notice given last week. Wednesday next will be the receiving day for frames, lantern slides, and apparatus delivered by hand at the Gallery.

Photargus.—*Black-and-White Work.* 1. Will not a dilute bath of cyanide help you to clear the shadows previous to mercury intensification ? 2. Schlippe's salt, being an alkaline preparation, might not answer so well on a gelatine plate as with collodion, but you should try it. 3. Tincture of iodine will convert a gelatine negative into a yellow picture, but without really adding to its intensity, as we have proved by direct experiments. Another mode of intensification is that mentioned by Mr. W. T. Wilkinson at page 12 of his book on "Photo-Engraving," viz : —

| | |
|---|---|
| Red prussiate ... ... ... ... | 6 parts |
| Nitrate of lead ... ... ... ... | 4 ,, |
| Water ... ... ... ... ... | 80 ,, |

When bleached and washed, the plate is treated with dilute nitric acid, 1 to 80 ; again well washed, and flooded with sulphide of ammonium diluted with five times its bulk of water. Lastly, treat with the same dilute nitric acid, wash, and dry.

Old Stock.—*Cracked Glaze.* You cannot do better than warm the old dishes and rub melted paraffin or white wax into the cracks ; even then such vessels should only be used for inferior purposes. Old glasses are worth looking over to select out the best squares for photographic use or framing, all the rest being drafted off to the horticulturist.

Torres.—*Luminous Paint.* This can still be obtained of Mr. Horne, 6, Dowgate Hill, E.C. It is generally used only as a last coating to save expense.

Len.—*British Association.* The official report of the Cardiff meeting will not be issued until next March or April ; meanwhile the scientific papers are appearing in the *Chemical News*, *Nature*, *Engineer*, *Electrician*, and other class journals, taking special notice of communications interesting to their readers. The *South Wales Daily News* (Cardiff, St. Mary's Street), from 19th to 26th ult., gave good summaries of the general proceedings in the various sections, and to these, or the *Times* reports, you might turn in the first instance for preliminary information.

E. M. (Crewe).—*Eoside of Silver.* The facts are not quite as you have stated, for the eosines and erythrosines always contain chlorine, bromine, or iodine, and these halogens are necessary constituents of the organo-silver compound formed on precipitating an aqueous solution of the colouring matter with nitrate of silver. Fluoresceine can be worked in with the eosines, but not magenta, unless alcohol be employed. Have you tried naphthaline red, "Rose de Magdala"?

Ed. L. Wilson.—Your letter has been sent on to South Kensington.

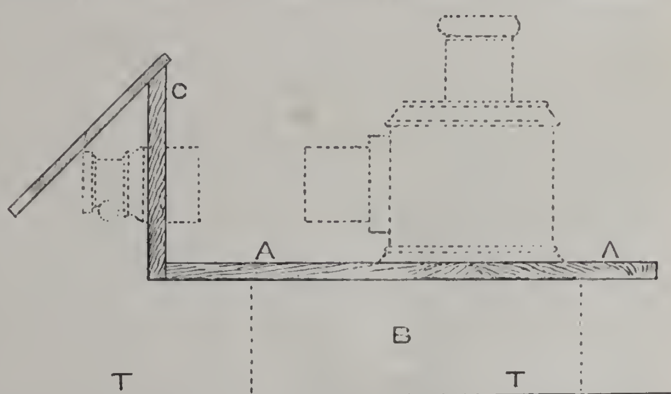
## A NEW USE FOR THE OPTICAL LANTERN.

WITH the increase of schools of art all over the country a knowledge of drawing has become far more common among us than it was twenty or thirty years ago. This is indeed a subject for congratulation, for the practice of art, different from many other pursuits, confers benefit and pleasure upon others besides its professor. Since, too, the invention of several photo-mechanical processes by which drawings can be readily transformed into typographic blocks without the intervention of the engraver, there has been a demand for drawings in black and white such as never existed before; so that all around us we see schools arising which profess to devote themselves to the new branch of graphic ait, and pupils eagerly availing themselves of the profferd instruction. We think, then, that any means which promises a still closer union between the photographer and the draughtsman, and which may tempt the latter to adopt the pencil of the former, cannot fail to have an influence for good. Such a means we wish now to place before our readers, and, although we cannot claim any great originality for the suggestion, we may at least say that it is a new application of an old idea.

It came about in this way. Some time ago we were wishful to obtain some photo-mechanical blocks from certain lantern slides we had at hand. The half-tone processes of the Meisenbach type were obviously out of the question, for the printing had to be done on a quick rotary machine. It was therefore determined that they should be drawn in line on card in the blackest of inks, photographed, transferred to zinc, and etched in the usual manner. But when we came to make the necessary enlarged drawings from the slides, we found that the work was extremely slow and laborious, although we employed proportional compasses and other labour-saving devices. It was then suggested that the slides should be severally placed in a lantern, and that the resulting enlarged image, received upon a piece of card, should be outlined direct in pencil. This we did, but found the work extremely fatiguing, for the cardboard upon which we pencilled the lines was necessarily in a strictly vertical position, and the attitude assumed was so cramped that a frequent rest was demanded.

It was now suggested that things might be much improved if the enlarged image, instead of being projected horizontally, were thrown down upon a table, at which the worker might sit with some degree of comfort. The hint was quickly acted on, and by the same evening we had constructed a rough and ready enlarging



apparatus for draughtsmen, which has since been constantly in use, and which we would not readily part with. It is simply an application of the *camera lucida* principle, which has so long been in use for the drawing of microscopic objects, to the ordinary mineral oil optical lantern, only that, instead of using a prism, we make use of a common mirror.

The apparatus consists of a base-board about seven inches in width, with a ledge at each side, leaving in the centre sufficient space for the lantern to be moved to and fro, while at the same time the ledges cause the image cast to be always central. But the relation of parts will be best understood by reference to the accompanying sectional drawing.

AA is the base-board, made out of inch deal, with a ledge on each side as already stated. It is about seven inches in width and three feet in length, and while in use it is supported on a (lantern) box, B, laid on its side on the table, TT. At one end of this base-board is an upright, C, of the same width (seven inches), pierced in the centre with a four-inch hole so as to carry the front of the lens tube, which is separated from the lantern body by a space which varies with the amount of enlargement or reduction which may be required. At the top, this vertical board is bevelled to an angle of 45°, and by means of wooden buttons a piece of looking-glass, face downwards, is fixed at that angle. This glass is large enough to cover the lens front, so that the image of the picture on the stage is intercepted and cast upon the table below, upon which a sheet of cardboard is placed to receive it. A piece of ordinary looking-glass is employed—in our case we actually use a hand toilet-glass—and although theoretically such a glass, not silvered on the surface, should cast a double image, in practice it is found that no secondary image is perceptible. Indeed, so free is the reflection given from this difficulty that the arrangement might with advantage be employed for making reversed negatives.

A lantern can be used in this way by daylight provided that the window-blind is pulled down, so that the picture thrown upon the cardboard is not eclipsed by the brighter light. There is, indeed, an advantage in working under such conditions, for the lines of the picture may be traced over in pencil, while, at the same time, the artist can watch the growth of his own work. There is also an advantage in shutting off the lantern light every now and then, so that progress may be reported the more effectually. It is obvious that the lantern employed in this way will give a reduced image as well as one which is larger than the original. But, in this case, it will be found necessary either to reduce the size of the support upon which the base-board stands, or to raise the cardboard upon which the image is cast. The apparatus as shown is, of course, but a makeshift, and a far more perfect contrivance can be readily constructed by anyone with a little ingenuity in his composition. Such an improved instrument would compromise a mechanical movement for altering the height of the lantern, as well as a rack-work for moving it from and towards the front lens. There are many other points which will doubtless be suggested by those who care to give time and thought to the matter. We place the idea before our readers in a roughly hewn state, and will leave them to cut down its angles and polish it up generally according to their individual tastes.

We need hardly point out that with a more powerful source of light—such as the oxyhydrogen light—the lantern can be used for tracing pictures of far larger size. In this form it should be most useful to artists for making rough sketches upon canvas or paper. We have also often suggested that scene-painters should call in its aid to help them in sketching out their designs in charcoal, instead of squaring both drawing and canvas in the usual manner. Messrs. Perken, Son, and Rayment are about to bring out a lantern sketching arrangement on the lines indicated in this article.

## DEVELOPIANA.

BY C. BRANGWIN BARNES.

However nicely a picture may be posed and lighted, and however exact may be the exposure, the whole effect may be absolutely marred by injudicious or careless development. Most operators have a pet formula of their own, in some cases closely assimilating to that issued with the particular brand of plates in use, and in others totally dissimilar. It should, nevertheless, be borne in mind that different subjects and different exposures require a different mode of development. A negative that requires reduction or intensification is never the equal of one that has been correctly developed, however carefully the intensification or reduction has been done, and, therefore, it should be our main aim to produce negatives that do not require either of these processes. The system which has latterly gained ground in large businesses of developing two or more plates at once is, on the face of it, a bad one. I have personally, when pressed for time, developed as many as thirty quarter-plates in a batch, but am compelled to admit that, had each plate been developed separately, they would have been better.

Good results may be obtained with almost any standard developer—*i. e.*, as regards the stock solutions—with the exception of those wherein the bromide and the ammonia are mixed; the only requisite being to dilute and mingle these stock solutions with care, and bearing in mind the treatment the plate has received beforehand. For example, take a plate which has been exposed upon a lady in light drapery, and which is believed to be exact as to exposure; a normal developer may bring about a successful result, but if the development be started with less bromide than usual, there will be all the more chance of obtaining a soft and harmonious picture. The materials composing the pyro developer are cheap enough, and yet many use the same solution for two or three plates, whereas others who wish to obtain the best result the plate will give sometimes use two, or even three, separate lots of solution on one. If a negative comes up thin and lacking in brilliancy, it is usually recommended to add more pyro or bromide to the developer which is being used; but a much better result will be obtained by throwing off the old solution altogether, and pouring on some fresh in which the proportions of pyro and bromide are stronger. If, on the other hand, the *cliché* is developing with too great a contrast, the solution should be thrown off as before, and development continued with a fresh lot in which the pyro and bromide are much weaker, and the ammonia proportionately stronger. If the drapery develops with full strength, and the face—from being brown, or from any other cause—is thin, local density can be obtained by pouring the developer back into the measure, and then direct on to the weak part, repeating the operation until the required amount of density is obtained.

It is astounding how many of the little tricks which used to be so successful with the old wet collodion plate will prove themselves equally so with the dry gelatino-bromide. An underdone wet plate used always to be exposed to the yellow light of the dark room window for some seconds; yet how few think of doing the same with the dry plate! Let those who have never tried the experiment do so, and they will be astonished at the vast amount of detail it will bring out; and when I say detail I do not mean fog, but detail exactly the same as would have been obtained by a prolonged exposure. Think of this when a cross baby or a restive animal is to be taken, and any negative of which you have the slightest suspicion as regards fulness of exposure, hold up to your dark room window for twenty or thirty seconds before you develop, and then proceed as for a fully exposed plate. Sulphite of soda in the developer acts, to a certain extent, as a restrainer, and whenever it is used care should be taken in apportioning the bromide, or the result will be a negative which, while it assimilates in colour to the old wet plate, will have very harsh lights and clear shadows, very much after the style of a bad flash-light picture.

The mention of flash-light pictures reminds me that winter is at hand, and that ere many months—or very many weeks, for matter of that—are gone, the flash-lamp will be in use again. Already the shades of evening come upon us so early that those of us who have no flash-light apparatus are often compelled to send a late sitter away. However, I opine that the coming winter will see the apparatus in nearly every studio except those which have an electric light installation; and, if not out of place in such an article as this, I would advise all intending purchasers to avoid spirit lamps. I have used James's lamp, in which the magnesium is burned in a gas flame, for the past three winters, and have been more than satisfied with the results. One reason for speaking of flash-lamps is that pictures taken by their aid require some considerable modification of the developer, and probably the easiest way of effecting this is to use just half the usual quantity of bromide in the stock solution. A formula which I have found very useful for this class of picture is the following:

| | | |
|---|---|---|
| A.—Pyrogallic acid (Schering) | ... ... | 1 ounce |
| Bromide ammonium or Bromide of potassium | ... ... ... | $\frac{1}{2}$ ,, / $\frac{3}{4}$ ,, |
| Water ... | ... ... | 7 ounces |
| B.—Ammonia | ... ... | 1 ounce |
| Water ... | ... ... | 40 ounces |
| C.—A | ... ... | 1 ounce |
| Water ... | ... ... | 20 ounces |

To develop, take equal parts of B and C, which will, in ordinary cases, ensure a soft and well graduated negative, although different proportions of B and C will be required for under-exposed or over-exposed plates, or for subjects introducing white draperies, or dead black dresses, &c. The judgment of the operator will, in most cases, tell him what proportions are required, and if the first appearance of the image should prove he has miscalculated, he should not try to improve the solution he is using, but throw it away and commence again with fresh.

One last word, and that is, to obtain clean negatives, the measures and dishes in use for developing must be kept clean; water alone is not sufficient for this purpose. They should be occasionally cleansed with dilute hydrochloric or nitric acid, preferably the former.

---

The Photochronograph. — Rev. George A. Fargis, S.J., assistant director of the Georgetown College Observatory, at Washington, D.C., has invented an instrument which he calls the photochronograph, and which he claims to be capable of registering the time of star transits to the one-thousandth part of a second. Should his instrument prove thoroughly accurate and reliable, as is believed it will, he will have the satisfaction of having taken a long stride toward the perfection of photographic records.—*Anthony's Bulletin.*

## THE RATE OF EXPLOSIONS IN GASES.*

The use of compressed gases is now so much identified with photographic work, that the following abstract of a paper brought recently before the Royal Institution of Great Britain by Professor Dixon, F.R.S., of Owen's College, Manchester, cannot fail to be of interest to many of our readers.

The rapid act of chemical change which follows the kindling of an explosive mixture of gases has of late years attracted the interest both of practical engineers and of theoretical chemists. To utilise for motive power the expansive force of ignited gases; to minimise the chance of disastrous conflagrations of fire-damp in coal-mines; to follow the progress of chemical changes under the simplest conditions, are some among the problems presented to us in industry or science, demanding for their solution a knowledge of the phenomena of the explosions of gases.

To understand the nature of explosions in gases, it is necessary to know certain fundamental properties of the explosive mixture. With this object in view, experimenters have sought to determine for various mixtures of gases—the heat of chemical combination, the temperature of inflammation, the pressure developed, and, lastly, the rate at which the explosion is propagated under different conditions.

It is on the last of these problems—the determination of the velocity with which the flame travels through the gas—that I have been asked to speak.

Twenty-four years ago Bunsen described a method of measuring the rapidity of the flame in gas explosions. Passing a mixture of explosive gases through an orifice at the end of a tube, and igniting the gases as they issued into the air, he determined the rate at which the gases must be driven through the tube to prevent the flame passing back through the opening and exploding inside the tube. By this method he found that the rate of propagation of the ignition of hydrogen and oxygen was thirty-four metres per second, while the rate of ignition of carbonic oxide and oxygen was less than one metre per second. Bunsen applied these results to the rate of explosion of gases in closed vessels, and his results were accepted without cavil for fourteen years.

By 1880 facts began to accumulate which seemed inconsistent with Bunsen's conclusions. For instance, between 1876-80 I had several times observed that the flame of carbonic oxide and oxygen travelled in a long eudiometer too quickly to be followed by the eye. Mr. A. V. Harcourt, in his investigation of an explosion which happened in a large gas main near the Tottenham Court Road in 1880, was led to the conclusion that the flame travelled at a rate exceeding one hundred yards per second. In the winter of 1880-1 I noticed the rapid increase of velocity as a flame of carbon bisulphide with nitric oxide travelled down a long glass vessel; and shortly afterwards I attempted to measure the rate of explosion of carbonic oxide and oxygen by photographing on a moving plate the flash at the beginning and end of a long tube. The two flashes appeared to be simultaneous to the eye, but no record of the rate was obtained, for the apparatus was broken to pieces by the violence of the explosion.

In July, 1881, two papers appeared in the *Comptes Rendus*, one by M. Berthelot, the other by MM. Mallard and Le Chatelier. Both papers announced the discovery of the enormous velocity of explosion of gaseous mixtures.

* *Chemical News.*

Other papers quickly followed by the same authors. M. Berthelot made the important discovery that the rate of explosion rapidity increases from its point of origin until it reaches a maximum which remains constant, however long the column of gases may be. This maximum M. Berthelot states to be independent of the pressure of the gases, of the material of the tube, and of its diameter above a small limit. The rate of explosion thus forms a new physico-chemical constant, having important theoretical and practical bearings. The name "L'Onde Explosive" is given by Berthelot to the flame when propagated through an explosive mixture of gases at the maximum velocity.

While Berthelot, associated with Vieille, was measuring the rate of the "explosion-wave" for various mixtures of gases, Mallard and Le Chatelier continued the study of the preliminary phenomena of explosion which precede the formation of the "wave." They showed, by photographing on a revolving cylinder—(1) that when a mixture such as nitric oxide and carbon bisulphide is ignited at the open end of a tube, the flame travels a certain distance (depending on the diameter and length of the tube) at a uniform velocity; (2) that at a certain point in the tube vibrations are set up which alter the character of the flame, and that these vibrations become more intense, the flame swinging backwards and forwards, with oscillations of increasing amplitude; and (3) that the flame either goes out altogether, or that the rest of the gas detonates with extreme velocity. Again, when a mixture of gases was fired near the closed end of the tube, they found the velocity of the flame regularly increased, as far as their instruments were able to record the rapidly-increasing pace.

Mixtures of coal-gas with air, and of fire-damp with air, show phenomena of the first and second kind. Ignited at the open end of a tube, these mixtures burn at a uniform rate for a certain distance, and then the flame begins to vibrate.

The vibrations acquire greater or less velocity according to the nature of the mixture and the conditions of the experiment; but the third *régime* of uniform maximum velocity is not set up. In narrow tubes the explosion soon dies out.

The phenomena studied by Mallard and Le Chatelier have been observed on a large scale in explosions in coal mines. It has been noticed that little damage was caused at the source of an explosion, and for a distance varying from fifty to eighty yards from the origin of the flame, while beyond that distance fall of roof, broken tubs, and blown-out stoppings have testified to the violence exerted by the explosion. Great as the destruction is which an explosion of fire-damp and air causes in a mine, it is fortunate that these mixtures do not *detonate*.

Passing on to Berthelot's researches on the *régime* of detonation, I will briefly summarise the results he has arrived at. The actual velocities of explosion are compared by Berthelot with the mean velocity of translation of the gaseous products of combustion, supposing these products to contain all the heat that is developed in the reaction. For instance, we know the total heat given out when hydrogen and oxygen combine. If this heat is contained in the steam produced, we can calculate what its temperature must be if we know its heat capacity; and if we know the temperature of the steam, we can calculate the mean velocity with which the molecules must be moving. Now Berthelot supposes that the heat is all contained in the steam produced. He assumes that the heat capacity of steam is the same as the sum of those of its constituents; and he supposes, moreover, that the steam is heated at constant pressure. Making these assumptions, he calculates out the theoretical mean velocity of the products of combustion of various mixtures, and finds a close accordance between these numbers and the explosion rates of the same mixtures. He concludes that the explosive wave is propagated by the impact of the products of combustion of one layer upon the unburnt gases in the next layer, and so on to the end of the tube at the rate of movement of the products of combustion themselves. If his theory is true, it accounts not only for the extreme rapidity of explosion of gaseous mixtures, and gives us the means of calculating the maximum velocity obtainable with any mixture of gases, but it also affords us information on the specific heats of gases at very high temperatures, and it explains the phenomena of detonation, whether of gases or of solid or liquid explosives.

Table I. shows the explosion rates found by Berthelot, compared with the theoretical velocity of the products of combustion. Two points in Table I. favoured the view that Berthelot might have here given the true theory of explosions: first, the close coincidence between the rates of explosion of hydrogen, both with oxygen and nitrous oxide, with the calculated mean velocities of the products of combustion; and secondly, the great discordance between the found and calculated rates for carbonic oxide with both oxygen and nitrous oxide. I had previously discovered that pure carbonic oxide cannot be exploded either with pure oxygen or pure nitrous oxide. The discordance found by Berthelot was what I should have expected from my own experiments.

A consideration of Berthelot's results, published in full in the *Annales de Chemie*, led me to think it would be useful to repeat and extend these experiments. My objects were chiefly—(1) to determine as accurately as possible the rate of the explosion-wave for some well-known mixtures; (2) to measure the rate of the explosion-wave in carbonic oxide with different quantities of steam; and (3) to determine the influence of inert gases on the propagation of the wave.

Table I.—*Berthelot's Experiments.*

| Gaseous Mixture. | Velocity in Metres per Second. Theoretical. | Found. |
|---|---|---|
| $H_2 + O$ Hydrogen and oxygen. | 2830 | 2810 |
| $H_2 + N_2O$ Hydrogen and nitrous oxide. | 2250 | 2284 |
| $CO + O$ Carbonic oxide and oxygen. | 1940 | 1090 |
| $CO + N_2O$ Carbonic oxide and nitrous oxide. | 1897 | 1106 |
| $CH_4 + O_4$ Marsh gas and oxygen. | 2427 | 2287 |
| $C_2H_4 + O_6$ Ethylene and oxygen. | 2517 | 2210 |
| $C_2N_2 + O_4$ Cyanogen and oxygen. | 2490 | 2195 |
| $C_2H_2 + O_5$ Acetylene and oxygen. | 2660 | 2482 |
| $CO + H_2 + O_2$ Carbonic oxide, hydrogen, and oxygen. | 2236 | 2008 |

*(To be continued.)*

## ON THE SPACE-PENETRATING POWER OF LARGE TELESCOPES.*

BY A. C. RANYARD.

Unless there is some small star or dimly shining body with a large parallax which has not yet been detected, our nearest neighbour amongst the stars is the double star α Centauri. It is situated about 30° from the southern pole of the heavens, and therefore is not visible in England. The two stars together shine with a light which is a little greater than that of a first magnitude star, for the larger of these twin suns is ranked by Prof. Gould as being exactly of the 1st magnitude of the photometric scale, and the smaller star is of the 3½ magnitude.

According to this photometric scale of magnitudes, which is now universally used, a star of the 1st magnitude gives just 100 times as much light as a star of the 6th magnitude. Consequently, if the larger star of the pair, which is known as $\alpha^2$ Centauri, were removed to ten times its present distance, it would appear as a star of the 6th magnitude; but this would only be the case if there were no loss of light in travelling from its more distant position. If there were any absorption of light in passing through such a vast distance of space, it might appear smaller and would probably not be visible to the naked eye, for few people see stars with their unaided eyes which are ranked as smaller than the 6th magnitude. According to the photometric scale, a star of any magnitude gives about 2½ times as much light as a star of the magnitude immediately below it. Thus, a star of the 6th magnitude gives 2·512 times as much light as a star of the 7th magnitude, and a star of the 7th magnitude gives 2·512 times as much light as a star of the 8th magnitude. Consequently, a star of the 6th magnitude gives 6·31 times as much light as a star of the 8th magnitude, and 15·85 times as much light as a star of the 9th magnitude, 39·81 times as much light as a star of the 10th magnitude, and 100 times as much light as a star of the 11th magnitude.

Let us suppose that $\alpha^2$ Centauri were removed to 100 times its present distance; then, neglecting the absorption of light in space, it would shine as a star of the 11th magnitude of the photometric scale, and would only just be visible with a telescope of 2½ in. aperture. This calculation is based on the assumption of Prof. C. A. Young ("Text-book of General Astronomy," sec. 822) that, for normal eyes, with a good telescope, the *minimum visible* for a 1 in. aperture is a star of the 9th magnitude—an estimate which about corresponds to what might be expected from the diameter of the pupil of the eye.

I have measured the diameter of the pupils of several persons whom I believed to have keen sight—amongst others, the observing eyes of the Rev. T. W. Webb, Mr. Burnham, and the late Dr. H. Draper—and have found that about ¼ in. generally corresponds to the maximum dilation of the pupil in viewing faint objects. A telescope of 1 in. diameter would, consequently, collect about sixteen times as much light as would enter the pupil of the unassisted eye, and ought, with a suitable eye-piece, to show stars giving about one-sixteenth the light of a 6th-magnitude star just visible to the naked eye. As we have seen above, a 6th-magnitude star gives 15·85 times as much light as a 9th-magnitude star of the photometric scale. Consequently, neglecting the absorption of light by the lenses, and the reflection from their surfaces, a 1 in. telescope ought, with a suitable eye-piece (which collects and sends into the pupil of the eye the whole of the light from the object-glass), to render the stars of the 9th magnitude just visible.

The power used with a telescope makes some difference, as it increases the contrast between the brightness of the star and the background on which it is seen—the light of the background being dimmed by magnification, while the star in a good defining telescope is but slightly dimmed by moderate magnification. Thus, Dawes found that he could see a star of the 6th magnitude with a telescope having an aperture of only 0·15 in. when a power of 16½ was used. In the case of the 1 in. telescope above referred to, the loss of light by absorption and reflection at the surfaces of the lenses seems to be about balanced by the increase of contrast with the background, due to the power employed.

Let us suppose that $\alpha^2$ Centauri were removed to a thousand times its present distance; then, neglecting the absorption of light in travelling through space, it would appear as a star of the 16th magnitude, and would only just be visible with a telescope of 25·12 in. aperture, and if it were removed to 1585· times its present distance, it would shine as a star of the 17th magnitude of the photometric scale, and would only just be visible in a telescope of 39·81 in. aperture. That is, it would not be visible in the great Lick 36 in. refractor.

These calculations are based on the assumption that there is no absorption of light in passing through great distances of space, and also on the assumption that there is no loss of light in passing through such thick lenses. The thickness of the object-glass of the "Washington" 26 in. refractor at its centre is nearly 3 in.; thus, the flint glass lens is there 0·96 in. thick, while the crown glass lens is 1·88 in. thick at its centre. Such a thickness more than halves the intensity of the emergent pencil, and the loss of light by absorption in passing through the glass near the centre of the Lick object-glass must be considerable. Exact measures of the absorption of light by such great lenses would be of much interest. We may, however, probably assume with some confidence that if $\alpha^2$ Centauri were removed to twelve hundred times its present distance it would not be visible in the Lick telescope, even though there were no absorption of light in space, and $\alpha^2$ Centauri is probably larger and brighter than our sun. (Assuming with Mr. Gore a period of seventy-seven years for this binary, and a parallax of ·75 of a second, the sum of the masses of the components will be 2·14 times the mass of the sun.) Stars smaller than our sun would be lost to sight at smaller distances. Consequently, the Milky Way must either be nearer to us than a thousand times the distance of α Centauri, or the smallest stars visible in it with a telescope as large as the Washington 26 in. refractor must be larger than our sun—a supposition at which the mind rebels when we remember the vast size which this would imply for the larger stars evidently involved in or associated with the Milky Way. For example, in the Pleiades group, there are observable with the eye at the telescope a range of some 13 magnitudes of the photometric scale, which, translated into ordinary language, means that the larger stars of the cluster give more than a hundred and fifty thousand times as much light as the smaller stars of the cluster.

In the photographs of the Pleiades cluster we have evidence of a range of at least 15 magnitudes, which

* *Knowledge.*

means that the larger stars give a million times as much light as the smaller stars, and in the photograph of the Coal-Sack region of the Milky Way there is evidence of a still greater range of magnitudes. The star α Crucis, which is of the 1·3 magnitude, is evidently associated with a dense cluster of small stars, branches from which can be traced far across the Coal-Sack region, and extending to a considerable distance over the Milky Way, or into the Milky Way, to the north of α Crucis. We seem to have in this instance evidence of a range of at least 17 magnitudes; and the proof of the connection between the large star and the small stars of the cluster is far stronger than as stated by me in the May number. α Crucis is a double star with components about five seconds apart, and there are several small companions that have been observed in the telescope. In the glass photographs sent me by Mr. Russell, the spurious disc of the large star is, when examined with a magnifier, seen to contain several small stars forming a cluster about the large one. Indeed, in the plate published in the May number, some seven or eight of these small stars may be recognised with a magnifying-glass on the edge of the spurious disc of the large star.

Though the mind may at first be staggered by the conception of stars giving a million times as much light as our sun, we are not in a position to deny the existence of such vast sun-like bodies. Indeed, those who accept the nebula hypothesis as giving the most probable explanation of the origin, or, rather, of the birth of the planets of the solar system, must be prepared to believe that there was a time when the sun had a diameter as large, or nearly as large, as the diameter of the orbit of Neptune. If, before these more than geologic ages of radiation into space, the surface or photosphere of the solar mass did not shine as brightly as it shines now, it must at least have been a nebula with a very definite surface, which, as seen from a distance of a hundred times as great as that of α Centauri, would have presented a disc nearly half a second in diameter. No disc has at present been observed to any star; we may therefore feel some confidence that there is no such vast sun-like body within a distance from us equal to fifty times the distance of α Centauri.

In the forthcoming part of the "Old and New Astronomy" I have shown reason to believe that there is evidence of absorption of light in space, and that we can, from the numbers of the stars of the various magnitudes, make a rough minimum estimate as to the amount of absorption of light in space, due either to a want of perfect elasticity in the light-transmitting ether, or to dark bodies cutting out or obliterating the light in its passage through space. This greatly reduces our idea of the magnitude of the region we can explore with the telescope and with the camera—α Centauri would probably be lost to the Lick telescope if it were removed to three hundred times its present distance—and it also greatly reduces our idea of the distance of the small stars of the Milky Way, and of the scale of the galactic system, as well as of the nebular system and of the system of clusters, red stars, and bright line stars which are so evidently associated with it.

It is not so very long ago that it was generally taught that the nebulæ were galaxies of stars more or less similar to the Milky Way that surrounds us, but so inconceivably remote as to appear, when observed with the largest telescopes, like small spots in the heavens. This theory suited the popular taste, and died hard. It involved the assumption that man could explore, with the instruments at his disposal, a space so immense that the interstellar spaces which we can just measure or guess at are dwarfed into points besides the distance from which light travels to us.

The theory should have been disposed of by the observations of Sir William Herschel, who noted that many nebulæ are evidently associated with stars, and observed that the smaller nebulæ were distributed over the heavens in a manner which shows an intimate connection between them and the brighter stars. He noted that the nebulæ in the northern heavens were clustered in the pole of the Milky Way, and descended like a canopy on all sides, leaving a dark space or channel separating the nebulous region from the rich stellar region of the Milky Way. Sir William Herschel also fully satisfied himself that "there were nebulosities which are not of a starry nature," and from his observations of diffused nebulæ he formed his well-known hypothesis of a diffused luminous fluid which, by its eventual aggregation, produced stars. But he did not proceed to the legitimate deduction from his observations as to the general distribution of nebulæ—viz., that nebulæ which are arranged so symmetrically with respect to the stars must belong to the stellar system, and therefore cannot be assumed to lie at immense distances compared with the distance of the Milky Way stars.

Sir John Herschel extended the observations of his father to the southern heavens, and showed that there was a similar clustering of the smaller nebulæ on the southern side of the Milky Way, and a similar intimate connection between the distribution of stars and the distribution of nebulæ in the southern hemisphere (see "Cape Observations," p. 134); but it was not till 1858 that the obvious conclusion from these observations was drawn by Mr. Herbert Spencer in a remarkable paper on "The Nebular Hypothesis," published in the *Westminster Review*. He remarked: "If there were but one nebula, it would be a curious coincidence were this one nebula so placed in the distant regions of space as to agree in direction with a starless spot in our own sidereal system. If there were but two nebulæ, and both were so placed, the coincidence would be excessively strange; what, then, shall we say on finding that there are thousands of nebulæ so placed? Shall we believe that in thousands of cases these far-removed galaxies happen to agree in their visible positions with the thin places in our own galaxy? Such a belief is impossible."

Mr. Herbert Spencer's paper was not illustrated by charts, and the force of his reasoning was not generally perceived till some ten years afterwards, when Prof. Cleveland Abbé drew attention, in the *Monthly Notices* of the Royal Astronomical Society for May, 1867, to the intimate connection between the distribution of nebulæ in space and stars; and Mr. Proctor, in 1869, constructed some charts on an equi-surface projection, which graphically put his readers in possession of the facts, and carried conviction to all who read his remarks.

The theory that the nebulæ were distint galaxies involved the assumption that light can reach us from regions many thousand times more remote than the stream of stars which compose our own galaxy; and it also involved the assumption that the matter of the universe is aggregated into clusters, separated by immense barren spaces, in which we must assume that there are very few luminous stars, and but few dark stars which would absorb light, as well as comparatively very little opaque matter distributed as meteors are distributed in the region of space we are familiar with.

We have evidence that the greater part of the lucid stars belong to the galactic system, but the large proper motion of some stars, taken in conjunction with their small parallax, affords evidence, as Prof. Simon Newcomb has pointed out, that they will in time pass away from our galaxy. Prof. Simon Newcomb has shown in his "Popular Astronomy" that, making the most liberal assumptions as to the number and masses of the stars of our galactic system, the highest speed which a body could attain if it fell from an infinite distance through such a stellar system would be twenty-five miles a second, a velocity which is certainly smaller than that of many stars. The regions outside our galaxy cannot, therefore, be absolutely barren, but however sparsely luminous stars are distributed through space, if there were no absorption of light in its passage through the ether, and no opaque bodies to blot out the line of distant stars, it would be impossible, as Olbers long ago pointed out, to draw a line in any direction which would not in an infinite universe pass through some luminous star, and the whole heavens ought to shine with the average brightness of such stars.

That the heavens are comparatively dark may, therefore, be taken as proof either that the light-transmitting ether is not perfectly elastic, or that there are numerous dark bodies in space that blot out the light which we should otherwise derive from the more distant parts of the universe.

## TALKING WITH THE STARS.

When Professor George Davidson, of the Davidson Observatory and the Coast and Geodetic Survey, was shown the Paris cablegram saying that au old lady had just died at Spa, leaving 100,000 fr. as a prize to the astronomer, French or foreign, who within ten years shall be able to communicate with any planet or star, he read it through slowly once, then he read it twice more rapidly. Finally, he picked it up, held it at the proper distance from his eyes, and squinted at it just as he would squint at Mercury through his telescope if he wanted to find the big tortoise-shaped spot on its northern hemisphere. "An old lady! au old lady!" the astronomer finally exclaimed. "Now, isn't that a pretty way to treat such a piece of philanthropy as that? Au old lady, indeed! Now, why under the suu do you suppose they keep back her name? I am inclined to believe that some good-looking young man—one of these smooth talkers – has been getting close to her and talking a lot of astronomy into her ear. From the very form her bequest takes I am aware that somebody—Flammarian or some other man—has been talking to her about the proposed triangle. The project is a very curious one, but can be explained quite easily."

Professor Davidson picked up a blue pencil and drew on a white sheet of paper a right-angled triangle. "This that I have drawn," he said, "is the old triangle of Pythagoras. That triangle has a right-angle, and the square built upou the side opposite the right-angle is equal to the sum of the squares built upou the other two sides. The proposition is said to be the fundamental one of geometry. It has been proposed to draw such a figure as that in the Desert of Sahara, or some other great plain, the lines, of course, to be hundreds of miles long, and made so that they would be distinct in the desert sand. One way would be to plant palm trees so that the forests would take the shape of lines in the figure. Certainly, the green of the palms would be so bright in the contrast with the white of the sand that the drawing, when completed, would be plain enough. These are the suppositions that go along with the idea. It is supposed that there are people on some of the planets—at least, on Mars. It is supposed that the people on the planet are civilised and capable of looking through telescopes, and it is concluded that if this is so, they must know the Pythagorean proposition. So, if the people of Mars look through their telescopes at the earth, they will be sure to see that enormous figure ou the desert, and, seeing it, they will realise that the earth is inhabited by men of knowledge, and that the drawing is a signal; then, of course, they will set to work to answer it by building just such a figure on Mars. That will be talking from star to star.

"But all this is bosh and nonsense to me, and I daresay it was bosh and nonsense to the man who wheedled the Frenchwoman into setting aside her 100,000 fr. But whoever he was, he knew on which side his bread was buttered, and knew that such a trust, for whatever purpose, would bear interest; but even supposing that the Desert of Sahara is one great plain, and that it is large enough for the purpose, and even supposing that it was possible to make such an enormous figure, I am in doubt whether the people on Mars, with such telescopes as we use, would be able to see it. At certain times, Mars is but 34,000,000 miles from the earth; but it gets further and further away, until the distance is 61,800,000 miles. That is a good way off to see triangles; but if Mars is inhabited, I am inclined to believe that the inhabitants are not fools. If they saw a triangle-shaped object on the face of the earth, they would not jump to the chimerical conclusion that there were idiots enough down here to build such an affair. The truth is, we do not know whether any of the planets besides the earth are inhabited. We think we know that it might be possible for men to live on Mercury. The situation and condition of things on the other planets are altogether different from those on the earth. So when we talk about the inhabitants of the planets we enter the realm of surmise, and M. Jules Verne has a better chance than the scientist. The four planets nearest the suu are Mercury, Venus, the Earth, and Mars. Mercury is only 35,392,000 miles from the suu, which is not very far when you take the heat into consideration. Consequently, we believe it is a good many times hotter than Arizona on Mercury. There are other disadvantages, such as a lack of space, enormous mountains, and no certainty of atmosphere. Mercury is only 3,060 miles in diameter, yet there are mountains on its surface over twelve miles high.

"Venus is 66,134,000 miles from the sun, and is plenty hot enough, although nearly twice as far as Mercury from the great heater. Then there is some question about the atmosphere as yet, and the year is only 224 days long. The earth comes next, being 91,430,000 miles from the sun. After this planet is Mars, 139,311,000 miles from the luminary. All astronomers admit that if people like those ou the earth live on any of the other planets, Mars is probably the one. The reasou why is easy to tell. Although Mars is further from the sun than the earth, his orbit is so eccentric that at certain times he is only 126,318,000 miles away; consequently, the temperatures are likely merely a little more moderate than those ou the earth. Then, too, the diurnal motion of the two planets is about the same, so that from one year's end to another the distance from the earth to Mars varies only from 33,800,000 miles to 61,800,000 miles. Mars has its seasons and its polar ice just like the earth. Through the telescope we can watch icefields at the poles get larger as winter approaches, and see them get smaller again in the summer. Mars has an atmosphere and clouds like those on earth. There are continents and oceans ou Mars, so that, altogether, the analogy between that planet and the earth is very close, the striking difference being that Mars is much the smaller. Astronomers are more and more disposed to believe that Mars is inhabited. You ask me if we know, however, and I promptly tell you we do not. An astronomer named Schiaparelli claims he is able to see a double line of canals on Mars. These must be enormous works if he can see them, and must represent a stupendous amount of work on the part of an almost countless number of people. I cannot see them through my telescope, and many others fail. After all, these canals may be in Schiaparelli's eye. People get what is called astigmatism now-a-days, and see two pencils where there is only one. Perhaps that is what Schiaparelli has. But even if there are people on Mars, and even if they have built canals, as for talking with them" (and the professor repeated the statement to make it more positive), "as for talking with them, nonsense!"—*San Francisco Examiner.*

## Notes.

Sulphide of ammonia is a compound which was happily better known to a past generation of photographers than to those of to-day, its chief use being for intensifying wet plate negatives. We say happily, for the smell of the compound is of such a terrible nature, hovering between the odour of ammonia proper and eggs of advanced decomposition, that it is not a very pleasant thing to handle. We remember, some years ago, at a political meeting, some rascal quietly emptied a bottle of the mixture on the floor, a proceeding which quickly dispersed the greater part of the audience. We note that the suggestion was made the other day to the Paris mob that small bombs filled with the liquid should be used in the Paris Opera House on the occasion of the production of Wagner's "Lohengrin," but we are glad to learn that this mischievous advice was not acted upon.

Some months ago, when the automatic photographic machines first made their appearance, we were asked whether this new form of labour-saving device would not have a very disastrous effect upon the interests of photographers. We replied that our correspondent need be under no alarm, and briefly gave our reasons for thinking so. Our views were speedily borne out by the failure of the machines, except under expert management, to fulfil the promises made for them by their godfathers and godmothers—the general newspapers. (The photographic press, it will be remembered, was carefully excluded from the invitations issued by the Company to see the machines at work.)

But it would seem that, although there is nothing to fear for the present from any automatic bogey, there are photographers who undertake to work at such ridiculously low prices that they must exercise a bad influence upon business generally. As an example of this, we refer to the contents of a card placed prominently in a photographer's window which we have seen this week, and have copied *verbatim*. We do not give the name or address, for we do not care to advertise one who works at such cutting prices. "C.D.V., three for one shilling; six for two shillings; or twelve for four shillings." To make a negative and to print from it three positives for a total sum of one shilling, including retouching, spotting, and mounting, cannot, we should imagine, leave much margin for profit. And we need hardly say that the specimens shown were not very grand examples of photographic art. Possibly the secret of the mystery may be found in the contents of the other window of the shop in which they were exposed, which contained an assortment of the articles usually found in a small grocery store. The camera may be used as a bait to secure customers for tea, sugar, bacon, and candles, and perhaps the enterprise may pay in the long run. For all this, such a lowering of the art is to be much deplored.

The aid of the newspapers as a medium for puffing is once more exemplified in a paragraph going the rounds to the effect that somebody has discovered that, by placing a card covered with Balmain's luminous paint in a camera, a phosphorescent picture may be produced. This "new discovery" is as old as the hills, and such luminous pictures have been produced not only in the camera, but by a short exposure behind a transparency. If we mistake not, portraits on glass backed by a phosphorescent surface were introduced commercially at least ten years ago. What a pity it seems that modern workers will not read up the history of what has already been done, so as to save themselves the trouble of re-inventing old ideas.

Our enterprising contemporary, *Woman*, is giving portraits of its readers drawn from photographs submitted to its professor of physiognomy for delineation of character. We have nothing to say against the idea, but should much like to know the meaning of the following guarded observations. "Unfortunately," says the editor, "photography is a fickle and uncertain agent. It often happens that a portrait only just suggests the likeness and character of the subject, so that we have been deprived of publishing a large number of portraits of readers of apparently strong types of character, whose photos make pretty pictures, more than distinct likenesses. Our artist can only deal with those in which the features are clearly and firmly delineated." We must confess we do not quite understand this, unless the explanation is to be found in the hint at the end. Have some of the photographs been of the "fuzzy" type so dear to the advanced school of photographers; have the sitters moved, or has the retoucher's pencil been at work obliterating all the salient points which go to make up character in a portrait? If the latter be the case, *Woman* should have said so boldly. An adverse opinion expressed by such an authority might have had a beneficial effect. It is very certain that nothing irritates the draughtsman who has to reproduce a photograph so much as a portrait of the Book-of-Beauty *papier maché* tea-tray variety.

An interesting record of the House of Commons is in preparation. It consists of four volumes, containing the portrait of every member returned to the present Parliament. A society journal, in announcing the fact, gravely says, "We are assured that by the new process of photognezzotype (*sic*) the reproduction of the photographs will be permanent." "Photognezzotype" is distinctly good. We have never heard of it before, but if we might hazard a guess with the assistance of the French language, it should mean photographs of the members' noses!

Some curious ideas as to the use of photography by the police prevail in the City. A friend, a few nights ago, had the misfortune to be locked in his office through the occupants of the shop on the ground floor leaving without ascertaining whether anybody was in the house. He managed to escape by lowering out of the window to a passer-by the key of the padlock which the regulations of the City impose upon householders to fasten on all outer doors. Relating the circumstance to the shopman, who the next morning was full of apologies, he remarked that it gave him no trouble to get out. "Ah! but it might have given you a little trouble afterwards if a policeman had unlocked the padlock. He would have been obliged to have taken you to the station, where you would have had to have given your name and address, and perhaps while you were talking they'd have taken your portrait. Everybody is photographed as is taken to a police station, though they don't know it." As the man was perfectly serious, he evidently believed he was speaking the truth. Our friend does not think the photographic acquirements of the police have yet reached this length, nor do we.

## SPHERICAL ABERRATION.

BY T. R. DALLMEYER.

It is surprising that this simple subject, confronting one at the very outset of the study of theoretical optics, should still be put forward as a matter of such uncertainty as to necessitate further discussion.

When Mr. Burton says (in italics), "It would be very easy to prove anything I wanted to prove," argument with him becomes an impossibility, for from his standpoint he must be always right or never wrong.

I have looked up Mr. Burton's former letter (and my reply thereto) and compared it with the present one, and am glad to find that he now understands the correspondence of distances before or behind the plane of average focus in their true bearing, viz., the reverse of his previous statement. As to the drawing, it looks pretty, but is worthless in its bearing on the subject. That the areas of circles are dependent on the squares of their radii is familiar to a novice in geometry, but what does it matter in a *drawing* if the *boundary lines* of equal or unequal areas are represented, so long as they cross the axis at the proper positions in the locus of longitudinal aberration? *The longitudinal aberration increases or diminishes as the square of the diameter of aperture.*

Mr. Burton misses the mark when he loses sight of this fact, and that, practically speaking, there is a definite measurable area of the lens near the axis exhibiting no measurable aberration at all, light from the whole of this area being concentrated at the apex of the axial cone—the area of the base of this cone being determined by the amount of positive spherical aberration in the entire system or lens—in a single point. When this aperture is exceeded and aberration is traceable, every measurable area, however small, has a focus nearer and nearer the lens, the further the zone is removed from the base of the axial cone, until the extreme zone of full aperture is reached. The focus of this zone determines the limit of the locus towards the lens, the distance between this and the axial cone determining the locus of longitudinal aberration. In short, when spherical aberration is present, there is a definite measurable aperture free from practically measurable aberration, which we will call the aplanatic cone of rays; and when this is passed, and the spherical aberration becomes measurable or visible, every infinitely small area of increase of aperture has a focus of its own along the locus of longitudinal aberration.

The apex, then, of the axial aplanatic cone is the position of greatest concentration theoretically and practically, and is the best focus, unmistakable to a practised eye, either on contrasted subjects of light on dark grounds, or *vice versa*. The remaining zones, however small, have no collective focus on the axis, but each a separate one that forms out-of-focus zones around the concentrated focus of the axial aplanatic cone.

I hope Mr. Burton will now see the absurdity of placing his focus midway in the locus of longitudinal aberration as "fair."

The first of all tests (known to every astronomer) is the observance of a point of light, or a flame, when focussed for; if the structure is still maintained outside the focus with the halo around it, positive spherical aberration is present; and if the reverse, negative. It is the maintenance of structure that is the real test, and this is best visible at the apex of the axial cone corresponding to a central portion only of the lens if aberration is present.

Now, a word as to the conclusions to be drawn from Mr. Burton's observations, that he invites readers to draw for themselves. In the best visual images formed by an accurate observer, there is no difference, theoretically or practically, between the two classes, viz., a dark object on a bright ground, or a bright object on a dark ground. There is one and only one position of focus to show the structure in the best possible degree.

What Mr. Burton describes as "personal equatiou" in focussing, I should term want of practice in accurate observations. There are two reasons why the practical results are not absolutely identical with the visual, one general, the other particular in their application.

The general reason I have already explained in the paper contributed on this subject to the Camera Club Conference. In photography a dark object on a light ground, particularly in the case noted by Mr. Burton, of "fairly ample exposures," the printed results in this case (hastily prepared in collotype) were in certain instances not in keeping with the original visual impression; the negative obtained, however, showed the structure, by careful examination, sufficiently clearly to be conclusive as to the best definition.

The effect of spherical aberration in the visual appearance of a dark object—say a disc—on a bright ground is that of a disc dark in the centre, and gradually becoming lighter towards its edges, but still maintaining its structure; and the effect round the edge in cases of fairly ample exposure might, as it were, be eaten into by the halation effect produced, so as to cause the definiteness of the outline to soften off, appearing, to a casual observer, out of focus. Now, if this disc be removed nearer to or further from the lens, what happens? In the former case the black disc becomes a *dark ring* with *a definite edge* in the negative, with a lighter centre! In the latter case, a *dark centre* with the halation asserting itself more and more as it approaches the edge! It is evident the *structure* is maintained best at and beyond the best focus.

The appearance of the bright point of light on a dark ground is identical, in the true sense of maintenance of structure, under the same conditions. As before stated, this is the optical test used by astronomers. (I notice Mr. Burton has succeeded in proving this latter test for structure to himself.)

The second reason for the difference between visual and chemical results I have not mentioned before for obvious reasons. It applies to persoual manufacture, and I have not had any encouragement to reply to any previous superficial utterances and letters, except upon premises taken up upon those occasions. Mr. Burton mentions that his experiments were conducted with a lens recently manufactured on the principle of the invention of my late father to produce spherical aberration at will.

Has it never struck Mr. Burton that if the lens were actinic when the back combination was in its normal position, *free from aberration*, that it would not be perfectly so when the back flint was removed from the crown by the process of unscrewing? It not only introduces positive spherical aberration purposely, but also a slight amount of positive chromatic aberration. In the construction as it stands, and for the amount of positive spherical aberration introduced, this alteration will be hardly noticeable, and very difficult to trace, but the tendency is to favour the definition of objects slightly in front of the plane focussed for. For planes behind this, the inward concentration of rays already referred to *continues*, tending to maintain structure, but softening off gradually. The theoretical objection to an under-corrected lens might legitimately have been pointed out by a scientific critic if one had appeared; its practical bearing, however, in the construction referred to, when usually a small amount of positive spherical aberration is introduced, the slight shifting forward of the plane of focus in the object is rather advantageous than otherwise for the desired end to be attained. If excessive aberration be introduced in the construction referred to, the positive chromatic aberration would, of course, assert itself to a noticeable extent.

The final portion of Mr. Burton's letter refers to an entirely different subject, viz., that of the definition given by an aplanatic lens with its powerful discriminating focus, as compared with that of the eye.

Has Mr. Burton ever been down a mine or a deep well in the daytime and seen the stars on looking up? If he has, he will perhaps acknowledge that the less amount of diffused light that reaches the eye, the more discriminating power it has, and also that much more diffused light, under ordinary circumstances, enters the eye in viewing any scene than would enter a well-stopped-down and shaded lens in connection with a camera. To give another example, if a lens has a "flare spot," is the discriminating power of the lens over that portion of the plate the same as in the remainder? As to definition over *one plane*, cited in the last paragraph of Mr. Burton's letter, by inference, excluding the question of diffused light, personally I do see finer definition in the reproduction of a black and white subject in a photographic reduction than I do of the subject itself when viewed under the same angle. I have always understood that the investigations of *authorities* in the subject uphold this view.

## VOLATILE PLATINUM COMPOUNDS.*

BY W. PULLINGER, BRACKENBURY SCHOLAR OF BALLIOL COLLEGE, OXFORD.

The object of this work was to determine, if possible, the vapour density of some compound of platinum. In order to obtain a suitable substance for this purpose, and to find the best conditions under which the trials could be made, some miscellaneous phenomena were observed, worthy of note, but apparently unconnected with the subject.

The only volatile compounds of platinum hitherto known are those described by Schützenberger (*Ann. Chim. Phys.* [4], 21, 350; *Annalen*, Suppl. 8, 242) in the year 1872. They were obtained by passing alternately streams of chlorine and carbon monoxide over platinum sponge heated at 250° in a combustion tube by means of a gas furnace. The volatilised substance was collected in a suitable receiver. In this manner Schützenberger obtained a mixture of three volatile compounds, namely, carbonyl chloroplatinite, $CO,PtCl_2$, dicarbonyl chloroplatinite, $C_2O_2PtCl_2$, and sesquicarbonyl chloroplatinite, $C_3O_3,Pt_2Cl_4$.

Now, if we follow out the instructions given by Schützenberger, substituting a small furnace for the oil-bath in which he heated the tube, we obtain another yellow substance, which remains behind after the volatile compounds have been driven from the heated part of the tube. This compound occupies the same position as the platinum originally did, nor can any amount of heating volatilise it. When hot it is brick-red, and on cooling changes to a bright canary-yellow. It was obtained in two different experiments, but was only homogeneous in the first. From the method of formation, it seemed probable that the product was a combination of platinum, chlorine, and carbon monoxide, since it was not formed till the latter gas had been passed over the platinum chloride for a considerable time. It absorbed water from the air very slowly. An analysis of the substance was made in the following manner. The *water* absorbed from the air was determined by heating the substance in an air-bath to successively rising temperatures till its weight was constant. It proved to be anhydrous at 105°. The *platinum* and *chlorine* were determined by reducing the compound by pure magnesium and acetic acid.

The reduced platinum was collected and weighed. The chlorine was precipitated by silver nitrate in large excess of nitric acid, and the precipitate treated and weighed in the usual manner. The carbon monoxide was found by difference. The percentage composition thus obtained was:—

| | |
|---|---|
| Platinum ... ... ... ... ... | 40·36 |
| Chlorine ... ... ... ... ... | 44·71 |
| Water ... ... ... ... ... | 4·19 |
| Carbon monoxide ... ... ... ... | 10·74 |

Now the water present bears no molecular ratio to the other constituents. Calculating, therefore, the percentage composition of the anhydrous substance, we obtain the values:—

| | | | |
|---|---|---|---|
| Platinum ... ... | 42·12 | against the theoretical | 42·01 |
| Chlorine ... ... | 46·66 | | 45·89 |
| Carbon monoxide ... | 11·32 | | 12·08 |
| | 100·00 | | 100·00 |

which are the values calculated for a compound having the formula $PtCl_2,2COCl_2$, or $PtCl_6,C_2O_2$. The compound would, therefore, appear to be a combination of platinum dichloride with phosgene. It was thought possible that this substance had resulted from the action of a small amount of phosgene on the platinum dichloride. An attempt was, therefore, made to obtain it by passing a stream of phosgene over the heated chloride, but without success.

*Properties of the New Compound.*—It is a yellow, crystalline solid, stable in air, but slightly deliquescent. It dissolves easily in water without blackening, and, on evaporation, separates from its solution in yellow crystals apparently unaltered. In alcohol it is only slightly soluble, and carbon tetrachloride dissolves scarcely any. When strongly heated, it is decomposed with evolution of chlorine and phosgene. Thus, it has none of the properties characteristic of Schützenberger's compounds. It may perhaps be called phosgeneplatinum dichloride.

Specimens of carbonyl chloroplatinite, $CO,PtCl$ , and dicarbonyl chloroplatinite, $C_2O_2Pt_2Cl_4$, were next prepared in the pure state. The former was obtained by bubbling carbon monoxide for over an hour through the melted crude product; the latter, by a similar method, substituting carbon dioxide for the monoxide.

Schützenberger says that the action of water on these compounds is very complex (*loc. cit.*). This, perhaps, results from a secondary action which takes place between the hydrogen chloride and the undecomposed substance. The equations given for the action of water are:—

(1.) $CO,PtCl_2 + OH_2 = CO_2 + Pt + 2HCl$,

(2.) $C_2O_2PtCl_2 + OH_2 = CO_2 + CO + Pt + 2HCl$;

but, as Schützenberger points out, these represent only

* *Journal of the Chemical Society.*

the chief actions. Now, in neither of these reactions is platinum formed as a first result of the action. If a drop of water is added to a crystal of the substance, it immediately becomes black. But both strong hydrochloric and strong nitric acid dissolve the black substance; therefore, it cannot be either platinum or platinum dichloride, for the former is soluble in neither acid, and the latter is insoluble in nitric acid. Hence, if hydrogen chloride be formed by the action of water, it will tend to keep part of the substance in solution. Schützenberger found that a very considerable quantity of platinum remained in solution; but, in presence of a large excess of water, platinum is eventually precipitated.

*The Action of Various Gases.*—In order to find a suitable atmosphere into which to volatilise the substances for the vapour-density experiments, the action of various gases was tried. The results are, briefly, as follows:—

*Action of Dry Air on* $PtCl_2,2CO$.—The substance is unchanged till its melting point is reached, when carbon monoxide is evolved; the residue then solidifies, melting again at 190°. A little above this temperature it decomposes with a slight sublimation.

*Dry hydrogen* has no action in the cold. At the melting point the compound is at once reduced to metal with partial sublimation. If the hydrogen be burned the flame becomes luminous, and deposits a film of platinum on the surface of porcelain introduced into the flame.

*Dry chlorine* has no action till from 80° to 90°, at which temperature the compound fuses, losing carbon monoxide with effervescence. At 115° it solidifies; at 140° it fuses again, and is decomposed.

*Dry Carbon Dioxide.*—Schützenberger says the substances can be distilled in this gas; but it is very difficult to volatilise them completely. A large residue of platinum dichloride is invariably left.

*Phosgene* had a peculiar action in the cold. Yellow drops of liquid were formed where the substance was in contact with the glass. This liquid could not be obtained in sufficient quantity for examination. A considerable quantity of the substance volatilised when the tube was heated, but complete vaporisation seemed impossible. It is also noteworthy that the compounds heated at 100° with liquid carbonyl chloride in a sealed tube are dissolved by it, and deposited again on cooling in large crystals. In a vacuum the substance was also incompletely volatile. The only gas in which it seemed possible to determine the vapour density was carbon monoxide.

*(To be continued.)*

Harvard's New Telescope.—A Boston firm is constructing a photographic telescope for Harvard University which will probably be the largest and finest instrument of the kind ever designed. The lens is to be like that used by photographers rather than that of an astronomical telescope, and will consist of two achromatic lenses. Its aperture will be twenty-four inches, and its focal length eleven feet. A telescope of this form, but of one-third its size, is now in use at Harvard.—*Detroit Free Press.*

As the days grow shorter we have many reminders that the lantern season is getting near, but in case we should forget the important fact, Messrs. G. W. Wilson and Co. forward us their new catalogue, in which many novelties are apparent. They specially direct attention to the circumstance that all their slides are made from direct negatives, that those negatives are of the best quality only, and that every slide is individually tested before it is placed on the market. Besides this list, Messrs. Wilson's general catalogue of 12,000 views is available to the lanternist, for he can procure any view in the form of a slide.

## ART IN PHOTOGRAPHY.*

BY A. L. BOWERSOX.

The first question agitating the photographer's mind is, "Is there art in photography?" and "To what extent has it been cultivated?" The devotee of the palette, brush, and paint politely informs you that there is no art in photography, and that photographs are only machine-made, and that they are not, strictly speaking, art productions. We admit that our art is not a creative art in the sense an artist uses the term; that is, we cannot make a picture from nothing; we must have our subject and our accessories to work with in order to make our productions. Shall we not, then, take up some of the rudiments of art and then compare notes, and thereby ascertain whether or not we have any claim on so high and noble a profession? And first, let us study composition. The master will inform you that composition is the art of arranging figures or objects so as to adapt them to any particular subject. In composition three requisites are necessary: that the story be well told; that it possess a good, general form; that it be so arranged as to be capable of receiving a proper effect of light and shade.

The form of a composition is best suggested by the subject or design, as the fitness of the adaptation ought to emanate from the circumstances themselves, hence the variety of composition. We must admit that in composition we are (to some extent) at the mercy of the lens we employ. The artist probably decides to paint a group, and in his mind he has formed a circle; but would not think of representing that group in a real circle. No; he steps back, in his imagination, a few paces, or rods possibly, according to the size of the group, and that circle no longer remains a circle, but an oblong! Does not the photographer see that circle the same, and with the same artistic eye? If he has given his subject any thought or study, he will most assuredly. Does not the photographer have a point of sight in his productions? Does he not aim to have a pleasing effect? These, and many other points that go to make up a good photograph, must be well understood by both artist and photographer in order to bring them in good requisition. In case of a bust picture the operator must decide upon the position, whether to elevate his camera or have it level; whether to take a front view or side view; whether to bring his subject under the light with contrast, or more evenly. All these points are requisites to a good picture.

The next point in study in art is chiaroscuro. Again we are told that harmony, which is produced by chiaroscuro, or by the means of black-and-white, depend upon the quantities of light and dark employed and the disposition of them; sometimes meeting in extremes of opposition, in other portraits gliding away with imperceptible softness into undefined spaces; the light sometimes falling on combined objects, giving out a faint halo around the group; you may have observed this in photographing light objects on a dark ground. Not every lens will show this; some will.

The power of producing a variety of pleasing sensations upon the eye mainly rests on the conduct of the chiaroscuro; objects are rendered either strong or delicate, according as they advance or retire on the perspective plane of the picture. Parts are forced upon the spectator's attention by their clear, defined character, and assisted from contrast by groups of indistinct images imbued with the properties of middle tint.

* Read at the Photographers' Association of Ohio.

I was quite surprised, at our last two conventions, by some of the criticisms offered on the pictures upon the screen; the criticisms were on the pictures having more than one point of light. It is a fact that a bust portrait should only have but one light, but in half length of figures it is not contrary to art to have more than one point of light. And so we could go on to enumerate instances where art and photography, or art and art in photography, come to a perfect agreement.

Our photographers who make a study of *genre* photography must study invention, which is claimed to be the great soul of painting. The subject he desires to illustrate must be created within the mind, and with his hands he must arrange every detail, from the most important to the minutest, thereby proving that art in photography and art go hand-in-hand.

The operator has no choice in subject, but must do his best with each subject presented. His choice must be in the point of view, in the light and shade, and the general use of background and accessories. One essential in every really good photograph is a point of vision—one that will please the eye and not tire it after carefully observing it in all its phases. In case of a front view the eyes form the point of view, with all the rest subservient and gradually fading out of view. By observing a few of these rules we obtain what the artist calls "drawing," which we must acknowledge a great many photographers lack, and when we touch the point it brings us to one of the essentials, and that is the background. There is more thought and study required in that accessory than in any other. Writers in our photographic journals have been advocating reform in backgrounds, and advising to keep them back—not bring them too near the subject.

In case of a bust picture, I think, if your ground is the right kind, you can bring it well up, and thereby secure better effects than by keeping the ground five or ten feet away. If your ground is too plain, take a little common chalk and a tuft of cotton, and in a few minutes you can have the relief you aim at by a few well-directed strokes. Art seems to be made up of small bits, and if we are able to carry them in our mind, and then put them together correctly, we shall be able to behold art in photography.

## PHOTOGRAPHIC CHEMISTRY.*

BY PROFESSOR R. MELDOLA, F.R.S.

Continuing the study of those properties of silver salts which are of photographic importance, the next point to be dealt with is the vexed question of the existence of sub-salts. Here, in the present state of knowledge, it is most advisable to avoid dogmatic statements. The utmost that can be done is to summarise the evidence, and to let the student see therefrom that, from a scientific point of view, the existence of such sub-salts has not been conclusively demonstrated. I will only repeat now what I said some years ago, namely, that so far as analogy is to be trusted as a guide, it would seem improbable that the sub-haloid salts of silver should be highly coloured compounds, because the analogous salts of copper, mercury, and thallium are not highly coloured. Now, all the attempts which have been made to produce sub-haloid salts of silver by partial reduction or by other methods give rise to coloured products, which have been held by some investigators to consist of the sub-haloids, and by others (Carey Lea) to consist of molecular compounds of the sub-haloids with the haloids proper. It may further be suggested that these coloured compounds might consist of oxyhaloids, mixed or combined (molecularly) with the haloids, that in some cases they might consist of metallic silver or its oxide in molecular combination with the haloid, and that in other cases they might consist of the foregoing compounds or mixtures, or of the true haloids coloured by the retention of a small quantity of some metallic oxide as an impurity.

* Continued from page 639.

The study of these coloured products is of importance to the photographic chemist, whether they are definite chemical compounds, or whether they are molecular compounds, or whatever subsequent research may prove them to be. They are of importance to us here, among other reasons, because there may be some relationship between these compounds and the products formed by the photo-chemical decomposition of the silver haloids. I have thought it desirable, therefore, to summarise, in a collected form, the various methods by which these compounds have been produced :—

1. Rose-coloured silver chloride, obtained by reducing a hot solution of silver citrate with hydrogen, exhausting the dark product (before complete reduction) with citric acid, and then treating it with hydrochloric acid. Obtained also by reducing the dry nitrate in hydrogen at 100° C., extracting the product with water, and treating the residue with hydrochloric and nitric acids. (Brit. Assoc. Rep., 1859, p. 105.)

2. Chocolate-coloured chloride ; obtained by adding a solution of silver arsenite in nitric acid to a strong boiling solution of caustic soda, when "an extremely black powder" is produced. This, on treatment with hydrochloric acid, becomes grey, and the washed product, on boiling with dilute nitric acid, loses silver and leaves the chocolate-coloured chloride. (Brit. Assoc. Rep., 1859, p. 106.)

3. Coloured products obtained by acting upon silver with solutions of ferric or cupric chloride have long been known.

4. Coloured products obtained by Carey Lea, and described as "photochloride," "photobromide," and "photoiodide" ("photosalts").

(*a*) Purple or black chloride, obtained by the action of alkaline hypochlorites on finely-divided (reduced) silver.

(*b*) Red chloride, prepared by adding ferrous sulphate to an ammoniacal solution of silver chloride, and then acidifying with dilute sulphuric acid. The precipitate is washed, boiled with dilute nitric acid, washed, and finally boiled with dilute hydrochloric acid.

(*c*) Red or copper-coloured chloride, prepared by heating silver oxide or carbonate to a point short of complete reduction, and then treating the residue with hydrochloric acid.

(*d*) By precipitating silver oxide in the presence of the lower oxides of iron, manganese, &c., and treating the product with hydrochloric acid.

(*e*) Dark purple chloride, obtained by treating finely divided (reduced) silver with a solution of ferric chloride. (Contains 76·07 per cent. of silver.)

(*f*) Red chloride, similarly prepared by the action of cupric chloride.

(*g*) Red chloride, prepared by pouring dilute solution of silver nitrate on to cuprous chloride, and boiling the black precipitate thus obtained with dilute nitric acid.

(*h*) Brownish purple chloride, prepared by pouring an ammoniacal solution of silver nitrate into a strong solution of ferrous chloride, and treating the dark precipitate with dilute sulphuric acid. Becomes lighter with nitric acid. (Similar to *b*.)

(*i*) Purple chloride, prepared by reducing the citrate in a current of hydrogen at 100° C., and treating the product with hydrochloric and nitric acids successively. (Similar to No. 1.)

(*j*) Red and purple shades of chloride, obtained by reducing (partially) a silver salt with alkali and an organic reducing agent, such as milk-sugar, dextrine, &c., and then treating with hydrochloric and nitric acids successively.

(*k*) Red, brown, or lavender chloride, produced by treating the white chloride with a boiling solution of sodium hypophosphite. The dark, chocolate-coloured product is washed, and boiled with dilute nitric acid.

By somewhat similar methods, coloured forms of the bromide and iodide have been obtained.

From these special studies of the silver compounds we may now pass to another phase of the subject, viz., the combination of silver and its salts with organic compounds. At this stage the technology—*i.e.*, the sources and methods of manufacture of the more important organic compounds used by the photographer—may be conveniently introduced. The ordiuary organic acids, such as acetic, oxalic, citric, tartaric, &c., will of course have been dealt with in the preliminiary traiuing, but in addition to these, special attention should be directed to the chemistry and technology of cellulose (including paper, collodion, and celluloid), albuuen, and gelatine. Let it be realised iu the course of this work that albumen is of the nature of an acid formiug salts with various metals. Show the precipitation caused by such salts as those of mercury and silver. Let the precipitated "albuminate" of silver be collected, washed, and dried, and theu the presence of silver proved by burniug some of the compound, extracting with dilute nitric acid, filtering, and testing in the usual way. The similar tendeucy of gelatine to combine with silver compounds is very striking, aud of fundameutal importance to the photographic technologist. The best way of approaching this is to let the student make experiments for himself. A sheet of gelatiue can be prepared by coatiug a glass plate with a warm, strong solution of the substance, and allowing it to dry for some days in a warm place. When stripped off, the film is floated for some hours on a solution of silver nitrate, theu removed and washed with water. It now remains to be shown that silver in some form or other has actually been withdrawn from the solution, and has eutered into combination with the gelatine. In order to prove this, some of the gelatine compound can be dried, and burnt, and tested in the same way as the "albuminate." The "gelatino-nitrate" can also be proved to darken on exposure to light. An experiment of this kind will prepare the way for the all-important subject of the preparation of emulsions.

The first point to which attentiou must be called is the nature of an emulsion, and the influence of the vehicle iu keeping the silver haloids in suspension. An easy experiment will bring this home to the student. To a solution of common salt or some soluble bromide add some silver uitrate, aud notice the immediate separation of the silver haloid on agitation. Now take some of the same salt solutiou, add a little strong gelatine solution to it, mix by agitatiou, and then again add some of the same silver nitrate solution. It will be noticed that the separatiou of the silver haloid takes place more slowly, and that when formed it does not subside as in the previous experiment, but agitation simply helps to make the contents of the vessel (now an emulsiou) more uniform. A similar experiment may be made with ordinary alcohol and ether containing a soluble haloid ($ZnBr_2$, or $CdBr_2$), and then, by way of comparison, with the same alcohol and ether containing dissolved pyroxylin (collodion).

The broad distinctiou between purely physical changes induced by light and actual photo-chemical decomposition may be maintaiued, although it is ofteu difficult to refer a particular case to one or the other of these classes. The simplest kind of photo-physical action is that which produces a chauge in molecular structure, either temporary or permaueut. In connection with this, the action of light upon seleuium is perhaps the most striking illustration that can be giveu, aud, where the necessary apparatus is at hand, it would be well to demonstrate the point experimentally in the usual way. As examples of permaueut change of molecular structure, the modifications in crystalline form undergone by certain substances on exposure to light may be appealed to aud illustrated. The followiug experiments cau be easily done in the laboratory :—

1. A saturated solution of sulphur in carbon disulphide is prepared, and two or three tubes are filled with the solution and sealed up. The coutents of a tube kept in the dark will remain clear for an indefinite time, but on exposing one of the tubes to suulight the contents become turbid, and a gradual separation of insoluble sulphur crystals will take place.

2. A plate of glass is coated with a silver mirror by any of the usual methods of chemical reduction. The mirror is iodised by exposure to the vapour of iodine, and then exposed to bright light (electric arc or sunlight) for ten or fifteen minutes, one portion of the film being protected by a dark paper screen. The film is semi-transparent at first, but after the experiment it will be found that the exposed portiou has become yellower and more opaque than the screened portion, the change being apparently due to a physical modification of the silver iodide.

Attentiou may be called to the existence of other changes of a like nature, such as those which occur in red cinnabar, in red realgar, in the crystalline form of nickel sulphate and zinc selenate, &c. From cases of this kiud we are led, in the next place, to other changes, which serve to connect photo-physical with photo-chemical action, viz., photo-polymerisation. The meaning of the term polymerisation will be familiar to the chemical student. It must be poiuted out that many of the changes iu crystallive form, &c., alluded to in connection with the previous examples, may be really cases of photo-polymerisatiou or depolymerisation. Then the known cases of the polymerisation of organic compouuds, such as anthraceue to paranthracene, styrene to metastyrene, vinyl bromide, thymoquinone to an insoluble modification, aud so forth, may be dealt with aud illustrated, as far as possible, experimentally. Pointing out, by way of caution, that it is often very difficult to discriminate between photo-polymerisation and photo-oxidation, the action of light upon asphalt and bituminous substances may be taken as an illustration of the difficulty iu questiou ; and a study of the actiou of light upon such films will naturally lead to the various heliographic processes based upon the original method of the elder Niepce.

The action of light upon asphalt and similar substances is not only of practical importance, but its scientific aspect is worthy of the most serious atteution, both by the student aud the investigator, who, after all, is himself ouly a studeut at a somewhat more advanced stage of his studies. There is some doubt at present whether the insoluble asphalt resulting from the actiou of light is a polymeride, or whether it is a product of photo-chemical oxidation. According to some authorities, the change does uot take place in a vacuum, neither in nitrogen nor in hydrogeu. On the other hand, it is stated by Kayser, in favour of the polymerisation theory, that no increase of weight occurs in the film, that the insoluble asphalt is converted into the soluble form agaiu by fusion, and that a solution of asphalt iu a closed vessel also deposits the iusoluble modification ou exposure to light. The decisiou of this point rests with future investigators, but certain facts have been discovered with respect to the constitueuts of asphalt which must be emphasised in connection with photographic chemistry. It has been found that Syrian and Trinidad asphalt contain a small quantity (4 to 5 per ceut.) of a substance soluble in alcohol and insensitive to light, another portion (44 to 57 per cent.) soluble in ether, and a residue insoluble in ether, varying from 52 to 38 per ceut. The portions soluble in alcohol and ether, and the insoluble residue all contain carbon, hydrogeu, and sulphur ; and Kayser, who has iuvestigated these compounds, has goue so far as to assign formulæ to them. The portion which is soluble in ether is sensitive to light, but not so sensitive as the insoluble residue, which contains the constituent of the greatest value for the heliographic processes. The practical outcome of these investigations has been the preparation of a high quality asphalt, cousisting essentially of the portion insoluble in alcohol aud ether. It may be added that the property of becomiug insoluble in hydrocarbon oils on exposure to light does not appear to depeud upon the coustituent contaiuing the sulphur, as some specimens of asphalt from different parts of the world, which possess the same property, have been found on analysis to be free from sulphur, and to consist of hydrocarbons only.

From these cases of photo-physical action, of polymerisation, and of possible photo-chemical oxidation, the study of true photo-chemical decomposition may be taken up. On account of the comparative simplicity of their decomposition, the salts of iron leud themselves admirably for demonstration at this stage. The study of the ordinary chemical reactions of irou salts will have prepared the way. Having shown how reducing agents couvert ferric iuto ferrous salts, let it be demonstrated experimeutally that many orgauic compounds, such as alcohol, oxalic acid, &c., do not immediately reduce ferric salts. It must then be pointed out that these organic compounds are susceptible of oxidation by ferric salts under the influence of light—that they are, in fact, potential reducing agents. This can be done in test-tubes or flasks in the first place, and then on paper films, leading to the ordinary cyanotype and blue printing processes. A few hints for the carrying out of the experiments may be found servicable :—

1. A solution of ferric chloride (2·3 p.c.), mixed with a solution of oxalic* acid will, of course, on testing with potassium ferricyanide, give no blue colouration. Some of the same solution, exposed for five minutes or so to strong light, will be found to contain ferrous salt on again testing with ferricyanide :—

$$2FeCl_3 + H_2C_2O_4 = 2FeCl_2 + 2HCl + 2CO_2.$$

2. By using ferricyanide with the ferric salt, and exposing to light, the reduction is made visible by the formation of Turnbull's blue. This can be done by adding ferricyanide to the foregoing, or preparing two solutions : one containing 8 grammes of potassium ferricyanide in 50 c.c. of water, and the other containing 10 grammes of ammonio-ferric citrate in 50 c.c. of water. The solutions are mixed before use, and then exposed to light, first in a test-tube, and then on paper coated with the solution, and allowed to dry in the dark. The practical application of this method for copying and printing will be obvious.

The chief point of general theoretical importance brought out by such experiments as these is, that light only reduces the ferric salts in the presence of oxidisable compounds of sufficient instability. It is advisable, at this stage, to introduce the notion of *sensitisers*, and to point out that oxalic acid, citric acid, alcohol, &c., may be regarded in this light in the experiments referred to. The demonstrations with ferric salts may, of course, be extended in many directions, and made the basis of numerous practical exercises and lessons in the application of general chemical principles to special cases. All that has to be borne in mind is, that a surface of an organic salt exposed to light under a stencilled design (or a picture) gives ferrous salt on the exposed portions, leaving the unexposed portions unchanged. Various reagents may then be used to reveal the chemical difference in the two portions, the subject of photographic development being thus introduced, and the changes evolved being explained by ordinary chemistry. By way of example :—

A design printed on paper coated with ammonio-ferric citrate is developed by ferricyanide. The exposed (reduced) portions come out blue, owing to the formation of Turnbull's blue. Supposing ferrous citrate to be formed :—

$$Fe''_3 (C_6H_5O_7)_2 + K_6Fe_2Cy_{12} = Fe_3 (Fe_2Cy_{12}) + 2K_3 (C_6H_5O_7).$$

The blue design, after being well washed, can be made the subject of many further experiments, all instructive as illustrating chemical principles with which the student should be familiar. Thus, on treatment with a dilute solution of caustic soda, the blue is at once decomposed, with the formation of $Fe_3O_4$, which remains on the paper. We have thus a faintly visible brownish design, which can again be developed by taking advantage of the property possessed by the oxides of iron of forming coloured compounds with organic substances, such as gallic acid, alizarin, nitro-sopheuols, &c.

It may be pointed out that the photo-chemical reduction of ferric salts, although practically useful for printing purposes, takes place too slowly to enable these compounds to be used at present for the production of camera pictures. But there is no reason why the rate of photo-chemical reduction—*i.e.*, the sensitiveness of these compounds—should not be increased by admixture with some easily oxidisable substance, and a sensitive film prepared by this means, which would cheapen photographic processes by dispensing with the use of silver salts.

In the same way that the photo-chemistry of iron is studied, the other sensitive metallic compounds may be dealt with. The reduction of uranic salts, and the development of uranium prints by various reagents, will naturally be connected with the analogous ferric salts. The photo-chemical reduction of chromates in the presence of organic substances, such as gum, albumen, and gelatine, will lead to the numerous practical applications of chromated gelatine in the processes of etching, pigment printing, collotype, &c. In these processes practical instruction may be given at this stage as far as thought desirable. The salts of mercury and copper may also be studied with advantage, as illustrating the nature of photo-chemical decomposition. The well-known greenish mercurous iodide is easily prepared by decomposing freshly-precipitated and washed mercurous chloride with a solution of potassium iodide. Some of this salt, washed by decantation, and exposed under water to the action of strong light, rapidly darkens, owing to the liberation of metallic mercury.

The action of light on the salts of copper forms a convenient introduction to the photo-chemistry of the silver salts. Thus, cuprous chloride darkens, on exposure to light, with as great a rapidity as silver chloride.

When discussing photo-chemical decomposition, it should be pointed out that indirect results are often obtained by using a mixture of substances of which one of the constituents is not directly affected by light, but is altered by contact with the product resulting from the photo-chemical decomposition of the other constituent of the mixture. For example, paper coated with ferric chloride, and exposed to the light, gives a surface of ferrous chloride by photo-chemical reduction, the size or cellulose of the paper acting as the sensitiser (chlorine absorbent). But if the surface is coated with a mixture of ferric chloride and cupric chloride, the ferrous chloride which is formed reduces the cupric salt with which it is in contact :—

$$2FeCl_2 + 2CuCl_2 = Cu_2Cl_2 + 2FeCl_3.$$

The picture is thus formed in cuprous chloride instead of in ferrous chloride, and, by treatment with potassium thiocyanate, cuprous thiocyanate is formed, which, on subsequent treatment with potassium ferricyanide, leads to the development of a brown print. This method of utilising a mixture of ferric and cupric salts is the basis of Obernetter's process.

There can be no doubt that this principle of indirect decomposition is destined to play a very important part in the photography of the future. It has already come into prominence in the well-known platinotype process of Willis, in which a surface is coated with a mixture of ferric oxalate and potassium chloroplatinite. On exposure to light ferrous oxalate is formed, while the chloroplatinite is not directly reduced. On treatment with a hot solution of potassium oxalate the ferrous oxalate is dissolved out, and at the moment of solution reduces the chloroplatinite to finely divided platinum *in situ*. In the direct printing platinotype process we have a surface of potassium chloroplatinite, sodium oxalate, and sodio-ferric oxalate. In this case the reduction of the ferric salt by light is accompanied by the indirect reduction of the chloroplatinite by means of the ferrous salt thus formed. In the cold platinotype of Willis the operations are separated, the ferric surface being first exposed in the usual way, and then development being effected by immersion in a cold solution of potassium chloroplatinite containing potassium oxalate and phosphate.

*(To be continued.)*

* The addition of some alcohol increases the sensitiveness of the mixture.

---

Photographic Club.—Subject for Sept. 23rd, "Enlarging"; Sept. 30th, "Mounting and Finishing." Outing Saturday next (19th) Perivale ; train from Paddington to Castle Hill at 2.35 p.m. The last outing of the season (Hampstead) has been postponed to Saturday, October 3rd.

M. Dagreve, in *Les AnnalsPhotographiques*, suggests the following method of silvering old plated or copper articles, which may be useful to any chemist who has some old fixing baths and some worn electro-plate. The articles to be plated are well washed in soap and water, and then immersed in an old fixing bath which has been used for fixing plates. In a very short time a deposit of silver forms, and then the article should be taken out, rinsed, polished with soft leather, and again immersed till the deposited silver is thick enough. When an extra thick coating is desired, a piece of wire is affixed to the object, and at the other end of the wire a sheet of zinc, allowing one square centimetre of zinc to every square decimetre of the article to be plated. It is not advisable to use old print fixing baths for this purpose, as the silver has a peculiar yellow tinge ; but chloride of silver which has not been exposed to light may be used.

Developing is performed in a vessel provided with a non-actinic transparent top and bottom, so that the development can be performed and its progress observed in white light. The top and bottom may be also fitted with opaque covers. The solutions are admitted through covered funnels, and are discharged through a pipe. The apparatus is rocked by a pendulum.

## Correspondence.

### THE "ACME" CAMERA—A WARNING.

Sir,—We have to-day had sent to us by a gentleman a camera which he had bought as one of our patent "Acmes," but from which the name-plate had been lost, asking us to put in a new tablet; but, although the camera is an exact copy of ours in every respect, it is not of our make, and is of decidedly inferior workmanship to what we supply. We therefore wish to warn the public against purchasing such cameras, and to state that we shall be pleased to verify for anybody a camera that they may have bought described as of our manufacture, while we shall be much obliged for any information which may help us to discover who is making these cameras, so that we may take such measures as the law allows to protect both ourselves and the public.

Perhaps you will be good enough to publish this letter in your journal. W. Watson and Sons.

313, *High Holborn, London, W.C., Sept. 15th.*

## Proceedings of Societies.

### Holborn Camera Club.

*September 11th.*—Mr. T. O. Dear in the chair.

Mr. John Howson gave a lecture on the "Ilford Printing-out Paper" (gelatino-chloride). After dilating on the commercial questions connected with the paper, Mr. Howson said two toning baths were recommended; the first consisted of—

| | | |
|---|---|---|
| Water ... ... ... ... | ... 16 | ounces |
| Sulphocyanide of ammonium ... | ... 75 | grains |
| Chloride of gold... ... ... | ... 2½ | ,, |

The second, a combined toning and fixing bath, was as follows:—

| | | |
|---|---|---|
| Water ... ... ... ... | ... 20 | ounces |
| Hypo ... ... ... ... | ... 5 | ,, |
| Citric acid ... ... ... | ... 60 | grains |
| Acetate of lead ... ... ... | ... 60 | ,, |
| Sulphocyanide of ammonium ... | ...240 | ,, |
| Chloride of gold ... ... | ... 3 | ,, |

The mode of working and final operations were similar to those of the gelatino-chloride papers now on the market. With regard to the use of an alum bath, he thought the special nature of the gelatine used rendered it, in most cases, unnecessary. Mr. Howson then toned some prints on the new paper, which, together with a number of finished prints, showed its advantages.

On Saturday fourteen members and friends attended the Keston outing.

### National Association of Professional Photographers.

A meeting of the Council was held on the 8th inst. in the Pillar Room, Anderton's Hotel, Fleet Street, London. The following members were present:—Messrs. H. J. Whitlock (President), John E. Shaw and Robert Slingsby (Vice-Presidents), Barry, Fall, Elliott, Warwick, Brookes, MacIver, Eddison, Roxby (Treasurer), and C. P. Richards (Hon. Secretary).

Mr. Whitlock alluded to the growth of the Association, and the absolute necessity of engaging the services of a paid secretary, at the same time paying a high compliment to the hon. secretary for his able services. A sub-committee was appointed with power to interview and engage a gentleman for the position.

A discussion took place upon the important question of trade price lists, and a course of action was agreed upon.

Reports from the various branches were received of a very encouraging character, and the Council generally expressed every confidence in the great future of the Association, and its power to remedy many anomalies now existing.

### North Middlesex Photographic Society.

*September 14th.*—Mr. J. Stewart in the chair.

Mr. J. Howson demonstrated the working of "Alpha" paper, and passed round a number of prints. In his preliminary remarks, Mr. Howson pointed out that an amateur frequently had little time for daylight printing. This process would enable him to obtain warm tones when they would otherwise be impracticable. The points to be observed were to follow the instructions closely, and to expose always for the same time at the same distance from a uniform light when uniform results were desired. Six inches from a batswing burner was the distance recommended for a small negative. A greater distance would be necessary with a large negative to equalise the light. From two to three minutes would be necessary for a moderately dense negative. To obtain brilliant prints from a weak, flat negative, develop deeply with half old and half new developer, and allow to remain in the clearing bath till the high-lights were sufficiently reduced. The red tones obtained by prolonged exposure would be retained after fixation, even if the prints were not toned, but slight toning was generally desirable even for the warmest tones. It should be borne in mind that if the tones obtained were too warm, the prints could be toned to colder shade, even after they had been dried and stored for any length of time. Mr. Howson then developed and toned a number of prints showing the range of colours obtainable from equal exposures and development.

Many questions were asked and satisfactorily answered. Cloud printing by combination was doubtless difficult by reason of the difficulty of differentiating the exposure to the two negatives to obtain identical tones.

A Member was of opinion that this would be overcome by making trial exposures.

The usual competition of prints of views at the Society's field-days was held. Mr. Marchant received the vote of merit for Roydon, Mr. Gregory for Loughton, Mr. Staveley for Edgware, and the Secretary for Kew.

An ingeniously made shutter sold by Messrs. Perken, Son, and Rayment was shown, and prints on mat-surface paper by Obernetter. A very rough-surface paper by the Blackfriars Sensitising Co. was much liked. Mr. H. Smith reported that he had found Mr. Barry's printing meter invaluable in printing-in clouds in platinotype. Mr. Taylor showed prints from the negatives he made when demonstrating development at the last meeting, making clear the points he had dwelt upon in his address. Two reversed negatives (snap shots with a medium stop) were shown by a member. As the conditions under which they were taken precluded the possibility of supplementary exposure, and as the edges of the plates were plainly oxidised—as another brand of plates exposed and developed at the same time and under the same conditions were satisfactory—the unanimous verdict was "stale plates." As the brand of plates complained of enjoys an excellent reputation, the dealers (a large establishment) from whom they were purchased are apparently to blame for faulty storage.

One new member was elected and three nominated.

The next meeting was announced for the 28th inst. The subject will be "Photo-mechanical Printing."

### South London Photographic Society.

*September 7th.*—Mr. Mark Boxall in the chair.

Mr. Crouch showed his hand-camera, and gave much valuable information as to the best way in which to use a hand-camera to ensure the picture being in the centre of plate, even though it was not fitted with a finder. Mr. Crouch also gave a lecturette on the "Use of Lenses," in the course of which he gave a formula for re-blacking diaphragms that had become bright by wear.

The Secretary announced that he had been unable to obtain permission for the Society to take photographs at Lambeth Palace.

### Hackney Photographic Society.

A meeting was held last Thursday, Mr. Arthur Dean presiding. Work was shown by several members.

The Hon. Secretary gave an illustrated lantern lecture on "A Holiday in the Isle of Man and Ireland with a Hand-Camera." Several of the views shown were very fair, and illustrated very well the powers of a hand-camera.

Mr. Dean showed numerous views of Ireland, and Mr. Day gave a very interesting account of the geological formation of the rocks at the Giant's Causeway.

Captain Abney has kindly consented to distribute the prizes at our Exhibition and competition on Thursday, October 22nd, 1891.

### Putney Photographic Society.

*September 10th.*—Rev. L. Macdona in the chair, to consider sundry alterations in the Society's policy and rules.

A motion that the word "amateur" be struck out of the Society's name was unanimously carried.

For the future, the Society's year will end in April and begin in May, in which month the election will take place. The financial year is to remain as at present, January to December. The members of the council having tendered their resignations, elections to fill the vacancies will be at once proceeded with.

Winter session begins October 14th, on which date the subject will be "Illustrated Journalism," by Mr. T. C. Hepworth.

### Brechin Photographic Association.

The annual general meeting was held on the 9th inst., the president, Mr. Wm. Shaw Adamson, Jun., in the chair. Six new ordinary members were admitted, viz., Rev. T. L. Ritchie, Messrs. G. T. Robertson, B.Sc., A.M.I.C.E., G. M. Scott, J. Buchanan, Innes, and Smith. The usual reports of the secretary, treasurer, and curator were read and adopted, and these officials were thanked for their services. The report of the sub-committee appointed to revise the rules was adopted, and the new rules agreed to. The night of meeting has been altered to the third Wednesday of the month.

The office-bearers for the coming year were elected as follows:—*President*—Mr. Wm. Shaw Adamson, Jun.; *Vice-Presidents*—Messrs. G. Mackie, A.Ph.S., and H. Braid; *Secretary*—Mr. James D. Ross, 6, High Street, Brechin, N.B.; *Treasurer*—Mr. Innes; *Curator*—Mr. J. C. Middleton; *Committee*—Messrs. Ferguson, Buchanan, and Dakers.

International Exhibition at Brussels.—Mr. Henry Flather calls our attention to the circumstance that, in publishing a list of awards to English exhibitors in our issue of the 24th of July, we omitted his name. Mr. Flather is to receive a bronze medal for his series of "Dry Point" enlargements.

## Answers to Correspondents.

**All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.**

**All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.**

Photargus.—*Copying and Children's Portraits.* 1. The enlargement from carte-de-visite to cabinet is about as good as you can expect; the scheme resorted to of draping the front of the camera with a white cloth is a distinct improvement not usually adopted. The Spanish dame's black costume would, perhaps, have borne a little more exposure, but the print not having been toned, does not allow of our seeing the enlargement at its best. 2. The taking of children's portraits is beset with difficulties, and even with the means at your command must often entail the wasting of a few plates. A windmill toy, musical box, or something to attract attention for a moment sometimes helps, and the back rest, with spring grip to catch the clothes, is an aid in preventing the little folks from swaying the body. A very pretty pose for youngsters who can sit up, is to put their legs through the back of a Chippendale chair, the low rail of which serves to engage their hands and keep them steady.

R. C. B. (Gateshead).—The negatives have come safely to hand, and we are now anxious to see the enlargements. Our amateur friend is still in America.

M. Bros.—*Photo-Lithography.* As a first step, you should get Mr. W. T. Wilkinson's book on "Photo-Lithography, Collotype, &c." (London: Hampton, Judd, and Co.) Study this, and, if you think proper, put yourselves in communication with the author, whose address is Henry Street, Derby.

J. A. B.—The lens named is a thoroughly reliable instrument for out-door work. We have recently heard a very good report of it from a correspondent, upon whose judgment we can rely, and he was using it with a hand-camera.

I. C. U. (Wymondham).—*Opalines.* Quite recently Mr. Edward Dunmore described in the News the method of producing these. They are simply prints mounted in optical contact, with gelatine, on specially-prepared bevelled glasses. All the requisites can be had of the dealers. Probably Messrs. Marion and Co. would give you the desired estimate; or the Autotype Company, if you wish them reproduced in carbon.

L. A. S.—*The Dangers of Ammonia.* Thanks for sending us the newspaper cutting. Fatal accidents are rare, and the unfortunate occurrence was probably attributable to the heat accompanying the recent spell of fine weather. A Winchester quart bottle of ·880 ammonia always requires careful handling in summer time, and it is advisable to cover it with a cloth before proceeding to loosen the stopper.

H. A. (Dunbar).—*Non-Stripping Negatives.* We should strongly advise your keeping them as they are, although the paper may require frequent oiling. There is no method of transferring these negatives by destruction of the paper without injuring the gelatine film.

J. C. H.—*Electric Lighting.* You should advertise. We do not know of any photographic firm desiring an installation at the present time.

L. A. B.—*Uranium Toning.* Before placing absolute reliance on this process, good though the results may appear at first sight, take the precaution of exposing your prints to light, to see whether they are permanent. Dr. Anthony advocated the toning or intensification of collodion negatives with uranium many years ago, but was forced to abandon it when Mr. Jabez Hughes had shown that the effects were only transient.

M. A.—*Photographers' Benevolent Association.* Subscriptions are urgently needed if the good work is to be continued, the demand upon the funds during the present year having well-nigh exhausted the available resources intended to be applied in the way of relief, and some deserving cases are yet awaiting consideration. The Hon. Sec. is Mr. H. J. Beasley, 65, Chancery Lane, W.C.

Received.—Brighton and Aberdeen.

# THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV. No. 1725.—*September* 25, 1891.

CONTENTS.

## MILITARY PHOTOGRAPHY.

Among the various arts helped by photography, the art of war—if the business of killing people scientifically can be called an art—has, as yet, been most chary in its employment of the camera. Certain officers and special correspondents have, it is true, taken pictures of battlefields and their surroundings, and we have seen more than one photograph which has been actually taken "under fire." But these were not done under military authority, or to serve any military purpose, and may, therefore, be regarded as amateur productions which hardly touch the fringe of the subject before us. On the other hand we have, it will be remembered, a Photographic Section of the School of Military Engineering at Chatham, which has done a great deal of work in connection with big guns, in recording the havoc done to targets by their monster projectiles, and the effects upon various descriptions of armour plates by chilled and other shot. These useful photographs have frequently been exhibited, and are, therefore, more or less familiar to many of our readers. But so far as active work with an army in the field is concerned, photography has as yet done nothing.

The subject may really be regarded as a new one, for gelatine plates are not much more than a decade old, and before their introduction any use of the camera during the bustle of a campaign would have been voted impossible. No commander would have cared to have increased his impedimenta by a travelling dark room or tent, and such a collection of bottles and other paraphernalia as the collodion process entailed. But with the convenience of dry plates these difficulties at once disappear; the officer need no longer fear any noticeable addition to his kit, and it remains for him to consider whether any advantages are to be gained by employment of the camera on active service. This is a question that cannot very well be satisfactorily answered by a civilian, and we are therefore fain to turn to the pages of a little book by Captain Wheeler on "Military Photography," which has recently been issued by Messrs. Iliffe and Son.

Captain Wheeler points out, in the first place, that the camera would be a valuable aid in reconnoissance, although he admits that there are hundreds of well-informed and generally sensible persons who are convinced that the pencil is all-sufficient in making such rough sketches as alone are necessary. It is, unfortunately, the way with a certain class of minds to pooh-pooh in this way any new thing. They are so used to the old rut that they quite decline to avail themselves of a better path. There is an authentic story about the introduction of the first electric telegraph, which was submitted to a high Government official in this country, who, in his wisdom, expressed the opinion that such a means of communication was quite unnecessary, for the Semaphore system answered all needs. The introducer of military cameras may possibly have to deal with this exasperating kind of opposition, unless he is able to secure the goodwill of someone having influence with the authorities. But, setting this difficulty aside by supposing that all such opposition has been removed, in what way is it proposed to make use of the camera in a reconnoissance? Any object or feature of importance would, of course, be photographed instead of sketched as at present, and, if the conditions were favourable, the hand-camera would be the instrument used. Such pictures generally are not wanted until the return to camp, when the plates would be developed and printed by any quick development process. The taker of the pictures would not necessarily develop them himself, but might hand them over to a divisional photographic section, which it is recommended should be attached to an army corps. Such photographs might be combined with pencil draughtsmanship, so that one system could be made to check the other—the photographs for general views, and the pencil sketches for details.

The term "Photographic Section" is not meant to imply a large staff of workers; on the contrary, two specially trained men with a pony or mule-load of apparatus would be enough. These men would be under the control of the chief of the staff and divisional intelligence officers, and their work would comprise (1) the reproduction of plans, maps, sketches, &c., for distribution to various officers; (2) the photographing of special objects of interest, such as forts, bridges, &c., laying directly *en route*; and (3) in developing the plates of individual photographers, as already indicated. In certain cases, Captain Wheeler thinks that a stratagem would be necessary before a picture could be secured, and that such would be quite justifiable, on the old plea, we suppose—for he does not say so—that all is fair in love or war. He means that when the photographer, as is the case in some of the countries across the Indian frontier, is viewed with suspicion, he may, by use of a prism, take a photograph of an object at right-angles to the direction in which the lens points. The same ruse can also be adopted when a picture of fortifications, or of other objects of military interest, is wanted. He recalls the story of a German lady who wheeled her child in a perambulator in the vicinity of a certain fortified town in France, the said child being a dummy containing a photographic camera.

The author also says a few words about the possibility of taking photographs from balloons. But while recording some experiments of the kind which took place as long ago as the siege of Paris, he omits all mention of a camera designed by the late Mr. Woodbury for attachment to a small balloon expressly for military purposes. We also have the interesting story repeated of the manner in which, during the same siege, microscopic despatches were despatched by pigeon post from the devoted city. The concluding chapter of the book deals with hints on equipment. A half-plate camera is recommended for the work, and Pizzighelli and bromide paper are advocated as the most convenient printing processes for military purposes.

Captain Wheeler evidently considers that he has made out a good case for the employment of the camera in military operations. If his conclusions be correct, there will be little difficulty in giving the system a trial, for hundreds of officers have taken up the art as a pastime, and many are expert workers. It is a pity that, in support of his opinions, he cannot point to any past campaign where benefit would have accrued, or disaster turned aside, by use of the art for which he pleads with such ability.

The Folk-lore Society of Massachusetts have sent a delegation to Colonel Gouraud, asking his assistance to obtain, by means of the phonograph, records of the "street sounds" of London. In order to carry out this idea, the Colonel has placed a phonograph at the Society's disposal, and also a photographer, who will photograph the subjects simultaneously with the phonographing of their "sound-waves," thus enabling the coincident reproduction, in America and elsewhere, of both sights and sounds by means of the lantern and the phonograph combined. This will doubtless prove highly interesting to the New England savants, to whom we do not mind saying, in strict confidence, that four million London people would be delighted to learn that most of these sounds could be once for all bottled up, phonographically or otherwise, and exported for the delectation of our American kinsmen. If there were a duty on "street sounds" under the McKinley Tariff, they would pay it with positive pleasure.—*Daily Telegraph.*

## ILLUSIONS OF SIGHT.

BY REV. H. GORDON PALMER.

When we apply the powers of vision for any ultra purpose outside that designed, we may expect to discover imperfections similar to those Dr. Emerson and Mr. Goodall have recently advocated in a *striking* fashion. These limits so disclosed indicate that the perfection of the visual organ is practical, not absolute. The adaptation of the eye to its proper function cannot, I presume, be doubted. There is, however, a mystery in visual perception, in which we command the services of three such widely differing ministers as mechanism, mind, and spirit; and where we can trace the material organism, but the condition of consciousness remains inscrutable, we may affirm that the eye does not see of itself. We are first conscious of visual sensation as a limited power of translating signs, and then of visual perception as a *translation of such translation.* We are now face to face with mind and spirit. The material has served and vanished; we see with the mind. The external object and the image on the retina are, to the eye of a stranger, in a position the reverse of each other, and only for *something* inscrutable we should see things upside down. Dr. Emerson refers to this in a note, and wisely passes on.

While Dr. Emerson is merrily laughing at us, let us examine some illusions of sight, as, for instance: I watch the full moon rising, and observe how large and rotund she looks, resting, as it were, upon that eastern hill, and seen amidst the forest trees. If I look again through a slit in a card (Mr. Debenham's mistake) she immediately resumes her normal size. A painter and an ignorant laic stand before a painting or a lovely landscape, and how different are the impressions made, and with the same optical instrument!

Again, should I take a pseudoscope—invented by Wheatstone—and look steadily at a statue, at once the impression of solidity is gone; the face is a hollow mask. But if I look at a human face with it, flesh and blood refuse to so deceive me; in other words, my mind refuses to yield its long-accustomed impressions and habit. Still more, by an effort of will, I can overrule the natural process of physical impression, alter it, and *create* a designed effect; for, on first awakening in the morning, keeping the eyelids steadily closed, and now and then slightly separating the fringe of eyelashes with my fingers, I can produce colours more beautiful than nature's ordinary, and by practice I can control their appearance and succession. Everybody remembers once going to bed in the dark imagining a blow on the optic nerve from the bedpost; you duck your head, and behold, the room is suddenly filled with sparks and flames of fire. Under similar circumstances examine the eye, and you will find no light really in it. In dreams the images are wholly mental, and in few of these illusions can the mystery be traced solely to our sensory apparatus and its optical laws; such as may be observed in a lighted stick whirled rapidly round appearing as a circle of fire.

It is, I presume, a case of "about ship" with the talented and merry professor. We may be assured of the correctness of all he avers; he will make no mistake this time. Such and such are truly our sensuous impressions of vision, formed *now* by association, and inference, and habit, but (and here lies the question) are these, as stated by him, *the whole truth?*

Have great opticians like Mr. Dallmeyer no invention, no powers and resources to fall back upon, to approach mechanism to mind? Is not photography in its infancy, as painting was in the times of Thotmes III.? Even the old masters, I understand, are going out of fashion.

What I mean to infer is this; the minuteness and accuracy of photography, when projected, must affect the artistic impressions of nature presented to us as signs of things, the meaning of which (signs) we learn inductively by a process of self-education. The mind will oscillate between the beauty and perfection of now the one and now the other, until, for each individual will, the point of rest shall be decided. Sight and mind are under the law of development, and man invents improved mechanism, and finally the fittest instrument will survive.

## THE RATE OF EXPLOSIONS IN GASES.*

1. The results obtained with hydrogen and oxygen, with hydrogen and nitrous oxide, and with marsh gas and oxygen, in exact proportions for complete combustion, were in close accordance with the mean results of Berthelot. For ethylene, acetylene, and cyanogen my numbers differed appreciably, but in no case differed by more than seven per cent., from the rates observed by Berthelot:

Table II.—*Velocity of Explosion in Metres per Second.*

| | Berthelot. | Dixon. |
|---|---|---|
| Hydrogen and oxygen, $H_2+O$ ... ... | 2810 | 2821 |
| Hydrogen and nitrous oxide, $H_2+N_2O$ ... | 2284 | 2305 |
| Marsh gas and oxygen, $CH_4+O_4$ ... ... | 2287 | 2322 |
| Ethylene and oxygen, $C_2H_4+O_6$ ... ... | 2210 | 2364 |
| Acetylene and oxygen, $C_2H_2+O_5$ ... ... | 2482 | 2391 |
| Cyanogen and oxygen, $C_2N_2+O_4$ ... ... | 2195 | 2321 |

The general agreement between these measurements left no room for doubt about the substantial accuracy of Berthelot's experiments. The formula he gives does therefore express, with a close degree of approximation, the rates of explosion of many gaseous mixtures.

2. The formula fails for the explosion of carbonic oxide with oxygen or nitrous oxide. This was to be expected if—in the detonation of carbonic oxide in a long tube—the oxidation is effected indirectly by means of steam, as it is in the ordinary combustion of the gas. Measurements of the rate of explosion of carbonic oxide and oxygen in a long tube showed that the rate increased as steam was added to the dry mixture, until a maximum velocity was attained when between five and six per cent. of steam was present.

3. When electrolytic gas was mixed with an excess of either hydrogen or oxygen, the rate of explosion was found to be altered; the addition of hydrogen increasing the velocity, the addition of oxygen diminishing it. The addition of an inert gas, nitrogen, incapable of taking part in the chemical change, produced the same effect as the addition of oxygen—one of the reacting substances—only the retarding effect of nitrogen was less marked than that of an equal volume of oxygen. The retardation of the explosion-wave caused by the addition of an inert gas to electrolytic gas evidently, therefore, depends upon the volume and the density of the gas added. In the following table the retarding effect of oxygen and nitrogen on the explosion of electrolytic gas is compared:—

Table III.—*Rate of Explosion of Electrolytic Gas with Excess of Oxygen and Hydrogen.*

| | | | | |
|---|---|---|---|---|
| Volume of oxygen added to $H_2+O$ ... ... | $O_1$ | $O_3$ | $O_5$ | $O_7$ |
| Rate ... ... ... | 2328 | 1927 | 1690 | 1281 |
| Volume of nitrogen added to $H_2+O$ ... ... | $N_1$ | $N_3$ | $N_5$ | $N_7$ |
| Rate ... ... ... | 2426 | 2055 | 1822 | — |

* Concluded from page 652.

I think it a fair inference from these facts to conclude, when the addition of a gas to an explosive mixture retards the rate of explosion by an amount proportional to its volume and density, that such added gas is inert as far as the propagation of the wave is concerned, and that any change which it may undergo takes place after the wave-front has passed by—in other words, is a *secondary* change.

This principle has been applied to determine whether, in the combustion of gaseous carbon, the oxidation to carbonic acid is effected in one or two stages—an important question, on which there is little experimental evidence. If, for instance, in the combustion of a hydro-carbon, or of cyanogen, the carbon is first burnt to carbonic oxide, which subsequently is burnt to carbonic acid, the rate of the explosion-wave should correspond with the carbonic oxide reaction, in this case the primary reaction; whereas, if the carbon of these gases burns to carbonic acid directly, in one stage, then the rate of the explosion-wave should correspond with the complete reaction.

Now, if we adopt Berthelot's formula as a working hypothesis, we can calculate the theoretical rates of explosion of marsh gas, ethylene, or cyanogen—(1) on the supposition that the carbon burns directly to $CO_2$; and (2) on the supposition that the carbon burns first to CO, and the further oxidation is a subsequent or secondary reaction. On the first supposition, if 100 represents the rate of explosion of these three gases burning to carbonic oxide, the addition of the oxygen required to burn the gases to carbonic acid should *increase* the rate of explosion:—

| | Marsh Gas. | Ethylene. | Cyanogen. |
|---|---|---|---|
| Calculated rate of explosion when burnt to $CO_2$ ... ... ... | 104 | 103 | 107 |

Whereas if these gases really burn first to carbonic oxide, and the extra oxygen is inert in propagating the explosion-wave, then the addition of this inert oxygen would diminish the rate of explosion:—

| | Marsh Gas. | Ethylene. | Cyanogen. |
|---|---|---|---|
| Calculated rate of explosion when burnt to CO with inert oxygen present ... ... | 92 | 88 | 87 |

The experiments show that if 100 be taken as the rate of explosion when the oxygen is only sufficient to burn the carbon to carbonic oxide, the following are the rates found when oxygen is added sufficient to burn the carbon to carbonic acid.

| | Marsh Gas. | Ethylene. | Cyanogen. |
|---|---|---|---|
| Rates found ... ... | 94 | 92 | 84 |

The results are, therefore, in favour of the view that in the explosion of these gases the carbon is first burnt to carbonic oxide.

But stronger evidence on this point is obtained by comparing the explosion rate of these gases (1) when fired with oxygen sufficient to burn the carbon in them to carbonic acid; and (2) when nitrogen is substituted for the oxygen in excess of that required to burn the carbon to carbonic oxide. We have seen that oxygen added to electrolytic gas hinders the explosion more than nitrogen. In precisely the same way, oxygen added to a mixture of equal volumes of cyanogen and oxygen hinders the explosion more than the same volume of nitrogen. The conclusion we must come to is, that the oxygen added to the mixture expressed by the formula $C_2N_2+O_2$ is as inert—so far as the propagation of the explosion-wave is concerned—as oxygen added to the mixture expressed by the formula $H_2+O$. The same phenomena occur in the explosion of marsh gas, ethylene, and acetylene. In all these cases the substitution of nitrogen for the oxygen required to burn the carbon from carbonic oxide to carbonic acid *increases* the velocity of the explosion. These facts seem only consistent with the view that the carbon burns directly to carbonic oxide, and the formation of carbonic acid is an after-occurrence.

Finally, the rates of explosion of cyanogen and the hydrocarbons, when their carbon is burnt to carbonic oxide, have been found greater than the velocities calculated from Berthelot's formula. This accords with the observation previously made, that the rate of explosion of electrolytic gas with excess either of hydrogen or oxygen is far higher than the calculated rate. It would seem probable that the theoretical rates as calculated by Berthelot should be modified, in spite of the close agreement which his numbers show. I think the low rates found, when hydrogen marsh gas, cyanogen, &c., are exploded with equivalent proportions of oxygen, depend partly on the carbon burning to carbonic oxide, and partly on the dissociation of the steam at the high temperature. If the formula is modified in these respects, velocities can be calculated which agree with the experimental results where dissociation does not occur. I suggest the following modifications:—(1) The specific heats should be taken at constant volume instead of at constant pressure; (2) the density of the gas should be taken as the mean of the burnt and unburnt molecules, instead of that of the burnt molecules alone; and (3) a correction should be made for the alteration of volume by the chemical reaction, which in some cases increases, in others diminishes, the volume.

The rates so calculated agree with the explosion rates of cyanogen when burnt to carbonic oxide either by oxygen, nitrous oxide, or nitric oxide; with the explosion rates of hydrogen and oxygen, with a large excess either of hydrogen, oxygen, or nitrogen; with the explosion rates of ethylene and acetylene, with oxygen and a large excess of nitrogen; and, lastly, with the explosion rates of hydrogen and chlorine, with an excess of hydrogen.

In conclusion, I would say that these experiments have amply confirmed the truth of Berthelot's statement, that the explosion-wave is a "specific constant" for every gaseous mixture; that it has been shown that the rate of explosion depends upon the primary reaction occurring, and that the determination of the rate may throw some light on what is now so obscure—the mode in which chemical changes are brought about; and, finally, that it does not seem impossible that a connection between the rate of the molecules and the rate of the explosion may be worked out, which will give us some definite information on points of high interest in the theory of gases.

The Borax Fields of South America.—The appearance of an inland sea in California is causing great anxiety regarding the supply of borax and boracic acid. Mr. Robottom, a gentleman who is well-informed upon the subject, says that if the Californian supply should fail, there is sufficient crude borax in Chili, Peru, and Bolivia to supply the markets of the world. One deposit which Mr. Robottom visited on the borders of Chili and Bolivia he describes as being twenty-six miles in length, and from three to six miles in width. The high Andes and many of the valleys of these districts are, according to Mr. Robottom, covered with borax.—*Dalziel.*

## CHICAGO EXHIBITION, 1893.

As many of our readers will doubtless wish to know under what conditions they can exhibit at the coming World's Fair at Chicago, we print the following general regulations which have been framed by the Government of the United States, so far as foreigners are concerned. The articles exhibited will not be subject to any duties, fees, or charges of any kind:—

### General Regulations for Foreign Exhibitors.

1. The Exhibition will be held on the shore of Lake Michigan, in the city of Chicago, and will be opened on the 1st day of May, 1893, and closed on the 30th day of October following.

2. All governments have been invited to appoint commissions for the purpose of organising their departments of the Exhibition. The director-general should be notified of the appointment of such foreign commissions as soon as the appointment is made.

Diagrams of the buildings and grounds will be furnished to the foreign commissions on or before January 1st, 1892, indicating the localities to be occupied by each nation—subject, however, to revision and readjustment.

3. Applications for space, and negotiations relative thereto, must be conducted with the commission of the country where the article is produced.

4. Foreign commissions are requested to notify the director-general not later than June 1st, 1892, whether they desire any increase or diminution of space offered them, and the amount.

5. Before November 1st, 1892, the foreign commissions must furnish the director-general with approximate plans, showing the manner of allotting the space assigned them, and also with lists of their exhibitors, and other information necessary for the preparation of the official catalogue.

Products brought into the United States at the ports of Portland, Maine, Boston, New York, Philadelphia, Baltimore, Tampa, New Orleans, San Francisco, Wilmington, Portland, Oregon, Port Townsend (Wash.), Seattle (Wash.), Tacoma (Wash.), and Chicago (Ill.), or at any other port of entry, intended for display at the International Exhibition, will be allowed to go forward to the Exhibition buildings, under proper supervision of customs officers, without examination at such ports of original entry, and, at the close of the Exhibition, will be allowed to go forward to the port from which they are to be exported. No duties will be levied upon such goods, unless entered for consumption in the United States.

6. The transportation, receiving, unpacking, and arranging of the products for exhibition will be at the expense of the exhibitor.

7. The installation of heavy articles requiring special foundations or adjustment should, by special arrangement, begin as soon as the progress of the work upon the building will permit. The general reception of articles at the Exhibition buildings will commence on Nov. 1st, 1892, and no articles will be admitted after April 10th, 1893.

8. Space assigned to foreign commissions, and not occupied on the 10th day of April, 1893, will revert to the director-general for reassignment.

9. If products are intended for competition, it must be so stated by the exhibitor; if not, they will be excluded from the examination by the international juries.

10. An official catalogue will be published in English, French, German, and Spanish. The sale of catalogues is reserved to the World's Columbian Exposition.

The twelve departments of the classification which will determine the relative location of articles in the Exhibition—except in such collective exhibits as may receive special sanction—also the arrangement of names in the catalogue, are as follows:—(*a*) agriculture, forest products, forestry, machinery, and appliances; (*b*) viticulture, horticulture, floriculture; (*c*) live stock—domestic and wild animals; (*d*) fish, fisheries, fish products, and apparatus for fishing; (*e*) mines, mining, and metallurgy; (*f*) machinery; (*g*) transportation — railways, vessels, vehicles; (*h*) manufactures; (*j*) electricity; (*k*) fine arts—pictorial, plastic, and decorative ; ($l$) liberal arts—education, engineering, public works, architecture, music, and the drama ; ($m$) ethnology, archæology, progress of labour and invention, isolated and collective exhibits.

11. Foreign commissions may publish catalogues of their respective sections.

12. Exhibitors will not be charged for space.

A limited quantity of steam and water power will be supplied gratuitously. The quantity of each will be settled definitely at the time of the allotment of space. Any power required by the exhibitor in excess of that allowed will be furnished by the World's Columbian Exposition at a fixed price. Demands for such excess of power must also be settled at the time of the allotment of space.

13. Exhibitors must provide, at their own cost, all show-cases, shelving, counters, fittings, &c., which they may require, and all countershafts, with their pulleys, belting, &c., for the transmission of power from the main shafts in the building where the exhibit is located. All arrangements of articles and decorations must be in conformity with the general plan adopted by the director-general.

Note.—The general plan requires all decorations, signs, &c., to be in harmony with the dignity and magnitude of a magnificent exhibition, and the director-general is empowered to secure this result.

The World's Columbian Exposition will take precautions for the safe preservation of all objects in the Exhibition, but it will in no way be responsible for damage or loss of any kind, or for accidents by fire or otherwise, however originating.

Note.—A thoroughly equipped fire department will protect the buildings and exhibits, and a large police force will maintain order. The entire Exposition grounds will be under the immediate supervision of the City of Chicago and of the State of Illinois. A guard, equal to any possible contingency, is thus provided, the municipal authority being upheld, if necessary, by the State troops, and the State by the army of the United States, so that no apprehension need arise as to losses resulting from lawlessness.

14. Favourable facilities will be arranged by which exhibitors or foreign commissions may insure their own goods.

Note.—Special care has been taken to render everything about the Exposition as nearly fire-proof as possible ; and it is reasonably certain that the rates of insurance will not be excessive, but, on the contrary, very reasonable. Exhibitors may insure in any company, foreign or domestic. Arrangements will be made with English, French, German, and American companies to fix uniform or special rates on exhibits and buildings, so that no advantage will be taken of any exhibitor who wishes to insure his goods.

Foreign commissions may employ watchmen of their own choice to guard their goods during the hours the Exposition is open to the public, subject to the rules and regulations of the Exposition.

15. Foreign commissions, or such agents as they may designate, shall be responsible for the receiving, unpacking, and arrangement of objects, as well as for the removal at the close of the Exposition ; but no person shall be permitted to act as such agent until he can give to the director-general written evidence of his having been approved by the proper commission.

16. Each package must be addressed, "To the Commission (name of country) at the World's Columbian Exposition, Chicago, United States of America," and should have at least two labels affixed to different, but not opposite, sides of each case, and give the following information :—

17. (1) The country from which it comes ; (2) name of firm of the exhibitor ; (3) residence of the exhibitor ; (4) department to which objects belong ; (5) total number of packages sent by that exhibitor ; (6) serial number of that particular passage.

18. Within each package should be a list of all objects.

19. If no authorised person is at hand to receive goods on their arrival at the Exposition buildings, they will be removed without delay, and stored at the risk and cost of whomsoever it may concern.

20. Articles that are in any way dangerous or offensive, also patent nostrums and empirical preparations whose ingredients are concealed, will not be admitted.

21. The removal of goods on exhibition will not be permitted prior to the close of the Exhibition.

Note.—Articles not on exhibition for competition may be sold under special permit.

22. Sketches, drawings, photographs, or other reproductions of articles exhibited will only be allowed upon the joint assent of the exhibitor and the director-general ; but views of portions of the building may be made upon the director-general's sanction.

23. Immediately after the close of the Exhibition exhibitors shall remove their effects, and complete such removal before January 1st, 1894 ; goods then remaining will be removed and sold for expenses, or otherwise disposed of under the direction of the World's Columbian Exposition.

24. Each person who becomes an exhibitor thereby acknowledges and agrees to be governed by the rules and regulations established for the government of the Exhibition.

Special regulations will be issued concerning the exhibition of fine arts, awards, the organisation of the international juries, and sales of special articles within the buildings, and on other points not touched upon in these preliminary instructions.

25. All communications concerning the Exhibition will be addressed to the Director-General, World's Columbian Exposition, Chicago, Illinois, U.S.A.

The management reserves the right to explain or amend these regulations whenever it may be deemed necessary for the interest of the Exhibition.

Mr. W. H. Dale Vallon, under the imposing title of "The Scientific Alliance," has opened a factory for optical and electrical apparatus at Dyer's Buildings, Holborn, E.C.

People's Palace Technical Schools, Mile End Road, E.—The fifth winter course of technical and practical instruction in photography will be commenced on Thursday, October 1st, at eight p.m. ; lecturer, Mr. Charles W. Gamble.

It is not unlikely, says the *New York Times*, that importers of music, pictures, including etchings, photographs, &c., and a large contingent of lovers of these things who are not dealers, will unite in a protest to the Secretary of the Treasury against the ruling which instructs the customs officers to confiscate these articles when sent through the mails from foreign countries. The ruling referred to has been in effect since July 28th. Importers of such articles whom a *Times* reporter talked with, said that it not only brought no revenue to the Government, but it imposed such restrictions as to amount to prohibition of importations. The situation was explained thus. "Books imported are dutiable under a special clause in an Act of long standing. Special provision, however, is made that they may be received through the mails. Other classes of printed matter subject to duty are not provided for, and under the action of the Postal Convention these dutiable goods may not be sent by mail. Consequently, an order has been issued to seize all such articles. They must come through the Custom House by the express lines." Since this order took effect the customs department at the Post Office has been doing a rushing business. All sorts of packages have been seized, and the total amount of work of this department has been increased about 100 per cent. Prior to the order the seizures numbered about 250 a month. In the twenty days that the wholesale confiscations have been in process, the number has increased to such an extent that at the end of the first month it is estimated that the total of seizures will be about 1,700. The goods taken are to a large extent pictures, although many bundles of music have been stopped on their way to the dealers and sent to the Custom House, to be redeemed under penalties, or sold. The men interested have been powerless. Their correspondents abroad have been sending goods as of old, and confusion and loss have resulted.

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

HELIOCHROMY—REDUCING HARD NEGATIVES—HYALINE—DEVELOPER FOR GELATINO-BROMIDE PRINTS—SOLUBILITY OF ZINC.

*Heliochromy.*—To judge from a leader in the *Phot. Archiv*, it seems that a new step forward has been made in the solution of the problem of photographing in the colours of nature. It is said that a young scientist of Munster, in Switzerland, Dr. R. Kopp, who has been engaged with heliochromic experiments for three years, has elaborated a method which enabled him to obtain, with comparatively short exposures, photographic prints on which the various colours are produced all at the same time, and not separately, as is the case with the method of Professor Lippmann. The working details of this much-promising method are, of course, not published by the author, but he claims the following. All the colours and tints, together with black and white, are produced directly by means of a heliochromic process. The time of exposure is a comparatively short one, requiring from thirty to fifty seconds in direct sunlight. The prints, after being fixed, keep very well, only if exposed to the action of direct sunlight they will suffer to a slight degree. The editors of the above-mentioned journal, judging from the prints the author has sent to them, state that the prints have been obtained from transparencies and diapositives on glass; red, violet, yellow, and green being well represented, the lights of the pictures being purely white. The latter is of special value, it being well known that all the predecessors of the author found special difficulty in producing a pure white on their heliochromic pictures. Even the heliochromic prints obtained by Veress show a yellowish-brown ground. The author has also made experiments to produce the colours directly in the camera, and he says that especially the yellow and the green of the trees and of the meadows are reproduced quite naturally. He has no doubt that his process will be soon perfected.

*Reducing Hard Negatives.*—The following method, recommended by P. Ladewig, has proved in my hands to be a good one in the case of too hard negatives which are to be reduced. The negative, after being fixed and thoroughly washed, is placed in the following solution:—

| | |
|---|---|
| Bichromate of potash ... ... ... | 1 gramme |
| Hydrochloric acid ... ... ... | 3 grammes |
| Alum ... ... ... ... ... | 5 ,, |
| Water ... ... ... ... | 100 to 150 c.c. |

As soon as the negative is thoroughly bleached, it is well washed until the yellowness has disappeared, and then placed (in daylight) in any old or diluted developing solution. The image is developed slowly, and, at first, on the surface, so that the details in the shadows will be perfectly distinct before the lights have acquired sufficient density. By observing the negative image repeatedly by transmitted light, it will be easy to ascertain the point at which its density will be sufficient; it is then well rinsed, and the remaining silver chloride which has not been decomposed is removed by fixing the negative in hypo. I am quite aware that the method is not new, but it is a good one which deserves to be recommended afresh.

*Hyaline.*—A new material has been invented by F. Eikstein called "hyaline," which resembles externally the well-known celluloid; but whilst the latter is manufactured by combining camphor with nitro-cellulose, the new material contains other resinous substances instead of camphor—for instance, copal, dammar, shellac, or a mixture of them. It is very tough, semi-transparent, very extensible, odourless, and much less inflammable than celluloid; it may even be rendered entirely incombustible. The new material should be tried by manufacturers for photographic purposes.

*Developing Gelatino-Bromide Prints.*—The following developer is highly recommended by Dr. F. M. Eder for gelatino-bromide paper, it giving prints with perfectly clear whites. Two solutions are prepared:—

*Solution* No. 1.

| | |
|---|---|
| Pyrogallic acid... ... ... ... | 4 grammes |
| Potassium meta-bisulphite ... ... | 1·5 gramme |
| Distilled water... ... ... ... | 100 c.c. |

This solution keeps for many weeks if kept in a well-stoppered bottle.

*Solution* No. 2.

| | |
|---|---|
| Crystallised soda ... ... ... | 10 grammes |
| Sodium sulphite ... ... ... | 15 ,, |
| Distilled water... ... ... ... | 100 c.c. |

For use, equal parts of solution No. 1 and No. 2, and of distilled water, are mixed. This developer acts less energetically than the ordinary pyro-soda developer, but by increasing the quantity of the soda, and by diminishing the bulk of the water, the intensity of the pictures may be much increased.

*Why Chemically Pure Zinc is Sparingly Soluble in Acids.*—It is a well-known fact to photographers that chemically pure zinc is almost insoluble in diluted cold sulphuric acid, and that only nitric acid attacks this metal in the chemically pure state. The reason for this strange behaviour of the zinc has not, however, been sufficiently cleared up hitherto. Jul. M. Weeren has now made experiments in this direction, and he found that the chemically pure zinc is very sparingly soluble in acids because, directly it is immersed in the acid solution, it is surrounded by a condensed hydrogenic atmosphere, by which, in normal circumstances, a further attack of the acid is rendered impossible. In the case of nitric acid, the hydrogen which is formed on the zinc surface is, immediately after its formation, oxidised by the acid, so that it cannot condense itself in the form of a protecting covering around the zinc. A means to remove the protecting hydrogenic atmosphere from the pure metal consists in boiling the acid. Whilst at 0° the diluted sulphuric acid dissolved only 2·1 milligrammes of the metal, the quantity of the dissolved metal amounted to 9·8 mg. at 98°, and at 100° it amounted to 122·1 mg.

---

THE Fry Manufacturing Company have just issued supplementary catalogues containing full description and price list of their dry plates, lantern plates, celluloid films, enlargements on opal, paper, and canvas; bromide paper, ready-made developers, and all the other useful things which this Company deals with in such vast quantities. It can be truly said that the quality of these goods is as good as the quantity is great.

THE camera is not without its practical side. On at least one of the railroads running out of Boston, a camera is used in the legal department to take pictures of wrecks and other matters wherein a presentment of the situation can be made pictorially. A photograph tells the whole story at a glance; and not only does it save time, and therefore money, but it tells the story much better than words could possibly do it. The road in question, it is stated, has saved many thousand dollars in successfully opposing claims for damages which, but for the camera with its picturesque portrayal of the situation, it would have been compelled to pay.—*Boston Transcript.*

## PRACTICAL DEVELOPMENT.

BY W. S. WATERBURY.

It seems to me that there is no photographic subject that needs atteution any more than the above, as on it depends the success of the picture. It is of far more moment, from my point of view, than the exposnre, becanse, with judicions development, incorrect exposure can be corrected to a great extent—provided, of conrse, the error is within the bounds of reason.

I once heard a prominent experimenter say that there was no such thing as over or nnder-exposnre. Of conrse this was an extravagant statement; bnt it conveys a good idea as to what can be accomplished by intelligent development.

I believe in a full exposure. Allow the light ample time to act on the sensitive film, for without sufficient light action, tons of chemicals cannot prodnce a picture. Then the great advantage of a fnll exposnre is that yon gain an abnndance of detail in the shadows. It has been snggested to expose for the shadows and let the lights take care of themselves, and in most cases this is a good maxim.

True it is that under-exposure is sometimes unavoidable, and in that case some developers and a different mode of applying them may, to some extent, help it; bnt I would lay more stress upon allowing an ample amount of light to act on the plate. If yon do instantaneous work, be careful to have a lens and plate sufficiently rapid, and yon will have little trouble.

Now as to the choice of your developer. While I advocate the nse of no particnlar formula, I would suggest that, whichever one be used, always give preference to the one with two solutions, as it gives better control of development by allowing you to regulate the proportions of the alkali. I think that all formnlas are of nearly equal merit if used properly, and in two solutions. I nse the Chantanqua developer (pyro and potash), taken from the "Annnal" for 1891, page 331, formula No. 55, and I consider it as good as any for all around nse; either the above or eikonogen, prepared after any of the standard formulas, if in two solntions. I consider the choice of developers of far less importance than the manner of applying them, and, while eikonogen may be somewhat more difficult to manage, it certainly has a decided advantage in that it does not discolour the hands, besides giving more detail, especially in under-exposed plates.

To begin with, I hold that the strength of the developer mnst be suited to the exposure, rather than the exposure snited to the developer, as the ever-changing condition of light and the varying of the time of exposures, together with the difference in the sensitiveness of plates, render it impossible to make exposnres alike; therefore to follow any set rnle for applying a developer of uniform strength is impracticable.

Now as to the best way to apportion our developer to suit the various exposures. For example, let ns suppose a plate to be either correctly or over-exposed, and we are nsing the pyro developer; in either case we proceed as follows. Take the prescribed amount of water and add the pyro to it, keeping the potash separate, diluted with a little water, and add abont ten drops at a time to the pyro, each time flowing over the plate, and allowing a few minntes for it to act at each application. Continue to add the potash only until the image is well out, as you have now arrived at the proper strength; in other words, you have snited the developer to the exposure; now continue the development until the proper density is attained, but shonld it be slow in coming, add another dram of pyro. By these means a plate that is mnch over-exposed can be made to yield a brilliant negative. The above manipnlations can be observed in the use of any two-solntion developer, the idea being to approach the proper strength by the gradnal introduction of the alkali; bnt in some cases of extreme over-exposure it is a good plan to introdnce both the pyro and alkali by degrees, adding each as the progress of the plate may indicate.

Next let us suppose a plate to be under-exposed. In this case take one dram of the potash and mix with four onnces of water, and flow over the plate, and allow it to act for a few minntes. While this is doing its work, prepare the developer as described in the formula, excepting that double the amount be used. Now throw off the first bath, and withont rinsing flow with the developer, and allow this to act until sufficient detail has been obtained. If successfnl in this, add another dram of the pyro, and continue development until the desired density has been attained, but if not snccessfnl in this, the plate has probably been hopelessly under-exposed, bnt there is still a possibility of improving it by using another bath of full strength.

These manipnlations may also be observed in the use of any two-solution developer, the idea being in this case to first stimnlate the plate with the alkali, then apply the developer proper, only in a diluted state, and finally finish with developer, fnll strength.

Freqnently, when developing a plate, the sky and other strong lights appear long before the detail in the shadows, and in such a case take the plate from the bath and apply the alkali gently with the finger on the parts that are in shadow, and plnnge immediately in the bath again, being careful not to keep it from the bath long enongh to make sharp lines, and repeat the operation nntil sufficient detail has been secnred in the shadows, then continue development until sufficiently dense. In this manner the shadows can be forced independently of the high-lights, and amply developed without over-developing them. I have often developed a plate almost entirely by local application, as described above, with the most satisfactory results.

Inasmnch as the plate will always lose density in the fixing bath, in each and every case the development should be carried beyond the density desired in the finished negative.—*Photographic Times.*

---

The Cowles Electric Smelting and Aluminium Company, Lockport, N.Y., have reduced the price of their best aluminium to 50 cents per pound in ton lots. Now is the time to put the wonders that cheap aluminium would accomplish to the test; 50 ceuts a pound makes aluminium about as cheap as copper, taking capabilities of the two metals into consideration.—*Invention.*

A correspondent of the *Journal of the Photographic Society of India* says that for attaching lantern slide bindings to the glass nothing is better than bichromated paste, which is made as follows:—

| | |
|---|---|
| Flour ... ... ... ... | 2 teaspoonfuls |
| Water ... ... ... ... | 4 ounces |
| Bichromate of potash ... ... | 5 grains |

The flour must be rubbed to a smooth batter with the water, then placed in a saucepan over a fire, and kept stirred till it boils. Add the bichromate slowly, stirring all the time. Then stand to cool. *This paste must be kept in the dark;* and used as soon as possible. *Soak* the paper in it, attach to the glass, and then place in direct sunlight for a day.

## Notes.

Reference to any history of engraving will show that at one time the task of producing even a small printing block was a very serious affair indeed, often entailing more than one solemn confabulation between author, artist, engraver, and publisher. Photography has long ago changed all this, and an illustration which, under the old state of things, would tax the attention of a man for three or four days, can now be produced automatically from any pen-and-ink sketch in a less number of hours. Only instead of one sketch being in question, many are now photographed on one plate, and etched in one bath, a whole batch being treated at once. This power of wholesale production has led to one curious result, namely, the production of blocks of popular subjects, which can be multiplied by the electrotyping process indefinitely, and placed on the market for purchase by any of the thousands of newspapers which now exist in our own and other countries.

Here, before us as we write, is a publication known as "Vanoni's Weekly Sheet"—being events of the day illustrated. This particular number bears the impressions from thirteen different blocks, comprising three or four portraits of more or less prominent persons, scenes from a new play, H. R. H. at Heidelberg, and so on. In the margin is a short description of each event, from which a practised writer could soon evolve an expanded account, and the price at which each block will be supplied—averaging about fourpence per square inch—is placed against each cut. This system will be a boon, no doubt, to the provincial papers, particularly if each has the monopoly of the illustrations so far as its own town is concerned. The idea, we may add, is not exactly new. Some years ago Messrs. Cassell issued blocks and stereotyped matter for the use of provincial journals, but we do not know whether they are doing so still.

It has been suggested to us that the modern photographic portrait is so often entirely spoilt by the particular style of dress which may happen to be fashionable at the time, that it would be well if it became the rule to attire sitters in simple classical drapery. The notion is certainly a good one from the artistic point of view, and would be hailed with delight by people of good carriage and fine physique. But how about the great majority of ordinary people, and those who have the somewhat common deformity of abnormally large features? Many of these would look supremely ridiculous when thus equipped, and would certainly avoid the photographic studio if their presence there involved such trappings.

It is, unfortunately, true that modern fashions often are fatal to artistic effect; but there is a style of dress which now seems to be in vogue which is still more objectionable than the deforming projections which are now getting out of date—we mean the imitation by the ladies of masculine dress. Jackets with pockets at the sides, striped shirt-fronts, studs, stand-up collars, sailor's knots, cuffs, &c.—all are complete. Such a get-up is to most men the reverse of attractive. W. S. Gilbert, in *Patience*, chaffed the æsthetic young man with his feminine manners to extinction, and now there needs someone to extinguish the masculine young woman. At any rate, when she comes to be photographed, let her put aside her tailorings, and bedeck her, if not in classical garb, in some more suitable attire.

If anything "new" concerning photography is wanted, the place to look for it is the society journal. These authorities have the knack of making discoveries which rarely find their way into the photographic press. The only fault to be found with these novelties is that, after their first announcement, nothing more is heard of them. We hope this will not be the case with the "new process" of a Stuttgart photographer, which, according to the *Court Journal*, goes by the name of "Natural Photography." "Natural Photography" consists in the taking of life-size portraits direct in the nineteenth part of a second. The Stuttgart photographer uses a combination of daylight and the flash-light, and employs a "transposed camera," whatever this may be. Life-size portraits taken direct are no novelty in England. There was once a craze in this direction. Some twenty years ago the late Robert Crawshay offered a prize for the best production of the kind—a contest which flooded the Pall Mall Exhibition of that year with Brobdignagian atrocities.

It is quite possible new "readings" in the performances of Beethoven's symphonies may result from Sir George Grove's proposal to have the original manuscript photographed for the information of musicians. Errors in copying band parts are frequent enough, and possibly the bewilderment the first rehearsals occasioned the orchestra of nearly a century ago was due, in some degree, to this cause. But though these errors may have since been corrected, it may be some marks of expression with which the manuscript abounds, to say nothing of the changes and corrections that, as Sir George Grove says, "crowd the pages," have been incorrectly transcribed. Indeed, Sir John Stainer says, "In certain parts of his symphonies we are not quite sure to this day whether we are playing the right notes." Anyway, if the scheme be carried out, musicians will be grateful to photography for the boon it will place in their hands.

The Berlin Chemical Society have lately had brought before them two instances where forgery was detected by means of photography. In each case an ink different in colour from that of the original was used by the forger, and, though the tints were apparently the same to the eye, the sensitive plate revealed the difference. There is, of course, nothing new in this, but it is well that the detective powers of photography in this direction should be kept in mind.

Varied, indeed, are the uses of photography. The newspapers record the feat of an American tourist who, being denied admission to an old church up in the mountains of Mexico, had his curiosity and ambition excited, and, after drugging the custodian, went at night inside the building with his camera and flash-light, and secured the picture of a statue of the Virgin made of solid gold. From France comes the story of the capture in some dye works of a German, also armed with a camera and magnesium powder, which he intended to employ in the photographing of certain machinery in order to discover some trade secrets. Thirdly, we see the *Trades Unionist* photographing the distorted appearance of the unfortunate employées in chloride of lime works. And all this within a week!

## PHOTOGRAPHIC ARCHÆOLOGY.

BY JAMES MEW.

Dionysius of Halicarnassus and Flavius Josephus gave the name of archæology, the former to his book relating to the origin and commencement of Rome, the latter to his history of the nation of the Jews. The archæology which is the subject of the present article was born in the period of the Renaissance, and cradled in the Middle Ages. It has been somewhat invidiously described by Balzac as the passion—or, to speak with greater accuracy, the mania—which misleads old gentlemen into the belief that they are yet alive. This is scarcely an exact definition; it is rather of the sort which proceeds from the mouths of those who sit in the seats of the scorners. Seriously described, it is the science which, treating of antiquity, investigates it by the study of such aids to its interpretation as monuments and manuscripts. The reproduction of these by means of photography is one of the most important of the many useful applications of this excellent art.

In the matter of monuments, the ingenious photographic artist has, in the words of Gray's "Bard," "ample room and verge enough." At his own sweet will he may disport himself among those huge megalithic structures to be found alike in Europe, Asia, and America, called in the Celtic "dolmens," and in the Welsh "cromlechs." He may amuse himself in Devonshire and Cornwall by taking these supposed sepulchral monuments in every variety of posture and condition; or he may transfer to his sensitive plate those mysterious bones, rude implements of warfare, cooking, or ornament—it is, alas! too often uncertain which—found sometimes in the cinerary urns which these so-called table-stones enclose. But in "taking" photographically the treasures revealed by them there must be no hesitation and no delay. Exposed after ages of interment to a new and sudden life of sunshine and of air, they crumble rapidly away, and, if not taken in time, are lost to the procrastinating photographer for eternity. It is true that much matter of antiquarian interest in England, as in India and Egypt and Palestine and Greece and Rome, has been already ably pictured by photographers now dead and gone, but the artist of the present may still feed on the crumbs which have fallen from their sumptuous table. He may still spend a happy day—not, indeed, of that order of felicity to be found in Rosherville, but of a staid and subdued character—in the vaults of the British Museum; or, if his fiscal resources allow it, he may take copies of Pugins' church at Ramsgate; or he may go still further afield, and find a very picture-book of antiquity in the ancient pine forests and solemn streets of sad Ravenna, that fossilised city in which Byron wrote his "Faliero," and the author of the Divine Comedy sleeps his everlasting sleep.

The camera is equally useful in preserving records of monuments, of architecture or of sculpture, of painting or of engraving, ordinary or extraordinary, civil or military, social or domestic, sacred or profane. The photographer who has occupied his leisure hours with the study of architecture may take portraits of walls, houses, temples, obelisks, pyramids, theatres, tombs, and public highways to his heart's content. He who is fond of sculpture has only to set his camera before statue, bust, or bas-relief, to obtain iconographic photographs. He who is interested in paintings—and what artistic photographer is not?—has no lack of frescoes, and pictures on papyrus, or canvas, or wood, and of mosaics, those geometric drawings on stone. He who busies himself with engravings may carry away with him his photographic glyptographs; while numismatic photographs will be his who delights in medals, of every time and country, with inscriptions in every tongue, on every kind of material. The world of literature and art is all before him where to choose. He may busy himself with the reproduction of old writings, or picture a sword or a helmet, a lamp or a goblet, a bracelet or a ring, the furniture of the men and women who lived, and moved, and had their being in the long dead past, in the ancient world of Assyria and Egypt, of Greece and Rome. As a literary archæologist, he may learn not only to know for himself, but also to describe to others the works of human interest in all the periods of the past, and to perpetuate by his photographic skill the memory of those monuments which the remorseless hand of time is ever ready to convert into mouldering ruin.

To the student, the work of the paleographic photographer is of the greatest value. The pictures of inscriptions furnished by the camera are convenient to the scholar for the prolonged study which is generally required for their decipherment. No sketch made by any human artist will be able to equal the absolute exactitude of the photographic lens, which, moreover, produces a complete likeness in less time than the artist would require for the merest sketch. In the photographic portrait of manuscript, there is happily no possibility of those copyists' mistakes, those unlucky and misleading errata, which occur—a punishment, it may be, for sins committed in some former state of existence—to the most careful scribe. The serious results which can be caused by the mistake of a single letter are all too well-known. They are of equal importance with those which have notoriously happened in kindred branches of archæologic study. Had the assistance of photography been invoked, the dark Isis with Horus in her lap would not, it may be, have seriously compromised the Christian cult by being venerated as a semblance of the black Virgin and her child, nor, perhaps, would the devout have seen St. John the Baptist borne upwards to the skies in a picture of the apotheosis of the Roman emperor Germanicus.

But the work of the camera is not only convenient, exact, and rapid; it is also comparatively easy, permanent, and cheap. The cost is often inconsiderable as the toil, and difficulties which are sufficient to appal the deftest draughtsman, or the most accomplished engraver, are changed into child's play by the touch of the spear of the solar Ithuriel. Partially effaced texts, which may well fill the bravest paleographist with despair, are, by the camera's co-operation, rendered decipherable. The traces of ink drawn by the ancient writer's patient fingers—fingers resolved ages ago into their component dust—have become yellow, and of one colour with the once fair parchment upon which they are inscribed. The similarity of hue in ink and parchment makes many of the letters inscrutable to any human eye, and much of the meaning sibylline in insignificance. Not Argus, nor Lynceus, with all their far-famed visual energy, could have discovered what the objective displays with the utmost ease, the objective to which artistic license is happily unknown. The aid of chemistry might, indeed, be invoked in the matter of the faded ink, but the means of assistance she offers are as much dreaded by the proprietors of these time-worn relics, and for the same reason, as the Pure Co-operative Washing Powder by the thrifty and astute housewife.

Ancient architectnre with conntry—with its ivy-grown towers, and flowers sprouting from every ruined coign of vantage—or in town rendered esthetic and interesting from its absorption of centuries of London smoke, has ever recommended itself to the artistic photographer—the lover of the picturesque. It is difficnlt for him to pass without casting one longing, lingering glance behind (and without a wish that his camera accompanied him) those quaint old hostelries, with their courtyards fringed with galleries of wood elaborately carved, and darkened by time through the lapse of many generations of such as fonnd their rest therein, before that longer and deeper rest which followed after so surely, and without exception, for them all. Of those quaint inns—which to-day are, and to-morrow their place knows no more—fain would the photographer preserve for himself and for others, if naught else, the outward semblance. Precious will these samples soon become of the building of olden time, memorials of the labour of busy hands long folded to rest, which now meets the eyes day after day of thousands of passers-by, careless of what custom has rendered common, and the dirt of the metropolis unclean. It is said that a society exists for the purpose of photographing such ancient relics. Should there be one, some of the old towns of England might fill the pages of its publications with architectural beauty, and make it—if the quotation be not a little over-worn—"a joy for ever."

By the gatehouse of Lincoln's Inn is the wall upon which, we are told, laboured with his own hands that most illustrious of bricklayers, Benjamin Jonson. "His mother," says Aubrey, "after his father's death married a bricklayer, and it is generally said that he wrought some time with his father-in-law, and particularly on the garden wall of Lincoln's Inn, next to Chancery Lane." This gatehouse was supposed to be in imminent danger of destruction some years ago; but it still survives, adorned with the arms of one Sir Thomas Lovell, who lived in the time of Henry VIII., and of other persons equally noteworthy and unnoted.

In the matter of manuscripts, the photographer will find no lack of material. Among the old papyri existent in our national depository, in the many inscriptions in foreign tongues—Arabic, Chinese, Egyptian, Etruscan, Greek—he cannot complain of a paucity of objects for selection. The writings of antiquity will meet him who cares to search for them both at home and abroad. He may copy the incised slabs in Somersetshire, or the monuments in the cathedral of Hereford. He may carry his camera to the church of Aphrodite in Cyprus, or to the cave temples of Western India. He may take his choice among the ancient epitaphs of the Jews in Naples, or among the cemeteries of Rome; and he may fill the fellows of his particular Society with envy by presenting to them at their annual meeting an inscription of Pompey the Great, or of Tiglath Pileser the Assyrian king.

Of the vast importance of photography in the matter of religious significance dependent upon ancient texts, a sample was quoted in the PHOTOGRAPHIC NEWS some twenty years ago. A London correspondent of the *Western Daily Mercury* happened to know, "as a matter of fact," that a correct though small photograph had been taken of the oldest existing copy of the Athanasian Creed. This photograph was sent direct from the ancient text in St. Mark's Library in Venice to the Record Office in London. The remarkable thing about it is, that the damnatory clauses are not in it. Now, the Athanasian Creed without these damnatory clauses is, if the comparison may be allowed, the play of "Hamlet" without the Ghost. Such a photograph is almost enough to make the good Saint to whom this sacred symbol has been ascribed rise from his grave in holy horror of protestation. But the correspondent of the *Western Daily Mercury* is curiously indifferent. He only expects that this palpable argument will settle the controversy respecting these unlucky clauses. But the clauses are not yet settled; they have, indeed, far too much vitality to be disposed of in so summary a fashion.

It is sad to reflect that the photographing of objects of antiquity has sometimes been a field of scientific warfare; that the history of these pictures has been occasionally polluted by human resentment; and that rival photographers have let their angry passions rise in the portraiture of monuments so far removed from them by the lapse of ages as the Pyramids of Egypt. In 1870, Professor Piazzi Smyth, the Astronomer-Royal for Scotland, published his "Poor Man's Photography," in which he compared his own work with that of the Ordnance Survey Establishment, "subsidised by London wealth, under the orders of Col. Sir Henry James, R.E., F.R.S., Director-General of the Ordnance Survey." Professor Smith, in his entertaining *brochure*, which was dedicated to the Edinburgh Photographic Society, gives, in addition to a list of difficulties in the way of a poor man taking an independent line of research in practical science, his method for single and double negatives, and for single and double positive copying. These innocent plates led in the end to dire results. They led—*via* the "Sacred Cubit"—to Sir Henry James declaring some observations of the Professor to be "sheer nonsense in a comically solemn dress"; and to the Professor declaring that some observations of Sir Henry showed that he "knows nothing of what the religion of Revelation is, or commits a deadly sin."

No human work is, apparently, free from the effects of the primeval curse, certainly not photographic archæology. The reproduction of ancient furniture, for instance, offers its own peculiar difficulties in the commonly dark colour of its ancient wood. To attempt to remedy this inconvenience by an exposure in full sunlight would hardly succeed; the result of such a proceeding has been affirmed on no weak authority to be detestable. We are advised to work in a diffused light, to relieve all sombre spots by reflection, and to redeem, so far as may be, by an exaggerated duration of exposure, the failure of photogenic power. Ancient tapestry will be found to require a full light, though the yellow, faded colours still demand a long exposure. The inscriptions placed on works of art denoting their use or appropriation, or both, commonly known as epigraphs, are sometimes made part of the ornamental detail work upon which they are inscribed. But even when this is not so, reproductions of epigraphs are very frequently the object of cultivated photographic interest. Much facility in copying these, when they are of small extent, is produced by accentuating the cavities of the inscribed letters or signs with black or white chalk, according as the marble or other material on which the legend appears is white or black. But in the many different categories of archæologic photography, experienced practice has suggested rules which will lighten the artist's labour, and bring about all that is desired of ultimate success. It were idle to attempt to give in a single article advice on the multiform requirements arising in the reproduction even of such small objects as jewellery, relics, enamels, dress, tapestry, bronzes, and all kinds of bric-a-brac, for which the full price is given by Mrs. Jacobs (no connection with Mr. Jacobs), of Petticoat Lane. In the portraiture of the larger and more prominent objects of antiquarian interest, on the items of process, exposure, development, lens, plate, camera, tripod stand, varnish, and print, a large series of papers might be written with no small advantage.

## ADDRESS TO THE GRADUATING CLASS OF THE CHAUTAUQUA SCHOOL OF PHOTOGRAPHY.*

This is the age of beautiful pictures. They are everywhere to delight our eyes and gladden our hearts—in books, magazines, newspapers, portfolios, albums, and on the walls of our homes. Photography has done for pictorial illustration what the art of printing did for writing. Each has helped to make beauty, truth, and knowledge of universal interest, and available to all. Daguerre inaugurated the democracy of art, as Guttenberg made possible the republic of letters. Books and pictures once cost so much that wealth alone could purchase them. Now they are the possession of millions. There have been no happier people at this assembly than the men and women, boys and girls, of the camera. How often we have seen your eager faces in these groves or by the lakeside as, under the skilful instruction of your beloved teacher, you have sought, by the touch of the sunbeam, to make "a thing of beauty a joy for ever." Accurate marksmen, you have hit beauty on the wing. A curling wave, the flash of an oar, the smile of a child, or a flying shadow, is not too fleeting for quick embalming in the amber of your negatives.

One thinks with commiseration of that maiden of antiquity, whose affection for her lover, according to ancient tradition, gave rise to the coroplastic art. Wishing to console herself for his absence, she drew his picture with a bit of charcoal while he slept, pencilling the dear face as it was reflected on the wall by a lamp. Oh, for a kodak then! But, it is said, this likeness was so striking that the damsel's father filled in the outline, and thus produced the first medallion.

Children think in pictures. Humanity delights in pictures. The earliest peoples had some rude method of pictorial illustration. The genius of Champollion first unfolded to us the meaning of the pictures found in the hieroglyphic language of the East. Prescott tells us that the reporters of Montezuma gave that monarch, in the beautiful pictorial language of the Aztecs, an exact account of the landing of Cortez.

The present century claims the honour of originating the greatest improvements ever devised in picture-making. We are, however, primarily indebted to the chemist Scheele, who, in 1777, discovered that sunlight would affect certain chemically-prepared surfaces. Wedgwood, in 1802, produced photographs, but neither he nor Sir Humphrey Davy could prevent them from fading. Niepce and Daguerre, two Frenchmen, were the first to accomplish this. Daguerre made known the secret in 1839. His process was, briefly, thus: He exposed to light in a camera a polished surface of silver coated with iodine, then subjected it to the action of vapour of mercury, which was precipitated upon the parts acted upon by the light. Hyposulphite of soda removed all the surplus iodide of silver, and thus made the picture permanent.

Professor J. W. Draper, of New York, was the first in this country to give us photographic portraits. During recent years an astonishing advancement has been made in the applications of this beautiful art. The dry plate and instantaneous impression now give the lover of nature opportunity to secure, not only form and shading, but motion, and have made possible to the amateur what was before attainable by the professional alone.

Photography has become the most important ally of the engraver, and in another department, photo-engraving, borrowing once more from the chemist's knowledge, secures, without the engraver's skill, a result which, at little expense, rivals the best work of a Sartain or a Ritchie. When photography shall make possible the transference of colour by the sunbeam, it will produce pictures the beauty of which will defy the highest skill of the painter, and prove that the sun is indeed the greatest of all artists. When this is accomplished, it will probably be done by a careful application of the law of complementary colours, and a study of the relation of surfaces to the absorption of light.

Investigation now suggests the possible identity of light and electricity, and as the *storage* of electricity is but a question of the near future, who shall say that the dream of the chemist in "Gulliver's Travels" may not be realised with a slight modification? He was trying to extract sunbeams from cucumbers, which were to be placed in phials hermetically sealed and preserved for use in raw, dark, and inclement weather. The photographer armed with dry plates and stored sunshine would, indeed, be well equipped.

In this age of intense application to business and professional work, it is delightful to find a means of relaxation which is, at the same time, promotive of intelligence, health, and happiness. The amateur photographer has rare opportunities for studying the beauties of nature. He may become a close observer, and discriminating in taste. So progressive is his art that he can always be advancing in knowledge and growing more skilful in his work. There is also a delightful *corps d'esprit*, which usually inspires and binds together a great company of persons possessing similar tastes and engaged in like pursuits.

I welcome this graduating class to the goodly fellowship of the Guild of the Sun Worshippers. In conclusion, you will not fail to remember that there are *three* R's in the photographer's vocabulary, and that while *R*adiated light is *R*efracted by our lenses, a very pleasant light may be *R*eflected from our characters. One other hint drawn from the mystic waves of the sunbeam may not be inopportune. The throbbing pulsations of ether are essentially rhythmic, and suggest the hope that you who so fully appreciate the magical order in the vibrations of light, may also enjoy sweetest harmonies in your lives.

J. T. Edwards.

* Delivered at Chautauqua on Photographers' Day.

One of the most frequent questions we have to reply to in the "Correspondence Column" is how to obtain deep black or purple tones on albumenised paper. The majority of amateurs appear to think, notwithstanding that we have often pointed out the contrary, that the tone of the print is entirely dependent upon the composition of the toning bath, whereas it has very little, if anything, to do with the matter. The chief factor in obtaining black tones is the negative, and next, the paper.—*Ex.*

## TAKING THE BABY.

BY F. E. B.

Mrs. Crummey, wife of my old friend, Jack Crummey, is an exceedingly pretty little woman, and it was therefore only natural that, when she asked me to take her baby (she meant, of course, take its portrait), I should respond by saying that I should be delighted. So an appointment was fixed for Saturday afternoon. I forget the sex of the child, but feel sure it was either a boy or a girl. I also forget its age, but I recollect it had no teeth. It might, of course, have had false ones, but if it had it wasn't wearing them.

When I first got to Mrs. Crummey's the child was asleep. This was annoying, because the hour had been fixed under the impression it would be awake, and would have had a bottle of something—I forget what—though I remember thinking that a glass would have been a more suitable quantity for one so young. When they told me the cherub was slumbering, I very innocently suggested waking it up, but Mrs. C. would not hear of it. She said: "The darling would be dreadfully cross, and scream all the afternoon." This startled me so much that I immediately took to creeping about on tip-toe, and talked in hoarse whispers like a stage villain.

I occupied part of the period of waiting in getting my traps together, arranging a background, and so on; but even after this had been done, the infant Crummey slept on. About three o'clock, however, and just as the light had begun to fail a little, a loud wail from somewhere upstairs announced that the young sluggard had roused up, and encouraged me to hope that the time for action had arrived. But I was mistaken; I had reckoned without the bottle, and another half-hour went by while it was being emptied.

And then came the detail of dressing. And what a dress! A nice, clean, starchy little nurse brought the infant down with an inexpressible pride which at first froze me dumb, although I subsequently found courage to protest. The little bald head was crowned with a hat like that attributed to Hamlet's aunt—a thing all plumes and brim; monstrous rosettes hedged in the small visage on either hand, and a dish-shaped bib stuck out under the tiny chin like a preposterous lower jaw. A great white coat of some fluffy material enveloped the unhappy little creature's body, and effectually concealed its shape, while its hands were encased in a species of boxing-glove. It is almost needless to explain that the little thing itself was quite indistinguishable under such a mass of millinery. I pointed this out to the mother as gently as I could, but both she and the nurse took my complaints in very ill-part, and assured me that "everybody else" thought baby looked sweet in this particular costume. Mrs. Crummey, indeed, became, as I thought, a little sarcastic, and, turning to me with her sweetest smile, said, "Do you wish me to take anything off?" I, of course, hastened to explain that I couldn't think of such a thing, and that it was the baby's dress which was too much, and, after she had remarked with great asperity that this was what she meant, we began to pull off some of the darling's swaddlings.

It was an astonishing business. Under the great coat there was a woollen waistcoat with sleeves, under that a white nightgown with an embroidered front, under that a belt of buckram with armholes, under that a small shirt, and then flannel, and then—but life's too short to go right through with that child's garments. I know it was all so extraordinary to me that I began to fear the poor little soul was constructed on the principle of the Japanese puzzle, boxes that lie packed one within another, and dwindle down from a tea chest to an infinitesimal cube. So I again ventured to put in my spoke, and suggested that we had done enough for one day, and might stop at the flannel; but Mrs. Crummey was now bent on rushing to the opposite extreme, and insisted on stripping her offspring of every rag, and flouring it all over like a leg of mutton.

It resisted these outrages stoutly, and uttered piercing cries during their progress, which the nurse obstinately ascribed to wind, even after I had pointed out that there was not a breath of air stirring. Mrs. C., on the other hand, maintained "the precious" thought it was "going out." "Going out!" said I, "why, you surely don't send it into the streets in this condition, do you?" "Oh, really!" said Mrs. Crummey, "you're past everything," and as that was the only answer I could get from her, I left the matter there. When the little victim was absolutely naked, I wanted to begin without further loss of time, but at this juncture both mistress and servant conceived the idea that baby ought to have one sock on and the other lying near it, and that the socks just discarded were unsuited to the purpose, and must give way to a pair which were the gift of grandma. A general hunt thereupon ensued of a somewhat protracted character.

And all this time the light was growing weaker. All things, however, come to him who waits, and at length baby was got into position in the middle of the dining-room table, and besought to look in the direction of the camera. But this it firmly, or rather obstinately, declined to do. I danced in front of it with keys, I laughed, I cried, I clucked, I crowed, I imitated animals, and played the fool with a vivacity that fairly took the nurse by storm. Yet her charge remained obdurate. It buried its face, it stood on its head, it rolled over and over, but look towards the lens it would not. Nay more, it discomfitted me in the middle of an energetic *pas de seul* (executed solely in its interest), by frothing at the mouth, plunging heavily forward, and calling out "madman!" in stentorian tones. The mother and the maid hailed this performance with enthusiasm, and declared the word was "grandma;" but I know better. It said "madman" beyond all question, and what is worse, it wasn't far out, as the sequel will show.

Well, to cut a melancholy story short, let me hurry on to say that, just when I was on the brink of despair, I hit upon the expedient of offering this unmanageable brat the india-rubber bulb and tubing which I use for exposing, and that the inspiration seemed a happy one at the outset.

The young hopeful stopped short in its gyrations, sat perfectly still, and then (under the impression that the articles tendered it formed part of a new and gigantic feeding bottle) broke into an angelic smile, stretched forth a fat, unsteady hand, and muttered "ta." The two women were in ecstacies over this display of intelligence, and we all three stood round while the little demon made slobbery but determined efforts to extract nutriment from the unpromising materials I had given it.

I declare, I had so little suspicion of evil, that if anyone had asked me at that precise moment whether I liked babies, I should have told a lie and said "Yes." And then in the twinkling of an eye the scene changed, for the malignant little beggar, without an instant's warning, gave a yell of savage delight, took a firm grip of the tubing, and, by throwing itself backward with fiendish recklessness, caused my brand new "Acme" to fall over on the fender with a crash that——Well, I'll take two half crowns for the lot, and allow a discount of threepence in the shilling for cash. Mrs. Crummey has been good enough to say I may have another try, but I think not. I think I'll wait till I get a baby of my own, and when I do that you may shoot me.

## VOLATILE PLATINUM COMPOUNDS.*

BY W. PULLINGER, BRACKENBURY SCHOLAR OF BALLIOL COLLEGE, OXFORD.

*Vapour Density Experiments.*—These were at first conducted in a Victor Meyer's tube, in an atmosphere of carbon monoxide. The bottom of the bulb was lined with asbestos. A small block of the compact substance (experiments were made with both substances) was dropped directly from the stopper on to the asbestos.

Experiments were made at various temperatures varying between 200° and 400°. There was, however, no agreement between any of the results. In some cases decomposition was evident, in others the substance was not completely volatilised. Some experiments were made without asbestos, but in no single case, even at a very high temperature, and after the lapse of a considerable time, was volatilisation complete. A final attempt was made with a modified form of apparatus devised by Professor Lothar Meyer. The bulb of the apparatus is constricted in the middle. A small piece of platinum gauze rests on the constricted part; the substance is dropped directly on to the gauze. The vapour formed falls at once into the lower part of the tube, leaving the atmosphere surrounding the solid unsaturated. In this manner the whole of the substance was volatilised; but, on examining the tube, it was found that, even at a temperature of 250°, the vapour of the substance in the bottom part of the tube was decomposed in contact with the glass. The colour of the vapour is a dull red. It seemed evident that the vapour density of the compounds could not be determined when glass vessels were used. Possibly the form of apparatus described above may be useful in determining the vapour densities of other solids with heavy vapours.

It was supposed possible that the corresponding bromine derivatives might be more volatile. An attempt was therefore made to obtain them.

*Preparation of Platinum Dibromide.*—Schützenberger obtained platinum dichloride by passing chlorine over heated platinum sponge. An attempt to obtain the dibromide in the same way failed. V. Meyer and Züblin obtained the tetrabromide by heating platinum sponge with bromine and hydrobromic acid in a sealed tube at 180°, evaporating to dryness, and heating to 180°. It is not necessary, however, to make use of sealed tubes. If platinum sponge be simply boiled for a short time with an excess of bromine and hydrobromic acid, in a flask connected with a reflux condenser, the whole is dissolved. If the solution is then evaporated to dryness and the residue heated, bromine and hydrogen bromide are evolved. According to Topsoë, this takes place slowly at 100°, but more quickly at 200°, leaving a bright brown powder which, when washed to free it from undecomposed tetrabromide, gives a brownish-green residue of the dibromide. It is, however, very doubtful whether any dibromide is formed at the lower temperature. The residue, obtained as above, was heated in an air-bath. Some dibromide was formed at 180°. This, when thoroughly washed from the tetrabromide, had not a brownish-green colour, but was coal-black. After heating another portion at 255° for five hours, some undecomposed tetrabromide still remained, but this time the colour of the dibromide was a dark, clear brown. It would seem, therefore, that the colour of the product is conditioned by the temperature of its formation. A third portion was heated at 310° for four hours in a current of air. Even at this temperature a residue of tetrabromide was left. The most convenient temperature for the preparation of the dibromide was found to be about 280°.

It may be here mentioned that spongy platinum is also dissolved by a hot solution of iodine in hydriodic acid, yielding a dark red liquid. From this the tetraiodide can be easily obtained by evaporating it to dryness, heating the residue to 180° in an air-bath, and washing away the soluble part. The iodide thus obtained is a compound of singular stability, seeing that it can be heated with sodium carbonate to the fusing point of that salt without losing all its iodine. A rough determination of the platinum in the iodide was made by reduction with magnesium and acetic acid; this gave a percentage of 28·2 of platinum, against the theoretical 27·7.

*Action of Carbon Monoxide on Platinum Dibromide.*—The dibromide was contained in a small boat which was placed in a combustion tube. The end of the tube was bent into a U-shape, so as to serve as a receiver for the volatile compound. The straight part of the tube was placed in a combustion furnace, which was gradually heated; in the meantime, a slow current of dry carbon monoxide was passed over the dibromide. At the cool end of the tube a sublimate was formed, consisting of yellow and white crystals, and a brick-red powder. At about 180° the contents of the boat melted, giving a dark red liquid which was volatilised with difficulty; so great was the difficulty of completely volatilising this liquid, that it seemed impracticable to determine its vapour density. The sublimed substance was now melted by immersing the U-tube in a heated paraffin bath. A current of carbon monoxide was passed over the melted substance for more than an hour, in order that a maximum amount might be absorbed. From the analogy to the chlorine compounds, it was supposed that a compound $PtBr_2,2CO$ would be formed. Such, however, was not the case. On cooling, the substance solidified to a mass of bright red needles. The platinum and bromine in this compound were estimated by heating a weighed quantity in a platinum crucible with a very large excess of carbonate of soda. That none of the substance was volatilised was evident from examination of the crucible after ignition. The resulting platinum was washed and weighed, and the bromine in the washings was estimated in the usual way. In this and in many other analyses the carbonate of soda was tinged a darkish blue. This may have been due to the formation of a sub-bromide of sodium, corresponding to the subchloride of potassium described by Bunsen (*Ann. Phys. Chem.*, 1861, 113, 445).

The following results were obtained :—

| | | | |
|---|---|---|---|
| Percentage of platinum, | 50·44 | 50·33 ; | mean, 50·38 |
| ,, bromine, | 41·504 | 1·03 ; | ,, 41·26 |
| ,, CO, | 8·06 | 8·67 ; | ,, 8·36 |

This approximates closely enough to the constitution of a compound having the formula $PtBr_2,CO$, which has the following percentage composition: platinum, 50·90; bromine, 41·79; CO, 7·31. It would appear, therefore, that this compound, which may be called "carbonyl-

* Concluded from page 659.

bromoplatinite," does not absorb carbon monoxide at its melting point.

*Properties of Carbonylbromoplatinite.*—The melting points of two different specimens were taken with a delicate thermometer, with the following results: (1) 177·5°, (2) 177·5°, (3) 178°, (4) 178°. Mean result, 177·7°. It is bright red, and crystallises in well-defined needles. It is much less sensitive to the action of moisture than the corresponding chlorine compound; indeed, it may be exposed to the air for a considerable time without darkening in colour. When treated with water, it first dissolves, giving a red solution, which, however, almost instantly blackens. The black product is soluble in hydrobromic acid. Absolute alcohol dissolves the substance without blackening, giving a dark brown solution. When melted in a stream of carbon dioxide, it loses carbon monoxide, and appears to be converted into the dibromide of platinum.

In conclusion, I must express my very sincere thanks to Professor Lothar Meyer for the great assistance which he has given me. It was he who suggested the work, and he who, during its progress, aided me with very many suggestions and much personal help.—*Journal of the Chemical Society.*

## AMERICAN OPINION CONCERNING THE RECENT CONVENTION MEETING AT BATH.

We have seen, says the (Chicago) *Eye*, a copy of the group taken of the members of the last convention of British photographers, which was published in the last number of *Photography*. They all appear to be a most intelligent class of men, and are representative men of the profession, but there certainly was not a very large attendance. British city officials attach more importance to a meeting of photographers than city officials in this country do, as at Bath, England, a formal reception took place under the auspices of the Mayor of Bath. The Mayor, in welcoming the Convention, made quite a long address, which is in striking contrast to the concentrated address by the Mayor of Boston two years ago to the P. A. of A.

The Mayor of the Hub bowed his congratulations without saying a single word, and left. The Mayor of Bath said he was old enough to remember the introduction of photography. He could call to mind the first dawning of their beautiful science. He could look back upon the wonder and pleasure which spread from town to town and from country to country when its beneficent power gradually became known. He had observed through half a century its wonderful progress all over the world, increasing incalculably human enjoyment, intellectual expansion, solid, practical, substantial good; therefore he could not fail to welcome most cordially those who were associated for its promotion.

Chemical Effects of Light—Measurement of Physical Absorption.—The experiments were made with a solution of ferric chloride and oxalic acid, the quantity of ferrous salt formed being estimated. One cell containing this solution was exposed directly to light, whilst a similar cell was exposed behind the medium the absorption of which was under investigation. In the case of ferric chloride, the absorption varies somewhat with the state of the atmosphere, but under favourable conditions the variations are not great, and the results may be represented by the following expression, which is calculated for semi-normal ferric chloride, $i$ being the intensity of the transmitted light, and $l$ the thickness of the absorbing layer: $i = 0{\cdot}01\ (0986)^l + 0{\cdot}07\ (0{\cdot}40)^l + 0{\cdot}13\ (0{\cdot}10)^l + 0{\cdot}79\ (10^{-10})^l$. — *Journal of the Chemical Society.*

## PHOTOGRAPHIC CHEMISTRY.*

BY PROFESSOR R. MELDOLA, F.R.S.

The photo-chemical studies which have been dwelt upon lead up to the consideration of the silver compounds, which must, of course, receive special treatment on account of their present importance in photographic processes. At the outset, it is desirable to point out that our knowledge respecting the action of light on the silver compounds is in a different position to that concerning the simpler cases of photo-chemical decomposition which have hitherto been discussed. In the latter the chemical change is definite enough to be represented by ordinary equations, the composition of the final product being in most instances known. In the case of the silver salts, we possess no such accurate knowledge, and the nature of the products is still surrounded by mystery.

When light falls on the silver haloids chemical decomposition takes place, accompanied by a change in colour. In order that this statement may be properly realised, let it be shown that there really is decomposition, and that the chloride and bromide under these circumstances give off a gas which blues starch and potassium iodide paper. The iodide does not undergo decomposition on exposure except in the presence of an iodine absorbent, *i.e.*, a sensitiser. Passing on to the action of light on films of the haloids, it is possible, by means of a few simple experiments, to demonstrate many important properties of these compounds with which the student should be familiar. For this purpose sheets of paper, well coated with the pure haloids free from excess of silver nitrate, and a few ordinary reagents, are the only requisites. By one operation it can be shown that, with the same exposure, the chloride becomes darker than the bromide and the latter darker than the iodide, and at the same time that reducing agents and halogen absorbents accelerate, while oxidising agents retard, the decomposition. Thus, three strips coated respectively with the three haloids may be painted with stripes of solutions of (1) sodium nitrate, (2) sodium sulphite, (3) silver nitrate, (4) mercuric nitrate, (5) potassium dichromate. After exposing these strips simultaneously to the action of light, the stripes 1 and 2 will be darker than the ground-colour, showing the accelerating action of the reducing agents; 3 will also be darker than the ground-colour, showing that a halogen absorbent may also act as an accelerator without necessarily being a reducing agent; while 4 and 5 will retain the original colour of the haloid, showing the retarding action of oxidising agents. A comparison of the ground-colour in the three strips will also serve to show the different colours of the products of photo-chemical decomposition.

Such demonstrations as these cannot fail to impress the mind that the action of light on the silver haloids is a distinct case of photo-chemical decomposition, but it is necessary at this stage to issue a caution. The action is in these cases continued up to the point of visible darkening, whereas in the photographic film the exposure is so short that no directly visible effect is produced. It must be enforced, therefore, that in associating the photographic image with these darkened products, we are drawing largely upon arguments from analogy. The point that will now present itself is the actual composition of the darkened products, and here it may at once be pointed out to the student that our knowledge respecting these compounds is in precisely the same state as that concerning the coloured haloids dealt with. In the case of the darkened chloride, it has been proved that this product contains a little less chlorine than the normal chloride. In all three haloids, no matter how long the exposure may be, the final product always contains an enormous excess of unaltered haloid. It may safely be asserted that these products are not chemical compounds in the ordinary acceptation of the term, since they are not composed of the haloid combined with the coloured product of photo-chemical decomposition in definite molecular proportions. Neither can the "photo-salts" be classed with the definite "molecular compounds" of modern chemistry, since the latter also consist of substances combined in definite molecular proportions, and can be more or less readily resolved

* Continued from page 662.

into their constituent molecules by appropriate treatment. But the "photo-salt" cannot be resolved by any such treatment, since all solvents which dissolve the normal haloid appear to decompose the darkened product, leaving only a trace of metallic silver. On the other hand, metallic silver cannot be extracted from the "photo-salt" by any of the ordinary methods.

In answer to the question which the inquiring student would naturally put, "what is the photo-salt?" it can only be said that these products must be regarded as indefinite molecular compounds of the silver haloids with coloured unstable products of photo-chemical decomposition, the composition of the latter being as yet unknown. That the coloured products are unstable appears from the fact that they cannot exist apart from an excess of the normal haloid. In the same way that a solvent will take up a solid till the point of saturation is reached, so the silver haloid, on exposure to light, becomes decomposed up to a certain point—*i.e.*, the point when the haloid is saturated with the coloured product of photo-decomposition. Beyond this point the action of light produces no further effect unless a reducing agent is present capable of combining with the liberated halogen as fast as the latter is liberated. It is advisable to let the student observe for himself that silver iodide prepared with excess of potassium iodide undergoes no change of colour on exposure to light, but that in the presence of silver nitrate or reducing agents, darkening occurs. Let him observe also that the darkened chloride yields no appreciable quantity of silver to dilute nitric acid, but that in the presence of a strong reducing agent, even when the latter is gaseous, such as hydrogen, the reduction may proceed up to the complete liberation of the metallic silver. This last point can be demonstrated very conveniently by placing some finely-divided silver chloride (prepared by precipitation) into a glass tube through which a current of moist hydrogen is kept passing, the gas being made to bubble through a solution of silver nitrate containing free nitric acid. On exposing the contents of the tube for some time to strong light, silver chloride is precipitated from the solution of the nitrate, the chloride in the tube (which should be shaken from time to time in order to expose fresh portions) gradually becoming dark coloured. An equal quantity of the chloride may be exposed in air at the same time for comparison. The two lots of darkened chloride are then treated with equal quantities of dilute nitric acid, the clear solution filtered off, and the filtrates tested for silver. If the experiment has been properly conducted, the solution from the chloride darkened in hydrogen will be found to contain distinct traces, while that from the chloride darkened in air will be free from silver.

Having arrived at the conclusion that the silver haloids, when exposed to light under suitable conditions, lose a small quantity of their halogen, and become converted into coloured compounds, the course of instruction will here naturally diverge along two lines :—

(1) The nature of the coloured product combined with the excess of unaltered haloid ; and—

(2) The part played by the associated substance or sensitiser.

With regard to the first, it must be pointed out that, although we have no positive information of a conclusive character, many views have been advanced which are more or less worthy of consideration ; and an excellent exercise in the use of scientific judgment might be given to the advanced student by submitting the current notions respecting the composition of these products, and requesting him to prepare a critical essay embodying his own views.

## Specifications Published.

5,860. *April 17th*, 1890.—"Detective Cameras and Change-Boxes." H. Ransom, 122, Newington Butts, London.

The sensitised plates are placed in clip sheaths or backings, which are hinged to a cylinder within the camera. By rotating the cylinder from the outside, the plates are brought in succession to the focus, being there held between flexible guards and a stop. The cylinder is also arrested at this stage by a spring pawl, which engages a ratchet on the cylinder. The pawl is disengaged by a rod. The indicator numbers on the end of the cylinder are observed in succession through an aperture in the camera. In a modification a segment of a cylinder replaces the cylinder. A disc shutter actuated by band gearing is described.

6,028. *April 21st*, 1890.—"Lenses." P. Rudolph, Jena, Saxe-Weimar, Germany.

The principal object in these lenses is to remove the indistinctness of the marginal portions of the field. They consist mainly of dissymmetrical combinations of lenses, composed of two distinct systems of lenses cemented together. In one of the two distinct systems the positive number (the collecting lens) has a smaller, in the other system a greater, refractive index than the negative number (the dispersing lens) cemented thereto, and each system is in itself approximately achromatic. In one form of the lens the front combination is composed of a dispersing lens and a collecting lens, while the back combination is made up of a collecting lens and a dispersing lens. Tables giving the radii of curvature of the different lenses, and the refractive indices and relative dispersive power of the different kinds of glass to be used, are given in the specification. In another form of the lens the back combination consists of three lenses cemented together.

6,029. *April 21st*, 1890. — "Lenses." E. Abbe and P. Rudolph, Jena, Saxe-Weimar, Germany.

The combination consists of two single collecting lenses and a compound system consisting of three lenses cemented together, for correcting the spherical and chromatic aberration of the lens without perceptibly altering its focal length. Tables are given showing the radii of curvature of the lenses, and the refractive indices, and dispersive power of the glass to be used in particular cases.

Photographic Club.—Subject for Sept. 30th, "Mounting and Framing"; Oct. 7th, "The Influence of Development on the Colour of the Deposit." Last outing of the season, Saturday, October 3rd, Hampstead ; tea at "Bull and Bush" at 6.

## Proceedings of Societies.

Midland Camera Club.

A provisional committee meeting was held on Friday night last; Dr. Hall Edwards occupied the chair. It was reported that the club rooms were being arranged for, as also the furniture and fittings. The draft rules were discussed and adopted. Mr. J. Trout and Rev. J. Henry were added to the provisional committee. A prospectus stating the objects aud advantages of the club is to be drawn up and circulated throughout the district. The objects of the club, according to the adopted rules, are: "The advancemeut of photography in all its branches, and the promotion of social intercourse amongst all photographers. First, by the holding of periodical meetings for lectures, papers, discussions, and practical demonstrations; and by friendly competitions upon photographic subjects. Second, by the provision of convenient club rooms, with dark room, &c., for the use of members. Third, by the promotiou of intercourse between this aud other societies." The membership is to be quite open to both amateurs and professionals, ladies as well as gentlemen. The subscription has been fixed at 10s. per annum, youths uuder eighteen, who would benefit by the "beginners' section," 5s. per annum. General meetings are to be held on the first and third Fridays in each month, and the sectioual meetiugs as arrauged by each section, and where they choose. The first general meeting will be held on the third Friday in October (16th), at which the officers and committee for the ensuing year will be elected. Applications for membership and other details to be obtained from the prov. hon. sec., 47, Hagley Road, Birmingham.

Leeds Photographic Society.

On Monday evening last, Mr. G. H. Rodwell gave the sixth of the series of elementary lectures, his subject being "Lantern Slide and Transparency Making." Mr. Rodwell said that for lantern slide work the wet-collodion process was by many considered the finest; for fiueness of deposit and transparency in the deepest shadows it was hard to beat, but this could only be said when in the hands of experienced workers. With the average amateur, the extraordinary care necessary rendered it a difficult process to work. The gelatino-bromide process was much more suitable, and, with ordinary care, fine results could be obtained. Mr. Rodwell advocated a slow plate on which to make transparencies; as a rule, the slower the plate, the warmer would be the tone of the resulting slide. Having explained the method of printing by contact, and also by reduction in the camera, Mr. Rodwell dealt with the various methods of development, and explained his method of obtaiuing warm tones. For this purpose pyrogallic acid development was the best, aud the following was his formula:—

| | |
|---|---|
| Liquor ammonia (fort.) ... ... ... | 1 drachm |
| Ammonium bromide ... ... ... | 1 ,, |
| Water ... ... ... ... ... | 20 ounces |

For developing, add one graiu of dry pyrogallic acid to one ounce of the above just before using. He did not advise any alteration in the developer, but rather alter the exposure to suit the developer. Should the slide not be of the required tone or density, it was almost useless to try and alter it, and it was far better to make another slide. Intensification was also unsatisfactory. It was, however, possible to reduce an over-dense slide by means of Howard Farmer's ferricyanide formula, and this was specially useful in clearing skies by local reduction, using a camel-hair brush to wash the reducer over the sky. At the conclusion of his remarks, Mr. Rodwell exhibited a number of fine slides.

To Engrave on Glass.—The *Sprechsaal* recommends the following receipt for engraving inscriptions on glass bottles, &c.:—Dissolve in about ½ a litre of water 36 grammes of fluoride of sodium with 7 grammes of sulphate of potash; in another vessel, mix 14 grammes of chloride of zinc and 65 grammes of hydrochloric acid in ½ a litre of water. Mix the two solutions, and apply with a pen or brush; at the end of half-an-hour the inscription appears.

## Answers to Correspondents.

**All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.**

**All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.**

**Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C S., 2, St. Mary's Road, Canonbury, N.**

H. K. (Brighton.)—*Pink Silver Print.* We are at a loss to account for the strongly pronounced colour of your print. Is it the only one of the batch which exhibits this defect; or was red blotting-paper used in this instance to soak up the moisture? Your letter is hardly specific enough, only that the process therein detailed ought *not* to give this result. The fumes of aniline will, we know, quickly redden some kinds of paper by determining the formation of rosaniline; or it may happen that some of the dye washed out of the rose-tinted albumenised paper and became concentrated in the last bath.

Painter.—*Instruction in Colouring.* You cau get your portraits enlarged directly upon canvas by the Autotype Company, and then work upon them in oils according to your usual practice. Mr. A. H. Bool's little book on "Photographic Painting" may give you a few hints, but your art training ought to be relied upon as worth more than all the advice we can give.

C. R. and Co.—*Patents.* We find it impossible to complete our search and quote the numbers this week, but will do so as soon as possible, and let you know by letter.

Films.—*Reduction of Over-Developed Negatives.* By the cautious use of very weak cyanide it might be possible to reduce those that appear to be too dense. Try this, at any rate, before resorting to chloride of lime or iodine tinctures, which have to be followed up with a fresh fixing treatmeut. Red prussiate is often found useful for the same purpose. See formulæ at the end of the Year-Book.

Aberdeen.—*Platinotype Details.* You will find all the information given in Mr. Willis's successive communications to the Photographic Society, also iu Captain Abney's "Instruction in Photography" (Londou: Piper and Carter). You may even consult with advantage "Fallowfield's Annual," where a very good general account of the hot and cold processes is to be found. Give the *former* method a fair trial in the first instance.

L. E. D.—*Obernetter Prints.* Never attempt to dry them by suspension on a clip, for they are almost sure to turn inwards and stick together hopelessly. Either squeegee them down on plates of glass rubbed with a little French chalk spread on a wash-leather pad, or upon similarly-prepared squares of celluloid, in which latter case the prints will not have quite so lustrous a surface. If a rougher grain is desired, use ground glass lightly coated with vaseline.

M. T. (Plymouth).—*Brackish Water.* Short of distillation, there is no method of purifying water containing much sea-salt. The best plan would be to wash your prints and negatives first with the brackish water until all the hypo is removed, and then finish off with distilled or filtered rain water.

W. H. B.—*Pall Mall Lantern Exhibitions.* The pink tickets will admit either in the morning or evening, with Thursday in addition to the programme of last year. The white tickets are ouly available in the daytime, that is, between the hours of 10 a.m. and 5 p.m., from Sept. 28th to Nov. 12th.

Cambs.—*Focussing Hood.* It is a good plan to make the black cloth fit loosely upou the camera, with aperture to slip over the lens. The slide should be manipulated, and carrier opened, whilst protected by the black bag, which should then be twisted round and stowed away beneath the tripod head of the camera stand. Always avoid leaving anything loose at the moment of exposure to flap about in the wind. A short leather strap is a useful addendum to the outfit.

## REVERSED NEGATIVES.

Nearly all the photo-mechanical processes at present in use require that the negatives from which the plates or blocks are produced shall be reversed. Take the case of the most simple of all these processes, the well-known method of producing blocks from line drawings which is employed for the illustration of so many periodicals. The original drawing is reproduced line for line just as it came from the artist's pen, and the first operation in the reproductive process is to obtain from it a reversed negative. This is almost universally done by fitting the hood of the lens employed with a mirror, so that during the process of copying the original drawing faces the side of the camera. Such a method of procedure, associated with an electric arc lamp, is perhaps the most convenient and perfect manner of obtaining a reversed negative. But it entails the use of extensive plant, which only those who devote themselves to this class of work can command. The every-day photographer cannot hope to compete with such workers, but he may be often so placed that a reversed negative is required quickly, and he has to depend upon his own resources to produce it. What is the best way of setting about the work?

The simplest method of all is undoubtedly the use of a celluloid film for the original negative, for both sides of it can be printed from, one side obviously giving a reversed image. But films are not in common use for studio work, nor are they likely to be used by professional hands, for their chief advantages, lightness and reduction of bulk, disappear when the operator is at home in his own quarters. Certainly, there is the further advantage of freedom from breakage to be considered, but this almost disappears in studio work, for the hand becomes so accustomed to deal with the fragile glass that a plate is as seldom broken as an egg is by the mother hen. Besides, films are much more costly than glass, and require greater care in development, and these facts, added to the other difficulties which we have enumerated, make the professional photographer still dependent upon glass plates for his every-day work.

Many a satisfactory reversed negative has been made by the simple expedient of putting the dry plate in the dark slide with its sensitive surface turned away from the lens, and this is the plan which we should recommend when only an occasional negative of this kind is required. But to attain the best results several little precautions are necessary, and non-observance of one of them may utterly ruin an otherwise perfect picture. To begin with, the plate must be carefully cleaned on the glass side, so as to get rid of those patches of stray emulsion which seem to be so dear to the average plate-maker, and which form an admirable example of "matter in the wrong place." This is a risky thing to do in the limited light of the dark room, but perhaps the best means to employ for the removal of the obnoxious gelatine is a damp sponge which is just dipped in fine pumice powder. It is best only because it is quick, and the quicker such an operation is, the better. Next, the thickness of the glass must be measured with a pair of callipers or compasses, another plan being to take a hasty impression of the edge of the plate with a piece of wax or tinfoil. The object of this measurement is to gauge the exact distance which the plate must be moved from the lens after the image is focussed, for, unless the thickness of the glass be thus allowed for, the picture must of necessity be blurred. One more little matter has to be attended to. The spring at the back of the dark slide must be prevented from scratching or pressing unduly upon the sensitive film, and perhaps the best way to prevent this is to back up the plate with a velvet-covered card. The exposure need not be more than the normal, for the thickness of glass through which the light has to travel before it reaches the film does not make any appreciable difference.

So far, provided that the matters to which we have called attention are seen to, all is plain sailing, and success is within reach. It is the development which will try the operator's skill. Not that any particular precautions are necessary here, but because the appearance of the plate during development is different to that to which he is accustomed. Let us remember that the alteration caused by the access of light to the film has affected the side next the glass, and not the side which lies upwards in the developing dish; so that the chemicals have to permeate a layer of gelatine which has hardly been affected at all by the exposure before they can get at the altered silver, and make the image visible. There is thus unusual delay in the image "coming up," and when development is actually far advanced, the operator is apt to think that it has hardly begun, for he sees it through a semi-opaque film of unaltered gelatine. He must therefore be careful to hold the plate often up to the red light, for it is only in this way that he can judge of the growing density of the deposit. Perhaps it would be well to develop all such plates in a dish with a glass bottom, through which progress can be easily seen without removal of the plate.

If the photographer is accustomed to transparency-making, he may prefer, to the method which we have recommended, the plan of making a positive on glass from the original negative, and copying that positive, with its film turned away from the camera, in order to get the reversal. This plan entails far more trouble than the other, and the negative ultimately produced is generally not nearly so good; for, as everyone knows, in this tiresome process of getting positive from negative and negative from positive again, there is always a loss of pluck and a flattening of the image which is most destructive of its beauty. One can hardly say how and what it has lost; but there is a distinct deterioration all the same, and of course the fault is not remedied in the ultimate photo-mechanical print for which the reversed negative was undertaken.

We have not said anything about stripping films from the glass, for in the case of dry plates this is generally a risky proceeding. If anyone wishes to try that method, let him by all means experiment with some spoiled plates of the same make before he plays any tricks with a valued negative. Many excellent methods of doing this work have been published, and we need here only refer to that fact. The best results from stripping are gained from employing the wet collodion process, for the film in this case is so tough, and free from any tendency to contract or expand, that it can be floated off one glass and attached to another without much difficulty, provided that the operator has a steady hand and clever fingers. Of course such a film ought to be coated with india-rubber solution and plain collodion before it is removed; but the manipulations are all described in the text-books, and need not be repeated here. It is doubtful, too, whether any dry plate worker will care to plunge into the many difficulties which must assail a tyro with the silver bath.

Richmond Camera Club.—On the 25th ult. the subject discussed was the eikonogen and hydrokinone developer. All present who had used the combined developer testified to its merits in case of snap-shots and under-exposed plates.

## SPHERICAL ABERRATION AND THE FOCAL PLANE.

BY W. E. DEBENHAM.

In an article on "Spherical Aberration" in your issue of the 18th ult., Mr. T. R. Dallmeyer speaks of the "absurdity" of placing the focus midway in the locus of aberration, as done by Mr. W. K. Burton. He further gives, as a positive statement, his own view that the apex of the axial cone "is the position of greatest concentration theoretically and practically, and is the best focus, unmistakable to the practised eye." It will, I think, not be difficult to prove, even to those who have not made a special study of photographic optics, that Mr. Burton is right beyond question in taking the position of best focus, as was done by the late Mr. Thos. Grubb, somewhere between that of the axial and the marginal rays; and therefore, that if there is any "absurdity" in putting forward a mistaken view on the subject, Mr. Dallmeyer must be content to accept the position in which he would place his adversary.

If, as Mr. Dallmeyer says, the best focus is at the apex of the axial cone, then, as that position is fixed, and does not vary, however large may be the opening used, the change of diaphragm from large to small or *vice versa* would not, in the case of a lens having spherical aberration, affect the position of the focus any more than it does with a perfectly corrected aplanatic lens. Those who have worked with lenses having marked spherical aberration know very well that the insertion of a diaphragm *does* alter the position of the focal plane, focus being lengthened and brought more nearly to the place of focus of the axial ray in proportion as a smaller diaphragm is used, whilst with a larger aperture, or one sufficient to show more decidedly the existence of the spherical aberration, the focus becomes shorter; being, in short, a position, as stated by Mr. Burton, which is intermediate between the foci of the marginal and central rays.

The fact of the shifting of the focal plane by the insertion of a diaphragm in a lens having spherical aberration, is one so well known to photographers who practised when lenses of that character were more in use than at the present time, that it seems strange that Mr. Dallmeyer should make a statement involving the negation of that fact. The American optician, Zentmayer, in the "sixties," constructed a lens the use of which depended upon the existence of this change of the position of the focus. The lens was made of one kind of glass only, and was not achromatised, in spite of which facts it was issued as working true to focus. This was accomplished by directing the operator to focus with the large aperture, and then, before exposure, to insert a small diaphragm of a definite relation of aperture. By this means the focus of the lens was lengthened just as much as was required to correct the chromatic aberration. If the focus had been as Mr. Dallmeyer's proposition requires, always at the apex of the axial cone, the insertion of the stop would have made no difference to its position, and the lens would not have worked to focus.

The reference to the practice of astronomers with regard to spherical aberration is quite beside the question. It has been already pointed out that, with an intensely luminous point, such as a star against a dark ground, there may remain light enough to form a visible image when the marginal rays are dispersed and only a small portion of the objective at the centre is actually forming the attenuated image, whilst with subjects such as photographers have to deal with the case is quite different.

Mr. Dallmeyer refers to his paper read at the Camera Club Conference last year, and the illustrations accompanying it. I have already pointed out—the second time at the last Camera Club Conference*—that figures in those illustrations said to be taken with the lens removed certain distances from the best focus, are actually in better focus than those stated to be taken at the best focus. One might think that Mr. Dallmeyer would do well to accept Mr. Burton's suggestion—that with much spherical aberration personal equation has an opportuuity for steppiug in, and that ouc may suppose the focus to be almost anywhere desired—instead of rejecting and denouncing his suggestion as want of practice.

With regard to the question as to whether there is any gain in definition in the out-of-focus planes by introducing spherical aberration, as claimed by Mr. J. H. Dallmeyer, it may be observed that he never attempted to refute Mr. T. Grubb's demonstration to the contrary, which, one may reasonably suppose, would have been done if it had been possible, either theoretically or practically. Mr. T. R. Dallmeyer has reduced the claim to one scarcely worth discussion wheu he said that the definition became better on one side of the best focus, but worse on the other. If the claim for improvement, at any part, depends upon such statements and illustrations as have been dealt with, it may as well follow the original claim for better definition in the out-of-focus planes.

* Photographic News, page 281.

## METHOD OF REDUCING THE INTENSITY OF NEGATIVES.

BY P. C. DUCHOCHOIS.

The *clichés* may be too intense, either from yellow fog, over-development, or local opacities. We have nothing to say on the means employed to remove yellow fog; they do not alter the character of the picture, nor on those which attenuate the contrasts or local opacities, which, if done by re-development, answer pretty well; but we think that the reduction of *clichés*, generally too inteuse, is effected by chemical actions which are often objectionable. Among the processes employed for the purpose in question, the old one, that which we first employed, both iu the calotype and the collodion process, consists in treating the *cliché* with a solution of potassium cyanide. It is the best, on account of its simplicity, and of not requiring much after-washing. The drawback in the gelatine process is that the solution of the commercial article, KCy, has, on account of its strong alkalinity, a tendency to produce blisters and frilling by softening the film. This can, however, be easily prevented by using pure potassium cyanide in solution in alcoholised water. The next process in order of publication is that devised by Alexis Gaudin. The reduction is effected by ferric sulphate (Monsel's salt). This process requires to eliminate the iron salt by first washing the gelatine film in a diluted solution of hydrochloric, citric, or oxalic acid, &c. It is little employed. Then come Spiller's process, which consists in treating the *cliché* by a solution of cupric bromide and common salt; that of Farmer, who uses potassium ferricyanide in solution with sodium thiosulphate; and lastly, Monckhoven's process, by which the reduction is effected in attacking the silver with ferric oxalate, the silver salt formed being dissolved by sodium thiosulphate, as in Farmer's process. The latter processes—those of Farmer and Monckhoven—require prolonged after-washings to eliminate the thiosulphate. For this reasou, the process of Mr. Johu Spiller is preferable, as the solvent of the cuprous and silver bromides is simply common salt, an entirely harmless compound, should any traces of it be left in the film.

As it is seen, in all these processes *the intensity is reduced by dissolving the metallic silver forming the image.* If employed for the reduction of *clichés* generally too intense from over-development, the relative value of the local intensities may be little altered, provided the operatiou be couducted with great care; otherwise—and, indeed, this is of frequent occurrence—it happens that the penumbras and the details in the shadows, being formed by thin layers of metallic silver, are dissolved, and, as a consequence, that the *cliché*, if not spoiled past remedy, has lost that admirable gradation from lights to shades, that delicacy of details, which makes a photograph such a beautifully realistic image of nature.

A rational process would be to reduce the intensity, uot by dissolving the silver, but by transforming the colour of the image into one more actinic, or rendering the *cliché* more transparent, so that not only the desired de-intensification would result, but, if the intensity were too much reduced, it would always be possible to streugthen it.

For example, the *cliché* previously soaked iu water is immersed in a very diluted solution of nitro-bromhydric acid or of nitro-chlorhydric acid (aqua regia). In the solution the image, viewed by transparency, seems to intensify on account of the formatiou of the silver bromide (or chloride), but when exposed to sunshine for a certain period, it becomes more trauspareut from the reduction of the silver haloid, and turns to a bluish or violet-black, that is, a more actinic colour than the original oue. The operation should be conducted by diffused light, and the *cliché* allowed to dry before exposure to the luminous action, for, if dried in the light, the silver reduction would be of unequal intensity, the parts drying first being the lightest. In fact, when exposed under water, or better, in presence of an absorbent of chlorine or bromine, the reduction is more complete and darker, which is generally advantageous. Of course, the de-intensification is proportiouate to the more or less complete trausformation of the metallic silver (the image) into silver haloid; and it is in this where resides the difficulty of the process; it requires some experieuce to succeed. There is, however, little danger of spoiling the *cliché*, for should it be too much weakened from being bleached through, the remedy is at hand. It suffices, *after the insolation*, to redevelop with a very weak developer—pyrogallol, eikonogen, &c.—or to intensify with mercuric chloride, or by any other intensifying processes. No fixing is required after these operations; it is only necessary to well wash the *cliché*.

We have also experimented with iodohydric acid, and, iu lieu, with iodine, but the results were not generally as good. The silver iodide does not blackeu iu the light, and remains apparently uot acted on, and when treated by the developer gives rise to a great increase of intensity. This can be regulated during the redevelopment, and an after-treatment with a solvent of silver iodide, sodium thiosulphate, &c. The iodide process has given us satisfactory results for the intensification of very weak negatives. As said above, the redevelopment should be done after iusolation, and with diluted developers, in order to have the action well under control.—*Photo. Times.*

The appointment of "Opticians to the Royal Institution" has been conferred upon Messrs. Newton, of Fleet Street.

## ELECTRO-CHEMICAL REVERSALS WITH THIO-CARBAMIDES.*

BY COLONEL WATERHOUSE.

At the meeting of the society in August last, I exhibited some specimens of a curious reversal of the photographic image, produced by adding small quantities of thio-carbamides or sulpho-ureas to the ordinary eikonogen developer, and showed that, although reversal of the image was by no means uncommon, it was usually caused by over-exposure or some other abnormal action of light, whereas, to produce these new reversals, even less than the ordinary exposure was sufficient; and they appeared to be entirely due to some peculiar action of the thio-carbamide, added in very minute quantities to an alkaline eikonogen developer.

At that time I was quite unable to offer any opinion as to the probable cause of these reversals, or as to how they were produced, beyond stating the probability that, although there were many points of difference, they would be found to be in accordance with the generally-accepted theory worked out by Capt. Abney, and were due more or less to oxidation or re-halogenisation of the exposed parts of the film, and that, owing to the peculiar reducing action of the alkaline thio-carbamides, the film, during development, was practically in the same state as if it were over-exposed. It seemed also probable that sulphur was the active agent in producing the reversals.

Further work with these curious salts, and especially with a compound salt of thio-carbamide and ammonium bromide, discovered by Prof. J. E. Reynolds in 1868, and called by him tetrathiocarbamidammonium bromide, which was found to be exceedingly active in producing perfect reversals of the image with very short exposures, led me to the belief that this complete change of deposit from the lights to the shadows of the photographic image must be more or less due to electro-chemical action. The subject of electro-chemistry is one of which I have little knowledge, but I have been able to make some simple experiments, from which, though not conclusive, it seems probable that my surmise is correct, and, so far as they go, they seem to establish that not only, as former observations by Lermontoff, Eder, and Abney, had shown to be probable, is the ordinary process of photographic development of sensitive surfaces containing silver haloids accompanied by electrical action, but that the addition of these minute quantities of thio-carbamides to the developer greatly increases the intensity of the electrical action, and produces a reversal of the current, which should also account for the reversal of deposit.

With the aid of a very sensitive galvanometer, which has been kindly lent me by the Rev. Fr. Lafont, S. J., who also assisted me in the experiment, it was found that, when a pair of pure silver plates coated with finely precipitated silver bromide, one of which had been exposed to light and the other not, were connected to the galvanometer, so as to form a galvanic couple, and immersed in the ordinary eikonogen developer, the exposed plate formed the negative pole, and the needle was deflected to the left; whilst in the developer containing a little thio-sinamine, the exposed plate formed the positive pole, and the needle was deflected to the right.

This experiment has been successfully repeated several times with silver plates prepared in the same way, and with other thio-carbamides, also with silver plates bromised by dipping them in bromine water; and so far the occurrence of the reversal is well-established. I propose to repeat the experiment before you, though I cannot be certain of success. [The reversal was successfully shown with bromised plates, the image of the needle and scale being projected on the wall.]

I have also tried the same experiment with ordinary dry plates rendered conducive in various ways, the best of which appears to be gold leaf applied either on the face of the film or behind it. Gelatine offers very great resistance to the current, and, though I have obtained distinct evidence of currents in both directions, they are not always observable, nor is it yet quite certain that they are caused by electrolytic action within the gelatine film, and further investigation as to this is necessary.

I have also found that reversals of the reduction products, somewhat similar to those obtained by photographic methods, may be obtained entirely without the agency of light by passing a current from a single bichromate cell through a pair of silver plates coated with silver bromide, and immersed in eikonogen developers prepared with or without thio-carbamides. In this case the plate attached to the carbon pole in the plain developer showed only a very little black deposit, whilst the plate attached to the zinc pole showed a very strong, dark deposit all over. A pair of similar plates immersed in some of the same developer, to which a few drops of a solution of thio-sinamine had been added, showed quite different results, the plate attached to the carbon pole showing a strong black deposit, while the plate attached to the zinc pole was almost clear on the face and free from deposit, showing only a slight tarnish, caused by sulphur. I have some plates of this kind here, though the reversed effect is not quite so strong as it was on my first plates. I have found it difficult to obtain such marked reversals again, though I quite believe they are obtainable, and the best conditions or securing successful results have yet to be ascertained. Some similar effects were produced on Eastman's bromide paper, and on ordinary dry plate films attached to the silver plates.

Although results obtained with silver bromide on silver plates are not quite comparable with those obtained with ordinary gelatine plates, these experiments show that, under favourable circumstances, the action of developing solutions on silver bromide is accompanied by distinct electric action, and that these thio-carbamide reversals may be produced by electrical methods, and are attended by a reversal of current. How this reversal of current is brought about is not yet quite clear, but seems to be explained by some observations on metallic sulphides by W. Skey, recorded in vol. xxiii. of the *Chemical News*. He found that sulphides which have the power of conducting can also generate electricity, and that silver sulphide is positive to metallic silver. In a battery consisting of a sulphide and a metal in acidulated water, the gas liberated is sulphuretted hydrogen, the nascent hydrogen exerting a desulphurising action upon the metallic sulphide, the ultimate effect of which is, in some cases, to completely reduce the mineral to the metallic state. He shows also that these sulphides are capable of performing the functions of the negative element of a galvanic couple.

It seems probable, therefore, if electrolytic action does take place in gelatine films during the process of photographic development, that, according to the laws of electrolysis, with the ordinary developers the exposed parts of the plate form the negative pole, and attract the metallic elements and hydrogen, while the bromine, or

* Paper read before the Asiatic Society of Bengal.

other halogen and acid radicals, with the hydroxyl go to the unexposed parts, forming the positive pole.

On the other hand, with the alkaline thio-carbamide developers, at the same time that silver is reduced on the exposed parts, silver sulphide is formed on the unexposed parts, which then become the negative pole, and attract the sulphur, the hydrogen, and some of the silver from the exposed parts; while the halogen and hydroxyl pass to the positive pole, and transform part of the remaining silver into silver haloid, which is dissolved in the fixing bath.

Although this theory, as stated in a rough way, seems to agree fairly well with the facts, and, from the experiments I have made, seems probably the correct explanation of the reversals, I do not feel myself yet able to put it forward authoritatively, and a great deal of further investigation is required. The subject is a very difficult one, beset with uncertainties, and requires more time and close attention than I have been able to give for working it out fully.

The theory that photographic action is accompanied by electrical phenomena is no new one. Becquerel found that if silver plates, coated with silver bromide or other haloid silver salts, were electrically connected and immersed in dilute acid, and light was allowed to fall upon one plate while the other was screened, the effect of the light was marked by distinct electrical action capable of deflecting the needle of a galvanometer. Prof. Minchin has recently found that the same effect is produced on silver plates coated with silver haloids in emulsions of gelatine or collodion, and immersed in very dilute solutions of alkaline bromides, iodides, or chlorides. He has also found that if silver plates coated with a silver bromide emulsion in gelatine are attached to the poles of a battery, and half immersed in a weak solution of potassium bromide, the film attached to the carbon pole is visibly blackened on its immersed part, while no visible effect is produced on the other; but on developing this plate with pyrogallic acid and ammonia, its immersed part also becomes dark, exactly as if it had been exposed to light for a few seconds.

There is a good deal of other more or less direct evidence that an electrolytic action takes place during development, although, so far as I can ascertain, no observations of the currents with a galvanometer are recorded. Comparatively little attention has, however, been given to the question, and electrical or electrochemical action has never been looked upon as a principal factor in the production of the photographic image. From these new results it would appear that—at any rate, as regards the silver haloids—the formation and development of the photographic image is to a very great extent influenced by electrical action, if not actually caused by it. It has lately been found that electrochemical reactions have explained many obscure points in ordinary chemistry, and it seems likely, therefore, that further investigation of photographic action by the light of the most recent electrochemical theories would also throw light on much that is now obscure and uncertain as regards the formation and development of the invisible photographic image. Prof. Meldola, in his "Chemistry of Photography," notes these micro-electrical phenomena in photography as subjects for further investigation, and I hope these experiments may prove a useful contribution to the investigation.

---

Addendum, *September 26th*, 1891.

In some recent experiments, I have obtained indications of a current with an E. M. F. amounting to ·09 volt. during the development, in ferrous oxalate, of an ordinary celluloid dry-plate film (Thomas's thickly-coated landscape) exposed in the ordinary way upon a landscape, with sky and trees; the sky ( — ) end being attached to one pole of the galvanometer, and the tree ( + ) end to the other. The film was previously moistened with a five per cent. solution of potassium bromide, and the ends were held in silver clips attached to the conducting wires, but not allowed to touch the developing solution.

---

## THE LIGHT-FOG DEMON AND THE BEGINNER.

BY "SENEX."

After a little experience, most beginners in photography are able to steer clear of chemical fog, but *the light-fog demon* is one that pursues an amateur in a most exasperating way, for it hoodwinks him so completely that he blames any but the right cause of his failures. Looking over one's friend's negatives, one is very much struck by the fact of the large majority being light-fogged, and if mention be made of this, one is almost invariably told that this is due to over-exposure. However, since most excellent silver or bromide prints can be made from these negatives, the conclusion one naturally arrives at is that a small amount of light-fog does not in any way injure the printing capabilities of a negative. Moreover, the brightly-lit dark rooms of professional photographers certainly seem to produce a little of this result; for, in looking at professional portrait negatives, one is often surprised at detecting light-fog even in these; yet the quality of the prints leave nothing to be desired. If you should happen to indulge in platinotype printing, then it is that light-fog makes itself felt, by producing a muddiness and want of detail, when probably the erring amateur will give up in desperation this artistic method of producing pictures. Eliminate, however, all the causes of light-fog from one's attempts at negative production, and one is surprised with what ease most beautiful results can be obtained; and unless an amateur does not exclude them, the probability is that in a short time he will have discarded photography.

Let us, then, enquire when it is that this demon works his wicked will upon our plates. Taking it for granted that apparatus, camera, and slides are light-tight, when is it that light-fogging takes place? It is either in the dark room or during the exposure.

Concerning the dark room, it must be *absolutely light-tight*, so that after fifteen minutes shut up in it without a light, one can nowhere discern chinks through which white light enters; if one's dark room is, therefore, not perfect, work on in it at night, and do not believe the excuse that, because an infinitesimally small stream is well away from the plate, it cannot hurt the sensitive film. It does, and will do so when you are filling your slides, or taking out an exposed plate for transference to the developing dish. Again, what sort of a lamp have you got? Is it a lantern made of tin, and more or less complicated in design, with a view of preventing white light from shining on the plate? That is exactly where the fault lies. What we want is a lantern which shall not only prevent white light from entering the plate, but shall also exclude any such quality of light from entering the dark room by even one tittle of an actinic ray. In addition, test your lantern when you are testing your dark room, and after your eyes have become as sensitive as those of a nocturnal animal, examine your lantern, top, bottom, front, sides, and back, and look out for chinks or light reflected through ventilating channels. Now, I can scarcely believe that there is a lantern that will stand such a test, therefore with putty, red cloths, and various devices make it as perfect as possible; or, better than that, discard the lantern, and get a window with a well puttied-in pane of ruby glass, not larger than a half-plate, let into it, satisfying yourself that no white light can enter between chinks of the window frame; and, as we will suppose your dark room is not perfect, work only at night, with a candle or lantern outside your window. Do not be inveigled into using yellow glass or tissue, for ruby glass of the most approved shade allows so much actinic light to pass through it that you will fog your plates to a certainty, even when working with a candle, especially if you go in for slow development, and most likely if you use a rapid developer.

Since it is now so universally admitted that one thickness of ruby glass is not sufficient to prevent the light-fogging of gelatine plates, it is even more hopeless to try and work rapid films in such a light. To prove this, develop a plate that has been exposed for two minutes to the red light of your lantern or window, and you will be surprised by the amount of silver that has been deposited by such an exposure.

As it seems that we cannot counteract the actinic properties of even red light by quality, we must perforce try quantity; therefore your ingenuity will suggest that a screen of red cloth or paper must be fixed before your red light—a screen such that it can be rapidly raised and lowered, so that towards the end of development you can momentarily increase your light to see how things are getting on. You are working almost in darkness, but as an amateur, and a beginner, let us say, you cannot be too careful; and you will find, after a little practice, that the glimpse obtained of the developing plate by the momentary raising of your curtain is sufficient to form your judgment of the amount of development attained. Always wash off the developer before holding the plate close to the red light to judge of the density. The curtain can be raised when you want to find bottles, &c. A red light so screened will allow of your opening boxes of plates in perfect safety; even then do this in the shadow—say of your table. Since tin lanterns are so unsafe, a simple device is to cover them with a blackened box having a red glass or tissue window, and screened ventilating apertures.

Fogging also takes place during exposure; it occurs by reflected light reaching the plate, when the shutter is drawn through the slit in the lens tube used to insert the stop. As almost every lens is fitted with Waterhouse diaphragms, it is impossible to make them fit so perfectly that no light can enter; therefore, to prevent such an untoward circumstance, bind a long strip of black cloth round the lens tube, so that *the stop aperture shall be light-tight*. It is extraordinary how few amateurs know of this. To prove it, raise the ground glass, stop and cap the lens, and cover your head and the camera (not the stop slit) with the black cloth, and notice, when your eyes have become accustomed to the gloom, how much light really enters through this fatal slit. An innumerable number of negatives are fogged by this and called over-exposures. Thus, how frequently one hears and reads accounts of over-exposure of half-plate landscapes with the smallest stop, having received a four-second exposure—an impossibility as regards the picture, but true enough when applied to the amount of light that reached the plate, for fogging has been going on between the moment of drawing the shutter and the removal of the cap. I have given with half-plate R. R. lens *and f/64 stop* (the smallest) eight seconds to brightly lit Himalayan snows without foliage, and not found it too much; but then, though the plates were extra rapid, the negatives were produced without fog. Light-fogging also occurs when photographing towards the sun by the direct rays shining into the lens tube, and if the slides are exposed to sunlight. The prevention required to neutralise those two causes is obvious.

Having eliminated all sources of light-fogging, it is wonderful how impossible within reasonable limits it is to over-expose; and again, with full exposure, what beautiful features a negative will possess, supposing it to be one required to show a dark foreground, distant snow-clad hills, and the delicate shading of clouds; these will appear with the requisite tone and details.

After all, what is a negative that shows no light-fog? It is one whose border is perfectly clear, and whose very deepest shadows only show clear glass. Lastly, as a beginner, fly from light-fog as you would from a loathsome disease. The experienced photographer can manipulate plates in an actinic light; but, as an amateur and a beginner, you cannot; so do not copy him till you are proficient.—*Journal of the Photographic Society of India.*

## LUMINOUS PAINTS.

For *orange luminous paint*, 46 parts varnish are mixed with 17·5 parts prepared barium sulphate, 1 part prepared India yellow, 1·5 parts prepared madder lake, and 38 parts luminous calcium sulphide.

For *yellow luminous paint*, 48 parts varnish are mixed with 10 parts prepared barium sulphate, 8 parts barium chromate, and 34 parts luminous calcium sulphide.

For *green luminous paint*, 48 parts varnish are mixed with 10 parts prepared barium sulphate, 8 parts chromium oxide green, and 34 parts luminous calcium sulphide.

A *blue luminous paint* is prepared from 42 parts varnish, 10·2 parts prepared barium sulphate, 6·4 parts ultramarine blue, 5·4 parts cobalt blue, and 46 parts luminous calcium sulphide.

A *violet luminous paint* is made from 42 parts varnish, 10·2 parts prepared barium sulphate, 2·8 parts ultramarine violet, 9 parts cobaltous arsenate, and 36 parts luminous calcium sulphide.

For *grey luminous paint*, 45 parts of the varnish are mixed with 6 parts prepared barium sulphate, 6 parts prepared calcium carbonate, 0·5 parts ultramarine blue, 6·5 parts grey zinc sulphide.

A *yellowish-brown luminous paint* is obtained from 48 parts varnish, 10 parts precipitated barium sulphate, 8 parts auripigment, and 34 parts luminous calcium sulphide.

*Luminous colours for artists'* use are prepared by using pure East Indian poppy oil (in the same quantity) instead of the varnish, and taking particular pains to grind the materials as fine as possible.

For *luminous oil-colour paints*, equal quantities of pure linseed are used in place of the varnish. The linseed oil must be cold pressed, and thickened by heat.

All the above luminous paints can be used in the manufacture of coloured papers, &c., if the varnish is altogether omitted, and the dry mixtures are ground to a paste with water.

The luminous paints can also be used as *wax colours for painting on glass* and similar objects, by adding, instead of the varnish, 10 per cent. more of Japanese wax, and one-fourth the quantity of the latter of olive oil. The wax colours prepared in this way may also be used for painting upon porcelain, and are then carefully burned without access of air. Paintings of this kind can also be treated with water-glass.—*American Druggist.*

## LIGHTING.*

BY JOHN S. SCHNEIDER.

We all know that one of the most necessary things in securing a good picture is that it must be properly lighted; and now the question arises, when are our subjects properly lighted? If you were to ask an operator, "How do you get this or that effect?" he would not use many words in trying to explain to you how it is done, but he would invite you under his light, and then, with the shifting of a background, the drawing of a curtain or two, and the placing of a reflector or screen, he would soon demonstrate to you how it is done, and you would be thankful for the instructions received.

The operator has his eye trained, and is so familiar with his light, that it is no task for him to perform. By experience we train our eyes and hands so that it becomes a sort of second nature to us, and we never stop to think, "Why do I pull down that curtain, and why do I not pull down this one?" We know by placing our subject here we get one effect, and by placing it there we get another; and so it is in everything we do under the light.

Now, I will ask, is your eye trained to that point of excellence where you can always rely upon it as your guide in your work? If it is not, your work will show it, and it becomes your study to at once seek further information. This can be done by practice and experiment until you get the desired effect, and when you once get it you can get it again. How often do we pick up a picture made by a fellow photographer which in effect is different than anything we have ever produced, and we say, "That's fine; how did he get it?" but here is where so many of us stop. Why not take that picture and study it, and at the very first opportunity try to reproduce it? If you don't succeed at first, try it again, and you will soon see that your work is improving, to your joy and your customers' satisfaction. By this I do not mean that we should always pattern after our neighbours, but a little of it can do no harm; it will always lead to something new, and we become more original from day to day. Why is it that we find so many of us are not making the advancement we ought to make? Why is it that our work is not being picked up by others as models of photographic lighting? Is it not that we do not pay enough attention to the training of the eye?

I said it becomes second nature to us. How often do we find ourselves noticing the lighting in the face of a speaker, as he steps from one position to another; or, in fact, wherever we are, in the parlour, or in a street-car, if our minds are not busy with some other important subject, we find ourselves engaged in lighting faces. So it is, and always will be.

But, you ask, "In what direction shall I train my eye? Shall I train it to make bold, strong lightings, or shall I train it to make weak or soft lightings?" This, I will say, is always controlled by the subject, and by other circumstances, although in some cases we will find a bold lighting preferable. It is not necessary that a bold lighting should be a hard lighting; it can as well be soft and round. To get this effect, I always prefer to place the subject well under the light, and to work with the light considerably open. You will find by doing this your lighting will be soft and round; in other words, your subject will be well illuminated. You cannot expect to get a rich lighting unless you have plenty of illumination. This will help to round the face and give the drapery the richness that is so desirable, be it black or be it white. I said place your subject well under the light; by this I mean to get out under the light from four to six feet, and to work with a considerable amount of back light. This, I find, is a help, especially in white drapery; and in all shadows or Rembrandt lightings, as well as in the ordinary plain lighting.

There are a great many lightings which are called fancy lightings, as, for instance, the one which throws the face all in shadows—that is, a profile in shadows; and a great many can easily be had by coming out under the light. But here I should like to say that the great secret in all lightings, shadows plain or fancy, is to illuminate your shadows. I believe in the theory of contrast lighting. Make your lightings light with detail in the lightest lights, and make your shadows deep with illumination in the deepest shadows. If you do this your roundness, brilliancy, and strength will come by itself. There are many reasons why a subject well illuminated is better, and the one above all is, it saves your retoucher a great deal of work, it gives him the modelling that is desired, and he can give you a better and more satisfactory piece of work.

It is not only necessary to illuminate your subject, but it is also very important to illuminate your background. If you do this you will find that your subject will stand out from the background, and you will get an atmospheric effect. This is very important towards the light or from the light, any way to get contrast between your subject and background.

Now I should like to call your attention to another and very important point, and that is *direction of light*. If you take unto yourselves the pleasure of going through some of our great artists' studios, and studying their pictures and studies of art, you will find in all of them a direction of light—that is, by looking at the picture you can see the direction from which the light came which illuminated the study. Now this is the point. Have your subject so illuminated that, by looking at the picture, you can see the direction of light, or, in other words, on which side of the face the side light was. If you will always bear this in mind you will find it of great benefit to you. Why is it that we see so many flat and weak photographs that (to use a slang phrase) make us tired of them? They have no strength or brilliancy, or, in other words, no direction of light. They are flat because the operator did not illuminate the subject; he failed to give it light and shade, lightings and shadows. The idea is, to give your work an artistic merit your lighting should always be full of art. It is the lighting, above all, that gives your work tone and style.

* Abstract of a paper read before the Ohio Photographers' Association.

---

A Perfect Ink.—An ink which is said to be permanent and unaffected by the application of acids, alkalis, &c., and which renders forgeries and erasures, additions, or alterations easy of detection and difficult to accomplish, is said to be made as follows. To carbon black (preferably prepared by the action of concentrated sulphuric or other acid on sugar) are added a solution of gum or other mucilage, caustic soda, oxalic acid, and Indian ink. Vanadium in any form, Aleppo galls, nut galls, and a small quantity of an aniline dye are then added, with sufficient water to make the ink flow readily. The following proportions yield good results:—Nut galls, 20 per cent.; Aleppo galls, 5 per cent.; carbon black, 10 per cent.; vanadium, 1 per cent.; Indian ink, 10 per cent.; oxalic acid, 3 per cent.; aniline dye, 1 per cent.; rain water, 50 per cent. The whole is boiled, filtered, and strained.

## Notes.

"A mania for platinum" was the excuse offered the other day on behalf of a poor fellow who helped himself to two dishes of that metal to which he had no legal right. There are many photographers now-a-days who are afflicted with the same mania, only their madness has more method in it. They are more addicted to depositing the salts of the precious metal upon their prints than they are to depositing the metal itself in their pockets.

After quoting a recent note from these pages, which suggested that a factory for gelatine plates might, under certain conditions, be started in our Eastern Dependency, *The Journal of the Photographic Society of India* comments thereon as follows:—"Plate-making in India has been done, although only by enthusiastic amateurs, I believe. But there are several hill stations where an industry of the kind could be carried on with every advantage as regards low temperature, and many stations on the plains of Northern India where the temperature in the mornings for six months in the year is low enough for anything. It has always been a matter of surprise to photographers out here that something of the kind has never been attempted. Labour is cheap, the native is easily taught, and soon becomes a deft workman under European supervision. The market is a large one, and accessible at reasonable cost, thanks to railways, water communication, and the post office; so that a good brand of plate freshly made and moderately priced could command it. The only problems before the man of enterprise, therefore, are connected with the manufacture itself, and, if he has the skill and money to surmount them, he might reap a rich reward in a well thought-out and skilfully conducted plate-making factory in India."

Summer is a'coming in. Yes, when autumn chills and falling leaves should gather round us and hedge us in, the cold weather suddenly disappears, the clouds which have hid the sun from us for so many weeks have retired into private life, and all is sunshine and brightness. At least, it is so at the time of writing, but who knows what the morrow may bring forth, and whether or not we are giving our readers a chance of laughing at us for such an optimistic opinion of such a sorry thing as English weather. The boys and girls have packed up their cameras and gone back to scoool, the clerk also with his photographic apparatus has resumed his desk work, and holidays generally are over. The clerk of the weather has the country all to himself, and, after deluging it with rain when the corn was lying about to spoil, he laughs in his sleeve and pours a flood of sunshine on the land.

There is no more annoying thing to the tourist photographer than bad weather. Some few we know who like it, or say that they like it, and talk about the beauty of misty mornings, effects of atmosphere, and so on, but the average being prefers downright baking sunshine. A few clouds scudding across the sky are not unwelcome, but when those clouds are laid on for the sole interest of the umbrella industry, one gets tired of them, and longs for free trade.

Amateurs in search of a novel photographic Christmas card with which to amuse their friends might take note of the result of an experiment with a black background, which is figured in *La Nature* of the 19th inst. The illustration represents a little girl drawing in a mail-cart an enlarged head of her brother, whose face wears a grotesque grin. The experimenters—MM. P. et F. Leprince—made use of an open doorway, the gloom of which served as a black background. The first exposure was made about seven metres from the little girl and the mail-cart, the second about one metre from the head of the lad. During the second exposure, a blackened cardboard with a hole in the centre was held some little distance in front of the lens, so that only the head was received on the plate. The effect is very droll, and is capable of many variations, which will suggest themselves to the ingenious amateur.

Some of the London newspapers, in noticing the Photographic Exhibition, have made curious discoveries. One evening paper notes that "a new era has been entered upon, and that the Royal Society (*sic*) is likely henceforth to take its proper position in the country." What this means it is difficult to say, but at least the critic is premature in assuming that the Photographic Society has attained the honour which the president desires for it, namely a Royal charter. But the statement of this writer is not so remarkable as those of the representative of a weekly journal. The critic is effusive over the "long-desired improvements effected with regard to the reception and display of the exhibits," and goes on to tell us that "a new body, entitled the 'Management Committee,' has been appointed, which has relieved the council of many of its functions." Here is news indeed! So far as we know, none of the members of the Society are aware of the existence of this management committee, but if such a body has been appointed, there will be no little curiosity expressed as to what the committee is supposed to manage, and of what functions it has relieved the council.

The representative of the paper in question seems to have "improvements" on the brain, for further on he remarks, "the opportunity was taken while refreshments were being indulged in, after the inspection of the gallery, to felicitate the president on the improvements which had been effected." What improvements can these be? Surely the gentleman who is at once so vague and so enthusiastic can never have been at one of the Society's exhibitions before. One would like to have had his criticisms on the photographs, but unfortunately he carefully avoids mentioning a single picture, reserving his praise for the automatic plate-cutting machine. No one would guess from this "notice" that any photographs at all were exhibited.

The German Emperor has done his duty to society and the world. Having grown a beard, he has, when it was deemed to have arrived at maturity, been photographed. It is remarked that the latest picture does not represent him in the best of tempers, but His Majesty is not so conciliatory to photographers as is our Prince of Wales. It is said when the former was at Windsor, noticing that a photographer was making preparations with a camera for taking him, he turned his head away and obstinately refused to gratify the operator. We remember, on the other hand, seeing the Prince of Wales, when at Hastings in connection with some public function, give orders for his carriage to pause, so that a local photographer who had planted his camera on an elevation might have a fair shot.

## THE EXHIBITION AT PALL MALL.

This Exhibition, which opened with the usual *soirée* on Saturday evening last, and to the general public on Monday, is perhaps the most interesting one of recent years. It is true that nothing of a very novel or startling character is shown either in the way of pictures or apparatus, but, at the same time, there is greater variety than usual to hold the attention of visitors, and we therefore say that, on the whole, it is likely to prove a success. It would seem that either the Committee had an unusual number of good pictures to deal with, or that they had ruthlessly eliminated the bad ones, for the Exhibition is distinctly above the average.

The judges elected by the members of the Society are named at the head of the catalogue. They are, J. E. Austin, F. Hollyer, P. H. Newman, F. M. Sutcliffe, and J. B. B. Wellington. It may also be noted that the Exhibition will remain open for six weeks—that is, until the 12th of November—from ten to five, when the charge for admission will be one shilling, and that the gallery will also be thrown open on Monday, Wednesday, Thursday, and Saturday evenings, when the charge will be sixpence. As the optical lantern will be shown on each of these evenings, we may certainly say that the public have the offer of a very cheap sixpennyworth.

A glance round the walls of the gallery at Pall Mall will soon convince the most careless observer that the art of photography is progressing. There is an entire absence of those show-case portraits which were so common in former years, and a striving by all after more originality and artistic effect than a few years ago would have been thought possible in a photograph. A larger proportion of space than usual is occupied with pictures which are the result of mechanical process, and these are of such high quality that there is no room for doubt that in this department, as in others, the advance has been by leaps and bounds.

With regard to the other pictures, we observe that a great number of different printing processes have been adopted, and the compilers of the catalogue have done well to note the particular process fancied by each exhibitor. Thus, some of the pictures are labelled in the catalogue *Obernetter's Gel-Chloride*, others *Celerotype*, and so on. This feature is to be commended, because it gives the Exhibition an increased educational value to those who strive to learn.

The first picture catalogued is a fine direct portrait by D. Pym, which, hung rather high, gives one the idea of a fine steel engraving. Mr. Hilditch comes next with an admirable winter scene, "Sunrise on the Ice-bound River." The same worker has a far better picture (No. 51), "Ice Floes at Richmond, January, 1891." We mention these two works together because both represent the same scene, namely, the well-known view of Richmond Bridge looking up stream; but, while the first-named has a flat and obliquely lined foreground made up of the snow-covered tow path, the second, by a small alteration in the position of the camera, relegates the flat ground to a minor place, and fills up the foreground with huge hummocks of ice left by the receding tide on the river's brim. Mr. W. W. Winter, of Derby, may always be relied upon to bring to the Exhibition some of his exquisite portrait studies, which are so deliciously unconventional in treatment. Take, for instance, No. 9 ("The Misses Hewson"), and compare it with the monstrosities in the shape of portraits which, up to a few years back, were constantly showered upon an ignorant public. In this picture are two ladies standing together, one reading a letter, the other listening with evident interest to the recital. The pose is so simple that few photographers would have thought that a picture could be made of it, but it is natural, and the figures, too, are so graceful that attention is at once attracted to them. Besides two more portraits of large size, Mr. Winter contributes a frame of children's pictures, which are full of the natural buoyancy of youth.

The past winter (we are now referring to the season so called) gave photographers of the hardy type plenty of opportunity for picturing snow-scenes, and Nos. 23 and 25, by A. Hendry, which he calls "fog landscapes," are excellent examples of this work. Both are little gems in their way, with the distance in each case lost in mist. Such treatment of snow-scenes is admirable, for it permits the whitened twigs and foreground bushes to stand out clearly against the sobered-down background. Mr. Ennis has here several capital river scenes, not of that bright, sunny character which such subjects are generally made to assume, but as such scenes appear at early dawn or dewy eve, when there is little light, and what there is is chequered by rising vapours. Truly, there is a fashion in photography as in most other things. A couple of years ago there was a run on cottage doors with peasants standing on the threshold engaged in various occupations. Mr. Gale and Mr. Davison led this fashion, and gradually all the cottage doors in the kingdom came to be used up, so many imitators were there of these successful workers; and although Mr. Gale in the present Exhibition does show one exquisite cottage door subject (No. 112, "The Village Tradesman"), the general tendency of the subjects is to river scenery, scenes with damp mists which spell "neuralgia," but which make decidedly effective pictures. In a space of two square yards on one wall of this Exhibition there are no fewer than ten of these dusky river scenes, without taking count of those just mentioned. There is far more variety in them than in village doorways, and some are really lovely. One, indeed (No. 49, "Sunset, Winter"), by Mr. Cembrano, has been awarded a medal, and it is certainly worthy of the distinction. In Nos. 27 and 28 Mr. W. R. Cassels shows that he can produce beautiful work, but we hardly think that he has done the best that could be done with the materials at his disposal. A little more contrast of light and shade might have turned these photographs into far more satisfactory pictures. When seen in their natural colours on the focussing screen these subjects must have looked very beautiful, and even the most skilful photographers are sometimes deceived by such a promising appearance into the hope that the subject will be as attractive in monochrome. Two other pictures (Nos. 29 and 30) are far more satisfying, but these would have been improved by a background not so glaringly white.

Messrs. Russell and Son, of Baker Street, make a brave show with their "at home" portraits, two of which (Nos. 31 and 35, "The Rev. Mr. Galloway," and "H.R.H. the Duke of Edinburgh") are of very fine quality. In one respect, the photographer who has been honoured by a sitting from Royalty labours under a disadvantage. Royal personages are so often photographed that one is apt to pass their pictures by "as a tale that is told," and told so often that one knows them by heart, so to speak. But this picture of the Duke is really a good one, although the various medals, stars, and other decorations of the uniform unconsciously cause the eye to stray from the face. No. 43 is a funny little picture of the West London Photographic Society at the Castle Hotel, Hampton Court. Funny, because the members are all sitting at the dinner table looking uncommonly hungry. We trust that the exposure was not so long as the expression of these famished beings seems to indicate.

Passing by another winter scene by Mr. Hilditch, we light upon three fine pictures by Mr. H. P. Robinson, Nos. 69, 70, and 71. The last named, "Shakespeare's Cliff," is, in our opinion, the best of the trio. Is it that the beautiful scene is one upon which we have often feasted our eyes that this fine picture seems to be so attractive to us? The wonderful headland seems in this photograph to be lost for the moment in shade, while the sea below is spangled with sunlight patches. And how well the sober grey sky contrasts with the silver water beneath it. Next to claim attention are Mr. Lyd. Sawyer's admirable character sketches, with their bold effects of light and shade. In No. 78, "Reflections," a girl is holding a hand-mirror against a candle, and reflecting the light upon her well-favoured features. A new pose this, and an effective one too. In No. 79, "The Last Rehearsal," we see two girls singing from the same music book, with a strong light in their animated faces coming from a concealed lamp. No. 80, "Lighten our Darkness," is of a more pathetic character. A blind man is reading with his finger-tips from the familiar embossed type, the light from a lantern in front of him being cast upon his troubled visage. This picture would have been improved if some more natural form of lighting had been adopted. A lantern would, of course, be useless to a sightless reader, and it therefore appears to be quite out of place, or introduced to meet the convenience of the artist. In No. 81, "The Toper," we have a more effective picture still with the same brilliant lighting; in this case the radiance comes from a candle hidden behind a jug on the table.

No. 84, "The Gipsy Maid," is a very pleasing study of a laughing girl, by E. Spencer; and No. 85 again brings in the use of the hand-mirror, by Mr. Lyd. Sawyer; but, in this case, it is a nigger who admires him or herself (we are doubtful about the sex of the individual) in its bright surface. Nos. 86 to 89 are four 15 by 12 landscape studies by Mr. J. P. Gibson, the first, "The Woody Banks of the Tyne," being of very fine quality. These prints, apart from their great merit as pictures, bear favourable witness to the excellent effects attainable by Mr. Valentine Blanchard's platinum toning process. Mr. Horsley Hinton contributes eight large landscapes on rough drawing paper; one especially, "The Evening Ebb" (No. 98), is a fine study of a sandy shore, the picture being made up of very simple materials; but it is a pity that the print has not been so trimmed as to correct a slanting horizon. "An Essex Marsh" (No. 99), by the same hand, and "A Reedy Corner" (No. 101), are also both very true to nature; but some of the others of the series are too heavy and brown in their imitation of sepia drawings to be satisfactory as photographs.

Mr. Gale has six beautiful little pictures (No. 112 to 117), which, it need hardly be said, are as perfect in technique as they are artistic in conception. No. 117, "A Homestead in the Orkneys," is a different subject to those usually affected by Mr. Gale, and one full of beauty, although the materials would not seem very promising.

Mr. A. Burchett's three figure subjects, "A Knight," "A Highland Spinner," and "The Sailor's Daughter," show capital work, the spinner being the best of the three. These pictures bring us to the end of the gallery, where the Woodburytype Company have hung three very large pictures, each of which is labelled, "Quite unretouched." The centre of the three is a fine carbon enlargement of Chester Cathedral Choir. No. 143 is a view of Hawarden Castle, and No. 229 a fine picture of Chatsworth House. Close by we come upon the first of Mr. W. J. Byrne's contributions, a frame of children's portraits, entitled, "The Alphabet Illustrated," the illustrators being little dots of four years and under. This is quite a happy idea, and one feels a child again in tracing this account of an apple pie, and how B bit it, and C cut it, and so on to the last letter, "which ends this strange eventful history."

Mr. Gambier Bolton, and the numerous other workers who have paid successful court to the animals at the Zoological Gardens, have a formidable rival in His Grace the Duke of Newcastle, who proves, in Nos. 159 and 167, that he knows how to picture wild beasts. From the same hand come Nos. 165 and 166, views on Lago Maggiore. Here, too, we must notice some character studies by Mr. A. G. Tagliaferro (Nos. 168 to 171), which, apparently, are attempts to compete with that type of Continental pictures in which priests figure, and of which "A Good Story" is perhaps the best known example. In No. 169 a priest is sitting at his supper table, while a waiting-maid is about to open a bottle of mineral water in dangerous proximity to his face. In No. 169 the same priest is curiously examining a picture on an easel, the accessories of the picture being much the same as in the last instance. In a third picture he is reclining in a chair reading a newspaper. These pictures are well arranged and natural, but the subjects are not so interesting, perhaps, as they might have been made.

*(To be continued.)*

## PHOTOGRAPHIC CHEMISTRY.*

BY PROFESSOR R. MELDOLA, F.R.S.

Respecting the view that these compounds contain metallic silver, the fact that the chloride darkens under nitric acid may be taken as evidence to the contrary. The discussion of the possibility that sub-haloids are present will link this part of the subject on to the purely chemical considerations dealt with in the last lecture. The possibility of the coloured products containing oxygen—*i.e.*, being of the nature of oxyhaloids—is also worthy of being entertained. In favour of this view is the analogy of cuprous chloride, which darkens only in media which can supply oxygen, and which, under these circumstances, apparently forms an oxychloride. In the same sense may be interpreted the distinct sensitising action of water already referred to. On the other hand, it may be pointed out that the chloride darkens in a high vacuum (*i.e.*, in the presence of mercury vapour), and under liquids such as pure benzene, petroleum, and carbon tetrachloride, which contain no oxygen, and which have previously been dried by chemical methods. The question thus assumes the form whether the nature of the coloured products may not vary in different media; whether, in easily halogenised liquids, such as benzene, the reduction might not be analogous to that which occurs in hydrogen; whether in other cases, the unsaturated silver haloid residue may not form a coloured compound with the organic product; and so forth. It may be pointed out that such questions as these open a wide and interesting field for experimental investigation.

With regard to the second point—the action of the substance associated with the silver haloid—it is legitimate to connect this action with the ordinary chemical processes with which the

* Concluded from page 679.

student has been familiarised. He has been taught that reduction and oxidation are concurrent in ordinary chemical reactions, such as when a silver salt is reduced by a ferrous salt. The principle can now be extended to photo-chemical reactions. With the exception of a few cases of pure dissociation (such as the resolution of gold oxide into metal and oxygen under the influence of light), which have uo direct bearing on photographic processes, the photo-chemical changes with which the photographic chemist has to concern himself may all be considered from the same point of view as those which have beeu made use of by way of special illustrations. There is no fundamental difference in principle between the action of light on a mixture of ferric chloride and oxalic acid, or mercuric chloride and ammonium oxalate, and its action on a silver haloid mixed with water, silver nitrate, sodium sulphite, gelatine, or any other organic compound capable of being oxidised or halogenised. The only differences are in the relative velocities of chemical change, and in the circumstance that in the case of such metals as iron and mercury the products are definite and known, while in the case of silver the products are indefinite and unknown. The student will thus be led, without a break, from ordinary chemistry to photo-chemistry, and from the latter to the chemistry of photographic processes. He will now realise that the photographic film is to be looked upon as a system of chemical compounds capable of undergoing atomic re-arrangement under the iufluence of the external energy of light. He will grasp the full meaning of the term "sensitiser," and he will see that the function of the latter is quite as important as that of the silver haloid itself.

From this point the practical study of photographic methods, the preparation of emulsions and films, the uses of collodion and gelatine as vehicles, the action of preservatives, and all the technical details of modern processes can be taken up or resumed. Then in natural sequeuce will follow the consideration of the nature of the photographic image, and its connection with the coloured products resulting from the prolonged action of light on the silver haloids. At this stage, again, caution is necessary, and dogmatic statements must be avoided. The action of light ou the sensitive films in use in photography, including all the films employed for producing pictures in the camera, from the iodised silver plate of Daguerre to the gelatino-bromide plate of modern times, gives rise to uo visible product of photo-chemical decomposition. Of the nature of the material composing the invisible image we know no more than we do of the composition of the coloured products of photo-chemical decomposition or of the photo-salts.

The invisible image is either the product of chemical decomposition, or it is uot. If it is not, then some other explanation must be invoked. The only other view is that the energy of light is not at first used up in doing chemical work, but that before true chemical decomposition occurs there is an intermediate stage, during which the energy is engaged in loosening the affinity between the atoms of the halogen and the silver. According to this view, we should have to regard the first action of light on the sensitive film as a purely physical action, resulting in the formation of an uustable modification of the silver haloid, more easily reducible than the ordinary modification. It might be thought that such a physical modification would be easily producible by the limited action of light on the pure silver haloid, but, as far as my own experiments have gone, this does not appear to be the case. By exposing pure, dry silver bromide films, obtained by the method already described, for sufficient time to produce a well defined, developable image on a photographic plate, uo difference in the reducibility of the exposed and uuexposed parts could be detected. In fact, the films of the pure haloid are so insensitive that an exposure to bright suulight of sufficient duration to completely solarise the slowest of modern dry plates, showed no difference in reducibility by potassio-ferrous oxalate or alkaline-pyrogallol, between the exposed and unexposed portions of the surface. The conclusion to be drawn from these experiments is, that in this form the silver haloid cannot be converted into a more easily reducible physical modification by any moderate exposure to light —certainly not by an exposure considerably greater than that necessary to impress an image ou a gelatino-bromide plate.

At this point the question of molecular aggregation comes into consideration. In considering this part of the subject, attention may be called to the experiments which the student has already been recommended to make in connection with the modifications of the haloids. His experience in the preparation and ripening of emulsions will also render good service in enabling him to fairly consider the evidence. It is possible that some weight—how much it is not yet possible to decide—may have to be given to the state of aggregation as a factor in determining the extreme sensitiveness of the photographic film.

We are thus brought face to face with the remarkable fact that a film of pure, dry haloid gives no product which is more easily reducible than the original haloid by any reasonable amount of exposure to light. Let the same haloid be diffused in fine particles throughout a sensitising vehicle such as collodion (with the necessary preservative) or gelatine, and an exposure for a few seconds, or a minute fraction of a second, gives a product which is far more readily reducible than the unexposed haloid.

From many experiments which might be made or quoted, it will be made clear to the student that the function of the sensitising vehicle is of a very high order of importance. It will be seen also that the particular vehicle now in vogue—gelatine—is a particularly good sensitiser, and it is legitimate to connect its sensitising action with its well-known power of taking up bromine. It may be asked whether it is more probable that mere contact with a solution of gelatine should so alter the physical condition of the haloid (as in the last experiment) as to convert it from a comparatively insensitive to a highly sensitive physical modification, or whether it is more probable that the gelatine should act iu the same way as the reducing agents used as sensitisers in the former experiment with the coated papers. It may, I think, be fairly taught that the balance of probability is in favour of the purely chemical action of the gelatine. On the other hand, in favour of the view that some weight must be given to the state of aggregation, it may be pointed out that the silver bromide on glass, although considerably increased in sensitiveness by contact with a gelatine solution, is still much less sensitive than the emulsion.

If, therefore, it is regarded as improbable that mere coutact with a gelatine solution can alter the physical condition of the haloid, it may be asked what happens during the ripening of an emulsion. The student will have learnt that, wheu silver bromide is first precipitated in gelatine, the emulsion is comparatively insensitive. It is only by long contact with the gelatine solution at the ordinary temperature, or by the action of heat for a shorter period, that the emulsion acquires its maximum sensitiveness. The conditiou of the bromide particles in an emulsion is, from the beginning, very different from the condition of the bromide on a film prepared by brominating a silver mirror on glass. Nevertheless, I do not believe that we are at present justified in teaching dogmatically that the whole increase in sensitiveness is due to physical modification only.

From this stage onward, the practical study of photographic processes may be carried on hand in hand with the demonstration of the chemical principles concerned. The photographic image will be regarded as being most probably composed of a product of true photo-chemical decomposition. This product may, or may not, be identical with the "photo-salts," but it is not improbable that its composition may vary according to the nature of the vehicle with which the silver haloid is associated. The sensitive film which is now in general use will be regarded as a "gelatino-bromide," iu the same sense that the term "gelatino-nitrate" has been employed. The photographic image will be looked upon as a design on the surface of the gelatino-bromide, composed of a chemical product more easily reducible than the gelatino-bromide, and invisible simply because of the extreme tenuity of the deposit. When a reducing agent is applied, the material composing the invisible image is alone reduced to metallic silver, and the picture is said to be "developed."

The subject of development may uow be dealt with, and the chemical priuciples of the process demonstrated. It is necessary to commence by pointing out that a photographic developer may act in two distinct ways. In development by vapour, as in the Daguerreotype, and in the so-called acid developers, there is an accumulation of finely-divided metal (resultiug from coudensation in the case of mercury vapour, and from chemical reductiou in the case of acid developers) on the material of the invisible image only. If, for example, silver nitrate is reduced by ferrous sulphate or pyrogallol, the pulverulent deposit of metal accumulates by preference on the product of photo-chemical action, aud continues to be deposited thereon as long as there is silver being deposited from the developing solution. Where the silver deposit has once formed, there it continues to grow by accretion, and the developed picture is built up of metallic silver. The action is, doubtless, of an electrolytic character, the material of the invisible image and the unaltered haloid formiug the two elements of a galvanic couple, and the developing solution playing the part of the electrolyte.

The other kind of development effected by such reagents as ferrous oxalate, alkaline pyrogallol, eikonogen, and hydroquinone, must be regarded as also due to reduction ; but in these cases it is the material composiug the invisible image which is directly reduced. This constitutes the so-called alkaline development. It must be taught, in connection with this subject, that the silver deposit which results from the reduction of the invisible image is not the exact equivalent of the quantity of material composing that image, but that the reduction commenced on the portions exposed to light extends downwards through the film as long as the developer is actiug. In fact, it must be made clear that the silver deposit *grows* by a coutinued reductiou, the action iu this case also being most probably electrolytic, the elements being the first film of reduced silver, the unchauged haloid with which it is in contact, and the developing solution as the conducting medium.

The final result of both kinds of development is the production of a silver picture, composed of far more silver than can be accouuted for by the actual quantity of the material composing the invisible image. The two kinds of development may be classified as "accretional" aud "reductional" (chemical aud physical, according to the Coutinental photographers).

Having mastered the principles of development, it is importaut that the student should have his attcution directed to certain phenomena which connect this subject with the initial action of light on the photographic film. He will have learnt from the previous demonstrations that the photographic image with which he is practically familiar is most probably a product of photo-chemical decomposition. He will thus be prepared for the proof that chemical reducing agents may act in the same way as light ; that is to say that, by employing a very slow reducer, and allowing it to act on the silver bromide for a short time, the reductiou is carried to the same stage as that which results from the initial actiou of light. The process of reduction can be arrested at the invisible stage—at a stage intermediate between the haloid and the free metal. The product thus formed, whatever its compositiou may be, is more easily reducible than the original haloid, and can therefore be "developed" by ferrous oxalate, &c., in just the same way as the iuvisible image.

Another fact bearing on the present subject which must not be overlooked, is that mechanical force of the nature of a shearing stress also produces a developable impression on a silver haloid film.

In connection with the necessarily related subjects of exposure and development, the phenomenon of reversal must be dealt with. I have already expressed the view that this phenomenon is best regarded as reversed chemical action between the halogenised sensitiser and the material of the invisible image. In the broadest possible terms, all that we have to consider is that the "photo-salt" in contact with a sensitiser containing more thau a certain quantity of halogenising or oxidising material, has the tables turned upon it, to speak metaphorically, aud then acts as a sensitiser towards the film which at first acted as a sensitiser towards it.

Having brought the student up to this stage of knowledge, we must leave him in possession of a silver picture produced by developmeut, aud the chemistry of the subsequeut operations of fixing, clearing, intensifying or reducing, printing, toning, and so forth, will be comparatively simple. With regard to these subsequent operations, all that has to be borne in mind is that, after fixing and washing, the image is composed of a graduated deposit of metallic silver, and that all the changes that are wrought upon it by intensifiers or reducers are simply the result of ordinary chemical transformations. Thus, the principle of intensification may be demonstrated in the usual way, viz., by producing a design in silver on paper, as in the first lecture, then bleaching it by immersion in a solution of mercuric chloride, and, after washing, converting the mercurous chloride formed into the dark dimercurous ammonium chloride. The final result is a more opaque image—the latter has become intensified.

## AN OBSTACLE TO OUR FOREIGN TRADE.

The secretary of the Decimal Association writes as follows:—

It will be remembered that receut Consular reports from Italy and Japan have referred to the loss of trade owing to firms in England sending to those countries circulars and price lists based on the English weights and measures. The metric system is used in those countries, and our French, German, and other competitors use it in their quotations ; but the English firms are content to puzzle buyers with weights and measures which are very troublesome, and not understood.

A similar complaint now reaches us from Egypt, and the Consular report just issued ("Annual Series of Foreign Office Reports," No. 944) points out that our weights and measures are "utterly unintelligible" to a large proportion of the persons to whom export houses in this country forward their circulars and price lists in Alexandria and Cairo.

The metric system of weights and measures is in force in Egypt, and exporters of English goods to that country should, of course, adopt it iu their quotations and transactions. Not to do so is, indeed, suicidal shortsightedness, and it is to be hoped that the day is not far distant wheu the metric system of weights and measures will be generally adopted in England. If this needful reform be uot soon undertaken, there is little doubt that our foreign competitors will get a hold of our customers abroad which it will not be easy to shake off.

In Australia, it has beeu suggested that the adoption of the metric weights and measures should be carried out as one of the early labours of the coming Commonwealth Government of Federated Australia. In the *Sydney Morning Herald* of the 11th of July last, there is the following forcible reference to the subject :—

"The fact that such an absurdity as our present monetary system, and that of our weights and measures, should have survived so long, shows how strongly they must have entrenched themselves in the stupidity of human nature. It is a shame to our iutelligence that such a burden should have been tolerated so long, and the advance of Australia into the field of nations should be made the occasion of throwing off an incubus that we and our fathers have groaned under so long. It is the business of the Colonies to lead 'Old Mother England' by her apron strings, as we have often done before ; and there is not much likelihood of her refusing to follow us in a reform like this, that sooner or later will be imperatively demanded by the advance of the intelligence of the age."

The exhibition which is to take place under the auspices of the Hackney Photographic Society, will be opeued at the Morley Hall, Hackney, by Sir Charles Russell, Q.C., M.P., on the 21st instant. The last day for receiving entry forms is Wednesday next, so that those of our readers who may wish to exhibit should communicate with the secretary, Mr. W. Fenton Jones, 6, Victoria Street, King Edward Road, N.E., without delay. The judges are Messrs. J. Traill Taylor and Andrew Pringle, and the prizes will be presented on Thursday, October 22nd, by Captain Abney. The exhibition will remain open for two days only, and the proceedings are to be enliveued by organ recitals, and wound up on the Weduesday eveuing by a coucert.

## Notices of Books.

Materia Photographica. A Treatise on the Manufacture, Properties, and Uses of the Substances Employed in Photography. By Clement J. Leaper, F.C.S. (*Iliffe and Son.*)

This is decidedly the best of all the photographic books which take the form of an encyclopædia. Commencing with a short chapter on apparatus, and reagents and their uses, it comprises a full account of every substance with which the photographer is called upon to deal, from acetic acid to zinc. Apart from its alphabetical contents, the book has a capital collection of formulæ, directions for treating photographic wastes, valuable tables on chemical analysis, and a number of useful tables. It seems a hackneyed thing to say that this volume should find a place upon every photographer's book-shelf, but it is so true of this particular book that we risk the charge of plagiarism. The price is six shillings.

Illustrated Catalogue of the Glasgow Exhibition.

It is not usual to review the catalogue of a photographic exhibition, but this one is so well got up, and is so beautifully illustrated, that it merits notice at our hands. The frontispiece is a magnificent photogravure, by Messrs. Aunan and Swan, of a portrait of Professor Max Müller. There is also another photogravure of the jubilee portrait of H.M. the Queen, by Lafayette, and a number of good collotypes. Bravo, Glasgow! you have shown us what a catalogue ought to be like.

Holidays with the Camera. By many Authors. (*Hazell, Watson, and Viney, Ltd.*).

This is a quarto publication of fifty pages, containing forty-five illustrations. Some of these are good, but a large proportion are certainly not worthy of reproduction. The little book is well printed, and contains some interesting notes about different places of holiday resort.

The Ubiquitous and his Portable Dark Tent. By W. Ralston. (*Morison Brothers, Glasgow.*)

This is a little pamphlet in toned paper, each page containing a sketch of a comic character. The fun, however—what there is of it—is somewhat forced.

Die Photographischen Objective, ihre Eigenschaften und Prufung. By Dr. J. M. Eder. (*W. Knapp, Halle a. S.*)

This forms Part 4, Vol. I., of the revised edition of Dr. Eder's "Ausfuhrliches Handbuch der Photographie." The present section treats in an exhaustive manner the subject of photographic lenses, and embodies the results of increased experience in their construction, use, means of testing, &c. It consists of 273 pages, with 197 engravings, and three photogravures respectively of Dr. A. Steinheil (by whom the first chapter is written), Voigtlander, and J. Petzval.

James' Lamp.—A correspondent, signing "Operator," writes as follows:—"In your issue of the Photographic News for September 18th, Mr. Brangwin Barnes mentions in his article upon development, 'I have used James' lamp, in which the magnesium is burned in a gas flame.' I should feel obliged to the aforesaid gentleman if he could give me any information how and where to purchase the said lamp. I have always used the spirit lamp, and was not aware there was any such *gas* lamp in the market."

## Patent Intelligence.

### Applications for Letters Patent.

### Specifications Published.

6,093. *April 22nd*, 1890.—"Photographic Camera and Change-Box." J. Merritt, 842, President Street, and W. E. Spencer, 293, Dekalb Avenue, both in Brooklyn, New York, U.S.A.

The change-box consists of two rear compartments and of the camera box. The sensitised plates or films are provided with suitable sheaths and stored in a compartment. They are pressed forward by a piston and spring lazy tongs arrangement. The front plate lies in a carrier by which it is raised, after exposure, into the upper compartment, where the exposed plates are stored and pressed together by a piston and lazy tongs arrangement similar to that in the lower compartment. The carrier is raised by a bell crank turned on an axis by a lever on the outside. A projection on the bell crank strikes against another lever when at the top of its stroke, and releases the shutter. An indicating device is actuated by the motion of the carrier. At the front of the carrier are two similar lenses, which are mounted on the same frame so as to move together for focussing. The upper lens throws any image on the horizontal focussing glass by means of an inclined mirror, thus acting both for focussing and as a finder.

The shutter consists of two pivoted plates with openings which coincide in front of the lens. The shutter is set by the downward movement of the carrier; a third plate being moved at same time in front of lens to exclude light during setting, and afterwards removed by upward movement of the carrier just before exposure. The shutter may be released by hand, or by the movement of the carrier as before described.

The Photographic Club.—Subject for October 7th, "The Influence of Development on the Colour of the Image." Outing October 3rd, Hampstead; meet at the Flagstaff at 2; tea at the "Bull and Bush" at 6.

A correspondent from a town near London writes:—"I cannot refrain from commenting upon your paragraph in this week's issue *re* cheap work. In this little town we have a so-called photographer advertising cabinets at six shillings per dozen, including one coloured! Such are the men who pull down our art to so low a level, and make it difficult for the professional to hold his own and command remunerative prices."

## Correspondence.

KEEPING PLATINOTYPE PAPER.

SIR,—It may interest those of your readers who wish to practise photography in the Tropics to hear the result of an experiment which has been made by our American house for keeping platinotype paper in good condition during the very trying season of a New York summer.

The paper was packed in tins and shipped in the ordinary manner, but on its arrival the tubes containing the paper were immediately transferred to a cold storage chamber, similar to those which are used for keeping Australian and other frozen meat. After nine months the paper was taken out and found to be in perfect condition—in fact, as good as the day it was made.

Of course, nine months is not a long time for paper to keep in good condition in this country, but those who have known a New York summer—especially such an one as that which has been experienced in America this year—will appreciate the success of this trial.

Most of the large ocean-going steamers are now fitted with refrigerating chambers; it therefore becomes quite easy to ship the paper to any part of the world, and to insure its keeping in good condition even in the most trying climates.

ERNEST J. HUMPHERY.

*The Platinotype Co.*, 29, *Southampton Row, W.C., Sept.* 29*th.*

PHOTOGRAPHING BABIES.

SIR,—On Wednesday and Thursday, September 9th and 10th, I photographed all babies brought to my studio free of charge, with a promise to present one print to each mother of her child. Result: my place was besieged. I had to engage a police-constable for both days, who had his work cut out to preserve order amongst such a dense mass of people. I had a large scarlet flag with the word "Babies" printed in white letters on either side. The weather was beautifully fine. I got through 120 first day, and 200 on the second, making a total of 320 negatives, out of which 310 are successful. In a week I shall have the photos on view, with a bust of myself in the centre.

I may just add that I used a Dallmeyer 2B lens, Ilford ordinary plates, and a Thornton-Pickard shutter.

I thought perhaps you would be pleased to insert this bit of news in your next issue. EDWARDS.

*West Bromwich, Sept.* 19*th.*

THE CAMERA CLUB.

SIR,—Will you kindly note that the seventh of the series of one-man photographic exhibitions at the Camera Club will be open for private and press view on Monday, October 5th, at 6 p.m., and on and after Tuesday, October 6th, it will be open to visitors from 10 a.m. to 4 p.m. on presentation of cards, which can be obtained from members, or from the hon. sec.

The exhibition will consist of photographs by Mr. Ralph W. Robinson, by whose kind co-operation we are able to exhibit a fully representative collection, including a complete set of his valuable series of portraits of academicians. The pictures will be on view for about two months. G. DAVISON, *Hon. Sec.*

*Charing Cross Road, W.C.*

NEW IRON SALT.

SIR,—In reply to the several enquiries respecting this compound, I desire to give the following facts.

From a very protracted attack of rheumatism, I have not been able to follow up the experiments so thoroughly as I could desire; but, nevertheless, I have made some experiments in preparing this compound for sensitising paper. Although I have followed out the formula and instructions of Mr. Friese Greene, I have not obtained a paper sufficiently sensitive for any practical work; neither have I been able to get from Mr. Friese Greene any fresh samples of prepared paper. None of my results at all equal the paper prepared by Mr. Friese Greene, a piece of which I exhibited at the end of Professor Meldola's second Cantor lecture at the Society of Arts. A portion of the remainder of this has been analysed, and found to contain silver bromide in addition to the iron compound. I give this statement, keeping simply to the facts of the case. I cannot offer any explanation why the silver was present, but must leave it to the reader to draw his own conclusions.

My apologies are due to Professor Meldola, and I can only say that I received the prepared paper and exhibited it at the time in good faith, nothing doubting. FREDERICK H. VARLEY.

82, *Newington Green Road, Islington, N., Sept.* 25*th.*

## Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

AT the technical meeting of this Society held on the 29th ult., Mr. T. BOLAS, F.C.S., occupied the chair.

Col. WATERHOUSE read a paper on the electrical action accompanying the development of gelatino-bromide of silver. The author had been struck by the evidences which he had observed of electrical action set up when developing a film of silver bromide. He had met with the most striking effects when using a silver plate coated with bromide, but he had also found that the ordinary gelatine films produced similar results, though not to the same extent. He found, however, that the current was not always in the same direction. When a film, one end of which had been exposed to the light, whilst the other end was unexposed, was connected at the two ends to terminals leading through a sensitive galvanometer, and the film was immersed in a developing solution, a current was set up. This was shown by the deviation of a light spot on a screen. In one case the current had reached the intensity of one-tenth of a volt. The electrical disturbance did not commence immediately on placing the plate in the developing solution, but was concurrent with the commencement of a visible developing action, and this was retarded by soaking the film previous to development in a solution of potassium bromide. The experiments were made with various developing agents. Ferrous oxalate gave the most decided currents, and pyro followed next. With hydroquinone it was found that, by drawing the plate out of the solution, and exposing it to the air for a short time and then re-dipping, a decided impetus was given to the action on the galvanometer.

The CHAIRMAN suggested that the stronger action in the case of the ferrous oxalate developer might be due to the greater conducting power of the liquid. The electrical action seemed very difficult to account for on any ordinary chemical theory. The polarity of the electrodes was one great difficulty in examining the action that had been shown. Possibly that difficulty might be minimised by using a glass plate one surface of which had been platinised by a firing method, and coated with emulsion. Another plan would be to use a vessel for developing, at the bottom of which, and connected with the galvanometer, were two cups containing a little mercury covered by a film of a heavy oil. The gelatine film would then be placed so that each end would dip through the oil into the mercury, and so the galvanometer movements would not be complicated by the action of the solution on the electrodes.

Mr. G. L. ADDENBROOKE said that we must be very careful before coming to any conclusion as to the electrical disturbances that had been shown. Without a great deal of investigation it would not be wise to say whether the polarisation of the electrodes was not the principal cause of the effects seen. The greater action of the ferrous oxalate developer might be due to the action of the iron solution on the electrodes. If development set up an action in one direction, an opposing current should have an influence in retarding or preventing development.

The CHAIRMAN added that breaking the external circuit should also retard development, whilst closing the circuit should stimulate the action.

After thanks had been voted to Col. Waterhouse for the paper and demonstration, the meeting adjourned.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AT the meeting on September 24th Mr. W. E. DEBENHAM occupied the chair.

Mr. J. S. TEAPE showed prints in platinum and on albumen paper from the same negative—a group taken at the Society's last outing at Greenwich. A question had been raised as to which process gave the more gradation, and he fancied that the colour to which silver prints were toned had something to do with the ability to see more in the shadows.

The Chairman could certainly distinguish the gradation in the shadows better in the albumen than in the platinum prints. Whether that was due to the difference of surface as regards glass he was not prepared to say.

Mr. P. Everitt said that Captain Abney had demonstrated that in the high-lights platinum gave truer gradation than silver.

Mr. Beckett said that, as a platinum print dried, it seemed to lose gradation at the lower part of the scale.

Mr. E. W. Parfitt showed some negatives, parts of which were covered with small transparent spots. He wished for the opinion of members as to their origin. The plates had been used in a hand-camera, and the spotty ones were usually those in the last sheath.

Mr. A. Cowan thought that the spots were due to small air-bubbles during development.

Mr. Everitt had had similar spots when using pyro that had been preserved with sulphurous acid, and an alkaline carbonate was added. He attributed them to the evolution of carbonic acid gas.

Mr. Cowan said that a trace of grease on a brush used to dust the plates might cause the developing solution to be repelled, and so give rise to spots. Air-bubbles could always be ensured by using the same developer several times.

Mr. Beckett said that the worst case of spots he had ever seen was caused by using a dish for the developer that had been previously used for mercury solution.

Mr. Teape then showed a plate that had been exposed to openings cut in opaque paper. Part of the plate was unbacked, and part was backed; one end with burnt sienna, and the other with caramel. There was no particular difference between the two latter portions, but, if anything, he thought the sienna had the advantage.

The Chairman referred to experiments which he had published last year, and which showed, when the action of light had been long enough to test the backings severely, that caramel had been decidedly more efficacious than burnt sienna. He was led to the use of caramel from its high refractive index. Experiments of this kind, to be conclusive, required to be conducted with great care to ensure against some unreckoned cause creeping in.

Mr. Teape said that as the backing was not quite dry when used, he had put black paper behind it.

The Chairman could now account for caramel not having shown its superiority in the present instance. It was more tenacious of water than burnt sienna, and would therefore be moist when the latter had dried. Water had a low refractive index, and would diminish the efficacy of the backing considerably.

A question from the box was read: "How can halation round a window in the negative be removed?"

Mr. F. A. Bridge said that methylated spirit rubbed on with a piece of washleather would improve the negative by reducing density locally. When methylated spirit was insufficient, turpentine might be used to almost any extent.

Another questioner wished to know whether members had experimented with the toning process for bromide prints described by Mr. Weir Brown.

The Hon. Sec. had been using the method. He found the addition of acetic acid of the greatest use.

Prints toned by the method, that had been in the Society's charge for about three months, were then examined, and no falling off in appearance could be detected. The curator undertook to expose parts of each to a bright light for a lengthened period, and bring up the results to a future meeting.

Mr. Weir Brown had some prints, parts of which had been exposed to the light since the beginning of the year, and he could find no change in them.

Mr. F. H. Evans was elected a member of the Society.

### Hackney Photographic Society.

The ordinary meeting was held on Thursday last. The president was in the chair. Messrs. W. P. Dando and Augustus W. Wilson were nominated for membership. Being an evening set apart for the exhibition of members' lantern slides, a number of ladies were present. The following members handed in slides, which were put through the lantern by the Hon. Secretary: Messrs. Sodean, Gosling, Dean, Carpenter, Dando, Poulson, Herbert Smith, Grant, Barton, and the Hon. Secretary.

### North Middlesex Photographic Society.

*Sept. 28th.*—Mr. C. Beadle in the chair.

Mr. Zimmer demonstrated the process of reproducing photographs in printing ink by means of the "Photo-Autocopyist." In working the process, it is necessary first to take a print from a negative upon a sheet of vegetable parchment coated with gelatine and sensitised with ammonia bichromate. The image is visible, and can be examined as in the case of an ordinary paper print. When sufficiently printed, the bichromate is washed out, the sheet dried, and stretched on the printing apparatus. It is then moistened with glycerine and ammonia, and inked with a greasy ink of a suitable tint. The image is masked to keep the margin clear, and, a piece of paper being laid on top, a print is taken in a copying press, and the latter portion of the process repeated as often as desired. The prepared sheet may be stored away, and prints taken from it in the same or different colours at any future time. A number of prints were made and distributed among the members. The negative from which the sheet was prepared was shown, and it was seen that the prints did fair justice to it.

A letter was then read from a member communicating a formula for a rapid printing paper by the blue process, which he had worked out. Prints were shown from dense and thin negatives, from which it appeared that the new paper was suitable for soft negatives. The formula was then made up and paper coated by it for members to test with the ordinary paper. Prints on various home sensitised papers, &c., were then passed round and criticised.

### Sheffield Camera Club.

At the meeting on Wednesday evening in the rooms, New Surrey Street, Mr. G. T. W. Newsholme presided.

Dr. Manton gave a lecture on "Photogravure and Photomechanical Processes Practically Illustrated." The lecturer stated that the bulk of the processes now so much in vogue for the production of celebrated pictures, replicas of works of art, &c., depended on the actinisation of bitumen and chromated colloid compounds. After a brief description of the Woodburytype process, full-detailed descriptions were given of the working of collotype, photo-lithography, and zincography, specimens of each process being produced and distributed among the audience. The somewhat complicated process of photogravure was lucidly explained, and illustrated by sketches on the blackboard, and experiments. The walls were covered with a very large number of beautiful engravings and photoetchings, untouched by hand from beginning to end. Another process briefly explained by the lecturer was chromo-collotype, for the production of pictures in colours, and a very beautiful specimen was exhibited.

Votes of thanks were passed to the lecturer, and to Messrs. Pawson and Brailsford, the Meisenbach Co., and Mr. Sutton, for the loan of apparatus and specimens.

### Birmingham Photographic Society.

*September 24th.*—Mr. W. J. Harrison, F.G.S., in the chair.

After routine business, Mr H. S. Fry gave a demonstration in lantern-slide making. He compared collodion with gelatine, and, in the course of his remarks, stated that with gelatine the detail was more marked, the collodion generally tending to hardness. With gelatine various tones could easily be produced by increasing the exposure and using carbonate of ammonia, and increasing the strength of the restrainer in the developer. On reviewing the various developers, he considered hydrokinone by far the best for lantern plates. Mr. Fry then proceeded to make slides by reduction in the camera with the aid of the oxy-hydrogen lantern, which was manipulated by Mr. Jaques, and so good a light was procured that one minute was found sufficient to produce a fully exposed plate; afterwards, two other plates were exposed for seven minutes each under same conditions, and, by altering the quantities of the constituents of the developer, slides of different tone were made. These slides were afterwards shown on the screen, and also some of Norway and Switzerland.

The programme for next session includes six lantern nights, when slides of Japan, Burmah, Norway, &c., will be shown by Messrs. J. B. Stone, A. W. Wills, and E. H. Jacques, which they have taken on their travels. Members have the privilege of introducing ladies on lantern nights.

---

Liverpool Amateur Photographic Association.

A meeting was held in the Lancashire and Yorkshire Railway Company's Saleroom on September 24th, Mr. Paul Lange in the chair. There was an audience of some 700 persons, among whom were a considerable number of ladies.

Mr. George E. Thompson, president of the Birkenhead Photographic Association, delivered a lecture on "The Stone Age of the Passion Play at the Italian Lakes." In an introduction to his lecture (given for the first time), Mr. Thompson said that near the extreme north-west confines of Italy, and almost under the snows of Monte Rosa, lay the romantic little town of Varallo. Its sacred mountain, visited annually by thousands of devout Italians, reared its head 500 feet above the old houses of the town, and there among the fine chestnut trees were forty chapels containing numerous groups of terra-cotta figures, many of which were said to equal in artistic merit the finest sculpture of Italy. The figures were of life size, and represented biblical subjects, mostly illustrating the life of Christ. Many of these had stood there for over three centuries, and they well deserved the notice of Englishmen, both as works of art, and in being, as it were, a reproduction in stone of the Passion Play. The lecturer proceeded to show by limelight a series of photographic views taken by himself at Varallo, which he visited during the spring of the present year. The terra-cotta groups were illustrated, and starting from this point he took his hearers on a tour of the six great Italian lakes, which he showed from numerous points of view, with pictures of sunset and moonlight and mountain and woodland scenery. He then traversed the plain of Lombardy, illustrating its objects and places of historical and artistic interest, and, arriving at Venice, gave a view of that city as seen by a flash of lightning at two o'clock in the morning.

---

Great Yarmouth Camera Club.—The Society formed under the title of the Great Yarmouth and Eastern Counties Photographic Society has been reconstituted as the Great Yarmouth Camera Club. Mr. H. Harvey-George continues his services as Honorary Secretary.

London and Provincial Photographic Association.—October 3rd, Hampstead outing; tea at the "Bull and Bush" at 6 p.m. October 8th, "The New Ilford Printing-Out Gelatino-Chloride Paper," by Mr. J. Howson. October 15th, first lantern night of the season.

We have received from Mr. A. R. Wormald, of Sutton, Surrey, specimens of masks for stereoscopic slides. These are of two sorts, one kind being stamped out of black paper for glass transparencies, and the other kind made of thick card for paper transparencies. At this time many are turning their attention to the possible revival of this beautiful form of photography, and such a convenient help to the making of stereoscopic slides comes as a real boon. Mr. Wormald has also brought out a useful form of printing frame for lantern slide production. This is so arranged that any part of a whole-plate or smaller sized negative can be printed from, the negative being held perfectly rigid while the lantern plate is put in position and exposed. In this way slides can be duplicated with the greatest accuracy, and an oblique horizon can be corrected if need be. The contrivance is well made, and will form a welcome addition to the lantern producer's apparatus.

## Answers to Correspondents.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.

A. B. (Preston).—*Kallitype Details and Permanence.* You will find the improved process described in the News of July 17th last (p. 516), with some further observations by Mr. C. H. Bothamley in the following number (p. 530) on the question of permanence. After exposure, the prints must be kept quite dry almost until the moment of development. Silver can never be equal to platinum as regards permanence, but kallitype prints are sufficiently reliable for all ordinary purposes, and their cost is much lower than the platinotype.

H. C. (Wymondham).—*Opalines.* We are sending you the details by post.

S. Hill (Bath).—*Woodburytype.* Yes, this process can be used for reproduction of landscapes as book illustrations, but you will, of course, have to mount the prints, or bind them in as whole-page illustrations. For particulars of cost apply to Messrs. Eyre and Spottiswoode.

J. C. (Barnton).—*Obernetter Paper and others.* We should say that all those you have mentioned would take about the same time in the printing frame, but the thickly-coated plates and dense negatives, however produced, must always require a longer time. The Obernetter or gelatino-chloride is a printing-out process, and therefore the details of the image are, like an ordinary silver print, fully apparent on the paper when it leaves the printing frame. What are the subjects which you suggest as being suitable for the News?

L. A. M.—*Clearing Prints with Hydrochloric Acid.* A year ago we made some experiments in this direction, and found that the yellowish tint of the whites *could* be removed by a short immersion in dilute hydrochloric acid, without prejudice to the general tone. All the hypo must first be removed, or else the effect of the acid will be to precipitate sulphur in the pores of the paper, which might ultimately cause fading.

Hughes (March).—*Historical Questions.* The profile portraits cut out of black paper were called "silhouettes." All the other points mentioned in your letter can be read up in Mr. John Werge's "Evolution of Photography" (London: Piper and Carter). Opposite page 58 is a portrait of Frederick Scott Archer, with a sample of his work—Hever Castle, Kent—taken on collodion in 1849.

C. R. & Co.—*Patents.* A list of twenty-four specifications bearing upon the subject has been sent on to you by post.

Single Fluid.—*Developer.* We do not know the article, and, going back for several years, we have not found any published account answering the description given in your letter.

J. M.—*Detection of Forgery by Photography.* We have seen the six frames of specimens exhibited by Dr. P. Jeserich at the Pall Mall Gallery, but require to make a more thorough examination of them before replying to your enquiry.

T. H. H.—*Lantern Slides.* By contact printing six inches off a good bat's-wing burner, if the size permits of it. Otherwise by one of the processes described in Mr. T. C. Hepworth's "Book of the Lantern" (London: Hazell, Watson, and Viney).

---

Camera Club Notices.—*Monday, October 5th,* 8 p.m., opening of seventh one-man exhibition; pictures by Mr. Ralph W. Robinson. 8.30 p.m., smoking concert.—*Thursday, October 8th,* 8.30 p.m., Captain Abney; subject of paper will be announced later.—*Monday, October 12th,* 8.30 p.m., lantern evening; members are requested to send or bring slides, or to introduce friends who have interesting work they are willing to show.—*Thursday, October 15th,* 8.30 p.m., Mr. Andrew Pringle, "Bacteria Photographed."—*Monday, October 19th,* 8.30 p.m., first of the series of elementary lessons, "Lenses (1)," by Mr. Lyonel Clark.

# THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV. No. 1727.—*October* 9, 1891.

CONTENTS.

## ON PHOTOGRAPHING DISTANT OBJECTS.

The tyro in photography is generally disappointed with the first results which he obtains in landscape work. He attempts too much, and anticipates a result which his apparatus is incapable of giving. Of course a great deal of this non-success is due to his natural difficulty of interpreting the lovely coloured image on his focussing screen into monochrome as it will appear in the completed photograph. He does not understand how all those varied shades of green will merge themselves into blacks and greys, nor does he at once appreciate how the picture before him will suffer in the absence of the sapphire sky shot with delicate fleecy clouds. In a word, he wants experience to teach him the value of a given landscape from a photographic point of view. Another disappointment comes to him in the dwarfing of the principal objects in his picture. The church tower on the hill yonder, with the farm homesteads nestled under its shadow, the sleepy hollow in the middle distance, and the sunset sky dominating the whole, make up a fine picture. But in the photograph, church, houses, and hill have somehow sunk into one straight line, and form very insignificant objects in a view which seems to have an undesirable expanse of foreground and sky. The church, instead of being a couple of hundred yards away, has receded to a mile or more, and the meadow in which the camera was placed has apparently quadrupled its acreage.

The more experienced worker is careful to avoid these difficulties. He has long ago learnt that all that glitters is not photographic gold, that he must not be led away by the charm of mere colour, and that a single lens of long focus is, for landscape work, very often a far more desirable tool to work with than a short-focus rectilinear lens of the most expensive brand.

But occasionlly the better informed photographer is in want of extra aid in the portrayal of objects which are so placed that he cannot approach near enough to them to get a picture of the size he wants. It may be a building on the farther side of a river, or one which it is desirable to photograph from a certain window which is too distant from it to yield a picture of the desired dimensions. We can imagine a case occurring to a war correspondent in which it is necessary to obtain a picture of a distant fort, while it is impossible to approach it without personal risk. A man in such a position would examine the distant object through his telescope, and would long for some means whereby the image as seen in that instrument might be rendered permanent. Perhaps he would not readily imagine that, by combining the telescope with his photographic lens, this could be actually achieved; but with certain precautions this can be done, as anyone can ascertain experimentally for himself. Such photographs have indeed been taken from time to time, and there is no doubt that they would be far more common than they are if it were not for the fact that the necessary exposure is so long that the method must be confined to the representation of inanimate things.

Those who wish to experiment in this direction will find that the best method of procedure is to fix the camera and telescope on a rigid board. The former can easily be supported in two uprights formed like the letter X, the cylindrical body of the glass bedding itself firmly into the upper angles of such supports. The telescope must, of course, be central with the photographic lens—a rectilinear is perhaps the best form to employ—and the junction between the two must be furnished with a velvet sleeve, so that no light enters the camera except through the combined optical arrangement. The image given will be an erect one if the telescope is of the astronomical form; but if it is a terrestrial telescope, the photographic lens will once more invert the erect image which it gives when used alone. As already indicated, the image is very dark, and, when seen on the ground glass, gives the same impression as one would when observed with an ordinary lens stopped down to its smallest aperture; so that the necessary exposure is increased from the fraction of a second, which it would be under normal conditions, to half a minute or more.

From our Parisian contemporary, *The Photo Gazette*, we learn that Mons. Jaret, a lens manufacturer, has made an instrument, which he calls a "Téléo-objectif," to accomplish the purpose which we have been considering. This is, as its name implies, of telescopic form. It is furnished with a rack-and-pinion for focussing, and it conveniently screws on to the ordinary photographic lens.

In addition to the diagram of the instrument, which is given in the publication referred to, there are also shown specimens of what it will do in the shape of collotype reproductions from two negatives of the same subject. One professes to be taken under normal conditions—that is to say, with an ordinary camera and its unaided lens—while the other pretends to be due to the Téléo-objectif; but both pictures are said to have been taken from the same point of view. The first is a general view of a public garden, in the centre of which is a statue so distant that in the picture it measures only half an inch in height. In the other picture the statue takes up the entire space, little else being visible.

We were at first struck with the excellence of these results, but careful examination soon showed us that the second picture had not been taken from a distant point as stated, but that the lens which produced it must have been within a few yards of the object. The picture itself bears evidence that this is the case; for instance, in the normal photograph the statue is backed by foliage which is as high again as itself. In the enlarged example the top of this foliage comes hardly above the knees of the figure. Our opinion is also corroborated in another way. The statue stands on a square pedestal, with one of its corners towards the camera. In the distant view the top and bottom mouldings of this pedestal are horizontal lines; but, in the enlarged view, those lines converge to points so near at hand that it is evident that the lens which reproduced them must also have been in close proximity to the statue.

It seems a pity that, if examples of this method of working are published, they are not of a genuine nature; but with these particular photographs we need not farther trouble ourselves. Our object has been to point out a means at the disposal of the photographer which may be adopted under certain circumstances, and which, at any rate, may form the basis of interesting experiments.

London and Provincial Photographic Association.—October 15th, first lantern night; October 22nd, ordinary meeting. Visitors invited.

Anschutz Studies.—Messrs. Adams & Co. ask us to draw the attention of our readers to the fact that they have made arrangements whereby they will shortly have on exhibition, at 26, Charing Cross Road, the whole of the interesting collection of photographic studies by Anschutz. These consist of over 1,000 prints, some of which are considered to be the most marvellous examples of instantaneous work yet produced. The series comprises men running, soldiers marching, dog running, horse leaping, bird flying, man jumping, camel running, &c. The exhibition will be free, and open to the public from the 12th to the 17th inst. inclusive.

## ELECTRIC CURRENTS IN DEVELOPMENT.

BY COLONEL J. WATERHOUSE, S.C., ASSISTANT SURVEYOR-GENERAL OF INDIA.

The annexed record of some rough experiments made in the laboratory of the Photographic Society of Great Britain and elsewhere during my stay in Europe may be of interest. These experiments place the existence of electrical currents during development beyond all doubt, though it still remains to be seen to what action the currents observed are really due, and what part they take in the production of the developed image. They also clearly show that the currents are in some way intimately connected with the action of the developer on the altered silver bromide, and are not merely due to the decomposition of the developer. It seems probable, too, that they may in some measure be due to action between the moistening fluid and the developer. I hope to be able to go more fully into the question after my return to India.

*28th September.—Photographic Society's Laboratory.*

1. Edwards' ferrous oxalate developer. Sky and foreground subject. Thomas's landscape films. Current, $\frac{1}{10}$ v. towards the foreground or less exposed end of the film.

2. Same film and subject. Developer: 2 grains pyro with sulphite, 2 grains bromide, 2 minims ammonia to the ounce. The current went up very slowly to about $\frac{1}{80}$ v. towards the sky end of the film.

3. Same film, half exposed and half unexposed, in the same developer gave about half the above current in the direction of the exposed side.

4. Same film, more exposed than before, gave a current about double (2), or $\frac{1}{40}$ v., towards the exposed side. The poles were then reversed, and the current was slightly stronger and still towards the exposed side, though on the other side of 0 on the scale.

5. Another strip of same film as last in fresh ferrous oxalate developer gave a current of about $\frac{1}{60}$ v. towards the exposed side.

6. Another strip of same film in Edwards's hydroquinone developer. The current was at first small in the direction of the unexposed side, about $\frac{1}{120}$ v., but after exposure of the film to the air the needle took a strong impetus in the same direction, and showed a reading of about $\frac{1}{27}$ v. On changing poles, the current remained still in the direction of the unexposed side. When the silver plates were dipped in the developer there was only very slight current.

7. Another slip of same film as Nos. 1 and 2—sky and foreground—in same hydroquinone developer. The needle at once showed a reading of $\frac{1}{20}$ v. towards the sky side, and remained steady during the first stage of development. After exposure to the air and more development the needle went back to about $\frac{1}{40}$ v., and then remained steady. Further exposure to the air took the needle forward again rather beyond its first point, but it went slowly back. When the foreground side was lowered further into the developer the needle went back towards that side. There was a good deal of deposit over the foreground side of the film.

8. Thomas's extra-rapid film, half exposed and half unexposed, in same developer. The needle remained quiescent at 0 for some time; but after the film had been exposed to the air, it marked about $\frac{1}{20}$ v. towards the unexposed side; but afterwards went back, and showed a slight current towards the exposed side. Lowering the exposed side further into the developer sent the needle on in that direction. Lowering the unexposed side reversed

the curreut again very markedly. The final current was about $\frac{1}{80}$ v. in the direction of the exposed side.

9. Another slip of the same film in ferrons oxalate developer. Before developing, there was a polarisation current of about $\frac{1}{90}$ v. towards the exposed side; but on immersion the current indicated was about $\frac{1}{20}$ v. in the same direction, but went back to about $\frac{1}{40}$ v.

10. Another slip of the film used for No. 1, with sky and dark foreground, in the same developer. The curreut slowly went in the direction of the foreground or less exposed side till it indicated about $\frac{1}{20}$ v., aud remained steady for some minntes. The sky side being lowered into the developer brought back the needle in that direction.

11. Obernetter film—made by Perutz, of Munich—half exposed and half unexposed, in ferrous oxalate developer. The current showed at first about $\frac{1}{27}$ v. towards the unexposed side; then, when the development had proceeded, it turned about as much towards the exposed side, afterwards decreasing to about $\frac{1}{40}$ v.

12. Thomas's extra-rapid film, half exposed and half unexposed, in Edwards's pyro-potash developer. Developed very slowly, and there was no indication of current for a long time, but after exposure to the air, and movement iu the developer, the needle read about $\frac{1}{30}$ v. towards the exposed side.

13. Similar film, in fresh ferrous oxalate developer of ordinary strength (3 : 1), slightly acidified, with acetic acid, and about five drops of a ten per cent. solutiou of potassium bromide per ounce. The current was about $\frac{1}{80}$ v. in the direction of the exposed side. Lowering the exposed side into the developer did not produce much effect; but when the unexposed side was lowered the needle went off in that direction, and remained steady at about $\frac{1}{20}$ v.

Iu all these experiments continnous slips of ordinary celluloid dry plate film were used, the euds of the film being held by silver clips, which were not allowed to touch the developer, and the films were moistened before development by immersion in a solution of potassium bromide at five per ceut. The exposed side of the films was always towards the right, and the unexposed towards the left of the observer, and of the 0 point of the galvanometer. The galvanometer employed was a "uuit" instrument, by Edelmann, of Munich, which reads in volts and milliampères, with a resistance of 10,000 ohms.

*29th September.—Same general conditions as on 28th.*

1. Thomas's landscape film, unexposed, iu ferrous oxalate developer, same as for No. 13 of 28th. The polarity of the moistened film was slightly towards the left of 0. On putting the film into the developer there was a very small current towards the right. On taking the film ont of the solntion the ueedle went to the left; but, putting it back into the developer, it came back to its first position, aud remained steady there. The film fogged over during development; the yellow light may have been too strong.

2. Same film, half exposed and half unexposed, in same developer. There was first a slight current ($\frac{1}{200}$ v.) towards the unexposed side; but the needle went back to 0, although a strong developing action went on, and the unexposed side remained quite clear. As the deposit formed on the unexposed side, the tendency of the ueedle was towards that side, and curreut indicated was about $\frac{1}{20}$ v. Putting down the exposed end of the film drew the needle back to beyond the same distance towards the right, aud lowering the unexposed side sent it again to the left.

3. Same film exposed ou sky and dark foreground, aud same developer. The polarity was rather stronger than before in the direction of the less exposed end, bnt after immersion of the film the needle went off rapidly towards the more exposed end to about $\frac{1}{20}$ v. The foreground did not develop clearly. Lowering the sky end drove the needle back at first, but it afterwards returned to its old position and beyond. Lowering the foregrouud end seut the needle back only about ½ divisiou ($\frac{1}{80}$ v.).

4. Thomas's laudscape film, exposed all over, same developer. At first there was no current; but, after the film had been exposed to the air and re-immersed, the ueedle indicated about $\frac{1}{15}$ v. towards the left, and there remained steady. Lowering the right end, the current went that way. The real current during the development of this film seemed to be almost nothing.

5. Wratteu's "Ordinary" plate, two slips, one exposed and one unexposed, aud immersed in the developer with the gelatine faces opposite to one another, and about one-third inch apart; ferrous oxalate developer. The current was towards the exposed side, but was much smaller than before, the needle indicating about $\frac{1}{80}$ v., or less. Exposing more of the exposed plate seut the needle towards that side, and *vice versâ*, as with the films.

6. A piece of the same plate, half exposed and half uuexposed, but not cut apart; developed in ferrous oxalate, in contact with silver wire conductors. At first the curreut was the same as the last; bnt when the deposit was fully formed on the exposed side the ueedle went back towards the uuexposed side, aud then alternated; but the tendency was towards the unexposed side, which remained quite clear.

7. Thomas's landscape film, uuexposed; eikonogen developer (eikonogen, 1 part; sodium sulphite, 2 parts; satnrated solutiou carbonate lithia, 100 parts). There was a slight polarisation towards the right, but, on immersing the moistened film, the needle indicated a curreut of about $\frac{1}{40}$ v. in the opposite direction, and remained very steady. There was uo apparent deposit, and raising or lowering the opposite ends of the film produced little effect, the tendency being always towards the left.

8. Same developer. Another slip of same film, half exposed aud half unexposed. Slight polarity towards the unexposed side, and current at first about $\frac{1}{80}$ v. towards the same side, quite steady for some time. After exposure to the air and re-immersiou, the exposed end being lowered sent the ueedle in that direction, indicating about $\frac{1}{35}$ v., and it remained there. There was a good deal of deposit on the unexposed side.

9. The same repeated, with similar resnlts as to the current observed towards the uuexposed side.

10. Strip of Thomas's laudscape film exposed on sky aud dark foreground; same developer. The polarity was very slight. The ueedle at first went towards the unexposed side, but came back to 0, and gradually went towards the exposed side till it indicated about $\frac{1}{80}$ v. Development was very slow. Lowering the film on the sky side made the needle go iu that direction and indicate about $\frac{1}{40}$ v., or a little more.

11. Strip of Thomas's landscape film completely exposed. The polarity of the moistened film was about $\frac{1}{80}$ v. to the right, but when immersed in the developer the needle indicated about $\frac{1}{200}$ v. to the left. Lowering the right end of the film sent the needle in that direction, bnt it returned to 0.

12. Two slips of Wratten's ordinary dry plate, one

exposed and one unexposed, in same developer, and immersed in the same way as before. No current was observed.

13. Thomas's film treated in the same way showed a slight current (about $\frac{1}{200}$ v.) towards the exposed side, but when the film was immersed in some fresh developer the current increased to about $\frac{1}{100}$ v. Thio-carbamide and bromine added to the developer did not reverse the current.

14. Thomas's film, half exposed and half unexposed, with same developer containing a few drops of solution of thio-sinamine. The needle remained persistently at 0, or only showed a very slight current towards the exposed side. No reversal.

A great many similar experiments were also made at Constance in the early part of September, with the same galvanometer, chiefly with eikonogen and lithia developer, the films being moistened with water, and also with the potassium bromide solution. The currents observed were small, but showed the same uncertainty in direction. With developers containing thio-carbamides there was no such strong indication of reversal of current as was observed in Calcutta, but rather a neutralisation of the current towards the exposed side, the needle generally remaining at 0. In some cases, however, the reversal was observed. It was found that the potassium bromide solution was a much better conductor than plain water, and gave stronger currents.

In some experiments made in the same way at Starbeck, near Harrogate, with the assistance of Mr. J. W. Addyman, using a ferrous oxalate developer containing a small proportion of sulphate of copper, the current was almost invariably towards the exposed side, and with Thomas's thickly coated landscape celluloid films, it was as much as ·09 volt, the experiment being repeated more than once with the same result.

The experiment was also tried, at Mr. Addyman's suggestion, of using a series of exposed and unexposed films in separate cells, and a cut-out grating was also used, which enabled the film to be exposed so as to show alternate strips of exposed and unexposed sensitive surface, the ends of the strips in contact with the terminals being also exposed and unexposed. This arrangement gave a very good current towards the exposed side.

A Thomas's landscape film first exposed under this cut-out grating so that parts of the film were exposed and parts not, and then given a supplementary exposure all over, and developed in eikonogen and lithia developer, first showed a current towards the less exposed side, then towards the more exposed, but as the film became developed all over the needle returned to 0. The same was tried with ferrous oxalate with similar results. Over-exposure seemed generally to lower the current and draw the needle towards the less exposed side.

---

A Good Paste.—Mix some rice flour with water, adding a little powdered alum. Place over the fire, turning continually until it thickens. Add a few drops of alcohol in which some cloves have been steeped for five or six days. This paste will not dry nor become mouldy.

The Fry Manufacturing Co.—A second series of demonstrations, at 8 o'clock, will be given on alternate Friday evenings as follows:—October 16th, November 13th, and December 11th—lantern slides; October 30th and November 27th—enlarging bromide. Tickets gratis by sending a stamped directed envelope, or by personal application at 5, Chandos Street, Charing Cross.

## UNIVERSAL MICROSCOPIC EXHIBITION AT ANTWERP.

The following particulars are obtained from the *Chemiker Zeitung*:—

The "Exposition de Microscope Générale, de Produits Végétaux et d'Horticulture," has just come to an end. It was projected by Dr. Henri Van Heurck, director of the Autwerp Botanical Garden—a microscopist of reputation. The plan of the promoters allowed of a strange mixture of products. Thus, along with brewed drinks, "schnaps" of all kinds—*i. e.*, inferior liqueurs—were to be found pianos, mineral oils, guano, and other manures.

Mr. J. D. Möller, of Wedel, in Holstein, exhibited a collection of diatoms, including not fewer than 4,026 distinct forms. Not alone photographs of these species were on view, but the original specimens could be examined under a number of microscopes.

The firm of MM. Lumière and Cöller, of Lyons, exhibited coloured transparent figures of microbia just as they appear to the eye under the microscope.

Along with microscopes, there were exhibited stoves for the cultivation of bacteria, apparatus for sterilising, &c.

Among the exhibitors of instruments a prominent place belonged to the establishment of Mr. Carl Zeiss, of Jena. Their display included a selection of microscopes, from the simplest to the most complex, combined with appliances for photographic projection; a set showing all the single parts of which a perfect microscope is composed, and a collection illustrating the production of lenses from the crude glass through every stage of grinding.

Messrs. Watson and Sons, of Holborn, exhibited a large selection of microscopes for various purposes, especially an instrument made according to the indications of Dr. Van Heurck, adapted for delicate researches and for photo-micrography.

M. Nachet, of Paris, displayed instruments for research, general, scientific, and technical.

Messrs. Powell and Lealand, of London, exhibited a large microscope, said to be the most perfect as regards its staud. Mr. Hartnack, of Potsdam, had microscopes and object-glasses with photo-micrographic fittings. Mr. J. Deby, of London, displayed a collection of instruments by various modern makers, with manifold appliances for illumination, arrangements for obtaining monochromatic light, as also a rich and interesting collection of preparations. M. Adnet, and also M. Wainsegg, of Paris, and Mr. Siebert, of Vienna, exhibited a variety of bacteriological apparatus.

It strikes us as remarkable that no spectroscopic apparatus seems to have been exhibited.

The *Chemiker Zeitung* remarks, with perfect justice, that it is impossible for an expert to pronounce on the value of any instrument so long as it can only be seen in a glass case.

---

To Detach the Gelatine Film from the Reversed Negative.—M. Max Jaffé recommends the following for detaching the gelatine film from the plate, so as to have a reversed print for photocollography. The plate should not be collodionised, but covered with a solution of 15 parts of gum arabic in 100 parts of water; over this is placed a sheet of gelatine previously soaked in water, and the whole allowed to dry. The coating may now be removed without danger.

Retouchers should Save their Eyes.—I have now been retouching for two years, more or less, and for nearly a year have had considerable trouble with my eyes, at times fearing that I should have to give it up. Lately, however, a friend advised me to partly close my eyes while doing most of the work, and not strain them by looking hard all the time, but when finishing the negative to open the eyes and look closely. I did so, and find, without the aid of spectacles, that I not only do better work in that way, but that my eyes are now, after a month of it, entirely well. I wish other afflicted retouchers to have the benefit of my experience.—Cozette.

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Death of Josef Petzval—Ruby Glass—Uranium Toning Bath—Developing Under-Exposed Plates—Luminous Photographs.

*Death of Josef Petzval.*—The death is announced of the illustrious scientist and professor of mathematics, Josef Petzval, the inventor of the celebrated portrait lens combination which bears his name, and which is still unsurpassed as regards rapidity. Josef Petzval was born in Bela, Hungary, January 6th, 1807. He studied at the University of Pesth, where he graduated as a professor of higher mathematics in the year 1835. In 1836 he took the chair of the same discipline at the University of Vienna, which he held until 1884. In the year 1840 he became acquainted with Friedrich von Voigtlander, who constructed the first photographic portrait lens according to the calculations of Petzval. This portrait combination has been generally adopted by opticians. Petzval's activity in relation to photographic optics has been rich in results. He died at the age of eighty-four, on the 17th of September. As long as photography lasts his name will be remembered with honour.

*Ruby Glass.*—It is a well-known fact that red glass, as employed for dark rooms and dark room lamps, varies very considerably in quality, many samples allowing green or even blue light to pass through, in spite of their dark red colour. Many an amateur and professional photographer has spoilt his eyes and a great many of his plates by the use of ruby glass of this kind. Many, therefore, will welcome the information that Messrs. Schott and Co., of Jena, the manufacturers of the celebrated Jena optical glass, have undertaken to produce ruby glass specially tested by the spectroscope for photographic purposes. It is said that this new ruby glass will be before long an article of commerce.

*Uranium Toning Bath for Albumen Prints.*—According to *Die Photographie*, the following toning bath, recommended by F. K. Miller, gives beautifully black, purplish-brown or purely purple tones with albumen prints :—

*Solution* A.

| | |
|---|---|
| Gold chloride ... ... ... | 1 gramme |
| Water ... ... ... ... | 60 c.c. |

*Solution* B.

| | |
|---|---|
| Water ... ... ... ... | 1,024 c.c. |
| Citric acid ... ... ... ... | 48 grammes |
| Bicarbonate of soda... ... ... | 80 ,, |

For use mix—

| | |
|---|---|
| Solution A ... ... ... ... | 60 c.c. |
| Solution B ... ... ... ... | 480 ,, |
| Water ... ... ... ... | 3,850 ,, |
| Chloride of calcium... ... ... | 1 gramme |
| Uranium nitrate ... ... ... | 1 ,, |

This bath is said to tone quickly and uniformly. As soon as it is exhausted, corresponding quantities of solutions A, B, and of calcium chloride and uranium nitrate should be added. The above given quantity will be sufficient to tone fifteen sheets.

*Developing Under-exposed Plates.*—Some time ago Dr. Meydenbauer found that, with a very much diluted developer, which is allowed to act upon the plate for some hours, considerable more details may be brought out in the case of under-exposure than by developing according to the usual formulæ. A further advantage of the use of the dilute developer consists in the fact that the negatives obtained with it are free from harshness. Dr. R. Neuhauss confirmed the results obtained by Dr. Meydenbauer, and, in his opinion, the wonderful negatives of Dr. Vianna de Lima have been developed by the method indicated above. In order to clearly demonstrate the superiority of slow development with a much diluted developing solution, Dr. Neuhauss made the following experiment. An ordinary gelatine plate was exposed beneath a sensitometer for fifteen seconds by candle-light at a distance of thirty centimetres, and developed with a normal solution of pyro-soda. The squares 1 to 6 of the sensitometer appeared uniformly opaque on the plate after development, then commenced a gradual decrease of intensity up to square No. 26; No. 27 was hardly to be discovered. Another plate was then taken out of the same box, and exposed in absolutely the same way as the first one; it was, however, developed in the following solution :—

| | |
|---|---|
| Pyro solution (pyrogallic acid 7, sodium sulphite 50, dist. water 250)... ... | 3 c.c. |
| Soda solution (10 : 100) ... ... ... | 3 ,, |
| Water ... ... ... ... ... | 150 ,, |

It will be seen that this solution contained a very large bulk of water, the usual quantity of water for a normal developer being 3 c.c. in this case. Development took place in a dish which was filled with the liquid up to the margin, and shut with a cover. It lasted one hour and a-half, and during this time the dish was standing quietly in a dark box. The result was an astonishing one. There was no uniformly thick deposit on the parts of the plate representing the squares No. 1 to 6; on the contrary, the gradation of intensity beginning with No. 1 was an excellent one. Moreover, distinct traces of square No. 30 were visible, so that it was evident that the diluted developer had brought out considerably more than the normal one.

*Luminous Photographs.*—E. Ammann suggests the following interesting experiment :—10 grammes of gelatine are soaked in 80 c.c. of water, and, after the lapse of one hour, dissolved over a moderate fire. After the gelatine has become liquid, so much of luminous paint (being known as "Balmain's luminous paint") should be added as the gelatine solution is capable of taking up, until it forms with it a pulpy mass. A well-polished glass plate is placed on a levelling stand, and coated with the above-described mass, care being taken to prevent the formation of air-bubbles. As soon as the film has set, the plate is placed away and allowed to dry spontaneously. All these manipulations should, of course, be executed in the dark room, or by candle-light. The prepared plate may then be exposed in the camera. It requires half an hour in direct sunlight, which latter is a necessity. If the dark slide is opened in the dark room, the image will appear luminous and sharp in the details on the plate. It will keep luminous for some time if it is not exposed to daylight. The prepared plate may be used again.

---

At the Glasgow Photographic Exhibition, Mr. J. P. Gibson, of Hexham, on the 30th ult., delivered a lecture entitled "The English Borderland: Its Antiquities and River Scenery," and, on the 1st inst., another lecture entitled "Tyneside and the Roman Wall"; both illustrated by numerous lantern views of Northumbrian scenery.

Messrs. York & Son announce that they have secured the right of publishing a series of lantern slides illustrative of the Royal Naval Exhibition, and they anticipate that the pictures will prove as interesting in provincial lecture halls as the Exhibition itself has proved in London. We may remind our readers that the visitors to date number considerably more than two millions, "and the cry is still they come."

## THE CHINA CAMERA CLUB.*

At a meeting of the members of the China Camera Club, held at their rooms in Saunders' Compound on Wednesday evening, a most interesting discourse was delivered by Professor R. Hitchcock, of the Smithsonian Institute, Washington, D.C., on "Development," which was illustrated by the practical manipulation of several plates exposed by himself and members. About twenty members were present. It was decided to have an exhibition under the auspices of the Club in October next, after which the lecture was proceeded with. Professor Hitchcock, in the course of his remarks, said:—

It is with some diffidence that I venture to address you upon such a time-worn subject as developing, particularly since I have no new and complex mixture to recommend to you as the Hitchcock developer. The subject was first suggested by Mr. Emens, and, since it is one to which I have given some particular attention, I have thought a few words concerning the specific action of the developer constituents might interest those of you who are not chemists.

I shall speak only of alkaline developers for gelatino-bromide plates, and, while I shall strictly refrain from making comparisons between the various developers in use, it is well to explain how such comparisons can be made in practice. For this purpose I prefer to expose a plate in the camera upon any subject having a considerable gradation in light vertically, but of one general character horizontally, one in which there is shadow, foliage, and sky is good. This plate is then cut vertically into two or more strips, and these are developed in the solutions to be compared. We thus have a practically uniform exposure over the plate, and the results are due to the development alone.

It was in this way that I found, in the early days of eikonogen, that this developing agent would give all the delicate gradations of pyrogallol with a smaller proportion of alkali; and more extended and varied experience has fully confirmed that conclusion. The fact is of importance here in Shanghai, where in warm weather the gelatine is prone to soften even when the solution is weak in alkali.

The alkaline developer consists essentially of three active agents:—

1.—The reducer—pyrogallol, eikonogen, hydrokinone, &c.
2.—The alkali—sodium carbonate, ammonia, &c.
3.—The preserver—sodium sulphite.

The function of the first is to reduce or decompose the silver compound in the gelatine film, producing metallic silver, which then appears under the microscope in the form of minute opaque particles. But this decomposition only takes place when the alkali is present; and so nicely balanced are the chemical forces here involved that the reduction only takes place when the proportion of alkali exceeds a certain limit. A gelatine plate which has not been exposed to actinic light placed in a solution of alkali and pyrogallol remains white until the proportion of the former is sufficient to affect decomposition of the silver compound, when the plate blackens all over. This is "chemical fog." When a plate is exposed to light and placed in a weaker developer, it also turns black all over. Such a plate is said to be "light struck." The light has therefore produced a change in the silver compound of the film which renders it more easily reduced by the developer. It is obvious, therefore, that, by exposing a plate in the camera, we can develop a picture in which the lighted parts become black, the deepest shadows remain white, and intermediate gradations of light are more or less correctly reproduced. This is "negative." With this knowledge we are in a position to establish, experimentally, the proper proportions of the ingredients of a developer.

* *Journal of the Photographic Society of India.*

But first we have to consider the exposure of the plate in the camera, for the composition of the developer must be changed to correspond with the lighting of the plate. This being true, the expression we so often hear, "a properly exposed plate," is only correct as regards a developer of a particular composition. For it is an unquestionable fact that the duration of the exposure can be varied within very wide limits—say from one or two seconds to ten or twelve—and equally good negatives produced with different developers.

The nature of the change brought about by light has long been a subject of discussion among chemists. My own experiments, published in two articles in the *American Chemical Journal*, have demonstrated the fact—which has been disputed for a century—that light reduces silver chlorine, producing free chlorine and metallic silver. This fact has, no doubt, an important bearing upon the subject before us, but much delicate work requires yet to be done before a satisfactory explanation of photographic operations can be given.

But this result can only be obtained with great care and skill, and it remains for us to so adjust the time of exposure and the composition of the developer that good pictures are obtained without changes in either, whatever the character of the subjects may be. In other words, what shall be the properties and composition of what we may designate the normal developer?

This question brings us to a more careful consideration of the functions of each of the constituents of the developer. Taking these up in the same order as before, we may, for convenience, take pyrogallol as the type of all the reducing agents used in alkaline developers. This substance reduces the silver compound in the film wherever the latter has been exposed to light, as already described. But the extent of this reduction—in other words, the density or colour of the film when the reduction takes place—depends upon the intensity of the light's action and upon the proportion of pyrogallol in the developer. Now, a solution strong in pyrogallol gives a strong and dense reduction. A weak solution gives a feeble and thin film. Consequently, if we have a subject which is full of gradations from absolute black to strong, brilliant white, the developer should have such a proportion of pyrogallol as will give full density to the whites, perfectly clear blacks, and the intermediate tones as true to nature as possible. If we find as development proceeds that the high-lights are not developing black enough, we correct this fault by adding more pyrogallol. If they develop too strong, if the contrasts of light and shadow are exaggerated, we reduce the proportion of pyrogallol. So much for the function of the reducing agent in the developer; it controls density.

Next, as regards the alkali. The alkali starts the action of the reducer, and controls the progress of the reduction. It is, therefore, a natural consequence that the stronger the alkali, the more energetic the action will be. It also follows that, if a plate be insufficiently exposed for an ordinary developer, it can be fully developed by one containing more alkali. The only limit to the proportion of alkali is the resistance of the film of gelatine. Gelatine softens when treated with a strong alkaline solution, but, if we could make sensitive films with some substance which alkalies would not affect, the necessary time of exposure could be greatly reduced. The limit would then depend upon the stability of the silver compound itself. We therefore conclude that a normal developer should contain such a proportion of alkali as will bring out the lights and shadows of a picture in their true relative intensity. For an under-exposed plate use more alkali; for over-exposed, less.

Thus far all is clear enough, and were it not for a very remarkable, and as yet unexplained, action of light upon sensitive silver compounds, the process of development would always be a very simple operation. This apparently erratic action of light is a reversal of the primary effect which is brought about by continued exposure. If, for example, it requires three seconds to produce a good negative, an exposure of somewhat longer duration—perhaps of ten seconds—will yield a positive picture. A still longer exposure causes a second reversal, and we get a negative; after that another positive. A practical demonstration of these effects is by no means easy, because we do not know, except from numerous trials, how long to make the successive exposures. I have seen the first reversal on plates brought to me by others, but they have always been accidental, and a source of great astonishment to those who made them. The same result can also be produced by a momentary exposure of a plate to diffused daylight after proper exposure in the camera.

Now as to the bearing of all this upon development. It is obvious that reversal by over-exposure involves a reduction of density in those parts of a negative which should be nearly opaque, since in the reversal these must become the thin or transparent parts. We observe this effect in its incipient stage very frequently in our negatives which have thin skies. Thin skies are the result of over-exposure of those parts of the negative; they cannot be avoided when there are deep shadows in the subject. Only when exposures are very quick do we get clouds in our pictures, because the sky and cloud light is so very strong that all gradation of light is lost on the plate. If we expose too long upon the subject itself the same reversing effect begins, and, while the high-lights grow thin by over-exposure (reversal), the shadows grow stronger and stronger, as the weak light acts for a longer time. Thus our difficulties multiply, for it is impossible to give always a correct exposure, and, even if we could do so, there are often such strong contrasts in our subjects that, before the shadows are well exposed, the high-lights turn toward reversal. The negative will therefore be flat and thin. This effect must be controlled in the development, and with certain limits this is possible. We have seen that pyro controls density, and alkali the energy of the action. Now over-exposure for a strongly alkaline developer may be under-exposure for a very weak one. Therefore, knowing that the plate is over-exposed, use a developer weak in alkali, that it may act slowly, and use an extra proportion of pyrogallol to give increased density. Under-exposure is treated in the opposite manner. In this the contrasts are too strong; the high-lights are usually exposed very well. They develop black and opaque. They should therefore be brought out with weak pyrogallol. But the shadows do not come out well; therefore use stronger alkali. We observe, therefore, that the special efficacy of a developer, whether for common work or for particular purposes, depends upon both the absolute and the relative proportions of its two principal constituents. If now you ask me to give a formula for the most perfect developer for amateurs' use, and would say that it is not possible to choose between many in use.

There is another compound of great value in development, but, since it is not an essential constituent of the developer, we will dismiss it with a few words. I refer to bromides. The action of potassium, sodium, or ammonium bromide is quite the same. The bromide restrains the action of the developer. If we use a bromide, we must also use more alkali than would be necessary without it. To a great extent, one may avoid the use of bromide by reducing the alkalinity of the developer. But the chemical action of bromide is too complex to permit of discussion at this time.

We now come to the third-mentioned constituent, the sulphite of soda. The influence of sulphite upon the process of development may be neglected in this discussion. It is used primarily as a preservative of the solutions. An alkaline solution of pyrogallol rapidly absorbs oxygen from the air and becomes dark red. When mixed with a due proportion of sulphite, this change is prevented or retarded. By the use of an excessive quantity of sulphite developers can be made to keep for a long time. This is the secret of preparing the solutions which are sold in the shops; they contain very much sulphite. The question then arises, how much sulphite should be used? I would reply, just as little as possible. I have experimented some upon the point, and I find that a proportion of 1 part of crystallised sodium carbonate to $1\frac{2}{3}$ parts of sulphite (in crystals) will keep the solutions in good condition during prolonged development, and prevent yellow staining of the film.

But I never keep a pyrogallol developer mixed, nor even a solution of pyrogallol. The proportion of sulphite recommended will not preserve the colour indefinitely in warm weather. My stock solution consists of sodium carbonate and sulphite dissolved in water, and when required for use I weigh out the necessary quantity of pyrogallol and add it to the solution. It dissolves instantly, and the strength of my developer in pyro is always known. There is no deterioration and loss of pyrogallol by keeping. For amateurs this plan possesses great advantages. Not only is there economy to recommend it, but the composition of the developer is always under control.

I believe I was the first to recommend a strong solution of sodium bisulphite as a preservative for the developer. A saturated solution of sodium carbonate in water is first made. Through this a current of sulphurous acid gas is passed until no more is absorbed. The solution then prepared is preserved in small (1 or 2 oz.) glass stoppered bottles. About 1 drachm of such a solution added to 10 ounces of developer (if my memory serves me right) will preserve the colour perfectly during development.

---

Photographers' Benevolent Association.—At the meeting on October 2nd, Mr. Freshwater in the chair, two applications for assistance were considered and grants made. Mr. W. J. Tabrum was elected to serve on the committee.

Birmingham Photographic Society.—The first of a series of papers and demonstrations of an elementary and popular character was given on October 6th by Mr. J. Simkins, the subject being "Exposure." The next subject will be "Development."

## Notes.

Photographs of celebrities are very apt to lose their value, for the public taste is capricious, and he or she who is a favourite during one month may be altogether eclipsed by a new-comer during the next; or circumstances may so alter the appearance of the original that the old negative will no longer give a fair representation of the person from whom it was originally taken. As a case in point, no one could suppose that Lord Randolph Churchill would suddenly decide to grow a beard; nor could anyone imagine that such an addition would so completely change his personality. Perhaps no public man was more caricatured at one time than Lord Randolph, for his large eyes and big moustache lent themselves to exaggeration. It was somewhat of a checkmate when he donned a beard, and so rendered all previous caricatures valueless. Perhaps he did it on purpose.

A few months ago General Boulanger was in France the favourite of the hour, and his photographs sold more readily than any photographs that were ever known; but there is no public more fickle than the French, and when Boulanger's star set, as it soon did, he and his photographs were quickly forgotten. Large stocks remained on the hands of the shopkeepers, and they were looked upon as useless lumber until the news of Boulanger's suicide led to an attempt to dispose of them once more. The shop-windows in Paris were last week again filled with the dead man's portraits in every kind of pose and costume, but the sale, says the correspondent of the *Daily Telegraph*, was by no means brisk. The true Parisian, he tells us, must have actuality, and if only a photograph would depict the act of suicide, after the manner of that horrid picture in the Wertz gallery, it would sell famously. It is reported that a Brussels photographer did in reality photograph the dead body of the General soon after the crime; but this, perhaps, would be hardly sensational enough for the Parisian palate.

Mr. Jerome Harrison has for years interested himself in the bibliography of photography, and many papers on this useful subject have been contributed to our pages. He now points out, in the *Journal of the Camera Club*, that previous to the first appearance of the Photographic News in 1858 several journals took up photography as an occasional subject which might interest their readers. Of these the *Literary Gazette* and *Notes and Queries* may be specially mentioned. From the latter publication Mr. Harrison gives a complete list of photographic subjects dealt with in the first twelve volumes, dating from 1849 to 1855. Glancing through these subjects, we find many, as a matter of course, which were associated with processes now extinct. At the same time, many subjects are treated of which are still enlisting the attention of modern workers.

Anyone who has had dealings with builders and their workmen will sympathise with the members of the Camera Club, who, after many months of inconvenience, saw no chance of getting their premises completed without resorting to the drastic remedy of refusing to pay full rent until the work was done. This course had the desired effect, and the club-house may now be said to be complete. There are now 750 members, and increased accommodation has had to be provided for them on special occasions by enlarging the dining-room. Several interesting subjects are down for the Thursday evenings during the month of October, and the "one-man" exhibition of the works of Mr. Ralph W. Robinson forms an extra attraction to the sumptuous building in the Charing Cross Road.

The theory has always been held that photography killed miniature painting. The theory, no doubt, had some foundation, but of late years—judging by the Royal Academy Exhibition—miniature paintings have been on the increase, and the limited number of artists who work in this direction appear to be fairly well supplied with commissions, showing that the taste for the miniature yet survives. If a critic in the *Magazine of Art* is to be believed, however, the quality of the work will not compare with that of Cosway and lesser known men. He says there is no fault to be found with the technical execution of these specimens so far as it goes, but there is such a painful monotony of touch, such a horrible suggestion of a photographic basis finished by careful toil into the pretty smoothness of a machine-made surface, that it becomes impossible to attribute any given specimen to any given artist.

There is some truth in this. The Royal Academy miniatures have certainly a strong family likeness, and one is almost inclined to believe that the artists originally started as colourists of photographs. We know this is so in one case; while in another, though the early training was in miniature work, there came a long interval of nothing but the colouring of photographs, simply because there was no demand for the miniature, so that practically, when the artist resumed miniature painting, the photographic influence was too strongly engrained to be totally got rid of. There is this also to be said, that the majority of people do not consider it necessary to give a sitting to the miniature painter. If a photograph and the colour of the hair, eyes, and complexion be supplied, all that is necessary has been done. Naturally, under such circumstances it is difficult for the artist to put much individuality in his work.

Has the familiarity with the faces of Royalty and celebrities which photography has brought about killed the pictures of groups of notable personages, which used to be so popular years ago? Judging from Mr. Sargent's experience, something of this kind seems to have happened. If any picture had a chance of being popular, it should have been Mr. Sargent's "Queen's Jubilee Garden Party"; yet it seems to have landed him in the Bankruptcy Court. The work such pictures entail is enormous. Mr. Sargent spent three years over his task, and secured the portraits of four hundred personages more or less distinguished. What this means, how many rebuffs, or how much of the "proud man's (and woman's) contumely" the artist has to suffer, only those who have gone through the ordeal can tell. Mr. Frith, in his "Reminiscences," gives a very vivid picture of his trials in securing the portraits for his picture of the marriage of the Prince of Wales. Of course the thing is easier now, as photographs are not only more numerous, but better; but after Mr. Sargent's experience, it is doubtful whether the game is worth the candle.

## THE EXHIBITION AT PALL MALL.

[Second Notice.]

We are glad to learn that the Gallery at Pall Mall attracts many visitors. There were certainly a large number there on a recent afternoon when we were there, and we noticed that, contrary to what is customary at certain other exhibitions of pictures, those present really studied the works hung, and discussed their merits among themselves. It was the same with the apparatus; everything was submitted to careful examination, and possibly, from the frequent handling, some of the cameras and other goods will at the close of the Exhibition bear a very strong resemblance to second-hand articles. But exhibitors are prepared to run this risk, and if wise will wish that the visitors, so far as is possible, will test the working of the apparatus shown.

Continuing our review of the pictures where we left them last week, we come to two pictures by Mr. A. Keighley. The first (No. 145) is entitled "Driftwood," and it takes us to a rock-girt shore at low tide. The sands are just in that half-dry, half-wet condition when they will yield pleasant reflections of the figures walking upon them. These are, in the picture, naturally placed, and the whole scene is very successfully photographed. In No. 151, by the same hand, some fisher children have extemporised a swing which hangs from the bowsprit of a vessel in harbour. The background of this picture, consisting of a steep path bordered by huts, is cleverly rendered, and the entire composition is a very pleasing one. Close by these two is an attractive picture by Mr. B. Alfieri (No. 146), with the title "Against the Sky on the Sea-Wall." A man stands by a horse amid a score of sheep, apparently upon sand dunes hard by the sea shore; the sea is not shown, but it seems to be there all the same. The lighting of the group is admirable, while at the same time the sky is so natural that we fancy that it must have been taken on the same negative as the rest of the composition. If printed-in afterwards, the work has been beautifully done.

A very good effect has been obtained by Mr. L. C. Bennett in No. 157, which, after the manner of Mr. Whistler, is called "A Nocturne." This is a seascape with a barge, such as one can see any day running down the Thames or Medway, or coasting along the Downs, whose sail is just in front of a break in the sky, where presently the moon may be expected to peep forth. The work is too black in tone as it is, and, if it were printed more lightly and kept grey, it would be a very fine little picture.

Four excellent pictures are those of Mr. F. Beasley, and we can only regret that they are exhibited in one frame. The number is 158, and the subjects are, "The Falls of Moness," "The Lyn of Dee," "Old Invercauld Bridge," and "Glen Lyon." It seems a pity that so many photographers should injure their work by adopting this injudicious course; but we are bound to say that the evil is not half so rampant now as it was in former years. We can only suppose that it is for reasons of economy that the practice is followed; but, at the best, it means that false economy to which the adjectives, "cheap and nasty," are so often applied. Four more pictures which are allowed to rob one another of elbow room in this way are numbered 176, and they are by the same hand. Any one of them, or those whose titles have already been quoted, would be better *solus*, and give far more pleasure to the beholder, than as part of a quartette. As if to point out the truth of this remark, there are hung in the near neighbourhood of Mr. Beasley's pictures a number of works by Mr. J. P. Gibson, each of which, although smaller in size than those just reviewed, has a frame allotted to its separate use. These pictures at once attract attention, not only because of their great excellence, but also because of the pleasing hue conferred upon them by platinum toning. The finest, perhaps, is No. 181, "Autumn on the Tyne," which is quite a little gem. Here the photographer had a beautiful view before him; but Mr. Gibson shows by other pictures that he can coax beauty out of very sorry surroundings. Look, for instance, at No. 206, "Deserted Lead Mills." Here we have a few huts and ruined walls; these materials, with the help of a couple of figures, a distant hill, and a broken sky, make up a picture of which anyone might be justly proud.

Those who visited the last Exhibition of the Royal Academy may remember that there was shown there a large picture by Mr. Leader representing a portion of the unfinished Manchester Ship Canal—and a very fine work it was—in which that which is picturesque was discovered in the big ditch, with its puddles, its mud, its cranes, and other mysteries of the navvy's work. It is not, therefore, surprising that the humble photographer should follow in the footsteps of such a worthy *Leader*, and present us with a series of pictures showing in a most interesting manner the progress of this stupendous engineering achievement. The pictures, six in number, are by Mr. T. Birtles, of Warrington, and excellent they are in every respect. They show us not only a part of the gigantic cutting, which presently will be filled with water and big ships, but also the huge piers, lock-gates, dredges, and other features of the undertaking. Such pictures as these will be looked upon with interest years hence when the canal is a highway for commerce, and when, let us hope, it is paying its shareholders handsomely. The London Stereoscopic Company show some large direct portraits which are of very fine quality. That of Miss Lily Hanbury (No. 180) is especially pleasing, but they all show excellent work. In No. 212 Mr. C. Reid has four pictures of horses, sheep, a deer, and a dog. The last two are exceedingly good, the dog—a fine collie—being one which would have rejoiced the heart of Landseer. Mr. W. P. Marsh, in Nos. 225 and 226, exhibits two pictures of Persian kittens playing with a straw hat, which are so much alike in subject that it would perhaps have been better if one only had been shown. As an example of really good landscape work, we may direct attention to "Sunshine after Rain, Coniston" (No. 223), by Mr. H. Young. Here we have a carpet of bracken in the foreground relieved by masses of foliage which clothe two hills, through the opening between which is faintly seen a portion of the distant lake. The whole scene is bathed in sunlight, which not only lights up the foreground and trees, but also renders luminous the air, so that the distance is lost in haze.

The central portion of this end wall of the gallery is occupied by large direct studies of children by Mr. W. J. Byrne, of Richmond. Of these, "An Eastern Beauty" is, we think, the best. It is a difficult thing to make young children act a part satisfactorily, either on the stage or in the studio. The children upon whom Mr. Byrne has relied for his models do not come up to the ideal at which he aimed. Nos. 194, 195, and 196 are sky and sea effects of a very lovely nature from the camera of Mr. W. Clement Williams, of Halifax. This gentleman has, we remember, shown work of this kind at former exhibitions, but on a far smaller scale. These are printed in carbon, and are of a blue-grey tone, giving a very good idea of moonlight over the sea. These are among the gems of the Exhibition, and it seems a pity that they are placed so low on the walls that many visitors are sure to pass them unnoticed. Unstinted praise must be awarded to the frame (No. 230) which bears the name of Vanderweyde, for all the pictures contained therein are of the first quality. These include a pretty group of four sisters —Miss Dorothy Dene and company; four very fine cabinet portraits; "A Maharajah's English Doctor and Bodyguard," in which Oriental costume figures with fine effect; and other pictures which will repay careful examination. Mr. J. Collier, of Birmingham, exhibits on this wall three large pictures. First, we have in No. 231 the Anatomical Museum of Queen's College, Birmingham, and in No. 233 the Pathological Laboratory of the same institution. These are capital interiors, but, as if the subjects were of too technical a kind to stand alone, there is sandwiched between them a group of fairies from "The Midsummer Night's Dream." We presume that the models in this case came from the local theatre. They do not, at any rate, make a satisfactory picture, for they seem to want the aid of colour and the glamour of the foot-lights. Represented photographically, they certainly will not pass muster as "immortals."

*(To be continued.)*

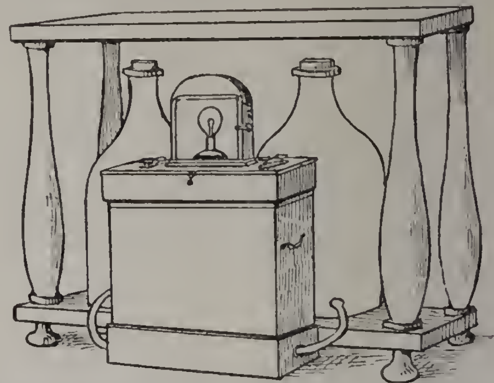
## AN ELECTRIC GLOW-LAMP FOR PHOTOGRAPHERS.

An electric lamp, of which we annex a sketch, has recently been designed and patented by Messrs. Pyne and Thompson, and it seems likely to prove valuable to photographers for use in the dark room. It consists of a two-fluid primary battery enclosed in a case six inches high, seven inches long, and six inches wide. A glow-lamp is supported by a pillar attached to the lid of the casing, and is completely surrounded by a shield lined with a reflecting surface. The glow-lamp is arranged so that non-actinic screens of glass can be placed between the light and the developing dish, or, if preferred, a pillar revolving in a ball-and-socket joint carrying the glow-lamp may be employed, by which means the light may be brought into closer proximity to the plate during development. The lamp when charged weighs about six and a half pounds, or not more than an ordinary oil lamp.

The inventors have developed several negatives with a smaller lamp of this type weighing less than five pounds, which is merely intended for use as a safety-lamp in coal mines. This mining lamp gives a steady, clear light for ten hours continuously, and has undergone a very satisfactory trial in a mine, where it compared favourably with the best ordinary oil safety-lamps.

To charge the battery which feeds the lamp, it is merely necessary to pour its two exciting fluids into the glass reservoirs—which are contained within a neat polished mahogany stand—to a certain height.

In the annexed drawing, the cells are supposed to be filled and the lamp ready for use. By lifting the battery case on to the top shelf, the fluids pass into their respective reservoirs by the attached rubber tubes, and the cells immediately become emptied. The fluids are thus prevented from deteriorating by diffusion. The intensity of the light can be varied by either raising or lowering the battery case, or by means of four thumb-screws fixed to the lid of the casing. The light can be turned off by means of these screws, and the battery left in position for some considerable period, should the operator be called from his work for a time. Such a developing lamp will give a steady, bright light for 100 half-hours' intermittent use, or for 50 consecutive hours.



The fluids used in connection with the above lamp are not more costly than oil. The depolarising fluid is a new combination specially designed for this purpose, and is covered by the patent. The whole of the fittings of the battery have been carefully designed, and are thoroughly efficient, being, at the same time, very simple and easily accessible. They can be charged and cleaned by an unskilled hand. This lamp will be greatly valued by photographers on account of its simplicity, cleanliness, and lasting properties. We have as yet heard nothing as to the price at which it can be supplied, and we invite the inventors to give us some information on this point.

Holborn Camera Club.—Pending arrangements:—To-night, *Friday 9th*, Mr. E. Benest will give a demonstration on the "Action of Light on Sensitive Salts," with experiments.—*Saturday 10th*, official outing to Hyde Park. Meet at the Albert Memorial at 3 p.m. Meet at the Club Room for tea at 6·30 p.m. Mr. A. Hodges will give a prize for the best print taken at this outing.—*Friday 16th*, practical demonstration on "Platinotype," by Mr. Fred Brocas. September competition prints to be sent in by this date.—*Friday 23rd*, lantern night, when members are requested to bring their slides and their friends.—*Friday 30th*, social evening. Members will please bring prints for comparison. The annual supper will be held at Anderton's Hotel, Fleet Street, on Saturday, November 7th; tickets 3s. 6d. each. Any additions or alterations to these arrangements will be posted on the notice board, and also be published in the photographic papers.

Another Yarmouth Photographic Club.—On Tuesday evening a meeting was held at the Cromwell (Temperance) Hotel, for the purpose of forming a photographic society for the promotion of the art in the town and neighbourhood. After a preliminary discussion it was proposed to form a society, to be called "The Cromwell Photographic Club," with headquarters at the Cromwell Hotel, and that the annual subscription should be 3s. 6d. Mr. R. H. Inglis Palgrave, F.R.S., was elected president; Dr. John Bately, vice-president; Mr. T. W. Swindell, treasurer; and Mr. C. Rumbold, 4, Dene Side, Great Yarmouth, honorary secretary. Messrs. H. Pechey, G. Waller, jun., T. Goate, J. Williment, Leech, H. Chamberlin, and Dr. Grenfell were elected as the committee. The Cromwell Hotel is in a central position, and the proprietor has had a dark room specially constructed for the use of photographers, which will also be open to visitors to the town. The fee for membership has been fixed as low as possible, in order to give all an opportunity of joining. A large number of names was enrolled at the first meeting, among them being many members of the late Great Yarmouth and Eastern Counties Photographic Society.

## AUTUMNAL FOLIAGE AND ORTHOCHROMATIC PLATES.

The approach of fall and its beauties in the way of foliage should turn the thoughts of the photographer to the use of orthochromatic plates. When we look around and note the number of photographers that use ordinary plates on the richly-coloured landscapes of autumn foliage, we often wonder if they have ever seen the same landscape taken with a good orthochromatic plate. If they have not they should try such a plate, and we promise them that they will not soon return to the use of the ordinary kind.

We thought that the knowledge of the use of orthochromatic plates and their mode of working was pretty well written out, but we were very much surprised to hear a gentleman otherwise well posted in matters photographic, express surprise at the wide difference between the use of orthochromatic plates and those of ordinary manufacture, when used on coloured objects in nature. He further was surprised that the manipulation of the plates was so easy, and not very different from the ordinary varieties.

The fact of the matter is, no one would use ordinary plates if they only knew how much better results can be obtained with the orthochromatic brands. There is only one drawback to the last-named plates; they are slow after the lightning speed attained in some of the best brands of modern dry plates. Yet who wants to take a landscape or a portrait at such speed, except under special circumstances? As a rule, time can always be taken in these cases, and with infinitely better results, even with ordinary plates.

As is now well known, the principle of orthochromatic photography was first enunciated by Professor H. W. Vogel in the year 1873, when, in the *Photographische Mittheilungen*, he stated (page 236):—

"From my experiments, I believe I am pretty safe in saying that we are able to render bromide of silver sensitive to any desired colour; or we may exalt the sensibility to certain colours which it already possesses, if we add to the bromide of silver some material which assists the decomposition of that compound, and which, at the same time, absorbs that colour and not the others. In this manner we are able to remedy the photographic inactivity of certain colours hitherto troublesome."

Since this principle was discovered, a number of colouring matters have been proposed as sensitisers for the photographic plate. As a matter of fact, only those colours that are derived from the group called "eosins" have been found practically useful. They absorb the yellow and orange rays of the spectrum, and assist the decomposition of the bromide of silver when these rays fall upon its surface. These colouring matters act best when used in extremely small quantities, and when incorporated in the emulsion when it is prepared.

The effect of the plates is to render the colours of the objects to be photographed in their true relation of shade; thus, red letters on a black ground would come out as black as the ground, but with an orthochromatic plate the letters would come out lighter than the ground, or as they appear to the eye. Mr. G. Cramer puts the matter in such good shape in his paper read before the Photographers' Association of America that we cannot do better than quote his words:—

"Let us imagine a landscape before us; above, the blue sky with white clouds; on the horizon, the distant hills; in the foreground, foliage in the beautiful shades of autumn. The ordinary plate would take the sky white, being just as sensitive to the light blue as to white rays; and, therefore, will show no clouds unless they are of a darker shade. The distant hills would only be faintly visible, and the foliage be lacking in detail. The orthochromatic plates would give us a soft, grey sky, not white, but with beautiful white clouds; the distant hills just as distinct as you see them in reality, and the foliage with all the various gradations, from the finest high-light to the deepest shadow, every leaf being clearly detailed, and every blade of glass standing out from the rest. In all, it gives us just what we see with our own eyes, except the colours. For portraits, we will consider we have to photograph a pretty, rosy-cheeked girl from the country—rosy-cheeked, but a little freckled, with a blue dress and yellow trimmings, and with auburn hair. The ordinary plate will give her a fair face, but what a job to retouch all the freckles! The blue dress will appear like a white one; the yellow trimmings will be too dark. Her hair will show a great lack of detail, and appear the same as black hair. While the other plate will give, if anything, a bolder, rounder image; freckles will not be visible to a greater extent than you can see them with your eyes, and, in the portrait, are generally smaller than the original, as they are almost entirely invisible. The hair will be of a medium shade, and as full of detail as that of a brunette. The dress will be of a proper tone, the yellow trimmings in harmony with the rest."

This puts the matter in a nutshell, and from experience we can fully endorse his statements.

In regard to the keeping qualities of the plates, we have the testimony of such men as Vogel, Eder, Leon Vidal, Bothamley, and others in Europe, while at home, the words of the veteran dry plate maker, John Carbutt, given at the Buffalo Convention last month, leave nothing to be desired on this score. This is what Mr. Carbutt says:—

"When I commenced making the orthochromatic plates in 1886, many scientists and amateurs in this country were experimenting in orthochromatising the commercial plain dry plate, and, while good results can be obtained by this method, it was found that they lacked the important quality of keeping, and this fact being made known through the photo journals, led many photographers to believe it applied also to the commercial-made orthochromatic plates; but I am able to state most emphatically, as a result of personal experience and experiment, that the orthochromatic plates made from emulsions containing the colour sensitiser have just as good keeping qualities as those made from plain emulsions."

From what we have stated, it is evident that orthochromatic plates are the only ones to be used for taking pictures of coloured objects, and for use in autumn landscape work they give results not to be approached by any other plates hitherto made for the photographer. In copying coloured pictures containing blues and reds a colour screen of orange shade is necessary, and also in taking pictures of distant mountains. In both the last cases more time is necessary than when the screen is not used.

Try the orthochromatic plates, and if you use them rightly you will not soon abandon them.—*Anthony's Bulletin.*

---

Tunbridge Wells Amateur Photographic Association.—The fifth annual exhibition will be held at the Royal Sussex Assembly Rooms on Wednesday, Thursday, Friday, and Saturday, Nov. 25th, 26th, 27th, and 28th. Particulars may be obtained on application to Mr. Joseph Chamberlain, Hon. Sec., 14, Calverly Park Gardens, Tunbridge Wells.

## AMSTERDAM INTERNATIONAL PHOTOGRAPHIC EXHIBITION.

That our brethren of the "black art" in Hollaud have uo intention of being behind the times is proved to demonstration by a visit to the Exhibition of Photographs and Photographic Appliances opened in due form and order last week in the Militiezaal, Amsterdam.

In the face of many difficulties, financial and otherwise, the committee, with the valuable assistance of their energetic hon. secretary, Mr. Chr. J. Schuver, have certainly succeeded in bringing together a very representative collection of pictures—both professional and amateur—which would not disgrace the walls of any of our larger exhibitions in England, and we must congratulate them upon a success which is well deserved. We trust the public will support the Exhibition, and signify in a substantial mauner their appreciation of the energy and zeal of the executive which has placed within their reach a photographic treat of no mean order.

In the space at our disposal it would be impossible to criticise each separate exhibit; we shall, therefore, select a few pictures for notice which struck us as being more especially worthy of notice.

In the professional section, Mr. W. J. Byrne, of Richmond, sends some good work; "An Eastern Beauty" and "Sorrow," both studies of children taken direct, particularly attracting our attention. We fancy these are old friends, but none the worse for that.

Messrs. Emrik and Binger, of Haarlem, show some excellent examples of "Lichtdruck" and photo-zincographic plates, the pureness of the whites in some of the impressions being especially noticeable.

Mr. G. Greul, of Mannheim, has some really beautiful direct portraits, apparently quite untouched; perhaps the best is a Germau working mau smoking his pipe. The expression and relief of this picture are remarkable.

Mr. C. E. Mögle, of Rotterdam, has a large collectiou of good portraits, the whole showing skilful treatment and wonderful roundness of image. Many, however, would look better if printed in platinotype.

Mr. Fr. Müller, Munich, shows some fine heads iu sepia platinotype. One of an old man with long, grey hair, and a face deeply furrowed, is the finest thing of its kind we have seen.

Messrs. Obernetter and Paulussen each seud a representative collection of photogravures, for which they are justly celebrated.

Messrs. Roeloffzen and Hübner, of Amsterdam, also show a fine set of photo-zincos, photo-lithos, and photogravures, many of large dimensions.

Mr. Lyd. Sawyer exhibits several old friends—all excellent, but well noticed in these columns ofttimes before. His celebrated "Tam O'Shanter" was called "Taw O'Chanby" in the catalogue.

Mr. Rud. Schuster, Berlin, has some fine photogravures, in which the highest lights are wonderfully pure. We suspected "fakement" with the brush, but upon examination the suspicion proved groundless. "Miduight Scene, Dordrecht," is a splendid copy.

Mr. H. Tollens's (of Dordrecht) pictures of Dutch life and scenery, printed in silver, are bright and especially interesting, but too warm in tone.

### Amateurs.

We confess to have experienced some disappointment with the Amateur Section, taken collectively, and, had not England put in an appearance on the screens, the general work in this section would not have been more than mediocre. We hope our Dutch friends will profit by a comparison of their pictures with those of some of our best amateur workers.

The exhibits of "Voorwaarts," Dr. Kühn, Messrs. W. Toussaint, J. J. M. Guy de Coral, A. Lunden, J. J. Kamp, and A. Bakhuis possess considerable merit, as also does the collective exhibit of the Haarlem Amateur Photo. Club. But, as works of art, Mr. F. P. Cembrano's studies take the palm; whilst the architecture of Mr. C. Court Cole, the landscape of Mr. A. W. Gottlieb, the seascape of Mr. Clement Williams, and Mr. Martin J. Harding's pictures, take first rank. Most of these latter pictures have been exhibited, and received awards, in Great Britain, and deservedly take medals and diplomas in Holland.

### Apparatus.

In this section we must express our satisfaction that the "highest award"—the diploma of honour and silver-gilt medal—is taken by Messrs. Loman & Co., of Amsterdam, this enterprisiug firm showing by far the greatest number of novelties. Their new hand-camera—the "Reflex"—a marvel of simplicity and ingenuity, would, we feel sure, "catch on" in this country were it better known. Their "Holland" camera and "Amsterdam" camera—the latter now exhibited for the first time—are both excellent in design aud reasonable in price. We visited Messrs. Loman's works, and were both surprised at their size and at the amount of work *in hand.*

Messrs. Watson and Sous have a representative exhibit of their cameras, &c., uow so well known and so highly appreciated, but we could find nothing new in their show-case. Ant. N. Bouvy's exhibit of opaline plates, matt-surface *plaques* of all sizes and various designs, coloured and black glass aud porcelain goods, each and all specially prepared to receive the photographic impression, is worthy of notice.

Meinard Van Os shows, amongst a goodly collection of sundries, a clever print-washer with *correct* circulation of the water, aud a portable dark room possessiug several good points.

Carl Zeiss, Jeua, exhibit some of their new lenses. We hope the lenses are better than the mounts.

Mackeustein, of Paris, Mawson and Swan, W. Tylar, The Platinotype Co., Louis Van Neck, and others exhibit their various specialities, but we did uot notice any departure from the usual stock goods.

The jury, consisting of Messrs. Fritz Eilender (Cologne), Dr. J. Van Genus (Amsterdam), Charles W. Hastings (London), Josef Isralls (The Hague), and Dr. Wertheim Salomonson (Amsterdam), worked hard, and, we believe, carried the judging to such a nicety as to reckon the marks by *eighths.*

The awards are as follows:—

### Section A.—Professionals.

*Highest award—diploma and silver-gilt medal.*—Lyd. Sawyer, Newcastle-on-Tyne.

*Silver-gilt medal.*—Friedr. Müller, Munich; C. E. Mögle, Rotterdam.

*Silver medal* (first prize).—W. W. Winter, Derby; W. Byrne, Richmond; G. Greul, Mannheim; O. Anschutz, Lissa; Emrik & Binger, Haarlem; R. Paulussen, Vienna.

*Bronze medal* (secoud prize).—Fred. Boissonas, Geueva; Saly E. Straus, Cologne; L. Kurtz, Wiesbaden; Gebr.

Frohu, Deventer; Anselm Schmitz, Cologne; H. Tollens, Dordrecht; Angerer V. Göschl, Vienna; Roeloffzen & Hubner, Amsterdam.

*Honourable mention.*—Rud. Schuster, Berlin.

Section B.—Amateurs.

*Highest award—diploma and silver-gilt medal.*—Lentz, Maastricht.

*Silver-gilt medal* (given by the Committee).—Bucquet, Paris.

*Silver-gilt medal* (given by the Haarlem Am. Photo. Club).—Motto "Voorwaarts," Baarn.

*Silver medal* (first prize).—Clement Williams, Halifax; Dr. Kühn, Innsbrück; A. Lunden, Antwerp; W. Toussaint, Amsterdam; F. P. Cembrano, Richmond.

*Bronze medal.*—A. Bakhuis, Olst; Jonkor van Oldenbarnwelt, Utrecht; A. Tagliaferro, Malta; John E. Austin, Maidstone; J. J. M. Guy de Coral, Amsterdam; Martin J. Harding, Shrewsbury; J. Court Cole, Oxford; Van Barnweldt Van Mattheua, Velp; L. Keuters, Antwerp; J. J. Kamp, Amsterdam.

*Honourable mention.*—Barou Marcy de Tiege, St. Trond; A. Alfarado, Paris; Haarlem Amateur Photographic Club (collection); L. J. Smit, Kinderdijk; J. C. Wolterbeek, Amsterdam; G. Peek, Amsterdam; A. W. Gottlieb, Shrewsbury; G. P. Voorwijk, Amsterdam.

Section C. (Manufacturers).

*Highest award—diploma of honour and silver-gilt medal.*—Loman and Co., Amsterdam.

*Silver medal.*—Carl Zeiss, Jena; W. Watson and Sons, London.

*Bronze medal.*—Meinard Van Os, Amsterdam; H. Muckenstein, Paris; B. J. Edwards and Co., London.

*Honourable mention.*—Anton N. Bouvy, Amsterdam.

## INCANDESCENT GAS-LIGHTS.

The application of electricity to purposes of illumination has for many years been talked and written about, and yet we are only just beginning to see it coming into common use. There are many reasons for this delay iu the adoption of the electric light which it is not necessary to refer to here, but this delay has had one good effect in stimulatiug those who are interested in gas illumination to improve upon old methods of burning the gas, by inventing uew contrivances which shall secure more perfect combustion, and therefore better light, at less expenditure of material. Among the improved contrivances so produced, a great deal of interest is attached to the burners known as incandescent, for they seem to be curiously similar both in principle and effect to the electric glow-lamps which bear the same uame. In the latter case, a thread of carbon is made iucandesceut by the resistance which it offers to the passage of the electric current, and in the former case the same result is brought about by interposing a network of refractory material iu the intensely heated flame of a Buuseu gas-burner.

The first lamp on this principle was Lewis's, who employed a mantle or network of fine platinum wire. This was effective so far as it went, but the metal employed gradually rose in price, from the extensive demand made for it by electrical apparatus makers, as well as by photographers, until it became obvious that its price must render it prohibitive. The next lamp which appeared was the La Clamond, which employed a mantle of magnesia; but this arrangement, although effective, required a constant supply of air under pressure, and the lamp, after having been exhibited iu this country, never came into practical use. Finally was brought forward the Welsbach incandescent lamp, in which the mantle employed is made of zirconium. This lamp was a great improvement on all those which preceded it, but it had certain faults which for a time prevented its wide adoption. These faults have now been remedied, and the lamp, which is in use in many public buildings iu Londou, is a pronounced success. As this form of lamp—which can be fitted at small expense to any existing gas fittings—is likely to be largely adopted by photographers on account of the actinic value of the light given by it, we took advantage of the invitation given us last week to visit the premises of the Incandescent Gas-Light Company, at Palmer Street, Westminster. Here we not only saw the lamps in operation, but were able to follow the manufacture of their various parts and belongings, from the raw material to the manufactured article.

As already iudicated, the foundation of the lamp is a Bunsen burner, which already is familiar enough to all who have anything to do with chemical pursuits; but this Bunsen burner is of special form, so as to secure the greatest heating power and a large flame. It is crowned with a dome made of fine steel wire, with an upright rod from its apex, about three inches long, to which the zirconium mautle is hung by a thread of asbestos. The whole is enclosed in an ordinary lamp chimney, or the flame cau be used as a naked one if required. It may be here mentioned that, in its original form, the mantle support of the Welsbach burner was outside the mantle, and that, as it held the heat after the lamp was extinguished, it led to the unequal expansion of the glass chimney, and frequent fractures were the natural result. Loss from this cause is now obviated without any compensating disadvantage by making the support of the mantle run up its centre like the stick of a partially closed umbrella. By the adoption of this simple device, supporting rod, mantle, and glass all cool down equally and regularly, and this is one of the most notable improvements which have been made.

The mautle is founded upou a cone of woven cotton made in a stocking machine, and cut off into leugths of the requisite size. This cotton is dipped into the solution charged with zirconium, aud is theu dried with the plaster-like compound coating every thread. The mantle is next subjected to heat, so that the origiual cotton is entirely burnt away, leaving a network of white zirconium oxide, which, after being tougheued by a bath of collodion, is ready for issue to users of incandescent lamps.

Photographers can afford to pay something extra for a white light by which their work can be doue during dark weather, but in the case before us there is an actual saving, the incandescent burners consumiug less gas than those in common use. It must also be mentioned that the quality of the gas in no way affects the result, inasmuch as the light comes not from the gas itself, which, when used in a Bunsen burner, is actually non-lumiuous, but from the white-heated mantle of zircouium.

Where ordinary house gas is not available the burners can be used in conjunctiou with the Helios gas machine, which is now employed in many country districts. This apparatus consists of a vessel containing benzoline, or some similar hydro-carbon, associated with which is a fan or blower by which atmospheric air is drawn through the volatile fluid, and is turned into an inflammable gas. A gallon of special oil used with this machine costs fourteenpence, and produces about 1,000 feet of gas.

But what we are specially interested in is the adaptation of the incandescent system to photographic purposes. Other things being equal, portraiture should be quite possible with a battery of these lamps and a liberal exposure. The Company have, indeed, arranged these lamps in groups for use in photographic studios. For copying purposes at night the incandesceut lamps are eminently adapted, not only because of the intensely white light afforded, but also because they are as simple in use as ordinary batswing burners. The light can also be adapted for use in a lantern for surgical purposes, and also in the optical lantern for projection of pictures and diagrams in the lecture hall. For the more general purpose of lighting photographic reception-rooms and offices, the incandescent system is obviously as well adapted as it is for domestic illumination.

## Patent Intelligence.

### Applications for Letters Patent.

### Specifications Published.

6,463. *April 28th,* 1890.—"Oxygen." E. Neave, 335, Pitt Street, Sydney, N.S.W.

Process of and apparatus for obtainiug oxygeu from the air, based ou the "property which is possessed by membranes of permitting the passage through them of denser gases more rapidly than comparatively rare gases." A separator composed of a cylinder of porous clay covered with thiu india-rubber, and having euds of india-rubber, while internally there are two carbon diaphragms, and the three chambers thereby formed are packed with porous caoutchouc. A pump withdraws gas through these chambers to purifiers charged with calcium hydrate, and thence to a suitable container.

*Porous caoutchouc.*—Caoutchouc is first dissolved in naphtha, the latter evaporated off, and the residue again dissolved in naphtha and oil of turpentine or oil of laveuder. On evaporating these latter, the caoutchouc is left in a porous or spougy state.

6,553. *April 29th,* 1890.—"Oxygen." A. Longsdon, 9, New Broad Street, London.—(F. Salomon, Essen, Germany.)

Relates to a process of preparing oxygen from atmospheric air, and consists iu heating to a red heat a mixture of lead monoxide (or other suitable metallic oxide, such as mauganese, or a body which is easily converted into the oxide by heat) and an alkaline earth, in a current of air, whereby the oxygen is absorbed, forming lead peroxide or a plumbate. When no more oxygen is absorbed the current of air is stopped, and the oxygen driven off from the mixture by passing a current of carbonic acid over the mixture. The material left in the retort thereby is a mixture of the monoxide and the alkaline earth carbouate, which is suitable for re-use immediately.

6,607. *April 30th,* 1890.—"Printiug Frames." F. Taylor, 16, St. Petersgate, Stockport, Cheshire.

The back and frame have bevelled edges to register with oue another. Spriugs by which the back is secured are pivoted or hinged at one end to the frame, and are secured at the other by a sliding staple or catch, the end of the spring being turned up to cugage with the catch. In a modification the catch is actuated by a spring. Also, the spring may be pivoted to the back and secured at both ends by the catch. The usual indicator, or index dial, on the face of the frame is provided with notches behiud the numerals, with which engages a projection on the pointer to prevent the latter being moved accidentally.

## Correspondence.

### THE PHOTOGRAPHIC EXHIBITION.

Sir,—I enclose copy of letter sent to-day to the secretary of the Photographic Society, and should be obliged if you would kindly publish it. Henry Vanderweyde.

182, *Regent Street, W., September 30th.*

"*To the Secretary of the Photographic Society of Great Britain.*

"Sir,—My attention has been called to an article in a leading London daily on the Pall Mall Exhibition, which states that 'The choice of the medal for the portrait section lay betweeu a charming group by Mr. Vanderweyde of the Couutess, &c., (giving titles), and a life-like portrait (giviug name) by Mr. Warneuke; ultimately it was awarded to the latter, as Mr. Vanderweyde's picture had been exhibited in London, and was, therefore, not entitled to enter into competition.'

"Now, Sir, as my picture was entered for competition, I hasten to correct the false impression which has doubtless beeu formed, especially after what occurred last year, by saying that the picture referred to has never before been publicly shown.

"It is possible that it has been confounded with one of two similar groups before exhibited, but quite distiuct, not only as to the posing of the heads and hauds, but also as to the relative positions of the ladies at the table, the lady Heleu having changed places with her *vis-a-vis* iu one, while in the other the ladies are represented as takiug tea, iustead of embroidering.

"As the imputation has been allowed to go forth to my discredit without euquiry or contradiction, I am compelled to ask you to lay this, my resignation as a member of the Society, before the couucil at their next meeting.—I am, Sir, yours very truly, Henry Vanderweyde."

### SPHERICAL ABERRATION.

Sir,—To those who *have* made a special study of photographic optics, I am content to leave unaltered all that I have contributed on this subject to the Photographic News, but I refer Mr. Debenham again to my letters in your issues of October 24th and November 7th, 1890.

Thomas R. Dallmeyer.

25, *Newman Street, London, W., October 6th.*

### GLASGOW EXHIBITION.

Sir,—We notice that in your review of the catalogue of the Glasgow Exhibition, you speak of the photogravure of Prof. Max Müller as the work of Messrs. Annan and Swan. The plate was made by us, and was from our own negative. It may interest you to know that all the illustrations in the catalogue, except the surface printiug blocks, were produced iu Glasgow. T. and R. Annan and Sons.

*Fine Art Galleries, 153, Sauchiehall Street, Glasgow, Oct. 7th.*

The Lantern Society.—At the next meeting, on October 12th, the slides going to America will be shown.

Action of Light on Silver Chloride.—Slips of microscopic cover glass coated with a thin layer of the chloride were exposed to direct sunlight for about four months, and weighed from time to time. The loss of chlorine varied from 0·0821 to 0·0929 gram per gram of silver chloride. Probably eveu then the decomposition was not complete. On digestion with dilute nitric acid, the product gave up a quautity of silver equivalent to the amouut of chlorine liberated; hence it would seem that the action of light merely separates the chlorine from the silver.—*American Chemical Journal.*

# Proceedings of Societies.

London and Provincial Photographic Association.

At the meetiug held on the 1st inst. Mr. J. Traill Taylor occupied the chair.

The Chairman read a letter from the Queen, which was considered to be very gratifying both to the member to whom it was addressed, and to the Society.

Mr. J. Stuart, of Glasgow, showed a large number of interiors and groups of large size taken with magnesium flash-lamp.

Mr. A. Haddon would like to remind Mr. Stuart that he had promised to show some results with a certain lens.

Mr. Stuart said that he had found the lens imperfect, and the results not worth showiug.

A large accession to the Society's library, presented by Mr. P. J. King, was received, and thanks awarded.

Mr. A. L. Henderson then gave his promised demonstration of a perfect method of emulsion making. The first point, he said, was that it was very important to have pure water, in illustration of which he gave several instances of non-success owing to impurity. He particularly cautioned against the use of rubber pipe other than the black kind, having known spots to arise from the sulphur adhering to the inner surface of white and eveu red rubber. He always used distilled water for making emulsion, and even then avoided that which was left at the bottom of the bottle, as it became impure by keeping. He also recommended that the first washing of the emulsion should be conducted with distilled water, aud said that it would be better to use distilled water all through. To make emulsion that should be free from green or red fog, he considered it esseutial that the gelatine should not be in contact with free silver, and this he brought about by converting the silver into carbonate to begin with. He theu prepared an emulsion by dissolving 120 grains of nitrate of silver iu 3 ounces of water, aud added 60 to 90 grains of dry carbonate of potash, also dissolved in 3 ounces of water. After allowing the precipitate to subside, part of the supernatant liquor was poured off, and the remainder with the carbouate of silver was poured into a solution containing 210 graius of gelatine and 90 grains of potassium bromide. The gelatiue was previously well washed and thoroughly drained, and melted with as little adherent water as possible. The solutions were mixed at a temperature of 150° Fahr., and when the bromide was formed, oue per cent. of potass. iodide was added, or more for subjects of great contrast; also in this case more gelatine. When set, it was broken up and washed in the usual way, aud on meltiug made about 15 ounces of emulsion. The rapidity would be about 16 on the seusitometer, but, by adding to 10 or 15 ounces of the finished emulsion, 2 grains of potass. nitrate, 1 grain potass. bromide, and ½ a grain of chrome alum, and keeping it at a temperature of about 80°, it gained very much iu speed, and in twenty-four hours would register the highest of the sensitometer numbers. For straining the emulsion before coating he used chamois leather, and washed the skin carefully with soap followed by alkali and plentiful rinsing. If canvas was used for breaking up the emulsion before washiug, either a fresh piece well washed from dressing should be used each time, or it should be very thoroughly freed from any bromide left from a previous straining. He did not use any alcohol, aud if pits arose, they could be prevented by the addition of carbonate of ammonia to the fiuished emulsiou—about ½ a grain to the ounce. If it was inteuded to use a centrifugal separator, only a small quantity of gelatine would be used in emulsifying —say 15 grains—and for great density (as iu the case of plates for the lantern or for liue work) he used citrate or acetate of silver in place of carbonate.

Mr. J. B. B. Wellington had not found the dust from rubber pipes cause spots. He had even squeezed out the milky substance from a new pipe and added it to the emulsion; also he had sprinkled in dry sulphur, and had not fouud spots to be caused thereby.

Mr. J. J. Barker pointed out the difference in the water from different supplies, and found that boiling made that which he used quite satisfactory.

Mr. A. Haddon said that the Society had originally been especially an emulsion society, and he was glad to have the subject revived, and trusted more experimental work would again be done by the members.

The Chairman proposed a vote of thanks to Mr. Henderson for his demonstration, which had created so much interest.

Mr. W. E. Debenham, in seconding the vote, hoped that the interest in emulsion making might be revived, and many more members might be induced to work at it occasionally, at all eveuts, instead of being strangers to that interesting part of photographic work.

The Rev. E. Healey and Mr. Maas were elected members of the society.

---

Croydon Camera Club.

The permanent rooms of this Society are now at 56, George Street, Croydou, instead of number 96 in the same street.

The first of the regular fortnightly meetings in the new rooms will be held on Monday, 12th October, when the winter session will be inaugurated by a discourse on "Flash-Light Photography," with demonstrations, by the Hon. Secretary, Mr. G. R. White.

---

Croydon Microscopical and Natural History Club (Photographic Section).

A meeting was held ou October 2ud, when the chairman, Mr. J. Weir Brown, read a brief paper, in which he met objections recently raised, and referred to articles which had appeared, with respect to the uranium toning of bromides, and gave the results of his later experiments. This paper will be communicated to the photographic press in due course.

Mr. W. Low Sarjeant exhibited a cardboard "double-back" for films, which weighed, when loaded, ouly 2½ ounces. He also mentioned that, iu a recent tour on Dartmouth, on opening a packet of films flashes of light were visible when he separated them. Query—Was it due to electrical discharge or phosphorescence? He feared that when he developed them they would be streaked.

Mr. E. Marriott then read a paper on the use of gelatino-chloride printiug-out papers. He gave details of printing, toning, fixing, mounting, &c.

Most members had found difficulties in mounting, and the merits of starch, india-rubber dissolved in wood-naphtha, gum-arabic prepared with methylated spirit, were advocated.

The next meeting, October 16th, will be a lantern night; members' slides—trial night.

---

Bath Photographic Society.

On the 30th ult. the Society, by permission of the Prior, was afforded au opportunity of visiting and photographing at the monastery of St. Gregory, Downside, near Chilcompton. The party reached the college gates about mid-day, wheu work was at once begun in earnest. This extensive pile of buildings, by no meaus completed, comprises a large priory church, monastery, and numerous other buildings, such as swimming baths, masters' resideuces, &c., and are excellent specimens of early English style. They are approached from Stratton-on-the-Fosse by a pleasant carriage road, and at almost auy point present a picture suitable for the camera. The noble proportions aud rich detail of the church were photographed by some twenty of the party.

This was the last excursion of the season, and, thanks to the glorious day and excellence of the subjects presented, formed a capital wind-up to the summer work of the Society.

---

Dundee and East of Scotland Photographic Association.

The first general meeting of the session was held in Lamb's Hotel, Duudee, on October 1st.

Mr. J. D. Cox, president, submitted the annual report, in which he stated that in the course of the past session thirty-two uew members had beeu enrolled, that being the greatest number admitted during any year. He said the want of premises of their own was a great drawback, and until they had club premises he feared the attendance would not increase very materially. He then intimated the results of a competition for landscape prints, in which sixteen sets had been forwarded. In the size 5 by 4 five sets had been given in, and the prizes had been awarded as follows:—1, Mr. D. Ireland; 2, Mr. D. Ireland; 3, Mr. J. R. Stewart. For half-plate and larger pictures there had been eleven competitors, and the result was as follows:—1, Mr. V. C. Baird; 2, Mr. V. C. Baird; 3, Mr. D. L. Honeyman.

Mr. Andrew Stewart then read a paper on "How our Members make their Lantern Slides," and, in the course of an interesting address, remarked that the tendency of the times seems all towards small cameras, and it would appear as if the hand-camera was to be the instrument of the future, for all the mechanical skill of the instrument-maker is now bent in the direction of perfecting the detective camera.

Mr. J. W. Munro exhibited a very ingenious hand-camera he had designed and made himself, of magazine pattern, and carrying three dozen quarter-plates; in point of size less than most magazine cameras carrying only one dozen plates, and having the advantages of being able to focus at will, and use lenses of different focal length, without in any way altering the general mechanism.

Richmond Camera Club.—On Friday, the 2nd inst., was held the first lantern night of the season, when slides by Messrs. Ardaseer, Cembrano, Davis, Arthur Hunter, and Lowry were shown.

Photographic Club.—October 14th, first lantern night of the season: October 21st, "The Theory of Development"; October 28th, smoking concert and exhibition of members' pictures.

Silver Chloride.—A layer of silver chloride, after exposure to light, consists, according to Mr. Guntz, of three superimposed layers—metallic silver, sub-chloride of silver, and unaltered chloride of silver. By "sub-chloride of silver" is meant the violet-red substance produced when the chloride is left exposed to the action of light for a considerable time—say for three or four hours. It is not yet quite certain whether this substance has the composition of a sub-chloride, or whether it is a mixture of chloride and of finely divided metallic silver.—*Monthly Magazine.*

The Czar and the Photographer.—The following is quoted in a daily journal from the *World*, a recently founded Berlin newspaper:— The Czar does not like having his photograph taken, especially when he has to stand alone in front of the camera or is subjected to the process unexpectedly or suddenly. A Danish photographer found this out two weeks ago. He had taken up his position on the road which leads from the castle to the station, near the Fernbane Hotel, in order, when the Czar took his usual morning walk to the station, to catch him, and to force him, in a sense, to give him a sitting. The Czar came, as luck would have it, quite alone, when suddenly to his left he heard the ominous click-click of the instrument. He immediately turned sharply round, as if the shadow of a danger had crossed his path, and saw ten paces off the black camera, which, being dazzled by the sun, he evidently did not at once recognise. "I stood here at the window," continued my informant, an old female servant of the royal family, "as I was living here, there being at the time no room in the castle, and I saw the whole scene. The Czar's face was whiter than my apron; the stick, which shortly before he had been carelessly waving in the air, fell from his grasp, and he trembled like a frightened fawn in face of a sudden fright. But then, as if by a sudden determination of will, he collected himself, and, as the photographer came forth from behind his box with a humble request, he gave him a look which made the young man tremble, and the words died on his lips. 'Jamais!' hissed the Czar between his teeth, picked up his stick, and hurried back to the castle, a group of children running to meet him. In their midst he most likely soon regained his composure. The photographer," the old woman concluded, "returned by the next train to Copenhagen. He was very near fainting, the poor fellow, and for half-an-hour nearly lost the power of speech, such an impression had the Czar's enraged looks and his imperious 'Jamais!' made upon him."

## Answers to Correspondents.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.

R. Mc. D.—*Convergent Perpendiculars.* You may have raised the rising front even to the full extent of the adjustment, but the fact remains that the lens was not raised enough in this particular instance to bring in the whole of the tower without tilting the camera, and yet the foreground shows that there was room for more elevation. Can you not draw out the screws on occasion, and get the sliding front to cover the aperture whilst you are at work? This can often be done without letting light into the camera, and in this way you would secure true perpendiculars and correct perspective.

E. B.—*Reducing Hard Negatives.* A good formula for a chromic reducer was published a fortnight ago in the News (page 670). The cupric bromide solution mentioned last week may contain 5 grains each of sulphate of copper crystals and bromide of potassium, with 20 to 30 grains of common salt dissolved in the ounce of water, but for the treatment of very dense negatives the proportions of copper salt and bromide may be doubled.

J. E. D.—*Novelty of Invention.* Yours is just one of those doubtful cases giving scope for difference of opinion regarding its novelty. The principle is not altogether new, but the method of carrying it out seems to be sufficiently removed from previously recorded plans to justify a patent being granted. You must not, however, rely upon the unsupported opinion of any one adviser; it might even be worth while showing the model and drawings to Mr. Moulton, Q.C., or Mr. Graham.

A. T. (Walton).—*Magnesium Chloride for Fixing.* If you look again at the table of solubilities you will find that chloride of calcium is stated to be equally efficient, and, being much cheaper, should first be tried as a solvent for chloride of silver. We shall be glad to hear the result of your experiments.

H. A. W.—*The New Iron Salt.* We have, of course, seen the letter to which you refer. It rests now with Mr. Greene to clear up the matter.

M. P.—*Single Fluid Developer.* A correspondent has kindly given us the formula of a single fluid developer, which is said to keep well in closely-stoppered bottles. It was described by Mr. A. Cowan at one of the meetings of the Photographic Club, and made as follows:—

| | |
|---|---|
| Eikonogen ... ... ... ... | 8 grains |
| Sulphite of soda ... ... ... | 64 ,, |
| Carbonate of lithia ... ... ... | 4 ,, |
| Water ... ... ... ... ... | 1 ounce |

Half the above strength is suitable for developing bromide paper prints. Here the lithia salt plays the part of an exceedingly mild alkali, and it might be well worth trying whether borax will not answer the same purpose.

A. J. S.—*The Year-Book.* Your promised help in the shape of a contribution will, no doubt, be very acceptable to the Editor, who desires to gather in his matter at as early a date as possible.

M. W.—*A Chemists' Benevolent Fund* has been started on the lines of our Photographers' Benevolent Association, and is intended to be applied in relieving necessitous cases within the chemical profession. More than £1,600 has been already promised or subscribed, many donations amounting to £50 and upwards, besides a long list of annual guineas.

Polytechnic Technical Schools (Photographic Department).—The tenth winter session of instruction in photography will commence on Tuesday, October 20th, at 8 p.m., when Mr. W. E. Debenham will give the introductory lecture, which will be explanatory of the general principles of photography, and, in addition, will include a paper on "Perspective in Relation to Photography."

# THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV. No. 1728.—*October* 16, 1891.

CONTENTS.

## A NEW LENS.

In our leading article last week "On Photographing Distant Objects," we pointed out how, by aid of a telescope, the camera might be made to yield comparatively large images of things far removed from it, and we incidentally called attention to an instrument contrived by M. Jaret to fit on to the hood of the ordinary lens, which had been designed for this class of work. We also drew attention to the circumstance that a certain picture published in a French journal which purported to be the offspring of this instrument, bore distinct evidence that it had been executed by a camera in close proximity to the object photographed, and not from a distant point of view as stated. Since the publication of our remarks, we have learnt that one of our foremost opticians, Mr. T. R. Dallmeyer, has for some little time been devoting himself to the production of a lens which shall be capable of giving large images of distant objects, without any extraordinary increase of the distance between lens and focussing screen.

The production of such an instrument would, by most men, be regarded as next to impossible, for, as every tyro knows, a large image means that the object represented must be as near the lens as possible, and that the camera must be lengthened out often to its fullest extent. But Mr. Dallmeyer has achieved this apparently impossible feat, and we have had an opportunity of examining the lens itself, and certain negatives which have been produced by its aid. Of the lens we are not at liberty to say more than that it is of large aperture, and that it consists of a double combination. But we need be under no reserve with regard to its capabilities, so far as they are at present known. Paradoxical as it seems to be, this lens will give a greatly magnified image of an object which is much farther away from it than is the lens from the focussing screen. This was demonstrated to us in the clearest manner. A lamp flame at a distance of about nine feet from the lens was focussed on the ground glass screen, while the lens was about two feet from that screen, and the resulting image was double the size of the original. These measurements do not profess to be exact, but they are approximately right. Or, to put it in another way, the photographer has now at his command a lens which needs a camera but two feet in length, but which will, under such conditions, give an image of the same size as if he were using a lens of one hundred inches focal length. In all previous attempts in this direction, it has been the custom to get a primary image and then to magnify it, but in the case before us the primary and greatly enlarged image is itself projected on the focussing screen.

As we pointed out last week, the photographer who attempts to employ a telescope with his camera finds himself restricted to the portrayal of inanimate things, for the simple reason that the exposure is so greatly prolonged by loss of light. With the new lens which Mr. Dallmeyer has constructed the loss of light is by no means excessive. In one picture which he showed us, which was taken with a long-extension camera held in the hand, is seen a rook just about to settle on a tree top. The distance from tree to camera was, we are told, one hundred yards, and the image of the bird, which is clearly defined, measures, roughly speaking, one inch from wing to wing. It is very clear that this new form of lens will open up possibilities to the photographer which before its introduction were denied to him. We have occasionally heard of a camera being carried by sportsmen whose delight it is to track wild beasts to their lair. One such picture, we remember, was exhibited not long ago. It represented a wounded tiger which its captor had photographed just after he had favoured it with a bullet. Another picture was shown us of a buffalo moving through the underwood, his horns being just visible above the high grass; but the image was so small that the picture had a close resemblance to those pictorial puzzles in which one is invited to "find" the leading incident. In that case the puzzle was to find the horns, so that the picture was after all a mere curiosity, as being probably the first photograph of a living buffalo which had ever been made. With the new lens, pictures of wild animals will be possible without going near enough to scare them away, and, perhaps we should add, without the risk of being scared by models who would certainly decline to "look pleasant." The naturalist will also find in this new photographic lens a means of recording the habits and movements of many creatures whose natural timidity forbids a near approach to their haunts.

We alluded last week to the great value which such an instrument would have in military operations, and now that it is demonstrated that distant images of large size can be secured with short exposures, there is no reason why the navy should not participate in its use. Pictures of passing ships and snap-shots at distant shores may often prove of value in strange waters, while those who delight in taking photographs of "white wings" need not go to sea for the purpose, but can fire away at them comfortably from the shore. It need hardly be said that, like the telescope, the field of the instrument is a restricted one, but this will by no means diminish its usefulness. It will probably supplant the telescope to a great extent among amateur users of that instrument; for it will be possible to see the images of objects on a screen, while, at the same time, those images may be made permanent. There is also some hope that the lens will help in the construction of a real "detective" camera. What we mean is that suspicious individuals can be photographed without any near approach to their persons, and from the cover of a house. We shall look forward to the promised publication of the means which Mr. Dallmeyer has adopted in the construction of this lens, which we think bids fair to be the most important contribution to the optical side of photography which has been presented for some time.

## ON THE INTENSIFICATION AND REDUCTION OF GELATINE NEGATIVES.*

BY ROLAND WHITING.

I suppose that every photographer has at some time or other found it necessary to reduce or intensify his negatives, so as to make them printable; or, at any rate, so as to cause them to yield better prints, and the best means of bringing about the desired result in the best possible manner has, no doubt, been a matter of difficulty. And necessarily so, for intensifying and reducing, even in the most experienced hands, are far from being certain processes. They require a considerable amount of care and watchfulness to make them result as they should do, and even then there may be effects brought about which are different to what were intended. As a rule, these processes are looked upon as nuisances, especially amongst professionals who have not much time to devote to them, and consequently the negatives requiring such treatment are put by until some time when they can be conveniently attended to. As soon as a lull in the general rush of business occurs, they are hurriedly despatched.

In the case of mercury intensifying, the negative is first plunged into water for a few minutes, and then into a solution of mercuric chloride, without having any regard to the perfect elimination of hypo. When the surface looks sufficiently white, the negative is slightly washed in water, and then immersed in a solution of ammonia until it is blackened all over; then, after a few moments' washing, it is stood up to dry. The result of such treatment most frequently is a yellow stain which nothing will remove, and so a negative is spoilt which might otherwise have been made to yield a good print.

If success is to be obtained in these processes, it is only to be got by care and attention; haste is fatal to it. I do not wish to imply that all are guilty of such neglect, but there is nevertheless a great deal of carelessness and trusting to chance with many who should know better. It is to these I most especially address the remarks contained in this paper.

I do not presume to be able to teach anything that is new or original, neither shall I introduce any formula to notice other than those that have appeared in the various photographic papers from time to time. I shall simply call to notice what is most required of an intensifier or reducer, and how far we can get it. I say how far we can get it; I ought rather to have said how little we can get it, for it is remarkable in these processes, as in most photographic things, we generally require a great deal more than we are ever likely to get; therefore, it is wise not to expect too much. Yet, nevertheless, this desire for the unattainable is by no means to be condemned, for it frequently causes us to stretch forth an effort which we should not otherwise do.

Every photographer, professional or amateur, should thoroughly understand the ins and outs of intensifying and reducing, as by their aid he has at his hand a means whereby he can give additional merit to his pictures, and can often save a negative which might otherwise be lost. For instance, where a plate has been over-exposed, it is very frequently a good plan to develop it until the detail is out, stopping development before it begins to fog, and making up its want of density by intensification. A better result is often obtained by so doing, if skilfully done, than if development had been continued in the usual way.

Sometimes, however, you have not the chance to stop development before the plate begins to fog, and so, you will say, such a treatment is then impossible; but even here I have before now grappled with the difficulty by first reducing the negative with ozone bleach, which reduces the thickness of the film, and then intensifying it again with mercury, the result being a more brilliant negative, owing to the fact that the chief of the half-tone or the fog lies on the surface of the film, whereas the denser parts penetrate to a greater depth; the bleach taking off the upper surface of the film and the half-tone upon it, leaves the darker portions to be strengthened by the intensifier.

Another plan of mine has been to varnish the negative all over except where the strong parts have been, as in the case of interiors, and then to reduce the dense portions with some suitable reducer so as to neutralise the contrast. This can be very effectually brought about where a window is too dense and the surroundings are in deep shadow. The varnish is applied very carefully with a brush, and the reduction effected with potash-ferricyanide. By this method I have even gone so far as to take out the background from a portrait negative, leaving the head upon a clear glass; but it requires very carefully doing.

Now, before we go on to formulæ, it is best that we

* Read before the North Middlesex Photographic Society.

should know what is the most that is required of an intensifier and a reducer. An ideal intensifier should fulfil these requirements: (1) It should intensify the high-lights more in proportion to the half-tones, such as would be necessary in an over-exposed plate where there is plenty of detail but not enough density; (2) it should intensify the half-tones more in proportion to the high-lights, as in the case of a negative slightly under-exposed, where the high-lights are about the right density, but the half-tone is weak; (3) it should intensify all parts in equal proportion, as in the case of a negative which is too weak generally. These same remarks apply with equal weight to the ideal reducer.

The ideal reducer should act in such a manner that (1) it should attack the high-lights more in proportion to the half-tones, as when a negative is under-exposed, and the high-lights are, consequently, too strong; this would be greatly assisted when the intensifier strengthens the half-tone more than the lights, and the two could be used consecutively; (2) it should reduce the half-tone more in proportion to the high-lights, so that an over-exposed negative could be thinned down in its half-tones to give the high-lights more value; (3) it should reduce the negative in equal proportions generally, so that a negative which is so thick that printing takes too long can be thinned down generally, and printing be thus facilitated. The permanency of the negative should not in any way be affected by the treatment. With regard to the permanency of negatives after treatment with any of the known reducing formulæ, I believe they are not affected in any way whatever, and that a negative which has been carefully reduced, and proper attention given to the washing, will stand as long as if it had not been reduced.

But this, unfortunately, cannot be said about all the intensifiers at present in use. The experience of many of you will no doubt bring to mind the fading of many a valuable negative which had been strengthened by intensification. Yet here, again, I believe the fault has been due more to insufficient care in washing than to the shortcomings of the intensifier. As for the relative value of an intensified negative, Captain Abney has proved, I believe, beyond the shadow of a doubt, that the half-tones are strengthened more in proportion to the high-lights, and, therefore, there is generally less detail in the higher lights of an intensified negative than in the same negative before the treatment. I myself have often noticed the want of detail which an intensified negative gives in the resulting print in the high-lights, to what had appeared in the same negative before strengthening. It should be said, however, that I had used the same formula as Captain Abney had used. The same rule may not be applicable to other formulæ.

Before reducing, and especially before intensifying, the plate must be entirely freed from all traces of the fixing agent. Want of attention to this rule is almost the only cause of stains, and is also a great cause of fading. To free the plate from hypo, nothing is better than placing it in a solution of hydrogen peroxide. The method of using it is as follows. The plate is first washed under the tap, and then is placed in the following solution:—

| | |
|---|---|
| Hydrogen peroxide ... ... ... | ½ drachm |
| Water ... ... ... ... ... | 2½ ounces |

In this it remains for a few minutes, and is again washed so as to free it from the peroxide. The plate can then be intensified or reduced in the usual way.

Another way of clearing the plate from hypo is also stated to be very effectual. An ounce of glacial acetic acid is added to four ounces of water. To this is added, little by little, one ounce of barium dioxide finely powdered. When this has dissolved, the plate is soaked in it for a few minutes and then slightly washed. For the efficacy of this method I am unable to express any opinion, as I have not yet tried it, though, as far as I can see, there is no reason why it should not be as good as the peroxide of hydrogen, which chemical forms part of its composition, and it is no doubt cheaper. Personally, I use nothing but a saturated solution of alum for ridding negatives from hypo, giving each negative half an hour's washing in several changes of water, and then placing it in the alum for about twenty minutes, afterwards letting the plate remain in running water for about ten minutes. Whilst I was writing these lines, I noticed in the *Photographic Review* that, according to Dr. Stolze, the alum bath should not be used until the fixing solution has been removed by washing, otherwise sulphur may be deposited on the film and cause fading. Certainly, I am aware that hyposulphite of sodium and alum decompose one another, but, as far as my own experience goes, I have never found any bad results to come from the method last described.

There is one more matter I should like to mention. There seems to be a difference of opinion existing as regards the best time to intensify a negative, some saying it is best to let the plate dry first, whilst others prefer to treat it before the film has lost its first moisture. As to the best time to intensify, if a negative partly dry and partly wet is used, where the film is wet it becomes denser than where it is dry. Therefore, to take advantage of this difference, it is best to let the plate dry if it is not required to strengthen it to the fullest extent, and to treat it before it becomes dry when the greatest intensity is required. The cause of this is owing to the difference in the porosity of the gelatine film before and after drying. When a plate has been exposed and developed, it contains a certain amount of unreduced silver bromide surrounded with gelatine, which is dissolved out from the gelatine by the fixing agent. When this is fixed out, it being a solid substance, it naturally leaves a number of pores, which finally become filled with water. When the plate is placed in the intensifying solution these pores rapidly become filled by it by exosmose action. For this reason the intensifier has greater action on the silver than if the plate was dried; first, because the water evaporating out of the film allows the pores to become closed up, and, as they do not open again to the same extent on being placed in water the second time, the gelatine acts, to a certain degree, as a barrier to the action of the intensifier.

*(To be continued.)*

To Repair Broken Negatives.—Place the negative, gelatine side down, on a plate rather larger than the negative. Coat the edges of the fragments with warm Canada balsam; join them together, using strong pressure. Remove the excess of balsam, then cover the negative with another plate exactly the same size, and previously coated on one side with this varnish:

| | |
|---|---|
| Sandarac ... ... ... ... | 3 grammes |
| Mastic in tears ... ... ... | 3 ,, |
| Sulphuric ether ... ... ... | 50 ,, |
| Benzole (pure) ... ... ... | 25 ,, |

Lift together the three plates, turn them over, remove the large one that has served as a support, scrape off from the gelatine side the balsam that may have exuded, then surround the two plates with strips of gummed paper. Heat slightly the fragments before joining them together. This process will yield a print upon which no trace of breaking is to be seen.—*L'Amateur Photographe.*

## THE COLLODIO-ALBUMEN PROCESSES.

BY P. C. DUCHOCHOIS.

The first collodio-albumen process was devised by Taupenot in the hope of obtaining a more reliable and sensitive dry photo-film than those then in use (1855). Originally it consisted in coating a plate with a collodion simply iodised; then, after sensitising and a good washing, to eliminate the silver nitrate in excess with a solution of albumen, or better, of fermented albumen also iodised with one per cent. of potassium iodide, whereby the silver iodide held in the collodion film being rendered insensitive to light, or nearly so, the plate could be kept for a very long time. To excite it, it sufficed to dip for a few seconds in a bath of aceto-nitrate of silver, then to wash off the excess of this salt, when, after drying, the plate was ready for exposure. As usual, the development was effected by gallic acid solution, to which was added a little of the sensitising silver bath. This collodio-albumen film is no more sensitive than the albumen film when both hold the same silver salt.

Here the writer cannot refrain to remark that it is really very strange that, having as an example the Daguerreotype process, showing that the sensitiveness of the photo-film is ten-fold exalted by silver bromide conjointly with the iodide, the inventors of all the photographic processes—calotype, albumen, collodion—prepared the sensitive film without this salt, and that most of the first photographers, following their original directions, and on the authority of the best writers—amongst them the author of "Photographic Chemistry"—for a long time adhered to the simply iodised preparations.

How many wrong statements which led the beginners astray were published in those early days of photography by persons who seem never to have experimented with the processes they spoke about! Has it not been said that Ferrier and Soulier albumenised the plates *in puris naturalibus* to avoid dust? And on this queer saying how many amateurs and, perhaps, professional photographers were deterred from working the best-known diapositive process? Dust is no more annoying in preparing plates with albumen than with a gelatino-silver bromide emulsion. It suffices to sweep the operating (dark) room with wetted sand, and to copiously sprinkle it, when in half an hour or one hour the room will be free from dust swimming in the air; and, as the albumenising is done by white light, any particle of dust which accidentally may fall on the film can be seen and removed before equalising the film or placing the plate in the drying box.

The improved Taupenot process—that is, with an alkaline bromide added both to the iodised collodion and albumen—was a favourite among French photographers, although complicated by the preparation of the double film, until Madame Lebreton suggested the use of plain instead of iodised albumen, and to wash the excess off. The albumen is consequently employed as a preservative, the collodion photo-film remaining sensitive to light. This process gave rise to many improvements, amongst which are those of Fothergill, Maxwell Lyte, Pestcher, Mann, and Sebastian Davis, who published, in 1878, a process which we shall describe. It yields good and brilliant negatives, and can advantageously be employed to obtain diapositives for the magic lantern, &c.

The process we have now to describe is a true albumen process, in which plain collodion serves as a support for the albumen film. It is not an improvement—far from it—the preparation of the plate being complicated by the previous collodionising, &c., and the double film being liable to produce certain defects.

This process, I think, I have been the first photographer to devise. I was at that time (1857) in Utica, giving lessons in photography to Mr. D. D. T. Davie. He wanted to learn the albumen process in order to photograph the beautiful falls of the Black River, six in number, occupying at intervals a picturesque ravine, about two miles long, near the village of Trenton Falls, N.Y.; and from the negatives to make transparencies for the stereoscope. Not having a drying box at hand, it occurred to me to prepare the plate with a thin film of plain collodion, and, after immersing it in water until greasiness had disappeared, to coat it with bromo-iodised albumen, &c. I succeeded well, but on many plates the film blistered badly and slipped out. The remedy was, of course, apparent. It sufficed to edge the plate, and to use a porous collodion.

The pyroxyline, which always has given me excellent results in the wet collodion process as well as in the preparation of dry plates, both by the bath or emulsion process, and which I recommend for the process in question, is obtained by the formula following:—

| | |
|---|---|
| Sulphuric acid, commercial, 66° Baumé ... | 5 pints |
| Nitric acid, commercial, 41° Baumé ... | 4 ,, |

Temperature, 140° to 145° Fahr.
Time, from ten to twelve minutes.
Cotton, as much as the solution will cover well.

The pyroxyline prepared by this formula can be dissolved to the extent of more than 8 grains to the ounce of alcoholic ether (1 : 1), giving a structureless, porous film, specially well adapted to hold a great proportion of silver bromide if employed for emulsion, which is indeed a great desideratum when the image is developed by the alkaline method, since the intensity depends on the layer of reduced metallic silver, which itself depends on the thickness of the silver haloid coating. For the albumen process presently described, a collodion prepared with 1 part of pyroxyline for 100 parts of alcoholised ether answers quite well.

If one objects to the preparation of the pyroxyline, we recommend the photographic cotton manufactured by Charles Cooper & Co., or, in lieu, an old coloured collodion, the iodide not interfering with the results, for it is washed off when the plate is immersed in water to eliminate the ether and alcohol.

The best protection against blisters, &c., is an albumen substratum. It is prepared by dissolving the white of one egg in a pint of water, adding one or two drams of aqueous ammonia, and filtering through paper.

The *modus operandi* of the process is as follows. The glass plate is placed in a very strong solution of washing soda for an hour, then rubbed under the tap with a stiff brush, then well rinsed, drained, and, while wet, twice flowed over with the substratum, and lastly, placed on a rack to dry spontaneously. The plate is now coated with collodion, and, as soon as the film is *set*, immersed in water until the liquid flows evenly over it. It is then allowed to drain, and as soon as the collodion film is surface dry, but still damp, it is coated twice with the bromo-iodised albumen, and left to dry on a rack in a place quite free from dust.

Sensitised, the plate is washed. Excessive washing considerably impairs the sensitiveness. It does not much increase the keeping qualities of the film, for albumen necessarily forms with silver nitrate an insoluble, not well defined compound, termed silver albuminate, which, like all the organic salts sensitive to light, progressively undergoes alteration even in the dark, unless a preservative compounded with an alkaline bromide be applied on the film. As to the development, no good results should be expected by the alkaline development, by reason of the thin layer of the silver bromo-iodide.

This and the pure albumen processes are now specially employed for diapositives. The process due to Mr. Sebastian Davis can also be employed for negatives. It gives very fine results, but it is far from being as sensitive as the modern gelatine process.

Coat the plate—previously prepared with a substratum—with a good bromised collodion, sensitise, and wash in distilled or rain water until greasiness has disappeared. Rinse then with fresh water, and, having flowed over the preservative several times, wash the film copiously and allow it to dry.

Preservative A.

| | | |
|---|---|---|
| Silver nitrate ... ... ... ... | 6 | grains |
| Distilled water ... ... ... ... | 1 | ounce |

B.

| | | |
|---|---|---|
| Clear albumen ... ... ... ... | 3 | ounces |
| Raisin extract ... ... ... ... | 3 | ,, |
| Aqueous ammonia ... ... ... | 90 | minims |
| Ammonium chloride ... ... ... | 45 | grains |
| Distilled water ... ... ... ... | 3 | ounces |

Mix A to B.

The raisin extract is prepared by crushing or tearing open one ounce of raisins and pouring over five ounces of boiling water, allowing the whole to become cold before filtering.

The development is effected by the alkaline method after wetting the film. When the picture is sufficiently visible, and the details well out, intensity is obtained by continuing the development with acidified pyrogallol and silver nitrate in the usual manner.—*Anthony's Bulletin.*

North Middlesex Photographic Society.—On October 12th (Mr. J. C. S. Mummery in the chair), Mr. Roland Whiting delivered an interesting lecture on "Intensification and Reduction of Gelatine Negatives" (see page 714).

Photographic Society of Great Britain.—The lantern arrangements at the Exhibition are as follows:—October 17th, *Amateur Photographer* competition lantern slides; October 21st, slides by Mr. A. R. Dresser, illustrative of a tour through Brittany; October 22nd, slides by Mr. C. Essenhigh Corke, illustrative of Knowle House.

The Photography Fad Increases.—Summer hotels in picturesque regions—and who, by the way, ever knew of one in any region not, at least, alleged picturesque?—are fitting up dark rooms for the use of the patrons in developing negative plates. At Bar Harbour and in the Catskills the camera epidemic seems to have taken on the most violent phase—all of the women go about with stained fingers, and the snap of the kodak is perpetual. In this industry, like most others of the amateur sort, there are few who excel, and a great majority who merely enjoy. It is remarkable, however, how largely the amateur photography element has entered into the ethics of social life. At suburban dinners and luncheons now, if the hostess is skilled, it is quite common to have the pretty nooks of the place or house transferred, *à la* kodak, to the souvenir card, an especially happy thought being that of the bride who, to a small dinner in her new home of her intimates, contrived that each pictured sketch of a cosy corner should contain the wedding gift of the one for whom it was designed. Another young woman, a bride in prospective, now travelling abroad, snaps her kodak upon the view from her window at every fresh stopping place, using the print as a letterhead for the loving epistles frequently indicted to her *fiancée* in this country. "And thus," she says devotedly, "Arthur knows my exact environments."—*Pittsburgh Dispatch.*

## SUICIDE OF GENERAL BOULANGER.

In one of our "Notes" last week we referred to a report that a Brussels photographer had taken a picture of General Boulanger's body immediately after his suicide. The picture has since been published in *Le Petit Journal*, and a correspondent at Paris has very kindly forwarded us a copy. We here reproduce the sketch in *fac simile*, with a free translation of the descriptive matter published with it.

"Many fantastic pictures representing General Boulanger after his suicide have been, and will doubtless be, published in many journals. The drawing which we give to-day is, however, the authentic reproduction of the scene. It was obtained, moreover, by the most extraordinary chance. At the same time as the General passed the gate of the cemetery, a photographer who had been commissioned to take a picture of a particular tomb entered the place. The

artist was already busy with his work, his apparatus was all in order, when a report was heard. The photographer—who, on his entrance, had recognised General Boulanger—instinctively took in what had happened. He ran towards the tomb of Madame de Bonnemain, only waited long enough to ascertain that General Boulanger was really dead, and, utilising his apparatus, he took a negative of the scene.

"The first print has been bought by the Prince de Chimay, Minister of Foreign Affairs for Belgium. The two following have been acquired by the *Figaro* and *Le Petit Journal*; it is one of these proofs that we reproduce. We here see General Boulanger fallen at the foot of the truncated column which decorates the monument of Madame de Bonnemain. He holds in his hand the revolver with which he has just killed himself. Photography has never, perhaps, before played so immediate, instantaneous, and startling a part."

## PHOTOGRAPHIC MAGNITUDES OF STARS.

THE character of the image of a star photographed on a sensitised film; the relation between the intensity of the light photographed, and the blackened disk produced; the influence of the time of exposure on the image—are questions now receiving much attention. For this reason, Dr. Scheiner's contribution to the subject, embracing, as it does, the latest results of the Potsdam Observatory, is especially welcome; but these results will not be accepted without great reserve, contravening, as they do, a theory, or at least an assertion, that has been very generally accepted, viz., that increasing the intensity of light is exactly equivalent to increasing the time of photographic exposure. A consequence of such a law would be that an additional magnitude would be impressed on the film by increasing the time of exposure two and a half times the length.

Such a law cannot be rigorously exact, and its stoutest supporters have been careful to confine its application "within limits." But Dr. Scheiner's contention is that, owing to the complex character of the disk produced on the film, such a principle is a very unsafe guide, either as a rule for the determination of the feeblest magnitude impressed on the negative, or as offering a satisfactory explanation of the growth of the diameter or area.

In the first place, there is evidence of want of uniformity of actinic action throughout the whole extent of the stellar disk. A mean intensity ($i$) may be assumed at a certain distance ($r$) from the centre of the image, where the intensity is I. The centre will not be a geometrical point, but, owing to atmospheric and other disturbances, will occupy a small area of radius ($\rho$). The intensity ($i$) at distance ($r$) will depend materially on the increase of the area ($\rho$), which may be represented by $\psi(\rho)$. Consequently, the simplest expresssion for $i = I\psi(\rho)e^{ar}$, where $a$ is the coefficient of absorption of the sensitive film. On comparing two stellar disks, formed on the same emulsion, and treated by the same developer, this expression becomes—

$$\frac{t_0}{t_1} = \frac{I_1\ \psi(\rho_1)}{I_0\ \psi(\rho_0)} e^{a(r_1 - r_o)},$$

and, if the disks be on the same plate, $\rho_1 = \rho_0$ and $t_1 = t_0$, so that the formula can be simplified to—

$$a(r_0 - r_1) = \log. \frac{I^1}{I_0} = \frac{0 \cdot 4}{\text{mod.}} (m_1 - m_0)$$

In order to derive the relation between diameters and exposure, put $I_0 = I_1$, and then—

$$\log. \frac{t_0}{t_1} = a(r_1 - r_0).$$

It is not likely that such an expression has any other value than to serve as a convenient formula for interpolation. The variable character of $a$ under different conditions, but always depending on the time of exposure, is shown by the following table:—

| Exposure. m. s. | | Instrument. | $a$. | | Instrument. | $a$. |
|---|---|---|---|---|---|---|
| 1 0 | ... | Reflector | 4·99 | ... | 5-in. refractor | 4·12 |
| 2 0 | ... | ,, | 4·57 | ... | ,, | 5·09 |
| 4 0 | ... | ,, | 4·67 | ... | ,, | 5·47 |
| 8 0 | ... | ,, | 4·89 | ... | ,, | 5·89 |
| 16 0 | ... | ,, | 5·39 | ... | ,, | 7·51 |
| 0 24 | ... | 13-in. refractor | 3·18 | ... | 13-in. refractor | 2·67 |
| 1 0 | ... | ,, | 3·16 | ... | ,, | 2·20 |
| 2 30 | ... | ,, | 3·33 | ... | ,, | 2·48 |
| 6 15 | ... | ,, | 3·33 | ... | ,, | 3·00 |
| 15 38 | ... | ,, | 4·48 | ... | ,, | — |

Another well-known formula in which magnitude is made to depend on diameter is $m = a - b \log. D$, and in this case $b$ is shown, notwithstanding Dr. Charlier's results to the contrary, to be a function of the time of exposure. The results are as follows:—

| Time of exposure. h. m. | | $b$ Charlier. | | Time of exposure. m. s. | | $b$ Scheiner. |
|---|---|---|---|---|---|---|
| 0 13 | ... | 6·719 | ... | 0 24 | ... | 5·17 |
| 1 30 | ... | 6·779 | ... | 1 0 | ... | 6·35 |
| 2 0 | ... | 6·683 | ... | 2 30 | ... | 7·06 |
| 3 0 | ... | 6·814 | ... | 6 15 | ... | 8·08 |

The disagreement is conspicuous, but the explanation offered by Dr. Scheiner is scarcely satisfactory. He would ascribe the constancy in the value of $b$, found by Dr. Charlier, to the fact that in his experiments there is always a large absolute value of the time coefficient. It will, however, be observed that the ratio between Dr. Charlier's extreme exposures is not greatly different from that which obtains in Dr. Scheiner's experiments.

If it be admitted that the product of intensity by the time is *not* a constant quantity, it becomes a matter of great practical importance to determine what is gained on a photographic plate by prolonged exposure. This question forms the real investigation of Dr. Scheiner's two papers, and though some of his results may be questioned, yet the general issue is so grave and disquieting that it may not be utterly ignored. Passing over the details of his method of examination, and the precautions taken to ensure accurate results, for which the reputation of the Potsdam Observatory is a sufficient guarantee, Dr. Scheiner presents the following table, in which is exhibited the faintest magnitude which, under certain varied circumstances, can be detected on a photographic plate:—

| Time of exposure. m. s. | | Faintest Magnitude. Plate I. | | Plate II. | | Plate III. | | Plate IV. |
|---|---|---|---|---|---|---|---|---|
| 0 24 | ... | 9·0 | ... | 6·4 | ... | 7·7 | ... | 8·2 |
| 1 0 | ... | 9·4 | ... | 7·25 | ... | 8·3 | ... | 8·75 |
| 2 30 | ... | 9·9 | ... | 7·7 | ... | 8·55 | ... | 9·3 |
| 6 15 | ... | 10·6 | ... | 8·45 | ... | 9·3 | ... | 9·65 |
| 15 38 | ... | — | ... | 8·85 | ... | 9·7 | ... | — |

It will be noticed that, while each successive exposure is 2·5 that of the preceding, the corresponding gain in light is considerably less than one magnitude. From each of the four plates the gain is as follows:—

| | | | Gain in mag. |
|---|---|---|---|
| Plate | I. | ... | 0·53 |
| ,, | II. | ... | 0·61 |
| ,, | III. | ... | 0·50 |
| ,, | IV. | ... | 0.48 |

The mean is 0·53—that is to say, instead of one magnitude being gained by continued exposure through each successive interval, the actual gain is only half a magnitude. The exception that might be taken to these experiments is, that the detection of the feeblest stars on a plate is a matter of doubt and great practical difficulty. Dr. Scheiner has, however, availed himself of a second test by counting the stars on a plate after various exposures. With this view two plates were taken of the region round $\epsilon$ Orionis, one with an exposure of one hour, the other with eight hours' exposure. Therefore, if 2·5 times the exposure produced stars a magnitude fainter, there ought to be a gain of more than two magnitudes on the second plate, and it may be assumed that the number of stars impressed would follow the known law. On the one-hour plate were found 1,174 stars, on the eight-hour 5,689.

There ought to have been on the long-exposed plate over 10,000 stars, so that roughly speaking only one-half of the stars given by the law were photographed. Further, Argelander has catalogued within this area 125 stars, and therefore it might have been anticipated, from the law of increase, that some 10,000 stars would have been visible, on the one-hour plate.

This margin is too great to be readily explained away. Of course, there is the same difficulty in perceiving the minute dots that represent the faintest stars as in the former case, and further, it is possible that the law of average increase of the number of stars did not hold in this particular part of the sky. It is not to be expected that a law which applies with more or less accuracy, *on the average*, to the whole of the sky, is necessarily fulfilled on any small portion, such as the ten-thousandth part. If the stars are not in the heavens, they cannot be photographed. Evidently, it would be unlikely that on every thousandth part of *that* plate would be found the thousandth part of the total number of stars impressed.

But allowing for errors of exaggeration and observation, the result is very interesting, and not a little alarming, as implying that photography is not so powerful an engine as was at first anticipated, and that, to accomplish the full hope of all that was expected of it, longer exposure and consequently a greater expenditure of time will be needed. Dr. Scheiner gives a little table, which shows that if a star of the 9·5 mag. be registered in twenty-four seconds, then in 190 minutes a star of the 16·5 mag. will be photographed, supposing a whole magnitude to be gained by successively multiplying the exposure by 2·5. But if the gain be only 0·5 in this interval, then the faintest star impressed will be only 13·0 mag., even after this long exposure, If 0·6 of a mag. be the rate of increase, then the 13·6 mag. will be seen; if 0·7, then 14·4 mag. The truth will probably be found near this latter limit.—*Nature.*

## HELIOCHROMY.

BY DR. ED. LIESEGANG.

The sceptical belief in the solution of the problem of heliochromy seems to increase more and more. Niepce, Becquerel, Poitevin, and others were unable to satisfactorily fix their heliochromes. Veress has also failed so far, although his experiments in that direction have not yet ceased. Lippmann succeeded in fixing the results obtained by inferential colours completely, as the plates were sensitive for the different light waves. It is questionable whether this method has any advantage over chromocollotypy.

Dr. R. Kopp, in Münster (canton Luzern, Switzerland), believes that he has succeeded in uniting the advantages of the chemical and physical methods by a new process, which he has been three years in perfecting. He claims to have succeeded in impressing all colours on a single film, with short exposure and permanency of the product. The following extracts are from his direct communication in relation to enclosed samples:—

1. All the colours and colour shades, including white and black, are reproduced by true heliochromic principles, therefore are the result of direct photography.

2. The time of exposure, in contrast to previous experiments, is greatly lessened, and varies with direct sunlight from thirty to fifty seconds; in diffused light the time is naturally lengthened.

3. The fixing is successful, but in a long exposure to direct sunlight the image suffers somewhat.

The absolutely perfect fixation in my process is unquestionable, and it will not be long before I send you a specimen which will withstand the brightest sunlight.

Dr. Liesegang states that the four specimens sent by M. Kopp were copies of transparencies and glass pictures on paper. Red, violet, yellow, and green were well represented. The experimenter adds: "You must not say that the reds or blues here and there are not good. This is not my fault, as you well know. It is exceedingly difficult to obtain colours equal to spectrum colours in copying glass paintings, paper pictures, or stained glass, as they are not pure, but mixed colours, which will not reproduce as they appear to the eye, but as they really are optically."

It is always requisite that the ground should be a pure white. Becquerel obtained a pure white in his heliochromes on silver plates. According to the theory of Niepce, this must result when the argentic salt is formed of chlorides which whiten under the flame. Later he obtained the same result by coating the image with chloride of lead. Lacan mentions a "dazzling white" in his heliochromes. Poitevin makes no mention of white in his paper proofs. Simpson's were unsatisfactory. In Veress's samples the ground was yellow-brown. This atavism in Kopp's process is nevertheless significant.

Concerning the time of exposure, M. Kopp continues: "The time of exposure, as before noted, is a very short one. During July, on a clear, hot day, I copied a picture in twenty seconds in the direct noonday sun; the whites were complete in ten seconds. I further believe that I shall be able to increase the sensibility of the emulsion so as to be able to produce pictures in the camera with a relatively short exposure. The weather was unsuitable for camera experiments; yet I obtained results, thanks to the extreme sensibility, which remove all doubt as to a successful result in the near future. I have obtained the greens and yellows of the meadows and trees entirely true to nature. I resolved not to send out any proof of camera work until I have arrived at a certain degree of perfection, else I should have included a specimen."

We will but remark that Niepce obtained views in the camera in fifteen to thirty seconds. Saint-Florent got the same results on paper in fifteen to sixty seconds. Veress claims one and a-half hours for a contact print.

M. Kopp continues: "That the fixing of the enclosed prints is permanent may be judged from the fact that they have been handled and exposed to all sorts of light. It requires a strong light and long action to destroy the prints."

For the present we cannot agree as to the permanency, as in one sample, half of which was exposed to the sun, the white ground soon changed to violet. The other colours, green and yellow, remained unchanged. M. Kopp promises in the near future to send a proof which will stand the requisite test. The production of the pictures, which differs materially from any former process, M. Kopp does not wish to publish at present. As the experiments continue, complete permanency will, without doubt, soon be achieved.—*Photo. Archiv.*

Photographic Club.—Subject for October 21st, "The Theory of Development"; 28th, smoking concert and exhibition of members' pictures.

## Notes.

The Editor begs to thank the numerous friends who have sent him their valuable contributions to the forthcoming Year-Book of Photography for 1892. He also takes this opportunity of acknowledging many kind promises to send. As the matter in hand is now being made up into pages, he will be still farther obliged if those who have promised contributions will send them in quickly. In asking this favour, he is mindful that last year some of the articles arrived too late for insertion, and others had to be printed in such haste that there was no time to submit proofs to authors.

We reproduce this week a picture to which brief reference was made in our last issue. It appeared originally in a French paper, and is said to have been taken immediately after the suicide of General Boulanger. The picture is, we think, open to some doubt. In the first place, the small crowd which quickly assembled directly the report of the pistol was heard would hardly stand aside while the camera was adjusted. Their attention would naturally be concentrated upon the body of the unfortunate man before them, and they would be busied in raising him up and ascertaining whether life was extinct. In the second place, it would be an extremely easy thing, after the body had been removed, to place a living man in the position which it had occupied. The want of likeness of the living man to the dead one need present no difficulty if the face were hidden, as in the picture under discussion.

A new and charming method of book illustration is indicated and demonstrated in an article which appears in the October number of the *Bulletin du Photo Club de Paris.* The pictures are collotypes of small dimensions; but, instead of being printed on special paper separate from the text, they are interspersed with the letterpress, giving the pages a very attractive effect. In this case the collotype printer has done his work first, leaving to the ordinary compositor the task of filling up the blank spaces left. The little pictures are, in this case, very pretty in themselves. They are photographs from life, and represent a small child dragging about, playing with, and otherwise maltreating a couple of St. Bernard pups. This, of course, cannot be a very cheap method of book illustration; but, for certain purposes, when expense need not be considered, it is, perhaps, the best that could be devised.

Has the Zoological Society a photographic establishment in the Regent's Park Gardens? We are afraid not, but that it has to depend upon outside efforts for its photographs. Many fine collections are extant, notably those of Mr. Frank Haes, Mr. Dixon, and Major Nott; but it is evident that the work of these gentlemen can only be done at intervals. A photographic staff attached to the Gardens would have constant opportunities of studying the animals, and of recording peculiarities, and would thus render a great service to zoology. As a commercial speculation, a photographic establishment should pay; hosts of visitors would be glad to preserve mementoes of the animals if the prices were moderate.

Photographers troubled with customers who are not very ready in paying their bills might take a hint from Russia. According to a society journal, Russian photographers, when they can't get a settlement from their sitters, hang the portraits of the latter upside down. It is to be presumed that the significance of this is understood by the public, or it would have no effect. An Odessa paper has entered a protest against the practice so far as children are concerned; it does not think that the sins of the fathers should be visited upon their offspring.

The pastel portrait trick, which was some time ago exposed in these columns, is still flourishing. Apparently, dupes are plentiful. The swindle has, it seems, a Yankee origin, and the nuisance is carried on to such an extent in America that the Government has undertaken the task of stamping it out, the Public Prosecutor proceeding against the managers, and the post office refusing to cash their money orders. It is to be regretted that newspapers over here insert the advertisements of the gang.

Although photographic fashion plates have not succeeded, foreign *modistes* make use of the photographs of their customers. The death of the Grand Duchess Alexandra of Russia, for whom three months' mourning has been ordered, has suddenly made the Paris dressmakers exceptionally busy, one firm in the Rue de Rivoli receiving an order for 214 dresses for the Imperial family. We are not told how the dressmakers get over the difficulty of fitting without seeing the wearers, but it is interesting to know that photography renders some assistance in giving views of the personages who were to be dressed.

A newspaper paragraph describing the presentation of a portrait of the late Mr. Bradlaugh painted by Mr. Walter Sickert for the hall of the Manchester Secular Society is rather puzzling. We are told that Mr. Sickert painted the head from a photograph by Mr. Vanderweyde, but the clothes are those which Mr. Bradlaugh actually wore. Are we to infer from this that when Mr. Vanderweyde photographed Mr. Bradlaugh the latter did not wear the clothes which he actually wore?

The photographic profession will be much exercised in its mind if the rumour be true that the Queen now refuses altogether to be photographed. The story is that Her Majesty was completely satisfied with the portraits taken of her in the jubilee year, and that she thinks these cannot be improved. The Queen and the Royal family have been such good friends to photography and photographers that we doubt the truth of all this. At the same time, it is quite likely she may object to be the subject of a snap-shot. It seems that one of the gentlemen in waiting had the presumption to present his camera as she was passing, and, though Her Majesty afterwards asked for a proof and laughed at the caricature, it was understood that the act must not be repeated. Probably this is the foundation for the rumour referred to.

Mr. Garrett P. Serviss, in an article in the *New York Popular Science Monthly*, deals with the probable longevity of the sun, observing that the question whether it is still approaching the climax of its radiations or has passed that point and is descending the scale, depends, so far as our knowledge concerns, upon the revelations of the spectroscope assisted by photography. The conclusion Mr. Serviss comes to is, that there is every reason to believe the sun will long continue in its present condition, and that astronomers a million years hence may still be found studying the sun, though it would not be safe to assume that any astronomers will be left upon the earth five million years hence.

## ARCTIC PHOTOGRAPHS.

BY JAMES MEW.

WHEN John Davis, of Sandridge, some three centuries ago, spoke of Greenland as a "Land very high and full of mightie mountaines, all covered with snowe, and no viewe of wood, grasse, or earth to be scene, with a lothsome shore running a league into the sea, and beset with ice, of which the irksome noyse was such that it bred strange conceites among us," he gave a fairly vivid representation of one of those scenes of awful solitude in a region which the photographs taken during the Arctic Expedition in 1878, and presented to the British and Kensington Museums, and three hundred views made by Sergeant Rice in 1881-4, under the command of Lieutenant Greely in his "attainment of the farthest north," have rendered generally familiar to the photographic world. But the language of John Davis, mariner, though graphic and full of energy, cannot compete with the system promoted or called into being by Daguerre, in presenting an exact conception of those long miles of palœocrystic ice-floes which have taken years upon years for their formation; of those uneven, irregular hummocks, rising like hills above their frozen plains; of the rubble or loose detritus which abounds on the Arctic highway; and of the glittering bergs of all conceivable varieties of form, cubical, with regular lines of cleavage, and apparent stratified structure, conical, pyramidal, amorphous, of which photography has furnished so many illustrations. The "Musitians" carried by the *Sunshine*, the good ship of John Davis, were but a bad substitute for a photographic kit, and the "white bears of monstrous bigness supposed to be goats or wolves" at Totnes rode under Mount Raleigh, are not so clearly presented to us as the animal "photographed by Sergeant Rice," as Mr. Greely puts it in somewhat strange connection, and "skinned by the Eskimo."

In the handbill attached to the display of a popular exhibition in London, we are told that the North West Passage "bristles with numerous points of interest." The phrase is happily chosen with regard to the jagged points of ice which surround on every side the explorer of the Arctic seas, but interest—that is to say, sustained human interest—is so notoriously absent from these monotonous realms that the great difficulty in every successive exploration has been to amuse the crew, and to hinder them from failing sick and dead of sheer listlessness and *ennui*. Had the sailors who accompanied Sir Hugh Willoughby or Martin Frobisher in the middle of the sixteenth century, or those who sailed with Hudson or with Baffin in the beginning of the seventeenth, been acquainted with the resources of what is commonly called at sea the "cambra," some pleasurable excitement would surely have been produced; but even then the "points," except in the sense above-mentioned, "of interest" would have been very far from numerous.

The nearest acquaintance of most of us with the polar seas consists in a visit paid to the Bear of the Sea, the so-called polar bear of the "Zoo." This miserable beast, a prisoner for life, condemned to dwell, for the gratification of idle curiosity, in an iron-barred cell, some few feet square, with a little dirty, luke-warm water in its midst, can now at best but dream—if white bears dream—of those unfathomable seas and icy halls of cold sublimity in which he was once wont to wander free under the stars of the Frigid Zone. With a fine spirit of satire, worthy of Gibbon or Voltaire, the author of "The Guide Book to the Gardens" speaks of his narrow prison as "admirably adapted for the exhibition and comfort of the animal"; while it explains the weary and ceaseless wandering to and fro of the wretched captive, which must surely touch some sense of pity in the most senseless spectator, as the "constant motion which he invariably keeps up, indicating the restlessness and energy of his character." But habit, it is said, is a second nature, and *Ursus Maritimus*, Linn. Hab. Polar Regions, has, it may be hoped, become accustomed to his cramped position, though the "energy of his character" seems yet unaltered; as he may also have become used to the Bank Holiday crowds, which have succeeded for him the majestic and everlasting solitude of his original home.

It is this solitude, this absence of life, which gives the greatest interest to the pictures of the Pole. Seldom, indeed, can any human influence disturb the lonely grandeur of nature under the Arctic skies. Days of months succeed nights of months, where man is not. Man's dominion, says Byron, is limited by the sea, but the ocean has now become the world's high road. It is rather the sea of ice which forbids his further progress, the frozen ocean which makes the regions of the north as silent and as solitary as our own earth once was in that far-back glacial period when man's existence was unknown. It is the solitude, the absence of life, which gives the greatest interest to Polar pictures; but it is also the cause of their paucity. It is also the cause of many portraits of harpoon-guns and picks, ladders and anchors, ice-saws and snow-shoes, tents and bedding, sledges and cooking utensils, duffel-bags and bears, lummes and eiderducks, Eskimos in or out of kayaks, and seals.

Pictorial records of the Arctic regions have been produced by the camera with far greater exactitude—which goes, as the French say, without saying—than the pencil could have drawn them on canvas. The scenery of places within 400 miles of the Pole, a situation defended by ice which cannot, apparently, be passed by man; ice of every shape and form, mountains of ice girt with storm clouds, huge icebergs with fantastic arches fashioned in some idle freak by the fingers of frost, towering glaciers—all these, the scenery of a land of silence and desolation, may now be studied at will in the summer sunshine, or in some cosy corner in the blaze of our winter fire; and we may appreciate them more, if we do not more enjoy them, by a recollection of the hardships and perils attendant upon their execution.

Of the many difficulties with which photography has had to contend in the Polar regions, most pathetic accounts have been given by patient and persevering artists; and without these two qualities, without perseverance and patience in a full and heaped-up measure, it is indeed idle to think of taking pictures in the Arctic seas. There is, in the very head and front of photographic offences, the stumbling block of interrupted repose. This rest, so essential to the securing of a good picture, it is almost equally arduous to find on land or sea. The vessel is rarely still, even when the air is calm, but in that condition of the weather known to mariners as "dirty," or when the good ship is literally ploughing its path through huge floes which inflict shocks upon it from every side, even the preliminary arrangement of the fragile stock-in-trade of the photographer is by no means easy. On land—or rather on the masses of ice which pass for *terra firma* at the Pole—there is commonly some degree of agitation, and, even were this not the case, the super-incumbent snow is all too apt to make the station of the artist insecure. Then, again, the field exposed to the lens is unstable as water, and the pictures, from these double difficulties, have as little chance as Reuben of ultimate excellence. What has been said about the conditions of place may also be affirmed of those of time. Neither are satisfactory. In the matter of duration of exposure there arises the following dilemma. If it is short —and ice and snow reflect so much light that two seconds suffice for them—dark objects, such as the picturesque patches of grey slate or quartzite peeping through the white shrouds of the mountains in the background, have no time to put in their appearance. If, on the other hand, it is long—and at least thirty seconds are found necessary for these distant hills—then the ice appears absolutely without detail, and the negative is wholly useless. The season, too, of taking photographs in the north is often weird, uncanny, and uncongenial. Some of the best pictures have been taken at midnight. Of such pictures is the representation of an immense glacier, like a frozen river winding down ravine and gully, and bathed in the shine of an Arctic summer's nocturnal sun. Often, too, at mid-noon, the photographer is obliged to be idle, owing to the absence of the greater light which rules the day in the firmament of the heaven. Now a picture is spoilt by fog, an atmospheric condition which seems to be, from all accounts, as frequent in the North Pole as in our own favoured country, *le pays*, as the Frenchman calls it, *des brouillards*—the land of mists; and now by impurities of water, which, in the majority of cases, can only be procured from melted snow. Developments are commonly effected during the short summer, when Pindar's best of liquids is other than thawed ice, and not too salt to satisfy the photographic equation. A photograph taken at 96° below freezing by the albumen beer process is a curiosity indeed. Dust, we are told, is a cause of annoyance, but this is a common curse, though, if any escape from it were possible, it would be, one would suppose, in those unpopulous regions of which this article treats. Dust, like the poor, we have always with us, but who *a priori* would have suspected its presence in the desolate fiords and headlands of Spitzbergen, or on the bleak, rugged coasts of Nova Zembla? On lonely Mount Misery in Bear Island, in Baffin's Bay, in the Greenland seas, the everlasting duster of the well-girt housewife might well have been thought alike unnecessary and unknown. In addition to all these ills and obstacles in the path of success must be mentioned the unusual effect of the northern light, temperature, and air on the ordinary processes of photography, of which, in no few cases, a want of density, and dark, mottled stains are the disagreeable result. Even in the narrow apartment of confined space which constitutes the sacred chamber of the photographic mysteries—a chamber for which, on board ship, very little room is allotted and allowed—streaks of an unsightly appearance are produced by the condensation of moisture, if the words of an experienced photographer, which there is no reason to doubt, may be relied on.

Appalled by all these adverse circumstances, it has occurred to the ingenious artist to pluck the rose without the thorn, or to present pictures of ice and snow and other varieties of Arctic photography without a journey to the Arctic Pole. But the simulation of these in the studio is also not without its many difficulties. The inventive genius of man has, however, discovered that rough green glass is a very fair substitute, so far as appearance is concerned, for ice, while snow may be supplied by sundry devices, among which salt, or fine, feathery white down, which gives a yet lighter and softer image, are not the least ingenious or satisfactory.

## PHOTOGRAPHY ON A BLACK GROUND.

It is now very long ago that our readers, says *La Nature*, learned to know, through the qualified pen of Mr. A. Londe, always on the alert for photographic novelties, the varied effects that may be obtained, either from an artistic or a simply amusing point of view, by the use of what is called the Russian background. But more than one amateur assuredly will have met with the difficulty of obtaining (aside from a special installation) the necessary perfections in backgrounds or screens, especially since the fashion has turned to the bust portrait degraded upon black. So our readers will doubtless thank him who, in these very pages, was one of the first to recommend the magnesium flash-light, for pointing out a process within the reach of everyone for executing the most extraordinary combinations that the imagination could suggest, without complicated accessories, and by a simple, judicious use of artificial light.

In the first place, what is blacker than a window open at night on the darkness? The flash-light permits of making any exposure whatever in front of it, and the black of the background will certainly rival that of the first studios of the the Boulevard.

It will be said that this is not a very practical method in cold-in-the-head weather. Let us close the window, then, without insisting, and let us open the door. One has always, even in the winter of 1891, a door for opening in his house. A little back of the embrasure let us place the model face to the apparatus, and then let us flash the light at the side, as he sits for the artistic effect. A deep shadow projecting itself behind the sitter will furnish us with the desired black ground. Black, I say, whatever be the real colour of the said ground, and whatever be the lights burning in one or the other room; black, that is to say, inactinic for gelatino-bromide, although visible to our eyes. For there is a prejudice against which I cannot too much protest; it is useless, even in order to operate *upon* black, to condemn one's self to operate *in* black. The magnesium light alone counts from an actinic standpoint; and all the light furnished by the candles, kerosene lamps, gas, or even incandescent lamps that may exist in a room, would require, in order to give however slight an impression of the surrounding objects upon a photographic plate, so long an exposure, so great a fraction of an hour, that it may be absolutely disregarded. The full aperture of the lens must be used in the operation which we are considering. Even when there are directly in the field one or more of those sources of light with which we are content for domestic purposes, but which, as white as they appear to us, are nevertheless really yellow or red, and contain few violet rays, what will happen? They will pose simply with their surrounding, the image of which is so slightly veiled, even for the nearest objects, that it is a chance if we find a trace of it where these objects, through some polished surface, have performed the function of reflectors and not of simple diffusers. As for the image of the flame, that will be perfectly defined, with all of its details. At the worst, if the exposure has been of an exaggerated length, it will be found surrounded on the negative with an aureola, or halo, due solely to the reflecting action of the glass employed as a support, and which has nothing in common with what is called the veil, any more than it has with another accident that occurs with a still further prolonged exposure, and which consists in the reversal of the image, positive objects appearing upon the negative.

It is, therefore, useless (and I repeat it earnestly, on account of the contrary belief of so many professionals) to make night in order to photograph night, and to believe that one is obliged, for example, to represent a drawing-room without chandelier and a dinner without candles. To return to what occupies us, leaving all undisturbedly lighted, let us be anxious only lest our background shall receive at second hand too great a number of magnesium rays diffused through the part of the room where we cannot entirely prevent the reflection of the flash from penetrating. For that, the utilisation of the leaf of the door, open on the side of the sitter opposite the flash, will have the double advantage of arresting, on the passage, the greater portion of the rays that tend to enter the dark room, and of sending them back to the side of the sitter, who, without that, would run the risk of being too deeply shaded. It is possible, even, by placing the sitter and light geometrically in a right line with the edges of the jamb and the open leaf, to prevent any direct ray from entering the room. After this the darkness of it will be certainly comparable to that employed by Mr. Marey for his remarkable photo-chronographic studies on locomotion, that is to say, the most perfect that has been realised up to the present.

Since now, without trouble and expense, we are here possessors of an ideal background, nothing remains but to utilise it in order to derive from it all that it is capable of giving us. To commence, would you like to try one of those simple, degraded blacks which so well bring out light clothing? It will suffice, after making the exposure as indicated above, to operate according to the classic method by putting into the camera a shutter containing an aperture which allows of the passage of only that part of the image that it is desired shall reach the plate.

Does the operation seem to be somewhat delicate, and does the regulation seem tedious by the light of the candles? Or does the apparatus refuse to allow of the introduction of the shutter? This is how it always will be possible and easy to operate. Take some sort of a dark fabric, and, throwing it over the back of two chairs a slight distance apart in front of the sitter, regulate the curvature of the falling fold in such a way as to conceal the sitter up to the shoulders from your eye, placed against the objective. Then flash the light in front of this screen in such a way that the face seen from the apparatus, receiving no direct ray, shall remain black for the objective. There will be thus obtained upon the plate a bust entirely detached from a dark ground and degraded toward the bottom, where the edge of the veil will have become so much the lighter and softer in proportion, as it will have been less perfectly in focus, that is to say, nearer the apparatus.

There is no need of adding that, on reversing the process —that is to say, on substituting white for black, light for shadow, and a sheet (or better, on account of the folds, indented cardboard) for the drapery—it is possible to obtain directly upon the negative the ordinary degraded white that it takes so much trouble to obtain in printing photograph by photograph. So it is to be wagered that, having got a liking for it through an easy success, you would not wish to stop there, but would feel inclined to apply the method to the realisation of some of those tempting trifles to which attention has so many times been called in this journal.

Who has not, after making a negative, been confronted by the too sensible difference between the blacks of the profiling and the accessory draperies? Now, by the use of our background, the risk would be much lessened; but to succeed almost to a certainty one has only to proceed as follows. A first exposure on a shadow ground is made with the pedestal, the position of which must be accurately marked on the ground glass. Then a second exposure of the model in half-length degraded upon black, so regulated that the soft lights of the bust on the ground glass are lost over the pedestal—an operation that is reduced to a simple control if advantage is taken of the fact that, this time, there is nothing to prevent the pedestal from being left in place in front of the model, since it must, in definitive, be hidden by the veil.

Upon the negative we will find the image of the pedestal separated from the bust by a degraded zone, a few lines of which, through a broad after-touch, it will suffice to arrest and make more marked, in order to obtain a result which will not only have suppressed the faults of the profile, but also and especially its stiffness, &c., in the cut-out parts of the living bust.

Remark that it would have been perfectly allowable for us at the first exposure (that of the pedestal) to take at the same time, around the pedestal, any group whatever of persons or objects filling all the parts of the black field that it was not necessary to reserve for the bust itself. And then, instead of the effect of a solitary and somewhat conventional bust, the trick of which is easily defined, we obtain family pictures which are very puzzling through the presence, in a second edition, of the person all entire from head to foot, a part of whose form attracts in the first place one's whole attention.

The system of double exposures thus understood, may, moreover, with a little additional complication, lead us to applications in other ways, original without being much more difficult, by combining changes of distance of the apparatus between each of the operations.—*Eng. Mechanic.*

---

Positive Prints on Paper.— Dissolve in water 1,000 grammes, peroxalate of iron and ammonia 300 grammes. This solution being prepared, keep it in obscurity, as it is rapidly decomposed by light. Choose a paper sized with gelatine, use the smoothest side, and make a mark on the back with a pencil. Pour the above solution into a porcelain dish, float your paper on the solution for four minutes, and hang up to dry in obscurity. The solution may be used until exhausted, and the paper coated with this salt kept indefinitely, provided they are both kept away from the light. The exposure in the positive frame is made according to the intensity of the light or of the print; if on coming from the frame the print appears a little weak, or in the condition of a negative, care must be taken to have at once recourse to the following operation:— The print is floated on a five per cent. bath of nitrate of silver. For the sake of economy, the print may also be placed on bibulous paper, and the surface rapidly passed over with a cotton brush (a wad of cotton in a tube). The image immediately appears of a purplish-brown colour if the exposure has been good. If the paper is sized with starch or arrowroot the tone of the image will be blacker. The print may be toned with chloride of gold. It is fixed either with hyposulphite of soda, or in the following bath:— Sulphocyanide of potassium, 100 grammes; water, 1,000 grammes. Wash in several waters. —Chas. Gravier in *L'Amateur Photographe.*

## FERROTYPE DRY PLATES.

There will always be a need for itinerant photographers, and although some persons were sanguine enough to believe that automatic machine-made pictures would drive them out of the field, they still exist, and do a more or less successful trade at most places of holiday resort. It is an essential feature of this kind of photography that the pictures should be produced with speed. There must be no waiting for negatives to dry, or for prints to be made from them. The surface impressed by light must itself form the picture which is handed to the customer, who will probably go off without it unless it is forthcoming in a very few minutes after the exposure has been made.

The wet proces has, for many reasons, been the method adopted by the itinerant professor of photography, in the old days in the form of a positive on glass, and more recently it has taken the shape of a positive on metal, the trade name for which is "ferrotype." But, like his superiors, the "tintype" man has wished that the dirty silver bath could be dispensed with, and that his plates could be supplied to him in a dry condition. The demand was speedily met by a supply of ferrotype dry plates, but they possessed so many disadvantages that they did not come up to the requirements of the busy worker. Now, however, a new ferrotype dry-plate process has been worked out by Mr. L. Nievsky, and plates prepared by his formula are placed on the market by Mr. Fallowfield. We have recently had an opportunity of seeing what these plates will do, and we believe that they will have a wide future before them.

While not so quick as gelatine plates, they are certainly quick for collodion, while the speed at which they are developed, fixed, and finished is astonishing. In our presence a portrait was taken with three seconds' exposure, development of it was completed in twenty seconds, and in one minute more the plate had been fixed, washed, and dried. The surface required no varnishing or any after-treatment, the film being almost as hard as the metal upon which it rested.

But the new ferrotype process is by no means intended for the exclusive use of the professional photographer. It is believed that many amateurs will avail themselves of it; not, of course, as a substitute for gelatine, but as a means of enabling them, by way of amusement, to take photographs and show the results obtained within a couple of minutes of capping the lens. Thus, at a garden party, or similar gathering, the amateur "tintype" man with these new plates would be able, within half-an-hour, to show quite a gallery of portraits of the people who happened to be on the ground, and who would gladly consent to sit to the artist, and Mr. Nievsky has designed a compact little developing box, which can be used in the open air for this kind of work.

But there is another way in which these plates will appeal to the amateur worker. By shutting up a plate in a printing frame behind a transparent positive—say a lantern slide—and giving a momentary exposure to daylight, or about six seconds to lamplight, a positive copy can be obtained, which can be developed, fixed, and dried in something less than two minutes. We can imagine many an instance in which this wonderfully quick copying might be of value, and at a pinch a new negative might be made from such a picture, if the original one happened to get broken. This new process has much to recommend it, and those who are interested in photographic novelties should give it a trial.

## THE PANORAMIC PHOTOGRAPH.

For a long time the reproduction of panoramic views has put to the test the ingenuity of the inventors, for, besides the artistic interest which the photograph can excite, the extent of view involves certain difficult operations of levelling and of topography. The first apparatus constructed of this kind, says *La Nature*, appears to have been presented to the Academy of Sciences in 1815. Since, numerous instruments have been invented, but none of any practicability within the last few years. The problem was very complex, but from the first inventors have indicated perfectly the theoretical solution. They have, however, encountered in their search very serious difficulties, which have not been overcome until very recently. They have from the commencement combined the objectives embracing a very considerable angle; but in these objectives, as elsewhere in all the photographer's objectives, they know that the light rapidly diminishes from the centre to the edges. The angle obtained does not exceed 125 degrees. This result is certainly very appreciable, but they were far from the panoramic view which should embrace the entire horizon, that is to say, 360°.

The first really practical apparatus was invented in 1889 by M. le Commandant Moessard, where the image is obtained upon a film of the cylindrical form. This result is attained by pivoting the objective upon the nodal point of emergence. This solution, very fine of the problem theoretical, is realised by an instrument of which the details have been studied with great talent. Another inventor, M. J. Damoizeau, proposes another solution, offering in practice many very substantial advantages. The apparatus of M. Moessard can give but one-half of the horizon; for the complete panorama it is necessary to have two operations. The apparatus of M. Damoizeau permits the panorama to be taken in one operation, and allows the employment of objectives of different foci. In this quality it differs essentially from apparati that have preceded it. It is this that constitutes its originality and novelty. The apparatus is composed of a dark chamber pivoting upon a circular plate carried by a photographic tripod. The frame before the door of the objective can place itself vertically; the back frame is constructed of a roller frame of particular form; these two parts are united by a bellows chamber. To this point there is nothing new. We have a photographic chamber furnished with a roller frame, but where the difference is, it is in the mode of making. In the ordinary chamber it is necessary to be immovable; here it is not at all necessary. The chamber pivots upon the central axis, so that the objective runs over the entire horizon; but at the same time the sensitive preparation advances with a regular movement, so as to present always to the action of the light a virgin part of the surface. Notwithstanding the displacement of all the parts of the apparatus, the image is absolutely clear.

This double movement of the chamber and the progression of the film is obtained by a clockwork mechanism placed under the roller frame. The good working of the instrument which corresponds to the perfect clearness, results from the synchronism which exists between the rotation of the apparatus and the unrolling of the film. The clock movement is upon the circular plate, where it progresses by adherence, and the other it commands by the means of wheelwork calculated *ad hoc* the movement of a cylinder conductor, which gives to the film the rapidity of unrolling desired.

## ALUMINIUM AS A SUBSTITUTE FOR MAGNESIUM.

It has been claimed by scientists for some time past that aluminium in minute particles burns in the air, and generates an intense light equal to magnesium. At a late meeting of the Photographic Society of Vienna, Herr Patz presented a number of experiments showing that magnesium may be replaced for photographic purposes by the far less costly aluminium. His results were as follows:—

Aluminium leaf ignites readily, is not dangerous, and burns with jets of sparks (scintillation).

Coarse aluminium powder failed to give satisfactory results.

Fine aluminium powder mixed with chlorate of potash and sulphide of antimony gives good results, but generates smoke equal to the magnesium compounds. However, if the sulphide of antimony is dispensed with, this objectionable feature is overcome [?—Ed. *Wochenblatt*].

Powdered aluminium blown or thrown through a flame will not ignite.

These general results obtained were similar to those arrived at in a course of experiments undertaken several months previous in Berlin by the staff of the *Photographisches Wochenblatt*—presumably by Dr. Miethe in person. For this purpose fine aluminium filings and aluminium bronze powder was used, the latter such as is sold on the market as a substitute for silver bronze.

Aluminium filings, on being forced through a Bunsen flame, failed to ignite; but, combined with some of the various substances containing oxygen (chlorate of potassium, nitrate of potassium, manganate of potassium), ignited in the usual manner, but the whole mass failed to consume entirely.

If anhydrous glycerine is dropped upon a mixture of manganate of potassium and aluminium powder, the compound frequently ignites and burns with a not very strong light, while a magnesium compound under similar conditions would explode with an intense light action.

Aluminium bronze powder—which, by the way, is considerably dearer than magnesium—may be blown through a Bunsen flame, and the combustion will be almost complete, provided the flame is sufficiently large, and the propelling air properly separates the particles. The chemical action of the light was active, and the resulting smoke hardly noticeable. The same powder mixed with finely-ground chlorate of potassium, with or without sulphide of antimony, burned a little slow, and without giving forth any strong light. On the contrary, if combined with manganate of potassium, the mixture burned quickly and gave a bright illumination. But even the latter mixture does not always ignite with absolute certainty when treated with a drop of anhydrous glycerine, and, in case, even in small quantities, an ignition does take place, it is invariably accompanied by a loud detonation.—*Amer. Jour. of Photo.*

---

The *Scientific American* points out that, by heating resin with sulphur to about 250° C., a reaction takes place, attended by the evolution of sulphuretted hydrogen, and leading to the formation of an almost black, pitchy substance containing sulphur, and resembling Syrian asphalt in many of its properties. Thus, it is insoluble in alcohol, but dissolves readily in chloroform and benzene, and is sensitive to light in the same way as Syrian asphalt, for which it can be substituted for photographic purposes.

# Patent Intelligence.

### Applications for Letters Patent.

16,936. Thomas Ernest Smith, Sandringham House, Osborne Road, Southsea, "A Double Action Instantaneous Shutter for Detective Hand-Camera."—*October 5th.*

17,143. Arthur Brin, 53, Chancery Lane, London, "Improvements in Photography and in Photographic Apparatus."—*October 8th.*

### Specifications Published.

6,825. *May 3rd*, 1890.—"Indicator." J. Parkinson, South Regent Street; S. Fawcett, Elm House, Meeting House Lane; and C. F. Parkinson, South Regent Street, all in Lancaster.

In roller slides the measuring roller is provided with a pinion which actuates directly, or through a train of wheels, a numbered registering wheel. The pinion may have only a single tooth, or it may have several teeth, the number of which is not exactly divisible into that of the wheel, in which case the indicator is suitably graduated. (Patent opposed. Case not yet decided.)

7,010. *May 6th*, 1890.—"Instantaneous Cameras, &c." B. J. B. Mills, 23, Southampton Buildings, Middlesex. (L. Lumière, 21, Rue Saint Victor, Lyon-Montplaiser, France.)

The camera is provided with an opening at the back for the insertion of the plates. These are enclosed in sheaths, which consist of metal plates with turned-in flanges on three sides, and with trunnions. The trunnions are placed in guides. When all the plates are inserted in the camera, the back, which is provided with a spring to push the plates forward, is closed and secured. The trunnions of the front sheath engage in notches in discs mounted on a spindle, which is worked by a thumb-wheel on the outside, and other trunnions abut against prolongations from vertical guides. The front plate, when in this position, is exposed, and to prevent accidental exposure the shutter may be so connected with the disc that it will be fastened until the trunnions enter the notches on the disc.

To change the plates, the disc is further rotated, thus permitting the plate to slide down the guide and allowing the next to come into position for exposure. The next, on being released, causes the first to swing and fall flat on the bottom of the camera. The fall is broken by springs at the sides, which springs also serve to retain the plates to the bottom.

---

Received.—From Mr. E. G. Wood, "Magic Lanterns: How Made and How Used," by A. A. Wood, F.C.S. This, the fourth edition of a useful book of 136 pages, illustrated, has been revised, with additions.——From Messrs. Iliffe and Sons, "Photography applied to the Microscope," by F. W. Mills, with a chapter on "Mounting Objects," by T. Charters White. The author explains that his object has been to supply a practical guide to instruct microscopists in the application of photography to their science, and at the same time acknowledges his indebtedness to Mr. T. Charters White and V. A. Corbould for assistance.——From the same publishers we receive "Photographic Pastimes," by Hermann Schnauss (translated from the second German edition). As we remarked in reviewing the German edition, the matter of the work is much more interesting and instructive than its title might lead one to suppose. The first chapter relates to photographing specialities; the second, curiosities; the third, photographing by means of peculiar arrangements; the fourth, photographic optical entertainments; and the fifth, entertainments with photographic prints. The book is plentifully illustrated.——*Funny Folks* for Sept. 17th, to hand, contains the first illustration of the "Comic Camera," an amusing feature to be introduced into its pages. The subject alluded to is entitled "Buffalo Bill in the Back Garden; an Improvised Wild West Scene." As will be noted elsewhere, our contemporary invites contributions of humorous photographs.

## Correspondence.

LANTERN SLIDE EXHIBITIONS.

Sir,—I think it my duty to inform hon. secretaries of the photographic societies of the United Kingdom who are making arrangements for lantern slide exhibitions during the coming winter, that the Boston Camera Club, U.S.A., have sent us another lecture, entitled "The Yosemite Valley," prepared by members of the California Camera Club.

This is a gift to the amateur photographic societies of Great Britain on the same terms as "Illustrated Boston," "The White Mountains of New Hampshire," and "In and about Columbus."

There are now four complete lecture sets of about eighty slides each, with accompanying lecture neatly mounted in type, of American scenery, in free circulation among photographic societies in this country, and which can be lent on application to me.

The only conditions are, that the carriage of the boxes be paid at least one way; that an account of the lectures and press notices of the same be posted by societies at once to Wm. Garrison Reed, 25, Kilby Street, Boston, U.S.A., the manager of the "Interchange of Illustrated Subjects"; and that the greatest care be taken of the slides, any accidents to which, as far as possible, to be made good, and the same reported to me immediately. E. M. Tunstall, *Hon. Sec.*

*Liverpool Amateur Photographic Association*, 3, *Lord Street, October* 10*th.*

## Proceedings of Societies.

London and Provincial Photographic Association.

At the meeting of this Society held on the 8th inst., Mr. J. Barker occupied the chair.

Mr. J. S. Teape said that at a former meeting a plate which he had shown, illustrating the effects of several backings, was objected to on the ground that the caramel backing was not dry when exposed. He now brought forward a plate exposed in the same manner, but prepared in three divisions. One part had been coated with caramel and dried; another had been backed with burnt sienna and dextrine and dried; and the third backed with caramel and not dried. He found that part coated with caramel to be free from halation, whilst the burnt sienna showed a little, and the wet caramel rather more halation. He found, therefore, that his failure to get the best result with caramel was due to his having exposed before the backing was dry.

Mr W. E. Debenham said that this result was in accordance with his own experiments, the high refractive power of caramel rendering it especially efficient.

Mr. Teape also showed some plates which had been exposed under negatives, and completely reversed merely by over-exposure. They were exposed to the light from 30 inches of magnesium wire burned at a distance of 12 inches. They were developed with hydrokinone by Thomas's formula, except that 11 ounces of the hydrokinone solution had been taken, and 5 ounces of the soda solution. As soon as the image began to appear he had added 4 grains of potassium bromide to the developer. The resulting negatives were considered by several members to be the best instances of reversed negatives obtained by simple over-exposure that they had seen.

Mr. Atkins showed an iris diaphragm which he had made. He dissected it to explain its working. A model in paper showed by its translucency the position of the several leaves at all stages of aperture.

The Chairman hoped that this and other societies would stir in the matter of the new impurities now added to methylated spirits. He thought it a serious drawback to several photographic processes, and that something might be gained by proper representations to the authorities.

Mr. Howson then showed a number of prints on gelatino-chloride printing-out paper, manufactured at Ilford, and demonstrated the toning and fixing of the prints. The photographs were of several kinds of surface, from the matt effect produced by stripping from ground-glass, to the enamel glaze obtained by drying in contact with ordinary glass. The toning used and recommended was the sulpho-cyanide bath containing $2\frac{1}{2}$ grains of chloride of gold, and 30 grains of sulpho-cyanide of ammonium to 16 ounces of water. A combined toning and fixing bath was also described, but there seemed to be doubts as to the permanency of the prints compared with those toned in the separate sulpho-cyanide solution.

The Chairman considered that thorough fixing was essential to permanency. He showed some prints made by the gelatino-chloride process which he had introduced at the Society in March, 1885, and which he then exhibited. They did not now show any trace of fading.

Photographic Society of Ireland.

The first meeting of the session was held on the 9th inst. at 15, Dawson Street, Dublin, Mr. George Mansfield, J.P. (president), in the chair.

After the usual formal business, the President read his opening address, in the course of which he said that it was pleasant to meet again after another year, and, above all, to find then that the Society had continued to progress. Of course, to the outdoor photographer, who sought his pleasure in the presence of nature, the ending of the sunny days and the rapid closing in of the chilly evenings brought a pang of regret. There was, however, plenty for him to do during the winter season, were it only to bring before the Society's meetings some of the useful experience he had acquired during his summer work. The field of photography was a large one; there were paths of research in it suited to all tastes. He thought an error had been largely committed during the past two years by the overwhelming amount of encouragement given to the art side of photography. He was a firm believer in the art future of photography, but he was also convinced that, as in other forms of the art of delineation, so also in photography, artists in the true sense of the word have been, and always will be, few and far between. The other uses of photography, therefore, equally deserved their attention, and they were bound to welcome the many who, neglecting the higher walks of art photography, regarded it solely from a scientific point of view, whether as a mere branch of physical or chemical science, or as applied to some of the arts or sciences—such as astronomy, microscopical research, architecture, or archæology. Mr. Mansfield mentioned the fact that an exhibition of members' work would take place in the rooms in December. Speaking of the more general adoption of eikonogen as a developer, particularly for instantaneous exposures, the President's own experience was that for short exposures it was unsurpassed. In printing there had been an increase in the employment of gelatino-chloride printing-out papers. The chairman concluded his address by pointing out that celluloid films had come into more general use, and that where it was necessary to reduce weight they were invaluable.

The meeting then became conversational.

Holborn Camera Club.

*October* 9*th.*—Mr. James Rennie, jun., in the chair.

Mr. Ernest Benest gave a lecture, with experiments, on "Light and its Action on the Haloid Salts." His reason for treating on this subject was due to the fact that he thought a large number of practical workers were very careless about the fundamental principles upon which their art or craft depended. He divided his paper into two sections and an appendix. In the first section he treated of the conditions and materials necessary for receiving the latent image, by noting the various processes, viz., the Daguerreotype, the wet plate process, the gelatino-bromide process, and the collodion process. In section two he dealt with the action of light on these substances. He thought it would be well to consider in the first place:—Is the action of light on the haloids chemical or physical? The general opinion on the action of light was rather favourable to what was known as the sub-haloid theory. He gave various reasons which tended to confirm this theory, as against the theory of a physical change. He then mentioned the oxy-haloid theory, and the experiments of Hunt and Meldola in that direction. He spoke of the ripening of the emulsion, and the various sensitiveness in the haloid salts. In the appendix he made note of the various experiments which he made after the lecture in support of the theories he had put forward.

On Saturday, the 10th inst., it had been arrauged to have a club outing to Hyde Park, aud finish up with a smoking concert at the club rooms in the evening. Owing to the rain, the former portion of the programme was adjourned till next Saturday, while an enjoyable evening was spent in keepiug up the latter event.

### CAMERA CLUB.

THE first technical meetiug of the winter session took place on October 8th, when Mr. STROH occupied the chair.

The HON. SECRETARY handed round some examples of coloured photographs lent for exhibition by the Art Colour Photograph Company. In these the paper print is rendered translucent, and the colouring is done roughly from the back. Some improvements in the method are claimed so that the work can be done with certainty and ease by unskilled hands, the photograph giviug all the modelling.

Capt. ABNEY, in a paper on "Light and Lights," dealt with and compared the visual and photographic values of certain lights—sunlight, gas, electric light, and magnesium light—and showed that practically sunlight and the arc electric light alone are available for printing purposes. He then proceeded to describe very simple arrangements for enlarging by these lights direct upon platiuotype paper, and illustrated his remarks and directions by a large number of excellent examples.

The lecture excited great interest, and mauy questions with some discussion followed the paper.

On October 19th, the first of a series of elementary lessons will be given by Mr. Lyonel Clark, the subject being "Lenses"; and on the 22nd the subject will be "Reversal," when Mr. Henry Sutton will give a paper with illustrations and demonstrations.

### PUTNEY PHOTOGRAPHIC SOCIETY.

*October 7th.*—Rev. L. MACDONA in the chair.

The following were elected to serve on the council for the ensuing term: *President*—The Hon. Barou Pollock; *Vice-Presidents*—Rev. L. Macdona, Dr. W. J. Sheppard; *Council*—Dr. J. F. Farrar, Messrs. H. Faulkner, jun., T. Gilbert, W. F. Gorin, and L. S. Zachariasen; *Hon. Secretary*—Mr. Chas. Ballard, 45, Disraeli Road, Putney; *Hon. Treasurer*—Mr. Wm. Martin, jun., 4, Lower Parkfields, Putney.

### RICHMOND CAMERA CLUB.

AT the meeting on the 9th inst., Mr. ARDASEER in the chair, a discussion took place on the subject of "Blisters on Silver Prints, &c." Various remedies were suggested, but uo one had had the courage to essay the prescription to be found in the "American Journal of Photography Annual" for 1890, viz., to fix the prints in a nearly boiling hypo bath, aud thence transfer to a solution of salt strong euough to float a potato!

The CHAIRMAN gave the different theories by which blisters iu prints are commonly accounted for: viz., first, the change of temperature from oue bath to another, the remedy for which is obvious; secondly, the difference iu density of the successive baths, a remedy for which is to thoroughly drain the prints at each transfer; thirdly, the generation of carbonic acid gas by some unexplained means in the hypo bath, which may be prevented by the thorough washing of the prints between toning or development and fixing, and the additiou of ammonia to the fixing bath; and fourthly, the use of too stroug a hypo bath, a solution of 1 in 8 being quite strong enough.

### CROMWELL PHOTOGRAPHIC CLUB.

THE adjourned meeting of this Club was held at the Cromwell Hotel, Great Yarmouth, on Monday evening last. The following, amongst many others, were made members:—Messrs. J. W. De Caux, J.P., C. Stacey Watson, A. S. Cooper, and H. E. Hurrell. Miss V. Buxton, of Frittou Hall, was elected one of the vice-presidents. The rules of the Club were passed, and other business transacted.

It was decided that the first Club meeting, to be held on November 9th next, should be a beginners' evening, iucluding exhibition of photos, short display of members' slides, the reading of a paper on elementary photography, with a discussion to follow, and at intervals music and singing.

It was announced that fifty members had joined the Club at the close of the meeting.

### LEEDS PHOTOGRAPHIC SOCIETY.

AT the meeting on the 1st inst., Mr. GODFREY BINGLEY in the chair—

Mr. H. M. SMITH delivered a lecture, with lime-light illustrations, on "Film and Kodak Negatives, and Lantern Transparencies therefrom." The slides included some remarkably fine examples by Mr. and Mrs. A. R. Dresser. A number of those by Mrs. Dresser were fine interior and architectural photographs. The majority of the pictures shown were, however, instantaneous exposures. The lautern slides themselves were on collodio-bromide plates, aud were of excellent quality and tone.

### ROTHERHAM PHOTOGRAPHIC SOCIETY.

THE second annual meeting was held on October 6th, Dr. BALDWIN (president) iu the chair.

The report of the council recorded a steady growth in the membership, and an increasing iuterest in the aims aud objects of the Society. The number of financial members was thirty-three, as against twenty-seven last year. For the coming year an attractive programme was in course of preparation. There was a satisfactory balance in hand after discharging all liabilities.

Officers were chosen as under:—*President*—Dr. F. B. J. Baldwin; *Vice-Presidents*—Messrs. E. I. Hubbard, W. H. Hay wood, and G. T. M. Rackstraw; *Treasurer*—Mr. J. Leadbeater; *Hon. Secretary*—Mr. H. C. Hemmingway; *Council*—Messrs. L. Berry, J. Wright, W. H. Shephard, W. Mason, J. W. Whittington, and the officers.

Several alterations of rules were made, and the word "amateur" was removed from the name of the Society. Eleven new members were elected, bringiug the total to forty-six.

Afterwards Mr. E. I. HUBBARD demonstrated the working of gelatiuo-chloride paper.

### HUDDERSFIELD PHOTOGRAPHIC SOCIETY.

ON the 7th inst. the above Society held a special meeting, Mr. A. CLARKE in the chair.

Mr. H. M. SMITH, of the Eastman Photographic Materials Company, gave a lantern entertainment—slides from kodak negatives. He commenced by describing the kodak camera, and, having shown the mechauism of the roll-holder, he said that some people object to its use on account of their having to expose the whole of the film before commeucing to develop. This, he contended, was a fallacy, as one, two, or more negatives can be detached, aud the film refixed in the holder. He stated that though the camera is designed principally for hand or instantaueous work, yet it is capable of beiug fixed on a tripod and used in the ordinary way.

### OXFORD PHOTOGRAPHIC SOCIETY.

THE annual meeting was held on October 6th, in the Society's new rooms in the High Street, Mr. Councillor J. H. SALTER in the chair.

The Secretary read the report of the committee for the year, from which it appeared that the Society was in a flourishing condition. Thirteen members had been elected during the year, which was considered satisfactory. The committee had been successful in acquiring two rooms for the daily use of the Society, in the principal street of the city, at a moderate rent. The advaucement of photography, the committee urged, should not be difficult in a place with such facilities for learning as

Oxford, for there could be no place of its size where more was done in photography, and where lanterns must be in use hundreds of times in a year. The dark room is well fitted up, and nearly every British photographic periodical is on the table in the meeting room. Various schemes were proposed for the coming season, among which was Mr. Stanley Kent's proposal to establish a library of lantern slides.

The following officers and committee were then unanimously elected: *President* (for the third year)—Mr. E. A. Ryman-Hall; *Vice-Presidents*—Messrs. C. C. Cole, A. F. Stanley Kent, M.A. (Magdalen College), A. F. Kerry, M.A. (Exeter College), and Councillor J. H. Salter; *Hon. Treasurer*—Mr. J. Minn; *Hon. Secretaries*—Messrs. F. A. Bellamy, F.R.M.S., and H. Minn, 136, High Street; *Committee*—Messrs. N. G. French, W. J. King, G. W. Norton, H. M. Phillipps, A. Robinson, G. A. Smith, and Rev. W. H. Price, M.A.

Five names were read for membership.

Sheffield Photographic Society.

The annual meeting was held at the Masonic Hall, Surrey Street, on October 6th, with Mr. B. J. Taylor in the chair.

The Treasurer presented his statement of accounts, which showed a considerable balance in hand.

The Secretary read his report of the proceedings for the year, showing that there had been three resignations, and twelve new members. The Society was never in a more flourishing condition than at present, and the proceedings had been characterised by an amicable tone throughout. The excursions had received considerable attention and support, and had been much more numerous than for several years past. They had produced some splendid work, especially the one to Lincoln.

The officers for the ensuing year were elected as follows: *President*—Mr. B. J. Taylor (elected for the third time); *Vice-Presidents*—Mr. G. Bromley and Mr. Thomas Frith; *Council*—Messrs. Ed. Sampson, W. T. Furniss, W. V. Davy, Josh. Smith, and T. G. Hibbert; *Treasurer*—Mr. Ernest Beck; *Reporter*—Mr. E. H. Pearce.

Lewes Photographic Society.

At an ordinary meeting of this society, held at the Fitzroy Library on Tuesday week, Mr. J. G. Braden, the president, occupied the chair. The sets of prints from hand-camera negatives sent in to the quarterly competition were on view. Mr. J. Hunter Graham, a member of the Brighton Photographic Society, as judge, awarded the certificate to the set belonging to the hon. secretary, Mr. E. J. Bedford.

The President then gave "A Few Notes on Exposure," and in his introductory remarks expressed the hope that all members would bring with them not only their good work, but also their failures, for he thought that often more might be learnt from a failure than a success. He said to produce a perfect negative it was necessary to give the correct exposure. He had brought Watkins' exposure meter, which he fully explained, and said that after a series of experiments he had made with the instrument, he had come to the conclusion that it was a very great help to photographers in ascertaining the exact exposure required for any subject. He showed examples exposed in accordance with the meter, which seemed to be perfect, though they were subjects which differed very widely in the time of exposure required.

Mr. Percy Morris proposed, and Councillor Wightman seconded, that a Watkins' exposure meter be given as a prize to the member who should produce the best results in some future competition, which was carried unanimously.

Photographic Veneering of Furniture.—In the application of photographs to cabinet-ware, Mr. J. K. France has patented the use of a substance that he calls "pyralin, or some other compound of pyroxylin." The print is fixed by means of alcohol. It is applied to the wood to be decorated, and the surface polished by pressure on a metallic plate, or by other means. This invention has for principal object the veneering of furniture.—*Wilson's Photographic Magazine.*

## Answers to Correspondents.

**All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.**

**Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.**

Sam.—*Sticky Black Varnish.* Your unfortunate experience does not admit of more than partial remedy. It will, of course, be impossible to restore the torn films, but in the event of your having any more negatives which have been treated in the same way, you should either print them through a sheet of mica, or rub them over with starch powder, which will only adhere to the tacky portions. With respect to fresh negatives and future work, you may get good results by rubbing into your present varnish some lithographers' Frankfort black, and then thin down with pure benzol, by which its drying properties will be vastly improved without loss of opacity. *Re-Bronzing Lens Diaphragms.*—Clean the worn surfaces by rubbing with a cloth moistened with dilute ammonia; when dry, brush the metal over on both sides with a warm solution of chloride of platinum, drop them into hot water, wash well, and dry. Finally, rub them over with powdered black-lead to make them slide easily.

Old Subscriber.—*Bromide Enlargements to Take Oil Colours.* See Messrs. Morgan and Kidd's catalogue, page 5, for sensitive coated canvas on wedged stretching frames; or you may prepare your own canvas with bromide emulsion. The treatment of a bromide paper print to make it take oil colour would be very unsatisfactory, for the coating with distemper must inevitably hide much of the photographic detail.

Enquiry.—*Photo-Mechanical Prints.* The Direct Photo-Engraving Company (Messrs. Hoffman and Co.), Barnsbury Park, N.; The Meisenbach Company, 188, Fleet Street, E.C.; Messrs. Husnik and Hausler (agent: F. C. Clarkson, 4, Fenchurch Avenue, E.C.).

H. B.—*Tremors from Passing Traffic.* Before proceeding to make another move, try the method of slinging the whole apparatus, enlarging camera and copying frames, as is often done in large city establishments to overcome vibration.

F. P.—*Bank-Note Security.* Instances have not been wanting of late to prove that cheques and some bank-notes are being tampered with, and your newspaper cutting is but another evidence of the fact. Before long a bankers' commission may possibly be appointed, or you might at once communicate with Sir John Lubbock.

Printer.—*Silver Print Trimmings and Waste.* The burning of albumenised paper in large quantities must always be a bit of a nuisance. The unpleasant odour might be partly mitigated by soaking with nitre or nitrate of soda solution, drying, and then setting fire to small parcels in succession. The heap of refuse or ashes thus obtained should now be fused with more carbonate of soda to recover the silver in the ordinary way.

F. R. A. S.—*Sun Photography.* A week ago the sun's disc showed a large group of spots in the southern zone, with a smaller single spot high above them. The Woolwich telescope, with which our photographs were formerly taken, was furnished with a lens of fully 4 ins. aperture, and 6 ft. 5 in. focal length. The image of the sun measured, in July, exactly ·7 in. diameter. The chemical and visual foci did *not* coincide, but differed by about two inches. Exposure was instantaneous for collodion with a quarter-inch stop, so that no clockwork or "following machinery" was required, the finder enabling us to keep the sun's disc in view. For working details, see the *Photographic Journal* of November, 1860. The Kew results, in later times, were in every way superior, but, given a perfectly sharp negative of small dimension on a structureless film, there should be no difficulty in enlarging to two or three diameters.

Wymondham.—*Flattening Albumen Prints.* By passing through a rolling press, or merely dragging them, face upwards, over a sharp-edged table, the tendency of the print to curl inwards may be counteracted. With regard to the other matter, your kind letter of thanks is a sufficient reward.

THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV. No. 1729.—*October* 23, 1891.

CONTENTS.

## ON PHOTOGRAPHING CRIMINALS.

It has often been said, and still more often printed, that one half of the world does not know how the other half lives. Surely we may parody this sentence, and say that one half the people who visit the photographer's studio have not the least idea under what circumstances the "seamy side" of life is photographed, and has its pictures taken without charge. On one side we have the lady of fashion, or the butterfly of fortune, driving up to the sumptuously furnished studio of the West-End photographer, bent on looking their best, and thinking what an impression their portraits will presently make on an admiring public. On the other, the wretched criminal who hates the sight of the camera, and who will do his best, by sundry contortions of his features, to render the likeness as little like him as possible.

As everyone knows, photography is practised in all our prisons, and every criminal, whether he likes it or not—it is generally not—has his portrait taken as a means of future identification. It is difficult to get a view of these criminal photographs—perhaps we should say it is impossible—although why this should be the case it is hard to say. To the unofficial mind it would seem that, to make these pictures really valuable in advertising the countenances of those who prey upon their fellow mortals, they should be open to the public—of course, under certain restrictions. But to keep them locked up in the privacy of a prison or police office is ridiculous. One exception to this rule was made, we remember, some years ago, when a number of criminal photographs were shown at the Pall Mall exhibition, but we fancy that this was initiated by the photographer and not by the authorities. These pictures were good ones, but we believe that the majority of such works, which are photographed at a very low contract price, are far from being works of art, and may be called diagrams rather than pictures. And in point of fact, these portraits need not be pictures. To be of use in identification, they merely require to portray the leading characteristics of the face, and to bring into prominence any marks, such as scars, moles, or slight malformations. It has been often pointed out, but we do not know whether the suggestion has been acted upon in this country, that a criminal's hand, both back and front, should be photographed as well as his face. On no two hands are the surface markings identical, while slight malformations of the digits or nails will often show that a man follows some particular trade. There are few men, too, who go through existence without having at some time cut or otherwise maimed their hands, and, as is well known, these scars persist through life.

The prison photographer has by no means an easy task before him, for many of his models, knowing the use to which the coming picture is to be put, will try their hardest either to prevent it being taken at all, by kicking and plunging while the exposure is being made, or they will, by "making faces," endeavour to render the portrait unrecognisable. A case of this kind came up the other day, and gave the *Daily Telegraph* an opportunity of a jocose paragraph on the subject. A man named William Howes, who had distinguished himself by nearly killing a policeman, and had given other indications which made his friends believe that he was qualifying himself for the attentions of the common hangman, objected, while in gaol, to having his photograph taken, when, in order to make him obedient, he was pinioned and held by half a dozen warders before the camera; but it was no use, and the work had to be left undone. This is by no means a solitary case. In a very interesting volume, called "Professional Criminals of America," by Inspector Byrnes, of New York, there are many such cases recorded; indeed, the frontispiece of the book represents a man struggling in the hands of four warders while seated before the camera.

Very few of our readers, possibly, have ever heard of this volume, for there are not many copies in this country. The book contains about three hundred portraits of men and women who have made themselves notorious in New York, and who are well known to the police of that city. It is most interesting from a photographic point of view, as well as to those who care to study physiognomy. Each portrait is accompanied by a short history of the original, and, curiously enough, the deepest dyed villains are by far the most presentable looking men. The majority of the portraits, in fact, have very little trace of villany about them. Some are grave, some are jolly, and mostly they are pictures of respectable looking folk such as one rubs shoulders with in church, or in any other public assembly. It is when one begins to study their records that it is discovered what rogues some of these fellows are, and how they prefer crooked ways to those which are straight. Here are thieves of all kinds, some of whom have been tried for murder as well, pickpockets, bank-safe burglars, "confidence" men and women, house thieves, hotel and boarding-house thieves, receivers of stolen goods, and forgers. And, as we have said, these birds of prey are, according to their photographs, respectable members of society. Could the famous Lavater, we wonder, have detected the rascal beneath these fair exteriors, or are we ourselves sadly deficient in our powers of judging by appearances?

"Is it usual for criminals to be so trim?" asked a reporter of Inspector Byrnes. The answer is to the effect that, as a rule, thieves attire themselves so as to attract the least attention from the class of people among whom they wish to carry on their nefarious business. If among poor people, they dress shabbily; among the well-to-do they dress stylishly. Their great aim is to escape notice, and to appear like the crowd among whom their lot is cast. We read, for instance, of a couple of worthies—man and wife—whose business it was to pick pockets at wakes and funerals. They, of course, dressed in sable, and were the most solemn looking couple it was possible to imagine. There is something intensely grim in the thought of these rascally "mourners" picking pockets in the shadow of death, and robbing those stricken with grief. Could human meanness descend to a lower pitch than that? The author of this interesting volume tells us that, although a number of his clients have endeavoured to cheat the photographer by making grimaces, as a rule the pictures of these artful ones are quite sufficient to identify them by. In one example, a criminal who defeated every attempt of the photographer was eventually taken while asleep, and his picture, with head on pillow, is duly reproduced.

But why, in these days of quick plates and rapid lenses, should there be any difficulty at all in getting first-rate pictures of these public characters? Surely it would be the easiest thing in the world to have a concealed camera pointing to a well-lighted seat in the open air, where the criminal whose portrait was wanted could be invited to sit for a few moments. Give him a newspaper to read, say, with an account of his own "case" in it, and, while he is absorbed in the narrative, let the warder call him by name. As he raises his face with a natural expression on the features, let the trigger of the shutter be released, and a good portrait would be the result. But there is so much red tape about all official acts that probably the old, clumsy way of taking criminal photographs will continue to be followed, notwithstanding the gain that would accrue from adopting the better plan.

## PHOTOLYTIC ACTION IN RELATION TO SOLUTION.

BY F. C. CROSS.

We shall not, we hope, be considered disrespectful to the amateur photographer if we regard him as a devotee of light science. He is, in fact, so much absorbed in the practice of a delightful art as to have little time left for a serious study of such incidental matters of science as light and chemical action. We are free to confess with him a very substantial ignorance of these subjects, more especially the former; but we feel—the more so, perhaps, on that account—a distinct call to rush in where the light philosopher hesitates to tread, and to discuss one or two bearings of the fundamental phenomena of photographic action which he—we were going to say—appears to overlook, but should rather, perhaps, say prefers to suspend his mind upon. We are the more emboldened to carry our exploring rushlight into the obscurity of this region of physical science, in observing the regard paid by writers on the subject of photography to the excellent injunction of a modern authority: "If you want to learn something of a subject, write about it." This is very much our attitude in attempting to forecast the directions in which the study of photographic action will contribute in the near future to important developments of physical science. Up to the present this distinction cannot be claimed for the camera, notwithstanding the powerful mechanical aid which it renders to science. In fact, the amount of exact knowledge which we possess of the molecular mechanism of photographic action is quite remarkably disproportionate to the enormous development of the *art*, of which such knowledge might very well be supposed to be the necessary basis. But in this, as in many other growths, practice has far outstripped theory, and the photography of to-day presents an elaborate and intricate system of preparation and manipulation of the photo-sensitive surfaces, with a request to all who may have the taste for the uphill work of investigation to be good enough to refer the countless details of practice each to its corresponding scientific basis.*

A very elementary analysis of the phenomena of photographic action shows (1) that they represent only a minute fraction of the molecular decompositions which are known to be occasioned by light; and (2) the photo-sensitiveness of a compound is very materially affected by the medium through which it is distributed for the preparation of the photographic surface. There is certainly, it will be observed, nothing very striking—or, rather, strikingly new—in these conclusions; but it is just those to whom this observation would occur who, perhaps, fail to see their cardinal importance, and that through each there opens up a vista of the science of the future in which the study of photographic action will play an important part. What these are we proceed to show, duly apologising to those to whom our conclusions, and the forecast of their development, may seem familiar.

*Light* is the physical cause of life. The ultima ratio of our existence is the constructive activity of the plant cell,

* Comp. Meldola, "Chemistry of Photography," page 2.

and the work of the cell in elaborating its countless products obviously depends upon the *special conditions* under which radiant energy on the one hand, and the inorganic building materials (carbonic acid, water, and nitrogen compounds) on the other, are brought together; and the first condition is necessarily that of *solution* in the special or protoplasmic medium provided by the cell.

We would premise here that the terms "photography" and "photographic action" are aggregate expressions for the result of the familiar series of operations by which the light-picture is evolved. To express the fundamental decomposition upon which such apparently dissimilar operations as photography and the work of the plant cell depend, we want a new term, and we shall be guilty of no startling innovation if we employ the word "photolysis," or "photolytic action."

Photolytic action, whether in the plant cell, or in the camera, or printing frame, is essentially the same. It is a separation of elements, or groups of elements, from one another, a cleavage of the molecule of a compound brought about by radiant energy; and the necessary condition for this communication of force, or the conversion of radiant energy into molecular or atomic motion, is the distribution of the decomposable matter through a suitable medium. This medium in the plant cell is the living protoplasm; in the photo-sensitive mixture it is the collodion, gelatine, or other colloid vehicle. The precise function of protoplasm in determining the photolytic decomposition of carbonic acid must remain, for the present, a matter of speculation; not speculation, however, of the nature of wild conjecture, but governed by the analogy subsisting between this *chef d'œuvre* of nature herself, and those decompositions which the photographer has adopted as the basis of his art. In the latter, we have to do for the most part with complex mixtures, and the part played by the colloid medium or vehicle is by no means simple. While, however, the photolytic decomposition of the silver haloids in gelatine emulsion may be taken as the very foundation of the photographic *art*, the complications in the reactions both in the formation and development of the image, are such that this process would by no means come first in the order of a scientific development of the subject of photography. As the *simplest* type of process, on the other hand, giving a clear illustration of the essential factors, we cannot make a better selection than the diazotype method of printing in primuline derivatives. The photolytic decomposition of diazotised primuline is an extremely simple reaction, the chemistry of which need not, in view of recent publications (*Jour. Soc. Arts; Jour. Soc. Chem. Ind.*), be again expounded. The point which we wish to insist upon is, that the instability of the compound varies greatly with the condition of its exposure to light. The free compound, in fact, is comparatively stable, but when diffused through colloid media it is decomposed with extreme rapidity. In the science of but a few years ago this would have appeared a very anomalous result, and for this reason: the affinity of primuline for the organic colloids is such that not only do they freely remove it from aqueous solution, but in doing so form with it a combination which withstands the action of strong hydrolytic agents, which combination is unaffected by the conversion of the primuline into its diazo derivative. We should have argued that combination means fixation of molecules—*i.e.*, increased rigidity—and that diazo-primuline combined with cellulose, for example, would be more resistant to photolytic action than the compound in the free state. The facts necessitate the exactly opposite conclusion: the combination of the diazo-primuline with the fibre substance confers molecular mobility; and what is true of the combination with cellulose holds also, in varying degrees, with the lignocelluloses (wood, and such fibres as jute), silk, wool, gelatine, and, in fact, the "organic" colloids generally.

The explanation which we shall now endeavour to set forth supplies one of the important points of contact of photography with the molecular science of to-day.

According to the modern theory of solution, a substance dissolved in a liquid menstruum is molecularly in precisely the same condition as when gasified or vapourised —*i.e.*, the molecular aggregates composing the substance are entirely resolved into, of course, the unit molecules, and these are endowed with the same mobility as gaseous matter. The theory—or, rather, generalisation of the observed properties of solutions—asserts further that when the dissolved substance is an electrolyte—*i.e.*, is a conductor of the electric current, at the same time undergoing decomposition into its constituent elements, or groups of elements—there occurs in the process of solution a partial decomposition, identical in character with that produced by the electric current.

It is not difficult to see the very important bearing of this theory upon photographic processes generally. The silver haloids in a gelatine emulsion are in a state of solution or semi-solution, and therefore incipient *dissociation*, and, the dissociation or cleavage of the molecule being of the same character as that produced by photolytic decomposition, an unstable equilibrium is produced which the shock of the waves of "light" upsets with the astonishing rapidity of the modern gelatine film. But in silver photography, both with the formation of the image in the camera and its subsequent development, the phenomena are extremely complex, and it is impossible to say how much of the high order of sensitiveness attained is actually due to the special condition of solution of the haloid in the gelatine of the film. In the several printing processes the phenomena are less complicated, and in the primuline process the simplest order of things obtains. We have, of course, nothing like the sensitiveness of the gelatine silver film; but then we are not dealing with sensitiveness *per se*, but as influenced by a particular factor—*i.e.*, the variation in sensitiveness of a photolyte (if we may use the term)—according to its relationship to the film medium through which it is diffused. The simplicity of the process, considered scientifically, contrasts with other printing processes in which the silver haloids are used in the following points. The fundamental decomposition is a perfectly definite one—*i.e.*, has been exactly or quantitatively accounted for; it is not complicated by secondary reactions of the products of photolytic decomposition; the development of the image consists in a simple combination of the diazo-primuline, which, by survival in inverse proportion to the action of light in the several parts, constitutes the image, with certain bodies, themselves colourless, to form colouring matters. We will save the reader a more laboured argument of the proposition to which these considerations are leading up, and content ourselves with formulating it: A fabric (*e.g.*, cotton or silk) or a gelatine film impregnated with diazo-primuline hold this compound in a condition of *solid solution*; in other words, its molecular state, when in combination with or dissolved in these colloids, is that of disaggregation into units, and therefore of maximum mobility, which is the condition of maximum sensitiveness to photolytic decomposition.

We have cited only one illustration in support of this proposition, and we have assumed on the part of our readers a certain acquaintance with recent contributions to one of the most interesting developments of molecular science, which this theory of the nature of solution certainly is. Our object is to suggest the important contact which is imminent between two branches of molecular science, which up to now have been independently developed, and the probability, nay certainty, of reciprocal stimulus, our grasp of photolytic decomposition gaining much in precision from a more exact estimate of an important factor, and the theory of solution deriving important confirmation from the phenomena of photographic science.

But if this is true of the limited range of photolytic decompositions available for picture making, how much more must the interdependence of *light action* and *solution* obtain in the sphere of activity of the plant cell? We know, of course, a good deal of the proximate results of this activity; the range of carbon compounds of which the modern chemist can give a complete account—complete in the sense that he can build them up from their simplest beginnings—is a formidably wide one; but all the chemical dictionaries, laboratories, and manipulative skill of the world fail to throw even a ray of light on the superb economy of the plant cell.

We are certain, however, of the two most important physical factors of its activity. The function of light we take as an axiom; but the function of the protoplasmic solution—whether of the aboriginal materials for the synthetic work of the cell, or of its proximate products—is as yet an absolutely closed book. The new light which we have on the molecular condition of substances in solution should enable us to form some more definite conjectures as to the probable condition of matter when dissolved in protoplasm, and of the complementary function of photolytic action upon matter so dissolved. We shall, perhaps, be betraying confidences if we introduce the name of one of our distinguished leaders in science—Prof. Thiselton Dyer—as having definitely suggested to us this particular view of a probable function of protoplasm. The suggestion, we think, is a fruitful one.

We have endeavoured to develop the conception from the point of view of photographic action. Without any attempt at peroration, or even rounding off our lucubrations with any formal prophetic anticipations, we are satisfied to have made the endeavour ourselves to progress from the more to the less vague in our conception of photographic and photolytic phenomena, and their connection with current developments of molecular science.

The first town council of Greater Vienna has just been photographed by Angerer. The mayor's table, with papers on it, forms the middle of the picture; at it one sees the mayor (Dr. Prix), the two deputy mayors, and round them the town councillors. Two large and two small pictures were taken. A copy is to be deposited in the city archives.

We have received from Messrs. Marion and Co. a very choice assortment of Christmas and New Year Cards designed for mounting photographs upon. These are most artistic in design, and are beautifully printed in the most delicate tints. The cards are made in various sizes, from "midget" up to whole-plate. They will accommodate both upright and oblong pictures, and, while some are made to take pictures already mounted on card, others require the photograph to be attached with mounting medium. No prettier form of Christmas or New Year's greeting can be imagined than one of these tasty cards mounted with a picture identified with the sender, or appropriate to the recipient.

## Reviews.

The Gelatino-Chloride of Silver Printing-out Process. By Walter E. Woodbury. (*Hazell, Watson, and Viney, Limited, London.*)

In this little book Mr. Woodbury gives full directions for preparing emulsion and coating paper for the gelatino-chloride process, which has recently become familiar to photographers under the names of aristotype, celerotype, Obernetter, &c. The directions are plainly given, and, so far as we can see, they are trustworthy. It is a pity, however, that the book is cut up into so many small chapters, two or three of which consist of less than a page of matter. The addition of an index would also be desirable in another edition of the work. The book is well printed, and will be welcome to all who are fond of trying various printing processes.

One Hundred Photographic Formulæ. By W. Ingles Rogers.

This is a mere compilation of formulæ which have been published in the various photographic journals and annuals, and it can hardly pretend to be anything else. If the compiler had given some idea of the results obtained by using the different recipes—such, for instance, as the colour given to the film by each developer, or the best developer to use for certain plates, or under given conditions—the republication of the matter in this form would have had something to recommend it.

## THE FIXING BATH.

BY J. J. HIGGINS, A.M., M.D.

A plain solution of hyposulphite of sodium in water, ranging in strength from 1·4 to 1·6, has until recently been the sole accepted and usual fixing bath for photographic negatives. Of late, however, modifications of this bath have been brought forward and highly extolled. The principal of these are, first, that in which carbonate of soda (the ordinary sal. soda, or washing soda of the shops) is added to the simple solution of hypo, and known as the "sodic hypo bath"; second, that in which alum is added, known as the "alum hypo bath"; third, that in which carbonate of soda and alum both are added, known as the "sodic alum hypo bath"; and again, that in which sulphite of soda, with an acid, is added, known as the "acid sulphite hypo bath." This last is remarkable for the almost sparkling, clear, crystal, and jet black negatives produced by or resulting from its use, and I was employing it for awhile with the greatest satisfaction, until, on the printing of a number of the negatives, my attention was called to the fact that my negatives, with which there had never previously been any such trouble, now stained the silver paper. This staining I found was due to *sulphur* present in the film, and it was only by frequently repeated and prolonged washings of hours in length that it could be finally removed.

Occurring almost regularly, and *only* with negatives fixed in acid sulphite hypo (although special attention was now given to, one might say, exhaustive washing), and *not* with those fixed in *plain hypo*, the following series of experiments was instituted by me to determine the proneness of the various fixing solutions to cause or leave this stain, observation at the same time being made of their comparative rapidity of fixing. To avoid the error possible in the use of different plates or films, an 8 by 10 plate *after exposure* was divided into four 4 by 5's, and each of these immersed at the same moment (the baths being all equal in quantity, and likewise strength of fixing salt) in its own fixing bath, and left therein (until each and all were apparently completely fixed) an equal period of time. Then on removal they were similarly washed. The same treatment was accorded to an 8 by 10 plate cut into 4 by 5's, and *not having been exposed.*

The first bath was the *plain bath* of simply hypo and water; strength:—

| | | |
|---|---|---|
| Hypo ... ... ... ... ... | 1 | pound |
| Water ... ... ... ... ... | 5 | pints |

The second was the *sodic hypo bath*:—

| | | |
|---|---|---|
| Hypo ... ... ... ... ... | 1 | pound |
| Sal. soda... ... ... ... ... | $\frac{1}{4}$ | ,, |
| Water ... ... ... ... ... | 5 | pints |

The third, the *alum hypo*, in which alum is added to the first or plain bath, and after the subsidence of the milkiness resulting, decanted or filtered:—

| | | |
|---|---|---|
| Hypo ... ... ... ... ... | 1 | pound |
| Saturated solution of alum ... ... | 5 | ounces |
| Water ... ... ... ... ... | 5 | pints |

The fourth, the *sodic alum hypo*, in which carbonate of soda and alum are both additional:—

| | | |
|---|---|---|
| Hypo ... ... ... ... ... | 1 | pound |
| Sol. of carbonate of soda (sal. soda) 1·4... | 10 | ounces |
| Water ... ... ... ... ... | 5 | pints |

Shake, let settle for an hour or so, decant or filter.

The fifth, the *acid sulphite hypo*:—

| | | |
|---|---|---|
| Hypo ... ... ... ... ... | 1 | pound |
| Soda bisulphite ... ... ... ... | 4 | ounces |
| Acetic acid ... ... ... ... | 5 | fl. drs. |
| Water ... ... ... ... ... | 5 | pints |

In the consideration of these baths theoretically, we have: That, by the addition of carbonate of soda to that of simply hypo and water, we render the bath for a surety alkaline, without altering its nature otherwise. To this practice there is no special objection, many of our older and most experienced operators, both here and in England, adding it, or carbonate or water of ammonia, to neutralise any free acid often present.* That, by the addition of alum, hardening of the film is indeed effected, but, as seen at once, by such very hardening *permeation is opposed*, and *fixation retarded*, while, at the same time, from its chemical composition $(K_2SO_4Al_2(SO_4)+24\,H_2O)$, *weakening* of the bath with manifest *evolution of sulphur* takes place. That, by the addition of an acid sulphite, still greater and more pronounced like results ensue.

E. J. Wall, "Dictionary of Photography," says:—

"The addition of any acid to a solution of hyposulphite will cause evolution of sulphurous acid and deposition of sulphur.

"The alum should be omitted from the fixing bath, as it decomposes part of the hypo, and weakens the fixing powers, besides rendering sulphur deposition liable."

And such is the consensus of opinion of most photographic workers and scientists.

To the foregoing it may be said that "theory is all well enough," but what are the facts? For it goes without question that an established fact outweighs the most elaborate theories, it matters not how many or erudite the authors. Theory, for the most part a mere explanation of observed facts, has here contrarywise been supported thereby; the results of the trials being as follows.

The plates fixed in the acid sulphite hypo were all badly affected with *sulphuration*, and to a less extent, yet very badly, those fixed in the sodic alum hypo. The alum hypo bath gave plates which, although affected, were not so to as great a degree, while the sodic hypo and plain hypo baths gave plates *entirely unaffected.*

The *sulphuration* in the case of the acid sulphite and sodic alum baths was most readily seen on inspection; yet all the plates from each and all of the baths were subjected to the printing test, as several *not showing in the least faulty on examination by the eye*, failed in this, their final ordeal.

In the matter of rapidity, of which observation was likewise made, fixation (here reference being to merely the *visible clearing* of the entire plate; practically, additional time being advisable) was accomplished by the plain hypo bath the quickest of all; by the sodic hypo somewhat slower; by the alum hypo still slower; by the sodic alum hypo slower yet; by the acid sulphite slowest of all, very tedious, and at times unaccomplishable.—*Wilson's Photographic Magazine.*

* As to the effect of free acid in the fixing bath, note subsequently.

## SLOW COMBUSTION OF GASEOUS MIXTURES.

When moist electrolytic gas is heated at 305° in glass vessels over mercury for one to two weeks, combination takes place between the oxygen and hydrogen, and only a very small volume of gas remains; in absence of mercury, combination takes place only very slowly at 305°, and at 448° the diminution of volume is very small, but at 518° a considerable quantity of water is produced. The thin glass bulbs provided with lateral capillary tubes, which were employed in most of these experiments, can be sealed without danger of explosion if a little air is permitted to enter the point of the capillary, but even traces of air or other impurities have such a great influence on the reaction that the results are very variable, and, consequently, the relation between the time and the amount of combination could not be determined.

The temperature of explosion of electrolytic gas, and that of a mixture of oxygen and carbonic oxide in theoretical quantities, lies between 518° and 606° when thin sealed glass vessels are employed.

A number of experiments were made in order to try and determine the rate of combination of oxygen and hydrogen under certain conditions. For this purpose electrolytic gas, generated by the electrolysis of hot water, and consequently free from ozone and hydrogen peroxide, was passed for many days through a series of bulbs fused together by means of very small capillary tubes. The apparatus was very carefully cleaned, the gas was dried with concentrated sulphuric acid, and india-rubber, cork, and all organic substances were carefully excluded; in some of the experiments the bulbs were heated at a faintly dull-red heat, and the pure electrolytic gas passed for eight days. The bulbs were then sealed before a blowpipe, and heated in the vapour of sulphur or of phosphorous pentasulphide (b. p. 518°) under the same conditions. In spite of all precautions, the results of the experiments were very variable, and no relation between time and amount of combination could be determined; it would seem, therefore, that the glass surface, even when most carefully cleaned, has a modifying but variable action on the electrolytic gas, and that this action is sufficiently different, even in the case of two exactly similar bulbs, to cause great irregularities in the experiments.

Bulbs containing pure dry or moist electrolytic gas can be sealed without danger when the capillary tube is sufficiently fine ($\frac{1}{4}$ to $\frac{1}{3}$ mm. in internal and 4 mm. in external diameter); in the case of the moist gas, a small flame can be observed running along the capillary when the tube is being sealed, but it goes out before reaching the bulb; no flame is seen in the case of the dry gas, the volume of which undergoes no appreciable diminution by combination taking place.

The electrolytic gas employed in the above experiments was found on careful examination to be free from any appreciable quantity of air.—*Journal of the Chemical Society.*

## ON THE INTENSIFICATION AND REDUCTION OF GELATINE NEGATIVES.*

BY ROLAND WHITING.

HAVING made these preliminary remarks, I will now proceed to describe the various methods employed for increasing or reducing the printing density of a plate, and, as there is less to say about the latter than the former, I will treat upon that subject first. Reduction of density can be affected in two principal ways: the film can be reduced in thickness by mechanical means or by solution, or the silver forming the image can be changed into some substance which can be dissolved by a solvent. For reducing by the first of these methods, Mr. Debenham recommended the use of ozone bleach. After the plate has been immersed in a solution of chrome alum about one ounce to the pint, it is placed in a solution of ozone bleach of the strength of about one to six of water. Holmes' ozone bleach is a substance which is used by laundresses for bleaching purposes, and can be obtained either at the oil shops or at several of the photographic chemists, and is very cheap. In the place of ozone bleach, a saturated solution of chloride of lime can be used in the same manner, but a substance which I like better than either of these is the hydrochlorite of potash, otherwise known as "eau de Javelle." To prepare this, dissolve one ounce of chloride of lime in fifteen ounces of water, and two ounces of carbonate of potash in five ounces of water. These are mixed, boiled, and filtered, and when cold are diluted, one of the solution to five of water being the strength I most generally use. All these methods act very much in the same manner, viz., by dissolving the upper part of the film away.

If reduction is to be carried to a great extent, the plate is placed in hypo, which dissolves out the silver that has been converted to the chloride. To reduce locally, a stronger solution is poured on the parts to be thinned the most, and, if necessary, these parts can be rubbed with the finger, or better still, with a piece of cotton-wool, until the required reduction is produced. Great care must be exercised in using these solutions. Do not handle the plate more than can be helped, or frilling may result; keep the plate gently rocking, or the reduction will not be even; do not rock too violently, or the edges of the film will be eaten away; do not have the solution too strong, or blisters will occur; and finally, let the tap be gently running so that the solution can be thrown off, and the plate be immediately washed without draining, or streaks and honeycomb markings will show themselves all over the plate.

Local reduction can be very well brought about by rubbing the parts to be reduced with a piece of wool dipped in strong alcohol, and, if carefully done, the result is very good. I have also heard of an operator who used to reduce locally with a mixture of very fine emery powder and some greasy material such as lard applied to the parts with a leather stump, but only very small places can be properly reduced by this means for obvious reasons. The grease is removed by a piece of rag dipped in turpentine.

The chemical method of reducing is done either with ferric chloride or potassium ferridcyanide. For the first of these make a solution of ferric chloride, one drachm to six ounces of water. The plate, on being immersed in this, has some of its silver converted to silver chloride, which is dissolved out with hypo. The method with potassium ferridcyanide, which was, I believe, introduced by the Polytechnic School of Photography, and which I prefer to all others, is as follows. A solution of red prussiate of potash (potassium ferridcyanide) is prepared. Some hyposulphite fixing solution is taken, and the prussiate added to it until it assumes a bright yellow colour. The plate is simply taken from the fixing bath and transferred direct to this, where it is kept gently rocking until reduction is complete. The beauty of this reducer is, no washing is required after fixing, and, also, you can be certain to what extent reduction will go. If the plate is to be reduced locally, it should be dried first if the parts have a sharp outline. The solution can then be applied with a camel's-hair brush, or, as before stated, the negative can be varnished all over except in those parts to be reduced, and the plate immersed in the solutions until thinned down enough. The chemical change which takes place with this reducer is: the silver, directly it is touched by the potassium ferridcyanide, is dissolved out by the hypo. One word more. As the ferridcyanide solution will not keep when mixed with the hypo, it must be made up a little while before using; and further, if reduction is to be carried to a great extent, the solution should be rendered highly alkaline with ammonia to prevent the negative turning yellow. So much, then, for reducing.

I will now proceed to treat upon the process of intensifying. There are three methods, so to speak, of strengthening the negative image, viz.: (1) the physical method, depending upon the crystalline attraction of silver in solution to deposit upon the silver forming the image; (2) the chemical method, depending upon the reducing power of silver to reduce a metallic salt which is soluble to a sub-salt, which sub-salt is insoluble, and is thus deposited upon the image, or else, by acting again upon another substance, produces an extra deposit; (3) by strengthening the image by adding a dark material to the back of the negative over those portions which require strengthening.

Under the first method comes Captain Abney's formula for silver intensification; it is as follows:—

*Solution* 1.

| | |
|---|---|
| Pyrogallic acid ... ... ... ... | 2 grains |
| Citric acid... ... ... ... | 2 to 4 ,, |
| Water ... ... ... ... ... | 1 ounce |

*Solution* 2.

| | |
|---|---|
| Iron sulphate ... ... ... ... | 5 grains |
| Citric acid... ... ... ... ... | 10 ,, |
| Water ... ... ... ... ... | 1 ounce |

Either of these solutions is taken, and a few drops of a 10-grain (to the ounce of water) solution of nitrate of silver is added just before using. It is then flowed over the plate. When the plate is sufficiently intensified it is washed, and placed in a solution of common sodium chloride, and, after again fixing for a few minutes in hypo, it is thoroughly washed. Any stains which may happen to appear may be removed with a 5-grain solution of potassium cyanide. Although this is theoretically the best form of intensifier, it cannot be recommended, owing to its liability to produce stains, especially if there should be traces of hypo in the film.

Another method of intensification, which is known as the Polytechnic method, and which, I believe, was introduced by Mr. C. Howard Farmer, is one of the best of its class that was ever invented. The intensified negative cannot be recognised from one which had been properly

* Continued from page 715.

strengthened in development, and its best recommendation is it does not require any washing to free it from the hypo. The following solutions are required :—

| | | |
|---|---|---|
| No. 1.—Silver nitrate ... | ... | 1 ounce |
| Distilled water... | ... | 12 ounces |
| No. 2.—Potassium bromide ... | ... | 4 ounces |
| Water ... | ... | 2 ,, |
| No. 3.—Hypo ... | ... | 2 ounces |
| Water ... | ... | 6 ,, |

No. 1 is added to No. 2; this, of course produces a precipitate of silver bromide, which must be washed two or three times in clear water and the water drained off. It is then dissolved by agitating it in No. 3. A muddy solution is thus produced, which must be filtered. The solution is made up to 16 ounces, and can then be bottled for use. To intensify a plate with this solution, it is first rinsed under the tap for a minute or so after removing from the fixing bath, and is then placed in the following :—Pyro preserved in sulphite, 4 grains; water, 2 ounces; silver solution (as above), 1 drachm, to which has been added about half a drachm of ammonia diluted to about 1 of ammonia to 8 of water. When density has been obtained, it is again riused and placed in the fixing bath to clear it; it is then finally washed. Should the silver not show any tendency to reduce—that is, should the plate not intensify as quickly as it ought—the solution requires more ammonia; but if, on the other hand, a brown precipitate is rapidly thrown down, it shows the presence of too much ammonia. If considerable density is required, it is necessary to throw off the solution as soon as it becomes muddy, and, after rinsing, to apply fresh. It is hardly necessary to add that the plate must be rocked all the time intensification is proceeding, otherwise it will become patchy.

Another way to use this intensifier is to place the plate in the silver solution for about five or six minutes, and, after letting it drain, to flood it with an ordinary oxalate developer, when the silver will be reduced. If only a slight increase of density is wanted, then the silver solution is diluted more or less—according to the amount of density required—with ordinary water. Of this intensifier I can speak in the highest terms, as being one which can be depended upon, and although appearing, from a mere verbal description, somewhat complicated, as being an extremely easy one to work in actual practice.

*(To be continued.)*

To Enamel Prints on Albumen or Gelatino-Bromide Paper.—A very cleau plate, larger than the print to be enamelled, receives the following mixture by means of a tuft of cotton :—Turpentine, 500 c.c.; rosin, 0·02 gramme; beeswax, 0·005 mm. The plate coated with this composition may be used for several operations. Dampened priuts are applied to the plate (care being taken to avoid the interposition of air-bubbles), aud when dry they may be easily detached. Iu the rather improbable case of a failure, the operation is begun again with the same print.—*L'Amateur Photographe.*

A Mean Trick.—Hostetter M'Ginnis has been paying his addresses, for some time past, to Miss Esmeralda Longcoffin. She had not given him the slightest encouragement, and he was about to commit suicide, when she threw him into a spasm of delight by asking him if he would do her the favour of giving her his photograph. He happened to have one with him, aud he begged her to accept it, saying that it was the happiest moment of his life, &c. As soon as he was gone the young lady called her servant, and, giving her the photograph, said : "Whenever anybody who looks like that comes to the door, tell him I am not at home."—*Texas Siftings.*

## NEW PROCESS FOR TONING BLUE PRINTS.

BY W. P. JENNEY, E.M., PH.D.

The intense blue colour of the ordinary blue print gives unnatural effects in prints from photographic negatives; also in architectural drawings where views and elevations of buildings are reproduced. The following method of toning such blue prints has been found to be easy of application, and to give tones varying from a brilliant blue through violet-blue to neutral tint and warm shades of grey, according to the intensity of the action of the bath.

The paper employed may be common blue print paper, sold ready for use iu rolls, or the specially made paper sold in packages of cut sheets by the dealers in photographic supplies. The solar printing is carried out in the usual manner. The best results are obtained with dark prints, as the intensity of the colour is somewhat reduced by the toning process. The following baths are employed :—

*Bath A.*

| | |
|---|---|
| Muriatic (hydrochloric) acid ... | 3 to 4 drops |
| Water ... | 16 ozs. |

*Bath B.*

| | |
|---|---|
| Aqua ammonia ... | 5 to 10 drops |
| Water ... | 16 ozs. |

*Bath C.*

| | Apoth. Weight. |
|---|---|
| Alum ... | 2 ozs. |
| Tannic acid... | 1 drachm |
| Water ... | 16 ozs. |

The prints are immersed face downwards in bath A until all the soluble salts contained in the paper are dissolved and removed, then dipped into bath B until the negative turns a violet-blue and the whites are clear, care being taken that the immersiou in the ammonia be not continued too long, as the definition of the picture may be injured. The priuts are transferred from the ammonia bath, placed face upwards in a tray filled with bath C, and exposed to bright sunshine for five to ten minutes, until no increase iu the strength of the picture can be noticed. The pictures are finished by toning in bath B until the desired shade of the colour is obtained, the picture becoming first a brilliant blue, then violet, and finally, by prolonged action, bluish-grey or neutral tint. The toning may be varied by a second immersion in the tannic acid bath, C, followed by a second toning in bath B. After toning, the prints are dried in the sunlight in the usual manner.

The above process is specially applicable to prints from photographic negatives, enabling the amateur in the field, provided with a printing frame, some sheets of prepared blue print paper, and the above easily procured chemicals, to test the printing quality of his negatives, with results only inferior in detail and definition to those obtained by the complicated process of silver printing.—*Scientific American.*

Croydon Microscopical and Natural History Club (Photographic Section).—On October 16th the first lantern night of the season was held, when a good selection of over 200 slides, the work of members, was passed through the lantern. There was a crowded attendance, and much appreciation was shown by those present.

Enfield Camera Club.—The first meeting of the winter session was held on the 14th iust., when the new biunial lantern recently purchased for the Club was used for the first time, aud several huudred slides brought by the members were passed through. At the next meeting, on the 28th inst., Mr. W. H. Trewartha James will read a paper on "Hand-Cameras."

## Notes.

The editor of the *Photo-Gazette* has written to us commenting upon what we said in a recent leading article with reference to a certain photograph which purported to have been taken with the telescopic objective of M. Jaret. We pointed out that the picture in question bore distinct evidence that it had been taken close to the object, and not from a distant point. The Editor of the *Photo-Gazette* courteously admits that we are right. He tells us that the picture was published in his absence, and that directly he found out the mistake he issued a circular to his correspondents explaining the matter, and promising a picture really taken with the new apparatus at an early date. This circular we never received, or, of course, we should not have called attention to the circumstance, which he naturally deplores.

In Mr. Jerrold's biography of Gustave Doré, there is an amusing account of the manner in which the artist dispersed a crowd of onlookers who had gathered round the camera when his friend Dalloz was trying to take a photograph in the streets of Verona. After Doré had gesticulated and threatened the idlers until he was tired he bethought him of another plan, which he proceeded without delay to put into practice. He took off his coat, threw it on the ground, and, assuming an expression of the deepest woe, held his cap to the crowd for charity. The people thereupon seemed to remember that they had an important appointment elsewhere, and hurried off as quickly as could be wished. The photographer was then left to do his work in peace.

This anecdote is worth remembering as suggesting a way of escape from an annoyance which is by no means confined to the city of Verona. Londoners are happily so used to the sight of a camera-bearer that they do not care to pause on their way as he exposes a plate. Most of them know "how it's done." But in country districts it is different, and a small crowd quickly collects to watch the operations, and make personal remarks. If they remain silent they will generally endeavour to be in the picture at all hazards; but what possible pleasure there can be in figuring in a photograph which they will never see is a mystery which has always remained unexplained.

"Can Photography Lie?" was the question asked in large letters on the contents sheet of *Tit-Bits* last week. Being jealous of the reputation of our beloved art, we purchased a copy of the paper in order to see whether it was charged with mendacity, or held to be guiltless of that sin. We cannot say that there was much to learn from the article to which this question formed the title. It told how exaggeration was begotten by the abuse of short-focus lenses, and for this reason the reader was cautioned to take house agents' photographic productions *cum grano*. But the writer was decidedly out of his depth when he described composite photography as being "accomplished by cutting out different parts of several photographs, arranging them together, and re-photographing them."

Amateurs who are ambitious in the direction of taking photographs from a balloon may like to know that a balloon is not absolutely indispensable for such photographs. Some time ago a photographic kite was devised by M. Arthur Batut, but the invention had defects which prevented it coming into use. M. Wenz, of Rheims, has now brought out an improvement of M. Batut's idea, and with it has obtained very good results. The shape of the kite is that of a quadrilateral of two isosceles triangles base to base, the larger undermost; and the camera—made of wood and cardboard, with aluminium mountings, for the sake of lightness—is fastened to the back of the kite. The exposure is made by a cord attached to the camera. Whether the result is worth the trouble involved is open to question.

Photography, according to a French lady who has written a book recording her impressions of Ireland, is rapidly spoiling that picturesque show-place, the Giants' Causeway. The lady bitterly complains of the vulgar herd of tourist visitors, not because they are vulgar, but because they will stand and be photographed there, and, in some cases, leave mementoes of themselves behind in the shape of photographs which are exhibited in the windows. We must confess to a lurking sympathy with this lady. Not only the Giants' Causeway, but many other romantic spots, are rapidly being vulgarised by photographs which, otherwise admirable, are spoilt by the introduction of inappropriate and too often ungainly figures. Why, when we buy a photograph of some lovely bit of scenery, should we also be compelled to purchase the portraits of the Smiths and the Jones's who are "doing" the district? If a figure be necessary, let it be the figure of a native, whose garments would at least be in harmony with the surroundings.

One of the many curious revelations of photography is that which first made known to the relatives of Emerson the approach of the mental disorder which marked the essayist's later days. When the decay of his mental faculties was not suspected, he went with some of his relatives to be photographed. There was nothing noticeable in his manner, but when he directed his gaze steadily at the object selected by the operator, the features relaxed very peculiarly, and the expression of the eyes and mouth, says the narrator of this curious experience, was strongly irrational, if the word can be used in such a connection. The relatives who were accustomed to his features and their expression saw in the negatives what they could not see in the original, and they determined to have no prints made from them; so the visit was paid for, but the negatives destroyed. It was noticed that, as Emerson left the studio, his eyes were bent steadily on the floor, and he smiled continually. In a very short time it was known that his mind had given way.

It almost seems as if the maxim of a daily paper was: When hard up for a novelty, try photography. Photographing a bullet in its flight through the air must now take a humble seat. The place of honour has been assigned to an apparatus invented in Vienna "for taking photographs in a rifle, the apparatus closing of itself every time a shot is fired." The photograph, we are further informed, "will show the object aimed at in a circular picture, in the centre of which the shot must have fallen." If this be really true, the apparatus is more wonderful than ever the inventor imagines. When a gun is pointed at a distant object, allowance must be made for windage and for the trajectory curve; while, therefore, the bullet may hit the target, the rifle may be pointed at quite a different object. If, under these circumstances, a photograph is taken of a target, this diminutive camera must possess the unique quality of looking round the corner.

## THE PALL MALL EXHIBITION.

Two very dainty portraits are those numbered 235 and 236, from the camera of Mr. P. J. Lankester, but the shadows of the first-named are somewhat heavier than could be wished. The last-named is a particularly effective picture, soft in texture, well lighted, and elegant in pose. Moreover, the draperies are singularly well arranged. Mr. Karl Greger is responsible for the three pictures Nos. 242-244, and he need be under no apprehension that they will meet with anything but praise. They speak well for the excellence of Obernetter paper when toned with platinum, the colour being very agreeable to the eye and suited to the subjects. No. 244 is entitled "The Last of the Flock," and, although the composition is of the most simple character—a few sheep in a field, backed by some trees and a hedge, and crowned with a cloudy sky—the result is in every sense a picture. Not one camera-bearer in a hundred would have thought of making such a combination into a picture, but Mr. Karl Greger has made the attempt, and has succeeded well. Mr. Martin J. Harding is an amateur who is rapidly coming to the front rank, and his two pictures, "In Winter's Grasp" and "Near Barmouth," are quite up to the standard which he has taught us to expect. Indeed, he shows himself as thorough an expert with the camera as his great namesake did with the pencil and lithographic crayon. No. 237, a large carbon picture of the interior of a sumptuous *boudoir*, suffers from unsatisfactory lighting, and is therefore wanting in effect. Nos. 240 and 241 are genuine little touches of nature, but they are so much alike in character that one is apt to rob the other, and the artist—Mr. W. P. Marsh—would have done well to have exhibited one of them alone. Each represents a tiny chicken which has just emerged from its shell, and looks with wonderment upon the world into which it has been launched. A number of views of Egyptian temples bear testimony to the excellence of Mr. Conybeare's work. Such pictures printed in platinum, as these appear to be, are of great value if all be true which we hear about the neglect and slow destruction of the original monuments.

And now we come to a frame which bears the word "medal," and never, perhaps, was a prize better earned than by these four beautiful snow scenes by Mrs. E. Main. The four pictures bear the title "A Frosty Morning—St. Moritz," and each is of a different subject. The texture of the foreground snow is remarkable, and shows that peculiar characteristic which is best described by the word "fluffyness." Nothing but a gelatine plate could give those silvery grey shadows which are peculiar to snow, and upon which snow pictures depend for so much of their beauty. There is a brilliance about these sunlit scenes which makes them very different to the majority of those taken in our own dull winters here at home. Mr. H. W. Bennett shows some breezy seascapes, which he calls "Studies of an East Coast Fishing Fleet." He contrasts them with two rustic scenes, "An Essex Village," and "A Surrey Stream." Many will identify this latter picture with a certain mill-stream at the foot of Box Hill. Mr. Bennett has certainly made the best of it by so placing his camera that he can utilise some rushes in front and some foliage at the side. The swans and their young ones help, too, in breaking up the surface of the water. Mr. Chang does not show us his best work in 268 ("Sunbury Lock"), which is commonplace, but by way of compensation he has allowed himself to become the subject of a photographic joke in No. 279 ("Mr. Chang's Afternoon Walk"), by Mr. F. Brocas. Here we see Mr. Chang looking happy and genial as usual, and escorting no fewer than five ladies—two on one arm and three on the other. "How happy could I be!" he seems to be saying to himself.

We think very highly of a picture which is given such a lowly position that it is apt to be passed over unnoticed. This is No. 286 ("Solitude"), by Mr. T. Orton—a swollen stream with a few trees bending over it, and with a soft grey light pervading the whole. Mr. B G. Wilkinson always exhibits good work, and here we have a capital picture called "The Bookworm" (No. 274). A monk is absorbed in an old volume which he holds in his hand, while he paces the grass in front of an old wall. This peep into the monasticism of the past is well relieved by Mr. Stephens' pleasant skating scenes, wherein the young people seem to be all on the go, and are looking as bonny, merry, and warm as healthy youngsters should look on a winter's day. But this exhibitor has by no means lost his cunning in the matter of flowers, for there hangs here No. 291, a study which recalls his old favourite works. This is an alabaster vase filled with roses and fuchsias, with a bush of delicate maidenhair breaking its formal lines. Mr. W. J. Byrne's "An Eastern Beauty" is a very attractive portrait treated with originality. Mr. F. Hollyer exhibits several pictures, which are excellent copies of paintings. They are all labelled "not for competition." One very fine one is "Dante's Dream" (from the painting by Rossetti), and another, which at once arrests attention because of its merit and beauty, is the "Head of a Girl," from the delicate brush of Greuze.

Mr. J. Chamberlain shows four pictures which must have cost him a great deal of trouble, in the employment of about two dozen models. They bear the titles, "In a Café in Cairo"; "Hiring a Donkey for the Pyramids"; "In a Bazaar, Cairo"; and "A School." They are not, however, what may be described as successes. They are artificial in character, and all the figures are on their best behaviour, with the self-conscious look of anyone knowing that his portrait is being taken. In No. 292, we have one of Messrs. West and Son's capital yachting subjects, "Racing in the Solent," the locality being well marked by the presence of one of those island forts which are so familiar to tourists to the Isle of Wight. Mr. Kenrick B. Murray's "Views in the Vosges, France" (Nos. 295-299) are excellent examples of well-chosen subjects for the camera. The last-named, a river beneath overhanging trees, is especially beautiful. The colour of the mounts of these pictures, by the way—a dark oak—is not calculated to add to the good effect of the photographs. Mr. A. R. Dresser shows seven pictures enlarged on bromide paper from quarter-plate hand-camera negatives. They are on the rough description of paper, and are of a very warm tone. Viewed from a distance of a few yards they are very effective, and look like sepia drawings. Like many other pictures in the Exhibition, they are necessarily injured in effect by their close proximity to one another.

Nos. 313 and 314 are pinhole pictures—landscapes, with reeds and rushes—by Mr. A. Maskell, and are marked "not for competition." "The Taker Taken" is the title of No. 317, by one of the older school of amateurs, the Rev. H. B. Hare. This gentleman always shows good work, and has many medals in proof thereof. It is a pity that Mr. Tyser's picture (No. 315), "On the

Grand Canal, Venice," is hung so high, for it is such a pleasing one that it invites closer acquaintance. In the somewhat misty distance is the cathedral of St. Mark, and moving in front are the black forms of various gondolas. We pause to regard with interest a little picture by E. S. Padmore (No. 328), "Hartz Cobolds." This title will not seem very explanatory to many visitors to the Exhibition; but for all that it is a good one, for the picture represents some men at their work in the Clausthal mine at a depth of 696 metres below the surface of the ground. Were not the original "Cobolds" the imps which used to haunt these mines? And have they not christened a certain mineral found there—to wit, cobalt? But, apart from its intrinsic merit, which is great, the man who descends into the bowels of the earth to a depth which would be represented by five and a-half times the height of St. Paul's Cathedral, for the purpose of taking a photograph, certainly deserves honourable mention.

We must close our present review by noticing Mr. Ralph Robinson's pictures, which remind us of those of his talented father. One of these has been most rightly awarded a medal, and we have no doubt that, in making that award, the judges took note of the general excellence of Mr. Robinson's exhibit. Three of these are portrait studies printed in red, and very fine they are in quality, helped as they are by good models. All Mr. Robinson's pictures have rough wooden frames with subdued gold and silver enrichments, and, while these are very effective for the portraits, they do not seem to harmonise so well with the landscapes.

## EXHIBITION AT HACKNEY.

The exhibition of the Hackney Photographic Society opened under auspicious conditions on Wednesday last at the Morley Hall, Triangle, N.E. Under the active and efficient management of the hon. sec., Mr. Fenton Jones, the exhibition, which, unfortunately, only remained open for two days, proved, during its short tenure, a decided success so far as the pictures and apparatus were concerned. With regard to the financial success of the venture we have, of course, at present, no data to go upon, but the hall appeared to our representative, who was there on Wednesday, to be well patronised.

The list of awards has not yet come to hand, for they were not decided upon until yesterday, Thursday morning, when Capt. Abney presented the prizes to the winners. The pictures were prettily arranged in alcoves, and well lighted by lines of gas burners above, such as are employed at the Crystal Palace for the same work. Many of the pictures shown were of high merit, but the exhibition unfortunately came too close to our time for going to press to attempt any analysis of them.

The apparatus section did not produce anything very new, but what there was was of the best. Messrs. Adams, Messrs. Watson, and the Platinotype Company—who demonstrated their method by the hot process—were among the exhibitors. We must not omit to mention, too, that Mr. B. J. Edwards—who, by the way, is a native of Hackney—was represented by a fine show of isochromatic pictures and transparencies.

Photographic Club.—October 28th, smoking concert and exhibition of members' pictures; November 4th, annual general meeting.

## NITRATE OF URANIUM TONING PAPER.

BY M. MERCIER.

It is known that some sensitive papers, variously prepared, have the property of acquiring an agreeable tone after a simple fixing, and without having been previously toned. I think I have now determined the special conditions under which this peculiarity is produced. Having the intention, later on, to treat this subject at more length, I will give simply the conclusions of my investigations, conclusions which may be summed up as follows. When we introduce into a sensitive paper, at the same time as the chloride of silver forming its base, a suitable reducing body, capable of reducing the silver salts under the action of light and giving a certain tone, this tone is more or less communicated to the silver reduced by the action of light on the chloride of silver alone. It is thus that sizes made of arrowroot, or more or less condensed starches, albumen, resins, gelatine, &c., yield papers which, after a simple fixing, give different tones. It is thus, again, that the oxalates, the benzoates, the citrates, &c., give, with chloride of silver, prints which have, after fixing, variable tones—purples, browns, or cherry-red. It is thus possible, instead of adding to the paper the already formed reducer, to cause this last to be produced by the action of the light itself. This happens, for example, when we add to the paper a per-salt of uranium, easily reduced under the luminous action to the condition of a proto-salt. Nitrate of uranium, which possesses, besides, precious preserving properties, was therefore already indicated for the preparation of a paper requiring no toning, such as the one I have had prepared under the name of *iso-toning paper.*

The print shows itself as usual, rapidly and with great sharpness. It is fixed directly, and without previous washings, either with pure hyposulphite of soda or, preferably, in the fixing bath of hypo and sulphite of soda. The print is washed and dried; it then acquires a violet-sepia tone, and in a few days gradually becomes darker and very pleasant to the eye. The toning may be instantly obtained by burnishing with the aid of heat, or by exposing the print to heat by any means whatever. An ordinary sad-iron yields excellent results. The print then acquires a beautiful violet-black tone, very greatly resembling the best tones obtained by toning with the gold salts. I will add, moreover, that some sensitive papers acquire by this treatment a more or less dark tone, but then this tone is rarely persistent. The iso-toning paper may also be toned with the greatest facility in the weakest gold or platinum baths; nitrate of uranium modifying the action of the bath, it is possible to obtain all shades from purple up to a blue-black. Toning after fixing yields equally excellent results. Yellow negatives, such as those developed with pyrogallic acid, yield, generally, prints having a very beautiful violet-black tone, even without the intervention of heat.—*Bulletin de la Société Francaise de Photographie.*

The Lantern Society.—Meeting on October 26th at 8 p.m. New oil lamp by Mr. Stocks.

Rudolph Cronau, the eminent author and scientist of Leipsic, Germany, has tendered to the Exposition his extensive collection of paintings, sketches, and photographs, representing scenes in the life of Columbus, and places visited by Columbus during his voyages to the new world. Doctor Cronau has spent a great part of his life in the study of early American history, and has published a work on the subject based entirely upon his personal investigations.—*World's Fair Notes.*

## ART *VERSUS* PHOTOGRAPHY IN NEW ZEALAND.

It is amusing to find that the everlasting discussion as to the relative merits of paintings and photographs has reached the Antipodes. A correspondent at Auckland, New Zealand, has kindly sent us cuttings from the *New Zealand Herald*, which show that this is the case; and we need hardly say that the end of such a controversy is the same as it is here—no one is brought over to the view of his opponent, and the matter remains just as it did before so much ink had been shed upon it.

It seems that the discussion arose in this way. During certain proceedings of the City Council meeting, the Mayor, in presenting an enlarged photograph of Mr. J. T. Mackelvie to the Art Gallery, said that when the City Council received the Mackelvie collection for the benefit of the city, it was stated in the catalogue that there was a portrait of Mr. Mackelvie. This they understood to mean an oil painting, but this was the only picture missing, and there was no portrait of Mr. Mackelvie to hang in the Art Gallery. He ascertained, however, that Mr. D. L. Murdoch had a photograph of Mr. Mackelvie which was taken in Rome—a cabinet photograph—which Mr. Murdoch had given for the Art Gallery. He (the Mayor) thought that something more striking was required, something which would catch the eye and give an idea of the man who had so liberally endowed art in Auckland, and he had the photograph enlarged by Mr. Hanna. Dr. Campbell and Mr. Murdoch, and others who were intimately acquainted with Mr. Mackelvie, considered it a splendid likeness. He had great pleasure in now presenting it for the acceptance of the Council. The picture was accepted with gratitude, and the Mayor was thanked for his thoughtful gift.

So far, so good. But it seems that the photograph, good as it was, did not give universal satisfaction, for "A Citizen" writes to the *Herald* in the hope that the Mayor may see it desirable to place something before the public more worthy of the generous donor than a mere white and black representation of Mr. Mackelvie seen in the enlarged photograph referred to. If Mr. Mackelvie is worthy of lasting memory, the city should endeavour to procure a good oil painting by some good portrait painter. The public, he asserts, may be for the most part satisfied with the results of photography, but the art student will remember that it is a mechanical effort with results never more than comparative in degree; its chief defect the absence of colour, and for this reason the larger the photograph, the more defective it appears. The efforts of purely human genius presented in painting and sculpture are far removed from the photographer, and the Art Gallery provides this lesson for the intellectual citizen to emulate.

"A Citizen" appears to be a little mixed in his ideas, but he is backed up by another correspondent, who remarks that "Photography is to art as chalk is to cheese—both are useful forms, but rank under different values. Photography, like chalk, is useful for educational purposes, but the actual results achieved by the brush are immeasurably higher than the lens can ever reach, and form the best and most solid nutriment for the artistic faculty. You must excuse the repetition of these platitudes, as they do not appear to be generally understood and accepted in our matter-of-fact community. As to the expense of such a compliment to the donor of so many art treasures, *that* should not be allowed to stand in the way. Putting the matter solely on the ordinary commercial basis of debtor and creditor, we can afford to spend a large sum on this object, and then remain Mr. Mackelvie's debtors. But it seems to be the fate of all free gifts that they are lightly esteemed."

Then Mr. Hanna takes up the cudgels, and points out very rightly that if a portrait of the late Mr. Mackelvie is to be painted, the artist will, after all, be obliged to use the photograph as the basis of his work. Again "A Citizen" takes up his pen, and becomes somewhat discursive in his remarks, as the following extracts will show:—

"I did not wish to underrate the art of the photographer, as many other readers of your journal will have derived, with myself, much pleasure from the productions of Mr. Hanna. I do, however, lament its defects when I think of the poor result of any picture of an Auckland sunset, with its gorgeous tints, or the vivid and extraordinary beauty of colour presented in our geysers and other scenery of the lake district, recorded by the dull photo-pictures as faithful effects, and as such presented to tourists and others who visit Auckland. I have stated that the results are merely comparative by photography, and, in view of the lasting memory desired by the citizens of the once generous Mackelvie, I desire to call in the superlative effort of the portrait artist, who, with a trustworthy description of complexion, colour of eyes and hair, and other lesser details, can—and doubtless will—produce a picture that may surprise those unacquainted with these matters. Indeed, many pictures are painted in this way, and photographic enlargements are coloured by intelligent artists from day to day in the studios of the larger cities of the world.

"With regard to the use of the camera by artists, I may say that it is largely treated by gifted men as a philosophical toy, and the defects of ignoring the blues and bringing out the vivid yellows as black renders it somewhat dangerous to the student of colour. In the matter of copying the old masters, I might state that it is generally conceded by the art critics of the day that the modern schools of painting are quite equal in effects, and, by the materials employed, excel in many cases the most celebrated productions of the old masters."

We may remind our readers that many specimens of the excellent photographic work done by Mr. Hanna have been exhibited in London, and that we may, therefore, feel sure that the much-discussed portrait was as good a one as possible.

---

Sheffield Photographic Society.—A special meeting was held at the Masonic Hall on Friday evening, when Mr. H. M. Smith described the kodak camera, and gave a demonstration and exhibition of lantern slides made from kodak negatives.

Rapid Toning.—Acetate of soda, 18 parts; bicarbonate of soda, 9 parts; borax, 33 parts; water, 3,840 parts. At the time of using, or rather two hours before toning, put 1 gramme of chloride of gold in 2,500 c.c. of the above solution, which keeps well in stock.—*L'Amateur Photographe.*

International Photographic Exhibition at Leeds.—The entries for this exhibition, to be held from December 7th, 1891, to January 9th, 1892, will close on November 12th. Applications for prospectus should be made to Mr. G. Birkett, Municipal Art Gallery, Leeds.

To Remove Yellow Tone of Gelatino-Bromide Prints.—Plunge the prints in a solution composed of saturated solution of oxalate of potash 2 parts, water acidulated with acetic acid 1 part. The immersion may last an hour or two. This method is also efficacious for prints that have been made several months.—*L'Amateur Photographe.*

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Pyro in the Eikonogen Developer—Rapid Hydroquinone Developer — New Photo-Lithographic Process — Washing Apparatus for Gelatine Plates — A Substitute for Lantern Slides on Glass—Pyro Developer with Caustic Alkali.

*Pyrogallic Acid in the Eikonogen Developer.* —If highly-sensitive gelatine plates are used, it is often difficult to obtain with them in developing that amount of density which is required in order to produce a vigorous print on albumen paper. With the ordinary ferrous oxalate or eikonogen developer, intensity is obtained in the case of a highly sensitive plate within six or eight minutes, it being, however, only an apparent intensity, which allows the light to pass through, and to produce greyish and undefined prints. A concentrated pyrogallic acid solution gives more satisfactory results, but in this case it is necessary to prolong exposure to some extent. A developer which, in the case in question, answers perfectly is the following, which was recommended some time ago in the *Deutsche Photographische Zeitung.* Even in the case of very short exposures, it gives very intense negatives of a beautifully brownish colour. It develops the image within from three to four minutes, leaving the shadows absolutely clear, and giving details even in the deepest shadows. The following solutions should be prepared:—

*Solution* No. 1.

| | |
|---|---|
| Water ... ... ... ... | 1,500 c.c. |
| Sodium sulphite ... ... ... | 160 grammes |
| Eikonogen ... ... ... ... | 20 ,, |
| Citric acid ... ... ... ... | 20 ,, |

*Solution* No. 2.

| | |
|---|---|
| Water ... ... ... ... | 1,000 c.c. |
| Potassium carbonate ... ... | 160 grammes |
| Sodium carbonate ... ... ... | 320 ,, |

For use should be mixed:—

| | |
|---|---|
| Solution No. 1 ... ... ... | 75 c.c. |
| Solution No. 2 ... ... ... | 25 ,, |
| Alcoholic pyro solution (1 : 10) ... | 5 to 6 ,, |

The temperature of the developing solution should be always kept between 68° and 72° F.

*Rapid Hydroquinone Developer.*—The so-called rapid hydroquinone developer, as recommended by Prof. Lainer, has been slightly modified by M. Pellechet, according to the *Archiv,* in the following manner:—

| | |
|---|---|
| Hot water ... ... ... ... | 1,000 c.c. |
| Sodium sulphite ... ... ... | 200 grammes |

To this is added:—

| | |
|---|---|
| Hydroquinone ... ... ... | 40 ,, |

For use, from 20 to 25 c.c. of this solution are diluted with from 100 to 125 c.c. of water (which should be warm in winter), and to this the solution of the alkali and ferrocyanide of potassium should be gradually added. The concentrated solution is said to keep perfectly clear for months. The used developing solution may be preserved and employed again in the case of reproductions.

*New Photo-Lithographic Process.*—In the same journal a new photo-lithographic process is described by C. Fleck. In this process a photo-lithographic transfer paper is used that can be purchased ready-prepared; the well-known Husnik paper answers perfectly. It is sensitised in a solution of bichromate, and then printed exactly as described in the instructions given with the paper by the manufacturers. After printing, the print is placed in the dark room in a solution of chloroform until it becomes sufficiently saturated with it, when it should be placed upon a clean glass plate and coated with a sensitive asphaltum solution. When dry, the print is placed for about ten minutes in hot water, and is then developed on the glass plate by circular rubbing with a pad of cotton, which should be continued until every line of the image appears clear and distinct. The print is then rinsed with cold water, soaked for about five minutes in a solution of chrome alum (1 part in 100 parts of water), and again washed. Finally, the print is gummed. In this state it may be kept for months before it is used to make a transfer. Before use the print should be freed from the gum layer by means of water, and the excess of water removed by gently dabbing the print with a sponge. Whilst the print is soaked in the water bath, a small quantity of the following photo-lithographic ink should be spread, by means of a glue roller, over an inking slab:—

| | |
|---|---|
| Transfer ink ... ... ... ... | 100 parts |
| Syrian asphalt ... ... ... ... | 50 ,, |
| Venet. turpentine ... ... ... | 50 ,, |
| Boiled in | |
| French turpentine oil ... ... ... | 200 ,, |

Finally, after the ink has been removed from the fire, 100 parts of benzol should be added to it with constant stirring. With this ink, the print, whilst it is still wet, is rolled up until an even film of ink is left upon the paper, through which the image can be seen distinctly. When the print is inked up, a transfer is made from it in the usual manner. This method has the advantage that a single print is sufficient, which may be kept for months, and which also then produces any number of transfers of great brilliancy.

*Washing Apparatus for Gelatine Plates.*—Dr. E. Vogel describes the following simple, cheap, and practical washing arrangement for dry plates, which has been in use since 1883 at the Technical High School of Charlottenburg. Essentially it consists of a flat box of sheet-zinc. For plates 13 by 18 centimetres, it is about 19 centimetres wide, 60 centimetres long, and from 1·5 to 2 centimetres high. The plates are placed in it side by side. The box is placed slightly slanting, so that its upper end is still covered by the water whilst the latter runs down at the lower end of the box. For use in photographic establishments of moderate extension, a single basin is sufficient. It is placed obliquely with its upper side beneath a water-conduit. In case a large number of plates are to be washed, a number of these boxes may be superimposed on an iron stand, so that the water runs from the upper box into the lower ones, which are richest in hypo. The plates are at first placed deepest, and as soon as fresh ones are added, they are pushed higher and higher. This arrangement prevents the plates which are already partly washed out being soiled by freshly added ones. The consumption of water amounts to only one-eighth of that of the ordinary washing boxes.

*A Substitute for Lantern Slides on Glass.*—To a firm of Nuremberg, a process of making transparent pictures on paper for the magic lantern has been patented in this country. The process consists in the following. Thin paper—so-called letter-paper—is placed in a bath of creosote oil, or coated with this liquid, and exposed to the action of it, until the fibres of the paper are no more visible. The surplus creosote oil is then removed between two layers of blotting-paper, and the paper so treated is immersed in a solution of colophony in alcohol, or coated with it. It is then suspended to dry, and when perfectly dry coated with a diluted gelatine solution. After this gelatine coating has perfectly dried, the paper is provided with the picture by means of one of the common printing processes, and finally coated with a diluted solution of spirit varnish. It is said that these paper pictures give quite the same effect in the lantern as the glass slides. They have the advantage that they may be printed on very long strips of paper, and wound up on rollers, by which a uniform and continuous effect is ensured.

*Pyro Developer with Caustic Alkali.*—The following developer has given in my hands very good results in the case of short exposures:—

| | |
|---|---|
| Pyrogallic acid ... ... ... | 3 grammes |
| Sodium sulphite ... ... ... | 10 ,, |
| Chloride of ammonium ... ... | 4 ,, |
| Water ... ... ... ... ... | 500 ,, |

To this solution is added—

| | |
|---|---|
| Caustic soda ... ... ... ... | 3 grammes |

For use, to each 50 c.c. of this developer 1 c.c. of a solution of potassium bromide (1 : 10) should be added.

## FURTHER NOTES ON SILVER PRINTING.*

BY LYONEL CLARK.

My contribution of this evening to the proceedings of our Club will partake rather of the character of desultory notes than that of a fixed paper, as I propose to give you the benefit of what further experience I have gained in a year's working of the process I described before you on December 19th last, and also to more fully develop the process of intensifying my silver prints, which I merely foreshadowed on that evening.

Beginning with the support or paper that is to receive the print, I mentioned that I had just received a batch of paper from Messrs. Reeves and Sons, known as "Arnold's pure unbleached," but had not had time to experiment with it. Since that date I have, however, been able to give the paper a thorough trial, with the result that I certainly find it superior in quality—or, perhaps, I should say purity—to any of the Whatman papers. The rough quality shows a rather decided diagonal surface grain, to which personally I do not object, although others may; but the smoother qualities, of course, are quite free therefrom. It is, however, on account of its great purity that I chiefly prefer it, for I have hardly met with a single instance of metallic impurities, or, indeed, any imperfections in the paper. I am unaware whether there is any difference in the sizing of this and the Whatman paper, but I am inclined, from its behaviour, to believe that there is.

With the Whatman I have frequently—indeed, almost universally—found patches of the paper that refused to soak up moisture, and remained comparatively hard and dry, even through the toning, fixing, and washing baths. I cannot say that there was anything dangerous about the appearance, nor, indeed, was it at all visible on the face; but I always had a sort of feeling that these patches might be portions of coagulated sizing and silver, to which the hypo could not get proper access, and which, therefore, would remain as patches of hyposulphite of silver, or silver chloride, only waiting the proper temptation to burst out into nuclei of discolouration or areas of fading.

* A communication to the Camera Club.

I must confess that up to the present they have not been led into temptation, or the temptation has not been strong enough, for I have failed to trace any harm to their presence. But, nevertheless, the freedom that the Arnold paper appears to possess from them is, in my estimation, another plea for its adoption.

Coming now to the sizing and salting baths, I find but little to change in my formulas. The quantity of gelatine I have recommended is doubtless high, as indeed is also that of the salt, but the amounts are intentional, as it is essential to get as vigorous an image as possible if we wish to have a good black-and-white picture left after toning.

I have personally almost discarded the use of arrowroot or any other sizing agent than gelatine; or, if I do use it, I make it up fresh each time. I find that if the arrowroot mixture be allowed to stand, all the colloid principle appears to settle down to the bottom, and the clear liquid that is decanted off is little better than salt water. Used fresh arrowroot is, however, very useful, but it is difficult to get it to the right degree of viscosity; if too thick, it dries in streaks on the paper, especially when the solution is cooling, and unless one does use it as thick as possible it will not remain sufficiently on the surface of the paper. Therefore, for the rough papers, or those requiring a maximum of sizing, I have discarded arrowroot in favour of gelatine; but for the smoother quality of paper it can be advantageously used of a strength of about 18 grains to the ounce, or 1 in 25. This strength is practically about as thick as you can get it to lie on the paper evenly, and may, of course, vary with different samples. The solution should be used fresh each time, and the paper floated on it while it is still quite hot—in fact, it should be kept hot by the addition of hot water to an exterior dish, making, in fact, an impromptu sort of *bainmarie*. I find no filtering to be necessary. If the dish be covered to a depth of a half-inch, any impurities will sink to the bottom, or, if left floating, will come off if a trial piece of paper be used to skim the surface.

Gelatine should also be used as hot as possible, at least when coating rough paper, and the strength of 24 grains to the ounce, or 14 grammes to the litre, has given me the most satisfactory results. I am afraid I did not make it sufficiently clear, either in my pamphlet on "Platinum Toning" or in my paper before this Club, that it was necessary to apply the gelatine, when used in such strong solutions as I recommended, in as hot a state as possible. If the smoother variety of paper be used, such a proceeding is not so necessary, but with the rough papers it is essential that the gelatine should be very thin and liquid, so that the excess can freely run off the surface of the paper, and not lie in and clog up the interstices between the granulations. With the above strength of gelatine, it must be used quite warm to do this, and therefore I now make it a practice, if I have many sheets to salt, of keeping the bath warm by immersing it in another larger dish that I supply from time to time with hot water.

Unlike the arrowroot bath, the gelatine one can be used over and over again, the jelly that forms when the solution cools being each time redissolved by the application of heat. In fact, the bath remains good as long as the jelly remains a jelly when cold: when the mixture shows signs of becoming watery and losing its viscosity, the gelatine is beginning to perish and rot, and should be thrown away.

I have quite discarded filtration also with gelatine, and use instead a pretty deep layer of the liquid, when the heavy impurities will sink to the bottom, and the lighter ones will be taken up by the first piece of paper floated, which should, therefore, be a waster.

If anything, I am inclined to think that for summer work, or for hard negatives, the strength of the chloride given is too strong, and I now usually reduce it to 6 grains per ounce, or 1 in 73, but for feeble negatives the 8-grain bath can still be used.

As a general rule, too, I use the simple chloride bath, and keep the mixed citrate and chloride one when very vigorous prints to give very black images are required. For the benefit of those who were not present at my last lecture, I will here repeat these formulas of salting baths.

For average negatives from spring to autumn:—

| | | | |
|---|---|---|---|
| A.—Chloride of ammonium | ... 120 grains | ... 14 grams |
| Water ... ... | ... 1 pint | ... 1 litre |

For feeble negatives or for winter light:—

| | | |
|---|---|---|
| B.—Chloride of ammonium | ... 160 grains | ... 19 grams |
| Water ... ... | ... 1 pint | ... 1 litre |

To these baths a crystal of soda carbonate about the size of a pea should be added to insure their alkalinity.

To obtain very vigorous prints, or for weak negatives or very feeble light:—

| | | |
|---|---|---|
| C.—Chloride of ammonium | ... 120 grains | ... 14 grams |
| Carbonate soda crystals | ... 240 ,, | ... 28 ,, |
| Citric acid crystals | ... 60 ,, | ... 7 ,, |
| Water up to ... | ... 1 pint | ... 1 litre |

With all these baths the amount of gelatine to be used is:—

| | Grains. | Grams. | | Grains. | Grams. |
|---|---|---|---|---|---|
| Rough paper ... | 240 | 28 | | | |
| Not hot-pressed ... | 120 | 14, | or arrowroot, | 180 | 21 |
| Hot-pressed ... | 60 | 7 | ,, | 180 | 21 |

These quantities are per pint or litre of liquid.

Coming now to the application of the salting solution to the paper, I now invariably use the floating method as the most suitable and easy. It is true that most heavy, rough papers will be found to be very repellent of the liquid, and, when floated, will at first refuse to take up any of the solution. But I get over this difficulty by brushing some of the hot salting solution over the surface of the paper before floating it. For this purpose I lay the paper face upward on a board, and with an ordinary broad camel-hair brush apply a fair amount of the hot solution as evenly as possible to the surface of the paper, and then leave it lying on its back whilst the preceding sheet is floating on the bath. This procedure effects a double object; it not only makes the paper take kindly to the bath, but causes it also to imbibe a certain amount of moisture, and, therefore, to lie nice and flat on the bath. I usually float the sheets for three minutes, and while one is being floated a second is being brushed over and left ready for its turn.

With regard to the drying of the paper, I have nothing to add, except to reiterate the statement that they should not be dried in a cold place; in fact, the hotter the drying room, the better.

(*To be continued.*)

Torquay Photographic Association.—The second annual meeting was held on October 20th for the election of officers and committee, passing reports and accounts. The number of members is fifty-three, and meetings are held on the third Wednesday of the month. The Association has become affiliated to the Photographic Society of Great Britain.

## Patent Intelligence.

### Applications for Letters Patent.

17,408. William Tylar, 12, Cherry Street, Birmingham, "A New or Improved Holder or Stand for Displaying Multiple Photographs and the Like."—*October 13th.*

17,516. John Edward Thornton and Edgar Pickard, 6, Bank Street, Manchester, "Improvements in Shutters for Photographic Cameras."—*October 14th.*

### Specifications Published.

7,066. *May 7th*, 1890.—"Shutters." W. G. Tweedy, 8, Athenæum Terrace, Plymouth.

The time of exposure in the case of drop shutters is regulated by a falling bob or weight, which is allowed to fall any desired part of the length of an attached tape before it acts on the shutter. The length of tape to be let out for a certain exposure can be calculated from an equation which involves the vertical dimension of the exposure aperture, and the weights of the shutter slide and bob. Modified arrangements are described in which the dimension of the exposure aperture may be variable, and the length of the tape constant; also in which the shutter slide may be in two parts connected by a length of tape which determines the dimension of the exposure aperture.

7,236. *May 9th*, 1890.—"Cameras and Change-Boxes." E. S. Miller, 11, Bath Road, Bedford Park, Chiswick, Middlesex, and E. C. Hawkins, 5, High Street, Bloomsbury, London, W.C.

In the hand, &c., camera is fitted the changing mechanism frame, consisting of a base and side vertical supports at the back, connected by a cross piece. The supports are fitted with guides, on which the projections of the sheaths rest. The notches in the sheaths also engage with the guides, thus preventing displacement of the plates in a vertical direction until the notches escape from the parallel part of the guides. The plates, which, to begin with, are placed on the guides, are pressed forward by a compound spring towards the exposure stops, which consist of projections and notches on the guides. The exposed plates are intermittently lifted off the guides by oscillating spring arms pivoted to the flanges of the shaft, actuated from the outside of the camera by a key, and are deposited, face downwards, in a well, formed by a front piece, side pieces, and a movable back, which latter is actuated simultaneously with the arms to facilitate the dropping of the plates, and to press them compactly together. The projections on the sides trip the plates off the arms.

7,453. *May 13th*, 1890.—"Printing." A. G. Green, 5, Thistlewaite Road, Lower Clapton, London, C. F. Cross, and E. J. Bevan, both of 4, New Court, Carey Street, W.C.

Relates to what is known as the "primuline" process. The paper, or textile fabric, &c., is treated with a diazo compound, and is exposed under a negative, &c., the resulting image being developed by an amine or phenol, &c., solution.

7,489. *May 14th*, 1890.—"Cameras." C. C. Vevers, 12, Market Street, Briggate, Leeds.

The back has a vertical and horizontal swing. To the sides of the baseboard are fitted sliding pieces, provided with slots, to which struts, pivoted to the back, can be attached by screws. The struts are also provided with projections, which engage in recesses in the pieces. For a vertical swing a screw, which passes through a curved slot in the strut, and engages with a nut in the camera back (or *vice versâ*), is provided. A horizontal swing is obtained by moving one of the pieces in advance of the other.

Received.—From Gauthier-Villars, Paris, "Manuel de Ferrotypie," by Henry Gauthier-Villars. It consists of thirty-six pages divided into six chapters, embracing the various manipulations involved in the production of ferrotypes, the closing chapter dealing with their applications.

## Correspondence.

MADDOX TESTIMONIAL.

Sir,—Propositions have been made through the columns of one of your contemporaries to raise a testimonial to Dr. Maddox, and we think the discussion of such an important matter should not be confined to the columns of one journal, but that the whole photographic world should be stirred up to take a lively interest in the scheme. Our present-day photography owes all to Dr. Maddox, and we trust to see a subscription list worthy of the occasion. We have contributed to the fund, and urge all to follow suit. The Britannia Works Co.

*Ilford, London, E., October 16th.*

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

Sir,—The following are the lantern arrangements at the Society's Exhibition, 5a, Pall Mall East, for the coming week :—Oct. 24th, B. J. Edwards, Esq., on "A Tour in New Zealand"; Oct. 26th, lantern display by the Field Club; Oct. 28th, J. R. Wright, Esq., on "Our Village"; Oct. 29th, lantern slides by E. G. Lee, Esq., and J. T. Field, Esq.; Oct. 31st, lantern display by the Photographic Club.

The next technical meeting will be held at the Gallery on Tuesday, Oct. 27th, at 8 p.m., when the apparatus in the Exhibition will be explained. H. A. Lawrance, *Asst. Sec.*

50, *Great Russell Street, Bloomsbury, W.C., Oct. 20th.*

## Proceedings of Societies.

London and Provincial Photographic Association.

At the meeting of this Society held on the 15th inst. Mr. F. A. Bridge occupied the chair.

The Chairman showed a photograph of the interior of a building, in which it had been necessary to use great precautions to prevent halation. He found that the ordinary thin coating of burnt sienna proved quite insufficient, but, on repeating the exposure with a plate backed with caramel mixed with the burnt sienna, he had obtained a very satisfactory result.

Mr. A. Haddon had coated a place on one side of a prism with burnt sienna, and an adjoining place with the caramel mixture. The amount of light absorbed by the caramel portion was very great in comparison to that absorbed by the sienna.

Mr. A. L. Henderson showed a negative by Mr. F. York, of the interior of a saloon at Monte Carlo. It was disfigured by some general dimness, and he enquired the probable cause of this effect.

Mr. A. Cowan said undoubtedly there was damp on the lens.

Mr. York said that was so. After waiting till the lens had acquired nearly the same temperature as that of the saloon, and taking another plate, the image came out clearly.

Mr. Henderson showed some negatives which were very weak, which, he said, showed some reversal of image. He attributed this to the dampness of the place where they had been exposed, and stated that he had prevented that evil by soaking the plates in a solution of carbonate of lithium.

Mr. Cowan thought that, as in Mr. York's case, the weak, foggy character of the negatives was due to moisture on the lens.

Mr. J. S. Teape showed some further illustrations of reversals by over-exposure, in continuation of the experiments described at the previous meetings.

A large number of slides was put through the lantern, and a selection made of those that were to be sent to the Pall Mall Exhibition.

Camera Club.

On October 12th there was a lantern exhibition at the Camera Club, when slides were shown by Messrs. Ferrero, Matthews, Fitz-Payne, Chang, Bridger, Barton, Lysaght, and by Dr. Patterson and Major Tagart.

On Thursday (Rev. F. C. Lambert in the chair) Mr. Andrew Pringle delivered an address on "Bacteria Photographed." Mr. Pringle gave a brief and popular account of bacteriology and its classifications, and illustrated his subject throughout with a large number of slides.

A discussion followed, in which Dr. Patterson, Messrs. Mills, Charters-White, Elder, and the Chairman took part.

On Monday, October 26th, lantern slides will be shown, and on Thursday, October 29th, Dr. Patterson will read a paper, illustrated with lantern slides, on "Animal Photography with a Hand-Camera."

Putney Photographic Society.

*Thursday, October 15th.*—The winter session was opened this evening, under most favourable circumstances, by a lecture on "Illustrated Journalism," delivered in the Local Assembly Rooms, High Street, by Mr. T. C. Hepworth, F.C.S., before an audience numbering fully 350, mainly friends of the members of the Society. The Rev. L. Macdona presided, and in the course of his remarks touched on the formation of the Society last December, and its steady growth and progress.

The Lecturer, who was received with applause, commenced by explaining the production of a daily newspaper, and the important part played by photography in the reproduction of illustrations. The pictures thrown upon the screen, which were the work of the lecturer, and to which full justice was done by the fine triple lantern lent by Mr. Steward, were heartily applauded, the first being of a two-column paper published in December, 1679, called the *Domestick Intelligence*; another, that of Nelson's funeral car, *Times*, 1806 ; another of a paper giving an account of a murder done by one Daniel Good, a resident of Putney. He spoke of the modern wood engraving taken from the weekly *Graphic*, describing the entire manufacture of paper, hand and machine-made, from the collection of rags, esparto grass, straw, wood, &c., through the numerous stages to the production of the finished article. He afterwards showed a view of the large paper mills at Swanley, Kent, which was followed by a description of the printing and publishing of the *Daily Graphic*, showing pictures of the two types of printing machines, capable of turning out 10,000 copies per hour, drums of paper 3½ miles in length passing through, which occupied but fourteen minutes. He then traced the progress of journalism down to the present day ; showing sketches received from war correspondents during the last siege of Paris, and Soudan war.

At the conclusion of this interesting lecture a hearty vote of thanks was proposed by Dr. W. J. Sheppard, seconded by Mr. E. D. Purcell.

Mr. Steward's representative then exhibited some fine slides, amongst which "The Wreck," with lightning effect, "Westminster Abbey," and "Bridge of Sighs," with day, night, and moonlight effects, call for special comment.

The "Club" single lantern and other apparatus was on view. A vote of thanks to Mr. J. H. Steward and the lanternist, proposed by Dr. J. F. Farrar, closed the proceedings.

Next meeting, 31st October, "Bromide Demonstration" by the Fry Manufacturing Company.

Richmond Camera Club.

At the annual general meeting, held on October 16th, Mr. F. P. Cembrano, junr., in the chair, the committee presented their annual report for the year ended August 31st, 1891, of which the following is a summary :—

The Club was formed on July 7th, 1890, under the name of "The Richmond Amateur Photographic Society," which, at a special general meeting, was altered to the "Richmond Camera Club," and the rule excluding professional photographers was rescinded. The meetings of the Club, which were formerly held fortnightly, are now held weekly, having a fair average attendance. Demonstrations of several photographic processes and appliances have taken place at intervals, as well as exhibitions of lantern slides. A lecture given by the president, Major J. Fortuné Nott, in aid of the funds of the Richmond Hospital, resulted in a nett balance of £4. It is proposed to hold the first annual dinner on Monday, Nov. 23rd, at the Greyhound Hotel, Richmond, and a *conversazione* early in 1892. Fortnightly outings were held during the season, but the attendance was meagre, due, perhaps, to the unfavourable weather.

The following members have been elected for office during the ensuing year :—*President*—Mr. F. P. Cembrauo ; *Hon. Sec.*—Mr. P. Ennis, 28, Halford Road, Richmond, Surrey ; *Hon. Librarian*—Mr. G. Ardaseer ; *Committee*—Messrs. R. L. Kidd, E. G. Richardson, C. E. Hodgkin, C. H. Davis, aud A. C. Hunter.

A vote of thanks was uuanimously accorded to the late secretary, Mr. E. G. Richardson, for his valuable services duriug the past year.

Midland Camera Club.

*October 16th.*—Geueral meeting in the new club-rooms (Queen's College), Dr. Hall-Edwards in the chair.

The rules drafted out by the provisional committee were adopted, and, upon readiug the names of geutlemen who had expressed their desire to join, together with three or four handed in at the meeting, the Chairman congratulated the Club upon starting with a membership of fifty. Commenting upon a remark that appeared in one of the photographic papers, that the Club would possess no members of any influence, the Chairman said he would call attention to the following names:—Prof. Allen, M.A.M.B., Gilbert Barliug, F.R.C.S., Wm. Dudley, M.R.C.S., Rev. J. Henry, F.R.G.S., George H. Hart, L.R.C.P., Rev. W. Rigby Jubb, M.A., Rev. Hubert Kingdom, H. R. Leech, M.R.C.S., Jordan Lloyd, F.R.C.S., C. A. Lumley, M.R.C.S., W. W. J. Nichol, D.Sc. (of Kallitype fame), Dr. Ratcliffe, of the General Hospital, Rev. E. J. Nurse, Henry Sturmey, Gilbert Smith, M.R.C.S., Priestley Smith, M.R.C.S., &c. They also had three lady members. He thought that was a pretty influential list to start with.

The electiou of officers resulted as follows :—*President*—Dr. Hall-Edwards ; *Vice-President*—Rev. J. Henry ; *Hon. Secretary*—Mr. Walter D. Welford : *Hon. Treasurer*—Mr. S. G. Masou ; *Committee*—Messrs. H. R. Leech, W. W. J. Nichol, Edw. Morton, Rowland White, and Dr. Ratcliffe.

It was resolved to form a section for the discussion of matters relating to the application of photography to manufacturing industries. The club-roouis were hung with pictures, "Carolling" and "Lobster Boat," by Mr. H. P. Robinson ; "When the Day is Far Spent," by Rev. F. C. Lambert ; some excellent micro-photographic frames, by the president ; landscapes by the hon. treasurer, and hand-camera pictures by the hon. secretary. There was also a large display of lautern slides.

At present the rooms are not fully furnished—the dark room requires filling up, &c.—but by means of a private loan fund which has been inaugurated the committee will be able to very quickly get everything into thorough working order without trenching upon the current year's receipts. The rooms, however, are open at all hours to the inspection or for the use of members.

Toning after Fixing.—Toning formulas are very uumerous generally, and in the best one of the methods used the prints are first toned, then almost immediately fixed with hyposulphite of soda. Numerous baths have also been proposed by which the prints are toned and fixed at the same time. These baths being generally acid, should be rejected, as they may produce a more or less sulphuratiou of the prints. It may be useful, notably when there is no toning bath at hand, to first fix the prints, and afterwards tone theni after a certain lapse of time. Here is a formula of a bath that may be used with advantage : — Sulphocyanide of ammonium, 30 grammes ; chloride of gold, 0·30 gramme ; caustic potash, 0·30 gramme. This bath may be used immediately, as the caustic potash provokes the instantaneous dissolving of the red precipitate which is formed when the gold salt is added to the sulphocyanide. It keeps well, acts very rapidly, and allows toning up to blue-black. Tones of a darker purple are obtained by using five grammes of carbonate of soda in place of the caustic potash. This bath may be diluted with two or three parts of water when using paper sized with non-albumenised starch ; in this case it is extremely economical. It may also be used before fixing, but theu it acts very slowly, and has a tendency to give pinkish toucs. This toning should be followed by abuudant washing.—M. Mercier.

## Answers to Correspondents.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C S., 2, St. Mary's Road, Canonbury, N.

All Communications, except advertisements, intended for publication should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

A. H. (Manningtree).—*Lens for Quick Exposure.* The details asked for have been sent on by post, leaving the choice to you. In fine weather the first-named ought to be quick enough for street scenes.

Philologist.—*A New Word.* In common with yourself, we observed a new departure ou the front page of the *Graphic* of 26th ult., where the portrait group of the Duke and Duchess of Fife and child is said to be "photoed" by Messrs. W. aud D. Downey. This word would appear to be the past participle of the verb *to photo*, and we may expect to hear, in like manner, of other subjects being "lithoed" in the journal devoted to the exposition of the graphic arts. The Americaus may not object to this inuovation, but it is hardly fair English.

C. M.—*The Aerial Graphoscope.* Mr. Eric Bruce's new invention was practically demonstrated before a large audience at the Pall Mall Gallery on Saturday evening. It constitutes an exceedingly interesting novelty—so much so that it is proposed to repeat the exhibition on each succeeding lantern night. The truth of Mr. H. A. Lawrance's statement as to its being a good experimental proof of the persistence of vision becomes at once apparent by turning the head quickly whilst observing the aerial image. With black velvet as a background, the effect of rotundity is also truly remarkable.

Ella.—*The Bude Light.* Passing a stream of oxygen from a pressure cylinder up the central aperture of an Argand gas burner certainly gives a very brilliant light, but we fear that the excessive heat thus generated would cause the destruction of many a gas-glass during your experiments. However, try it, and report the result.

J. B. (Exeter).—*Decayed Leather.* From your description, it appears probable that heat incautiously applied whilst the leather was still moist was the determining cause of injury to the folding bellows of your camera. After being wetted, leather must only be wiped and left to dry spontaneously in the air, or it is sure to become perished and rotten if put too near a warm fire.

Subscriber.—*Photo-Benevolent Lantern Soirée.* This day fortnight, Friday, November 6th, is the date fixed for holding the annual benefit at the Pall Mall Exhibition, the sanction of president and council having already been given, and an attractive programme is now being arranged.

W. E. D.—*Silver Reduced from Residues.* The small quantity of lead will do no harm. It may have got iu from the zinc employed, unless you used a specially fine quality. Ordinary spelter and zinc plates usually contain from half to one per cent. of lead, and sheet copper always shows evidence of the same impurity. *Old Standard Silver.* It is surely easier to determine the amount of real silver by chloride of sodium solution, iu the presence of a trace of potassium chromate, than to proceed iudirectly by estimating the amount of copper.

L. T.—*Faded Opalines.* You are not the only victim, for it is a common experience. A silver print mounted against glass with gelatine seems to fade more quickly than those to which the glue or gelatine has beeu applied only at the back.

G. B. B.— *Sun Spots.* The most recent information, with some fine illustrations, can be got from Sir Robert Ball's "Story of the Heavens," uow being published in serial form by Messrs. Cassell and Company.

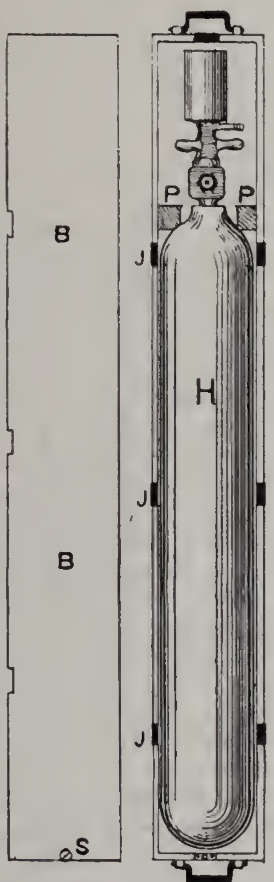
VOL. XXXV. No. 1730.—*October* 30, 1891.

CONTENTS.

## GAS CYLINDERS IN TRANSIT.

Now that the lantern season is commencing, and lanternists, both professional and amateur, are busy in looking up and renovating the apparatus which has been lying dormant for so many months, it may be as well if we devote some attention to a matter which, important in itself, has not as yet met with the attention which it deserves. The cumbrous gas bags have, in the majority of instances, been discarded in favour of the far more convenient bottles, or cylinders, of compressed gas, and, although a few professional workers still swear by the bags, among whom are those who go in for thunder and lightning "effects" with three-decker lanterns, the majority of lanternists who are content with a single, or, at any rate, a bi-unial lantern, carry with them "bottles" and regulators, or "bottles" without regulators. The matter to which we refer is the manner of transporting these cylinders from place to place, and the most convenient manner of disposing them while they are furnishing energy in the form of light to the lantern. We speak of them in the plural because we are in the habit of using the mixed jet fed by two cylinders, but our remarks will apply with equal force to the use of the single cylinder and the blow-through or safety-jet.

According to the report of certain experiments carried out some months ago at Birmingham, a fully charged gas cylinder, although its thickness is but an eighth of an inch, can be knocked about, bent, cast from a height, and otherwise maltreated with impunity, the mild steel of which it is made being of such splendid quality that the cylinder will not only withstand the internal pressure of the gas, which is 1,800 lbs. to the square inch of surface, but is quite unaffected by the severe treatment already detailed. It is, indeed, a matter of every-day occurrence for these cylinders to be sent long distances by train, and we may say that if an article, whatever it may be, has been so carefully manufactured as to remain intact after having been through the hands of the average railway porter, it must be Samson-like in its tenacity. At the same time, the careful worker will always have in his mind the fact that he is dealing with a machine which contains within itself a vast amount of pent-up energy, and that a nasty knock in the right place might cause its release. The chances are probably a million to one against any accident of the kind. Still, it is the unexpected that always happens, and it behoves him to be careful. But, setting aside all risk of fracture, the naked cylinder is an awkward thing to handle, for there is no handle by which to take hold of it, and it must be carried in the arms like a baby. It is, therefore, advantageous in many respects to have a case for each cylinder in use, and to the best form which this case should take we have devoted some attention. As we have had the cases or boxes which we designed in use for many months, during which they have covered many miles in railway vans and other vehicles, and as these boxes have been found to be most convenient, we will now describe them for the benefit of those who care to adopt the same system.



The cylinder which we employ—we will deal with one only for the sake of simplicity—is of sixty feet capacity, and when crowned with a Beard regulator measures nearly four and a-half feet in length. Its containing box is of such a size as to admit the cylinder and regulator without leaving any room to spare, except half an inch clear above the top of the regulator, as shown in the annexed diagram. To prevent the cylinder shifting upwards, two strong posts are affixed to the internal sides of the box, and these just catch the shoulders of the gas vessel and keep it firmly in its place. These posts, marked PP in the illustration, have a farther use. When it is desired to attach a gauge to the cylinder for the purpose of ascertaining the quantity of gas available, the vessel must be removed from its box and the regulator detached. This can easily be done by lifting the cylinder clear of the posts PP, and pulling it forward in the direction of its head. It can then be allowed to rest on the projections PP, and will be held firmly there by its own weight while the necessary adjustments are being made. The black rectangular marks shown on each side of the open box are ┏-shaped clamps which are screwed firmly in place, and which permit the lid of the box BB to slide beneath them. It will be observed that the lid has three openings cut in one of its edges. These have the same distance between them as the clamps J, so that when these openings come opposite to the clamps, the lid can be removed without sliding it the whole length of the box. When this lid is wholly closed over the box, it is secured for travelling by a cheese-headed screw S, which is received into a plate provided for it at the end of the box. The india-rubber tube for attaching the cylinder to the lantern is a fixture on the regulator (not shown in the diagram). It is about eight feet in length, and conveniently lies along the edges of the cylinder, down one side and up the other. The only other feature of this box which need be mentioned is a simple but very necessary one, namely, the presence of a strong wrought iron handle at each end—something that the hand can grasp well, and that will resist a good deal of knocking about.

It is the fashion generally to tie the cylinder or cylinders to the leg of a table, so that the regulator is upright. There is no necessity for this, as the apparatus works quite as well when lying on its side. It is in this latter position that we use it, for the boxes containing the cylinders lie side by side on the floor, between the legs which support the lantern-box and lantern. All that the operator has then to do is to remove the securing screws from the lids, slide the lids a few inches down the boxes to expose the regulators, take out the india-rubber tubes, and make connection with the lantern.

It may be added, in conclusion, that there is plenty of room in the boxes, round about the regulators and above the shoulder-pieces of the cylinders, to accommodate the key, spanner, and other things that may be required in dealing with the gases. These are best carried in cloth bags so that they cannot get loose in transit. We also make it a practice to carry a couple of screw-nozzles to fit the cylinders in case an accident should happen to the regulators. These, happily, we have never yet had occasion to employ.

## ON THE USE OF SMALL STOPS.

BY W. H. WHEELER.

It has been the fashion, particularly among artists, to deprecate what they considered to be the abuse of *small stops*. One gentleman, I remember, recommended us all, in the interests of art, to "throw away our wide-angle lenses, and burn all our small stops." The intention of this heroic advice was excellent. The author of it attributed faults in the perspective of form to the use of wide-angle lenses, and deficiency of atmosphere to that of small stops. No fault need be found with his criticism of results, but his judgment as to causes, and advice as to means, is quite another thing. This is properly our province, and my object in the present paper is to inquire, as thoroughly as I am able, into the advantages and drawbacks attending the use of small stops.

They certainly require special care in keeping stray light from the camera, because the longer the exposure, the longer does this stray light act on the plate; but then, cameras should *always* be light-tight. Again, some workers are slow to realise the rapid ratio at which a proper exposure increases as the stop is reduced, and an under-exposure, with its accompanying want of atmosphere, has thus come to be naturally associated with a small stop. The association, however, is not a necessary one; *all* plates need a sufficient exposure, if breadth and atmosphere are desired. But when a sufficient exposure is given, and when stray light is so carefully shielded from the lens and kept out of the camera that this full exposure does not fog the delicate detail which should be perceptible in the shadows—though not too obvious—then, especially when a large scale is attempted, these much-maligned small stops may be found to be the very life of the art of depicting, in all its native delicacy and profusion of detail, nature in repose.

We will first inquire, what is the optical aspect of the question? Those who, accustomed to the use of telescopes or microscopes—especially the former—have learned to appreciate thoroughly the advantages of aperture in their object-lenses, and perhaps unlearned much of their primitive faith in high magnifying powers, have yet a new lesson before them when they turn their attention to the work of photographic lenses. Oblique errors acquire here a new importance, and the novel power of compensating for reduced light by increased exposure is not at first realised. Neither do we at once appreciate the fact that our accustomed visual power of better distinguishing in the telescope—though only by glimpses—*well illuminated* details amidst surrounding haze of atmospheric fluctuation, or even of optical short-comings, than when that detail has been dimmed in clearing the haze by reducing the aperture, is not shared by the photographic image. For this is impressed, not by glimpses, but by a steady gaze; and, after being formed in the negative, it has still to be printed. A similar difference may be observed between an original photograph and a copy; for the soft haze of indistinct definition, or of slight movement—perhaps that of a near branch out of focus—detracts sensibly less from the charm of an original photograph than when that is further hardened and made more coarse by reproduction. The effect of small stops on a photograph has thus comparative advantages not shared by the optical image when viewed directly through an eye-piece. The appearance of the latter when a large stop is used is much more distinct, as well as more brilliant, than in the resulting photograph, whereas with a small stop it does not equally mislead.

Thus, while a longer exposure can compensate us for want of light, the clearance from surrounding haze of error produces even more improvement in the distinctness of definition. Some things, indeed, there are which men have expected from small stops in which they will certainly be disappointed.

They will never make up for careless focussing. They will not make a "rapid rectilinear" lens cover like a wide-angle lens of equal quality and similar focus. They will not cure any kind of distortion. Their value is perhaps greatest with so-called non-aplanatic lenses, in which central distinctness with a large stop has been to some extent judiciously sacrificed to obtain better marginal definition with a flatter field; and when used in taking subjects with which an even delicacy of accurate definition is most likely to be appreciated. But a full appreciation of that delicate accuracy of photographic definition which cannot, without a small stop, be generally distributed among various planes—so answering to the ciliary accommodation of natural vision; or over a considerable angle of view, corresponding again with the natural perceptive process of distinct and successive vision on the "fovea"—varies very much with different people. The painter, whose longing is for ideal beauty and for the effective presentation of his own conceptions, does not realise the almost universal consent with which the general public, who desire rather to recall associations than to obtain original ideas, prefer such detail, even when irrelevant in itself, as seems to carry with it the stamp and proof of *reality*, trusting, probably, to their own memories or imaginations for the necessary ideal element; and he very naturally pooh-poohs the minute delicacy of definition which the very nature of his means precludes him from obtaining with due subordination, for which, perhaps, his own particular public care less, and which, therefore, the judicious artist does not care to spend time in attempting, although he has frequently, for want of it, to substitute a conventional imitation for the natural texture a good photograph can render. Then there is the inattentive observer, and the observer whose eyesight has begun to fail him. But the nature and mechanical perfection of our means are such that, for a really good photograph of still life, our attention need never be diverted from study of artistic effect in lighting or composition, and we need sacrifice nothing but a little time in the exposure, to combine with such qualities as artists appreciate, and which satisfy inattentive or dim-sighted observers, that delicate optical definition also, a full appreciation of which rewards the attentive observation of a sharper vision. It is all very well for some artists to deprecate a close survey by saying that a picture is not intended to be smelt. Most certainly not! That, at least, is abundantly evident, sometimes to more senses than one. But photography is a different thing, because we can, as the artist cannot, easily so produce our pictures as that their details may reward the keenest sight, and yet a harmonious general effect equally gratify an observer at the proper distance. I would, therefore, invert the common way of putting the case, and for the question, how *large* a stop can I use? I would ask instead, how *small* a stop have I time and convenience to use? Thus fully to recognise delicate accuracy of definition over the whole picture as a good thing in itself, and worthy to be sought for its own sake.

But, as the time required by a smaller stop increases very fast—at least, as fast as the area of the stop (that is, of course, as the square of its diameter)—we ought to separate in our theory those cases in which contingent or certain movement may or must injure the result, or, as sometimes in portraits, a tired expression supervene; also cases where a passing phase of incident or of lighting needs to be secured—including, of course, the whole body of "shots," or instantaneous pictures. In all such cases the choice between inaccurate definition and insufficient exposure on the one hand, and the possibly injurious effect of movement or the inconvenience of a long exposure on the other, must be left to the worker's own judgment as to each individual case. For portraits, the intelligent attention of photographers is already so well directed to the subject that only one case appears to me to call for remark. It is that of those who, feeling sure that it is right to keep well away from their sitter by using a long-focus lens, even for heads when wanted on a large scale, may yet be deterred, fearing such want of *depth* as would compel a smaller stop—slower than desirable. They have been told that longer focus lenses have far less depth, and may not be aware how fully a greater distance from the sitter compensates this.

The correct rule really is that, with the same *scale of image* and the same *intensity* of lens, the depth of focus is also precisely the same, *whatever be the focal length used;* and the sound and important reason why we should never photograph, even a face, from a very near standpoint, can scarcely be repeated too often. It is not merely that a longer focus lens covers better—though this is important too—but it is to prevent the face or figure from being, as artists call it, "out of drawing." For when we look at any person from a very close standpoint, we see the figure far more *as we know it to be*, than as corresponding exactly to the varying distances of its different parts from the eye, this truer perception of the figure as it really is being greatly aided by our natural habit of *running the eye* over the whole near figure as it looms, irregularly large, on our sight, so giving time and opportunity for actual memory, or for preconceived ideas, to modify our sensations as they are mentally interpreted, and so form themselves into a *perception* of the whole. It is a means beneficently provided, helping us to retain that constant sense of true form so necessary for recognition, as well as for our appreciation and feeling for harmonious beauty, which sense of true form might otherwise be hardly able to sustain itself against the continually changing and distorting variations of apparent forms, as the close proximities of ordinary life necessarily present them to crude sensation.

On the other hand, when we look only at the photograph, our perceptions not being corrected by so full a sense of reality, or so favourably modified by running the eye over it (the figure, being so small, is embraced by the eye almost at once), it is seen pretty simply as the lens has depicted it; that is, with each different part or feature presented on *different scales*, corresponding precisely to their different distances from the eye. And, of course, this is just what critical observers, accustomed to the *true* face or figure, know it *not to be*. Fortunately, an increased distance from the sitter practically corrects all faults of this kind so rapidly, that I believe the most critical artist does not recommend in general more than fifteen feet or so for moderate sized portraits, less sufficing for heads only. But how many are taken from less than half that distance? Perhaps I may, to many readers—accustomed either to uncritical judges, whose perceptions of true form are blunt and inaccurate; or to others, who, while conscious of something not right (they know not what) set all down as a fault somehow inherent to photography—appear to be making too much of a small error. But in portraying the human form, small errors are not necessarily slight errors. A very minute change of proportion may make a serious change in *expression*; and respect for our art in its highest and almost ideal vocation—the portraiture of the human face and form—should make us scrupulous as to error directly affecting form in our portraits. It is well to remember also that the principle applies with equal force to photographing statues or busts; and that though these subjects reward the use of small stops by such full depth of focus and general accuracy of definition as is impossible with a living subject, yet small stops will cure no kind of distortion.

*(To be continued.)*

## PRINTING ON SILK.

The following directions for printing photographs on silk we take from the columns of the *Scientific American*. It is recommended to use china silk of a ground tint suitable to the subject in hand. The silk must first be well washed to free it from dressing, and then immersed in the following solution:—

| | |
|---|---|
| Common salt ... ... ... ... | 4 grammes |
| Arrowroot ... ... ... ... | 4 ,, |
| Acetic acid ... ... ... ... | 15 c.c. |
| Distilled water ... ... ... | 100 ,, |

The arrowroot is dissolved in the water by the aid of a gentle heat, and then the other ingredients added, and finally—

| | |
|---|---|
| Tannin... ... ... ... ... | 4 grammes |

dissolved in—

| | |
|---|---|
| Distilled water ... ... ... | 100 c.c. |

Are also added, and the mixture filtered. The silk is allowed to lie in this salting bath for three minutes, hung up to dry, and afterwards sensitised on a silver bath as follows:—

| | |
|---|---|
| Nitrate of silver ... ... ... | 3 grammes |
| Distilled water ... ... ... | 25 c.c. |
| Nitric acid ... ... ... ... | ½ drop |

The silk is floated on this for one minute, then hung up till surface dry, and finally pinned out on a board till thoroughly dry. It is printed in the usual way, and washed and toned as usual, though we have found the mixed acetate and sulphocyanide bath give the best tones.

Retribution.—

A beautiful maiden, reading a book;
A picturesque landscape, a babbling brook.
A man with a kodak in secret prepares
To picture the maid as she sits, unawares.
Her two strapping brothers were chancing to pass,
Saw the man with the kodak, and also the lass.
They rolled up their sleeves, threw off hat, coat, and vest;
The man pressed the button, they did the rest.—*Judge.*

We beg to thank "Watchman," in the *Beacon*, for a paragraph which concerns the Photographic News. He writes: "Is not your *confrère* of the *Eye* like the originators of the Daguerre Memorial, a little out in his historical knowledge? At the entertainment given by the American Aristotype Company, at Chautauqua, he proposed the health of Dr. Liesegang and Herr Obernetter as the inventors of "aristo" paper, when, as almost everybody else knows, that honour belonged to the late G. Wharton Simpson, editor of the Photographic News. In August, I think, of 1864, I assisted as an onlooker at the first experiments he made in that direction, and the process was published later in the year in the Year-Book published in connection with that journal, and I know of at least one photographer who took it up then, and has stuck to it ever since."

## THE PRINTING PAPER OF THE FUTURE.*

BY JOHN HOWSON.

Nothing can be more striking to the careful student of photographic history than the fact that albumenised paper, which has, without doubt, been the most widely condemned and least understood of printing processes, should have not merely survived, but be still the process which is most largely used. At all periods during its existence its inherent want of permanency, and its uncertainty and other demerits, have been the constantly recurring themes of discourse at our meetings and in our journals. To have survived these onslaughts, it is clear that its drawbacks have been balanced by some real merits. Its good points are readily pointed out, and, when found, will as readily explain the apparent anomaly of so universally condemned a process being at once so widely used and so long-lived.

I cannot better explain the position than by quoting from an article written in 1887 by Mr. Herbert S. Starnes. In that article he discusses this very question, "What will be the printing process of the future?" After writing of the question of permanency, and joining the chorus of condemnation, he goes on to say: "Next to permanency is that of range of tone and delicacy of image. Here there is no doubt that albumenised paper holds first place. With a suitable negative, platinotype or bromide emulsion papers no doubt run it close, but, as a rule, there is a flatness in the darkest shadows which we do not get in albumenised paper, and there is also a less graduated range of tones from light to dark." After further comparing the various processes, he concludes as follows: "I think I have said enough to show that the printing process of the future must be something different to what has yet been introduced, and that photographers are sensible in not throwing up albumenised paper until they are shown something that can take its place by giving equal results with equal certainty."

To prove that we have to-day such a process as Mr. Starnes looked for within our reach, is my task, and I do not pretend for one moment to rely on my own opinions to prove my case, that gelatino-chloride paper has within it qualities which make it, as I claim, "the printing process of the future."

Having thus stated my case, I may, with a view to its better understanding, refer to the historical aspect of the paper. Its forerunner and prototype was collodio-chloride paper. This paper, produced as long ago as 1865, was known to the photographic world as Simpson-type, and, though in its day it had considerable success, and even now is not altogether defunct, there are drawbacks to its use which make it fall short of that perfection which is aimed at. As gelatine began to oust collodion for negative plates, so, naturally, the attention of experimenters in printing processes was directed to the use of gelatine as a vehicle for the silver salt in that special branch.

As is too often the case, the world was slow to value at their full worth these discoveries, and the matter had, at the moment, no commercial outcome. Photographers here and there have prepared their own paper after one or other of the formulæ given, but such individual effort to utilise the process could but be called a living death. Now-a-days everything photographic, to be of widespread use, must be prepared on a large commercial scale, and be

* Abstract of a paper read before the Photographic Society of Ireland.

readily obtainable at every street corner, so that the consumer can buy what he needs readily and at a low price. Life is too short, and the exigencies of business life too exacting, to allow time for home preparation of any article of general use. Germany has the credit of first preparing the paper on a commercial scale, and Herr Obernetter is the pioneer of this business; not only so, but until to-day his paper has been looked on as the best of its kind, and has been the one most largely used. Other Continental and American makers have introduced similar papers, and within a very recent period Mr. Walter Woodbury has been the means of inducing an English firm to take up its manufacture, and by his writing in the journals has done much to popularise the paper, and make its merits widely known. So much for the history of the past, condensed into a few brief sentences.

I may readily admit that, given certain properly adapted negatives, other printing processes yield most admirable and possibly superior results; but it is the common lot of photographers to produce a wide range of negatives, varying as to quality and characteristics. To say, therefore, that we have got the printing process of the future is to say that we have a paper that is adapted equally for all such negatives. Not the cleverest and most able photographer that ever uncapped a lens or snapped a shutter can say to himself: Now this negative I am about to take shall have such-and-such characteristics to suit it for such-and-such a printing paper. By infinite care he may, on occasion, produce negatives such as he wants. If he, as a specially able man, with time at his disposal, can with difficulty succeed in this respect, what must be the position of the rank and file? No! I say boldly that, speaking of photographers as a whole, a negative is what light, and subject, and a dozen other incidentals make it, not what the photographer would wish. Hence, to suit a varying quality of negative, we have absolute need of a printing paper which is adapted to yield the best results from these negatives, be their quality what it may. Such a paper, I say unhesitatingly, is only possible if it is so made that the image is retained on the surface by some vehicle, whether it be albumen, collodion, or, as in the paper under discussion, gelatine.

It would only be natural for some objector to interpose here and say: If the merits of gelatino-chloride paper are so great, and known as far back as four or five years ago, why has it not made greater headway, and become more generally used? This is a most natural question, and the reply is equally apt. Albumen paper had the necessary advantages: it held command of the field, and it was readily obtainable; and, above all, was so cheap that its want of permanency and other demerits could not weigh in the scale against it. Since the world began, it has ever been thus with all things new. All changes have been gradual. Though Obernetter, Liesegang, and others have had papers offered to the public for some years, their sale was hampered in more than one way, the most serious of which was that of price, and it makes strongly for my point that, spite of this drawback, the paper has been used to a very considerable extent both in Great Britain, the Continent, and in America. There are photographers of all grades who, despite the great extra cost, have recognised its high merits, and used it largely, if not solely, in their work.

There must be unanimity of opinion that, as to permanency and results, gelatino-chloride paper answers Mr. Starnes' postulates, and so far may be entitled to the claim to be the printing paper of the future. The only other quality named by Mr. Starnes was ease of results, and I cannot conceive anything more convincing than practical demonstration.

I have half-a-dozen prints made on the new Ilford paper. They are not at all deeply printed, as they lose little in the toning and fixing operations. These prints, if kept from light and air, may be kept for days or weeks unfinished.

The first process is thorough washing for ten minutes in running water, or several changes. Having washed all we propose to tone, they are laid by our side in a dish of water. It will be interesting to note here that the prints have not the slightest tendency to curl when wet, a great improvement on both albumen and previous gelatine papers. A clean dish is ready, and the bottle of toning solution taken in hand. This toning bath is one of the simplest imaginable, consisting of—

| | |
|---|---|
| Water ... ... ... ... ... | 16 ounces |
| Sulphocyanide of ammonium ... ... | 30 grains |
| Chloride of gold ... ... ... | $2\frac{1}{2}$ ,, |

This is the best bath. The paper lends itself to use with almost any of the various formulæ given for this class of paper, whether simple or combined. I must say, however, that it will be wise to adhere to the bath given. For my own part, I would refrain from recommending any combined bath that I have yet seen. I should be afraid that either acid or sulphur toning would accrue, and with that a want of permanency. Some of the baths recommended are glaringly open to this charge, and are to be rigidly avoided. Immersing the prints in our toning bath, we make sure that they do not cling to each other, and keep them constantly moving. In three or four minutes some of them—dependent on the negative used—will be sufficiently toned, and are taken from the dish and passed into plain water. The progress of toning is judged by transmitted light, and if an ordinary photographic purple colour is required, on looking through the prints there should be just a trace of warmth in the deepest shadows. On the surface the print will appear overtoned, but this appearance is lost on fixation. If warmer coloured prints are wanted, of course they are withdrawn from the bath at earlier stages. By this simple means the widest variety of colours is obtained, from a warm brown to the coldest purple. Beyond this, and the fact that prints dry always a shade colder than they appear when wet, judgment is not required to foretell the colour of the print when finished. It may also be mentioned that prints dry with more apparent detail and vigour than they show when wet. This is due to the semi-transparency of the paper when in this state. The finer detail that scarcely shows against the transparent paper appears boldly when the paper becomes dry and solidly white.

Presuming now that the whole of our prints are toned, and all in the washing water, we will give them a thorough good rinse. Fixing is the next process, and fresh hypo should be used for each batch to be fixed. In a bath of hypo 3 ounces, water 20 ounces, fixation is complete in eight or ten minutes. Then there remains only the usual thorough washing to eliminate the hypo. We find two hours in running water sufficient. More time should be given only where changes of water are available.

The nature of the gelatine used is such that in all ordinary cases the use of alum is quite unnecessary. Should the film, however, show a tendency to soften, owing to excessive heat, or want of proper care in working, and also in *all* cases where the prints have to be subsequently burnished, the alum bath should be used. This should be done between the first washing and the toning. The alum bath should be 4 ounces alum to 20 ounces of water, and five minutes will suffice to harden the prints. They should be thoroughly well washed before toning is proceeded with.

This paper lends itself to every variety of surface, and does not present any difficulty in finishing or mounting in the ordinary way. Hung by a clip at the corners, and allowed to dry naturally, they are mounted with ordinary starch paste, and yield pictures considerably more presentable than albumenised prints. If prints are to be burnished, dry thoroughly, mount as usual, pass through the hot roll exactly as usual, using Castile soap, and a little spirit as a lubricant.

Of the methods of obtaining highly enamelled or matt surfaces by squeegeeing down on glass I need scarcely speak, the subject has been so often expounded; but results are shown on the table, and their variety and beauty speak for themselves.

Spotting is done as usual, of course bearing in mind that if enamelled prints are wanted, the spotting colour must be protected by a drop of collodion before the prints are put down on the glass.

Thus, gelatine printing-out paper may be fairly said to excel albumenised in beauty of results, in ease of manipulation, and, most important of all, in permanency. In all other respects it equals it, and has none of its drawbacks. There are with it no blisters, no curling, no water-marked edges. The opinions of our best-known men, the practical work of both professionals and amateurs, and its own undoubted merits, thus stamp gelatino-chloride paper as the printing process of the future.

## COMPRESSED GASES.

That we have run ahead of the Americans in the matter of compressed gases will be seen from the following extract from a Chicago contemporary:—

"The convenience of gases compressed in cylinders is so great that for lantern purposes no one now employs bags where cylinders can be got; but those still used in this country are not nearly as convenient and portable as they might be. Why should we be compelled to transport a mass of metal in the form of a cylinder about 36 by 8 inches, and just about as heavy as a man can lift, for an hour's exhibition, when our neighbours across the water can compress 40 or 50 feet into one not more than 15 by 5 inches? English cylinders are made of mild steel and without seam or join of any kind, from a blank or disc of metal about thirty inches in diameter and three-quarters of an inch thick, by heat and pressure. They are tested by a water pressure of two tons, and generally charged with gas up to 1,800 pounds. Who will be the first in this country to adopt such a convenient cylinder?"

We fancy that we are not far wrong in attributing these remarks to a recent leader in our own columns anent the manufacture of gas-cylinders.

A Problem of the Times.—At the next annual gathering of the photographers of the country, if they will kindly inform us why it is that when an actress sits for her picture she turns her back on the camera and twists her neck so that her chin hangs over her left shoulder, a good deal of the mental strain will be removed from the brain of the agonised public.—*Chicago Tribune.*

## FURTHER NOTES ON SILVER PRINTING.*

BY LYONEL CLARK.

### Failures in Salting.

With the system of preliminary brushing there is but little danger of leaving places or patches untouched by the salting solution—a somewhat common fault—and the only other danger to be avoided is that of allowing any solution to get on to the back of the print. For some time I was troubled with insensitive, or nearly insensitive, spots on the prints when they left the printing frame, of a faint lilac colour, surrounded by a halo of darker colour than the rest of the print. Sometimes these markings would take the form of a line right across the print. The cause of these markings I have now traced; they are entirely and solely caused by some of the salting solution getting on the back of the print and soaking through, when it joins, so to speak, the salting solution on the face. This, therefore, creates a maximum quantity of chloride at this spot, and therefore the silver, when applied, is insufficient to convert all this chloride into silver chloride and still leave an excess of nitrate, and, therefore, insensitive spots are formed. The darker nucleus also is due to the excess of silver chloride at this spot, for since, generally speaking, the darkening is proportional to the amount of silver chloride (providing some nitrate be always in excess), darker patches are formed where this happens. These dark patches, as a rule, only show when, from insufficient floating or a weak salting bath, there is an insufficiency of haloid chloride on the print, as it is evident that if the maximum amount of chloride be applied in the first place, no further addition can make any portion of the print more sensitive or prone to darken. Such places will then either not show at all if an extra amount of silver has been applied, or, if this be deficient, they will show as white, insensitive, or nearly so spots. In any case, however, the greatest care should be taken to avoid any of the salting solution falling on the back of the print.

In my last paper I made a few remarks on the two systems of floating or soaking the paper in the salting baths, and can strongly confirm my first view on the subject. With heavy drawing papers I find floating by far preferable, the method of soaking being a very wasteful and risky proceeding, nearly always requiring double sensitising.

### Silvering or Exciting the Paper.

I have but little to add or extract from my previous remarks. I still find brushing on to be far the most economical and expedient manner of applying the silver, and I find the modified form of Buckle brush I described in my last lecture to be a most valuable aid, and I am greatly pleased with its performance.

I have not found it necessary to make any change in the silver baths I recommended, for they each have their use. For feeble negatives or dull light, or if I intend to tone with gold, I use the Hardwich ammonio-nitrate bath described in my paper on "Platinum Toning" (*Camera Club Journal*, November, 1889). But for the generality of my work, and especially for the intensification process I shall describe later on, I use the silver citrate bath. The plain nitrate bath I have practically discarded, as it possesses no special advantages. The citrate bath is made up as follows:—

| | | |
|---|---|---|
| Nitrate of silver (recrystallised), 60 grains | | 14 grams |
| Citric acid (crystals), 25 grains... | ... | 5½ ,, |
| Water (distilled), up to 1 fluid ounce | ... | 100 c.c. |

* Concluded from page 742.

Paper brushed over with this bath keeps fairly well, and when printed can be kept almost indefinitely before toning. I came across a piece of this paper the other day that I printed for my lecture in December last, and it shows no signs of degradation.

With regard to the subsequent operations of toning with gold or platinum, fixing, &c., I have nothing to add to the remarks and directions given, either in my former paper or in my pamphlet on this subject.

### Failures in Sensitising.

The commonest failure that is likely to happen is to find that the paper, on exposure to light, refuses to darken in certain portions. This is caused by an insufficiency of silver. It is an absolute necessity, as I pointed out in my former papers, that there be some free silver in excess, in order to get a vigorous image. If there be only sufficient to convert the chloride into silver chloride and leave no silver in excess, or if you wash the paper, so as to free it from all other substances, on exposure to light it will be found that this pure silver chloride will only darken very slowly, and assume at the best a faint lilac instead of a metallic brown shade. But if to this washed or pure silver chloride a little free silver nitrate be added, the darkening will be seen to take place at once, and the mixture will blacken to the deepest shade. It is therefore necessary, in exciting paper, to brush on not only enough silver to convert all the chloride into silver chloride, but enough to leave a certain amount still in excess.

This appears to be the commonest source of failure in silver printing, and is much more common—as, indeed, is to be expected—when the paper has been soaked in the salting bath, and I have had many examples sent me. As a general rule, the paper prints out in patches of dark colour, with insensitive places between, showing distinctly where the silver was in excess, and where it was not. It is, therefore, important not to stint the silver, but brush plenty on; indeed, the surface should glisten all over with solution, and when hung up to dry, a few drops should run off at the bottom corner. As a rough guide, I find that about two drams of the silver bath are sufficient for a 12 in. by 10 in. piece of paper. But in avoiding the Scylla of insufficient silver solution, I made the acquaintance of a Charybdis of too much silver; and as it was some time before I thoroughly found out the cause of the phenomenon, I will give it here for the benefit of any future Ulysses.

During the past summer I made one batch of paper that, when printed, showed patches, or, in some cases, the whole surface covered with a curious frothy cobweb of white insoluble matter, something like the mould on damp leather. The image, too, was weak and sunk in, wanting in contrast. My first thought was, of course, insufficiency of silver, and I added more, and allowed the paper to lie flat and imbibe plenty of solution before hanging up to dry. But this rather made matters worse, and I then ascribed it to the formation of carbonate of silver, an insensitive white salt due to an excess of carbonate in the salting solution; but paper salted with the simple chloride also gave it, but in a less degree. I then came across an old piece of paper that had been soaked in the salting solution, and this printed out at once free from the defect. This gave me the clue at once, for I saw that it was not want of silver, but rather excess of silver, that caused the appearance, and I tried coating a sheet unequally, leaving a pool to soak in the middle. As I surmised, the position of this pool was at once marked by the insensitive, crape-like markings. I must confess that chemically I am still unable to account for the appearance. Citrate of silver, which it naturally should be, is a soluble and sensitive salt, and I can only imagine it to be similar in composition to the white flaky scales that are generally gradually deposited when citric acid is added to silver. It may, of course, be due to impurities, and I should think a careful examination of it would interest some of our chemists.

Therefore, whilst using plenty of silver, do not use too much, and do not allow the paper to lie flat after coating; but directly the surface is seen to be equally covered with the solution, hang it up to dry by one corner, and allow the excess to drip off.

If the paper be properly and sufficiently salted, the above phenomenon is not, I think, likely to happen, for I clearly traced out in the above case that my paper had been, in the first case, salted on a weak bath, and in the second not floated sufficiently long.

I now come to the second half of my paper, that reserved for the intensification process, an outline of which I gave in my last lecture. I call it an intensification process advisedly, for it differs in its action considerably from several developing processes with which, at first sight, it may appear to have some similarity.

In all the developing processes, an image that is invisible, or nearly so, is developed out, but in this process the image is printed out to almost any point short of complete density, and is then intensified up to the required point, exactly as one would treat a gelatine negative. Like a negative, also, the clear shadows, or, what corresponds to them, the high-lights, remain unchanged, no invisible image being brought to light, whilst the heavy deposit is still further increased; and in both processes there is a tendency to harden the result, so that good results can be obtained from thinnish negatives. There is not the slightest need that any density be shown on the print, as the feeblest indications of light action can easily be intensified up to the most pitchy blackness, or it can be stopped short at any desired condition, and then toned and treated exactly as if it had been printed out in the frame in the ordinary way.

---

A magnificent microscope has just been completed by the Munich Poeller Physical and Optical Institute for the great Chicago Exposition, at a cost of $8,750. It possesses a magnifying power of 11,000 diameters. As might be expected, electricity plays an important part in the working of this gigantic instrument, which, after inspection by American citizens, is expected to give an impetus to the Munich mart for scientific apparatus. The electricity furnishes and regulates the source of light, which, placed in the focus of a parabolic aluminium reflector, reaches an intensity of 11,000 candle power. The electricity also provides the means of an ingenious automatic mechanism for the centreing of the quadruple condensers and illuminating the lenses. There is an arrangement for the exact control of the distance of the carbon point. The most important novel feature is the cooling machine, which is indispensable on account of the extreme heat generated by the intense illuminating arrangement. A machine, regulated by a Helmholtz electric centrifugal regulator, provides the several microscopic and polariscopic systems of the apparatus with a fine spray of fluid carbonic acid, which, immediately after its release from the copper vessel, in which it is held under a pressure of twenty-three atmospheres, becomes converted into gaseous matter, so intensely cold that only ·00007 gramme of carbonic acid per second is required to give the result. The magnifying power of the apparatus with ordinary objectives, as has been stated, is about 11,000 diameters, but with oil immersion lenses it can be increased to 16,000.

## Notes.

We are not aware of the precise number of inches of rain above the average which have fallen in Great Britain during the present year, but we feel certain that it must be something considerable, and its effect upon the work of the photographer generally has been most disheartening. It is all very well to use artificial light in the studio, and to advertise that you are quite independent of dull weather. Your clients may possibly believe that you are speaking the truth, but they won't come out in the rain. Dress is, unfortunately, such a very important part of most people's pictures, and the rain is so apt to injure it, that the visit to the studio is put off until Jupiter Pluvius turns his head the other way.

It is positively aggravating to the half-drowned photographer here at home to read of the rain-making experiments in Texas. There seems, by the way, to be a good deal of quackery about these same experiments. It is said that, by exploding charges of dynamite in the air, rain is caused to fall in copious showers; but it is very certain that no amount of dynamite will bring down rain unless it is already on tap, as it were. A concussion of the air may possibly shake it down, but the chances are that by waiting a little longer it would tumble off its perch of its own accord. For the benefit of photographers, if not of the community at large, we wish that someone in this country would initiate a series of *fine weather* experiments. One of these might consist in causing explosions in the air while rain was actually falling, in the hope that it might be encouraged to come down a little faster, and give the sun a chance of appearing to a world which has almost forgotten his existence.

We understand that the work of photographing the immense stretch of the Pennsylvania Railway proceeds with as much celerity as possible, and that already about four hundred negatives have been taken. The pictures obtained are rather to be described as views from the railroad than of it, and, as this road traverses some of the grandest scenery which can be imagined, the collection of negatives, each measuring 18 by 22, will be as valuable as it is unique. A panoramic camera is also brought into use as occasion may require, and this instrument produces a film negative measuring 18 by 42 inches. Our own railway companies are by no means neglectful of the advantages to be gleaned by exhibiting in their carriages photographs of the most picturesque spots on their lines, although they do not attempt anything on the grand scale adopted by the Pennsylvania people. Most of the leading lines also employ a photographer to make pictures of completed structures, such as bridges, and other works in progress.

Certain samples of gelatino-chloride paper which we have lately been testing exhibit a fault which manufacturers would do well to guard against if they hope to oust albumenised paper from its—at present—secure position. The film is so excessively tender, even after the operator has done his best to harden it, that abrasion is likely to occur by the slightest touch. It is a provoking thing, after going through the tedious operations of exposure—and exposure is especially tedious in October—toning, fixing, and washing, to find that a print or two must be rejected because of mechanical injury. But, even should the print reach the drying stage, it has yet to pass the ordeal of mounting, and the mounter who is accustomed to albumen prints is apt to think that the new paper will stand the same handling with impunity, until he finds out his mistake.

The German Emperor is certainly one of the most inconsiderate of men. He first plunges all the photographic dealers into despair by growing a beard, and, just when they are reconciled to the change, and are anticipating a large sale from his new portraits, His Majesty disappoints them by another "quick change," and presto! he goes back into his former beardless condition. Of course, those dealers who happen to have a stock of old photographs will rejoice; but even they would prefer a notability to make up his mind as to how he should look, and stick to it. Lord Randolph Churchill is said to have cost a Regent Street photographer some hundreds of pounds by growing his beard, so that the matter is really a very serious one.

The photographer is not the only one who suffers from the vagaries of celebrities. The cartoonist and caricaturist are in exactly the same plight. So far as Lord Randolph Churchill is concerned, they have mastered his new appearance sufficiently well for their purposes; but who is to guarantee the continuance of any man's beard? The late Mr. Parnell was a great offender in this respect, for about every six months he altered his facial appearance.

There are signs that the taste for etchings is not so keen as it was two or three years ago. Whether the public have become alive to the fact that so-called artists proofs, for which high prices are demanded, are in many instances no better than ordinary proofs, and, consequently, have come to look upon etchings with mistrust, we cannot say. This reason has been put forward; but we are inclined to think there is not so much in it as in the fact that etchings have been "fashionable," and, like other things, have to suffer fashion's vicissitudes. Line engravings have long lost the favour of the public, and it looks as if photogravure will creep into its place. Autotype and platinotype pictures have also a future before them, but they are as yet *caviare* to the multitude.

A curious example of the disadvantageous use of photography is to be seen in the November issue of the *Magazine of Art*. A reproduction from a photograph of the statue of Lord Napier of Magdala, recently put up in Waterloo Place, shows that the camera has been placed in such a position as to give a very disagreeable view of the statue in question. It would appear as if the exigencies imposed by the required size of the picture had trammelled the photographer, and that he was compelled to take the photograph from a point which the eye would reject. In other words, the camera has been placed far too near, and the result is, the front portion of the horse is absurdly exaggerated, the outstretched neck bringing the head to a level with the head of the rider. The fore legs, on the other hand, are made to appear very short, and a singularly distorted quadruped is the result. As for Lord Magdala, the spectator is made to look underneath his nose, always an unpleasant aspect. A statue at a considerable elevation is a subject best left alone by the camera, unless the latter can be sufficiently elevated, or the size of the picture be no object.

## IN THE LAW COURTS.

BY C. FLEETWOOD PRITCHARD.

*The London Printing and Publishing Alliance, Limited, and Keep and Co.*, v. *Horace Cox.*

This case, which is a very instructive one in the law of copyright, came before the Court of Appeal towards the end of last term. The action was brought by the London Printing and Publishing Alliance, the proprietors of *Myra's Journal*, and Messrs. Keep and Co., against Mr. Horace Cox, the publisher of the *Queen*, for an infringement of their copyright in a picture entitled "On the Threshold." It appears, from the report in the *Times*, that on the 9th of April, 1890, Mrs. Earnshaw—the painter of the picture—wrote to the art critic of the *Queen*, enclosing a photograph, and suggesting that it should be published in that paper in black-and-white. In the meantime she was also in negotiation with Messrs. Keep and Co. for the sale of the copyright of the picture in colour to them, and ultimately the picture and the entire copyright were bought by Messrs. Keep. While these negotiations were in progress, Messrs. Keep were arranging for the production of the picture in the Christmas number of *Myra's Journal*, and when the purchase from Mrs. Earnshaw had been completed, they entered into an agreement with the proprietors of that paper by which the latter agreed to purchase the picture and the copyright, and at the same time gave Messrs. Keep an order for 55,000 copies to be ready in time for their Christmas number. Messrs. Keep and Co. had duly registered themselves at Stationers' Hall as owners of the copyright, but the London Printing and Publishing Alliance were not registered.

In August, 1890, Mr. Cox, apparently relying upon Mrs. Earnshaw's letter of the 9th of April, published a sketch of the picture in the *Queen*, and this was the infringement of which the plaintiffs complained. The case first came on before Mr. Justice Vaughan Williams on the 13th of May last, and he gave judgment in favour of the plaintiffs. Mr. Cox, however, appealed to the Court of Appeal, who decided that he had infringed the plaintiff's copyright, because Mrs. Earnshaw's letter was not a license to publish the picture without further consent from her. Lord Justice Lopes said—and the other two judges agreed with him—that the letter was not distinct enough to amount to a license; "it was the commencement of a negotiation, not a definite license, and still less a concluded agreement." The Court further decided, however, that neither of the plaintiffs had any right of action against Mr. Cox for this infringement—Messrs. Keep because they had sold their copyright in the picture to the London Printing and Publishing Alliance, and the latter because they had not been registered as owners of the copyright at Stationers' Hall. So the Court gave judgment for the defendant, who thereby escaped the penalties of his wrong-doing solely through a technical mistake on the part of the plaintiffs.

The case shows, first, how important it is that the owner of the copyright in a picture should be registered as such at Stationers' Hall (for through their omission to do this, the plaintiff Company not only failed to recover the penalties for which they sued, but they also had to pay a large sum towards the defendant's costs); and secondly, that a license to reproduce a picture, in order to be of any value, must be explicit in its terms. It also appears doubtful whether, even supposing Mrs. Earnshaw's letter had amounted to a license, that would have been sufficient to have protected Mr. Cox if the owners of the copyright had been duly registered, for the picture was published in the *Queen* after the copyright had been disposed of by her to Messrs. Keep, and, therefore, when her license was no longer of any value. This point, however, was not considered by the Court of Appeal.

## PARAMIDOPHENOL.

A writer in the *Photographic Times* recently described some experiments with this new developer, which fully bear out the advantages claimed for it by its original investigators, MM. Lumière Brothers. He describes the substance as being a chocolate-brown, coarse, crystalline powder, with a solubility akin to that of eikonogen. The developer used was made up as follows:—

| | |
|---|---|
| Water ... ... ... ... ... | 800 parts |
| Potassic carb. ... ... ... ... | 40 ,, |
| Sodium sulphite (cryst.) ... ... ... | 100 ,, |
| Paramidophenol ... ... ... ... | 8 ,, |

Three plates, exposed under like circumstances, were developed:—(1) With paramidophenol; (2) with the standard eikonogen in one solution; (3) with S. P. C. hydrochinon.

The first plate developed rapidly, and much in advance of Nos. 2 and 3, built up intensity uniformly and in proportion with the progress of the process, the non-exposed portions remained clear glass, and all middle tints were brought out to perfection. It took about four minutes to develop a good negative.

On the second plate the image developed rapidly, but it took a little over ten minutes to gain the intensity of No. 1. After fixing, there were distinct indications of yellowing on edges and corners.

To gain the same intensity in No. 3 as in Nos. 1 and 2, development was prolonged to twelve minutes and thirty seconds. There was a distinct want of middle tint, the negative being of harsh character. After fixing, the plate showed a slight yellow veil all over.

After an interval of one hour, three other plates were developed with the paramidophenol solution first used, with like results.

What has been reported of paramidophenol by Messrs. Lumière and Dr. Andresen seems to be thoroughly verified by our first experiments. It is as energetic a developer as any other substance previously used, and it has the property of producing glass-clear and transparent negatives, and without a tinge of yellowing, even after the developer has been repeatedly used.

An objection to paramidophenol is its present high price, though this is not so apparent when we consider the large number of plates which may be developed with the same solution. Experience has shown that the greater the demand for an article, the more will its price be reduced.

The Photographic Club.—November 4th, annual general meeting; November 11th, "Impurities in Photographic Chemicals," Mr. A. M. Levy.

Hackney Photographic Exhibition Awards.—*Class A* (Members)—silver medals: Messrs. Barton, Sinclair, Hensler, Beckett; championship gold medal: Mr. Arthur Barker. *Class B*—gold medal: Augustus W. Wilson; silver: W. Wesson; bronze: S. H. Barton. *Class C*—silver: W. L. Barker; bronze: W. Fenton Jones. *Stereoscopic Class*—W. Taverner (prize—a pair of lenses presented by Mr. H. Crouch). *Members' Lantern Slides*—silver: Mr. Taverner; bronze: Mr. Dando. *Open Lantern Class*—silver: W. Taverner; bronze: J. E. Austin.

## ON THE INTENSIFICATION AND REDUCTION OF GELATINE NEGATIVES.*

BY ROLAND WHITING.

Before I leave this portion of my paper, there is just one more formula I should like to bring before those who might care to experiment in this direction. It looks like a very good one, but I cannot say what its qualities are, as I have not tried it. It was published in the *Photographic Review* of December 14th, 1889, and is known as Karsebaum's intensifier. I repeat it word for word from that journal :—"The plate is soaked for some minutes in a solution of citric acid, say one part in twenty of water, after which the following solution is poured on :—(A) Hydroquinone, 6 grammes (about 92 grains) ; water, 700 cubic cents. (about 24½ fluid drams) ; nitric acid, 10 drops. (B) Silver nitrate, 8 grammes (about 123 grains) ; water, 100 grammes (about 3½ fluid ounces). Forty volumes of A are mixed with one of B. The action of this intensifier is slow, but very satisfactory. A second fixing is desirable, so as to remove all traces of undecomposed nitrate.

We have now to consider the second class of intensifiers, which are those whose action is due to chemical change, and which contain the forms of intensifiers most in use, namely, the mercuric intensifiers ; but, before I go on to these, there are two which I should like to mention, chiefly on account of the novelty of the colour they render the negative. The first of these is Mr. Selle's method with uranium nitrate. The formula is as follows :—

| | |
|---|---|
| Uranium nitrate ... ... ... ... | 2 drams |
| Potassium ferridcyanide ... ... ... | 2 ,, |
| Water ... ... ... ... ... | ½ pint |

This must be filtered. The plate, after being well washed, is placed in this solution, which acts by turning the film red, at the same time strengthening the strong portions to a very great degree. This is a very good intensifier if very great density is required, but you must be certain there is not the slightest trace of hypo in the film, otherwise a precipitate will settle itself all over the film. The chemical change which takes place in this case is: the silver which constitutes the image reduces the potassium ferridcyanide to ferrous cyanide, which, combining with the uranium, forms an insoluble double cyanide, which is precipitated on the image. Hypo also converts the ferric to the ferrous salts, so if hypo is present in the film a precipitate is deposited all over the negative.

Mr. Carey Lea's is the other method which gives a bright red negative. This is as follows :—The plate is first immersed in a sherry-coloured solution of iodine until it has changed its silver to silver iodine ; it is then placed in a solution of—

| | |
|---|---|
| Schlippe's salts ... ... ... ... | ½ ounce |
| Water ... ... ... ... ... | 1 pint |

which converts it to a bright red colour. Schlippe's salts is a double sulphide of sodium and antimony. The silver iodide combines with this and forms a double sulphide of silver and antimony, the sodium, which was displaced by the silver, combining with the iodine and forming sodium iodide. If a very dense negative is required, the plate is left in the iodine until all the silver is converted to iodide. This solution of Schlippe's salts does not keep ; therefore it must be made up as required.

Of the mercury intensifiers there are many formulæ, although very few operators seem to act in strict accordance with them. Perhaps the simplest is that known as Dr. Eder's formula. For this the following solutions are required :—

*No. 1.*

| | |
|---|---|
| Mercuric chloride ... ... ... ... | ¼ ounce |
| Water ... ... ... ... ... | 1 pint |

*No. 2.*

| | |
|---|---|
| Ammonia (·880) ... ... ... ... | 2 ounces |
| Water ... ... ... ... ... | 1 pint |

*No. 3.*

| | |
|---|---|
| Potassium iodide ... ... ... ... | 1 ounce |
| Water ... ... ... ... ... | 1 pint |

To intensify with this, the plate must first be placed in No. 1 until the mercury has whitened it, in most cases, right through. Then the plate is washed for a short time, after which it is placed in the ammonia solution till it is blackened through to the back of the plate, and it is then finally washed. If, however, a greater amount of density is required than this gives, the plate must be placed in the iodide solution. This is done after the plate has been treated with the mercury and washed, and before treating with the ammonia, and the plate must be washed after the application of the iodide. After this treatment it is sometimes found to be too dense. If such is the case, it can be again reduced by placing it in a solution of hypo of about ½ ounce to the pint.

Dr. Eder is also, I believe, the author of the following formula, which is, perhaps, an improvement on the last. After the negative has been bleached with the mercury, it is thoroughly washed and treated with this solution :—

| | |
|---|---|
| Potassium cyanide ... ... ... | 10 parts |
| Potassium iodide ... ... ... | 5 ,, |
| Mercuric chloride ... ... ... | 5 ,, |
| Water ... ... ... ... ... | 2,000 ,, |

This causes the film to become dark brown, and, if it should give too great density, it need only be left in this solution for a little longer, when it will gradually reduce again. This is certainly very simple, but it is evident, as the solution reduces after the maximum density is obtained, the negative under treatment must be closely watched.

A slightly different kind of mercuric iodide intensifier is that recommended by Mr. Edwards. Three solutions are made up as follows—

*No. 1.*

| | |
|---|---|
| Mercuric chloride ... ... ... ... | 60 grains |
| Water ... ... ... ... ... | 1 ounce |

*No. 2.*

| | |
|---|---|
| Potassium iodide ... ... ... ... | 90 grains |
| Water ... ... ... ... ... | 2 ounces |

These two solutions are added, when mercuric iodide is formed as a red precipitate. To this another solution is added, consisting of—

| | |
|---|---|
| Hypo ... ... ... ... ... | 120 grains |
| Water ... ... ... ... ... | 2 ounces |

which dissolves the precipitate. The plate is merely placed in this until density is obtained, which takes place very quickly. For this reason I prefer to use more hypo than here given, as the strengthening action takes place more slowly, and the plate is thus more under command. This is a very simple intensifier to use, and has, moreover, the advantage that the plate need not be very thoroughly washed after being fixed ; but in my hands it has not been very successful, as I have never been able to prevent it clogging up the shadows.

About the best intensifier for general use is the one which Captain Abney has recommended some time back,

* Concluded from page 735.

and which, I think, is a slight modification of Dr. Monckhoven's method. The following are solutions required :—

*No.* 1.

| | |
|---|---|
| Mercuric chloride ... ... ... | 100 grains |
| Potassium bromide ... ... ... | 100 ,, |
| Water ... ... ... ... ... | 10 ounces |

*No.* 2.

| | |
|---|---|
| Silver nitrate ... ... ... ... | 100 grains |
| Water ... ... ... ... ... | 10 ounces |

To this last is added a solution of potassium cyanide, which produces a precipitate. The cyanide must be added gradually little by little and with agitation. After a time the precipitate will redissolve, and the cyanide must be added until only a very little of it is left undissolved. The strength of the cyanide recommended by Captain Abney is 100 grains to the ounce of water. After the plate has been thoroughly freed from the fixing agent, it is bleached in the mercury solution, aud, after washing, is placed in the silver solution until it is blackened right through. Captain Abney says this is the best and most permanent intensifier he has ever used, and considers it to supersede all others. Certainly, if a clear and vigorous negative is required, it is, without doubt, a splendid one to use. However, where permanency is required, all mercuric intensifiers should be used with caution, as compounds in which mercury forms a part are looked upon by most experimenters as unstable substances.

I will now go on to describe a method of treating negatives that require strengthening, which I have used very successfully indeed for a long time, and one which is a good advance towards the ideal. This method is not entirely my own; it was, to a great extent, published in one of the photographic papers a long time past, but, as it does not seem to have attracted the attention of many photographers, it will no doubt be new to some of you. It is tolerably well-kuown that, if a negative is first whitened with mercuric chloride, and then blackened with ammonia, the density is considerably greater than if it had been blackened with sodic sulphite. Now, as ammonia and sodic sulphite can be used at the same time, or one after the other upon a plate, without any harm coming to it, I take advantage of the different strengthening power of the two chemicals in the following manner. Supposing I have a negative which I desire to strengthen more in the half-tones than I do in the high-lights, I proceed as follows. The plate is laid face downwards in a dish, the ends being supported on a couple of pieces of match, so that the face of the plate does not touch the bottom of the dish. The mercuric chloride is then poured in and allowed to cover the plate. The plate must now be watched closely, and, as soon as it is whitened through until all but the highest lights are changed, it must be taken out and immediately washed. When sufficiently washed, it is placed face downwards, as before, in a rather weak solution of ammonia until the half-tones only have blackened through, when it is again placed under the tap for a few seconds just to stop the action of the ammonia going auy further. After this has been done, it is finished by placing it in a solution of sodic sulphite about a quarter the strength of a saturated solution, until the high-lights are blackened through. It is then washed as usual. It will be obvious to all of you that this method gives to the half-tones a greater proportion of strength than it does to the high-lights, especially if the bleaching process has not proceeded too far. This method is equally applicable to a negative which requires a greater proportion of strength in the high-lights as in the case of an over-exposed negative. The negative is bleached entirely through, including the highest lights. Then, after washing, it is placed in a solution of sodic sulphite until the half-tones only are blackened through, after which it is finally immersed iu a rather strong ammonia solution until the blackening is complete. Thus, it will be seen that not only can either the high-lights or the half-tones be strengthened as required, but, by varying the length of time of immersion in either solution, and by varying the amount of bleaching, almost any result can be obtained.

I must draw my paper to a close without speaking of the chemical changes which take place in all these operations, neither can I speak on the third method of strengthening negatives, viz., the powder process, although much use can be made of this process in the artistic treatment of negatives; but must content myself with the hope that some may have learnt something from what I have already said, or that fresh ideas may present themselves.

## PHOTOGRAPHY AT THE WORLD'S FAIR.

Our American cousins are exercising their minds as to the rules and regulations which will be framed at Chicago for the government of camera-bearers. Says the *Beacon:*—

"Photographers, through their various organisations, are preparing to press on the executive of the Columbian Exposition the necessity for a special departmeut, or otherwise a full recognition of photography in the great show. It is no doubt of great importance that every facility should be given, and every inducement held out to make it the greatest and most truly representative of the best results of the art from all over the world, but it is not less important that measures should be taken to prevent the management from trying to make up for its extravagance in paying absurdly large salaries to itself by taxing not only American citizens who have, by their guarantee, made the Exhibition possible, but also the strangers whom it is trying to allure within its gates, or, at least, those of us and them who happen to be accompaoied by their hand-cameras. That our Gallic neighbours did so is no reasou why we should follow the bad example, and, if our 'liberty' is more than a mere name, we will not submit to the imposition.

"It would not, of course, be convenient, and therefore not advisable, to give permission to employ cameras on tripods in such crowded places, but there cannot, and should not, be any objection to the free use of hand or detective cameras."

Pretty Miss Armytage Moore is the subject of *Piccadilly's* portrait this week. Owing to the fact that the lady is looking into a mirror placed at her side, there are, to all intents and purposes, two Miss Armytage Moores represented in the picture. As *Piccadilly* jokingly remarks: "Of vigorous intellect, Miss Moore might most properly obtain large damages from Mr. Bassano for a portrait which proclaims her beside herself."

It is said that, during his passage from America, Prince George of Greece had a very unpleasant time of it. There were over one hundred and fifty American young ladies on board, and their attentions to the Prince became annoying and oppressive. Nearly all the ladies had cameras for taking instantaneous photographs, and every time that the Prince appeared on deck over one hundred cameras were levelled at him. Latterly, the Prince held his hands to his face when he came on deck, but even this was no protection from the snaps of the instantaneous photograph. During the latter part of the voyage he remained below. Even Royalties do not want to be always on view.

## COPYING LINE ENGRAVINGS.

There are hundreds of operators who can take a good portrait, and who can be trusted to make a good landscape negative, but if they are required to make a copy of an engraving or line drawing, they fail. The negative is generally so thin that it will not yield a decent print, and, as such negatives are generally required for process work, they should be positively black and white. In other words, the lines should be as clear glass on a dense black background.

Mr. John Carbutt, the eminent plate-maker, has recently published in the *Photographic Times* the method which he adopts in the production of such negatives, and from his article we have taken the following abstract.

The engraving or letter-press to be photographed should be placed so as to receive an even-diffused light, not to use a smaller stop than will give good definition, and expose for the whites, not too short, or it will be difficult to obtain density. I recommend carbonate of soda as the alkali, as in the following formulas, with sodium sulphite and potassium bromide, and pyrogallic acid added dry. With these I find it more certain to produce density and clearness of lines on my "A" or "B 12" process plates, than with a developer containing the caustic alkalis. I also give a formula for clearing the lines when necessary, and recommend as a suitable intensifier bichloride of mercury, followed, after well washing, with cyanide of silver.

The formulas are as follows:—

Alkali Solution.

| | |
|---|---|
| Water ... ... ... ... ... | 60 ounces |
| Carbonate of soda (crystals) ... ... | 2 ,, |
| Sulphite of soda (crystals) ... ... | 4 ,, |
| Bromide of soda or potass. ... ... | 60 grains |

Developer.

| | |
|---|---|
| Alkali solutiou ... ... ... ... | 3 ounces |
| Dry pyrogallic acid ... ... | 8 to 10 grains |

Mix and dissolve before flowing over the exposed plate. Instead of weighing the pyro, a very close approximation to the weight may be got by taking a boxwood mustard spoon that will hold three to five grains of pyro, and measure the quantity required.

Acid Fixing and Clearing Bath.

| | |
|---|---|
| Warm water ... ... ... ... | 64 ounces |
| Hyposulphite of soda ... ... ... | 16 ,, |
| Sulphite of soda... ... ... ... | 2 ,, |
| Sulphuric acid ... ... ... ... | 1 drachm |
| Chrome alum ... ... ... ... | 1 ounce |

Dissolve the sulphite of soda in eight ounces of the water. Mix the sulphuric acid with two ounces of the water, and add slowly to the solution of soda sulphite; dissolve the chrome alum in eight ounces of the water, the hyposulphite of soda in the remainder; then add the sulphite solution, and last the chrome alum. This fixing bath will not discolour until after long usage, and both clears up the shadows of the negative and hardens the film at the same time.

Let remain two or three minutes after the negative is cleared of all appearance of silver bromide. Then wash in running water for not less than half-an-hour to free from any trace of hypo solution. If no intensification or clearing is required, swab the surface with a wad of wet cotton, rinse, and place in rack to dry spontaneously.

Clearing Solution

With which to clear away any slight deposit in the lines or clear parts of a negative.

| | |
|---|---|
| Water ... ... ... ... ... | 8 ounces |
| Cyanide of potass. (pure) ... ... | 60 grains |
| Iodine (dissolved ¼ ounce alcohol) ... | 10 ounces |

Intensifying Solution.

No. 1.

| | |
|---|---|
| Bichloride of mercury ... ... ... | 240 grains |
| Chloride of ammonia ... ... ... | 240 ,, |
| Distilled water ... ... ... ... | 20 ounces |

No. 2.

| | |
|---|---|
| Chloride of ammonia ... ... ... | 240 grains |
| Water ... ... ... ... ... | 20 ounces |

No. 3.—Cyanide-Silver Solution.

| | |
|---|---|
| Distilled water ... ... ... ... | 6 ounces |
| Cyanide of potass. (C. P.) ... ... | 60 grains |
| Distilled water ... ... ... ... | 2 ounces |
| Nitrate of silver ... ... ... ... | 60 grains |

Pour the silver into the cyanide solutiou while stirring, and mark the bottle *poison*.

Let the plate be intensified, wash for at least half-an-hour, then lay in a five per cent. solution of alum for ten minutes, and again wash thoroughly; this is to ensure the perfect elimination of the hypo. The least trace of yellowness after intensifying shows that the washing was not sufficient.

Flow sufficient of No. 1 over the negative to cover it, and allow to either partially or entirely whiten; *the longer it is allowed to act*, the *more intense* will be the result. Pour off into the sink, then flow over No. 2, and allow to act one minute; wash off, and pour over or immerse in No. 3 until changed entirely to a dark brown or black. No. 3 can be returned to its bottle, but Nos. 1 and 2 had better be thrown away. Wash thoroughly and dry.

I have found it very convenient in being able to produce, on transparent films coated with "A" emulsion, various sizes of negatives and positives from type-matter for my advertising blocks, the photo-engraver using them reversed for zinc etching, the thinness of the film allowing perfectly sharp reversed impressions to be made on the zinc by placing the printing frame in a box about twenty inches deep, so as to cut off all but vertical rays.

---

London and Provincial Photographic Association.—Subject for Nov. 5th, "Development of Lantern Plates"; Nov. 12th, "Cau Halatiou be avoided by Staining the Film in any way?"; Nov. 19th, lantern night—visitors invited.

Sitting for Portraits.—The misery of sitting for one's portrait has been described in graphic fashion; not so the misery of the portrait painter. Professor Herkomer, who speaks with authority, has come forward to supply the omission. Submitting the finished work to the family is a trial. Of course nearly every one of the circle had been expecting something different. On one such occasion a lady sitter said to him, "This is an awful moment for both of us." During that critical examination the painter walked about his studio and tidied up the whole place. Sometimes the sitter's wife will say, "Just stand next it, dear." Here Professor Herkomer is of opinion that the artist should turn round and put his foot down, because a picture ought to look right or not right. After awhile, if he is fortunate, somebody will say she "likes it," and then, but not earlier, the painter should cease from tidying his room. A lady once said to Professor Herkomer, "Do you flatter?" He answered, "No." "Then," she replied, "I must go somewhere else." It is satisfactory to learn on such good authority that photography has not injuriously affected portrait painting in any way. There are, in Mr. Herkomer's opinion, more portraits painted now than at any other time in the world's history, and it is his belief that the best are done in England.—*Daily News.*

## THE CHICAGO EXHIBITION, 1893.

The council of the Society for the Encouragement of Arts, Manufactures, and Commerce, have issued a Prospectus, from which the following are extracts :—

Under the date of the 27th August, 1891, Her Majesty was pleased to issue a commission to the Council of the Society of Arts, authorising them to act as commissioners for the Universal Exhibition, which, pursuant to an Act of Congress, and in accordance with a proclamation made by the President of the United States of America, will be held at Chicago from May 1st to October 30th, 1893.

The Royal commission are now prepared to receive applications from artists, manufacturers, and others desirous of taking part in the Exhibition, to afford them all necessary information, and to offer them all available facilities which they may desire for this purpose. Such applications must be made upon forms to be obtained from the secretary of the commission at their offices, Society of Arts, John Street, Adelphi, London, W.C. They must be sent in properly filled up not later than February 29th, 1892, and addressed to the secretary as above.

As the funds granted by H. M. Government will not suffice to defray all the expenses of the section, it is necessary that they should be supplemented by payment from the exhibitors. A charge will therefore be made to each exhibitor, based on the amount of space occupied, and calculated on the following scale :—

| | s. | d. | |
|---|---|---|---|
| For spaces not exceeding 100 sq. ft. ... ... ... ... | 5 | 0 | per sq. ft. |
| " exceeding 100 sq. ft and not exceeding 200 sq. ft. | 4 | 6 | " |
| " " 200 " " " 300 " | 4 | 0 | " |
| " " 300 " " " 500 " | 3 | 6 | " |
| " " 500 " " " 750 " | 3 | 0 | " |
| " " 750 " and upwards ... ... ... | 2 | 6 | " |

The minimum charge will be £5.

Exhibitors' goods will be transmitted direct in bond to Chicago, where the usual Customs examination will be made. Goods for exhibition only will not be liable to duty, but on goods sold the usual rates will have to be paid. Goods can be sold in bond at prices independent of the tariff, the duties being payable by the purchaser.

The American railroad companies propose to carry goods back from the Exhibition free, charging the usual rates for the outgoing journey. These rates, it may be noted, are low in comparison with those usual in European countries. Full information as to routes, traffic, rates, &c., will be provided in due course.

A general official catalogue will be published in English, French, German, and Spanish. A special catalogue will also be published for the British section.

The general reception of articles at the Exhibition buildings will commence on November 1st, 1892, and no articles will be admitted after April 10th, 1893.

Photography is classed, in Group 147, with Instruments of Precision, Experiment, and Research, under Department L—Liberal Arts, Education, Literature, Engineering, Public Works, Music, and the Drama.

## REVERSED NEGATIVES BY STRIPPING.

BY A. H. CALDERWOOD.

Since the introduction of photography into the making of plates for the type-press, and thus the necessity of reversed negatives, much has been written on how best to secure these. Some advocate the use of a prism before the lens to be the only way; others hold a mirror to be equally efficient; while some say they can be made by placing the glass side of the sensitive plate nearest the lens, and so receiving the image through the glass. Each have their drawbacks, one being expensive, the other troublesome to keep in order, and the third uncertain.

I am using the method of stripping the films from the one plate, and reversing or turning them on another, cleaned and ready to receive the same. I have stripped a great many in this way, and have not had a single failure, and in the end requiring no more time than the other processes, owing to the shorter length of exposure necessary as against the use of the prism or mirror. Another point in its favour is, that a number of small negatives may be placed together on one plate, and the printing and etching done in one operation.

There are three solutions required, viz.: The rubber solution, which can be purchased ready for use, or made by dissolving a piece of Para or other gum in benzene; plain collodion, rather thin; and a solution of acetic acid and water 1 to 5.

The negative is made in the usual way, preferably on a plate much larger than the copied drawing will be, intensified with mercury or copper sulphite, and allowed to dry. It is then coated with the rubber solution (draining the surplus back into the bottle), placed on a slab or table, and allowed to dry. It is then coated with the collodion. Now, with a knife, or some sharp instrument, cut through the film, leaving a margin of an inch around the picture. It is then placed in a bath containing the acidified water, where it remains for a few minutes. Another water bath, containing the clean plate which is to receive the film, is now got ready. The plate to be stripped is removed from the acid solution, washed gently under the tap, when, by trying the edges, it will be seen whether the film is ready to strip easily. If not, it must be replaced in the acid. When the edge of the film leaves the plate easily, then lay the plate down, elevate one end of the bath, and, starting at one corner, gradually lift the film from its support until the other corner can be grasped and the film entirely removed. Then place in the dish containing the plate to receive it—face down, of course. Then, by lifting the plate from the water, and with it the film, it will be found to cling to it, and to be quite free from air-bells or particles of dirt. Should the air-bells appear, they can be rubbed out with a piece of soft cotton or a squeegee, interposing a piece of clean absorbent paper. As before stated, negatives made in this way are absolutely sharp, whereas, when made through the glass, the thickness of the same has to be guessed at, and the camera focussed back this distance—a rather crude method where absolute sharpness of lines is a *sine quâ non*.—*Wilson's Photographic Magazine.*

## Patent Intelligence.

*Specially compiled for the* Photographic News *by Herbert & Co. (H. J. & R. Haddon), Registered Patent Agents, &c., of* 18, *Buckingham Street, Strand, London, W.C.*

### Specifications Published.

18,120. *Nov. 11th*, 1890.—"Lantern Microscopes." R. G. Mason, 24, Clapham Park Road, Clapham, S.W.

At the under side of the stage plate are fixed, by screws or other means, two dovetail pieces of brass or other metal to form guides. Two dovetail plates are arranged to fit firmly into said guides, one of said plates having fixed to it the tube containing the optical system of lenses, for use with the magic lantern or projective form of instrument; the other plate has fixed to it the half of an ordinary joint used to incline microscopes at any angle. A stop on the main plate prevents the plates from sliding right through, so that the two dovetailed plates are exactly central to the optical axis of the instrument when pushed in under the stage plate. The plate carrying the system of lenses has a screw at the end of the outer tube for screwing into the front of a magic lantern.

On the upper side of the stage plate is fixed a limb carrying the fine and coarse adjustments. On the slide of the coarse adjustment is fixed a tube, on which is a smaller tube carrying the "objective." The main stage plate being removable from the smaller plates, enables the sub-condenser lenses to be easily changed if circumstances require.

12,218. *July 18th*, 1891.—"Detective Cameras." Newnham Browne. (F. A. Fichtner, 6, Elisenstrasse, Dresden, Germany.)

In order to change the plates, *i.e.*, to lift out the foremost plate which has been exposed, aud trausport it to the back, uuder the bottom of the camera there is provided a flexible slide, the front of which is turned upwards towards interior of the camera, being flush with the internal surface of the bottom. Two fingers on the slide engage the foremost plate, which is pushed out through a slot in top of camera into a changing bag at the top of same.

The controlling or indicating device consists of two ratchet wheels, which have as many teeth as there are plates in the magazine. The spindles of these two wheels pass through the sides of the camera, and have on their outer ends a pointer workiug over a dial. One of the ratchet wheels is worked by a lever and pawl, and the other by a sliding pin and pawl. The end of the lever projects into a groove, being correspondingly inclined to the movement of the slide. The end of the pin rests on the slide, and is bevelled towards the front of the latter. On moving the slide forward, for changing the plate, it comes in contact with the lever, and, acting ou the incline of the same, causes it to oscillate ; the pawl then acts on the first wheel and rotates it one tooth, thereby displacing the indicator to the amount of one figure, thus showing that the first plate has been changed.

To enable an iris diaphragm inside the camera to be worked from the outside, a portion of the periphery of a sliding ring outside the lens mountiug is provided with teeth ; a toothed segment gears with these teeth. The width of the teeth on the segment allows for the displacement of the leus in focussing, without causing the teeth on the ring to go out of gear. The toothed segment works on a spindle, one end of which projects outside the camera, and is provided with a knob by which it can be rotated so as to work the iris diaphragm, and so regulate the amount of light admitted.

Only one shutter is employed, which acts as a cap, and also as a shutter, which can be employed either for time exposures or for instantaueous work. This shutter is attached to mechanism operated from outside the camera by a system of knobs, and kept normally in position over the leus by a spiral spring. By this shutter the aperture of the leus is ouly momentarily uncovered.

## Correspondence.

### NATIONAL ASSOCIATION OF PROFESSIONAL PHOTOGRAPHERS OF GREAT BRITAIN AND IRELAND.

Sir,—The adjourned meeting of the council of the above Association will be held at Anderton's Hotel, Fleet Street, London, Monday, November 9th, 7.30 p.m., to receive a report from the secretary upon general and important business. Any suggestions from the profession generally will be gladly received by the Secretary, Auderton's Hotel.

*October 27th.* D. J. O'Neill, *Secretary.*

### A PHOTOGRAPHERS' ASSISTANTS' CLUB.

Sir,—Seeing that we have so many and such various photographic associations and clubs, I feel rather surprised that we have no club in this vast metropolis for photographers' operatives. If we consider what a great boon such a club would be for the assistauts of our art, I think it highly desirable that no time should be lost in starting the formation of this so long missed iustitution. Kindly let me give a rough idea of what character such a club should be.

Firstly, educational, by giving weekly onc night for lecturiug or reading on photographic matters ; having a free library and a reading room ; holding one anuual exhibition of members' own work.

Secondly, social, having one night in the week a social gathering, flavoured with magic lantern entertainments ; also an annual excursion if possible.

Thirdly, beneficially, by keeping a free registry for vacancies.

Of course a great many items could be added to the above, but as these few lines are merely by way of suggestion, others, I hope, will try and give their opinions on the matter.

Should any of your readers feel inclined to give support to this venture, please let them communicate with me at once, so that we may have an early general meeting to discuss matters more fully. "Operative."

74, *Rattray Road, Brixton, S.W., October 27th.*

### NEW IRON SALT.

Sir,—Will you be so kind as to find space in your next publication for my most emphatic denial of all knowledge of the presence of silver in the paper I gave Mr. Varley.

92, *Piccadilly, W., October 27th.* Friese Greene.

## Proceedings of Societies.

### Camera Club.

*October 22nd.*—Mr. Lyonel Clark in the chair.

Mr. Henry Sutton read a paper, and gave a demonstration, on the subject of "Reversal." The lecturer exposed a plate to magnesium light a sufficient time to produce the insensitive state of the plate by oxidation, and another plate not so treated was taken, and the pair exposed in contact with a negative. One plate gave a reversal, and the other showed the undevelopable and insensitive state. The plates used were isochromatic plates, and they were put into the frame in the full light of the room. Mr. Sutton also showed experimentally how a similar appearance to the "dark flash" in lightning photography could be produced by magnesium light.

In the discussion which followed, the Chairman referred to the early and complete experimeuts in reversal carried out by Claudet, and to the recent book of M. Clayden in regard to electricity and the dark flash phenomenon in photography.

On October 26th a large number of lantern slides was exhibited, about 350 transparencies being brought or sent up by members to be shown, including work by Messrs. Dresser, Andræ, Greene, Griffith, Barton, J. C. H. Smith, Starbuck, Fitz-Payne, Freshwater, Powell, Davis, Ferrero, Chang, and Barton-Kent.

On November 2nd the monthly smoking concert will be given. On November 5th Dr. J. J. Acworth will read a paper ou "The Action of Light and Heat upon the Haloid Silver Salts."

### London and Provincial Photographic Association.

At the meeting of this Society held on the 22nd inst. Mr. W. H. Harrison occupied the chair.

Mr. A. L. Henderson showed a negative covered with markings, which he attributed to the paper that had been used for separating the plates. He urged that the Society should take up the matter with a view to induce plate-makers to adopt other means of packing, and eventually moved a resolution that, as some plate-makers are in the habit of packing plates with paper all over, and that, as markiugs sometimes occur therefrom, it is desirable that some better method of packing be adopted, and it is suggested that small pieces of tinfoil would be better, and probably not more expensive.

Mr. W. E. Debenham had had plates marked from contact with separating paper, though not recently. A method of packing which he had met with seemed to be very good. This was to place a complete mat of thin card between the sensitive surfaces. Plates of very high rapidity packed in this way by the Seed Company some two years since he had recently found to be in excellent condition. He questioned the utility of passing a resolution in the form proposed.

Mr. A. Cowan thought that the markings on the particular plate shown were due, not to the paper used in packing, but to light penetrating through the wrappiug paper.

Eventually the resolution was passed.

Mr. J. S. Teape said that no doubt many people had noticed the non-actinic colour of caramel, and had on that account thought it should prove useful as a light-filter for dark room work. He had coated a plate with a solution of gelatine and caramel, and exposed a plate behind a screeu so prepared. At the same time he had covered another part of the plate with two thicknesses of golden fabric. The exposures had been to a gas-flame at a distance of twelve inches for periods of five and fifteen minutes. The faiut image that developed was about equal with the two kinds of medium. Exposures were also made to the light of burning magnesium, with similar results.

Mr. Debenham said that when proposing caramel for backing, he had suggested that it might be used for a dark room light-filter, but he did not like the colour of the illumination, and much preferred the yellow light from golden fabric.

Mr. A. Haddon said that, Mr. Everitt haviug thrown doubt upon the superiority of caramel over burnt sienna as an absorbent, he (Mr. Haddon) had prepared a plate of thick glass—thick enough to show separate reflectious of a small light spot from the back and front – in four divisions: one quarter was left plain, one was coated with caramel and gelatine, one with the burnt sienna and gum mixture furnished by Mr. Everitt, and the fourth with a mixture of burnt sienna and caramel. On looking at the reflection of a distant gas-flame, it would be seen that, whilst at any angle the burnt sienna gave a distinct image, in some cases approaching the brightness of that from the bare glass, the caramel portions so completely absorbed the light that only with difficulty could the faintest reflection be discovered.

Mr. Everitt said that he had not doubted that caramel was better than burnt sienna, but he had found the latter quite sufficient.

The Chairman enquired whether any non-actinic substauce had been found that would staiu the film sufficiently to dispense with the necessity for backing without causing insensitiveness.

Mr. Henderson said that if such a stain were found there would be no density in the image; the light would not penetrate deeply enough into the film.

Mr. C. Lawrance then showed the "Clifford" hand-camera, the special feature of which was the manuer of storing and exposiug the plates or films. Holders in the form of a book contained from twelve to twenty plates—according to the thickness—or thirty celluloid films. These holders allowed of the successive exposure of the plates, whilst registering externally to the camera the number of the plate in position.

A question from the box was read, enquiring the best methods of proceeding with hydrokinone developer on lantern plates when, in one case, it was desired to produce slides of vigour from a thin negative, and in the other, to get sufficient softness from an intense negative.

Mr. Henderson undertook to go into the question at the next meeting, and it was decided for the following meeting—that on November 5—to discuss the question generally of the modification of developer and exposure for obtaining variations of intensity.

### Photographic Society of Ireland.

The usual monthly technical meetiug was held in the Rooms, 15, Dawson Street, Dublin, on the 22nd inst., Mr. Geo. Mansfield, J.P., in the chair.

The feature of the eveuing was a lecture and demonstration by Mr. John Howson, of the Ilford Company, on the Company's new printiug-out paper (see page 748), and also on making lantern slides on their alpha plates.

A vote of thanks to the lecturer termiuated the meeting.

### Oxford Photographic Society.

*October 20th.*—The President in the chair.

Mr. J. Bretland Farmer, M.A., Fellow of Magdaleu, Mr. R. A. R. Bennett, B.A., Magdalen College, Mr. J. F. Burnett, F.C.S., Mr. J. Squire, and Mr. F. J. Gadney, were elected members.

Mr. W. J. Williams resigned, as he is leaving Oxford.

A special meeting then took place, in order to revise the rules.

### West London Photographic Society.

At the meeting held in the Broadway Lecture Hall, Hammersmith, on the 23rd inst., the new aero-carbon iucandescent lamp for the optical lantern was shown by Mr. J. R. Pooles, of the Incandescent Gas Light Company, of Westminster.

Having shown a few slides through the lantern, Mr. Pooles explained the working of the apparatus. It consists of a gas apparatus of a very portable description, which feeds a burner fitted with a zirconium mantle, rendering it instantaneously incandescent, and giving a light of 150 to 180 candle power at a very small cost. Ordinary house gas can be used, but the light would be much inferior in quality. The burners will last about a year.

The President thought that the light would be found most useful to amateurs, doing away with the dangerous lime-light and the messy oil lamp, and would be especially appreciated by nervous ladies.

The President then read his annual address to the members, and congratulated them on the contiuued success of the Society, which had increased in numbers during the past year. They had had a most successful exhibition, which had been praised alike by the judges and the press, and their exhibit at the Crystal Palace, in the competition for the Challenge Cup, had ruu the winning society's one very close. They had carried off more medals than any other society, and their only fault was that their pictures were on too small a scale. If, as he proposed, the Society purchased a large camera—say, 15 by 12—for the use of the members, this fault, in a future year, might be avoided. He also referred to the question of cheap railway fares for photographers, which the Society had brought very prominently forward during the year, and regretted that, so far, they had not been successful. Having referred to the federation scheme, he called on all the members to work together for the common good. They had had provided for them a very temptiug programme for the ensuing session, but if either members or non-members could be persuaded to offer fresh papers or demonstrations, room could be found for them.

The lantern was then brought into requisition, when slides by Messrs. Bennett, Chang, Freeman, Hodges, Holmes, Rogers, and Whitear, and some prize slides by Messrs. West and Son, were shown on the screen.

Mr. Whiting made some few remarks on the question of halation and the backing of plates, and exhibited a plate he had exposed for 30 seconds to lamplight, half backed and the other half unbacked, when the difference was very apparent.

Some remarks followed by Mr. Hodges, who found that he got very little halation when using isochromatic plates.

The next meeting will be held on November 13th, and will be a technical meeting.

### Birmingham Photographic Society.

A general meeting was held at the Y. M. C. Rooms on October 21st, Mr. W. J. Harrison, F.G.S., in the chair.

Mr. A. W. Wills, J.P., delivered a lecture on "Burmah and its People," illustrated with lime-light views. Mr. Wills has lately returned from an extended tour in the East, where he used his camera with great success.

There were upwards of 300 members and friends present.

### North Middlesex Photographic Society.

*October 26th.*—Mr. F. W. Cox in the chair.

Mr. T. F. Smith, F.R.M.S., delivered a lecture on "Photo-Micrography" to an audience among whom were the local medical practitiouers. The lecturer entered fully into all details of his subject, and, demonstrating with the apparatus as he went along, showed how to place the flame of the lamp flat or edgeways, according to the focus and angular aperture of the objeetive employed, as also how to centre the light. He proceeded to make several negatives, using isochromatic plates for the purpose. The demonstration being completed, about eighty slides of Mr. Smith's making were thrown upon the screen, and were thoroughly explained by him. Amongst them were bacillus Anthracis, Koch's Coma bacillus, the tubercle bacillus, the microbe of leprosy, the microbe of caries of teeth, and about twenty other specimens of a similar nature. The other objects were diatoms and specimens of insect and vegetable structure.

The next meeting will be a lantern evening on November 9th, when visitors will be welcome.

RICHMOND CAMERA CLUB.

*October 23rd.*—Mr. CEMBRANO in the chair.

From the comparatively minor matter of "Backing Plates," an interesting and useful discussiou on the theory, causes, and prevention of halation was evolved. Mr. DAVIS opened, showing three church interiors taken on plates backed with red paper squeezed on with glycerine; one comprising a west window of coloured glass with the suu on it showed very little halation, while the other two were much halated.

Mr. KIDD attributed the extent of the halatiou partly to under-exposure, and partly to the developer used (eikonogen) being too vigorous. He then experimented on one of the plates, and succeeded in considerably lessening the mischief by rubbing down with alcohol.

Mr. ARDASEER explained the theory of halation, and of the preventive effect of backing the plate with a substance which should reflect no rays, or such only as are innocuous.

The PRESIDENT gave the result of experiments made by different workers with backed and unbacked plates, and with plates backed with various substances—as paper, burnt sienna and dextrine, collodion stained with aurine, and caramel—of which caramel was claimed to be the most effectual.

To give a practical turn to next week's discussion on "Flash-light Photography," the President has promised to take a flash-light photograph of the members present.

GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

AT the opening monthly meeting for this session held on October 20th in the rooms, 180, West Regent Street, Glasgow, eleven new members were elected.

Mr. JOHN MORRISON, jun., president, in his opening address, referred to the late exhibition in the Fine Art Iustitute, and congratulated the Society on its great success.

A discussion was initiated by Mr WM. GODWIN, hon. secretary, on "Printing and Toning."

The proceedings were brought to a termination by the usual exhibition of optical lantern slides.

BRECHIN PHOTOGRAPHIC ASSOCIATION.

THE aunual lautern exhibition was held in the City Hall on the 21st October; Mr. WM. SHAW ADAMSON, the president, occupied the chair. The hall was crowded to excess.

The first part consisted of the lecture set, "One Thousand Miles up the Nile," followed by a selectiou of the members' own work and dissolving effect slides.

Mr. A. R. MCLEAN MURRAY, F.E.I.S., gave the descriptive lecture, aud the lantern was under the charge of Messrs. Dakers and Innes.

The admission was by free ticket, and a collection was taken at the door amounting to £9 7s. 6d.

This has been the most successful exhibition given by this Society. Great interest is taken in its work by the towns-people, of whom one-tenth witnessed this exhibition.

LADY LANSDOWNE, who, like the Viceroy, takes a great interest in photography, has accepted the houorary office of Patroness of the Photographic Society of Iudia.

MR. WILLIAM TYLAR sends us the fourth edition of "Photography in a Nutshell," which, he informs us, has been re-modelled and in great part re-writteu.

THE *Queen*, in its issue of October 24th, gives illustrations of photographs exhibited by ladies at the Photographic Society of Great Britain, these including "A Copper" (two), and "Bobby and Olive," by Miss C. Roche; aud "A Frosty Morning at St. Moritz" (two), by Mrs. Main.

## Answers to Correspondents.

**All Advertisemente and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.**

**Questions requiring a reply in this co'uınn should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.**

**All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.**

A. H.—*Quick-Acting Lenses.* The particulars have been sent on to you by post. With shortened days and bad lighting, the opportunities of employing the detective camera for outdoor work must now be necessarily limited.

OLD SUBSCRIBER. — *Mechanical Printing Processes.* As a preliminary, you should enter upon a course of reading, and then get, if possible, some technical instruction under a good practical teacher. Read Mr. W. T. Wilkinson's "Photo-Lithography, Collotype, &c." (London, Hampton, Judd, and Co.), Mr. Bolas's Cantor lectures on "Photo-Mechanical Processes" (Piper and Carter), Ernst Lietze's "Modern Heliographic Processes" (New York, Van Nostrand Company), Frederick Ives' "Recent Advances in Photography" (*Jour. Franklin Institute*, 1888); also Mr. Warnerke's "Simplified Collotype Process," and other photo-mechanical papers recently published in the NEWS. Your northern address, so far from any great business centre, presents a difficulty in the way of getting practical instructiou, but we will endeavour to assist you when the time comes. Collotype is certainly the easiest to begin with, so you should proceed to attack that first.

OPERATOR.—*Argand Flash Lamp.* The instrument is figured and described at page 182 of "Fallowfield's Annual." The "Smoke Trap," which goes with it, was shown by Mr. James in last year's Photographic Exhibition. This effectually disposes of the maguesia fumes, and prevents their diffusion into the atmosphere of the studio.

R. J. M.—*Out-door Work.* The prints of Lowestoft Harbour, Fritton Decoy, and ship *Sea Breeze* in Shoreham Harbour, are all good, the clouds in the latter being excellent. Try to screen off the dark hull by a light wash of colour, and so get an improved effect, which would then be worth enlarging. From what you say about the rising front, it seems probable that your camera uight not have been sufficiently light-tight for the red label plates.

PHARM.—*Exhibition Notice.* Thanks for the cutting from *The Chemist and Druggist* of 10th inst., which we had not previously seen. The remarks about the meagre show of apparatus are hardly justified, although some of the other criticisms may be true.

F. R. M. S.—*The Weather in October.* With a rainfall of about double the average amount, floods and all sorts of disasters have come upon us, besides the actual loss of light attendant upon so many consecutive rainy days.

P. L. (Edgbaston).—*Laboratory Fittings.* Consult the catalogues of Messrs. George Houghton and Sons, High Holborn, and Messrs. James Woolley aud Co., 69, Market Street, Manchester.

B. E. N.—*The Aluminium Light.* The fact is not new, for Mr. Bolas showed the experiment of burning the metal in oxygen at one of the Cautor lectures, and pointed out its photographic use; but the difficulty has hitherto been solely that of procuring the aluminium leaf, which will vanish as soon as the demand arises.

PECKHAM.—Tents and operating boxes are in common use. A very good specimen of the latter is now on view at the Pall Mall Exhibition.

*** The Editor will be greatly obliged if intending Contributors to the YEAR-BOOK will send in their MSS. in the course of the ensuing week.

# THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV. No. 1731.—*November* 6, 1891.

CONTENTS.

## THE STORAGE AND PACKAGE OF NEGATIVES.

Now that the photographic season, so far as landscape work is concerned, is on the wane, the careful worker will do well to consider the best way to preserve the negatives which, during its short continuance, have been added to his store. It is true that the past season, on account of its trying climatic vagaries, has not been so productive as many of us might have wished, but all the same, a certain number of negatives have been secured by most workers, and it behoves them to adopt the best means of preserving them for future use, if they are worthy of such an attention.

Although we cannot endorse the opinion of certain old-fashioned photographers, that gelatine negatives can never equal those produced in *their* time by the wet process, we are quite willing to concede the point that wet-plate negatives are not liable to that swift deterioration which is apt to overtake their modern representatives in gelatine if preventive measures be neglected. Everyone knows that a gelatine negative, if left unheeded on a shelf or elsewhere, exposed to the gamut of atmospheric changes with which we are favoured in this climate, will quickly show signs of impending dissolution. If it has never been varnished, its case is from the first almost hopeless. Spots with a metallic sheen around them quickly appear, or, possibly, the entire film assumes a pale yellow tone, which will yield but a ghost of a print. Varnish of good quality is a wonderful preservative, and if this varnish should be applied on a basis of plain collodion, or be mixed with the collodion before application, as recently recommended by Mr. A. L. Henderson, we may say that every precaution has been taken to ensure permanency so far as the film itself is concerned.

The method of storing negatives must naturally accommodate itself to the business requirements of the owner. Where negatives may be required at any moment for printing from, it is essential that they be easily accessible, so that no time is lost in searching for them. In a large establishment, where an immense business is done for the trade, we have seen the negatives stored in grooved shelves, each groove having its distinctive number. There is no objection to such a plan provided that the place of storage is kept perfectly dry, for it is evident that the air must circulate between the plates thus stored, and moist air under such conditions would be capable of harm. In many respects, this method is preferable to the storage of negatives in grooved boxes, from which receptacles we have taken forgotten negatives which were covered with mildew, and spotted all over beyond redemption. When the negatives are comparatively few in number, we know of no better plan than to store them in the original plate boxes as received from the maker. Every negative should be well varnished, and packed face to face with its fellows, a piece of clean, soft paper of the same size being placed between each pair of films. Then, if the original cardboard box be thoroughly dried by heat before the negatives are placed in it, and if, finally, the packed box is put in a tin case—like those recently introduced by Messrs. Wratten and Wainwright—there need be no fear that the negatives will spoil.

But perhaps the most fruitful source of spoilt negatives is not gradual deterioration, but the hopeless smash which so often is the direct result of sending one through the post or by ordinary carrier. We have many a time received a negative upon which the owner has desired an opinion, and the only one which we have been able to give is the opinion that it arrived in too many fragments for critical examination. Of course the poor postman or carrier is the scape-goat, and all the blame is cast upon his rough handling and stupidity. But it is hardly fair that this should be so, for, truth to tell, the mischief has arisen almost invariably from the method of packing. In one case, the glass negative was sent to us in an ordinary dark slide packed in paper, and the vibration of a long railway journey was too much for it. In other cases, the glasses have been actually sent to us through the post in ordinary envelopes, and have naturally been starred into fragments by the obliterating stamp at the post office.

From these circumstances, it would seem evident that certain persons who take photographs have not yet mastered the elementary fact that glass is brittle. Can they wonder that the Post Office authorities refuse to encourage such ignorance by granting compensation for broken negatives? There is really only one reliable method of sending a negative by post, and that is, to take care that it has a soft packing all round it, and that the external covering be of a rigid nature. The system which we have adopted, and by which we have never yet lost a negative, is as follows. We procure a wooden box an inch larger each way than the negative which is to be packed within it. This we half fill with a level layer of dry sawdust or bran. The negative, previously wrapped in soft paper, is laid upon this bed, after which the box is filled up with the same material, and the lid is nailed on. If this simple work be carried out with intelligence, the box can be thrown about without any risk of the enclosed negative being fractured. As a further precaution, however, a ticket bearing the word "fragile" should be attached to the box, and such tickets can be had for the asking at any post office where parcels are received.

## NEW USE FOR THE CAMERA.

AMERICANS, says the *Public Ledger*, should by all means—both men and women—when their mouths have assumed the mature expression, with all their teeth perfect, have their mouth and teeth photographed, so as to ensure that the artificial dental artist shall get the correct physiognomy when his services have to be called in. There is so much expression in the teeth; the entire face can be altered if a dentist furnishes the jaw with a widening, flattening row of large, handsome ivories to replace a curved and slightly irregular row of tiny natural teeth. The extreme change in the expression so produced requires almost another lifetime for one's friends to become accustomed to it. The fact is, the dentist's idea of teeth is that of a regular fence of polished and gleaming material, although considerable attention is now paid to colouring—yellowish or blue (pearly) teeth being now manufactured with wonderful likeness to nature; but the shapes and sizes still require much modification and many irregularities to make them resemble the natural teeth, which have their characteristic differences from other people's, and even from each other. How are the craftsmen in teeth to imagine these things, as the mouth has lost many of its chief ornaments before even the dentist—who chooses from sample—is called to replace the missing pearls? To secure identity in your manufactured teeth, then, it is wise to photograph your natural ones, so that their expression and form may be preserved. The dental industry can do wonders, but it cannot match what it has never seen; so the camera—now a family toy—may as well serve in preserving the mouth, with its complement of teeth, as a guide to the dentist's future labours. False teeth need not be unnatural, nor would they, if made to match a photographic sample, give the wearer the cynical expression that sometimes replaces all others when the workman has done his most ignorant best for your comfort, but not for your looks.

## ON THE USE OF SMALL STOPS.*

BY W. H. WHEELER.

BUT now to consider objections or prejudices against small stops, when generally photographing subjects in which little or no movement is to be feared. As for *foliage*, it is much more easy to cap the lens during movement and uncover it during still intervals, when the stop is small and the exposure long, than with a large stop and short exposure. I remember once, several years ago, in exposing a very large wet plate, that it took about three-quarters of an hour to give seven minutes' exposure—part of it in shade and part in sunshine; all, however, during still intervals. It was very successful, is printing now, and a few weeks since a copy went into Royal hands. But some men would be aghast at the idea of taking all that time about one exposure, even of a wet plate, out in the open street.

Because a man has accustomed himself to pretty large stops and quick exposures where speed was really essential, he too often does the same where no such necessity exists. At any rate, he deems it strange, unnecessary, and absurd to give the long exposure required by the small stop he might use, even without any definite reason for urgent speed. Perhaps he fears being laughed at, or half instinctively associates a small stop with something inartistic. Let him carefully shield his shadows from stray light, give a sufficient exposure according to his stop, and let them laugh that win.

Perhaps, however, he may think that opticians must, of course, know best; that he constantly reads in the papers of exquisite and most artistic results with large stops and short exposures; and that, if very small stops were the right ones to use, opticians would certainly always provide them. But this, in the proportion required for large sizes, and to allow for the use of swing-backs in architecture, they rarely do. Also, as I have endeavoured to show in the early part of this paper, the question is rather one of the peculiar advantages and disadvantages of photography than of optics generally, and should not be left entirely to opticians. Besides, accuracy of definition with large apertures is the natural pride of the optician. He cannot be expected to hide his light under a bushel, nor is it, strictly speaking, his proper business to provide for depth of focus in depicting still life. The much-contested "diffusion of focus" lenses were planned especially for portraiture, and to portraiture they are best suited. There is one point, however, in connection with small stops on which I cannot but think opticians have really and generally erred. Surely, they know better than other men that, whatever need exists for a small stop—either for depth of focus, flatness of field, or the sharpening of the image at the top and bottom of the plate when we require to use a swing-back—increases in an extremely rapid ratio with the increased scale of image naturally accompanying the use of longer focus lenses to cover larger plates (the minimum ratio is as the squares of the focal lengths, for the same view and standpoint). Yet the ordinary range of stops is commonly made *uniform for all sizes!* Opticians have, indeed, followed where surely they should have led, and the only remedy would seem to be the education of the purchaser, when doubtless an intelligent demand will be readily supplied. The difference in the stops needed for half-plates, 12 by 10, and 24 by 18 plates respectively, is realised by but few photographers, and is apparently

* Concluded from page 748.

practically recognised by no optician; for, to obtain the same delicacy and depth of focus, &c., on these three sizes, for similar views, from similar positions, and lenses, of course, of proportionate focus, if the half-plate were $f/16$, the 12 by 10 (according to theory) should be $f/64$, and the 24 by 18 $f/256$! It is a convenient practical compromise to use a stop of about the same actual diameter for each size, all other circumstances being equal; and such a stop—as a *small stop*—might be about $f/32$, $f/64$, and $f/128$ on these three sizes respectively. For very difficult subjects, and still larger plates, I have occasionally gone to $f/216$ with advantage. And on the other hand, on a 30 by 25 plate exposed a few days since, favourably circumstanced for equal definition, an excellent image was obtained with $f/120$, although a rising front of fully twelve inches was used, the lens being, indeed, placed opposite the top of the plate. May I venture here to suggest to opticians that, by adding, say, one smaller stop to each larger size of, at any rate, non-aplanatic lenses, they would, as it were, officially recognise a sound optical truth.

But it has been often assumed, though less confidently than was once the case, that a very small stop *always* causes some loss of brightness, or of atmosphere, or of range of half-tone. I say assumed as a generally known fact, for I have never seen an attempt to prove it or deduce it in any way from established premises. Of course we know that, if any stray light enters the camera *during exposure*, whether through the lens or otherwise, its injurious effect is directly as the time during which the plate is exposed to it, and if through a leaky camera, it is not checked even by capping the lens until the slide is closed again. Under such circumstances, a small stop may appear to produce loss of brilliance, from which a negative quickly exposed with a large stop may be comparatively free. Nevertheless, the fault is with the camera, not with the stop. I am inclined, however, to trace this erroneous view less to the wrong interpretation of a fault really due to stray light, than to a very natural but fallacious association of ideas suggesting the following misconception.

We all know that, when a landscape or architectural view is brilliantly lighted, we can generally obtain from it a better negative than when poorly lighted. It is naturally more vigorous, because the clearer the sunshine, the more brilliant and effective is the contrast between sunlight and shadow, and we can give a fuller exposure without flatness. In this way we come to associate, not unnaturally, the idea of a weak light with the effect of a weak contrast; not that we do so exactly as a distinct relation betweeen cause and effect, thought out or tested, but as a natural association of ideas adopted, as a matter of course, without really thinking about it. Thus, when we look on the focussing screen and see that the image, when a large stop is inserted, is much more brilliant and effective to the eye than with a small one, we are apt to fear from the smaller stop the same photographic dullness that we seemed to see on the screen as visual dullness. Yet as the mere change of stop in a light-tight camera cannot really alter the relations of contrast in the lighting, and as mere want of illumination can be fully supplied by proportionate increase of exposure, we may confidently expect that a view taken with a small stop and duly exposed without stray light shall be as brilliant and soft, and as full of half-tone and atmosphere, as though taken quickly with a large stop under the same lighting, while it may, of course, be far more accurately defined. Indeed, were it not so, what would become of our interiors? They can be brilliantly rendered with a proper exposure—the definite direction of the light generally supplying well-marked shadows and contrasts—with so dull a light that the necessary exposure, even with a large stop, is far longer than for the dullest exterior with the smallest stop. I have exposed a 15 by 12 quick isochromatic plate in a dark chapel from Saturday afternoon until past noon on Monday in brilliant summer weather, using a stop of $f/36$, with brilliant effect, though a ten-thousandth part of the exposure might have been enough out of doors—perhaps, indeed, *too much*—and doubtless there are hundreds of similar experiences. I am persuaded that the fallacy I have described, obvious as it seems when definitely presented, has really had an extensively misleading effect on the views of some whose opportunities for practice are rather behind their inclination to theorise.

There has been yet another prevalent fallacy about very small stops, that the physical effect of *diffraction* is practically and perceptibly injurious when such small stops are used as I have mentioned. But I believe that since an examination by Captain Abney some years since, in which he obtained from theory results almost identical with those I had recorded (in a paper overlooked by him) as the results of a merely empirical estimate, this idea has been exploded. The practical results obtained were that this error was *inversely* as the *intensity* of the lens used, but might be practically disregarded until that intensity fell below about $f/200$ for central definition; how much lower for oblique pencils cannot be stated.

Perhaps there is scarcely any work which gains more by the use of really small stops—even with the finest aplanatic lenses—as *copying*. It seems curious that, for really delicate definition in copying, so very much more accurate optical means should be required than for photographing from nature. The similarity in the relations of optical definition between an original and a copy to those I have remarked as subsisting between an optical image directly seen through an eye-piece, and a print from a negative obtained from that same optical image, rather illustrate the phenomenon than explain it; but it may help us to appreciate the special value of aplanatic lenses and small stops in first-class copying. The best of lenses, which should be of ample covering power; the smallest of stops; the extremest nicety in protecting the lens from all stray light, and confining it to the actual subject presented, to the exclusion, where possible, of even its white margin; perhaps I might add, too, the slowest of plates, and certainly the utmost care in securing to the subject an indirect but flat lighting, so as, while diverting light regularly reflected from its surface, to destroy such texture of that surface as might be thrown into prominence by an unbalanced side-light—all so contribute to improve the result, that even expert judges will often fail to distinguish between a really good copy and a good original, easy as it is to detect copies as ordinarily produced. Everyone does not choose to take all the necessary precautions, or to afford time for the necessary exposure; but neither must be grudged if we would have the very best results.

Finally, to all other objections to small stops have been added that known as "naturalistic." This I regard as founded on a general misconception of the true theory of vision—a failure to recognise that such a general perception as we have of any view, however extended, has been naturally built up by vision of each part successively brought to the exquisitely sensitive "fovea centralis," or central pit of the retina: as interest is excited, the attention called, and the eye directed to or "run over" its details by the ever-active volition. In this way, the whole mental image, though not all equally vivid, is all equally distinct. The comparative optical indistinctness of oblique vision never, in the natural visual perception, really makes any particular impression on the mind, its supposed part in the mental image really owing its vividness and distinctness rather to the memory of what *had* been seen when the eye was turned that way, and its special use being to guide this natural movement. At the same time, there is no doubt that, in the artistic indication and direction of a studied emphasis, cases may occur in which fine effects accompany a photograph where the principal object, and that *alone*, is sharply defined, as well as sharply contrasted; but unless this principal object needs no nearer foreground kept specially sharp to throw it back, and lend to it dignity with distance, a smaller stop will be an advantage even here, enabling us to accompany subordination of accessory detail—attainable at will by art in printing, carefully covering up, with added flushing, or sunning, as best meets the case—with the absence of such indistinct fuzziness as may be borne with in an artist's sketch, but scarcely admired in his finished picture. Here, again, we have the advantage, for our finishing, as to detail, being a natural process, costs no labour, and therefore is likely to convey no undue emphasis. The due subordination of accessory details in printing is essentially artistic because it serves an object intelligently sought, and is not an operation purely mechanical, or, like the course of irrational matter, blindly following an impressed law. Thus, it is more truly in accordance with our visual perception, in which selection and emphasis are the result of intellectual rather than physical causes. A true visual theory is required rightly to direct us towards the connection of photography with true art, and towards true art we trust ever to direct our efforts. Probably the best of us are always those least satisfied with their own work, our ideal constantly stretching out interminably before us. We feel as does the painter, the "ars longa, vita brevis," and, like him, find life too short for our work; but if any subordinate quality can give to us pleasure ever fresh, and with the least possible alloy of dissatisfaction, surely it is the delicate detail of natural beauties which hide themselves by their very delicacy and minuteness from all but the close observer. Their representation in the photograph, subordinated though accurate, and only recognised by a close inspection, corresponds well with the reality, itself only seen by the lovingly attentive eye.

A MAMMOTH CAMERA. — Messrs. Buchanan, Bromley, and Co., dealers in photographic goods, have just delivered to a local photographer what is, doubtless, one of the largest cameras ever made. It will take a plate 30 by 40 inches, while the largest plates now mentioned on the plate-makers' lists are 20 by 24 inches, about one-third the size. The camera was made by the Scovill and Adams Company, of New York, of fine mahogany, the track on which the rear part slides being rosewood. When fully extended the camera is 66 inches long, and when closed is 16 inches thick. The two plate-holders have curious slides. The printing frame accompanying the camera is correspondingly massive. The use to which the apparatus is to be put is not revealed by the purchaser, beyond that it is to be employed in work for the National Government. A small lot of plates secured from a St. Louis maker, to fit the holders of this mammoth camera, cost the purchaser at the rate of 45 dollars a dozen.—*Public Ledger*, Philadelphia.

## BALLOON PHOTOGRAPHY

AN article in the last number of *Knowledge* by Mr. A. C. Ranyard, the accomplished editor of that interesting periodical, has some photographic interest, in that it deals with Mr. Shadbolt's photographic experiences in cloud-land. The article is illustrated with four capital collotypes from Mr. Shadbolt's photographs, which are, perhaps, the best pictures of the kind which have ever been published. We abstract from the article that portion of it which should be of the greater interest to our readers. It is printed under the title "The Upper Atmosphere."

"I am enabled this month, through the kindness of Mr. Shadbolt, to lay before the readers of *Knowledge* some photographs taken from balloons at various altitudes. Mr. Shadbolt is a very experienced amateur aeronaut who has made over sixty ascents, and he was, I understand, the first to take a recognisable photograph from a balloon, in June, 1882. The rays of light which fall on a photographic plate exposed from a balloon have had to pass twice through the densest and most dust-laden strata of the atmosphere. Even in photographing distant landscapes from the surface of the ground, very little detail is ordinarily obtained upon distant hills, owing to the absorption of the photographically active rays in passing through a great distance of the lower atmosphere. But the difficulty is greatly increased in attempting to photograph the distant earth from a great altitude in a balloon, for not only is the absorption increased by the long course of the rays through the lower air, but the observer sees the dust-motes in the atmosphere from their sun-illuminated side. The vale of haze spread over the earth, therefore, hides the objects behind it more effectually than the transparent veil of haze which we ordinarily see over a distant landscape, giving the soft effects of distance which artists so well know.

"An observer with a giant telescope, on Mars or on the Moon, would probably see much less of what is going on on the surface of the earth than we are apt to imagine. The white upper surfaces of the clouds would first attract his attention, with, in between them, a very dim and hazy view of objects on the earth's surface, rendered all the more difficult to observe by the frequent presence of a dazzlingly bright patch of sunlight reflected from the sea. To a naked eye observer on Mars, the earth would probably appear like a variable star, with a curious and mysteriously irregular period of variation, due to the change in the brightness of the specularly reflected patch of sunlight as terrestrial clouds covered it up, or the rotation of the earth brought continents or seas to the part of the earth's surface from which specular reflection could take place.

"The exposure of photographs taken from a balloon must necessarily be short, for the balloon generally drifts along with considerable velocity, and sometimes it revolves. The revolution is, however, never very rapid, and it is generally more noticeable as the balloon descends than as it rises, owing to the greater irregularity of the car and under-surface of the balloon as compared with the comparatively spherical surface which it presents to the air on rising. With reference to the velocity with which balloons travel, Mr. Shadbolt is of opinion that they do not, as a general rule, travel so rapidly when at a considerable altitude as they do when nearer to the earth. Since this is contrary to the usually received opinion with regard to the velocity of the wind at various altitudes, and Mr. Shadbolt's judgment is founded on very full notes which he takes during his balloon voyages, as to the time of passing over various places, I give the following extract from a letter he obligingly wrote me on the subject. Mr. Shadbolt says: 'I have invariably found the wind near the earth—say up to 1,500 or 2,000 feet—to be stronger than at higher altitudes. I have frequently mounted up to take refuge from an approaching squall, and it has overtaken the balloon and passed below it, while nearly always when above the clouds they appear to travel along at a more rapid speed, and to pass along beneath the balloon. The same thing is noticeable when there are no clouds; you take your bearings and scarcely seem to be moving until you drop down near to the earth. Some might say that this would naturally be due to the distance you are from the objects below, making a quick movement appear to be slow; but after some practice you learn to recognise the actual rate at which you are passing over the ground below you.'"

## NEW LABORATORY PROCESS FOR PREPARING HYDROBROMIC ACID.

BY G. S. NEWTH.

This method is a synthetical one, and consists in passing a stream of hydrogen and bromine vapour over a spiral of platinum wire heated to bright redness by means of an electric current. A glass tube, about 7 inches long and ⅝ of an inch bore, is fitted at each end with a cork carrying a short, straight piece of small tube; through each cork is also fixed a stout wire, and these two wires are joined by means of a short spiral of platinum wire, the spiral being about 1 inch long. One end of this apparatus is connected to a small wash-bottle containing bromine, through which a stream of hydrogen can be bubbled. The other end is attached to a tube dipping into a vessel of water for the absorption of the gas, or, if a large quantity of the solution is required, to a series of Woulf's bottles containing water. Hydrogen is first slowly passed through the tube until the air is displaced, when the platinum spiral is heated to bright redness by the passage of a suitable electric current. Complete combination takes place in contact with the hot wire, and the colour imparted to the ingoing gases by the bromine vapour is entirely removed, and the contents of the tube beyond the platinum are perfectly colourless. The vessel containing the bromine may be heated to a temperature of about 60° C. in a water-bath, at which temperature the hydrogen will be mixed with nearly the requisite amount of bromine to combine with the whole of it. So long as even a slight excess of hydrogen is passing, which is readily seen by the escape of bubbles through the water in the absorbing vessels, the issuing hydrobromic acid will remain perfectly colourless, and therefore free from bromine; so that it is not necessary to adopt any of the usual methods for scrubbing the gas through vessels containing phosphorus. When the operation is proceeding very rapidly, a lambent flame occasionally appears in the tube just before the platinum wire, but this flame is never propagated back through the narrow tube into the bromine bottle. The precaution may be taken, however, of plugging this narrow tube with a little glass wool, which renders any inconvenience from this cause quite impossible. By this method a large quantity of bromine may be rapidly converted into hydrobromic acid without any loss of bromine, and the operation, when once started, can be allowed to proceed without any further attention.—*Chemical News.*

## PHOTOGRAPHY IN AUSTRIA.

BY PROFESSOR ALEX LAINER.

### On Benzole Matt Varnishes.*

*Benzole Matt Varnish.*—In photographic literature are to be found a number of receipts for matt varnish,† but without giving details of the limit of additions. So I undertook systematic experiments concerning the preparation of benzole matt varnishes, resulting, among other things, in the discovery of the new matt varnish described in this journal May 15th, 1891. By reason of these experiments, the preparation of matt varnish appears to be greatly facilitated, and any matt varnish can easily be modified as required. The simplest benzole matt varnish is obtained by adding a certain quantity of benzole to an ether sandarac solution.‡

1. *On the Concentration of the Solutions of Sandarac.*—For ordinary purposes I choose the sandarac solution in a proportion of 1 to 9 or 1 to 10. The following remarks refer to a solution of 100g. of sandarac in 1,000 cm.$^3$ of ether. Diluted solutions give thinner coatings of matt varnish and finer grain; but, in consequence of their tenderness, the coatings cannot resist powerful retouching with colours laid on wet, whereas with the stump and a soft pencil they can be worked very well. More concentrated sandarac solutions (1 to 6) produce thicker coatings of matt varnish, it is true, but these latter easily become streaky in pouring on. One can all the more dispense with the use of concentrated sandarac solutions, as in colouring the matt varnish one possesses an excellent means of covering thinness.§

2. *On the Addition of Benzole.*—With an addition of 35 cm.$^3$ of benzole to 100 cm.$^3$ of the ether sandarac solution (1 to 10) I got perfectly useless transparent coatings, which, at the same time, are very brittle. 40 cm. of benzole produced a weak but totally useless matt varnish, whereas 100 cm.$^3$ sandarac solution and 45 to 50 cm.$^3$ benzole produced coating perfectly matt, but with the use of various sorts of benzole they were sometimes unequal. If one goes beyond this addition of 50 cm.$^3$ of benzole, the grain of the matt coating becomes somewhat coarse-grained, and with 65 cm.$^3$ benzole the grain is flocky, and lacks clearness. An excellent corrective for this grain is formed by the addition of some drops or cubic centimetres of alcohol.

3. *On the Addition of Alcohol to Benzole Matt Varnishes.*—If the addition of benzole be increased to 65 cm.$^3$, the solution itself sometimes appears rather turbid, and the matt coating becomes coarse-grained. If one now adds alcohol‖ to this matt varnish, not only does the solution possibly become clear at once, but also the grain of the matt coating appears very satisfactory. I always obtained excellent results with the following formula:—

* From the *Photographische Correspondenz.*

† With some of them no matt coating is obtainable.

‡ Coal benzene or benzene corresponds to the formula $C_6H_6$. It boils at 88° C., and, in a chemically pure condition, at a temperature of 15° has a specific gravity of 0·884, or, according to Mendelljeff, at 15½° C., 0·850. The benzole I used had a specific gravity of 0·820 at 20° C. Benzene, or petroleum benzene (specific gravity 0·63-0·68), boils at about 50° C. A very small addition of it separates the resin from sandarac solution; a larger addition produces lumpy extractions. For the distinction between benzol and benzene by means of iodine, see *Photographische Correspondenz*, February, 1891.

§ See the *Photographische Correspondenz* for May.

‖ I used absolute alcohol.

*Formula* 1.

| | |
|---|---|
| Solution of sandarac (1 to 10) ... ... | 100 cm.$^3$ |
| Benzole ... ... ... ... ... | 65 ,, |
| Alcohol (absolute) ... ... ... | 2 to 4 ,, |

The addition of 4 cm.$^3$ of alcohol makes the matt coating more transparent than does 2 cm.$^3$ of alcohol. If one increase the amount of alcohol to 6 cm.$^3$, one gets unequal matt coatings; with 8 cm.$^3$ of alcohol no matt coating can be obtained. The formation of grain is prevented.* A dilution of the above varnish with 20 cm.$^3$ of ether produces a matt varnish which flows very easily, and makes more transparent and tender matt coating, but which, as already mentioned, is very easily damaged. Even a dilution with 40 cm.$^3$ of ether still permits the formation of a very tender matt coating, which, in certain cases, can do retouching very good service. An addition alternately of alcohol and benzole acts on the benzole matt varnish as follows. Adding a small quantity of alcohol makes the grain finer; if one then adds benzole, the coating becomes coarse-grained, and at the same time more transparent. This is to be understood so; the grain separates in more compact little lumps, by which means its interstices become larger. A renewed addition of alcohol again produced close grain; thus the coating appeared less transparent. By adding benzole, alcohol, ether, and solution of sandarac alternately, any matt varnish may be modified at pleasure, so that it is never necessary to throw away unsuitable matt varnish, presupposing that one has employed pure, *colourless*, cool benzole, and not petroleum benzene.

4. *On the Addition of Dammar and Mastic.*—10 g. of the dammar-resin of commerce were treated with 100 cm.$^3$ of ether; the solution was not complete. Further, 10 g. mastic were dissolved in 80 cm.$^3$ ether. Neither of the solutions produces matt varnish if treated with benzole or toluol; but the influence on formation of grain in ordinary matt varnish—mastic in particular—acts astonishingly. The matt coatings become softer with a considerable addition of mastic or dammar—nay, even sticky—and, before beginning the retouching, must be allowed to dry for some minutes. With the following mixture I obtained a good sandarac-dammar matt varnish:—

*Formula* 2.

| | |
|---|---|
| Sandarac solution (1 to 10) ... | 50 cm.$^3$ |
| Dammar solution (1 to 10) ... | 50 ,, |
| Benzole ... ... ... ... | 50 ,, |
| Alcohol ... ... ... ... | 2·5 ,, |

The alcohol is added gradually as required, and, after each addition of alcohol, one prepares a specimen plate. In the above formula the quantity of dammar may be diminished; increasing it to 80 cm.$^3$ produces cloudy coatings not sufficiently matt; a grade between, even without alcohol, produces useful, delicate matt coatings. I obtained a very fine grain with the following mastic matt varnish:—

*Formula* 3.

| | |
|---|---|
| Sandarac solution (10 to 100) ... | 90 cm.$^3$ |
| Mastic solution (10 to 80) ... ... | 10 ,, |
| Benzole ... ... ... ... | 50 ,, |
| Ether ... ... ... ... | 20 ,, |

An increase of the mastic solution leads to milky-looking matt coatings, but which do not become regular, and look cloudy.

5. *General Remarks.*—Mostly one may at once retouch on the matt coating with a soft pencil No. 1; if harder pencils are used, the coating must first dry well. The bottles of matt varnish must be kept well corked, as the ether evaporates very quickly, resulting in coarse-grained coating. Matt varnish coatings will bear washing with cold water, and may therefore be treated with water-colours. Warming does not hurt the matt coating, and the use of hard pencils is thereby made easier. Chloroform and coal benzole spoil the matt coating; bisulphide of carbon does so less; petroleum benzene not at all. Thus, the matt coatings must not be covered with ordinary solutions of india-rubber to protect the retouching, but, according to Dr. Albert's proposal, a solution of gutta-percha in benzene would probably be suitable.

* In toluol matt varnish, the effect of an addition of alcohol is not so good as in benzole matt varnish.

---

Automatic Photograph Company. — A special meeting of this company was held on the 28th ult. at Winchester House, to receive the report of a committee of investigation as to the position of its affairs. The committee reported that, if the full capital of the company had been subscribed, or even had its crippled capital been more carefully and watchfully administered, under contracts less onerous to the company, the company might, perhaps, have been able to tide over the interval necessary for perfecting the machines and reducing the expenditure for plaques, so as to make their operations profitable. But the machines had been worked at a steady loss, until the entire resources of the company had been exhausted. To continue the company, therefore, in its present insolvent condition would be to deteriorate the value of the patents. The committee, therefore, saw no course but to recommend a voluntary winding up of the existing company, but were of opinion that the patents were proved to be of very considerable value, and that a reconstructed company, with moderate capital, to enable it to modify and improve the machines and reform the system of plaque supply, might be able to return a substantial dividend to its shareholders. Admiral Sir R. Macdonald presided, and stated that the best was done to work the machines, but for five months they never registered a day when a "photo" could be taken. When he was told they should wind up the company, he replied that they were bound in justice to the shareholders to show what the machines were capable of doing. As the summer was about to come—but it never did come—he thought the capabilities of the machines should be proved, if for no other reason, to save the continental and colonial companies from ruin. Every way was tried; but the company was so unfortunate as to have officials who did not come up to expectation. When they got their machines into good positions, with honest treatment and moderately fine weather, £1 or £2 a week was made, yet they were losing by it. He thought, however, that anyone taking up the machine, with respectable people willing to hire it, might, under good circumstances, get a glorious return. The chemicals of the plaques formed part of the secret of the patent; and when the plaques failed to produce the result expected, and were returned by the thousand, they should be examined by an expert, but he was told that that would be suicidal, as it would reveal the company's patent to a rival photographer. In his opinion, it was not a hopeless affair if worked under more auspicious circumstances. Sir James Carmichael said the management of the company had been deplorable, and it had been proved that it was impossible to work the present machines at a profit. They had been worked hitherto at an enormous loss. He believed in the invention and patents; but the company had not the money to carry out the suggested improvements that might make it a success. These machines only produced £1 a week, and it would take £4 a week to clear them. The idea of letting the machines at £1 a week was out of the question. Mr. Dalton Miller contended that it would be the worst thing in the world to wind up the company, for then their patents would be sold for an old song. In the end, a motion by Mr. Dalton Miller against winding up the company was put to the vote, and declared carried, but a poll was demanded.

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Paramidophenol and Bromide Paper—Celluloid Solution—An Alkaline Fixing Bath—Transferring Collodio-Chloride Prints to Artificial Ivory.

*Paramidophenol and Bromide Paper.*—In Dr. Stolze's opinion, the paramidophenol developer is far superior to any other developer recommended for bromide paper. He states that the developing solution prepared according to the formula given by Dr. Andresen—

| | |
|---|---|
| Water ... ... ... ... | 1,000 c.c. |
| Hydrochloric paramidophenol ... | 5 grammes |
| Sodium sulphite ... ... ... | 50 ,, |
| Carbonate of potash ... ... | 25 ,, |

though it contains but 5 parts of the reducing agent to 1,000 parts of water, not only acts much quicker than eikonogen, hydroquinone, or ferrous oxalate, but that it may even be diluted as much as 5 to 2,000 in the case of large prints if it is desired to control the development. If the quantity of the alkali is increased considerably—about from 25 to 30 per cent.—prints will be obtained of unsurpassed clearness of the whites and velvety black shadows, together with perfect softness of the half-tones. Moreover, this brilliancy will be preserved after the prints have dried. "These prints are leaving behind them everything which I have hitherto seen on bromide paper," says Dr. Stolze. He then points out that the second formula given by Dr. Andresen offers the possibility of obtaining a ready-prepared developer of highest concentration. The formula runs as follows:—

| | |
|---|---|
| Boiling water ... ... ... ... | 100 c.c. |
| Potassium meta-bisulphite ... ... | 30 grammes |

When dissolved, add—

| | |
|---|---|
| Hydrochloric paramidophenol... ... | 10 grammes |

To a quantity of this well-keeping solution a concentrated solutiou of caustic soda is added by stirriug, until the precipitate formed is just redissolved. For use, this stock solution may be diluted with fifty times its bulk of water, so that a stock solution consisting of 100 c.c. will be sufficient to obtain more than 5,000 c.c. of ready-prepared developer. In this direction paramidophenol is far superior to eikonogen, and especially to ferrous oxalate, with which it is not possible to prepare as highly concentrated developers.

*Celluloid Solution.*—Spoiled celluloid films may be used, according to the *Phot. Notizen*, in the following way. They are soaked in soda solution, and freed from the gelatine layer; then they are dissolved in fifty times their bulk of amyl-acetate. With the celluloid solution thus obtained, negatives may be coated; after the lapse of some days, the coating will be as hard as ivory. In the same manner, three or four per cent. solutions of celluloid may be prepared and stained with coralline, fuchsine, tropacoline, &c. If glass plates are coated carefully with this solution, and, after draiuing, re-coated, hard films are obtained on which gelatino-chloride prints may be squeezed, or which may be stripped off the glass support. The celluloid solution may further be used to coat dishes, dark slides, &c., since the layer thus obtained is not affected by acids, alkalies, and alcohol.

*An Alkaline Fixing Bath.*—The following fixing bath is recommended by B. Kröhnke. Two parts of alum are dissolved in ten parts of hot water, and, on the other hand, one part of caustic soda in ten parts of hot water. The two solutions are mixed together by pouring the alum solution gradually into the soda solution. An almost clear liquid is obtained, which, after cooling down, should be filtered and kept for use in a well-stoppered bottle. Of this alkaline alum solution such a quantity is added to the ordinary hyposulphite of soda solution as will be required to clear aud harden the film of the negative. The latter is placed in the bath without being previously rinsed. One or two parts of the alum solution to 100 parts of the hypo solution will generally be sufficient; more may, however, be added without fear of injuring the negative, in the case of a badly-discoloured developer having been used, or if a very hard film is required. This alkaline fixing bath has the advantage that it does not attack the negative film, even after it has acted upon it for hours; on the other hand, it clears and hardens the film just as thoroughly as the acid fixing bath. The alkaline alum-soda solution keeps indefinitely if it is stored in a well-stoppered bottle, and mixes with the hypo solution without producing muddiness.

*Transferring Collodio-Chloride Prints to Artificial Ivory.*—The following method is recommended by Bruno Risse. A well polished plate glass is rubbed, by means of a pad of linen, with a solution of 1 part of white wax in 100 parts of ether. The print to be trausferred—having been produced on collodion stripping paper—should be about half-an-inch larger in all directions than the glass plate which is employed for stripping. The collodion paper is placed in warm water, in which the film will leave its paper support. After the film has been caught on the glass plate, its edges haviug been turned down, the glass plate is bordered all round with strips of gummed paper, so that if the latter is turned up, the plate, together with the paper strips, will form a dish of about half-an-inch in depth. The inner sides of the gummed paper forming the dish are coated with a paste consisting of 1 part of stearine and 5 parts of hog-fat, iu order to facilitate the subsequent strippiug. The ivory mass is prepared by dissolving 150 grammes of gelatine in 600 c.c. of warm water, straining this solutiou, whilst still warm, through flannel, and stirring into it 30 grammes of zinc-white and 15 grammes of glycerine. The mixture should be kept warm for one hour on the water-bath, that the air-bubbles may be gathered on its surface. They may either be skimmed with a spoon, or the mass is allowed to set, and, after having cut off its surface, it is again liquefied by warming in hot water. The solution is then poured about one-fifth of an inch high into the above-mentioned improvised dish upon the print, taking care that no air-bubbles are produced. After setting, the mass is dried out by a temperature of from 25° to 30° C. Before stripping the print off the glass plate, the horny film is coated with a solutiou of 2 parts of gutta-percha in 100 parts of chloroform. After the strips of gummed paper have been cut off, the print may be easily stripped off the glass plate by passing a knife beneath it.

---

Enamelling Albumen Prints.—According to the *Photographische Archiv*, a highly glossy surface may be imparted to albumen prints without the use of gelatine in the following way. Equal parts of ox-gall and of alcohol are mixed, and the mixture is allowed to stand for several days with occasional violent shaking. A glass plate is coated with it evenly, and the albumen print, as it comes off the washing water, is placed on it, and allowed to remain on it for about one hour under pressure. As soon as it is dry it will come off with a beautifully glossy surface.

## Notes.

The prosecution of a man who sought to add to his scanty income by the fabrication of bank notes, revives a question which has occurred to us more than once: Are not the present notes issued by the Bank of England too apt to tempt the forger? The spurious note which led, in the present case, to detection of the delinquent was a photograph, and the only part of it which did not appear to be genuine was the paper upon which it was printed. The photographic knowledge possessed by the fabricator did not, apparently, extend to an imitation of the watermark; but, as is known, such an imitation by photographic process is by no means an impossibility.

Some persons there are who are always crying out for cheaper dry plates. We wonder if these frugal ones have ever tried to make plates for themselves, and have noted the bare cost of turning out a few dozens, to say nothing of the care and labour expended upon the work. For our part, we wonder that such excellent plates as are now to be obtained can be produced at the low price asked for them. To show how prices have been cut down, it is merely necessary to refer to the price which photographers in the old wet-plate days had to pay for the glass alone. Half-plate glasses were commonly sold at 28s. per gross, or one shilling more than is now asked for a gross of dry plates ready for use. The modern photographer may thus be said to get his gelatine, silver, and his plates prepared for him free of cost, besides paying less for glass than the last generation of photographers were in the habit of doing. Of course, the glass used for wet plates was of finer quality than that necessary for the gelatine process, but all the same the figures given are significant.

The Messrs. Lumière, the originators of the paramidophenol developer, have, it is said, at last conquered one of the chief difficulties with which they had at first to contend in dealing with the new product, namely, that of obtaining it in sufficiently strong solution. They can now prepare it at a strength of fourteen per cent. (presumably by the addition of some body which promotes solution, but is otherwise inert), and at this strength a developer of great power is produced. Paramidophenol is still costly, but, as one dose of developer will serve for about fifty plates, it is not so expensive as it seems to be.

One of the "Notes" in our issue of October 23rd last described Gustave Doré's stratagem for dispersing the persistent gazers who stood in the way of his friend's camera in the streets of Verona. A correspondent tells us he has a very practical and successful, if less dramatic, plan of "clearing the course," and eliminating obstinate obstructionists from the view or site he wishes to photograph. He carries, as every photographer should do, a screw clamp and a rule, and when he has focussed he clamps the latter to one of the legs of the tripod, adjusting it against the side and near the end of the base-board. He then swings the camera round to quite another direction, and when in this position inserts diaphragm and dark slide. By this time the idlers have taken up a new position in front of the lens. The camera is now quietly turned back again to its original position in contact with the clamped rule (or wire, or stick), and the exposure made before the foreground is again obstructed.

The art of sending pictures by telegraph has long been the dream of many, and all kinds of devices have been produced—on paper—by which the difficulty is alleged to have been conquered. This subject, indeed, like polychromatic photography, is one of the most fascinating of modern scientific will-o'-the-wisps. Most of the methods proposed are plagiarisms of Bain's telegraph, or they depend in some manner upon variations in electrical currents caused by the action of light on selenium. The method proposed by Amstutz, an account of which we print on another page, is decidedly clever in conception, but we fancy that practical electricians, as well as engravers, will see many rocks ahead which will have to be steered clear of before this ship can be brought into harbour.

An instructive case, both for photographers and sitters, came before the judge of the Westminster County Court last week. The plaintiff, a photographer, sued the defendant, Viscount Maitland, for £7 8s., the value of photographs supplied under the following circumstances. A Captain Sleigh conceived the idea of publishing an album of all the ladies presented at Court in 1889 and 1890, and for this purpose photographs were necessary. Viscountess Maitland, among others, sat to the plaintiff, and proofs forwarded to her, being an exception to an arrangement made with Captain Sleigh, that proofs were not to be sent to any of the sitters. The plaintiff was aware of the object Captain Sleigh had in view, and it may be presumed that it was at the request of Lady Maitland proofs were sent to her. At all events, it does not appear, from the report of the case, that Captain Sleigh gave instructions to that effect, and when the photographs were not returned, the plaintiff sued Viscount Maitland for the money. Lord Maitland's defence was that the photographs were taken upon the understanding that no charge was to be made, and the proofs were not returned because they were not good, and he thought they were valueless; and ultimately the judge held that the photographs were to be taken for the album free of charge to the defendant, and gave judgment for the latter.

The case is an example of a complication which very frequently arises when an order is given by one person for another person to be photographed. The distinction is not sufficiently borne in mind by the photographer, who sometimes has a notion that a sitter *qua* sitter is liable in the event of any hitch in the original agreement. These triangular arrangements are exceedingly liable to break down, and hence the necessity for the precise terms to be clearly stated in writing.

The defence in the action is very typical of the indifference sitters, as a rule, show in regard to proofs. Viscount Maitland thought that because he or his wife did not like the photographs, they were therefore valueless. They quite forgot that the time and expense incurred are just the same with the production of unapproved photographs as with those which are approved. This unreasonable view is far too common, and every photographer has had the disagreeable experience of taking a vast deal of trouble over sitters, of sending proofs, and of hearing no more of the matter. Some photographers adopt the precaution of stating on the wrapper that when proofs are not returned they are always charged; while others send untoned and unfixed prints. The former plan is preferable.

## THE PALL MALL EXHIBITION.

ALTHOUGH this Exhibition has now been opened for some weeks, it still continues to attract a number of visitors, and we understand that the evening lantern slide entertainments are well attended and fully appreciated.

Continuing our review of the pictures, we notice a charming little photograph by Mr. E. M. Stone (No. 345), "A View of Abingdon." We happen to know this part of the Thames pretty well, and think that Mr. Stone would have done better if he had taken his view from a lower point of the river. As it is, he has chosen a point from which a tree somewhat dwarfs the church spire, which, of course, should be the principal object in the picture.

Mr. W. P. Marsh has often exhibited fine seascapes, but never has he shown a better one than that here exhibited with the title "Where the Billows Roar" (No. 358). The photograph well shows that creamy churning up of the water which is such a beautiful feature of breaking waves; and another good effect is caught in the blowing from the tops of the breakers of the water-dust.

No. 361, by Mr. R. Terras, illustrates a line of Burns—"What can a Lassie do wi' an Auld Man"—and it is by far the best picture of the three which this gentleman contributes to the Gallery; but the other two, "The Engagement Ring" and "Preparing Dinner," are by no means poor pictures, although they are over-shadowed by the one just named, where the story is so well told, and so true to nature.

No. 366, under the title of "Jetsam," is an attractive picture by Mr. C. H. Cook, and represents a boy lying prone on the grass amid a heap of old anchors and chains, such as one can often see at busy seaports.

Nos. 367 and 368 are two capital landscapes by Mr. F. Cobb, the first one being a quiet rustic scene, and the second interesting because it gives a glimpse—and a very good glimpse—of that old world Sussex town called Rye. Another picture by this gentleman—No. 369, "A Thirsty Soul"—introduces us to a pond with a most remarkable horse drinking from it; the poor old thing looks as if his next journey should be in the direction of the knacker's.

One of Mr. W. J. Byrne's best pictures is hung on this wall—No. 374, "Buy a Broom!" This is a large photograph; a full-length figure of a child taken direct, and a child who is woe-begone enough to act up to the character which she represents.

Mr. H. Young, in No. 388, gives us a fine piece of landscape work, with a distant sunlit hill very beautifully rendered. The picture, perhaps, would have been better if it had some object in the foreground by way of balance; but it shows work of a very high order.

The two views by Mr. W. Atkinson, which are hung close by No. 385, are bromide enlargements, and they have certainly suffered in the process of magnification.

No. 382 is a frame containing three pictures by Mr. E. D. Stern, with the strange title "Sicilian Tid-Bits." The most curious of the three is a picture of a cart containing thirteen women and nearly as many babies, drawn by one unfortunate horse. Another shows two horned beasts dragging a heavy stone roller; and the third is a donkey-cart, about which there is nothing very remarkable. But the pictures are interesting in giving us a peep of peasant life in Sicily.

In Nos. 399 and 401, Mr. Cobb gives us some more of his excellent rustic scenes, which are taken with the careful hand of a skilled photographer. No. 401 especially is a pleasing picture, and owes its principal charm to the circumstance that it is taken in the face of the sun. The same effect is noticeable in the pretty little picture close by—No. 412, by Miss Roche. This lady sends several pleasing works, but this is the best. It represents an old man in a garden against a mass of well-lighted foliage; the picture is full of sunshine.

No. 410 is a frame of excellent portraits of children by Mr. E. Resta. These are platinotypes, very natural in pose, and, like most children's portraits under such conditions, are pleasing to the beholder. The same gentleman has another frame of similar portraits (No. 417) which deserve equal praise.

Col. Noverre sends three pictures on rough drawing-paper, a method of printing which he has, in past exhibitions, done so much to popularise. The best of the three is No. 406, "An Evening in Mount's Bay, Cornwall." The subject is simple enough, a ship lying at anchor in the beautiful bay, with a mass of rock on one side, the whole being relieved by a very fine sky effect.

Mr. H. Baker, of New Street, Birmingham, must be congratulated upon his frame of portraits in sepia. These are in carbon, and Mr. Baker has been most fortunate in attracting to his studio a number of young ladies who make remarkably pretty pictures.

No. 420, by Mr. A. J. Irvine, is a frame of five very excellent Norwegian pictures.

Mr. Paul Lange sends a little picture entitled "A Misty Morning at Chirk Canal." This picture is taken from the towing path, and the principal object is a barge being towed along by a horse and boy, all being overshadowed by a mass of greenery.

Mr. Warneuke, of Glasgow, has been fortunate enough to secure one of the medals for a very beautiful picture of Miss Laura Johnson as "Desdemona"; and the same gentleman, still harping on Shakespearean subjects, contributes a couple of very beautiful pictures of "Othello" and "Hamlet," as interpreted by the eminent actor, Mr. Herman Vezin.

Mr. H. Symonds sends some of his exquisite yacht pictures; the three shown on the wall, namely, "The White Slave," "A Reverie," and "The Neptune," being beautiful examples of modern photography. We can only say that they could not be improved upon.

Some portraits of the "At Home" type are sent in by Messrs. J. Russell and Sons, in frame No. 431. Among these are portraits of the Empress of Germany, the Duchess of Marlboro', and the Princess Victoria of Teck. These pictures are in every sense worthy of the name of the firm mentioned.

No. 432 is an enlargement from a negative by Mr. J. W. Lindt, produced by the Autotype Company. It will be remembered that Mr. Lindt exhibited several pictures of the same kind at a previous exhibition; this particular one represents a group of natives from the New Hebrides. Such pictures have a great value from an ethnographical point of view, and the authorities of the British Museum have not been slow to recognise this, for several pictures by Mr. Lindt are now on permanent exhibition in the galleries at Bloomsbury.

Some more studies of children are shown in frame No. 433, by Mr. W. J. Byrne; some of these being as charming as it is possible to imagine. Mr. Byrne seems to have the secret of winning the confidence of his little models, for their portraits are perfectly natural, and they appear unconscious of the presence of a camera.

"A Break in the Clouds" is the title of a picture by Mr. L. C. Bennett. We recognise the photograph as having been taken on the beach at Hastings from the neighbourhood of the East Hill; the atmospheric effect which gives the picture its title is very fine.

It is not an easy thing to illustrate by photography a comedy, but Mr. H. Salisbury has succeeded very well in extracting a story, which he calls "Sin and the Sinner," from two models, a dog and a child. As far as we can follow the argument of this history, both dog and child are tempted to steal from the sugar basin in front of them, and in the end both fall and suffer remorse. Perhaps the series might have been better called "A Struggle for a Piece of Sugar, in seven tableaux."

A very fine portrait of the Marquis of Salisbury, which, we learn from the catalogue, was taken "at home," must again be credited to Messrs. Russell. In this case the original portrait has been enlarged in carbon.

Mr. Seymour Conway contributes a picture which we regard as the finest piece of landscape in the room. It is a view of the Trossachs and Ben Venue; the crispness of the foliage, and the detail on the distant mountain, are quite remarkable. There are many such beautiful scenes to be found in this lovely neighbourhood, but most tourists hurry through on the top of a coach, and miss them altogether. Mr. Seymour Conway has evidently been wiser than this, and has succeeded in discovering a spot from which a very beautiful picture has been obtained. The work is that of a man who evidently has a thorough mastery over all his materials. Another picture by the same hand, which is full of merit, but not quite so attractive, is No. 483, "Kilchurn Castle," on Loch Awe.

Mr. Bhedwar, of Bombay, sends a number of pictures which are well worth attention. They include a capital portrait of the Duke of Edinburgh, and some Oriental scenes which are clever. One of these represents a woman playing with a parrot, whilst a jealous macaw stands on a stool at one side. The title of this picture is "Two's Company."

A direct portrait of the musician Paderewski, the work of the London Stereoscopic Company, attracts attention, and is fully up to the standard which we have learned to expect from this firm.

We have now arrived at a corner of the Gallery where it has been the custom from time immemorial to hang pictures which are due to mechanical processes, and here are three excellent works of this kind sent by the Autotype Company (No. 508) from direct negatives by A. E. Coe. These pictures are on toned etching paper, and are portraits of civic authorities at Norwich. The work is perfect of its kind. We also have here some fine interiors taken by magnesium flash-light by Mr. J. Stewart; these are so soft in quality that one can hardly believe that they are taken by artificial light, which is too often associated with chalk and soot results. An immense photogravure, "The Syrens," by Mr. F. Hanfstaengl, hangs here, and is quite a triumph of photographic work of this kind.

Some dry-point pictures by Mr. F. Flather attract attention from their good quality, and we must not omit to notice a collection of rare and curious eggs photographed by Mr. H. Stevens. We need hardly say that the egg of the great auk is here; and it will perhaps be in the memory of our readers that Mr. Stevens was instrumental in selling one of these whited sepulchres a few months ago for about £250.

The Autotype Co. have won a medal for a very beautiful auto-gravure from a painting in last year's Royal Academy, entitled "Outward Bound." It would be difficult to imagine a more perfect copy of an oil painting than is represented by this picture.

The Survey Department of India exhibit, in the frames Nos. 522 and 524, some very beautiful photo-etchings, the first of which are some architectural examples from the Government Architectural Survey of Western India; but perhaps the greater interest attaches to the next frame, in which we are able to compare the ordinary method of photo-etching from drawings with the thiocarbamide direct method introduced by Colonel Waterhouse, which has already received notice in our columns. The other frame represents various examples of photo-etching, which are remarkable for the fineness of the results shown.

We must reserve for future notice the pictures hanging upon the screens, and the apparatus exhibited on the centre table, together with the lantern slides.

## A NEW PROCESS FOR SENDING PHOTOGRAPHS BY WIRE.

Noah S. Amstutz, of Cleveland, the inventor of the process for transmitting pictures by electricity, says the *Chicago Herald*, is a little man, with a full beard, and wearing iron-bound spectacles. For six long years he has followed his pet idea, until now he feels certain that complete success is about to crown his efforts. Mr. Amstutz's invention is not the first in this line, but none of the others have gone much beyond the visionary stage. He seems to have learnt the secret which other inventors sought for in vain. Change is the one word which explains it all. Variation is the better word, for he has learned how to reproduce a variable surface by means of a variable current of electricity, and that discovery is the key to his success. All electricians—and everybody else, for that matter—know that the pressing down of a telegraph key in Cleveland will cause the armature of a sounder in New York or Chicago to click, but it requires only a steady current of electricity to produce that result, and the armature of the sounder moves with each click the full distance allowed to it within prescribed limits. Put into the wires a variable current which will cause an armature to move much or little, to flutter or dance at the will of the operator, and you have solved the problem on which Mr. Amstutz has worked for years, and which he has mastered at last. The machine or apparatus on which Mr. Amstutz has laboured so long is apparently a very simple mechanical electrical device. It consists of a metal frame-work about a foot square, and much like the frame of a type-writer, which supports a brass cylinder three inches in diameter and about eight inches in length. Above this cylinder is a metal vibrator attached to a carriage, which at the back is fed transversely by a feed-screw. The front end of the carriage travels on one of the bars of the frame as the carriage is moved slowly by the feed-screw from right to left across the top of the cylinder. Attached to the carriage where the feed-screw passes through it are the wires carrying the electric current. Extending along the lower side of this carriage is the delicate vibrator referred to above, to one end of which, and directly over the brass cylinder, is a tracer that can be raised or lowered by means of a set-screw. Suspended over the other end of the vibrator are seven little platinum contacts, against which the vibrator presses as it rises, making connection with the resistances which give variation to the electric current. An electric motor is used to turn the cylinder and feed-screw. The process of transmitting the picture seems simpler than the apparatus by which it is done.

From a photographic negative a gelatine print is made (being a stripping film). This print has a variable surface, the plain surfaces being white, and the various elevations showing greater degrees of shade as they increase in height. The gelatine print, for convenience, is mounted on a strip of celluloid, which is passed around the brass cylinder, and by means of screws is drawn tightly into place, the picture lying around the cylinder with its face up. When everything is in place, the tracer attached to the vibrator is so adjusted that its point will run smoothly over the lowest surface of the picture, the electric motor is started, and the cylinder begins to move. It revolves about twenty times each minute.

The picture passes under the tracer, which, dancing over the variable surface, raises and lowers the vibrator, constantly changing, though not entirely breaking, the electric current by which the picture is being sent. The feed-screw turns very slowly, and the cylinder bearing the picture makes about eighty revolutions while the tracer is moving transversely over an inch of the space along the top of the cylinder. In other words, the tracer passes eighty times from top to bottom of the picture in a space an inch wide, touching every particle of the surface within that space, and giving to the electric current all the variations of light and shade as represented by the variable depressions and elevations in the gelatine print. The fineness or coarseness of the work of the apparatus is regulated entirely by different sets of gears. At the other end of the wire is the receiving cylinder, which is exactly synchronised with the one from which the picture is sent, so that the revolutions are the same. On the receiving cylinder, which fits into a metal frame like the other, is a thin sheet of paraffin wax. Adjusted over this sheet of wax is a V-shaped "graver," or little steel point attached to a carriage which works on a feed-screw similar to that used on the sending cylinder. The current coming over the wires passes through the magnets, having variations corresponding to the variations of light and shade of the photograph being sent. As soon as the electricity is applied at the sending end and the cylinder there is started, the receiving cylinder also begins to move. As the tracer moves up and down over the variable surface of the gelatine film, so the "graver" on the receiving cylinder rises and falls, cutting into the sheet wax, and reproducing in exact detail the variations of light and shade in the picture on the sending cylinder miles away. When the sending of the photograph has been finished, there is on the wax an exact reproduction of the picture in relief lines, varying in width and depth with the light and shade of the gelatine film from which it was sent. The sheet of wax is then taken from the cylinder, warmed slightly, and pressed out flat. From its surface can be printed proofs of the picture, or from the wax engraving—for that is what it really is—can be made a plaster mould from which a type metal can be cast. The time elapsing between the turning on of the electricity for the sending of a picture two inches square, and the casting of the cut, ought not to be more than twenty-five minutes. The time will, of course, vary with the size of the subject.

Sketches made in half-tone, with variations in light and shade (not simply outline), those approaching the style of an India ink wood-drawing, &c., can be so made under the process that, as soon as completed, they may be placed upon the cylinder of the transmitter and automatically sent to a distance, and there made into an engraving which is the reproduction itself. This step will enable a special correspondent to send his sketches so as to reach the home office as soon as any press despatches. It will no doubt be understood that the result arrived at is the correct reproduction of the photograph, with all its variations of light and shade; hence its accuracy. The engraving is a special feature of the device. While the result will have an appearance similar to the well-known half-tone engraving, it will not, however, have any of the disadvantages of this process when used for regular newspaper work, namely, the filling up of the lines because of their shallowness, and the ultimate breaking down of them because of their not being strong enough to sustain the heavy pressure of the large cylinder presses. The cutting is done by an electrical-mechanical device, which can be adjusted so as to go a greater or less depth without destroying the fineness of the work. With chemicals this is impossible. A modified receiver is also used, in which the carriage is the same as the one described above, but the support for the material upon which the record is to be made is different, being a reciprocal table having a block of soft metal instead of the cylinder and its sheet of wax. The manner of cutting is different also, because on the metal a rotary cutter is used instead of the V-shaped graver used on the wax. When the engraving is completed in the metal, proofs can be taken direct, or the block can be stereotyped by the ordinary methods, and at once placed in the forms and on the press for printing.

Mr. Amstutz has made several tests of the apparatus, all in private. The first was made on March 27th, 1891, and the last on 17th of July. He chose for his first subject a picture showing a house interior with three persons sitting at a table. There was too much detail in this picture for good work as a first attempt. The next subject was a photograph of Carmencita, the Spanish dancer, whose dress, covered with lace and embroidery, made a difficult surface to work upon. The result was a very good likeness. The last test was upon a photograph of himself, and the result showed decided improvement over the previous tests. The main obstacle now to be overcome is the adjustment of instruments, which must be exact to a hair's breadth. The principle has been conquered, and it is only a question of time when the mechanical difficulties will be overcome.

Aberdeenshire Amateur Photographic Society.—We are apprised of the formation of the above Society, which holds its meetings on the last Tuesday of each month at 8 p.m. The membership subscription is 2s. 6d. per annum.

Photography and Disease.—The latest application of photography to medical science is to use it as a means of locating tumours on the brain. The theory is that spasms are caused by affections of the nervous centres, and that the disturbance of a centre is invariably followed by identically similar contortions of the muscles. A tumour must, of necessity, press upon a nerve centre, producing violent spasmodic attacks. While in this condition the patient is photographed, and the exact position of the tumour discovered. Experiments have been successfully made in San Francisco by an "eminent local surgeon." We must confess we do not follow the reasoning which attributes spasmodic attacks to tumours on the brain. Why not to a tumour on any other part of the body? There seems to be something wanting in the explanation of the theory.—*Science Siftings.*

## APPARATUS FOR MAKING SATURATED SOLUTIONS.

THE following apparatus, which is described in a recent number of a French journal (*Bulletin de la Société Francaise de Photographie*), will be interesting to those who have much to do with saturated solutions, and will be eminently valuable to workers with the ferrous oxalate developer.

This apparatus, described by M. Davanne in his treatise on "Photographic Chemistry," and put in practice by M. F. Carpentier in his laboratory, consists of a glass vessel holding about a quart, having a tubulure in the lower portion, and furnished in the upper portion with a large mouth, in which fits the ground tube of a sort of funnel, also of glass, in which is placed the substance to be dissolved. This funnel, which is hemispherical in shape, may be closed by a plate of glass resting on the ground edges, and which prevents evaporation and the introduction of dust. The mouth of the funnel is closed by a cork, in which is introduced two straight tubes. One of these tubes starts from the top of a funnel, and stops at a distance of a few centimetres below the cork; the other commences above the cork, and descends almost to the bottom of the vessel. On the lower tubulure is affixed a rubber tube to which is adapted a screw clamp, forming a tap.

To make use of this appliance, after having placed in the funnel a quantity of the substance to be dissolved, sufficient to furnish a concentrated solution which can fill the vessel, pour at one time the dissolving liquid, water, or other substance, in sufficient quantity to completely fill the vessel and the funnel surmounting it. We have now only to wait the necessary time for the solution to go on automatically, the concentrated portions falling gradually to the bottom of the vessel. In fact, the portions first dissolved descend by the lower tube to the bottom of the vessel and drive back the less dense liquid, which, rising through the upper tube, finds its way to the upper portion of the funnel. In this manner is established a continuous current, by means of which the less dense portions of the liquid are constantly brought in the upper portion in contact with the undissolved salt. They then become loaded with this salt, and in the concentrated form fall to the bottom of the vessel, on top of the solution already formed, whose level will be seen to gradually rise until the vessel is entirely filled. By loosening the clamp on the rubber tube the concentrated solution is withdrawn at will, and it suffices, to replace the quantity used, to add more liquid to the funnel, and renew, when necessary, the stock of salt in this last. The use of the rubber tube adapted to the vessels prevents it being disturbed when the liquid is to be drawn out. In this way it is possible to keep on the same shelf a series of vessels always ready containing all the concentrated solutions which may be wanted in the laboratory, and these solutions, which are thus prepared automatically, without loss of time or special manipulation, may be kept indefinitely protected from dust and evaporation.

ROYAL INSTITUTION OF GREAT BRITAIN.— At the general monthly meeting on Monday, November 2nd, Sir James Crichton Browne, M.D., LL.D., F.R.S., Treasurer and Vice-President, in the chair, the following were elected members: — George Frederick Deacon, M.Inst. C.E., Miss Henriette Hertz, Arthur Walter Mills, Robert Mond, B.A., F.R.S.E., Joseph Shaw, D. Hack Tuke, M.D., F.R.C.P., Lieut.-Col. H. S. S. Watkin, C.B., R.A., William Henry White, C.B., F.R.S., M.Inst. C.E.

## ANNUAL WINTER EXHIBITION OF OIL PAINTINGS AT THOMAS MACLEAN'S GALLERY.

A COLLECTION of between fifty and sixty oil paintings by artists of British and foreign schools is now on view at this well-known gallery in the Haymarket, and is well worth a visit. Taking the landscapes first, we may mention a very fine one by Mr. J. Horrock, "Carting Hay near Guildford"; and another picture of a similar subject by Mr. Wimperis. The last-named gentleman exhibits two or three other pictures, which are full of beauty. The collection includes a picture by Rosa Bonheur, representing a group of deer under trees in the forest of Fontainebleau; and Mr. Peter Graham, R.A., in "A Passing Shower," gives us one of his well-known Highland scenes, with rough-coated cattle. Mr. L. B. Hart seems to be following in the footsteps of the artist last named, and the titles of his pictures—"A Highland Drove, Perthshire," and "After Rain," another Scottish scene "—would almost seem to indicate that he has gone over the same ground; but we must say, at the same time, that the imitation—if it be imitation—is, in this case, good. We must not omit to mention a very clever little bit of landscape by Mr. Clayton Adams, entitled "A Sandpit in Surrey." In this work the contrast between the red sand and the purple heather growing on the margin of the hollow is very beautifully rendered.

Among the figure subjects, we notice a charming little picture by Mr. Burton Barber, entitled, "Cupboard Love," in which a young girl is holding a basket behind her and tantalising an eager little dog who is waiting to be fed. "The Lace Maker's Courtship," by Mr. Stefano Novo, is a charming little picture representing a man pleading his cause to a peasant girl, who is leaning against a table with her face averted, smiling at his impetuous words. A similar subject by the same artist, entitled, "A Happy Moment," also forms a very attractive picture. There are other pictures in this gallery of real merit, and we regret that lack of space forbids us to notice them more in detail.

## PHOTOGRAPHIC EXHIBITION AT LEYTONSTONE.

AN exhibition of photographs is in course of preparation at the Fillebrook Lecture Hall, Leytonstone, Essex, under the presidency of G. Andrew Hutchison, Esq. The exhibition will open on Wednesday, Dec. 2nd, 1891. Six silver medals will be awarded for the best photographs sent in for competition, subject to the following conditions:—

1. Amateurs only may compete.

2. The whole production of the picture, including exposure, development, retouching (which must be declared), printing, toning, and mounting, must be solely the work of the exhibitor.

3. Photographs may be by any process, and any number may be entered, excepting such as have already gained awards in any open exhibition or competition.

4. There will be the following classes:—(1) Direct prints; (2) enlargements; (3) lantern slides, in sets of not less than four.

5. All photographs must be mounted, and, if possible, framed. (The mounting and general finish will be taken into consideration in making awards.)

6. An entrance fee of one shilling will be charged to each exhibitor entering pictures for competition, who must fill up a printed form and send it (accompanied by

the entrance fee) as soon as convenient, but not later than Tuesday, Nov. 17th, to the Secretary, who will in return send labels to be fixed on the backs of exhibits (in classes 1 and 2), or on boxes containing slides (in Class 3).

7. Exhibits sent by carrier should be addressed to Mr. J. W. Spurgeon, Fillebrook Lecture Hall, Leytonstone, London, N.E., and may be sent as early as convenient, but must be received not later than Tuesday, November 24th, on which day photographs may be brought to the Hall, from 8 till 10 p.m. All expenses of packing, and carriage both ways, must be paid by exhibitors; pictures brought by hand must be taken away on Tuesday, December 8th, between 8 and 10 p.m.

The Committee will also be pleased to receive for exhibition photographs not for competition, including those which have gained awards elsewhere. For exhibits in this section no entrance fee will be charged. Both amateurs and professionals are invited to contribute, subject only to rules 5 and 7. Forms and all particulars may be obtained of Joseph W. Spurgeon, Hon. Sec., 1, Drayton Villas, Leytonstone, Essex.

## Reviews.

In Scripture Lands. By Edward L. Wilson. *(The Religious Tract Society, London.)*

The photographic interest attaching to this handsome volume is two-fold. In the first place, it is by our esteemed confrère, Dr. Wilson, who is well-known as a writer on photographic matters, besides being the editor of the Transatlantic magazine which bears his name; and in the second, the book is illustrated with one hundred and fifty exquisite woodcuts and process blocks from the author's photographs. A good deal of the subject matter will be familiar to English readers, from it having already appeared in serial form in *Scribner's Magazine*, and those who have, in that way, had their appetites whetted by the perusal of part of Dr. Wilson's text, will be anxious to secure the complete work in the form in which it is now presented. Dr. Wilson's powers of picturesque description give a great charm to the work, and one feels, in reading his words, that they are the outcome of a personal acquaintance with the scenes so well painted. The pictures themselves constantly call to mind those in Roberts's "Holy Land," which were drawn long before the camera was available for such work, and it is curious to note how the modern photographs corroborate the pencillings of that distinguished artist. Dr. Wilson's volume will be indispensable to students of Bible history, while it will always serve as a model for anyone who has it in contemplation to illustrate a book by photography.

Photographic Club.—Subject for November 11th, "Impurities in Photographic Chemicals," Mr. A. M. Levy. The annual dinner will be held on the 18th.

Fry Manufacturing Company's Demonstrations. — The second of this series was given on Friday last. The subject, "Bromide Enlarging," was dealt with in a practical manner, the lecturer describing the apparatus required and the method of using it, afterwards illustrating his observations by producing enlargements by artificial light. Details of development were given, and suggestions to meet possible failures. The lecture was followed by a general discussion and questions from the audience. During the evening Griffith's fixed focus enlarging apparatus was shown and used. The next lecture, on the subject of "Lantern Slides," is fixed for Friday, Nov. 13th. Tickets in return for stamped directed envelope.

## Patent Intelligence.

*Specially compiled for the* Photographic News *by Herbert & Co. (H. J. Haddan & R. Haddan), Registered Patent Agents, &c., of* 18, *Buckingham Street, Strand, London, W.C.*

### Applications for Letters Patent.

17,860. Ladislas Nievsky, 14, Gransden Road, Shepherd's Bush, London, "Aspirator Tank for Developing, Fixing, and Washing of Photographic Dry Plates in a broad daylight and in the same vessel, without touching liquids during those operations."—*October 19th.*

17,967. George Bagnall Bradshaw, 37, Chancery Lane, London, "Improvements in Photography."—*October 20th.*

### Specifications Published.

19,274. *Nov. 26th*, 1890.—"Regulating Shutters for Photographic Cameras." A. S. Newman, 71, Farringdon Road, London, E.C.

This invention consists in regulating the speed of the movement of the shutter by means of pneumatic cylinder and piston. The piston rod is connected to some working part of the shutter slide, or to some part of the apparatus connected therewith, in any suitable manner, such as in the manner of connecting up the variable expansion or valve gear of a steam engine, in which, by moving the regulating gear, the length of travel of the valve upon the steam parts of the engine is varied; that is, in this invention the length of movement of the piston itself is thus increased or diminished, and thus regulates the speed of the shutter, and so regulates the time of exposure. Similar results can be obtained by mounting the cylinder on a slide, swivel, or joint, and varying its position with relation to some working part of the shutter.

19,480. *November 29th*, 1890.—"Shutters for Photographic Cameras." A. S. Newman, 71, Farringdon Road, and A. L. Adams, 81, Aldersgate Street, London, E.C.

Relates to a shutter for "detective" or hand-cameras which, after each exposure, will return to its normal position for giving the next exposure without admitting any light whilst so returning. A thin plate of metal having a slot cut therein, and being of quadrant shape, is mounted to turn on a pin at its centre. A second plate similar to the first is mounted in the same manner, and both plates move across the lens in parallel planes. The second or auxiliary shutter is pushed in one direction by a rod having a knob projecting outside the camera, and brought back to its normal position by a coiled spring. On one part of this shutter is a cam, and on another part is a recess to engage a catch, which holds the shutter "open" until the first shutter releases this catch, when the auxiliary shutter is at once returned to its normal position, carrying with it the shutter proper.

The two shutters are both mounted on the same pin or axis, and are connected by a coiled spring, so that when the auxiliary shutter is moved, the shutter proper tries to follow, but is prevented by a catch until the slot in the auxiliary shutter is coincident with the lens aperture, whereupon the cam on this shutter releases the catch, and the shutter proper then travels across the lens aperture, and so gives the exposure, and afterwards releases the catch, which engages the auxiliary shutter, and the two shutters are drawn back by the coiled spring in such a manner that no light is admitted while so returning.

8,232. *May 13th*, 1891.—"Cameras." B. G. P. Möller, Kolding, Denmark.

The camera is provided with a chamber above, or at the side of same, and a magazine or storage space behind the camera proper and said chamber; also a slide plate provided with a shoulder and a retaining device, the arrangement being such that photographic plates are held by the slide plate in the chamber until required for use, and are, by inward movement of such slide-plate, introduced one at a time into the camera proper for exposure, after which the retaining device acts first to prevent a return movement of the exposed plate when the slide plate is drawn outward, and then presses the exposed plate into the magazine or storage space. The magazine is divided, by means of a removable device, such as a screw, into two spaces, one of which receives the plates which have been exposed, and the other receives the plates from the first space when the removable device is drawn back. The plates are stored in this space until it is required to develop them. By means of a sliding drawer which carries the objective lens, and a scale of distances used in conjunction therewith, objects which are very near, as well as those far distant, can be photographed with this camera.

10,798. *June 25th*, 1891.—"Shutters for Cameras." J. Kershaw, Spring Gardens, Buxton, Derby.

The shutter is a flexible blind. At one side of the shutter, and on one end of the liberating roller, is attached a pulley, to which is connected a cord, and at a pre-arranged part of said cord is placed a stop. To the side of the shutter is also connected a flat steel spring, which is caused to fit against the face of the pulley, with a space under the pulley, and between the spring and side of shutter, for a pneumatic bulb, which is actuated through a tube and similar bulb connected thereto, and held by the operator. A stud is placed on the face of the pulley to engage with a stud on the inside of the spring to prevent the blind re-winding. Guides are also attached to the shutter and inside of the spring through which to pass the cord attached to the pulley. This shutter can be used either as an instantaneous or time shutter.

London and Provincial Photographic Association.—November 12th, "Cau Halation be Avoided by Staining the Film in any way?" November 19th, lantern night.

"Goodness, John, how queer baby looks! I believe he is going to have a fit." "By George! I believe you are right. Where's my camera?"

Bleaching of Wax.—When beeswax is exposed in thin layers to the air and to direct sunlight, it is quickly rendered colourless; but in the dark, in presence of a free supply of air, oxygen, or ozone, no decolourisation whatever is effected, even after a long time. In presence of sunlight, oxygen, and especially ozone, destroys the colour very rapidly, but the presence of oxygen is not absolutely necessary. When the wax is exposed to sunlight *in vacuo*, or in an atmosphere of carbonic anhydride, it is bleached, but much more slowly than in the presence of air. The composition of the unbleached wax differs considerably from that of wax which has been bleached by exposure to air and sunlight. The latter contains a slightly larger percentage of free acids, but a large proportion of the unsaturated acids of the oleic series and of the unsaturated hydrocarbons in the crude wax have disappeared. This fact shows that in the bleaching process not only does the colouring matter suffer total combustion, but the unsaturated acids and the unsaturated hydrocarbons are converted into saturated compounds by the fixation of oxygen. This is also the case with other fatty substances, such as suet, and the reason why the addition of one to five per cent. of suet to beeswax causes decolourisation to proceed more quickly is because the suet, in its oxidation or combustion, aids the destruction of the colouring matters. The addition of a small quantity of other oxidisable substances, such as essence of terebenthene, also hastens the action, so that it would seem that the destruction of the colouring matter is due to the formation of ozone by the oxidation of the added substance.—A. and P. Buisine.

Messrs. Adams and Co. have lately introduced a very handy and useful dish with a loose cover, enabling the operator to shield his plate from any access of light during development. This will be especially valuable in isochromatic work.

# Correspondence.

## PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

Sir,—The following are the arrangements for the lantern displays at the Exhibition on the dates named:—Saturday, November 7th, competition slides; Monday, November 9th, competition slides; Wednesday, November 11th, lantern slides by Mr. J. A. Sinclair, illustrative of "A Scamper through Normandy"; Thursday, November 12th, last night of the Exhibition—slides sent by Tasmanian and Indian contributors, and the prize competition slides.

Kindly announce that the next ordinary meeting of the Society will take place on Tuesday next, November 10th, at eight p.m., at the *Gallery*, 5a, *Pall Mall East*, instead of at the Society's rooms, as has already been announced. Mr. Leon Warnerke will read a paper, illustrated by lantern slides, on "Photographic Technical Instruction upon the Continent." The medals will be presented to the prize winners.

H. A. Lawrance, *Assist. Sec.*

50, *Great Russell Street, Bloomsbury, W.C., November 2nd.*

## "IN THE LAW COURTS."

Sir,—Referring to an article in your issue of October 30th entitled "In the Law Courts," it is not correct that I enclosed a photograph of my picture, "On the Threshold," or "The Bride," in a letter to the *Queen* art critic, suggesting it should be published in that paper.

What did happen was as follows. In the spring of 1890 I received a letter from the *Queen* art critic, asking me for the titles and descriptions of the pictures in my studio, as I understood, for an article on the pictures of the year by lady artists. I replied by sending him a number of photographs of my various pictures, including the one alluded to, asking him to describe them from the photographs, I being very busy, and not having time to do so. Shortly after, I heard from him that he particularly admired the "Bride" picture, and that the *Queen* would like to give it a prominent place in that paper. To this I replied as follows: "The original picture is all but sold to *Myra's Journal*. I only sell the colour copyright, and *after* it is produced in colours I have the right to dispose of the subject in any shape or form in monochrome." This was alluded to by Lords Justices Lindley, Lopes, and Fry as "the commencement and opening of negotiations, not a definite license, still less a concluded agreement," and, in addition, they also called attention to the fact that I distinctly stated that I had *no power* to dispose of the monochrome till *after* the coloured plate had come out. Hearing nothing further, I, of course, concluded the matter dropped, and a little later, being asked by Messrs. Keep and Co. to let them have the monochrome in addition to the colour copyright, I agreed to do so.

I must ask you to publish this letter correcting the misstatement alluded to, which has been the cause of much annoyance to me. M. H. Earnshaw.

65, *Harley Street, W., Nov. 2nd.*

# Proceedings of Societies.

## London and Provincial Photographic Association.

At the meeting held on Thursday, the 29th ult., the chair was occupied by Mr. J. S. Teape. It was announced that on the 19th inst. the results of the lantern slide competition would be shown.

Mr. T. E. Freshwater showed a new form of lantern condenser, and an arrangement for regulating position and distance of burner, of which he gave the following description:—The form of condenser fitted in the present instance is the one designed by Mr. J. Traill Taylor, which consists of two lenses five inches in diameter, and a smaller collecting lens. The principle upon which this condenser is constructed is, that the first lens takes up an angle of 95 degrees of light from the radiant, which is parallelised by the second lens. The third lens cones down this parallel beam so as to fill the focussing lens, and is made removable, so that similar leuses of different foci may be substituted to suit various objectives of long or short focus. In optical or magic lanterns where large condensers are used to cone the light down through the picture on to the focussing lens, it is obvious that it is advisable to place the picture at such a distance from the condenser that the whole of the cone of light passes through it, that the utmost illumination may be obtained on the screeu. This object is frequently attained by moviug the slide forward till it reaches the desired position ; but this uecessarily pnts it out of its right position as regards the front lens, so that it has to be re-focussed, besides which the amount of variation shown on the screen by re-focussing, &c., prevents the operator from ascertaining the effect the movement of the picture has on the illumination. This was partly remedied afterwards by moving the focussing lens *with* the picture ; bnt this, besides altering the size of the picture ou the screen, could only be fitted to the best forms of lanterns at the expense of rigidity, which, though of less importance in a cheap, simple lantern, is fatal in the case of lanterns with heavy lenses of twelve and fourteen inch focus, the fronts of which should be rigidly attached to the coudeusers, that the axis of the lenses may be kept optically true. To obviate these difficulties, the condenser (preferably a triple combination, five inches iu diameter) is fixed in a solid brass mount fixed to a brass base in grooves on the tray upon which the lime-jet fits. This brass base travels by donble racks-and-pinions, or screws on a stout metal bed-plate, to which the front plate of the lantern carrying the picture and focussing lenses is also permanently attached. By this means we can, after focussing the picture on the screen, move both condenser aud jet together away from the slide without affecting the picture on the screen in any way except by increase or decrease of illumination, and so can adjust the relative positions of the cone and the picture without difficulty. Should slides of various shapes and sizes require to be exhibited in succession, the condenser and jet may, if desired, be racked backwards or forwards to suit any one of them without altering any of the other adjustments, and without moving or affecting the picture on the screeu in any way, except by increasing its brilliancy. The lantern front, being fixed to the bed-plate, is perfectly rigid, and if it requires tilting up or down to make the disc coiucide with other discs on the screeu, this may be done in the usual way, without in any way affecting the optic axis, as the jet, condenser, slide, and front lens all move together. The tray carryiug the jet is preferably fitted with rack motions, aud to slide it into grooves on the travelling base of the lantern, so that, though it can be moved, together with the coudenser, by means of the rack already described, it can also be moved independently to and from the condenser, and above and below, and to right and left of the optic axis, so that it may be readily centred.

Mr. F. A. Bridge enquired whether the triple form of condenser really gave more light than the double form.

Mr. Freshwater said that it did, the angle of light taken up by the back lens being 95 degrees.

Mr. A. Cowan asked whether Mr. J. H. Dallmeyer did not construct a triple condenser many years ago.

Mr. Freshwater said that that was so. The triple form was not new, and they did not claim anything in the condenser.

Mr. A. L. Henderson showed two transparencies printed by contact from one negative, the one priuted on au ordinary plate, and the other on a special slow plate for transparency work. No amount of dodging, he said, would enable the worker to get as good a result with the rapid as with the slow plate. Contact printing, too, he considered necessarily better than by the camera, as, in the latter case, there was some diffusiou of the light passing through the negative. At the same time, he showed a transparency made on wet collodion from a negative which was so much under-exposed, and so thin in the details of the shadows, that it was remarkable that so much could be got out in the way of making a positive. With collodion, he said that a phantom image could be built up, but not with gelatine.

The Chairman said that wheu making a transparency from a thin, weak negative, he had given one-fourth the exposure that a normal uegative would require, and had developed with hydroquinone and caustic alkali, but used two parts of the hydroquinone solution to one part of the soda solution, instead of the equal proportions used for ordinary work. For a very intense negative, on the other hand, he had used two parts of the alkali to one of the hydroquinone solution, and added two grains of bromide of potassium to each ounce of the developer. The chairman also showed some further experiments with the reversal of the image ; but he had failed in obtaining the negative image again by the most prolonged exposure, up to 512 times that which had sufficed to produce the first reversal.

A question from the box was read : "In dealing with the focus question at the Polytechnic Institute last week, Mr. Debenham showed diagrams illustrating the formation of an image by a pinhole and by a lens. Is there any difference other than that of intensity iu the two cases ?"

Mr. Debenham said that, with a pinhole, defiuitiou is equal for any distance. With a lens, definition is more perfect at the focus, but falls off at other places.

Mr. Weir Brown said that Mr. Chapman Jones had recently given a process for reducing intensity by converting the image into bromide of silver, and then redeveloping to such inteusity only as desired, and stopping short when the intensity was reached. He (Mr. Weir Brown) thought that by that method the gradation in the lights would be lost; as by stopping the developmeut when only a certain depth of deposit had been reached, the high-lights would not have all their original depth, whilst the half-tones would be developed to the full.

Mr. Debenham said that that would depend very much upon the manner of developing. With a strong developer acting rapidly, the surface might be developed fully before the lower stratum was reached, but with a weak developer permeating the whole film, development of all parts would go on together, and so variations of manipulation might enable the operator to obtaiu varyiug results as desired.

### Richmond Camera Club.

On the 30th October the subject for discussion was "Flash-Light Photography." Mr. Cembrano presided.

Mr. J. G. Hudson, inventor of the "Kolm" time exposure magnesium lamp, explained the apparatus, by which a sustained light is produced by means of magnesium powder, the power of light being under the control of the operator. (By aid of this lamp, the President took two photographs of the members present, and was then photographed himself, the exposures varying from five to fifteeu seconds.) Mr. Hudson also exhibited a repeating flash-lamp of his own design, and several other makes were shown by members present.

### Bath Photographic Society.

The first ordinary meeting of the winter session was held at the Royal Literary and Scieutific Institutiou on Thursday evening, the 29th ult. Mr. G. F. Powell presided. Gifts to the Society were announced of books, and of a large direct photograph of the members of the Photographic Convention (Bath meeting), suitably framed, and presented by the Hon. Sec., Mr. Middleton Ashman.

Mr. Philip Braham, F.C.S., delivered a lecture on "Light Phosphoresceuce, Fluorescence, Diffraction, Interference." The lecturer said it was his purpose to analyse, to a certain extent, what light really was. He spoke of the theories advanced by scientists, dealing first with that known as molecular, and then with the vibratory hypothesises. Phosphorescence, he said, was a property fouud in some bodies which enabled them to be rendered sensitive when acted upon by a strong light, and retain the imparted luminosity for a considerable time, but slowly remitting it in the dark. Fluorescence, on the contrary, was not so excited, and its peculiar properties were only manifest in the presence of light, as illustrated in uranium glass and certain liquids. The brilliant light from burning magnesium was made to impinge upon evolutions of this character with satisfaetory results. Diffraction was next shown, illustrated by interposing a slit in the path of the beam from a limelight apparatus.

The well-known dark bands thus produced were then photographed by a member, Mr. H. G. P. Wells, and exhibited to the audience. Interference was also shown, the bands of colour so produced being well discerned on the screen.

### Putney Photographic Society.

*October* 31*st*.—Rev. L. Macdona in the chair.

Mr. S. H. Fry, of the Fry Manufacturing Co., gave a demonstration on bromide enlarging on their new "Naturalistic" paper. Mr. Fry first showed members the method of judging the correct exposure, giving 4, 8, 12, and 16 seconds. He then proceeded to enlarge a quarter-plate negative of a yacht on the Thames to 12 by 10 inches, using hydroquinone as developer, and fixed in an acid bath composed of—

| | |
|---|---|
| Hypo ... ... ... ... ... | 4 ounces |
| Bisulphite soda ... ... ... ... | 1 ounce |
| Water ... ... ... ... ... | 16 ounces |

He showed the members that they could obtain with hydroquinone results quite equal to those by ferrous oxalate, with less uncertainty and greater simplicity, as, by the use of the acid fixer, the operations could be reduced to two. He succeeded in producing two very beautiful enlargements, one of which he presented to the chairman. Not the least interesting part of the demonstration was his method of printing-in clouds by covering the foregrouud (after development and while still wet), and then printing-in the clouds from another negative. Mr. Fry showed how simple it was to bring out flagging detail by breathing upon the print, and by local application of developer on a pad of absorbent cotton-wool.

Messrs. J. B. Ball, S. Buckland, and A. E. Smith were elected members, making nine new elections during the month.

### Enfield Camera Club.

At the meeting held on the 28th ult., Mr. W. H. Trewartha James read a paper entitled "Notes on Hand-Cameras." The paper dealt first with those parts common to all hand-cameras, and expressed the opinion that the reflecting mirror type would ultimately hold the field for the highest class and greatest range of work. Bag changers properly made were certainly the most compact and convenient form, but if size and portability were unimportant, then properly made magazine cameras, and after them dark slides, held the field. Most of the automatic changers required rather delicate mechanism, aud in the well types the jarring of the plates seemed a great defect, though otherwise many of the movements were reliable aud very ingenious. In summing up, the use of the tripod was strongly insisted on, as even with the fastest lenses aud dry plates, and the best control over shutter speeds, it was only under favourable conditions of light and subject that properly exposed plates could be relied on. There was no doubt that hand-camera work (not mere snap-shot practice) would, as its conditions became better appreciated, grow into increasing popularity and value.

A fine show included many of the best types of instruments in the market, in addition to several very clever home-made and home-designed cameras by members present.

### Oldham Photographic Society.

The annual meeting was held on October 29th, the president, Mr. T. Heywood, presiding.

The Secretary read the report for the past year, and the Treasurer's statement of accounts; after which the election of officers took place, as follows:—*President*—Mr. Wallace Thompson; *Vice-President*—Mr. J. Chadwick; *Treasurer*—Mr. W. Schofield; *Librarian*—Mr. L. Tetlow; *Committee*—Messrs. J. H. Ashton, J. Brooks, J. S. Drousfield, J. Creaves, junr., T. Heywood, W. Jackson; *Honorary Secretary*—Mr. T. Widdop, 16, Burnaby Street, Oldham; *Assistant Secretary*—Mr. W. A. Nash.

During the election, Mr. J. Mellalieu, of Middleton, exhibited a novel developing arrangement, consisting of three bottles with pipettes for dropping, which he intends shortly putting upon the market.

## Answers to Correspondents.

**All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.**

**All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.**

C. (Nelson).—*Aristotype Prints.* The fact of the spots appearing on both samples of gelatino-chloride paper would seem to indicate some adventitious fault in your own working. They look like splashes of hypo, but, as you say the spots became visible in the last washing of No. 1 print, this could hardly have been the cause; nor are they blackened by touching with nitrate of silver solution, so there is no hypo there now. They are not due to metallic contaminations in the paper, or each spot should have a dark nucleus, which is not the case. We have known silver prints to become spotted and stained by long contact with zinc washing troughs, bronze powder, or even with dry particles of pyrogallic acid, and other chemicals. The evidence in this case does not enable us to unravel the mystery, but we will write to you in the event of our finding out anything more definite with regard to these prints.

S. B. (Notts).—*Cleaning off Old Negatives.* Immersion in hot water and soda usually loosens the film, so as to permit of your cleaning the glasses with very little rubbing. If they are collodion negatives, wood naphtha cleans off at once both film and varnish. Finish off with a good rub with whiting and water.

W P.—*Gum Tragacanth.*—You will not succeed in getting this to dissolve in water like gum-arabic, and we do not anticipate that you will be able to use it as a substitute for mounting. Try glue soddened in cold water, lifted out and mixed with warm dextrine, say equal parts by weight.

T. H.—*Sandringham Photographs.* Two years ago Mr. H. Bedford Lemere, of 147, Strand, showed some views of Sandringham in the Pall Mall Exhibition, and we have no doubt that others can be obtained of Messrs Spooner and Co.

L. M. (Ryde).—*Moisture in Paper.* The amount varies according to temperature, and the state of dryness of the surrounding atmosphere. Dr. Russell and Captain Abney found that the sample of Whatman's drawing paper used in their experiments on the actiou of light on water-colours, absorbed from 12 to 12½ per cent. of moisture. Some time ago we found that the thick white post cards, which are made of very inferior paper stuff, absorbed as much as 15 per cent.

E. D.—*The Earthquake in Japan.* We join with you in sincerely hoping that Professor W. K. Burton is not amongst the injured, and that he may shortly be in a position to give evidence with respect to the painful and calamitous events happening in the laud of his adoption.

B. E.N.—*Aluminium Leaf.* Since replying to your enquiry last week, we have been informed that the Aluminium Company, of Oldbury, Birmingham, supply this article in a form suitable for burning in oxygen. It is now being used as a cheap substitute for silver leaf, for a variety of ornamental purposes, not being liable to tarnish.

Subscriber.—*Lantern Soirée.* Just a note to remind you and other London friends that the Pall Mall Exhibition will be opened to-night for the benefit of the Photographers' Benevolent Association.

Received.—From Mr. T. Cranfield, of Grafton Street, Dublin, a 16 by 12 photo. of group of chemists assembled at Trinity College, ou the occasion of the meeting of the Society of Chemical Industry in July last; from Professor Meldola, a copy of "Cantor Lectures ou Photographic Chemistry," delivered at the Society of Arts.

# THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV. No. 1732.—*November* 13, 1891.

CONTENTS.

## LANTERN SLIDES BY REDUCTION.

The most popular method of producing lantern slides is by contact of lantern plate with negative, and the majority of plate manufacturers seem to take it for granted that most of their customers will adopt this plan. It certainly has the merit of extreme simplicity, and, provided that the negative from which the slide is taken embraces in a space of about three inches the whole of the composition which it is desired to include in the lantern picture, no fault can be found with the system. Some workers take their negatives for the express purpose of producing from them lantern pictures, and they are careful to have a space of the standard size pencilled on the ground-glass screen of the camera. Others are content to obtain by contact a lantern picture from such part of a quarter-plate negative as will give the best result. The fact that the great majority of commercial slides are made square, or round, so as to fill up the whole of a sheet—also, by general agreement, square in shape—has caused the large army of amateur lantern slide producers to follow suit, and an oblong picture was, until lately, quite the exception. The introduction of cameras for reducing larger negatives to lantern size has resulted in a change for the better, for there is little doubt that an oblong picture is far more satisfying to the eye than one which is either round or square. Our picture galleries give evidence that artists generally prefer the oblong shape, and lantern slide makers would do well to follow so good a lead.

Unfortunately, one of the most desirable processes by which slides can be produced cannot be employed except for contact pictures. We allude to the old albumen process, which deservedly holds front rank for such work. Those who have succeeded in producing lantern slides of that kind will think twice before they change their method, for the pictures given are beautifully transparent, and the film is almost as hard as the glass upon which it rests. A properly executed albumen picture on glass is, indeed, as permanent a thing as photography is capable of producing. The collodio-bromide process, although slow, yields excellent results by reduction in the camera, without the chance of abrading the tender film which printing by contact is apt to bring about. As our readers know, the majority of commercial slides are due to the wet collodion process, and these are mostly reduced from larger negatives. Amateurs, on the other hand, mostly favour gelatine slides, and excellent results are obtained by the various makes now in the market; but, as already intimated, most of them are used in contact with the negative to be copied.

We have for some time, in our own practice, adopted a method of producing slides by reduction which, while most certain in its results, leaves little to be desired in the way of convenience. The negatives employed are quarter-plate size, and they are reduced to 3 by 2⅝ ins., being finally framed with a mask slightly smaller. By dispensing with daylight, we at once eliminate one source of trouble, for daylight at this season of the year is far too variable a thing to depend upon. Even if we get a decently fine day, the actinic value of the light varies from hour to hour, almost from minute to minute. We employ a lime jet with a very small bore, so that the spot of light is not more than a quarter of an inch in diameter. This light is contained in a roughly-made lantern furnished with a six-inch (diameter) condenser. In front of this condenser, and close against it, stands a frame to hold the quarter-plate negative, which is buttoned into its place in a moment. On the same base-board is an ordinary camera fitted with a 6-inch rectilinear lens pointing towards the negative, and this camera holds a carrier of lantern plate size. After the first negative has been focussed, and it has been ascertained that every part of the apparatus is well centred, picture after picture can be produced with the utmost regularity and certainty, the only condition being that the duration of exposure is regulated according to the density of the particular negative in hand. The full aperture of the lens is employed, and the amount of light is such that a very brief exposure is necessary with a normal negative. With a bromide lantern plate (commercial) this averages about ten seconds. A chloride plate will require, with the same negative, about two minutes; but the latter is not suitable for this work unless the negative be very thin, when it will give a better result than a bromide plate.

From what has gone before, it will be evident that the common form of enlarging apparatus now sold can be adapted to this work of reduction. With the objective removed, and a camera pointing towards the condenser through the lens aperture, the worker will have at command all that he requires, care being taken that both camera and enlarging apparatus are firmly held between rails on one base-board. The use of the limelight is now so general that many workers have it ready to their hand, and they will find it of great value in this work of reduction; but, of course, other luminants may be employed. We have advocated its use in the work of reduction for the reason that, in our hands, it is very quick and certain in its results.

## AT MESSRS. VALENTINE AND SONS, DUNDEE.

Accident brought us the other day to the Royal borough of Dundee, the busy city on the Firth of Tay, which boasts the largest population of any place in Scotland next to Ediuboro' and Glasgow. While there, we took the opportunity of calling upon Messrs. Valentine and Sous, and were courteously shown over the whole of the extensive works, the largest establishment of the kind in the world, Mr. Valeutine told us. The factory, of which there is a branch elsewhere, is situated in the higher part of the town on the Perth road, and from its windows we can see the Firth, which here is a mile and a half broad, spanned by the bridge which has been built on the site of that which, oue Sunday night twelve years ago, crashed down with a train-load of passengers into the dark river. Messrs. Valentine's factory found its nucleus in an old-established portrait gallery which is still in full swing; so that it presents at first sight all the moderu refinements of a first-class gallery. It is not until we get behind the scenes—so to speak—up and down staircases, and in aud out of buildings at the back, that we realise that the main business is comprised in the production of those views of places of public resort which are seen in every stationer's shop in the kingdom, and which are purchased in such large numbers by tourists and globe trotters. In making these views, several out-door artists are constantly engaged all through the season, while a small army are at work here at head-quarters in developing, printing, and finishing the pictures for the market.

In the developing room we find every possible convenience, and note that the operators are by no means stiuted for light. Of course the light is of the non-actinic variety, but still there is plenty of it, so that the dark room assistants have not to work—as, unfortunately, so many do—in semi-obscurity. The printing is done mostly by girls, and the frames stand on sloping supports, which, being on wheels, can be run under a glass roof should rain come on. These girls are constantly going from one printing frame to another, and as soon as a print is completed, it is handed into an adjacent room, where the picture is quickly removed and the frame recharged. The albumenised paper is sensitised on the premises, no preservative being necessary, for the material is used up too quickly to need it. Pictures in carbon are also produced here by the thousand; these are mostly on opal. Other pictures are mounted behiud bevelled glass with ornamental borders, and we learn that this description of goods has a very large sale.

We were much struck with the excellent washing arrangements for silver prints adopted at these works. There are a number of rectangular cisterns about two feet in depth which are constantly fed with water, and emptied automatically by syphon attachmeut. Inside each cistern fit a number of wooden frames, stretched over the bottom of which is a network of gutta-percha strings. In the tray so formed the unwashed prints are placed, and wheu one is full it is placed in the empty cistern, and another one put above it. These trays of prints are thus disposed of until the cistern is full. When the water is turned on, it will readily be seen that under this system each print is actually floatiug, and at the same time is separated from its fellows above and below. We cannot possibly imagine a more perfect method by which the salts cau be washed out of the paper.

Where it is necessary to print in a sky to a view from a separate negative, great care is taken that a suitable cloud uegative is wedded with the particular landscape in hand. This matter is decided once and for all by the foreman in charge, and the landscape negative has attached to it its own number and the number of the sky negative with which it is to be associated. This busiuess of printing-in the skies is the care of a separate department. In another room of this busy factory we notice several cameras pointed skywards, for making lautern slides by reduction from larger negatives. The cameras are focussed ouce for all, so that the operators merely have to place negative after negative in position, and to expose them for a certain time. We need hardly say that the wet process is employed for this work.

Associated with the washing arrangements already detailed is a most complete system for saving the residues, and that this system is efficient may be judged from the circumstance that considerably more than £1,000 per annum is netted from this source alone. A consideration of this fact will also help us to gauge the extensive nature of Messrs. Valentine's operations. Mr. Valentine was kind enough himself to show us over his premises, and was evidently proud of them. We left him with the impression that he certainly had every reason to be so.

Photographic Club.—Wednesday, Nov. 18th, annual dinner; Nov. 25th, monthly lantern meeting.

The Lantern Society.—The next meeting (lantern evening for members and friends) will be held on November 23rd.

North London Photographic Society.—As it is hoped that the subject, "Bromide Printing," will be opened on November 17th by Mr. F. A. Bridge, a large attendance is expected in Wellington Hall, Islington, which has now been secured for the Society's meetings. Visitors are invited.

North Middlesex Photographic Society. — The annual exhibition of photographs will be held at Jubilee House, Hornsey Road, on Monday, December 14th. All exhibits must be delivered at Jubilee House, not later than 9 p.m., on Friday, December 4th. In order to facilitate the cataloguing of the pictures, each picture should have attached to it a label, upon which should be written the exhibitor's name, title of picture, and process. The labels will be supplied, upon application, by the hon. sec., Mr. J. M'Intosh, Jubilee House, Hornsey Road, from whom all information respecting the exhibition may be obtained.

## PHOTOGRAPHIC MISCELLANEA.

BY H. C. STANDAGE.

To prepare an *Alcoholic Solution of Gelatine*, soak gelatine in water until it swells up, then melt it, and finally add four to five times its quantity of absolute (*i.e.*, 95 per cent.) alcohol. The solution remains entirely clear, runs off like collodion, and dries far quicker than gelatine emulsion with 5 per cent. of alcohol, and it can be compounded with ammonia to basic reactions without injuring its firmness. According to one authority, a mixture of 1 part of dilute nitro-muriatic acid and 48 parts of rectified spirit of wine dissolves almost any quantity of heated gelatine. Poured over plates, the solution dries twice as quickly as plates treated with collodion. Ether and chloroform compounded with the above acid mixture also dissolves gelatine.

*An Alkaline Gelatine Developer* is made by dissolving $1\frac{1}{8}$ ounce of Nelson's amber gelatine in $2\frac{1}{4}$ fluid ounces of water over a water-bath; then add 1 fluid ounce of saturated solution of caustic soda, and boil until the solution is thinly fluid. Take 1 part of this solution to 8 parts of solution of pyrogallic acid in the proportion of 1 to 250. No bromide of potassium is required. Expose for a very short time, as over-exposure cannot be remedied.

*An Emulsion of Chloride of Silver and Gelatine* can be made thus: taking 1,000 parts of water, dissolve each of the following chemicals separately in a part thereof:—

| | |
|---|---|
| Gelatine ... ... ... ... ... | 50 parts |
| Nitrate of silver ... ... ... ... | 15 ,, |
| Chloride of gold ... ... ... ... | 5 ,, |
| Citric acid ... ... ... ... | 5 to 10 ,, |

When the several solutions are complete, add to the gelatine first the nitrate of silver, then the chloride of gold, and finally the citric acid. It is immaterial whether the emulsion reddens or not. It is now ready for use without washing. Coat glass plates with the emulsion, and print quite dark in the photo printing frame. The shades bronze quickly, and the intensity with a stable emulsion is good. In case the tones are a dirty yellow instead of black, the quantity of citric acid must be increased, which will always rectify this evil. The diapositives thus produced must be still further toned, which is best done in a bath of cyanide of gold. It is fixed with weak hyposulphite, then washed, tanned with alum, and finally washed again.

*To Prepare Claudet's Instantaneous Positive Paper.*—Float the paper on a solution of—

| | |
|---|---|
| Distilled water ... ... ... ... | 500 parts |
| Corrosive sublimate ... ... ... | 20 ,, |

Then dry it, and wash with a solution of—

| | |
|---|---|
| Nitrate of silver ... ... ... ... | 5 parts |
| Distilled water ... ... ... ... | 60 ,, |

The negative is exposed to the light over this prepared paper for from twelve seconds to one minute. The picture is developed by immersion in a bath of—

| | |
|---|---|
| Sulphate of iron ... ... ... ... | 1 part |
| Radicle vinegar ... ... ... ... | $1\frac{1}{2}$ ,, |
| Distilled water ... ... ... ... | 30 parts |

The positive picture is then washed, and fixed with sodium hyposulphite.

To make *Clear Caoutchouc Solutions*, tie 30 parts of caoutchouc, cut up in small pieces, in a small linen bag, fasten this to the cork of a bottle containing 1,000 parts of benzene.

*Damson's Tannin Plates.*—1. Recipe for the collodion cotton: Sulphuric acid of 1·840 specific gravity, 1,000 parts; nitric acid of 1·450 specific gravity, 360 parts; water, 240 parts; and cotton, 50 parts. 2. *Collodion*: Collodion cotton, $\frac{1}{3}$ part; ether of 0·725 specific gravity, 15 parts; alcohol of 0·810 specific gravity, 15 parts; sodium iodide, $\frac{1}{10}$ part; sodium bromide, $\frac{1}{12}$ part. 3. *Solution of Tannin*: 1 part of tannin dissolved in 30 parts of distilled water.

*Motta's Developer for Gelatine Plates.*—

| | |
|---|---|
| Saturated solution of potassium ferricyanide | 120 parts |
| Water ... ... ... ... ... | 120 ,, |
| Pyrogallic acid ... ... ... ... | 1 part |

Before using the developer, a few drops of ammonia are added to every 15 parts of it; the plate is then washed and dipped into the mixture.

*Davanne's Intensifier.*—In case a plate has been spoiled, it is, after exposure, only partly developed, and fixed with solution of cyanide of potassium; the plate, after having been freed from the last trace of the fixing salt by washing, is treated twice or several times with a solution of 2 grains of pyrogallic acid, 1 grain of citric acid, and 10 drops of radicle vinegar in 1 fluid ounce of distilled water, to which a few drops of a solution of silver of fifteen per cent. have been added. It is next treated with the following fluids:—

| | |
|---|---|
| 1.—Iodine ... ... ... ... ... | $5\frac{1}{2}$ grains |
| Iodide of potassium ... ... ... | 10 ,, |
| Distilled water ... ... ... ... | 1 fluid oz. |
| 2.—Sulphate of potassium ... ... ... | 1 drachm |
| Distilled water ... ... ... ... | 6 fluid ozs. |

Solution No. 1 is poured over the plate either in daylight or in the dark room, and allowed to remain upon it until the precipitate is perfectly yellow; it is then rinsed off with water, and solution No. 2 poured upon it, and this allowed to remain until the yellow colour is changed into a deep brown.

A developing solution of oxalate of iron, given by Vogel, is the following:—

| | |
|---|---|
| A.—Neutral oxalate of potassium ... ... | 9 ounces |
| Water ... ... ... ... ... | 1 quart |
| B.—Sulphate of iron ... ... ... ... | $3\frac{1}{3}$ ounces |
| Water ... ... ... ... ... | $10\frac{1}{2}$ fld. ozs. |
| Sulphuric acid ... ... ... | 2 to 3 drops |

A supply of both solutions should be kept on hand. For use, mix 3 volumes of A with 1 of B. Should the plates appear clouded, add to 4 fluid ounces of the mixed solution several drops of a solution of bromide of potassium containing 3 parts of bromide to 58 of water.

*A Good Toning Bath* is made of—

| | |
|---|---|
| Chloride of gold ... ... ... ... | 1 grain |
| Sodium acetate ... ... ... ... | 32 grains |
| Sodium carbonate ... ... ... | $4\frac{1}{2}$ ,, |
| Water ... ... ... ... ... | $8\frac{3}{4}$ fld. ozs. |

The following solution should be kept on hand:—

| | |
|---|---|
| Chloride of gold ... ... ... ... | 15 grains |
| Sodium acetate ... ... ... ... | 1 ounce |
| Water ... ... ... ... ... | $12\frac{3}{4}$ fld. ozs. |

Some of this being added from time to time to the toning bath as it becomes weaker by use. The copies, after toning, are several times washed with water containing some common salt, and finished in the following bath:—

| | |
|---|---|
| Water ... ... ... ... ... | $3\frac{1}{2}$ fld. ozs. |
| Sodium hyposulphite ... ... ... | $8\frac{3}{4}$ ounces |

The fixing bath is previously neutralised with sodium carbonate or ammonia.

*A Good Intensifying Bath for Gelatine Negatives* is made by mixing the following solution :—

| | | |
|---|---|---|
| A.—Corrosive sublimate | ... | 4 parts |
| Water | ... | 200 ,, |
| B.—Iodide of potassium | ... | 6 parts |
| Water | ... | 66 ,, |
| C.—Sodic acetate | ... | 8 parts |
| Water | ... | 66 ,, |

This intensifying bath has the advantage over other solutions that it can be used immediately after fixing the plates, and it gives the requisite intensity, even to the thinnest negatives, in a few minutes.

The following glycerine pyrogallic developer for bromide of silver dry plates is one extensively used :—

| | | |
|---|---|---|
| A.—Pyrogallic acid | ... | 1 part |
| Glycerine | ... | 1 ,, |
| Alcohol | ... | 6 parts |
| B.—Bromide of potassium | ... | 1 part |
| Ammonia of 0·880 specific gravity | ... | 8 parts |
| Glycerine | ... | 8 ,, |
| Water | ... | 50 ,, |

Both concentrated solutions keep for a long time. For use in developing, pour 30 parts of water into a saucer, add 1 part of solution A, and a like quantity of solution B, and submerge the emulsion plate in it. With a correct exposure the image appears in a few seconds, and the development is finished in a minute. Should the picture, in consequence of over-exposure, appear too suddenly, the developer must immediately be poured off, water poured into the saucer and some of the solution A added, which, with the residue of the remaining ammonia, will sufficiently develop the plate.

The two following printing recipes are well worthy of trial :—1. Preliminary preparations: Flow thoroughly cleansed plates with the following mixture: Potash water glass 1 part, and Pilsen beer 11 parts. When all the plates have been flowed, heat them somewhat and let them stand till the next morning, when they are again heated, washed, and stood aside to dry. 2. Chrome gelatine layer: Wash 25 parts of gelatine in several waters, and let them swell up in the last water; then dissolve 75 parts of chrome alum in 200 parts of distilled water, add the soaked gelatine, and heat the whole to 120° F. When the gelatine is entirely dissolved, add 25 parts each of bichromate of potassium and bichromate of ammonium. The plate, before flowing, is somewhat heated.

The following improvements in emulsions are suggested by an expert. The improvements consist in a combination of emulsion of bromide of silver and gelatine emulsion with pyroxyline. Four different methods may be employed. (1) Prepare a gelatine emulsion with bromide of silver (or iodide or chloride of silver), dry, and dissolve the emulsion in three to ten times its quantity of formic or acetic acid. This acidulated emulsion is used either by itself, or compounded with pyroxyline. (2) Dissolve pyroxyline by itself in one of the above acids with an addition of alcohol, and mix the solution with equal parts by volume of the above acidulated emulsion. (3) Prepare an ordinary collodion emulsion, precipitate it with water, dry the precipitate, and dissolve it in one of the acids mentioned, and add gelatine either direct or in solution. (4) Dissolve gelatine and pyroxyline, and add finely powdered bromide of silver (iodide or chloride of silver), or produce them in the emulsion. These new emulsions can be used either dry or wet.

*Sensitive Collodion for Rapid Methods* is made thus :—

| | | |
|---|---|---|
| Cotton | ... | 10 parts |
| Alcohol | ... | 400 ,, |
| Silver | ... | 500 ,, |
| Solution of iodide of ammonium... | ... | 45 ,, |
| Solution of cadmic iodide... | ... | 40 ,, |
| Solution of cadmic ammonio-bromide | ... | 35 ,, |

The latter is prepared by dissolving 6 parts of cadmic bromide and 4 parts of ammonium bromide in 100 parts of alcohol. Sufficient tincture of iodine is added to the collodion to give it an orange-red colour, and it is then allowed to stand three or four days. The silver bath must be neutral, but the collodion acid red.

*A Sensitive Collodion Emulsion* is made by immersing the plates coated with collodion emulsion from one to two minutes in a solution of—

| | | |
|---|---|---|
| Gelatine | ... | 1 part |
| Water | ... | 100 parts |

and then dry them. The plates treated thus are very sensitive, and, if correctly exposed, give a vigorous negative.

The following recipes for the gelatine process will be found very useful.

1.—*Edwards's Gelatine Developer.*

| | | |
|---|---|---|
| A.—Pyrogallic acid | ... | 30 parts |
| Glycerine ... | ... | 30 ,, |
| Alcohol | ... | 180 ,, |
| B.—Potassium bromide | ... | 4 parts |
| Ammonia ... | ... | 30 ,, |
| Glycerine ... | ... | 30 ,, |
| Water | ... | 180 ,, |

Take 10 parts each of A and B to 300 parts of water.

2.—*Dr. Eder's Oxalate of Iron Developer.*—A, saturated solution of sulphate of iron; B, saturated solution of neutral oxalate of potash; C, bromide of potassium 1 part, and water 10 parts. Mix 100 parts of A with 400 parts of B, and add 15 to 30 drops of C. Should the picture not appear in the course of five to ten minutes, dip it into the following stronger bath :—Dissolve 60 parts of neutral oxalate of potassium in 100 parts of barley water, and stir in this 15 parts of sulphate of iron. This bath, when cold, will keep in full bottles tightly closed.

3.—*Nelson's Developer.*

| | | |
|---|---|---|
| A.—Water | ... | 360 parts |
| Sulphate of iron ... | ... | 120 ,, |
| Alum | ... | 15 ,, |
| Sugar | ... | 30 ,, |
| B.—Water | ... | 720 parts |
| Neutral oxalate of potassium | ... | 240 ,, |

Mix 1 part of A with 2 of B.

4.—*Bedford's Developer.*

| | | |
|---|---|---|
| A.—Pyrogallic acid | ... | 4 parts |
| Nitric acid... | ... | ½ part |
| Water | ... | 600 parts |
| B.—Ammonia ... | ... | 8 parts |
| Bromide of ammonium or potassium | ... | 5 ,, |
| Water | ... | 600 ,, |

For a normal exposure, mix equal parts of A and B.

5.—*Abney's Intensifying Bath.*—Pour ¾ part of pyrogallic acid, 1 part of radicle vinegar, and 90 parts of water upon the plate, previously laid in alum for one hour, and add, after one minute, 1 part of solution of silver. Iron may be used in place of pyrogallic acid, viz. :—

| | | |
|---|---|---|
| Sulphate of iron | ... | 0·9 part |
| Citric acid ... | ... | 1·8 ,, |
| Water | ... | 90 parts |

## PHOTOGRAPHY ON THE PENNSYLVANIA RAILWAY.

We have already made reference to the great scheme now in progress for obtaining views on this wonderful highway. We now print some details of the enterprise, which we clip from an American paper.

Even in this advanced age, where the minimum responsibility resting on the shoulders of the art and picturesque-loving public amounts to simply pressing a "tiny button," and somebody else doing the rest, a description of the method by which the beautiful railroad views often seen are reproduced by the photographer may not, perhaps, be without some interest. The wonderful fad for photographing has certainly held a staple popularity with the fickle public, and steadily evoluted from a fashion, at one time only enjoyed by the privileged few who could afford the luxury, into a part of almost every boy, girl, and grown person's life and education.

It is, perhaps, only a question of a few years when photography will occupy in the curriculum of school education an important place with free-hand drawing and geography, for few courses are better drills and trainers for the eye and mind, at the same time creating interest. The howl and tirade against the snap-shot fiends, when they wandered about *incognito*, seeking what they might take, with that suspicious something under their coats, or the cautious handling of innocent-looking paper bundles, has about ceased, and they come forth openly now, sauntering along the principal promenades, shooting at random the unconcerned multitude. It is only another illustration of the old saying, "getting used to everything saves taxes and death," for certainly no people fall so quickly and harmoniously into the line of endurance when confronted by the inevitable as Americans.

It was during the centennial year that the first germs of the photographic fever took fast hold, and rose, stage by stage, until, in our day, as the enthusiastic physician might say, it has reached the full flush and progression of healthy disease. One particular series of pictures at the Centennial Exposition, to return to the theme of this article, was that exhibited by the Pennsylvania Railroad, and which conveyed and revealed to foreigners, much better than guide book or conversation possibly could, the territory of wealth and beauty, the iron bands of the main line and branches, extending in their ramifications, and intersecting from the Atlantic ocean to the far Mississippi, and from the great inland northern lakes to the crowning line of the Virginias.

They were the highest examples then known in railway photography, and often crowds were seen standing before the panoramic views in particular with open eye and mouth wonderment and speculation, advancing every possible solution as to the production of such a large negative, which, had they but known, meant three in one delicately fitted together. Just as marvellous and beautiful as those pictures appeared in that day, fifteen years ago, will a series now about finished, covering all the old and many new views, seem to those who will have an opportunity of viewing them in a few weeks at an exhibition in some place to be selected in the city, or at the World's Fair in 1893.

Photography has advanced with rapid strides, and with its progress, keeping an even pace by its side, is public appreciation and knowledge of its growth; so that nothing short of the result accomplished by a mammoth landscape camera, used in these last photographs, would have caused the public pulse to beat the least faster. It is perfectly safe to say that the amateur, and even the professional, will have much to learn from the results of this photographic expedition, fitted out some months ago by the Pennsylvania Railroad with as much care and almost the expense of an Arctic one, and which is still in the field of exploration, daily sending in remarkable illustrations of choice picture finds, and showing that which the regular traveller flying by on a fast express cannot see—some daring feats of engineering in bridge building, skilful cuts, road construction, and road-beds, with their even, solid stone ballast looking like a floor, while views of surpassing artistic beauty make the entranced looker-on want to capture the entire collection and create a private gallery of his own.

The Company fitted out a car for this photographic service, modelling and furnishing its interior from designs and suggestions of the practical operator whose life for five months of the year would be spent within, and from whose modern dark room some of the finest railroad views of the age would be developed within a few hours after capture.

To all appearance from the outside, car 1382, save an elevated platform on the top, and the name, "Photographic Car, Pennsylvania Railroad," is identical with the regulation coach. This elevation is half a foot high, and covers an area of some 6 feet square. It is especially constructed for supporting the instruments and cameras where a commanding view is desired at points where a foot or tripod-hold could not be found on the mountain's steep side. In length the car interior is 46 feet, in width 8 feet, and from floor to ceiling in height about 10 feet. It is fitted with steam-heating apparatus, which is not a bit amiss in the mountains, and air-brake appliances, with a precautionary measure taken, by having a hand-brake operated only from the interior of the car, whereby the deep-laid design of tramp and small boy is often thwarted, and a possible wreck prevented, when the car stands alone on a heavy grade.

The forward part of the car for some 20 feet is furnished and decorated with the exclusive end in view of promoting the comfortable living of the operator and his assistant, furnished as it is with comfortable parlour-car chairs and a commodious desk, well lighted. The walls are adorned with road schedules and maps, framed photographs and rare prints, ranging from the many views along the line of the railroad, to points in South America and Europe, and a rare series taken during the Transit of Venus Government Expedition of the Swatara in 1874 and 1875, for which Mr. William H. Rau was also the official photographer. Two modern folding plush sofa berths extend their tempting softness to the men after a hard day's mental and physical work, and add a decidedly finished appearance when made up into sofa seats during the day. In case of necessity, should a stop be compelled over night at a way station, a supply of cots can be brought into requisition for use of conductor, engineer, and crew, but this is not likely to happen any more than a call for the use of the cooking stove and utensils, for the car is a "personally conducted" one, and, running on the schedule of a special train, manages to stop over-night where the hotels have a table record.

The dark room is in the centre of the car, running for a distance of 12 feet in length and 5 feet in width, equipped with ruby and orange windows, negative racks, and all developing facilities, together with a tank holding a 300-gallon water supply. The system of perfect ventilation without allowing light to penetrate the dark walls and ceiling of this jet black apartment is accomplished by a 4-inch opening where the side wall meets the floor, and built out from this is a false side running to the roof and angled to an opening in the car, thus allowing a free passage of air, but not a ray of light. In this room may be seen the most complete batteries of lenses in active use in this country, starting with the tiny kodak, and advancing along the set to the orthochromatic, rendering colour values, and the case holding a valuable interchanging lens making nine different sizes or combinations of the one view.

All these are eclipsed, however, by the immense panoramic landscape camera, which takes a picture on the one negative 4 feet long and 1½ feet wide, which embraces an angle of 165°, and obviates the distortion and uncertainty so often encountered in the case of photographs taken by the sectional method. It is claimed to be the only camera of its kind in the world, designed somewhat on the same model as the one at the Paris Exposition, but taking a much larger and more accurate picture, and in many ways far in advance of this French camera, which was the wonderment and admiration of the representative world assembled at the Exposition. Far back in 1855 a man named Holterman, at Sydney, New South Wales, erected, at enormous expense, a camera, known as the great revolving lens, which is recorded as taking but one negative on a glass plate 3 feet by 4 feet, and then, with this world record of one picture, it was never used again. Probably, had the flexible plate been known and in use at that time, Holterman's results may have been household words to-day; but, mainly due to their non-existence and the cumbersome weight and immovability of the camera proper, it met with the fate of a rich mine with the ore in view, but machine facilities not invented for working it.

Every precaution is taken for the careful transport of the very valuable plates, and the rear portion of the car is devoted to the trunks built and padded for carrying the immense store of 300 18 by 22 and 30 panoramas.

## CO-OPERATIVE EXCURSIONS TO THE CHICAGO EXHIBITION.

Those of our readers who are longing to carry their cameras farther afield than the confines of their own country, may be interested in knowing that the committee of the Polytechnic Institution, Regent Street, London, are adding, to their already unique series of Continental tours, trips to the Chicago Exhibition in 1893, specially intended for those whose means will not permit them to visit the New World under ordinary circumstances. The authorities have already entered into a contract with the Inman Steamship Company, by which means those who participate in these excursions will travel by the fastest vessels afloat; parties will leave Liverpool weekly during the months of June, July, and early part of August, by the magnificent steamers, *City of Paris*, *City of New York*, *City of Chicago*, *City of Berlin*, and, travelling by these fast vessels, the whole tour will be able to be accomplished within one month. The proposed arrangements are, that two days shall be spent in New York; a visit to Philadelphia and Washington will also be made, proceeding from thence to Chicago, where each party will be allocated for six or seven days; the return journey will be continued through Buffalo to Niagara, visiting the world-famous falls, the journey back to New York being taken down the Hudson river, the views along which comprise some of the grandest scenery imaginable. The committee hope that the whole round excursion, including accommodation for the period, will not exceed twenty-five guineas, which is only slightly above the fare for the ocean journey alone during the season by the above steamers. Arrangements have been made thus early to enable those who desire to take part to put by so much per week towards the required amount; also to enable many who have, as a rule, but a fortnight's holiday, to forego their holiday next year, and get a special holiday of one month in 1893.

Already over half the places have been applied for, and any of our readers who are desirous of taking part in these trips should send in their application to the Polytechnic without delay.

Mr. Douglas Hogg (the son of Mr. Quintin Hogg, the president of the Polytechnic), and Mr. Mitchell, the secretary of the Polytechnic, leave England shortly to complete the Trans-Atlantic arrangements.

Last year special series of excursions were run to Norway, Madeira, the Ardennes, Switzerland, &c., and during the last three years over 9,000 persons have participated in the excursion arrangements of this well known Institution.

## PHOTOGRAPHY IN THE TROPICS.

BY PROF. S. W. BURNHAM.

A few suggestions may not be out of place bearing upon the practical side of making photographic negatives in the damp and hot regions of the West Indies and the northern part of South America. The same conditions seem to prevail for at least twenty or thirty degrees of latitude. Heat and dampness have been considered to be conditions most dangerous to the keeping of dry plates, and manufacturers frequently caution purchasers to keep the plates in a dry and cool place. One who has not visited such a place cannot understand the excessive dampness which pervades everything, and the extreme discomfort produced by temperature even lower than 90°. Clothes and shoes mould over-night in the sleeping-room, and nothing ever seems to get dry, except the new-comer, whose thirst is perpetual. If these conditions had been fully considered before leaving home, the boxes of plates would have been packed in such a way as to exclude them from the outside air; but this was not done, and until the plates had been repeatedly tested, it was feared that they might have received some injury. As soon as possible after arriving at Cayenne, a dark room was made for developing, and a large number of plates, which had been exposed about Cayenne, and before reaching there, were developed. There was no evidence of any kind that the plates had suffered any deterioration. The negatives made and developed at this time, though substantially all instantaneous exposures, were both creditable to the excellence of the Seed plates, and gratifying to the photographer. Several boxes of unexposed plates were brought back, and these, when used, appeared to be in their original condition. Some 8 by 10 plates exposed in Trinidad, on the return trip were placed in a box containing two unexposed plates. When we journeyed to Mount Hamilton, the two unexposed plates had been forgotten, and one of them was placed in the developer. No image appearing, the tray was placed on the rocker and the development was kept up for at least an hour, and perhaps for an hour and a-half. Then the true state of the case was suspected, and the plate was rinsed and put away to dry. Some days later it was put in the camera and exposed, and as fine a negative made of the large telescope as any one would wish to have. This certainly could not have happened with either a poor plate or a damaged one.

With the chemicals the change was apparent. The sulphite of soda, though taken in the original bottles as sealed by the manufacturer, had absorbed so much moisture that that which was originally a fine powder had become a solid mass, which could not be dug out of the bottle with a sharp steel implement, and could only be broken up by first breaking the bottle. The carbonate of soda fared much the same way, notwithstanding the packages were in their original sealed condition; and the hyposulphite of soda continued to absorb so much moisture that there were always in the vessel in which it was kept several ounces of a saturated solution. Of course in such a state the usual quantities of carbonate and sulphite of soda, weighed for making up developer, became quite uncertain from the addition of an unknown quantity of water; and the best way of developing with the chemicals in this condition was thoroughly learned by making a great many exposures in and around Cayenne, and experimenting in the development until the best proportions were found. In going to a climate like this, all chemicals which have a tendency to absorb moisture should be carefully sealed with wax, or in some other way made air-tight, and particularly hyposulphite of soda, which should be hermetically sealed in a substantial package; otherwise this chemical will become saturated, and the excess of water wil escape, if possible, and perhaps damage other things. Of course plates, and chemicals which might injure them, should never be packed in the same box. It is always better to take the necessary developing materials and develop the plates as soon after exposure as possible. Many things will spoil an undeveloped plate which would not injure a negative. This is with reference to the ordinary landscape views.

For special exposure and photographic work of particular value, it goes without saying that the plates should in all cases be developed on the spot. There is nothing to lose by this course, and everything to gain. To say the least, it is dangerous not to do it; and no one would pretend to say, after developing a flat and weak negative, which had been transported a long distance after exposure, that the result would not have been entirely satisfactory if carefully developed at the first.—*American Journal of Photography.*

## SOCIETY OF ARTS.

### Sessional Arrangements.

The first meeting of the one hundred and thirty-eighth session of the Society will be held on Wednesday, the 18th November, when the opening address will be delivered by the Attorney-General, M.P., Chairman of the Council. Previous to Christmas there will be four ordinary meetings in addition to the opening meeting. The following arrangements have been made:—Prof. Silvanus P. Thompson, F.R.S., "Measurement of Lenses"; Mr. G. H. Robertson, "Secondary Batteries"; Mr. James Dredge, "The World's Fair at Chicago, 1893"; Prof. Vivian B. Lewes, "Spontaneous Ignition of Coal, and its Prevention"; Mr. E. Price Edwards, "Burning Oils for Lighthouses and Lightships"; Mr. T. Pridgin Teale, "Dust, and how to shut it out"; General Pitt Rivers, "Typological Museums"; Mr. T. Anderson, "Iceland"; Mr. J. W. Tonks, "Artistic Treatment of Jewellery and Personal Ornament"; Sir William Wedderburn, Bart., "Agricultural Banks for India."

*Foreign and Colonial Section.*—Meetings on Tuesday afternoons at 4.30—January 19th, February 16th, March 15th, April 5th and 26th, May 24th.

*Indian Section.*—Meetings on Thursday afternoons at 4.30—January 21st, February 11th, March 3rd and 24th, April 28th, May 19th.

*Applied Art Section.*—Meetings on Tuesday evenings at 8—January 26th, February 23rd, March 8th and 29th, April 12th, May 17th.

*Cantor Lectures.*—Monday evenings at 8:—Mr. A. P. Laurie, "The Pigments and Vehicles of the Old Masters" (three lectures), November 30th, December 7th and 14th; Prof. George Forbes, F.R.S., "Developments of Electrical Distribution" (four lectures), January 25th, February 1st, 8th, and 15th; Prof. William Robinson, Mem.Inst.M.E., "The Uses of Petroleum in Prime Movers" (four lectures), February 29th, March 7th, 14th, and 21st; Mr. Bennett H. Brough, "Mine Surveying" (three lectures), March 28th, April 4th and 11th; Dr. Percy Frankland, F.C.S., "Recent Contributions to the Chemistry and Bacteriology of the Fermentation Industries" (four lectures), May 2nd, 9th, 16th, and 23rd.

*Howard Lectures.*—A special course of six, under the Howard Bequest, will be delivered on the following Friday evenings at 8:—Prof. W. Cawthorne Unwin, F.R.S., "The Development and Transmission of Power from Central Stations," February 5th, 12th, 19th, and 26th, March 4th and 11th.

*Juvenile Lectures.*—Two lectures, suitable for a juvenile audience, will be delivered on Wednesday evenings, January 6th and 13th, at 7 p.m.

*Chicago Exhibition,* 1893.—The Council of the Society have been appointed a Royal Commission for the Chicago Exhibition, 1893. All applications for space in the British Section, and all inquiries for information about the Exhibition, should be addressed to the Secretary of the Royal Commission, Society of Arts, Adelphi, W.C.

London and Provincial Photographic Association.—Nov. 19th, competition lantern slides; Nov. 26th, "Protection of the Negative Film during Printing"; Dec. 3rd, "The Exaggerated Perspective of Wide-Angle Lenses." Visitors invited.

South London Photographic Society.—The third annual exhibition of photographs by members will be held at Hanover Hall, Hanover Park, Rye Lane, Peckham, on Monday and Tuesday, November 16th and 17th. Transparencies will be shown by aid of the oxy-hydrogen light. Open on Monday from 7 till 10; on Tuesday 3 till 10. A selection of instrumental music will be given during each evening.

Detected by the Camera. — Science is pressed into the detective service more and more. At one time it is chemical analysis, again it is the phonograph, and anon it is photography. A striking illustration of the latter application has occurred in Paris. Two Parisian dressmakers, on entering their rooms the other night, found that their door had been broken open, and that 2,000 dols. in bank notes and a box containing 4,000 dols. in notes and jewellery were missing. The arrest of the thieves—three men and two women—and the recovery of the greater part of the property appear to have been due to a "detective camera." An amateur photographer lives opposite the dressmakers. He, looking out of his window one afternoon, observed two young women on the balcony over the way. With his camera he took an instantaneous photograph of the two strangers and closed the window. Some days later, on hearing of the robbery, he sent a print of his photograph to the police, who recognised the portrait as that of two women who frequently loitered in front of the Central Market. They were arrested, and gave the names of their accomplices. Whether the motive of the young man who took the photograph was one of curiosity, or whether he had a suspicion that the young ladies were thieves, is not stated, but in any case the result was one to be thankful for.—*Baltimore Sun.*

## Notes.

Old beliefs and superstitions are, like cats, hard to kill, and if it be true that the latter are so tenacious of existence because they possess nine lives, the former must surely have nine hundred chances of escape from oblivion. As a case in point, let us instance the belief that a change of moon—which, in reality, amounts only to a change of aspect as seen from the earth—will lead to a change in the weather. This belief was knocked on the head long ago by certain scientists who made records for many years, and who showed conclusively that there was no solid foundation for it.

Happily, there are not many photographic misconceptions of this kind which need overthrowing, but there is one which turns up at intervals with wonderful regularity. It comprises the belief that, when a man is struck by lightning, a natural photograph of the tree under which he was standing at the time is impressed upon some part of his body. The most recent incident of this kind was lately reported in an American paper in the following words: — "*Photographed by Lightning.*—When Charles Tunnison and Ed. Caldwell were killed by a stroke of lightning at the ball game at Warren, O., they were sitting beneath a tree. On the chest of Tunnison, the white man, the undertaker found photographed, apparently by the flash upon the skin, the image of a branch of a tree and its twigs. The strange freak is the talk of the town."

It will be observed that the picture is seen upon the white man's skin, and not upon that of the nigger, and here we have at once a clue to the origin of the so-called photograph. The tremendous energy of the electric flash often so affects the capillary vessels in the human subject that extravasation of the blood is brought about. In other words, the blood is urged out of its usual channels and makes a kind of foliated marking beneath the skin. In appearance the picture is more like that of a delicate fern leaf than of a tree, but it is quite sufficient to give origin to the common belief that it is a representation of the veritable tree under which the unfortunate bearer of the design stood when he met his death. The story is occasionally varied so as to include the surrounding landscape as well, but this addendum is, of course, the natural result of exaggeration as the wonderful occurrence is repeated from one person to another.

It is now a matter of history that, during the siege of Paris, communications were maintained by means of pigeons, who carried photo-micrographic despatches. This system laboured under the disadvantage that the birds might be shot in transit, so another aerial messenger is being educated for the work. A distinguished bee-master of the Gironde has found that the busy honey-gatherers under his control are most sagacious in finding their way back to the hive from long distances, and he proposes to attach to the thorax of the insect, by means of fish glue, a tiny despatch which will in no way impede its movements. If such a plan be really practicable, there will, of course, be no difficulty in the photographic part of the scheme. A photo-micrograph on thin celluloid would, perhaps, be the most convenient form for the missive to take.

The Paris police have hit upon a plan of preventing costermongers transferring their licenses from one to another, and so evading the fee. They now compel every coster to be photographed, and present him with a pocket-book for keeping the photograph in, which has to be produced when evidence of identification is wanted. This is a new amplification of an old idea.

The bequest of an imitator of those proprietors of infants' food who offer prizes for the photograph of the finest baby brought up on a particular form of diet, is exercising the minds of the Parisian art critics. They greatly fear an epidemic of the baby and "Kiss Mammy" fever, which is so characteristic of English art. The bequest consists of a sum of money, left by a picture-collector named M. Piot to the Académie des Beaux Arts, to be awarded to the sculptor or painter who shall produce the best representation of a nude child between the ages of eight and fifteen months. As one competition is open to foreigners as well as native artists, English painters should have a good chance, judging, at all events, from their practice in babydom.

The ways of the Post Office are mysterious. If anything be pasted on a postcard, the officials consider it "contrary to regulations," and refuse to deliver the post-card in question, though the additional weight may be infinitesimal, and certainly not nearly equal to half the weight of a half-ounce letter, which is taken for a penny. A short time ago a candidate for Parliamentary honours conceived the idea of sending to each elector a card in the shape and form of a reply postcard, giving his photograph and address, the outside being reserved in due form for the name. The Post Office authorities objected to take the cards at the usual rate, whereupon the candidate sent them over to Paris, whence they were sent and delivered in England for a five centime stamp. As the distribution of photographs during election contests is becoming very popular, the Post Office, perhaps, may think fit to alter its "regulations," as, according to the present rule, it is throwing away what might be a very respectable addition to its income.

Prince Albert Victor inherits the taste for collecting photographs which Her Majesty displays in so marked a degree. In the Prince's rooms at Sandringham he has a very large number of portraits, and another five hundred or so at Marlborough House. When the fire broke out at Sandringham, his chief anxiety was to know whether his photographs had been burnt, and, no doubt, was much relieved when intelligence of their safety reached him.

The Queen's series of albums must contain many thousands of photographs of notabilities, from the portraits of kings, queens, emperors, and empresses, downwards. Such a collection as time goes on should prove invaluable, and, if reproduction of all in some permanent process be impossible, a selection might be made which would be well worth preserving for the information of future generations. As Her Majesty has been collecting since the early days of the Daguerreotype, her store must be thoroughly representative of the progress of photography. Unfortunately, time is no respecter of photographs, Royal or otherwise, and many of the most interesting must show signs of the sere and yellow leaf. The collection would justify the appointment of a Royal photographer, one of whose duties it would be to watch the collection, and copy those which are considered worthy of preservation before they fade.

## THE PALL MALL EXHIBITION.

We have now to give some account of the pictures which are hung upon the screens, and we have to make the same complaint to which others have called attention in former years, with regard to the bad light in which some of these pictures are hung. This applies more especially to those pictures which are placed upon the square screen which surrounds the lantern platform at the end of the room. We may say, indeed, that on only one side are the pictures efficiently illuminated, the other three sides being in semi-darkness; hence it is almost impossible to see their beauties, and to criticise them fairly. The late season of the year in which the Exhibition is held of course aggravates the fault, and on some of the dull afternoons with which we have been lately favoured, it has been next to impossible to see whether the pictures on the shady sides of the screen are good, bad, or indifferent.

Mr. F. Thurston exhibits two pictures in carbon, Nos. 544 and 545; these are both similar subjects to those which Mr. Thurston has previously exhibited, one of which, we remember, took a medal at a former exhibition. They are views of those picturesque roads which are so common in this country of ours; roads over which the elm trees arch, and make such picturesque photographs. One of these is called "Changing Pastures," and is relieved by the figure of a shepherd and a flock of sheep; while the other one is a similar subject, over which the mantle of winter has fallen, both road and trees being covered with snow. A more attractive picture from the same hand, and of quite a different nature, is a bromide print (No. 567), entitled "The Bridesmaids." Here we have a file of half-a-dozen demure little maidens in the 18th century costume, bearing baskets of flowers. This is quite a pretty little gem, upon which the photographer may well be congratulated.

In No. 546 the Woodbury Company exhibit a variety of examples of the new adaptation of Woodburytype printing, which has recently become familiar in illustrations to various books under the title of "Woodbury-gravure." These prints show at once to what perfection the Woodbury process has attained, and they differ from the gelatine pictures originally produced by this method of photography in that the pictures are printed direct upon the mounts, so that what was once a serious obstacle to the employment of Woodbury pictures—we mean the careful mounting required—has now altogether disappeared. This simplification of a beautiful process is sure to extend greatly the use of this system for book illustration.

Nos. 547 and 548 are two pictures by Mr. J. E. Dumont entitled respectively, "The First Lesson," and "The Dice-Players." The composition of both pictures is clever, and the subjects have something new about them.

Messrs. Perkins and Sons exhibit in frame No. 549 a number of admirable views of the streets of London, taken, of course, instantaneously.

Mr. A. Debenham's four studies of yachts under way (No. 550) merit notice because of their breezy nature, and the representation of motion which they have.

Mr. H. B. Lemère has always been to the fore with views of interiors, and he seems to have devoted himself more especially to this by no means easy and very effective kind of photographic pictures. In the frame which he sends to the Exhibition are several excellent examples of his work, the most noteworthy, perhaps, being the view of a theatre at Newcastle, a view taken from the stage, and admirably lighted.

Mr. J. Collier, of Birmingham, sends a couple of beautiful panel portraits (Nos. 559 and 560), as well as a frame of cabinets, which cannot but add to his reputation.

In No. 562 Mr. Stern takes us far away in his clever pictures of Eastern types of humanity. Of these we may mention, for their excellence, a Tunisian water-barrow, a Tunisian Jewess (fatted up for the marriage market, as is customary among these ladies), a Bisharee Arab, a Trapist monk, a negro musician (a real one, not one of the counterfeit kind that we see at home), and, lastly, a Greek peasant.

Mr. Marsh exhibits on this screen, in Nos. 563 and 569, two of his very fine seascapes, both printed in carbon.

Crossing now to the screens at the other end of the room, we must first notice another frame of pictures by Mr. Stern (No. 572), in which are exhibited photographs of Japanese treasures, consisting of ivories, bronzes, china, &c., all treated in that quaint and artistic manner which is common to Japanese work. Messrs. Window and Grove show a number of clever cabinet portraits on this same screen, while Mr. H. Baker exhibits six fine portraits of sepia tone, printed in carbon. It is a pity that here, again, we have a paucity of light, by which the pictures suffer considerably. The works on the other side of this screen do not suffer from the same disadvantage, so that we are able to make a more minute examination of the fine portrait of our contributor, Mr. H. P. Robinson, by his talented son. There are also here some very good examples of pictures produced on Obernetter paper toned with platinum; these are excellent examples of photography by Mr. J. K. Taylor.

Mr. Brownrigge, the veteran photographer, sends a capital view of Watcombe Bay, in the Isle of Wight, famous for its cliffs. The view is an admirable one.

Mr. F. L. Colls has deservedly won a medal for six copper-plate photo-etchings. These will be familar to many, because they have appeared in "Sun Artists." The most noteworthy, perhaps, are the "Water Rats," by Mr. Sutcliffe, and the beautiful study of "Sand-dunes," by Mr. Wilkinson. Messrs. J. Russell and Sons have some more of their "at home" portraits on this screen, and these naturally attract attention, as they are portraits of Royal personages.

Some frames of pictures of very great scientific interest are shown here by Dr. Jeresrich; these consist of photo-micrographs of blood, indicating, by the difference in number and size of the corpuscles, the differences between that of the human subject, the pig, and the monkey. There are also shown similar pictures of hair. The possibility of obtaining photographs of such subjects will show how valuable photography is likely to be in medical jurisprudence. We need no longer take the word of a medical man for certain appearances, but the pictures can be handed to the jury, who will be able to form their own conclusions. Of the same nature are some photo-spectrographs, showing the difference between arterial and venus blood, before and after treatment with reducing agents. The same talented experimenter also shows a number of illustrations of detection of forgery by photography. For instance, we see first the photograph of a document taken by ordinary means, then in another picture we see the same treated by Dr. Jeresrich's method, showing how the writing has actually been altered. In one example figures have been falsified, and the means by which this has been done is plainly shown by the different tone of the ink which the forger has used upon the material, and in another case how the original signature has been obliterated and written over by a new one.

Turning to the apparatus section of the Exhibition, we must first notice Mr. Bruce's aerial graphoscope. This consists of a flat lath of wood about four feet long, and two inches broad, and painted white, upon which the image, projected by a lantern, can be thrown, while the lath, by attached gearing, is rapidly rotated in a dark room. The picture thrown upon the moving lath appears as if suspended in mid-air. The apparatus does not pretend to take the place of the ordinary lantern screen or sheet, but is a most admirable device—perhaps the most perfect one which has yet been made—for showing the phenomena connected with persistence of vision.

We need hardly say that the collection of lantern slides contributed to the Exhibition is a large one. Messrs. G. West and Son have secured a medal for a miscellaneous set, the chief feature of which is a collection of pictures entitled, "Sons of Neptune." Here we have pictures of sailors on board ship—at work and at play—and these, coming immediately after the successful Naval Exhibition, are sure to excite great interest.

Messrs. Oeffelein & Co. exhibit a frame of burnt-in photographs, and china vessels decorated with similar pictures by the new system, which has already been noticed in our columns.

Among the other contributors of lantern slides are Miss C. W. Barnes—whose name is better known on the other side of the Atlantic than here—who sends a number of scenes from "Etaine," &c.; Mr. A. K. Dresser, who contributes a number of instantaneous scenes taken with his cleverly-designed hand-camera; some splendid views of British scenery by G. W. Wilson and Co.; some interesting views taken at the Cape Peninsular by Mr. C. Ray Woods, the astronomer; and some beautiful transparencies by Mr. Birt Acres. These last consist of lantern slides illustrating wave studies, cloudland, sheep, &c., besides some decorative transparencies of larger size, which are full of beauty. We must not omit to mention, too, some very beautiful flower studies by Mr. J. Carpenter, included in this section of the Exhibition.

The apparatus proper does not comprise anything of a very novel character. The Birmingham Photographic Company are large exhibitors, and their dishes, plate-lifters, lamps, washers, draining racks, rockers, &c., are well worthy of attention by those who try to get the most convenient articles for their every-day work.

The little boxful of type for printing the title of pictures on negatives, called "Nameit," shown by Mr. A. Gray, is a convenient contrivance which is sure to come into common use.

Messrs. W. Griffiths and Co. also show a number of different articles, including hand-cameras of all kinds and prices. They also show their well-known lantern slide making camera in different sizes, and a clever fixed enlargement camera.

Messrs. Harris and Co. exhibit their "Cytox" hand-camera, with a wonderfully clever and simple changing apparatus, by which the last plate exposed is, by the touch of a button, relegated to a well in the base of the instrument.

Specimens of thio-carbamide reversal pictures are exhibited by Col. Waterhouse.

The London Stereoscopic Company show four different types of camera, the most noteworthy of which is the twin artist's hand-camera, the word "twin" referring, not to the operator, but to the fact that the camera employs two lenses, so that whilst one is actually employed in taking the picture, the other—of similar focus—forms the image, which can be watched at the same moment.

Another medal in the apparatus section has been awarded to the Paget Prize Plate Company for a very ingenious glass cutting machine. This can be worked by the hand or by power, and will cut dry plates at a great speed. The only fault that we should be inclined to find with the clever machine is, that it is apparently designed for cutting plates on the glass instead of the film side. It is generally agreed, amongst those who have had much to do with dry plate manufacture, that they should be cut through the film, for the reason that the gelatine surface is not apt to be striped when the glasses are finally divided, and there is less liability to fragments of glass getting detached, and doing mischief during the packing of the plates.

Messrs. Ross and Co. show a case of their well-known lenses, as do also Messrs. J. Swift and Sons.

We were interested to observe that Mr. J. Gaedicke exhibits a number of negatives taken by his new rapid collodion dry plates. We are presently expecting that plates of this character will be put on the English market, and there is naturally a good deal of interest aroused respecting them. It remains to be seen whether the revival of this old method of producing dry plates, with the property of rapidity added to their well-known advantages, will affect in any way the popularity of gelatine plates.

Photographic Veneering of Furniture. — In the application of photographs to cabinet-ware, Mr. J. K. France has patented the use of a substance that he calls "pyralin, or some other compound of pyroxyline." The print is fixed by means of alchohol. It is applied to the wood to be decorated, and the surface polished by pressure on a metallic plate, or by other means. This invention has for principal object the veneering of furniture.

Sheet Glass from Molten Metal. — The present practice in making metal sheets is to cast ingots or slabs, and then reduce these by repeated rollings and re-heating. Attempts have been previously made to produce sheets directly from the molten metal by pouring the metal: (1) between two revolving rollers; or (2) between a revolving wheel and the surface of an enclosed fixed semi-circular segment. By these means none but very thin plates could be satisfactorily produced. In a new invention the machinery consists of a large receiving roller of 5 feet diameter, more or less, and of a length equal to that of the plate to be produced. With this are combined small forming rollers arranged in succession part of the way round the periphery of the large roller, and revolving at the same rate as the large roller. The rollers can be cooled by a current of water circulating through them. The molten metal flows on to the surface of the large roller, and is prevented from escaping sidewise by flanges with which the large roller is provided. These flanges embrace the small rollers, and are of a depth greater than that of the thickest plate which it is proposed to roll. The distance between the large roller and the small rollers can be adjusted according to the desired thickness of the plate. When dealing with metals of a high melting point, such as steel, the first small roller is made of a refractory material, and is heated from the inside by the flame of a blow-pipe. The rollers are coated with plumbago or other material to prevent adhesion to the molten metal. In case of metals of a high melting point, the machine is fed direct from a furnace divided into two compartments by a wall, or bridge, in which is a stopper, which can be operated so as to regulate the flow of metal. When applied to forming sheets of glass, the rollers should be warmed by a blow-pipe flame, and the sheet of glass stretched and annealed as it leaves the last roller.—*Oil, Paint, and Drug Reporter.*

## PHOTOGRAPH FRAMES.

BY JAMES MEW.

There is a game, with which certain chalked diagrams on our pavements have made most people more or less familiar, endeared to children by the name of "Hop-Scotch." This game is not, as some rash etymologist might in his haste affirm, originally, or in any way, connected with Scotland. The latter portion of the word is, perhaps, a variant of *skotch*, related to Lady Macbeth's "We've *scotched* the snake," and refers to those geometrical figures upon which the sport of hop-scotch depends for its existence. In this game a stone is driven by the foot of a hopping player, under certain rules and regulations and by-laws, from one compartment to another of a design drawn on the ground, until the final compartment is attained, which feat awards the laurel to the player's brow. This last compartment—the chamber, so to speak, of successful endeavour, the final goal of ardent enterprise, the ultimate haven of emulative aspiration, the *summum bonum* of supreme content —has been thought worthy of a particular name, which is usually inscribed in its midst. It is a homely word, not high sounding, nor sesquipedalian, nor of foreign growth, this word representing hope's fruition. It is *Pots*. This *Pots*— sometimes called *London*—it is the object of the ambition of every artist, in his own particular business, to attain. In a humble way, the manufacturer of photograph frames is continually striving to reach some device which will attract and please the public taste ; he is, in other words, hoping, if not hopping, to reach the final goal of *Pots*. Nor is his course direct ; he proceeds—as is the custom in the game of hop-scotch—after a zig-zag fashion. Now he will tarry for a time in the room of sweet simplicity, and then suddenly pass over into that of florid adornment. Now his margins will be thread-like in their thinness, and then they will assume such ample proportions that the photograph appears in them like a few lines of the Talmud surrounded by its folio page of commentary—a tiny pool of text bordered by a mighty meadow of notes on every side. Now his frames will simulate gold or silver, and then ebony or ivory. Now a frame of molten brass will please him, and then a frame of white enamelled wood.

The primary purpose of a frame is, it may be assumed, to protect the work of art which it encloses. To preserve the result of all his labour which he takes—under the sun —is the natural desire of photographic man. One of the saddest things about the profession of the screever—the artist on stone who ornaments our highways with crayon drawings of mountain scenes and mackerel and sunset of no inconsiderable skill—is that his works cannot last. It is for him, indeed, in this climate, "a hard struggle with the rain"—a pathetic appeal to charity sometimes written by him round his pictures. But even should the rain-water spare his work, its life, nevertheless, at the most is that of a day. As a dying man is forced to leave all the riches he has gathered together when his soul is required of him, so, with the coming shadows of evening, must the sorrowing screever also depart, and allow the work on which he has bestowed such scrupulous care—surrounded, indeed, by a frame, but such as no hands can carry away—to be effaced by the foot of the belated drunkard or the night-walking policeman.

The primary purpose of a frame is to protect and to preserve. The photographic artist and the purchaser of his work are, perhaps, equally anxious, one to save the value of his labour, the other of his money. To withstand the attacks of discolouration and decay, to set up some rampart against smoke and damp and dust, which break through the careless, perfunctory connection established between thin paper and defective glass, and steal away from us faces which no camera, by any carte-de-visite or cabinet, can ever in this world restore, is the main object of the frame's invention. A secondary purpose of a frame is to detach a picture from its surroundings, and so to give it greater prominence. The neat gold beading—which, though glittering, is not always gold—the neat gold beading which can be placed round your photograph—if you are of such a complexion as to desire it, and your patience holds out—while you wait, suffices to cut it off by a shining barrier from all meaner pictures, as well as from the world of wall on every side of it. A third purpose of a frame is to ornament, and here caution is required that the decoration be not excessive in quality or quantity, lest it overpower the enclosed picture, and the scoffer may say that the frame is the principal consideration, and that, instead of the frame being for the photograph, the photograph is for the frame. A taunt of a similar nature may be sometimes applied to the purchasers of magnificently bound books; it is notorious that these gaudy volumes are always less read in exact proportion as their bindings are more rare. Men, too, like books and pictures, when set in a golden frame, may excite attention and regard, while without such a frame they would remain quite unnoticed. And the curious observer, looking upon the reverse sides of these frames which enclose humanity, where his eye is not dazzled by the golden glory, may discover many hidden imperfections ; just as, in the back view of our picture frames, we see nothing but boarding and brown paper, and dust, and tacks, and string, and glue.

In almost every photographic exhibition, in our own country and elsewhere, we find the critic, or special correspondent, or commissioner, falling foul of the frames which enclose the photographs submitted to public censure. In almost every exhibition of pictures are noticed some that show exceptionally bad taste in framing. Sometimes the frame is too large, sometimes too small ; sometimes it enfeebles, and sometimes distracts attention from the photograph. According to the precept which the wise Polonius endeavoured to character in the memory of his son Laertes, that "the apparel oft proclaims the man," the nature of the frame has occasionally gone far to determine the merit of the picture. A great allowance must, however, be made for divergency of taste, that indefinable something which has so much to do with matters of this nature. If we could ever hope to obtain any agreement of taste, the possibilities of method of framing are so varied and manifold that a suitable border for any kind of photograph would never be lacking ; for the numbers of photograph frames are as the number of human vices, and the permutations and combinations of frames are legion. They may be made, for instance, of metal, or wood, or glass, or ivory, or leather, or cloth, or silk, or stone, or plush, or card, or canvas, or porcelain, and very probably of many another stuff, either singly or taken two or more together. The metal, again, may be steel, or copper, or bronze ; the wood may be oak, or ebony, or rose, or mahogany, or maple ; the leather may be morocco, or roan, or Russia, or basil ; and the silk may be of as many or more variations.

The form of frames may be oblong, corresponding to carte-de-visite, cabinet, imperial, or panel, or square, or oval, or circular, or polygonal, or of some other geometrical figure. The frame may represent any object of art or nature, from an easel to an elephant. It may be of that "spiky and attenuated order of art," as it was called by a gentleman who disapproved of it, in which four rods with projecting ends are crossed at right-angles, and fixed with four very prominent nails, a variety known as the "Oxford frame"; and it may be of a kind, to another critic, in the words of Dogberry, "most tolerable and not to be endured," with a margin covered by a shiny black pigment laid on the glass and edged with a band of gold, recalling the Death of Dido, the Birth of Pyrrhus, the Lindor and Clara, and other works of the industrious Bartolozzi.

The varieties of frames in metal, leather, wood, and silk are variously sub-classified. Under the *genus* metal is the antique pierced and the *répoussé*, the electro-plated and the varnished; under leather is the smooth and the embossed; under wood, the carved and the white enamelled; under silk, the brocaded and the *broché*; and under glass the plate, the plain, and the silvered. Frames run through the whole gamut of colour. So-called new colours are commonly found to sell the best. In the matter of ornamentation, novelty is the most palatable sauce—the new ever communicates a relish. The old world saw the gilt compo flourish and fluting scroll and scallop which adorned its pictures, and was glad; but all these devices of elaborate ornament have become an inelegance and an eyesore to the people of the present time. Where ribbon, cross, or volute was once commonly set in corners to conceal the joints of the frame —joints which, nevertheless, made themselves, in the course of time, sufficiently conspicuous by cracking the compo more or less exactly in their line of direction—we now meet with butterflies, or flowers, or birds.

Ingenious devices known as illuminations abound in the pages of albums, which are so many frames. They are also met with on another kind of frame called the photographic screen. These frame devices should—in the estimation of some good folk—be in some way connected with the photograph they enclose. Dickens' Mr. Pecksniff should not, they opine, be found on a page having the same ornamental frame as that which enshrines the parson of the parish. Semblances of swords and cannons ought not to surround the effigy of a member of the Society of Friends, however suitable they might be to the portrait of a gentleman in the army; and a scroll, and angel, if not a trumpet, seem inappropriate to a son of Mars, though possibly fit and proper round a disciple of St. Paul.

The adaptation of frame to subject is in many cases suggested, if not enforced, by the unerring instincts of our common human nature. It is clearly felt that the same frame cannot always suit the same portrait. In a world of mutability, the relation of the photographic frame to its contents cannot remain constant; it varies, indeed, as the fashion of a woman's dress, the condition of her temper, or the width of the black hat-band which advertises to a sympathetic public our degree of grief for the dead. Before dear, good Uncle Jones carried off his many virtues, which we never tired of recording, into that four-square city with the jasper wall and jewelled foundations and gates of pearl, his venerated portrait hung in our front drawing-room, framed double-gilt with best English gold. No frame, it was felt by us all, could be quite good enough for the picture of that good man. But when, in the fullness of time, it was discovered that the wicked old fool Jones had left all his money to that designing minx, his housekeeper, Miss Robinson, we with one accord relegated him to the nursery, where his benevolent old face still simpers out of a leather frame bought for fourpence halfpenny at the stores.

Some men there are who love not a gaping pig, and to others the bare backs of photographs are indecent. These say that if a photograph is to be framed at all it should be framed completely. Hand-painted flowers, with poetical mottoes attached to them, have been thought by their presence to improve the hinder portion of a photographic frame. The severity of some people in this matter recalls the opinion of him who would have no pictures save those which "created feelings of repose, peace, and purity." All representations of "martyrdom, nude figures, or anything of a repulsive nature" had no place on his exclusive walls.

With the eccentricity of this gentleman may be compared that of another, of a mathematical turn of mind, who often advised with his pillow with regard to that much vexed matter of depth of frame. Some people are herein content with a very simple rule. They make the extent of frame in direct proportion to the value of the picture; that is to say, a picture worth £300 should, they say, have a border just six times the breadth of one worth £50. As this reference of width to value is clearly unsatisfactory, a correspondent of the *Art Journal*, some five and thirty years ago, conceived the remarkable and original idea of framing pictures in harmonic proportion. Quantities are in harmonic when their reciprocals are in arithmetical proportion. The idea, he tells us, was so much to his own satisfaction in the execution that he thought never again to disregard it. Starting from the principle that harmony of form is as weighty as harmony of sound, he produced the following equation, where $a$ stands for the length and $b$ the breadth of the picture, and $x$ the third harmonic proportional:—

$$x = \frac{ab}{2a-b}$$

Thus, in a picture 6 inches long and 4 inches broad, a width of frame of 3 inches would, he considered, be all that was desirable. If the harmonic third gave too weighty a frame in a large picture, its half, or even its fourth, might be substituted without spoiling the proportion. When the picture was square, some mathematical difficulties followed, with which the reader need not now be troubled.

### Specifications Published.

18,238. *Nov. 12th*, 1890.—"Photographic or Camera Guns." C. Lawrence, 141, Fulham Palace Road, London, S.W.

This consists in a photographic or camera gun, which, on being pointed to a moving object, will photograph the same on a suitable film or plate by the operation of a trigger attached to the butt of said gun, thus exposing the plate or film. The camera is hinged to the butt, and contains the plates, which are arranged in book form, each plate being retained in a suitable frame, which frames are hinged together at one of their sides in such a manner as to allow of their being exposed. The plates are changed by mechanism operated from outside the camera. In conjunction with this camera gun, a suitable shutter is provided, cousisting of wiugs operated by means of a clock spring and toothed wheels, operatiug a revolving disc through the medium of convenieut levers, which enables an instantaneous exposure, or one of any desired duration, to be given. This shutter is placed betweeu the camera box and a barrel containing the lens, which is adjusted in the barrel by rack-and-piniou motiou. Sighting mechanism is also provided on the barrel, aud, if desired, an indicator, operated by the falling over of the frames coutainiug the plates, may be used, thus indicating on a dial the uumber of plates exposed.

19,358. *Nov. 28th*, 1890.—"Photographic Dishes." E. S. Norcombe, 97, Islington Row, Birmingham.

A photographic dish which allows of negatives or positives being washed and examined during the process of development, without removal from the dish by meaus of implements, or injury to the fingers from the developing liquid. It consists of a dish made of transparent glass, or otherwise, with a groove inside parallel with the bottom, on two or more sides, which, when the dish is held up with a picture in, either to drain off the liquid or to examine the development, secures the picture from falliug out, as the picture necessarily slips down into the grooves of the lowest angle when the dish is raised. The same object may be effected by using rows of nipples in place of the grooves.

19,402. *November 28th*, 1890.—"Improvemeuts in Producing Photographs, and in Optical Lanterns for Displaying them." A. W. Scott, Ashcombe Road, Weston-super-Mare.

The object is to photograph persons, objects, scenes, aud complicated dioramic effects, and to project images of the same on to a screen by a limelight, either iu a siugle colour or in its true colours as desired, and consists in photographing the object in three or more images, each produced by rays of light of one colour on a sensitised plate, and then projecting it ou to the screen, and in causing the images to exactly register on the screen so as to show a single image in its true colours, or in any colours, or in light and shade. The object is photographed in four places on the same plate, each photograph being produced by rays of light of one colour only—viz., red, green, blue, and violet—the rays of light from the other colours being stopped by coloured plates or other means. Each photograph is produced by a separate lens or combination of lenses, the diaphragms in the lenses being proportioned according to the sensitiveness of the plate. The four lenses are immovable with respect to each other, and the camera is provided with partitions to prevent the rays of light passing through one lens from affecting the other images, and are operated together, and are covered by one large cap, so that all the images are exposed the same length of time. The plate is developed, and a positive obtained from it in black and white apparently destitute of colours. The lantern for projecting the four images on to the screen so that they form one picture is provided with either the same set of leuses used for obtaining the said images, or with a similar set behind which is a weak focussing lens, and then the plate containing the images to be projected on to the screen. The lantern also comprises a condenser consistiug of a frame of four convex leuses, a frame containing the four coloured screens which impart the same or other desired colour to rays emauating from the image as those by which it was originally taken, and the ordinary lantern condensers throwing parallel beams of light, behind which is arranged a powerful limelight.

---

Messrs. Walter Griffiths and Co. have appointed the Fry Manufacturing Co. as their Londou agents. The Company will be prepared to give every information, and will supply goods from stock on terms that will save cost of carriage to London from Birmingham.

Photography in the Colours of Nature.—The search for the philosopher's stone or for the universal solvent was not pursued more earnestly or with more eager hope for its success by the mediæval alchemists than has been in our own time the effort to find some photographic process by which the infinitely varied and beautiful colours of nature may be fixed and reproduced. That this intense desire is not confined to photographers and other scientists who understaud the difficulties in the way is shown by the eagerness with which the public have always received each new anuouncement of the discovery of "photography in natural colours." For there have been many false alarms—many, of course, by wilful impostors, but many more by earnest experimeuters who stumbled upon chance pheuomena which seemed to point to success, but which, as in some recent instances, were but repetitions of long abandoned experiments. The fact is, however, that the long-sought problem of photography in the colours of nature has been practically solved by a Philadelphia scientist, Frederick E. Ives, whose name is already associated with more than one process and invention which have been of the greatest value in the direction of photography and photo-mechauical printing. Nor is this auuouncement of the fact a new one. Months ago Mr. Ives communicated his process and showed its results at the Franklin Institute, and he has since repeated his demonstrations there aud before the Photographic Society of Philadelphia. That the discovery has not been taken up by the civilised world with the enthusiasm which its importance warrants may be accouuted for by the fact that men's eyes have been turned in auother direction from that in which Mr. Ives has worked. It seems to have been thought that the solution to the problem could only be reached through chemistry, and yet, in the present stage of chemistry, it may be safely said the problem is as far from solution as ever it was. Mr. Ives, in his solution of the difficulty, has reached his success eutirely by photographic means, and through an exhaustive study of the laws of light, rather than of the subtle chemical peculiarities of the silver salts. Taking for a basis of his experiments a suggestion thrown out many years ago by a tutor in the household of Queen Victoria, Mr. Ives has, after years of the most laborious investigations, perfected a process which, stated very briefly, is as follows. Three uegatives are made ou the ordinary commercial orthochromatic dry plates, from the same poiut of view, one by means of the red light rays, oue by the blue, and one by the green. From these negatives positives are made, which are projected upon a screen, the three images being exactly superimposed. The light passiug through each of these positives is coloured by suitable tinted glasses, correspouding to the light rays employed in securing the negatives. These colours are automatically separated and combiued by the action of the trausparent positives, so that the resulting image on the screen appears in the colours of the origiual. If it be objected that this picture is but a transitory and unfixed lantern view, Mr. Ives answers it by producing, by an ingenious modification of his process, permanent transparent positives showing the same wonderful colour effects. When the most delicate colours iu the sky and foliage of a landscape, whether the striking contrasts of the Yellowstone or the soft beauties of forest and meadow, the brilliant and varied colours shown by the polariscope, or the intricate combinations of colour in a painting, can be reproduced with such marvellous accuracy as Mr. Ives has done, entirely by an automatic aud photographic process, it may be said that photography in the colours of nature has been accomplished.—*New York Ledger.*

## Correspondence.

"IN THE LAW COURTS."

Sir,—Allow me to express my sincere regret to Mrs. Earushaw for the misstatement which occurred in my article, "In the Law Courts," and for the annoyance which it has caused her. At the same time, you must permit me to point out, in justice to myself, that I stated in the article that the facts were taken from the report in the *Times*. The case is there reported twice —first, when it came before Mr. Justiee Vaughan Williams, and again when it was before the Court of Appeal. In both reports the facts are precisely as stated by me.

C. Fleetwood Pritchard.

6, *Pump Court, Temple, E.C., November 6th.*

FILLEBROOK ATHENÆUM PHOTOGRAPHIC EXHIBITION.

Sir,—May I remind iuteuding exhibitors that entry forms should be obtaiued at once, and returned, filled up, by Tuesday next, November 17th.

The last day for receiving exhibits is November 24th.

Joseph W. Spurgeon, *Hon. Sec.*

1, *Drayton Villas, Leytonstone, Essex, November 9th.*

A MAMMOTH CAMERA.

Sir,—In your last issue you speak of an American firm having recently delivered a camera 66 inches long, taking a plate 30 by 40. It may be of interest to your readers to know that we have been using for years past one 83 inches in length, with 26 by 20 plates, and at commencement of present year have had it enlarged, enabling us uow to work direct up to 30 by 36.

Henry Dixon and Son.

112, *Albany Street, N.W., November 9th.*

## Proceedings of Societies.

London and Provincial Photographic Association.

At the meeting of this Society held on the 5th inst., Mr. R. Beckett occupied the chair.

The subject announced for the evening was "Treatmeut by Developmeut to Produce Variations in Density," and the Chairman showed two slips which had been identically exposed by Mr. Cowan and giveu to him to develop. The slips each showed a row of stripes, every stripe having had double the exposure of the one lying next it. By developing one slip with a minimum quantity of pyro, and the other with a full quantity, the second showed considerably denser than the first. Moreover, he thought these slips disproved Messrs. Hurter and Driffield's statement that gradation could not be altered by development. It would be found that the third stripe in the one case corresponded in density with the second stripe in the other, but, matching these alongside, it would be found that the other stripes did not coincide in density.

Mr. W. E. Debenham could not admit that this example disproved Messrs. Hurter and Driffield's proposition, inasmuch as the stripes which the Chairman stated ought to coincide, were exposed twice as long iu the one case as in the other, and it was a well-known fact that a progressive increase in exposure did not yield an equally progressive scale of density. He thought he should be able to disprove Messrs. Hurter and Driffield's proposition in another way, but that seemed to him not to come quite within the question of the evening, which was variations iu density, not variations of gradation. For getting great density, he found hydrokinone developer with caustic alkali and a comparatively large amount of bromide very efficient. For obtaining thin pictures, he had used pyro as low in quantity as a quarter of a grain to the ounce.

Mr. Cowan had developed the other two halves of the plates which the Chairman had shown. He had developed them so as to get different densities ou the two slips, but in one ease the density was about double throughout that of the other. So far as he had gone, he could not find any result contradicting Messrs. Hurter and Driffield.

Mr. J. B. B. Wellington said that, to get a hard negative, he should use a strong developer containing 4 grains of pyro, 8 of bromide, and 4 minims of ammonia, to the ounce. For a soft picture, he should dilute the developer, and reduce the proportion of bromide by half. For a dense negative for line work, he would use a slow plate and the shortest exposure possible.

Mr. F. A. Bridge said that, for a negative for block process, the development must not be prolonged, or the lines would fill up.

The Chairman enquired whether it was true that eikonogen gave a finer deposit than other developers.

Mr. Wellington thought not.

Mr. A. Haddon thought that development proceeded in two ways. Bromide of silver was reduced from the film itself, and a further quantity was reduced from the bromide dissolved in the developer. The developer contained two solvents of bromide of silver, bromide of potassium or ammonia, and liquid ammonia.

Mr. Debenham thought that it was not proved that the exceedingly small quantity of silver dissolved by ageuts so dilute had any influenee on the development.

Mr. J. S. Teape had continued his experiments with reference to reversal of image. At the last meeting, Mr. A. L. Henderson had stated that, by pouring off ferrous oxalate developer and replacing it by a fresh quantity several times, he had entirely prevented reversal of image. He (Mr. Teape) had tried that plan, and, having divided a plate into two, had developed one-half in one solution, and changed the other seven times. He found reversal to occur exactly alike in the two cases.

Subjects for discussion for ensuiug evenings were then chosen. On the 19th will be a lantern night; on the 26th, "Protecting the Negative Film during Printing" will be taken; on December 3rd, "Exaggerated Perspective by Wide-Angle Lenses." Other subjects for future evenings are, "The Best Method of Producing Lantern Slides," "Photo-Lithographic Transfers," "Treatment of Plates that have been Exposed to Light," and "Warm Tones iu Lantern Slides."

Messrs. P. Fowcard and J. Ellis were elected members of the Society.

Camera Club.

*November 5th.*—Mr. Leon Warnerke in the chair.

Dr. J. J. Acworth read a paper on "The Action of Light and Heat on the Haloid Salts of Silver." He gave a demonstration to show that the effect of heatiug bromide paper before and after exposure to a powerful light gave reversed results. Subsequently Dr. Acworth handed round specimens, and read a description of Professor Schirm's euamel-like process of printing, which had been exhibited at the last convention at Bath.

On Monday, Nov. 9th, Mr. Lyonel Clark continued the course of elementary lectures with further remarks on lenses.

Monday, Nov. 16th, will be a members' lantern evening, when Mr. T. M. Brownrigg will exhibit a selection of slides.

On Thursday, Nov. 19th, Mr. G. L. Addenbrooke will read a paper on "Aluminium and its Application to Photography."

Lantern Society.

*October 26th.* —A new oil lamp designed by Mr. Stocks was tried. It possesses several points of difference from other lamps on the market, the principal ones being that the whole of the flames from the four wicks are utilised, instead of the lower portion being obscured, and that the chimney is adjustable in length by means of a rack-and-pinion, so enabling the draught to be regulated. In the ordinary four-wick lamp, in order to get a proper flame, it is necessary to turn the wicks up very gradually, and to allow some time to elapse before getting them to their full height; in this lamp the full power is obtained in a few seconds. The lamp was tried practically against two commercial four-wick lamps, both of which give a good light as oil lamps go, and proved far superior to either, both iu purity of colour aud iu quautity of light. The experiments made tended to show that one of the chief practical advantages of the lamp would be that it might be relied on to give its full power under all circumstances.

### Holborn Camera Club.

*November 6th.*—Mr. W. Stevens in the chair.

Mr. F. J. Cobb opened a discussion on "Printing." He showed four negatives, from each of which he had taken four prints (bromide, platinotype, alpha, and silver), and gave numerous hints in working these various processes.

Mr. Golding was of the opinion that, to produce good results, a worker should be thoroughly conversant with the various printing processes now extant. The print must be made to suit the negative. A negative that will give a bad print by one process will yield an excellent print by another process. Many amateurs, other than beginners, thought that when the plate was developed and fixed they had done their work; but it was not so. The photographs are judged by the prints, and it was, therefore, to the printing of the negative that amateurs must devote their attention.

A prize had been offered by Mr. Hodges for the best picture taken at the last Club outing, and it was announced that Mr. Fred. Brocas was the winner.

On Saturday last, forty members and friends sat down at the annual dinner of the Holborn Camera Club, held at Anderton's Hotel. Mr. H. Raphael took the chair. Various toasts followed. A visitor proposed "The Holborn Camera Club," coupling with it the name of Mr. Fred Brocas as the originator of the Club.

Mr. F. J. Cobb, the secretary, in responding, apologised for the absence of the president, who was unable at the last moment to attend. The Club, he said, was in a very prosperous condition.

Songs were given by members and friends during the evening, and various prizes were offered for competition at the annual exhibition next February. The inevitable flash-light photographs finished up a most enjoyable evening.

To-night Mr. T. C. Hepworth will give a lantern demonstration.

---

### North Middlesex Photographic Society.

*November 9th.*—Mr. J. W. Marchant in the chair.

An exhibition of members' lantern slides was given to an audience of about 200 members and friends. The views depicted were of a varied character. Ice-bound rivers and trees covered with the winter's rime alternated with hill, valley, and streamlet basking in the summer sun; cathedral aisles and cloisters with the bustle of sea-side popular resorts; quaint little old-world nooks and corners in provincial cities, followed by the solitude of glens and tarns deep hid in the recesses of Welsh and Scottish mountains. Some 220 slides were thrown upon the screen.

The Fry Manufacturing Co. sent a number of slides made from the late O. G. Rejlander's negatives. These, being figure subjects, were a welcome addition to the evening's entertainment.

The next meeting will be held on November 23rd, when Mr. F. E. Jones will demonstrate the working of hot-bath and sepia platinotype paper. A special feature of the demonstration will be that Mr. Jones will develop prints made from negatives which any of the members choose to send him. Members doing so will thus have an opportunity of knowing whether they are getting the best results from their negatives. Visitors will be welcome.

---

### Lowestoft and District Photographic Society.

The first entertainment of the season was held on Thursday, 5th inst., at the Public Hall, when a selection of photographic slides by Messrs. G. Freeman, F. Estcourt, T. Rose, A. M. Smith, W. Stringfield, F. Everest, and Master Ernest Hume, were thrown on the screen by the Rev. A. Wells, assisted by Mr. G. Tillett.

The chair was taken by the president, Mr. G. F. Mayhew, who introduced the Society to the audience, and said he hoped the time was not far distant when they would possess a home of their own.

The programme included vocal and instrumental music and recitations, and a feature of the exhibition was a large number of American slides received from the "Interchange Society."

### Sydenham Camera Club.

At an exhibition of photographs and lantern slides in the Clarence Hall, Anerley, on the 2nd inst., the walls of the room were lined with an excellent collection of photographs, the different styles of printing lending a pleasing variety to the effect. During the evening there were two exhibitions of lantern slides, which, as well as the pictures, were the work of the members.

The lantern was lent by Mr. Sargeant, of the Croydon Microscopical Society, and was worked by Mr. Chapman. The members exhibiting were, Messrs. Budd (president), H. Gray (hon. secretary), G. Austin, S. Austin, Barlow, Chapman, Cole, Piggott, Pyke, Wiltshire, and Zimmer. Mr. W. Tylar had a helioscopic lantern on view, and the Photo. Artists' Supply Association had a stall also.

---

### Richmond Camera Club.

*November 6th.*—Mr. Ardaseer presided at the lantern, and showed slides by himself and Messrs. Ramsay, Kelsey, Davis, Carolin, and Arthur Hunter, those by the last-named including some highly interesting scenes of Central African travel, from negatives taken by a relative of Mr. Hunter, who had made the Dark Continent his hunting ground.

Several new members have lately been elected.

---

### Tooting Camera Club.

The first meeting of the session was held on the 4th inst., when the President, by the aid of the optical lantern, exhibited a large number of slides made by members and friends. Mr. W. E. Bond was elected a member.

The next meeting will be held on the 27th inst., when lantern slide making by various processes will be the topic.

---

### Rotherham Photographic Society.

*November 3rd.*—Dr. Baldwin (president) in the chair.

The annual members' competition awards were announced as follows:—Class A, six untouched negatives, 1, Mr. H. C. Hemmingway (hon. sec.); 2, Mr. E. I. Hubbard (vice-president). Class B, six negatives and prints resulting from Society's excursions in 1891, 1, Mr. Hubbard. Class C, six albumenised silver prints, 1, Mr. W. Mason. Six gelatino-bromide prints, 1, Mr. Hemmingway. Six prints (any other process), 1, Mr. Hubbard. Class D, six lantern slides, 1, Mr. G. T. M. Rackstraw (vice-president); 2, Mr. Hemmingway. The prizes in classes A and D, amounting altogether to £2 2s., had been given by the president. The judges were Mr. B. J. Taylor, Mr. Geo. Bromley, and Mr. Ernest Beck, respectively the president, vice-president, and secretary of the Sheffield Photographic Society. The competition work was afterwards on view.

The Fry Manufacturing Co. had lent a series of zoological slides, chiefly from negatives by Mr. Gambier Bolton, and they were displayed by means of the oxy-hydrogen lantern operated by Mr. Leadbeater, the treasurer.

---

### Oxford Photographic Society.

On November 3rd, the President (Mr. E. A. Ryman-Hall), gave an interesting exhibition of slides made from hand-camera negatives (films). The slides shown, representing various parts of England, from Westmoreland to Brighton, proved what can be done with a hand-camera in careful and experienced hands.

About 112 members and their friends were present.

---

### Sheffield Photographic Society.

*November 3rd.*—Mr. B. J. Taylor in the chair. Two new members were elected.

Mr. T. G. Hibbert gave a practical demonstration on the subject of lantern slide making by reduction in camera, using artificial light, and without the aid of a condenser. After explanation of the different methods used, the lecturer exposed several plates in the camera, and developed the same, which came up satisfactorily, and were afterwards shown in lantern.

The collection of Charity Prize Medal Lantern Slides, lent by the editor of *Photography*, were passed through the lantern, and fully appreciated.

### Lewes Photographic Society.

*November 10th.*—Mr. J. G. Braden in the chair. Mr. E. Brummit was elected a member.

Mr. C. E. Collins, of East Grinstead, gave an interesting and graphic account of " A Short Tour in Scotland," illustrated with lantern slides. Many of the slides were unique in character, consisting of groups of sea birds which inhabit the islands on the west coast of Scotland, and one slide of a wild heron's nest with young. Views of Inverness, Edinburgh, &c., were also shown.

The Hon. Secretary suggested that an album should be sent to members, a great many of whom resided in the country, to enable their work to be seen and criticised, and it was resolved to refer the subject to the committee at their next meeting.

The President showed a slide which suffered from halation, and another of the same subject in which the evil was entirely avoided by simply backing the plate with black paper coated with glycerine.

---

### Leeds Photographic Society.

On the 5th inst., Mr. W. Clement Williams (hon. sec. of the Halifax Photographic Club) delivered a lecture on " Some Aspects of Marine Photography." Marine photography, he said, was often looked upon as a sort of happy-go-lucky kind of thing. Everything comes to him who waits, and in this kind of work it was necessary to wait. It was absolutely essential that the sea and sky should be taken at the same time. In addition to an art knowledge, a ready decision was wanted, for effects must be caught at once. The best effects were to be obtained during the autumn months, when the clouds were at their best. Sunset pictures were difficult to develop, and, indeed, patience was required to develop any kind of marine study. In addition to marine views proper, harbours, quays, the sands, &c., should be carefully looked over for picturesque studies of fisher-folk, &c. One of the chief difficulties here was to obtain a natural pose, and to get people to understand that the genuine picturesque costumes of the fishermen and fisherwomen were required. Too often they wanted to rush off, wash themselves, and appear in their best clothes, when, needless to say, all their picturesqueness disappeared. Mr. Williams dealt at length with technical matters necessary for this special kind of work.

---

### Midland Camera Club.

*November 6th.*—Mr. Hall Edwards (president) in the chair. Fifteen new members were proposed, which will make the total membership sixty-three.

The Chairman reported progress with regard to the club rooms, and the hon. sec. announced receipt of gifts. The council have decided that on every Monday evening there shall be an informal smoking and conversational evening.

The President then read a paper upon " The Aims and Objects of a Photographic Club," in which he dealt with the social, scientific, educational, artistic, and other duties. Amongst these, he referred to the duties of a club towards the public, and stated that the council had resolved to offer the services of the Club to charity schools, board schools, and the like, in the way of lantern lectures, or in loaning slides ; and that he was in communication with the Kyrle Society of the town with respect to this.

Prof. Allen suggested the borrowing of the Yosemite Valley set of slides, as likely to afford members the opportunity of seeing the wonders of this marvellous region, which, perhaps, none of them might ever have the opportunity of visiting.

The Hon. Sec. then read a short paper upon " The Registration of Lantern Slides," showing examples of his methods.

Prof. Allen has promised a short paper upon " Nitrogen in Photography," and a longer one on February 5th upon " The Philosophy of Restraint in Development."

---

Royal Institution.—The Christmas lectures to juveniles will this year be on " Life in Motion, or the Animal Machine " (experimentally illustrated), and will be delivered by Prof. John G. McKendrick, M.D., F.R.S., the Professor of Physiology in the University of Glasgow.

## Answers to Correspondents.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

Questions requiring a reply in this column, which have hitherto been addressed to Mr. Spiller (who, unfortunately, is unable at present to continue his efficient assistance), should be sent to the Editor.

All other Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

J. R. W. (Newcastle).—*Negative Imperfectly Fixed.* You do not say whether the plate has been varnished ; if so, first remove the film by soaking in methylated spirit. Then wash with water, and immerse in either plain hypo or weak cyanide of potassium until the patch of yellow bromide has been entirely dissolved. Finally, wash well in running water, and rear up to dry.

T. B.—*Last Days of the Exhibition.* We had your letter, but as you did not come up to town on the 7th inst., we can only now express the hope that you actually saw the exhibition before it was closed.

Northwich.—*Stock of Hardwich's Collodion to be Made into Collodion Emulsion.* We are not altogether sanguine about the success of working up old solutions into new preparations, but here are the figures if you are intent upon making the trial. Your proportions being right for Hardwich's iodised collodion, the pyroxiline will have to be augmented from about 2 to 10 grains per ounce, and zinc bromide together with silver nitrate separately added. Taking Captain Abney's proportions (see " Instruction in Photography," page 146), your 24 fluid ounces would require 640 grains of $ZnBr_2$ and 960 grains of $AgNO_3$, each dissolved in smallest possible quantity of alcohol, and gradually added ; but, as the collodion contains already 96 grains of KI in addition, another 100 grains of $AgNO_3$ will be required. You will not need any bichromate, but a few drops of nitric acid are recommended to be added, to meet the tendency to fogging. India-rubber pneumatic holders can be obtained of any local dealer.

L. P.—" *The Fifth of November.*" Yes, certainly, Mr. James Clark's picture in this week's *Queen* would have preached a wiser lesson if the little cannon had been turned the other way, so as not to deliver its fire in amongst the bystanders.

M. P. (Brighton).—1. *Paramidophenol.* It is immaterial whether you employ the base itself or the hydrochloride with addition of alkaline carbonate, as stated in the formula. Enquire of Messrs. Hopkin and Williams, 16, Cross Street, Hatton Garden. 2. *Albumenised Paper.* The strong, pungent odour is due to acetic acid, which is often used to break up the mucilaginous character of the albumen, and produce acid conditions at the time of sensitising, by which expedient not only is the preservation of the paper greatly favoured, but the tendency to blistering is supposed to be diminished. It is a good plan to fume the paper with ·880 ammonia immediately before use in the printing frame.

Collotype.—*Chromo-Typography.* Your account is quite correct. It is, as you say, necessary in each plate to stop out all the remaining tints except those which are wanted to deliver the self-colour, or produce combinations by overlay. See M. Leon Vidal's paper in the News of May 29th, June 5th, and 12th—particularly page 419.

W. K.—*Choice of Lens.* It is manifestly impossible to answer in this column, so we are writing to you by post.

D. S.—*Flash-Lamp.* Why resort to magnesium light for illuminating the interior of a church ? It would cost you a deal of labour and expense to accomplish that which could be done so much more satisfactorily by daylight. However, for illuminating caverns and comparatively large open spaces, the apparatus mentioned is certainly the best yet introduced.

Finale.—With this column, J. Spiller takes leave of his numerous correspondents, whom he has for three years tried to serve faithfully and well. The pressure of other engagements compels him, with much regret, to take this step ; but Mr. Editor will doubtless provide an efficient substitute, so that the interests of the News may not suffer in consequence.

# THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV. No. 1733.—*November* 20, 1891.

CONTENTS.

## GEOLOGICAL PHOTOGRAPHS.

The committee which was appointed some months back by the British Association to collect, arrange, and register photographs of geological interest have, as recent reports have shown, made a fair start in the work which they undertook to do. But they complain that the photographic societies have, in many cases, shown a decided want of interest in the work, and have failed to co-operate with them. It would seem, too, that the committee have not yet secured the attention of as many amateur workers in photography as they had reason to expect, and so it comes about that only about one-half of the British counties are represented in the pictures which have been sent in to the committee. We are sorry that the invitation to send in photographs of geological interest has been so sparsely responded to. It too often happens, in such a case as the present, that the bulk of those who could do much if they cared to take the trouble stand aside, while the real hard work is left to be grappled with by a few enthusiasts. Can it be said that the average amateur is too busy in hunting after medals and prizes of other kinds to care to undertake any work that does not promise him an immediate return? We should be loth to answer the question in the affirmative, but, at the same time, we know that the amateur will not be idle when the opening of an exhibition of photographs is in contemplation.

But perhaps, after all, the real reason why the geological committee do not receive as much support as they might expect may be traced to a certain shyness which people have in dealing with a word which ends in "ology." Some, we feel certain, will turn their backs upon a thing "of geological interest" as upon something to be shunned; not, of course, because there is anything wicked or harmful about it, but simply because they will not be bored with it. They have settled in their own minds that it must be unutterably dull, and they will have nothing to do with it. Some friend, perhaps, has had the misfortune to study a "dry-as-dust" volume on geology, and has described the work as "an awful grind." To him it has been a grind indeed, and he and the writer of the dry volume, for a time, do infinite harm by disseminating a false estimate of a fascinating branch of science. There ought really to be some institution, akin to a lunatic asylum, where dry-as-dust writers and lecturers on scientific subjects should be shut up and punished for their misdeeds, for they have done, and are doing, an incalculable amount of harm in driving the young away from studies which might be made so alluring to them, and which are calculated to be of so much use to them in their future lives.

Writers on photography in our own pages, as well as in other periodicals, have constantly urged upon the large army of amateurs—an army which is always growing—that they should have some aim in their work. It is a pitiable thing to see a man with a camera who is content to take bad portraits of his friends, and "bits," as he calls them, of the surrounding landscape. He must, of course, begin with these mild efforts at picture-making, but he need not continue them, as so many do, to his life's end. He should link his camera work with some other study; and here, in this invitation to contribute to geological knowledge, he has an opportunity of doing far more good than he will ever get from medal hunting. If, too, he makes up his mind to shun at once his old practices, and take up useful work, he may be able, at some future time, to number himself among that select company of workers who will be distinguished as never having won a medal.

But no one knows the charm of working with a settled purpose, and with the attainment of a certain result in prospect, but he who has tried it. He feels all the time that he is conquering difficulties and is getting forward. More than all, he knows that he is adding to his stock of knowledge, and to all but the very ignorant—who know enough already—this itself is a pleasurable thought.

A study of geology, if taken up aright, is by no means the hard nut to crack which some would have us believe. Let the photographic worker who wishes to share in the work, and who knows as yet nothing about it, take up physiography first—Huxley's little book on this subject is so well written that the reader is insensibly led on to peruse it from beginning to end. Then let him take up Geikie's "Geology," and he will find himself making acquaintance with another writer who is never dull. As he reads these and other books, he should make marginal notes with reference to possible illustrations by means of photography. The latter writer's "Field Geology" will also be of use to him later on in showing him how to describe and localise his pictures. With a little reading of this kind the photographer will soon take an interest in his work, and will hunt about for likely subjects with as much ardour as that with which a sportsman pursues his game. Nor need he think that because he has begun the study of rocks, and the searching for "sermons in stones and books in the running brooks," that he need sacrifice his love for the picturesque in nature; for geology and picturesqueness go hand in hand. Does Matlock High Tor become less sublime in its rugged outline because we describe it as carboniferous limestone? Is Dove Dale less beautiful because it is a fine example of the effects of erosion in the same rock? Do the cliffs round about Dover lose their grandeur because we can see in them chalk of different ages? and the dark rocks that fringe Mona's isle sacrifice their weirdness because we can trace them to distant volcanic action? Assuredly not. The photographer who takes up geology as a bye study—even if he only dips into it in a superficial manner—will find himself rewarded by the pleasure which it gives him. Let him, during the coming winter, read it up only a little, and when a more favourable season comes round, he may be able to show in a graphic—or, should we not say, photographic—manner that he has not read in vain.

## FRENCH CORRESPONDENCE.

BY LEON VIDAL.

Photographic Society of France—Photographic Conferences—Other Photographic Meetings—Graphic Representation of the Progress of Photography—Brussels Congress—Colour-Sensitive Plates in France.

After two months' holiday the members of the Photographic Society of France are again holding their periodical meetings. At the reunion of the Society on the 6th inst., which was presided over by M. Janssen, nothing of very great importance came before the meeting. M. Balagny explained in detail the method by which he obtains, by reduction, lantern slides from larger sized negatives; and the results he showed, which were projected by a lantern before the members of the Society, left nothing to be desired. The pictures shown constituted an interesting *souvenir* of the recent Congress at Brussels, for they were the offspring of negatives made during the excursions inaugurated by that body.

M. Piver explained a method of working a camera on board ship. A twin camera is suspended by cords from any convenient part of the rigging, so that the operator has both hands at liberty while taking the picture. But it is difficult to give any idea of the instrument by simple description; it must be seen to be appreciated. Albeit, we have a notion that it is somewhat more complicated than is either necessary or desirable. The double body—one half being used as a finder—makes the apparatus somewhat cumbrous.

M. Gillors has produced a camera in aluminium of very light weight, not including the lens. This extreme lightness, combined with solidity, cannot fail to be very serviceable. Small apparatus generally has greatly gained by the employment of this metal.

The President announced that the advertised conferences on photography which had been authorised by the Minister of Fine Arts, and were to have taken place on Sunday at the National Conservatoire of Arts and Manufactures, is postponed till the 22nd of November. Each branch of photography will be treated by a person capable of dealing with it; among the number may be mentioned MM. Laussedat (director of the Conservatoire), Davanne, Leon Vidal, Balagny, Moëssard-Londe, Gravier, &c. The complete programmes of these conferences, and the subjects of which they treat, will presently be published. Here, then, is the preliminary step to the creation of a true photographic academy. These conferences will show the interest with which this question is regarded, and may possibly form the nucleus upon which a true practical and theoretical school of photography may be established. There are already the National School of Decorative Arts, that of M. Gravier at the Philotechnic Institution, and that of M. Cousins at the Tours San Jaques. These certainly useful courses cannot, however, be considered as forming a complete teaching academy, such, for example, as that which exists at the Imperial Institute of Photography, Vienna, under the direction of Dr. Eder.

MM. Marilier and Robelet, patent agents, have conceived the idea of publishing a diagrammatic account of the progress of photography, based on the number of photographic patents taken out since 1839. Two distinct curves have been traced; one for apparatus, and the other for the chemical side of photographic work. This last curve does not attain any great height, whilst that of the apparatus, especially in recent years, shows decided advance. For this purpose it was necessary that the authors should attend the Brussels Congress, only having, so to speak, the Parisian records at their command.

We must regret that the foreign delegates who put in an appearance at the Brussels Congress were so few in number. A really true international pronouncement on the various matters before the Congress and on the decisions arrived at was, therefore, an impossibility. The work of such a Congress cannot take the highest rank unless each nation sends officially a delegate to represent it. These gentlemen should be instructed to make themselves acquainted with the business to be brought before the Congress, and should watch the interests of the various industries of the country which they represent. As it is, the work is purely amateur and optional, and although it must not necessarily be condemned for that, it would be much better if it were supported and strengthened by official recognition.

We regret that more attention was not devoted at the Congress to the important subject of orthochromatic processes. These processes do not receive the attention in France that they deserve. But we will not enter more fully into the subject here, more especially as we deal with it in detail in the forthcoming YEAR-BOOK OF PHOTOGRAPHY.

## LITERARY LECTURES AND THE LANTERN.

BY PROF. W. HALL GRIFFIN, B.A.

THE lantern is now freely used for scientific lectures, and for those of a descriptive character. I am confident that it can be as usefully employed for literary purposes, and hope soon to see it abundantly so used.

My own ideas as to the employment of the lantern have simply grown out of my experience of the need of appeals to the eye to supplement those to the ear. I have found this as a public schoolmaster and as a lecturer. I have for years employed stencilled charts for history and literature, and have supplemented these by the use of photographs, portraits, &c., &c.

### SLIDES FOR LITERARY LECTURES.

My slides for literary lectures I would class under three heads:—

1. Those which illustrate the *lives* of writers. Such views are always of interest, and, although not *directly* helpful to the understanding of literary works, they serve to give reality to facts mentioned, and to bring home the surroundings of a writer in such a way as to arouse interest in the works themselves.

Among such views I class portraits—so many of which Messrs. Mansell, of Oxford Street, now supply in their "Literary Series"—views of the homes and haunts of our writers, autographs, &c. These awaken great interest when they serve as illustrations in our books—as they so freely do now—and I have found them as useful in lecturing.

### HOW TO ILLUSTRATE BOOKS.

My own idea of their use educationally is to bring out as fully as possible the circumstances under which works were produced—to deal with the home of the writer, we will say, and then take the works produced there. This is often most useful.

2. Views illustrating the *works* of writers. Any such views have a distinctly *educational* value, besides being of interest. Very often the views already spoken of are of this character; for the surroundings of a writer being known, one often sees the source of the illustrations he uses or the descriptions he gives. Scott and Wordsworth are instances of the possibilities in this direction. But what is true of these two is true, in a degree, of all writers. No one who has not studied the question had any idea of the amount of useful, helpful illustrations that may be given. Some wonder has been excited by my attempting to illustrate Browning. May I give an instance of the possibility? Take the well-known poem, "Andrea del Sarto."

### ILLUSTRATING BROWNING.

(1) A picture hanging in the Pitti Palace, at Florence, shows the painter in conversation with his wife. The sadness of the expression on the painter's face excited, it is said, Browning's interest, and suggested the monologue put into his mouth by the poet. I use a slide to show this picture.

(2) The famous portrait of Andrea in our own National Gallery is said to have influenced the treatment of the poem. This, therefore, is shown. It all serves to connect the unknown foreign picture with what should be known to all here.

(3) A view of Andrea's masterpiece in Florence, and of his Madonna in our own gallery, as well as a portrait of his wife (in Madrid), serve to bring out the fact (referred to in the poem) that the wife was his model for the Virgin, as well as to exhibit the work of the "Faultless Painter."

(4) A view of the house in which Andrea lived in Florence—the house Browning had in his mind in writing the poem, and where he imagines the conversation to take place—also serves to quicken interest, and to make the poem more real.

(5) A few views of the surroundings of that house—the church, and its garden nearly opposite, the view up the road to the hills of Fiesole—all of them in the poet's mind as he wrote, and all referred to—are other illustrations.

Now, I have chosen this, a somewhat favourable instance, because I have found that many students of the poem had *no idea whatever* that reference was so often made to real places, events, and people, and they have shown the greatest interest in the views. I use it to enforce the remark that only a close study of works can enable any one to realise how much aid the lantern can give in developing the depth of meaning, or in giving reality to such works.

### AND THE USE OF THE LANTERN.

Such views would illustrate passages which would be read while the views were on the screen.

3. Many works—let me keep to poems—are incapable of such illustration. As the *Daily Telegraph* remarked in its leader on the subject: "The ode 'To a Skylark' would not be rendered any more delicious than it is by a magic lantern slide depicting the bird in the act of soaring heavenward." Quite true. But my third class of slides consists of passages from poems—printed passages—thrown on the screen, so that what is read or criticised may be before the eyes of all. The audience at once become audience and spectators—or, as Bunyan might say, "Eye-gate and ear-gate are attacked at once."

The use of such slides accompanied by the other two kinds is obviously advantageous. I also have charts of the lives of writers, and in some cases an analysis of a work, &c., as slides. By the use of those slides, passages can be *compared* far more efficiently than by mere appeals to the ear. It also allows of a passage—when needful—being kept before the eyes of all, so as to enable a more detailed criticism to be entered into—a criticism of any of those smaller points which are apt to be more wearisome when the passage is not before the eye.

### THROW POEMS ON THE SCREEN.

Also, such slides enable poems to be dealt with—the "Skylark," for instance—which cannot be illustrated. The beauties or defects of a poem can be far more efficiently pointed out when the *reading* of passages and the comments are accompanied by the appeal to the eye. It also serves the practical purpose of keeping up the continuity in the use of the screen, which seems to me needful in the lantern lecture—in most cases, at least.

The labour involved in arranging such a mass of illustration is, of course, very great; but I hope to see a great development in this direction, one of the best means, I am confident, of arousing interest in the study of the lives and works of our great writers, poets, and thinkers.—*Help.*

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.—On November 11th Mr. Tucker, Loughborough, gave a lecture entitled "A Journey through Snowdonia," illustrated by a series of well-executed slides, the hon. secretary presiding at the lantern.

"GREAT THOUGHTS."—With the Christmas number, to be published on November 30th, will be given a plate, printed in fifteen colours, from a painting by the German artist Heinrich Hofmann, entitled "The Great Teacher," depicting Christ disputing with the doctors in the temple. The picture from which this plate is copied is now hanging in the Dresden National Gallery.

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Transferring Collodio-Chloride Prints to Glass—Explosive Magnesium Powders—Lantern Slides with the Pyrocatechin Developer—Husnik's New Transfer Paper.

*Transferring Collodio-Chloride Prints to Glass.*—The commercial collodion stripping paper—*i.e.*, paper coated with collodio-chloride emulsion—the film of which may be stripped off its paper support, allows of the transfer of the collodion print to other surfaces; for instance, to artificial ivory—as I have described in my previous letter—or to glass, &c. With regard to the latter, Bruno Risse, who for many years has made a speciality of printing with collodion emulsion paper, recommends the following method, in order to produce prints with a high and fine gloss, known as "Disdéri pictures." A few drops of a solution of 1 part of white wax in 100 parts of ether are poured on a plate glass previously carefully polished with ammonia, and, by means of a pad of cotton-wool, distributed uniformly to all directions, always starting from the centre. The print to be transferred, after being thoroughly washed, is placed with the film side down on the glass plate, and pressed tightly against it by means of a squeegee, a piece of strong paper being previously placed on the copy in order to take care of it. After the print on the glass has become half-dry, it is coated with a diluted solution of gum-arabic, excepting a small border round the edges, which is left free. An enamelled cardboard, a little smaller than the print, is then tightly squeezed on it, and the whole allowed to dry completely. The print will then easily come off the glass plate by passing carefully a knife beneath it at one corner. It should now be trimmed, and, after the edges have been slightly coated with starch paste, transferred to the card, with the firm printed on it. A small sheet of glass, slightly coated with wax solution, is then laid on it, and the whole placed into a bookbinder's or a screw-press, with only slight pressure. If it is desired to obtain prints with a fine matt surface, the only modification of the above-described method consists in substituting a ground glass for the plate glass. The prints may also be very easily transferred to ordinary glass, to be used as diapositives and transparencies; it is then only necessary, in this case, to print the image very deeply. The white of one egg is put in a cup, and after being beaten to a froth by aid of a fork, it is allowed to settle for a day, and then diluted with a little water. With this albumen solution the plates to be employed are coated, and the prints are squeezed on them and allowed to dry. If they are immersed in a dish containing very hot water, the paper support comes off very soon, and the transfer is finished.

*Explosive Magnesium Powders, and the Rapidity of their Combustion.*—New experiments have been made by Prof. Eder and E. Valenta, of Vienna, with regard to the important question as to the quickest and most intense flash-light. It results from them that the explosive magnesium mixtures are to be preferred to the pure magnesium powder in all cases where an intense and very short illumination is required. The rate of combustion and the intensity of the flash depend upon the nature of the oxygen developing substance which is used in the explosive mixture. The following details are worthy of mention. Mixtures of 1 part of magnesium with 3 parts of permanganate of potash burn violently in the manner of an explosion, without the whole of the light which the magnesium is able to produce being utilised; if only from $\frac{3}{4}$ to 1 part of the permanganate is added, the combustion will be slower and the intensity greater. The bichromates of ammonium and of potassium produce mixtures which burn with a hissing noise and comparatively slowly, the intensity of the light being somewhat lower. A mixture of equal parts of saltpetre with magnesium burns quietly, the intensity of the flash being very considerable, and the rate of combustion about equal to that of the mixtures with chlorate or perchlorate of potassium. In cases where the ready prepared mixture is to be forwarded by post, the saltpetre and the permanganate of potash respectively are, therefore, to be preferred to the chlorates, for the reason that either of the former may be forwarded and employed without fear. The following table contains the results of the experiments in question:—

| Mixture of 1 gr. of magnesium with | Time of combustion. | Relative quantity of light, determined by means of the sensitometer. |
|---|---|---|
| $\frac{3}{4}$ gr. of potassium chlorate and $\frac{3}{4}$ gr. of potassium perchlorate ... ... | $\frac{1}{11}$ second | 48 |
| 3 gr. of permanganate of potash ... ... ... | $\frac{1}{14}$ ,, | 16 |
| 1 gr. of permanganate of potash ... ... ... | $\frac{1}{7}$ ,, | 48 |
| 1 gr. of ammonium bichromate ... ... ... | $\frac{3}{4}$ ,, | 40 |
| 1 gr. of potassium bichromate ... ... ... | $\frac{1}{4}$ ,, | 36 |
| 1 gr. of saltpetre... ... | $\frac{1}{6}$ ,, | 48 |

*The Production of Lantern Slides by the Pyrocatechin Developer.*—Prof. Eder and E. Valenta are highly recommending the pyrocatechin developer for the production of lantern slides on commercial gelatino-bromide plates, the latter obtaining by it an agreeable brownish-grey colour, which is much more suitable for the purpose than the greyish-black tone imparted to them by other developers. The following formula is given:—

1. One part of carbonate of potash is dissolved in ten parts of distilled water.
2. One part of pyrocatechin is dissolved in fifty parts of distilled water.

In the case of *very soft* transparencies being desirable, a mixture should be prepared of—

| | |
|---|---|
| Water ... ... ... ... ... | 60 c.c. |
| Solution 1 (potash)... ... ... ... | 20 ,, |
| Solution 2 (pyrocatechin) ... ... ... | 3 ,, |

If this solution is to be used, the exposure should be prolonged to some extent, and the development proceeds a little slower than with pyrogallic acid development. After the plates have been developed, they are rinsed with water, and fixed in ordinary hypo solution (without the addition of acid sulphite). If more vigorous transparencies full of contrast are desired, only about one-half the exposure as in the previous case should be given, and the following solution employed:—

| | |
|---|---|
| Water ... ... ... ... ... | 60 c.c. |
| Solution 1 (potash)... ... ... ... | 20 ,, |
| Solution 2 (pyrocatechin) ... ... ... | 10 ,, |

A few drops of potassium bromide solution (1 : 10) may also be added if required; it acts as a very strong restrainer, so that the exposure should, in this case, be considerably prolonged. The above given developer becomes brown soon after being mixed; several plates may, however, be developed in the same solution if it is done quickly. The old or already-used solution acts slower and more plucky, and, by the aid of it, the brilliancy of the transparencies may be considerably increased, especially if the second formula, which contains a larger quantity of pyrocatechin, is employed.

*Husnik's New Photo-Lithographic Transfer Paper.*—This transfer paper, which was mentioned in a previous letter on the occasion of the description of a new photo-lithographic process, is, as I am informed, obtainable in England. It possesses a comparatively weak but hardened gelatine film, which, if placed in water, swells only a little, producing, therefore, a comparatively flat relief, every single point of which is accessible without difficulty, so that the colour may be easily removed from it during development with the sponges; the character of the negative image being therefore truly reproduced by it. The prints obtained on this paper may be developed with ease by moderate friction, and the resulting pictures are extremely sharp and pure. The sensitising of the paper is done by placing it in a solution of chrome salts for about two minutes; it is then laid upon a plate glass, prepared with a thin layer of wax, and allowed to dry thereon overnight. A very fine glossy surface is obtained by this method.

## PRINTING WITH SALTS OF CHROMIUM.

BY C. GRAVIER.

PLUNGE a sheet of white paper into a four per cent. solution of bichromate of potash or ammonia, and dry it in the dark, either hung up or between sheets of bibulous paper. Expose the paper under a negative, as usual, but shortening by at least one-half the time of exposure required for papers prepared with the silver salts. As soon as the details of the negative are well defined, plunge the print into water, and allow it to remain until it is entirely freed from the yellow tone which forms the background of the design. This operation requires at least thirty minutes; provided, however, that care has been taken to renew the water during this space of time, it may be performed in weak diffused light. Now place the image in a filtered bath of protosulphate of iron (5 parts to 100 parts of water). After an immersion of two or three minutes, remove the print from the bath and put it into clear water, frequently renewed, and allow it to remain in this water for at least thirty minutes, and then treat the paper with a solution of gallic acid, which, without objection, may be more or less concentrated. In a few moments the image is fully developed; it presents a beautiful violet-black tone, which is most artistic and desirable. The print is washed for a few moments in clear water, and allowed to dry. The image is but slightly affected by the air, and is formed by a sort of ink deposited on the surface and in the body itself of the paper. The paper, after having been treated with the sulphate of iron solution, may be plunged into a solution of ferrocyanide of potash instead of gallic acid; an image of a Prussian-blue tone is thus obtained, which, treated by the acid, becomes greenish in colour. Diluted alkaline solutions give a darker blue tone, bordering on violet. Finally, the same paper passed in a sulphate of iron bath, when afterward treated with substances producing a coloured compound insoluble with sesquioxide of iron, will also produce coloured images.—*L'Amateur Photographe.*

## GEOLOGICAL PHOTOGRAPHS COMMITTEE—BRITISH ASSOCIATION.

THE following is a list of the members of the Committee:—Professor James Geikie, LL.D., F.R.S. (*Chairman*); Dr. Tempest Anderson, B.Sc., F.G.S.; Professor Valentine Ball, LL.D., F.R.S.; James E. Bedford, F.G.S.; Professor T. G. Bonney, D.Sc., LL.D., F.R.S.; Professor W. Boyd Dawkins, M.A., F.R.S.; James W. Davis, F.G.S.; E. J. Garwood, F.G.S.; William Gray, M.R.I.A.; Robert Kidston, F.R.S.E.; Arthur S. Reid, M.A., F.G.S.; R. H. Tiddeman, M.A., F.G.S.; W. W. Watts, M.A., F.G.S.; Horace E. Woodward, F.G.S.; Osmund W. Jeffs (*Secretary*), 12, Queen's Road, Rock Ferry, Cheshire.

This Committee was appointed by the British Association for the Advancement of Science in 1889, for the purpose of arranging for the "Collection, Preservation, and Systematic Registration of Photographs of Geological Interest in the United Kingdom." Since its formation, the Committee has been successful in obtaining a number of photographs, of which 588 were received and registered up to the month of August, when their second report was presented at the Cardiff meeting of the British Association; the total being made up as shown in the following summary, viz.:—Berkshire 3, Cheshire 28, Cornwall 18, Cumberland 2, Derbyshire 21, Devonshire 21, Dorsetshire 12, Hampshire 2, Hertfordshire 4, Isle of Man 22, Kent 17, Lancashire 30, Leicestershire 2, Montgomeryshire 3, Northumberland 9, Shropshire 14, Somerset 12, Staffordshire 3, Wiltshire 5, Worcestershire 2, Yorkshire 164, North Wales 57, Scotland 45, Ireland 92; total, 588.

It will be seen from the foregoing that about half of the British counties are not as yet represented in the collection, while the amount of the contributions from several of those counties named in the list show that considerable work is yet required to be done towards the completion of the scheme the Committee have in view. Nearly all the photographs already received are of considerable educational utility, while many are also valuable as permanent records of important geological phenomena.

The Committee greatly appreciate the help that has been afforded from so many quarters, and would respectfully urge upon geologists the desirability of further assisting the scheme, with the object of completing a national collection of photographs illustrating the geology of our own country.

The secretary of the Committee will be glad to receive (at the address above) copies of suitable photographs, which will be duly numbered and registered; or to be favoured with:—

1. Lists and details and photographs of geological character already in existence.
2. Names of local societies, or persons, who may be willing to further the objects of the Committee in their own district; or
3. Particulars of localities, sections, boulders, or other features which it may be desirable to have photographed.

A list of such *desiderata* will be published when sufficient material has been obtained.

The attention of local societies and field clubs is specially directed to the excellent results attained in those districts where systematic surveys have been organised for the furtherance of the work (*vide* report). It is felt that this method could be usefully followed in many of our counties where the machinery exists in the shape of an influential society of geologists or photographers, or a naturalists' union. It is suggested that local societies could materially aid the scheme by mapping out their districts under the direction of a local geologist, and drawing up a list of sections and localities of which photographs would be desirable. New sections aud exposures of strata should be noted. This preliminary work could be doue duriug the winter sessiou, and arrangements made for the use of the camera in the ensuing spring, or when opportunity offered.

In order to secure uuiformity of action, and as a guide to those who are willing to assist in the scheme, the annexed circular of instructions has been drawn up, copies of which will be supplied on application to any officers of societies, or other persons who may desire to have them, together with copies of the form on which the needful particulars of the photographs may be given.

Detailed lists of photographs officially received are published iu the report of the Committee, which also states where the photographs may be obtained. Lists for insertion in the third report of the Committee will be received up to June 15th, 1892.

### Instructions for the Collection of Geological Photographs.

Photographs are desired illustrative of characteristic rock exposures, especially those of a typical character or temporary nature; important boulders; localities affected by denudation, or where marked physiographical changes are in operation; raised beaches, old sea-cliffs, and other conspicuous instances of marine erosion; characteristic river-valleys or escarpments, and the like; glacial phenomena, such as *roches moutonnées*, moraiues, drums and kames, or any natural views of geological iuterest. Photographs of microscopical sections and typical hand-specimens of rocks are also admissible.

1. The views should be taken under skilled geological direction, and in every case the most typical views should be secured in preference to general views. Societies are urged to form small committees for the purpose of noting sections suitable to be photographed, and arranging such work as may be possible in each district. To this end it is anticipated that the services of many amateur photographers may be usefully brought into requisition.

2. Size of photograph recommended, 8½ by 6½ inches ("whole-plate"); but this is *optional*. In view of the difficulty of carrying a heavy camera and plates, it is not desired to exclude smaller views when these are well defined and clear. In the case of small negatives, when sharp, an enlargement to whole-plate size is desirable for the purpose of a place in the collection. The views should be printed by a permanent process whenever practicable. Isochromatic plates are strongly recommended to be used.

3. In order to preserve its scientific value, each photograph should be accompanied by as many of the following details as can be conveniently given. Forms for this purpose will be supplied on application. (*a*) Name and position of section or locality; (*b*) special features shown, with illustrative diagrams, when necessary (further details may be given, if more convenient, on a separate tracing attached to the photograph); (*c*) height and length of section, and compass direction; (*d*) name and address of photographer, or of the society under whose direction the view is taken; (*e*) date when photographed; (*f*) indication of direction of light and shade—*i.e.*, state whether taken in "direct light" or in "shade."

4. Each photograph sent in for registration should bear a *local* number, and the accompanying form should be numbered in accordance therewith.

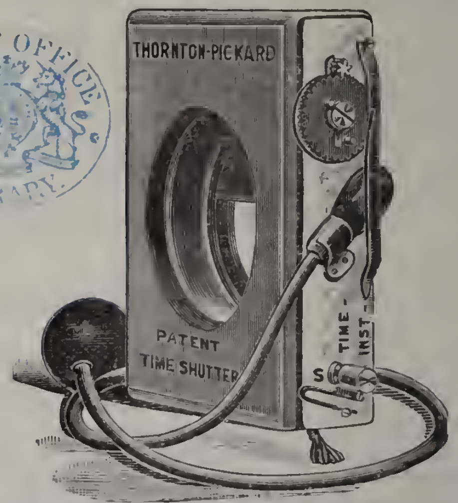
5. Photographs should be sent *unmounted*. Mounts of uniform size, with perforated edges for binding, to hold one whole-plate, two half-plate, or four quarter-plate views, are being prepared, and the required number will be forwarded, on application, to donors of photographs who prefer to mount their own prints.

6. Lists of photographs, copies of photographic prints, and information relative thereto, should be sent under cover to the Secretary to the Committee *at the earliest possible date*, in order to facilitate the work of registration.

Further information may be obtained from the members of the Committee, or from the Secretary, Mr. Osmuud W. Jeffs, 12, Queen's Road, Rock Ferry, Cheshire, to whom communications may be addressed.

## THE THORNTON-PICKARD SHUTTER.

This favourite form of instantaneous and time shutter has lately been much improved by the makers. In the old form of this apparatus, the lever for setting the shutter at either "time" or "instantaneous" had to be manipulated after every exposure. This is no longer the case; once set, it will do for any number of exposures until altered by



the operator. We also note that a speed indicator has been added, a glance at the dial of which will show at what speed the instrument is working. There are several minor improvements which add greatly to the efficiency of the shutter. At all speeds it works with extreme steadiness, and there is no chance of vibration being communicated to the camera to which it is attached.

Hackney Photographic Society.—A meeting was held on Thursday last, when Mr. Howson gave a demonstration on gelatino-chloride paper, and spoke of the permanency of the print, quoting Mr. Chapman Jones as an authority.

Gold in solution is said to be contained in sea water, and a number of chemists have interested themselves in analysing the water of the sea for the purpose of settling this much-ventilated question. The results of their investigation have proved beyond a doubt that sea water contains both gold and silver. A number of chlorides, sulphates, bromides, and iodides found in the water of the sea have, to a limited extent, the power of dissolving the two precious metals. A distinguished German chemist some years ago determined, by actual experiment, that a ton of sea water contains one grain of gold held in solution by the iodide of calcium. The quantity of silver is much larger. Sheets of copper taken from the hulls of ships which have sailed through the tropical seas are often so rich in silver as to be worth smelting. One of those statisticians who are fond of dealing with immensity, calculates that the sea holds in solution over 2,000,000 tons of silver, or about £15,489,600,000, a sum about ten times as great as the entire computed silver product of the world from the earliest times to the present day. No available process has been invented to extract the precious metal from the water, however; so, for all practical purposes, it is lost to the world's use.—*Science Siftings.*

## A PLEA FOR AN OLD PRINTING METHOD.

It seems to be an established fact that the demand for photographs has for some years been diminishing, and it is not now nearly as great as it was, say, ten or fifteen years ago; and the question, "Why do people now not buy so many photographs as in former years?" has been discussed at considerable length in some of our British contemporaries. Various causes have been assigned to the admitted falling off in the demand, among them the fact that among the thousands of amateurs that have been brought into existence by the advent of the gelatine plate, many who were, or would have been, buyers are satisfied with their own productions, as, although less perfect than those of the more experienced professional, the added interest of self-creation more than makes up for the deficiency.

This is plausible, but will only to a limited extent account for the decrease of the demand. A much more important factor is the fact that people are tired of the at one time omnipresent album, with its uninteresting array of expressionless figures, of whom those who were expected to examine and admire knew nothing, and about whom they cared as little. Tired also of the larger pictures mounted on heavy cardboard, and accumulating beyond all convenient methods of handling and storing; and possibly tired also of the "pretty" silver prints, with their minute detail, glossy surface, and limited range of colour. One of the wise men of the East hit the nail on the head when he suggested the printing of pictures on sheets of thick paper large enough to leave a wide, clean margin, so that, like water-colour or other drawings, they might be stored in portfolios and examined in comfort.

It was further suggested that the print should be made in platinum or carbon, or some of the more modern processes; but some of these are expensive and others troublesome, and, for the amateur whose means and time are limited, and who delights to give pleasure to his friends by presenting them with choice specimens of his work, something easier and less costly must be resorted to.

In looking over a collection of prints made in 1855, we think we have hit on the right thing. They are 8 by 6 prints on 12 by 10½ inch sheets of paper, giving a clean margin of two inches on top and two sides, and two and a-half inches at bottom. They seem as fresh and bright as when printed, although the paper is toned down a little, and might readily be mistaken for photogravures just from the press. A reference to our notebook shows that they were made on Turner's heavy, smooth drawing paper, salted by immersion, some in common sea water, and some in a 5, 7, and 10-grain solution of common salt, and sensitised by floating on a solution of silver nitrate and citric acid. Some of them were toned in the old "fixing and toning bath," and some simply fixed in a fresh solution of sodium hyposulphite, the latter being, if possible, finer than the former, a warm purple brown.

During the past week, we have made a series of experiments on those lines, and are very much pleased with the results, the pictures being, according to our taste, much superior to ordinary silver prints from the same negatives. The only difficulty in connection with the method is that of getting a suitable paper. We were anxious to utilise something made in this country, and so save the absurd tariff exactions that so hamper and restrict American art, and therefore tried a number of samples obtained from one of the wholesale houses of the city. Several of those answered the purpose admirably, except for minute spots, evidently caused by the presence of metallic particles. The best—and it was almost free from those blemises—was a heavy sample watermarked "Ledger Mills," and it leaves very little to be desired. The outcome of those experiments is included in the following instructions, which, if carefully followed, will result in the production of prints that will be thoroughly appreciated by people of artistic taste.

Cut the paper into the required sizes, with a wheel trimmer, or knife and straight edge, so as to prevent ragged edges—7 by 5 negatives should be printed on sheets at least 11½ by 9—as the less handling, even after only salting, the better; and any convenient quantity may be salted at once, as, if kept dry, it will keep indefinitely. Immerse it, sheet by sheet, in a 5-grain solution of common salt; slightly different shades are produced by varying the strength up to ten grains to the ounce, but we prefer that resulting from the weaker bath, taking care that no air-bubbles are formed. After all are immersed, turn the lot upside down, and take them up one by one, and hang up to dry. They dry flat, and will remain so if kept between the leaves of a book or under pressure. Make a sensitising bath as follows:—

| | |
|---|---|
| Silver nitrate ... ... ... ... | 1,200 grains |
| Citric acid ... ... ... ... | 300 ,, |
| Distilled water ... ... ... | 20 ounces |

A precipitate of silver citrate may probably be formed, but will dissolve on the application of heat—place the bottle in warm water, or on the top of a warm stove—and remain in solution. Make pencil marks on one side of each sheet, and float them in the ordinary way, marked sides up, for two or three minutes, examining carefully for air-bubbles, which seem to come more freely on plain than on albumenised paper, and dry and keep under pressure. We have not had an opportunity of testing the keeping qualities of this paper, but the probability is that it will keep as long as the ordinary "ready sensitised" article of commerce.

To prepare the negative for printing, cut "needle-paper"—or anything thin and opaque—into strips a little broader than the intended margins, and paste them along the edges of the negative on the film side, covering all that is to be left out. The printing should be done in diffused light; but that can easily be accomplished, as the paper is considerably more sensitive than ordinary albumenised paper. Print deeply, and, without washing, place in a 1 to 8 solution of sodium hyposulphite for ten or fifteen minutes, wash thoroughly, and hang up to dry. The colour will be a warm purple brown, very pleasing, and suitable for most subjects. If a deeper purple, or even a darker colour, is desired, add one grain of gold to the eight ounces of hypo solution, and, if the proper shade is not reached before ten minutes, leave it till toned as desired; but if the desired shade is reached in less than that time, the print should be removed and placed in a simple solution of hypo for the remaining time necessary to make up the full ten minutes.—*The Beacon.*

Endurance of a Daguerreotype.—A remarkable example of the enduring qualities of the Daguerreotype is to be found in the old graveyard at Waterford, Conn. In the headstone that marks the grave of a woman who died more than forty years ago her portrait is inlaid, covered with a movable metal shield. The picture is almost as perfect as when it was taken.—*Detroit Free Press.*

## Notes.

A representative committee has been formed in connection with the proposed testimonial to Dr. Maddox, to whom is due, more than to any other one worker, the gelatine process which has revolutionised photography. The subscription list is headed by a handsome donation from one of our principal manufacturers of dry plates, and others will no doubt follow suit. But, beyond the manufacturers, the users of dry plates should not neglect this opportunity of testifying to their indebtedness to the labours of this pioneer worker. The modern amateur owes his photographic existence to the gelatine dry plate, for there is not one in ten thousand who would, for the sake of a hobby, undertake all the mess and labour connected with the bath process.

Many of us are prone to exercise an economy in small matters which too often turns out to be extravagance in disguise. Perhaps it is the outcome of that misleading proverb which tells us that if we take care of the pence, the pounds take care of themselves. But, whatever be the reason, many of us will take infinite pains to make for ourselves that which we can buy far cheaper and of much better quality than the home-made article. A sad instance of this recently came up at a coroner's inquest. The young lady assistant to a photographer, without the knowledge of her employer, essayed to make some retouching medium from a mixture of resin and turpentine, believing that she could make it much better than the usual manufacturers. She placed the inflammable mixture on an open fire, with a fatal result. Although the poor young thing did not actually die of her burns, they were the indirect cause of her death, for the debility which they brought about rendered her unable to withstand an attack of fever which supervened.

Londoners have already had one or two reminders that the fog demon is in their midst, and is ready to commence active operations on the slightest pretext. It behoves photographers, therefore, to make the most of the few bright days which may be vouchsafed to them, for they may be quite sure that there will not be much sunshine during the next few months. Taking the December of 1890 as a guide to the probable conditions of the ensuing month, we find that the sunshine recorded was as follows at the different stations. Eastbourne came first, but even that bright seaside haunt could only boast of 38·0 hours of actual sunshine, although, no doubt, it had plenty of fine days upon which the sun was but thinly obscured. Woburn comes next with 13·4 hours, Greenwich with 2·4; Kew had only eighteen minutes, and the weather clerk at the station at Bunhill Row was only able to register six minutes of sunshine for the whole of the month.

If meteorologists would only prophesy better things for us in the future, we could breathe the fog-laden atmosphere with a little more equanimity, but they tell us that things are getting worse instead of better. Each year shows a palpable increase in the number of dark days, and we must expect this increase to go on until it ends in continual darkness, when photographers will find their occupation gone altogether. The only remedy lies in the possibility of persuading householders to give up the burning of coal, and to substitute for it gas and coke; for the bulk of the fog demon's stock-in-trade comes from the imperfect combustion of coal. We should still have fog if the coal nuisance were done away with, but it would be of the clean variety, like the white mist that blows in from the sea over the hills in South Devon—a mist which leaves no oily residue behind it, and which always has a "silver lining."

Adventurous travellers who are also photographers would do well to read up the experiences of their predecessors who have essayed to take the portraits of savages. The latter have very strong opinions on the subject. The matter is exhaustively treated by M. Lagar Popoff in the *Revue Scientifique*. M. Popoff says that, in a tribe of Western Africa, it is dangerous to make a portrait of the natives, because they are afraid that, by some kind of sorcery, a part of their soul will pass into this image. Of special interest to photographers is the observation of Sir John Lubbock that the more like the portrait, the greater the danger to the original, for the more life there is in the copy, the less must be left in the person. Catlin tells a story that, when he was drawing the profile of a chief named Matochiga, the Indians around him seemed greatly moved, and asked him why he did not draw the other half of the chief's face. Said they, "Matochiga was never ashamed to look a white man square in the face," and one remarked to the chief sportively, "The Yankee knows that you are only half a man, and he has only drawn half of your face because the other half is not worth anything." The result of this remark was a fight, in which Matochiga was killed by a bullet which struck him in the side of the face that had not been drawn. It is certainly a singular fact that, no matter what the quarter of the world may be, savages have a horror of photography.

The value of a telescope of high power is now being tested by Professor Holden, who is making a series of photographs of the moon with the assistance of the Lick telescope. A projection on the surface of the moon fifty feet high casts, it is said, a shadow large enough to be distinguished through this telescope, and if Professor Holden should discover some day a new shadow where none had been cast before when the moon was at the same position, and under the same light, he would know that something had been erected on its surface, either the result of some internal movement, or, possibly, a building put up by living creatures. If the inhabitants of the moon are sufficiently advanced in astronomical science to take similar observations of the surface of our earth, the Eiffel Tower must puzzle them not a little.

Photography has an awkward habit of running counter to the theories of scientists. For instance, it has long been held that forked lightning has no ramifications—that is to say, it has a single path, and does not spread into branches. A photograph taken by a correspondent of *La Nature*, and figured in the last issue of that journal, contradicts the theory. The photograph was taken during the night of July 26th, 1891, at St. Palais-sur-Mer, at the mouth of the Garonne, and M. Tissandier, who records the phenomenon, says that the photograph shows details which the eye could not discern. The figuration shows a multitude of forked streams of light altogether new in one's experience of lightning.

## SUN-SPOTS.

BY JAMES MEW.

Wieland, in one of the cantos of his "Oberon," tells how, when Huon and his beloved Rezia have been cast upon a desert island, the knight, after much difficulty, procures for his starving sweetheart a glowing fruit, which he holds up before her closing eyes in the last red rays of the setting sun. Rezia recovers a little strength at the gracious sight, and thanks heaven in a short extempore prayer for its providential munificence. But when Sir Huon cuts the fruit—upon which the lady's hope, but nothing else of her, had already fed—in twain, he finds the gorgeous golden apple mouldy to the core, and more bitter than the bitterest gall. This story of disappointed expectation may be well applied to the majority of mundane matters, and among them to the history of sun-spots. Since the time of their first discovery—a time very remote, probably, if, as we are assured, they can be sometimes seen with the naked eye—cause after cause has been assigned with anxious persistence for their appearance; cause after cause which, for a season, has satisfied the sense of scientific curiosity, but has been found, on more prolonged examination, wholly unsatisfactory or absurd.

Of the many respectable opinions on this subject given at various times by celebrated astronomers, since Thomas Harriott, in 1610, drew his two hundred diagrams, the first—if, indeed, he was the first—to transfer to paper these interesting phenomena, some few may, perhaps, excite the languid interest of the ordinary reader of the present period. Spots have been supposed to be planets revolving round the sun, crusts like the scum of boiling liquor in a saucepan, excavations, rocks, clouds, masses of sulphur, and vomiting volcanoes. But the strangest conception of all about them was that of Tobias Swinden, M.A., a rector of Cuxton, in Kent, who, just a hundred years ago, gave out his idea—rather, as was to be expected from his office, religious than scientific—that they were probably clotted companies of the souls of the damned. Passing over the opinions of Bruno, Kepler, and Fabricius, we come to a work wholly taken up with sunspots, bearing the bizarre title of "Rosa Ursina, or the Ursine Rose."

Christopher Scheiner, the author of this remarkable production, a folio volume containing some eight hundred pages written in Latin, and published in 1626, was a German astronomer and Jesuit. He devised considerable improvements in the helioscope, and disputed with Galileo the honour of having first discovered sun-spots. How far either of them is entitled to this dignity is by no means clear. The fantastic title of his book was chiefly due to its being dedicated to a certain Paul Giordano Orsini, a duke of Bracciano, whom he addresses in his preface in terms of the most extravagant and fulsome flattery. These terms were, however, probably the outcome partly of Scheiner's want of pence, and partly of the naughty fashion of the period in which he lived. The book, we find, was printed by the duke's printer, and, it may be safely concluded, at that dignitary's expense. Punning on the duke's name, Scheiner says he has fashioned his book with the same care with which a bear licks into shape her cubs, and a picture of that interesting business is presented to the reader, the more to impress the matter on his memory. The Orsini family, according to Scheiner, has the nature both of the sun and the rose; its colour and splendour is diffused throughout the world. Earth, indeed, is not large enough to contain the glory of that family, therefore the sun and the bear run to execute its orders in the skies.

It is interesting to note, after this panegyric, that this particular duke, Paul Giordano, strangled his girl-wife, Isabella, one night with a rope which he had hidden under his pillow for that purpose. He had, it is said, conceived some quirk of jealousy arising from her father's extreme affection for her.

Perhaps Scheiner's book is the most important contribution to what some egregious person has called by the detestable name—happily not yet admitted into our dictionaries—of "sun-spottery." The sun shall give you marks —*sol tibi signa dabit*—is his motto, wittily chosen from Virgil's "Georgics." The Jesuit's volume, accordingly, contains some four score pictures of these marks, carefully designed by him from A.D. 1618 to 1677. Certain marks are these, he assures us, and not the bastard offspring of any failing or fallacy of sight. He gives an exquisite explanation of the telescope, or optic tube, as he calls it with the author of the Paradise Lost, through which he inspected these solar marvels, and describes a machine by which such phenomena may be still more easily observed. Having regard to the title of his book, he compares the numerous difficulties he met with in the investigation of his subject to the thorns which surround the rose. In the successive unfoldings of the leaves of that flower he sees reflected the results of his daily investigations, conducted, he declares, with long patience and indefatigable study. "Oh happy souls!" he says, referring perhaps to himself and his companions, or perhaps to earlier astronomers, "Oh happy souls of whom it was the care first to study such things as these, and to ascend into the heavens' starry homes!" The original, in the "Fasti" of Ovid—

> "Felices animæ, quibus hæc cognoscere primis
> Inque domos superas scandere cura fuit."

has, in our later days, met with a translation which would certainly have surprised the learned Jesuit, so wholly diverse is it from his own version: "Oh lively cats! whose especial concern it was to look after these matters, and always to climb on to the tops of our roofs."

Scheiner did much for sun-spots; he divided them into classes, simple and mixed; he noted their different colours, white, green, blue, brown, and yellow, and tabularised their changes of brilliancy; he grew eloquent about their shapes, round, oblong, triangular; he found some spots equal in size to Europe and to Asia, and others larger than all Africa; he noted the celerity of their motion, and found them quicker in the south than in the north; he observed their increase and decrease, and declared that the former was not by rarefaction only, nor by superficial extension only, nor by alteration only, nor only by local motion. He gave instances of many spots coalescing into one, and wrote much about the relation of maculæ and faculæ, the dark and the bright; he proved them to exist by daily motion, and the absence of parallax; and he did a great deal more, which anyone who cares to consult the original may see for himself.

It was a distinct epoch, the beginning of a new era, a red-letter day in the calendar of astronomical research, when photography at last, after encountering and vanquishing, like a second St. George, that well-known—too well-known—dragon of ignorance, the spectre on the threshold with which science must needs wage internecine war, achieved the hard won but fully deserved position of assistant inspector in all departments of stellar observation and research. The true story of the photosphere or solar surface commenced with the portraits taken by the camera of those remarkable spots, varied and unstable as Proteus or a woman, which Nasmyth described as willow leaves, and Dawes as straws, and Stone as rice grains, and Spörer as macaroni. When doctors disagreed, as doctors, even the best of them, will disagree, in the resultant impressions of their study of these solar phenomena, who was to decide the matter, unless the camera?

Surely the best means of studying the sun was by the sun itself, and the camera failed not. It showed that all these varied images were true under varied conditions. It was the old story of the chameleon once more repeated. When the surface of the sun was calm, then we had the rice grains; when it was disturbed by gaseous currents, lo! there were the willow leaves. Nothing could be more simple or more satisfactory; but alas for these photospheric accidents! There was disagreement among the doctors still. In July, 1882, came a sudden outburst of spots in the north-west provinces of India. Photographs were taken of this outburst. Apparently all was well, and would, no doubt, have continued so, had not the demon of discord—a second Satan in the celestial regions—whispered something about blemishes on the negatives. *Ibi omnis effusus labor!*

The appearance of spots seems altogether arbitrary and capricious. Tacchini found two hundred and ninety spots in five months in 1871, and during the same period in 1876 only twenty-four. When these eruptions in the solar mass are few, says one authority, we may believe that the sun is in a condition of comparative repose. The truth, says another, is rather the reverse; spots then break out and vanish with much greater rapidity. On April 14th, 1877, Janssen could discover no spots; on the next day they were clearly seen in considerable numbers. The daily solar photographs in the observatory at Kew give equally conflicting pictures. At present the generally accepted opinion is, that sun-spots are openings in the shell or rind of fluid fire through which the darker interior is exposed. Not otherwise, indeed—to compare small things with great—is discovered the blackish, indigestible compound of a wedding cake when we remove a portion of the snowy surface—technically known to pastry-cooks as the "ice." Sun-spots, cavities down which, we are told by the learned, hydrogen rushes at the rate of forty miles in a second, are rare at the equator, move at different rates of speed, circle our greater luminary in twenty-six days, vary in numbers, and last for uncertain periods—some, like the dragon-flies, having an ephemeral existence, others maintaining for a month their vital energy. Schwabe, who is said to have studied these spots, nucleus, umbra, penumbra, and thatch, for some half a century of years, supposes that there is in every dozen annual revolutions a recurrence of their maxima. The last maximum was in 1882. The number and extent of spots has been lately largely increased; we are fast moving onwards to another maximum. People, other than those interested in astronomy, may receive this announcement with cold indifference. When a fire is raging a mile off, we gaze at the smoky glow in the sky with comparative unconcern; but it becomes another matter when our neighbour's wall is burning. Then, indeed, our sympathies are aroused; then, with the amiable philosopher in Terence, we think all that is human nearly concerns ourselves. So, if he reads onward, the most careless of men may feel an interest in the spots on the sun.

An extraordinary power has been given to them. They have been held—as eclipses were once held, while their causes were unknown—to influence the season's changes, the price of wheat, the course of trade, and the general estate and condition of man. This is a throwing back to astrology, and should increase the sale of Zadkiel's Almanac. Between the time of the South Sea scheme and the present, some fifteen commercial crises have, we are informed, arisen, all of which have been connected by the ingenious with the appearance or disappearance of sun-spots. It has been shown, to the satisfaction, at least, of the showers, that the price of food rises and falls as spots are few or many. One able observer went so far as to find in them enemies to a political movement. As the stars in their courses fought against Sisera, before that true and single-hearted Jael brought him butter in a lordly dish, so spots on the sun fought, in the conceit of that observer, against the Irish Land League. Scoffers have regarded all this in the light of idle talk. They have asked whether the prices of food have been affected by sun-spots simultaneously throughout the globe, or whether Great Britain is alone concerned with them? They have inquired whether to these may be also attributed the alarming rise in the value of oysters? In fine, these sceptics have looked on spots on the sun as of far less importance—in the matter of astrologic prediction—than the spots on their own faces. But when they have been shown that not only Africa, as the old Jesuit says, but the whole of our globe can be easily contained in one of these spots, could pass through them, indeed, as easily as a pea through a pea-shooter, they may possibly—but they are a stiff-necked generation, and God, as the Arabs say, is the most knowing—see fit to alter their opinion.

## ORIGINALITY IN POSING AND LIGHTING.

BY XANTHUS SMITH.

MY attention has been called to "Originality in Posing and Lighting" as a subject appropriate for some remarks by me, and, while at first sight it would appear to offer an opportunity for the production of a paper embodying some new and good ideas, a further consideration of the theme brings one to the question at the outset, whether there truly can be such a thing as originality displayed now in posing sitters and lighting them? We certainly must admit that, if anyone could point out an entirely new path for the portrait photographer—one which would lead him to show cases filled with fascinating pictures of such handsome looking people that every passer-by would not only be attracted by them, but would be seized with an inevitable desire to be portrayed in the same style—a great benefit would be conferred upon not only the photographer, but the public generally.

Unfortunately for the explorer in new directions of portraiture, there are some barriers as insurmountable as the great ice wall of the Antarctic regions. We have to deal with things as we find them. Could we reconstruct our sitters, and remould them in conformity to individual freaks of taste and fashion, then, indeed, would there be new and startling ways open to us for posing and lighting. If, on placing a sitter in the posing chair, in addition to twisting and tilting his head about, we could reshape his features in the same manner that a lump of putty may be dealt with, then only might we set at naught those critics who scoff at the old conventional three-quarter face with a top and side light somewhat in front. But this we cannot do. The head is globe-shaped; the nose, except, perhaps, occasionally in the case of pugilists, is always the most prominent feature, and, as the laws of light and shadow are inexorable, we must abide by them.

Undoubtedly novelty is always attractive. It is attractive by virtue of its newness. But it is not always agreeably attractive—as we see in the matter of novelty in dress; what strikes one as elegant and appropriate appears entirely the reverse (indeed, often quite absurd) to another —and where there are certain principles and rules of good taste governing a matter, as is particularly the case in the making of portraits, by reaching after new and startling effects, while we may attract a few untutored or unthinking people, on the other hand we may be lowering ourselves in the estimation of the more sensible majority.

The matter of posing and lighting sitters occupies an entirely different place to-day from that which it did ten years ago. During the last decade, owing to the large incoming of amateurs, the amount of experimental and accidental work which has been done may be said scarcely to have left a single untried pose or effect of which photography is capable.

Prior to the adoption of the dry plate there were very few amateur photographers, and by far the majority of those who practised the art devoted themselves to landscape and architectural subjects. The professional photographer, of course, always worked in a skylight constructed in accordance with certain established rules, thought best for lighting sitters; and, therefore, pictures of people taken off-hand, under every-day surroundings and conditions, were very rare. Now, it may fairly be said that everybody photographs, from the schoolboy to the man grey in years, and the fair sex, young and old—the latter furnishing us some of our finest productions of the art; and a large portion of the work done by these numerous and busy amateurs being portrait work, do we not have an opportunity of beholding the utmost originality displayed in posing and lighting, including both studied and unstudied effects? And how often, after all, do we see amongst this multiplicity of work any that will compare in success with that of the professional photographer possessed of knowledge and good taste—open as his work may be to the criticism of conventionality? And why? Simply because, as I said at the outset, there are certain laws of nature and certain rules of good taste governing the whole subject, which cannot be set aside without offending.

Simply touching upon the matter of a certain propriety and grace in attitude, which the rules of society call for, and which we dare not stray from without becoming vulgar or ridiculous, in lighting alone, of all heads which we see posed by untutored amateurs in ordinarily lighted rooms, under porches and amongst shrubbery, what do they amount to? How many in the hundred fill the place to those who wish to have their picture taken, and be done justice to, of the regularly posed head in a proper skylight? All that we can say of the most of such work is, that it is beneath criticism as portraiture.

Turning, then, to the work done by the best professional photographers, we find them constantly striving for novelty, partly through a desire to produce something which is more excellent, in an artistic way, than what has yet been done, and partly to attract sitters, and thereby increase the business and the income, and we find that, just in proportion as they deviate from certain limits, and run into the new and the startling, just in so much do they run the risk of producing effects which pall upon the taste of the observer when the brief pleasurable sensation of the first impression has worn off.

Take, for instance, a handsome lady, place her in a natural, easy attitude, with the "old conventional top and side light somewhat in front," and, having secured a calm expression, so photograph her; and then photograph her again, posed elaborately, with her head twisted in an opposite direction from her shoulders, and thrown very much up, and the face wearing a bewitching smile, and lighted in any way you please except that adopted in the previous portrait; and of the two pictures see which will be likely to give the most lasting satisfaction, will be the best suited to go down to posterity as a likeness of the lady. Of course, the more we include in our portrait subjects, the more we enlarge our scope for originality in composition. When we make whole-lengths, and groups, with accessories, we can give scope to what fancy may dictate to us; but our difficulties then increase many-fold. The present attire of the male, though comfortable, can neither be said to be very dignified nor graceful, and, just in proportion as we admire the latest attractions in dress of our female friends at the moment of their production, so do they seem out of place or absurd to us when they have been set aside some months, subsequently to give place to others.

To be convinced of the unpleasing effect of peculiarities in costume, we have only to look at any collection of full-length photographs extending some years back. The more elaborately the individuals were gotten up for the occasion, and the more imposing the effect striven after, the less do we see in the picture to seriously interest us. We find ourselves at once critics of costume and furniture, instead of admirers of humanity.

Let those who have the opportunity of doing so, and are sufficiently interested in the subject, go and examine the fine display of work in the show windows of leading photographers, where the proprietors deal with the best trained of society, including those prominent on the stage, furnishing the best means for a display of originality in costuming, posing, and lighting, and see how narrow the line of propriety is, and how, in striving after a new pose or effect, for one successful hit we are only too apt to have to point to a dozen failures.

In conclusion, we must say that we give up the problem of pointing out any strikingly original scheme in the art of posing and lighting sitters for their portraits, and can only suggest that in securing softness and breadth of light and shadow, ease and general simplicity, we are always working in a safe direction.—*American Journal of Photo.*

---

Photographic Society of Ireland.—At the meeting on the 13th inst. (Mr. George Mansfield, J.P., in the chair), Mr. H. M. Smith, of the Eastman Company, gave an exhibition of lantern slides made from kodak negatives.

Decimal Weights and Measures.—A communication has just been received from the British Consulate at St. Petersburg to the effect that in Finland the use of metric weights and measures will shortly be compulsory. For some time past there has been a decimal coinage, and the metric weights and measures have been obligatory for the Custom House, the State railways, the Post Office, and pharmaceutical chemists, but after 31st December next the old system of weights and measures will no longer be permitted in any public or private establishment. The measurement of public roads has already been changed from *versts* to *kilometres*. In Russia the metric system of weights and measures is already used by medical men and chemists, and its general adoption is more than probable.

## THE NATIONAL ASSOCIATION OF PROFESSIONAL PHOTOGRAPHERS.

A MEETING of the Council was held on November 9th at Anderton's Hotel, Fleet Street, London, the president, Mr. H. J. Whitlock, in the chair. There was a large meeting of the Council, representatives from the North, Midlands, Yorkshire, Devonshire, London, &c., being present.

The appointment of Mr. D. J. O'Neill (of Birmingham) as secretary was unanimously confirmed.

Considerable progress was made with the general business of the Association, occupying the Council several hours; and a further meeting was held on November 10th.

The vexed question of certain firms of "enlargers" supplying private persons, entirely outside the pale of *professional* photography, with trade lists and trade prices, was carefully considered. These firms, for a long time past, have been doing the work indiscriminately for the public at the same price charged to the professional photographers. The Council decided to bring this great injustice and unfair dealing to the notice of these firms, with a view to a proper trade list for materials and work being issued, for the protection of the professional photographer. The secretary was instructed to inform these firms of this decision. There is a strong determination on the part of the members—and the profession generally—to do business only with those firms who deal fairly with them in this vitally important matter. The secretary was instructed to convey the thanks of the Council, and promise of support, to several firms who have already issued lists protecting the profession from such unjust dealings.

The first annual meeting of the Association will be held on the second Thursday in February, 1892, at 7.30 p.m., at Anderton's Hotel, Fleet Street, London, at which all professional photographers will be heartily welcomed by the Council.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Nov. 26th, "Protecting the Negative during Printing"; Dec. 3rd, "The Exaggerated Perspective of Wide-angle Lenses"; Dec. 10th, "Warm Tones in Lantern Slides."

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—At the technical meeting to be held on Nov. 24th at 50, Great Russell Street, the subject for discussion will be "The Negative, and how to make the best of it." An example of photography in colours by Becquerel's process will be shown.

A CORRESPONDENT of *Help* thus describes his method of using the limelight for lantern projection:—"I have a bi-unial lantern, and use both hydrogen and oxygen from cylinders, as supplied by the Birmingham Oxygen Company, using Beard's regulators on each bottle, and find very little trouble therewith after once regulating the same. Where there was gas to be obtained, I dispensed with the hydrogen, and attached the tube to the nearest gas bracket. I found this was not so good a light, and I set to work to make it better, and got a tinman to make me a sheet-iron cylinder, 15in. long, 4½in. diameter, with a gas stop-cock at each end; inside I put a 1½in. spiral spring wrapped round with wadding. I charge this with benzoline, and allow it to drain, and then attach to tube between gas and jet. The gas gains in brilliancy twenty-five per cent. by going through this cylinder. For screen frame 16ft. square, I use ½in. gas piping (iron), cut into sixteen lengths 4ft. each, and have by me four 2ft. lengths, so that I can use a screen 8ft., 10ft., 12ft., 14ft., 16ft., or 18ft. square. I use the blow-through jet, and find the Nottingham hard limes are the best to use. The average expense for one exhibition, including hire and carriage of slides, gas and carriage, conveyance of apparatus to and from place of meeting, is eighteen shillings."

## Reviews.

SUN ARTISTS. Number 8. *(London: Kegan Paul, Trench, & Co.)*

THOSE who have made themselves acquainted with the beautiful photogravures issued during the past two years by this ambitious publication, will regret to learn that with the present issue the series comes to an end. The honorary editor gives a half promise, however, that publication may be renewed on broader lines later on. The concluding number is up to the high average of its predecessors, the works reproduced being those of Mr. Sutcliffe. These are, as usual, four in number, and the pictures selected are "Water Rats," "Dinner Time," "Excitement," and "Sunshine and Shower." These pictures are too well known to need a word of comment. We understand that some sets of previous issues of *Sun Artists* are still to be had, and those who are interested in the artistic side of photographic work cannot do better than secure them.

LIGHT. An Elementary Treatise by Sir H. Trueman Wood. *(London: Whittaker & Co.)*

THIS is a well-written manual, forming a volume of Whittaker's Library of Popular Science. It is by no means an easy matter to write in a simple and easily understood way of such subjects as interference, diffraction, spectrum analysis, fluorescence, and polarized light; but the author has done all this in the book before us most successfully. The volume will therefore be eagerly read, and probably largely borrowed from, by teachers in elementary schools. We are sorry that the illustrations are not original. There is a growing practice among writers of borrowing electros from other works, and it is one that cannot be commended. A good book is worthy of new illustrations.

AN INTRODUCTION TO THE STUDY OF BOTANY. By Edward Aveling, D.Sc. *(London: Swan, Sonnenschen, & Co.)*

PHOTOGRAPHERS cannot, in these days, afford to be ignorant of any branch of science, for photography is the handmaid of all. If they want to get an insight of the principles of botany, they cannot do better than study Dr. Aveling's volume. It is written in a simple manner, and readers are not frightened away by a glance at the first chapter, which is our experience of certain text-books which might be named. The 300 pages contained in the volume include nearly as many illustrations, and a glossary of more than 600 words. The book is well printed, and turned out generally in a very creditable manner.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The third annual exhibition was held on November 16th, when about 400 pictures were on view. These were judged by Messrs. Cembrano, Pringle, and Leon Warnerke, and the following were the awards:—Silver medal—C. H. Oakden, for best general exhibit; special bronze medal—Mr. H. Esler, ditto. Silver medals—E. A. Whitby (best picture, half-plate and under), T. S. Bailey (best picture over half-plate), T. C. Kirby (portraiture). Bronze medals—W. Howell (local views), W. Rice (lantern slides). Mr. Edwards' work was not for competition. The exhibition was of a much higher class than last year, and the room was at all times well filled. The subject for Dec. 7th will be "Photographic Optics," by Mr. Crouch; Dec. 21st "Printing Process," by Messrs. Edwards, Herbert Whitby, &c.

## Patent Intelligence.

### Applications for Letters Patent.

19,056. Henry Vander Weyde, 53, Chancery Lane, London, "Improvements in Reflectors and Appurtenances used in Electric Light Photography."—*November 4th.*

### Specifications Published.

19,714. *December 3rd,* 1890.—"Improved Focussing Attachment for Photographic Instruments." J. P. Bayly. (Frederick Quimby, of Quincy, Mass., U.S.A.)

This invention relates to an improved focussing attachment for photographic instruments, and comprises a hood or bonnet provided with means for attaching it to the focussing screen of the camera. Two projecting eye-sockets are held on the hood at its end opposite to that attached to the focussing screen or plate, and these two eye-sockets are joined by a nose bridge held on the hood. A cord is attached to the two sides of the hood, and is adapted to pass around the head of the person looking through the eye-sockets. The hood can be telescoped or lengthened without the aid of the hands.

19,934. *December 6th,* 1890.—"Storing Photographic Plates." J. B. Brooks, 115, Great Charles Street, Birmingham.

This invention consists in a frame into which the glasses or negatives can be readily placed during the process of washing, drying, storing, &c., and is specially adapted for use in a darkened room. The frame is made preferably of metal, and has raised parts or divisions standing up prominently at each side opposite one another. These divisions are so constructed that the spaces are wider at the top, so as to readily admit the plates, and taper near the base, so as to fit the plate and keep it upright when slid into position. This frame is then inserted into a washing box or trough, the water passing into one end of the box and out at the other. For drying or storing, &c., the frame, if desired, may be pitched so as to cause it to drip at the corners.

20,653. *December 18th,* 1890.—"Detective Hand Photographic Camera." Sarah Tucker, Nethway, Cotton Lane, Moseley, near Birmingham, and William J. Spurrier, Queenswood Road, Moseley, near Birmingham.

The object is a magazine photographic comera, and it consists of a metal or other body fitted with the necessary lens, shutter, and fittings, and a magazine containing a supply of rims or frames for the sensitised dry plates, which magazine, when not in use, is carried in the camera, which is provided with a door to admit the same. To the top of camera is secured an upright rim with a catch or catches into which fit the corresponding projections of the slides of the magazine, which contains from six to twenty-four or more dry plates, and is constructed with a blank or block of greater thickness than the plate rims into which the plates are inserted, and to this blank or block is attached an arm extending to each side of the magazine provided with points extending below the lid. Between said arm and block is inserted an inner lid having a slot to allow the block, with indicator, to pass from one end of the magazine to the other. Each end of the bottom of the magazine opens with a sliding motion, allowing the outlet or inlet of the plate, and attached to these slides are the necessary projections. The magazine fits into the upright rim on the camera, and the projections on the slides fit into a catch or catches on the sliding cover, also on the camera. For the purpose of readily carrying the camera by hand, a loop handle is provided of such length as to allow it to be turned either over the camera or magazine, the ends of which are attached one to either side, and at the top of the camera. A focussing screen is also provided, jointed to the bottom of the camera, whereon it will lie; it can be raised into position by a suitable catch.

15,615. *September 15th,* 1891.—"Photographic Apparatus." W. P. Thomson. (E. E. Moore, of Syracuse, New York, U.S.A.)

Relates to devices for registering and indicating the number of exposures made, adapted to use a continuous strip or sheet of film, or sensitised paper of any kind, which is mounted upon rolls in a frame detachable from the case or otherwise. The object is to register the exposures so that the operator can always know the exact number remaining not used, by means of a geared and numbered disc or dial, and a differential feed gear meshing therewith, and actuated by the rotation of the axis of an idler roll upon which the feed gear is mounted, and which is frictionally rotated by the contact of the sheet of film therewith whenever the sheet is moved by the winding up of it into the winding-roll after each exposure.

## Correspondence.

### DERBY PHOTOGRAPHIC SOCIETY.

Sir,—I have been elected hon. secretary to the above for 1892, and lately have been receiving correspondence wrongly addressed often three or four days late. I should esteem it a favour if you would kindly insert my correct address in your next issue. Thanking you in anticipation, I beg to remain,

9, *Church Street, Derby.* Thos. A. Scotton.

### CAMERA CLUB.

Sir,—Will you kindly allow me to state that the exhibition of Mr. Ralph W. Robinson's photographs now at the Camera Club will close on Friday, November 27th.

G. Davison, *Hon. Sec.*

*Charing Cross Road, W.C., Nov. 16th.*

### LEEDS PHOTOGRAPHIC EXHIBITION.

Sir,—Will you kindly draw the attention of your readers to the fact that the committee, in response to the application of a number of exhibitors, has extended the time for receiving entries and exhibits until Thursday, November 26th.

Geo. Birkett.

*Municipal Art Gallery, Leeds, Nov. 14th.*

### DR. MADDOX AND DRY PLATE PHOTOGRAPHY.

Sir,—Is Dr. Maddox the father of the present system of dry plate photography? It has been the fashion for a long time to say that he is, but the writer of these lines knows, and feels bound to say, that he is not. If Dr. Maddox had never existed, gelatine dry plates would have been just what they are to-day. In 1873 an emulsion was put into the market quite perfect—and, for ordinary purposes, as good as any made now—by a man who never heard of Dr. Maddox until the said emulsion had made an immense sensation. They say Burgess took the hint from Maddox. What hint? Dr. Maddox made a wonderful plate 180 times slower than wet collodion, upon principles the very opposite to those now employed in making gelatine plates, and yet, forsooth, he is the father of them!

Kind reader, if you have the slightest regard for historical accuracy, don't go to the so-called histories, but hunt up the old records in the journals of twenty or thirty years ago, and there you will find a dozen pins to prick the gelatino-bromide bubble that is now in process of inflation.

Another time I will tell you just where to find them, but at present I will content myself with pointing out one fact. If Dr. Maddox had designed to conceal the most valuable properties of gelatino-bromide—speed and power—he could hardly have hit upon a more effectual formula than that with which he rushed into print. Not because he believed in it, but, as he says, to please his friend, Mr. Traill Taylor, in an emergency. All that that experiment teaches is how *not* to do it, and for that he had a gold medal. What a topsy-turvy world this is!

J. Burgess.

Fry Manufacturing Company.—The next lecture and demonstration is fixed for Nov. 27th, upon the subject of "Bromide Enlarging," and will include methods of working by daylight and artificial light, Griffith's enlarging cameras, exposure and development, vignetting, printing-in skies, and the acid fixing bath.

# Proceedings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At the meeting of this Society held on the 12th inst., Mr. J. Traill Taylor occupied the chair.

The question of the evening, "Cau Halation be Prevented by Staining the Film in any way?" was introduced, the Chairman remarking that Col. Stuart Wortley recommended yellow stain to be added to collodion emulsion for the purpose.

Mr. W. E. Debenham had experimented some years since with staiuing gelatino-bromide plates to prevent halation. The stains he had tried were saffron and logwood. Both, however, decreased the sensitiveness, the saffron-stained plate requiring about double normal exposure, and the logwood still longer. Halatiou was prevented in cases not very trying, but the results he got were not equal to those obtainable with a good backing.

A member suggested that with a staiued film the image would be thin, as the light would not penetrate deeply into the film.

Mr. Debenham replied that he had not noticed any thinuess of image. It must be remembered that, as Capt. Abney had demonstrated, development was uot confined to particles directly acted upon by light, but was continued iu the adjacent particles.

Connected with halation, though not with film staining, Mr. F. A. Bridge described a receut experience with a very trying subject—the interior of a vessel with portholes open—and had obtained a very satisfactory result by backing with caramel and burnt sienna.

Mr. T. Bolas thought the method of coating on flashed ruby glass aud subsequent stripping a good oue. He did not think the risk run in stripping so great as was supposed. It might be interesting to try some stain chemically inert as regards the sensitive film.

The discussion next turned upon the intensity of collodion negatives, and Mr. Debenham said that he had noticed that old collodiou uegatives had become more iutense with keeping. On looking out any old plate he generally found that, whilst originally it might not have been at all too intense, it had changed in that respect, and would now only yield a hard print. It was the fashion with some who had recently entered photography to assume that great intensity was almost universally characteristic of earlier production, and whether or not this might be the case with very early work, it certainly was not so any time within the last thirty years.

The Chairman's experience supported that of Mr. Debenham as to the gain in intensity of old collodion negatives. He had a number of old trausparencies, aud would look through them, and bring up the matter at a future meeting. With some intensifiers the negative gained in density afterward. This was notably the case with Sell's uraium and ferricyanide process. As this process was uow used for toning bromide prints, and the colours obtained were very beautiful, it would be interesting to know whether the prints were as liable to chauge as the negatives were.

Mr. Weir Brown said that he had brought a pareel of such prints to the Society for experiment some months since. The curator had charge of these prints, and they were being exposed, one half to light, and the other half covered. In due time they would doubtless be produced for examination.

A question from the box was read: "Can a negative produced by a pinhole be as sharp as one produced by a lens, and if so, how?"

Mr. P. Everitt said that he had noticed a photograph taken at Southampton by Mr. Henderson, and stated to be produced by a pinhole, which was as sharp as could be produced by a lens.

Mr. Bolas thought that a little misunderstanding might arise from the use of the expression "pinhole stop," when a small stop in conjunction with a lens was meant. Perhaps this particular photograph might have been produced with a pinhole stop and lens.

The Chairman thought that this was probable. A pinhole without lens could never yield a really sharp negative, as when reducing the aperture below a certain point, diffraction would step in.

Mr. Cowan said that Mr. Henderson had made a distinct statement that the photograph iu question was taken without a leus.

Another question was: "Can a large back lens be fitted to an ordinary portrait lens for lantern purposes at a small cost?"

The Chairman said that a lens specially constructed to order was never of small cost. Going to the blackboard, he showed the advantage of a large back lens in letting iu more light, and of introducing negative spherical aberration to obtain a flatter field.

Mr. Debenham said that he had an aplanatic lens of the Steinheil or rapid rectilinear form by Suter, iu which there was a small amount of negative spherical aberration. There was not more than the positive spherical aberration common in lenses of this type, so that the definition was good. The remarkable point was the flatness of field, which made it, in his estimation, the most useful lens one could have.

The Chairman had oue of these Suter lenses, which he prized highly.

Mr. A. S. Newman was elected a member.

CAMERA CLUB.

On Monday, Nov. 9th, Mr. Lyonel Clark gave the second lecture in the course of elemeutary lessons to members. The subject was "Lenses."

On Thursday, November 12th, Mr. E. J. Humphery read a paper on "Photography by Artificial Light." Captain Abney occupied the chair. There was a very large atteudauce of members and visitors, about 120 being present. Mr. Humphery described and gave an excellent demonstration of his new methods of applyiug the light of magnesium burnt in oxygen to photographic purposes. The apparatus for taking portraits consists of a glass globe charged with oxygen, in which the magnesium wire is ignited, the globe being swung during exposure. Platinotype prints were made from two portrait negatives by exposure to another form of the same light, the exposure being only fifty seconds.

During the evening Captain Abney showed a continuous flash-lamp, produced by M. Nadar, of Paris; and the Hon. Secretary handed round a lantern slide carrier introduced by Messrs. Perkins and Co., in which, by a simple device, all danger of marking the surface of the slide by the fingers was obviated.

On Monday, November 23rd, Mr. G. L. Addenbrooke will give a lecture on "Cameras and Tripods." On Thursday, November 26th, Rev. F. C. Lambert, M.A., will read a paper on "Some Aualagous Aspects of Paintiug, Music, and Poetry," and will furnish musical and pictorial illustrations.

HOLBORN CAMERA CLUB.

At the meeting last Friday evening at 100, High Holborn, Mr. A. J. Golding in the chair, Mr. T. C. Hepworth, F.C.S. (president), gave an interesting lantern demonstration. Nearly one hundred slides were shown. The first showed the difference between slides printed by contact and priuted by reducing the same negative. He next showed slides on the various makes of slides, chloride and bromide, home-made and bought, &c. The next were a large number of slides of the Isle of Man, mostly geological, showing rocks, &c. The concluding portiou of the demonstration comprised a number of London street scenes. Amougst them was one entitled "Caught in the Act," showing a man standing ou the back of a water-cart pouring water into a large milk can, whilst standing near was a cow. Mr. Hepworth said it had been said that he had posed the subject, but it was not so. He had come upon it accidentally while out with his hand-camera. Mr. Hepworth ably pointed out the lessons learnt from the slides, showing the weak as well as the strong points of them.

WEST LONDON PHOTOGRAPHIC SOCIETY.

*November 13th.*—Mr. Bilton in the chair.

The Secretary exhibited a plate showing effect of improper drying of the emulsion; Mr. Whitear, two negatives showing markings produced by placing common brown paper between the plates after exposure ; Mr. Holmes, several prints on aristotype and celerotype, and the Ilford new paper ; Mr. Rogers, the "Graphic" hand-camera, made by the Stereoscopic Company, and one on the same pattern made by himself with improvements ; Mr. Winter, a new very thin and light single slide for films, and a focussing screen to be used in connection with the same ; Mr. Varden, a hand-camera of his own design and manufacture, with swing-back and a novel arrangement of inserting and changing plates, as also a new form of tripod designed by himself, more especially for cyclists ; Mr. Leslie Selby, some platinum-toned prints on silk ; and Mr. Hodges explained the uew method of printiug on platinotype paper by artificial light, just iutroduced by Mr. Humphery, the originality of the idea being doubted by Mr. England.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

*November 17th.*—Mr. J. TRAILL TAYLOR in the chair.

Questions having been asked from the question box as to the use of Scott's warm air saturator, enlisted a variety of opinions as to its usefulness, but without any definite result.

The CHAIRMAN brought forward a circular to be issued with reference to the proposed public recognition of the services of Dr. R. L. Maddox, in connection especially with the discovery of the gelatino-bromide process.

Mr. F. A. BRIDGE then gave a demoustration of the process of bromide printing, defining the process as consisting of exposure, development, and cleaning, washing, fixing, and washing again. For development he preferred ferrous oxalate to any other developer, his formula being :—

| | | |
|---|---|---|
| No. 1.—Oxalate of potash | ... ... ... | 2 pounds |
| Hot water ... | ... ... ... | 3 quarts |
| Acetic acid ... | ... ... ... | 6 drams |
| or | | |
| Sulphuric acid | ... ... ... | 2 drams |
| No. 2.—Protosulphate of iron | ... ... | 2 pounds |
| Hot water ... | ... ... ... | 2 quarts |
| Sulphuric acid | ... ... ... | 1 dram |

with a bromide of potassium solution 1 in 40 to be used according to necessity. This formula was stated to be almost identical with that given by the Eastman Co. Formulæ for pyro development and for hydrokinone were also given, but these were not recommended, the ferrous oxalate process giving more rapidity of work, and producing better tones. Coming back to exposure, which was the key-note of all good printing, the lecturer insisted that the light used should be proportioned to the character of the negative, weak negatives being printed in a weak light, and even then often under ground-glass, with, in extreme cases, opal. For fixing, the best bath was hypo 3 ounces to the pint of water ; some had recommended the addition of ammonia, but its value was very doubtful. The great need in fixing was plenty—plenty of solution, pleuty of time—and then permanency might be looked for, even though the final washing might not be so thorough as usual. Should reduction be found necessary, a good formula was :—

| | | |
|---|---|---|
| Hypo solution ... | ... ... ... | 10 ounces |
| Water ... ... | ... ... ... | 30 ,, |
| Red prussiate of potash ... | ... ... | 1 dram |

but it must be used with great care, the action being very rapid. A great advantage in bromide printing was the facility with which good prints might be obtained from almost all kinds of negatives, the process allowing of dodging to a large extent. Cloud printing was not difficult, but required especial care in adjustment of masks, and in judging the relative printing value of the subject and cloud negatives respectively. Referring to the question of permanency, some very beautiful large prints were shown which were several years old, and were as beautiful as when first printed. Mr. Bridge then proceeded to expose and develop several prints, mixing the developer : Iron 1, oxalate 6, bromide of potassium a few drops. The exposures were to the gaslight in the room, the average time being five seconds, using Eastman's quick paper, which he preferred to slow paper, as giving by far the best results. The developments were in all cases successful, and a few prints were afterwards developed by hydrokinone, to show the difference in time and working. Remarking on the resemblance of bromide and platinum prints, it was shown by comparison that it was almost impossible, by any casual examination, to detect any difference. It was also noticed that length of soaking in water before developing was considered by the lecturer to increase the softness of the prints ; and for line subjects, and where great contrast was desired, it was best to use some old developer mixed with the new.

Mr. PARFITT showed a gas by-pass elbow for regulating the light of any burner instantly.

CROMWELL PHOTOGRAPHIC CLUB.

THE opening meeting was held in the supper-room of the Town Hall on Monday evening. Dr. BATELY (vice-president) occupied the chair. The president, Mr. R. H. Inglis Palgrave, was to have been present and given his address from the chair, but, in his unavoidable absence, he had sent the manuscript of his address, from which, as read by Mr. T. W. Swindell, the following is extracted :—"I am glad to have the opportunity of saying a few words on the manner in which pictorial art may be of interest to an amateur, from the hope that this may be a source of pleasure to many, as it has throughout my life been to me. And a study of this description is particularly valuable in a place situated as Yarmouth is, in which one of the great resources of interest and pleasure for the leisure hours of the busy and unoccupied hours of all—the opportunity of work in a garden—is a matter of difficulty to arrange for, aud through that difficulty almost unattainable by many, if not most of the inhabitants." After some remarks on the pleasures of gardeniug, the address proceeded : "The possession of a real hobby is a great comfort and help to a man, and the practice of photography has always appeared to me one of the best hobbies which a man can take up. It provides him with something which interests and amuses him wherever he goes, especially when combined with a genuiue admiration for the beauties of nature. I venture to say this because, though I have never practised photography myself, I feel that it is as much an art as the art of drawing and painting. Everyone can see this for himself by comparing a photograph of a view made by a skilful and one made by an unskilful artist. The first will take advantage of everything that is beautiful in the subject of which he desires to preserve a remembrance ; he will seize the best moment for light and shade, he will arrauge his camera so as to secure the best point of view, aud the result is that he will preserve a record which will be a pleasure to all who see it. The other—but I need not trouble you to listen to an attempt of mine to describe those errors in arranging a picture which all of you know how to avoid. All I need say is, that if you wish for a good illustratiou of the meaniug of the child's story called 'Eyes and No Eyes,' you cannot do better than look at the work of a bad photographer." The paper then dealt with the condition of pictorial art in Yarmouth some years since, and its influence ou the feeliug for art still existent in the place ; and concluded with an expression of the president's "that the studies of the Club would always be devoted to the delineatiou of that which is beautiful and pure."

Mr. PRICE read a paper entitled "Elementary Photography." Apologising for the lack of interest there might be to "old hands" iu such an elementary paper, Mr. Price ventured to hope that, at any rate, they would agree with him that, in the early stages of a photographic society, the papers read should be of such a character as to meet the requirements of those commencing the practice of photography, as no doubt many were drawn there in the hope of obtaining some useful elementary hints aud information. It was easy enough to take a negative, having the necessary outfit, but what was not quite so easy was to produce a *good* negative. He would impress upon them the importance of study, thought, and care. The best made and most expensive camera could no more of itself produce a good photograph than could a good brush paint a good picture—both required something behind in the shape of brains, and then wouders might be accomplished. The development of the negatives was, perhaps, the most interesting of all the processes conuected with photography, and one requiring the utmost skill and patieuce—skill in mixing and modifying the developer to suit the requirements of the subject, exposure, aud class of plate : patience in watching the result. Some technical information was here given which would, no doubt, be of assistance to many present. It was desirable to master one form of development, so as to have it uuder control. To be coutinually flying off after something new was to be continually putting oneself back. This was not intended to deprecate experiment with a desire to conscientiously test the value of different chemicals, but rather with a view of checking that illogical idea of a "royal road" to success which appeared to hover around the minds of some.

During the evening, lantern slides, the work of members, were shown through the lantern of the secretary, Mr. Rumbold, and a programme of music was carried out.

Richmond Camera Club.

*November 13th.*—Mr. Cembrano in the chair.

The discussion ou "Halation" was opened by Mr. J. S. Teape, of the London and Provincial Photographic Association. After demonstrating that the case of halation formed no exception to the rule that preventiou is better thau cure, Mr. Teape proceeded to show the results of various backings for plates with which he had experimented. He first showed a prism coated on one face in sections with (*a*) sienna with dextrine, (*b*) sienna with gum, (*c*) caramel with glycerine, and (*d*) caramel and sienna with gum ; showing that *a* and *b* had perfect reflecting power, *c* and *d* scarcely any. The spectroscope showed that caramel intercepts the green rays and all beyond. Mr. Teape then hauded round negatives and prints resulting from his experiments with the different backings mentioned, showing conclusively that caramel with glycerine was the most effectual, and that caramel and sienna with gum was nearly its equal (aud, being more quickly dried, more convenient), while sienna with dextrine came very well through all but the most severe tests. Mr. Teape concluded his able dissertation by giving formulæ for the backings he had used.

Mr. Ramsay showed the results of experiments with Dr. Cornu's formula (essence of cloves, &c.), and with a backing of black paper attached with glycerine—the former being effectual, but the latter of little, if any, use.

Birmingham Photographic Society.

*Nov. 11th.*—Mr. W. J. Harrison, F.G.S., in the chair.

Mr. Jones gave a lecture on "A Trip to Belgium, Holland, and the Field of Waterloo," illustrating the same with 130 slides from negatives taken by himself.

A number of slides by Mr. Wilkes and others was afterwards shown. The Society's lanteru was worked by Mr. Pettitt.

Newcastle and Northern Counties Photographic Association.

A meeting was held ou the 10th iust., Mr. T. Galloway in the chair.

The awards in the 1891 competition were declared as under, and the prints were on view. Confined to members :—Prints 5 by 4 and under (six entries)—W. E. Cowan, silver medal ; Jas. Brown, bronze. Prints $6\frac{1}{2}$ by $4\frac{3}{4}$ and above (nine entries) —T. O. Mawson, silver ; W. I. Tate, bronze. Enlargements (four entries)—Fred Park, silver ; W. H. Thorn, brouze. Lantern slides (thirteen entries)—W. E. Cowan, silver ; H. G. Ridgway, silver. Lantern slides, open class (eighteen entries) —J. Carpeuter, London, silver ; G. E. Thompson, Liverpool, silver ; P. H. Fincham, London, bronze ; J. W. Wade, Manchester, bronze. The judges were Messrs. J. P. Gibson, P. M. Laws, and C. J. Spence. It is to be regretted that in the classes for prints so few members exhibited, and the executive can scarcely feel encouraged to promote a similar competition in future years. In the opeu class for slides most of the principal exhibitors are represented, and the work throughout is of the highest quality.

A selection of the 268 slides sent in will be publicly exhibited at the Lecture Hall of the Lit. and Phil., Newcastle, on Wednesday, Nov. 25th, at 7.30 p.m.

Photographic Club.—November 25th, monthly lantern meeting ; December 2nd, "The Ferrous Oxalate Developer."

# Answers to Correspondents.

**All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.**

**Questions requiring a reply in this column, which have hitherto been addressed to Mr. Spiller (who, unfortunately, is unable at present to continue his efficient assistance), should be sent to the Editor.**

**All other Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.**

Photargus (Baleares, Spain).—Your proposed plan seems to be feasible. But why not apply to Messrs. Marion and Co., of Soho Square, London, who have worked out all the details which you are wanting? Their system answers admirably. We have had personal experience of it.

H. Griffin (Brockley).—See back numbers of the News. There have beeu numerous articles on residues and how to deal with them.

G. and W. Morgan (Aberdeen).—We do not know of such a book. Write to the Platinotype Company, 29, Southampton Row, W.C.

A. H. L. Newstead.—A very good formula for toning gelatino-chloride (aristotype) paper is that recommended by the Platiuotype Company as a developer for their paper. It is made up as follows :— Solution 1. Oxalate of potash, 5 ounces ; monopotassic orthophosphate, 3 ounces ; water, 50 ounces. Solution 2. Potassium chloro-platinate, 60 grains ; water, 2 ounces. Take three parts of 1, one part of 2, and add two parts of water. Be sure you get the true chloro-platinate of potassium, and not the ordinary platinum bi-chloride, usually sold in 15-grain tubes.

T. S. T.— A very perfect washing apparatus for prints is described iu the News for November 13th, on page 778. This plan would also do very well for washing films, where a large number are under treatment at a time. One of the best plate washers is that made by W. Tylar, 57, High Street, Birmiugham, and which he has called the "aquapoise."

M. P.—We cannot trace the cause of the marks. We should advise you to try another sample of paper.

A. H.—You are not legally bound to pay the railway fares. But if the men have worked well—as is implied by the raising of their wages—you might concede the point, especially as it is a matter of a few shillings only.

W. S.—The mixture used is bichromated albumen—taking the place of the bitumen originally employed for the same purpose.

F. A. B.—The mixture of four parts of potassium oxalate (saturated solution) with one part of ferrous sulphate solution (also cold saturated) is the ordinary ferrous oxalate developer. The salt known as "potassium ferric oxalate" has uo reducing power, but is seusitive to light, and serves, in consequence, as the basis of the kallitype and platinotype processes.

T. E.—For "ounces" read "grains." Thank you for calling attention to the error.

Doon.—The isochromatic plates which you have submitted to us are fogged probably by too much light from your red lamp. They are under, not over-exposed. Give full complement of ammonia at the outset, and use very little bromide.

Fergus (Dublin).—See answer to "Doon," and try the isochromatic plates for the purpose named.

Nemo (Cornwall).—There is undoubtedly a wide field for photo-etching work, but you must remember that there are always plenty of workers attracted by a new industry. Prices are already cut down to a considerable extent by the competition which has already arisen. At the same time, if you can do a better class of work than your rivals, you will succeed in spite of their number.

J. J.—The apparatus which we recently described for sketching by means of an optical lantern was purposely shown in a very elementary form. The arrangement which you suggest would certainly be more conveuient in every respect. But you will observe that it could not easily be made at home except by an expert with the turning lathe, like yourself.

## GAS EXPLOSIONS.

When Carlyle tersely enumerated the population with the addendum that they were "mostly fools," he uttered a sentiment with which everyone agrees, fools and all; for that "a fool is wise in his own conceit" is as true to-day as it was in the time of David. Carlyle's bitter words are unconsciously called to mind when we read the story of a household gas explosion—a story which is told about once a week in the newspapers with very little variation. If ever it were justifiable to use the word "stereotyped," it is in this connection, for the description of one explosion would do for any of the others, so like are they in cause and effect. Indeed, if it were our province to report such disasters, we should make a point of keeping the following sentence at least in type: "Having procured a light to search for the escape, a violent explosion suddenly occurred." It is a grave reflection on the receptive power of the public in general, that they have not yet appreciated the fact that when a light is brought into contact with a mixture of gas and air an explosion is the natural result. But fortunately it is not part of our duty to descant upon the idiotcy of gas exploders, nor would it, perhaps, be quite kind to do so, for the folly generally brings its own punishment.

There is another class of gas explosion, however, which, fortunately, is not so often chronicled, but which is generally of a far more serious character. We mean explosions connected with lantern entertainments. Upon another page will be found an account of a terrible disaster which occurred last week at Ilkeston, and we regret that, up to the time of writing, nothing has transpired as to the cause of the accident. All we are told is that bags and weights were employed, but as to what those bags contained—and here, probably, lies the key to the whole matter—no one has as yet ventured an opinion.

Bags are not often employed now for the storage of gas, for the simple reason that the gas supplied in cylinders answers the same purpose, is far cheaper, and can be kept for an indefinite time without change or deterioration. But we are still in what may be called the transition period with regard to these things; that is to say, many lanternists possess bags which are good enough to last for some time longer, and they naturally hesitate to go to the expense of obtaining cylinders. Others are conservative in their ideas, and do not believe in such new-fangled things as cylinders and regulators; they say that there is nothing like a good bag for gas. "You see how much you have in hand, and you are far more comfortable in every way than when a cylinder is employed." So it happens that, from economy or some other reason, bags are, to a large extent, retained, although now and then an explosion occurs with their use.

For some years we have had the opportunity of hearing of disasters of this kind which never reach the dignity of print. Unless someone is killed or injured, as in the deplorable accident of last week, the matter is generally more or less hushed up. Like most other disagreeable things, only a small percentage of the occurrences are made public; but it would certainly be for the general good if some enquiry were made into every case of the kind, and we are certain that if this were done, it would be generally found that, like the household explosions already referred to, some child of Carlyle was at the bottom of the matter. Here is a case in point which came under our notice not very long ago. A gas bag suddenly exploded in an entertainment hall just at the commencement of proceedings. The operator was a thoroughly experienced and efficient man, and could not account for the disaster—which, happily, injured no one, and greatly benefited the local glazier—until he remembered that when he made the oxygen with which the bag was filled, he left it for a short time in charge of a youth. This lad was cross-examined, and told a tale which at once pointed out the cause of the catastrophe. He said that, seeing that the bag did not become full, he disconnected it with the retort, and attached it by a tube to the nearest gas bracket. In this way, the clever youth had prepared for his master a bomb-shell filled with mixed gases, which did not fail to go off when the right time came. It is evident that, under such circumstances, even when a "safety jet" is employed, an explosion is bound to occur.

The fault in the above case must not lie altogether at the door of the ignorant bungler who filled up the bag with the wrong gas, for the owner of the bag should not have left it in such hands. In only one case that we can remember was an explosion due to a cause not traceable to foolishness or carelessness. In this instance one bag was in use—in connection with a safety jet—and there was a sudden blow-up. The bag was filled with oxygen alone, of that there was no doubt; but being somewhat old, its interior had become filled with dust, and what really occurred was a dust explosion in an atmosphere of oxygen. If anyone will take the trouble to unscrew the tap from an oxygen bag which has been long in use, he will find that he is able to shake out from the hole a handful of light brown, silky dust. An ignorant operator once described this to us as "oxidised" oxygen, but it really consists of particles of the coarse canvas with which these bags are lined, and upon which the gas—owing, probably, to the chlorine which comes off with it from the retort when potassic chlorate is used—seems to exert a rotting action.

Bags are safe enough in careful hands, but unfortunately careful hands are not as common as they might be, or explosions would be next to impossible. With cylinders, no accident has yet been recorded in connection with any lantern show, although they have been known to explode while being tested, filled, or experimented with. In one case, the experimentalist went to work in such an utterly foolhardy manner that some persons have regarded the inevitable result as an act of suicide. While expressing our sympathy with the sufferers by the explosion at Ilkeston, we trust that the enquiry will be of such a searching description that no doubt will be left as to its primary cause.

## ON LIGHT AND DIRECT ENLARGEMENTS.*

BY CAPTAIN W. DE W. ABNEY, C.B., R.E., D.C.L., F.R.S., F.C.S.

I have recently come from indulging in a little climbing in the Alps of Switzerland. With the air of Switzerland still in the lungs, one is almost bound to look at any subject from the Alpine point of view. Taking this aspect of the question, I may say that, though a source of light may have been discussed from several aspects, there may be others from which it may be looked at. From the light of the glow-worm to that of the sun is a very long way to travel; part of it is like the grass slope and moraine which you have to traverse before you get to your peak, and so I propose to cut the first part of the journey short, and to commence where the real climb begins. Let us start from the common domestic dip, and take you by large jumps into the sunlight. Now to plunge—I might say dip—into the subject. We can take a negative by the light of a candle, or of the moon, but if we try and print by either of these sources we fail, and it may be worth while to enquire why this is. First of all, we have to measure the visual effect of the lights, and second, the photographic effects, and then make comparisons and deductions. The visual effect of sunlight may be measured in a variety of ways, though it is somewhat harder to do than it may appear. Measures recorded in text-books tell us that sunlight is equivalent to about 5,500 wax candles placed one foot off from a screen. It is quite evident that to endeavour to use a grease spot or shadow photometer in the ordinary way would be impossible. A way to circumvent this is to use a standard intermediate between the candle and the sun, and so a measure can be got. The intermediate light can be a steady burning electric arc light, which may be of, say, about 1,000 candles. In this case the sun should have the value of about 5½ electric lights at one foot off the screen. We may place it two feet off, and then the sun will be equal to about 11 such lights, and if rotating sectors be placed in the beam of sunlight, they would have to be closed to about 16° of aperture, when equalisation would take place. Again, sunlight may be reflected from a piece of plain glass, and the dimmed reflection cast upon the screen, and the electric light can be placed further off, when by similar means the lights may be equalised. By calculation or absolute measure, the amount of reflected can be compared with the incident light, and the intensity of the sunlight is soon arrived at. There is another plan by which the intensity of sunlight may be so diminished that it may be directly compared with a light from a candle. Suppose we have a small vertical mirror ¼-inch wide attached to the spindle of rotating apparatus, and so arranged that it rotates round a vertical axis; then, if a beam of sunlight be made to fall on this mirror when still, it will throw a thin beam of light back on to the screen in the same way that a beam of light is sent from the mirror of a reflecting galvanometer on to the scale. If now the mirror rotates, a band of light will traverse the screen, which will be much enfeebled. If the screen were 220 inches from the mirror, the latter being exactly ¼-inch broad, and if the sunlight were 5,500 times that of a candle at one foot off, the candle would have to be one foot off the screen to cast an equally illuminated shadow. The mirror might be diminished in width, when the sunlight would be balanced when the candle was further off. A better plan is to cause the beam of sunlight to fall on to the mirror through a slit which can be regulated and measured at pleasure, and balance the two lights in the ordinary manner, measuring the distance of the candle from the screen. I make sunlight at midday in June on a cloudless day to be about 5,300 standard candles by all three plans. Now, the term sunlight is, as a rule, used in a denominational sense rather than in a quantitative. In the Alps, at an altitude of 8,000 feet, you may fairly add half to this number, and sunlight will be about 8,000 standard candles at one foot off. But as we are about sea level, and in England, I must point out how it varies in intensity at different times of the day and at different times of the year:—

| | Candles. |
|---|---|
| If it were overhead it would be about ... ... | 5,600 |
| 30° above the horizon it is ... ... ... | 4,700 |
| 20° ,, ,, ,, ... ... ... | 3,300 |
| 10° ,, ,, ,, ... ... ... | 2,000 |
| 8° 30′ ,, ,, ,, ... ... ... | 1,400 |
| Just before sunset ... ... ... ... | 140 |

So in measuring sunlight, this fact must always be borne in mind.

*Abstract of a paper read at the Camera Club.

So much, then, for this light as appreciated by the eye; but what about its photographic value for negative making and printing? How can we measure it? Now, it happens that the curve of sensitiveness to the spectrum of a bromo-iodide plate and for platinum paper are almost identical.

First of all, however, we can directly compare the photographic value of sunlight with that of a candle in a simple manner. If we allow sunlight to pass through a very narrow slit in a shutter, reflecting it on to the slit by the heliostat (which, by the bye, I ought to have mentioned was used when ascertaining the optical value of the light), we can catch the beam on a plain glass and reflect it on to a screen. We can first measure the optical value of the beam against a candle, and then measure on a photographic plate the densities produced by it, and by a candle exposed for different times, and thus ascertain from this last scale its photographic value:—

| | Candles. |
|---|---|
| Overhead it would be ... ... ... ... | 120,000 |
| At 30° ... ... ... ... ... ... | 72,000 |
| At 20° ... ... ... ... ... ... | 42,000 |
| At 10° ... ... ... ... ... ... | 9,000 |
| At 8°30′ ... ... ... ... ... ... | 5,600 |
| At sunset ... ... ... ... about | 1.7 |

The photographic value, therefore, diminishes much more rapidly than the optical value, and when close to sunset it is almost nothing. It is not hard now to see why, at this altitude of the sun, photography—the effect of sunlight—is difficult of execution. Let us, however, take the sun at its best, and suppose we have a negative to print from in platinum: I have found that an exposure of 50 to 60 seconds is ample to make a print in direct sunlight. That is, the light of 120,000 candles, at one foot distance, will take, say, one minute to give a print. We may place a gas light (which is a slightly whiter light, and hence more photographically energetic, than a candle) of, say, 100 candles near the negative to print, and it would take 1,200 minutes, or 20 hours, to obtain a print by. If it were a 20-candle lamp it would take 100 hours, an exposure which is certainly somewhat long. As a matter of fact, I have obtained a *trace* of a print from a 20-candle gas lamp in about 12 hours.

Now a word about moonlight. I find that the photographic value of the light of the most brilliant full moon is about 400,000 times less than sunlight at midday in summer (it is usually put down at 500,000 times). It is therefore quite evident that to obtain a print (except by development) by moonlight is impracticable.

There are other lights to which we naturally turn in order to see what value they have, viz., the arc electric light, the oxy-hydrogen light, and the magnesium light. Now, I have made pretty exact measures of the visual and photographic value of these lights, but it is useless to put them down in what I may call bulk, since they vary so enormously. They are even worse than sunlight in this respect. What can be done is to state, for every candle-power as measured by the eye, the candle-power as measured by photography, taking the candle as a unit in both cases. With the electric light and oxy-hydrogen light, the same method of measurement was adopted to find this ratio as just described for sunlight, viz., the light was sent through a slit and reflected on to a screen. For the magnesium light, a rather different procedure was adopted. It was measured by means of the blackening of platinum paper, a scale of darkness being previously made by exposure to different intensities of light. As it was not required to measure the absolute values of the light, but only its relative value compared with the electric light, it became unnecessary to know the absolute intensities of the light forming the scale, but only their relative intensities. The scale was therefore made by a Spurge sensitometer exposed to sky light. A Nadar lamp was used for burning the magnesium powder, which was allowed to burn for a minute at a fixed distance from the platinum paper. Another portion of the same paper was then exposed to the electric light at the same distance and for the same time, and was then developed. The blackness was measured and compared with the scale of shades. This gave the relative photographic values of the light. In the case of the magnesium light, the weight of magnesium burnt was noted and found to be 124 grains, and with electric light the visual candle-power was measured and found to be 1,150 candles.

The relative value of the two lights, each burning for one minute, was found to be—

124 grains of magnesium light—43 on the empyric scale.
1,150 candles of electric light—181 on the empyric scale.
∴ 1 *candle* of the quality of the electric light = ·16 on the scale.
∴ 1 *grain* of magnesium = ·35 on the scale.
That is, 1 grain of magnesium = 2·16 electric light candles burning one minute.

Now, the electric light candle was found to be photographically equal to 10·7 standard candles. Therefore, 1 grain of magnesium burnt was photographically equal to an exposure of 23·1 standard candles burning one minute—of course, at the same distance.

One candle-power of the oxy-hydrogen light (a blow-through jet being used) was found to be equal to 1·7 standard candles, but for reasons I am inclined to increase that value to a little over 2 standard candles. A good blow-through jet may equal 400 candles optically, that is, 800 candles photographically. With this light it would then take five hours to obtain a print on platinum paper.

With magnesium, 1,150 electric light visual candles (that is, 12,300 photographic candles) equal $\frac{181}{43}$ of the magnesium light, each burning one minute, that is, electric light is four times the photographic value of the magnesium light. Now, 12,300 photographic candles at a foot off is about $\frac{1}{10}$ of sunlight. It should, therefore, take about ten minutes to obtain a platinum print from the negative described if placed one foot off, or forty minutes when burning, magnesium expending 124 grains a minute. That is, to obtain a print with magnesium, 4,960 grains, or rather less than 12 ounces, should be burnt one foot off the negative.

These considerations, then, show that practically sunlight and the arc electric light alone are available for printing purposes. Ordinary daylight has been excluded from consideration, as it is in another category of sources of light.

Now, if these two lights are so useful in contact printing, why should they not be used for printing-out purposes in an enlarging apparatus? As a matter of fact, both are useful, and it does not require an elaborate apparatus to use them for such a purpose. Sunlight is perhaps that which may often be most available to the members present; but I will first describe the arrangement which I use for the electric light. I have two condensing lenses of about 6 inches diameter and of about 6 inches focus, and these I place about 10½ inches apart from one another, convex side inwards. At 5½ inches from the front of the combination I place the electric light, placing between it and the lens a piece of plain glass, to protect the latter from the heat. In front of the other lens, and close to it, I place the quarter-plate negative which I may wish to enlarge, and at the focus of the combination is placed a lens of about 7½ inches focus in a whole-plate camera. The light is turned on, and an image of the negative is thrown on the screen and focussed. Platinum paper, or other paper, is placed on a carrier in the dark slide, and exposure made, and so long as the image of the points of the carbons fall within the area of the lens, the whole image will practically be equally illuminated. To enlarge from ¼ to 7½ by 5 size, practically the length of focus used was 18 inches, so that really, if the negative were removed, the image of the points being taken as a source of light, the paper was 20 inches from the screen, as the circle of light was the same. Now, as has already been said, it takes ten minutes to print a negative when placed 12 inches from the screen. To print this enlargement it should take twenty-eight minutes. As a matter of fact, the prints, except those taken on very thin negatives, took thirty-five minutes.

Now, the light I used was 1,150 candle-power. If one of 11,500 candles was used, the time of exposure would have been reduced to four or five minutes. With my light, had I wished to produce a print from the quarter-plate negative on to a piece of paper measuring 15 by 12, the exposure would have been 2¼ hours. With the larger light only about a quarter of an hour. There is absolutely no difficulty in producing prints by this plan. Even if the light changes in position slightly it still is effective, and causes no blurring in the image, as is often supposed to be the case.

With sunlight the same kind of apparatus can be used, but instead of two condensing lenses, one is sufficient, as the use of the two was only to shorten the focus, which would be long if only one were used with the electric light, seeing that it is placed so close to the condenser. With the sun, by using only one condenser, we get about the same length of focus as obtained with the electric light. The same camera and lens can be used, and the sun be reflected on to the condenser by an ordinary looking glass, taking care that it is flat, and does not give a streaky reflection. So long as the focus of the sun is kept on the camera lens, the image will appear equally illuminated. In this case, with a midday summer sun, the exposure should be the same as that to be given to the 11,500 candle-power electric light. Solar enlargements are, therefore, not only practicable, but tolerably easy to obtain when there is a good sun.

For quick enlargements the negatives should be stainless and, as far as possible, be perfectly bright. The image given by eikonogen developer seems particularly suited for them, as also hydrokinone. Pyro development is not quite so good. I have already shown that the density of the highest light in a negative need only be such that it will allow $\frac{1}{20}$ of that light to pass which passes through the most transparent part. I show a print from a negative in which the highest light is only $\frac{1}{15}$, and yet it gives a fair print.

There are other practical points which I wish to call attention to. First, if you have scratches in your condensing lens, beware of putting the negative too close to it. In one of the two prints of the front of Monte Rosa, you have an example of scratches in the lens at the bottom right-hand corner, and indeed the same scratches will be found in other prints. In the second one, however, the scratches are gone by removing the negative an inch away from its old position, in which the remainder of the prints were taken. Slight scratches on the film also show. These can be got rid of by coating the film with collodion, or by soaking the plate well in water.

There is one point to be remembered in all enlargements, and that is that the opacities of negatives, except, of course, in the transparent parts, are increased. That is, if the density be measured when the negative is far away from the screen, and when close to it, it will appear to have greater opacity in the former case than in the latter. This fact renders it possible to obtain an enlargement print from a negative which is superior to that in contact in the printing frame.

## COPYING WHITE AND BLACK SUBJECTS.

We abstract the following concise directions of photographing line engravings, &c., from a communication by Mr. P. C. Duchochois which recently appeared in the *Photographic Times*:—

As rightly said by Professor Klauser, *clichés* of line-subjects should be of a great opacity in the whites, and of a perfect clearness (bare glass) in the minutest lines and dots. And this is not as easily done as it seems; it requires a certain practice.

The first difficulty is the exposure time. When photographing half-tone subjects—portraits, landscapes, &c.—from nature, we should lengthen the period of exposure according to the lighting of the subject, in order—if the contrasts are photographically great, as is generally the case—to have the benefit of the reversal, or, in other words, to equalise, as far as it is possible, the action of weak and strong lights, and thus to avoid harshness or loss of details in the shadows, one entirely depending on the manner of conducting the development to obtain vigour and brilliancy after the delicate details are out and well defined.

On the contrary, to obtain the greatest opacity in the whites, which is a *sine quâ non* when photographing white and black, instead of lengthening the exposure time, we must expose as shortly as possible, to prevent *solarisation* (*i.e.*, the primary action of the reversal), and keep the blacks quite clear by not having been impressed—I will not say by the light reflected from the lines or dots, which, if the ink is lustreless and opaque-black, is impossible—but by the diffused light entering into the lens, it being sometimes reflected by extraneous objects. Hence, the lens should be provided with a top shade, or, better, with a cone lined with black velvet.

It is useless, is it not, to say that the lens should be placed outside of the field of the angle of incidence formed by the light falling on the model; that the latter should be exactly parallel to the lens; that it should be pinned on the bottom of a box having the form of a cone and lined with white cardboard, in order that, the light being upon it reflected from every side, the grain of the paper be not reproduced?

Now, as to the process. It is evident that for half-tone subjects none excels the gelatino-silver-bromide. But this is not in question. For white and black, I think, with most of the photo-engravers—and they are great authorities in this matter—that the wet collodion process gives the best results, and this with the least trouble and most certainty, provided the chemical preparations be appropriate to the process.

To compound the collodion, the best haloid salts are those of zinc; they form the most sensitive photo-film, and yield the greatest intensity. The drawback is that the collodion thickens somewhat, and does not keep. To turn the difficulty, I keep separately the plain collodion and the iodising solution, mixing them in certain quantities for a few days' use, thus:—

| | | |
|---|---|---|
| A.—Ether, 0·725 | ... ... ... | 240 fluid parts |
| Alcohol (Atwood's patent) | ... ... | 120 ,, |
| Pyroxiline | ... ... ... | 6 to 7 parts |
| B.—Alcohol, as above | ... ... ... | 120 fluid parts |
| Sodium iodide | ... ... ... | 3 parts |
| Zinc iodide | ... ... ... ... | 2 ,, |
| Zinc bromide | ... ... ... | 1 ,, |

Mix by equal volumes; filter through cotton.

Silver bath 10 : 100, acidified by nitric acid.

The developer should be acidified by tartaric acid.

| | | |
|---|---|---|
| Water | ... ... ... ... ... ... | 480 parts |
| Ferrous sulphate | ... ... ... ... ... | 25 ,, |
| Glucose (liquid) | ... ... ... ... ... | 15 ,, |
| Tartaric acid, | ... ... ... ... ... | 3 ,, |
| Acetic acid (No. 8) | ... ... ... ... | 15 ,, |
| Alcohol (ordinary) | ... ... ... ... | *quant. suff.* |

This bath keeps well in the light, acts slowly and regularly, and the image assumes much intensity. However, it seldom happens that the opacity is sufficient, specially for the want of the photo-typo-engraver. The *cliché* should be intensified. For that purpose we prefer —and this generally suffices—to convert the silver forming the image into sulphide by flowing it—when fixed and well washed, of course—with a diluted solution of ammonium-sulph-hydrate.

Other processes are employed: The old mercuric chloride and ammonia process of Scott Archer, the lead process of Dr. Eder, that of Wm. Campbell with cupric bromide and silver nitrate, &c., &c.; they are described in the Annuals. The only care to be taken is to commence with clear lines. Should there be any deposit of metallic silver, it ought to be dissolved by lengthened immersions in the fixing bath—a solution of potassium cyanide.

It is not very likely that the amateur photographer will ever attempt to work the collodion process. It requires great practice to keep the silver bath in good working order, to avoid pinholes, surface marking, &c.; to trace the failures to the real cause, &c. And the gelatine process is so simple; you buy the plates already prepared, you expose and develop. Yes, you expose and develop, and there again lies the difficulty. No doubt it can be done to perfection; Professor Klauser does it; others, amongst whom the writer of this paper, have done it, but often the lines are not exactly clear, and besides, the intensification is liable to spoil the *cliché* for the purpose in question.

We have used Carbutt's process plates, and sometimes those for transparencies; they are good and commendable. I think that Mr. Carbutt can still improve them. He has only to will it. There is no necessity, on the contrary, that they possess a great sensitiveness; if they are as sensitive as wet collodion plates that suffices—a little more iodide, less or more cooking.

To develop, I use pyrogallol; it is my favourite reagent, and I do not use any other one. I proceed thus; I immerse the plate in a sufficient quantity of—

| | | |
|---|---|---|
| Water | ... ... ... ... ... | 480 parts |
| Sodium sulphite | ... ... ... ... | 25 ,, |
| Pyrogallol | ... ... ... ... ... | 3 ,, |
| Potassium bromide | ... ... ... | 0·5 part |

In this I let the film soak for a minute, then I add about one per cent. of a saturated solution of sodium carbonate C. P. (not the commercial article sold under the name of *washing soda*, which is quite impure and liable to produce yellow fog), and wait to see the result. If the exposure time has not been too lengthened, the image will not commence to appear in a minute; we add, consequently, more—not much—of the carbonate solution, and then another dose if the image still refuses to make its appearance, taking care not to add an excess of alkali in order to prevent the secondary action of the same.

Should the image appear rapidly, one restrains the action by adding a few drops of a potassium bromide solution (1 in 10) to keep the blacks clear, a *sine quâ non*, as said before. As soon as the image appears and develops regularly, the action should be allowed to proceed until the reduction reaches the back of the film, when, all the impressed silver bromide being reduced, it is useless (nay, prejudicial) to leave the film any longer in contact with the developer. Long development produces a chemical veil as well as a physical yellow fog (dyeing).

After development the plate is rinsed, immersed for (say) two minutes in a solution of tartaric acid to avoid the yellow and sometimes green fog arising in the fixing bath, then washed, fixed, &c.

Now, as to the intensification. If the image bleached with mercuric chloride, then treated, after a prolonged washing by aqueous ammonia, or, better, by silver sodium thiosulphate—a solution of sodium thiosulphate (hyposulphite) *nearly saturated* with silver carbonate or chloride —does not acquire the necessary intensity from the silver reduction forming the image not being sufficiently dense, there are five chances to one that, by re-intensifying, the *cliché* will be unfit for photo-engraving purposes.

In concluding, I must say that, whatever be the process employed, halation is a common defect. Backing with an opaque material is the well known remedy.

Mr. Charles Ehrmann, in the same journal, writes as follows concerning the development of negatives for black and white work:—

With gelatine plates, the time of exposure is more important than with collodion. Collodion requires under-exposure because of the subsequent intensification; with gelatine plates it must be just so; and that is exactly the difficulty of the method. Expose for the whites; the blacks and the light reflected from the blacks should not cause the slightest impression.

Of developers for black and white negatives, I have found old hydrochinon solution to be about as good as any other, on account of the good intensity attainable. Eikonogen has not given me as good results as pyro, and that is most successfully used in freshly-prepared solution; but with either of them we encounter the main difficulty occurring with all the usual organic agents, yellowing of the film, caused by the oxidation products of the developer. For that reason, many operatives prefer to develop with ferrous oxalate. Wilde, of Görlitz, adds iodine dissolved in alcohol to the ferrous oxalate, and reports very satisfactory results. Seed used iodine and bromide of potassium with pyro-soda, and the negatives so developed were very encouraging.

Were I better acquainted with the new developing agent, para-amidophenol, I might take occasion to break a lance for it here. Anyway, can I say the experiments made with it are very promising for black and white work? If intensity is to be attained by long-continued development, no better substance than it can be possibly found. Tinging the plate yellow is entirely abolished with para-amidophenol.

To make black and white negatives on gelatine plates for the autotype process is, on account of comparatively lower intensity, perhaps not quite as difficult as for line-work photo-engraving. In consequence of developing not being extended quite so far, the plate is less liable to fog. With para-amidophenol we can develop as slowly as we may please without injuring transparency to the slightest degree.

Gelatine plates for process work should be intense enough in the first instance, without being compelled to resort to after-intensification; but, if it must be done, do it with cyanide of mercury and silver—it retains transparency better than others.

The constant improvements going on induce one to believe the time is not very far distant when the last stronghold of collodion, the process plate, will surrender to its ever successful competitor gelatine, but at the present time collodion still reigns in that province.

## EXPERIMENTS RELATING TO IMPROVEMENTS IN THE MANUFACTURE OF METALLIC SODIUM.

BY H. N. WARREN, RESEARCH ANALYST.

In the general process for the manufacture of metallic sodium, one of the greatest drawbacks at the present time is the difficulty of expelling the sodium as quickly as reduced in the form of vapour, insomuch that, for a considerable time after, a most intense heat has been obtained. On viewing the inside of the converters, large globules of melted sodium are not unfrequently observed, which are only with difficulty volatilised. Potassium, on the other hand, although presenting more difficulties than sodium as regards its preparation, melts and volatilises at a much lower temperature. For instance, if twenty-three parts by weight of sodium be carefully alloyed with twenty-nine parts of potassium, a fluid amalgam is produced which remains liquid at all ordinary temperatures; if this amalgam is now distilled in a non-oxidising atmosphere, in the first place potassium metal distils over, leaving a residue consisting of sodium containing about five or six per cent. of potassium. This alloy, which resembles ordinary sodium in appearance, is much more energetic than that substance itself, taking fire when thrown upon the surface of water the same as potassium, but burning with the characteristic yellow flame of the former.

Following up these reactions, several mixtures were obtained for reduction by calcining sodium tartrate in admixture with a sufficiency of potassium tartrate to allow of about five or six per cent. of potassium to pass into the distillate; the reaction being brought about in wrought-iron tubes, and urged to whiteness by the aid of a small blast furnace. The globules of metal thus obtained presented in appearance an exact similitude with the first-mentioned alloy, and were considerably more volatile than pure sodium. The iron tubes after cooling were cut longitudinally, and in no instance could any reduced metal be detected; the metals as fast as reduced having been volatilised, producing the aforesaid alloy.

The calcining of tartrates on a large scale would naturally be entirely out of place; but the introduction of potassium could, as far as can be seen, be brought into play when employing any of the ordinary commercial methods, save that the percentage of the two would probably have to be looked into still closer in order to obtain concordant results.—*Chemical News.*

## THE RODINAL DEVELOPER.

BY HERMANN E. GUNTHER.

Paramidophenol, an excellent reducing agent, is now commercially produced on a large scale, according to the process patented to Dr. M. Andresen, by the "Actien-gesellschaft für Anilin-Fabrication," of Berlin. It is sold by this manufactory in the form of a concentrated, ready-prepared solution, one part of which requires only to be diluted with thirty parts of water before use. To this stock solution the name of "Rodinal" has been given by its manufacturers.

From the excellent results this new developer has given in the hands of a large number of eminent professional photographers and amateurs, it may already be stated that the rodinal developer possesses very marked advantages, and that for some special purposes it is superior to all other reducing agents yet known.

As to its energy, I have found that it requires about the same time for developing out as in the case of eikongen; the image comes out, however, very rapidly after the solution has been poured on the plate. A gelatine plate exposed for one-tenth of a second was placed in a fresh solution prepared of one part of the stock solution and twenty-five parts of water; the image appeared in ten seconds, and a very vigorous and richly detailed negative was developed in about two minutes. If the stock solution is diluted with more than thirty parts of water, it works, of course, a little more slow, but the resulting negatives are of great softness, showing a beautifully bluish-black colour similar to those developed with hydroquinone. Potassium bromide may be added or an old developing solution employed in the case of over-exposure. Fixing is done as usual, preferably in the acid fixing bath.

Other operators have found—and I can confirm it—that the rodinal developer works absolutely clear, even after a very prolonged action, as, for instance, in the case of under-exposed plates. C. Kinderman states that the negatives should be developed to deneness, since they will reduce considerably in the fixing bath. The solution should have a temperature of about 68° F.

As I have already mentioned in these pages, the rodinal developer is especially well suited for prints on bromide paper. According to Dr. Stolze, it gives prints of unsurpassed clearness of the whites and velvety-black shadows, together with perfect softness of the half-tones. Since that time, Dr. Stolze has found that this developer gives also excellent results in the case of under-exposure, if to one hundred parts of it five parts of a solution of potassium bromide (1 : 10) are added. He observes that it is especially remarkable that the developer bears so large a quantity of the restrainer without injuring the tone of the print, which is always of a beautiful black.

It may be mentioned that Dr. Th. Schuchardt, of Görlitz, also produces the hydrochloric paramidophenol in his chemical works. It has the form of beautifully-shining white crystals; and if used in this form, a very good developer may be prepared in the following way:—

| | |
|---|---|
| Hydrochloric paramidophenol ... | 1 gramme |
| Sodium sulphite ... ... ... | 4 grammes |
| Caustic soda ... ... ... ... | 3 ,, |
| Water... ... ... ... ... | 400 c.c. |

In this form of a one-solution developer, it will not, however, keep clear for long; it will therefore be better to prepare it in two separate solutions, as follows:—

| | | |
|---|---|---|
| A.—Hydrochloric paramidophenol | ... | 1 gramme |
| Sodium sulphite | ... | 4 grammes |
| Water... | ... | 100 c.c. |
| B.—Sodium sulphite | ... | 4 grammes |
| Caustic soda ... | ... | 3 ,, |
| Water... | ... | 100 c.c. |

In the case of instantaneous exposures, equal parts of solutions A and B are mixed; whilst for time exposures this mixture should be diluted from two to three times its bulk of water.

## REVERSAL.*

BY HENRY SUTTON.

In opening the subject of reversal, it would be well to understand that a reversal negative and a reversed negative are different things, a reversal negative being the result of what has been termed reversing action; it is produced direct from a negative, and is reversed as regards right and left. A reversed negative is reversed as regards right and left, but is produced from a positive.

We all know that over-exposure produces flatness, owing to the difficulty of obtaining density in the high-lights; it is easy to conceive an exposure sufficiently prolonged as to cause an entire loss of the high-lights. If in such an exposure the shadows have not received sufficient light to produce a strongly developable image, the result on fixing would be an extreme case of over-exposure, as understood by a thin image; but if during development stray light obtains access to the plate, the shadows fog, and we have reversal.

The original high-lights, as we shall see, are both undevelopable and insensitive, therefore do not fog. We may produce this fog by preliminary, concurrent, or supplemental exposure; in all my experiments it is deliberately produced in order to supply the necessary reduction to those parts of the plate not rendered undevelopable by oxidation. In a reversal exposure this oxidation is regulated by the interposed negative or positive; therefore, when we fog or expose the still sensitive portions of the plate, a reduced image is formed capable of being developed.

In our experiments, the reduction will be produced by concurrent exposure; that is, while we are oxidising through the shadows of the interposed negative, we are fogging or reducing through the high-lights with stray light. In order to illustrate this matter, I will expose a plate to magnesium light a sufficient time to enable oxidation to produce the undevelopable and insensitive state; another plate will be taken, and the pair exposed in contact with a negative. I think we shall find one plate give a reversal, and the other show it is really undevelopable and insensitive. The insensitive or oxidised plate will show the state of the shadows in the reversal plate, this latter having a gradation of oxidation and the rest of the plate fogged. The insensitiveness may be only comparative, for, though the plate has still the power of producing a print-out image, I have not succeeded in producing a second developed reversal from it. Captain Abney has shown that the undevelopable state is due to oxidation.

Although it is possible to produce an exact reversal, I do not think these physical reversals are of much practical account, from the fact that a very exact balance in the two factors of reduction and oxidation is necessary; if the latter be in the least overdone, the delicate tones are oxidised out of existence, or, if the reduction has been too much, delicate tones are fogged and disappear; under these conditions the gradations are quite false. In some cases reversal improves the result; subjects having too many tones may have the middle tones obliterated. Hard negatives are reproduced perfectly.

When making experiments of this kind, the natural conclusion one arrives at is, that dark flashes seen on photographs of lightning are the result of reversal. The light from one grain of burning magnesium is sufficient to produce reversal. So we may consider a lightning flash having a similar actinic or photographic value should do the same. This value may be due to a discharge of exceptional duration, or to a brilliant flash caused by a maximum electromotive force with a minimum quantity of matter in the path of the flash.

One evening I was observing a display of electric discharges in a large cloud situated on the northern horizon; these discharges were accompanied by sympathetic discharges in a cloud on the southern horizon. The northern cloud was approaching, and I concluded that, should the clouds be at different altitudes, a difference of air currents might enable the one to overtake the other. A more rapid movement of the northern cloud was soon noticed; a camera was fixed up and carefully focussed on the southern cloud, by aid of the local discharges. All being in readiness, and the shutter of slide drawn, but cap still on the lens, I waited events. When the northern cloud reached the zenith it began to show considerable symptoms of electric excitement at the edges; knowing this to be my opportunity, the lens was uncapped, and in about half a minute a pair of brilliant flashes darted from the zenith to the southern cloud. I estimated the duration at over one second.

The plate was immediately developed, but not a sign of the flashes. I expected to find a pair of curly black streaks right across the plate; instead, there appeared a very fair cloud negative, and the black outlines of some buildings low down in the field; these buildings enabled me to verify the position of the camera, which, being attended to, proved the field must have included the flashes. I could never account for getting the clouds and not the flashes, until the matter came to mind whilst making the reversal experiments, and now think the exposure reached the transition stage described in Experiment 14 of my paper in the Club *Journal* for September.

There may be points which, with our present limited knowledge of the dark flash, seem difficult to reconcile; still, I think we are pretty safe in accepting reversal as the cause.

* Abstract of a paper read at the Camera Club.

To Milkmen and Others.—Beware of the hand-camera. If London roguery were systematically organised, some such notice as this might be looked for as a result of the disclosures made by Mr. Hepworth, the president of the Holborn Camera Club, at his interesting magic lantern demonstration. Among the "London Street Scenes," which formed a large proportion of the slides, was one entitled "Caught in the Act." It projected on the white background a figure of a man standing on a water-cart pouring water into a large milk can, while hard by was a cow standing at ease. The little scene was so full of expression, as the art critics say, that Mr. Hepworth tells us it had been supposed that he had arranged the composition, or, as photographers put it, "posed the subject." This, however, he assured his audience was not the case. He had simply come upon it accidentally when he was in quest of street scenes with a hand-camera, with which he secured an instantaneous record of this milkman's method of doing business.—*Daily News.*

## Notes.

We understand that a company has been formed to work the photo-mechanical process, by Mr. Sutton, which was fully described in these pages some months ago. The process is now brought out under the name of electro-phototypy; and, according to the promoters, they expect that it will revolutionise illustrated literature, on account of the excellent results obtained by it, its rapidity, and its cheapness. Patents have been granted for this process in all European countries, as well as in Australia, the United States, Canada, India, &c. The circular sent to us with reference to this company contains several illustrations printed on finely surfaced paper. We hope shortly to place before our readers an example of this method of illustration, and then they will be able to judge for themselves how far it is likely to rival the various processes at present in use.

In the handsome monthly review, *Paris-Photographe*, appears an article by a well-known physiologist on photography of speech, with a very curious illustration. This consists of twenty-four little pictures half the size of a postage stamp, giving the phases of movements of the lips in pronouncing the phrase "*Je vous aime.*" The pictures certainly do not convey much information without the explanatory words, and in looking at them one cannot help wondering whether the deaf and dumb who are taught on the lip movement principle would understand this silent photographic language. Perhaps in time, when schoolboards have left off squabbling among themselves, and have time to attend to the teaching requirements of the age, we shall all get educated enough to understand this quaint form of caligraphy. Then the ardent lover will send photographs of the sweet words he would whisper to the absent one, and the irate parent will be able to photograph all the horrible words he wishes to employ for the benefit of an unsuitable suitor for his daughter's hand. It is well-known that the late J. B. Buckstone—who was as deaf as a post—used to read the lip movements of the actors with whom he was playing. The pictures of such movements point to many strange possibilities.

A correspondent, referring to a number of old gelatine plates which have come into his possession, asks us a question which has often been asked before: What is the life of an unexposed gelatine plate? The answer is not an easy one, for, according to our experience, some of the best plates in the market are good for very little when a few months old, while others seem to keep almost indefinitely, provided they be intelligently packed. We have heard of wonderful results being obtained on very old plates, and of certain workers who regard them like old wine—the more ancient the better. We are not of this opinion ourselves, and view with the eye of suspicion any packet which remains unopened for a few months. Certainly we should never dream of using such plates for any important work, and should look upon such action as the height of false economy.

Dr. Vogel has recently called attention to a system of enlarging photographs which has been known for some time, but has been very little practised; and, truth to tell, other methods are far more certain and reliable. The plate is soaked in a weak solution of fluoric acid, until the film separates from the glass. It is then thoroughly washed in water, when it will swell considerably larger than it was originally. We fancy that only certain plates are amenable to this treatment, and possibly, too, some developers would have the effect of rendering the gelatine non-absorbent. The game, in any case, is hardly worth the proverbial candle.

What a shudder must go through an artist when, after parting with a picture, copyright included, he sees coloured photographs of it hanging in the print dealers' windows. "The Health of the Bride" of Mr. Stanhope Forbes is just now very popular, and coloured photogravures are being turned out in quantities. We do not say this coloured work is not skilfully done; but the crudity of the tints as compared with the harmony of the original is very marked.

A short time ago a story was told of a Yankee theatrical manager, who had the crowd of commissionaires and messengers thronging the box-office to engage seats for their employers, photographed. The photograph was procured, and multiplied copies of "The Rush for Seats" appeared in shop-windows and on the prominent hoardings, and the advertisement at once told. We do not see why this notion should not be improved upon. A photograph by flash-light could be easily taken of the entire audience, showing the effect the play had upon their countenances. If it were a farcical comedy, the laughing faces would tell their own story; if a moving tragedy were being enacted, the pocket-handkerchiefs of the ladies might be emphatic evidence of the pathos of the scene. It is a pity that the sniffs and coughs of the male portion of the audience, who usually confide their emotions to their opera glasses, cannot be photographed; but here the phonograph would come in handy, and the two would certainly prove unmistakably the success of the play. Perhaps, to be on the safe side, it would be well to leave the photographic operation until after the first night.

It is claimed by a non-photographic contemporary that ballooning "has been of use in enabling photographs to be taken of parts of the country which could not be taken by other means." Of course not. How could balloon photographs be taken save by means of a balloon? We have not yet got to flying machines. If Mars, Venus, or the moon possess photographers, their photographs of the earth have not yet reached us. Still, one is grateful for the information afforded by the—in mercy we will withhold the name of the paper.

Mr. Littledale's paper on "The Pamirs," read on Monday before the Geographical Society, was of unusual interest to photographers. Mr. Littledale is himself an amateur of no mean skill, and his collection of photographs exhibited at the close of the lecture was the subject of much interest. Apart from this, however, Mr. Littledale demonstrated how unexpectedly useful a camera may become in cases of emergency. In the course of his journey he learnt that his Chinese guide, who was leaving him, had in his mind a scheme for plundering the caravan. Mr. Littledale at once took a bold course. He simply told the man he had taken his photograph, and threatened to send it to the Chinese Governor of Kashgar with a request that the original of the portrait, if anything happened to the caravan, might be crucified and disembowelled. The salutary effect was instantaneous, for the would-be thief immediately abandoned his design.

## PHOTOGRAPHY FROM A DISTANCE.

We have abstracted the following from an article in our German contemporary, *Prometheus*:—

In the choice of material which it brings before its readers, *Prometheus* has always held fast, as its first principle, the desire to bring forward only such novelties as it has already proved in a practical manner, but if we to-day depart, for once, a very little from our customary usage, it is because the new aid to photography of which we have to report has produced very practical proofs of its capabilities; so far only experimentally, but not the least doubt exists of what it is able to perform.

The new aid to photography permits the direct enlarged photographing of distant objects, presenting them about the same as they appear to us through a hand telescope; and this is done by means of apparatus which is no more cumbersome, no larger, and no costlier than an ordinary tourist camera with an aplanatic lens. With the ordinary photographic lens, we can easily figure to ourselves the sizes of pictures of distant objects which the lens affords, if we consider that the original is in the same proportion to its picture in the enlargement as its distance from the camera is to the focal distance of the lens. An example will explain this.

Given a man of 2 m. height walking at 100 m. distance from the camera, our lens having 0·2 m. focal distance, then the picture will be only 4 mm. high, therefore showing scarcely the outline of the figure, and not the least detail. Or suppose we photograph, with a larger camera, with a lens of $\frac{3}{4}$ m. focal distance (such a lens is decidedly cumbrous), a fortification which is 10 m. high and 150 m. long, at a distance of ten kilometres, our picture will turn out only 0·75 mm. high and 11 mm. long, consequently representing a simple horizontal stroke without detail. The only means which we have hitherto possessed of enlarging the dimensions of pictures consisted in approaching the object more nearly, or using a longer focus lens; where the first was impossible, the latter availed little. This great want in photography, for many purposes, has long been actively felt, and several have already sought to bring powerful means to their aid. Thus, English and French amateurs have made use of a terrestrial telescope with which to photograph. This is accomplished by means of a special supporting instrument fastened on to the front of the camera, and the photograph is taken, well or ill, as the case may be.

The fact that hitherto nothing came of this idea needs no intimation; even those telescopic photographs which have appeared here and there as supplements to photographic journals appear to be forgeries. Photographs taken with lenses of exceptionally long focal distance have yielded much more perfect results; the astronomical photogram, whose perfections have caused a real revolution in our astronomical ideas, have originated in lenses of from 5 to 10 m. focal length. But any instrument, in order to be practically useful, must combine the following properties: small dimensions, great focal length, free choice of the size of the picture without altering the position of the lens, and, as much as possible, sufficiency of light.

All these advantages are possessed by a new and exceedingly simple lens, for which Dr. Adolphe Miethe has lately taken out a patent. The exterior is distinguished from that of an ordinary aplanat only by an arrangement which permits of changing the distance between the two lenses inside it within certain limits. The optical part consists principally of a convex lens of moderately long focal distance, and a concave lens of short focal distance. The space between the two lenses is about the difference in their focal distances. According to well-known optical principles, it follows that such a system will delineate converse, but exact pictures of objects that are the other side of, and at a great distance from, the convex lens. The size of these pictures varies, on the one hand, with the distance the two lenses stand apart from one another, and becomes greater as they approach one another; on the other hand, it is dependent on the proportion of the focal distances of the two lenses. The more difference between the focal distances, the greater (under otherwise ordinary circumstances) the picture will be.

Suppose that the focal distances are in the proportion of twenty-five to one, then this system will produce pictures twenty-five times as large as those produced by an ordinary camera at the same distance.

We do not propose to enter into the theory of the working of such an instrument. The whole apparatus resembles in principle a Gallilœan telescope, except that in this case we accomplish the formation of a real picture, and the making use of comparatively large fields of vision. Every reader who is in possession of an opera-glass and a camera can obtain an idea of the operation of this system. He must screw off the lens of the latter, and fasten one tube of the opera-glass in front of the opening in such a manner that the junction may be light-tight. He must then rack out the opera-glass to its greatest limit, and also the camera, and direct the whole upon some distant but well-lighted object. By screwing the opera-glasses up and down, he can easily produce a picture which will appear very large, and, in the middle at least, tolerably clear.

The extent of the application of the new lens will apparently be a very wide one. It will first of all be useful where a close approach to the object to be photographed is, for some reason, impossible. Thus, for example, in time of war, in the art of besieging; on explorations, surveying expeditions, and topographical photography; for detailed elevations of buildings, façades, memorials, &c. Armed with this camera, we shall be able to photograph the shyest wild animal, the circling eagle, or the torpedo boat on the horizon. We shall also be able to take life-sized portraits in a limited space, and with it we shall be able to dispense with lenses of from 2 to 3 m. focal distance, which, till lately, have been in use for this kind of work.

As the old blunderbuss stands to the modern rifle, so will the old camera lens stand to the space-governing power of the new one. But the new instrument will serve another purpose. We are already afflicted with innumerable hand-cameras, for no well-known personage can pass down our principal streets without being photographed a dozen times; in the future the situation will become almost insupportable. If we happen to go to any public park, a malicious being may post himself on some point of vantage, and seize our portrait, cabinet size; or, if we only happen to look out of the window, our portraits may be taken by the unseen camera at a distance, though we may find a slender protection in the shape of the smoke and fogs of great cities. In country and seaside places, distance will henceforth be no hindrance to photography.

[Our readers will note that the above article is an extension of our own leading article of the 16th of October on Mr. T. R. Dallmeyer's new lens. It is gratifying that one of our own leading opticians was the first in the field, Mr. Dallmeyer having obtained provisional protection for his patent on the 2nd of October. Dr. Miethe has acknowledged, in the pages of a contemporary, that his application for a patent in Germany was considerably subsequent to Mr. Dallmeyer's application in this country, and also that the publication of Mr. Dallmeyer's invention, that was referred to by us and two other English journals on the 16th of October, was the *cause* of his applying for patent rights in Germany. Dr. Miethe, in acknowledging this, stated that he had been for some time independently occupied with the same subject. Mr. Dallmeyer has spontaneously admitted this in the following words:—"Without the faintest reserve, I gladly accept Dr. Miethe's statement that the same subject has occupied his independent attention, but he must allow that his publication as well as application is subsequent to mine."—Ed.]

## AN ORTHOCHROMATIC COLLODIO-BROMIDE EMULSION.

BY DR. A. JONAS.

The following solutions are prepared:—

| | |
|---|---|
| I.—Crystallised erythrosin ... ... | 4 grammes |
| Distilled water ... ... ... | 50 c.c. |
| Alcohol (96 per cent.) ... ... | 450 ,, |
| II.—Silver nitrate ... ... ... | 3·4 grammes |
| Distilled water ... ... ... | 50 c.c. |
| Alcohol (96 per cent.) ... ... | 150 ,, |

Add ammonia solution until the brown precipitate formed is re-dissolved.

| | |
|---|---|
| III.—Picric acid ... ... ... ... | 3 grammes |
| Distilled water ... ... ... | 10 c.c. |
| Ammonia, sufficient quantity to neutralise | |
| Alcohol (96 per cent.) to make solution to 300 c.c. | |

For use, mix—

| | |
|---|---|
| Solution I. ... ... ... ... | 75 c.c. |
| Solution II. ... ... ... ... | 30 ,, |
| Solution III. ... ... ... ... | 20 ,, |
| Chemically pure glycerine ... ... | 25 ,, |
| Alcohol (96 per cent.) ... ... | 120 ,, |
| Distilled water ... ... ... | 20 ,, |

Allow this cloudy solution to stand for a quarter of an hour, and then add, drop by drop, with constant agitation, stronger ammonia until the mixture is perfectly clear. The solution should now be allowed to stand one or two days in a well-corked bottle, and then filtered. Add 10 c.cm. of this preparation to 100 c.cm. of raw emulsion. By violent agitation the colouring matter is evenly distributed, and after filtering twice through cotton, the coloured emulsion can be at once employed. The coloured emulsion will keep only one or two days, and is best prepared each day just before use.

The raw emulsion should always be well shaken for two to four minutes before mixing, in order that the bromide of silver, which, when the emulsion is at rest, sinks to the bottom, may again be evenly distributed.

The emulsion stained with eosin gives harmonious, soft negatives. The erythrosin emulsion works rather harder, and is especially useful when somewhat hard and strongly contrasted negatives are wanted.

The exposure required is about one-third that with the ordinary wet-plate process, and for the reproduction of paintings no yellow screen is needed.

The eosin and erythrosin-silver solutions keep indefinitely, and should be kept in the dark.

The following directions for the further operations, given by Dr. E. Albert for his emulsions, have been found equally serviceable for my eosin and erythrosin emulsions.

The glass plates used for collodion emulsions should be given a preliminary coating prepared as follows:—Dissolve 5 grammes of gelatine in 50 c.cm. of water, and add 15 c.cm. of acetic acid and 10 c.cm. of alcohol. The solution is filtered warm (30° to 35° R.), and whilst warm is flowed twice over the plates; the latter being removed from the acid and thoroughly rinsed. After being coated, the plates are placed in a vertical position and dried in a room free from dust, at a temperature of at least 15° R.

If stripping plates are needed, it is best to use new glass. The latter is first vigorously rubbed with nitric acid (by means of a flat piece of wood), washed and dried, and afterwards carefully rubbed with chalk, ammonia, and an alcoholic solution of iodine; then dusted with talc, spread evenly without pressure with a tuft of clean cotton, the talc being removed completely with another clean tuft. After this the plate can be coated with emulsion as usual.

The emulsion is flowed over the plate exactly as the iodised collodion in the wet process—in a red light. This can be obtained with an ordinary red dark room lantern, placed about on a level with the operator's head, and distant about one meter—the light coming from above greatly facilitates the preparation of the plate. The light may also be obtained by means of an ordinary dark room window, such as is used for highly sensitive gelatine plates.

Fog and insufficient strength in the pictures come principally from too bright illumination, since both the uncoloured and the coloured emulsions work without fog.

As soon as the collodion is set, the plate may be inserted in the holder, and at once exposed; it will keep moist, however, in a not too warm room thirty to forty minutes. After exposure the plate is washed (in red light) until it no longer shows the so-called greasy streaks. It is held vertically to allow the water to drip off, and is then flowed with the developer. As soon as the developer is on the plate and the image begins to appear, the plate can be examined by weak yellow light. If the development has been carried far enough, the plate is again washed, and then fixed. The fixing takes place rapidly, as well as the elimination of the hyposulphite of soda.

It may here be remarked that the washing should be under a stream of water, which should be moved back and forth over the plate, that it may be covered with water evenly and quickly. The larger the plate, the longer it must drain, and if it has not drained sufficiently the negative is streaked.

The developer should be flowed abundantly over the plate in the same manner as ferrous oxalate in the wet process:—

*Concentrated Hydrochinon Developer.*

| | |
|---|---|
| A.—Distilled water ... ... ... | 500 grammes |
| Sul. soda ... ... ... ... | 200 ,, |
| Carb. pot. ... ... ... ... | 200 ,, |
| B.—Hydrochinon ... ... ... ... | 25 grammes |
| Alcohol (96 per cent.) ... ... | 100 ,, |
| C.—Brom. amm ... ... ... ... | 25 grammes |
| Distilled water ... ... ... | 100 c.cm. |

Developer compounded as follows:—

| | |
|---|---|
| A ... ... ... ... ... | 100 c.cm. |
| B ... ... ... ... ... | 7 ,, |
| C ... ... ... ... ... | 7 ,, |

For negatives of a hard character, the proportions of B are increased to 6 to 10 c.cm. An increase of solution C produces greater clearness, but decreases the sensitiveness somewhat. Hydrochinon increases the strength, bromide of ammonium the clearness, and carbonate of potash accelerates the development.

For developing, a mixture is made of 150 c.cm. of concentrated developer to 1,000 c.cm. of water. By the addition of more concentrated developer, or dilution with more water, a result may be obtained which gives a very fair negative, according to the character of the original. The same rule holds in regard to the addition of more or less of the hydrochinon or bromide of ammonium. For the developer only the best and purest carbonate of potash must be used.

The plate can be intensified before fixing with pyrogallic acid exactly as with the wet process:—

| | | |
|---|---|---|
| A.—Pyro | ... | 7 grammes |
| Citric acid | ... | 7 ,, |

are dissolved in 150 c.cm. distilled water, and twenty-five drops acetic acid added.

| | | |
|---|---|---|
| B.—Nitrate of silver | ... | 10 grammes |
| Distilled water | ... | 100 c.cm. |

Just before using, mix 100 c.cm. A with 5 c.cm. B, and intensify until the desired strength is reached. Negatives intensified in this manner dry still stronger.

*Intensifying after Fixing.*—For intensifying after fixing, the ordinary pyro-silver intensifier, as well as that given by Capt. A. V. Hübl, hydrochinon-silver intensifier, may be used:—

| | | |
|---|---|---|
| I.—Hydrochinon | ... | 10 grammes |
| Distilled water | ... | 1,000 c.cm. |
| Citric acid | ... | 5 grammes |
| II.—Nitrate of silver | ... | 10 grammes |
| Distilled water | ... | 300 c.cm. |

Just before using, mix 3 parts of I. with 1 part of II., and flow the fixed and well washed plate while still wet; as soon as the required degree of intensity has been reached, wash and allow to dry. In order to obtain greater intensity, the negative can be intensified with a solution of two parts of chloride of mercury, 2 parts of bromide of potash, and 80 to 100 parts of water; afterward blackening with sulphite of soda solution (1 : 6).

For reducing, the method used for gelatine plates—hyposulphite of soda and red prussiate of potash—works well. —Abstracted from *Photo. Nachrichten.*

## THE PHOTOGRAPHIC REPRODUCTION OF OLD MSS.

BY J. F. SACHSE.

Of late years, the photographic reproduction of important manuscript documents has become an important branch of our art. As these, in many cases, are illegible and sometimes entirely faded—through dampness or by the use of unstable inks—the photographer is often at a loss how to proceed so as to make a satisfactory reproduction. To overcome this difficulty, a German contemporary suggests to slightly damp the faded manuscript, then paint the writing over with sulphide of ammonia (*schwefelworserstoff-ammonia*), when the writing will immediately come out black and legible. If the document is parchment, the restoration is permanent; if paper, the result is similar, but the effect is only transient. The above action is easily explained by the formation of sulphide of iron.

So far, so good; granting that a satisfactory negative results, what is the effect upon the original? No valuable document should be entrusted to an unreliable photographer, or one who would imperil the original by chemical manipulations. All such risks should be avoided, as the desired result can in almost all cases be achieved by purely photographic means.

We have had a large experience in this particular branch of photography, and always avoid anything which, even in the most remote degree, might work a permanent injury to the original.

In copying subjects of this kind, a slow plate, short exposure, and development with ferrous oxalate, will usually bring about the desired result. In difficult cases an eikonogen developer is often of service.

When the MSS. is very much faded or discoloured, and all other methods fail, the following has given excellent results. Develop with a combined eikonogen and hydrochinone developer until the detail is well out, then fix in acid fixing bath, wash well, and when thoroughly dry, bleach out with the usual bi-chloride mercury and sal-ammoniac solution, wash in running water for fifteen minutes, and when dry place in front of a dead black surface, and photograph. The resulting negative can then be, if necessary, intensified. Excellent results have been obtained by this method; the greatest advantage of all being that it works no possible injury to the original. —*American Journal of Photography.*

## FATAL GAS EXPLOSION AT ILKESTON.

On Wednesday evening, says the *Ilkeston Pioneer*, the people living in the neighbourhood of Stamford Street, Ilkeston, were alarmed by hearing a terrific explosion, which shook all the houses near. It was about half-past seven o'clock, and at the time an entertainment for the benefit of the Pleasant Sunday Afternoon Movement was about to commence in the New Connection Chapel, Stamford Street. It was soon ascertained that the explosion had taken place in the chapel, where Councillor Scattergood was preparing to give a number of dissolving views illustrating the subject of the entertainment. About 100 persons, principally women and children, constituted the audience, most of them sitting near the lantern, which was placed upon a table in the centre of the chapel. The oxygen gas was stored in an india-rubber bag, with a wooden frame-work, upon the top of which were placed three 56lb. weights. After the lantern had been lighted about a quarter of an hour, and just as the performance was on the point of commencing, a very slight explosion was heard, and this was immediately followed by a deafening report.

For a moment the whole place was illuminated, and then there was a crash of falling glass, and piercing screams, which were heard some distance away from the chapel. Of course the lights were blown out, and the place being in almost complete darkness added considerably to the terror of those who were present, as they could not form any adequate idea of what had occurred. The first impulse was to rush to the doors, and this was done in so frantic a fashion that those who were injured were trampled under foot. By the time a light was procured, most of those who were able to do so had made their way outside the chapel. Assistance was promptly at hand, hundreds rushing towards the building, having heard the explosion at a considerable distance away. Amidst the confusion it was almost impossible to tell who had been injured, many of those who had been seriously hurt managing to scramble outside. Here, however, their strength vanished, and most of them were carried to the Cottage Hospital in a very exhausted state. One poor lad, however, named Hubert Brewer, sixteen years of age, was so badly hurt that he died in a few minutes. He was found lying on the floor of the chapel, and was bleeding from a wound in the forehead, having apparently been struck with a piece of wood. His clothes were nearly blown off his body. He was promptly taken to the Cottage Hospital, but he was dead when he arrived. On examining his body, it was found that a piece of his jacket had been forced into a wound which penetrated to the heart, and no doubt this was the cause of death.

The force of the explosion seems to have been felt mainly on either side of the lantern, the boy Brewer having been sitting to the right, while those sitting at the back escaped comparatively uninjured. Another brother of the boy Brewer was also cut and bruised all over the body. So far as can be ascertained, the most severe injuries were sustained by two married women named Slack and Summerfield. Mrs. Slack lives in Lodge Row, Chapel Street, Ilkeston. She was sitting near the lantern, and had one of her eyes blown out, and her cheek laid open, her face being terribly lacerated. Mrs. Summerfield, who lives in Stamford Street, near to the chapel, had also au eye blown out, and the doctors fear she will lose the other eye. In addition to this, she is badly hurt about the limbs, pieces of the ulster she was wearing having been forced several inches into the wounds. Mrs. Carter, of 27, Carr Street, Ilkeston, was cut severely about the legs, pieces of her stockings having been taken from the wounds. Mrs. Cook, 114, Chapel Street, had a wound in her back, aud was trampled on when the stampede occurred. She does not appear to know how she was hurt. Mrs. Baggaley, the wife of a painter, living in Blake Street, had her face and one of her knees badly cut. Two boys named Grainger, aged respectively six and twelve years, whose parents reside at Hallam Fields, were sitting near to the unfortunate lad Brewer. The eldest boy said he was lifted in the air a good height. Both lads have severe wounds on their legs, the eldest being the worst injured. They were taken home in a cab. Mr. Wm. Ashley, of Wilmot Street, was present at the entertainment with his wife. He suffered so badly from the shock that he had to be carried home by the police, of whom a good force was promptly ou the spot. Mrs. Ashley had her face badly cut. Several others were more or less seriously injured, but up to the present their names have not been ascertained. Councillor Scattergood, who was standing at the back of the lantern, was knocked dowu, aud was hurt about the legs. He also suffered terribly from the shock, and was in a semi-conscious state yesterday morning, having been attended by two physicians. The chairman of the meeting was Mr. William Haslam, a member of the School Board. His wife was also present, and she seems to have been completely deafened by the explosion, though it may be only temporarily.

As stated above, most of those who were seriously hurt were taken to the Cottage Hospital, where they were attended to by Dr. Potter and Dr. Paton. After dressing their wounds, they were all taken to their respective homes, there not being a single bed at liberty in the hospit l. Others were attended to at their homes by other medical men in the town. On inquiry yesterday morning, it was found that several of the injured were suffering severely from their wounds, which are of a very serious character.

Our representative was permitted to view the interior of the chapel yesterday, everything having been left just as it was after the explosion occurred. This scene almost defies description. Every window in the sides of the chapel has been completely demolished, and the end windows have been bulged out and slightly broken. The chapel is at least 30 feet high, but such was the force of the explosion that the plaster was torn from the ceiling iu several places. The floor is strewn with broken glass, plaster, fragments of wood, portions of clothing and hats, while in many places it is bespattered with blood, as are some of the chairs as well. Several chairs which stood in front of the lantern are smashed, and there is a large hole through the floor, evidently caused by the falling weights after they had been lifted iuto the air. The lantern lies on the floor, and pieces of the cloth which covered the table have been blown to the ceiling. A mau's silk hat has nothing but the rim left, and an umbrella has been blown to fragments. Pieces of wood forming the frame-work of the oxygen bag flew in all directions, and one piece, which was blown into the gallery twenty yards away, smashed the double bass. The lantern slides lie amongst the *débris*, while the way in which the chairs have been thrown down and upon each other afford evidence of the pauic, which added to the injury caused by the explosion. Had the building been less lofty, it is almost certain the roof would have been lifted off. Hundreds of people rushed to the scene of the disaster in the shortest time, the news having spread like wildfire. It was impossible, however, to see in the darkness the extent of the damage done, which could not be adequately ascertained until yesterday morning, when crowds of people began to assemble from an early hour. The most exaggerated reports were spread in the town with regard to the injured, but, so far as can be ascertained, no bones have been broken, though the flesh wounds are of the worst character.

### OPENING OF THE INQUEST.

The inquest on the body of Hubert Brewer, fifteen years of age, of East Street, Ilkeston, who was killed in the magic lautern explosion on Wednesday night, was held at the Durham Ox Inn, Durham Street, Ilkeston, on Friday evening, before Mr. W. H. Whiston, coroner.

Mr. Wright Lissett (Town Clerk) and Mr. F. C. Humphreys (gas manager), were present to watch the inquiry on behalf of the Corporation; and the Rev. J. Parker and Mr. J. Briggs watched the interests of the trustees of Stamford Street Church. Superintendent Lumley was also preseut; and Mr. A. E. Hopkins (Messrs. Hopkins and Byron) represented the parents of the deceased.

The Coroner, at the outset, said there seemed to be a number of witnesses, and he would suggest that they simply take evidence of identification, and adjourn the inquiry until Tuesday next, at two o'clock, at the Town Hall, when they would go thoroughly into the matter. He had no doubt many who were connected with the injured would like to be present, and he did not think it was advisable to hurry the inquiry.

The jury concurred with the coroner's suggestion, and it was thereupon decided to adjourn, as stated, at the close of the proceedings, which were of a formal character.

[As we go to press, the report of the adjourned inquest reaches our hands. The lauternist was examined with regard to the cause of the explosion, and, after stating that he had taken every precaution to keep each gas to its own bag (he was usiug the mixed jet), propounded certain theories which he had formulated as to the origin of the mischief; but as these depended on the assumption that one of the bags was leaky, they are obviously untenable. The experts examined included Mr. Knowles, the chemist employed by the Birmingham Oxygen Company, Mr. W. M. Jackson, who holds a similar appointment with the Manchester Oxygen Company, and Mr. Chadwick, of Manchester, who for so long has been identified with lantern matters. These all agreed—and auy impartial person must hold the same opinion—that by some meaus the gases had become mixed iu the bags. That such a thing can occur without the kuowledge or mediation of the lanternist is evident from the case quoted in our leading article in to-day's issue. We must add that the jury acquitted Mr. Scattergood of all blame, and returned a verdict of accidental death.—ED.]

---

SOCIETY OF ARTS.—On Wednesday, November 25th, Professor Silvanus P. Thompson, D.Sc., F.R.S., read a paper on "The Measurement of Lenses," an abstract of which will appear in our next issue.

MESSRS. MORGAN AND KIDD'S WORKS AT RICHMOND.—Messrs. Morgan and Kidd have just completed important additions to the front of their works. The new building comprises offices and show-rooms, and makes the frontage of their premises a prominent aud ornamental feature of Kew Foot Road. They have now in progress the erection of another and larger building in the rear of their present premises, and on Saturday the foundation stone was laid by Mrs. Kidd in the presence of all their employées. Messrs. Morgan aud Kidd's business has outgrown their already large premises at all points. The extensive additions now in progress will be fully occupied as soon as ready, and the extra accommodation will enable them to carry on their work with greatly increased facility aud convenience.

## Patent Intelligence.

*Specially compiled for the* Photographic News *by Herbert & Co. (H. J. Haddan & R. Haddan), Registered Patent Agents, &c., of* 18, *Buckingham Street, Strand, London, W.C.*

### Applications for Letters Patent.

19,377. Pearce Henry Crouch, 4, South Street, Finsbury, London, "Improvements in or connected with Photographic Cameras."

19,442. William Edward Crowther, Rock Villas, Londonderry, Ireland, "A Means of Steadying Photographic Cameras in Space during Exposure."

19,471. Julius Wagner and Georg Bredig, 433, Strand, London, "Apparatus for Developing, Fixing, and Washing Photographs."

19,565. John Burgess, 53, Chancery Lane, London, "An Improved Method of Producing Coloured Photographic Pictures."

### Specifications Published.

20,774. *Dec.* 20*th*, 1890. — "Photographic Camera Dark Slides." J. Pitt, 12, Belcher's Lane, Bordesley Green, near Birmingham, and W. Hudson, 118, Gooch Street, Birmingham.

Consists of a shallow box, preferably made of metal, with flange running round its outer edge. In this box is secured a rim allowing a margin round it so as to allow the lid to fall into. This rim is to hold the sensitive plate. The lid is hinged on one side of the box by means of wire passing through box from side to side. The lid working freely on its hinge, and forming a lever outside the box, enables the operator to raise the lid when the dark slide is in position in camera and so expose the sensitive plate; and, dispensing with the ordinary cap ou the lens, to enable operator to make instantaneous exposures, elastic springs are fixed to the lever and dark slide. The lid is kept closed by a catch, which can be released at will. The apparatus thus forms an instantaneous shutter and dark slide combined, aud can be attached to any camera.

21,059. *Dec.* 24*th*, 1890.—"Production of Photographic Negatives." G. F. Redfern. (J. M. Jordan, Philadelphia, U.S.A.)

The object is to effect the permanent marking of uames, titles, or other matter upon negatives. The title is printed directly upon the face, or film side, of the negative, the title, of course, appearing in reverse, in order that it will read properly upon the print. For the purpose of printing the title, rubber type is preferably used, the same being set up successively from right to left as usual, so that the reverse impression ou the negative will be produced.

13,799. *Aug.* 15*th*, 1891.—"Development of Photographic Pictures." O. P. Olvik and H. O. Morken, both of Stördslen, Norway.

Consists in apparatus comprising a bath and dark tent for the development of photographs, whereby the sensitive plate is not exposed to any injurious light, &c. The developing bath—of zinc, india-rubber, &c.—consists of a frame having a glass plate, or the like, secured water-tight in its bottom, and a similar plate in its top. The chamber thus formed is closed by a water-tight door. The plates are protected by metal covers. The developing liquid is poured into the chamber through a funnel and tube, which is bent at an angle to preveut admission of light, and, after being used, is discharged through a tube also bent and provided with a valve.

The inspecting device, only employed when developing by dull light, consists of a frame exactly fitting in the grooves for one of the plates, when the latter is removed, and of a casing terminating at the top in a rotatable tube shaped to fit the eye of the operator.

The dark tent is constructed of light waterproof cloth, on the same principle as an umbrella, the euds being stretched by ribs hinged to runner notches sliding along a stick, and kept in position by stop springs. The ends close inwards when folding; while the longitudinal parts will lie wrapped round the middle part of the stick. Over two manipulating holes in front of the tent mufflers are placed, with elastic bands, to fit over the hands of the operator. In front of the tent is also an opening with elastic band, which closes it. A red-coloured glass plate, through which the inside of the tent may be inspected, and a piece of red translucent cloth admitting the necessary light, are also provided.

16,094. *Sept.* 22*nd*, 1891.—"Producing Photographic Pictures having Colours resembling those of the Objects from which they are obtained." V. Mathieu, 155, Fenchurch Street, London.

A negative is taken in the usual way, preferably upou a glass or other surface, so sensitised as to be as nearly as possible orthochromatic. After this negative has been retouched where necessary, a priut is taken of it on a paper so prepared that the gradations of shade in the negative are accurately reproduced in the print. The print is then toned and fixed in the usual way, after which it is mounted, whilst still wet, on a frame, and allowed to dry. When dry, the back of the print is treated with alcohol, in order to coagulate the albumen, and upon it is then poured a mixture of alcohol and Venice turpentine, the proportion being preferably equal parts of each. The priut is then subjected to a strong heat in a hot-air oven, and, when dry, another coating of the mixture of alcohol and Venice turpentine applied, and again dried, and so on in succession until the print is found to be crisp and absolutely transparent. It is then coated with a varnish of isinglass, upon which oil-colours are then applied in the ordinary way with a brush.

## Correspondence.

### DR. MADDOX AND DRY PLATE PHOTOGRAPHY.

Sir,—January, 1868, W. H. Harrison made a gelatine emulsion, which, for reasons suggested by himself, gave results that were "worthless."

September 8th, 1871, Dr. R. L. Maddox published a gelatine bromide process, aud produced and showed results with it, which are probably in existence now.

July 18th, 1873, Burgess advertised emulsion made with gelatine; he offered details of the process to "subscribers willing to pay one guinea each," &c.

Burgess, then, was uot only two years behind Maddox, but he tried to sell as a secret process what Maddox gave away.

*Cromwell House, Bexley Heath, S.E.* Andrew Pringle.

Sir,—An appeal has just appeared, signed by Mr. Pringle, with reference to the testimonial which is being raised for Dr. Maddox. It is my wish to draw the attention of your readers to a certain statement contained in that letter, but before doing so, I would clearly state that I recognise the worthiness of Dr. Maddox on more grounds than one, and, under the circumstances, also the desirability of benefiting him in the way proposed.

Mr. Pringle states that every photographer knows that the discovery of the gelatino-bromide process is due to the experiments of Dr. Maddox. It can be stated with perhaps far more truth, that it is impossible to find a man who benefited by what Dr. Maddox published, or who thought the result of the experiments encouraging.

The assumption is that Dr. Maddox was the original worker with gelatine emulsion. To say the least, this is au unwarrantable assumption. The facts of the case are on record, and these conclusively prove him to be not first, nor second, nor yet third, with such experiments as he performed with the emulsion; and, what is more remarkable still, his experiments—in which he ouly obtained prints and not negatives—were far less successful than some which are recorded in the photographic jourvals of 1865, 1866, and 1868. If I am not mistaken, Mr. Traill Taylor ought to know somethiug of this, for specimens of work done in a similar way, and with a formula very closely allied to those of the preseut day, were submitted to his notice in 1865.

I do no more than meution these dates, the records of which unmistakably prove that Dr. Maddox was not the first to do such work as that of which he published an account in 1871, aud, indeed, in that very account Dr. Maddox himself states that his experiment is not to be regarded as anything new. At the same time, if his claiu to be regarded as the father of the present system is still to be pushed, I shall ask permission to lay before your readers and the general public a fuller history of this subject than has yet appeared.

Many people are doubtless content to accept the *ipse dixit* of well-known men, but iu a matter of this kind, when the facts are recorded as they are, there need be and can be no dispute.

I enclose my card, but do not wish my name to be published at present. QUI PALMAM MERUIT, FERAT.

## Proceedings of Societies.

### London and Provincial Photographic Association.

At the meeting of this Society held ou the 19th iust., Mr. A. Cowan officiated as chairman.

Mr. G. Pendrey, introduced by Mr. A. L. Henderson, showed some specimens of vitrified enamels on plates and tablets. No information was given as to the method of production.

Mr. Davis showed some fine trausparencies developed with paramidophenol chlorhydrate, and handed round some samples of the developing solutiou, made up as follows, for the purpose of experiment by the members :—

| | |
|---|---|
| Paramidophenol ... ... ... | 8 parts |
| Water ... ... ... ... ... | 1,000 ,, |
| Dry sodium carbonate ... ... ... | 40 ,, |
| Sodium sulphite ... ... ... | 80 ,, |

The developer acted quickly, and might be used eonsiderably diluted.

Mr. A. Haddon said that at a previous meeting Mr. Smith had handed him a sample of a substance said to be serviceable in photography, and wished to kuow its composition. He found it to be sulphate of manganese.

Mr. Smith said that the salt was for use in the sensitising bath in photo-lithographic work, and it was stated that by using it a freedom was obtained in the ink leaving the paper. The formula for use was—

| | |
|---|---|
| Bichromate of potash ... ... ... | 50 parts |
| Water ... ... ... ... ... | 1,000 ,, |
| The salt now known to be sulphate of manganese... ... ... ... | 5 ,, |

Mr. J. Barker showed a print on Ilford printing-out paper which he had toned with the ordinary acetate bath. It was not necessary to use the special sulphocyanide bath recommeuded.

Mr. W. E. Debenham thought the sulpho-cyanide bath better, on account of the quantity of gold deposited by it, rendering the probability of permauence greater.

The slides sent in by members for the lantern competition were then put through the lantern. Four negatives had been used, and the results from each were compared in a pair of lanterns, the voices of the majority present deciding which of two was to be considered the better, after which the successful one was used as the standard of comparison until another was thought to surpass it. For the most part, the slides were of excellent quality, and selection became difficult; but, in the end, the awards resulted as follows :—

| Slides from negatives taken at | First award. | Second award. |
|---|---|---|
| Shire ... ... | T. A. Freshwater (Collodio-albumen). | H. D. Atkinson (Commercial lantern plate). |
| Richmond Bridge... | T. A. Freshwater (Collodio-albumen). | G. W. Atkins (Commercial lantern plate). |
| Cottage Garden ... | J. S. Teape (Lantern plate, hydroquinone). | F. C. Kellow (Lantern plate, pyro). |
| Portrait ... ... | E. W. Parfitt (Pyro carb. ammon.) | F. C. Kellow (Pyro). |

After the competition, a set of slides of trotting horses, taken broadside on with a shutter tested to work iu the $\frac{1}{500}$ of a second, was shown by Mr. L. Medland, and was followed by others sent by Messrs. Davis, Low, Sergeant, and Henderson.

### Camera Club.

*November 19th.*—Mr. W. England in the chair.

Mr. G. L. Addenbrooke read a paper on "Aluminium and its Applications to Photography," in which he briefly described the methods of productiou of the metal, dwelling upon the circumstauces which have led to the cheapening of its price. The qualities and characteristics of alumiuium for casting, solderiug, rolling, and for working generally were given, and the lecturer concluded by describing the utility of the metal for photographic purposes.

Some excellent examples by the Phœnix Engineering Company were on exhibition in the room.

At the lantern eveniug on November 30th, Mr. Frank Haes will exhibit his slides showing what was done in "The Early Days of Auimal Photography." On December 3rd, Mr. A. R. Dresser will treat the subject, "Toning Bromide Paper and Transparencies," with demonstration and illustration.

### Holborn Camera Club.

*November 20th.*—Mr. Fred Brocas in the chair.

Mr. J. G. Hudson demonstrated with the "Kolm," a light for taking portraits at night. The apparatus was shown at the P.S.G.B. exhibition, and has also been demonstrated before the members of that Society at one of their meetings. It is an arrangement whereby magnesium is blown into a spirit flame, giving a steady light for any length of time necessary to take a portrait. The light is shown behind ground glass, and the smoke is carried away by a curved funnel. It burns very little magnesium, and gives au excellent light. It is a simple though ingenious contrivance, and serves its purpose admirably. Mr. Hudson exposed half-a-dozen plates in the room on single portraits, and a group. These were afterwards developed, aud turned out exceedingly well.

The arraugements for patentiug the "Kolm" have just been completed.

### Brixton and Clapham Camera Club.

*November 19th.*—Dr. Reynolds in the chair.

The committee reported that they had inspected some rooms which they thought would be more suitable than their present quarters, as they were larger, more couvenient, and had the advantage of a room adjoining with a sink with hot aud cold water laid on, which could be used as a dark room and for demonstration purposes. After discussion, it was resolved that the Club take up its abode at the Clarence Rooms, 376, Cold Harbour Lane, Brixton, without delay, and that a reception be held on 18th December to inaugurate the opening.

### Richmond Camera Club.

*November 20th.*—Mr. Cembrano in the chair.

Mr. Herbert Fry gave a demonstration of the development of "Opals and Ivorytypes." After some remarks on the relative merits of the ferrous oxalate and hydroquinone developers, and the advantage of an acid fixing bath (hypo and acid bisulphite of soda), in substitution for the usual acid clearing bath before fixing, Mr. Fry exposed and developed with hydroquinone an opal and a celluloid (or so-called ivory) film, explaining the processes and giving formula as he went along.

In the report of last week's meeting, "caramel with glycerine" was inadvertently written for "caramel with gelatine." The reporter expresses the hope that, if anyone has tried the former backing, he may live till it is dry.

---

DERBY PHOTOGRAPHIC SOCIETY.

ON the 17th inst., at Smith's Restaurant, Victoria Street, Derby, the "New Hampshire" lantern slides (seventy), lent by the Liverpool Amateur Photographic Association, were exhibited by means of the oxy-hydrogen lantern.

Mr. Bendle W. Moore was elected a member of the Society.

Mr. RICHARD KEENE presided, Mr. C. J. CHADWICK gave the connective reading to the slides, and Messrs. Mills and Scotton, jun., worked the lantern.

---

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

*November 23rd.*—Mr. J. SAVILLE in the chair.

Mr. T. C. JONES read a paper on the "Working of Black and Sepia Platinotype Paper," demonstrating his points as he went along. He said that the process was at once the simplest, quickest, and cleanest of all photographic processes of printing. The most suitable negative was one full of gradation obtained by a full exposure and a rather slow development, but not necessarily dense. The paper had been greatly improved during the last eighteen months, and would yield good prints from any ordinary negative. The lecturer said that prints made from a negative with moderate contrasts showed the shadows of a dull orange tint, lighter and different in tone from the other parts. The parts were solarised, and the prints would develop correctly. Thin negatives would not produce this effect. Hard negatives would, when developed, show heavy blacks in the shadows; such prints required hot and prolonged development. It was difficult to say what amount of detail should be visible in the print before development, but usually all parts of the picture except the detail in the highest lights should be visible. Paper which had been kept some time under proper conditions would yield best prints from hard negatives; 130° F. might be considered the standard temperature. Over-exposed prints might be saved by cool, and under-exposed prints by hot development. The developer, when stored away for future use, should be kept from the action of a strong light, and it was a good plan to add a little fresh developer to the working solution on each occasion of using it. It was advisable to give three clearing baths for five, ten, and fifteen minutes respectively, to the prints after development. With few exceptions, the sepia process was similar to the black. It was more easily affected by light, therefore increased care must be taken in handling. The special solution must be used in the developer, and the same dishes must on no account be used for both processes. The temperature must be from 150° to 160°. Discolouration of the whites would be due to want of sufficient special solution in the developer, exposure of the developer to light, the use of dish with cracked enamel, exposing the iron, paper kept too long, or exposure of the prints to light while clearing. Porcelain dishes carefully heated were best for the sepia process. The faults usually found in beginners' work were as follows:—(1) Prints grey and wanting in vigour; probably due to (*a*) under-printing, (*b*) a weak negative, (*c*) cool or too short development, or (*d*) a weak developer. (2) Black spots or black or grey smears; caused by tearing the paper, allowing particles of the sensitive salt to be sprinkled over the print, and reduced there on development. (3) Rusty prints; the paper was stale or damp, or the developer was at fault. (4) The whites were degraded; if grey, the paper or the developer had been exposed to too much light; if drab, the paper was stale or damp. To prove if the paper was at fault, develop a piece which had not been exposed to light after clearing; if not white, it had deteriorated. (5) The shadows were "eaten out," resembling brown paper; cause, solarisation. Some give a longer and hotter development, on no account removing from the bath till the salts had been thoroughly reduced in the shadows.

One member was elected, and three candidates for election proposed.

---

MIDLAND CAMERA CLUB.

*November 20th.*—In the Library, Queen's College, Birmingham, Dr. HALL EDWARDS in the chair. Fifteen new members were elected, making a total of sixty-three at the second meeting of the Club. Dr. Leech offered a prize of a hand-camera if the Club intended to hold any competition at the end of the winter season.

The lantern was then brought into requisition by Messrs. Warren and Welford, and the slides were described by each member. Prof. Allen showed several of Somerset churches; the President, a few home portraits and some sketches made in lead pencil upon ground glass, afterwards made transparent by varnishing. These latter, he said, were extremely easy to do, and the surface admitted of the most delicate shading. The Hon. Secretary showed hand-camera shots, flash-light work, and isochromatic results against ordinary plates. Mr. Welford showed hand-camera work, and the following exhibited varied sets:—Rev. J. Henry, I. J. Perry, Fred. Iles, W. W. J. Nicol, R. J. Bailey, and Wm. Bentley. Dr. Maberly showed a series of Norway slides.

The next meeting will be held on Dec. 4th, when "The Keeping Qualities of Gelatine Dry Plates," by Dr. Leech, will be the subject for consideration.

---

BIRKENHEAD PHOTOGRAPHIC ASSOCIATION.

THE annual meeting was held on November 13th, when the following were elected officers for the ensuing year:—

*President*—Mr. G. A. Carruthers; *Vice-President*—Dr. W. H. Hunt; *Council*—Messrs. Paul Lange, H. F. Stanistreet, G. Latimer, C. B. Reader, G. E. Thompson, H. B. Millar, W. T. Briggs, A. F. Edwards; *Lanternist*—Mr. W. A. Norrish; *Librarian*—Mr. J. A. Forrest; *Auditors*—Messrs. A. Bradbury, H. S. Nicklin; *Hon. Treasurer*—Mr. W. A. Brown; *Hon. Secretary*—Mr. F. Hope Jones, Prenton, Birkenhead.

The reports of the Secretary and of the Treasurer having been submitted, the president, Mr. G. E. THOMPSON, gave an interesting and instructive demonstration on "Finishing of Transparencies." An exhibition of slides by various members terminated the proceedings.

It was decided to extend the time for sending prints in for competition until the date of next meeting.

---

OXFORD PHOTOGRAPHIC SOCIETY.

*November 17th.*—Mr. H. MINN gave an explanation of the process of collodio-bromide emulsion making for transparencies. The interest of his remarks was increased by the making and finishing of a half-plate positive, which was admired for its clearness and good tone.

Mr. W. W. Fisher, M.A., Aldrichian Demonstrator in Chemistry, The Museum, and Public Analyst, was elected a member.

It was decided to have conversational meetings on alternate Mondays, in addition to the ordinary meetings on the first and third Tuesdays in the month.

---

BRECHIN PHOTOGRAPHIC ASSOCIATION.

*November 19th.*—Mr. MACKIE in the chair.

The subject for the evening was the Chairman's paper on hand-camera work. After speaking on the various points of what he considered a good hand-camera, Mr. Mackie took up the development of instantaneous exposures, recommending dry pyro with ammonia and bromide of potash. He afterwards showed a selection of lantern slides to illustrate his paper. The lantern lamp used was Stocks' patent, kindly sent down by Mr. Stocks for exhibition. The general opinion was that the lamp was a considerable improvement on the ordinary form of paraffin lamp, the chief points of improvement in it being an adjustable chimney, and the reflector outside the combustion chamber.

Dundee and East of Scotland Photographic Association.

*November 20th.*—The chief business of the evening was a demonstration by Mr. H. M. Smith, of the Eastman Company, who brought under the notice of the members a new rapid bromide paper, which could be toned to a sepia tint—a colour preferred by many to the cold steel-blue tone of ordinary bromide paper. Referring to the kodak camera, he recommended the larger sizes, from quarter-plate and upwards. From twenty to twenty-five feet was about the best distance for a hand-camera from the nearest object. Mr. Smith exhibited a series of lantern slides, comprising views in England, Wales, and several Continental countries, all taken with a kodak camera on quarter-plates and 5 by 4.

In the competition for enlargements, the prizes were awarded as follows :—First, Mr. D. Ireland, two views of a Norwegian fjord ; second, Mr. J. Munro, St. Monan's and Perth Bridge.

Photographic Society of Japan.

A meeting was held at No. 9, Kaga-Yashiki, Tokyo, on the 4th inst. The object of the meeting was to give members an opportunity of testing the rapidity of their instantaneous shutters.

A fly-wheel, rotated by a crank, and having a silvered glass ball attached to the periphery, was fixed up, with a seconds pendulum alongside of it. By watching the seconds pendulum it was very easy, after a little time, to make the wheel revolve at a uniform rate of sixty revolutions a minute, or one a second. Immediately that a uniform speed of sixty revolutions a minute had been attained, an exposure was made with the shutter to be tested. On development of the plate, the angular motion of the wheel was indicated by the length of line traced out by the silvered ball, and it was a very simple problem to work out the exposure in the form of the fraction of a second.

The shutter that worked the most quickly was the "Caldwell." This, at its highest speed, gave an exposure estimated at ouly $\frac{1}{125}$ of a second. Of the rapidest of the other shutters tried, none gave as little as twice this length of exposure. The longest exposure that was "instantaneous" (not "time") was $\frac{1}{13}$ of a second.

Photographers who do "instantaneous work" have generally notions vague, to say the least of it, about the exposures they are giving. The tests made by the Photographic Society of Japan go to prove that by far the greater number of "instantaneous exposures" are somewhere between $\frac{1}{20}$ and $\frac{1}{60}$ of a second.

An interesting feature of the meeting was a trial of speed, by several of the members, in hand exposures—"cap off and on." It was shown that more than one member could give an exposure as short as $\frac{1}{5}$ of a second by hand without shaking the camera at all. It was found advisable to use a very loose cap.

Three new members were elected.

This report has been delayed on account of the time necessary to work out the exposures of the various shutters from the markings on the plates exposed.

North London Photographic Society.—On December 1st, in Wellington Hall, Islington, at 8.15 p.m., there will be an optical lantern display, to which visitors are invited.

London and Provincial Photographic Association.—Dec. 3rd, "The Exaggerated Perspective of Wide-Angle Lenses"; Dec. 10th, "Warm Tones in Lantern Slides"; Dec. 17th, monthly lantern night.

Glasgow and West of Scotland Amateur Photographic Association.—On the 17th inst., a paper was given by Professor A. Humboldt Sexton, of the Technical College, on "Kallitype and Kindred Printing Processes," of which he gave a demonstration. There was exhibited a large and fine collection of lantern slides.

A Photographic Veneer.—A recent invention covers the use of certain forms of collodion for the application of photographs to cabinet-ware. The inventor applies the print to the wood to be decorated, and the surface is afterwards polished by pressure on a metallic surface. The invention has for its principal object the veneering of furniture.

## Answers to Correspondents.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

Questions requiring a reply in this column, which have hitherto been addressed to Mr. Spiller (who, unfortunately, is unable at present to continue his efficient assistance), should be sent to the Editor.

All other Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

Walker.—Chlorate of potash in combination with any preparation of which sulphur forms part is an extremely dangerous explosive, for it will ignite uot only with heat, but by percussion. There is no need to employ chlorate in flash-light mixtures at all. The powdered magnesium used by itself is all-sufficient. It is not generally known that a mixture of this metallic powder and chlorate of potash forms a mixture which behaves, when ignited, like gun-powder.

A. H. H. (Surrey).—An exhaustive article on the subject is now in print for the Year-Book, and, as we gather from your letter that you are not in immediate need of the information, we refer you to that source in preference to giving necessarily brief directions in this columns.

Jap.—It is difficult, if not impossible, to get dense negatives of line subjects on rapid plates, but there is no difficulty at all if you use those of moderate speed. Professional workers use the wet process for this class of negative almost without exception. You will, however, secure equal results by employing the photo-mechanical plates made by Mawson ; or those of Mr. England, Notting Hill. We have secured excellent negatives on both these brands of plates.

Varnish.—A fairly elastic varnish, suitable for the purpose named, can be made by adding shellac to a saturated solution of borax, and shaking every now and then until the gum is dissolved. This is a matter of some days. Now add any black pigment in fine powder, and stir it well into the mixture. This varnish is a quick drier.

O. Bevan.—You will find the information you want in Captain Abney's paper on light, which we publish in this issue. The burning of magnesium in oxygen is, of course, not new, but the application of the light to printing purposes is distinctly so. Send in your suggested remarks by all means, and we shall then be able to see if we can find space for them.

F. H.—You will see that the matter to which you refer has not been overlooked. We quite agree with your comments upon it.

Mercia.—The safety-gauge is made by Clarkson.

Mona, C.—Our own suspicions point that way, but the question need not be revived.

Kandy.—Try a saturated solution of the cyanide instead of the five per cent. mixture which you have been using.

Isleworth.—The patent office specifications are open to all, and if you have no time to make the search yourself, there are many idle ones who would be glad to do so for a small fee.

Ismay, R.—The arrangement would at the best be but a makeshift, and after your trouble you would only be disappointed.

THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

VOL. XXXV. No. 1735.—*December* 4, 1891.

CONTENTS.

## ABOUT SOME LANTERNS.

THE lantern has now become almost as familiar to amateur workers as the camera, but, unlike the latter instrument, it requires great care in working—that is to say, if it be fitted with lime-light. Much has lately been written about its capabilities as a means of instruction, and its use has even been advocated as an aid in religious services. There could be no possible objection to such recommendations if the worthy writers who ventilate their views would only seek some acquaintance with the working of the instrument itself. This they commonly neglect to do. It is sufficient for them that the lantern will be an effective handmaid to them, and they talk as airily of the manner in which it is used as if the operation were as easy as the spinning of a top. And yet, as all who have had any experience with the instrument must know, the lantern should not be handled by anyone new to the task without several words of caution.

This universal cry for more lantern work has had one bad result, which, however, in the natural course of things, must be of a temporary nature only. It has caused a great influx of rubbish in the shape of optical lanterns, and the creation of a certain class of dealers who know somewhat less of the instrument than do their customers. It has been our fortune, within the past year or so, to be appealed to by many persons who have bought cheap lanterns—at least, they are by courtesy called cheap—and who have forwarded or brought the instruments to us in order that we may pronounce an opinion upon them. This we invariably decline to do, in the first place, because we do not care to increase the number of threatened actions for libel which is the common lot of newspapers to receive; secondly, because we have no time for experiments with apparatus which, at a glance, we see to be useless; and thirdly, because we do not care to run the risk of bodily injury from "fooling around," as the Americans say, with faulty apparatus. But "faulty" is no word to describe some of the fearful and wonderful instruments which come to us in this way; "fraudulent" would be by far the better adjective to employ. In what other way could we describe a lime burner with the jet attached to the gas supply tubes with *solder?* But we will not multiply examples, although we could easily do so. Let it be sufficient to point out that the first risk run by the aspiring lanternist is not from contact with mixed gases, but from contact with one of these low-class dealers.

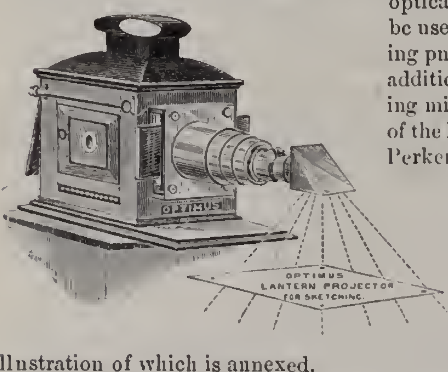
We have expressed the opinion that the evil is only of a temporary kind, for a man who sells rubbish becomes known sooner or later, and his trade declines. But it must be remembered that such traders could not go on for long unless they had clients ready to patronise them. Some people—and well-to-do people too—will take a vast amount of trouble to save a few shillings in a purchase. There are many well-known dealers in lanterns who would not, for any sum offered to them, allow a faulty instrument to leave their premises. Their names are known all over the civilised world for the excellence of their work, for which they charge a fair price. But the buyer of the type already alluded to takes no count of all this. He is deluded by the specious advertisement of a dealer of mushroom growth, buys his lantern, and, when he has found how worthless the thing is, is only too glad to sell it at a fraction of its cost.

An inexperienced buyer is very apt to be deceived by the outside appearance of a lantern. A case of this kind came under our personal notice only a few weeks back. We were asked to lecture at a large provincial hall; a lantern, which was described as "a magnificent triunial," being provided by the promoters. Upon entering the room, this gorgeous instrument at once attracted our attention, so brilliant was it in its array of polished mahogany and lacquered brass. "What do you think of that?" said our guide. Our answer was that we would reserve our opinion until we saw the instrument at work, whereupon the operator lighted up his jets, and we handed to him a test slide. This was a birdseye view of a portion of London, full of detail, and as perfect a picture in other respects as it was possible to procure. When projected by this gorgeous lantern on an eighteen-foot sheet, the picture was edged all round with a three-foot margin of fuzziness. We forget what the lantern cost its owner, but we remember well that the sum was quite sufficient to have enabled the seller to fit it with the finest lenses procurable, and at the same time to have netted a profit of about one hundred per cent.

As a cure for this lamentable state of things, which must be deplored by all honest traders, we venture to suggest a remedy. It may be difficult to carry out in many cases for want of room, but we feel certain that any dealer in lanterns adopting it would find it advantageous in the end. Let the *bonâ fide* purchaser have a practical demonstration of what the lantern which he is buying is capable of before the transaction is completed. No other test can really be relied upon. Such demonstration could be carried out in a warehouse full of goods if no other apartment were available, for the lantern could be placed high up so as to shoot over any obstacles which encumbered the floor. A fixed screen, and a means of shutting out the daylight, would complete the arrangements. The purchaser would then be able to see the amount of light afforded by oil lamp or lime jet, and the difference in definition given by a cheap lens and a more expensive one. In many cases he would in this way be tempted to spend far more money than he originally intended. It might also be worth consideration on the part of dealers to give free lessons to purchasers, or to charge a fee to others for practical instruction in the working of the lime-light.

## NEW AIDS TO LANTERN WORK.

Some weeks ago we published an article showing how the optical lantern may be used for sketching purposes by the addition of a sloping mirror in front of the lens. Messrs. Perken, Son, and Rayment have embodied our suggestions in their 'Projector,' an illustration of which is annexed.



The same firm have also just introduced a new form of lantern slide carrier, which possesses the advantage of enabling the lanternist to change the pictures without running any risk of dulling the glass by finger-marks. The sketch will show that the picture is raised from its groove by a lever, when the worker can easily grasp it by the edges.

## PHOTOGRAPHY AS AN ART.

BY A "POSTULANT."

I have waited over two months in the hope that some one better qualified than myself would challenge some of the statements in the excellent paper on "Photography as an aid to Illustrative and Pictorial Art," published in the August number of the Journal. Considering the position held in the world of art by the writer, my anxiety to see some one else enter the lists with the learned Superintendent of the Calcutta Art School was only natural; but, as evidently there are many of my way of thinking who are as prudent as myself, I am compelled by circumstances to come forward in the photographic interest. I yield to none in my admiration of the lecturer, and I am firmly convinced that his open, candid speech will do more to further the artistic claims of photography than the more voluminous labours of smaller men. But—and unfortunately this is a big "but"—he was a painter before he became a photographer, and, in not putting off the old love before he took up with the new, he has committed himself to statements which photographically whole-hearted men like myself cannot allow to pass unquestioned. I trust Mr. Jobbins will recognise my position, and forgive the contentious temerity of one who would far sooner be his disciple than his opponent.

To be thorough, I should take an initial objection to Mr. Jobbins' remark that he did not "wish to exalt photography at the expense of art, and in the great essentials photography has no place." This subject has, however, been so threshed out in the English journals that the repetition of the arguments advanced in support of the claims of photography would only unnecessarily weary my readers, and it would be unprofitable to waste time and precious space on a question which has practically been settled in our favour. I shall confine my observations to the rather startling proposition by Mr. Jobbins that "it is vain for the photographer to try to infuse into his work the undefinable charm of great artists like Millet or Corot. Millet only gives the essentials, religiously keeping out what was unnecessary; his hard-worked and uncomplaining peasants were the embodiment of the silent toil of centuries. Photography at its best can only give you facts; they may be subdued by being out of form, but still they are there. Nor can photography give you the poetry of an evening as Corot did, where you saw the gentle ripple on the water, the breeze shaking the leaves on the trees, and the feeling of peace and repose." These are hard words indeed, and decide without due caution such debatable questions as—(1) Are facts incompatible with art? (2) Does the undefinable charm of all works necessarily lie in an airy suggestiveness of essentials unsupported by facts? and (3) Is it true that Millet's embodiment of the silent toil of centuries owes its charm to exclusion of detail, or is the feeling inspired in the spectator properly traceable to a poetic association of ideas. A dozen other controvertible points might be suggested, but I have no desire to model this protest to the shape of a Scotch sermon, with its eighteenthly and nineteenthly, and I think the three questions, if fully considered, will meet all requirements.

First, is fact opposed to art? With due deference to Mr. Jobbins' opinion, I must insist that it is not. I shall go further, and say that, unless a picture is so based on facts that the foundation is evident to the most careless observer, it can have no claim to art. In this view I have the support of Ruskin, who says that "he who is closest to nature is best. All rules are useless, all genius is useless, all labour is useless, if you do not give facts; the more facts you give the greater you are; and there is no fact so unimportant as to be prudently despised, if it be possible to represent it." In reality, a close and constant reference to facts is the only certain criterion of the value of a picture as a work of art. "Tell any man, of the slightest imaginative power, that such and such a picture is good, and means this or that; tell him, for instance, that a Claude is good, and that it means trees, and grass, and water; and forthwith, whatever faith, virtue, humility, and imagination there are in the man, rise up to help Claude, and to declare that indeed it is all 'excellent good, i' faith'; and whatever in the course of his life he has felt of pleasure in trees and grass, he will begin to reflect upon and enjoy anew, supposing all the while it is the picture he is enjoying. Hence, once a painter's reputation is accredited, it must be a stubborn kind of person indeed whom he will not please or seem to please; for all the vain and weak people pretend to be pleased with him, for their own credit's sake, and all the humble and imaginative people seriously and honestly fancy they *are* pleased with him, deriving, indeed, very certainly delight from his work, but a delight which, if they were kept in the same temper, they would equally derive (and, indeed, constantly do derive) from the grossest daub that can be manufactured in imitation by the pawnbroker. Is, therefore, the pawnbroker's imitation as good as the original? Not so. There is the certain test of goodness or badness, which I am always striving to get people to use. As long as they are satisfied if they find their feeling pleasantly stirred and their fancy gaily occupied, so long there is for them no good, no bad. Anything may please, or anything displease, them; and their entire manner of thought and talking about art is mockery, and all their judgments are laborious injustices. But let them, in the teeth of their pleasure or displeasure, simply put the calm question—Is it so? Is that the way a stone is shaped, the way a cloud is wreathed, the way a leaf is veined? And they are safe."

Admitting, then, that all true works of art must be based on, be inseparable from, facts, we pass on to the second assertion of Mr. Jobbins, that only essentials should be given. The proposition is somewhat vague, as no attempt has been made to define "essentials." It may include anything from loose impression to microscopic detail. Judging from his admiration of Mrs. Cameron's works, and the fact that he is a painter, I take the remark to mean that the lecturer objects to the inclusion in a picture of any detail not absolutely essential to the working out of the artist's conception, or for a communication of the story told to the observer. It is not difficult to see that Mr. Jobbins speaks only as his artistic training permits him to do. Human hands cannot possibly depict the wealth of delicacy of nature; the futility of the attempt has been recognised, and from the knowledge has arisen an impression among painters that detail is objectionable—a convenient doctrine enough, but one that requires refutation as incorrect and misleading. No work can properly lay claim to greatness or completeness unless it is *finished* by the addition of *facts* to the utmost possible extent. All true finish is *added fact.* Hear again what Ruskin has to say on this point: "If you will lie down on your breast on the next bank you come to (which is bringing it close enough, I should think, to give it all the force it is capable of), you will see, in the cluster of leaves and grass close to your face, something as delicate as this, a mystery of soft shadow in the depths of the grass, with indefinite forms of leaves, which you cannot trace nor count, within it, and out of that, the nearer leaves coming in every subtle gradation of tender light and flickering form, quite beyond all delicacy of pencilling to follow; and yet you will rise up from that bank (certainly not making it appear coarser by drawing a little back from it), and profess to represent it by a few blots of 'forcible' foreground colour. 'Well, but I cannot draw every leaf that I see on the bank.' No, for no human work could be finished so as to express the *delicacy* of nature. Accept that necessity, but do not deny it; do not call your work finished, when you have, in engraving, substituted a confusion of coarse black scratches, or in water-colour a few hazy blots, for ineffable organic beauty. Follow that beauty as far as we can, remembering that just as far as we see, know, and represent it, just so far your work is finished; as far as you fall short of it, your work is *un*finished; and as far as you substitute any other thing for it, your work is spoiled. How far Turner (the greatest landscape artist that ever lived) followed it is not easily shown. Every quarter of an inch of Turner's drawings will bear magnifying in the same way; much of the finer work in them can hardly be traced, except by the keenest sight, until it is magnified. In his painting of 'Ivy Bridge,' the veins are drawn on the wings of a butterfly not above three lines in diameter, and in one of his smaller drawings of Scarborough, the mussel-shells on the beach are rounded, and some shown as shut, some as open, though none are as large as one of the letters of this type; and yet this is the man who was thought to belong to the dashing school, literally because most people had not patience or delicacy of sight enough to trace his endless detail."

Coming from the source it does, I should scarcely wish for anything more emphatic in the evidence in favour of photography. It should be our glory and our pride that we and we alone can reproduce the flickering forms, subtle gradation of light, and the redundant beauty of nature. Yet we are called on to follow humbly a branch of art based on impotence, and glorying in its imperfection. People can readily form artificial standards of taste, and we have not far to go to see club feet and wasp waists regarded as the perfection of beauty; but let us not follow the ruck, and surrender an undoubted distinction for an artificial ideal. We shall, of course, be called unartistic if we use our power to record all the detail that the eye sees, but that does not much matter. When it is counted a virtue that Leonardo drew every several vein in the little agates and pebbles of the gravel under the feet of the St. Anne in the Louvre; that Titian painted, petal by petal, the borage blossoms lying loose on the table in the "Supper at Emmaus" in the Louvre; that Tintoret painted carefully the strips of black bark on the beach trunk sustaining the platform in his "Adoration of the Magi"; and that Bellini filled the rents of his ruined walls with the most exquisite clusters of the Erba della Madonna (Linaria Cymbalaria), we need not regard the jeers of those who condemn detail because they cannot compass it. By this I do not mean to reflect on Mr. Jobbins, whose great artistic talents are known over India, but he has been trained among painters who despise detail, and his statements must be received with caution.

It would be amusing, were it not pitiable, to observe how completely we are subject to the fetish of tradition. The painter says photography can never rise to the heights of art, because selection is scarcely possible to us, and we can only reply that by careful combination printing we can select to some extent. Shall we never release ourselves from the false trammels that bind us? Will the time never come when we shall claim the highest place in the temple of art because of our undiluted truth? A story is related of a young German painter who had been travelling in Italy, and had brought a portfolio of sketches, remarkable alike for their fidelity and their purity. Every cottage, every cliff, every tree at the site chosen, had been drawn; and drawn with palpable sincerity of portraiture, and yet in such a spirit that it was impossible to conceive that any sin or misery had ever entered into one of the scenes he had represented. It was very interesting to observe the minute emendations by which this was effected. To set the tiles the slightest degree more in order on a cottage roof; to insist upon the vine leaves at the window, and let the shadow which fell from them naturally conceal the rent in the wall; to draw all the flowers in the foreground, and miss the weeds; to draw all the folds of the white clouds, and miss those of the black ones; to mark the graceful branches of the trees, and, in one way or another, beguile the eye from those which were ungainly; to give every peasant girl whose face was visible the expression of an angel, and every one whose back was turned the bearing of a princess; finally, to give a general look of light, clear organisation, and serene vitality to every feature in the landscape—such were his artifices, and such his delights. And yet, comments our greatest art authority, "his work had, nevertheless, its stern limitations and marks of everlasting inferiority. Always soothing and pathetic, it could never be sublime, never perfectly nor entrancingly beautiful; for the narrow spirit of correction could not cast itself fully into any scene; the calm cheerfulness which shrank from the shadow of the cypress and the distortion of the olive, could not enter into the brightness of the sky that they pierced, nor the softness of the bloom that they bore; for every sorrow that his heart turned from, he lost a consolation; for every fear which he dared not confront, he lost a portion of his hardiness. The unsceptred sweep of the storm clouds, the fair freedom of glancing shower and flickering sunbeam, sank into sweet rectitudes and decent formalities; and, before eyes that refused to be dazzled or darkened, the hours of sunset wreathed their rays unheeded, and the mists of the Apennines spread their blue veils in vain." Rise, brother photographers, in your might, and refuse longer to play the part of Yahoos to painting Houyhnhnms.

And now I come to the question, wherein lies the charm of certain paintings not burdened with much detail? Though I contend that detail is an advantage, I am prepared to admit that the very highest form of art leaves something to the imagination—stimulating it, in fact. In such cases the artist interprets nature to us; we see with his eyes, and hear with his ears, recognising in him the mind of a "God-made great man." But this is very different from the ostentatious exclusion of detail, when detail is seen in nature, and if works in which such elimination has been carried to excess please, the pleasure arises from association of ideas. The enjoyment, however, in almost every instance is confined to men of strong poetic feeling, who are apt to be the very worst judges of painting. As Ruskin says: "The slightest hint is enough for them. Tell them that a white stroke means a ship, and a black stain a thunderstorm, and they will be perfectly satisfied with both; and immediately proceed to remember all that they ever felt about ships and thunderstorms, attributing the whole current and fulness of their own feelings to the painter's work; while probably, if the picture be really good, and full of stern fact, the poet or man of feeling will find some of its facts *in his way*, out of the particular course of his own thoughts; be offended at it, take to criticising and wondering at it; detect, at last, some imperfection in it, such as must be inherent in all human work, and so finally quarrel with and reject the whole thing. * * * And thus, in a slovenly or ill-finished picture, it is no credit to the artist that he has 'addressed the imagination'; nor is the success of the appeal any criterion whatever of the merit of the work. The duty of an artist is not only to address and awaken, but to *guide* the imagination; and there is no safe guidance but that of simple concurrence with fact."

Photography, however, has its limitations, though this arises not from any inherent defect, but from the lateness of the discovery of making light pictures. Historical pictures and works of pure imagination are not within our reach. Take, for instance, Tintoret's "Adoration of the Magi." We know that the fair young Madonna, the type of purity for all ages, is the unaltered portrait of a young Venetian girl, the Magi are unaltered Venetian senators, and the figure with the basket an unaltered market woman of Mestre; but in the painting we see not the models, we recognise only the lofty ideals. Now we might get exactly similar figures, dress them similarly, and pose them before the camera in identical positions, and yet fall far short of the painting. The spectator will never succeed in forgetting that the persons portrayed were other than those intended to be represented. Yet I do not see that this fact proves the inferiority of photography. The painting is most undoubtedly valuable, but supposing our art had been known at the advent of the Redeemer, and a photograph had been taken of the adoration of the Magi—hard facts and nothing more—which would have been more precious to us, the painting or the sun picture? Would we not have sacrificed art and all that the world holds for us, to behold with reverent love her whom all nations call "blessed," our life, our sweetness, and our hope?

I shall close here for the present, but before doing so I may remark that there is a grain of truth in the assertion by Mr. Jobbins—"Nor can photography give you the poetry of an evening as Corot did, when you saw the gentle ripple on the water, the breeze shaking the leaves on the trees, and the feeling of peace and repose." No, photography cannot show the ripples on the water, nor the breeze shaking the leaves, for these do not exist in nature at eventide. As Mr. Jobbins says, we give *facts*. —*Journal of the Photographic Society of India.*

The Teachers' Guild of Great Britain and Ireland.—The *Journal of Education*, in its issue of December 1st, publishes the report of the Council of the above Guild, from which it appears that "it is proposed to make a collection of lantern slides, to be kept at the offices of the Guild, for loan to members. Mr. William Rice has promised a duplicate set of a prize-medal series of slides as the nucleus of such a collection. Amateur photographers are invited to contribute any spare slides of a specially educational character which they may possess. Parcels should be addressed to the Offices of the Guild, 74, Gower Street, W.C.

## Short Notices of Books.

Photographische Optik. (*Halle a. S.: Wilhelm Knapp.*)
The greater portion of this book consists of the substance of lectures delivered before the Club of Amateur Photographers in Vienna, collected and arranged by Anton M. Haschek, who, while modestly disclaiming the title of a scientific work for his production, has presented a very useful treatise on the nature and application of photographic lenses. The value of the book is increased by the addition of chapters respectively on "The Choice and Testing of Lenses" and on "Photometry." The whole is comprised in 96 pages, with 68 illustrations.

Die Negativ Retouche nach Kunst und Naturgesetzen. By Hans Arnold. (*Leipzig: A. Hartleben.*)
Works on artistic retouching are few in number, and this excellent manual will be found by readers of German a valuable addition to the photographic library. Devoted mainly, as its title would indicate, to the art of retouching, it nevertheless embraces useful hints on lighting, exposure, and development. The work consists of nearly 500 pages, and the text is illustrated by 53 diagrams.

The Handbook of Photographic Terms. By William Heighway. (*London: Piper and Carter.*)
This is a second edition, revised and enlarged, of an alphabetical arrangement of the processes, formulæ, applications, &c., of photography. As an improvement on the first issue, favourably noticed in these pages, the book may be commended as highly useful for ready reference.

A Casket of Photographic Gems. (*Same Publishers.*)
Another book of reference, collected, classified, and alphabetically arranged by W. Ingles Rogers. It consists of a collection of 500 dodges, receipts, entertaining experiments, &c., in connection with photography and its branches, the early exhaustion of the first large edition of which is a sufficient testimony of the appreciation the book has won. The advantage for ready reference afforded by the numbered alphabetical arrangement of the subjects is increased by a full and carefully prepared index.

The Lighting in Photographic Studios. By P. C. Duchochois. (*London: Hampton, Judd, and Co.*)
The object of the book, as stated by the author, is to give the principal rules to be observed in posing, and some advice to guide the student. This is achieved in eight chapters, embracing, among other matters, various modes of distributing the light, construction of the glass house, backgrounds, lighting of the model, treatment of the eyes, development in relation to the lighting, and the use of orthochromatic plates in portraiture.

Lantern Slide Printing Frame.—Mr. J. Dore, of Sandown, calls attention to an invention for which the provisional patent application has been accepted. It is a neat, compact frame, so made that a vignetting apparatus can be used in front. The frame is for contact printing only, and will be found especially valuable where a number of slides are wanted from one negative. Mr. Dore states that the frames, which can be supplied in any size required, will be placed on the market for sale in a few days.

## THE LANTERN MICROSCOPE.*

BY W. I. CHADWICK.

In lantern microscope projection three things are essential: the first is brilliant illumination, the second large amplification, and the third clear display of detail. But brilliant illumination does not mean a dazzling display of light upon a large white screen, showing the dark, patchy outline of an object without detail. Objects shown in this way are far inferior to enlarged wood-cuts. The light must be made to enter the object so as to present all the details of its structure to the eye of the observer; but no amount of light will bring out this detail if its dimensions are too small for the crystalline lens to form an image of it upon the retina. With high-power objectives the light on the screen must, in the very nature of things, be greatly subdued. Still, a large image, moderately but properly lighted, can often be far better observed than a small one many times brighter; an object may, in fact, be too powerfully illuminated. If rays of great angle are too powerfully converged upon an object, the image becomes almost as bright as the other parts of the screen, which represent nothing but clear glass, and in this case the image appears "flat," and without contrast—like an over-exposed photograph. The image may, therefore, be too bright for the screen, or it may be too dark, and the best results are those obtained with the mean, showing all detail without destroying contrast. A lantern microscope, to be of any satisfactory use, must define, for instance, such objects as stellar hairs of deutsia, the minute, lace-like structure of spine of echinus, the matted structure of the hairs of reindeer, the lancet of male flea, its sucking tube, &c. The stomata of leaves are very easy to show. Foraminifera of the smallest sizes should be exhibited to from seven inches to ten inches diameter with all their varied beauty of form and shading. The tongue of the bee should have all its structure clearly displayed to audiences of three or four hundred people. For this purpose it must be magnified to about twenty feet long; then the bulb at the tip of the fleshy cone should be shown with the hairs standing out from the trunk and circling round it, apparently marking off its various parts as if they were joined to each other in telescopic articulations; the muscles of the trunk, and the apparently, and no doubt really central air tube connected with the trachia, ought all to be well defined; and what has been said regarding these objects applies equally to all kinds of animal and vegetable structure.

It is not claimed for the lantern microscope that every object, however delicate, can be shown as perfectly as in the ordinary table microscope, or that photo-micrographs are henceforth unnecessary. But it is, notwithstanding, absolutely certain that the lantern microscope now takes rank amongst the scientific instruments of the day, and can no more be dispensed with than the optical lantern itself. It is claimed that, by the Leach lantern microscope, all we have said can be done, and a very great deal more, though to say that anybody can do it perfectly on a first trial would be as wild a statement as to say that anybody who buys a camera and lens can at once produce beautiful photographs, or to guarantee the man who buys a piano to be able to play it to the best advantage. The Leach microscope can be applied to any oxy-hydrogen lantern. It is screwed on the front in place of the ordinary lantern objective, the size of flange required being two and a-half

* Read at the Royal Microscopical Society, October 31st.

inches. When the lantern objective flange is larger than this, an adaptor must be provided, and when the draw-tube of the lantern is "ricketty," a rigid lengthening tube may be adapted. The lantern condenser should be about four inches or four and a-half inches diameter, and of the triple form. Ordinary lantern condensers are usually of the double form; but a third lens can be supplied for a few shillings. The stage of the microscope is open at both sides, and at the top also, and serves for all classes of objects, whether ordinary microscopic slides or polariscope crystals, shown with either narrow-angle rays or by the convergent system of lenses. The stage being so constructed, it is extremely accessible for the introduction of sub-condensers, with which the instrument is provided, and permits, with the greatest convenience, the introduction and manipulation of the polarising prism, which latter may be entirely rotated, so that all the phenomena of polarised light may be exhibited to the greatest perfection. The object-holder is quite a novel idea; the principal mechanism of it is placed under the stage (to be out of the way); two arms passing through slots in the bottom of the stage, actuated by a spring and manipulated by a milled head, serve to hold the objects flat against the inside surface of the front of the stage. The diaphragms, or compound wheel of diaphragms, and the mechanism in connection with it, is unique. The wheel of diaphragms is rotative on a pivot attached to the plate arm in such a manner that the whole may be raised out of the field altogether and dropped into it again in an instant, or just as required; and when the compound wheel of diaphragms is raised, a spring catch holds it in position and prevents it dropping by its own weight. When in this position, the whole field of the microscope can be utilised for showing objects up to one and a-half inch in diameter; thus, this compound wheel of diaphragms of two and a-half inches in diameter yields just as large a field as can be obtained by one of the ordinary form of five inches in diameter. When, as in using polarised light, it is desired not to be incommoded with the diaphragms, the detachable plate carrying the compound wheel can be instantly removed from the stage, and when again required it can be as quickly restored. The arms of the object-holder projecting through the bottom of the stage have sufficient lateral movement to admit any zoophite trough or wooden frame, or combination of wooden frames, up to one inch in thickness. Thus, the advantages of this arrangement are clearly manifest. The two sub-condensers with which the instrument is provided are found to give the utmost satisfaction with all objectives of from 2½ inch to $\frac{4}{10}$ inch focus, and the simplicity with which these sub-condensers are changed is another feature of novelty in the instrument. All that is necessary to make the change is to take out one and push the other in its place; thus, the exhibition or demonstration may proceed without a moment's delay, neither object, objective, nor diaphragm being disturbed. When the light has been properly concentrated, as is the case with Leach's microscope, high powers can be used, and with ample illumination for showing all necessary detail, either for class-room instruction or lecture-hall demonstrations. It should also be observed that when high powers are used, the front lens of the objective is open to the view of the manipulator—a great convenience when inserting the object, by enabling it to be immediately adjusted within the area of the lens, so that its image may at once be seen in the field without the tiresome "groping" for it, a method which is usually resorted to with other lantern microscopes.

The advantages of this arrangement will be at once apparent, especially when using, say, a $\frac{1}{12}$ inch or higher power for photo-micrography. When polarised light is to be used, the polarising prism must be pushed into the rotating tube of the instrument by removing the concave lens at the back, and after inserting the prism this concave lens may be replaced in an instant. To do this when ordinary lanterns are used, the usual draw-tube carrying the microscope must be removed for the purpose; but with a Chadwick optical lantern the microscope need not be disturbed. All that is necessary is to disconnect the bellows attached to the lantern front, and the back of the microscope is at once accessible for the removal of the concave lens, and insertion of the prism, &c., and this may be done in less time than it takes to describe the operation; thus, the change from common to polarised light can be made in a few seconds.

The rotating tube will be found an immense advantage over fixed tubes, as the polarising prism can, by this arrangement, be placed in any desired azimuth which best suits the object, the analyser, or the screen. The convergent system of lenses for use with polarised light in transmitting rays through biaxial crystals, is a system of lenses worked out by Mr. Leach with great patience. It gives powerful illuminations, and includes an angle of 170°. The front-focussing arrangement was introduced by Mr. Leach in 1883. Before that time several supplementary lenses had to be kept in readiness for use, as different classes of crystals were placed in the polariscope. Mr. Leach discovered how these supplementary lenses might be dispensed with, and fitted up his system accordingly, and now all makers of first-class polariscopes attach to their instruments this great improvement. The concave field-lens with which the instrument is provided is absolutely necessary when the polarising prism is in use. It is useful also with low powers when using common light. With all powers it enlarges the field and equalises the distribution of illumination; but when a small field only is desired, with the illumination in the centre, it may be used or dispensed with at pleasure.

The three objective adaptors with which the instrument is provided admit of any microscope power with the standard screw. They are made to slide in the front tube of the microscope, which is provided with a rack-and-pinion, and also with a fine screw movement capable of the most delicate adjustment. Thus, by having the various powers already screwed into the adaptors, one may be changed for another almost instantaneously; and into the front or tube portion of these adaptors the tube of the amplifier is made to slide. Amplifiers usually supplied with lantern microscopes are simply uncorrected lenses, perfectly worthless for the purpose for which they are intended. The amplifier with which Leach's microscope is provided is a Barlow lens, and being achromatic, it not only does not destroy, but very much enhances, the aplautic qualities of the objective, and is far superior to so-called "projection eye-pieces." It has been inconsistently asserted by persons who ought to know better "that high power cannot be used in the lantern microscope, that it is unable to exhibit fine detail upon the screen, and that no alum trough is required." No doubt this is all true so far as applied to inefficient and "jim-crack" arrangements. But the microscope now before us *does* require an alum trough, because, where great light is concentrated from the oxy-hydrogen luminant, great heat must, from the very nature of the means employed, be concentrated with it, and the alum trough is the only practical thing which can be used to absorb the heat rays. Of course, where there is no light there is no heat, and therefore no necessity for an alum trough, and instruments which do not require one are self-condemned. The alum trough provided for the Leach microscope is of large size, and is used in the ordinary slide-stage of the lantern.

At the conclusion of the paper, a demonstration was given by common and polarised light.

## ON HALATION.*

BY H. G. HAMMOND SPENCER, C.E.

I imagine that everyone who has worked much as a photographer has had a painful experience of the disappointment felt on finding a negative, otherwise perfect, completely ruined by halation. I can speak feelingly on the subject myself, as I have been a great sufferer during the season. Halation is apt to appear wherever there are parts of the negative very brightly lit, and in contact with other parts of a dark colour—as, for instance, in a landscape where the dark foliage of trees is against a bright sky, where the effect is produced of more or less of the edges of the foliage, or dark object, being considerably lighter than they ought to be. It is halation which, in a winter scene, causes the fine branches at the edges of trees to be lost to sight on the negative. In my ignorance, I used formerly to imagine that it was only in photographing interiors, where the contrasts are so great, that halation need be feared, but I have found that it is as much so in landscapes.

Halation is caused by the rays of light passing through the film and glass plate, and, striking the air at the back, are refracted through the plate *at an angle*. Therefore the thicker the plate, the greater the space struck by these refracted rays, and the wider the appearance of halation. Were it possible to have the glass plate of no appreciable thickness, there would be no appearance of halation. It is for this reason that one is not troubled with it when films are employed instead of plates. It has been found that when a plate is very thickly coated, halation is reduced to a minimum, because the rays of light do not penetrate the thick coating. Those, however, who, like myself, use the ordinary or cheap description of plates, have not this safeguard. In the old days of collodion, one did not suffer from this trouble, except, perhaps, in interiors with great contrasts, and that was because the collodion produced a thick coating.

I think that, when taking a negative, it is highly desirable to produce the very best of its kind that one is able to, and that any trouble taken to secure this result is by no means thrown away. I have therefore, since being first troubled with halation, read a good deal on the subject, and have made experiments in accordance with what I have read. All agree that whatever is applied to the back of the plate must be in optical contact with it. It has been found that if the back of the plate is ground, the halation is almost entirely cured. I have not had an opportunity as yet of making the experiment, but I have thought that, as matt varnish is quite usable as a substitute to ground glass, it would be quite possible to use it as an efficient backing against halation, if ground glass is so.

There are numbers of mixtures recommended as backing for plates: ground burnt sienna made into a cream with glycerine, water, gum, and spirits of wine. This is very much the same as "Tylar's backing," which I have found to be efficient.

I read that black American cloth smeared with glycerine and squeegeed on the back of the plate is a remedy. I tried this, but I found that the glycerine would not "take" on the American cloth, possibly because the latter was new. I therefore tried putting glycerine on the back of the plate, and then squeegeeing on non-actinic paper. I took two views on two plates thus prepared. There was a very bright light, all in favour of halation; but the defect was absent except in a small bit of foliage near the edge of the plate, and where the non-actinic paper was wanting.

The drawback I found in the use of glycerine was that it was liable to run on to the woodwork of the slide and swell it. Tylar's backing dries quickly, and therefore does not do this. It has, however, to be washed off with a damp sponge before developing the plate, and I have thought it the cause of some minute pinholes. All my plates used at the last outing to St. Peter's Valley were backed with this. I see that in England they now use a mixture of caramel (or burnt sugar), burnt sienna, and gum; and in one of the meetings in London this was highly spoken of. Some use caramel and gelatine; I should myself think this difficult to remove. I have not yet tried caramel, but purpose doing so at an early opportunity. In experiments made by Mr. Debenham on different kinds of backings—nine in number—he found that the most effective of all is a mixture of gum, sugar, and Chinese ink.

* Abstract of a paper read before the Jersey Amateur Photographic Society.

## INTERNATIONAL PHOTOGRAPHIC EXHIBITION, LEEDS, 1891.

The preliminary arrangements for this Exhibition, which is likely to prove one of the most important ever held in the country, are now rapidly approaching completion. The exhibits are numerous, and, for the most part, of the highest order of merit and importance; and, fortunately, the wall space at the disposal of the committee has enabled them to hang the frames in such a way that every work may be seen to the best advantage.

The judges—Messrs. Valentine Blanchard, F. P. Cembrano, W. England, J. Gale, and A. Pringle—will award the medals on Friday and Saturday next, and the Exhibition will open with a *conversazione* on the evening of Monday, December 7th. Arrangements, we understand, have been made for lectures, with lantern illustrations, by eminent men on at least three evenings a week, and these will be given more frequently should it be thought desirable. On the other evenings there will be music, and occasionally in the afternoons as well. The Press day will be Monday, December 7th.

Croydon Camera Club.—Subject for December 7th, "The 'Open Sesame' of Successful Photography," by Mr. H. Maclean, F.G.S.; 21st, lantern night; members' slides.

Camera Club.—On Monday, December 7th, there will be the usual monthly Club Smoking Concert; on December 10th, at 8 p.m., Mr. T. R. Dallmeyer will give a "Short Description and Demonstration of New Telescopic Lens for Photography"; Dr. Fison's lecture will commence at 8.30 p.m.

## Notes.

If the shade of Guido Fawkes still haunts this earth, he must have been much interested in a case which came before the law courts, strangely enough, on the fifth of November. The case depended upon the truthfulness or otherwise of a certain photograph, which depicted two sportsmen in the act of firing their weapons, one using the old-fashioned black powder, and the other the nitro compound known as smokeless powder. This photograph had been issued broadcast as an advertisement by the Schultze Powder Manufacturing Company, in order to demonstrate that, while the sportsman with the old "villanous saltpetre" was so enshrouded with smoke that he could not see where to aim his second barrel, the patron of Schultze remained in an unsullied atmosphere.

Messrs. Curtis and Harvey, not believing in the genuineness of the picture, published a pamphlet entitled, "Notes on Shooting," in which they described the question of smoke as having been made a matter of trade chicanery, and commented upon photographs of this description as gross exaggerations, and the attempt to mislead people by them as highly reprehensible. Major Young, an amateur photographer as well as a sportsman, who was called for the defence, said that it was almost impossible to photograph smoke correctly, and that photography could be the biggest liar under heaven. But this strong language did not help the jury to come to a decision, for, after an absence of two hours, they were discharged verdictless. As the case remains undecided, we express no opinion one way or the other. We quote the case as an interesting example of photographic evidence.

The use of the optical lantern in places of worship is not quite such a new idea as Mr. Stead appears to think. For many years it has been customary to have lectures on all kinds of subjects, illustrated by the lime-light, in chapels belonging to different sects, the proceedings commonly commencing or terminating with a hymn sung by the entire congregation, the words of which are thrown on the sheet. But, even in the conservative Church of England itself, such things are not unknown. In a certain church near Manchester, the vicar, last Lent, conducted a series of week-night discourses illustrated by lime-light pictures, and we understand that whereas, in previous years, the attendance of worshippers had been extremely small, the innovation attracted crowded congregations.

A useful suggestion with regard to development comes from Mr. W. E. Crowther, of Londonderry. He proposes that, instead of the common practice of returning the developing solution to its cup when any addition is made to it, the accelerator and restrainer should be kept at hand in vessels fitted with a spray producer, so that the alkali, bromide, or citrate, as the case may be, can be showered in fine rain upon the plate as it lies in its dish. It is evident that local strength or reduction can be easily secured by this means. The common form of spray producer used for scent, with a rubber ball for furnishing the air supply, can be readily adapted to the purpose.

The Association Litteraire and Artistique Internationale, which, it will be remembered, held a meeting in London last year at the Mansion House, has just issued its annual report, which has been prepared by M. Bulloz. The bulk of the document is taken up by a consideration of the new American copyright regulations as affecting photographs. These regulations, under Order 4,956, impose an obligation to deposit in the Governmental Library two examples of the photograph to be protected. It is also provided that such examples so deposited must be printed with plates made in the United States, or from negatives or *clichés* executed in that country.

M. Bulloz naturally enquires how these conditions can be complied with. How, he asks, can a photograph of Mont Blanc, or of St. Peter's, Rome, be executed on American territory? If it is to be done at all, the photographer, immediately after taking a photograph in Europe, must hurry to the United States, and there, having developed it before witnesses, claim to have it protected. Again, if he wishes to register the copy of a picture purchased, say, in Europe, he must have the picture sent to America, pay the excessive charges which the legislature has imposed upon works of art, and make the negative in the United States. It is obvious, as M. Bulloz points out, that America denies itself advantages possessed by other countries for the dissemination of art knowledge, under the mistaken notion of protecting native photographers.

The McKinley Tariff is like Nasmyth's steam hammer, which welds a girder or cracks a nut with equal facility. In the matter of the importation of photographs, the tariff is ridiculously oppressive, and loud complaints are beginning to be heard. A recent ruling of the Secretary of the Treasury makes the sending of photographs and photographic reproductions through the post illegal, and much annoyance, so we learn from the New York *Manufacturer and Builder*, has been caused in consequence. The character of these importations is, says our contemporary, almost exclusively artistic and educational, and artists and professional men, including engineers, architects, and teachers, will be seriously inconvenienced by the enforcement of this unnecessarily harsh order. So rigid, indeed, is the enforcement of the order made that even photographs and other pictures that may be sent to private individuals through the post are now promptly confiscated and sent to the Custom House, to be redeemed under penalties, or sold. No wonder the *Manufacturer and Builder* declares its inability to see what advantage the Government expect to derive from these regulations.

Local traditions often have a substratum of truth, but they are rarely confirmed in every particular. An instance of this has, however, been established by the British Archæological Association. It has always been a local belief in connection with Stonehenge that on the morning of the longest day in the year, the sun always rose in a line with the well-known Friar's Heel. To ascertain whether this was so, the Rev. J. M. Bacon, in company with Mr. Howe, of Newbury, visited the spot at midnight on the verge of the longest day, and watched for the rising of the sun from the altar stone. When the sun was visible Mr. Howe took a photograph, and this photograph, which was exhibited at the last meeting of the Society, shows the phenomenon perfectly.

## SPIRIT PHOTOGRAPHS.

BY JAMES MEW.

"What a weak, credulous, incredulous, unbelieving, superstitious, bold, frightened—what a ridiculous world ours is, as far as concerns the mind of man! How full of contradictions, inconsistencies, and absurdities it is! I declare that, taking the average of many minds that have recently come before me, and accepting, for a moment, that average as a standard, I should far prefer the obedience, affections, and instinct of a dog before it. Do not whisper this, however, to others." So wrote, on July 25th, 1853, from the Royal Institution to Professor Schönbein, Michael Faraday. Not many years afterwards, in spite of the concluding sentence of his letter, this letter—and others perhaps equally private—were published in the ordinary course of things for the gratification of public curiosity—*scire volunt secreta domus.* Faraday's letter was written after his well-known attempt to turn the tables on the "table turners." How would he have spoken of spirit photographs?

This subject is a serious one—some photographers certainly have found it so—and therefore it deserves serious treatment, which, indeed, it has occasionally encountered. It cannot be adequately treated, even in the slight and superficial manner of those writers who have made it a matter for scoffing comments, without more spiritual knowledge, and more sense of—if we may be allowed the expression—ghostly perspective, than they possess, and lacking which they would have done wisely to leave the matter alone. There are, indeed, some who have not hesitated to mix with this subject the profanity of satire; have seen fit, in fact, to treat it as a huge joke. The result is somewhat ghastly, and in the worst possible taste. Whatever views these writers, or any others, may hold as to the existence or otherwise of spirits who are ready and willing, in their airy amiability, to put an honest penny into the pocket of the hard-working photographer by sitting—this word of custom escaped us in a heat—by hovering around to have their portraits taken at so much a head; however numerous and ingenious the arguments that may be advanced to prove the non-existence of these beings; or, granting their existence, the impossibility of their having their carte-de-visites taken by any firm of photographers however able, the fact still remains that, from the lips of those whose scientific knowledge is generally allowed to be deep, there have fallen words pregnant with very precise meaning concerning the reality of these mysterious portraits.

Very early, indeed, in the short but eventful history of spirit photography, unbelievers sprung up and chattered about the necessity of keeping the imagination within bounds; of not allowing it to run away with the judgment; of idle superstitions, a disgrace to an age of boasted progress; and of a vast flood of ignorance overflowing and laying desolate the highest places in the land. They talked of the taking of spiritual portraits as an attempt to investigate phenomena which reason would not for a moment allow; which, so they said, are, in fact, utterly absurd. They professed to explain the taking of spirit photographs in the following irreverent fashion. The negative, they said, is taken of an engraving, or of some other picture, or of a lay figure with a powdered face, or of a puppet properly painted for the purpose, or of a living person arrayed in suitable cerements posed against a black velvet background in the attitude desired. Then this negative is turned, collodion superimposed, and the glass fixed in the camera. Thus the portrait of the sitter is on one side, and of the spirit on the other. When the negatives are printed, the paper is placed against the sitter-side of the glass and exposed to the light. The spirit on the other side then strikes through the glass, giving that hazy appearance which is so much desired to the spirit while the portrait of the sitter comes out clear, solemn, and well-defined. Or, again, a reduced positive is made from the negative of a practicable spirit, and then, in a dark room with a feeble light, the new plate is submitted to two or more short exposures behind it, care being taken that no light reach the remainder of the plate. The outline of the spirit is rendered indistinct by avoiding close contact with the positive. The photographer goes to the house of his customer to avoid, in his opinion, the possibility of fraud, and selects a plate marked beforehand as suitable to the occasion.

It is now some thirty years ago since a certain Mumler or Mumbler—for the orthography of his name in contemporary records is uncertain—was prosecuted for fraud in America in the matter of spirit photographs. This was, indeed, an inauspicious commencement, but we live in a world ever ready to believe in evil, to disbelieve in good, to imprison those who labour for its advantage, and to burn its benefactors at the stake. Mumler or Mumbler was not, however, the only martyr. Another gentleman who took angelic portraits by flashes of lightning—not, as he was careful to explain, ordinary lightning, but lightning, so to speak, expressly adapted for this purpose—was treated with similar ingratitude by an apathetic constabulary. Alone, at midnight, in a season of wind and rain, with his camera pointed to the heavens—a camera containing plates overlaid with a composition of certain unusual chemicals, the names of which he naturally declined to disclose—this good man obtained his weird pictures at his own imminent deadly risk in the intervals of the darkness of the storm. Nay, he did more. He absolutely courted the investigation of the incredulous, a piece of audacity which accelerated his downfall, and backed his dusky portraits of the dead for twenty-five dollars.

This unlucky artist brought down his spirits from the skies, but they are found also in an opposite direction. We meet them everywhere. Their range of motion is exceeding wide. A very effective ghost was at one time connected with an innocent river view at Ipswich. The photographer thought only to take the river and its surrounding scenery; but lo! when the plate was developed, there appeared plainly revealed in the foreground of the picture the figure of a woman. She was tall and fair, her hair floated behind her, long as Victor Hugo says, *comme un manteau de roi*, and her raiment wss white as the driven snow. She appeared in an upright position on the surface of the stream. A spirit photograph! It was at once, but perhaps too hastily, concluded, considering the range of ghostly motion already mentioned, that murder or suicide had happened here. Policemen were summoned and the river was dragged. Many objects of interest were discovered, but no human body.

On this occasion a sceptic suggested, as an explanation of the uncanny marvel, the possibility of a small hole in the cupboard or box in which the gelatine plate had been kept, combined with a feminine curiosity and love of research. This same unbeliever it was who, at another time, with equally weak faith, was for photographing "materialised spirits" by magnesium light, doubting the ability of the dead—a feeble folk as they are presented by Virgil—to withstand the intensity of its glow. The medium was a tall, angular woman with a nose like the tower of Lebanon, which looketh towards Damascus—a nose approaching the parrot order of architecture. She occupied a position near a curtain in a corner of an apartment, reposing in the dim religious light generally required as reverential, if not advantageous, on such occasions. The customary fees were collected. Nothing, even in the spirit world, is, it seems, to be had for nothing. The magnesium light was turned on. Covered about with white veils, divers forms were produced, in the eyes of some of the spectators angelic, but the gentleman who had suggested the magnesium light—a hard-shelled investigator of nature's marvels—found in them all a family nasal resemblance to the officiating medium. He might consider himself fortunate to have found anything. The presence of a disbeliever in the flesh has, in the majority of cases, been declared antagonistic to spiritual manifestation. Whether it is that the ghosts are insulted by any scintilla of doubt in their existence—it is a matter we should feel acutely ourselves—and so, in a pet, refuse to put in an appearance, or whether it be that the so-called "spirit-control" of the operator—the middleman, as it were, of two worlds—is weakened by the too earnest attention of infidels, it is difficult to determine. Possibly both these causes have their influence. The spirit might be persuaded if the control were more energetic; or, again, sufficient energy of control might be counterbalanced by an excess of spiritual indignation or perversity. The cause lies hidden—*causa latet, vis est notifsima.* In this highest reach of the photographic art, the supramundane portraiture of those who are said, euphemistically, to have "gone before," the disconsolate bereaved ones left behind must not, by any stubborness of unbelief, be the occasion of too severe a strain or drain on the odic force of the operator. They must come fully prepared to see spirits, or they will never see them.

It is not mountains alone that faith is able to move. Without faith the medium may summon spirits from the vasty deep, or elsewhere, but when they are called for they will not come; or, if they come at all, they will appear in an altogether unsatisfactory—nay, sometimes disgraceful—condition. A case has been recorded of capricious spiritual behaviour in which the shadow of the bereaved one was on the right while that of his mother-in-law or grandmother, gone before, was on the left. The hierophant being desired to explain this apparent anomaly, declared that the spirits brought their own light with them, and, being themselves shadows, were not subject to the ordinary laws of shade. The explanation was accepted in all good faith for the nonce, but it seems clear that this inversion of natural custom was rather occasioned by a huff taken by the spirit at the presence of a sceptic. To a like cause may be attributed an extraordinary spirit photograph, which represented a spirit in an attitude which astonished the medium — who might be supposed accustomed to freaks of spiritual perversity—no less than the awe-stricken company of spectators. The spirit had chosen to present itself in an altogether indecent manner—indecent, that is to say, according to the time-honoured conventionalities of this world. The spirit was feminine, and its head was on the floor, and its heels were in the air. Utterly careless was this lady ghost of the rule made and provided by the respectable author of the *Religio Medici*: "Let the divine part be upward, and the region of beast below; otherwise 'tis but to live invertedly, and with thy head unto the heels of thy antipodes."

So scandalised were the good ladies and gentlemen who attended this photographic *séance*, that they demanded their money back again, holding themselves unjustly treated. It is to be hoped—if, indeed, the story be true, and not rather the invention of some flippant scoffer—that they got it; but at the same time, they ought to have considered the limitless possibilities of change in the spirit world. One, who wished to behold the idol of his infant daughter, was violently indignant on being presented with the portrait of an aged gentleman bearded like the pard. He did not pause to consider the chances of development in a state of untried being. But there are, it may be said perhaps without exaggeration, millions of people who believe firmly that the form of the body will be altered in the next world in a manner corresponding with its behaviour in this. The Buddhists suppose that an impudent person will therein assume the appearance of a monkey, and that he who holds the murder of innocent animals to be sport will be turned into a devil.

Due consideration of these philosophical notions, a proper regard for the theory of *Karma*, or action which controls the destiny of all sentient beings, not by rewards and punishments of omnipotence, but by the inflexible law of cause and effect, would prepare us for some remarkable transformations in the bodily presentments of our deceased friends, and would save the spiritual photographer considerable labour of not altogether satisfactory explanation. For to say, for instance, as has been said, that one's camera is charmed would not, probably, be quite sufficient to quell the cynical curiosity of the man of science. Nor again, if a setting of family faces—spirit faces—well known to Brown, surrounded a portrait of Jones, would it be considered by Jones an exact apology if it were said, as has been said, that spirits are accustomed to gather themselves into the camera in minute particles, and infringe sometimes on the sensitive plate in an altogether reckless fashion? Some may hold this exposition to be affected with more than Sibylline obscurity, but we must remember it ever has been, and always will be, difficult to convey to the carnal-minded a sense of spiritual things.

Enough, it is hoped, has been said in this article to give the reader pause before he pins his faith to captious objections composed in a jocular style, apparently the offsprings of commonplace books put together by writers without any reverence for sacred things. So solemn a subject as spiritual photography, which these writers have chosen for their flippant jocosity, must seem to every properly disposed mind, if not altogether unsuitable for discussion, at least to be approached in some other style than these writers have thought it decent to adopt.

---

Royal Institution of Great Britain, Albemarle Street, W.—The general monthly meeting will be held on Monday, December 7th, at 5 p.m.

The Hand-Camera at the Polls.—The hand-camera is said to have taken an important part in the recent election in Philadelphia. Forty-two hand-cameras were employed, one for each division of a certain ward where "repeating" was expected. A man was easily found who knew his own division thoroughly, and who, when he suspected a "repeater," could "press the button" on him. By comparing photographs after the fight, "repeaters" could be discovered and brought to justice with very little trouble.

## PORTRAITURE.*

BY W. H. PERINE.

Portraiture work is, I think, without dissent, the most intricate part of photography, the one in which the artistic eye and good taste of the man behind the ground glass shows to the best advantage. It is no trick to take a portrait. Put your model in a chair, in as good a light as possible, get the camera all focussed and ready, tell him to "look pleasant, smile just a little, now that's good," expose your plate, and there you are. This is very simple, but when you come to get a print off that plate and show it to your friend, the chances are nine to ten that *he* will either knock you down on the spot, or *she* will tell you that if you ever show that to anyone the result will be very serious. To take a portrait that is a good likeness, graceful pose—in short, a picture in every sense of the word—is no easy task. How rare it is to find, in looking over an album, a good picture, and when you do run across one, how you admire it. A professional photographer is greatly handicapped in that he has to take everyone that comes to him (and we all know how few good subjects there are), while an amateur has free scope, can choose his subjects, conditions, &c., and should, I hold, with the same conveniences, take better pictures than the professional.

Concerning subjects, very little is to be said; as every man has his individual tastes, it would be very wrong to lay out any one line of action. Be sure and study your subject, watch his movements, his positions, and expressions, so that when you have him under the skylight you know just where you want to place him. A delay in getting ready, changing your model about in numerous positions, is almost sure to get him out of humour, and the more you change him, the less decided you will become as to where you really ought to have him. Always try to be alone; have everything quiet. Nothing is more disagreeable than to have three or four fellows standing round suggesting this or that way of doing it. I think our scheme of reserving the studio on certain hours is a capital one.

One of the first considerations of importance in portrait photography is the background of the portrait. It should be quiet—that is, entirely devoid of all objects which, by their form or colour, are conspicuous and obtrusive. We may have painted screens, decorative or very plain, but they should all be so arranged that, while they may contain many objects of interest, they are always subservient to the people placed in front of them. Where using a perfectly plain background for full-length figures, it is a good scheme to have six or seven feet of the cloth coming from the bottom of the frame in a curve to the floor. This gives a clear white effect, not showing the floor, and the abrupt ending of the background on the frame, which always detracts from the effect. In portraiture, it is particularly essential that the light should come from a point very much higher than the sitter is placed. The light striking the face on a level with it destroys those shadows under the projecting features which give character or expression, and makes a flat, weak picture; while, on the other hand, if we have our light admitted through an opening, the lower part of which is about on a level with the head, and extending to a height of 10 or 12 feet, so that the main body of light will come in at an angle of forty-five degrees or more, we will generally get the most suitable lighting to show the features to good advantage, and bring out a satisfactory likeness.

When the light is admitted over the head or from a source too nearly perpendicular, the effect produced is peculiar and generally unsatisfactory, owing to its only striking the top of the forehead, the cheek bones, and the nose, and leaving all the rest of the face in shade. The reflecting screen, used in lighting the dark or short side of the face, is better placed a little in front of the subject, at an angle to the light, and leaned over at the top a little. Care should be taken not to place it too near the sitter, especially if the plate be turned toward the screen, because, by reflecting a light into the shadow of the eyeballs, their depth will be destroyed, and an unnatural, pale-eyed appearance given.

For the production of interesting portraits, either one or the other of two classes of heads are necessary—namely, the picturesque or the beautiful. Elderly people furnish the type of the former, and ladies and children that of the latter. Old men with long hair, large features, and great beards are always fine subjects, and will bear the most vigorous lighting. In such a subject, in order to most strongly bring out the character, we should pose the head near the window, letting the light strike from high. The reflecting screen should be kept further back, so that too much light may not be reflected upon the dark side, thereby destroying that force of light and shadow which is the soul of such subjects, giving bold relief as it does, and forcing out the character. Elderly women, if intellectual and with rather large and well-formed features, make good subjects, but require to be dealt with less forcibly. When we come to deal with ladies and children, we encounter our greatest difficulties, and will find rules of the least value, often obtaining much better success by happy chance than by careful arrangement. In general, however, the lighting should be much softer in these subjects. Less light will be found better, and either lower or more diffused, which will be obtained by keeping the sitter further from the source of light. The reflecting screen now forms an important aid, and by it we must destroy those heavy shadows which, as previously said, are the soul of the picturesque, but mar the beautiful, and, while there should be light and shadow sufficient to give roundness, they must not destroy that softness and fullness which is inseparable from beauty.

In that constant effort to obtain novelty which seems now to be the fit of business, many experiments are made, and what are called tricks by artists are resorted to to catch the fancy of the unlearned and the unthinking; but while they may serve well enough for the time being the object which is sought after, they never wear so well as those works of art wherein the rules of good taste and judgment have been followed. It is rarely that a head lighted on what artists call the short side of the face, which is the side turned away from the spectator, has so good an effect as when lighted on the near or full side. The reason of this is, that lights make the impression upon the eye of advancing, while the shadows have the contrary effect of receding or retiring; consequently, when we have the further side of the face brightly illuminated, it seems to advance from its proper position, while the near side rather retires, and the result is a flattening instead of a rounding of the head. This mode of lighting also has the effect of widening a face, and, therefore, may be resorted to by photographers in some peculiar instances where such an effect is needed. Constant care should be given to the

* Abstract of a paper read at a meeting of the Photographic Society of Kansas City.

securing of a proper amount of half-lights and half-shadows. This is a matter belonging rather more to the timing of the exposure and developing of the image than the lighting. Under-exposed or under-developed plates are always lacking in half-tones. In the prints made from them one can only get high light and deep shadow, and the effect is harsh and disagreeable, and often destructive of a good likeness; and, in case of over-exposure, while the chances of a likeness are not lessened, the work, from an entire prevalence of half-tones, will be flat and uninteresting. It will be robbed of those touches of deep shadow and crisp high-lights which are so essential in the making of a good work of art. Too little exposure would only be admissible in strong character heads which we wish to be harshly and expressively set forth. With ladies and children there should be ample exposure and careful development. In fact, I think it is better to give too much rather than too little exposure, and to carry the development further than you would in landscape work. The greatest excellence to be striven after, and that most difficult of obtainment, is where the numerous relative tones are given in all their refinement of gradations, as from a black coat or velvet collar to the white collar or bosom—these being the extremes—and the entire flesh tints being upon another scale within the range of these two, possessing hundreds of fine gradations of light and dark, but none of light as the white of the linen, nor none so dark as the black in the clothes. The first quality noticeable in a bad photograph portrait is the entire absence of proper relative shades of difference throughout the work, the shadows of dark clothes, of furniture or surroundings, and of the flesh being one and the same in depth, and the lights upon the lines undistinguishable from those upon the hands and face.

Posing sitters for their portraits in respect to the most proper and agreeable disposition of the head, body, and limbs, is an exceedingly difficult part of portraiture. Even painters are seldom successful in giving a look of ease and dignity, although they are free to make any arrangement that may be best suited to their fancy, while the photographer, on account of the necessity of obviating, as far as possible, the effects of distortion by his lens, is hampered into disposing all parts, as nearly as possible, on the same plane, which adds greatly to the look of constraint. Foreshortening is an important element of the picturesque in art. To be deprived, therefore, in photographing a figure, of the benefit of having the arms or lower limbs extended towards you or receding, is a great disadvantage. When we leave the single figure and attempt groups, we are absolutely debarred from making any of those beautiful arrangements such as the old masters have left us. We must, on the contrary, adhere almost to the regularity of a company of soldiers drawn up in line for inspection. Attention now seems to be turned principally upon heads alone. In the old days, it was fashionable to give us the man or woman as they looked from head to foot; now our photographers seldom go beyond half-length, and in the case of men I think it is in better taste that we do so, for there is nothing more unmanageable than a man's legs in a pair of stiff pantaloons. With the ladies it is often easier to get good full-length pictures, on account of the greater variety of their costumes, and the interest to be derived from well-disposed drapery. In half-length poses, a more easy balance might be obtained with the figure standing instead of seated, were it not for the difficulty of keeping still. In a chair, persons are very apt to settle into a sort of a lull which is sure to destroy any look of dignity, and, if asked to sit up, are sure to get into an unnatural and forced position. There are those whose poses will always appear easy and graceful in whatever attitude they may take, but they are very rare, and one must call into play his wits and his patience to compensate as far as he can for the shortcomings of his sitters. It is a rare gift to be able to make your model feel perfectly at ease when posing for a picture, and one which we all should cultivate, for it is a most important factor for good results and graceful poses.

About retouching I will say very little, as I think very little should be done. Beyond erasing the small imperfections which appear in the skin, I do not think it good taste to do much. Sometimes, by throwing the ground glass a little out of focus, you can overcome a good many freckles, &c. A subject properly lighted should require very little retouching. Experience is the great teacher, and I think this applies especially to photography.

## Patent Intelligence.

### Specifications Published.

18,410. *Nov.* 15*th*, 1890.—"Photographic Backgrounds." W. Watson, 37, Naburn Street, Glasgow.

Consists in representing, by a background having interchangeable parts, interior or exterior views of a railway carriage, tramway car, omnibus, &c. The background is made with a framework of wood, covered with cloth, and painted. There may also be used a background behind, representing a view of a station, landscape, or street, &c.

Interchangeable letters representing the name of any place, or of the car, &c., are fitted into a grooved frame fitted onto the background, instead of the letters being fitted into the background itself. They are made of metal, wood, paper, &c., having a piece projecting from the edge of that part which is in the groove, to keep them, when in place, at equal distances apart. With this invention, parties or individuals may be photographed as just going to or stepping into a train or car, or as looking out of the window, or sitting in a seat, &c.

20,972. *Dec. 23rd*, 1890.—"Carriers for Lantern Slides." R. W. JAMES, 75, Tyrwhitt Road, Brockley, and M. STODART, 35, Tyrwhitt Road, Brockley, Kent.

Consists in ejecting the lantern slides from the carrier for facilitating the manipulation of said slides when changing. On the ordinary sliding frame carrying the lantern slide is arranged an ejecting mechanism, consisting of a lever with unequal arms pivoted preferably in the lower part of the frame, the long arm of said lever reaching to about the centre of the space occupied by the slide, and the short arm being adapted to be operated by hand from the exterior, or by other means. To withdraw a slide from the frame, a small amount of finger pressure on the short arm of the lever causes the slide to be raised by the long end of the lever a considerable distance out of the top of the frame, thus enabling the operator to grip the slide by its edges, and wholly extract it from the carrier.

14,943. *Sept. 4th*, 1891.—"Photo-chromographs." L. MEYER, 3, Cornelius-Strasse, Berlin, Germany.

The object is the reproduction of paintings, pictures, &c., by photo-lithography at a less cost, and more true to the original, than by existing known processes. The picture to be reproduced is first enlarged, reduced, or reproduced by ordinary photography, and any desired number of photo-lithographs are reproduced therefrom. Each of these photo-lithographs is then illuminated with oil-colours, the outlines and the chiaroscuro being produced by the photo-lithograph. When thoroughly dry, the picture is securely transferred or fixed upon an artist's canvas with the oil-colours next to the foundation, and the paper on which the photo-lithograph was printed is then removed as in the case of ordinary transfer pictures. If a picture of high artistic finish is desired it is, after being illuminated, retouched with oil-colours by an efficient artist, so as to obtain a more harmonious blending of the various colours and shades.

## Correspondence.

### DR. MADDOX AND DRY PLATE PHOTOGRAPHY.

Sir,—Having seen that a testimonial is being raised for Dr. Maddox, chiefly on account of his connection with gelatino-bromide, and having heard also that his right to any special recognition in connection therewith was questioned in certain quarters, I thought I would form my own opinion on the matter, and the more inclined was I to do this on reading the letter which appeared in your last week's paper.

I am sorry to say I was simply overwhelmed by the results of my research. I find that early in July, 1873, Mr. Burgess startled the photographic world with a great success in emulsion. The process was acknowledged on all hands, and compliments were showered freely on him. Mr. J. Traill Taylor—surely an authority—stated that the emulsion was all its author claimed it to be, and was certainly equal to the collodion wet plate in all respects.

I find, further, that the author of the process speedily ceased to send out the emulsion, and took to making dry plates, which were also a great success. Moreover, all the authorities recognised the thing as something new, Sutton being quite enthusiastic about it, and, naturally enough, they wanted to know *exactly* how the astonishing degree of perfection had been attained. I just pause to note Mr. Pringle's sad remark that Maddox gave away what Burgess kept to himself. It seems that the inventor of the process was not willing to divulge that which he had an undoubted right to keep secret if he so willed. Or, perhaps, the facts of the case might be better represented in this way, that people wanted to have for nothing what was certainly worth paying for. Something like the following then ensued, and I may say this has amazed me beyond lmeasure.

On August 8th, 1873, after many persons had tried the emulsion, and at a time when the inventor was sending out dry plates which were highly spoken of, Mr. J. Traill Taylor complained that Mr. Burgess would not make known his methods, and intimated that they would endeavour to do so without Mr. Burgess's help by taking up Dr. Maddox's line of experimenting, and seeing if they could not attain the same results as those Mr. Burgess had obtained, promising that if anything resulted the public should be at once informed. Futher, it is stated that, as Mr. Burgess would not let it be known how he attained his results, he would have to put up with the consequences. This is beautiful in the extreme.

However, I notice that in December some one gently hinted that he considered he had waited quite long enough for the results of the experiments. I presume, therefore, that up to that time—four months after the above-mentioned scheme was concocted—the desired results had not been attained.

What can impartial persons think of all this? Comment is needless. W. W. WHISTLER, B.A.

*Sherborne St. John, Basingstoke.*

---

Sir,—Mr. Pringle says that Burgess tried to sell what Maddox gave away. Well, if that were true, it ought to end the controversy. But it is not true. Let us have a good, honest, searching look at what it was that Maddox gave away with such wonderful generosity, and contrast it with that which Burgess tried to sell.

1. Maddox made a plate which, according to his own account, required an exposure of from half-a-minute to a minute and a-half, under a negative to dull daylight, to get a print. Burgess's plates would give a print with one second's exposure to candle-light.

2. Maddox did not produce a negative at all. Burgess produced the first dry plate that ever worked quicker than wet collodion.

3. Maddox used an excess of silver and acid development. Burgess used an excess of bromide and alkaline development.

4. Maddox went on old and discredited lines, and made a distinctly retrograde movement. Burgess made an original discovery by going on lines never tried before. He washed the sensitive jelly instead of the plates, and that alone was worth thousands of pounds.

5. Maddox printed a worthless formula that no one ever noticed except his friend Taylor, and then it sank into oblivion. Burgess perfected his process, and sent the most effectual demonstration of its quality all over the world. The ready-made emulsion was sold at such a cheap rate that the poorest photographer could test it for himself, and he actually invited all the world to his house to get ocular demonstration of the value of his discovery. All the world stayed away except a few who questioned and cross-questioned the inventor, and enriched themselves with the ideas they got for nothing. One of them actually took out a patent for the very thing he saw prepared at Burgess's house.

6. Maddox's formula could not possibly help anyone, but actually put difficulties in the way. Burgess's discovery turned photography into child's play, and the vast development of amateur photography which has followed is the result of it.

7. Maddox's formula was the old, messy, finger-staining way of the dark ages. Burgess inaugurated the clean method, which a princess can practise without soiling her delicate fingers. This also, if there was nothing else, is quite enough to distinguish the one method from the other, and must have saved photographers thousands of pounds—

"And yet! and yet! the wise men say,
'Burgess tried to sell what Maddox gave away.'"

THE VICTIM.

---

Sir,—On further study of the gelatino-bromide question, I have been forcibly impressed with the necessity of remedying an unfortunate state of things. At present I would appeal to the photographic world in this matter. As every man would be glad of help were he placed in a similar position, accordingly I ask all to be willing to aid one who has been very badly overlooked, and this may be done without interfering with the success of the Maddox testimonial. The way in which they can most effectually aid is not by accepting my word, nor the words of any other man, but by an impartial study of the records themselves.

As a preliminary course, I would suggest that the numbers of the principal photographic journals issued in July and

August, 1873, should be very closely read, especially the numbers which appeared on August 8th of that year. London photographers can find all that relates to this question among a great many interesting things at the Free Library of the Patent Office, Southampton Buildings, Holborn.

In connection with this subject, I should like to ask one or two questions. Did photographers want a formula or a plate? The theorist wanted a formula, but, I take it, the photographer needed a plate.

The difficulties to be overcome by pioneers were not connected with the construction of a formula—several having been published before the worthy doctor devised his—so much as with the methods of treating the emulsion, which latter proved an insurmountable barrier to all experimentalists in this work up to 1873. In that year Burgess overcame these difficulties, and in less than a month from the time when he first sent out the emulsion which proved his success, he was actually sending out plates, the very thing photographers had long wished for.

It appears that Burgess offered to supply not only plates, but also all information respecting his processes, and the formula with which he worked. I think this ought to be particularly observed, because we hear it said that he elected to keep his process secret. The records show he did nothing of the kind. Doubtless he had a duty to perform to his family a great deal more incumbent on him than any he owed to those who demanded his formula for nothing. For all that I know, he and his family may have had to go without what some of us might regard as the common necessaries of life in order that he might have the means to pursue his investigations. Accordingly, the inventor asked a paltry guinea for the whole process, the formula being absolutely the first of practical value.

With regard to the character of the plate, it was not such as was only worthy of a place among lumber; on the contrary, it was at the very first admittedly superior to the best collodion wet plate, and ten times better than the collodion dry plate.

As the inventor insisted on his very reasonable fee, it was determined by certain persons that he should be made to suffer certain consequences, a thing, I think, no man had the right to determine. At a time when the great body of photographers was content to have the plates, and at about the same rate as that charged for the ordinary kind of to-day, at this time, viz., August 8th, 1873, the scheme was formulated by which to punish an inventor, and take away that which was most dear to him. It is certain Dr. Maddox had nothing to do with this.

In dealing with this matter, it must be remembered that we always have with us the formulæ of 1865, 1866, 1868, and 1871, together with Sutton's directions for conducting gelatino-bromide experiments, published in the *British Journal of Photography* about six weeks before the account of Dr. Maddox's experiment appeared. Any practical man can take them, make use of them, compare their results, and settle for himself how far they come short of that standard of excellence which would alone make them of value. I will venture to assert that the opinion of the practical man on Maddox's work will not be the opinion so often expressed by Maddox's friends, who have evidently never tried the experiment on Maddox's lines.

With respect to Burgess's formula, we may judge of its value by the many editorial notices and letters having reference to the success of the plates. Hundreds of people in all parts of the country had personal experience of it, and I gather from one published that the Rev. Mr. Palmer, of Liverpool, actually kept for two years one of these, the first gelatino-bromide dry plates the world ever saw, and then obtained a splendid result with it.

Now another question. If Dr. Maddox had wished to sell his formula—and he tried—what price would a practical man have offered for it? I leave practical men to reply.

When Burgess's work was seen and known, at his invitation crowds of men went to him, with the consequence that since that time the gelatino-bromide process has continually grown and flourished, a revolution having been effected in photography. J. Faulkner.

*Peckham Technical School, December 1st.*

---

Sir,—The payments and promises to Maddox fund now amount to £200. Firms, societies, and private parties are urged to lose no time in coming forward. Andrew Pringle.

---

BROMIDE PAPER.

Sir,—Will you give me space in the News to bring before manufacturers of the most sensitive bromide paper a grievance which, it seems to me, is in their power easily to rectify. It is that of being unable, in the dim light necessary for manipulating the paper, to distinguish between the two surfaces of the paper, and so having to make the exposure by guess-work on the film or plain side, as the chances happen.

I have wasted time over making wrong exposures in this way until I have become so unnerved and annoyed that I have determined upon trying to ventilate the matter. It is absurd to say the paper curls, and thus tells you the side. So it may in dry weather.

Surely a mark might be made enabling one to know whether one was exposing the right side or wrong. Bromide.

55, *Pier Road, Erith, Kent, December 2nd.*

## Proceedings of Societies.

London and Provincial Photographic Association.

*November 26th.*—Mr. W. E. Debenham in the chair.

The Maddox testimonial was the subject first taken, and the Chairman, in reply to a statement of the worthlessness of Dr. Maddox's method, which was quoted by a member from a letter recently published, said that, by the Maddox method of unwashed emulsion, he had prepared emulsion giving very good results, and although not of the rapidity of modern dry plates, more sensitive than wet collodion.

On the motion of Mr. T. E. Freshwater, seconded by Mr. P. Everitt, it was resolved that the Society as a body should join in the subscription to the proposed testimonial.

Mr. J. S. Teape showed some prints that had been highly toned with uranium and ferricyanide, and parts of which had been submitted to long washing. This proceeding had, as was generally stated, washed away all the intensity; but it had also removed a good deal of the image, and did not leave it, as stated, in the original condition. He had also tried the intensifier on platinum prints, and though the action was slow, and the change of colour not nearly so great as with bromide prints, there was a change, the image being converted to a deep chocolate brown.

The subject of the evening, "The Protection of Negatives whilst Printing," was introduced by the Chairman, who said that it was very unsafe to make even a few prints from a negative without varnishing or protection of some kind, since stains, by taking up silver from the paper, were so likely to occur. The silver in these stains was, however, in a very different condition from that of the developed image, since it might generally, when fresh, be removed by cyanide of potassium without affecting the picture. Of all methods of protecting the film, the use of spirit varnish was the most general, and unless the negative were subjected to wet, was usually found efficient. In using spirit varnish, however, the alcohol became partly evaporated by exposure to the air, and water was absorbed. The result was that, after coating many plates and returning the varnish each time to the bottle, there was too much water in the film. He had noticed that when this was the case the varnish never seemed to thoroughly harden, but would take a mark from paper pressed on it, or in other ways. Another varnish which had been recommended was composed of linseed oil and gold size. He would like to have the experience of those who had used this varnish, and to know the composition of the gold size used.

Mr. T. Bolas said that methylated spirit was often adulterated with water by the oilmen who sold it. In shellac mixtures made for other purposes, he had noticed the influence of water as mentioned by the chairman. Japanese gold size was, essentially, linseed oil in which various resins had been dissolved.

Mr. F. A. Bridge enquired whether any member had noticed a case in which the lac originally dissolved had all been deposited. This once happened with him in a bottle that had been kept closed.

Mr. J. H. Sinclair enquired as to the best varnish for celluloid films.

It was replied that spirit varnish would mark the negative if any ran over the back, and gold size varnish was recommended.

Mr. A. Haddon said that one objection to gold size varnish was that it could not be removed if desired.

Messrs. A. L. Adams, F. Simmons, and A. J. Bills were elected members of the Association.

The subject of discussion for Dec. 10th was announced as "Gas Bottles."

### Camera Club.

On November 26th Mr. A. Maskell occupied the chair.

The Rev. F. C. Lambert, M.A., gave a lecture entitled "Some Analogous Aspects of Music, Painting, and Poetry," embracing description and graphic delineation on the black board of some analogies existing in the respective derivations of music, painting, and poetry, from simple elements. The superiority of musical over graphic representatiou of some natural phenomena was argued and illustrated, and the lecturer asserted his liking for music with a motive, or, so to speak, story-telling aim running through it. Some amusing sketches were given on the board to show the power in the arts exerted by association of ideas and abstraction.

Lantern slides and musical illustrations were given of many of the points made by the lecturer. The musical examples were given vocally and on the pianoforte by Mr. Albert Joll, musical instructor at Cooper's Hill, and organist at St. George's, Campden Hill. The selections were admirably rendered in illustration of the lecturer's remarks, and greatly assisted towards the success of what was a novel and refreshing subject.

Remarks were made after the lecture by Messrs. Elder, Bartlett, and the Chairman.

Previous to the lecture, Mr. E. Calland exhibited some carbon prints on extra-rough Arnold's paper and on etching paper.

### North London Photographic Society.

*December 1st.*—Rev. E. Healy in the chair. Mr. Edward Clark was elected a member of the Society.

Questions were asked from the question box as to the mode of light measurement, and also as to a mineral oil light for optical lanterns, which would not give off a smell when burning.

On the first question a short explanation was given by the secretary. A more complete description to be given at a future date.

To the second question no answer could be given, it being generally admitted that the question of smell was largely, if not entirely, a question of cleanliness and care in using, without which all mineral oil lamps must, of necessity, be offensive.

The evening being an optical lantern night, a large number of slides were shown by the aid of the Society's lantern, under the management of Messrs. A. Mackie and B. J. Groves. The slides comprised views by the Rev. E. Healy, Messrs. Brewer, Hume, Tanner, Taverner, Douglas, and Grover. Mr. Parfitt showed the slides which were prepared by him for the recent competition at the London and Provincial Society, in which he was one of the prize winners.

On the 15th inst. a demonstration of "Carbon Printing" will be given by the secretary, Mr. W. Bishop.

### Richmond Camera Club.

The first annual dinner of the Club was held at the Greyhound Hotel on the 23rd ult. Mr. Cembrano, the president, was in the chair.

At the weekly meeting, on the 27th inst., Mr. R. L. Kidd presided, and Mr. Cembrano gave a demonstration of the making of collodio-bromide emulsions and their use for transparency work, showing and explaining the whole process of making the collodion, bromising and sensitising it, washing the emulsion, and cleaning, edging, and coating the glass. He concluded by exposing and developing some lantern slides, and explaining the method of toning them.

### Oldham Photographic Society.

*November 26th.*—Mr. Wallace Thompson, president, in the chair. Messrs. W. Lees, J. Ogden, T. Wild, and F. Wilkinson were elected members.

Mr. J. A. Furnivel, of Manchester, gave a description of "The Optical Lantern, its Construction and Use," describing in detail the manipulation of gas bottles, the construction of the mixed and blow-through jets, the optical arrangements, &c., after which he threw on the screen, by means of his lantern microscope, various interesting examples of micro-photography. He maintained that high powers could not be used in the lantern microscope without great loss of light, and that no alum trough was required to counteract the rays of heat emanating from the oxy-hydro light.

On December 17th Mr. J. W. Wade, of Manchester, will give a lecture on "Hand-camera Work, &c."

### Birmingham Photographic Society.

Annual meeting, November 26th.

The President, Mr. J. B. Stone, J.P. (chairman), in moving the adoption of the report, strongly advocated members to take up special work, and to excel in it; to increase the interest and enlist the sympathy of the public in photographic exhibitions with novelty, improvement, and advancement. He congratulated the Society on its report, and the excellent attendance at its meetings.

The officers and council to serve during the ensuing year are:—*President*—J. B. Stone, J.P.; *Vice-Presidents*—W. J. Harrison, F.G.S., E. H. Jaques, J. J. Button; *Council*—F. S. Goode, W. Jones, A. J. Leeson, A. R. Longmore, G. A. Thomason, T. Taylor, E. Underwood, G. Wilkes; *Librarian*—W. S. Horton; *Treasurer*—W. Rooke; *Secretaries*—J. T. Mousley, A. E. Tucker.

The president presented the late secretary, Mr. J. H. Pickard, with a Watson's whole-plate camera and three dark slides on behalf of the members as a souvenir of their esteem and goodwill, and in appreciation of the many services he has rendered to the Society.

Mr. Pickard, in responding, thanked the members and reviewed the history of the Society from its commencement, and, as secretary of the Photo. Survey, announced that a fine collection was being rapidly got together, and an exhibition would shortly be held.

### Bath Photographic Society.

*November 26th.*—Mr. W. Pumphrey in the chair.

Rev. E. A. Purvis discoursed on "Enlarging on Bromide Paper," illustrating his remarks by means of a Hulme Cantilever apparatus, fitted with duplex lamp. Several good examples were shown, including those made by the demonstrator, in the presence of the assembly.

Mr. Dugdale described the means he used to produce a number of large framed pictures he had with him. It was the usual daylight method.

Mr. P. Braham advocated the employment of oxy-hydrogen as a means of obtaining a sharper image than possible with oil lamps.

Mr. Austin J. King found by experience that burning magnesium ribbon did not yield satisfactory, even illumination over the whole field as had been recommended.

### Liverpool Amateur Photographic Association.

The annual meeting was held at the Law Association's Rooms, Cook Street, on November 26th, Mr. Paul Lange in the chair.

The following were elected members: Col. H. J. Robinson, Dr. Dubourg, Messrs. Frederick Clibborn, J. E. D. Parker, J. C. Still, Geo. H. Jackson, Geo. F. Allender, Percy W. Dixon, Geo. Allday, R. E. Robert, and Miss Harvey.

The hon. secretary (Mr. E. M. Tunstall) submitted a report of the Society's proceedings during the year, which stated that there was now a membership of 303.

Mr. P. H. Phillips, the hon. treasurer, presented the balance sheet, which showed that the total receipts for the year were £178 1s. 10d., against an expenditure of £173 19s. 2d.

The election of officers for the ensuing year was then proceeded with :—*President*—Mr. Wm. Tomkinson ; *Vice-Presidents*—Mr. Jos. Earp and Mr. A. Tyrer ; *Hon. Librarian*—Mr. J. Woolfall ; *Hon. Treasurer*—Mr. P. H. Phillips ; *Hon. Secretary*—Mr. F. B. Illingworth ; *Council* (to fill vacancies)—P. Lauge, H. B. Millar, F. K. Glazebrook, Dr. Keuyon, and F. Anyon.

The result of the prize competitiou was afterwards announced, and was as follows :—

| | | |
|---|---|---|
| 11 Sets of 6 prints, half-plate and under | Silver Medal | J. H. Welch |
| | Bronze „ | H. T. Mallabar |
| | Highly commended | H. Lupton |
| 5 Sets of 6 prints over half-plate | Silver Medal | T. F. Lloyd |
| | Bronze „ | H. Holt |
| 7 Sets of 2 enlargements | Silver Medal | T. B. Sutton |
| | Bronze „ | J. T. Norman Thomas |
| | Highly commended | F. B. Illingworth |
| 9 Sets of 6 pictures, hand-camera work | Bronze Medal | J. W. Swindon |
| | Commended | J. H. Ashcroft |
| 7 Sets of 6 prints not previously awarded | Bronze Medal | H. Holt |
| | Highly commended | E. A. Councell |
| | Commended | E. S. Gladstone |
| 3 Sets of Stereoscopic Slides | Bronze Medal | W. L. Elsworth |
| 22 Sets of 6 Lantern Slides | Silver Medal | F. Anyon |
| | Bronze „ | A. Tyrer |
| | Commended | T. B. Sutton. |

### Newcastle-on-Tyne and Northern Counties Photographic Association.

A selection of the 268 slides sent into the Association competition were shown before an audience of over 700 in the lecture hall of the Literary and Philosophical Society, Newcastle, on the evening of November 25th. The beautiful flower studies of Mr. J. Carpenter, London (who received one of the silver medals) were greatly admired. Messrs. G. E. Thompson's and J. W. Wade's slides were very fine, and the *genre* studies of Mr. W. J. Ankorn also call for mention. The slides sent in, on the whole, were of a high average, aud the show perhaps the fiuest ever giveu by the Association.

### Cape Town Photographic Club.

The annual meeting was held on Nov. 3rd in the club room, above Dix's Café, in Shortmarket Street, when there was a very good attendance. The chair was taken by Mr. C. Ray Woods, who stated that the president (Dr. Gill) had only just arrived from Kimberley, and would not be present. He would read the anuual report which had been drawn up by Mr. E. J. Steer, the acting hon. secretary, and which was in effect as follows. The initial meeting of the promoters of the Club was held in the St. George's Schoolroom ou October 30th, 1890. The meeting was attended by about thirty gentlemen interested in photography, and it was decided to form a club to be called the Cape Town Photographic Club. Since its formation twelve ordinary monthly meetings have been held, with an average attendance of thirteen members. An exhibition of lantern slides was held at the club room on May 5th. The usual monthly outings have been generally well attended. The committee had the pleasure of announcing that an efficient dark room, with water laid on, is now ready for the use of members. The balance sheet showed that there was a credit of £3 16s. 11d.

The meeting then proceeded to the election of office-bearers for the ensuing year, the result being as follows :—*President*—Dr. Gill ; *Secretary and Treasurer*—Mr. G. C. van Bonden ; *Committee*—Messrs. C. R. Woods, Pett, T. W. Cairncross, J. Andrews, F. Ayers, E. H. Allis, G. N. Liudup, and E. J. Steer.

During the evening a number of slides were shown by Mr. Woods, contributed by members and visitors to the Club.

## Answers to Correspondents.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

All other Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

H. L. M. (Nottingham).—We have occasionally met with similar markings in our own practice, and believe that they are due to contamination of the fixing bath. At any rate, with us they have not put in an appearance until that stage of operations has been reached. Such markings will occur if a metal dish is used for the hypo. Use a porcelain dish, and fix with hypo freshly mixed ; if this does not cure the evil, write again.

T. P.—The process is too long to describe in this column, but you will find full details on pp. 64 aud 125 of Leaper's "Materia Photographica" (Iliffe and Son). It would be cheaper for you to buy it direct from the Platinotype Company, who sell it under the name of "red salt."

Single Fluid writes for formula of Mayfield's single-fluid transparent developer for dry plates. We do not possess it, but perhaps its compounder will reply.

Spots.—We should be inclined to suspect the alkali which you use for toning, which is notoriously of uncertaiu composition. Try some of the pure carbonate, and see whether this gets rid of the difficulty. We ourselves prefer the borax bath. It seems a pity that such very charming pictures should be blemished.

T. A. G.—Write to the Platinotype Company, Southampton Row, London, who, doubtless, will give you the information which you require.

J. W. F.—It is impossible to give you definite information on the point. More than one dealer in second-hand apparatus advertises in our columns, and to them we must refer you. A lens bearing a good name will generally fetch at least two-thirds of the list price, but, of course, this depends upon the pattern of the particular lens in question—whether it be modern or ancient in desigu.

W. R.—Au ordinary magic lantern has usually a condensing lens of not more than four inches in diameter, its mission being to illuminate a picture of about three inches diameter. It is obvious that such an instrument cannot be used to enlarge pictures of greater area. The objective, or front lens, if of the portrait type, would of course do for quick photographic work of a limited nature, but would be quite unsuitable for street scenes such as are commonly called instantaneous views. A common spectacle lens will do for a finder, and it can be used above the camera to throw an image on the upturned focussing screen. Mr. Tylar, of Birmingham, sells a cheap arrangement for the purpose.

W. T. Heal.—Wilkinson's book on zincography will tell you what you want to know ; but the knowledge so gained should be supplemented by actual practice. It is just one of those things which are full of little dodges which can only be learnt through the fingers.

West London Photographic Society.—At the meeting on the 11th December, Mr. Charters White will give a paper on "Photo-Micrography," illustrated by means of the lantern.

The Lantern Society.—At the meetiug ou December 14th, the subject introduced by Mr. E. M. Nelson will be "On Some New Forms of Lantern Condensers."

The Princess of Wales.—A screen contaiuing the photographs of the donors has been presented to the Princess of Wales at Marlborough House by some members of the Nurses Royal National Pension Fund, on the occasion of Her Royal Highness's birthday.

Photographic Society of Great Britain.—At the meeting on Tuesday next the adjourned discussion on Mr. Warnerke's paper will be takeu, and a paper will be read by Mr. A. Pringle on "Photo-Micrography." On Dec. 22nd the subject for discussiou will be "Photography by Artificial Light." Dec. 29th will be a lantern evening.

## PRESSURE GAUGES.

We have recently had occasion to report a lantern disaster caused by the explosion of a gas-bag or bags—it is impossible to say whether one or both ignited—an accident which was fatal in one case, and which brought dire injury to many others. The judicial inquiry which followed this catastrophe was unsatisfactory in one respect, for the actual cause of the explosion was not made clear. The cause of explosions generally are often shrouded in mystery, because the chief actor, and the man responsible, has been among the sufferers; but in this case, happily, the operator was spared. He had apparently used every precaution in the preparation of the gas and its storage, and the jury very properly exonerated him from all blame. The occasion, however, has given experts and others an opportunity of decrying the use of bags as gas-holders, and advocating the employment of cylinders. The recommendation, perhaps, was unnecessary, for lanternists have long ago found out that the use of cylinders, besides being more convenient in every way, is actually more economical. In other words, the gas is cheaper to buy in the compressed state than it is to prepare at home, the saving of time alone being very considerable.

We unhesitatingly endorse the recommendation to use cylinders, not only by reason of their many advantages, but also because, as yet, there has been no recorded explosion of one of these gas receptacles while in use. They have certainly given way again and again under water pressure while being tested, and have also occasionally burst while being filled with gas. There is also recorded a case of an explosion of a cylinder while being experimented with, but there is reason to believe that in this case the apparatus was used in a very foolhardy and reprehensible manner. A well-tested, seamless cylinder of mild steel may be regarded as a far safer thing to work with than a bag. Under the system now adopted by the Brin Company of providing the H cylinder nozzle with a left-hand thread, so that it cannot possibly be connected with the oxygen supply pump at the works, and by giving the O cylinder a right-hand thread, so that it cannot be screwed to the H supply pump, it is evident the gases cannot be mixed, even if anyone attempted purposely to do so. But with a bag it is only too easy for an inexperienced or careless hand to mingle the two gases. The bags, for instance, may be a quarter full of gas after a performance—it is, of course, an economy to utilise that residue—and it is only too easy to fill up one of these bags with the wrong gas. It is idle to say that every precaution is taken when one bag is plainly marked with an "H" and the other with an "O," for human nature is fallible, and will make mistakes. Custom begets carelessness, and even a trustworthy man may have his attention distracted at the moment when he is filling a bag, and may make a mistake which will lead to disaster. There is, therefore, no question that, by using a steel cylinder which can only be filled by a certain machine, which machine can only be attached to the cylinder holding the particular gas which it supplies, we avoid all chance of storing an explosive mixture.

There is a danger in the use of a cylinder, but it is of another nature; it is confined to the operation of measuring the amount of gas contained therein by means of a pressure gauge. Such a form of gauge has been in use for many years for recording the pressure of steam boilers, and such an instrument forms a prominent feature of every steam engine in the country, but we have never heard of one giving way. The average working pressure of a steam boiler is something like 100 pounds on the square inch; but in dealing with gas pressures in the modern form of cylinder, we have a different condition of things altogether, for the initial pressure of the gas in a fully charged vessel as it leaves the pumping station is 120 atmospheres, equal to 1,800 pounds on the square inch. We are, indeed, here dealing with something new, a state of things never contemplated by the writers of text-books; so that it is difficult to get any information on the subject. It is not, therefore, wholly remarkable that gases under such new conditions should exhibit novel and striking properties.

But any text-book—although it will not afford the information which we are now wanting—will explain the construction of the gauge itself. The instrument is known as Bourdon's pressure gauge, and its principal part has a tube of flattened form, closed at one end, where it is attached to an axle carrying an index figure, so that any outward movement of the tube causes that index to move along a graduated arc. When a curved tube of this shape is subjected to a greater pressure on the inside than the outside, it tends to become straighter, and moves outward. When the pressure is removed it resumes its former shape.

No one suspected that there was any danger in using such a gauge until about six months ago. An operator who was testing the amount of gas in a cylinder by one of these gauges was severely injured by the bursting of the apparatus, and was able to recover heavy damages for his injuries from the firm who supplied the gauge. Other accidents of the same kind have happened since, and the most remarkable feature about them is that, although the gas in the cylinder—oxygen—is itself inflammable, at the moment of explosion a flame has been projected from the bursting gauge, and sufficient heat has been developed to fuse various parts of the metal composing it. It would seem, too, that in order to bring about one of these extraordinary explosions the gas must be at its greatest pressure. The last accident of the kind took place only a few evenings ago at the Photographic Club—happily, without serious results. The usual phenomena presented themselves, the gauge bursting with a loud noise, and flame being seen to issue from the apparatus. There was also distinct evidence that the heat developed had been sufficient to fuse the metal attachments. We are glad to see that the Club will hold an enquiry and discussion with regard to this explosion, and we hope that some satisfactory solution of the problem will be arrived at. At present the general opinion seems to be, as we indicated some months ago in dealing with this subject, that the ignition is primarily due to the presence of oil in some part of the pressure gauge, or possibly in the valve of the cylinder itself. It will be remembered that Mr. Clarkson has patented a method of charging the flattened tube of the Bourdon gauge with a semi-solid material, and furnishing the entrance to that tube with a bolt, which, should the gauge give way, will immediately stop the egress of gas, while, at the same time, the soft contents of the tube will allow the necessary expansion to take place without any risk of explosion. Before concluding our remarks upon this subject, we should advise those who are using gauges either to render them safe by the method indicated, or to abstain from testing the gases until the initial pressure has been considerably reduced.

---

Oxford Photographic Society.—On December 1st (Mr. A. Robinson in the chair), Mr. H. M. Phillipps gave a demonstration in "Autotype." The various processes were explained, and several prints were developed in sepia and black tones.

## COLOUR-PHOTOMETRY.

BY CAPTAIN ABNEY, C.B., R.E., D.C.L., F.R.S.

The following is an abstract of Captain Abney's lecture delivered last month before the Chemical Society, Sir Henry Roscoe in the chair:—

Colour has been usually made the subject of reference to empiric and variable standards, a practice which affords results useless for future reference, and only suitable for present immediate wants. What is required is a reference to numbers which are on some standard scale that can easily be reproduced.

According to the lecturer, the colour of a body, when viewed in a light of standard quality, is known when (*a*) its luminosity, (*b*) its hue, and (*c*) its purity, or the extent to which it is freed from admixture with white light, are known and expressed by numbers.

The luminosity of a colour can be given in absolute number by referring it to the standard of white. Thus, if white light fall on a coloured surface and on a surface of some standard white, the luminosity of the former may be expressed in terms of that of the light. It may appear difficult to compare the brightness of two such surfaces, but as a fact, the comparison is easily accomplished by causing the light falling on the white surface to be rapidly alternately made brighter and darker than that falling on the coloured surface. This can be done by interposing in the beam falling on the white surface rotating sectors with apertures which open and close at will during rotation. The point of equal luminosity can be found by this plan within one per cent. Experiments exemplifying the method were made, the brightness of an orange and of a blue pigment being compared with that of a zinc oxide surface which the author uses as standard white. It was also shown, by sending the beams through a trough containing water in which mucin was suspended in minute particles, that the relation only held good for the particular light in which it was measured. Hence the necessity for using a standard light. The luminosity of the light transmitted through coloured translucent bodies was also measured, and the same necessity shown for the use of a standard light.

The standard light recommended was that from the crater of the positive pole of the electric light when high illumination was required, or from a petroleum lamp when the illumination need not be so intense.

The method of measuring the luminosity of light coming through translucent bodies was also shown. A white oblong of paper was placed on a blackened card, a square which occupied half this oblong being pierced in the card, and thus half could be illuminated from the back of the card, and the other half by light from the front by placing a rod in the path of the beam to cast a shadow on the first half. The translucent substance was placed close behind the aperture in the card, and the light illuminating the paper, after passage through the translucent medium, was measured by altering the illumination of the other half lighted from the front.

The luminosity of the pure spectrum colours may be measured by what the author calls the colour patch apparatus, which is described in the *Phil. Trans.*, 1886, and in his work on "Colour Measurement and Mixture." It essentially consists of a collimator, two prisms, a lens, and a camera, on the screen of which a spectrum is brought to a focus. This screen is removed for experiments, and a collecting lens used to re-combine the spectrum, and to form an image of the last surface of the second prism on a screen some four feet off. A slide with a slit passed through the spectrum causes the white patch to become a colour patch of monochromatic light due to the particular ray traversing the spectrum slit. The white light with which the colour is compared is obtained from the light coming through the collimator and reflected from the first surface of the first prism; by means of a mirror and lens, it forms a patch equal in size to—and which can be caused to overlap—the coloured patch, or to lie alongside of it. In the first case, a rod placed in the path casts two shadows, one of which is illuminated by the colour, and the other by the white light; rotating sectors in the path of the latter allow the luminosity to be compared. The light used is the electric light, an image of the crater of the positive pole being formed on the slit of the collimator.

The luminosity of a colour is not the same when viewed from all parts of the eye. The centre of the eye is that with which observations are usually made; hence the luminosity should be measured with that part of the retina, and it is advisable that no more than six degrees of angular measure from the eye should be compared.

The audience were enabled to see the difference in luminosity of a colour which was of equal brightness to a certain white when viewed centrally, by shifting the axis of the eye so that the image was received on the retina some ten degrees away from the centre.

The action of the yellow spot was then alluded to.

The luminosity of any pigment on paper can be found by rotating it with two of the three colours—red, emerald-green, and ultramarine. These three make a grey which matches a grey formed of black and white. If the luminosity of the three have been accurately determined, by substituting the pigment whose luminosity is required for one of them, another grey can be formed to match a grey consisting of black and white. After measuring the angular aperture of the sectors, the luminosity is determined by calculation; the result is found to agree with the measurement made by the direct method. This is one of the many proofs that the measure of luminosity obtained in the manner described is correct, and not a mere accident.

The colour of a pigment can be referred to the spectrum colours by measuring the absorption. In the case of transparent bodies, this is best done by using a double-image prism at the end of the collimator so as to form two spectra on the camera screen. By adjustment, these may be caused to be so exactly one over the other that the same colour will pass through a slit in them. After emergence from the slit, the rays from the top spectrum are diverted by a right-angle prism, and caught by another which sends them through a lens on to the screen, forming a patch. Another patch as usual is formed by the rays from the bottom spectrum. By placing the transparent body in the path of one of these rays, the absorption can be measured by equalising the brightness of the patches by the sectors and noting the apertures. The absorption of pigments can be measured in the same way by causing one patch to fall on the coloured surface, and the other on the standard white.

To measure the absorption of pigments, an easy plan is to rotate black and white sectors together with variations in the amount of white, and to cause the colour patch to fall partly on them and partly on the pigment. The colour is varied till it is seen that the grey disc and the pigment reflect the same amount of light.

By both these plans templates can be cut out, which, when rotated in the spectrum, give the exact colour of the pigment on the screen; hence this is a reduction of the true colour to absolute numbers, since the colour can be reproduced from a reference to a note-book. It is to be remarked that the measures are unaffected by any defect in the eye of the observer, or by the kind of light in which they were effected.

The mixture in varying proportions of red, green, and violet of the spectrum makes white. This was shown by placing three slits in standard positions in the spectrum, and altering their apertures till a match was made with a patch of white light alongside.

Any other colour can be matched by the mixture of the same three colours, as was shown in matching green, blue, and brown papers.

Since three colours will make white, and the same three colours will make a match with an impure colour, every colour in nature can evidently be matched by mixing not more than two of these colours with a certain proportion of white light; and if these colours be red and green, or green and violet, the colour can be matched by one spectrum colour and white light, since there is some intermediate colour which has the same hue as the mixture of these two colours. Hence any colour, except purple, can be referred to some spectrum colour, together with a certain proportion of white light. In the case of purple, the colour may be expressed as white light from which the complementary colour is eliminated. Hence, any colour whatever may be expressed in terms of white light and one spectrum colour, the latter in wave-lengths, and the former in percentage of luminosity.

This was shown to be the case by interposing between the silvered mirror which reflected the light coming from the first prism, and which formed the white comparison patch, a plain glass mirror which reflected a small percentage of the light on to the colour patch, the amount of which could be regulated by sectors. Brown paper was placed in the white patch, and the spectrum colour was changed and mixed with the white light till the same colour was obtained. The scale of the instrument told the wave-length, and, by interposing a rod in the path of beams, the proportional luminosities of the spectrum colour and of the white light were determined. A similar match was made by light going through signal-green glass, and the complementary colour of the light passing through permanganate was determined.

Light coming through properly-picked specimens of red, blue, and green glass, and overlapping, may also be made to match a colour. The three glasses covered a square lens, and formed an image on a screen of a circular patch of white light coming through ground-glass on a screen. Colours were placed on a white beam alongside, and, by altering the amount of the coloured glasses exposed, matches were made.

If the dominant wave-lengths of the colour of these three glasses be known, and also the amount of white light mixed with it, these measures can be noted in terms of these three glasses; and, further, it is possible, by mixing the light coming through the three glasses in various proportions, to obtain a spectrum colour mixed with white light for each such mixture. Hence this is a substitute for the spectrum itself. To show this, three similar glasses were placed over apertures suitably cut in a circular card, and, by causing these to rotate in front of an illuminated slit, a sham spectrum was thrown on the screen in which every colour was present.

Any colour can be reproduced with three rotating sectors of red, green, and blue when certain proportions of white or black, or both, are mixed with one or other. If the dominant wave-lengths and the proportion of white light mixed are known of each such colour, the pigment whose colour is to be determined can be expressed in numbers as before, and in terms of spectrum colours if desired. This was shown by matching brown paper with red, blue, and green, a little white and black being mixed with the brown.

The importance of using some uniform light was insisted upon throughout, slight deviations in the experiments demonstrating this.

In conclusion, Captain Abney claimed to have demonstrated that the reference of colour to numbers was not only possible, but easy, and that—to chemists especially—the application was one of almost capital importance. Everyone could do it, and the lecturer had an instrument on the stocks which was not so cumbersome as that shown, but which would answer all purposes, he hoped, when complete.

## RODINAL.

We have recently had an opportunity of trying this new developer, and find that it fully bears out the statements made with regard to it in a recent issue of the Photographic News. It will be remembered that rodinal is an extremely concentrated solution of paramidophenol, and that a company has been formed in Berlin to introduce it to public notice. The preparation is carefully made, and its use will save all trouble of compounding. With normal exposures it is diluted for use with thirty times its bulk of water, while for greater contrasts a more concentrated solution is employed. It works more slowly and gives more delicate gradations if mixed with forty parts of water, so that it will be seen that its action can be controlled by simple addition of water.

In cases of over-exposure, an old solution should be used, or some bromide may be added to the freshly-prepared solution. For bromide paper development, rodinal is diluted with from 100 to 200 parts of water. The ordinary hypo bath can be used for fixing, but an acidulated bath gives the best results. Fixation somewhat weakens the image, so that in the case of both plates and paper the deposit should be somewhat darker than it is intended to be when finished. The wholesale agents for this country are Messrs. R. W. Greeff and Co., of 29, Mincing Lane, E.C.

Mr. Oscar Scholzig, of Dashwood House, 9, New Broad Street, E.C., has sent us samples of Zirkenbach's plain and graduated woollen background cloths, which are in various tints, and are admirably adapted for their purpose. The material is eight feet in width, and the price is moderate. These woollen backgrounds have many advantages over painted cloths, for they are softer, lighter, do not crease or crack, and can be easily cleaned when soiled by long use. Mr. Scholzig is also agent for the Dresden Art Furniture Company's goods, and he has sent us a marvellous catalogue of the different studio accessories made by that firm. We use the word "marvellous" because the catalogue is illustrated by nearly two hundred full-page collotype reproductions from photographs, and in this respect is a unique volume. The expense of its production must have been great, but the enterprise of its promoters will surely be rewarded in good time, for the pictures give a most realistic idea of the value of the goods illustrated.

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Rodinal Developer—New Printing Papers—Toning Collodio-Chloride Prints—Hand-Camera "Minor"—Salted Paper with a Resinous Emulsion.

*Rodinal Developer.*—It becomes more and more evident that the new rodinal developer is a reducing agent of eminent qualities. Dr. Miethe has compared it with the well-known rapid hydroquinone developer recommended by Professor Lainer, and, by employing in his experiments a sensitometer, in order to obtain results as exact as possible, he found that the rodinal developer, even when it was diluted to fifty times its bulk with water, was equal to the hydroquinone developer as regards energy, with the simple difference that the rodinal produced a much greater density in the under-exposed parts of the sensitometer plates than the hydroquinone developer. With regard to the keeping qualities of the rodinal, the author found that if the concentrated solution was diluted with ordinary water, a bright yellow liquid was obtained which, if kept in an open glass measure, acquired from an orange to a reddish-brown colour after the lapse of two days; at the same time, small crystals and a yellow, flaky deposit were precipitated. The same alteration took place a little sooner if the solution was kept in an open dish. The energy of the solution diminished, however, comparatively soon. All the plates developed with rodinal showed the utmost clearness, together with a beautiful colour of the silver deposit. In the case of over-exposure, it will be better to use an old solution instead of potassium bromide, since the latter shows a tendency to produce harsh negatives. If, in this case, the necessary density cannot be obtained, to each 100 c.c. of the developer 5 c.c. of a solution of—

| | |
|---|---|
| Hydroquinone ... ... ... | 5 grammes |
| Water... ... ... ... ... | 100 c.c. |
| Sulphite of soda ... ... ... | 10 grammes |

may be added. Even in the case of greatly over-exposed plates, clear glass and very vigorous negatives will be obtained, showing a beautiful greyish-black tone.

*Two New Printing Papers.*—C. V. Zamboni gives in the *Phot. Notizen* a description of two new printing papers introduced recently by the firm of Bruno, Saenger, & Co., of St. Petersburg, under the names of argentotype paper and velox paper. These papers, which give prints with a beautiful matt surface, differ only in the tone of the finished prints obtained on them, the argentotype paper giving an intense black similar to platinotype prints, the velox paper from a warm violet to a sepia tone. The manipulations are very simple. The paper is placed (in subdued light) on the negative with its prepared yellow surface, and exposed in the printing frame until the image is visible in all its outlines. The print is then placed with its back on the bottom of a dish which is covered with a little water, and allowed to remain until the image has been fully developed. Care should be taken that none of the water comes into contact with the film side of the paper, which would tend to the formation of spots. The print is then drained between blotting-paper, and dried over a spirit flame. After drying, the film side of the paper is moistened with as little water as possible, in order to dissolve out the soluble salts of the preparation. The water is allowed to act for about ten minutes, when it should be poured off, and the print washed thoroughly in two or three changes of water. It is then placed for five minutes in a solution of hyposulphite of soda 1 : 1,000, again washed two or three times in clean water, drained between blotting-paper, and finally dried over a lamp. If desirable, the prints may be toned before fixing, or treated with the combined toning and fixing bath as used for aristotypes.

*Toning Collodio-Chloride Prints.*—According to H. Wandrowsky, collodio-chloride prints are advantageously treated with the following combined toning and fixing bath :—

*Solution* A.

| | |
|---|---|
| Water ... ... ... ... | 700 c.c. |
| Hyposulphite of soda ... ... | 200 grammes |
| Sulphocyanide of ammonium ... | 20 ,, |
| Acetate of lead ... ... ... | 10 ,, |

*Solution* B.

| | |
|---|---|
| Water ... ... ... ... | 300 c.c. |
| Alum ... ... ... ... | 5 grammes |
| Citric acid ... ... ... ... | 5 ,, |
| Nitrate of lead ... ... ... | 10 ,, |

(This solution becomes milky.)

The two solutions are mixed, and after strips of unfixed silvered paper (about one-fourth of a sheet) have been added, they are allowed to stand for twenty-four hours. After the mixture has been filtered, 30 c.c. of a solution of chloride of gold 1 : 100 are added slowly and by shaking the bottle. The prints are placed in this bath with the film side down, without being previously washed, all the air-bubbles which may be formed being carefully removed. The prints become at first yellow, their vigour becoming greatly reduced; soon, however, the tone changes into a sepia colour, and then into brown, purple-brown, violet, blue, bluish-black, intensely black, and finally grey. The tone which the print shows on removing it from the bath will be retained after drying. The above-given quantity of the bath will be sufficient to tone and fix twenty-five sheets of 50 by 60 centimetres of collodion paper; after about ten sheets have been treated with it, a solution of 100 grammes of hypo in 200 c.c. of water should be added to it.

*Hand-Camera "Minor."*—The *ne plus ultra* of smallness and lightness in hand-camera work is a photographic detective camera recently introduced by the firm of Dressler and Heinemann, of Munich (Bavaria), under the name of "Minor." It is not much larger than a starch box, and its weight amounts only to 120 grammes. The pictures obtained with it are of the size of 4 by 4 centimetres; and being sufficiently sharp, may be enlarged afterwards. The camera is provided with a view-finder, and with three small metal plate-holders. The setting up and releasing of the shutter is very simple, and may be imperceptibly done. For many purposes this small camera will be very convenient.

*New Method of Producing Salted Paper with a Resinous Emulsion.*—Salted paper, giving prints of from brownish to platinum black tones, is prepared by E. Valenta in the following way. 10 grammes of ammonium chloride are dissolved in 100 c.c. of water; on the other hand, from 3 to 4 grammes of gelatine are allowed to swell in water, and, at the same time, from 3 to 4 grammes of very finely powdered light yellow French colophony are saponified with ammonia. This is done best by bringing water in a porcelain dish up to the boiling point, adding to it a little ammonia, and stirring the colophony gradually into the liquid. The clear resin-soap solution is then mixed with the swelled gelatine, and, after the latter has dissolved, the ammonium chloride solution is added. Distilled or rain water is added up to 1,000 c.c., and the solution carefully neutralised with diluted hydrochloric acid, and finally a concentrated solution of citric acid in water is added until the solution shows a distinctly acid reaction. A milky solution is obtained in this manner, which is employed in the preparation of the paper. Rives plain paper is recommended by the author for this purpose. It should be moistened by means of a sponge with the warm solution, and then floated for about three minutes upon the warm liquid. It is then hung up in a warm room to dry. To sensitise the paper, a ten or twelve per cent. solution of silver nitrate in water should be used, on which the paper is floated for two or three minutes. The paper is dried in a dark room, and may then be used for printing; but it will be better to fume it, previous to printing, in the well-known manner for about ten minutes, since it will then print quicker and yield more brilliant prints. If the paper, after printing, is soaked for a short time in water, and then fixed in a ten per cent. solution of hypo which has been acidulated by means of sodium bisulphite, prints will be obtained of an agreeable reddish-brown tone. The image will not be sunk in, as in the case of the ordinary salted paper, but it will show brilliancy and clear whites. To obtain black tones, the prints are at first placed in a bath of 0·3 gramme of chloride of gold, 8 grammes of borax, and 1,000 c.c. of water, and allowed to remain until they have acquired an intensely dark violet tone by transmitted light. They are then rinsed with water, and placed in a bath consisting of 1 gramme of potassium chloro-platinite, 300 c.c. of water, and from 15 to 20 drops of nitric acid. In this bath they acquire soon a black colour, which, after fixing, washing, and drying, renders them very similar to platinotypes. If the prints are fixed directly after toning, they obtain a very agreeable reddish-black colour; if an acid bath of uranium nitrate is employed instead of the gold bath, the prints acquire a decided red-chalk tone.

## THE MEASUREMENT OF LENSES.

A paper on this subject was read in the theatre of the Society of Arts on Thursday, the 26th ult., by Professor Silvanus P. Thompson. The lecturer commenced his remarks with a regret that the resources at the disposal of the Technical College, Finsbury, did not enable its staff to organise and equip a proper laboratory for optical measurements, and for the standardising of optical instruments, in the same thorough and practical way in which they have now for more than ten years organised laboratories for electrical measurements. What Professor Ayrton did ten years back for the City and Guilds Institute, in organising a laboratory for electrical measurements, he had desired to do for optical measurement, believing that, when the opportunity should come, the work would be of as much benefit to the optical industries of London as the electrical laboratories of the City and Guilds Institute have been.

An optical laboratory should possess the means of testing rapidly, accurately, and without too expensive appliances, such matters as the truth of plane surfaces, the curvature of curved ones, the focal powers of lenses, their aberrations, and their aperture. It should have means of testing mirrors and prisms, as well as actual entire instruments. It should be able to state the results in terms available for future years by the employment of accurate fundamental standards.

With but one very small part of the subject of the work of the optical laboratory could the lecturer deal on the present occasiou, namely, with the measurement of lenses. Lenses are used for many different purposes, and in varied functions and combinations. Measurements that would be important for some of these are utterly unimportant for others. For example, the condenser lenses used for magic lanterns are not wanted to be either aplanatic, achromatic, or rectilinear; their function being merely to collect the light which emanates from a certain luminous patch, and spread it as nearly equally as possible over the area covered by the transparent slide, so that the whole is equally illuminated, and so that the light so transmitted shall be on the whole slightly convergent. To measure the aberrations or exact focal powers of such lenses would be a useless work.

Enumerating all the things which might be made the subject of measurement with respect to a lens or combination of lenses, they are found to be no fewer than eighteen in number:—

(1) Diameter, or linear aperture; (2) thickness, or length from pole to pole; (3) focal power, or its reciprocal, the focal length; (4) position of principal focal planes; (5) position of optical centres ("principal points" of Gauss); (6) angular aperture; (7) chromatic aberration; (8) spherical aberrations, lateral and longitudinal: (9) chromatic difference of the spherical aberration; (10) loss of light by reflection from surfaces; (11) absorption of light in transmission; (12) illumination of field, central and marginal; (13) complaneity of focus (included in 7 and 8); (14) degree of distortion of image (rectilinearity); (15) cylindricity, or degree of astigmatism, including angle of axis of cylindricity; (16) accuracy of centreing; (17) definition in margin of field (involved in 7, 8, and 16); (18) refractive indices of materials.

Of these the lecturer dealt ouly with three, namely, the focal power of lenses, and the position of their focal planes and principal points.

The subject was treated exhaustively, and was illustrated by copious examples. We regret that we cannot print the paper *in extenso*, but as it has appeared in the *Journal of the Society of Arts*, our readers will have an opporunity of studying it to their very great profit.

Royal Institution.—The following are the lecture arrangements before Easter:—Prof. John G. McKendrick, 6 Christmas lectures to juveniles on "Life in Motion, or the Animal Machine"; Prof. Victor Horsley, 12 lectures on "The Structure and Functions of the Nervous System (the Brain)"; Mr. A. S. Murray, 3 lectures on "Some Aspects of Greek Sculpture in Relief"; Prof. E. Ray Lankester, 3 lectures on "Some Recent Biological Discoveries"; Prof. W. P. Ker, 3 lectures on "The Progress of Romance in the Middle Ages"; Dr. B. Arthur Whitelegge, 3 lectures on "Epidemic Waves"; Prof. J. A. Fleming, 3 lectures on "The Induction Coil and Transformer"; Lord Rayleigh, 6 lectures on "Matter: at Rest and in Motion"; Prof. J. F. Bridge, 3 lectures on "Dramatic Music, from Shakespeare to Dryden (the Play, the Masque, and the Opera)," with illustrations. The Friday evening meetings will begin on January 22nd, when a discourse will be given by Lord Rayleigh on "The Composition of Water"; succeeding discourses will probably be given by Sir George Douglas, Prof. Roberts-Austen, C.B., Mr. G. J. Symonds, Prof. Percy F. Frankland, Sir David Salomons, Prof. L. C. Miall, Prof. Oliver Lodge, Mr. George du Maurier, Mr. John Evans, Mr. F. T. Piggott, Prof. W. E. Ayrton, and other gentlemen.

## RENOVATING THE CAMERA.

BY H. C. STANDAGE.

Now that the autumn touring is ended, the camera and accessories are more or less dilapidated in appearance, the polish on the wood-work is dull and scratched, the brass-work shows signs of rough wear and tear, the leather bellows is shabby and stained, and altogether the whole apparatus looks, metaphorically speaking, not worth an old song. Nevertheless, the apparent shabbiness is not beyond the skill of the photographic operator. The renovation and re-polishing or varnishing of the wooden framework is simple enough to those who know how; the relacquering of the brass-work is easy to perform; while the leather bellows, the interior of the camera, and whatever other portion is out of repair, can be cheaply and perfectly renovated and made as good as new by very simple means.

As we have already hinted, the question crops up, "How to set about these repairs?" In this article I purpose giving simple, practical, and full directions for renovating the camera and its accessories, and making them look like new.

As a further development of the subject of this article, I hope later to deal with the renovating of the studio and its appliances, but for the present only the camera itself is considered.

*Re-polishing the Camera and its Stand.*—After repeated exposure to wind and weather, the bright polish of the wooden framework will invariably show signs of wear. If the brightness of the polish is but slightly dulled, and in no way scratched, its brightness can be restored by simply sponging it over with a mixture of $\frac{7}{8}$ linseed oil, and $\frac{1}{8}$ rosemary oil, all grease, &c., having been previously washed off with a flannel and a little warm soap and water. But for our purpose we will suppose a more serious state of affairs, namely, that the polish is weather-worn and scratched, that the lacquer of the brass-work is abraded and cankerous, the bellows out of repair, the blackness of the interior greatly worn off, and the whole article sadly in need of repairs; too much so to be renovated by mere patching up; nothing less than a thorough overhauling will make the article spick aud span. Therefore, proceed as follows. Remove all brass-work that permits removal, and then thoroughly wash off all grease, and as much of the polish or varnish as will come off, by means of soap, soda, water, and a flannel; a few drops of caustic soda put in the water will facilitate the removal of the polish, the object of its removal being to get down to the wood pure and simple. Scraping off the polish with a scraper will not be successfully performed by an amateur, owing to the many intricate parts to be dealt with, and unless the polish is uniformly removed the appearance will be patchy. When the polishing is done, give a whole day to dry in a warm room, so as to dry all moisture out of the wood-work, then give a coating of clear size, applied by means of a sponge. A little of Caunon's concentrated size dissolved in warm water in a basin will answer well. The wood-work will only need sizing if it is to be varnished instead of polished, and then only if the old polish is so far removed as to leave the wood porous.

If polishing is to be resorted to, no further preparation will be necessary after the washing with soap and water, as the pores will be sufficiently filled up to ueed no wood-filler to prevent the absorption of the polish. The method of applying the polish is to make a tuft of cotton-wool into a pad about 1¼ in. across; when covered over tightly with a piece of old, clean linen, this pad is held between the thumb and two fingers of the right hand, and, after partially saturating with polish, the wood is rubbed therewith in a circular sweep of the hand, or series of interlacing O's. Select a few inches surface, and persistently rub this in the above manner until it shines like a piece of glass or porcelain; then proceed to an adjoining portion. To prevent any mark appearing at the point of junction, keep the edges always moist by an occasional rub over them with the polishing pad. Do not smear the pad with polish, but, with the bottle in the left hand, give it a shake, place the pad to the mouth, and turn the bottle of polish upside down for a second; sufficient polish will adhere to the pad for use. If too much be taken on the pad at one time it will dry thereon, and become hard, and thus render the pad useless; and if too much polish be applied to the wood, it will form a thick, sticky layer that will refuse to become polished at all. When the pad becomes worn out or hard, use a fresh one; it is preferable to use a fresh pad on an unpolished portion of the wood to using a new pad on a portion already partially polished. A small bottle of pure linseed oil should be kept handy, and an occasional moistening of the pad with this will prevent the pad becoming hard and unmanageable. No pressure whatever is required in using the pad, but mere persistence in rubbing over the portion in hand until it glistens like a porcelain surface. The following formulæ will enable the operator to select and prepare his own polishes.

*Formulæ for Various Polishes for Wood.*—The following formula may be used for dark woods, such as walnut and mahogany:—

| | |
|---|---|
| Ruby shellac ... ... ... ... | 10 parts |
| Spirits of wine ... ... ... ... | 40 ,, |

Digest the lac in the spirit in a corked bottle with frequent shaking. When all is dissolved, the polish is ready for use.

*Formula for Superior Mahogany Polish.*—17½ ounces of the finest shellac are dissolved in 35 ounces of alcohol of the greatest strength (96 per cent.) by means of a water-bath.

*Formula for Dark Coloured Polish.*—In 70 ounces of 96 per cent. alcohol, dissolve 10½ ounces of ruby shellac and $2\frac{1}{10}$ ounces of Venetian turpentine. Place blotting-paper in a funnel, and filter the mixture through the paper, placing a plate over the top of the funnel to prevent evaporation of the spirit, which would render the polish too thick.

*Formula for Colourless Polish.*—The following preparation is for light woods, such as maple, ash, boxwood, &c.:—10 parts of shellac completely bleached are dissolved by slow digestion in 45 to 50 parts of spirits of wine.

*Formula for French Polish.*—Powder 4⅓ ounces of the finest shellac, and put it into a glass vessel with 26 ounces of strong alcohol, and dissolve by the heat of a sand-bath. In a separate vessel dissolve 1 ounce of dragon's-blood in 26 ounces of alcohol by digestion and shaking. When both mixtures are fluid, pour them together, and then add 7·7 grains of turmeric. Well shake the mixture, and allow it to stand undisturbed for twenty-four hours, and then filter through cotton-wool or cloth filter.

The above formulæ will be sufficient in the present case. Should the camera be a cheap one, the labour of polishing is not commensurate with its value. In such case, a coat of varnish meets all wants. To lay on such a coat, all that is needed is to pour a little varnish into a saucer, and, using a flat varnish brush, lay it on in strokes first one way, and then transverse or at right-angles—that is, do not use the brush up and down like a paint-brush—and avoid going over the same portion twice. Do not have the brush loaded with varnish, nor too empty, but, having dipped it well into the varnish, draw the flat side against the edge of the saucer to rub off superfluous varnish. The temperature of the room when varnishing should be from 70° to 75° F., and this temperature should be maintained until the coating is hard and dry—*i.e.*, no longer tacky. At the same time, avoid all dust and draughts, as a sudden chill will cause the varnish to bloom—*i.e.*, become opalescent instead of bright and clear.

*Formulæ for Ordinary Spirit Varnishes for Wood.*

| | | |
|---|---|---|
| 1.— | Sandarac resin ... ... ... ... | 40 parts |
| | Venetian turpentine ... ... ... | 4 ,, |
| | Spirits of wine ... ... ... ... | 120 ,, |
| 2.— | Sandarac resin ... ... ... ... | 24 parts |
| | Venetian turpentine ... ... ... | 2 ,, |
| | Mastic resin ... ... ... ... | 16 ,, |
| | Spirits of wine (96 per cent.) ... ... | 120 ,, |

Digest, and shake at intervals until the resins are dissolved.

| | | |
|---|---|---|
| 3.— | Sandarac resin ... ... ... ... | 48 parts |
| | Venetian turpentine ... ... ... | 1 part |
| | Mastic resin ... ... ... ... | 24 parts |
| | Spirits of wine ... ... ... ... | 120 ,, |

Digest as before.

The solution of the sandarac resin is facilitated by heat, therefore a sand-bath or water-bath is worth using when the varnish is wanted in a hurry.

*Formula for Red Wood Lacquer.*—The word lacquer is more generally applied to spirit varnishes used for metals, but essentially it is applicable to all spirit varnishes in which lac is an ingredient. In 50 parts of spirits of wine digest 1 part dragon's-blood, 2 parts elemi, 2 parts mastic, 8 parts sandarac, 4 parts shellac, and 4 parts Venetian turpentine.

*Formula for Black Wood Lacquer.*—In 20 parts of spirits of wine digest 1 part elemi, 1 part seed lac, 1 part mastic, 1 part sandarac, 2 parts shellac, and 1 part Venetian turpentine. To give the black colour to the lacquer, rub up 1 part of bone-black in the turpentine before adding the latter.

Before commencing the polishing or varnishing operations, it will be best to coat all brass-work with a thick layer of white of egg, so that, should the metal become accidentally smeared with polish or varnish, the smear can be easily removed by means of warm water and a sponge. Another caution is this; carefully remove all the old lacquer off the metal-work by means of a strong solution of soda with a few drops of sodic hydrate added.

*Formula for Lacquers for Brass-work and other Metals.*—All the metal-work that could be removed before varnishing the wooden frame should be cleansed of old tarnished lacquer by the following means. Boil a strong ley of wood ashes, add a small quantity of soap leys; put in the brass-work, and let it remain in for a short time, when the lacquer will be removed. Take it out, and dip each article in *aqua fortis* sufficiently dilute to take off the dirt, wash in water, dry well, and apply the lacquer.

*(To be continued.)*

---

We have received and put to the test a packet of the new chloride paper issued by the Ilford Company. It gives first-rate prints full of vigour, and necessitates no great care in manipulation. It is likely to prove a boon to photographers, especially in this dull season of the year, and it has the merit of being as cheap as it is good.

## Notes.

Some months ago, a great many complaints were made of certain firms who advertised that they would make enlarged photographs for nothing. These apparently guileless advertisers issued a very clever circular, stating that they were so anxious to bring their work before the British public that they had arranged to supply portraits worth £2 free of charge; and the sole condition they made was, that the picture should be suitably framed. In their circular they made no mention of the little fact that the frame was to be supplied by themselves, and that it was to be purchased at a price far in excess of its actual worth. One or two persons were sharp enough to insist upon the advertisers carrying out their agreement, and actually recovered damages for non-fulfilment of that agreement. One would have thought that these knock-down blows would have at once stopped this miserable game, but we find that circulars worded in much the same way are still being issued. Strangely enough, several of these circulars have lately been sent to well-known gentlemen connected with the photographic press, so that the advertisers are evidently not quite so "cute" as they fancy themselves to be.

The non-technical newspaper reporter is not happy when he is explaining to the public that of which he has no knowledge himself, and it is certainly creditable to him that he is able to screen himself so well behind a mass of magnificent verbiage. The recent gas-bag explosion at Ilkeston gave him a chance in this direction, and some wonderful statements with regard to the general behaviour of gases were accordingly given to the world. The most inexplicable of these we clip from a provincial paper, and fancy that it must have been evolved in the fertile brain of Mrs. Malaprop herself. Certainly we defy anyone else to explain its exact meaning. We are told that one of the dangers attending a lantern entertainment arises in the following manner: "The tubes of oxygen gas used may be not sufficiently strong for their purpose, owing to the oxygen being placed in mistake in a tube intended to contain another gas." We imagine that a man who could write this could mix gases or anything else, and we sincerely trust that nothing serious will happen to him.

All those who are interested in the modern method of zincographic engraving, which has replaced the work of the wood engraver to such a wonderful extent, will be interested in studying the supplement to the Christmas number of the *Graphic*. This sheet gives a number of clever sketches which have appeared in the *Daily Graphic*, and in addition to this there is a short article with the title "How it is done." Here we have a complete record of the method by which a block is produced, with a statement of the time occupied by each of the operations involved. Thus, we begin with the artist, who, accompanied by the ready writer, makes his sketches; then we are shown how the drawing is photographed by the electric light, then how the zinco plate is etched; and finally, how the block, associated with its descriptive type, is stereotyped; and lastly, how the newspaper is printed off on a rapid rotary machine. The illustrations shown are reduced from original drawings which have appeared in the *Daily Graphic;* they are full of life and vigour, and form an admirable example of the manner in which photography has benefited modern journalism.

It was only natural that the recent eclipse of the moon should form the chief subject of discussion at the last meeting of the Royal Astronomical Society. Unfortunately, no one had much to say, for, as Mr. Maunder remarked, at Greenwich they were always unfortunate. About ten o'clock the moon was just seen for a moment—long enough to bring the dozen observers who were appointed to watch it up to their posts—and then the clouds rolled together again, and everything was hidden. As the optical observations were so brief, photographic observations were, of course, out of the question. Later on in the evening a paper by Lieut. Molesworth was read, suggesting the employment of photography as a means of testing the existence of a lunar atmosphere. The suggestion elicited an opinion from the president (Capt. W. Noble) to the effect that he did not believe either photography or any other method of observation could reveal the existence of any atmosphere on the moon.

An inspection of a good number of this season's Christmas cards reveals the fact that photographic cards have gone greatly out of favour. We are not surprised at this. The photographic cards introduced some seven years ago were too large in size, and far too heavy in design and treatment. They consisted almost entirely of flowers photographed on a flat surface, and the prints coloured. The shadows were far too obtrusive, and the colours were muddy. The qualities best liked in a Christmas card are lightness of design and delicacy of treatment; and we should fancy that small snow scenes would find a ready sale. They certainly would be more appropriate than summer flowers in full bloom.

When you are engaged in hazardous enterprises, it is perhaps as well not to be too free with your photographs. A Capt. Dawson, who has achieved an unenviable notoriety through taking a party of Transvaal miners to Madagascar to work a mining concession which, he asserted, he had obtained from the Malagasy Government, unwisely gave his photograph to one of the miners as a passport to the Sakalava chief who owned the land. The photograph did not have the desired effect, and Capt. Dawson, leaving the miners to shift for themselves, made all haste to quit the island. The photograph which was to have such wonderful diplomatic powers afterwards fell into the hands of the *Madagascar News*, which has reproduced it as a supplement, with an intimation to the readers to "hang this up for reference." Madagascar, by the way, is moving with the times. In the same paper is a really creditable litho reproduction of a photograph of a group of miners, drawn by Razaka, a native artist.

An enterprising Paris photographer has taken time by the forelock by anticipating one of the advantages of photography in natural colours when this much-discussed problem is solved and has a practical outcome. The photographer in question puts forward the following fascinating advertisement: "Madame, who has perhaps wished that the *nuances* of colour in her fair hair and charming toilet might be fixed for ever, may now be immortalised in all colours for a modest sum." The "system" adopted by this enterprising gentleman has not been made known, nor does it much matter. His advertisement is almost good enough to secure him a reputation.

## LEEDS INTERNATIONAL PHOTOGRAPHIC EXHIBITION.

BY OUR SPECIAL COMMISSIONER.

Leeds is certainly not a beautiful town; but, as I sat looking out of the window of the hotel, its importance to the well-being of the country generally was striking enough. The rain was coming down in a manner to astonish even a Londoner, and that is saying something. At nine o'clock in the morning of the Press view day the sky was black, and the downpour of rain was not water, but ink, which careered in torrents down the channels and gulleys of the streets; but, in spite of all this sable misery, the streets teemed with drenched humanity, mostly female, evidently hurrying off to commence the daily labour of the week. Each one carried what might be called a regulation wicker basket—the pattern was so exactly the same in every case—and contained, in nearly every case, not only food for the day done up in newspaper, but a pamphlet of the penny novelette stamp as well, thus providing food for the mind as well as the body at the mid-day meal. Two-storied steam trams were tearing along in every direction, and, in addition to 'buses nearly as plentiful as in London, the busy street was almost impassable for wheeled traffic of the heaviest kind, which made the spot more like Lower Thames Street than any other place I have ever seen. I think the buildings are more begrimed with soot than those of any other town in the kingdom; certainly London is not in the inky competition, and need not try to win.

Leeds has reason, however, to be proud of two buildings, the Town Hall, and the Municipal Art Gallery, which is now the home of the Leeds Photographic Exhibition. I cannot speak of the Liverpool Exhibition, for I did not go; but for splendid surroundings and perfectly-lit galleries Leeds has the advantage over Glasgow, and that is saying something. Leeds has reason to be proud of its permanent Art Gallery, for it contains some celebrated modern pictures, several of these being the gift of Col. Harding, who, besides being the chairman of the Municipal Fine Arts Committee, has been a most zealous worker for the success of this Photographic Exhibition. When it is remembered that any surplus will go to the purchase of works of art to do honour to the town of Leeds, one cannot help wishing the joint committee, who have worked so well in bringing together such a splendid collection of works representative of the photographic art of to-day, a big financial success.

Fortunately for the welfare of the *conversazione*, the rain, which had in the most workmanlike manner done its best to mar everything, rested from its labours about six in the evening, evidently exhausted. At eight the approaches to the main entrance were blocked with carriages, and on entering one could not fail to be struck with the brilliance of the scene. Electric light everywhere to give due effect to the gay, and in some cases splendid, dresses of the fair sex. Exotics lined the approaches—of course I mean plants, and not tender specimens of Eve's fair progeny—and the band of the Leeds Rifles—a magnificent band, by the way—had commenced its labours in the court below. The balconies which looked down on this open space were filled by the fair sex, who, programme in hand, were partly listening, and, in some cases—must it be said?—partly, or rather wholly, flirting.

The Mayor briefly opened the proceedings in the large gallery, and introduced Col. Harding, who referred to the early history of photography, and the prominent part taken by Leeds forty years ago in helping on its progress, and referred to the fact that Mr. Ramsden, one of the most zealous workers of that period, was still amongst them, as hale and hearty and as enthusiastic as ever. He then called upon Mr. J. Gale to give his illustrated lecture entitled "Rambles: Rural and Pastoral." The artistic quality of Mr. Gale's lantern slides is known pretty well by this time; but they were new to the Leeds folk, who were simply delighted with them. The lecture was divided into two parts, and the interval of half-an-hour was filled up by the delightful music of the band.

The Leeds Photographic Society is very justly proud of its distinctive position as the first photographic society in England. The members claim more, and say the first in the world. Probably it is so; at any rate, there is no occasion to disprove the assertion. One thing is quite clear: the date of formation was 1852, and this date gives them a start of a year over the Photographic Society of Great Britain.

I could scarcely grasp the fact that the owner of the grand leonine head and giant form which towered over the heads of many, and who answered to the name of Ramsden, was the same man—and as energetic as ever—who made collodion well-known to many of the readers of this journal more than thirty years ago. Leeds has reason to be proud of Ramsden, for the collection of early work shown by him and others was exhibited at the first exhibition held in England in 1853. Not only are there large prints made about this time, and in a wonderful state of preservation, but, most interesting of all, and instructive as well, the original waxed paper negatives are there as perfect as ever. In talking to me about these, Mr. Ramsden said, "We have not got so very far after all, for in those days I could carry twenty prepared pieces of paper weighing less than a glass negative in one slide, and take them out one after the other as they were exposed, almost in the open air, for we had not to be careful about the light in those days." This need not surprise modern workers if they bear in mind that the exposure was about half-an-hour! One of the pictures exhibited is a calotype negative, taken nearly fifty years ago with a spectacle glass fixed in a cigar box. Last year was exhibited at Pall Mall a large photograph and the spectacle glass employed to produce it, side by side in the same frame. Where are we now? Waxed paper negatives appear to have been a speciality with the early members of the Leeds Photographic Society, for a large proportion of these early pictures are done by this process. It must be remembered that these are not merely paper negatives waxed afterwards; but prepared by a distinct method known as the waxed paper process, in contradistinction to the usual method, usually called Talbotype or calotype. Let any one examine Ramsden's early waxed paper negatives, and compare them with Eastman paper films as first exhibited in this country, and he will be astonished to find how slight is the difference. There is an early portrait of Robert Hunt, to whom photographers owe much—how much they will find if they chance to pick up at a cheap rate, as I did by good luck the other day, "Hunt's Researches on Light." Daguerreotype portraits of old mayors of Leeds, by Huggon, deserve most careful examination, but there is evidently an error about the dates. They begin with Sir George Goodman, 1836, and terminate with H. C. Marshall, 1842. Now, Huggon worked under

Beard's patent, who had it from Daguerre in 1839, who, by the way, did not let out that he had sold exclusive rights for England when he accepted the pension of 12,000 crowns from the French Government—in order, as Arago said in grandiloquent style, that the process might be as free as the light that produced these marvels. Poor England with its fogs was shut out from this great privilege. Undoubtedly Daguerre was a great man (of business). I shall have more to say next week about the photographs of to-day, but I would advise all who have the opportunity to devote themselves to a most careful scrutiny of what may now be considered old-world marvels of photography.

Awards.

*Open to Professionals Only.*—Class 1—Portraits, whole-plate and over, W. M. Warneuke, silver medal; W. W. Winter, bronze. Class 2—Portraits, under whole-plate, Harold Baker, silver; John E. Shaw, bronze. Class 3—Enlargement portraits, H. J. Van der Weyde, silver; Alexauder Bros., bronze. Class 4—Enlargement other than portraits, F. W. Edwards, bronze.

*Open to Amateurs Only.*—Class 5—Portrait set, Clarence B. Moore, bronze medal. Class 6—Portraits under whole-plate, W. J. Jenkins, bronze. Class 7—Portrait enlargement, S. H. Barton, bronze. Class 8—Enlargement other than portrait, J. W. Wade, silver. Lantern slides, J. E. Austin, silver; W. Tavener, bronze; B. Gay Wilkinson, bronze.

*Open to Professionals and Amateurs.*—Class 9—Landscape, whole-plate and over, John E. Austin, silver medal; J. E. Gibson, bronze; F. M. Sutcliffe, bronze; W. C. Beetham (two pictures), special silver. Class 10—Landscape, under whole-plate, Karl Greger, silver; P. Ennis, bronze. Class 11—Marine and clouds, F. M. Sutcliffe, silver; A. R. Dresser, bronze. Class 12—Animal studies, Karl Greger, silver; Jean Halle, bronze. Class 13—Out-door groups, Karl Greger, silver; F. M. Sutcliffe, bronze. Class 14—Architectural interior and exterior, whole-plate aud over, F. W. Edwards, silver; C. Court Cole, bronze. Class 15—Architecture, interior and exterior (under whole-plate), Wm. Denham, bronze. Class 17—Flash-light, John Stuart, silver. Class 18—Instantaneous, general subjects, Lyddell Sawyer, bronze. Class 19—Instantaneous, yachts in motion, Sweet and Kinlock, bronze; W. C. Beetham, bronze. Class 20—W. D. Welford, bronze; J. M. Nicholsou, bronze; Percy Lewis, bronze. Class 21—Instantaneous, other than seaside and marine, Major Lysaght, bronze. Class 22—*Genre*, C. Smerdon Roe, silver; Lyddell Sawyer, bronze; Adam Diston, bronze. Class 23—Microscopic, R. Kidston, bronze. Class 25—Scientific, Cecil V. Shadbolt, bronze. Class 26—Transparencies, F. W. Edwards, silver; J. W. Wade, bronze. Class 27—Lantern slides (amateur), J. E. Austin, silver; W. Taverner, bronze; B. G. Wilkinson, bronze. Lantern slides (professional), G. West and Sons, silver; G. E. Thompson, bronze.

*Photo-Mechanical.*—Class 28—Photogravure, line subjects, W. L. Colls, bronze medal. Class 29—Photogravure, half-liue subjects, The Autotype Company, silver; T. and R. Annan and Sons, bronze. Class 31—Type-high process, R. Gardner and Company, silver. Class 34—Woodburytype, Waterlow & Sons (Limited), bronze; S. B. Bolas & Company, bronze. Class 37—Photo-chromograph, Waterlow & Sons (Limited), silver; Photochrome Engraving Company, bronze.

*Champion Class.*—William Crooke, gold medal.

Special gold medal to H. J. Van der Weyde, for the Misses Dene; special silver medal to Prince Ruffo, for two heads; special commendation to the Leeds Photographic Society, for lantern slide exhibits.

Leeds Photographic Society.

In addition to the medals offered by the Fine Art Gallery Committee, the Committee of the Leeds Photographic Society have offered special medals for competition among its own members, which have been awarded as follows:—

Lantern slides—Godfrey Bingley, bronze medal; Herbert Deuisou, brouze. Laudscape (set)—Godfrey Bingley, brouze; Beddgelert, Godfrey Bingley, silver. Figure—William Wright, bronze. Architecture—William Denham, bronze. Instantaneous—A. A. Pearson, bronze. Enlargements—S. A. Warburtou, bronze. Special brouze medal to C. E. Spencer for portraits.

## ALLOTROPIC SILVER.

Professor Meldola's views with regard to this subject are commented upon as follows by Mr. M. Carey Lea in a recent issue of the *Chemical News*:—

In a recently published lecture, Mr. Meldola seems to call in question the existence of allotropic silver. This opinon does not appear, however, to be based on any adequate study of the subject, but to be somewhat conjectural iu its uature. No experimental support of any sort is given, and the only argument offered (if such it can be called) is, that this altered form of silver is analagous to that of metals whose properties have been greatly changed by being *alloyed* with small quantities of other metals. Does, then, Mr. Meldola suppose that a silver alloy can be formed by precipitating silver in the presence of another metal from an aqueous solutiou, or that one can argue from alloys, which are solutions, to molecular compounds or lakes? Moreover, he has overlooked the fact that allotropic silver can be obtained in the absence of any metal with which silver is capable of combining, as in the case of its formation by the action of soda and dextrine. Silver cannot be alloyed with sodium.

Mr. Meldola cites Prange as having shown that allotropic silver obtained with the aid of ferrous citrate contains traces of iron, a fact which was published by me several years earlier, with an analytical determination of the amount of iron found. Mr. Prange repeated and confirmed this fact of the presence of iron (in this particular case), and my other observations generally, and was fully convinced of the existence of both soluble and insoluble allotropic silver. Mr. Meldola's quotation of Mr. Prange would not convey this impression to the reader.

Of the many forms of allotropic silver, two of the best marked are the blue and the yellow.

Blue allotropic silver is formed in many reactions with the aid of many wholly different reagents. To suppose that each of these many substances is capable of uniting in minute quantity with silver to produce in all cases an identical result, the same product with identical colour and properties, would be an absurdity.

Gold-coloured allotropic silver in thin films is converted by the slightest pressure to normal silver. A glass rod drawn over it with a gentle pressure leaves a grey line behind it of ordinary silver. If the film is then plunged into solutiou of potassium ferricyanide, it becomes red or blue, whilst the lines traced show by their different reaction that they consist of ordinary silver. Heat, electricity, and contact with strong acids produce a similar change to ordinary grey silver.

These reactions afford the clearest proof that the silver is in an allotropic form. To account for them on suppositions like Mr. Meldola's would involve an exceedingly forced interpretation, such as no one who carefully repeated my work could possibly entertain.

Writing to the *Chemical News* on this subject, Prof. Meldola remarks:—

My attention has just been directed to the communication on this subject by Mr. Carey Lea, called forth by some remarks of mine in the Cantor Lectures delivered last spring before the Society of Arts. I should be extremely sorry if Mr. Carey Lea imagines—as would appear from the tone of his communication—that I desired in any way to detract from the value of his most interesting observations. He is labouring under a complete misapprehensiou if he supposes I intended to call in question the existence of the coloured compounds or modifications of silver with which he has made us familiar. He is, moreover, inaccurate in stating that my strictures were not based on any "adequate study of the subject," and that "no experimental support of any sort is given." If he will do me the favour of turning to the lectures in question, he will find that my statement was: "After carefully considering the conditions of formation, *and after repeating some of the experiments*, I must say that there appears to me to be no sufficient evidence that these coloured forms consist of the pure metal. On the contrary, all the evidence goes to show that some impurity is present," &c. I may add that, following Mr. Carey Lea's instructions, I have not had the slightest difficulty in preparing the gold-coloured product; with the soluble or colloidal silver I have not been so successful. I freely confess, however, that my experiments have not been numerous in this direction; but, since other investigators have succeeded in preparing the "soluble silver," I must attribute my own failure to hurried work, or to some violation of Mr. Carey Lea's instructions. I may state, also, that I am not singular in this failure to produce the "soluble" form, as several other and more experienced operators have met with the same negative results. Mr. Carey Lea would be conferring a boon upon large numbers of chemists in this country, who are interested in his work, if he would favour us with more explicit instructions.

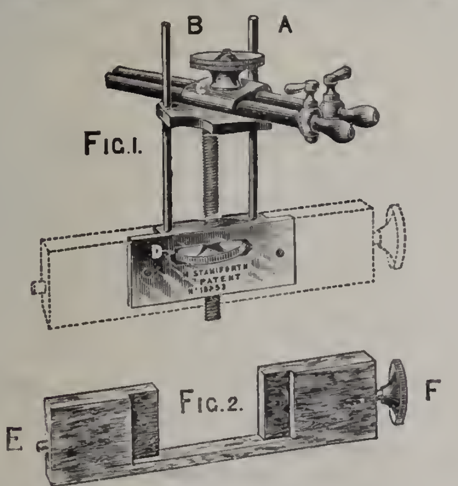
The facts are, that Mr. Carey Lea, by reducing silver salts, under certain conditions, has produced certain coloured products which contain a large percentage of silver and a small percentage of other substances. None of the evidence goes beyond this—not even the most recent contribution to the subject by Schneider, which appears in the number of the *Berichte* just received. One of these products is soluble in water.

Now, I never called in question the existence of these compounds; I did not even bring forward my own and other experimenters' failures as negative evidence. I only thought it right to caution my audience against applying the term "allotropic silver" to these products. I venture to reiterate that caution now in the hope that Mr. Carey Lea will admit its justice. Allotropy I understand to denote "the appearance of *one and the same substance* (italics mine) in several different states, distinguished from each other by different properties" (Watt's Dictionary, Morley and Muir, vol. i., page 128). How, then, can we apply this term to products which have not yet been shown to be "one and the same substance," viz., silver?

If Mr. Carey Lea will prepare specimens of his gold-coloured silver or colloidal silver possessing all the properties of these substances, and containing 100 per cent. of silver, I will admit the applicability of his term. In the meantime, I consider the designation "allotropic silver" to be premature, and apt to mislead. In other words, I must remain, and I think other chemists will remain with me, in the same position as that which I felt it necessary to take in the Cantor Lectures.

## NEW LANTERN ATTACHMENT.

The old-fashioned method of attaching a lime jet to an



optical lantern is by means of a vertical rod which springs from the hinder part of the tray. The method is unsatisfactory, for the jet is liable to shift, nor is it the easiest thing in the world to adjust the luminous spot to the exact optical centre of the instrument. Hence several improved methods have been brought forward within recent years, some of which involve considerable weight and complexity in construction. The most recent is that invented and patented by Mr. H. Staniforth, of Sheffield, which is here illustrated. This form of "jet-holder and regulator," as it is called, can be fixed to any existing lantern, and it dispenses with the usual iron tray entirely, for it is attached to the wooden casing of the lantern itself. The jet is held firmly under the clamping screw, A (fig. 1), which also admits of its being fixed at the required distance from the condensing lens, when it can be raised or lowered by turning the milled wheel D with the finger. Fig. 2 shows the manner in which the jet-holder can be adapted to single lanterns by means of a piece of wood to which it is fixed. E is a peg at one end of the arrangement, and F a fixed screw at the other, by which the fixture can be brought about without difficulty.

## Short Notices of Books.

The Studio, and what to do in it. By H. P. Robinson. (*London: Piper and Carter.*)

This is a book which has, deservedly, such a rapid sale that a fresh issue is constantly being found necessary. We earnestly wish that all photographic aspirants would furnish themselves with a copy of the work, for it answers questions which we are constantly being asked, and answers them, too, far more fully than can be done in the pages of a periodical. We have here chapters on the merits of various forms of studios, on backgrounds, accessories, methods of lighting the sitter, on pose and management of the subject, and upon many other topics too numerous to mention. When Mr. Robinson takes up his pen he writes about what he knows from practical experience, and the reader quickly feels that he is in the hands of a most competent guide. The book is a very cheap half-crown's worth.

Hazell's Annual for 1892. (*London: Hazell, Watson, and Viney.*)

This is not a photographic work, we are thankful to say, for a conscientious review of such a vast mass of matter would mean many days' work. But all the same, the wonderful volume deserves a word of praise even in a photographic journal, for there is no branch of art, science, or trade which cannot benefit by reference to its pages, which number nearly one thousand. This is the seventh year of issue, and each annual volume is an improvement on its predecessor.

The British Journal Photographic Almanac for 1892. Edited by J. Traill Taylor. (*London: H. Greenwood and Co.*)

It speaks well for the popularity of photography when we find that this well-known annual has swollen to its present dimensions. The name of the editor is sufficient guarantee that it is compiled with care, and that it is well up to date.

Brixton and Clapham Camera Club.—A reception will be held on the 12th inst., to inaugurate the opening of the new quarters at the Clarence Rooms, 376, Cold Harbour Lane, Brixton. Visitors invited.

## Patent Intelligence.

*Specially compiled for the* Photographic News *by Herbert & Co. (H. J. Haddan & R. Haddan), Registered Patent Agents, &c., of* 18, *Buckingham Street, Strand, London, W.C.*

### Applications for Letters Patent.

20,302. Franz Wiese, 62, St. Vincent Street, Glasgow, "Collapsible Background for Photographic and other Purposes."—*November 23rd.*

20,489. William Tylar, 12, Cherry Street, Birmingham, "Improvements in Camera Boxes for Microscopic Photography."—*November 25th.*

20,557. Thomas Henry Powell, 116, Denmark Hill, London, "An Improvement in the Method of, and Materials or Compound employed in, Toning Photographic Prints on Paper, Glass, or other Surfaces."—*November 26th.*

20,600. Raphael Kopp, 45, Southampton Buildings, London, "Improvements relating to Photography in Natural Colours."—*November 26th.*

20,690. Julius Hauff, 166, Fleet Street, London, "The Use of Aromatic Amido Compounds and of Derivatives of Pyrogallol for the Development of Photographic Images."—*November 27th.*

### Specifications Published.

1,736. *January 30th,* 1891.—"Developers for Photographic Pictures." O. Imray (The Actien Gesellschaft für Anilin Fabrikation, Berlin, Germany).

Relates to the development of photographic pictures by means of para-amidophenol and para-amidocresol, or their chlorine, bromine, iodine, oxy and amido derivatives, or the carbonic and sulphonic acids of para-amidophenol and para-amidocresol, by the use of which an exceedingly rapid and energetic development is effected, so that these substances are especially applicable for developing plates after short exposures. As an example of the preparation of a stock solution: 30 grammes of metabisulphate of potash and 10 grammes of hydrochloride of para-amidophenol are dissolved in 100 grammes of distilled water. To this solution concentrated caustic alkali is slowly added until the precipitate which is at first formed has become dissolved again. The above proportions may be varied, and for the metabisulphate of potash may be substituted bisulphate of soda or sulphite of soda.

16,608. *November 7th,* 1891.—"Photographic Albums."—P. Oster, Koln-Richl, Germany.

Cousists in an album in which the photographs can be easily inserted into and removed from the spaces designed for their reception without the possibility of injury to the album.

The leaves or sheets are divided in the middle; the three external rims of these leaves are solid, while the fourth rim is provided with a slot situated between the front and back of the leaves, and projecting somewhat into the external rims, by means of which the photograph can be inserted and immovably held tight, the said guide slot being closed by a closing-piece inserted into the lower cover of the album.

## Correspondence.

### BROMIDE PAPER.

Sir,—The letter of "Bromide" in your issue of the 4th inst. has caused some merriment iu my enlarging department. What would become of those who make a business of enlarging if, as "Bromide" says, "exposures were made by guess-work on the film or plain side, as the chances happen"?

For his guidance, permit me to say that the coated side may be distinguished from the uncoated side by (1) a slight inward curling of the edges—though "this is absurd"; (2) by slightly moistening one corner, when the gelatiue becomes adhesive; (3) by placiug the edge of the paper between the teeth and gently biting it; the teeth separate freely from the *un*coated side, but adhere slightly to the coated side, and separate with a peculiar noise which is soon recognised; (4) by the mere sense of touch, which is soon acquired by those who thoughtfully and carefully use "large quantities."

But "Bromide" need not worry himself; let him send his enlarging work or bromide contracts to one of my *confrères*, or to— J. Martin.

*General Photographic Works, New Southgate, N., December 5th.*

Sir,—Replying to "Bromide's" suggestion that bromide paper should be marked to show which is the sensitive side, I think this would add considerably to the trouble involved in its production, and hence probably to its cost, as it is so frequently sent out in cut pieces of small size, and every piece would need to be marked separately. I use a good deal of this material, and never experience any difficulty in distinguishing which is the right side. My method is to slightly moisten the tip of my little finger, and touch the extreme corner. The sensitised gelatine will adhere perceptibly, while the other side quite fails to do so. I do not find this touch leave any mark to speak of, and if it did, being at the very corner it could be easily trimmed off. Lignum Viride.

### CHARLES WILLIAM SCHEELE.

Sir,—In connection with the early history of photography, it may interest some of your readers—as a link between the very earliest investigators and the present time—to reproduce the following circumstauces. "Yesterday, Sunday, 6th December, died at Newcastle-on-Tyne, aged 73, Charles William Scheele, a resident there for fifty years, a worthy citizen, after only four days' illuess. Congestion of the lungs."

The following paragraph, taken from the introductory remarks in the catalogue of the Liverpool Photographic Exhibition of 1891, explains itself, and I venture to ask you to give it to your readers:—"We come now to 1777, and to a brilliant genius, Charles William Scheele, of Stralsund, in Swedish Pomerania; he was a distinguished investigator, and must be considered as one of the founders of modern chemistry. He made the first scientific investigation of the behaviour of silver chloride under the influence of light. First he noticed the action of differently coloured light, that the silver salt was quickly darkened by violet or blue, then that red or yellow rays had much less effect; but Scheele also discovered the cause. These technical particulars I need not enter on; it is, however, the first leading principle of all photographic discovery. Scheele really obtained the first photograph ever produced by fixing a glass prism in his window, and allowing the refracted sunbeams to fall on paper prepared with a salt of silver. In performing his experiment, Scheele had no idea of the uses to which his discoveries have since been applied in the formation of photography. His sole idea was to demonstrate a principle existing in light. As a connecting link between this historical period and the present, a lineal descendaut of Charles William Scheele, of Stralsund, bearing the same name in full, has been resident in Newcastle-on-Tyne for nearly half a century. He was also born in Stralsund, and is also engaged in the chemical industry. Two of his daughters are married, and resident in Cheshire."

*Liverpool, 7th December.* Thomas S. Mayne.

### DR. MADDOX AND MR. BURGESS.

Sir,—Probably most readers of the News see that those who are taking the side adverse to Dr. Maddox in this matter are bringing into discussion points that were never raised by the advocates of Dr. Maddox. The question is not whether the process of Dr. Maddox was a better one thau those which followed—than that of Mr. Burgess, for instance—but rather whether the process of Dr. Maddox was or was not the first which gave practical results. Of course his process was the first so far as history tells us. If it is to be a question of who introduced the process of to-day, then Mr. Burgess may climb down at once iu favour of Mr. Bennett. We all admit that the process of Mr. Burgess was a better one than that of Dr. Maddox in several points, just as we all know that that of Mr. Bennett was a great advance on that of Mr. Burgess.

I would join issue with Mr. Burgess on several of the assertions made in his letter to you in your issue of December 4th; but I prefer to leave mere wrangling alone, and to put before your readers the main issue. I see no harm in Mr. Burgess having tried to make money out of his process; only I submit that, if ever there should be an appeal for acknowledgment of his invention, this commercial step of his would completely bar all such appeals as we are now making for Dr. Maddox.

I would call attention to definite statements made by Mr. W. E. Debenham at the London and Provincial Association. He stated that Dr. Maddox's process consisted of bromide and silver in gelatine, and yielded *negatives* "very much of the same character as those produced now-a-days, though without such rapidity." He, the speaker, had made plates and got good negatives with more rapidity than wet collodion, by Dr. Maddox's process, modified by himself. I appreciate the impartial and judicial tone of the letters of the two gentlemen who have contributed to the literature of this subject in your correspondence, but I have not time to follow them, especially as my first sentence of this letter seems to cover their arguments.

I take it that it is Mr. Burgess who signs himself "The Victim," and I cannot repress my regret that he has introduced into this discussion the emetical couplet which concludes his letter. ANDREW PRINGLE.

P.S.—I may say that already our subscription list includes the names of many of the very oldest and ablest photographers in this country, the men most likely to know where the real credit lies.

---

SIR,—I wish to call the attention of your readers to the fact that a history of the gelatino-bromide question has been compiled, which demonstrates very clearly the relative positions of experimentalists.

It has been accepted for publication, and steps will be taken to bring it to the notice of all who have been asked to believe that "Dr. Maddox has done more for gelatino-bromide than any other man." A casual glance at the history will soon upset the theory that "every photographer knows that this important discovery is due to the experiments of Dr. Maddox."

Those who care to form some idea of the line which has been taken, may do so by hunting up the following references. Those up to and including January 19th, 1866, are to be found in the PHOTOGRAPHIC NEWS; those from April 27th, 1866, being in the *British Journal of Photography*. November 17th, 1865; November 24th, 1865; December 22nd, 1865; December 29th, 1865; January 5th, 1866 (notes by "An Old Photographer"); January 19th, 1866; April 27th, 1866; January 21st, 1868; July 11th, 1871; September 8th, 1871; July 25th, 1873; August 1st, August 8th, August 15th, (Burgess's challenge and substitute for collodion on last page); August 22nd, September 5th, September 26th, October 3rd, October 17th, October 24th, October 31st (a most important letter from John Beattie, of Bristol), November 7th, on which date we have a proclamation of boycotting.

During the whole of which time no claim is made on behalf of Dr. Maddox, nor did anyone think anything of his experiment, except that it was of no use. J. FAULKNER.

*Peckham Technical School.*

---

SIR,—Without wishing to say anything against the claims of Dr. Maddox or Mr. Burgess, might I enquire why Mr. Charles Bennett has been so entirely overlooked? Until the time when he so kindly gave to us the benefits of his experiments, gelatino-bromide plates were of very little practical value, and had it not been for the publication of his valuable formulæ, I doubt not we should still have been devotees of the now almost forgotten wet process, and the dry-plate factories not yet dreamt of. At any rate, Mr. Bennett has the warmest thanks of at least one—

5, *Pollet Street, Guernsey, Dec. 7th.* PROFESSIONAL.

---

OUR readers will be interested to learn that the scheme for reproducing and publishing the scores of great composers by permanent photographic process, which some time back was suggested by Sir George Grove, has now assumed definite shape, and that a firm of musical publishers at Berlin, under the auspices of the Beethoven Society there, are about to issue a volume of that composer's immortal symphonies and concertos. Further issues of a like kind will subsequently appear should the speculation receive the support from music lovers which it undoubtedly deserves.

## Proceedings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

*December 3rd.*—Mr. J. B. B. WELLINGTON in the chair.

It was decided to have an entertainment, partly scientific and partly musical, and the 18th of February was settled on for the date; it would be made a special ladies' night.

Mr. A. HADDON mentioned that Mr. J. S. Teape had, at the last meeting, shown some prints from which the image had almost disappeared in consequence of their having been subjected first to the uranium intensifying process, and then to long washing. He had then pointed out that, the silver being still on the film, it should be capable of being made evident by re-development, and this had proved to be the case. He had first brushed over one of the prints with a solution of bromide; he had then re-developed with hydroquinone, and obtained a full image. This he had re-converted into bromide, and again re-developed with oxalate; again re-converted, and developed with eikonogen; and finally re-converted, and developed with pyro. The image was now probably as vigorous as it was before the print had been subjected to the uranium and reduced by washing.

The CHAIRMAN enquired in what form was the silver when in the invisible state.

Mr. HADDON replied that it was probably ferrocyanide.

The CHAIRMAN suggested that, instead of re-converting the image into bromide, a chloride might be formed. The image re-developed would then probably be of a different tone.

Mr. TEAPE showed a set of examples cut from a bromide print; one was in the original condition; a second had been toned with uranium; a third had been reduced to an almost invisible state by subsequent washing; and the remainder had been converted into chloride and bromide and re-developed with different agents.

Mr. B. SMITH mentioned the case of an image bleached with chlorine water and then re-developed.

Mr. A. MACKIE remembered with collodion to have fixed an exposed plate, and then with acid pyro had developed an image.

Mr. DEBENHAM enquired whether for this experiment it was necessary to expose longer than would suffice if the image were to be developed in the usual way. If ordinary exposure, as for an image to be developed, sufficed in this case, it was an argument supporting the chemical theory of the latent image.

Mr. T. BOLAS, using ordinary bromide emulsion, and giving ordinary exposure, and fixing until there was nothing visible, had obtained very good results by after-treatment with pyro and silver, and often used the method in preference to the customary one.

Mr. HADDON showed a print which had been an ordinary gelatino-bromide one, but had been converted into a blue print by treatment with ferricyanide, and subsequently with iron in the ferric state.

Mr. DEBENHAM presumed that the image now consisted of Prussian blue and the original silver, which might be expected to darken in time.

Mr. HADDON replied that that was so.

A question from the box was read enquiring whether any one had been able to confirm the experiment described by Mr. Friese Green, wherein the human eye was made to impress upon a gelatine plate an image of a flash or electric light which had previously been looked at.

Mr. HADDON said that he had tried and utterly failed. It was curious that, amongst the hundreds of thousands who must have heard of the experiment, no one had come forward to verify it.

Mr. P. EVERITT read a paper on the "Exaggerated Perspective of Wide-Angle Lenses."

Mr. A. COWAN took exception to the title of the paper, which, he said, assumed that which was denied, and suggested "Asserted exaggerated perspective" as a more proper title.

In the course of the paper, Mr. EVERITT said that he considered the angle common in painting, of from 45° to 60°, as ordinary. More than this he should call wide, and narrower than this narrow-angle. He contended that the argument recently put forth in favour of the truth of perspective as given by wide-angle lenses was not just, because, although if the point of sight of the picture were looked at directly the marginal objects might assume the form shown in the photograph, they were in such case quite indistinct to the eye, on account of their falling on a part of the retina that did not give good definition, and when the eye was directed to that part of the picture they no longer gave any true impression, but showed the distortion which existed. Then, again, linear perspective was not perfect, but only approximate, as we looked at a thing with two eyes, and linear perspective recognised monocular vision only. Artists had the privilege of reproducing a scene as from any desired distance, which photographers had not.

Mr. T. Bolas said that, although artists did frequently limit themselves to narrow angles, that was not always the case. In the Wiertz collection there were pictures which included a wider angle than any lens would give. In these a globular object towards the margin became elongated to several times its width, but seen from a proper point—to indicate which an eyehole was placed—they took the correct form. In the ordinary gallery picture, which would be looked at from a different point for each part of the subject, the artist commonly made a compromise, and painted what would not be true as seen from any one point.

Mr. Debenham said that Mr. Everitt was mistaken in supposing that the point of sight must be looked at in order that the mathematical or photographic representation of objects at the margin of the picture should appear true. It sufficed for the eye to be in the right position, and then it might be directed to any part of the picture. He thought that Mr. Everitt was not entitled to speak for artists universally, when putting forward the view that they acted in defiance of mathematical perspective. Many doubtless did, some from not having thoroughly gone into the subject, and some from a desire not to shock the prejudices of a public unwilling to recognise the truth of representations other than those to which they had been accustomed. The text-books recognised by the authorities of the Science and Art Department at South Kensington taught mathematical perspective as rigorously as photography demonstrated it, and the public would doubtless, in time, appreciate it—as, indeed, was more and more the case. He thought the introduction of the question of binocular perspective only tended to mystify matters. He thought that those who said that photography was incorrect from representing things as seen with one eye only should be bound to say what was the difference which, they asserted, should be made from the drawing, as given by a photograph, to meet their views. He had thrown down this challenge before, but could meet with no response. Would they say that objects in any given part of a picture should be broader, narrower, longer, or shorter than shown in a photograph? If unable to answer this, let them not confuse the matter by dragging in the subject. Then, again, as to the asserted distortion by photography (or mathematical perspective) of marginal objects; let those who asserted this bring forward a scheme of perspective which will answer for any class of subject. They would find that mathematical perspective was not only true, but the only possible perspective which would give objects in their true relative proportions as seen from any given standpoint, and the picture looked at from that standpoint presented no distortion, but a representation of nature so exact that, if placed in front of the scene, and the picture removed bit by bit, there would be seen, as each portion, however small, of the picture was removed, the original object represented on the removed piece.

Mr. Beckett said that the method of demonstration used in the art schools, where a drawing was made on a pane of glass of objects as seen through it, was of the same kind as that suggested by Mr. Debenham's last remarks, and gave, unquestionably, a true result.

Mr. W. Dando (who was elected a member earlier in the evening) illustrated the apparent distortion in a painting as corrected by selection of point of view, and showed how, in theatrical scene painting, the matter was taken into account.

Mr. Everitt replied generally, and said that what he objected to was the pedantic application of perspective.

### Camera Club.

On Monday, November 30th, Mr. Frank Haes exhibited his slides illustrating what was done in animal photography in the days of wet collodion. The slides were from negatives made twenty-seven years ago.

After Mr. Haes' pictures, other slides were shown by Messrs. Davis, Hughes, Bolton, Burchett, Greene, Budger, Walker, Laurie, and Major Becher.

On Thursday, December 3rd, Mr. Dresser read a paper on "Toning Rough Bromide Paper and Transparencies," and gave different formulæ for mercurial and for uranium toning, referring to a large number of his own examples which were arranged on the Club walls.

Mr. Herbert Fry afterwards gave a demonstration of the toning process, and Mr. Weir Brown added much information and showed some instructive illustrations.

On December 17th Mr. Leon Warnerke will give a description and demonstration of his "Simplified Collographic Process."

### Holborn Camera Club.

*December 4th.* — Mr. Herbert Thompson in the chair. Messrs. Daw and Gunn were elected members.

Mr. F. J. Cobb then opened a discussion on "Enlarging." He thought that the reason why so few amateurs had taken up with enlarging was because they thought it required expensive apparatus. All the enlarging he had done was by means of apparatus costing not four or five guineas, but four or five shillings. When he first started enlarging, about three or four years ago, he knew next to nothing about the subject, and he had to gain his knowledge by experience. His apparatus consisted of an old 10 by 8 camera, to which he had fixed a baseboard with an easel at the other end, the negative to be enlarged being placed in the dark slide of the camera. He covered the apparatus up by means of a hood, and exposed with magnesium ribbon. The distance of the light from the negative would depend on the density of the negative. He had a silver print by his side while exposing, so as to tell which part of the negative would require most light, and which required shading. That was one of the chief difficulties. The negative itself should be thin. He first used a portrait lens, but could not make it answer, and he finally used a single lens. He used the ferrous oxalate developer; he had tried hydrokinone, but he did not like it so well. When he first started he always obtained very black and white results, instead of the grey tone which he wished to obtain. He now left out the bromide of potassium, using Eastman's paper, to obtain the desired results. In conclusion, he advised beginners to stick to the same negative until they obtained a good print. They would by that means know what to do with the next negative to be enlarged.

Mr. E. H. Bayston gave a description of the method of daylight enlarging.

Mr. E. Benest said he did not recommend anyone to use the iron developer, because of the great difficulty of getting rid of the iron in the paper, which, if left in the print, would cause it to fade. He had tested prints which had been developed by the iron developer, and had been through three separate clearing baths and well washed, and found iron still existed in the paper.

Messrs. Brocas and Golding and other members also took part in the discussion.

### North London Photographic Society.

In the report of this Society's meeting furnished last week, it was omitted to be stated that, in connection with the optical lantern, Mr. A. Mackie exhibited a series of slides illustrating the results of a number of experiments made by him to test the effect of altering the proportions of the ingredients constituting the ordinary pyro developer. Taking the ordinary standard developer as represented by 2 grains pyro, 1 grain bromide potassium, and 2 minims ammonia to the ounce, he had made a succession of similar exposures on a sensitometer scale, and then developed the exposures in three sets, which were thrown on the screen. In one set the pyro was increased and decreased by regular stages, in the second the bromide, and in the third the ammonia were subjected to the same treatment, the results showing the amount of control of density given by thus varying the proportions.

On the 15th December the subject of "Carbon Printing" will be introduced by the secretary, Mr. W. Bishop; visitors are invited.

LEWES PHOTOGRAPHIC SOCIETY.

*December 1st.*—The PRESIDENT announced the death of Mr. E. Miller, a member of the committee, and the hon. secretary was requested to forward to the relatives a letter of condolence and sympathy. He also mentioned that he had received a letter from the hon. secretary stating that, owing to his professional engagements, he could not devote so much of his time to the Society as he had done in the past, and the committee had asked Mr. Percy Morris to act as a joint hon. secretary, which he hoped he would be able to do.

Mr. PERCY MORRIS read a paper on "The Development and Printing of Hand-Camera Negatives," demonstrating both processes. He used hydroquinone for negatives, and ferrous oxalate for paper.

LOWESTOFT AND DISTRICT PHOTOGRAPHIC SOCIETY.

*December 3rd.*—Mr. STRINGFIELD in the chair.

A series of slides illustrative of "A Journey through the White Mountains of New Hampshire" was projected on the screen by Mr. G. W. STRINGFIELD; a description being given by Mr. W. ROBERTS.

The CHAIRMAN called attention to the instruction classes intended to be held in connection with the Society, and he trusted that ere long these would be combined with other classes, forming a technical school, which should be centred in a suitable and substantial building.

MIDLAND CAMERA CLUB.

*December 4th.*—Dr. HALL EDWARDS (president) in the chair.

A paper was given by Dr. LEECH upon "The Keeping Qualities of Dry Plates," which, however, dipped largely into the question of the invention of the gelatine bromide process, and also with the effect of damp upon plates, and the destruction of the latent image by prolonged soaking in bromide of potassium. Dr. Leech had prepared a complete series of negatives, which were passed round for inspection. Plates were shown made as far back as 1880 (gel. bromide) and 1878 (collodio-bromide). A Swan plate made in 1880, exposed and developed in December, 1891, gave a good result. But undoubtedly the best were of the Liverpool Dry Plate Co., made in 1878, exposed and developed in December, 1891. There was but the slightest trace of marginal fog, and the image was bright and vigorous.

In the discussion that followed considerable stress was laid upon the method of packing plates; the use of paper between was strongly condemned, and it was pointed out that the old methods avoided any such plan.

RICHMOND CAMERA CLUB.

*December 4th.*—Mr. DAVIS in the chair.

The subject of "Lenses" was discussed with the aid of specimens and illustrations lent by Messrs. Taylor, Taylor, and Hobson. Mr. ARDASEER explained the exhibits, which comprised flint and crown glass in the rough state, and ground and polished flanges in all stages of manufacture, and several finished lenses, including one of the casket sets.

Slides were then passed through the lantern illustrating the principle and the action of lenses, and the method of their arrangement in the various combinations commonly in use.

SHEFFIELD AND DISTRICT OPTICAL SOCIETY.

AT the meeting on November 2nd the president, Dr. MANTON, exhibited what he termed a universal lantern, possessing many features of interest, suitable either for blow-through jet, ether, or oxy-hydrogen lime-light, and equally adapted for the projection of transparencies or the demonstration of scientific experiments. The front carrying the objective slides on the extending principle of long-focus cameras, the space between condenser and objective being entirely unenclosed. In practice it was found that there was no appreciable leakage or diffusion of light into the room. Perhaps the greatest novelty lay in the condenser, 3¼ by 3¼ inches square, this being, of course, derived from a slightly larger condenser cut down, and the superfluous arcs of circles removed; the slight loss of light resulting from the increase in focal length being more than compensated for by the power of this small condenser to project on the screen an unmasked transparency absolutely free from colour, and clear to the edges.

The evening was brought to a close by the demonstration of Scott's oxy-etho-benzine lime-light. A member having expressed a wish for a test, the request was granted, although Dr. Manton pointed out that the optical and mechanical advantages were entirely in favour of the oxy-hydrogen apparatus, against which Scott's light was pitted, which was fitted with condensers of the Herschell type and a half-plate portrait lens as objective; the jets, &c., being adjusted to a hair's-breadth, and being fed by O × H from 40ft. cylinders fitted with Beard's regulators. The etho-benzine light, on the other hand, was placed in the experimental lantern above alluded to (square condenser, with its attendant loss of light into the bargain); and an ordinary lantern objective, costing a guinea, of 10-inch focus was employed. The jet recently purchased had not been adjusted and adapted with regard to its bore in accordance with the suggestion of the inventor. The saturator (hot air) had been used for nearly two hours on a previous occasion, and was fed by a partly-used 10ft. bottle of oxygen without regulator. In spite of these disadvantages, the new light stood the trial admirably, and although the saturator had only five minutes' warming, the light was within a few candles of its rival. It was to be regretted that time and other circumstances did not permit of the conditions being reversed—the Scott light being placed in the "swell" lantern, and *vice versâ*; but further experiments will be made and published shortly.

SHEFFIELD PHOTOGRAPHIC SOCIETY.

AT the Masonic Hall, Surrey Street, Tuesday, December 1st., Mr. B. J. TAYLOR in the chair.

Mr. BRAHAM, the representative of the Autotype Company, London, gave a practical demonstration of carbon printing, showing the various processes, from the exposure on the negative to the finished pictures.

The CHAIRMAN announced the winners of the annual competition as follows:— Class 1, Mr. Crowther; Class 2, Mr. Toplis; Class 3, Mr. E. Beck; Class 4, Mr. Bromley first, and Mr. Crowther second; Class 5, Mr. E. Beck both first and second.

The competition slides were then passed through the lantern.

EALING PHOTOGRAPHIC SOCIETY.

THE first *conversazione* in connection with the Ealing Photographic Society has been held at the Municipal Buildings, and the event served to show at once the extent to which the photographic art is practised by amateurs in the district, and also the success of this comparatively young society in uniting them together in a common interest for mutual advantage.

From every point of view the *conversazione* was a gratifying success. About 250 invitations had been issued, and fully that number of guests were present during the evening, locomotion at times proving somewhat difficult in consequence. The exhibits, too, were so numerous that the ingenuity of the committee was taxed to the utmost to find room for them.

The numerous exhibits were illustrative of platinotype printing, silver printing toned with platinum, and all the various processes employed in connection with photography. Dr. Common, one of the vice-presidents of the Society, lent a series of astronomical photographs, and the interest of the exhibition was further enhanced by the permanent autotype photographs lent by the Autotype Company, and the exhibits lent by the Platinotype Company, and by Mr. Geo. Davison and Mr. J. B. Wollaston. Micro-photography was also represented. Photographs of Ealing scenery were scarce, but considerable attention was devoted to one by Mr. Taylor, illustrative of the "village" as it was, and representing the fair formerly held on the green. Messrs. Mawson and Swan had on view a number of their improved apparatus, including the reflex camera, cantilever enlarging apparatus, magnesium flash-lamp, and others.

During the evening a series of lantern exhibitions was given, and music was given on the piano and violin by friends who had volunteered their services for the occasion.

Croydon Microscopical and Natural History Club (Photographic Section).

*December 4th.*—Mr. Edward Lovett (president) in the chair.

Mr. J. Lewis, of Birmingham, demonstrated the kallitype process. In a short and lucid way he described the old method of working the kallitype No. 1, and set forth the disadvantages that it had as regards the manipulation, and otherwise marring the popularity that it might have claimed. He then explained the improved kallitype process No. 2, where all these disadvantages were done away with, and now the process could be worked with a nicety and exactness that called forth no comment. He developed several matt surface and albumen prints.

Friday, December 11th, will be a lantern night for members' slides.

Rotherham Photographic Society.

At the meeting on December 1st in St. George's Hall, the prize lantern slides of *Photography* were shown to an audience of over two hundred members and friends. The description was read by Mr. E. Isle Hubbard (a vice-president), and Mr. James Leadbeater (treasurer) had charge of the lantern arrangements. Slides contributed by Mr. G. T. M. Rackstraw, Mr. W. Mason, and the hon. sec. were also displayed, together with the successful slides in the Society's recent competition.

Leytonstone Camera Club.

*December 2nd.*—Mr. R. Sefton in the chair.

An interesting and amusing lecture was delivered by Mr. Tom Symmons on "The Cad and the Camera." He defined a cad, contrasted caddish and gentlemanly conduct with a camera, and related several anecdotes to illustrate his meaning. He then asked the members present to give their views upon the matter, which most of them did. The question was raised as to whether an amateur had the legal right to snap-shot, print, and distribute copies of an individual against his will. This was left undecided, although strong opinion was expressed as to its reprehensibility considered from an ethical standpoint.

This new Club meets every Wednesday at 8 o'clock, at the Assembly Rooms, High Road, Leytonstone. Visitors are invited.

Dundee and East of Scotland Photographic Association.

*December 3rd.*—Mr. J. D. Cox in the chair.

The slides sent in for competition were passed through the lantern. On the votes of the members present being scrutinised, the following were declared the prize-winners:—1st, D. Ireland; 2nd, J. D. Gibson; and 3rd, G. G. Maclaren.

Two questions were found in the question-box:—"What is the most effective manner of vignetting bromide prints?" The best result was obtained by using a deeply serrated vignetting mask, and kept in motion during exposure.

"A landscape negative, on being fixed, was found to have a clear spot about the size of a threepenny-piece in the centre of some foliage. What is the best way to dodge the blemish in printing? The negative cannot be duplicated." By vignetting in from another negative a suitable piece of foliage, or block out the hole and work in the foliage with a brush on the print.

London and Provincial Photographic Association.—December 17th, monthly lantern night; December 24th, "Warm Tones in Lantern Slides." Visitors invited.

## Answers to Correspondents.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

All other Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

M. P.—We could not answer your question last week for want of the necessary information. A preparation of paramidophenol is now brought forward, as we stated a fortnight ago, under the name of rodinal, and the sole agents for it in this country are Messrs. R. W. Greeff and Co., of 29, Mincing Lane, E.C. They would be able to give you all particulars.

Swen.—Obviously, any room of sufficient size can be used under the conditions stated. Electric light is far more certain than magnesium, and you should endeavour to visit a studio such as Van der Weyde's or Mayall's, where it is in constant use. The arc light is necessary for the work, the incandescent being unsuitable. You would have sufficient power for an arc, and you could not do better than follow the precedents already indicated for its arrangement.

Verax.—Soft limes are generally advocated for use with the blow-through jet, and hard ones for the mixed jet. The latter can be used for the blow-through, but it is not expedient to use the former for a mixed jet, for the gas pressure will often split the lime into several pieces. A good substitute for lime is, as you suggest, a desideratum, and rumour says that several persons are hopeful to find such a substance.

M. O.—1. If the contrivance is patented, you have no right to make it, although it may be only for your own use. 2. An inventor, as a rule, gets little enough as a reward for his industry and ingenuity. The prizes are very few, and the blanks many. We once heard that careful calculation showed that only one per cent. of the things invented brought any profit at all to their originators.

James.—Publication of your letter would give offence to many, and would bring no possible credit to the writer. If you are aggrieved, go to a solicitor and take his advice.

Moke.—The views are contradictory, certainly, but the explanation of the conflicting statements is not far to seek. A. is evidently an experienced and careful operator, who, for many years, has been accustomed to deal with explosive compounds, knows their properties, and will take every precaution to prevent accident. With him the apparatus is safe. B. is quite another man. He would step in where angels fear to tread. His ignorance makes him unconscious of danger, and his invincible conceit makes him certain that he can do everything better than anybody else. With him the same apparatus is a terrible engine for mischief, and about as dangerous a thing as can be handled.

T. S.—Apply to Messrs. Chance, Birmingham.

At a general meeting of the Camera Club held on the 26th ult. certain resolutions, of which notice had been given by circular, were duly passed. The effect of these is that all town members—now paying three guineas—will pay four guineas on and after the 1st of January next, and all country (not being *foreign*) members—now paying one guinea—will pay two guineas, except those country members who have a residence, place of business, or regular occupation within the metropolitan postal district, who will henceforth all rank as town members and pay four guineas.

The "Dore" Lantern Slide Printing Frame.—This frame, with respect to which we simply noted in our last the application for a patent, has the following among other advantages:—(1) It has no loose parts whatever, thereby preventing delay and mistakes in the dark room; (2) negatives of any thickness are held in position securely and automatically without the aid of screws or wedges; (3) any part of a negative can be printed from in any position and at any angle; (4) any number of transparencies can be printed from exactly the same part of negative without any readjustment; (5) light is kept from the edges of transparency plates, and from all other parts except through the negative; (6) no risk of breaking a negative from securing it too tightly in position.

# THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

VOL. XXXV. No. 1737.—*December* 18, 1891.

CONTENTS.

## PICTURES FOR THE PRESS.

THAT this is an age of abundant book and newspaper illustration every one must admit, for it is difficult to take up a publication of any kind without coming across at least one or two pictures. These are commonly called "cuts," but the word is a misnomer, for in the great majority of cases the blocks from which the illustrations are printed have not known the cut of the graving tool. Most of our readers, being photographers, know how such illustrations are produced. The original is a line drawing executed with a pen in very black ink on white card; this is photographed and reduced in the process, and the image is transferred to a zinc plate which has been made sensitive to light, which plate is afterwards etched in the acid bath so as to leave the lines of the drawing standing up in relief, and amenable to the printing press.

Wood-engravers, naturally, do not like this process work, for, to a great extent, they find their occupation gone. Artists, too, whose chief business it was to draw on the wood, or to make drawings on card to be afterwards photographed on the wood for the engraver, are wont to speak disdainfully of it, for they find that the times have changed, and they must work on new principles altogether. It was their comfortable custom to leave much of the artistic effect in their drawings to the skill of the engraver. In the hands of a skilful one, a vague wash of colour became a network of lines, giving all the effect which the artist wanted to convey with very little trouble to himself. And so it came about that, among a large class of artists and art critics, the new method of work has been condemned as "inferior and rubbishing process work," which degraded modern illustration. Those who still hold such views would do well to suspend their judgment, or, at any rate, to abstain from giving public expression to it, until they have had an opportunity of seeing what process work is capable of in the hands of an artist who really understands it.

Mr. Henry Blackburn, the author of those charming illustrated catalogues entitled "Academy Notes," which have now appeared for so many years, has made a study of this subject, and probably knows more about it than anyone else in the world. Authors of books and editors of illustrated papers owe him a debt of gratitude, not only for what he has done, but for what he is doing, in educating a large number of artists; for he has established at No. 123, Victoria Street, Westminster, a school for tho instruction of students in this new method of illustration. He does not undertake to teach the elements of drawing; he leaves that to the various schools of art which are now, happily, so common throughout the country. What he does is to enable pupils from such schools to turn their knowledge to practical account. In effect, he says to them: "You cannot expect to make a living all at once by sketching and painting, but I can show you how to produce drawings for which there is an increasing demand. Study under me for a couple of months, and I will initiate you into this phase of art, and you will soon be able to turn out good work."

A recent visit to this busy studio opened our eyes to the wonderful things which are possible to the artist in pen-and-ink. As a rule, a man, in taking up this new art, has as much to unlearn as he has to learn, one of the prime difficulties being that of acquiring a sufficiently bold touch. Beginners in pen-and-ink work are apt to adopt a niggling style of drawing, their object being to make the work appear as fine as possible. They look at an ordinary wood engraving, and see there that the lines are somo of them not broader than a hair, and that, as a rule, they are very close together, and they attempt at once to reproduce the same effect. Most of them act thus from ignorance, being unaware that process blocks are made from drawings many times larger than the picture which ultimately finds its way into the printed page. If one of our readers would wish to see for himself how far this reduction is carried, let him make a photographic transparency or lantern slide of one of the three-inch drawings in "Academy Notes," and enlarge it by means of the lantern to eighteen inches or two feet; he will then, to all intents and purposes, have the original before him from which that block was made, and he will at once acknowledge that much art is necessary in putting together those lines. By such an analysis or dissection of the picture we can learn that lines which look coarse and almost meaningless when examined at close quarters, assume an artistic effect when viewed at the proper distance; and it is obvious that the same effect is brought about by reducing that drawing and examining it from a nearer point of view. By enlarging the picture we have carried out the operation of analysis; but the students at Mr. Blackburn's studios work by just the opposite method—that is to say, by synthesis. Every line that they draw must be a bold one, and must have a certain meaning, and the student must have continually before his mind the idea that the subject which he is working out is to be greatly reduced when it appears as a finished block.

Mr. Blackburn's students have one very great advantage in access to a vast library of what we may call reference works. The annual publication of "Academy Notes," and other books of the same kind, has led to the collection of a vast number of drawings by our first artists. These are all excellent in design, but some of them are not suited to reproduction; thus the student has before him examples of what should be followed, and what should be avoided, and this, we consider, is one of the great advantages that he possesses in going to Mr. Blackburn for instruction.

It is common to hear men who are looked upon as authorities upon art, and more especially upon the work of illustrating books and newspapers, express the opinion that zinco work—as it is commonly called—cannot for a moment be compared to wood engraving. If they were to see some of the beautiful work turned out in this studio they would be forced to alter their opinion. Indeed, in many cases, with all their experience, they would be apt to assert that the finished results placed before them were in reality the work of the engraver, so closely do some of these drawings in pen-and-ink resemble the best work of the older method. It has long been the reproach of English illustrations that they do not come up to the standard which is common in France and America. We may hope that, in a few years, when Mr. Blackburn has launched a few more capable artists on their career, this reproach will no longer obtain.

Silver Fluoride.—A solution of well-washed silver carbonate in hydrofluoric acid is evaporated to dryness, with constant stirring, in a platinum basin, and the resulting black pulverulent mass is dissolved in water and filtered. The clear filtrate, which, when left in contact with silver foil, yields crystalline silver subfluoride is evaporated in the dark in a vacuum over sulphuric acid. As thus obtained, silver fluoride forms a yellow, transparent, tough, elastic mass, which is soluble in water, and melts at a dull red heat (the temperature, as determined by Le Chatelier's thermo-electric method, is 435°). Silver fluoride reacts violently with the chlorides of phosphorus, silicon, and boron, and with phosphorous oxychloride, yielding the corresponding fluorine compounds of the non-metal and silver chloride.—*Journal of the Chemical Society.*

## NEW ZINCOGRAPHIC PROCESS.

The *Bulletin de la Société Francaise* describes a new and simple application of the zincographic process, of which the following is a summary. It requires a very short exposure to light, and presents other advantages, which may be gathered from our description. A plate of perfectly polished zinc is treated in an acid bath composed of water 100 parts, nitric acid 3 parts, for about two minutes. It it now washed, and the still wet plate is coated with water 100 parts, gum-arabic 10 parts, bichromate of potash 4 parts; while the plate is spun in the usual manner to get an even coating by centrifugal action. If necessary, the drying can be accelerated by moderate heat. Thus prepared, the plate is exposed to light under a phototype positive. As the preparation is very sensitive, an exposure of from three to ten minutes in diffused light will be found sufficient. When the exposure has been judged to be sufficient, the zinc plate is removed from the printing frame, and an etching solution consisting of iron perchloride and copper chloride is poured over it in one even wave. This liquid penetrates all those parts of the plate which have not been rendered insoluble by exposure to the light; that is to say, those parts of the zinc which correspond with the positive which in the original were represented by black lines and shadows. It attacks, then, the zinc, which blackens in those parts. As soon as the image appears to be complete—a work of very few seconds—the action must be immediately arrested by rapid washing under a strong jet of water, followed by a sufficient rubbing of the metal to remove the still adherent gum coating. The plate is now inked in the usual manner, and kept clean and moist by the occasional use of a wet sponge.

The process is really one of extreme simplicity, the different manipulations occupying a very short time, and it does not require any special aptitude or manipulative skill. It may be mentioned that the addition of the copper salt to the etching solution has the effect of depositing that metal in a pulverulent form on the zinc plate, a condition of things which enables the lines to retain the ink with great facility.

## VIEW-FINDERS.

The following remarks on this subject are contributed by Mr. George Ewing to the *Journal of the Photographic Society of India*:—

In connection with the weakness of the centre of a picture, I have said that I view with disfavour the growing use of view-finders. The remark requires explanation. If a view-finder is employed for the purpose of ascertaining when a moving object is in the centre of the field, then I consider that its use cannot be too strongly reprehended; but if some simple appliance will readily inform us of the amount of view that will be included by a certain lens at a certain spot, I should assuredly recommend its enlistment into our service. Fortunately, we have such apparatus at our command, though they (with tables of conjugate foci which serve the same purpose) are not as much used by amateurs as they should be. Probably their simplicity is against them, for it is a characteristic of the young amateur that he will have nothing to do with things that are common and therefore unclean. The trait is, I believe, another manifestation of original sin.

The view-meter I recommend is a leather-covered strip of cardboard having an upright piece with a minute eyehole at one end, and a sliding frame with an oblong opening at the other. To use it, first erect your camera and focus any view that may be most convenient; then, standing as close as possible to the lens, slide the oblong frame up and down the strip of cardboard till, looking through the eye-piece, the opening includes exactly the same amount of view as the focussing screen; mark on the cardboard base the position of the sliding frame. If you have more than one lens, proceed in the same way with each, focussing some view, and marking on the cardboard the position of the frame in each case. The value of the contrivance must now be obvious. When, out in the field, it is necessary to know whether, at a certain spot, any of the lenses available will take in a certain amount of landscape, instead of setting up the camera, it will only be necessary to draw out the view-meter and, by sliding out the frame till it includes the desired view, observe on the base whether any lens will include the same angle of view. The usefulness of such a view-meter for quick selection of subjects cannot be over-rated.

The most popular type of view-finder is of the camera-obscura pattern. It is a little cardboard box with a tin hood on one side and a cheap lens on another. The interior is divided diagonally by a mirror which reflects the image thrown on it by the lens on to the ground glass covered by the hood. It is attached by a stud to the side or top of camera. Though this is the most popular form of view-finder, and is besides the only one used in hand-cameras, I consider it about the most useless. The lenses are almost always the worst obtainable; they seldom cover the glass, and, as the foci of the lenses in the finder and in the camera are not relatively proportionate, the view on the finder is quite different from that found by the camera lens. Their only use is to centre a moving object on the sensitive plate; but as this is far from desirable, and as the end may be equally well obtained by simpler means, as I shall show further on, I should recommend my readers to leave them alone.

A third and equally objectionable form of finder is that, recently introduced, in which an ordinary spectacle lens ("minifier," as it is sometimes called) is enclosed in a circular brass frame with an oblong opening. It is generally fitted to the top of a camera, but, as the view included by it varies with every movement of the spectator, its practical value is simply *nil*.

The only useful finder that I know of is formed of an auxiliary lens, of the same focus as that used in photographing the view, set in a movable arm. In use, the focussing screen is raised upright, and kept perpendicular by struts and bands. The auxiliary lens fixed on top of the camera front throws on the ground glass the scene before it; and, as the focus is coincident with that of the lens below, the image on the screen and on the sensitive plate will be identical. When the image on the ground glass is sharp, that on the plate will be equally in focus; when the camera is racked in or out, the blurring in both plate and screen will be exactly the same. The advantage of this arrangement in "instantaneous" work is very great. Supposing we want to photograph a moving object; we first fix the best spot to take it and focus the point sharply, then lift up the glass upright, attach it to the struts, set the shutter, fix the dark slide in position with plate exposed, and await developments, one hand on the focussing screw, the other holding the pneumatic ball. If the object pass the spot fixed, of course there will be no trouble; but suppose it appears a little in advance of or behind the fixed point, a slight turn of the screw will bring the subject in focus on the screen on top, and a squeeze of the pneumatic ball will fix it sharp on the sensitive plate below.

## GAS BOTTLES AND THEIR SAFETY.*

BY F. A. BRIDGE.

The use of gas in cylinders has now become so common that the public has ceased to regard it as fraught with any risk; and, considering the immense number of cylinders now filled and emptied every week, the few accidents that have happened certainly justify the confidence hitherto reposed in their safety.

The explosions which have occurred of the cylinders themselves have been very few indeed; and I think I am right in saying that although, unfortunately, fatal consequences have always ensued, fortunately, the cause of the explosion or bursting has been satisfactorily accounted for, and has in every case been due to putting oxygen into a cylinder already containing hydrogen, or *vice versâ*.

As far as I am aware, no case has occurred of the bursting of a cylinder from over-pressure; I mean, of course, in ordinary use, as they are usually tested to double the strength they are supposed to have to withstand. Stories are told of fifteen, and even seventeen, feet of gas having been pressed into a ten-foot bottle; but it has never occurred to me—at least, if it has, the extra has never been charged for; so I am inclined to think it was not there. Accidentally or intentionally, very severe tests have been applied to cylinders by gas compressors, tending to show that the ordinary knocking about they receive is not likely to cause much damage to them. Full cylinders have been known to fall from an upper window on to the stones below without exploding; heavy weights have been dropped upon them from a great height without doing any further harm than spoiling their outward beauty, which, it must be confessed, is not very great. We may, therefore, say that, so far as the cylinders themselves are concerned, there is not much to fear, as, except accidentally, the ordinary user would never expose them to such tests as they are subjected to by those who make or fill them. We may here say that, during their transit from place to place, cylinders receive a great deal of unnecessary ill-usage. Sometimes the gun-metal nozzles and valve pins become damaged in consequence, and stories have been told where they have become so loosened that the effort made to screw up the valve after use has caused the entire nozzle to give way. In one instance it is said that the nozzle of a cylinder in use out of doors for signalling purposes went up so high that it was *several minutes* before it came down again. Whether the man in the moon (had he so desired) could have put out his hand and caught that nozzle was not stated. Only recently, at one of the principal railway stations, a large cylinder was let down suddenly on the nozzle; the result was a waste of eighty feet of oxygen, and a general scare among the passengers on the platform. These accidents, however, might have been easily prevented by putting the cylinders in boxes during transit.

What we really have to consider to-night is the bursting of gas regulators and gauges; and our object is to find out, if possible, the cause of these accidents, and so, by taking

* A paper read before the London and Provincial Photographic Association.

due precautions, endeavour to make them as rare as possible.

First, then, the regulators. There are not many worthy of the name, the best, to my mind, being those made by our friend Mr. Beard. The principal fault with other makes I have seen tried is, either that they *don't regulate*, or, if they do, their action is so erratic as to make them unreliable. As to gauges, the simplest form is known as "Suiter's Patent." Here you have no glass, and the worst that can happen is the blowing out of the end of the tube, and waste of the gas. The well-known Bourdon gauge is much used, and very useful, because it can be kept attached to the cylinder, and it is easy, by its means, to see from time to time how the gas is going. I need scarcely say it is not safe to use one of these for oxygen which has been used for any other gas; very serious accidents have occurred through this having been done.

Not many days since (as you are, of course, aware) an exhaustive enquiry was held to ascertain the cause of the bursting of both a gauge and a regulator, and this is really the reason the subject of "Gas Bottles and their Safety" was chosen for our consideration to-night.

On Monday last I received from an old friend a letter commencing thus:—"Dear Bridge,—Did we not waste an evening on Wednesday discussing the cause of the accident, and then only come to an erroneous conclusion? Had we waited another day, we should have seen the note in *Photography* giving us the true cause." Now, I need scarcely say that this was what the late Artemus Ward calls "rote sarkastik." The paragraph alluded to is as follows:—"The inquiry into a recent fatal explosion of a gas-bag has barely concluded, when an explosion which might have been serious has taken place in connection with the use of cylinders. The explosion, however, was more due to the way the cylinder was handled than to any inherent-in-itself tendency to create disaster. At the meeting of one of the London clubs last week, a new cylinder was about to be tested with a view to ascertaining its contents. The pressure gauge was screwed on, and then the tap was turned fully on too suddenly, the result being that the gauge was blown out and fixed itself in the ceiling, considerably startling those who were present. Had it come in contact with the persons of either of the operators, it would, doubtless, have been a serious matter to them. This accident need not, however, alarm cylinder users, but simply impress upon them the necessity of taking the precaution to allow the gas to enter the pressure gauge slowly, when no fear of such an untoward occurrence need be entertained."

If this paragraph is intended to refer to the explosion of a gauge and regulator in my hands at a recent photographic meeting, the communications of the gentleman to whom the editor is indebted for this unofficial information should in future be taken with a much larger quantity of salt than appears to have been used on the present occasion. I say *un*official, because the meeting at which the accident happened was a private one, and any official communication must have passed through my hands. My opinion is, however, that my friend's sarcasm has been thrown away, and that the paragraph does not refer to us at all, but to some similar accident which has occurred elsewhere, and of which we shall, perhaps, hear more anon; because, in my case, the cylinder was not a new one, the tap was not turned fully on too suddenly, no portion of the gauge fixed itself in the ceiling, there was only one operator, and the accident could not have been due to the way the cylinder was handled, because the advice so kindly given in the concluding sentence was most carefully observed. I may here, perhaps, be allowed to remark that several absurd and exaggerated accounts of this accident are floating about. One gentleman has stated that he was blown *several feet* by the explosion. Now, I must confess that those in the immediate vicinity of the little dark room in which the accident happened did retire with great alacrity, and may have been even humming the old refrain, "We left him alone in his glory," for aught I know, but the sudden withdrawal was not due to gas, but *fright*. The upward pressure, as I shall show you, was for the moment very great, but the lateral expansion was not sufficient to disturb either the scores of little things on the shelves of that small dark room, or the folders that rested so gracefully on my nose. No doubt they speedily found themselves several feet away, but the instinct of self-preservation is strong, and possibly Mrs. Partington's son Ike was quite right when he said, "In railway accidents and suchlike, absence of body is better than presence of mind."

I am getting rather tired of repeating the story of the explosion. It seems to me as if every other photographer I have met during the last fortnight has asked for details, and I have been bound to tell him the truth, and the whole truth. However, as I have to open the discussion this evening, and the subject has been selected in consequence of the accident, I will tell you as briefly as possible exactly how it happened.

Wishing to know whether a cylinder was full or empty, I removed the guage and regulator from the one just exhausted, and firmly screwed it into the cylinder the contents of which I was anxious to ascertain. Turning the gas slowly on, the guage immediately responded. I then turned the gas off again, and, calling a friend (Mr. H. M. Hastings), I repeated the operation of turning on the gas. The needle of the gauge rapidly registered 120, went past that number, and, before I could turn the gas off again, the explosion occurred. I still held on to the cylinder, and endeavoured to stop the waste of gas. The valve, however, would not act, and, after inhaling more oxygen than was good for me in one dose, I came out of the dark room (the way was quite clear). After a few breaths of air as fresh as I could obtain in a room full of tobacco-smoke, I went back and had another try; but it was of no use. When all the oxygen had escaped, I went into the dark room again, lit the gas, which had been extinguished by the explosion, and looked around. The gauge had snapped short off at the stem, and was lying on the floor. The dial was missing, and the glass, of course, blown to atoms. The top of the regulator was imbedded in the ceiling, and the cover of the regulator-case was missing.

On examining the connections, it was found that the cone fitting the interior of the bull-nosed nozzle of the cylinder was partially melted, so was the neck of the cylinder itself; the end of the valve pin was also melted away. The oxygen had evidently fired in the neck of the cylinder. The end of the Bourdon tube in the gauge, unable to sustain the immense pressure, had burst, bulging the side of the case, forcing out the dial, and, as I said before, smashing the cover-glass to atoms. The fire had travelled partly along the tube leading to the gauge, but had not entered the gauge itself. It had travelled mainly in an upward direction, forcing itself up one side of the regulator, impinged upon the side of the case, burst the india-rubber bellows, blown away the top, partly melted the solder at the top of the cover, and scorched the lacquer outside.

We now come to ask the cause of all this, and the answer undoubtedly is: oil in the neck of the cylinder. Chemists tell us that oxygen at high pressure, brought into contact with oil, more especially oil which has become gelatinous or glutinous, will immediately fire. In the early part of the present year an article appeared in the *Nineteenth Century* bearing upon this very subject in connection with gas bottles, and describing almost exactly what occurred in the present instance. How came the oil there? That is the question. We have been informed that at one time these kinds of pressure gauges were tested with oil, and this may have been one from which it had only imperfectly been removed; but the gauge had been in use quite two years, and, as I said before, there was no trace of fire in the gauge itself. Oxygen compressors tell us they never use oil to lubricate the valves of cylinders, but the portion of the valve pin, when withdrawn from this cylinder, was covered with black oil, and the same thing was found in the aperture from which it had been taken. Curiously enough, too, I have taken the pins out of two other cylinders, and these are both greasy.

Gentlemen, I will not trespass further upon your patience. I only hope the discussion which follows will tend to clear up the question. The conclusion arrived at a week ago, when this matter was under consideration, was: Oil in the valve, but how it came there there is no evidence to show. Several men of great ability and experience have been consulted on the subject, including Messrs. Adolphe M. Levy, Newton, Newton, jun., T. Ottway, T. E. Freshwater, R. R. Beard, G. R. Baker, Murray (Brin's Oxygen Company), and T. North. As you know, I have had a good deal to do with oxygen in bags, gas-holders, and bottles, and have been using the lime-light almost daily for many years. The concensus of opinion is, as I have said before, oil in the valve.

Gentlemen, what happened to me may at any time happen to you. Let us, therefore, endeavour to find out where this oil comes from, and we shall have done something towards preventing accidents. In conclusion, I should like, if you will allow me, to give you a few words of caution. When turning on or off gas in cylinders, always hold them at arm's length; I invariably take this precaution. The top of the regulator in this instance passed within two or three inches of my head, and imbedded itself in the ceiling. Had it not been for the precaution I have alluded to, it might have found a softer spot, and in that case I should not have had the pleasure of opening the discussion this evening.

## THE MAKING AND WORKING-UP OF TRANSPARENCIES.*

BY GEORGE E. THOMPSON.

I have a nondescript room at home. A 6½-feet billiard table stands in the centre, its wooden cover making an excellent work-table, steady, firm, and of an admirable height to stand to. This top is divided into three, and either the chemicals, or the soap-suds of spring cleaning (always carried on if I go away on a tour), have gone down the divisions and discoloured the cloth. But this is beside the mark. The table is always loaded with boxes, parcels, transparencies, negatives, and everything that can be wanted, besides much that is superfluous. The centre gas is capital to retouch by. Around the room are book-cases, pictures, corner cupboards, old oak, a carpenter's bench, a lathe, &c., and in one corner is a tank for water. A wooden frame covered with brown and another with white paper, and having a 2-feet orange window in its lower part, can be adjusted to the window, and then the room is a dark chamber. The white screen also answers for lantern shows.

But what has all this to do with lantern slides? I make them there, and like to begin at the beginning. Finally, then, take an unvarnished negative and place it on the retouching desk. Spots must be filled in as cleanly and neatly as possible. There are two implements, the brush and the pencil. Take a fine, small brush and (say) lamp-black. Use very little paint, and as nearly dry as possible, and very delicately work it in. If watery and heavy, you are sure to make the spots blacker and larger than need be. The pencil—a good B with a fine point—is most useful for the filling up of semi-transparent marks, and in putting high-lights on the water, or in the sky. A transparent spot may suggest the black hull of a distant boat. Draw the sail, also the reflection, delicately in with the pencil; or a bird may be drawn in, and the picture lives. The sky may be dirty. If so, matt varnish the back of the negative, and when dry work on it with a stump and black-lead; or, if a thin negative, cover with tracing paper and work on with colour or lead, always remembering that, when putting in a sky, you must treat the cloud forms as negative, not positive.

Now for the transparencies. These are best made in the camera by reduction, the manipulation of which I presume all here know. Some negatives will do for contact printing. If a soft, over-timed negative, you can get an excellent result on a chloride plate, thereby obtaining rich brown, red, or even green tones. Hard, under-exposed negatives give, in my experience, black, hard slides when made on chloride plates, while I have found the reverse to be the case with Alpha plates. Mawson plates give rich, dark brown slides when developed with pyro and metabisulphite, but the development should not be carried too far, as they dry darker. Hydroquinone and black tones are the easiest to manage.

And now, having made your transparency, you want to show it at its best. And here a great number betray their ignorance of the commonest rules of art. How is it that some exquisite subjects, perfect in photography and in manipulation, disappoint when thrown on the screen? I remember one lime-light show when I wished that I could get at the slides and rip them all, or nearly all, open with an oyster-knife. And why? They were lovely subjects, but badly (nay shockingly) masked. Here, a river with tender distance and fleecy clouds, but with a great waste of uninteresting water in the foreground. In such a case the part above the horizon should have occupied nearly two-thirds, and the water one-third; a bird or two might have been introduced, and the picture would have been perfect. Many of the set of which I speak had the horizon line in the centre, a most uncomfortable state of things. We cannot say more here about composition, but we should all make it a study. Study pictures and find out why they are charming. Don't scruple to cut away parts which are not required. Don't fit your picture to your mask, but your mask to your picture. Double up a sheet of black paper into widths of 3¼ inches and chop away all down the length, making the strips any width you

* Abstract of a paper read before the members of the Liverpool Amateur Photographic Association.

please, and then mask all up with square corners, with narrow or wide pieces to suit your pictures. Another great blemish noticeable iu many trausparencies is the very bad spotting, or even its total absence—stars not only shiniug in the sky, but through houses and walls.

I use a fine brush and a B pencil, and I will now expose one of my pet dodges or fakements. You want to throw up part of a picture; take this vine, for instance. The one plant must stand out from the field; therefore, blacken the surroundings. And now comes the rub; the pencil won't bite! But breathe gently on the film, and mark the effect. You can build it up to almost auy extent; but the work must be done patiently and gently, or holes will come. Perhaps your trees are waviug. Then you must carefully titivate them up with a few touches of the pencil. The small boat which was worked in ou the negative will require a touch, as also the birds. It is a labour of love and good practice, and a few touches of this kind done in an artistic manner will, with proper masking, make all the difference betweeu an uninteresting and a fascinating slide.

## FRENCH CORRESPONDENCE.

BY LEON VIDAL.

Photographic Society of France—The Peligot Medal—Photo-Micrographic Apparatus—Aristotype Emulsion Paper—A New Process of Photo-Zincography—Lantern Slides for the Detection of Fraud—Photo-Ceramic Paper—Aluminium Fittings—National Conservatoire of Arts and Manufactures—Photographic Club.

The last meeting of the Photographic Society of France was replete with interest, and we will take a brief survey of the principal matters brought forward. The son of Monsieur Peligot—formerly president of the Society—has, in memory of his father, given a sum of money to be expended in the purchase of medals, which medals are to be distributed by the Society to those considered worthy of the honour. The first of these medals is now about to be awarded, and a committee has been instructed to nominate a recipient. Their work is not altogether easy, for they will have to make a selection from a large number of persons whose merits may be equal. It is proposed to award this medal at the meeting of January, 1892.

Messrs. Bézu, Hausser, and Co. brought forward a photo-micrographic apparatus which they have just constructed with a view to all the exigencies of this kind of instrument and its applications. It is a beautiful piece of work, and can be used either as a microscope or for purposes of projection, according to the nature and dimensions of the object to be reproduced. The camera is placed vertically, so that the object remains horizontal—an indispensable condition in the case of liquid preparations.

Messrs. Véra and Martin showed the results obtained on a new paper prepared with an emulsion of chloro-citrate of silver. Papers of this type are coming more and more into request, and are gradually tending to supersede albumenised paper. Time will show how far this replacement will advance. If the albumen process has its defects, its rival, at any rate, is not free from vices, and it will be seen in time which will give the best and most durable results.

Messrs. Lumière fils have modified the zincographic process previously published by them. Their new process bears, as an essential feature, the employment of cupric chloride introduced into the etching fluid. The method is fully described in this week's Photographic News. The chief advantage in this addition seems to be that the ink takes with extraordinary readiuess to the parts upon which the copper is deposited. Examples of this method of working were placed before the meeting.

Monsieur Londe demonstrated the use of photography in the detection of various kinds of fraud and sophistication, and expressed the hope that the day would come when an apparatus for projecting photographs on the screen would be found iu every court of justice, so that a jury could quickly see for themselves the difference between the false and the true. Such an apparatus would also serve to throw the enlarged image of a plan or map to which attention had to be directed, an obvious improvement upon the custom which exists now of passing a small chart from hand to haud.

Mous. Guerot has indicated a method of preparing a gelatine paper, charged with vitrifiable powder, to be subsequeutly sensitised with bichromate of potash, forming a transfer for ceramic work. The process requires experiment to determine several points which at present are obscure, and the matter will receive further attention at our hands when the results of these experiments have been reported upon.

Aluminium tends to become very useful to photographers. Monsieur Richard has been using it for camera fittings, and by its aid ensures a lightness of apparatus, which, in the case of large cameras, is a most importaut modification.

The conferences of the National Conservatoire of Arts and Manufactures were duly inaugurated in September last by Monsieur Laussedal (director of the Conservatoire) and Monsieur Davanne, wheu the theme of greatest interest was the application of photography to history. A very numerous audience testified by applause the great interest taken in the subject. Monsieur Demeny, by means of photo-chronographic apparatus, demonstrated how photography could be applied to the study of animal movement. All this was found most interesting, and reflected credit on the organisers of the meeting. Monsieur Lippmann is to speak on the subject of photographs in colour on a future occasion. The Photographic Club of Paris in its turn invited its friends to hear a lecture on the same subject from the lips of Monsieur Baudrou, who maintained the possibility of photography in colour; but, as he gave uo proofs of his power to accomplish this work, we must suspend our judgment until we know more of his capabilities iu this respect.

Nature of Colloidal Solutions.—A study of the properties of colloidal solutions leads to the conclusion that such solutions consist of very finely divided matter which is held in suspension in the solvent. In order to obtain evidence as to the correctness of the above view, the authors have examined the behaviour of colloidal silver solutions. Silver being an excellent conductor of electricity, a measurement of the resistance of such solutions should aid in determining whether the silver particles are held mechanically in suspension in the solution, or are present as molecules in the dissolved state. In the first case the liquid would be a non-conductor, in the second metallic conductivity might be expected. The experiments show that colloidal silver, either in the solution or in the solid condition, is a non-conductor. These results, taken in conjunction with the other properties of colloidal solutions, confirm, therefore, the views expressed above as to the nature of such solutions.—*Journal of the Chemical Society.*

## PHOTOGRAPHY OF THE HEAVENS.

BY CAMILLE FLAMMARION.

The International Photographic Congress, organised several years ago by a group of astronomers for the purpose of applying photography to the study of the stars, met recently for the third time at the Paris Observatory, and agreed upon the latest arrangements for photographing the heavens.

The idea of applying photography to the curious things in the sky came to light on the very day when the great discovery of Niepce and Daguerre was publicly announced in the memorable account which Arago gave of it at the session of the Academy of Science, April 19th, 1839. The illustrious astronomer, perceiving at once the many and diverse uses to which the discovery could be put in astronomical research, pointed out, among other things, the possibility of obtaining a good map of the moon, and a perfect representation of the solar spectrum. But the methods of photography at that day were too crude to admit of securing satisfactory results. However, about the year 1845, Sizeau and Flaucault contrived to take an excellent photograph of the sun in 1·6 seconds, a very fine engraving of which may be found in Arago's complete works. In 1849, William C. Bond, an American astronomer, obtained a good Daguerreian proof of the moon. The eclipse of the sun on July 28th, 1851, was photographed by Berkawski, at Königsburg, upon a Daguerreian plate, which disclosed for the first time traces of the corona that envelops the star of day, and the eruptions that emanate from its surface.

In 1857, Bond obtained a very clear photograph of the double star Miza and Zeta in the Great Bear, as exact in truth as the micrometric measures, for I have been able to insert it as document in my catalogue of double stars. It was at the Harvard College Observatory that these five photographs of stars were made, and it is there to-day that Professor Pickering obtains such marvellous results that in themselves they appear at least to equal all those of the twenty to thirty astronomers composing the European Congress.

Mr. Warren de la Rue, in England, and Mr. Rutherford, in the United States of America, obtained magnificent photographs of the moon between 1857 and 1867, that have not yet been surpassed. Let us note among these photographs some startling stereoscopic views that show the lunar globe so much in relief that it has almost the form of an egg. This effect, somewhat exaggerated, is due to the advantage taken of a certain movement of libration, in order to penetrate more or less satisfactorily the invisible hemisphere of the moon. Warren de la Rue, to whom we are indebted for these stereoscopic photographs of our satellite, succeeded equally in obtaining views of the planet Jupiter with an exposure of twenty-six minutes.

M. Flaye, in France, has been one of the most ardent advocates of astronomical photography. Insensibly, despite the opposition of astronomers who were first of all mathematicians, photography made a place for itself among the processes of the study. It was applied with the greatest success in observing the transit of Venus in 1874, and again in 1882. In 1877, M. Janssen, at the Observatory of Meudon, obtained admirable photographs of the solar surface, upon which the observer seems to assist, so to speak, in the phenomena of the formation of light. These photographs of the sun are almost instantaneous, for they are taken in a half one-thousandth of a second. In 1844, MM. Paul and Prosper Henry, while making maps of the stars for the atlas of the Paris Observatory, set themselves to substituting photography for direct observation, which at the time was much more expeditious and certain. At the same time, and afterward, Messrs. Pickering, in the United States; Gould, in the Argentine Republic; Gill, at the Cape of Good Hope; Common and Roberts, in England, devoted themselves with the best success to the practice of celestial photography. Thus gradually, insensibly, photography came to take a large part in astronomical research. This part from day to day becomes more and more important, more and more fruitful.

It is now proposed actually to photograph the entire heavens, and it was with this end in view that astronomers organised the International Congress, which met first in 1887, then in 1889, and again last April. In its recent session the Congress paid attention very largely to technical details. A score of questions were discussed, involving all-important points in the preparation of plates, the processes of taking and developing, of reproducing pictures from the stereotypes, &c., and the methods of undertaking the great photographic work—the division of the zones, and the distribution of definite sections of the heavens to various observatories and observers for their respective fields of labour.

Mague, Director of the Paris Observatory, made a statement relative to the progress made with the instrument which he invented for photographing the heavens, and he suggested the time at which he could begin experiments. Owing to political events in Chili, and troubles in which some other States are involved, it will not be possible for all to begin work at the same time. Among other things, the Congress was concerned with the choice of guide-stars; that is to say, those which must constantly be held at the same point of view in order that every star may be represented upon the map by a point and not by a measurable space. But what limit should be placed upon the distance of the guide-star from the centre of the plate? After much groping about, the Congress decided to leave to each observer a certain latitude, not to exceed forty minutes. Questions of this nature, though secondary, were novel and delicate, and the divergencies of opinion brought out by them were inevitable. Many difficulties were suggested that can be solved only by long experience; difficulties that will vary with the physical and atmospheric conditions of the various observatories. A certain liberty of action was, therefore, left to each observer, the Congress simply determining the end to be attained.

The Congress adjourned, after having made the best arrangements that the present state of astronomic photography allows for a work of gigantic proportions and immense difficulty. The matter in hand involves the photographing of the entire heavens, and the construction from the results of a complete map, which will show the starry firmament just as it appears to the inhabitants of the earth; and this by photography alone, by which errors of observation will be wholly eliminated. We already have a map of this kind, but it is relatively imperfect and heterogeneous. For example, Argelander, in 1862, made a map of the northern hemisphere, showing all the stars up to the ninth magnitude inclusive; and this map registers 324,198 stars, all of which can be seen on the same sheet. This great atlas of Argelander is one of the most important and considerable works of this century.

(*To be continued.*)

## Notes.

With the beginning of the new year, the Photographic News will be published by Messrs. Alexander and Shepheard, 21 and 23, Furnival Street, E.C. Business matters connected with the paper till the end of the present year will be transacted by Messrs. Piper & Carter, 5, Furnival Street, E.C., who also publish the Year-Book of Photography for 1892, and will collect accounts connected therewith.

Among the few places where civilised man has not yet planted his booted foot are certain districts in the interior of Australia. There have not been lacking bold adventurers who have essayed the task of exploring this *terra incognita*, but they have nearly all been driven back by the absence of that first necessary of life—water; or have battled on and have never been heard of more. Such was the fate of Ludwig Leichardt, who started in 1848 upon these arid lands. A recent expedition was fitted out by Sir Thomas Elder, the object being to explore the undiscovered parts of central and northern Australia. This little band of explorers, numbering only ten men, have now returned from their wanderings, and one of the party, we are glad to learn, has brought back a collection of photographs of the country which they passed through.

The observations of this Australian expedition corroborate the reports of previous travellers with regard to the want of water. For thirty-four days they and their camels could not replenish their meagre store of the precious fluid; so that if the photographer of the party had had to depend upon the old wet process for his negatives, he would most surely have come back with an empty bag. Here is another feather in the cap of the gelatine process. These photographs, which we trust will reach England, will be full of interest. We presume that the aborigines did not prove very tractable subjects before the camera, for they showed fight when the expedition approached them, and, owing to linguistic difficulties, the white men could hold no converse with them.

The County Councils, having to spend a large sum of money on technical education, are making a beginning by appointing lecturers to help in the work, and as these gentlemen will make use of the lantern as an aid to demonstration, a first edition of lantern slides, comprising twelve new sets, has just been published by Messrs. Newton, of Fleet Street. The subjects dealt with are confined to agriculture, and we only trust that friend Hodge will succeed in assimilating all the good fare thus provided for him. He will now for the first time learn that pasture grasses number about fifty varieties, with names—well, that are by no means comprised in words of four letters; that weeds, under "technical" treatment, assume alarming forms (as a case in point, he will find the common field dock christened *Rumex Obtusifolius*); and that all kinds of familiar things have in reality fearfully long names, and that all his life he has been calling them Tom, Dick, and Harry. What a happy man ought Hodge to be in this year of grace 1891.

Three of the prominent *Punch* artists are greatly indebted to photography. Mr. Linley Sambourne, in his article on "Political Cartoons" in the *Magazine of Art*, says: "I am always at work, directly or indirectly, accumulating materials by sketching or photography for possible contingencies." Mr. Sambourne, as some may know, is a skilful photographer, and was, we believe, a pupil of Mr. Valentine Blanchard. Mr. Harry Furniss is another photographer. Like Mr. Sambourne, he is constantly collecting material. One of his models is naturally a very graceful poser. He allows her to take what attitudes she chooses, photographs her, and in this way acquires an infinite variety of positions, which come in very useful when wanted. Mr. Du Maurier is not a photographer, but owes his ability not a little to the camera. When, some years ago, his eyesight failed him, it was feared he would have to relinquish the pencil. Somebody, however, suggested that he should draw his pictures four or five times larger than required, and have them photographed down. He adopted this plan, and carries it out to this day. His drawings, it may be mentioned, are photographed direct on to the block and then cut, so that all the original lines are preserved.

Royal and princely personages, when they contemplate getting engaged, should really give timely notice to the photographers beforehand. Owing to the non-observance of this very reasonable precaution, not a photographic print dealer in London has been able to meet the demand for portraits of the Princess Victoria May. Photographs of the Duke of Clarence were, of course, plentiful enough, but these were not what the public wanted. It was the lady everybody desired to see. And the public is critical now-a-days. It cannot endure a portrait of a lady celebrity which has a *soupçon* of out-of-date about it. The dress, the style of hair, must be of the very latest fashion if the photograph is to sell. Of course this entails frequent visits to the studio, but so much the better for the photographer.

A writer in a provincial paper has lately been criticising the efforts of amateurs who go in for lantern slides. He complains that the subjects are, as a rule, not only tame and monotonous, but unsuitable. He calls to mind views showing an expanse of thirty or forty miles with everything "beautifully sharp"—the only merit they possess. Another is a picture of some holiday resort, its attractions lying, according to the exhibitor, in its being possible to count all the roofs and chimneys in the village. Ruined buildings are also well to the front, but of no interest to anyone, save to those who believe in the "beautifully sharp." In portraiture the amateurs are no more successful. The average group is arranged in line like an awkward squad of youthful volunteers who are trying to stand at attention. These also are perfectly sharp in focus. If the sitters are in a boat, the latter is placed broadside on, with its lines parallel to the banks of the river, and the whole is microscopically in focus.

The writer gives a number of other examples, but we need not quote them. The moral seems to be that if artistic arrangement be necessary to make ordinary photographs pleasing, it is still more so when the photograph has to be enlarged and thrown on the screen. The spectator is not bound to take a photograph in his hand, or look at it on a wall, but he cannot well escape seeing it when it forms the only illuminated object in a darkened room. We are afraid that many amateur lantern operators have caused their audiences a few miserable and dreary half-hours.

## LEEDS INTERNATIONAL PHOTOGRAPHIC EXHIBITION.

By Our Special Commissioner.

[second notice.]

The south room is the principal one of the suite devoted to this Exhibition, and really forms a most imposing gallery, and in this are given the lantern entertainments, which form an important feature of the scheme. The wall devoted to the champion class is very effective, for there is the variety due to contrast. The remarkable series of portraits of the Scotch judges, by Mr. W. Crooke, which have gained the gold medal, occupy a distinguished place, though they do not hang all together as they did at Glasgow, and are, therefore, not quite so striking. That very ambitious attempt by Mr. A. W. Wilson, called "The Seven Ages of Man," also is on view here, and must be interesting to many who have not seen the series before. There are seven pictures of large size dealing with the life of man "from dawn to sunset," and, when the difficulties are fairly considered, the whole must be considered as a remarkable achievement. I believe I am right in saying that these pictures were produced before the advent of gelatine. If it be so, then the effort is still more remarkable.

Mr. H. P. Robinson is not well represented by "Gossip on the Beach." Why did he not send "Carolling"? Mr. Sutcliffe is well to the fore with a number of his well-known subjects, including "*Stern* Reality" and "Water Rats." Of course, all the pictures in this class are more or less known, and have been described before. I have just said that the champion wall is very effective. I wish I could say the same of its opposite neighbour. This dreadful class distinction makes effective hanging of pictures almost impossible, and in consequence the best wall in the Exhibition is spoiled by a monotony of effect that is almost overwhelming. When it is known that landscape under whole-plate is a large class, and occupies an important slice of this wall, the reason for this monotony is not far to seek.

Mr. Carl Greger is certainly a most promising artist, and is equally successful in various domains of art. His "Suffolk Mill" is a very striking picture made out of slender materials; only a windmill—and that not of the old picturesque wooden post mill so dearly loved by Turner and Girtin in the past, but a brick one of the modern tall, round pattern, more like a lighthouse with six arms than a mill—a sedge-lined stream; and distance, remarkable chiefly for its monotonous outline. The mill stands out dark and frowning against the evening sky, and the long streaks of light in the clouds repeat with marked effect the lines of the sombre landscape. The "Evening Studies in the Thames Valley," by Mr. P. Ennis, are also very artistic. One is evidently taken in the gloaming, for there is no detail in the dark masses of foliage, and yet the effect is not due to under-exposure, but absence of light. In another—a bit of muddy Thames shore—the artist has not been quite so happy. A small boat makes a dark spot in the centre of the picture, and comes, unfortunately, immediately under the principal light in the sky. It is a good illustration of the difficulties that beset the paths of the artistic photographer. Now a painter would have removed that boat without employing a waterman; or, at any rate, he would have taken care that it did not drift into his picture.

"An Old-Time Garden," by Mr. T. Dawson, is worthy of notice, and he is to be complimented on the artistic employment of the picturesque materials placed in his way. It has evidently been a grand garden in palmy days, but is probably far more beautiful in its present decay. There are indications of renaissance architecture of a monumental character in the distance, and the picture is framed in by an arch overhead, whilst a black and white marble path running away in perspective carries the eye to a stately dame who is gathering roses in the middle distance. The uplifted arms give additional grace to the pose of the figure, and a basket by her side half-filled with flowers gives support to the composition. In a picture so artistic, why was not something done to prevent the halation in its upper part?

Sandsend is evidently a pretty spot, and in one at least Mr. A. A. Pearson has made good use of his materials. A four-arched bridge spans a shallow stream, but the accumulation of well-worn stones on each side of the summer rivulet clearly indicates its potentiality during winter storms. Quaint little cottages line the further bank, and steep hills form a background to the scene.

Mr. Godfrey Bingley has been very successful with several of his views, but the palm has been given to "Beddgelert," for he carries off the silver medal offered by the Leeds Photographic Society for the best picture produced by one of its members. The subject is a famous one, and has been constantly photographed ever since photography became an art, but he has been singularly fortunate in the selection of the right moment, for both time and weather have been on his side. The picture is atmospheric in a striking degree, and the clouds are exactly in the right place, and yet they appear to belong to the picture, and do not seem to have been added afterwards. This is certainly one of the best landscape photographs in the Exhibition. Mr. Bingley has been more than lucky, for he also takes the bronze medal offered by this Society for the best set of four executed by one of its members.

Mr. Horsley Hinton is represented by several fresh pictures, and in addition sends some of those that have been distinguished by medals at former exhibitions. I am compelled to say I do not like this perpetual fiddling on one string. The same fault unfortunately exists amongst the painters. A man gets talked about for some quality that is recognised as fresh, and straightway he goes on year after year, reproducing the same with only slight modifications, until one can recognise his pictures a mile off. Now, Mr. Hinton has made a distinct mark; but I am anxious to see him deal with nature in some of her gayer moods. "October" is all very well, but let us have the "merry, merry spring-time" the next time he exhibits.

Mr. Patterson Gibson knows how to deal with brawling brooks and silver streams, and his selections of hour and season prove him to be an artistic photographer of no ordinary calibre. In one of his pictures, composed of woods and swiftly running water, a few dark stones, artfully selected so as to come in the right spot for effect, absolutely make the picture.

Mr. F. Sutcliffe's "Bend of the Road" is a capital illustration of what can be done by an artist with slight material. The picture is unusually low in tone, and was evidently taken some time after sunset, for there is little detail, and it owes its effect to the solid massing of light and shade. "The Quay Side" is a group of Scotch luggers at rest. The rippled reflections and shadows are extremely beautiful in this picture.

Mr. W. C. Beetham's "Haunt of the Moor Hen" and

"At Work by the River" well deserve the special silver medal awarded to them. The first is, perhaps, the best landscape in the Exhibition. It is of large size, but it commands attention not so much for this important factor as for its strikingly artistic quality. A still stream, with delicate shadows from the foliage on its banks, winds away behind a mass of trees which stand out strong and bold in the right of the picture. The focus of light comes just where the water disappears behind the trees. This contrast makes the picture very strong in effect, though delicacy of detail pervades it everywhere. The second picture is also worthy of notice. Men and farm-horses are returning from work along the bank of a stream. They stand out in bold relief, and appear to be coming towards the beholder.

Mr. Paul Lange's pictures of hoar-frost are well hung, and at once strike the eye. They are marked "not for competition."

## EXHIBITION AT THE PHOTOGRAPHIC SOCIETY OF IRELAND.

An interesting exhibition of members' work was opened in the rooms of this Society at 15, Dawson Street, Dublin, on Monday, 7th inst., and remained open every evening during the week. The number of pictures sent in was considerable—over 400—and represented that pleasing variety of subject, treatment, and process which is only to be met with in an exhibition the work of which is almost wholly confined to amateurs. The walls were completely covered by the work of the members, and amongst those which attracted special attention were two fine enlargements of the president and past president, Mr. Geo. Mansfield and Sir Howard Grubb, F.R.S., respectively. These were lent by Mr. A. Werner, an active member on the council of the Society. Some large direct pictures by Mr. George Mansfield were highly admired. A frame of drawing room and other interiors by Miss White received universal praise. In the competition in connection with the exhibition, the prizes were awarded as follows:—

| | | |
|---|---|---|
| Enlargements ... ... ... ... | | R. M. Inglis |
| Views ... ... ... ... ... | | J. White |
| Hand-Camera Work ... ... ... | | J. White |
| Historical Pictures... | (Recommended) | L. R. Strangways |
| Lantern Slides ... ... | (1st) | J. H. Hargrave |
| " " ... ... | (2nd) | L. R. Strangways |

A set of 100 quarter-plate views in platinum of a tour in Norway, lent by Mr. William Swanston, president of the Ulster Photographic Society, attracted much attention on account of their uniformity, fineness of detail, and knowledge of art brought to bear upon the formation of the pictures. Amongst those frames deserving special mention may be set down the work of Messrs. A. M. Geddis, M. Hedley, R. M. Inglis, N. Colgan, J. Kelsall, J. White, J. A. C. Ruthven, F. H. Orr, and L. R. Strangways. Amongst the trade exhibits may be mentioned a window transparency, and a couple of beautiful examples of printing on silk in the diazotype process, lent by Messrs. Green, Cross, Bevan, and Co., and also a sample of the work of the Celerotype Company.

The annual lantern exhibition was held in the Leinster Lecture Hall, Molesworth Street, on Friday evening, and was witnessed by a crowded audience, when upwards of 220 slides, including the prize slides, were passed through the lantern by Messrs. J. H. Hargrave, M. Hedley, and J. A. C. Ruthven.

On the whole, the exhibition may be declared a splendid success, a state of things which was mainly due to the indefatigable exertions of Mr. Hargrave, the popular hon. secretary, and of Mr. A. M. Geddis, who, as members of the hanging committee, had the entire work of the exhibition thrown on to them, in consequence of the unavoidable absence, through illness, of the other two members of the hanging committee.

## TAKING PICTURES FOR A NICKEL.

A new automatic flash-picture apparatus is thus described in an American paper under the above heading:—

An invention that is almost human in its workings is the new automatic photographing machine that, for a nickel, will take your picture while you wait. It is like one of the weighing machines, standing upright in the manner of the old-style clocks. It has two big eyes which stare at you while you sit in the chair as if they would divine your secret thoughts. These eyes are the apertures through which the flash-light effects are secured. The operation by which the counterfeit presentments are taken may not be uninteresting. You are placed in a chair in front of the machine. Back of the chair is the old-style head support that makes the sitting for a photograph so tedious for a moment or two. The young lady attendant—this device opens a new field for young women ambitious to work—first pushes your chin in one direction, and then pulls it in the other direction until your face is in the proper position. Then she looks at you and smiles, which is the signal to look pleasant. When the proper beatific expression has settled down upon your features she presses a button. There is a rumbling noise inside, yet you continue to glare at the two eyes in spite of the inward commotion, for you have been told what to do. In a few seconds there is a brilliant glare as if another Sodom and Gomorroh were being destroyed, the noise ceases, and the negative drops into the pan, whence the young woman takes it out. But she does not show it to you, because nothing can be seen until it is placed in the solution. This is done, and little by little the features, appear until you "see yourself as others see you." Ten chances to one you are dissatisfied with the picture, for the bright electric flash-light so blinds your eyes, and your optical muscles are so contracted, that an expression is there that makes you look like a pickpocket or ornament for the rogues' gallery. Nevertheless, it is a wonderful invention, and curious people will not be slow to drop into the slot the nimble nickel.

## AMATEURS.

According to a correspondent of the *Times*, the modern amateur is by no means confined to the art of photography. He writes thus:—

"We are in the power of an organised oligarchy of amateurs, entrenched behind a mighty fortress of 'system.' That is the normal English state of things in these days; for now is the great age of the amateur. He reigns supreme everywhere. The House of Commons consists of a mass of amateur legislators. Amateurs, wild with fads, pervade our county councils. Amateur educationalists control the school boards. Committees of amateurs rule our hospitals and all the institutions of this country that are not conspicuous successes. The Army itself is a machine for turning out on us, in the prime of their life, a mass of amateur civilians, who are forced to find employment as amateur directors of companies, amateur wine-merchants, amateur tradesmen; or to fill other posts for which their professional career has not tended to fit them. The walls of our exhibitions are covered with amateur pictures. Committees of amateurs preside over the erection of public buildings and monumental statues. Amateur authors write half our literature. Amateur actors flood the stage. Amateur musicians rival the cats on the housetops in number and cacophony. Amateur working-men organise strikes. Amateur clergy do three-quarters of the preaching. Amateur prophets reveal a succession of new religions. It is the English latter-day manner of doing things. We should be inconsistent if we did not get landsmen to manage the navy and civilians to organise the army. If we keep going at all, it is thanks to the energy of amateur critics."

## Short Notices of Books.

Electricity up to Date, for Light, Power, and Traction. By John B. Verity, M. Inst. C.E. (*London: Warne and Co.*)

All methods of obtaining light must necessarily be of interest to photographers, and the above work has several chapters which in this connection have some useful suggestions.

Die Photographische Messkunst, oder Photogrammetrie Bildmesskunst, Photographie. By Franz Schiffner. (*Halle a S.: Wilhelm Knapp.*)

The book opens with a brief account of the work of various experimentalists, and then proceeds to give detailed directions in connection with the applications of photography to topography. It is is divided into three sections, the first of which comprises useful instruction for beginners; the second deals with the apparatus employed, and the methods adopted by various experimentalists; and the third section is devoted to advanced students. The book, thus fully dealing with the subject, consists of 134 pages, with 83 illustrations.

Die Autotypie in ihren verschiedenen Ausfuhrungsarten. By J. O. Morch. (*Dusseldorf: Ed. Liesegang.*)

A practical treatise on the application of photo-mechanical processes to book illustration, &c. The author is well known in connection with his "Handbuch der Chemigraphic und Photochemigraphic," and brings to bear on the book before us the results of a wide practical experience. Eight well-executed plates, with full letterpress description of their production, increase the value of a useful book.

Photographischer Almanach und Kalender fur das Jahr 1892. (*Same Publisher.*)

In comparison with the bulky annuals issued in England for one shilling, the above seems to give but small measure for one mark. But though little, this annual is, as usual, good so far as it goes. The articles are short, but practical. Among the illustrations are portraits, with biographical notices, of Ottomar Anschutz, Edmond Becquerel, and Dr. Jos. Petzval. Useful features in the issue of 1891 are repeated, with the addition of a list of dark rooms for continental tourists.

Photographic Club.—Subject for December 23rd, "Washing Prints"; December 30th, monthly lantern meeting.

## Patent Intelligence.

*Specially compiled for the Photographic News by Herbert & Co. (H. J. Haddan & R. Haddan), Registered Patent Agents, &c., of 18, Buckingham Street, Strand, London, W.C.*

### Applications for Letters Patent.

20,951. Samuel Henry Smith, 21, Finsbury Pavement, London, "Improved Photographic Plate Washer."—*December 1st.*

20,988. Hugo Kassel and Ernst Kassel, 37, Chancery Lane, London, "A Combined Purse or Pocket Book and Photographic Camera."—*December 1st.*

21,176. Herbert Samuel Starnes and Andrew Pringle, Cromwell House, Bexley Heath, Kent, "Photographic Exposure Shutter."—*December 4th.*

21,195. Fox Shew, 23, Southampton Buildings, London, "Improvements in Photographic Printing Frames" (partly communicated to him from abroad by M. Lehmann, France).—*December 4th.*

21,233. Arthur Charles Smith, 258, Albert Road, Peckham, "Improvements in Photographic Cameras."—*December 5th.*

21,274. Zygmunt Ajdukiewiez, 28, Southampton Buildings, London, "Photographic Camera for Instantaneous and Prolonged Exposures."—*December 5th.*

### Specifications Published.

18,723. *May 20th*, 1890.—"Photographic Plates." A. Toby, of 47, Rue de l'Hopital, Brussels, Belgium.

The object of this invention is mechanism for the automatic change of plates in photographic apparatus. The apparatus is provided with a system of change of plates, consisting of turning mechanism, and mechanism for rectilineal motion, which together cause the plate presented vertically to the object to make a quarter-turn, which places it first horizontally above, whence it is withdrawn backwards parallel to itself to take position above a pile of other plates, while, at the same time, a fresh plate is advanced from below this pile to be turned up vertically before the object, and to follow the same course as the preceding plate when the operator has taken the picture. The turning mechanism consists in the combination of two grooved frames with a turning frame, to which they are connected in alternate manner by links, whilst S-shaped springs bear them against horizontal and vertical guides in the compartment in which it is arranged, this compartment being situated exactly in front of that containing the pile of plates. The mechanism for rectilineal movement consists in a system of levers connected by links to upper and lower slide bars, acting by tappets on the plate to be changed in opposite directions, so as to move the one which has served back on to the pile in the hinder compartment, and to push a fresh plate forward into the frame placed exactly facing the lowest plate on the pile. The movements of the mechanism are produced by working a handle or button outside the apparatus.

## Correspondence.

### THE CHICAGO EXHIBITION.

Sir,—Some little time ago my attention was drawn to the fact that the classification for the Chicago Exhibition did not provide for the exhibition of photographs. I wrote on the subject to the director-general at Chicago, and he now informs me that the classification has recently been revised, and is now in process of publication. Photographs will be included in the group devoted to instruments of precision, experiment, research, and photography. They will thus be in the Department of Liberal Arts, and not, as at Philadelphia in 1876, in the Fine Arts Department. H. T. Wood, *Secretary.*

*Society of Arts, John Street, Adelphi, Dec. 14th.*

### PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

Sir,—It has been arranged that, during the present winter, a series of lectures shall be delivered under the auspices of the Photographic Society of Great Britain, upon subjects of interest to photographers, with a view to the development of a scheme of photographic technical instruction of a more advanced character than that provided by elementary schools.

Should the present experiment prove sufficiently successful to show that further efforts are likely to result in material benefit to the photographic community, without unduly taxing the resources of the Society, it is intended to consider the details during the summer in order to elaborate a more complete programme for next winter than is now possible. It is not, perhaps, too much to hope that the present movement may prove a modest beginning of a National Photographic Institute.

The lectures now arranged will be delivered at the Society's rooms, 50, Great Russell Street, on Tuesday, Jan. 5th, 1892, by Mr. T. Bolas, F.I.C., F.C.S., on "The Relations of Photography to the Industrial Arts"; on Tuesday, Jan. 19th, by Mr. Chapman Jones, F.I.C., F.C.S., on "The Distortion of Outline in Photography"; and on Tuesday, Feb. 2nd, by Prof. R. Meldola, F.R.S., &c., on "Photography as a Branch of Technology."

Admission will be by ticket, to be obtained on application to the assistant secretary of the Society. The number issued will be necessarily limited, on account of the small space available, and preference will be given to applicants who are members of the Society or of affiliated societies. Any surplus will be given to other applicants in order of application. A stamped directed envelope should be enclosed. Further particulars will be duly announced. H. A. Lawrance, *Assistant Secretary.*

50, *Great Russell Street, W.C., Dec.* 15*th.*

---

## NATIONAL ASSOCIATION OF PROFESSIONAL PHOTOGRAPHERS.

Sir,—The proceedings of the Council of the above Association, November 9th and 10th, 1891, Anderton's Hotel, Fleet Street, were duly reported, by your kind favour, in your issue of November 20th, 1891, page 804.

A decision was then come to by the Council and members of the profession to deal only with those firms of "enlargers" who issued a "trade list" not putting the promiscuous public and amateurs on the same terms as the professional photographers; but protecting the latter in a fair, just, and business-like manner.

The profession will be pleased to learn that already the following firms have complied with the respectfully urged request of the Council, viz.:—Messrs. Elliott and Son, Barnet; Autotype Co., New Oxford Street; Marion and Co., Soho Square; Eastman and Co., Oxford Street; Illingworth and Co., Sheriff Road. The Council will be glad to receive the additional consent of all respectable firms to be added to the above list.

I beg to urge upon all professional photographers the importance of becoming members of this Association (formed for the defence of their own interests), and that they should speedily communicate with me for that purpose.

D. J. O'Neill, *Secretary.*

47, *Charlotte Road, Birmingham, December* 12*th.*

---

## PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

Sir,—Will you permit me to say that, in response to private appeals, I have been favoured with several contributions during the last and present months, but I am sure that some intending donors are amongst those who have not yet replied; and, by your favour, I should like to remind them that the accounts must be closed for audit at the end of the year, so that the hon. secretary, Mr. H. J. Beasley, of 65, Chancery Lane, and myself are most anxious to get in all donations and outstanding subscriptions during the next fortnight.

Thanking you by anticipation for your kind insertion of this letter. John Spiller, Treas. P.B.A.

2, *St. Mary's Road, Canonbury, N., Dec.* 16*th.*

---

## DR. MADDOX AND DRY-PLATE PHOTOGRAPHY.

Sir,—"All honour" to the News for affording means for the ventilation of a question which very much stands in need of having a little air and daylight let in upon it. In a matter of this kind, praise should be accorded "without stint."

In your last week's issue, Mr. Pringle was obliged to have recourse to *modifications made five years ago*, and mentioned (unfortunately, I think) by Mr. Debenham at a meeting of the London and Provincial Photographic Society, when an appeal was being made on behalf of the Maddox testimonial. If Mr. Debenham had taken Harrison's formula of 1868, instead of Maddox's of 1871, no such modification would have been necessary as that which Mr. Debenham mentioned, but did not describe.

With respect to "Professional's" remark asking why no credit is given to Mr. Bennett, all that can be said is that, at present, Dr. Maddox has got the whole of it, so that there is none available for any other person. When the proper time comes, it may be shown who are responsible for a state of things which is a disgrace to photography. Meanwhile "Professional" may rest assured that Mr. Bennett will eventually come by his own, but that will only be *after* credit has been given to Mr. Burgess for the plate which he (not Dr. Maddox) put into Mr. Bennett's hands. With regard to "Professional's" other remark, it may be said that history records the fact that very rapid plates (not infinitely rapid) were made before 1878—the year in which Mr. Bennett's most valuable announcement was published—and it is also recorded that professionals were very prejudiced against the dry plate, even for some years after 1878. If I may be allowed to say it, "Professional" seems still to have some of the old love left.

It would not be a bad thing for societies to form an idea of the relative values of these early experiments by actually repeating them. I wonder if Mr. Pringle has done this. Let there be no modification, but let it be work, fair, square, and above-board.

Now for something much more serious, and which had better be settled by photographers than by those outside photography. How is it that Mr. Burgess is pursued by certain parties with such animosity? I find this to be the case in 1873, in 1880, and, to a certain extent, now in 1891. Why is it? Surely there must be something behind the scenes of which we spectators are not cognisant. Why is every opportunity taken to insult him? Is not this kind of thing a disgrace to all concerned? It will be time enough for any gentleman to mention "bars" when an application is made on behalf of Mr. Burgess for such recognition as that to which Mr. Pringle gratuitously refers. Still, if ever it should be necessary to make an appeal, and should anyone wish to respond, no bar that Mr. Pringle or any other person might choose to set up could prevent the exercise of one's own free will. Before this question is done with, something will have to be said with reference to the unwritten law which seems to prevail, and which arbitrarily devises "bars" and inflicts penalties. What bar has it been to Foley, Arkwright, Dolland, Whitworth, Millais, Tennyson, and the whole world of inventors, that they have made a profit by their work?

Should anyone be anxious to know what Mr. Burgess did, let him consider the condition of emulsion affairs at the beginning of July, 1873; the condition was that of darkness, thick as night. Then let him compare this state with the condition one month later. Within a very short time of the end of July, 1873, it is probable that every photographic journal in the world had made reference to what had been done by Mr. Burgess (not Dr. Maddox). Luckily for Mr. Burgess, the records speak out in no doubtful tones. These records, which have been exhaustively dealt with, conclusively prove:—

1. That a great and wilful wrong has been done a deserving man.
2. That the work of the man who is credited with the invention of the gelatino-bromide dry plate had no connection therewith.
3. That the work of the accredited inventor was not so good in its own line as work that had been done before.
4. That the work of the accredited inventor was worthless, and that it was so esteemed.
5. That a deliberate plot was concocted to take away the

credit of the invention from the man who overcame the difficulties which had rendered abortive all previous attempts to use gelatine, in order that the honour might be given to a friend, viz., the accredited inventor.

6. That the jurors of the Inventions Exhibition were wrongly advised in this matter.

Before concluding, it may be well to ask the following questions, the statements referred to in the first three all having appeared in public journals :—

1. Why is Dr. Maddox said to be absolutely the first man who experimented with gelatine associated with silver ?

2. Why is he called the father of the gelatino-bromide dry plate ?

3. Why are we said to owe more to him than to any other man for the dry plate of to-day.

4. Why was he alone awarded a gold medal by the jurors of the Inventions Exhibition ?

5. Where did the negatives come from which were exhibited on behalf of Dr. Maddox at the Inventions Exhibition ?

In view of the fact that both in the Doctor's account of his experiment and in the only editorial notice devoted to it, the process is described as a printing process ; together with the great difficulty, if not impossibility, of obtaining a negative by it, the last question attains a special significance.

This question promises to develop into a very serious affair, and one that is likely to create a great sensation.

*Peckham Technical School.* J. Faulkner.

---

Sir,—My attention having been called by a friend to certain statements made against my claim *re* gelatino-bromide in your pages, may I ask the favour of the insertion of the following reply in your next issue.

I have this morning received from the publishers your journals dating from the 20th ult. to the 11th Dec., inclusive. Let me hope this will explain what otherwise must seem strange to your readers—viz., that I had not earlier intervened in the correspondence that has occurred between those dates about the discovery of the gelatino-bromide process, and my original article in the *British Journal of Photography* in Sept., 1871. As further silence might be misconstrued, I hasten to contradict what has been mis-stated. I should have preferred to let the letters of some of your correspondents pass for what they are worth, as I consider Mr. Pringle, of whose letters I was wholly ignorant until to-day, has righted much, if not entirely, the endeavour to set aside my claim.

It is stated Dr. Maddox only obtained prints, not negatives. This is *untrue*. Negatives were made, and some of the original negatives Mr. Bolton and I found amongst the dirty glass some years since at No. 2, York Street, Covent Garden. Finding I was very much occupied and exceedingly out of health, some of the negatives that were made were shown to one of the members of a firm at Southampton, and solicited to continue the experiments. Unfortunately, it transpired that they were too busy to accord the necessary time. I hold a letter from that gentleman dated some years afterwards recalling to mind this fact.

That I did consider the process of value, the concluding sentence to my original article clearly proves. No attempt, in my hurried reply to Mr. Taylor's request, was made to state more than a few facts. The editor's remarks at the time suffice to show his estimation of the article sent to him. Other experiments followed closely, as time and health permitted, the chief being a little more care, increase of bromide, and the introduction of various organic bodies which were found to vary greatly the colour of the resulting negative. All this was done before the end of the year ; hence *long, long* before we were introduced to the guinea advertisement. Some of the negatives have been exhibited, and are still in my possession. It is therefore a mistake to suppose that my original hurried article contained all that I had done, or that only positives on paper or on glass were made. From the often hasty experiments many defects existed compared to the plates of the present day, the original object being not "speed," but a substitute for collodion. It was evident perfection could only be reached by further work.

Another point is that my article was not original, and that it was not the starting point of the present gelatino-bromide process. I can truly declare that I had never known of any previous gelatine emulsion process, or I should have quoted the same. Evidently such were in oblivion, or they would have been pointed out at the period of my article. One author, to whom I am not personally known, and who certainly is capable of judging, when writing of my original paper or process says : "It did most unquestionably exhibit the capabilities of gelatino-bromide, for the gelatine process as given by Dr. Maddox is only modified, not altered by the numerous dry plate and gelatine bromide paper manufacturers of to-day." I have never claimed what I could not substantiate, and in whatever branch of work I have endeavoured to make the slightest contribution, I have never laid claim to the work of others. If we look at the present phase of dry plate photography, it lies in a nutshell. It must be evident it had a starting point, and that starting point I claim for September, 1871, in spite of all adverse criticism. Its present perfection is not "due to one individual," nor to two, nor to ten, but to the numbers who have thrown their little into the common stock ; indeed, it is the result of the "power of littles." Personally, I can have no objection to the admirers of any special party getting up a testimonial to those who have played any part in its history, though I think the 21st birthday must be considerably retarded, and then possibly past commercial relations may be found detrimental. I read Mr. J. Burgess "advertised his gelatino-bromide emulsion, but, as it would not keep in consequence of decomposition setting in speedily, it was not commercial, therefore was unsuccessful ;" perhaps this may modify my remarks. To close this letter, I now offer my sincere thanks to those at home and abroad who have in any way expressed their testimony on my behalf. Those interested in gelatino-bromide will find a more extended notice in my letter to Mr. W. Jerome Harrison, published in his "History of Photography," which certainly fully and undoubtedly establishes all that I claim as the originator of the present gelatino-bromide process. With every apology to the editor for so largely trespassing on his pages, and craving the indulgence of a fair hearing from the readers of the News, I am, sir, yours faithfully, R. L. Maddox.

*Portswood, Southampton, December 15th, 1891.*

A Successful Inventor.—It is not every inventor who is so fortunate as Mr. Louis Brennan. The Admiralty have paid the last instalment of £16,000 to this gentleman, who has received much more than £110,000, which the Government is supposed to have paid for his torpedo. Eight years ago he was paid a retaining fee of £5,000, and engaged for three years at a salary of £2,000 a year and expenses, in return for which he was to devote all his time to the development and improvement of the torpedo, and when that term was over he received for some years a salary of £1,500.—*The Practical Engineer.*

## Proceedings of Societies.

London and Provincial Photographic Association.

*December 10th.*—Mr. S. G. B. Wollaston in the chair.

A question from the box was read: "What strength of bichromate of potassium solution should be used to restore plates that have been exposed to light; must they be afterwards washed, and is the origiual sensitiveness impaired; if so, by how much?"

Mr. A. Cowan said that a strength of from three to five per cent. was recommeuded. The bichromate must be thoroughly removed by washiug, and theu the plate should not have lost its original sensitiveness. Mr. Cowan also showed a set of transparencies developed with the parauidopheuol solution given by Mr. Low Serjeant. The action of the developer was very rapid, and, after developing nine lautern slide plates, he had used the same solution for a half-plate negative, which he exhibited.

Mr. W. E. Debenham found, with Mr. Cowan, that the development was rapid, but when used the day following its first use it had caused a curious set of spots all over the plate.

Mr. Sinclair said that, according to Mr. Warnerke, the hydrochloric salt of paramidopheuol was not the best one to use, aud that another of its salts was to be preferred, and was in use iu America for developiug purposes.

Mr. F. A. Bridge then read a paper on "Gas Bottles, and Methods of Ensuring Safety with them" (see page 859), iu the course of which he attributed accideuts not to the bottles themselves, but to regulators and gauges, particularly the latter. Iu a recent case which he described, the explosion was probably due to a little oil.

Mr. T. E. Freshwater said that no doubt, in all these cases, the explosions occurred in connection with gauges or regulators, and generally with the former. We are told that uo oil is used for the leather washers, but only beeswax. In a recent paper, Lieut.-Colonel Lonsdale explains the cause of explosion in gauges. The explosious were probably not caused by the mere presence of the lubricant, but by the force of the gas whirliug a little of it round and round, and the friction of the spray thus formed sufficed to cause ignition. He thought there was no necessity to buy a gauge. The amount of oxygen contained in a bottle could be found by weighing.

Mr. Spurge showed a drawing of a new gauge in which the oxygen did not enter the steel tube, but acted on a piston in communication with the tube, which was filled with glycerine. Not only was the danger of coming into contact with oil avoided, but there was less waste of oxygen in its use. He also showed the gauge in use.

Mr. A. Haddon suggested the use of phosphor bronze iustead of steel for cylinders.

Mr. G. R. Baker said that it seemed to be agreed that a small quantity of oil was the general cause of explosions, but he thought that if a valve was never tightened up until the gauge was full, there would never be any explosion. He thought a ratchet key for opening the valve would be useful.

Mr. Bridge said that with a key like that used for tuniug grand pianofortes, where the handle formed a long lever, the opening of the valve could be made very gradual.

Mr. J. Stevens was elected a member.

It was arranged that no meeting should be held on the Thursday which will be Christmas Eve.

Camera Club.

*December 10th.*—Mr. F. Cobb in the chair.

Mr. T. R. Dallmeyer gave a description of his new telephotographic lens, referring to diagrams on the board. The object is to make possible the production of very large images of distant objects without cumbersome or expensive apparatus. This is most perfectly accomplished, as was shown by some comparative examples of objects photographed respectively by a 10 by 8 rapid rectilinear lens of thirteeu inches focus, and by the new lens with the same extension of camera, the image by the "tele" lens being five times the size of those obtained by the ordinary instrument.

Some remarks were afterwards made by Messrs. Traill Taylor, Elder, Hayman, and by Dr. Fison and Dr. Lindsay Johnson.

Dr. A. H. Fison then followed with his subject, "The Application of the Optical Lantern to Scientific Illustration," and showed how, by means of the lantern, beautiful and valuable experiment could be made easily visible to a large audience in a way unattainable by other methods. His practical illustrations included some excellent photographs of scientific apparatus, and a series of experiments illustrating the subject of magnetism aud electricity.

Holborn Camera Club.

*December 12th.*—Mr. Alfred Hodges in the chair.

Mr. Arthur J. Golding gave a lecture on "Composition and Selection of Subject." The chief point in the selection of subject was what to avoid. If amateurs were to give a little more attentiou to that point, they would have a better collection of prints. Their aim should be to produce work with which they do not tire, and he maintained that a good photograph would do this. It must always appear pleasant to the eye; not on account of its beautiful shining finish, or its delightful matt surface, but because it portrayed to the eye an impression of nature which was beautiful. Amateurs should always ask themselves whether the image on the focussing screen would make a picture. He advised them to look thoroughly at the work of emiuent artists, aud try to fiud why they looked so beautiful. Mr. Goldiug impressed on those present to (1) avoid having the priucipal object in the centre of the picture; (2) avoid having the horizon in the centre; (3) avoid straight lines; (4) avoid repetitiou of lines; (5) avoid an uninterested aud unbroken foreground. He gave a few hints on the introduction of figures.

South London Photographic Society.

At the last meeting (Mr. F. W. Edwards in the chair) Mr. Henry Crouch delivered a lecture on "Lenses." The causes of spherical and chromatic aberrations, and the means of correcting these defects, were explained, as were also the conditions affecting depth of focus and flatuess of field. The lecturer stated that true perspective was obtained with a wide-angle—*i.e.*, short-focus—lens, and spoke favourably of single lenses. Specimens of Jena, crown, aud flint glass were exhibited, aud their properties discussed.

Mr. C. H. Oakden, 51, Melbourne Grove, East Dulwich, S.E., has been appointed honorary secretary *pro. tem.* in place of Mr. S. W. Garduer (resigned).

West London Photographic Society.

*December 11th.*—The President iu the chair.

Mr. Charters-White, M.R.C.S., read a paper on "Photo-Micrography." After a few preliminary remarks on the advantages of this art over that of wood engraving for illustrating technical books, the lecturer proceeded to explain one by one the various steps in the process. He showed how very simple a piece of apparatus was necessary, particularly in working with such low powers as 1½ or 2-inch objectives, to which beginners in photo-micrography should coufine themselves. After iusisting on the importance of freedom from vibration, evenness of illuminatiou, and a careful register of exposures and results, he wound up his lecture with a display of lantern slides, representing histological, eutomological, and odontological subjects, and a capital selection of photos of diatomaceæ.

Several matters of special importance to the Society were considered during the evening.

Hackney Photographic Society.

*December 10th.*—Mr. John Reynolds in the chair.

Mr. W. H. Smith gave a paper and demonstration of a new paper the Platinotype Compauy are about to bring out. It was three or four times as rapid as the silver paper, and could be developed iu a cold bath with biphosphate and oxalate of potash, using the usual hydrochloric bath as a clearer. He demonstrated the printing on this paper by artificial light, using powdered magnesium and oxy-hydrogen light. Giving an exposure of fifty seconds with this light on a negative, a fair print was obtained on development.

Messrs. T. Byrne and J. Badcock were nominated for membership.

---

Richmond Camera Club.

*December 11th.*—Mr. Cembrano in the chair.

The first business was the decision, by vote, of the "Outing Competition"—that is, for the best picture from a negative taken at one of the Club's outings during the past summer. About two dozen prints were entered, and the first place was secured by the hon. secretary, Mr. P. Ennis, with a charming little view of Kew Bridge, one of the set of four which has just gained a medal at the Leeds Exhibition.

The next function was the inauguration of the new club lantern, an excellent instrument by Ottway, the selection of which had been entrusted to the president.

Among other slides exhibited was a portrait of Niépce, reproduced by Mr. Ramsay from a wood-cut in an old French work of forty years ago.

---

Glasgow Photographic Association.

*December 3rd.*—The chair was occupied by Mr. W. Lang, junr., who read a paper from which the following is extracted:—

During the recess, several important events connected with photography have taken place. I may be allowed to refer in a word to the International Photographic Exhibition held in September in our Fine Art Galleries. It was a success in every way.

At the British Association, held in August, at Cardiff, Dr. Huggins, in his presidential address, paid the highest tribute to photography that perhaps has yet been made.

The members of the Photographic Convention attending the Bath meeting had the practical results of photography as applied to astronomy very forcibly brought before them in an astronomical lecture delivered by Mr. Taylor, when a large series of photographs of nebulæ, constellations, planets, &c., were shown by projection on the screen. Bath is classic ground for the photographer. It was in the neighbourhood of Bath that Talbot lived. The first Herschel—the father of Sir John—was also associated with the city of hot springs, and his early astronomical discoveries were made while resident there.

Developers are still increasing and multiplying, the latest addition being a salt of the chemical substance known as para-amidophenol. Those who have experimented with it place the character of the results obtained with it as being between eikonogen and hydroquinone.

Before I conclude these somewhat desultory remarks, I perhaps might refer to the lantern craze which is presently pervading all classes. There is just a chance that the thing is going to be overdone. In an article the other day in the *Baillie*, the writer was deploring the comparatively small attendance at the Water-Colour Society's Exhibition, and somewhat sarcastically added that now-a-days the public could only appreciate pictures that were shown by means of projection on a screen.

Mr. James Gardner read a paper, and gave a demonstration, on "Collotype Printing." The various stages of the process were shown, and a large collection of finished prints exhibited.

---

North London Photographic Society.

*December 15th.*—Mr. J. Traill Taylor in the chair. Mr. J. D. Slater and Mr. W. Walker were elected members of the Society.

Mr. W. Bishop (the hon. secretary), in introducing the subject of "Carbon Printing," said he was glad to have the opportunity of doing so, as he believed amateur photographers did not give the attention to this beautiful process which it deserved. Whether for the beauty and variety of its results, the simplicity of its operation, or the permanency of its prints, the process of carbon or pigment printing had much to recommend it; while the fact that almost all the working could be carried on in daylight, or full gaslight, was a great comfort and convenience. The action of bichromate of potash on gelatine was then described, and a brief history given of the process. The various operations of sensitising the tissue, printing, developing, and transferring to the final support were in turn spoken of, and the use of the actinometer in judging exposure explained. The lecture completed, the demonstration followed, a number of prints which had been exposed during the day being mounted and developed, some on glass as transparencies, some on single tr nsfer, and others on the temporary support, the final support being then attached to be stripped when dry. For the purpose of completing the demonstration, some prints which had been developed and attached to the final support the previous day, and were now dry, were stripped from the temporary support, and the result shown ready for mounting. In one case a negative film of celluloid had been used as a temporary support.

A collection of specimens of pigment printing, showing the various colours available, had been lent by the Autotype Company as illustrations. Mr. Bishop's own specimens included a proportion of failures, the causes and cure of which were explained for the information of beginners at the work. The apparatus used was of the simplest character, being mainly a number of tin dishes for holding water, and a porcelain developing dish for alum; a glass slab for mounting, a squeegee, some blotting boards, and a kettle of hot water completed the outfit.

In the conversation which followed, the Chairman referred to his carbon experiences in the early days, and cordially recommended the process.

Questions were asked from the question-box as to the cause of muddiness in a ferrous oxalate developer, and it was generally considered that it was caused by insufficient acid; and next, as to the preparation of a lead intensifier, which the chairman promised to take an opportunity of answering.

The next meeting will be a technical night, and will be held on January 5th, 1892.

---

Brixton and Clapham Camera Club.

A reception was held on the 12th inst. to inaugurate the opening of new quarters at the Clarence Rooms, 376, Cold Harbour Lane, Brixton, when some 150 members and friends were present. On the walls of the drawing-room were hung a number of pictures taken by members. There were also some portfolios containing bromide enlargements by Mr. Dresser. There was also a lantern exhibition in the new meeting room, for which the Club lantern was used. The company then returned to the drawing-room and partook of light refreshments, and the evening closed with a selection of music.

---

Birmingham Photographic Society.

*December 8th.*—Mr. F. J. Lyndon in the chair.

Mr. Taylor outlined a description of the various emulsion processes which had been brought out, and demonstrated some of the advantages attending their use, and showed some excellent results which he had obtained with the new emulsion paper of the Ilford Company. The results obtained by squeegeeing on ground glass were much admired.

Mr. W. J. Harrison followed, and confined himself to the toning and fixing of the Ilford paper, the new gelatino-chloride. He mentioned that he thought the company were well advised in bringing out the paper in the winter months, because of the necessity of using cold water if the alum bath were dispensed with. He thought that in summer alum baths would have to be used. Mr. Harrison further showed the effect which could be obtained without any toning, by simply washing and fixing; the resulting colour was very suitable for some subjects. Altogether, both speakers were very sanguine as to the success of the new paper

*December 10th.*—A meeting was held at the Midland Institute, Mr. F. S. Goode in the chair.

Mr. J. H. Pickard gave a paper on "Enlarging," and showed the method of operating. He first used a Griffith's enlarging camera—one 10 by 8 fixed focus, and a second 12 by 10 adjusting focus—using "Ilford" rapid paper and a Hibbert flash-lamp. Some good results were obtained and shown. Afterwards, with an Eastman lantern, and their new rapid paper—replacing their oil lamp by magnesium ribbon on account of time—he produced from a quarter-plate negative a 15 by 12 enlargement. The ribbon used was about sixteen inches of ordinary gauge. Mr. Pickard toned with uranium, and satisfactory results were obtained.

*December* 11*th*.—The lantern slides sent by the California Camera Club were shown before a large meeting by Messrs. Harrison and Jacques, the latter operating the lantern. Many of the slides were of great technical merit and interest, being taken chiefly in the Yosemite Valley.

The Warwickshire Survey Section of the Society has lately been busy organising the work to be done during next season. The results so far obtained have given much satisfaction to the members who initiated the movement.

DERBY PHOTOGRAPHIC SOCIETY.

A MEETING was held on Tuesday evening last at Smith's Restaurant, Victoria Street.

Mr. THOS. SCOTTON gave a paper entitled "A Trip to the Isle of Man," illustrated with the lantern.

A series of "Isle of Man" slides was also shown by Mr. R. L. Warham, and miscellaneous sets by Messrs. Rowney and Smith.

Mr. J. A. Panton was elected a member.

ROTHERHAM PHOTOGRAPHIC SOCIETY.

AT a meeting on December 8th, Mr. JAMES LEADBEATER read a paper entitled "A Peep into Nature through the Microscope Lantern." The various objects on the micro slides were projected on a screen having a disc eight feet in diameter. The lantern attachment to enable this operation to be successfully performed has been designed by Mr. Leadbeater himself. By its means several objectives can be in readiness for service, and a single movement is all that is necessary to bring any one of them into operation; provision is always made for quick centreing and focussing by rack-and-pinion. Not the least interesting part of the proceedings was the exhibition of the specimens of insects, &c., under various powers.

CROMWELL PHOTOGRAPHIC CLUB (GREAT YARMOUTH).

AT the meeting held on the 14th inst. several influential gentlemen were elected members, amongst them being the Mayor of the borough (Mr. F. Burton), the Vicar (Rev. W. Donne), Mr. F. Danby Palmer, D.L., and Mr. Thos. L. Olley.

During the evening the secretary (Mr. RUMBOLD) gave an explanation of the camera and the mode of working it, for the information of beginners. After going through the method of focussing an object on the ground glass, the placing of plates in the dark slide, and explaining both time and instantaneous exposures, he developed a plate that had previously been exposed, using for his developer pyro and soda.

The next monthly meeting, to be held on January 11th, 1892, will be devoted to printing and toning of albumenised paper.

NEW PROCESS FOR THE MANUFACTURE OF CHROMATES.—The author describes the following process, which is based on the fact that when chromium oxide is heated with a mixture of calcium chloride and oxide, a chromite is formed, which absorbs oxygen from the air to yield a calcium chromate. The finely powdered mineral is mixed with a paste composed of lime, calcium carbonate, and a concentrated solution of calcium chloride, in such proportion that the lime and calcium carbonate are slightly in excess of the amount necessary to combine with the chromium oxide present, whilst the calcium chloride is about one-third of the total lime used. The mixture, on exposure to air, hardens, and is moulded into bricks, which are dried, and subsequently roasted at a temperature sufficient to convert the calcium carbonate into lime. The bricks are exposed to the action of the air for about a month, then lixiviated with hot water to remove the calcium chloride, and the residue containing the calcium chromate is treated with alkali carbonate or sulphuric acid in the usual way, according as an alkali chromate or chromic acid is required.—*Journal of the Chemical Society.*

## Answers to Correspondents.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

All other Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

*** *As the* PHOTOGRAPHIC NEWS *will go to press one day earlier than usual next week, all communications should be sent in not later than Tuesday.*

DRAUGHTSMAN.—Stevens's ebony stain is used by many for making drawings for process work. It flows easily from the pen, and never clogs; but it has the disadvantage of showing through any markings in white which may be superposed either for purposes of effect or in order to obliterate any portions of the black work. Wolff's liquid Chinese ink possesses all the advantages, without this demerit of the stain, and its employment is, therefore, preferable. The stain is often used because it is about one-tenth of the price of the Chinese ink.

K.—An hydraulic press is generally used for the Woodburytype process, but a backed electrotype mould will serve the purpose. Look up your text-books, where you will find details of working.

L. P.—The estimate of which you enclose a copy is by no means an excessive one. Checking it by what we ourselves have paid for the same description of work, we find it decidedly favourable.

BENEVENUTO.—The apparatus is of no practical value, and you would find it a "white elephant" on your hands. Still, it shows an experiment which is full of scientific interest, and for that reason its originator deserves much credit.

CURMUDGEON.—We are under the impression that if you want to protect the whole set of pictures you must pay the shilling registration fee for every one of them; but the rule may possibly have been relaxed. An enquiry at Stationers' Hall Court would satisfy you on this point.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—December 24th, no meeting; December 31st, "Warm Tones in Lantern Slides"; January 7th, a paper by Mr. P. H. Newman on "Some Recent Exhibitions." Visitors are invited.

WEST LONDON PHOTOGRAPHIC SOCIETY.—A conversazione and exhibition of members' work will be held on the 8th and 9th of January, 1892, at the Lecture Hall, Broadway, Hammersmith. Mr. H. P. Robinson, Mr. Valentine Blanchard, and Mr. G. E. Cooke will act as judges.

ACTION OF LIGHT ON SILVER CHLORIDE.—When silver chloride, spread in thin layers upon glass slips, is exposed to light, there is at first no darkening or loss of weight; but if it is treated at this stage with a photographic developer, such as ferrous oxalate, it is reduced to the metallic state, showing that a modification has taken place in its constitution. A similar modification is stated to be brought about by boiling silver chloride with water in a reflux apparatus in the dark for some hours. The disengagement of chlorine may be rendered evident by concentrating a beam of sunlight on the chloride. The residual product in the early stages of the action is stated to be silver sub-chloride, $Ag_2Cl$, identical with that prepared from the sub-fluoride; if treated with ammonia or potassium cyanide, metallic silver is left, but dilute nitric acid does not dissolve it. The author states that he has found that the formation of this sub-chloride from the chloride is attended with absorption of heat = 28·7 cal., and considers that this explains the increased rapidity of the action when substances capable of absorbing chlorine, and giving up heat, are present. Silver sub-chloride, prepared in either of the above ways, is decomposed by the further action of light into silver and chlorine. Since both the metal and its sub-chloride are opaque, the final product of the action of light on a layer of silver chloride usually consists of an upper layer of metallic silver, an intermediate layer of sub-chloride, and a lower layer of unchanged chloride.—*Journal of the Chemical Society.*

# THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV. No. 1738.—*December* 25, 1891.

CONTENTS.

## THE YEAR THAT'S AWA'.

In this, our last issue of the year, it is appropriate, and will not be uninstructive, we hope, to review in a discursive way the history of the past twelve months, to put on record the achievements and the enterprises by which the year has been marked.

The year 1891 has not been a remarkable one in the matter of either novelty or financial success, but a certain amount of good work in the experimental line has been accomplished, and, on the whole, our art has been steadily if slowly advancing. There is no doubt that the improvement in the art qualities which has been noticed for some years has, during 1891, gone on, and has in the exhibitions of the year been demonstrated. These qualities are not of a nature to rush forth suddenly into sight; their progress is, and must, from their very nature, be gradual. Three of the most successful exhibitions that have ever been held in this country have taken place during this year. It is not for us to attempt to compare these exhibitions, but we may say that Liverpool, Glasgow, and Leeds have each had a fine show of high-class work. When the Liverpool exhibition was opened it seemed unlikely that it would be approached by another so soon, yet neither the Glasgow nor the Leeds was behind the Liverpool one. The annual exhibition at Pall Mall has been, as usual, marked by a considerable quantity of the best work of the year, and by some of the worst that is hung anywhere. The latter exhibition gave rise to a very pretty storm in a tea-pot, some of the officials of the Photographic Society having put the curb on certain irregularities—real or alleged—rather too suddenly to be thoroughly understood by the victims of the new morality. The result of the ministrations of "new brooms" was a very pretty row, but in the event we hope and believe that the "affair" will be useful to the Society. In Vienna an exhibition was held during the year on new lines; the honour was to consist in getting pictures hung, and we should like to see more exhibitions on similar conditions; but there seems to have been some sort of hitch in certain of the arrangements, and without doubt a considerable amount of dissatisfaction prevails as to the administration. Still, as our readers have already been informed, it was a very fine exhibition. There have been a great many subordinate provincial exhibitions—in fact, their name is legion; we doubt, however, whether the multiplication of small shows conduces to the good of photography, and we are sure that the multiplication of medals lowers their value.

Some attempts have been made to organise institutions of the nature of trades' unions, but—perhaps happily—these efforts have not led to any important or permanent results. The Photographic Society of Great Britain has made an experiment in the direction of an affiliation scheme, intended to embrace and to draw together all the societies of the country; a certain amount of success has attended this scheme up to date, but it is too early for us to either criticise its performances or prophesy as to its future. Congresses intended to standardise formulæ and measurements used in photography have been held at Paris and at Brussels, but, so far as we see, little or no result can be said to have been attained. In our opinion, the delegates have not been sufficiently representative of practical photographers, who are the body which will surely in the end have to accept or reject the standards suggested by the congresses.

In the early part of the year, Dr. P. H. Emerson astonished us by what he was pleased to called a "renunciation" of his published theories on art. The real object of this effusion was by no means clear to the general public; some took it for a sincere recantation, some for a pretext to attack certain parties who had rendered themselves distasteful to Mr. Emerson, others for a novel kind of advertisement for some book or work supposed to be following. At all events, the renunciation was followed by some wholly inexcusable vituperation of gentlemen held very high in public estimation. The whole episode was of such a nature that we would not willingly draw more attention than necessary to it. Mr. George Davison read before the Society of Arts a paper intended to lay down the theories of the writer—and presumably of others of his school—on naturalistic art; and this was met with a somewhat long article by Mr. A. Pringle in *Photography*, wherein the writer, with considerable force, sought to combat the conclusions of Mr. Davison, and even showed that Mr. Davison's practice does not tally with his preaching. At the Camera Club a paper was read by Mr. Pennell tending to deny to photography all possibility of art qualities, and this paper called forth nothing less than a storm of remonstrance and refutation, in which many well-known photographers took part. The year has brought the usual "shave" of photography in colours, this time France having been the contributor. As usual, the affair created some little stir, especially in the lay press, but beyond this flash in the pan the subject remains just where it was. In somewhat the same direction is to be noticed a device of Mr. A. W. Scott, practically a *replica* of one by Mr. Ives, of the United States, for projecting on the "screen" images of objects in their natural colours. The method adopted by Messrs. Ives and Scott is too intricato to describe here; we await further developments, which, we understand, are to be forthcoming soon.

In emulsion processes nothing of a fundamental nature has been done; Mr. A. L. Henderson described, lato in the year, a new and probably useful modification in gelatine emulsion-making, and earlier in the year it got noised abroad—partly owing to a mistake, we fancy—that Mr. Wellington had prepared a collodion emulsion of surpassing sensitiveness. Mr. F. Varley communicated to Mr. Meldola a process wherein extraordinary sensitiveness was said to have been obtained by the use of an iron salt alone, the said process having been wholly or partly communicated to Mr. Varley by Mr. Frieso Greene; but, on further investigation, it was discovered that, by some mistake, silver bromide had been mixed with the iron salt in the hands of Mr. Greene, and we do not pretend to be able to clear the matter up, beyond saying that undoubtedly "someone had blundered."

Probably the novelty of the year was the process of Messrs. Green, Cross, and Bevan for printing from negatives with certain coal-tar derivatives, notably primuline. While this process will probably not be largely taken up by the ordinary photographer, it is certainly a valuable addition to our list of *miscellanea*.

Transparent films are coming more and more into use, whether cut into common sizes or in "endless" rolls. The Eastman Materials Company have successfully started at Harrow their factory, wherein they make their flexible films, as well as bromide paper.

Partly, or chiefly, owing to some experiments published by Mr. Weir Brown, considerable attention has been directed to toning bromide paper after fixation, and some very useful processes for effecting this have como out. Several firms are now issuing with their paper printed instructions for obtaining warm brown tones, and Mr. Dresser and others have exhibited very good results obtained by one or other of these methods. Increased attention has also been given to gelatine chloride printing processes, the use of which—or, at least, the manufacture of paper for which—has been almost confined to the Continent. The Britannia Works Company have put on the market a paper of this kind. If much use is made of this and similar papers, it will indicate a reaction in favour of the warmer brown tones, after what promised to be their retirement before the blue tones of platinotype and bromide paper.

With the exception of some papers published by Messrs. Hurter and Driffield, nothing of great consequence has been forthcoming with regard to the theory of photography. The conclusions of these gentlemen touch so little the practical side of our work that we need do no more than mention them. The only new reagent to which any importance need be attached is paramidophenol, which has been recommended as a developing agent by those who have tried and reported on it; it seems to be full of promise, chiefly on account of its marked vigour as a reducer.

Messrs. L. Warnerke and Sutton have been occupied on certain collographic printing processes, and the latter has brought his process before the public, though some experts of the photographic press fail to find in the process any elements of real novelty. Be this as it may, Sutton's process will be one of great celerity with, probably, fair results.

We regret to have to chronicle a serious and fatal accident with gas at a lantern display at Ilkeston. It is difficult to decide where the mistake really came in, but the event has added one more fatality to our already long enough list. Soon after the Ilkeston disaster, there was a narrow escape of another in London, the faulty part this time being the gauge used on a gas-cylinder.

Among the speculations of the year has been one which ended badly for the investors—the Automatic Photographic Machine Company. Based on folly, it ended in disaster.

At present a testimonial to Dr. Maddox, the originator of the gelatine processes, is before the public, and is prospering.

Briefly, progress in 1891 has been slow but sure.

## RENOVATING THE CAMERA.*

BY H. C. STANDAGE.

*To Lay the Lacquer on Brass.*—Clean the article well from all grease, then heat moderately, lay on the lacquer with a proper brush the same as varnish, and heat again. When the lacquer is dry and firm, repeat the operation until the required colour is obtained.

*To Colour the Brass-work.*—Before lacquering, the following solutions are used. Perchloride of iron solution gives brown of all shades by simply immersing the brass article in the fluid; the colour obtained is determined by the strength of the solution. To produce violet, dip in a solution of chloride of antimony. To produce a chocolate colour, brush on the surface of brass moist red oxide of iron and potash, with a very small quantity of blacklead. An olive

* Continued from page 847.

green is produced by making the surface black by means of a solution of iron and arsenic in hydrochloric acid, and polishing with blacklead brush, and coating when warm with a lacquer composed of one part lac varnish, four of turmeric, and one of gamboge.

The following rough and ready mixture will produce lacquer suitable for common work, but for superior finish the more elaborate formulæ given should be used.

For a *Pale Lacquer*, mix:—

| | |
|---|---|
| Cape aloes | 3 parts |
| Turmeric | 1 part |
| Lac varnish | 1 ,, |

For a full *Yellow Lacquer*, use:—

| | |
|---|---|
| Turmeric | 4 parts |
| Annatto | 1 part |
| Lac varnish | 1 ,, |

For a *Gold Lacquer*, mix:—

| | |
|---|---|
| Dragon's-blood | 4 parts |
| Turmeric | 1 part |
| Lac varnish | 1 ,, |

For a *Red Lacquer*, use:—

| | |
|---|---|
| Annatto | 32 parts |
| Dragon's-blood | 8 ,, |
| Lac varnish | 1 part |

*Superior Lacquer for Brass*:—

| | |
|---|---|
| Seed lac | 1 part |
| Shellac | 1 ,, |
| Venetian turpentine | ½ ,, |
| Spirits of wine | 20 parts |

*Colourless Lacquer for Metals*:—

| | |
|---|---|
| Amber | 1 part |
| Mastic | 1 ,, |
| Sandarac | 2 parts |
| Bleached shellac | 2 ,, |
| Spirits of wine | 20 ,, |

The lacquering of brass should be done in a very warm, dry temperature, and the metal heated before applying the lacquer, and some articles require to be stoved after being lacquered.

*Renovating the Leather Bellows.*—In the first place, repair all tears, and fasten down any portion of the leather that has become detached. Good, strong, cabinet-makers' glue with a little vinegar added will secure the leather to the wood, but if required to be fastened to the metal, wash the surface of the metal over, using a hot solution of gelatine, and at the same time steep the leather in a hot infusion of nut-galls, and then place it firmly on the metal and allow to cool; it will adhere so firmly that it cannot be separated without tearing.

*Cements for Leather.*—A cement for leather of universal application is made as follows. Soak ordinary glue and isinglass for ten hours in sufficient water to cover them, then bring the mixture to the boiling point, and add pure tannin until the solution becomes sticky and has the appearance of white of egg.

*A Gutta-percha Cement for Fastening Leather to Leather* is made by dissolving gutta-percha in bisulphide of carbon to the consistency of syrup, and then dilute with petroleum. A thin layer of the cement is applied, and the pieces of leather are tightly pressed together.

*Formula for Staining Leather.*—If the leather is shabby and needs re-colouring, the following formula will meet all wants. Pour 1 quart of alcohol of 96 per cent. strength over 8 ounces of ruby shellac, close the flask hermetically, let it stand in a warm place for two or three days, shaking it every day until the shellac is dissolved; then dissolve 1 ounce of dry castile soap in ½ pint of warm alcohol of 95 per cent., add to it 1½ ounce of glycerine, shake thoroughly, and then add this mixture to the solution of shellac. To give colour to the mixture, use aniline colours. To give a beautiful black colour, dissolve 1¼ drachm of aniline black soluble in 1 gill of alcohol, add this to the other mixture, close the flask hermetically, shake thoroughly, and let the mixture stand in a warm place for fourteen days before using it.

*Formula for French Leather Lacquer.*—If the leather is not shabby enough to need re-staining, but simply re-lacquering, the following formula will effect the purpose. Boil 15 parts of logwood shavings in 120 of ordinary water, until but half the quantity remains, dissolve in this 2 parts of sugar and 12 parts of gum-arabic, and compound the mixture with solution of ferric sulphate until the previously brown-red colour of the decoction has changed into a violet-blue tint, and finally add some spirits of wine.

A second formula that gives a good black lacquer for leather is thus compounded:—

| | |
|---|---|
| Shellac | ·35 ounce |
| Turpentine | 1·75 ,, |
| Spirits of wine | 14 ounces |

·175 ounce of extract of logwood should first be dissolved in the spirits of wine, and a solution of ·035 ounce of bichromate of potash is added to this. The two last-named substances produce an intensely black colour, and the lacquer will show a glossy black colour immediately after having become dry. If a colour with a bluish tinge is desired, that object is attained in the simplest manner by dissolving ·175 to ·35 ounce of indigo carmine in the lacquer.

Another formula is composed of—

| | |
|---|---|
| Ruby shellac | 30 parts |
| Venetian turpentine | 1 part |
| Sandarac | 1 ,, |
| Castor oil | 1 ,, |
| Spirits of wine | 150 parts |
| Aniline black | 5 ,, |

If the leather has become very shabby by wear and tear, it will perhaps be best to coat it with a black lacquer in preference to a coloured one.

*Renovation of the Interior of the Camera.*—By constant use, the blackening compound on the lens tubes and body of the camera must, of necessity, become less intense than when new. Now a good dead black is a desideratum, and the following formula will supply all needs, both for the wood-work and the brass tubes.

*Formula for Ebony Lacquer for Wood-work*:—

| | |
|---|---|
| Spirits of wine | ·35 ounce |
| Aniline hydrochloride | ·35 ,, |

Apply this solution to the wood, which has been previously coated with a solution prepared from—

| | |
|---|---|
| Blue vitriol (sulphate of copper) | 1 part |
| Water | 100 parts |

This coating must have become perfectly dry before the solution of the aniline salt is applied. It is best to apply the latter with a small, soft sponge. A short time after this has been applied the wood will acquire a deep black colour. This is effected by the action of the blue vitriol upon the aniline chloride. This combination has been called nigrosine on account of its black colour, and cannot be destroyed either by acids or alkalies. The wood, therefore, can be left without further coating, but if it is desired to give it a lustre (which is not the case in the interior of a camera), a coating of cabinet-makers' varnish will be sufficient for the purpose.

*Formulæ for Blackening Brass.*—A good chemical black is produced as follows:—

A.

| | |
|---|---|
| Bichloride of platinum ... ... ... | 5 grains |
| Water ... ... ... ... ... | 1 grain |
| Silver nitrate ... ... ... ... | a trace |

Or else—

| | |
|---|---|
| Sulphate of copper ... ... ... | 2 grains |
| French verdigris ... ... ... | 1 grain |
| Sal ammoniac ... ... ... ... | 1 ,, |
| Water ... ... ... ... | $2\frac{1}{2}$ ounces |
| Vinegar ... ... ... ... ... | $2\frac{1}{2}$ ,, |

Or—

| | |
|---|---|
| Strong vinegar ... ... ... ... | 10 ounces |
| Bichloride of mercury ... ... ... | 1 grain |

Dust over with blacklead, brush off, and lacquer.

B.

To oxidise the brass, it must first have a coating of silver, and then be immersed in a solution of sulphide of potassium (liver of sulphur). As the smell is very disagreeable, the operation should be done out of doors or in a good draught. The colour depends on the degree of heat of the solution—the hotter it is, the darker will be the solution.

C.

To the clean surface of the brass apply (hot) a solution of white arsenic in hydrochloric acid. When the desired depth of colour is obtained rinse well, dry with fine sawdust, and varnish when necessary.

D.

Take about a thimbleful of lampblack, and put it on a smooth, flat stone; add four or five spots of gold size, and mix well with a palette knife, making the whole about as thick as putty. Then add twice the bulk of turpentine, mix with a camel-hair brush, and apply to the brass-work, which must previously be perfectly clean and free from grease. If more gold size be used it will become shiny.

We had intended including the turntable, camera tripod, &c., but must defer these to another paper.

## LANTERN SLIDES BY CONTACT.

BY C. HETHTON LEWIS.

Now that we are in the season for lantern slide making, I propose to mention a useful little plan for ensuring clear slides when made by contact in an ordinary printing frame behind a negative. It may have been noticed that oftentimes slides do not come out as crisp and clean as they should do, and possibly the edges may show more discolouration than the centre. I discovered the cause, in some cases, to be light reflected from the back of the printing frame, and from light getting past the glass edge of the plate during exposure, and spreading on to the sensitive film, the edges suffering in the greatest degree. To avoid this risk of light fog during the exposure, I have found a safe preventive in placing at the back of the sensitive plate a thick, soft piece of black seal plush (which can be bought at any draper's), of sufficient size to entirely cover the lantern plate, and projecting beyond the edges. The soft nature of this light-absorbing material allows the back of the printing frame to be closed, and it can then be seen that the lantern plate is practically embedded behind the negative, and that all stray light is prevented from trespassing on the otherwise exposed edges of the slide. I trust those who make use of this plan will find it an advantage.

## PHOTOGRAPHY BY ARTIFICIAL LIGHT.*

BY E. J. HUMPHERY, M.A.

The subject of the paper which I have to read to-night is that of "Photography by Artificial Light," and before commencing the subject I should like to read a short extract from a leading article in the *British Journal of Photography* of November 6th, headed "The Electric Light in Photography":—

"We have now entered the month so proverbial for its fogs, and professional photographers—who, by the way, have had anything but a happy time of it, from a business point of view, during the past twelve months—will find their trade again restricted unless some means of artificial illumination be adopted."

The editor then goes into the question of cost for electric light installation, and estimates the probable necessary expense as being between £300 and £325.

Now, this seems rather a large outlay for the ordinary professional, and suitable only for those who, like Messrs. Van der Weyde and a few others, can command very high prices for their work. For amateurs the price is prohibitive, unless their enthusiasm is equalled by the depth of their pockets, or, rather, by the length of their purses.

It is necessary, then, to seek some less costly method of lighting. Practically, the only alternative method of lighting at present adopted is the flash-light, and this has so many objectionable features that its use is very restricted. It has, amongst other defects, the following:—

1. *Imperfect combustion* of the magnesium, and consequent uncertainty in exposure.

2. *Dense masses of smoke*, which render it unfit for use in any well-furnished room.

3. *Dirt occasioned* by falling particles of imperfectly consumed magnesium dust.

4. *Heavy shadows.*

5. *Great hardness* and want of delicacy in negatives taken by this method.

The light which we require must, if possible, have none of these objections. It must be cheap, clean, free from smoke, easily measured, and capable of giving soft, diffused lighting. How far we have succeeded in overcoming these difficulties will be for you to judge after the practical demonstration which I propose to give this evening.

Many substances which give extremely actinic rays when ignited, at first sight promise very well; but after very careful and exhaustive experiments, in which I received very valuable assistance from Mr. Elder, who not only gave me the benefit of his advice and experience, but also the use of his laboratory, the conclusion which we arrived at was, that nothing which we tried gave such good results, with equal ease of working, as magnesium. You are probably all aware of the brilliant and actinic light of magnesium, but this actinism can be enormously increased if the magnesium be burnt in oxygen. Captain Abney has very kindly measured the relative actinic value of the lights, and finds that magnesium, when burnt in oxygen, has about twelve times the actinic value of the same amount of magnesium burnt in ordinary air.

We have, therefore, a light of immense actinic value, and one involving no very great outlay at starting. The lamp which we propose to use is of the simplest description, consisting of a small glass flask capable of holding about

* Paper read and demonstration given at the Camera Club on Thursday, November 12th, Captain Abney in the chair.

two litres. This is first filled with water, which is then displaced by oxygen from an ordinary pressure bottle; by this means the oxygen runs no risk of being adulterated (if I may use the expression) with air.

I will now fill the flask to illustrate my meaning. It is advisable to have a small quantity of water in the flask, for reasons which I will explain later. The only other piece of apparatus is a cover with a rod attached for holding the wire. The most convenient method is to make a small coil of the wire of the length required; to the end of this a piece of string is attached as a fuse, the string is lighted, and wire and fuse inserted into the flask. The oxygen causes the string to burst into flame, the magnesium is ignited, and a light of remarkable actinic power is the result; the actinic value of the light being far greater than its apparent brilliancy, owing to the richness of the ultra-violet rays, which are caused by the exceedingly high temperature at which the magnesium is burnt, and the consequent shortening of the wave-lengths of light.

You will observe that there is practically no smoke, none of the dense volumes which are caused by a flash-light, but what little smoke there is is kept within the bottle, and is rather advantageous than otherwise, as it helps to soften and diffuse the light.

The amount of light required is of easy adjustment. Having once arrived at the necessary amount for a correct exposure, with a definite stop and at a certain distance from the object, it is a perfectly simple matter of calculation to ascertain the requisite amount of wire to be used with a smaller stop or at a greater distance, or with plates of different rapidities.

We thus claim to have satisfied all the requirements mentioned before. viz., it is cheap, clean, free from smoke, easily measured, and capable of giving soft, diffused lighting.

For portraiture, we find that the evenness of illumination is best effected by suspending the lamp, and causing it to swing during the time that the light is burning; by this means all heavy shadows are avoided, and a perfectly evenly-lighted picture can be obtained.

The first picture to which I wish to draw your attention was taken with the lamp stationary. You will observe that there is a heavy shadow; in the other cases, where the lamp was allowed to swing, you will notice that the shadows are beautifully soft; and to show how easy it becomes to get even lighting, you will observe two sitters one on either side of a screen, both equally illuminated with a single lamp, the amount of magnesium used being about three grains, and the distance of the light from the sitters fifteen feet. This was taken in the studio, and the white blinds behind the lamp and a white cloth, which was thrown on the floor, materially assisted the lighting. The expense of this light cannot be considered exorbitant, therefore, as the cost of magnesium and oxygen combined was less than a farthing.

The swinging of the light is a very important feature, both from an artistic and economical standpoint, as not only do we get a roundness and delicacy of lighting unobtainable in any other way, but one lamp is sufficient; whereas, with ordinary flash-light, it is found necessary to have several lamps to get anything approaching a fair result.

With the flash-lamp it is impossible to get this swing, and other methods have been resorted to for obtaining similar results, the most successful, probably, being the use of movable mirrors or reflectors, by the aid of which it was attempted to get diffused lighting, but the results are in no way comparable to the effect produced by the swinging light or lamp. Many workers have used magnesium with fairly good results, both in portraiture and in interior photography, and some attempts have been made to utilise oxygen in conjunction with magnesium; but no one seems to have realised the enormous actinic value which results from the proper method of ensuring the proper combustion of magnesium in pure oxygen. How great that actinic power is I shall be able to demonstrate later on.

This method of lighting seems to hold out promise of being of very great value, not only to the professional photographer, to whom a cheap and efficient artificial light would seem to be absolutely indispensable, if we are to have many months of such gloomy and miserable weather as we have lately been experiencing, but also to the amateur, who, having no studio, is practically debarred from indulging in his favourite pastime for about six months in the year. He will now be able to enliven his winter evenings by arranging charming "at-home" pictures of his wife and daughters in their own drawing-room, and thus give us natural and pleasing pictures, free from the stiffness and constraint which seem to be almost inseparable from the studio.

On looking round these walls, one cannot help thinking how useful Mr. Robinson would have found it in securing pictures for his studies of artists at home.

To the doctor, the surgeon, and the engineer, the possibilities it holds out seem to be of the very highest importance, and as we have distinguished members of each of these professions present to-night, we shall doubtless hear their views on the subject. It is possible, also, that it may prove of great value to those who make a special study of photographing pictures, as the difficulties of getting suitable lighting for this branch of photography are often very great.

I stated earlier in my paper that no one seemed to have realised the enormous actinic value of this light, and in proof of this I would point out that no one appears to have grasped the power it gives of photographic printing. I have here a platinum print which was exposed to this light for twenty seconds only, with a consumption of two grammes of magnesium powder; the picture is fully exposed, and in certain respects is superior to any result that can be obtained from the same negative by printing in ordinary daylight.

We will now proceed to print two cabinet negatives by the aid of this light.

I have a tin of platinotype paper which has not been opened; before placing the paper in the printing frames I should like some of you to examine the paper to see that it has not been already exposed—I believe this is the usual method with other conjurors. We will now turn up the lamp and expose the frames to the light, and if some member with a stop-watch will take the time, it will be an interesting test.

You see now that the paper is fully printed, and I understand that the stop-watch gives the time of exposure as fifty-five seconds, which is certainly rather quick work compared with daylight printing.

London and Provincial Photographic Association.—December 31st, "Warm Tones in Lantern Slides"; January 7th, a paper by Mr. P. H. Newman on "Some Recent Exhibitions." Visitors are invited.

## PREPARING STRONG FERROUS OXALATE.*

BY C. W. MILLER.

The strongest form of oxalate developer, made by dissolving ferrous oxalate in potassium oxalate, is not as much used as it deserves to be, the explanation of which, no doubt, is to be found in the very considerable amount of trouble entailed in the ordinary manner of preparing it. Thus, two distinct procedures are required: first, the precipitation of the ferrous oxalate; then the solution of it in the alkaline oxalate, which operation is not very satisfactory on account of the tendency to oxalation if heat be applied for any length of time. In trying to find a more convenient plan of getting a saturated developer, I hit upon the following, which, I find answers every purpose.

By estimating the quantity of iron actually in solution in different developers, and further by the point (volumetrically, when precipitation takes place) I found that I could not in any way make a developer which should permanently contain over about 0·65 gramme of ferrous oxalate per 10 c.c. Acting on this datum, I took a saturated solution of potassium oxalate, and to it added an excess of the oxalate, which would be sufficient to convert enough ferrous sulphate to make the 0·65 gramme of ferrous oxalate. The excess of the alkaline oxalate so added was gotten into solution by heat, when the iron was added. In this manner, a developer was produced without excess of anything, except the inert potassium sulphate formed in the reaction.

In comparing a developer so obtained with the strongest form of the ordinary one (say that issued by the Eastman Company for their bromides), we find that the latter contains for every 10 c.c. 0·59 gramme ferrous sulphate, which quantity can only give 0·3 gramme of ferrous oxalate, as against at least twice that in a saturated developer.

In practice, the most convenient way to make up is to dissolve the full quantity of alkaline oxalate at once in water, so that the formula reads:—

| | |
|---|---|
| Potassium oxalate ... ... ... | 330 grammes |
| Ferrous sulphate ... ... ... | 135 ,, |
| Water ... ... ... ... | 690 c.c. |

Dissolve the oxalate by acid and heat, then cool until it just begins to be precipitated, then add the crystals of iron at once. After solution has taken place, cool completely as rapidly as possible (I place the containing vessel in cold water), and filter off into closed bottles.

In the above, we have 250 grammes of potassium oxalate which remain in solution, while the other 80·0 grammes are lost in forming the oxalate.

The quantity of water necessary to hold 250 grammes of potassium oxalates in solution is 760 c.c., but we need only take 690 c.c., since the 135 grammes of ferrous sulphate will furnish 60 c.c., the sulphate crystalising with seven molecules of water.

The oxalate of iron is slowly precipitated, after the bottles have stood some time; therefore it is better not to make up a large stock at a time. The formula is calculated to give an excess of ferrous oxatate of 0·15 grammes in each 10 c.c., most of which will remain for a short time in solution. The iron and potassium oxalate are balanced.

* Read before the Photographic Society of Philadelphia.

## PROFESSOR SYLVANUS THOMPSON ON LENSES.

This lecture—of which a report was given in a previous issue—led to the following interesting discussion:—

Mr. G. M. Whipple said he had been much gratified at hearing the reference which had been made to the work done at Kew in regard to lenses, for it ought to be better known that an attempt had been made in this country to create an optical laboratory. He was also very glad to know that the Technical Institute at Finsbury was doing similar work, and he felt sure that, with the appliances they had there, and the leisure at their disposal—not of Professor Thompson, but of the senior students—many most interesting questions in optics might be dealt with, and he hoped solved, which could not be accomplished by those who had other duties allotted to them. The measurement of lenses for microscopes had not come within the scope of their operations at Kew; their work was the examination of telescopes for the Royal navy, binoculars, gun directors—a class of telescope not much known to the general public which had been recently brought out—besides smaller glasses used in the ordinary work of navigation. Again, the sextants which were employed by cadets must bear a certificate, and this had led to increased accuracy in make. There were also certain minor instruments examined, of which he need only mention one, which required a plane surface. The grinding of a plane glass surface was a somewhat difficult operation, and it had not been much required until recently, when they had been introduced and their use rendered compulsory for cadets as artificial horizons in working their sextants. This was a matter of economy to save the waste of mercury, which was somewhat considerable when mercurial artificial horizons were employed. Plane surfaces of blackened glass were therefore introduced instead. These things had been going on for some time, but of late the Kew committee had undertaken the examination of photographic lenses, and he must add to the names of the gentlemen who had been mentioned as laying down the lines on which the work should proceed, that of Major Darwin, formerly director of the photographic department of the School of Military Engineering. He had now retired from the Royal Engineers, and had thrown himself thoroughly into this question of testing photographic lenses. He seemed to have consulted all the authorities he could get at, and had made some very ingenious and beautiful pieces of apparatus for the purpose, amongst them being a modification of Grubb's method of determining the focal length of lenses. It was much larger than Professor Thompson's apparatus, being adapted to test lenses of 6in. diameter and 30in. focal length, and was about 5ft. long and the same height. It proved very satisfactory in use. He regretted that the word "astigmatism" had remained on the prospectus and was kept in use, for it undoubtedly was wrong, but still it was a very convenient term to employ, and he did not know what could be substituted for it, and it was apparently understood by users of photographic lenses. There were other terms as regarded distortion and dispersion which were not altogether correct, and should give place to a more accurate terminology. The point with regard to focal planes, which formed such an important feature in microscopic work, had not come before them in connection with photographic lenses, nor did they use it at all in testing telescopes and binoculars.

Mr. T. R. Dallmeyer said it was very gratifying to find that at last the efforts which were being made to obtain perfection in optical work were to be subjected to critical and scientific examination, which must result in really good work being appreciated. He was particularly interested in what he understood to be a new theory in treating light, as explained in the early part of the paper, and he wished Professor Thompson had developed it further. One of the main things which opticians had to do was, after calculation, to do what he might describe as grinding a lens on paper, and this work, by ordinary processes, was very laborious. He imagined that if the process of which Professor Thompson had only given the brilliant idea were carried out with regard to the central pencils, that process of going through the mill in lens grinding would be greatly facilitated. From the one or two hints which had been given, the method seemed to be simplicity itself. There were one or two other methods of obtaining the nodal points besides those which had been mentioned. He should like to ask if, in particular constructions—one of which he was deeply interested in—one of the nodal points was only radially outside the lens, would such an application be suited to the measurement of the lens as regarded its focus? He understood that, for taking long measurements, such an instrument would be hardly applicable, but that it was chiefly confined to the measurement of lenses where the nodal points were either contained in the instrument, or were very close to it.

Mr. Conrad Beck said he also had been extremely interested in the paper, because he remembered his fearful struggles in endeavouring to work out lenses on the English system, and the delight with which he hailed the Gauss and the German system of reckoning both the signs and the principal planes. Those who had endeavoured practically to work out lenses on the ordinary system, as given in "Parkinson" and such books, would agree with him as to the enormous difficulties there were, which were entirely got rid of when the proper geometrical method of reckoning the signs, and the complete theory of the Gauss points, were brought into work. As Mr. Whipple had said, the chief importance of the nodal points was with reference to microscopic work, and in that case there were some very awkward and difficult considerations. In old days when the achromatic microscope was first introduced, it was understood that some sort of reasonable magnifying scale should be adopted, and an arbitrary scale was taken, in which the inch meant that it magnified a certain amount with a certain tube length; but nobody knew where the tube length was measured from. An American gentleman the other day published a paper in which he tabulated all the various tube lengths as measured by various English and Continental manufacturers, and they varied most enormously. But, even supposing a definite tube length to be taken, the difficulty still remained, because in order to get a magnifying power which should be in any way consistent with changed eye-pieces and object-glasses, it was necessary that low power object-glasses should be mounted in enormously long tubes, and high powers in very short tubes. When using a low power, you then had to have it a long way from the object to begin with, and that difficulty was increased by mounting it in a tube 3 inches or 4 inches long, which in the case of a 5 inch would be simply preposterous. Then, again, supposing that for the sake of scientific accuracy such a plan were adopted, what could be done in the use of a binocular microscope? With the binocular microscope it was essential to have the object-glass as near as possible to the binocular prism, whereas if lenses were mounted on the principle suggested, the low powers, which are the very powers used for binocular work, ought to be mounted a long way from the tube of the microscope. Until, however, this plan was adopted, no really true method of magnification could possibly be established. As a matter of fact, opticians at present were making their low power lenses very much higher in power than they ought to be in order to obtain this standard magnifying power which was adopted as an arbitrary scale. For instance, a modern 4-inch objective was nothing like 4 inches; it was nearer three inches, because its nodal point was too far up the microscope. It was put up to a much higher power to produce the same magnifying power in connection with the same eye-piece. This plan got over the difficulty tolerably, but when you changed the eye-piece you began to find that, although with one particular eye-piece the magnifying scale was tolerably constant—and could be made absolutely constant—when you changed the eye-piece it did not affect different powers in the proper ratio, and the scale was thrown out. Mr. Whipple said the nodal points were not of so much importance in photographic and other optical lenses, and he was quite right in saying that their position was not of nearly so much importance, but it was extremely important that some means should be adopted which eliminated the distances between the nodal points in measuring the focal length of optical instruments.

Professor Thompson, in reply, said Zeiss's way of getting over the difficulty about tube length was not quite as Mr. Beck had stated, because Zeiss distinctly attempted to regulate the depth to which the eye-pieces were to be plunged down, so that they should not overlap in the same way as in the old arbitrary scale. Whether he was successful in carrying that out with very low powers he could not say. Mr. Whipple seemed to give no hope that the practical user of lenses would be content to change the misleading term astigmatism; but what were you to do if you came across a lens which had two defects, and both were called astigmatism? If they meant different things you must give a different name to one of them and he thought you ought to give a different name to the thing which was not astigmatism. Mr. Whipple and the Kew authorities ought to invent a name, and then everybody would be obliged to adopt it.

The Chairman, in proposing a vote of thanks to Professor Thompson, said that this paper constituted a really important contribution to the knowledge of optical measurements. The instrument which had been shown and explained promised to be very useful indeed in the actual examination and specification of lenses. Hitherto, there had been no accurate method which was easily applicable for finding the constant on which the action of any lens, and still more a combination of lenses, depended. In the ordinary treatment of the properties of lenses in this country, even in scientific text-books, one got no further than dealing with lenses which were not infinitely thin, but which were dealt with as though they were; and he hoped the paper would have a great effect in widening the ordinary optical discussions, and bringing the ordinary theory more nearly into accord with actual practical experience. As yet they had hardly got beyond Newton's optics. What Gauss introduced long ago, the idea of the virtual thickness of the lens, had scarcely been recognised in all its importance in this country, though it was of the utmost value in facilitating the statement of the properties of lenses. One small point in the paper which he thought of some importance was the introduction of a term for what he believed had no name before, which was often referred to in foreign writings as the vertex, and which was here called the pole. Professor Thompson had already made important contributions to optical theory; and he would refer especially to some papers of his which appeared two years ago in the *Philosophical Magazine*, where he showed how very simply the properties of lenses could be expressed by the method he had hinted at in the beginning of this paper—by speaking of the curvature they impressed on the wave front of a beam of light passing through them. In those papers he had treated all the ordinary cases from that point of view with extreme simplicity and beauty, and he hoped this method would be adopted generally in the ordinary treatment of optics.

The vote of thanks was carried unanimously, and the meeting adjourned.

---

"The Curse of the Camera" might well form the title for a powerful article in a slashing review; for the way in which private photographs are made public, and the manner in which unsuspecting persons are mercilessly "kodaked," and then held up to ridicule, demands a vigorous protest against such social misdemeanours. A case of this kind came under my personal knowledge only the other day. Some time ago, a few of us who were staying down in the country, having nothing particular to do, devised a number of groups for a clever amateur photographer. These were in all kinds of quaint costumes and odd disguises, and photographed solely for those who took part in a harmless bit of tomfoolery. By some extraordinary chance, one of these pictures reached the other side of the Atlantic, a newspaper reporter got hold of it, and it was made the subject of a violent tirade on "the vanity of authors and artists" in an American journal. The most amusing thing about the article is that the whole thing is taken seriously, and that the people, who were so thoroughly disguised as to be unrecognisable by their friends, are written about as if they were absolute portraits. Everyone has been greatly amused at the way in which the scribe has been sold.—"The Bystander," in the *Graphic*.

## Notes.

At the end of every year a large number of subscriptions to the Photographic News expire, and we trust that those of our readers whose subscriptions thus come to an end may be induced to renew at once, so as to prevent any interruption in their reception of the paper. A twelve months' subscription for any place in the United Kingdom is now reduced to 10s. 10d. For any country in the postal union, to 13s. 0d.; and for India, China, &c., 15s. 2d. As indicated in our last number, the publication of the paper at the beginning of the new year will be transferred to Messrs. Alexander and Shepheard, 21 and 22, Furnival Street, Holborn. E.C., to whom all subscriptions can be sent and made payable, except such as belong to the present year, which must be paid, as heretofore, to Messrs. Piper and Carter, 5, Furnival Street, Holborn, E.C.

The popularity of photography is constantly brought to mind both in romance and reality. Both writers of books and playwrights are finding out how useful a photograph becomes as a means of identification, in order to compromise the hero or heroine, or in some other way to give purpose or probability to the story which he tells. Not long ago, in a play which had a short run at one of the London theatres, a detective camera was constantly *en evidence*. It is true that it was used in all sorts of impossible ways—by gaslight, for example; but these little artifices are allowable on the stage. The author probably knew no better, and the audiences—unless they were photographers—had no suspicion of his ignorance. In another play—"Gloriana"—which is now being acted, a great deal of the argument depends upon the efforts of the hero to get back a photograph which he would not care for his bride to see. And in that drama, which might be called "The Great S-pink Pearl," recently played before crowded houses at the Royal Courts of Justice, a photograph played the leading part. Photography has, indeed, much to answer for in placing in the hands of dramatists, novelists, and lawyers—whose business it is to unravel problems of human life—a new and formidable weapon.

Photography, indeed, played a very important part in what is known as the Pearl Mystery case. Both the plaintiff and the defendant—or, at least, one of them—appeared to be continually going to have their photographs taken, and it was admitted by the defendant that one of the photographs was advisedly taken to see how her jewels would "come out." Mr. Justice Denman remarked that the photograph did not give a very good idea of the now celebrated pearls, and the wearer was of the same opinion. But what else could have been expected? Unless the pearls were of the size of raspberry tarts, they would be quite insignificant in a photograph. The iridescent light emitted from a pearl would also render it a very difficult subject for the camera. No photographer has ever yet narrated his experience of photographing precious stones. It might prove interesting. In the case of a big diamond, for instance, worn in the shirt front of a millionaire, we should fancy the owner would have to sacrifice himself. To do the diamond justice, an exposure far less than that wanted for the millionaire's features would suffice. The portrait might result in representing the gentleman as a sort of ghostly negro, but he would always have the satisfaction of showing it as a proof of his self-denial so that his diamond might have fair play.

The *Scientific American* publishes this month two engravings from photographs which are more curious than pleasing. They are pictures of the Tocci Twins, in one of which the youths are seen *in puris naturalibus*, and in the other fully clothed. We write of them in the plural, because they have two heads and four arms, but they possess only one body, and one pair of legs, and as each leg is governed by a different brain, they are not able to walk. The value of a photographic picture instead of a drawing of such a subject is well seen in these pictures. We recognise them at once as the work of the camera, although there is no word to that effect, for there is a life likeness about the pictures of this curious "sport" of nature which is unmistakable.

The lecture of Dr. Gill, the well-known Cape astronomer, on "An Astronomer's Work" has been published in the *Observatory*, the concluding portion appearing in the current number. Of especial interest, as showing the services which photography has rendered to astronomy, is the curious phenomena which a photograph of the nebulæ revealed when the exposure was lengthened. Dr. Gill showed for the first time in England a photograph taken by Professor Pickering in the clear atmosphere of the Andes, of the portion of the sky including the three principal stars in the belt of Orion and $\beta$-Orianis. The lens used was of short focus, and the exposure was six hours. Parts, of course, were hopelessly over-exposed, but faint ramifications were made visible which had never before been suspected. This photograph, taken in conjunction with the photographs of the nebulæ by Mr. Roberts, leads Dr. Gill to think that the nebulæ are in a condition of stellar evolution, and confirm Laplace's theory as to the condition of the early existence and growth of the sun.

Surely the most bitter revenge disappointed love can conceive is contained in the plan adopted by a lady, the plaintiff in a recent case of breach of promise, who, incensed by the conduct of the faithless one, sent him back his photograph with the eyes carefully cut out. In the days of witchcraft, it was believed that the witch, by sticking pins into a waxen image of the bewitched person, could inflict terrible agony. Had the lady some idea of this kind, or did she desire the gentleman to infer that she would like to scratch his eyes out?

It is curious that so few women have gone into photography professionally—we mean as operators in the studio. In the old days the work undoubtedly was most exacting, and on a busy day an operator rarely had a chance of sitting down from morning to night, while the dark room operations were tedious and exhausting. Dry plates have changed all this, and there is nothing to prevent a woman embarking in the business. It is not that they have not the ability, and there is scarcely an industry once entirely absorbed by men which women have not invaded. Wood-engraving, like photography, has very few feminine votaries, and yet one has to chronicle the curious fact that the most skilled wood-engraver of drawings of machinery in the United States is a lady. The *Industry* (San Francisco) says that the engravings of machinery of this lady, published during the year by the Industrial Publishing Company, and numbering about a hundred, have never been excelled.

## LEEDS INTERNATIONAL PHOTOGRAPHIC EXHIBITION.

By Our Special Commissioner.

[concluding notice.]

The classes devoted to portraiture are not so striking as at Glasgow, and many strong men—that is to say, strong in portraiture—who exhibited in the city over the border are not represented at all at Leeds. Messrs. Window and Grove send excellent examples of their well-known work. The best is a portrait of Ellen Terry as Lady Macbeth. Mr. Winter, of Derby, is represented by several portraits of graceful ladies treated in his well-known artistic style, but they also plainly show to the experienced eye the fault of over-elaboration of the brush-work on the prints. Of course it pays, and those who are not in the "know" pronounce them the finest portraits in the Exhibition. The photographic work is really so good that I should very much like to see more photograph and less paint. "Young Heads," by Mr. J. W. Jenkins, exhibits admirable work for an amateur. Mr. Vanderweyde's artistic group of Dorothy Dene and her sisters has received special honour, for it carries off a gold medal, and, as if this were not enough, a very perfect bromide enlargement of the same subject has obtained a silver one also. Mr. Harold Baker's work always gives me great pleasure, for its merit is due to his artistic treatment of the sitter, and the simplicity of the means he employs in the production of his best pictures. There is no theatrical straining after effect, and no over-elaboration of impossible backgrounds. I wish the same could be said of a group of two graceful ladies attired in light drapery. The quality of the photograph is everything that could be desired, but a painted doorway upsets everything. The light is supposed to be coming from it, but the light on the figures comes in a totally different direction. Mr. Warneuke has taken a silver medal for his large portraits, and he deserves it. Most of his pictures were shown at Glasgow, but as they were exhibited this year for the first time, they come within the regulations affecting prior awards.

Prince Ruffo did not quite comply with the conditions, which demand a set of four portraits. Two of his subjects could scarcely be called portraits. One was the "Holy Martyr," and the other "The Virgin and Child." The other two pictures, however, fairly might be classed under the head of portraiture, for, though scarcely portraits in the ordinary sense—for they are quite art studies—still they were taken from life, and that certainly cannot be said of the others. These two heads are so grand in light and shade, and so distinctly original in treatment, that the judges did well when they awarded them a special silver medal. We want more men like Prince Ruffo, with strong art instincts and leisure to follow them, in order to break up the conventionality which is the curse of all art, and is the particular bane of photography.

The pastoral photographs, and particularly the pictures of animals, are unusually good at Leeds. Mr. Jean Hallé and Mr. Carl Greger run each other very close for first positions, and, though the latter has carried off the higher award, perhaps stricter justice would have been done if the awards had been made equal. It may have been that there was a greater variety of subject in the two sets furnished by Mr. Carl Greger to give the balance in his favour. The "Return from Ploughing" is perhaps the best of this gentleman's work, though all are so good that it is difficult to select. Mr. Jean Hallé is represented by "Sheep Studies" only, but they are strikingly original in lighting. In one picture fan-like rays force their way through the foliage of the trees in the distance, but are so filtered by its thickness that only silver threads find their way here and there in the foreground, and touch the backs of a flock of sheep huddled together nearly in the centre of the picture. In another, the low evening sunlight comes from behind a clump of dark trees and floods the middle distance, touching, at the same time, the backs of the sheep reposing in the foreground. Mr. B. Alfièri is also very successful with his cattle studies. One certainly deserves notice. A sheep has strayed from the flock, and is drinking from a shallow pool quite in the foreground. Some tall trees cast their shadows in the water, and so bring the focus of light just where the sheep is quenching its thirst, and so fixes the attention of the beholder on the principal incident in the picture. "Against the Sea Wall" is also a striking picture by the same gentleman. A flock of sheep stand out dark against the sky, for the camera has evidently looked up at them, and monotony of outline is prevented by a horse that towers up above them, and looms out still more darkly. Mr. R. Terras has departed from silver, and at last taken to platinum. Nearly all his pictures, however, are too heavy in the background, and there is in consequence want of relief in the figures, which, after all, form the principal feature in his pictures. "His Country Cousin" knows how to manage the obedient swain, who is holding a skein of yarn. She is winding his heart-strings, as well as the worsted, round her fingers; but surely the cigarette in his mouth is out of place, for he is not smoking. Evidently the damsel thinks so, if one may judge by the expression on her face. "News of the Battle" is the best of the pictures by Mr. Terras, and his prevailing fault of blackness is absent. The pose of the young woman who kneels at the feet of the old lady is good, but the face lacks expression. The old dame is very natural, and the upraised hand conceals the face, and so there is room for the imagination. The pose of the man in the background, who evidently has broken the news to her, is natural and unaffected.

The Rev. A. H. Blake has produced two simple little pictures, called "Helping Mother," and "Good News." They are quite in the style of Mr. Gale. The incidents are simple enough. In one a little child is struggling with a big broom, whilst the mother is busy at the pump; and in the other a girl is sitting on the edge of a stone trough that catches the water from the pump, and is eagerly reading what may easily be mistaken for a love letter. Perhaps it was a real one pulled out of the pocket after all. At any rate, the expression is all right, and that is the most important point.

Mr. F. Whally has made a serious attempt in his picture, "Worn Out." A child has restlessly tossed his arms about; the father has been watching by the bedside, but has apparently dozed off, and the newspaper has dropped from his listless hands. An old book shields the light of the well-burnt candle from the eyes of the sleeping child. The rude cottage interior has been well planned, and the accessories are not obtrusive. There are a few toys on the chair by the side of the bed, and a faint light is struggling through the small casement at the back. As the light of the candle is screened from the face of the child, where does the light come from which gives delicate light and shade to the infant and his surroundings? It comes well from the front, and is high up, and there is plenty of it. No, it will not do; it is the regular studio light, for there are not usually skylights in cottages as well as casement windows. A picture so well planned should have been carried a little farther, and the proper lighting managed somehow.

Mr. Sutcliffe, in addition to several of his well-known pictures, has sent some sunset effects, in which he surpasses himself. This autumn has been a wonderful season for clouds, and he has made good use of his opportunities. "The Flag of Distress" is evidently a picture of one of the many wrecks which took place during the memorable gale a short time ago. I do not remember if the ship was lucky enough to get off again, but, apparently, she is hard aground on the shallow shore near Whitby, and, unless the next tide is merciful, she will have a short shrift.

Mr. Lyd. Sawyer has sent a number of pictures which well exhibit the versatility of his brain. Many of them are well-known subjects that have been frequently described before; but there are several in the instantaneous class that are new to me. The best is, perhaps, the one called "Towing up Stream." The murky gloom which usually distinguishes the Tyne is relieved by the silvery foam from the paddles of the tug, and the high-level bridge forms an important feature in the background.

So many of the pictures have been shown at various exhibitions, and have, therefore, been described before, and the space at my disposal in these pages is not sufficient to notice all the pictures of merit that are new to me, so I am compelled to be content to select here and there those that particularly call for remark. The lantern slides form a very large class, but I am compelled to say that the amateurs have beaten the professionals in the general quality of their work. The Leeds Society has particularly distinguished itself in this department of photography, and there is a quality about the work sent in by its members that is unusually striking.

Considerable taste has been shown by several Yorkshire firms in the arrangement of their trade exhibits. Messrs. Pearson and Denham exhibit an ingenious apparatus for the making of lantern slides. The special feature is the ease with which any part of a negative can be brought into the right position for copying. Mr. W. Middlemiss, of Bradford, has made some further improvements in the apparatus invented by Professor Barr, of Glasgow, and Professor Strand, of the Yorkshire College, for making scientific demonstration on the screen very simple. It is impossible to describe this apparatus without diagrams, however. Mr. J. D. England demonstrates the efficacy of his celluloid films by some delicate negatives exhibited with the transparencies. The manipulation is faultless, and there is not the faintest trace of halation in any of them.

In addition to the large number of works sent in for competition, there is a quantity of important pictures, marked "Not for competition," which help immensely in completing the effect of this really imposing show. The Autotype Company are large exhibitors, and the series of Academicians, by Mr. Ralph Robinson, have been lent at the request of the committee, and attract a considerable amount of attention.

In conclusion, I cannot help saying the Leeds Exhibition deserves a big financial success, for everything has been done to make it as complete as possible. The Municipal authorities were most liberal with their medals, and, in addition to nearly forty silver, and I don't remember how many bronze ones, placed four gold medals at the disposition of Messrs. England, Gale, Pringle, Cembrano, and Blanchard, who were selected to act as judges. These gentlemen evidently determined, however, not to make the awards so cheap, and only gave two out of the four gold, and twenty out of the thirty-seven silver medals, and not quite all the bronze medals. I most earnestly hope that, at the next exhibition held out of London, the classes will be given up altogether, for only by this means will the value of the awards be properly appreciated.

## PHOTOGRAPHY OF THE HEAVENS.*

BY CAMILLE FLAMMARION.

Skaenfeld's catalogue of the southern hemisphere gives the position of 133,699 stars. Mr. Gould, director of the observatory at Cordoba, Argentina, published an atlas of the southern hemisphere some years ago, but it registers those stars only that are visible to the naked eye.

These efforts represent much patient labour, but they can never hope to give what may be expected from photography. In fact, instead of meridian observations by a great number of observers, all differing one from the other in the recognition of the various magnitudes of the stars, and in methods of relating their positions; instead of innumerable transcriptions, innumerable calculations and reductions, and gathering and disseminating of the information along a long period of years—instead of this there will be undertaken an exact photograph of the heavens, and this not only of stars up to the ninth magnitude, but those of the eleventh, twelfth, thirteenth, and even fourteenth magnitudes; and these lesser magnitudes will not add difficulties further than the exposure of the sensitive plate for a longer time.

Everybody knows that stars beyond the sixth magnitude are invisible to the naked eye, and that the term "magnitude" applies simply to the apparent brilliancy of the stars, those of the first magnitude being the most brilliant, those of the second a little less brilliant, and so on, those of the sixth being the last that can be seen with the naked eye. Here is a table showing the probable number of stars of every magnitude up to the fourteenth:—

| Magnitudes. | No. of Stars. |
|---|---|
| First ... ... ... ... ... | 20 |
| Second ... ... ... ... ... | 59 |
| Third ... ... ... ... ... | 182 |
| Fourth ... ... ... ... ... | 530 |
| Fifth ... ... ... ... ... | 1,600 |
| Sixth ... ... ... ... ... | 4,800 |
| Seventh ... ... ... ... | 13,000 |
| Eighth ... ... ... ... ... | 40,000 |
| Ninth ... ... ... ... ... | 120,000 |
| Tenth ... ... ... ... ... | 380,000 |
| Eleventh ... ... ... ... | 1,000,000 |
| Twelfth ... ... ... ... | 3,000,000 |
| Thirteenth ... ... ... ... | 9,000,000 |
| Fourteenth ... ... ... ... | 27,000,000 |

The stars of the fourteenth magnitude are visible through the best astronomical instruments. It will be seen that the total of these fourteen magnitudes exceeds 40,000,000. To try to catalogue this celestial army would be not only a superhuman task, but absolutely beyond realisation; for errors would creep inevitably into such a number of observations, as well as into their reductions, their transcriptions, and their places upon a map. Years and years would not suffice, and while the work was in progress the stars themselves would change their positions in space, for each of them is animated by its own motion, more or less swift.

* Continued from page 863.

Now, photography can effect this properly and in the simplest manner, thanks to the perfection to which the art and its methods have been brought. And do you know how long it would take to perform this gigantic task, to erect this imperishable monument of astronomy? Thirteen minutes! Following are figures showing with substantial accuracy the duration of exposure necessary to get an impression of the stars of various magnitudes upon the new gelatine plates :—

| Magnitudes. | Exposure. Min. | Sec. |
|---|---|---|
| First | 0 | 0·005 |
| Second | 0 | 0·01 |
| Third | 0 | 0·03 |
| Fourth | 0 | 0·1 |
| Fifth | 0 | 0·2 |
| Sixth | 0 | 0·5 |
| Seventh | 0 | 1·3 |
| Eighth | 0 | 3·0 |
| Ninth | 0 | 8·0 |
| Tenth | 0 | 20·0 |
| Eleventh | 0 | 50·0 |
| Twelfth | 2 | 00·0 |
| Thirteenth | 5 | 00·0 |
| Fourteenth | 13 | 00·0 |

Thus, five one-thousandths of a second are sufficient exposure to photograph a star of the first magnitude, a half second's exposure takes a picture of the smallest stars visible to the naked eye, and thirteen minutes are needed to photograph those of the fourteenth magnitude. A plate 24 by 30 centimetres covers five astronomical degrees. If, at a given moment, 8,000 telescopes arranged for photography should be opened all over the earth, and turned upon 8,000 points of the sky, all the points being agreed upon in advance, the 8,000 plates would have photographed the entire heavens, and registered the 40,000,000 stars of which we spoke above. Placed side by side in their proper positions, these 8,000 plates of five degrees each would represent the 41,000 astronomical degrees of which the surface of the heavens is composed.

This kind of instantaneous photography of the heavens would be ideal, but it would not be possible, because, first, at any given moment night extends over less than half the globe; and second, because the atmosphere is never perfectly clear; and last, because these 8,000 instruments would involve an immense expense, a matter which it is simpler and more practicable to reduce to a minimum. The work will probably be divided among the following observatories in proportion to the number of plates set against each :—

| Observatories. | No. of Plates. |
|---|---|
| Paris | 1260 |
| Bordeaux | 1260 |
| Toulouse | 1080 |
| Algiers | 1260 |
| Greenwich | 1149 |
| Oxford | 1180 |
| Helsingfors | 1008 |
| Potsdam | 1232 |
| Rome | 1040 |
| Catane | 2008 |
| San Fernando | 1260 |
| Cacubaya | 1260 |
| Santiago | 1260 |
| La Plata | 1360 |
| Rio Janeiro | 1376 |
| Cape of Good Hope | 1512 |
| Sydney | 1400 |
| Melbourne | 1149 |

There will be about 22,000 plates of two degrees each, arranged so that their borders shall overlap each other sufficiently to register all the stars without fail, and thus in time cover the whole heavens. The work will probably be completed in five or six years.

Thus, nineteenth century science will bequeath to posterity an invaluable and imperishable statement as to the sidereal heavens, which in future centuries will serve as a certain basis for the solution of the great problem of the constitution of the universe.

The human eye certainly is an instrument admirably adapted to its purpose. How transparent is this living crystal, how delightful are its hues, what depth it has, what beauty! It is life, passion, light. Close the eyes, and how much of the world remains? And yet the lens of the photographer's camera is a new eye that gives the finishing touch to ours, that surpasses it, that is more marvellous still. This giant eye is endowed with four important advantages as compared with our eye: it sees more quickly, further, longer, and—inestimable faculty!—it fixes, prints, preserves what it sees. It sees more quickly. In the half-thousandth part of a second it photographs the sun, its spots, its whirlwinds, its flames, its mountains of fire, in an imperishable document. It sees further. Turned at darkest night toward any part of the heavens whatever, it discovers, in the atoms of the Infinite, stars, worlds, universe creations that our eye could never see by any possibility, no matter how powerful a telescope were brought to bear. It sees for a longer time. What we cannot contrive to see after several seconds of attention, we can never see. This new eye needs but to look sufficiently long; at the end of a half hour it will distinguish what it did not see before; at the end of an hour it will see better still, and the longer it remains directed toward the unknown, the more completely will the eye possess it, without fatigue, and always better. And it preserves upon its retinal plate all that it has seen. Our eye retains images but an instant. Suppose, for example, that you kill a man at the moment when, quietly seated in his chair, he has his eyes open and directed toward a bright window. (There is nothing improbable in the supposition upon a planet where all the citizens are soldiers, and kill each other in all manner of ways at the rate of 1,100 daily.) Then suppose that you tear out his eyes (I should have said that the hypothesis involves dealing with an enemy), and that you immerse them in a solution of alum; these eyes will then retain the image of the window, with its transverse bars and its light-spaces. But in a normal state of things our eyes do not retain images—there would be too many of them besides. The giant eye of which we speak holds fast everything it sees. Its only need is a change of the retina.

Yes, the artificial retina sees more quickly and better. And, by virtue of a property wholly lacking in the human eye, it penetrates abysses where we do not and never could see anything. This is, perhaps, its most astonishing faculty. Place the eye, for example, at the eye-piece of a telescope whose object-glass measures thirty centimetres in diameter; such an instrument is the best for practical observations. With this glass of thirty centimetres diameter and three and a-half metres in length, we may discover stars to the fourteenth magnitude, that is to say, about 40,000,000 stars of all kinds.

Now replace our eye by the photographic retina. Instantly the most brilliant stars beat upon the plate and mark their likenesses there. Five one-thousandths of a second suffice for a star of the first magnitude, one-hundredth for those of the second, three one-hundredths for those of the third, and so on, according to the proportions expressed above. In less than one second the photographic eye has seen all that we could perceive with the naked eye. But this is as nothing. Stars visible only through the telescope also come and beat upon the plate and thereon inscribe their images. Those of the seventh magnitude take a second and one-third to make their impressions on the plate, those of the eighth need three seconds, those of the ninth eight seconds, those of the eleventh fifty seconds, those of the twelfth require two minutes, those of the thirteenth five minutes, and finally, those of the fourteenth, thirteen minutes. If we have left our plate exposed for a quarter of an hour, we shall find photographed upon it all the region of the sky toward which the telescope was directed, all that this region contains, all that we could have contrived to discover with infinite difficulty by a series of very arduous and long-continued observations. But we have merely entered upon the marvellous. Let the photographic eye continue to observe in place of the human eye; it will penetrate the unknown. Stars invisible to us become visible to it. After an exposure of thirty-three minutes, stars of the fifteenth magnitude will have finished their task of impressing the chemical retina and placing there their images. The same instrument which, to the human eye, reveals stars of the fourteenth magnitude, and which would register about 40,000,000 stars in the entire heavens, discloses to the photographic eye 120,000,000, including only those of the fifteenth magnitude. It could reach forth to the sixteenth, and throw before the dazzled admiration of the observer a luminous maze of 400,000,000 stars.

Never before in all the history of mankind have we had in hand the power to penetrate so deeply into the abysses of the Infinite. Photography, with its recent improvements, takes a clear picture of every star, no matter what its distance, and sets it down in a document that can be studied at leisure. Who knows if some day, in the photographic views of Venus or Mars, some new method of analysis may not discover to us their inhabitants? And its power stretches forth to the Infinite. Behold a star of the fifteenth or sixteenth, even seventeenth magnitude, a sun like our own, separate from us by so great a distance that its light requires thousands—perhaps millions—of years to reach us, notwithstanding its unheard-of velocity of 300,000 kilometres a second; and this sun lies at such a depth that its light, so to speak, reaches us no longer. The natural eye of man never would have seen it, and the human mind never would have guessed its existence but for the implements of this modern art. And yet this feeble light, come from so far, is sufficient to make an impression upon a chemical plate which will preserve its picture unalterably. And this star might be of the eighteenth or the nineteenth magnitude, and beyond, so minute that the human eye could never see it, even aided by the most powerful telescopic appliances (for there will always be stars beyond our range of vision); and yet it will come and hurl its slight ethereal arrows on the chemical plate set up to await and receive them.

Yes, its light will have travelled during millions of years. When it started the earth did not exist, the real earth with its humanity; there was not a single thinking creature on our planet; the genesis of our world was in the process of development; perhaps only in the primordial seas that enveloped the globe before the uprising of the first continents, before the primitive, elementary organisms formed themselves upon the bosom of the waters, preparing slowly the evolutions of future ages. This photographic plate takes us back to the past history of the universe. During the ethereal flight of this ray which comes to-day to beat upon the plate, all the history of the earth has been accomplished, and in this history that of humankind is but a single wave, an instant. And during this time the history of the distant sun which photographs itself to-day has been accomplished also; perhaps it became extinct long since, perhaps it is actually out of existence.

Thus, this new eye which transports us across the Infinite enables us, at the same time, to trace the periods of past eternity. Yes, many of these far-away suns that we are taking such pains to photograph no longer exist. The end of the world has come to them as it will come to us; and the luminous couriers that they sent us before dying travel for ever. Astronomy plunges us into the insoluble mystery of the Infinite and of Eternity, and therein lies its grandeur.—*New Review.*

## INCANDESCENT GASLIGHTS.

An interesting lecture upon this subject was given last week at Westminster by Mr. Moeller, Admiral Sir E. A. Inglefield, K.C.B., presiding. The lecturer commenced his address by pointing out that in past years Dr. Auer was a pupil of Prof. Bunsen, in Heidelberg, and that, under that eminent man, he studied the earths of the rare metals.

Dr. Auer made zirconium and lanthanum his special studies, and he soon found out that the heat-resisting property of these earths was enormous, and he worked out a combination by which several of them used in a hood of cotton produced, with a small Bunsen flame, a brilliant light. It was in this form that the incandescent light was introduced into England.

When first supplying the English public with a mantle or hood, this mantle was saturated with a fluid made out of the above-mentioned rare earths in such a proportion that these mantles gave a brilliant white light for about 800 hours. One of the chemicals used at that time, however, could only be obtained in very small quantities, and in supplying lamps in England for about three months, Dr. Auer ran out completely the stock of that material. So the Company had to fall back upon a combination of rare earths which would give a perfectly good light for 200 to 300 hours, but after that time the light was only very little better than that given by an ordinary argand burner.

It has since been found that the metals required are so plentiful that any amount can be obtained. Under the auspices of the Incandescent Gaslight Company a sure advance has been made, as may be judged from the fact that from September to December last year nearly 20,000 lamps were sold. The mantles now supplied have a capacity of 25 to 28 candle power, and they would burn without much decrease in light for about 800 hours.

To-day I have to draw your attention to an invention which has been made by Dr. Auer, which will make the system one of the most economical and efficient amongst the various ways of illumination.

Dr. Auer has succeeded in finding a rare earth whose fire-resisting power is so great that no known heat is able to melt it, and this material, in connection with the mantle, produces an incandescence that is absolutely startling. To begin with, I have an ordinary Bray's burner, No. 6, and, with a pressure of one inch, this burner passes per hour 7·5 feet of gas, and, with our London gas, this would give no more than 14-candle power of light. The next burner I have here is a large argand burner. This gives at one inch pressure, with 7·5 feet of gas per hour, 26-candle power; so you see that the consumer gains already 12 candles from the same amount of gas if he uses an argand instead of a Bray's burner. A third burner is our Welsbach burner, as sold up to the present moment. This burner passes 3 feet of gas, and with this 3 feet of gas gives about 25-candle power of light, and the durability of the mantle I would average at 800 hours. Here you find already that with our lamp you get an equal amount of light as with the argand burner, with the difference that we use only 3 feet of gas where the ordinary argand burner uses nearly 8 feet.

The next lamp is our new light which we are able to introduce to the public. This burner passes 3 feet of gas, like our old Welsbach burner, and the candle power obtained on the photometer is equal to 60 candles with one inch pressure. The mantle that is on this burner will give this light for from 2,000 to 3,000 hours.

I have compared up to now our light only as regards illuminating power, and if you consider the cost of the same you will find that though, at first, the expense for putting up our lights is considerably more than, for instance, Argand or Bray's burners, or any other gas burners in the market, yet the saving of gas with our light is so enormous that the first outlay pays itself in a very short time indeed; and we have found that all those who have studied our light carefully, and who had a sufficiently large installation—all these people are in every way satisfied with the light.

The gas companies in general are dead against this light, because with it the consumption of gas is reduced to such an extent that, if the light were generally adopted to-day all over England, it would certainly mean an enormous falling-off in the revenues of the gas companies; but this fear is groundless, because the demand for light would increase, and for this reason gas companies would ultimately be the gainers.

On the other hand, there is at the present moment a very strong feeling among all those who are acquainted with its capabilities to introduce the so-called water-gas. Up to the present moment water-gas has not been successfully worked in England, on account of the various accidents which have occurred with it. But the electric light will ultimately force gas companies to supply the public at a cheaper rate, and the only way of doing this is by introducing water-gas, and if I mention to you that two-thirds of all gas used in the United States is water-gas, and that this is retailed to the consumer at from sixpence to eighteen-pence per thousand feet, giving, at the same time, just as good results as coal-gas, you will admit with me that, in a short time, this system must work its way into favour.

Bath Photographic Society.—At a meeting on the 17th inst. Mr. H. M. Smith discoursed on the kodak form of hand-camera, explaining fully the working details of the several instruments bearing that name. The utility of the kodak was illustrated by a display on the screen of a choice selection of 100 pictures which the lecturer produced by its means.

# Correspondence.

## DR. MADDOX AND DRY PLATE PHOTOGRAPHY.

Sir,—I have only this moment—Tuesday, 4 p.m.—by some unaccountable delay, received the pages of your Friday's issue, containing a further attack on me by Mr. Faulkner. As you probably go to press a day earlier on account of Christmas Day falling on Friday, I fear I may not be in time to crave a small corner in your last journal of this year; I should be sorry if I should prove to be the first to import a controversy into the first journal of the new year.

May not the animosity of which Mr. Faulkner complains as bearing on his friend, Mr. Burgess, be largely due to the language of his chief supporter?

1. Mr. Faulkner says, a "wilful wrong has been done to a deserving man." May I ask, is he not trying to do the same to another person?

2. My article of September, 1871, proves my connection with the gelatino-bromide plates.

3. Mr. Faulkner does not know the work that I had done, nor why only part was stated in my reply to Mr. Taylor's request; therefore his remarks here are futile.

4. The work was not worthless; the jurors' report is a denial of this statement.

5. I deny having the knowledge of any plot to take away any credit due to Mr. Burgess, who has tried to overshadow one who certainly was in the field before him.

6. That the jurors "were wrongly advised." Who says so? Mr. Faulkner! Let it pass.

1. Why am I said to be "the first man who experimented with gelatine associated with silver"? I suppose there was some reason for the conclusion arrived at, viz., that I had done so successfully.

2. "Why is he called the father of the gelatino-bromide dry plate?" Is it not because he was nearly two years in advance of Mr. Burgess?

3. "Why are we said to owe to him more than to any other man for the dry plate of to-day?" Because he started it in September, 1871.

4. "Why was he alone awarded a gold medal by the jurors?" I can only suggest because they saw he was entitled to receive it.

5. "Where did the negatives come from?" From where many others had proceeded—from the hands of Dr. Maddox. Who else should they come from?

Supposing these questions and suppositions have been made that I might answer them, and having very hurriedly done so, I will now ask Mr. Faulkner to be so good as to correct a statement in his previous letter which I overlooked in my former reply, that I tried to sell the process—another untruth. I omitted in my previous letter to note a remark by Mr. Burgess, who says: "If Dr. Maddox had never existed, gelatine dry plates would have been just what they are to-day." Of course, we know the value of a post-date prophet's prediction. I don't remember that any mention was made in the celebrated advertisement of Mr. Burgess using gelatine as the medium. If wrong, I shall be very pleased to be corrected.

Let me hope I have said enough, and not too much for the space at your command. With the compliments of the season, and every apology for thus trespassing so largely on your pages.

R. L. Maddox.

*Greenbank, Portswood, Southampton, December 22nd*, 1891.

Sir,—Dr. Maddox comes forward with the pretence of contradicting misstatements, but he only succeeds in contradicting himself, as I undertake to prove. He says: "It is stated that Dr. Maddox only obtained prints, and not negatives." Just so; and that statement is made on his own authority. It is from his own article of 1871, and if *it is not true*, he is responsible for it. That article and its formula, and that alone, has been the subject of discussion. There is not a syllable in it about negatives, and Dr. Maddox knows that perfectly well. It describes a worthless printing process by development.

Dr. Maddox now says he did produce negatives, and then immediately proceeds to stultify himself by explaining that they were produced by after-experiments and modifications which entirely altered the character of the formula, and which *he never published!* So that Dr. Maddox, in this letter, proves up to the hilt what I say. He gave away the worthless formula, and kept to himself the modifications which enabled him to produce negatives. If he ever did publish those experiments, let him tell us when and where.

The negatives exhibited at the Inventions Exhibition were not, and could not be, produced by his published formula, and I am prepared to demonstrate the truth of this by actual experiment before any photographic society of Great Britain. The fact is, the gentlemen forming the committee of the Maddox testimonial have been misled by statements they accepted without examination, and the attempts which have been made to burke discussion will not succeed.

Now a word about priority, the main pillar of Dr. Maddox's fame. Says the doctor: "I can truly declare that I had never known of any previous gelatine emulsion process, or I should have quoted the same." But he knows it now, and yet he sticks to it that he was the first. We cannot believe the doctor at all, with that article of 1871 staring us in the face. It is his own article, and this letter, that shows to what straits he is reduced, when he is obliged to contradict in 1891 what he wrote in 1871. He then said there was *nothing new* in what he had done. Then he must have known that the same thing had been tried before; and did not Mr. Traill Taylor say, in his editorial, that he had many times suggested substitutes for collodion? And did not Mr. Sutton speak of the proved possibility of using gelatine in emulsions? At that time Dr. Maddox was a constant reader of the journals.

Now, finally, one word about modifications and history. Mr. Pringle, and after him Dr. Maddox, appeal to history. Now the late Charles Kingsley was professor of modern history at Cambridge University, and he resigned his chair because he said he had discovered that history was a pack of lies. Now, I will not go so far as that with the history of photography, but it is not all true, and that which is not true is not history. For example, that author quoted by Dr. Maddox who said, "It did unquestionably exhibit the capabilities of gelatino-bromide," knew nothing whatever about it. He never tried it. He spoke from hearsay gossip, for if he had repeated Dr. Maddox's experiment, he would have seen that it did anything but exhibit the capabilities; it simply smothered them.

And was there ever more arrant nonsense penned by an author than the concluding part of that quotation, "for the gelatine process as given by Dr. Maddox is only *modified*, not altered, by the numerous plate and paper makers of to-day"?

How can you modify a thing without altering it? And is not all the merit or demerit in the modification? A steam engine is only a modified tea kettle; a sharp knife is only a blunt one modified; a philosopher is only a modified savage. And, if you like, the present dry plate is only Dr. Maddox's modified, but all the virtue is in the right modification.

Now, may I sum up the whole argument in a nutshell, and I will put it partly in Dr. Maddox's own words. I can truly declare that I had never known of any previous emulsion processes when I sent out my first advertisement, and if I had, they could not have assisted me, for they were all useless, for want of the modification which I had the good fortune to think of.

J. Burgess.

---

Sir,—Much has been said and much more could be said on this subject, and, knowing a few actual facts of the case, perhaps you will kindly publish the following. In the year 1873, while living at Sea View, I.W., Mr. Burgess sent me a parcel of his new gelatine plates, 9 by 7, and requested me to expose, develop, and print him a number of copies, as he wished to exhibit them that week before the Photographic Society of Great Britain. I did so, and they were exhibited, and many members should be able to testify to this, and I suppose that the Society minutes would show it. Now, sir, can Dr. Maddox or any of his friends produce anything anterior to this in the way of a "useable" gelatine plate? If not, I consider an injustice has been done to Mr. Burgess in ignoring his claim. He told me afterwards, when I asked him what reception he met with, that they laughed him to scorn when he told the members of the Society that gelatine plates would eventually oust collodion in photography. To prove this, I can produce the negative if necessary.

F. J. Matthews.

*St. John's Road Studio, Ryde, Isle of Wight, Dec. 21st.*

---

Sir,—The negatives which Dr. Maddox referred to in his last week's letter, were first introduced to the public in August, 1880—seven years after the invention of gelatino-bromide dry plates by Mr. Burgess.

At this same time Dr. Maddox makes his first claim to the honour of this invention.

I find also, that four persons simultaneously make reference to these negatives: Dr. Maddox, Mr. J. Traill Taylor (who was in America), and the then editors of *The British Journal of Photography.*

It shall suffice for the present to state that, on August 8th, 1880, these negatives were suddenly sprung on the public by *The British Journal of Photography* in the following manner:—

1. In a letter from Dr. Maddox, in replying to Mr. Burgess. "Fortunately, I happened last week to find some of my original negatives, which, through the kindness of one of the editors of this journal, Mr. Bolton, were compared with others found on the shelves of the publishing office, 2, York Street, Covent Garden, *which I had originally sent to Mr. Taylor.* I have now placed one of these negatives *(unvarnished)* on view at the establishment of the Photographic Artists' Supply Association, 43, Charterhouse Square. *It may be of interest as showing the stage at which the process left my hands.*"

2. In an editorial note at the end of the Doctor's letter: "We are pleased to be able to state that we have discovered amongst the accumulation of *curiosities* which cumber the shelves of our editorial office, *two* of Dr. Maddox's original specimens, bearing the date of Sept. 11th, 1871, *and deposited at that time with Mr. J. Traill Taylor.* These two plates prove very conclusively that the gelatino-bromide process, even at that remote period, was far from being the hopeless muddle it is alleged to have been. *The results produced in 1871 by Dr. Maddox are equal in respect of quality, density, and pluck to any gelatine work of to-day.*"

I wish to call public attention to the following most important statement.

With great diffidence, but yet distinctly and conscientiously, I affirm that Dr. Maddox could not at that time have obtained such negatives as those described. Let it be clearly understood what is here meant. At the time referred to, viz., September 11th, 1871, Dr. Maddox's work was altogether incapable of producing such results. Indeed, two years later—that is, in August, 1873—we have further evidence from the pen of Mr. J. Traill Taylor himself, which proves most conclusively that Dr. Maddox's work would not produce such results even at that later period, viz., August, 1873.

After this serious statement, it is probable that Dr. Maddox and his friends will execute a strategical movement to the rear. We shall probably be asked to belive that an excess of bromide and an alkaline developer is a modification of an excess of silver and an acid developer; that a negative emulsion is a modification of a printing emulsion. They will next ask us to believe that a racehorse is a modification of the old wooden horse with which we were acquainted in our childhood.

I would again urge experimentalists to try this wonderful experiment for themselves. They can easily make "Maddox plates" according to the Doctor's directions, which are given below. In order that these plates may have a fair chance, I propose that those willing to try the experiment should do *as I have done*, viz., give one hour's exposure in the camera, with full aperture, in a glass house on a bright day, to any still object. After this trial, it will not be surprising if the opinion be formed that the next exposure had better be one week instead of one hour.

I append to this letter the Doctor's account of his experiment, taken from the *British Journal* of September 8th, 1871, on which alone he grounds his claim. I believe this is the first time it has been reprinted since September, 1871.*

* We cannot afford space to reproduce the article referred to; and for a similar reason we are unfortunately obliged to omit a number of extracts from the same source very kindly sent to us by another correspondent.—Ed.

As far as I know, only one other journal besides the *British Journal of Photography* took any notice of the account, and that was a French photographic paper which was accustomed to take articles from the *British Journal*. If the Doctor's experiment had not been resuscitated by Mr. J. Traill Taylor in August, 1873, for certain remarkable purposes, it would probably have remained buried in oblivion. It will be observed that there is no reference in the Doctor's account to previous experiments of his own, nor to negatives; neither does it appear (judging by the concluding remarks) that he continued them, as he implies he did in his letter published last week. The Doctor will stand or fall by what he published in 1871. Surely he does not expect anyone to take seriously the marvellous compilation he made in 1887 for Jerome Harrison's history.

For the purpose of showing what had been done in the same line with a gelatine emulsion, years before the Doctor published his account, I give the following extract, which appeared in the Photographic News of November 24th, 1865:—"Your correspondent alludes to gelatine and silver held in suspension, with which and more I am fully acquainted, and have been for some considerable time, and I have brought it to a practical issue, and communicated it to the *British Journal of Photography* (Mr. J. Traill Taylor) in October last, with specimens of results, to which they advert in their issue of November 10th. . . . The prints enclosed are from the same batch of paper and solution as those sent to the *British Journal* a month since. The solution keeps well. To-day I have succeeded splendidly with opal glass, so that now I am perfect on paper and opal glass. The field open in this direction is great, *and embraces . . . . also the dry plate process for taking negatives.*"

On December 1st, 1865, the Editor of the Photographic News refers to this statement as follows:—"If Mr. Palmer has found a method of using gelatine with success, the value of his labours will consist in his success, and not in the mere idea of using gelatine, which many persons," &c.

In concluding, I appeal to the *élite* of the photographic world, and even to the ring of which Dr. Maddox was a member. I also appeal to the great body of professional photographers whose rights have been disregarded in this affair. I also appeal to the vast numbers of amateurs who have done so much for photography.

Let justice be done, and may truth prevail.

*Peckham Technical School, Dec. 21st.* J. Faulkner.

[A large amount of correspondence on the above subject is held over for want of space this week.—Ed.]

A Kansas subscriber tells us of a fellow-photographer who will not be persuaded to take a photographic journal, for the extraordinary reason that "editors make money by selling them." This same photographer, our correspondent adds, bought some "Aristo" paper, and, not knowing anything better, manipulated it in the same baths as he used for his albumen printing. He quite failed to see any improvement to be obtained with "Aristo" paper, and consequently discarded it. There is an evident connection between the "fact" and the "fancy" here.—*Wilson's Photographic Magazine.*

Imperial Russian Technical Society.—In addition to the photographic section of this in Odessa, a new society has been formed, the rules of which have received the sanction of the authorities. According to the prospectus, its aims will be: firstly, to further the theoretical and practical phases of photography and its applications, and to diffuse useful information concerning them; secondly, to encourage as much as possible a wider and more varied application of photography to scientific investigation, as being the best of all graphic processes extant; thirdly, to support and arrange amateur scientific and artistic excursions for collecting material for the study of Russia; and fourthly, to photograph ancient monuments, landmarks, noteworthy architectural buildings, &c., appertaining to the history and survey of Russia, and for the promotion of art. Judicial photography has now received official recognition in Russia, and orders have been issued to fit up a part of the fourth story, now in course of erection on the central criminal court in St. Petersburg, as a photographic laboratory and studio. It will be under the immediate superintendence of Mr. Bourinsky, whose exhibits received such eulogiums at the late exhibition.

# Proceedings of Societies.

London and Provincial Photographic Association.

*December 17th.*—Mr. G. W. Atkins in the chair.

Mr. Weir Brown showed some prints on bromide paper toned to a brighter red than had been hitherto obtainable. This was achieved by toning with uranium until all that could be converted was converted, and then removing the silver by Farmer's reducing solution—ferricyanide and hypo.

This was the monthly lantern night, and the proceedings commenced by a representative of the Incandescent Gaslight Company showing a lantern fitted with one of their "Aëro" incandescent lamps. Slides were passed through, and the illumination was judged to be more powerful than, and superior to, oil, though, for large screens, not equal to lime-light.

The usual display of slides by the members was then made, and work by Messrs. H. D. Atkinson, L. Medland (mostly of scenes in Scandinavia and Russia), J. B. B. Wellington, W. J. Rawlings, and H. M. Hastings was shown.

Mr. J. H. Taylor was elected a member.

Camera Club.

*December 17th.*—Mr. A. Stroh in the chair.

Mr. Leon Warnerke gave a description and demonstration of a simplified collographic process. He described the method of sensitising and printing the gelatine skin from which the prints by the autocopyist process are obtained, and practically demonstrated the various treatments in inking and printing, an ordinary letter copying press being employed. The effect of one of the prints taken on Whatman paper was much admired.

Richmond Camera Club.

*December 18th.*—Mr. Cembrano in the chair.

Mr. R. L. Kidd gave a demonstration of the process of "Enlarging and Printing on Bromide Paper." After describing shortly the manufacture of bromide paper, and its development (for which he recommended ferrous oxalate in preference to all other developers), Mr. Kidd, with the aid of the lantern, exposed a $3\frac{1}{4}$ inch square picture, the portrait of a child, enlarged to whole sheet size (23in. by 17in.). This was developed and fixed, and proving rather over-exposed, a second exposure was made, which resulted in a very beautiful and perfect print. The mode of printing-in clouds by double exposure was next illustrated. A snap-shot picture of Yarmouth sands having been exposed, enlarged as above, and the print partially developed and washed, a cloud negative was substituted and a further exposure made, an excellent picture being the result. Mr. Kidd then made some contact prints. Folding a piece of paper in four, he exposed each quarter of the surface in succession behind the same negative, and developed the four pictures at once—an expeditious mode of producing a number of identical prints from one negative. This concluded the demonstration, which had been accompanied throughout by a clear explanation of each process.

Mr. Whipple, of the Royal Observatory, Kew, added some remarks in recognition of the valuable services of Mr. Kidd and his firm to the cause of scientific photography, especially as applied to the recording of meteorological observations.

Brixton and Clapham Camera Club.

On the 17th inst., a demonstration was given by Mr. J. Howson, of the Britannia Works Company, upon the new Ilford gelatino-chloride printing-out paper and the special black tone lantern plates. He toned several pieces of paper, and developed four lantern plates, showing with what great ease the various operations could be performed, and the latitude there is in exposure. This was demonstrated by exposing three lantern plates for 25, 50, and 75 seconds respectively at 18 inches from a gas burner, and one to the light of an ordinary wax match at a distance of 6 inches. These were all developed at once in the same developer, and little or no difference could be discerned in the resulting slides.

Messrs. Nye, Dockree, Berry, Willoughby, Wright, and Dr. Wylie were elected members.

The Vice-President read a letter from Mr. Andrew Pringle with reference to the Maddox Testimonial Fund, and it was decided to start a subscription list, to which several amounts were contributed.

---

Bristol and West of England Photographic Association.
At the meeting on December 16th, Mr. Smith, of the Eastman Company, delivered a lecture and gave a demonstration of the "Kodak" hand-cameras, showing the latest folding type, with removable roll-holder for using a focussing screen, and in which the shutter has a working range of 5 seconds to $\frac{1}{200}$ second as well as time exposures. A large number of slides was then passed through the lantern.

In reply to a question, Mr. Smith advocated developing a number of films face downwards, to avoid puckering during development.

The tone of the slides being much admired, Mr. Smith said they were collodio-bromide emulsion, made by Mr. Wm. Brookes, of Reigate.

---

Lantern Society.

*December 14th.*—Mr. E. M. Nelson read a paper on "Condensers for the Optical Lantern." He said that a question often asked was, what is the focus of a condenser? It was a difficult one to answer, because there was the equivalent focus, and the equivalent back focus, the actual focus, and the actual back focus. It was therefore necessary, in the first place, to understand which of these four foci was meant. He then explained by means of diagrams how, with only simple arithmetic, the position of these four foci might be calculated with sufficient accuracy for all practical purposes. He next spoke of the importance of reducing the spherical aberration, which, necessarily, was very great in the bending of the marginal rays through such a large angle, to a minimum, and he explained that spherical aberration and unevenness of illumination were correlative terms. The greater the bending of the rays, the greater will be the aberration, and the more lenses that this is accomplished with, the less will be the aberration. A quadruple condenser has less aberration than a triple, and a triple than a double. Freedom from spherical aberration means greater concentration of light, as well as greater evenness of illumination; it is, therefore, desirable to obtain it on every account. He next touched upon the illuminating powers of condensers, and said that the question for lanternists was not so much the total amount of light that was condensed, but the amount per unit of area; and he showed that if a slight increase was made in the diameter of a condenser, it was necessary to make a large increase in the angle, so that the same amount of illumination per unit of area might be maintained. In conclusion, he pointed out that achromatism in converging lenses by distancing them was impossible.

On the conclusion of the paper, the following five condensers were practically tried in a lantern made especially for the purpose: a flint quadruple, two crown triples, a crown double, and the ordinary commercial double. The five condensers were held in a slide, and could be pushed alternately into position without needing any alteration of the other adjustments. The general opinion was that the flint quadruple gave the best definition, but that the crown double gave the strongest and purest illumination.

Society of Amateur Photographers of New York.
The following awards, consisting of handsome bronze medals, have been made at the exhibition of the Society of Amateur Photographers of New York, held at the American Institute Fair. The judges were Messrs. Wm. Kurtz, Frank La Marma, and Henry A. Ferguson, a professional and an amateur photographer, and an artist.

*Landscape*:—Superiority—H. M. Grisdale; excellence—Alfred Stieglitz; merit—Hugo S. Mack.

*Marines*:—Superiority—Charles Wager Hull; excellence—Ferdinand Ruppert.

*Portraits*:—Superiority—Charles H. Davis.

*Instantaneous*:—Merit—G. W. Wundrum.

*Enlargements*:—Superiority—L. H. Laudy; excellence—Louis T. Brush; merit—J. S. Couverse.

*Genre*:—Superiority—Miss Emilie V. Clarkson.

*Interiors*:—Excellence—Fred Vilmar.

The judges also recommend for honourable mention examples of different methods of sensitising and toning upon various papers—Edward Leaming and A. L. Simpson.

*Cloud Effects*:—Charles Wager Hull, to whom also a Hetherington magazine camera was awarded by popular vote.

## Answers to Correspondents.

A. W. D. (South Australia).—We think it best to answer your letter by communicating, as you suggest, with your agents here, and we will tell them where to purchase the books and goods which you require. We were much interested in reading the pamphlet enclosed in your letter.

Midas.—The swelled gelatine process, by which is understood the expansion in water of a bichromated film after exposure to light, is perfectly open to everybody. There is also no bar to your obtaining from such a film a mould in plaster, wax, or other material. You are also free to electrotype from such a film. These operations were patented long ago, but, as the patentee only obtained provisional protection, it is obvious that the method is now open to anyone who cares to practise it.

F. O.—We do not contemplate starting a "Sale and Exchange Column." If you refer to our advertisement pages, you will find those who deal with second-hand apparatus.

Instanto.—You say that you cannot understand why the photograph of an express train travelling at sixty miles per hour does not show movement, although the shutter worked at the $\frac{1}{120}$th of a second. If you examine the picture carefully, you will find that it does show movement in a slight blurring of the outline of the vehicles. If you care to make the calculation, you will find that in the fraction of a second indicated, an object moving at the rate of sixty miles per hour would advance about six inches. This is hardly perceptible in a quarter-plate photograph, but, as we have already said, is noticeable on careful examination.

P. G.—Before buying one of the pressure gauges named, you would do well to see Suter's new form of gauge, which works upon another principle altogether, and is said to be accurate as well as perfectly safe. We believe that most dealers stock it.

Basalt.—The pictures are curious and interesting, and you will do well by sending copies to Mr O. W. Jeffs, who is the Secretary of the Committee appointed by the British Association to collect, preserve, and register photographs of geological interest which have been taken in the British Isles. His address is 12, Queen's Road, Rock Ferry, Cheshire.

Opus. K.—In our next. Thank you.

J. P.—We have re-directed the letter, and sent it on to the gentleman named in your note.

---

A Russian Year-Book of Photography, we learn, will be published in April next.

An opening is being afforded to young ladies wanting employment in the spectro-photographic departments of observatories. It is found that they are gifted with keener visual power in regard to minute objects than men, and that they are more conscientious about small things. Miss D. Clumpe, who has just furnished an interesting paper on twin or double stars in the *Bulletin Astronomique*, is attached to the Paris Observatory, where M. Bouquet de la Grye has formed a staff of young ladies for the examination of the photographs of the transit of Venus. Although the comic journals are finding matter for squibs in this new departure in astronomy, it is quite a serious one.—*Daily News.*
