Boards of drainage, health, and like objects, whose *raison d'être* is decency, seem to possess very little of that virtue when they get a chance to spoil a beautiful prospect, and it would be serviceable if we could have a supervising committee of artists to keep a check upon their doings. Such a check was certainly wanted at Hastings a short time ago, in order to prevent a most wanton disfigurement to that place. All who have visited the beautiful seaside town must have admired the view of the East Hill, with its bold sandstone rocks, relieved by the old fishing village nestling under their base. The picture is a beautiful one, which many an artist has been tempted to transfer to canvas. Now, what ought to be done to the man who, in cold blood, has erected an enormous chimney shaft close to the beach where this sandstone mass forms a headland jutting out to the sea? This has been done recently by some board or other, the object beiug to carry off the smoke from the furnace of a pumping station. If such a thing were a necessity, surely the shaft could have been concealed in one of tho many crevices in the rocks which abound at the spot. But no! the orthodox brick chimney is the right and only proper thing, and there it stands, a monument to tho want of reverenco for natural beauty of those who put it there.

In this month's issue of *Knowledge*, two capital reproduced photographs are given; the subject of one being the head of Rameses II., the Pharoah of the oppressive; and of the other, an intaglio picture on the front of a temple erected to the same king at Thebes. The recent excavations at Luxor—which is one of several villages which occupy the site of Thebes—have brought these interesting relics to light, the first having been discovered under a heap of rubbish in January last. The head appears to be in a wonderful state of preservation; indeed, the work looks as if it were fresh from the sculptor's chisel. In no part of the world has photography done more useful work than in the historic land of Egypt, and explorers would almost as soon dispense with their picks and shovels as they would with their camera. Unfortunately, it is very necessary that these recovered treasures should be photographed as quickly as possible, for, unless carried off and taken care of in the Boulak Museum or some other similar resting place, they quickly become chipped about and otherwise disfigured by globe trotters.

From the great to the minute is not a very sudden descent in matters photographic. We are glad to see that Miss Buckland, in her admirable paper on "Bacteria," contributed to the same journal, acknowledges the advantages which have been gained by photographing those unpleasant micro-organisms of which we hear so much in these latter days. She remarks: "These *micro-organisms*, so exceedingly small as to be absolutely invisible to the naked eye, have yet been so carefully observed microscopically, and so faithfully reproduced and enlarged by photography, that they can be studied in all their wonderfully varied forms; and the differences between them are sufficiently marked to be appreciated even by the non-scientific observer. Some resemble dots in various groups; some are twisted spirals; some look like chains; others resemble small bags, with strings attached; some look like branches of trees, whilst others are simply rods crossing each other."

Not much is seen or heard of Dutch photographers or photographs in London, but some of the professional workers in that country turn out excellent pictures. Some really good photographs, we are informed by a correspondent, were recently seen by him in the shop window of Mr. P. Stutz, in Maestricht, an acquaintance of the late Mr. Walery. Mr. Stutz turns out bromide enlargements of exceptionally large size on Morgan & Kidd's paper; two which he has on view measure fifty by thirty inches, and such photographs he sells to the public in Maestricht at £4 each. This cheapness is chiefly due to money wages being so much less in Holland than in England; what the real wages may be is quite another thing, for the lower money income has greater purchasing power among our neighbours who live in a country of low prices and low rent. One of the large photographs just mentioned is a portrait of Mr. Hollmann, the musician. For the development of these paper positives, Mr. Stutz uses eikonogen, which, in his hands, works better and quicker than does ferrous oxalate; he says that this developer was well known and appreciated throughout Holland a long time before its introduction to England. Maestricht is a city of 30,000 inhabitants, and possesses three professional and about a dozen amateur photographers. Its streets and the fronts of the houses, with true Dutch cleanliness, are scrubbed twice a week with brooms, and, in response to the remark that if the *men* had to do it this waste of hard work would soon be suspended, Mr. Stutz said: "I doubt it, for if I ceased to scrub my frontage by way of example, my neighbour would say, 'See what a dirty man lives next door to me!'"

---

An advance has been made in what may be termed ceramic photography. Examples of the application of photo-collography to china were shown by M. Raymond at the last meeting of the Societé Francaise de Photographie, and were much admired. The pictures are said to be vigorous, excellent in colour, and to rob the original photograph of none of its value in the process of firing. Hitherto, experiments to combine collotype work with ceramic photography have been unsatisfactory, but M. Raymond's specimens show that the combination is not only possible but successful.

---

A compliment is paid to photography in the statue of the Princess of Wales, by Prince Victor Hohenlohe, recently on view at St. James's Palace. The statue is almost a literal reproduction of the admirable portrait of the Princess taken by Mr. Lafayette, of Dublin, and representing her in the doctor's cap and university gown. This photograph, it is well known, has influenced fashion—not the only photograph, by the way, which has had this effect; witness the Duchess of Devonshire and Minnie Palmer hats, the Sweet Lavender, the Duchess of Fife, and the La Tosca aprons, and the Cleopatra girdles, all of which were made familiar to the public by the exhibition of the photographs of the original wearers.

---

With a recent number of *Land and Water* was issued a specimen of what Mr. G. Teesdale Buckell, the inventor of the process, calls "Prismatic Etching or Colour Photography." Mr. Buckell gives an article on the process, from which, however, very little definite information can be derived. We gather that the specimens are obtained by three printings, the primary colours alone being used, and the results being, we presume, regarded by Mr. Buckell as incomplete, since he says they "do not, of course, bear comparison with those printed with greater care," criticism may be withheld. An announcement in Mr. Buckell's article will, however, excite the curiosity of photographers. He says: "Quickness of the action of light upon a sensitive surface is very important. Without this it is absolutely impossible to bring the darkest shadows of one colour up in the negative, and at the same time keep the high lights of another colour inactive on the sensitive plate. In doing this I have used a sensitiser discovered by myself which acts so quickly that an 'instantaneous' (25) plate which has had one end placed in it for a minute, and then the whole of the plate exposed, will be fully exposed in the detail of the darkest parts before the highest lights in the undipped part have begun to change." If this be so, an important discovery indeed has been made. We hope Mr. Buckell will lose no time in establishing its truth. Modern photographers are at first apt to be sceptical in regard to alleged discoveries.

---

Anthropology is but in its infancy. But for this, we might have had some enthusiast proposing that paterfamilias, in addition to the onerous responsibility at present cast upon him by the census as "head" of the household, should furnish the authorities with photographs of himself and the members of his family. Mr. Francis Galton would, we are sure, endorse the idea. The material for study afforded by several millions of photographs of families, extending in many cases over four generations, would be, in its quantity, rather appalling; but the anthropological student is not likely to find fault with it on this account; nor, indeed, would the photographic profession. The only stipulation, perhaps, the latter would like to insist upon, would be that the photographs should be taken to scale by professional photographers, and not left to the tender mercies of the amateur, of which class every household now boasts a representative.

---

Photographic reproductive processes are now so numerous that the nomenclature has become a little puzzling, and before long the subject will need a dictionary of terms all to itself. Quite recently the artistic world has been amused by the efforts of Mr. Joseph Pennell to "draw" Professor Herkomer into giving an explanation as to what he means by an etching. Professor Herkomer, however, refuses to speak, and so an interesting contribution to the history of engraving is lost. We believe that the controversy —if, indeed, it can be styled a controversy where only one side is heard—arose out of some "artist's proofs" of an "etching" by Professor Herkomer. Mr. Joseph Pennell, himself an authority on such matters, declares that these so-called "artist's proofs" are not worth the money demanded for them, and that the subscribers have not been treated fairly.

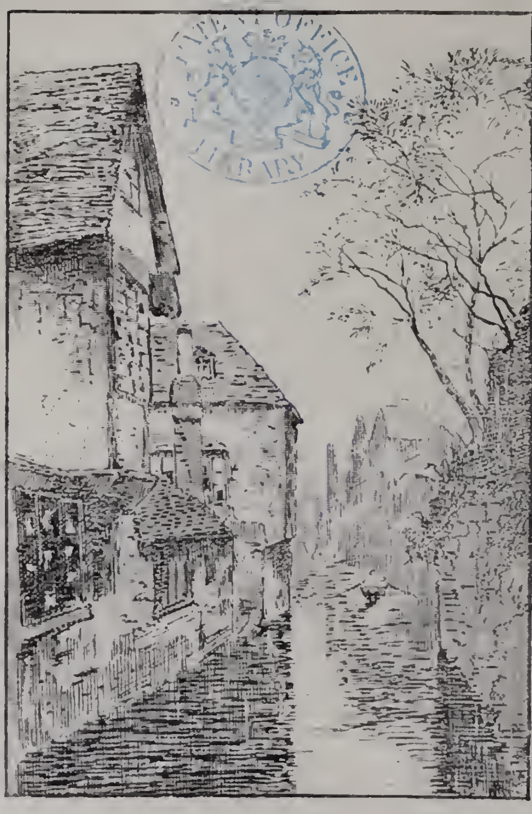
---

Mr. Pennell says that what Professor Herkomer chooses to call an etching is a photographic reproduction of a drawing touched up when on the plate with a needle. This is not Mr. Pennell's idea of etching, and most people will agree with him in thinking that an etching should be done entirely with a needle on a plate from which only a limited number of impressions can be taken. One would like to know by what name Professor Herkomer calls his process. Photo-etching would seem to meet the case. If a title has not yet been given, no time should be lost in supplying the deficiency, so as to prevent a recurrence of the misconception of which Mr. Pennell complains. Clearly, when any number of impressions can be obtained from a plate, it is not quite fair to charge an extra sum for "artist's proofs."

## A DETECTIVE SHOT.

The above heading looks as if it were taken from the contents bill of one of our organs which represent the "new journalism," but our readers will know that we are not prone to indulge in sensational matter, and that we refer to something far less exciting than the shooting of a policeman. "A shot," in photographic parlance, is a term which is now well understood, and we use it to call attention to the advantage occasionally secured by the use of a hand, or, as it is more commonly called—or mis-called—a "detective" camera.

A large number of persons look upon cameras of this kind as mere toys with which to while away an idle hour, or to perpetrate some practical joke at the expense of a good-natured friend, but the thoughtful know well enough that the instrument, used with judgment by experienced hands, is capable of doing valuable work. But perhaps it has not been pointed out how useful such a camera becomes when certain circumstances preclude the use of a tripod stand. As a case in point, let us take the attempted practice of photography from a boat in a choppy sea. Even in smooth water it is difficult to set up a camera on its stand in a small rowing or sailing boat, and when the water is lively it is impossible to do so. We remember on one occasion, when several vessels belonging to the Fleet were at anchor in the Downs, we succeeded in photographing each vessel in turn from a small fishing boat by means of a camera of the detective type.



The annexed illustration refers to another occasion where the hand-camera came to the rescue in a case of difficulty. We were crossing the East Bridge at Canterbury, under which flows the river Stour—or a tributary of that stream, we know not which. Often before had we admired the pretty peep at the queer old houses, with their reflections in the water, and once we had tried to photograph the view. But there are high railings to this bridge, and, to take the view, it is necessary that the camera front should be brought right up against them. Now, anyone who has struggled and wrestled with a tripod under such circumstances, will know well enough that the legs will assume every position but that desired by the operator; and that even if the lens be persuaded to project through the bars, it will either point towards the sky, or downwards towards the earth. It is, in fact, unmanageable, and the task is given up in disgust. Certainly one might take the camera off its stand, and fix it on a clamp attached to the railings; but clamps, useful things as they are, are not usually carried by photographers, for they are seldom wanted. But with our hand-camera, with which we were happily provided on the next occasion when we passed that way, all difficulty was at once removed. We held it rigidly against the bars for a moment, touched the button, and the picture was taken. There are many such nooks and corners in and about our old towns and cities which have not yet been photographed, because of the difficulty in finding room for the camera in the only position from which the view is worth looking at. We feel confident that in many of these cases the difficulty might be surmounted by the means which we have indicated, and the illustration is shown by way of emphasising this truth.

The picture in question has little archæological interest; it is merely a picturesque memorandum of a well-known view from the High Street, at Canterbury. The overhanging house on the left—which is evidently a very old one—is occupied as a dyer's; and the larger building seen in the distance on the right is a portion of the Blackfriars Monastery. Portions of this building are also remaining on the other bank of the river, but they are not visible in the photograph.

## THE WHEEL PUZZLE.

That able journal, *Wilson's Photographic Magazine*, has been puzzling its readers with the old question why the top of a wheel moves faster than the bottom, so as to give a less sharp image in photographs. The editor says:—

The veritable flood of explanations which has come down upon us impresses us with a realising sense of our responsibility as the editor of a scientific magazine, and with the awful readiness on the part of some of our vigilant subscribers to bring us up to trial should we slip or trip. From the beginning it was not our intention to ask our readers to go into the discussion of a problem which has excited scientists as much as the great coffer inside the Pyramid of Gizeh, for the last three hundred years or more—since the time, in fact, when Galileo discovered that if a point in the circumference of a wheel rolling on a plane surface were to trace its path upon a vertical plane placed beside the wheel, the path so travelled would form a very peculiar curve, which he christened the "cycloid."

As many as thirty diagrams have been sent us by various correspondents to prove their theories. Very strange to say, no two are alike. There are long lines of upward and downward curves; circles segmented; circles halved and quartered; triangles; semicircles crossed and recrossed; circles lapping one another; circles with many wicked-looking darts flying through the air at them; dotted lines rampaging over the paper like nebulæ; circles chasing one another along a track; and a model of a wheel with hand-power and diagrams and letters and tattoos all over its sides. They are accompanied by a great deal of sound, serious, scientific remarks, with the most of which we heartily agree. The communications came all the way from Cornell University (we *wish* we had room for this one for it is the very best, though it goes dead against us) to Boston (we beg Harvard's pardon for mentioning Cornell first), from Buffalo to Connecticut, and from New Hampshire to Milwaukee. The conclusion of the whole matter is about thus :

That a carriage-wheel, moving rapidly over the road, is, in one sense, like a crowbar (with one end resting on the ground) when impelled by, say, a man's arm, to move forward and backward. In that case the whole crowbar moves with the same speed, but the upper end, anyone can see, *moves more* than the lower end. Or, a wheel so moving may be like a hammer, and the contact of the wheel with the track is a series of blows, and each contact is a halt of that individual portion of the wheel. In that case, then, the upper, or *all* the other portions of the wheel, are moving faster than the point of contact. So, when photographing a wheel, there will, for that reason, be a blur, augmented by the lateral "wabble" of the wheel, unless it be that the shutter and plate are so quick that a sharp image could be had in spite of fate.

## PHOTOGRAPHY IN FRANCE.

BY LEON VIDAL.

ASTRONOMICAL CONGRESS—PHOTOGRAPHIC SOCIETY OF DOUAI—FRENCH SOCIETY OF PHOTOGRAPHY—NEW HAND-APPARATUS—BOLLARD'S ACTINOMETER—WOODBURYTYPE PRINTS—ORTHOCHROMATIC PLATES WITHOUT SCREENS—MEDALS AWARDED BY THE CONGRESS—CRYSTAL PELLICLE—PELLICLE FRAME—AQUA-VERNIS—IDEAL DEVELOPER—BIBLIOGRAPHY: NEW PHOTOGRAPHIC JOURNAL—THE BANK NOTES AFFAIR.

*Astronomical Congress of Paris.*—The important work of executing the chart of the heavens is progressing. A new International Astronomical Congress has just met in Paris, with the view of making final arrangements. Moreover, all the preparations are complete, and in three months from the present work will have commenced in all observatories. It is proposed to photograph something like forty millions of stars, and one may judge, by this figure, of the extent of an enterprise which promises to be the greatest achievement of the science of photography. Captain Abney, prevented by indisposition from attending the first meeting, was able to assist at this second session. We do not know exactly what has been decided as to the nature of the sensitive plates; but it seems to us that the orthochromatic plate, sensitive to red, offers itself as capable of producing the best results.

*Photographic Society of Douai.*—A Photographic Society of recent foundation, that of Douai (North of France), has just started an original competition. It has published a humorous novel, entitled "Le Mortier de Marc Aurèle." This pamphlet contains, here and there, blank pages, and in that portion of the text corresponding to these pages are found passages in italics. This is to indicate certain subjects of which artistic interpretations are to be made by photography, and which are destined to illustrate the blank pages. The idea is curious, but none the less good; also the subjects indicated might give place to studies, or very interesting compositions. We are glad to see in this idea a great encouragement to the illustration of books by photography. We shall follow this competition closely, in order to learn and publish its results.

*French Photographic Society.*—The last meeting of the French Photographic Society has not presented any very salient facts. The following is a *resumé*.

*Hand Apparatus.*—The hand apparatus is never missing. This time we have that of M. Bourdier, a repetition of the Dubroni apparatus, or of any other with nothing new. M. Hermagis' detective camera, designed and made by himself, for amateurs, is principally interesting on account of a mechanism which presents the plate face to face with the object, and afterwards raises it and brings forward the next. The movement is very rapid, and one can, if necessary, expose in one minute several negatives. There is, lastly, the detective camera of Lond and Dessonieux, which is composed of parts borrowed from others. There is a magazine for plates of M. Hermann Fol, of Geneva. The arrangement, which permits the operator to use it without taking his eyes from the subject, belongs to Smith's American apparatus. That adjustment is good, but we prefer an apparatus in which the changing of plates is performed in the same manner as in the one presented by M. Hermagis—that is, without having to turn over the apparatus. M. Lande has expressed his preference for an apparatus which is rather heavy than light; rather voluminous than reduced to a very small volume; rather slow than rapid as to the changing of plates. All tastes are certainly admissible, and still more certainly indispensable, so that we may be permitted to take the contrary position, and hope that further researches may produce the greatest lightness, the least volume, and the most rapid working powers that are possible.

*Actinometer.*—A new actinometer has been introduced by Mr. Edward G. Bollard, of Chester, his own invention. It consists of a tube, quadrangular, and about fifteen centimetres round. One of the extremities is open; the other has a shutter, and contains a cardboard covered with phosphorescent sulphide of calcium; in the centre is a small hole. This cardboard leans against a blue glass. This is exposed to light by opening the shutter. In about a minute, the maximum of sensitiveness is attained by the phosphorescent matter; then it is closed, and the operator watches from the other end, but taking care to note the precise moment in which the observations began. At a certain moment the exterior light—across the hole on the phosphorescent glimmer, the hole which at first appeared black—disappears, and at that moment must be noticed how much time has elapsed during the disappearance of the hole. Not having tried this apparatus, we cannot judge of its value, but at first sight it seems as if the Watkins' exposure meter is a more precise and more complete means of arriving at the desired result. We never have much confidence regarding those optical actinometers in which the indications are variable, and which depend upon the state of fatigue of the retina.

*Woodburytypes with White Margins.*—M. Gravier has found worthy of interest, and with very good reason, the new Woodburytypes printed with white margins. He presented for the inspection of the assembly divers proofs thus obtained in the studios of the Woodburytype Company. This is real progress, he said, because the mounting of proofs destined for illustrations to books can thus be doue very much better; and this opens new possibilities to the Woodburytype Company, especially in France, where only two houses have essayed this beautiful process. He meutioned the splendid application which M. Léon Vidal has made of this to some polychrome metallic prints, which may now be better obtained with margins. The means employed to obtain this result is easily explained. It consists iu leaving a hollow space all round the relief, which in the print will give an elevated margin. The margin is grey, but it can be easily cleaued by a sponge slightly wetted with tepid water.

*Orthochromatic Plates without Screens.*—Orthochromatic photography is slow in making its way among amateurs and professiouals. This is because people fight shy of employing a screen. Mr. Léon Vidal points out the idea, certainly not new, but which he has tried with success, of completing the prescribed form of preparing orthochromatic plates by the addition of a yellow colouring matter, inactive with regard to the orthochromatic colouring matters, but capable of acting as a yellow screen. Picric acid neutralised by ammonia seems to answer the purpose perfectly. The trial made by him on ordinary plates, or on orthochromatic plates sensitive to yellow or red, as the case may be, have produced the most conclusive results. In this manuer the orthochromatic plate attains the elements of complete correction, aud there is no further need to trouble about a screen. If this method is adopted, manufacturers of orthochromatic plates will in truth be enabled to aunounce that their plates may be used without a screen. The plates already prepared can be completed as to the yellow colouring matter, by immersing them for two or three minutes in a bath of water saturated with picric acid, aud neutralised by ammonia until litmus paper turns no longer red. After this the plate must be passed through a bath of distilled water, theu placed to dry, resting on one corner on blotting-paper, and in absolute darkness.

*Medals awarded by the French Photographic Society.*—Perhaps the French Photographic Society has been a little too zealous in already awarding medals to those constructors who have applied the resolutions of the International Congress of Photography of 1889. As there is going to be uext August in Brussels a new congress rectifying the first, we think that it would have been more suitable to wait till after the second congress before thus makiug use of the first and, necessarily, incomplete resolutions.

*Pellicle Frame.*—The house of Jannin and Jumeau have presented their pellicle, "Crystallos," which they have brought to as complete a degree of perfection as possible. They have added a pellicle frame or carrier, and a protective coating which they call "aqua-vernis." Packets of pellicles have been sent to all the members of the assembly without exception. This pellicle, which is very supple and very sensitive (already well known to us), appears likely to render great service to photography. Au apparatus cau be made which will carry one hundred pellicles, whereas only twelve glass plates can be conveniently packed at present.

*Ideal Developer.*—A new developer, in bottles, has been brought forward; its uame is the "Ideal." We publish the fact of the presentation; but why do honour to a composition the formula of which is not explained? The developer may be excellent; it has a very good name, but we never have much faith in very pompous titles. The "Perfect" is one of the same kind, the "Excelsior" also. Generally, the true quality does not justify the title in these preparations.

*Bibliography.*—Some new books have appeared issued by M. Gauthier-Villars. They are "The Practical Treatment of Photographic Enlargements" (second part), by M. Trutat—well known to our readers—a work which is very conscientious, and full of useful information. "Amateur Photographic Work in Winter," by M. Chable, president of the Photo Club of Neuchâtel. This interesting work treats principally of photography on glass applied to lanteru slides and to the stereoscope. "Photographic Optics, a Study of the Objective," by M. Soret, professor of physics at the Havre College. "Manual of Amateur Photography," by M. Panajou, chief of the Photographic Service of the Faculty of Medicine of Bordeaux. We have also "A Bulletin of Photography," as well as that of the Photo Club. This publication appeared yesterday, and gives promise of being very interesting. On the 20th of April will appear the "Paris Photographer," edited and published by the firm of Nadar. This publication will be of a humorous character.

*The Bank Notes Affair* has just had its *denouement* in the correctional tribunal. M. Schlumberger has beeu condemued to pay a fine of 500 francs, and damages, for having counterfeited a bank note with the sole aim (legally frustrated, however) of proving that the bauk-notes of France are very easily counferfeited, and to show the necessity of rendering this imitation more difficult. M. Schlumberger is going to appeal. It seems impossible that he can have incurred a penalty, especially as he took the precaution to put 50 liards instead of 50 francs, to indicate strongly the difference between his proof and a real note.

---

Utilisation of Atmospheric Oxygen.—The last new process for separating oxygen from the atmosphere by means of calcium plumbate, has been further simplified, as the following summary of a paper by G. Kassner, which appears in the *Journal of the Chemical Society*, will show:—The present paper is a continuation of a previous communication, in which the author described a new process for the utilisation of atmospheric oxygen and the compounds on which the process is based. With regard to the preparation of the calcium plumbate, further investigations have shown that, instead of heating two equivalents of calcium carbonate and one of lead oxide, it is preferable to use a slight excess of the former, say about five per cent. In this way a spongy product is obtained, which admits of the conversion of nearly the whole of the lead oxide into plumbate. It is more advantageous to employ limestone instead of whiting, and it has also been found unnecessary to use mechanical contrivauces for keeping the mixture in the form of a powder during the heating operation. This may be effected in an ordinary or reverberatory furnace supplied with a good current of atmospheric oxygen. For the production of oxygen on a large scale, the author now recommends heating the calcium plumbate in an ordinary furnace in the presence of carbonic anhydride, when oxygen is freely given off, according to the following equation:—$Ca_2PbO_4 + 2CO_2 = 2CaCO_3 + PbO + O$. It will thus be seen that, by this process, unlimited quantities of oxygen may be obtained from one and the same material. The author considers his process superior to the methods of Brin and Boussingault for the following reasons: The formation of calcium plumbate is effected in the course of a few minutes, its decomposition by means of carbonic anhydride is complete, whilst the working expenses, cost of plant, and the value of material are extremely small.

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

RETOUCHING ENLARGED NEGATIVES—EXPERIMENTS WITH RAPID DEVELOPERS—PRODUCING GROUND GLASS—BLEACHING GELATINE AND BLOOD-ALBUMEN.

*Retouching Enlarged Negatives.*—The following method of retouching enlarged negatives is practised by a well-known photographic firm of Berlin. *Papier végétal* is used for the purpose on account of its fineness and transparency. Two pieces of this paper of the size of the negative are cut out, one of them being mounted on the film side, the other one on the glass side of the negative. For mounting, the paper is at first slightly wetted, so that it will become quite tight after drying on the negative, when it is coated all round with glue, and transferred to the glass. In retouching, the larger portions of the negative which are too transparent are strengthened on the paper pasted on the glass side of the negative with powdered black chalk or plumbago, by means of a leather or paper stump. On the paper mounted on the film side of the negative, the flesh portions are equalised with the brush and Indian ink, bold effects of light being at the same time put in where it seems necessary. It is not at all necessary to work very accurately, since the light produces a softness of effect which could only be equalled by the most laborious retouching of the ordinary kind. The enlarged negative is then printed in the usual manner in the printing frame.

*Experiments with Rapid Developers.*—Mr. Victor Angerer, one of the most eminent photographers of Vienna, has made a series of experiments with different developers in order to determine which of them acts most energetically in the case of instantaneous exposures. For this purpose he used:—(1) The iron developer with the well-known accelerator; (2) the cristallos developer; (3) hydroquinone developer with ferrocyanide of potassium, according to the formula of Mr. Lainer; (4) the combined hydroquinone and eikonogen developer. The solutions were freshly prepared—except the cristallos developer—and the plates developed at the same time. The results were the following:—Developer No. 1 gave the fewest details, and a slightly fogged negative; No. 2. Plenty of details, but the lights too dense, no fog; No. 3. Plenty of details, very dense lights, and a slightly fogged negative; No. 4. An entirely clear and soft negative with very fine details, and with all the half-tones. The combined hydroquinone and eikonogen developer (No. 4), which was superior to all others, was prepared according to the following formula:—

*Solution* No. 1.

| | |
|---|---|
| Distilled water ... ... ... | 1,250 c.c. |
| Potassium sulphite... ... ... | 150 grammes |
| Eikonogen ... ... ... ... | $22\frac{1}{2}$ ,, |
| Hydroquinone ... ... ... | $7\frac{1}{2}$ ,, |

*Solution* No. 2.

| | |
|---|---|
| Water ... ... ... ... | 250 c.c. |
| Potassium carbonate ... ... | 75 grammes |

For use, five parts of solution No. 1 were mixed with one part of solution No. 2. The above experiments have been published in *Photographie* (1891, No. 4).

*To Produce Ground Glass.*—The following process to produce ground glass has been recommended to me by a professional photographer. A cup is filled up to one half with water, to which some emery powder is added. Stir well, allow to stand for about five minutes, and decant into another cup. Allow to stand again for five minutes, and decant the fluid into a third cup. In each of the cups remains a sediment of emery powder of various degrees of granularity. Take a well-cleaned glass plate, and commence to grind it with the coarsest grain; proceed with the grain of the second cup, and finish with the finest one. A semi-transparent glass plate of exceeding fineness is obtained by this method.

*Bleaching Gelatine and Blood-Albumen.*—M. Widmer, chemist, of Wiesbaden, publishes the following method: To 100 parts of the material in a hot concentrated solution, 1 part of powdered zinc and 1 part of oxalic acid are added. The mixture is well and continuously stirred, and the mass kept hot. By this method gelatine may be obtained more colourless than by any other. It will be evident that the proportions of the zinc and of the oxalic acid vary according to the colour of the original material, and the desired colour of the product. In the case of blood-albumen, it is necessary not to heat above 122° F., in order to avoid coagulating.

---

ROYAL INSTITUTION OF GREAT BRITAIN.—At the general monthly meeting on April 6th, the following were elected members: Mr. William Boyle Barbour, M.P.; the Right Hon. Lord Randolph Churchill, M.P.; Mr. C. E. H. Chadwyck-Healey, Q.C.; Mrs. C. E. H. Chadwyck-Healey; Mr. William Frederick Hamilton, LL.D.; Mr. William Robert Lake; the Rev. Edward G. C. Parr, M.A.; Messrs. Thomas Slingsby Tanner, Charles Humphrey Wingfield, and Latham Augustus Withall.

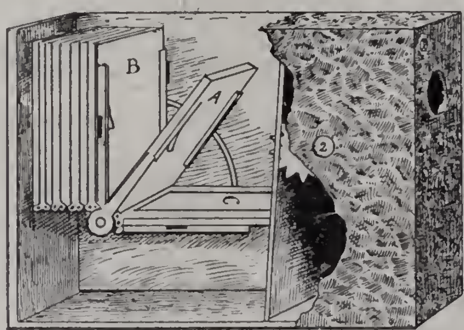
PICTURES OF NORWAY.—Mr. Sturmey gave last week before the Camera Club an interesting account of a tour in Norway, illustrated by about 100 lantern slides. These pictures, he told his audience, were taken on various makes of plates and films, and many of the negatives were executed under the wettest of skies. Starting from Leith with a large party of excursionists, Norway was touched—as is usual with tourists—at Bergen. The views of Bergen harbour, with quaintly shaped boats laden with dried codfish and wood, were very effective, and so also were the street views of the same town, a noticeable feature in them being the heavily wired telephone poles, which tell of far greater advances in this mode of communication than we can boast of in London. The views of Horgheim, and other places in the Romsdal Valley, must also be commended. But the camera must necessarily fail in giving a truthful interpretation of precipices which tower 3,000 to 4,000 feet above the houses. Mr. Sturmey, in considering this part of his subject, urged upon visitors to Norway the necessity of taking with them wide-angle lenses, otherwise many of the pictures which they take must lead to disappointment. Another point advanced was the great usefulness in Norway of a hand-camera, with which many passing shots from the steamer—of boats, fjords, cloud effects, &c., can be taken. Indeed, it seemed as if the majority of Mr. Sturmey's views were taken in this way without a tripod. Many of the pictures shown were most interesting from a geological point of view, and were taken, we understand, at the suggestion of a geologist who formed one of the party. Among these subjects were raised beaches and terraces, which gave evidence of former water levels, and notably a large expanse of polished and grooved rock with erratic blocks left behind by ancient glacial action. The waterfalls—some with a sheer fall of more than a thousand feet—of course formed a principal feature in this interesting collection of lantern slides. There were also shown the primitive, hut-like mills common to Norway, and found on nearly every stream. Beyond these we had a glimpse of the customs of the country and the inner life of the people which lent the necessary human interest to a very fair lot of pictures. The chair was occupied by Sir George Prescott, and there was a large attendance of members of the Club.

## MAGAZINE CAMERA.

The following description of Messrs. Hetherington and Hibben's magazine camera is taken from *Wilson's Photographic Magazine:*—

The engraving below is of a new hand magazine camera, which curries for public favour with a number of conveniences that, even in these days of very complete and perfect cameras, have not been before provided. It is light and compact, and, although always ready for instant service, it never fires off prematurely. This latter fault of many cameras is here well corrected. A button is a good thing to have to open the exposure, but, like a great many users of cameras, it is apt to go off before all things are ready. Sometimes an instant more of waiting would prevent failure and insure success. A button that yields to the slightest pressure and opens the lens more or less, is much more apt to cause one to spoil a plate than a button that does not open the lens until the pressure upon it is released. There is abundance of time, very often, between the time a button is touched by the finger and the instant the pressure is released, for the subject to move, the wind to rise, a cloud to obscure or change the light, or for one to change one's mind as to choice. Hence, a button that jumps at the first signal may often spoil everything, while the chances are that, if it does not jump until you let it go, it will be surer to secure a good result. This new camera works under the release of the button from the pressure.

We also call attention to some other of its characteristics, which will be made more understandable by reference to the engraving. Referring to the cut, A, B, and C are thin metal



leaves. There are twelve or more of these, as shown, all hinged or linked together by links, which are part of the construction of the carrier. These links are pivoted together by small rods, the ends of which project about one-eighth of an inch at each side. Their projecting ends travel in a slot in a metal plate on the inner side of the box, and these slots form the guides in which the hinges travel. This construction, giving entire control of the plate, is one of the chief claims of the patent on the Magazine—the slot turns at the first plate-holder, thus making a right-angle. When the pivots of the hinges approach the turning-down place of the slot, they will, of necessity, turn down and follow it, thus carrying the plate-holder through an arc of ninety degrees. The act of doing this draws forward the succeeding holder until it occupies the plane just vacated by the one turned down. A stop darts through the opening on the side of the camera and holds it firmly in place. The carriers are thrown down by turning a button which actuates a thin arm that engages with the sides of the holders. There is one of these on each side of the box. When the button is turned back for the next holder, the turned-down plate-carrier is left as shown, sensitive side down. The holders are flanged backward (not shown in cut), lapping upon each other like the shingles on a house-roof, and completely protect the plates, both exposed and unexposed, from any stray light during subsequent exposure. This is very necessary, as we have all been taught by experience. As each plate is turned down, it engages the star-wheel and revolves it, thus causing successive numbers to appear on the side of the box, as shown. The focussing device is entirely new in manner and mechanism, always in sight and touch. The shutter is "ever-set." Not less than one hundred consecutive exposures may be made without the resulting negative showing any variation of speed. It can be reset in ten seconds. The shutter works with release of pressure on the button, an advantage that will be appreciated by all experts in the use of the hand-camera. For example, you want an effect of light, a dash of sun, or you wait patiently for any moving object or person to occupy a certain position in the field of the lens. The opportunity offers, and, in the excitement of the moment, a hurried jab at the button is more than likely to result in an unsatisfactory plate; whereas, with the button pressed, you have but to "let go" at the right moment. The lens used is known the world over, and was chosen after thorough tests as being the most desirable for the purpose, the question of cost being subordinated. The box is very simple and plain externally—purposely so. It has been successfully used in the crowded Hebrew, Italian, and Chinese quarters of New York, as well as on Broadway, without attracting attention. It has seen service from the beaches of the Atlantic to the Indian reservation of the North-west. With the box tucked under the arm, there is nothing to do but turn down a plate—as easily as you would turn on the gas—and "let go" the button. No shutter to set, no doors to open, nothing that requires any examination or any unusual movement of the body or hands. The stops are changed from the bottom of the box by a device that does not require to be seen in order to control. The entire working parts of the camera, except the magazine, are attached to a grooved front-board, which can be readily detached for examination. It is believed to be the smallest, lightest camera of its class now on the market, and is the work of a thorough mechanic and skilful photographer.

## TESTING OF LENSES AT KEW OBSERVATORY.

The Kew Committee of the Royal Society give notice that they will be prepared, after May the 1st, to receive at the Kew Observatory, Richmond, photographic lenses, for the purpose of testing them and of certifying their performance, under the following conditions:—

1. The lenses are to be delivered either at the Kew Observatory, Richmond, or to the Secretary of the Horological Institute, Northampton Square, London, E.C.; or to Mr. R. Strachan, of the Meteorological Office, 63, Victoria Street, Westminster, S.W.

Every reasonable care will be taken of the lenses, but all risks attendant on their transit to and safe custody at the places designated in the preceding paragraph must be borne by the sender of the lenses.

2. No certificate will be granted for a lens unless it bears a distinguishing number on its tube. The maker's name need not be engraved.

3. Lenses may be tested before they are fitted into cameras, provided they are numbered, and are accompanied by their flanged mounting. They cannot, however, be received for examination if their diameters exceed four inches, or the equivalent focus thirty inches.

4. The lenses are tested in sets, and the trials begin on or about the 1st and 15th of every month. Lenses intended to be submitted to such trials should be deposited either at the Observatory or at the receiving houses *at least three days before either of those dates*, accompanied by a duly attested form of entry, specifying the class of test to which the lens is to be subjected.

5. The fee for testing each lens is for Class A 10s. 6d., Class B 2s. 6d. It will be payable when the lens is ready to be returned.

The Superintendent may decline, at his discretion, to receive any lens which he may consider unfitted for examination.

6. Duplicate certificates, with the customer's own name filled in, can be supplied to makers at a charge of 1s. each. The original certificates must, however, be returned whenever an application is made for duplicates.

Details of Trials to which the Lenses are Submitted during Testing.

*For Class A Test.*—Determination of the length of equivalent focus. Size of effective aperture with every stop in terms of focal length. Angle of field of view, and size of plate effectively illuminated. Number of external reflecting surfaces. Coincidence of visual and chemical foci. Presence of flare spot. Workmanship of surfaces, structure, and degree of transparency of glass. Centreing in mount. Defining power. Relative quality of illumination in different parts of field. Amount of astigmatism or optical distortion.

*For Class B Test.*—Determination of the length of equivalent focus. Size of effective aperture with largest stop. Angle of field of view. Size of plate effectively illuminated. Coincidence of visual and chemical foci.

Note.—All lenses certified at the Kew Observatory will be marked with a monogram composed of the two letters K and O, A or B, and a registered number, unless the mounting is such that the operation of engraving cannot be performed with safety to the lens. An additional fee of 6d. will be charged for engraving the monogram and number.

Applications for forms for the entry of lenses for testing, and all other correspondence, should be addressed to the Superintendent, the Kew Observatory, Old Deer Park, Richmond, Surrey (Test Department).

Office hours—10 to 4; Saturdays, 10 to 1.

*N.B.*—The Observatory stands in the Old Deer Park, and is reached through "Fuller's Gate," which is about one hundred and eighty yards distant from either of the two *Richmond* Railway Stations (*not* from either of the Kew Stations, which are two and three miles distant respectively).

## THE LATEST USE OF PHOTOGRAPHY.

BY J. F. S.

Multitudinous as are the practical applications of photography, yet hardly a day passes but some new use or application is heralded in the daily press. So great is this range, that it gravitates all the way from the discovery of celestial phenomena millions of miles from the earth, down to the designing adventuress in Chicago who had her love letters photographed for use in a breach of promise suit, for fear that the originals might be written in unstable ink. The latest announcement now comes from Germany, and the scheme will, without doubt, be improved upon in the future.

The opening scene is laid in a railway train running from Stettin to Berlin. Among the passengers was a young man, Isidore Grünschnabel, the only son of a wealthy clothing dealer in the former city, who, in addition to his extensive business, prided himself upon being a "Geheimer-geheim commercien rath" of his native town.

The young man was on his way to the imperial city with a well filled wallet, nominally to secure some job lots for his father's establishment; but in reality, as it afterwards turned out, his main object was to see *life* in Berlin, which city, it may be remembered, is itself on the Spree.

In the train, this verdant sciou of an old but commercial house became acquainted with a fellow-traveller—one Fritz Schnepperle—who was by birth a Berliner, by occupation a travelling "commis," or salesman, and, like many of his class, a sharper, always open for opportunities. During the journey, the young Grünschnabel made a confidant of his new-found friend, which culminated in asking him to act as his guide through the intricate mazes of the metropolis of the Hohenzollern. Well and attentively did Schnepperle listen, and acceded to his friend's request without much urging.

On their arrival in Berlin, the young Stettiner, under the guidance of his new-found friend, devoted himself so assiduously to his studies that, ere twenty-four hours had rolled around, young Grünschnabel was confined to his room at the hotel with a pronounced headache.

The patient reader will, no doubt, ask, "What has all this to do with photography?" A little patience, and the *denouement* will bring the answer.

The designing companion, Schnepperle, after leaving his young companion helpless in bed, now sent a telegram to Grünschnabel, Senior, stating that he had run across some large job lots, but was short 500 marks cash, which he wanted sent by return mail without delay, signing the name of Grunschnabel, Jun.

The father, who is also an honorary member of a photographic society, at once sent the money to the designated postal station in Berlin; but, with a latent suspicion that perhaps all was not right, he mailed at the same time a letter to the official at the station, enclosing a photograph of his son, and requesting that the money letter be delivered only to the original of the enclosed photograph.

The following day the personator called at the station for the letter. The official, Herr Spührnase, who entered into the spirit of the matter, compared the person with the photograph. A glance was sufficient, and the ever-present policeman was at once called into requisition.

On the following day the prisoner was arraigned before the Imperial Schwur Gericht, and, on being confronted with the evidence and photograph was found guilty of attempted swindle, and sentenced to a term of six years at hard labour in the penitentiary at Spandau.

During the course of the trial, the judge, Herr Von Bürstenbinder, took occasion to pay a high tribute to photography, and the great aid which it lent to the police department in detecting criminals and assisting in the administration of justice. In the present case, the honourable judge stated that photography had proven itself capable of even a higher scope, viz., as an agent to prevent the successful accomplishment of a well-laid scheme to fraudulently obtain a sum of money. After congratulating the postal official upon his vigilance, the judge stated that he hoped to see the day when photography would be regularly used in connection with identification in financial transactions; further, that here opened a field which, so far, had been overlooked in the past; also that he personally would request the "Photographische Verein zu Berlin" to formulate a practical scheme for the purpose, and bring the matter before the Imperial Chancellor for adoption throughout the length and breadth of the German realm.

Photographic Exhibition in Brussels.—Intending exhibitors are notified that the lists will be closed on the 1st May. Communications should be addressed to M. C. Puttemans, Ecole Industrielle, Boulevard du Hainaut, Brussels.

## Patent Intelligence.

### Applications for Letters Patent.

5,591.—Wilhelm Heinrich Conrad Bernitt, 45, Southampton Buildings, London, "Improvements in Apparatus for Producing and Delivering Photographic Pictures in exchange for Coin deposited therein."—*March 31st.*

5,627.—Richard Warren Stewart, R.E. Office, Devonport, "Taking Photographs of Small or Large Angles up to 360°."—*April 1st.*

5,800.—Thomas Scott and James Davenport, 70, Deansgate, Manchester, "Improvements in Photographic Dark Slides." (Complete Specification deposited.)—*April 4th.*

5,833.—James Yate Johnson, 47, Lincoln's Inn Fields, London, "Improvements in the Manufacture or Production of Sensitive Paper for Photographic Purposes. (*Pierre Mercier, France.*)—*April 4th.*

### Specifications Published.

16,982. *October 28th*, 1889.—"Colours." C. H. Wilkinson, Colne Valley Works, Slaithwaite, Yorkshire.

Relates to a system of colouring in which a scale or octave of colour is arranged corresponding to the diatonic scale in music. Consists in setting the primary colours, red, yellow, and blue *(sic)*, to correspond to the notes C, E, G, of the common cord in the natural key, and then mixing these colours in proportions founded on the relative rates of vibration of the notes in the musical scale, in order to produce the remaining prismatic colours, orange, green, indigo, and violet, to correspond to the uotes D, F, A, B. Intermediate colours are obtained corresponding to sharps and flats by mixing the principal colours on each side of them. The ascending and descending octaves of these colours are produced by mixing them with certain proportions of white or black. The system comprises also diagrams of colour harmonies consisting of notes, chords, or scales, in ranges or keys corresponding respectively to the notes, chords, scales, and keys of music. The system is applicable for use by textile manufacturers, dyers, printers of colour ou calico, paper, floorcloth, &c., colour makers, paper makers, ink makers, painters, designers, artists, &c.

17,006. *October 28th*, 1889.—"Stereotype." D. Reid, 143, Flinder's Lane, Melbourne, Victoria.

Key for securing stereotypes to their base blocks. The key is composed of two pieces of metal secured by rivets, and having bent edges to fit the grooves in the stereo and base block. The edges may be bent to different angles to suit the dovetail of the grooves in the blocks. The plates forming the key are in short lengths, the upper ones breaking joints with the lower. The upper plates of the key are capable of slight lateral movement, the rivet holes being elongated for this purpose.

### Patents Granted in America

448,825. *December 4th*, 1889.—"Dissolving Shutter for Magic Lanterns." John Shannon, Wixom, Mich. Serial No. 332,600. No model.

*Claim.*—A frame for receiving and displaying pictures in a magic lantern, such frame having an advance and sidewise movement in either direction for bringing its ends alternately in position for display purposes. In combination with a movable shutter actuated through the movements of the frame, substantially as and for the purpose specified.

448,821. *January 7th*, 1891.—"Picture Frame." John F. M'Bride, Chicago, Ill. Serial No. 376,952. No model.

*Claim.*—In a picture-frame, the combination of a back, a front formed of a sheet of suitable flexible material cut to form sections bent back to produce the display opeuiug, having convex bulging margins, and ornamental fastenings, securing the sections at their free ends to the frame.

As a new article of manufacture, a picture frame, having the back and the front of sheet celluloid severed by a cross-cut through the centre, thereby forming V-shaped sections bent back to produce the display opening, having convex bulging margins and ornamental fastenings, securing the sections at their apexes to the frame, substantially as described.

448,692. *January 31st*, 1890.—"Implement for Mounting Pictures on Glass." Richard H. L. Talcott, Boston, Mass. Serial No. 338,752. No model.

*Claim.*—An implement for mounting picture sheets on glass, consisting of a suitable handle or stock haviug secured on and projecting from its forward portion a metallic plate having a thin and continuous rigid edge, and a sheet of rubber by its intermediate portion overlying said edge, and by its terminal portions extended therefrom and under tension.

The carrying body or stock provided with the kerf, the metallic blade or tongue inserted in said kerf, and the sheet rubber by its intermediate portion covering the edge of said tongue, and by its terminal portions confined upon the opposite sides of the stocks, substantially as described.

448,801. *February 18th*, 1890.—"Photographic Roll-Holder." Hermann G. Ramsperger, New York, N.Y. Serial No. 340,862. No model.

*Claim.*—In a roller-holder, a perforating device adapted to penetrate the film, and a measuring device adapted to enter the perforatious.

The measuring device held in contact with the film by spring pressure and adapted to enter the film.

In a roller-holder, a perforating device, a measuring device co-operating with the perforating device, and a lock actuated by the movement of the measuring device to lock one of the rolls.

The combination, with the supply and receiving rolls and the film support, of a perforating and measuring device acting at opposite edges of the film support.

The combination, with the supply and receiving rolls and the film-support, of a perforating device, a measuring device, and a common tumbler, or its equivalent, for actuating the perforating device and for withdrawing the measuring device.

## Correspondence.

### THE NEW RAPID IRON PROCESS.

Sir,—It will perhaps put to rest Mr. W. E. Debenham's conscientious scruples if the history of the discovery of the new sensitive compound is laid before the world. As Mr. Debenham is so anxious to know who was the discoverer—Mr. Friese Greene or myself—I may tell him we both claim a share in the discovery. We started upon the work by making a definite study of a series of experiments. These pointed out a direct line of investigation to be undertaken. Mr. Greene having special facilities for carrying out experiments, very speedily was on the right track, and followed it until the new sensitive compound reached its present perfect stage. In thus working together we have further succeeded in rendering the process more sensitive by a discovery I had the good fortune to make.

Having, as I believe, fully apportioned the respective shares in the credit of this discovery, I would like to add that you were right in calling attention in your issue of last week to an error which had crept into an article in *Nature*, attributing the discovery solely to me, whereas Mr. Friese Greeue's name should have been mentioned as well. At the lateness of the hour by which Prof. Meldola concluded his discourse, and my anxiety to get through with the experiments and not keep the audience unduly waiting, it did not occur to me, or I would have most certainly drawn attention to the omission of Mr. Greene's name. Frederick H. Varley.

*April 3rd.*

### NATIONAL PHOTOGRAPHIC EXHIBITION, APRIL, 1891.

Sir,—Owing to the decision of the Liverpool Exhibition Committee to keep their Exhibition open until the 11th inst., and as many of their exhibits are entered for the Crystal Palace, I beg to inform you that it will be impossible for the judging here to take place before Thursday, April 16th.

S. G. Buchanan Wollaston.

*Crystal Palace Co., Crystal Palace, S.E., April 6th.*

Photographic Club.—Subject for discussion Wednesday, April 15th, "Priuting on Emulsion Papers"; April 22nd, "The Keeping Qualities of Developers," and "A Special Selection of Slides," by Mr. Frank Haes.

# Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

At the technical meeting on March 31st, Mr. Chapman Jones, F.I.C., in the chair, Mr. T. E. Freshwater showed his miniature lantern. A lantern display then took place, slides being contributed by Messrs. S. T. Chang, H. M. Hastings, Mawson and Swan, E. W. Parfitt, H. Chapmau Jones, H. R. Hume, F. Ashburner, W. England, and A. Mackie. Mr. T. E. Freshwater then exhibited some slides in his miniature lantern.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

*April 2nd.*—Mr. W. Coles in the chair.

Mr. Atkins passed round three negatives taken on the previous Monday—Bank Holiday.

Mr. J. R. Gotz gave a demonstratiou of toning of gelatiuochloride emulsion paper. He claimed that the paper was capable of producing any tone desired, according to the toning bath used. Some prints that had been previously exposed were then placed in various touing baths, and the results shown. The length of time the priuts remained in the bath materially influenced the colour. A bath of sulphocyanide of ammonia and gold was first used, producing purple tones. A bath composed of carbonate of soda and gold, although slow of action, gave a very good grey tone. Some fine sepia tones were obtained with platinum toning, but the bath that seemed to give the best general result was a combined toning and fixing bath. Mr. Gotz believed that when a thorough substitution of gold took place, the prints would be thoroughly permanent.

Mr. Everitt asked if Mr. Gotz would allow the prints to be submitted to the action of chlorine water.

Mr. A. Haddon thought this would be an unfair test, as the image might be quite permanent, and yet be soluble in chlorine water. The yellow in platinotype priuts was due to the iron not being properly dissolved out.

The action and tone of several other baths were shown, and examples of the toning produced.

Mr. Gotz also passed round samples of paper recommended for backing priuts after enamelling ; it prevented the mountant dulling the brilliancy of the gloss of the enamel.

PHOTOGRAPHIC SOCIETY OF IRELAND.

At a meeting held on Friday, 3rd inst., at 15, Dawson Street, Dublin, Mr. J. H. Hargrave, B.A. (hon. secretary), read an interesting and instructive paper on "Optical Properties of Shutters," and demonstrated, by means of blackboard and lantern slide diagrams, the various effects upon the light rays passing through the lens exerted by different makes of instantaneous shutters used in the following positions—viz., (1) In front of lens ; (2) between the combinations of a doublet lens ; (3) behind the lens ; (4) in front of the plate. Mr. Hargrave stated that a roller-blind shutter worked in the latter position was theoretically the best form, as it did not in any way affect the rays passing through the lens, but allowed every part of the plate to receive a uniform exposure.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

*April 3rd.*—At a general meeting held in Hauover Hall, the report for the past year was submitted, and stated that the year commenced with a roll of 63 members, the increase during the year had been 44, making therefore a present total membership of 107.

It was resolved that an entrance fee of 2s. 6d. be imposed on all elections after May 3rd next ; and that, as the Society is not able to obtain the use of Hauover Hall ou Friday evenings, the future meeting nights be the first and third Mondays in the month.

The following officers were then elected :—*President*—Mr. F. W. Edwards ; *Vice-Presidents*—Mr. Maurice Howell, Dr. Munyard, Mr. W. Rice, Mr. H. G. Banks ; *Committee*—Messrs. Boxall, Farmer, Fitness, Fellows, Groves, Herbert, Kelly, Lyon, F. Webb ; *Hon. Treasurer*—Mr. A. E. Whitby ; *Hon. Secretary*—Mr. S. W. Gardner, 7, Barry Road, East Dulwich.

The balauce sheet showed cash in haud £4, aud fixtures to the amount of £3.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

On Saturday, the 4th inst., a meeting of the members and friends of the Society was held at Beale's Restaurant to bid farewell to the president, Mr. J. Humphries, F.S.A., who is about to leave London for Glasgow, where he will in future reside. A smoking concert was organised ; Mr. W. T. Goodhew, vice-president, in the chair. The event of the eveuing was the presentation of an illuminated address bearing the signatures of the members, to Mr. Humphries. In making the presentation, the Chairman said that the success which had always attended the Society had been to a great extent due to the business abilities and amiability of Mr. Humphries ; and in bidding him farewell, the members felt that they were losing an officer whom they could not replace.

Mr. H. Walker, vice-president, in eudorsing Mr. Goodhew's remarks, said that Mr. Humphries' amiability was the velvet glove that covered an iron hand, ever ready to direct, and firm to control.

Mr. Lewis Medland, as a visitor and old friend, joined in wishing Mr. Humphries success in his future career.

Mr. Humphries, in reply, said that the work he had done for the Society had brought its reward in the kindly feelings it had generated. Although he could no longer atteud the meetings, he would always remain a member, and cherish the warmest feelings of friendship for those with whom he had worked.

RICHMOND AMATEUR PHOTOGRAPHIC SOCIETY.

The first field-day of the season took place on Easter Monday, when nine members visited Cobham and Ockham, and, in spite of the windy weather, succeeded in getting some good negatives.

Friday, the 3rd inst., was a lanteru night, when Mr. Faulkuer presided, aud Mr. Ardaseer showed and explained the new pneumatic shutter of Adams' "Ideal" hand-camera.

Mr. Cembrano lent his lantern, aud slides by the following members were shown : Commander Tailor, Messrs. Ramsay, Hunter, Ardaseer, Richardson, Faulkner, Perry, Bickerton, Garrett, and Cembrano, as well as a set of views of Windsor Castle by Mr. Brooks, of Reigate.

HOLBORN CAMERA CLUB.

The arrangements for the present mouth are as follows :—To-night Mr. Traill Taylor will lecture on "The Artistic Composition of Photographs." To-morrow the Club has a field-day, and will visit the beautiful park at Highgate recently given to Londoners by Sir Sydney Waterlow, the London Couuty Council having given permission for a party of not more than twenty-five to visit that beautiful estate on this occasion. The members will meet at St. Joseph's Retreat on Highgate Hill at 3 p.m. Friday uext is an iustruction night, when general hiuts to beginners will be giveu by Mr. Brocas ; aud on Friday, the 24th, Paris Exhibition slides will be shown by Mr. Meru. Prizes are offered for the best pictures takeu at the Club outings.

LEEDS PHOTOGRAPHIC SOCIETY.

On Thursday eveuing, the 2nd inst., Professor E. H. Jacob, M.A., M.D., read a paper ou "Winter Photography" before the members of this Society, and in the course of his remarks said that photography iu the winter—that is, when trees had lost their leaves—was far too much neglected by amateurs. He dwelt on the greater truth to nature of winter photographs, the values of the almost monochrome pictures being more correct than views which contained a profusion of colours, mostly green ; while from an artistic point of view, there were a large number of spring and winter views of great beauty. As subjects for pictures, he instanced: (1) Buildings, the greater part of which are frequently in summer obscured by trees or foliage, and interiors iu the same way are often shaded by trees. (2) Suow-scenes or pictures taken during a hoar-frost, which formed some of the most beautiful subjects for the camera. (3) Trees ; here the photographer had a great advantage over the artist with the brush, for the winter trees could be rendered with absolute accuracy; he thought people were unaware of the great beauty of most trees without leaves, especially the birch, the elm, and the oak; besides the artistic value, a collection of good photographs of leafless trees would be most useful from a botanical point of view, and should find a place in the collection of every school of botany. Some of the most beautiful trees he had seen were to be found in Nuneham Park, near Oxford, and in Studley Park. (4) General winter landscapes, where interest was given mostly by the conformation of the land, hills, buildings, or by contrast of bare trees with evergreens. Seaside views were better in winter than in summer, as the waves and sky were more varied. Dr. Jacob illustrated his paper throughout by a series of lantern slides of winter scenery, including a number of fine forest trees from the parks referred to above.

Mr. J. W. Addyman, B.A., brought before the members an account of the recent investigations of Col. J. Waterhouse, B.S.C., Assistant Surveyor-General of India, respecting electro-chemical reversals with thio-carbamides, the principal points established seeming to show:—(1) That the same kind of reversal of the deposit on silver bromide films can be effected by a developer containing thio-sinamine, both chemically and electrically; (2) that the reversal of the photographic image on such film by thio-carbamides is to a great extent, if not entirely, due to electro-chemical action; (3) that the development of the photographic image on silver bromide films is accompanied by electro-chemical action.

---

Croydon Microscopical and Natural History Club (Photographic Section).

*Friday, April 3rd.*—Mr. Edward Lovett in the chair.

Mr. A. R. Dresser, in a paper entitled "The After Part of Hand-Camera Negatives" (illustrated), gave a brief outline of the method he adopted for developing hand-camera negatives, entered largely into the intricacies of solar enlarging and making slides, and explained and illustrated a simple arrangement for enlarging or copying a negative that had been taken askew, the carrier holding the plate to be copied rotating within a turntable.

A large number of fine enlargements made from quarter-plate negatives were exhibited, and a good number of slides were passed through the lantern, and were well appreciated by the members.

---

Glasgow Photographic Association.

*March 19th.*—Mr. J. Craig Annan, vice-president, in the chair.

Ex-Provost Clark, Paisley, who was the lecturer for the evening, gave an interesting and graphic account of "Scenes in Ireland," with limelight illustrations. Views, in addition to those of scenery, were also shown descriptive of recent events in Ireland.

*April 2nd.*—The sixth general meeting of the session was held, Mr. William Lang, jun., F.C.S., president, in the chair.

Mr. James Gardner gave a practical demonstration of the application of the air-brush for working up bromide enlargements, and prints were shown illustrative of the method.

Mr. William Hume, Edinburgh, explained the construction and uses of his cantilever enlarging apparatus, and by its means showed a series of physical experiments projected on the screen.

Mr. William Lang, jun., F.C.S., read a paper on "Lantern Slide Making by the Woodbury Process," and gave a demonstration of its working.

Thereafter a number of members' slides were passed through the lantern.

---

Received.—Adams and Company's Catalogue and Annual for 1891, containing portraits on three different kinds of photographic paper, first of the series being that of Mr. W. H. Harrison, late Editor of the Photographic News.——*The Photographic Quarterly* for the current month, with a frontispiece, "The Love Letter," being a Woodburytype reproduction of the picture by J. E. Austin, which received a medal last year at the exhibition at Pall Mall.

## Answers to Correspondents.

*All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

S. D.—"*La Belle Bretonne.*" The address of Mr. Arthur Burchett was given in the catalogue as Willoughby Lodge, Hampstead, N.W. A fairly good reproduction appeared in the February number of the *Art Journal*.

Competition.—*Medals in Show Cases.* There is abundant precedent for it, but the display of medals (given for genre) in the same show-case with ordinary professional portraiture is a little misleading to the general public. You say the genre groups were never published, but surely copies were shown and a few orders booked. Whether this was the case or not, the possession of medals betokens a certain grade of art excellence, which, it is presumed, governs the whole work of the establishment. Your contention is that the particulars of award should be stated; but how would Mr. Robinson, for instance, go to work to afford this information, and would the public, even then, be very greatly enlightened by the mention of such particulars? After all, it is open to you to take the same course, and then, if successful, you can appear on a level with your competitor.

Pharm.—*List of Members.* A newly revised list has just been issued by the Photographic Society, showing the dates of election, from which it appears that there are *eight* original members. Mr. H. Perigal, F.R.A.S., who completed his ninetieth year on the 1st inst., is the father of the Society. A fine portrait of the venerable gentleman, taken by Mr. H. S. Mendelssohn, was shown three years ago at the Pall Mall Exhibition. Mr. Glaisher joined the Society in the second year of its existence; Messrs. Henry White and G. C. Whitfield in 1855; Sir George Stokes in 1856; and Messrs. Francis Bedford, Sebastian Davis, W. Peters, H. P. Robinson, and Josiah Spode in 1857; with Colonel Mitford in 1858. The names of the original members are George Shadbolt, W. Bois, F. E. Currey, W. Dillworth Howard, George Shaw, E. O. Tudor, and Sir Percival Radcliffe, besides Mr. Perigal already mentioned.

L. P. (Cheltenham).—*Negative Varnishes.* Messrs. Mawson and Swan have two qualities. The amber in chloroform can be had of Messrs. R. W. Thomas and Co., and the original Soehnée varnish of Messrs. Marion and Co.

Optics (York).—*Heavy Liquids for taking Specific Gravities.*

| | |
|---|---|
| Oil of vitriol ... ... ... ... | 1·84 |
| Methylic iodide ... ... ... ... | 2·20 |
| Concentrated arsenic acid ... ... ... | 2·50 |
| Mercuric potassium iodide ... ... ... | 3·20 |
| Mercuric barium iodide ... ... ... | 3·60 |

Guinand's flint glass and the heavy English qualities have specific gravities standing between those of the two last-named liquids, whilst Bohemian glass and common crown (without lead) seldom exceed 2·5 specific gravity. It would be easy, therefore, to test your specimens in the first instance by seeing whether they sink or float in the mercuric solutions. "Toughened glass" is rapidly corroded by sulphuric acid, which has no such effect upon ordinary flint or crown. It might not be advisable to leave the heavy glasses long immersed in the double iodides.

F. I. C.—*Messrs. Greene and Varley's New Sensitive Salt.* We have no information beyond that published in the short leading article, and report of Prof. Meldola's second lecture, which appeared in the News of March 20th. If confirmed, the discovery is one of supreme importance, and its spectrum examination will become a matter of very great interest, to see where the zone of maximum activity lies. The finished print is vigorous and excellent in colour, almost like the platinotype.

M. M. & Co.—*Gelatinised Parchment.* M. Raymond's agents in this country are The Autocopyist Company, 72, London Wall, E.C.; Messrs. De la Rue and Co., of Bunhill Row, also manufacture the vegetable parchment.

## SUTTON'S PROCESS FOR PRODUCING A PRINTING BLOCK.

This being the age of pictorial illustration, many thousands of workers must be constantly engaged in the work of converting drawings and photographs into such a form as will fit them for reproduction in an ordinary printing press. We use the word "ordinary" because the illustrations to which we refer are those expressed in lines or dots—such pictures, we mean, as the zincographic and Meisenbach processes are able to produce, and which, at present, are alone suitable for universal press work. The higher class of pictures, which come under the head of collotypes, Woodburytypes, photogravures, and other designations, we do not here deal with, because they require special appliances which are quite outside the *entourage* of the common printing office.

The thousands of men—artists as well as skilled artisans—who owe their bread to this very recent development of photography are, of course, interested in every change which may take place in the introduction of new processes or the modifications of old ones; and, when the fact is announced that a method has been devised for obtaining an electro printing block direct from the surface of an ordinary gelatine plate, it is apt to cause a flutter in the minds both of *employé* and employer—the first, perhaps, conjuring up a vision of being able, without capital, to set up in business for himself, and the second asking himself the question whether all the valuable plant in which he has sunk so much money is to become antiquated and out of date.

The announcement to which we refer was, as we stated last week, made at the Camera Club Conference by Mr. Sutton, who explained the method by which he worked. Briefly stated, it is as follows:—A negative image is obtained by exposing to light an ordinary gelatine plate beneath a positive, together with a lined screen, such as is used for the Meisenbach and other processes, with the obvious result that the surface of the negative so produced is cut up into dots innumerable. The negative is fixed in strong hypo, so that the operation shall be rapid, and is afterwards washed as quickly as possible, the object of haste in both cases being that the gelatine surface shall not absorb too great a quantity of water.

Now comes the novel part of the process. After the washing operations, the negative is made surface dry by pressing on an absorbent surface, such as a linen pad or sheet of blotting-paper, and is then gently heated. The action of the heat is soon evident, in raising into relief those parts which have been affected by light—*i.e.*, the blackened portions of the film—leaving the dots as depressions. After the plate is dried, its gelatine surface is brushed over with fine graphite or plumbago, to give it a conducting surface, and it is submitted to the electrotyping process by being placed in a bath of cupric sulphate in the well-known manner. The result is that a thin skin of copper is attached to the surface, and this is afterwards built up with lead, and mounted type-high on a wooden block. Such a block is then ready for the printer.

Such is the theory, and it was so far borne out by practice that Mr. Sutton was able to exhibit to the members of the Camera Club a couple of blocks produced by the process.

Immediately on the publication of Mr. Sutton's paper, we determined to test the process for ourselves, for we were willing to acknowledge that, if practicable, it would cause quite a revolution in the means at present available of getting printing blocks from photographs. But instead of following exactly Mr. Sutton's steps, we determined to try whether the production of line drawings and engravings, now commonly done by the zinc etching method, could not be brought about by the new process, for what should be good for dots ought to answer equally well for line subjects. Moreover, by adopting this class of work we at once dispensed with the line screen, and there is a natural temptation in working experimentally to simplify matters as much as possible.

We commenced operations by making a small negative of one of Hogarth's engravings, and we chose the subject principally because its lines were distinct and bold, and also because, in the event of publication of the experimental block, no question of infringement of copyright could arise. This negative was developed with pyro and soda, for we knew by experience that a certain make of plate developed by this formula would stand a very considerable amount of heat without any melting of the gelatine. The negative was fixed, and washed for ten minutes only; but during this period the full force of the water-tap was turned on to it, so that the washing, although occupying a short time, was thorough in quality.

This being done, the negative was pressed between blotting-paper so as to take off adherent water, and immediately held in a metal dish at some distance above a Bunsen burner, the dish being moved about so that it should get uniformly heated. The effect on the plate was almost immediate. It began to steam, and the exposed parts swelled up into high relief, just as we had experienced many a time and oft when necessity had caused us to dry a similar plate rapidly so that it might be quickly printed from. When the maximum effect was reached, we left the plate in its dish on the ring of a retort stand placed some fifteen inches above the burner, and it was quite dry in about twelve minutes. The relief still remained apparent, but we judged it to have been reduced in height more than one-half. So far, the experiment was successful, and in case of accident we repeated it with two more plates with equal success. But we should mention that with another brand of plate we came altogether to grief, the film contracting and leaving the glass bare all round the edges directly heat was applied.

Two of the successful plates were now placed in the hands of a skilful professional electrotyper to be covered with the copper deposit, one by a dynamo machine and the other by battery. We are sorry to say that the result was the reverse of successful in both cases. The copper, in both plates, left bare places in the gelatine, so that the copper shell, instead of being perfect, was full of holes. Whether Mr. Sutton adopts some means of hardening the gelatine, or in some other way protects it from the destructive action of the copper bath, we do not know; but our experiments show that the process is not devoid of difficulties. In a subsequent article we shall point out some modifications in the manipulations by which we think more successful results may be achieved.

## THE "SIR PAUL PINDAR."

This cut is from a photograph of the old house standing until lately in Bishopsgate Street, and which has now been

re-erected in the South Kensington Museum as a specimen of Old London architecture. It is an interesting memorial of the time when merchants used to live in the city, and not in the suburbs. The disappearance of this old landmark, which dates from the time of James I., was referred to in our issue of the 3rd instant.

## FURTHER NOTES ON ELECTRO-CHEMICAL REVERSALS WITH THIO-CARBAMIDES.

BY COLONEL J. WATERHOUSE S.C., ASSISTANT SURVEYOR-GENERAL OF INDIA.

As a postscript to my last paper on this subject, published in the Photographic News, it was stated that an experiment with a pair of silver plates coated with precipitated silver bromide, of which one had been exposed to light and the other not, when connected with a very sensitive galvanometer and immersed in a plain eikonogen-lithia developer, showed a distinct electrical current, the needle deflecting towards the left; but when a pair of similar plates were immersed in the same way in some of the same developer containing five drops per ounce of Professor Reynolds' compound salt of thio-carbamide and ammonium bromide, the current was reversed and the needle deflected to the right. It was found that with the ordinary developer the exposed plate formed the negative pole of the galvanic couple, and produces a negative photographic image, while with the thio-carbamide developer it becomes the positive pole, and produces a positive photographic image. This reversal of the current has since been successfully repeated with the same kind of plates and developer, and also with a developer containing thiosinamine.

Silver plates bromised by immersion in bromine water have also shown the reversal of current clearly, and I have been able to obtain it on ordinary gelatine dry plates, though in this case the currents are exceedingly weak. There is, therefore, practically little doubt of the fact of the reversal taking place.

With silver plates it was found that the observations were rendered rather uncertain by reason of the comparatively strong currents caused by polarisation, especially after the plates had been used a few times, being cleaned merely by a good rubbing with emery powder and polishing, and therefore more or less impure on the surface. They can, however, be rendered pure by heating to a red heat, and quenching in dilute sulphuric acid. It is desirable to always perform this operation before using the plates.

Experiment having shown that it was possible to obtain evidence with the galvanometer of electrical action between the exposed and unexposed halves of a gelatine dry plate during development with ferrous oxalate, various methods of rendering gelatine dry plates sufficiently conductive to show the currents formed during development were then tried. Among the substances used were:—1. Gilt plumbago, which did not answer very well. 2. Silver bronze powder, which is generally a very good conductor, but did not answer at all in this case; the current from a battery would not pass. 3. Reduced silver in very fine powder, as deposited from mirror silvering solutions; this is an admirable conductor for ordinary electrotyping purposes, and also answered well in this case when applied wet, and polished after drying so as to give a bright and fairly solid coating. 4. Silver leaf; this answered well, but not quite so well as gold leaf.

The gold leaf seems, perhaps, the best material to use, because the gold conducts the current without exercising any chemical action with the developer, which might of itself cause currents. It is not so readily attacked by the sulphur set free at the negative pole as silver is, though some action probably does take place.

Either gold or silver leaf can quite easily be applied to the plates. The following method is effective.

Take a piece of stout blotting paper rather larger than the sheet of gold leaf; moisten it slightly, so as to leave it evenly moist without being wet, and lay it down carefully over the gold leaf, smoothing it lightly into contact all over. Then lift up the paper, to which the gold leaf will attach itself. The sheet can then be cut into convenient sizes, and the pieces applied to the gelatine surface of the dry plates. A piece of hard, dry paper is laid over the blotting paper and well rubbed down with the finger. The blotting paper will then be found to come away quite easily, leaving the gold leaf attached to the plate.

Another method, which answers very well, is to coat the glass slips with a thin substratum of gelatine and chrome alum; when dry, the gold leaf is applied as above. Strips of sensitive gelatine film, which, in the case of Wratten's "Ordinary" plates, may easily be stripped from the original glasses, can then be transferred to wet blotting-paper and laid down over the gold leaf, much in the same way as the gold leaf. This method has the advantage that the gold leaf is not in contact with the developer, and the currents seem to pass quite as easily as when it is outside the gelatine films.

The dry plates used were Wratten's "Ordinary," in slips about 4 inches long and $1\frac{1}{4}$ inches wide, the same as the silver plates. The gelatine offers a considerable resistance to the electrical current. A current from a bichromate cell, which, when passed through a pair of bromised silver plates in eikonogen developer, will mark a deflection of between 80° and 90° with the tangent galvanometer, when passed through a pair of gelatine dry plates faced with gold leaf and immersed in the same developer, will mark only 40° to 50°. Consequently, the currents produced by the action of developers with or without thio-carbamides on exposed and unexposed dry plates are exceedingly weak, and only just perceptible with the very sensitive suspension galvanometer. With silver plates coated with silver bromide the currents are very much stronger; but, as stated above, the results are somewhat uncertain, owing to polarisation currents. In all cases the currents produced with the thio-carbamide developers are stronger than those produced with the plain developer.

It is not yet quite clear how this reversal of current is produced, but some observations by T. Skey, recorded in vol. xxiii. of the *Chemical News*, throw a good deal of light on the matter. He found that metallic sulphides which have the power of conducting are also capable of generating electricity; and from a list he gives of the relative polarity of different sulphides, it appears that silver sulphide is positive to silver. In a battery consisting of a sulphide and a metal in acidulated water, the gas liberated is sulphuretted hydrogen, the nascent hydrogen exerting a de-sulphurising action upon the metallic sulphide, the ultimate effect of which is, in some cases, to completely reduce the mineral to the metallic state.

This seems to bear out the observation, recorded in my first paper, of the *reducing* effect of the thio-carbamides in alkaline solution on silver haloids.

Skey also states that sulphides are capable of performing the function of the negative element of a galvanic couple.

We have seen that the galvanometer shows that, with the ordinary developer, the exposed parts of a sensitive surface of silver bromide form the negative pole of a galvanic couple; and, consequently, by the laws of electrolysis, they attract the deposit of reduced silver, the alkali metal, and the hydrogen, whilst the liberated bromine or other acid, radical elements, and the hydroxyl of the base go to the unexposed parts forming the positive pole.

On the other hand, with the thio-carbamide developers silver sulphide is formed by the action of the developer on the unexposed parts of the picture, which then become the negative pole instead of the positive, and attract the sulphur, the hydrogen, the alkali-metal, and some of the deposited silver formed by the action of the developer on the exposed parts of the plate, which now become the positive pole, and attract the bromine and the hydroxyl; the former combining with some of the remaining deposited silver to form silver bromide, which is dissolved out by the fixing solution, leaving more or less residue of reduced silver.

There can be little doubt, I think, that, roughly stated, this is probably the correct theory of the reversals, though much remains to be done in working it out fully in order to throw more light on the various reactions which take place. A further investigation might result in finding some method of making the photographic reversals more perfect, and it seems likely that an electrolytic examination of various developing agents would afford valuable information on the general theory of development. The currents produced are, however, so weak that their satisfactory observation would be a matter of some difficulty. The subject is one of which I have very little knowledge, but it is to be hoped that the investigation may be taken up by some one more competent to deal with it.

## TECHNICAL SCHOOLS FOR PHOTOGRAPHY.

BY MAX JAFFE.

[In view of the proposed Institute, the following article, sent to us by the courtesy of the distinguished author, and translated for the PHOTOGRAPHIC NEWS, will, we feel sure, be interesting to our readers.—ED.]

It is impossible that the manifold changes which, during recent years, have sprung into being in all trades, as much in technical matters as in commerce, could remain without influence on the relation of tradesmen to their apprentices. The many innovations which are constantly introduced, the increased, overpowering competition, which compels him to strive continually after the improvement and simplification of methods of working, added to many other things which would take too long to enumerate, rob the tradesman of so much time now-a-days that he can no longer, as was formerly the case, take part, in a thorough manner, in the supervision of his workshop; and, therefore, cannot bestow the necessary care upon the apprentices committed to his charge. Nor can he teach and improve them to that degree to which they were educated in former times. Any law for giving directions to the employer regarding the instruction of his pupils would avail little; only a total reformation of our modern methods of instruction would be of the slightest use; and that no reasonable person would be likely to expect. Consequently, a danger exists that, if no other remedy be created, the industrial arts, instead of still going forward, will suffer a relapse. Certainly there are frequently workmen to be met with who have attained a complete mastery of their trade, and thus reached prosperity; and the existence of a rare degree of cultivation, added to an equally rare degree of perseverance, which overcomes all obstacles, is occasionally to be found. Such exceptions must be considered in calculating the danger of a relapse in the progress of art industries.

Those who have no opportunity in their youth of acquiring proficiency in their particular trade or profession, and are compelled to work in order to live, can never hope to be able to execute any but purely mechanical work.

These facts have been long known, and have led to the creation of public institutions for trade education. They are seen to multiply in almost every civilised community, the Government going hand-in-hand with the principal representatives of certain industries in the founding and furthering of these technical schools.

If it is looked upon as a great benefit that technical schools exist in which a man can learn the trade to which he wishes to devote himself, on the other hand, it is not to be doubted that this privilege can only be valuable where the instruction is absolutely thorough.

Our high schools are organised on the pattern which the philosophical and clerical schools of ancient times, and, later, the monastical schools, furnished; and an abundance of intellectual culture goes forth from them yearly, benefiting and brightening the whole civilised community.

Where is the pattern of a technical school to be found? In the fact that capable workmen were formerly rendered efficient during their apprenticeship. It is only right, and corresponding to the knowledge-acquiring spirit of our times, that the particular branch of science on which an industry depends should be taught in the technical schools. One point, however, is quite clear, and that is that knowledge is not the purpose, but the means to an end, and that the principal necessity in a thorough education is technical proficiency. Hence it is proved that, as only the most highly intellectual men should be chosen as instructors in the high schools, only the most efficient representatives of an industry should be selected in the technical schools; only, that is, such men as have attained a thorough knowledge and complete mastery of their trade through actual experience.

It must be remembered that apprenticeship does for the pupil, in one respect, what even the best organised technical school cannot compete with; that is, the direct acquaintance with practical life and its claims. The scholar who has just left school, till then led continually by his teacher, is absolutely ignorant of practical life—another reason, surely, for being the more anxious for his technical education.

In what manner is this result to be arrived at in the profession of photography? Before we answer this question, it appears advisable to point out the position which our profession occupies, more especially as there has been such an enormous extension of it since the introduction of gelatine dry plates that its limits are absolutely indefinable; so that some people, otherwise intellectual, will not acknowledge the existence of a photographic profession at all.

It is not to be denied that grand things have been done by amateurs both in landscape and portraiture, but there is every justification for the existence of professional establishments, both in the present and in the far distant future. The energies of the photographic profession will be more and more directed to the application of photography to science, art, and industry; principally by the constantly improving photo-mechanical processes which bring photography in contact with the printing-press.

Our profession, like all others which find their foundation in art, is an art industry. On the other hand, it is continually dependent upon the results of scientific researches, and, in this respect, comparable to electrical industries. The photographer is just as little a scientist as the electrician, and just as little an artist as the art furnisher and art decorator, and his endeavour should be this: to be a thorough professional man whose knowledge is ennobled and inspirited by a scientific and artistic education. To obtain this result, special care must be taken in the foundation and organisation of technical photographic schools, to provide a thorough preparatory education in artistic and scientific respects. The next thing to be considered is the teaching of drawing. The exercises must be adjusted, on the one hand, to the preparatory knowledge which the pupil has already acquired, and, on the other hand, to his natural talents and the special branch of the educational course to which he intends to devote himself. It must be taken into consideration by all who go in for photography as a profession, that drawing is a particular necessity, for the formation of the taste in general, and principally, the appreciation of form, contour, and perspective, plane and solid. The drawing lessons should occupy the pupil the whole day, and he should study from the antique, the nude, drapery, &c., landscape, and every form of ornament. We consider art history an indispensable item; the pupil should be instructed so far that he shall be well versed in the development of the artistic life of all nations and ages, and in the characteristics of the various schools. These drawing lessons should be continued during at least a year for every student, and for such pupils as desire to learn retouching and painting of photographs, not less than two years. For these latter a course of anatomy should be provided. Besides this, all those who wish to learn the various photo-printing processes should have opportunity provided for them of practising on papers prepared and unprepared, as well as work on the lithographic stone.

(*To be continued.*)

Newcastle-on-Tyne and Northern Counties Photographic Association.—The next meeting of the above Association will be held in the Mosley Street Café, Newcastle, on Tuesday, 21st April, when a paper and demonstration on carbon printing will be given by Mr. T. Hedley Robinson.

Theory of the Phenomena of Dyeing.—All the phenomena of dyeing necessitate two essential conditions: the presence of acid or basic functions in the material to be dyed; the presence of the same functions in the colouring matters. The sole exception of this rule is that of the tetrazo colouring matters, which are taken up by cotton without a mordant, in an alkaline bath, and which will require a special study. We are entitled to say that the phenomena of dyeing, obtained with soluble colouring matters, are of a purely chemical order, and that the rules of chemical action are sufficient for their explanation. Léo Vignon.—*Chemical News.*

Transfer of a Photo from Chromate Paper to Zinc.—Place the chromate paper containing the photo for ten minutes between two sheets of paper which have been saturated in a 1-5 solution of nitric acid in water. Upon the zinc plate place a piece of paper which had been previously soaked in nitric acid, and pull through the hand-press, which will cause a slight etching of the surface of the zinc plate; the sheet of paper is taken off, and all traces of nitrate of zinc are carefully removed from the zinc plate by means of a blotter. The photo is then transferred upon the plate, gummed over, &c.; it is then rubbed in with ink, which has to be thinned with olive oil, and when all details appear sufficiently strong the plate is etched with a preparation made by adding a small quantity of phosphoric acid to a gum solution. When a drop of such a preparation placed upon a polished zinc plate discolours the same and effects its purity, then it is of sufficient strength.—*Lithographic Art Journal.*

## THE ETHER LIGHT.

So many questions are asked by photographers and lanternists with regard to the efficiency of ether as a substitute for the usual house gas in limelight work, that the following remarks upon the subject will prove interesting. They were originally contained in a private note addressed to the Editor from a German correspondent, and permission has since been obtained to publish the matter in the Photographic News.

I promised some time back to give you an account of my experiments with the ether light. It is about ten years ago that I began with lantern projections, which soon became my hobby, and have been ever since. I began with a "wonder" camera, which soon was followed by a pair of home-made, clumsy, wooden lanterns, but with good optical parts. If I remember well, it was in 1884 that I exchanged these giants for two sciopticons, with Newton's three-wick refulgent lamps. In 1886 I adopted the limelight. Luckily circumstances brought me into possession of a polariscope (after the design of Prof. Paalzow, of Berlin), and from that moment the ordinary blow-through jet did not do any longer. I was in search of more light. My gas jets were interchangeable ones, allowing their use as spirit jet, safety jet, or mixed jet. I must point out that the oxygen outlet was not *round*, but *flat, somewhat* like a slit of four millimetres in length and half mm. in width. These jets give a powerful light.

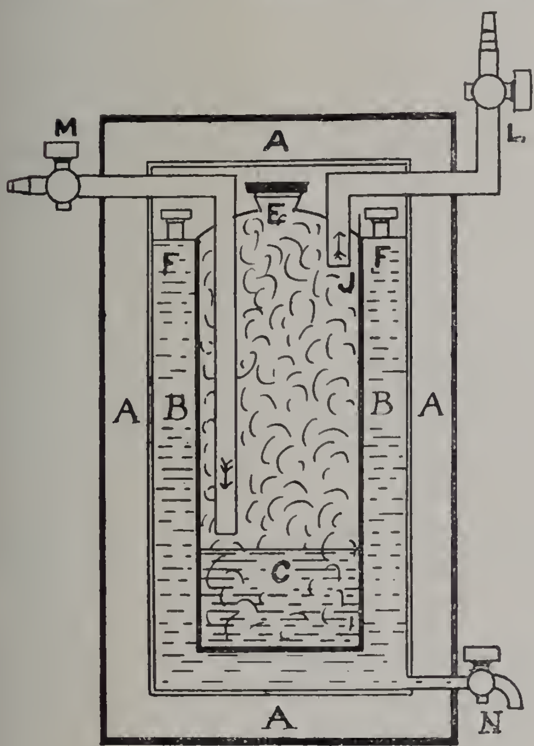

Fig. 1.—Gasoline Tank for Limelight.

Now the mixed jets' turn began, after I had convinced myself that there was no doing with the blow-through. Two bags were used, and everything went on smoothly; but I disliked the trouble of having to do with two bags. I remember having read in Liesegang's *Laterna Magica* (a quarterly paper), and also in his book, "The Projecting Art," of some gasoline light, and a Herr Fr. Jul. von Kalkow was mentioned as the inventor. I had such an apparatus made for me, and give you here a drawing of it, which will better explain than describing it at full length. The whole is made out of zinc (see fig. 1). A and B are cylindrical vessels, one within the other, but with a space between each. A is occupied by stuffing of wool; B contains hot water filled in from F, and, after use, let out by N. The inner cylinder, C, is stuffed with curled horse-hair, and, by unscrewing E, gasoline or ether can be poured into it as far as the mark at C, so as to keep the level of the liquid to the opening of the H tube. The vapour is emitted at J to the tap L, from whence a tube carries it onwards to the H jet.

Now, Herr von Kalkow blew ordinary air through this apparatus, filling a second bag with the so saturated air. Having, however, read that blowing pure oxygen through it was more advantageous, I took at once to this method. The result was a much superior light.

It was in the beginning of 1887 that I adopted this method, but Herr von Kalkow constructed his apparatus long before that time, and the first description given is in No. 6 of April, 1878, of Liesegang's *Laterna Magica*. In No. 27 of the same paper of July, 1885, I found a description of the Broughton tank. I had one made, for economy's sake, out of tin. Its performance, however, did not please me. I had several pops with it, and I took again to my first saturator. One day the following idea struck me. I took my Broughton tank to pieces, and

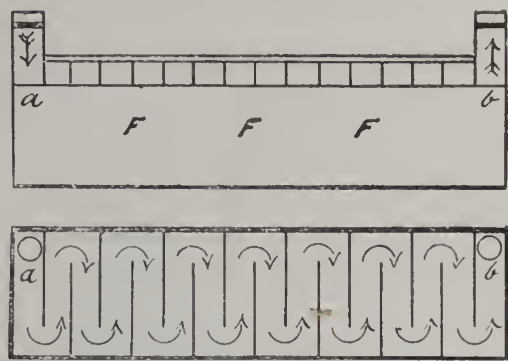

Fig. 2.—Modified Broughton Tank.

had all the partitions forming the circuit cut short to about one-third of an inch. I further did away with the chambers on the top, and in fig. 2 is shown, both in section and plan, the form of instrument I got.

Into the empty space below (FFF) I put layers of coarse flannel and thick felt (such as is used under saddles) till the box was full, then I *pressed* the lid with the circuit on to it, and had it soldered tight down—the flannels and felt pressed together, and the zig-zag canal kept open. This modification made the saturator work very well, better than the one on von Kalkow's principle. I attribute the improvement to the greatly extended circuit, and the consequent better saturation of the oxygen. This alteration I made towards the end of 1887.

When the lantern season for 1888 began again, I found in an English catalogue an "ether saturator" recommended. Opening my own improved one, I found it all rusty inside. Instead of having a new one made like it in a more suitable metal, I decided to try the English one. I at once set to try this new one (manufactured by Sutton and Cutts), but it did not answer; but I am bound to say that the fault was not with the saturator, but with the jet, which, as I mentioned before, had a *flat* (slit-like) opening. So I at once ordered a pair of interchangeable jets suitable for the ether light. They arrived, and since that time the saturator, as well as the jets, have done their duty I never have a blow-up or a pop, and always get a very good light for polariscope and microscope.

I learnt subsequently that Mr. Ives has also taken to the zig-zag circuit, but, if I am well informed, not before the year 1888, whereas I had already, towards the end of 1887, made a canal of this form to my tank.

Ives's patent, I am told, dates from 1882, and his improvement for the zig-zag from 1888. Scott's saturators came out in 1890. If these dates are correct, neither of them can claim the priority of invention, either for the stuffed saturator or for the zig-zag canal on the one hand, nor for applying heat to the saturator on the other hand. Previous to them there was Herr von Kalkow, whose saturator was described in 1878, and I myself used a zig-zag canal as early as 1887 on the top of a layer of porous material.

I quote these dates as they may interest you, as I have no pecuniary interest in the matter at all.

If the ether light is not generally used, I think it is in consequence of its being associated with that ill-bearing name, "mixed jet." If so, help can be brought with very little loss of light. I have designed a *blow-through* jet which is well adapted for the ether light. This same jet gives also a most brilliant light when two bags are used. It stands somewhat between the usual blow-through and

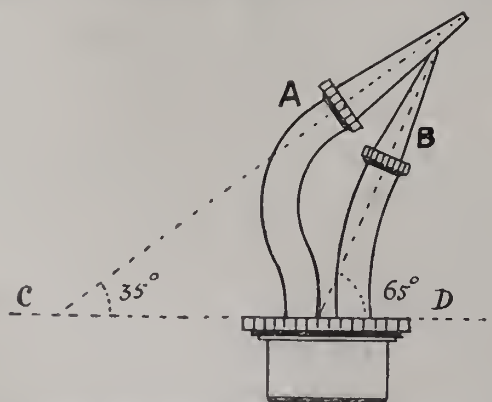

Fig. 3.—Blow-through Jet for the Ether Light.

the mixed jet, but *two* bags are necessary (see fig. 3). A and B are two ordinary nipples, of which A projects above B by about six millimetres (one-quarter inch). Both have equal bore of one millimetre (one-twenty-fourth of an inch). The A nipple makes an angle of 35°, and the B nipple one of 65° with the horizontal CD. From the point where the B nipple touches the A nipple, a small groove is worked into the under part of the A nipple, reaching to the point of the burner. I think it would be worth your while to have such a jet made, so that you could for yourself form an opinion of its merits. This form of jet is very advantageous for those demonstrators who would like a better light than is obtainable with the ordinary blow-through, and yet would not like to use a mixed jet.

With *one* bag for the oxygen and the gas from the main supply the jet *is not suitable*, but when two bags are used with a weight of one and a half hundredweight to begin with, the jet gives a light very near to that by the ordinary mixed jet. I should very much like to see such a jet worked with two cylinders, of which, as yet, I have no experience.

With the ether the jet is safer than the mixed jet, because the vapour and the oxygen are kept separate till the igniting point is reached, and another advantage is that the peculiar construction causes the hydrogen element to heat the oxygen nipple, and the heated oxygen increases the intensity of the light.

## CRYSTAL PALACE INTERNATIONAL PHOTOGRAPHIC EXHIBITION.

### First Notice.

This Exhibition, which nominally opened on Monday last, was, after the manner of exhibitions, not nearly ready for public inspection on the opening day. Some of the apparatus stalls were unoccupied, while at others the tapping of hammers and screeching of planes told of fixtures not yet in a fixed position.

So far as the apparatus section is concerned, the present Exhibition bears unfavourable comparison with that of two years ago, when from one end of the nave to the other the floor of the building was covered with the exhibits of our foremost manufacturers. This year about one-sixth of the same space is occupied with apparatus, and, although one or two leading firms put in an appearance, the majority are conspicuous by their absence. A visitor to the Exhibition held here in 1888 or 1889, and who afterwards came to that of 1891, might think that, perhaps, the trade had combined to boycot the scheme; but such is not the case. It is a simple matter of that consideration of the three letters, £ s. d., towards which most things human have to filter down. In a word, the manufacturers say that it does not pay them to exhibit at Sydenham; if it did, they would, of course, go there. But when goods have to be carried to and fro, an assistant taken from his ordinary work to be on duty at the Palace each day, and rent for space paid, there is little or no margin left for profit on any business which may be done. The Crystal Palace authorities would do well to look the matter fairly in the face, and see whether they cannot another year offer better inducements to our leading firms to exhibit their goods. To many people the apparatus is more attractive than the pictures, and they go to an exhibition like this principally to see what novelties there may be in the market. Visitors to Sydenham this year who have such proclivities will most certainly be disappointed; but it is as well to remember the salutary adage, "*Audi alteram partem*," and the other side say that if exhibitors would rent smaller spaces, and would take good care to put them in charge of pushing assistants, they would have no reason to regret their outlay.

But although the apparatus is not as plentiful as one could wish, we may certainly say that never has a better collection of photographs been seen at the Crystal Palace; and we are able to say this at a time when many of the pictures expected are not yet in their places; for, by an unfortunate misunderstanding, some two hundred pictures are detained at Liverpool. The date of the Palace Exhibition was so fixed that its opening should just tread on the heels of the closing day at the Liverpool Exhibition, so that many of the pictures shown at the latter place could be packed and sent to Sydenham direct. But this wise arrangement was suddenly knocked on the head by the resolve of the Liverpool people to keep the doors of their successful Exhibition open for an extra week. This will at once account for the many blank screens and alcoves on view at the Crystal Palace last Monday, and for the notification which adorned them, to the effect that several important exhibits would not be in position until Friday (to-day).

This unfortunate *contretemps* has, too, caused the judges, of necessity, to hold their awards until they could pass sentence on the Exhibition as a whole. It will, therefore, be better if we, too, reserve all notice of the pictures until our next issue; but we can most certainly hold out the promise that the collection will be one of very great interest to everyone of photographic tastes.

As usual, the lantern entertainments in the large theatre are rightly relied upon as a most attractive feature of the Exhibition, and the opening show on Monday was most satisfactory in every way. Mr. S. G. B. Wollaston is single-handed this year, and not only manages the Exhibition generally, but has personal charge of a fine double lantern built expressly for the building by Mr. Watson, of Holborn, the lenses being supplied by Messrs. Taylor, of Leicester. We may, therefore, take it for granted that the apparatus is of the best; but we did not before know that Mr. Wollaston was such a first-rate manipulator. No exhibitor can complain that his slides are not well focussed, or that the light by which they are shown is in any way faulty. If they do not show up as well as they expect, they may be quite certain that the fault lies in the pictures themselves, and not in the apparatus, or in the operator who works it so skilfully. The accompanying music by Mr. Weston, the assistant organist of the Palace, every bar of which is most cleverly adapted in character to the type of picture exhibited, is quite a treat in itself.

It is arranged that Mr. T. C. Hepworth is to act as demonstrator in the theatre every Monday, Wednesday, and Friday during the progress of the Exhibition. On the alternate evenings the more commercial aspect of lantern work will be exemplified by Messrs. Noakes, of Greenwich, with coloured pictures, dissolving views, effect slides, and items of a similar popular character.

## DETECTION AND DETERMINATION OF VERY SMALL PROPORTIONS OF ALUMINIUM IN CAST-IRON AND STEEL.

BY ADOLPHE CARNOT.

The author takes a rather large quantity of the metal—for instance, 10 grms.—and attacks it with hydrochloric acid in a platinum capsule. The use of glass or porcelain is avoided as much as possible, to prevent any accidental introduction of alumina from the apparatus.

When the metal is entirely dissolved, without allowing the solution to become peroxidised by exposure to the air, it is diluted with distilled water and put into a flask or a beaker, washing it several times by decantation, and retaining the insoluble portion—graphite, silica, &c.—upon a filter. A portion of silica may remain in solution, and must be eliminated afterwards; but this must not be done by evaporating the solution to dryness, as it contains an enormous quantity of ferrous salt.

The greater part of the free acid is neutralised with ammonia and then with sodium carbonate, and sodium thiosulphate is added. When the violet colouration has entirely disappeared, and no more ferric salt in the solution, which is now completely colourless, he adds 2 or 3 c.c. of a saturated solution of sodium phosphate, and about 20 c.c. of a solution of sodium acetate. The liquid is then heated and raised to a boil, which is kept up for about forty-five minutes, or as long as the slightest odour of sulphurous acid is perceived.

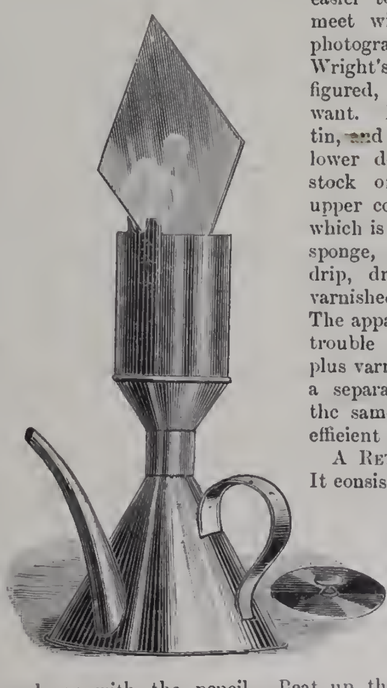
There is formed a precipitate, generally of little bulk, consisting of aluminium phosphate mixed with sulphur, and containing a little silica and ferric phosphate. This precipitate is received on a filter and washed with a little boiling water, and then placed on a capsule of platinum, and treated in heat with 10 or 15 c c. of hydrochloric acid diluted with water.

The solution is evaporated to dryness, and the residue is kept at 100° for an hour, so that the silica may become perfectly insoluble in acids. It is then re-dissolved in a little dilute hydrochloric acid, heat being applied to re-dissolve all the aluminium and iron phosphate; the liquid is filtered to remove the last traces of silica, diluted with 100 c.c. of cold water, and the precipitation of the aluminium phosphate is repeated by the same method—that is, by almost complete neutralisation of the acid with sodium carbonate, the addition of thiosulphate in the cold, and subsequently of a mixture (previously dissolved) of 2 grms. acetate and 2 grms. thiosulphate, boiling for half-an-hour, and filtration through a small filter of paper which has been washed with acids and leaves no ash.

The silica and the small quantity of iron which remained in the first precipitate have thus been completely eliminated from the second, which, after having been washed with boiling water, is dried, ignited, and weighed.

The aluminium phosphate thus obtained ($PO_5Al_2O_3$) contains 22·45 per cent. of aluminium. The operation requires only a few hours, and gives accurate results.—*Bull. de la Soc. Chim. de Paris.*

Handy Varnish Pot.—Any appliance which will make the extremely disagreeable and tedious operation of varnishing easier to the operator should meet with a welcome from photographers. Mr. W. E. Wright's apparatus, here figured, seems to meet a want. It is constructed of tin, and is in two parts, the lower destined to hold the stock of varnish, and the upper containing a funnel in which is placed a plug of fine sponge, through which the drip, drip from a freshly varnished plate can filter. The apparatus thus saves the trouble of running the surplus varnish from a plate into a separate bottle, while, at the same time, it acts as an efficient filter.



A Retouching Medium.—It consists of the white of an egg, with a little ammonia added to preserve the albumen from decomposition, and the inventor says it supplies a fine biting surface to work on with the pencil. Beat up the white of one egg to a froth; let it settle. Then add ten ounces of distilled water, shake up, filter, and add a few drops of ammonia. After the negative is washed, flow it with the albumen solution, and let it dry. Unlike many of the concoctions sold, it is harmless.—*Photo. Record.*

## Notes.

Our readers are requested to note that, as announced in the last issue of the Photographic News, the price of the paper is now reduced to twopence.

More work for the photographic process-block maker. The prospectus of a new magazine, *The Ludgate Monthly*, has been issued, and, judging from its specimen pages, the publication should "catch on," as they say over the water. The illustrations are well done, some being from tint drawings, and others owing their being to the zinco-line process.

It would be an interesting thing to know how many of these constantly cropping up new publications owe their inception to photography. Some of them, of course, could never have been launched at all unless some method of producing pictures without the aid of the slow cutting graver had been devised. The *Daily Graphic* is an example of one. Certain it is, too, that the army of second-rate comic papers (so called) could never have been possible without the aid of the photographer.

The World's Fair at Chicago is, according to a prospectus which we have received, to lick all creation. The *American Scribe*, in dealing of its wonders, breaks forth into poetry, as the following extract will show: "North of these buildings, in the main lagoon, will be an island of twenty or thirty acres in area. It is the intention to have this kept as wild and primitive as possible. There the visitor may wander through a miniature 'forest primeval,' pathless and untransformed by art, and may hunt the fragrant wild flower, or the *saucy chipmunk*, and generally commune with nature in its native haunts."

One expression we have emphasised by italics, for, although we have referred to every dictionary within reach, we have not found out what it means. A friend suggests that *saucy chipmunk* is American for amateur photographer. If this be so, we cannot see why he should be hunted; but then, in this country, we do not hunt "fragrant wild flowers." They are curious people, these Americans.

All who have made a study of the human countenance —a category which should, of necessity, include photographers—must have noticed that, in spite of the common notion that nature is diverse in her works, and seldom repeats herself, some human beings so closely resemble others of their species that one is almost persuaded to believe that every man has his double. That this is hardly an exaggeration is proved by what most of us have experienced, the addressing of an utter stranger in the street in mistake for an intimate acquaintance, and only finding out the error when confronted by the cold, disdainful stare of the insulted one.

Toole, the actor, it is said, once turned such an accident into a practical joke of a very humorous kind—humorous, that is, except from the victim's point of view. In a certain restaurant he had, in error, clapped a stranger on the back and exclaimed, "Halloa! George, how are you?" Apologies followed, and all was well so far. But Toole presently pointed out the victim to a friend of his who sauntered in, and, without referring to what had occurred, said, "I bet you a shilling that you won't go up to that old chap in the corner, as if you knew him, slap him on the back, and say, 'Halloa! George, how are you?'" The friend took the bet, and carried out its provisions to the letter, with a result that can be better imagined than described.

Two well-known men, who have recently gone over to the majority, had well-known doubles. One, the late Lord Granville, was exactly like Mr. Denny, of the Savoy Theatre, when made up for the Grand Inquisitor in "The Gondoliers"; and the other was the late P. T. Barnum, the great American showman, who was, in feature, the exact counterpart of Titus Vespasian, according to a certain Neapolitan sculpture, a cast of which stands in the Crystal Palace hard by the Egyptian Court.

The hackneyed phrase, "There is nothing new under the sun," has a peculiar suitability when applied to photography. Investigators and experimenters who stumble upon what they think is a novelty are continually being pulled up by some tiresome person with a good memory, who calmly says the same thing was done a quarter of a century or so ago. A case in point occurred at a recent meeting of the Royal Microscopical Society, in connection with a suggestion of M. Fayel as to a novel method of examining large opaque objects, which he terms "Photo-micrography in space." The plan proposed by M. Fayel is to direct a photographic lens to the object, and focus the image upon the ground glass of the camera. The ground glass is then removed, and the aerial image viewed with a compound microscope. No sooner was this method brought under the notice of the Society than Dr. Charters-White remembered a similar plan devised by the late Dr. J. Matthews for precisely the same purpose, and described and exhibited at the Quekett Club in February, 1879, under the name of the micromegascope. This brought up Mr. Mayall, who pointed out that the micromegascopé was known in the last century as the "megalascope," and was constructed by B. Martin. If the subject could have been pursued, it might have been discovered that Martin had borrowed the idea from somebody else. However, so far as is known at present, the honours rest with the "megalascope."

A proof of the widespread interest taken in photography is the frequency with which articles appear in periodicals intended for that omniverous person, the general reader. In Scotland they have

WAITING FOR WIND.

gone a step further, and the *Weekly Scotsman* now devotes a special column every week to the subject. We learn from this column that arrangements are being made for the establishment in Liberton, near Edinburgh, of a photographic society for amateurs. Soon, no town—one might almost write village—will be complete without its photographic society. Certainly, there is no subject so provocative of talk as photography, and yet the Photographic Society of Great Britain complains, or did complain, that it cannot get topics and papers for discussion.

---

Hitherto the opportunities for making cloud negatives which April usually affords have not been so frequent as the ardent amateur would like. Watching for the sun while a bitter north-east wind is blowing is not very pleasant work, though the amateur of the old school was indifferent to bodily discomfort. Carrying half a hundredweight of photographic baggage was probably good training. Whether the amateur of to-day, who likes everything ready-made for him, has the courage to risk a cold in the head in securing cloud pictures, is not quite so certain; anyway, if he does take out his camera for this purpose, and is successful, it is to be hoped that his results, when joined to landscape negatives, will not show the sun shining at the same time from opposite sides of the picture. It is all very well for him to improve an expanse of vacancy by putting in clouds, but, to use an expressive theatrical phrase, let him also "jine his flats."

---

Mr. Robert Buchanan, in his vigorous attack on the Zola and Ibsen school, is not very complimentary to photography. He compares the "present apotheosis" of dreary dramas to "a series of dingy, amateur photographs taken in the scullery during sunless weather," and he holds, in pursuing the comparison, that "there is even more falsehood to nature in a bad photograph than in a wildly executed painting." What have the believers in naturalistic, out-of-focus photography to say about this?

---

The death of Keeley Halswell removes from our midst a painter who, of late years, had made the upper waters of the Thames his constant study. He had his studio in his house-boat, and here he worked at those delightful sketches of river scenery which are identified with his name. Mr. Keeley Halswell, like Mr. Wyllie, studied river life and aspects and their constant variety in the only way possible—by living on the spot. Their successes suggest what an enormous field the Thames presents to the photographer who has the perseverance to grapple with the subject in its entirety. Plenty of photographs of the Thames exist, it is true, but if they could be all got together, the result would only be a very disjointed collection.

---

The latest application of photography to medical science is to use it as a means of locating tumours on the brain. The theory is, that spasms are caused by affections of the nervous centres, and that the disturbance of a centre is invariably followed by identically similar contortions of the muscles. A tumour must, of necessity, press upon a nerve centre, producing violent spasmodic attacks. While in this condition the patient is photographed, and the exact position of the tumour discovered. Experiments, says the *Mining and Scientific Press*, of San Francisco, have been successfully made by an "eminent local surgeon." We must confess we do not follow the reasoning which attributes spasmodic attacks to tumours on the brain. Why not to a tumour on any other part of the body? We should also like to know if one photograph will suffice, or if a series is necessary. There seems to be something wanting in the explanation of the theory.

---

The *Chicago Inland Printer* gives in its March number a reproduction of a photograph entitled, "An Old Love Maker," which visitors to the Pall Mall Exhibition of 1889 will possibly remember. The name of the company working the process is prominently displayed; the name of the photographer, Mr. H. P. Robinson, is omitted. The producers of other pictures given in the same number are treated with similar indifference. The only instance in which the photographer's name is mentioned is that of a photograph of a bridge at Berne, Switzerland; but then the photographer is a Chicago man, which, of course, makes a difference. American notions of copyright obligations are very elastic.

---

No fresh light upon the Pennell-Herkomer matter has been thrown by Messrs. Novello, the publishers of Mr. Herkomer's "Idyll," in their answer to Mr. Pennell. Messrs. Novello simply state their belief that the illustrations are all that is claimed from them. But this is precisely what Mr. Pennell wants to find out. He would like to know if the illustrations are etchings executed by Mr. Herkomer himself, or are photographic reproductions touched up with a needle, and this is what neither Mr. Herkomer nor Messrs. Novello will tell him. Possibly this withholding of information accounts for the flavour of acerbity regarding photography which marked Mr. Pennell's paper read at the Camera Club Conference.

---

Missionaries, like other people, have to move with the times. When Mrs. Jellaby flourished, flannel petticoats and pocket handkerchiefs were the articles of which it was considered the dark races stood most in need. We have got past these primitive ideas. A gentleman interested in the Blantyre Mission, South Africa, is of opinion that with the close of the lantern season there should be a good many photographic slides of "no further use" to their owners. He announces accordingly in a provincial paper that he will be very glad to receive contributions of such cast-off articles for the use of missionaries!

## THE PORTRAITURE OF THE UNSEEN.*

BY JAMES MEW.

A photo-microscopic album would be a novel and possibly pleasing variety for the jaded caller i' the afternoon, who is sick unto death of the feeble, fatuous family photographed groups, which have so often met her loathing eye. Such an album might be easily prepared. The common favourites shown by a magic lantern at a school treat could be without any trouble transferred to its pages. It might, for instance, contain the epidermis of the larva of a caterpillar (*tipula*), the tongue of a fly, the leg of a flea, the wing of a midge, the parasite of an ox, the *palpi* of a spider; and, if all these were not enough, specimens might be added of *orthoptera*, *dermaptera*, *hymenoptera*, *aphaniptèra*, *diptera*, *neuroptera*, *trichoptera*, *lepidoptera*, *homoptera*, and *heteroptera*, or, in common English, of cockroaches, earwigs, wasps, fleas, flies, dragonflies, caddisflies, butterflies, aphides, and bugs. Such a collection would add instruction to amusement. It might convey a religious as well as an æsthetic lesson. The exquisite marvel of divine workmanship in the oar-foot of the water boatman, or in the beak of the *cimex lectularius*, might be insisted on in the course of conversation, so long as the scientific names were preserved, without raising a blush in the peachbloom cheek of modest virginity, and with at least as much moral and religious benefit as the state of the weather, the behaviour of Mrs. Brown, or the difficulty of procuring a cook. But, if the above-mentioned album be not enough to divert conversation from these common and well-worn channels, other albums of a cognate interest could be conveniently produced.

Albums, for instance, of vegetable tissue containing leaves of the *deutzia*, raphides, and cuticles. Albums of crystallisations, showing the octahedrons or square prisms of strychnine, the oblique rhombic prisms of brucia, the regular white, brilliant cubes of arsenic, the acicular formations of caffeine, and the delicate profusion of silk-like spikes of quinine sulphate. Petrological albums displaying rock sections, thin slices of stone, to the representation of which the polariscope has lent its valuable opitulation.

Finally, if all these fail to interest, albums must be introduced of those minute organisms which seem to exist everywhere alike—in air and in earth, and in the waters above the firmament; in showers, and dews, and winds; in wells, and seas, and floods; in ice, and snow, and hail, and rain; in the waters under the earth, and in all green things upon the earth; whose name is legion; the vegetable pathogenic germs, whose paths are full of the crosses of destruction and decay; which destroy, but cannot, though living on life's lowest confines, themselves be easily destroyed, save, indeed, by a broth of their own immediate kindred—in a word, the *microbes*; albums of beings, of classification complex and variable, containing portraits of *Schizomycetes*, *spaltpilze* or fission-fungi, never fitly taken without photo-micrographic aid. In these albums, drawn by the powerful sun—like the fen-sucked fogs invoked by King Lear against his daughter Regan—or by the magnesium light, but, in either case, without bias and with unerring skill, the listless visitor may behold graphic presentments of creatures with which she has, at some time of her life, unless protected by particular favour of the gods, formed all too close an intimacy. Here are the *micrococci* with their circular presentments, the progenitors or clansmen of scarlet fever and small-pox, erysipelas, and pneumonia. Here are the stiff-necked *bacteria*, of whom Dr. Koch, of Berlin, first succeeded in photographing the *flagella* or tails; swift-moving, short, cylindrical. Here are their longer brethren, the *bacilli*, alas! too well known in hospitals of consumption, among them the *commabacillus*, whose portrait was first taken by Dr. van Ermengem in his etiology of cholera; albeit his claim to a relationship with that disease is not yet completely proven. And here are the curvilinear *spirillum*, reminding us of a corkscrew or the letter S, the quivering *vibrio*, and the *saccharomyces coprogenus* of Saccardo—better left concealed in the canonicals of lèarned obscurity.

All these and many more photo-micrographs may be exhibited at four o'clock tea, or any other festive occasion, nor do they seem altogether unsuited for the entertainment of what very good people will persist in calling the Sabbath. But, in a small chamber of this many-roomed palace of intellectual delight, there is one little picture upon which it were wiser not only not to speak, but not even to look. The dung fly's foot! The dung fly's foot, only too celebrated in photographic annals, is far better avoided. It disturbed the harmony of the past, and raised passions out of all proportion to its size. Let not its motto be "*Resurgam.*"

In conclusion, the careless spectator must not suppose that these portraits are taken with as little trouble as an ordinary human likeness. No! this tiny folk bristles with difficulties, which the photographer knows only too well. Consider, for example, the case of the familiar and, to some, insignificant flea, the human flea—for the race of fleas is large and varied—the beast known to the naturalist as *Pulex irritans*. His yellow colour constitutes at the outset a considerable stumbling block. He must meet with severe treatment in a solution of caustic potash; and yet not too severe, or he will dissolve into jelly. He must be soaked for a season in spirits of turpentine. His tissues must be bleached, and yet not too much, or they will become too transparent. The contents of his thorax and of his abdomen must be carefully expelled. He must be finally hardened with alcohol, and mounted in balsam. He must also be stained with many different stains to bring out his details, and all air-bubbles must be carefully eliminated from his likeness. The apparatus for taking him when suitably dressed varies from a simple combination of camera and microscope to a most complex piece of elaborate machinery, but without the assistance of the latter a satisfactory portrait can seldom be obtained.

* Concluded from page 279.

---

Photographic Club.—The subject for discussion on April 22nd will be "The Keeping Qualities of Developers"; April 29th, last lantern meeting of the season (visitors invited).

Mixed Hydrochinon and Eikonogen Developer.—On every side we hear of a developer, the composition of which we give herewith. It was first recommended by the Photographic Club, of Paris:—

| | |
|---|---|
| Sulphite of soda ... ... ... | 100 grammes |
| Eikonogen ... ... ... ... | 15 ,, |
| Hydrochinon ... ... ... ... | 5 ,, |

are dissolved in 1 litre of hot water. When cooled, 50 grammes of carbonate of potash are added. This developer is used by many Viennese amateurs, and they confirm what has been said of it, viz., that the mixed bath unites in itself the good qualities of both the hydrochinon and eikonogen developers; it works as energetically as the latter, without, however, veiling the shadows, and gives the characteristic strength obtained with hydrochinon. The temperature of the developer is important—the higher it is, the more energetic the action, and thus a shorter exposure is required.—*Photo. Rundschau.*

## PROCESS OF FIRING PORCELAIN IN FRANCE.

The United States Consul at Limoges says, in his last report to the United States Government, that the proprietors of the large porcelain factories there have been for a long time studying the question of reducing the price of fuel. At a recent congress of the manufacturers it was said that some new and cheap way of manufacturing porcelain must be found for France, or the industry which has become so famous, and which employs so many of the inhabitants, would be driven from French soil on account of the cost of firing. It was there ascertained that the cost of firing china in Bohemia was not more than ten francs a ton; in England it was only thirteen francs, while, for the same thing in France, at Limoges, the cost was between thirty-four and thirty-five francs. This difference being so great, and making it impossible for the French manufacturers to make their china as cheaply as their foreign neighbours, various devices have been tried, but with little success. In order to compete, wages have been reduced to the lowest point, and still the manufacturers are said to have lost money. The coal that is employed is necessarily costly, as a smokeless, long-flame variety is required. Many of the factories burn wood only, as that produces a purer white than the very best kinds of coal, but wood is dearer than coal. It is consequently only used in firing the muffles, and in the finest grades of porcelain. A few years ago a new process was tried, that baked the porcelain in a short time; but the cost made the process impracticable. It was under such circumstances as these that one of the most progressive houses in Limoges was induced to employ petroleum or residuum oils as a fuel; to accomplish which, an American firm using the Wright burner was requested to come and make a trial with the fuel. There was very much doubt and fear connected with the experiment; but, after a time, it was attempted, and the results were far better than anticipated. The heat was shown to be absolutely pure. No gases or smoke in any way discoloured the china, which came from the kiln much whiter, and in better condition, than when it is fired with the best of wood. In the muffles there was a decided advantage. The delicate colours, which show at once the presence of the slightest quantity of gas, were perfect. "This new discovery," says Consul Griffin, "promises to revolutionise the whole porcelain industry." It is estimated that, by employing these oils, there will be a reduction of about fifteen or twenty per cent. in the making of china. The only question now is the present classification of residuum oils in the Customs tariff, as the present duty on petroleum—one hundred and twenty francs per ton—is prohibitive; but strong pressure is being brought to bear on the Government to have fuel oils classified as fuel, which pays only one franc thirty centimes a ton. New life is given to an industry that was seriously threatened; and it is hoped that the French porcelain will be brought to a greater state of perfection by this new American invention.—*Society of Arts Journal.*

London and Provincial Photographic Association.—At the meeting on April 9th, Mr. A. Cowan in the chair, several presentations to the library were announced. It was decided to have another lantern slide competition on the same conditions as the last, the chairman undertaking to provide the negatives. This was the usual monthly lantern meeting, and a number of slides were shown, the work of Messrs. W. Park, J. S. Teape, P. Everett, A. Cowan, S. T. Chang, F. A. Bridge, T. E. Freshwater, &c.

## THE HOLBORN CAMERA CLUB.

The Holborn Camera Club is commencing its fourth year of existence in a very spirited manner, its membership having been recently increased to more than seventy. Arrangements for the ensuing twelve months are being completed, and special attention is being given to the outings during the summer months. Trips to Richmond and Waterlow Park have already been made, and during the months of May and June the Club will visit Pinner, Penshurst, near Tunbridge Wells, Purfleet, Hastings, and other picturesque resorts. A special feature of the year's arrangements is a monthly competition. During each of the summer months one print is to be sent in, and during the winter two lantern slides per month. Special subjects will be set by the committee, and at the end of the two seasons prizes will be given to the members whose prints and lantern slides have received the best average of marks. The Club meets every Friday, and one night a month is devoted specially to the instruction of beginners. Full particulars of membership, &c., can be obtained of the secretary, Mr. J. S. Smith, 97, Tabley Road, Tufnell Park, N.

### Specifications Published.

17,070. *October 29th*, 1889. — "Automatic Advertising Apparatus." Heinrich Friedrich Meyer, Landwehrstrasse 23, Bremen, in the free State of Bremen and German Empire, Manufacturer.

This invention refers to an apparatus for automatically changing light or reflected pictures and advertisements thrown on suitable places to be reflected and exhibited at a distance from the apparatus. These pictures change automatically at determined intervals, thereby attracting the attention of passers by.

An apparatus according to this invention comprises a magic lantern, a picture or advertisement carrying disc, a clockwork, and a train of wheels for putting the said advertisement disc in motion. In the lantern case, which is provided with a chimney and a door, there is a lamp, the rays of which are reflected by a concave mirror, through an aperture on to transparent plates, which are provided with pictures or advertisements, and carried on the disc. These transparent pictures or advertisements are reflected or transferred in a magnified state, by means of the object lenses, on to a suitable surface, and thereby made visible at a distance.

In order that the then exhibited picture may be exchanged for another, the disc is provided with a series of transparent pictures or advertisements, which can be removed at pleasure and replaced by others. The disc consists of two plates, in which, at certain distances, there are provided radial grooved bars, in the grooves of which the plates can be laid, and are then held tight by means of springs.

To automatically change the pictures by turning the disc, a clockwork contrivance is provided, which consists of two main parts, the works and the train of wheels.

A spring drum acting through a train of wheels imparts motion to the middle wheel, on whose axis the disc is fixed. The movement begins as soon as the pin of the running wheel is set free. This liberation is effected by the clockwork, which is constructed on the principle of an alarm clock, on the minute arbor of which a wheel is set provided with ratchet teeth. This wheel sets the pin free at any desired interval by means of ratchet teeth provided on its periphery engaging with the pin of the lever.

17,284. *Oct. 31st*, 1889.—"An Instrument for Demonstrating Astronomical Phenomena." John George Parvin, of 12, Duucombe Road, Horusey Rise.

This invention is intended to be used for indicating the position in the heavens of any planet, and of the moon, and fixed stars, at what hour the same will rise, pass the meridian, and set. It will also indicate the phases of the moon, and when lunar eclipses will take place.

It consists of a disc on which are drawn a series of concentric circles divided and inscribed appropriately.

Upon the said disc, and attached thereto by guides working on its edge, or otherwise attached so that it may be made to revolve concentrically with the first disc, is a second and smaller disc, on the outer edge of which is a circle divided into twenty-four hours and subdivisions, and in the central part of which, within the said circle, but not concentric therewith, is an opening of such size and shape as to represent the horizon of the place in which the apparatus is intended to be used, say, for instance, London. This disc is capable of being rotated on the first or larger disc, so that the two may be made to assume or pass through any desired relative radial positions, so as to show through the said opening the fixed stars drawn on the first disc visible at any given time.

At the centre of the first disc is attached one, two, or more indexes or pointers so arranged that it, or they, or either of them may be set to any required point or points, and preferably so arranged at the centre that they may be moved a limited distance in the direction of their length and on the said pointer or pointers. Attached to each is a small knob or indicator that may be moved either with, or independently of, the pointer towards or from the centre, and set at any required distance ; it is better to use two pointers, and make one of them "earth" and the other one "planet."

On the first-named—that is to say, the larger disc—is inscribed a series of circles divided and marked as follows, but the order of the circles need not be that stated below, as it may be varied considerably without departing from the invention.

The outer circle of the said disc is divided and numbered to represent right ascension ; the next inwards may be marked with the corresponding signs of the zodiac ; then may come an annular space over which the hour circle, forming part of the second disc, lies ; further inwards may be a circle, or circles, representing the division of the year into months and their subdivisions into days. On the space within these circles are represented some of the principal fixed stars, or so many of them as are within the zodiac.

If preferred, the right ascension circle may be placed nearer the centre and within the lines representing the zodiac among the fixed stars.

By setting the pointer marked "earth" to the day of the month, and the pointer marked "planet" to the right ascension of any planet, and setting the indicator on the planet pointer to the planet's declination, and then moving the apparatus so that the indicator on the planet hand is brought over the eastern portion of the horizon, the time of the rising of the planet is indicated by the pointer on the hour circle, and in the same way the time of its meridian passage and its setting may be obtained, and its position among the fixed stars.

At a meeting of the *Deutsche Gesellschaft on Freunden der Photographie*, Prof. Rietschel sent a ground-glass plate which, it is stated, was made by flowing the glass with a milk emulsion (a mixture of gelatine and milk).

West London Photographic Society.—At the meeting held at Broadway Lecture Hall, Hammersmith, on April 10th, Mr. W. A. Brown in the chair, slides by the following members were shown :—Messrs. Bennett, Chang, Dixon, Hodges, Kellow, Lamley, H. Selby, L. Selby, Varden, Whitear, C. Whiting, and H. F. Wilson.

# Correspondence.

## LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

Sir,—Will you allow me again to call the attention of those of your readers interested, to the fact that this Association is still taking steps to enlarge its library.

So far the Society has been helped in this endeavour by the presentation of works bearing on photography from many friends, as well as a considerable number of volumes from members.

While feeling greatly indebted to those who have already been so generous, the members still think that there are numerous well-wishers who, when once they know of the existence of the wants of the library, would hasten to forward gifts of photographic literature for that purpose. Parcels of such, or single volumes, will be gladly received and acknowledged if forwarded to the Hon. Secretary, Champion Hotel, Aldersgate Street ; or to Mr. F. W. Pask, Hon. Librarian, Leyton House, High Street, Leyton.

## THE QUAGGA.

Sir,—Some time ago I advertised in different newspapers in districts of this colony and Bechuanaland *re* the quagga. I mean the districts where he was likely to be found. I have also sent photos of the quagga wherever I thought I could get information. This brought me a host of correspondence from Mashonaland, Bechuanaland, Namaqualand, and the colony. One of the most important letters I have forwarded to Mr. Bartlett.

I learn with disappointment that the quagga is extinct in the lower parts of the colony, but my correspondent, who evidently has studied colonial natural history, and knows what he is writing about, has advised me to write to Namaqualand, where they are said to run over the immense sandy flats of that country. I wrote to two parties, one of which thought there would be no difficulty in getting one or two young ones. I have been careful to point out to them the difference between the quagga and the zebra. The quagga is undoubtedly, from what I learn, a distinct species, and very vicious. When wounded they will turn on anything, and tear limb from limb. The letter sent to Mr. Bartlett gives a detailed account of the life and manners of the quagga, which would be too long to insert here.

Namaqualand is a long way from here. I expect to have another letter in, say, three weeks from now. Should I succeed in procuring one, it is my intention to have him brought down to Prieska. I could then go there myself and arrange to bring him on here. We frequently have waggons here from Prieska. It is about a fortnight's ride from Kimberley. I am very hopeful of success. B. Harvey.

*Kimberley, March 22nd.*

P.S.—I omitted to state in my letter, giving a description of the *modus operandi* in photographing by the wet process at the Zoo, that the bath had a slight addition of potass. nitras. Old workers on interiors will know the why and wherefore. The plate was also backed with a thick pad of wet blotting-paper.

## M. LIPPMANN'S DISCOVERY.

Sir,—As I was the first to raise, in your paper, a doubt—since fully justified by the presidential address delivered at the Camera Club Conference—allow me now a small space in it to close the subject of the so-called discovery of photography in natural colours by a few practical conclusions.

I have strong reasons to believe that : (1) two plates sensitised by Prof. Lippmann's process, and exposed, one to the spectrum and another to an orange transparent glass, *will give the same result* of rainbow hues under identical treatment as to development and time of exposure ; (2) that a blue or yellow glass screen will *not* produce a blue or yellow negative by reflection ; (3) that the effect is most likely due to the extreme delicacy and transparency of support, as collodion or albumen, and not to the sensitiveness of the film.

Whatever may be the value for the abstract science of M. Lippmann's researches, every sensible man will respect his noble endeavours in that direction, but it would be a great pity if thousands of professional investigators should lose their time and means on photographic experiments based upon *un faux point de départ.* L. Nievsky.

*5, Gransden Road (Rylett Road), Shepherd's Bush, April 14th.*

## Proceedings of Societies.

Photographic Society of Great Britain.

At the meeting of this Society held on the 14th inst., the chair was taken in the first instance by Mr. J. Glaisher, the president. After the reading of Mr. Willis's paper the president left, and his place was filled by Mr. J. Spiller, vice-president.

The Chairman gave out that the council had appointed a committee to deal with questions relating to the exhibition, and to act as hanging committee. The members appointed were Messrs. Baggalley, Chapman Jones, Davison, J. Spiller, and Mackie.

A paper on "Platinotype," illustrated by examples and demonstration, was read by Mr. W. Willis. He said that the only new point that he had to introduce was the application of platinum printing to photographing on wood, but there were several observations relating to development to which he would invite attention. The first processes described were those introduced in 1872, 1873, and 1878. In the former process, there was at one stage about equal weights of platinum and silver in the print, but the silver was toned by gold and sulphocyanide, and the finished print contained all three metals. He had not found it practicable to carry the substitution of gold for silver to completion without producing a cold blue tone. In the 1878 process the image was formed of platinum only. In the cold bath process of 1888 the paper was prepared with ferric oxalate or tartrate, and the image developed in a bath which, in addition to platinum, contained a substance capable of acting as a developer. If, adopting the method of Herschel, a solution of silver or gold were applied to the iron-sensitised paper after exposure, an image in either metal would be obtained, but this was not the case with platinum unless some other salt was present to act as developer. There was a peculiarity in the appearance of the image whilst developing in the mixed platinum developing solution. The image at first appeared flat and weak; but the most noticeable characteristic at this stage was that it was granulated; the granulation disappeared as development went on. The difficulty with the cold bath process was to produce a perfect paper equal and regular in quality. The producing of a platinum image on wood was next described and shown. The specimens had been polished, and the wood prints were of considerable depth and richness. He had long experimented in photographing on wood, but had only thoroughly succeeded with the cold bath process. With the hot process he had found it almost impossible to get enough platinum in the image. With the cold process, where the platinum was applied after exposure, this difficulty did not occur. He did not use hydrochloric acid when working on wood, but oxalic or citric acid of a strength of $2\frac{1}{2}$ per cent. instead. Panels of white wood, of which he had found chestnut to be the best, covered with photographs of decorative subjects, were, he thought, of use. In the hot bath process variations of temperature and of strength of the developing solution produced different results. As the image, before development, consisted of a soluble salt, it was desirable to develop in such a way as to obtain the result before much of this ferrous salt was dissolved in the bath. In short, the problem was to accelerate development, but not to accelerate solution of the ferrous salt. To show the effects of differences of temperature and strength of solutions, strips of paper, equally exposed and differently treated in regard to temperature and strength, were handed round. On the whole, a low temperature rather shortened the range. Further modifications could be obtained by various additions, of which hydrochloric acid and chloride of potassium were mentioned.

Mr. J. Spiller recalled the interest which he had felt at the first demonstration of platinum printing before the Society in 1878. He would like to know whether Mr. Willis now preferred that method, or the cold bath process more recently introduced.

Mr. W. E. Debenham pointed out the great range of gradation in the specimens of the 1873 process, containing platinum, silver, and gold, and enquired whether Mr. Willis attributed that to the gloss which appeared on those prints, or to superior rendering of gradation by the process itself.

Mr. Chapman Jones said that with the cold bath process the strength of the developing bath changed with each print put into it. This he considered to be a great drawback.

Mr. J. Gale enquired whether the cold bath process was suitable for rough paper.

Mr. G. Davison said that the question raised by Mr. Debenham was of great importance, if it was a fact that greater truth of gradation was obtainable by one process than by another; but to make proper comparison, prints should be made from the same negative.

Mr. Willis, in replying, said that he really could not say whether he preferred the hot or the cold bath process. He thought, however, that when the paper for the cold process could be perfectly prepared, that process would be by far the best. As to Mr. Debenham's question, gradation was entirely under control. The negatives of the time at which platinum-silver-gold process prints had been made were of a much more vigorous character than those of the present day. He thought the gloss on the prints might have something to do with the gradation. That gloss was entirely due to starch, three coatings of which—with drying between each coating—had been applied to the paper. In reply to Mr. Chapman Jones, there was no difficulty in keeping up the strength of the developing bath by the addition of a certain quantity of fresh solution for each small number of prints placed in the developer.

A specimen of M. Lippmann's so-called photography in colours was then submitted for inspection. It had been brought to this country by Dr. Lindsay Johnson.

The Chairman, Mr. Spiller, looked upon it rather as an iridescent film than a true specimen of photography of the spectrum. There was a red place which might be assumed to correspond to the red end of the spectrum, and a green place; but no other colours were visible.

Mr. T. Bolas thought they could hardly assume, unless it were so stated, that the red on the plate corresponded to the red of the spectrum, and the green to the green. Capt. Abney had been understood to say that each colour required an exposure of a certain time to render itself on the plate, and that a shorter or longer exposure would produce another colour, in which case any colour might serve for producing the whole series. This particular photograph was nothing like so good a rendering of the spectrum as the one on albumen paper recently shown by Mr. Warnerke. Probably it was known to most present that Becquerel had obtained results much more suggestive of the spectrum than the one now before them. Most photographers had obtained an iridescent appearance on the edges of plates and on waste plates that was more like the spectrum than this. He appreciated M. Lippmann's services to chemistry—he was a man of science; but it did not appear to him that he had advanced the solution of the question of photography in colours.

Mr. Chapman Jones noted that M. Lippmann had succeeded in fixing his image, which Becquerel had not done. This, he thought, was the chief point in M. Lippmann's work.

Mr. L. Warnerke believed that Poitevin had succeeded in fixing the image. He then exhibited the photograph referred to by Mr. Bolas, which he thought had nothing in common with M. Lippmann's. As the red and deep orange had shown no action in the time (half an hour) which sufficed for the other colours, these two had been exposed for two days. The differences of colour in his examples were not due to mere amount of chemical action, for when he had exposed under a sensitometer screen, the image was of a brown colour throughout. He had not succeeded in fixing these images.

Mr. W. H. Harrison said that probably the first Daguerreotype was no better than the feeble specimen of M. Lippmann's work exhibited that eveniug, which their assistant secretary had said was given to Dr. Lindsay Johnson with reluctance, as the worst specimeu M. Lippmann had ever taken. He would ask their secretary if the specimeu had been exhibited to the Photographic Society of Great Britain that eveuing with Professor Lippmann's knowledge and cousent.

The Assistant Secretary replied that he did uot know.

Mr. Harrison continued that, therefore, any public discussiou upon it might be uujust to M. Lippmanu, who had proved the truth of the theory, first published by Lord Rayleigh, that heliochromes were due to the interference of light, aud could be fixed. It was too late iu the day to question the geuuineness of the discovery, which had been recognised by the members of the Academy of Sciences of Paris aud the Photographic Society of France, many of them accomplished men of science, and all truthful and honourable gentlemen, which meaut a great deal.

Mr. H. M. Elder said there were three different methods of producing photographs in colour: that of Nièpce de St. Victor, which was the plan adopted by Mr. Warnerke; the method of diffraction scattering small particles; and Lippmann's method, founded on Lord Rayleigh's paper on wave motion in a loaded medium.

The Chairman, in thanking Mr. Willis for his paper and demonstration, and Dr. Lindsay Johnson for bringing the specimen of M. Lippmann's work, said that he hoped they might yet see better specimens of the latter kind. In this specimen, although two colours could be seen, there was nothing in the nature of a photograph of the spectrum.

Messrs. C. T. Dent, J. H. Waller, and T. H. H. Harrisou were elected members.

### Camera Club.

On April 9th, the day following the close of the Annual Conference, there was a large gathering at the Camera Club, to attend the flash-light demonstration given by Mr. Cade (of Messrs. Marion and Co.). The "Slingsby" apparatus was used, and some very successful uegatives were taken of the room aud the company.

Mr. Stromeyer showed some prints from negatives taken with magnesium ribbon placed in the ordinary peudant lamp of a room, the lamp being in the picture. One of these showed very picturesque lighting.

Dr. Crocker handed round some photographs of medical cases, showiug the service rendered by flash-light on such subjects.

On Thursday, April 23rd, Mr. Frank Howard will read a paper on "Photography in Bye-Ways and Field Lanes." The paper will be illustrated by the lantern.

### Croydon Microscopical and Natural History Club (Photographic Section).

*Friday, April 10th.*—Mr. F. H. Baldock, F.C.S., in the chair.

Mr. J. Wier-Brown explained aud demonstrated his system of producing warm brown tones and sepia tones on bromide enlargements. He had slightly, but not materially, altered his mode of procedure since the first publication of the process. A number of landscapes were handed round, showiug both brilliant and soft effects in rich brown and sepia.

The speaker's attention was drawu to a paragraph iu a mouthly photographic publicatiou, in which it was stated that, if you left a bromide print thus treated for several hours iu plain water, you would find the image almost goue. He said this was very misleading, and a most incorrect statement, and might deter some workers from trying the process for themselves. It was true *only* as regards a print in which the toning had been carried to its extreme point, "a bright red," a colour which he thought would be seldom desired by photographers. That it was entirely untrue as regards prints toned to the warm brown or sepia point, he demonstrated by showing the two halves of a warm sepia proof mounted side by side, oue portion of which had beeu washed in running water for twenty-eight hours, without apparent, if any, reduction of the image. Prolonged washing after touing was quite uunecessary, and would not be resorted to by workers except by way of experiment. From five to ten minutes in running water was quite sufficient to remove the faint lemou-coloured stain from the high-lights, after which the prints should be carefully blotted off, and dried in a warm room. Prints so treated had been quite unaffected by all the light to which they could be exposed siuce they were first produced, and Mr. Weir-Brown stated his belief that they would withstand the action of the most trying atmospheric conditious to which photographs were subject under ordinary circumstances. If not satisfactory, the tone could be removed by prolouged washing, the print restored to its original colour, aud afterwards re-toned. The process was put forward for the benefit of those only who wished to make enlargements in tints warmer than the usual black-and-white of bromide, there being already abundant methods of producing every variety of colour on contact prints. The speaker stated that good results could not be produced on the most rapid papers, and that his success had beeu obtained on an emulsion of medium rapidity called by its makers "slow."

Mr. W. Low-Sarjeant exhibited and explained a uovel camera which he had just made for his own use. The camera is of the usual box form, covered with leather, and is divided into two chambers, the upper one being used simply as a view-meter, or to focus with for hand-work, and giving a full-sized view identical with that in the lower chamber or camera proper; the picture thus being seen aud focussed at the moment of exposure. A reflector placed at au angle of 45° in the upper chamber throws the image on to a ground glass which is fitted in the top of the camera, the ground glass being covered with a rectangular hood large enough to euable the image to be well seen in the brightest light; this hood, when not in use, folds down flush with the top of the camera. The lower chamber, or camera proper, is fitted with a swing back and focussing screeu for ordinary work. It is also fitted with a specially constructed focussing eye-piece hood, which entirely dispenses with the necessity of using a focussing-cloth. Double backs of a very light pattern are used, and the camera has a range of focus from three to twelve inches. A very iugenious shutter is fitted behind the lens—so that the lens can be changed without interfering with it—giving a rauge of exposure from extreme rapidity to hours if required; it is discharged by means of a pneumatic ball. A very novel feature in the shutter—which, by the way, gives an equal exposure to every part of the plate—is that, whatever speed the shutter is set to work at—even at its fastest—at the moment of exposure, without any alteration whatever to it, a time exposure of auy length can be given. The camera is also fitted with a black glass reflector placed in front of the working lens at the angle of polarisation 33° 15′ for photographing clouds. When not in use, the reflector folds into the front of the camera out of the way, or it cau be removed entirely. A false bottom with arc-shaped struts is attached to the camera to enable it to be tilted to the necessary angle for cloud photography. Although the camera contains so much, and is capable of doing every class of work, it is very compact; the quarter-plate size, with a 5½ inch lens focussed ready for use, ouly measures externally 8½ by 7 by 6 inches.

The next meeting will be held in the old school of art room on the 17th inst., when there will be an exhibition of hand-cameras.

The first excursion of the Photographic Sectiou of the Club took place on April 11th, when, by the permission of the Lord Archbishop of Canterbury, Addiugton Park was visited. The afternoon was fine, aud some good work was done.

### Birmingham Photographic Society.

*April 9th.*—Meeting at the Club rooms, Midland Iustitute, Mr. W. J. Harrison, F.G.S., in the chair, when five new members were elected.

The hon. secretary, Mr. A. J. Leeson, exhibited Wray's aluminium-mounted lens fitted with iris diaphragms. The lightness was remarkable, aud in point of fiuish perfect.

The programme for ensuing session was read as follows:—April 23rd, "Exposure and Development," W. J. Harrison; May 28th, "Stereoscopic Photography," Walter Griffiths;

June 25th, "Cameras and their Management in the Field," E. H. Jaques; July 23rd, Conversation Meeting and Exhibition of Survey Photographs; Aug. 27th, Development Competition; Sept. 24th, "Lantern Slide Making," S. H. Fry.

Mr. J. T. Mousley (excursion committee) read the list of excursions for the year.

The Chairman remarked that he was glad to see that the excursion committee had arranged for many of the outings to interesting spots in the Hundred of Hemlingford, which would greatly help the Survey Section in that important work.

Mr. Howson, in the course of remarks on alpha paper, said that with it different tones could be obtained, which was a great advantage and help, in many cases, to enhance the artistic value of a photograph, as one was able to give special tone to any separate subject by different exposure, different length of toning, &c., and also pictures might be made of uniform tone under varied forms of development, &c. After fully describing the process, Mr. Howson gave a practical demonstration of the mode of work, producing the varied tones by different ways of manipulation. He then showed the exposure and development of the Ilford special lantern slide plate, giving four distinct exposures from the same negative, and, by development in same developing solution, obtained exactly the same result, thus showing great latitude in development and exposure.

---

Hackney Photographic Society.

A meeting was held on Thursday last, Mr. J. Hubert in the chair.

This being an evening set apart for "Hand-Camera Work," by Mr. Walter D. Welford, some hand-cameras were shown, among them being the "Radial," which was explained by Mr. Dickenson, and the "Repeater," shown by Mr. Cusworth. Mr. Gosling showed his, a home-made one with dark backs.

Mr. Welford preferred to illustrate the uses of a hand-camera by means of the lantern. Nearly 200 slides were put through illustrative of various branches of photography, such as architecture, marine, detective work, &c., and were humorously described by Mr. Welford. The slides shown were good.

---

Holborn Camera Club.

At the meeting at the Club rooms on Friday last, the president, Mr. T. C. Hepworth, in the chair, Mr. J. Traill Taylor read his promised paper on "Art in Relation to Photography."

He commenced his observations by saying that he did not intend to give a formal lecture, but an informal talk. Painters, he said, would always have the pull of photographers because they could, like the bee, sip their honey in the shape of subjects from all sources, and could afterwards, at their leisure, and at home, select those which they preferred and bend them to their purpose, and eliminate others which they did not want. Photographers, on the other hand, had to take nature as it came, and had to be content with what they saw before them, and, considering how they were handicapped in this respect, he considered it very wonderful that with regard to composition, they succeeded in holding their own as well as they did.

We must remember that photography is an art as well as a science, and that there are certain received canons of art which must be observed. Painters have been so well grounded in these that they are apt to turn upon the poor photographer for the slightest fault which may be looked upon as an infringement of those canons.

In photography the first thing to learn is about the tools which were employed, but, assuming that this elementary knowledge had been already acquired by the members of the Club, he would not dwell upon that phase of photography, but would proceed to make a few general remarks upon the composition of pictures, and would illustrate his words by a number of photographs—a great many of which he had brought as examples of what to avoid. After a few words with regard to the importance of placing the horizon at a height regulated by the subject, he showed examples in which attention to this point had been disregarded. Straight lines, repetition of forms, and other common faults, also came under review. The posing of single figures, the redundance of accessories, and over-elaboration of dress, in causing the eye to stray from what ought to be the principal point of a portrait; the face, the posing of groups—illustrated by some very amusing examples—formed another section of the discourse. In connection with these groups, Mr. Taylor again referred to the very uncomplimentary remarks common to painters when criticising photographs, and showed some examples of a well-known painter's photographs, which were certainly open to censure as specimens of composition.

A short discussion followed, and the meeting closed with a vote of thanks to Mr. Taylor for his kindness in reading such an interesting paper.

---

Putney Amateur Photographic Society.

*April 8th.*—Rev. L. Macdona in the chair.

A set of "American" slides were exhibited to members and friends. Those of the ruins of Johnstown were of special interest. It was suggested that, had particulars as to plate and developer used, &c., been given in each case, instead of the maker's name, it would have been of greater interest to photographers on this side. The ingenious method of packing was also commented upon.

---

Brixton and Clapham Camera Club.

At the meeting held on the 9th inst., Dr. Reynolds occupied the chair.

Mr. Bevins gave a lecture on "Light," illustrating his remarks by diagrams and experiments with the Club lantern, and giving instructions for testing the safety of glass for dark room lamps by means of a prism.

The annual Club exhibition of members' work will be held at Gresham Hall, Brixton, this and to-morrow evening. Lantern shows will be held each evening, and a concert will be given on Saturday.

---

Richmond Amateur Photographic Society.

Friday, the 10th inst., was a lantern night for the exhibition of a series of American slides, and for deciding the slide competition. Mr. Horrigan presided. The American slides were first shown, after which voting on the competition slides took place. Each competitor was required to submit one contact slide from each of three negatives supplied for the purpose by Mr. Cembrano, and the result of the voting was to place Mr. Ardaseer first and Mr. Garrett second, while Messrs. Davis and Ford tied for third place.

The Society was indebted to Mr. Cembrano for the loan of his lantern.

---

North Middlesex Photographic Society.

*April 13th.*—Mr. J. W. Marchant in the chair.

Mr. Birt Acres, on the subject of "Monochromatic Rendering of Colours by Photography," said that it naturally divided itself into two portions, the historical and the practical. He gave a chronological *resumé* of the growth of photography in general, and of the researches into colour-sensitive dyes for the photographic plate in particular. The great mass of photographic workers, unless their attention had been specially directed to the subject, had little knowledge of the slow and laborious manner in which the science had been built up. The properties of lenses had been known as early as 420 B.C., a lens having been found in the ruins of Nineveh. From mediæval times till to-day, there had been an ever-increasing army of workers adding to the store of general knowledge. He instanced Roger Bacon, Baptista Porta, Kircher, Newton, Wedgwood, Humphrey Davy, Nicephore Niepce, Daguerre, Herschell, Read, Mungo Pontou, Faraday, Fox Talbot, and others, briefly pointing out the nature of their discoveries, and the dates at which they were made known. The early workers had attemped to secure the colours seen on the ground glass screen in various ways. Some had tried to obtain reproductions of the colours separately, and to combine them into a whole, and had used glasses of various tints to separate the colours. A difficulty met with was the reflection from every coloured object of white light. He then dealt with the colour-sensitive dyes which had been tried—eosine, erythrosine, cyanin, chlorophyll, &c., and said that the addition of ammonia, discovered and patented by

Tailfer and his colleagues, had been the factor necessary to secure success. By means of a prism, the lecturer projected on the screen a spectrum of the oxy-hydrogen light, showing the colours in great brilliancy. He pointed out that the ray which is lightest in tone to the eye was yellow, the others following in the order of light—blue, green, orange, red, and deep blue and violet. The rays, when photographed upon an ordinary plate, were more or less reversed, the blues and violets showing brightest. He then interposed coloured screens of various tints, showing how they cut off various rays. A series of monochromatic bands were then thrown on the screen, showing the spectrum photographed on ordinary and colour-sensitive plates with and without coloured screens. The series showed clearly that a very pale yellow screen, necessitating about a triple exposure, gave results in monochrome most nearly approaching the effects of colour as seen by the eye. Copies of paintings, portraits, and views, taken in duplicate on ordinary and isochromatic plates, were then thrown on the screen. The lecturer said that the difference in the cases of the portraits and the copies of oil paintings were so marked that he found it necessary to state that no retouching had been done. The views taken on ordinary plates were so good that it seemed nothing better could be wished for, yet, when the duplicate taken on the isochromatic plate was shown, the improvement was strongly visible.

Reports on plates and paper submitted for test were then given, and further samples of other dealers were distributed to be similarly dealt with.

---

Sheffield Photographic Society.

*April 7th.*—At the Masonic Hall, Surrey Street, Mr. B. J. Taylor in the chair.

It was arranged to have Saturday afternoon excursions, commencing May 9th to Oughtybridge; also that the first monthly excursion should be to York early in June, date to be arranged.

Mr. Alleyne Reynolds then gave his lecture, "A Tour Round Iceland," which was illustrated by a large number of slides, the negatives and slides being made and taken by the lecturer after having made four trips round that island.

---

Oxford Photographic Society.

*April 7th.*—The president, Mr. E. A. Ryman-Hall, in the chair.

Mr. A. F. Kerry, M.A., Exeter College, gave an instructive lecture on "Bromide and Kallitype Paper Printing." Many chemical experiments were made, showing the changes which take place in developing, &c. Some bromide prints were made, and the subsequent manipulations were carried out. The lecturer then spoke briefly on the Kallitype process. The development of some prints brought the lecture to an end.

Mr. Claude Rippon (Merton College) and Mr. H. H. Isons were elected members.

---

Leicester and Leicestershire Photographic Society.

*April 8th.*—After transaction of routine business, Mr. Porritt read his paper entitled, "Photography, Past and Present," with notes on the quality of dry plates and lantern slides, and a few remarks on the object of our excursions. During the course of his remarks, Mr. Porritt reviewed the practice of photography from the earliest date of collotype and wet plate processes, describing *en route* the *modus operandi* of each process, which was quite novel to the greater part of the members; from thence he described the gradual transition through the various wet processes up to the almost perfect condition attained by the present dry plate. Lantern plates were then treated, the lecturer betraying a considerable leaning towards the collodion made slide, some excellent specimens of which were passed round. Some good advice to the members with respect to the management of the forthcoming excursions was then offered.

The President (Mr. Pierpoint), in proposing a vote of thanks to Mr. Porritt, traversed at some length some of the points advanced by him with reference to the use of rapid *versus* slow plates for landscape.

## Answers to Correspondents.

**All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.**

**All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.**

**Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.**

H. B. (Reading).—*Direct-Printing Platinotype Paper.* You would do well to consult the practical guide issued a few years ago by the Photographic Society, entitled "Platinotype by Captain Pizzighelli and Baron Hubl," edited by Captain Abney, price two shillings (Harrison and Sons, 59, Pall Mall). Also, look for the report of Tuesday's proceedings, when Mr. Willis described the cold bath process and other modifications of the platinotype.

S. W. (Nottingham).—*Blinds in the Studio.* A very good arrangement is to have a set of dark green holland blinds, running on spring rollers fixed at the highest point in the roof, supplemented by blue gauze curtains working horizontally. Besides these, it is well to have the usual paper screen near the sitter, to diffuse the light and soften the shadows; and to place the camera beneath a hood, so as to shield off the top-light from the lens.

Optician.—*Toning Collodion Transparencies.* You should find no difficulty by using an excessively dilute solution of chloride of gold. Some prefer platinum, or the mercury and ammonia treatment, for a pure black. Will not the gelatino-chloride lantern plates suit you better, for then, as Mr. Cowan has shown, by merely altering the developer an infinite variety of tints can be obtained?

G. E. M.—*Gelatino-Bromide Emulsion.* The hand-coating of plates is practically abandoned, so that we can hardly promise you a good sale for the emulsion, however excellent the quality. The sensitive paper business is rather more hopeful, but several good sorts have already established themselves in public favour.

M. P.—*Photography in Colours.* A coloured electric spectrum of M. Lippmann was shown at the Parent Society's meeting on Tuesday, but only pink and green were apparent in the little specimen plate exhibited.

Inquirer.—*The Canadian Co-operative Scheme.* We have seen the promising advertisement in our contemporary, which seems to be put forward in good faith, although it partakes somewhat of the character of the personally conducted scheme shadowed forth in Mr. William Black's "Donald Ross of Heimra." £50 is said to defray the cost of transport, equipment, and all preliminary expenses, and the emigrant photographer has three courses open to him at the end of his first season, one of which is to return to England without losing any of his capital or accumulated profits. Write for the full particulars promised by the middle of the month, and judge accordingly.

A. M.—*Five Years' Old Dry Plate.* Our friend has shown us the transparency, and kindly given further explanations. He exposed for a portrait in 1886; then the plate (X L Edwards') was laid by, forgotten and undeveloped, until a fortnight ago he exposed again for a photo-microscopic object, and proceeded to develop with hydroquinone, when, to his surprise, a good portrait transparency of the original subject came out, showing no trace or outline of the microscopic object, although the subsequent exposure may have had the effect of converting a latent negative into the reversed image which he obtained on development.

Received, the *Weekly Scotsman* and *Kent Coast Times* of last week, each of which devotes a full column to the report of photographic matters, the former treating of amateurs' requirements under the head of "Photography as a Hobby," besides reporting lectures delivered in Edinburgh by Mr. F. Dundas Todd and Prof. Hunter. The latter news-sheet describes a famous professional studio on the south coast, in contrast with the operations of the camera fraternity on Ramsgate sands.

# THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV. No. 1703.—*April* 24, 1891.

CONTENTS.

## MR. SUTTON'S BLOCK PROCESS.

We last week gave in detail the results of certain experiments which we had made, and which were suggested by Mr. Sutton's paper on "Electro-Phototypy" read at the Camera Club Conference. The results we obtained were of a negative character, but an experiment generally has the advantage of teaching something, even though the primary object in making it may not prove to be attainable. It was certainly so in the case before us. First we ascertained that, owing to certain differences in the manufacture of gelatine plates, some will, after development with pyro, stand a great amount of heat, even while the gelatine retains water and is in a swelled condition; but that with others the gelatine, on application of heat, will either contract or melt off the glass entirely. It would, perhaps, not be difficult to trace the reason for this different behaviour in this respect on the part of certain well-known commercial plates, but it is not necessary, for our present purpose, that we should do so. We also ascertained that, in adapting Mr. Sutton's process to line subjects, such as are ordinarily turned into blocks by the zinco process (some of which illustrate an article on another page), the gelatine film which had withstood the heating operation refused to bear the ordeal of the electrotype bath. One more observation noted was the fact that, as might be expected, the relief on the gelatine plate, brought about by the application of heat, was very much greater while the film remained in its swelled condition, than it was subsequently when the plate had been dried.

This last observation made it at once obvious that, if we could obtain some kind of mould from the relief while in the latter condition, and in some material which would not suffer from immersion in the copper bath, so as to obtain a metal reverse from that mould instead of from the gelatine plate itself, a double advantage would be gained: firstly, in obtaining higher relief for the lines of the image; and secondly, in preserving the gelatine from destruction in the copper solution. The interposition of this mould would, of course, indicate the use of a negative instead of a positive image in the initial operation, but that is a mere matter of detail. With this view, we sought to obtain a cast of the gelatine plate in the finest plaster of Paris.

It was easy enough to pour the liquid plaster on the film, but, unfortunately, we could not persuade it, after hardening, to separate from it without partial destruction of the image. And even had this experiment been successful, the necessary waxing of the plaster before immersion in the copper bath—so as to destroy its porosity—would most probably have degraded the finer lines of the picture.

Our next experiment was more successful. We in the first place took a vigorous black-and-white negative from a line drawing, and from this a positive on a gelatine plate. This was developed, fixed, washed, and heated in the metal dish, according to Mr. Sutton's method, the heat being continued in a moderated form until the film was bone dry. Still keeping it in the metal dish, we surrounded it with an edging of wood about half an inch in height. We now melted in a ladle half a pound of ordinary fusible metal, which liquefied at a heat of about 150° Fah. Keeping this stirred with a stick of wood, so that its heaviest component, mercury, should not sink to the bottom of the ladle, we poured it carefully on the film. The result was encouraging, but by no means perfect, for the metal acted, to some extent, on the gelatine film, and made it granular, the granularity imprinting itself faithfully on the metal covering.

We now took another positive which we had in readiness, and, after obtaining the relief as before and drying it, we placed upon it a trace of vaseline, and then rubbed as much as possible of the greasy matter from it with the palm of the hand. This plate was now warmed in the metal dish, and once more the fusible metal was poured over it. In about ten minutes surface crystallisation showed that the metal had solidified, and it separated easily from the film, leaving the latter quito uninjured. From this metal plate we afterwards obtained an electrotype block, but we are not satisfied with the result, for the relief is hardly pronounced enough for ordinary printing.

There is also another way of obtaining a mould from a gelatine film of this kind, and that is by the hot moulding process commonly used in reproducing Meisenbach blocks, in preference to the common wax mould obtainable by pressure. In this hot process, a mixture of gutta-percha and other ingredients is heated, and while the plate to be copied rests upon a hot metallic surface, the mixture is poured over it, and afterwards slowly cooled. This process gives sharper results than the ordinary wax mould method, and it is easy enough to obtain an electrotypic copy from a mould so prepared.

In Mr. Sutton's paper read before the C. C., he said: "I must be understood as distinctly referring to half-tone block work." It is only fair to remind our readers of this fact. In our experiments we have trespassed on ground which Mr. Sutton had no intention of touching, and we have done so in the hope that others may be encouraged to experiment in a very interesting and important branch of photographic work.

## THE PROFESSIONAL SHOW-CASE FROM AN AMATEUR'S POINT OF VIEW.

BY REV. F. C. LAMBERT.

I CONFESS at once that curiosity often tempts me to stop and examine the contents of the photographer's show or door-case. I am willing to admit that there may be a measure of selfishness in the matter. It may be a wish to see how others manage to overcome what to me are difficulties, or to gather a hint in the matter of pose, lighting, or grouping; or it may be to air my vanity and pat myself on the back, metaphorically speaking, for the creditable way I have managed home portraiture under difficulties as compared with my more fortunate brother with his studio, screens, backgrounds, and other accessories.

Whatever be my motives, it is only befitting that, having had "more than I paid for"—as one ungenerous individual described my silent survey of his collection of yellow smudges—I should attempt to make some return by way of offering a suggestion or two. It may be as well, in the first place, to clear the ground by drawing attention to what, I cannot help feeling, are possible mistakes on the part of my professional brethren. They may often arise simply from want of thought upon so simple a matter, or it may be that they are too much occupied to attend to such trifles, yet I cannot think I am far different from an average specimen of the general public when I say that I, almost unconsciously, picture to myself the man, and also his surroundings, when I see his work. I have had the good fortune to make the personal acquaintance of a good number of professional men, and, with one or two exceptions, found them all I could wish. At the same time, more often than not, has my first impression, usually gathered either from the show-case or the window, been practically confirmed by the habits and character of the man.

It is chiefly to this point to which I would suggest some attention be paid. Supposing a family are taking a short holiday at a seaside resort. It is just such a time that the inclination and leisure are both favourably disposed towards the family party "being taken." What is more natural than that the party will first scan the various show-cases in the place, and be guided, not so much by the success of any one portrait, seeing that the "specimens" are probably unknown to the spectators; nor will they be wholly guided by price, because, when on a holiday, a few shillings saved in one way is spent in another; but the selection of the firm to which is to be entrusted the "portraiting" of "Pa, Ma, and the youngsters," will be decided by the *general impression* and variety of subject displayed, together with the general good taste running throughout the whole collection, which is felt rather than seen. One offensive specimen will undo the good effect or impression of half a dozen other satisfactory pictures. This point brings me to my first suggestion, viz., quantity or number.

I think it is a mistake to have too many specimens. When a window is full of photographs, the eye goes from one to the other, and is wearied by the very number of things to be seen, so that no one particular specimen is carefully examined, *i.e.*, no one makes any special impression. The mental effort is cut up into a shower of fine drops, instead of being pleasantly drawn into a stream. The expression for the general idea which most people get from looking at a window or case over-crowded with specimens, is that the contents are "very much of a muchness," and by this expression they simply mean that they have received no distinct impression of *quality*, and only a bewildering one of *quantity*.

Speaking as one of the general public, I should say, for myself, that I do not care to see more than a dozen specimens in any one case, and that I should prefer half-a-dozen —worth looking at. The half-dozen might stimulate the wish to see more; a score would make me feel I had seen more than enough.

But when, to the distraction of number, I find myself face to face with what I am told is a "cut-out" mount—viz., a contrivance whereby some two or three dozen portraits (of people who have nothing whatever to do with each other) are made to appear from behind a number of openings of very various shapes and sizes—and when, to this highly distressing arrangement, we add the utterly inexplicable device of causing these poor victims to appear tilted at all sorts of angles, then I am disposed to say to myself that the person who is responsible for this contrivance has made a mistake when he describes himself as "artist-photographer." The prevailing idea of this arrangement sometimes takes the alternative form of substituting for the one mount with many openings a large number of exceedingly thick mounts with gilt (real or sham) bevelled edges. These remarkable mounts are often adorned by a number of brass nails, whereby the structure is fastened to the back of the show-case; and, in order to introduce a dash of "high art," the case is not infrequently lined by very inferior velvet of a bilious green or yellow tint. It would be interesting to know why these extremely thick mounts are used for this purpose, seeing that they correspond to nothing ever seen outside the show-case.

From thick to thin mounts one may go at a step. A short time ago I saw some very nicely executed silver prints mounted on very thin cardboard, and attached to the back of the case by means of a couple of drawing pins for each mount. The natural result was that the mounts had curled so much that I could not help thinking that three of them placed edge to edge would make a very fair cylinder.

It is now very generally admitted to be a mistake to mix silver prints with others made by any of the black-and-white processes; and yet how often this is done, to their mutual detraction!

It is also, I think, a mistake to place your price list as a centre piece, and arrange your specimens in circles round it. By all means have your list of terms in a position where it can be easily seen and read—preferably towards one corner—for many people are reticent in entering a place of business simply to learn the charges. It is worth remembering that you do not wish to convey to the outside public the idea that your first and only thought is your price list, but rather that your chief aim is to produce *first-class work*, such as you can conscientiously ask a fair price for, and not be ashamed of the one or the other.

Again and again has attention been drawn to the twofold nuisance of show-cases not air-tight. On the one hand, a covering of condensed vapour on the glass is very annoying to the spectator; on the other hand, the presence of moisture to this extent is very far from being conducive to the longevity of the specimens. In most ordinary cases a few pence spent in the rubber door-lining would provide a ready means of very greatly mitigating this self-evident oversight.

There is, perhaps, even less excuse for the man who is content, week by week, to let his show-case present itself to his possible patrons with a cracked glass. If the artistically arranged show-case indicates an artistically minded proprietor, does it not follow that the cracked glass betokens a ! ! ! ! ?

Finally, as regards including in your show-case objects other than photographic specimens—*e.g.*, flowers, &c.—upon this matter I propose to say something hereafter, but now merely saying that if you desire to include flowers, see that they are renewed occasionally. I remember being detained at a railway station for some time, and was glad to find anything to help to occupy the mind. I did find a show-case containing what had once been flowers, but alas! there was at that time only to be seen a few dried-up brown stalks, and a little pool of putrescent water, very thick, very brown, and no doubt a perfect ocean of specimens for the microscopist interested in *infusoria*. And, by the way, to make the museum more complete, there were to be seen about half-a-dozen dead flies who had found their way into this chamber of horrors and been overcome by its contents. In the lower part were displayed a few pipes, cigar holders, &c.; and, as a background for these very useful "weapons of peace," was displayed a notice to the effect that the proprietor, in addition to his occupation of photographer and tobacconist, also catered for the public in the way of Furnished Apartments, and that his own particular requirement at that moment was thus stated: General Servant and Plain Cook Wanted.

*(To be continued.)*

London and Provincial Photographic Association.—April 30th, "Demonstration on the Polarisation of Light," J. J. Briginshaw; May 7th, "Toning Bromide Paper," J. Wier Brown; May 14th, last lantern night of the season.

Royal Institution.—Dr. E. E. Klein, F.R.S. (Lecturer on Physiology at St. Bartholomew's Hospital), will on Tuesday next, April 28th, begin a course of three lectures on "Bacteria—their Nature and Functions" (the Tyndall Lectures); and Mr. H. Graham Harris, M.Inst.C.E., will, on Saturday, May 9th, begin a course of three lectures on "The Artificial Production of Cold."

## A NEW ELECTRIC LAMP.

For many years the limelight has now held its own as an illuminant *par excellence* for the optical lantern; and it has been more used in this way than for any other purpose. Attempts have been made to enlarge its employment, and about thirty years ago it was tried for street illumination, but was speedily discarded. For the one work of illuminating magic lanterns, nothing has been found to improve upon it.

It may be different in a short time; that is, when electricity is laid on to our houses as gas is at present—a consummation devoutly to be wished, except, perhaps, by the gas companies. We shall then be very glad to put away our gas bags or cylinders as the case may be, to discard our rubber tubes and all other paraphernalia pertaining to gas, and procure an immediate light by the mere act of connecting our lantern with a couple of wires.

It is true that the electric light has already been tried for lantern work, but the inconveniences attached to obtaining the current from battery power, to say nothing of the expense, has hitherto made such trials only of an experimental nature. We may, of course, except the occasional use of an electric lantern in lecture halls for producing spectrum phenomena, and many of our readers well know that such lanterns have been advertised by our leading opticians for some time past. Such a lantern was constantly in use at the old Polytechnic Institution for explaining the elementary facts connected with spectrum analysis to popular audiences. In that case the necessary electrical energy was furnished by a battery of from fifty to sixty Grove cells, until the dynamo became available, when the tiresome and dirty batteries were at once discarded.

Of more recent times, too, and since the electric light has become more or less common in our public institutions, it has been tried for lantern work. Dr. Fleming has devised a special form of incandescent lamp, which he has adapted to the lantern by modifying the usual arrangement of the carbon filament, and making it in the form of a coil. He has thus succeeded in concentrating the light in one spot—an essential feature in any good illuminant for the lantern. But it is obvious that the incandescent light, under the last circumstances, cannot give sufficient radiance for an optical lantern except the instrument be of small capacity, and fitted for small lecture room work or home use.

A better idea of what can be done can be gleaned from the lantern which is now commonly used at the lecture theatre of the Society of Arts. This lantern is furnished with an arc lamp or regulator of the Siemens pattern, and the electric energy comes from a De Meritens dynamo machine, which is driven by a gas engine in the basement of the building. We have often seen this lantern in use, and we may at once say that its working, generally speaking, is not half so satisfactory as the familiar limelight. The light is cold and blue in tone, and, through shifting of the arc from side to side, the light is often removed from the correct optical centre, with the result that part of the screen suffers partial eclipse. It is evident that a better form of regulator than this is needed, and certainly a better one is that known as the Brockie Pell, as modified for lantern and lantern microscope use by Messrs. Newton.

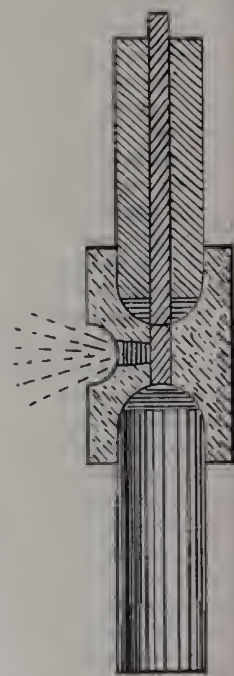
Before proceeding further, it may be just as well, for the benefit of those who are ignorant of the arc lamp, to say a few words about the difficulties with which anyone designing such a lamp for lantern use has to contend. The essential feature of the arc lamp or regulator is the presence of two carbon rods, generally placed vertically one above the other. No light is apparent so long as these two carbons remain separate, and even if a piece of paper be the only screen between them, still no current can pass. But directly they touch, the circuit is completed, and if they are then separated the arc or arch of light plays between them. This arc is, however, almost non-luminous, the light being wholly derived from the ends of the carbon rods being brought to a white heat. If, however, from any cause the light should cease, the carbon rods must again be brought together to touch one another before the arc can be re-established. So that in every contrivance called a regulator or lamp, provision is made for the carbons to touch and then to separate from one another automatically, so that the arc can be maintained. If the carbons were to remain touching, they would simply turn red hot at the ends, fuse together, and very little light would come from them.

If the reader will bear the necessities of the case in mind as just described, he will be able to appreciate the advantages of employing for projection purposes a lamp of the kind now to be described. It is in reality a combination of the arc and incandescent systems, and the quality of the light produced is superior to that given by either. This form of regulator, which is known as the electric sun lamp, was first introduced in Belgium about ten years ago. At once public attention was attracted to it—as it is attracted to anything new—and a few years later we find that the same lamp was awarded a gold medal at Paris. In 1882 it was first shown in this country, and everyone remarked how it differed from most other regulators in giving absolute steadiness of light. At the Health and Inventions Exhibitions at South Kensington it was again honoured by being medalled. But, although its construction showed much novelty and ingenuity, it had faults which prevented its coming into common use. These faults have since been remedied, and as we saw it in use a week or two ago at the St. Pancras Electrical Exhibition, we at once recognised its value for projecting purposes. The improvements have been carried out by Mr. F. R. Boardman, and, without describing them in detail, we may say that the principal one is a provision for making the lamp automatic in its action—a quality which, before Mr. Boardman took it in hand, it did not possess.

As just explained, this lamp is a cross between the arc and incandescent systems, but possesses advantages which neither one nor the other alone can boast. The lamp consists of a small metal insulated box—that is to say, it is made in two parts, which are insulated from one another, but bolted together. Two tubes are attached to this box, one on each side, each tube holding a carbon pencil about four inches long and $\frac{5}{8}$ of an inch in diameter. But the peculiarity of these carbons is, that one is hollow —that is to say, it is bored throughout its length, and an auxiliary carbon rod of less than a quarter of an inch in diameter slides freely in the tube thus provided. Another peculiarity which makes this form of lamp differ from all other regulators is the presence of a block of refractory material, which may be either a soft kind of Carrara marble, or an artificial stone resembling fire-clay.

Referring to the accompanying illustration, the lower carbon is solid, while the upper one has a hole through its length, as shown, and in this hole the sliding carbon rod is seen in section. There is an opening at one side of the marble block, and in the diagram it is shown how the rays of light proceed from that point.

The action of the lamp is as follows:—The two carbon rods are kept at a fixed distance from one another by the marble block, which, it is seen, is excavated at top and bottom for their reception. It is, therefore, evident, from what has already gone before, that no light can come from them while they are separated; but a sliding rod within the upper carbon furnishes the necessary initiatory touch. By the action of an electro-magnet, it automatically slides through the upper carbon and touches its opposite neighbour. Directly this is done, and the arc established, it is drawn back by the same agency. When the arc is established, it plays within the opening in the marble block, and, therefore, brings that block to a white heat.



The advantages of this form of lamp will be readily acknowledged by anyone who understands lantern work. To begin with, the light spot is small, and, unlike that afforded by many other electric regulators, it remains steady and in one position. The next point is that the somewhat cold glare common to arc lamps generally is modified by the presence of the refractory material, and the blue tone is changed to a somewhat warm light, more like that which is identified with the lime-light. Indeed, in one respect, we may compare this lamp to a lime jet, although, of course, it is far more brilliant; for the Carrara marble, under the influence of the intense heat to which it is subjected, must be actually turned into the same material which is rendered incandescent in the older fashioned light—viz., lime. And this forms rather a weak point in the newly devised lamp, because, when the marble is changed in that way and left idle, it becomes easily attacked by damp, and is apt to fall to pieces in a moist atmosphere. For this reason it is found essential, in some situations, to exchange the marble for a block of fire-clay, which is not subject in any way to atmospheric changes.

To sum up the advantages claimed for this form of regulator for projection purposes, we may note first its great illuminating power, the colour of the light, and its steadiness. The great simplicity of the apparatus is the next feature to be considered, for really there is no mechanism at all if we except the electro-magnet for connecting the smaller carbon and the two simple springs which keep the two larger carbons firmly pressed into the cavities provided for them. The economy of the lamp, in comparison with other forms of regulators, is great; for it is stated that two four-inch carbons will feed it continuously for more than fifty hours. And there is no waste in these carbons; they consume at the rate of one-sixteenth of an inch per hour, and leave no residue. As the carbon is sold at one shilling per foot, it will be seen that the expense of this material for each lamp is under one farthing per hour. The marble blocks last from twenty-five to thirty hours, but, as already indicated, the artificial fire-clay will last a great deal longer.

We hope soon to have the opportunity of trying this new form of arc lamp in the optical lantern. We understand that the heat from it is considerably less than that from the limelight—a fact which may, perhaps, be accounted for from the peculiar construction of the apparatus, which would cause a great deal of the heat to be absorbed. The lamp, we need hardly say, is also particularly suitable for lighthouse use, for mast-head lights for ships, for search lights, for naval and military purposes, and it may prove to be, from its great steadiness, one of the best forms of lamp that can be employed in the photographic studio. But the purpose of the present article is to show how well it is adapted for the work of projection, and, of course, under this head will also come its employment in photographic enlarging apparatus.

## CRYSTAL PALACE EXHIBITION.

### Second Notice.

As promised by the executive, the pictures were all in their places by last Friday; but, as the catalogue bore up to that day no corresponding numbers, it was rather difficult for the visitor to find the title of any particular picture except by a lucky guess. The system employed of distinguishing each alcove by a letter and number does not seem to be a very happy one, and is certainly an aggravation to those in search of any particular exhibit. For example, on page 26 of the catalogue we find the heading, "Alcove 4R," the next heading being, "Outside of Alcoves 5L and 5R (1)," followed by "Alcove 5L (Class A B)." Now no one—except, perhaps, that master of confusion, Bradshaw—can make out at a glance what all these reference figures and numbers signify. Surely, if the screens and alcoves were numbered like a street, with even figures on one side and odd numbers on the other, the method would be more easily understood by the non-mathematical mind.

The Art Division commences with Alcove A, and, so far as its contents are concerned, it might be called A1, for it holds the pictures sent in by Mr. Van der Weyde. Perhaps the most striking of these is the life-size and full-length picture of Miss Minnie Terry, and the very charming portrait of the Princess of Wales. Adjoining Alcove A we enter that marked 1L, and, although here we have a different type of photographic work, it is decidedly good of its kind. It consists of a number of views by Poulton, some of the best being those of fisher-folk taken at Whitby. Messrs. Byrne and Co., of Richmond, still keep up the high standard of work which they have taught us to expect from their studio, and show a number of life-size heads (taken direct), as well as an excellent selection from their "At Home" series. The next exhibit gives us a sample of process work in the shape of a number of beautiful photogravures by Boussod, Valadon, and Co. This firm also shows a number of copies of water-colour paintings reproduced in colour, and so well done that it is difficult to say where they differ from the original works. (This reminds us that in the apparatus section of the Exhibition there are shown certain photographs by "The Art Colour Photographic Company." We were assured by the attendant in charge that they were the direct product of the camera, and were not coloured by hand. We make no comment on this statement, but merely repeat it for the benefit of those who looked for an immediate result from M. Lippmann's experiments.)

The exhibit of Mr. E. T. F. Goodwin, of Upper Norwood, is of very high quality all through, platinotype portraits outnumbering those in silver, and we must give similar praise to the pictures shown by Mr. Pym, of Streatham. Mr. W. Crookes' (Edinburgh) collection calls for special mention, because it contains one of the most successful and realistic pictures which we have ever seen, and visitors to the Palace should be careful not to overlook it. Its title, "The Misses Curle," conveys little idea of its singular character, nor is it stated in the catalogue that it was taken by daylight combined with flash-light. The two ladies are talking in front of a fire-place, the light from which strikes their faces in a very natural manner.

Messrs. Cameron and Smith show many excellent copies of pictures by G. F. Watts, including "Love and Life," "Orpheus and Eurydice," &c., besides a number of good portraits. Next we have a peep into the past, by examining a loan collection of photographs taken by the late Mrs. Julia Margaret Cameron, who may be said to have been the first to recognise the necessity of observing the rules of art in photographic portraiture. These pictures having recently been exhibited in London, call for no special comment here. The Birmingham Photographic Society contribute to the Exhibition a collection of pictures of which the Midland city may truly be proud, for some of the gems of the show are among them. The work of Mr. W. J. Harrison is, of course, good, for he is one of our veteran workers. We must also give a word of praise to the pictures sent by Mr. A. W. Wills, who seems to be as much at home among the natives of Burma as he is when taking pictures in his orchid houses at home. Mr. J. H. Pickard has managed to get a marvellous picture from a simple bunch of grapes. Look at this, some of ye academicians, who paint year after year the same fruit studies with slight variation, and take a lesson, if not in colour, in delicate light and shade! But Mr. Karleese, with his beautiful scenes on the river Cole, and his frame of Warwickshire scenery, must take the palm from all who exhibit in this alcove, although he is run hard in subjects of the same kind by Mr. Leeson.

### List of Awards.

*Challenge Cup.*—Birmingham.

*Gold Medal for the Best Alcove.*—Van der Weyde.

*A Special Gold Medal* was awarded at request of judges to exhibit of Mr. Crooke, of Edinburgh.

*Silver Medal for Ladies.*—Miss Lilian Tomkinson.

*Silver Medal for Best Screen.*—W. W. Winter, of Derby.

*Bronze Medals.*—To Rev. Precentor Mann, J. E. Austin, F. W. Edwards, C. Whiting, R. Keene, Karl Greger, Lala Deen Dayal, A. S. Watson, H. Flather, Mesi, Bolas, & Co., W. L. Colls, J. Collier, W. M. Malby, R. H. Lord, H. Selby, A. R. Dresser, B. Karleese, J. H. Pickard, J. A. Hodge, C. C. Cole, and to F. W. Edwards.

#### LANTERN DIVISION.

*Bronze Medal* (Amateur).—Messrs. J. E. Austin, Beetham, Taverner, Dresser, and Dr. Thomas Morton.

*Bronze Medal* (Professional).—West & Son.

#### SCIENTIFIC.

*Bronze Medal.*—Stanley Kent.

*Judges.*—Valentine Blanchard, F. P. Cembrano, Frank Atkinson, F. Mason Good, P. H. Newman.

*Judges of Lantern Division.*—G. G. Baker-Cresswell, T. Freshwater, C. E. Gladstone, E. M. Nelson.

## TECHNICAL SCHOOLS FOR PHOTOGRAPHY.*

BY MAX JAFFE.

Lessons in the auxiliary sciences should follow on the drawing lessons, and also lessons in chemistry and physics as far as they concern photography and the photo-mechanical processes. However, this scientific instruction should not be conducted independently; it must be imparted with the general educational course, and by means of practice in the studios. In this stage of his school work the pupil must become acquainted with everything that he will have to use in practice, for this is the only manner in which the scientific instruction can be made of practical use to him. He must become familiar with the application of the utensils and apparatus that he will have to use subsequently; next, he must engage in practice in subordinate things, and take part in the necessary preparations for them; finally, he must be initiated into the sundry departments of the educational course in the easiest manner—that is, by practice.

This second part of the technical instruction, like the first, should occupy the pupil the entire day, and last for at least a year. Now follows the third part of this particular education, the practical instruction in photography and the photo-mechanical processes.

We now come to the question: In what manner is this to be accomplished? and come back to the earlier statement that the course of education is simply to follow the pattern which exists in the former apprenticeship; and means must here be provided for the scholar to gain experience of all the needs of real life. A scholar who has finished the course of the technical schools, and who had, up to the time of his leaving, only such problems to solve as were set for him by the masters, will be much disappointed by his entry into business practice, and feel strange in it, in the same way as we feel strange in those countries of which we have thoroughly learnt the language at school, but are not accustomed to its sound and form of expression.

Real life is only to be infused into the technical schools by means of productive work. The severe and constantly changing claims of practice form an education of a lively and invigorating kind, while the academical method of professional instruction will simply finish in monotony and pedantry.

There is scarcely a second profession in which the necessity of conducting education in the above-indicated manner appears so imperative as in ours. Let us compare another artistic profession; for instance, metal working. The scholar has an appointed exercise to perform—say, the fabrication of a candlestick in wrought iron in a prescribed style, from designs of his own drawing. If he has accomplished this commission satisfactorily, one can realise by this finished work that he is an accomplished draughtsman, and that he is well versed in knowledge of style, as well as that he has acquired a certain amount of experience in the treatment of wrought iron. It is entirely otherwise in our profession. There even the most interesting branches are seemingly easy of performance; indeed, anyone may have produced a good negative copy, or picture, or even a print, photo-lithograph, or a helio-engraving, without being able to say that he has penetrated into the spirit of the matter, and has a thorough command of every process.

In no other profession is it so valuable as in ours that one's knowledge be composed of the amount of experiences which each separate accident offers. This amount of experience is readily acquired by an amateur in self-chosen objects; but it is only acquired by a future professional man by dint of practice in the work which he intends to follow. To the uninitiated, and only half initiated, nothing appears easier than those processes on which the success of photography depends; the manner in which the multiplication takes place, and the development of the negative; especially in these days, when the sensitive plates can be bought ready for use. But, by closer consideration, it will be found—1st, that in spite of apparent easiness, success is only to be attained by long years of practice; 2nd, that for many purposes, especially the reproduction department, the gelatine plate gives insufficient results, therefore the old and difficult processes must be resorted to; 3rd, that proportionately little is done by the command of technique, but that much more is to be looked for from the knowledge of how to grasp the object to be photographed with the mind's eye, and how to use all accidental circumstances which would work together to favourably influence the result; that only in this many-sided combination of qualities the germ of the production of the negative is to be found,

In other professions there may be great difficulty in organising technical schools on the basis of production: in our profession the difficulty is not so great that it may not be surmounted with a good will. We have decided that the educational course shall be productive; it must, therefore, be established similarly to a professional business establishment. But it is not in any way intended to imply by this statement that the schools are to receive commissions from any quarter.

The final inspection of the professional instruction will always fall to the State. The educational management of each State has, in many branches of its business, a continual need of work in the photographic line, which need might be extended in many directions. These works would be furnished if possible by the technical schools. In this manner the schools could be supplied with the necessary funds for studying purposes, which would be otherwise unattainable.

Even the branch of portraiture could be used very productively for educational purposes; with it, a great deal could be done for medicinal, physiological, psychological, and other studies. Patterns or samples of portrait study might be made which might be sold at a certain fixed price like lesson-books. The landscape department could be made serviceable in manifold ways for studying purposes; for instance, for archæology, geology, geography, farming and husbandry, forestry, and the science of warfare.

This fact of the schools actually producing will have the following effect. The works issuing from them will have to undergo the severest criticism, and, therefore, they must continuously keep up with the prevailing spirit of the time. This circumstance will have this richly beneficial effect. Scholars who, through deficiency of talent or industry, cannot keep up with the course, can retire in due time, so as not to be a hindrance to the other more capable or more industrious scholars. On the other hand, it will necessitate the selection of only such men as teachers whose knowledge—in that department in which they teach—is fully up to the spirit of the time. It will also be indispensable that they possess in a very high degree capabilities to stimulate, educate, and cultivate the students. *(To be continued.)*

## THE PERMANENCY OF PHOTOGRAPHS.*

BY FR. WILDE.

It has been claimed for platinum prints that they are absolutely permanent. That reduced chloride of silver should not be equally permanent as chloride of platinum still remains to be proven. It is true that hyposulphite of soda does not come into play in fixing the platinotype, and all danger from that source is precluded. I have seen many clear and beautiful platinum prints, but also many which had turned very yellow. Platinum paper is notoriously unstable, and must be used fresh; if this is not done the result is doubtful, and the prints usually useless. Perhaps the poor specimens seen were the result of stale paper, or, possibly, the cause was that traces of muriatic acid remained in the paper. Last May I saw an exhibition of platinotypes, of universal excellence and clearness of tone, in a prominent photographic establishment. Several months later I again saw them in the same position. All had not kept equally well; a few had discoloured a little, but the majority were unmistakably yellow. Consequently, it is also requisite to exercise caution in the manipulation as well as in the selection of materials for platinotypes, if the prints are to remain without change. Such being the case, the much-vaunted platinum process has, as a matter of fact, no advantage over the silver print. Notwithstanding the beauty of the platinotype, which is acknowledged by photographers in general, the process is used by comparatively few. The cause for this may be that platinum paper is an expensive material, and the process requires much practice before the requisite experience is obtained which alone insures success. The failures are expensive, and cause much loss of time; and furthermore, specially prepared negatives are requisite to produce good results.

Now it is suggested to tone silver prints with platinum, and thus obtain prints with all the characteristics of platinotypes. Here the silver is replaced with platinum; accepted that it is true that platinum chloride gives more permanent prints than silver chloride, then by this method the substitution of platinum for silver would be easy and cheap; further, it does not bring into play a single process with which every photographer is not familiar. The process differs only in the substitution of a platinum for the gold bath. A platinum bath yields more and keeps longer than a gold bath. As a fact, the process gives excellent results, and is worthy of the attention of all photographers. In our own practice, we use a plain paper.

Platinum toning has been frequently broached, but the experiments usually resulted in measly prints if tried with albumen paper, or flat, grey prints on plain salted paper. The cause for these failures was that the baths for sensitising paper for platinum toning should contain ammoniated argentic nitrate. I never was in favour of such baths, as they do not keep, and are useless for albumenised paper. Still, it is convenient to have a bath which will answer for all papers. I made the trial with paper, sensitised on my regular bath for albumen (1·8) three minutes; then I fumed on both sides four to five minutes shortly before use. The result exceeded the expectation; quick printing, plucky, beautiful tones, brilliant high lights, with the richest scale of half-tones down to the deepest shadows. The paper used was a strong, heavy Steinbach, with a rough surface, notwithstanding which all the finest detail and modulations were present, which added greatly to the artistic effect. Before toning, the prints must be well washed until the water does not show the least trace of milkiness. They are then well drained, and placed in the platinum-chloride bath. They tone rapidly, after which they are placed in a strong bath of common salt; and from this into the fixing bath (hypo 1·6), in which they remain twenty-five to thirty minutes. After the fixing, I proceed as with silver prints. I place them in the salt baths until, according to the chewing test, there is no by-taste. These saline baths act well, and strengthen the tone of platinum as well as silver prints. Another matter which has a tendency to improve the prints is a rapid drying after a thorough washing. In mounting, a rapid drying by gentle heat also tends to act advantageously.

It is remarkable how indifferent the majority of photographers on the Continent are to the fuming of sensitised paper, in view of the great advantages to be gained with so little trouble and loss of time. Fumed papers are much more sensitive, and copy in less time than the plain. The prints are as strong with the use of a weak silver bath 1·12 to 1·16, as the unfumed sensitised on a concentrated bath 1·10 to 1·8. The prints on the former have a finer detail and shades in the half-tones, and details often lost come out here in all their beauty. Ready-sensitised paper only gives good results if fumed with ammonia. The prints then are equal to freshly sensitised paper. This paper is of great advantage to smaller photographic establishments, as it is possible to prepare a quantity of paper in advance. This saves time and trouble. The following formula has proved the most reliable in my experience; it seems to be of special trustworthiness, and deserves the attention of the practical photographer. The paper is floated for two or three minutes on a solution of—

| | |
|---|---|
| Nitrate of silver ... ... ... | 100 grams |
| Citric acid ... ... ... ... | 100 ,, |
| Water ... ... ... ... ... | 1,200 c.c. |
| Alcohol... ... ... ... ... | 100 ,, |

After each sheet has been sensitised, 10 c.c. of the following solution are added to the bath:—

| | |
|---|---|
| Nitrate of silver ... ... ... ... | 20 grams |
| Citric acid ... ... ... ... | 12 ,, |
| Water ... ... ... ... ... | 200 c.c. |
| Alcohol ... ... ... ... ... | 20 ,, |

When removed from the bath, the paper is drawn over a glass rod, and, after draining, placed with the sensitised surface on chemically pure blotting-paper. It is then covered on its back with a sheet of stout paper, and well and evenly wiped off by powerful rubbing and pressing. Finally it is dried spontaneously in the dark. If placed between preserving paper, it will keep for from six to eight weeks in summer, and for months in winter. The preserving paper consists of soft, very thick, unsized blotting-paper of white colour, which should be entirely free from wood, chemically pure, and saturated with carbonate of soda. It should be used in rolls of from five to six metres length, and kept, together with the sensitised paper, in pasteboard or tin boxes.

---

At a recent meeting of the Royal Meteorological Society, it was noted by Mr. F. J. Brodie, as one of the features of the past winter, that the number of foggy days in London was no less than twice the average.

The California Camera Club, says *Anthony's Bulletin*, gave a very interesting lantern exhibition during the last of March, on which occasion the views were entirely of picturesque English scenery, embracing many of the noted castles and ruins of the old country, and it was much enjoyed by all present.

* Concluded from page 265.

# Notes.

American genius is generally up to date, but although it has made all kinds of artificial things, from sham coffee berries to wooden nutmegs, it has as yet found the manufacture of an egg beyond its powers. If nature had kindly constructed eggs with solid interiors, the imitation thing would long ago have been achieved; but as it is, the Yankee inventor has in disgust to fall back upon nature.

As the photographer is still dependent to a large extent upon albumen for his prints, as the said albumen comes principally from eggs, and as eggs are impossible without the good offices of the hen, the following note with regard to the way in which our American friends propose to evade the tariff upon eggs should be of interest.

The suggestion is to feed the hens in Mexico on the cheap grain to be purchased there, and then to drive them into the United States before they have time to lay their eggs. In order to carry out this idea, it is intended to erect a long building, one half of which will find its termination in Mexico, and the other half in the United States. The obedient bipeds will feed and water at the Mexican end of the arrangement, and then, in order to escape the payment of duty, will run into the other end of the building, under the protection of the Stars and Stripes, and will there triumphantly lay their eggs.

Several photographers are advocating the use of celluloid as a material for the focussing screen, and as a substitute for glass. It certainly has advantages over the older material in the matter of weight and texture, but it is obviously limited to cameras of small size, owing to its liability to bulge out of shape with changes of temperature. It should be particularly valuable for photo-micrographic work, where a sharp focus is of so much importance, and where the coarse grain of glass makes good focussing so difficult.

Some very interesting photographs taken by Mr. Cecil V. Shadbolt, the son of a well-known photographic worker of a past generation, were projected upon the large lantern screen at the Crystal Palace on Monday last. They consisted of bird's-eye views of Beckenham, Thornton Heath, &c., taken from a balloon at various altitudes. As may be imagined, they had little artistic value, and were more like maps than pictures. The houses were hidden under their roofs, and formed, with their gardens, a kind of patchwork appearance upon the landscape. The altitude from which these pictures were taken averaged about 1,500 feet. We are of opinion that such pictures would be more interesting if taken much nearer to the earth, so that living beings could be depicted from such a novel point of view.

Dr. Charles M. Cresson, of Philadelphia, is credited with having taken the portrait of the much dreaded bacillus which is supposed to be associated with typhoid. The tiny organism was captured from suspected drinking water by agitating the liquid, and then decanting it into a funnel-like vessel terminating below in a very fine opening furnished with a tap. When the water in this vessel had been at rest for some time, a single drop was permitted to exude from the lower opening, and this was at once placed under a microscope. The typhoid imp is not unlike a dumb-bell in shape. By means of the camera its image has been enlarged to about 3,500 diameters.

"Ceramic photography made easy," might be the title of the process lately described and demonstrated before the French Photographic Society by M. Raymond. His process is briefly this: He prepares a collotype plate, and rolls it up in the usual manner with fatty ink, but this ink has been previously charged with vitrifiable colours. A proof is then taken upon paper charged with a soluble substratum, so that when the image has been transferred to the surface to be decorated, the paper can be stripped off, and the article fired in the ordinary way. It will, therefore, be seen that the process is analogous to the common method of decorating china ware, with the substitution of a photographic original for that supplied from a cut block.

Many old photographic ideas are continually cropping up as new things, and it is not uncommon for one of these to form the subject of a solemn communication to some society or other, and to give rise to grave discussion. The older hands smile sometimes when they see reports of such doings, but do not take the trouble to point out how ancient they are. That the taking of lightning flashes is no new thing—although often regarded as being a novel application of photography—is proved by a correspondent of the *Photo. Archiv*, who quotes from a paragraph published in 1864 at Leipsic. It runs as follows:—"Gunther thus conceived the idea of photographing lightning, and one night was, with Prof. Dove, observing a storm at the Berlin Observatory. The sky was favourable. Gunther prepared the plate, exposed it to the dark heavens, and closed the slide after a flash of lightning which crossed the field of view. The flash was taken. What a triumph for photography, and also for science, to succeed in copying, after nature, a flash of lightning!"

The Glasgow and West of Scotland Photographic Association are certainly taking time by the forelock in issuing the prospectus of an exhibition which will not open its doors until September. But they are doubtless right in doing so, for they hope, they say, to make this the largest and most interesting exhibition of photography which has yet been held in the West of Scotland, and with this view they have arranged that the pictures shall be hung in the finest hall for exhibition purposes in Glasgow. We learn that they have many promises of support from both professionals and amateurs. Particulars may be obtained of the hon. secretary, W. Goodwin, 3, Lynedoch Street, Glasgow.

A very perfect series of instantaneous photographs of the attitudes in fencing appeared in *La Nature* for last week. The photographs are eighteen in number, and were obtained by M. Marey's photo-chronographic apparatus at intervals of $\frac{1}{20}$th of a second on a sensitive pellicle moving between each picture, and stopping during the time of exposure, which was $\frac{1}{1000}$th part of a second. English athletes would like to see representations of boxing figured in a similar fashion.

An enterprising journal which is bitten by the present mania for giving portraits of everybody, from the somebodies down to the nobodies, must be prepared for sarcastic criticism. One newspaper, commenting upon the likenesses given in a contemporary of the members of the Labour Commission, professes to find, according to its "recognition of the portraits," that it now consists of Mr. P. T. Barnum, General Booth, the Siamese Twins, Sir John Astley, Mr. J. L. Toole, and others. It then kindly adds: "We were under the impression that some of these were no longer in active service, but 'the apparatus can't lie,' and there are the pictures." Photographers have, years and years ago, discovered that no two critics ever agree as to the resemblance of a portrait to the original. The enterprising journal referred to above may take comfort from the fact.

---

Mr. Carey Lea is still actively pursuing his researches into the nature of the various silver compounds. An article on allotropic silver appears in the April number of the *Philosophical Magazine*, taken from an advance proof sent by the author. Mr. Carey Lea points out that he dealt with the gold-coloured form of allotropic silver in a paper already published. In the present article he considers the relations existing between the allotropic forms of silver taken generally, and silver as it exists in its compounds, more especially in the silver haloids, and he has come to the conclusion that there is reasonable ground for supposing that in the latter allotropic silver may so exist. In a future paper he proposes to treat of the blue form in its soluble and insoluble varieties.

---

The Manchester Amateur Photographic Society displays considerable energy, and seems to be highly popular. It boasts of a journal which is published quarterly, from which we learn that the library has grown to such an extent that the librarian "requires more shelving." This is a very healthy sign.

---

The same society has tried the "Question Box" system, but has not found it to answer. The plan adopted was somewhat different from that in vogue in other societies. The old idea was that a "Question Box" is an excellent substitute for a paper when the latter is not forthcoming. If the experience of the old South London Photographic Society be any guide as to what has happened elsewhere, it often turned out the box was a delusion, for on more than one occasion when it was resorted to it was found that the "cupboard was bare."

---

The Manchester Society's box, on the other hand, was intended for the reception of questions by persons in want of information, and the answers were given by the members at the meetings when the box was opened. It has been found, however, that the answers were of necessity off-hand, and that sometimes no reply was given at all. Henceforward, members wanting information must send their queries to the secretary at least a week prior to the monthly meeting. Such a "Question" or "Information Box," as it ought to be called, is decidedly a good idea. There are many beginners too timid to expose their ignorance *viva voce* who would gladly send in their questions on paper.

In spite of the ingenious invention of a Plymouth undertaker described a few weeks ago in the *Undertaker's Journal*, which not only exhibits portraits of the deceased persons on their gravestones, but also records the visits of those friends who chose to leave their cards, we doubt whether the practice of attaching photographs to gravestones will ever become general. Most people, after they have gone through the melancholy duty of the funeral service, are apt to shun graveyards and cemeteries. Still it may be that undertakers, in view of a reform in funerals which would cut down "extras" to nothing, and considerably reduce profits, will take up photography as a substitute, and, with that persuasiveness which is so effective in the time of woe, induce people to have photographic adjuncts placed on the graves of their friends and relatives.

---

Already an example has been set by a firm of Canadian photographers, whose advertisement in the *Hamilton Evening Times* is so unique that we cannot forbear quoting it. "Green Bros., John St.," it says, "are the only undertakers in the city who take photos of deceased people. The eyes are opened, and taken as natural as if alive. By calling at office such portraits can be seen." Here is, indeed, enterprise. We are inclined to think the photographic profession would not mind handing over all the *post mortems* to the undertakers, for photographing a corpse is an operation from which most shrink. Besides, what photographer would have a chance against an undertaker who can produce portraits in which "the eyes are opened, and taken as natural as if alive"? As we have not seen "such portraits," perhaps it would be unfair to pronounce judgment on them; but, at present, it looks as if the ingenuity of "Green Bros." is likely to add a new terror to death.

---

What's in a name? Not much, perhaps, but, at least, it should not be misleading. The View-Finders' Club is an active photographic association, which has its habitat in Edinburgh. At the first blink, it would seem as if the object of the Club had to do with that useful little attachment without which the detective camera is incomplete; but this not the case. The Club interprets the word "view-finder" in a liberal sense, for its aim is "the education of its members in art principles, and the criticism of their work." It is a moot point whether the title is a happy one or not.

---

As might have been expected, the experiment tried by the English Art Club of having photographs of the pictures on sale in the Dudley Gallery, where the collection is now on view, has been much appreciated by the visitors, who have not been slow in buying copies. As the photographs are the work of that experienced operator in this branch of photography, Mr. F. Hollyer, their excellence is guaranteed.

---

The gentleman who wrote the *Globe* notice of the Crystal Palace Photographic Exhibition has not kept himself well posted up in photographic history. He says gravely that "Mrs. Cameron sends" some of her well-known specimens of artistic photography, and is evidently unaware that this lady has been dead many years.

## THE SECOND TRIENNIAL EXHIBITION AT GLOUCESTER.

The Gloucestershire Photographic Society is again to be congratulated on the complete success which has crowned the efforts of its executive. The lofty and extremely well-lit room furnishes an admirable home for the pictures, but was not available for use until Saturday, so all the work had to be crowded into two days; the brilliant effect, however, which greeted the eye on entering the gallery on the opening night conclusively demonstrated what could be done by the well-directed efforts of a few really earnest workers.

The formal proceedings attendant upon the opening were delightfully brief. The president of the Gloucestershire Science and Art Society, Mr. W. C. Lucy, in a few well-chosen words, declared the exhibition open, and after a few remarks from the Mayor of Gloucester, who told the audience that he was a photographer forty years ago, and also from the president, Mr. Walter B. Wood, the guests were invited to partake of refreshment before settling down to enjoy what was really the great feature of the evening, viz., a most delightful lecture on Iceland, illustrated by a remarkably fine series of slides recently executed by the lecturer, Mr. Paul Lange, who, in a bright and witty manner, told all the discomforts and perils that awaited him at every turn during the prosecution of his photographic labours. The audience had every reason to be delighted, for it was, without doubt, one of the brightest lectures ever delivered. Mr. Lange is a born lecturer. He was in touch with his audience from the moment when he opened his mouth, and held them under a delightful spell to the end.

This mode of opening an exhibition is a most agreeable departure from older methods, where torrents of platitudes run their resistless course, and we earnestly recommend promoters of exhibitions to copy Gloucester.

The judges were Messrs. H. P. Robinson, Valentine Blanchard, and Edward Brightman, and the following are the awards made by them:—

Class 1—*Portraits, Professional.*—Silver medal, W. J. Byrne; bronze, W. W. Winter.

Class 2—*Portraits, Amateur.*—Bronze medals, Shapoor N. Bhedwar and W. J. Jenkins.

Class 3—*Landscape, Professional.*—Silver medal, J. P. Gibson; bronze, A. Hendrey.

Class 4—*Landscape, Amateur, under 8½ by 6½.*—Silver medal, Karl Greger; bronze, Martin J. Harding.

Class 5—*Landscape, Amateur, 8½ by 6½ and above.*—Silver medal, J. E. Austin; bronze, E. Lloyd Edwards; extra bronze, W. H. Banks.

Class 6—*Instantaneous.*—Silver medal, Charles Reid; bronze, Lyddell Sawyer.

Class 7—*Hand-Camera Work, Objects in Motion.*—Silver medal, J. M. Nicholson; bronze, J. White.

Class 8—*Architecture, under 8½ by 6½ (Series of 3).*—Silver medal, Ernest Beck; bronze, C. Court Cole.

Class 9—*Architecture, 8½ by 6½ and above (Series of 3).*—Silver medal, W. J. Byrne; bronze, C. Court Cole.

Class 10—*Genre or Figure Picture.*—Silver medal, Lyddell Sawyer; extra silver, Shapoor N. Bhedwar; bronze, R. H. Lord.

Class 11—*Enlargements (not Portrait), Amateur.*—Silver medal, F. H. Worsley-Benison (subject to confirmation of Condition 5); bronze, W. H. Kitchen; extra bronze, C. W. Huson.

Class 12—*Enlargements (not Portrait) Professional.*—Bronze medal, Hedges and Sons.

Class 13—*Lantern Slides, Professional.*—Silver medal, George E. Thompson; bronze, Priestley and Sons.

Class 14—*Lantern Slides, Amateur.*—Silver medal, J. E. Austin; bronze, Edgar G. Lee; extra bronze, W. C. Beetham and Major Lysaght.

Class 15—*Scientific.*—Bronze medal, Cecil V. Shadbolt.

Class 17—*Special.*—Bronze medal, Maurice Bucquet.

The entries in the lantern competition were so numerous that extra medals were awarded. Serious criticism was not possible at the *conversazione*, but on looking at the general effect by daylight one could not help feeling that the very large number of small pictures, nearly all of the grey tint of platinum pictures, gave an undoubtedly monotonous character to the general effect, and it was only when the pictures were inspected one by one that this feeling disappeared, for it must be admitted that the average of excellence has risen enormously since the last exhibition three years ago. This disappointing effect is largely due to the division of the pictures into classes, and the consequent necessity of keeping the pictures in each class together, as far as possible. The members of the Society have adorned the lantern stand with some of their pictures, and, with a most commendable modesty, have not entered them for competition. On this screen are some admirable architectural bits (Mr. W. B. Wood), and among them the celebrated Norman doorway at Ludlow Castle.

Another screen is entirely filled by the splendid series of the Academicians, by Ralph W. Robinson; many of these are so well-known that they do not need further comment. They are marked "not for competition." The lecturer's rostrum is well covered by the well-known work of Mr. H. P. Robinson—one of the judges—and these also are marked as out of the running.

Mr. W. J. Byrne has surpassed himself in some portraits of children. Several of them are extremely simple in treatment, for there are no accessories to distract attention. They have the grace of unconscious pose, and the large-eyed, trustful innocence expressed by two of them make them no longer children, but angels. Sir Joshua Reynolds, had he been there, would have been envious.

Mr. Vandyke's powerful portrait studies are well-known, and so also is the work of Mr. W. W. Winter. The group of two ladies in white dresses, with its powerful light and shade, shows well in this gallery, but, being nearer the eye, the touching shows too palpably. Why do it, Mr. Winter? The picture is so fine that surely it would be better without this evident sophistication. There is a little picture of mother and child by this gentleman that is simply delightful. A roguish child, evidently a great pet, is lovingly squeezing the cheek of the fond, well-satisfied mother. During the run of the Exhibition, we predict that several "mothers' meetings" will be held in front of this picture.

Window and Groves' pictures are well known. There is one, however, of Mr. Gordon Craig in "Ravenswood" so broad in effect, and so powerful in light and shade, as to stand quite out from the frame. The beautiful mobile mouth, and the bright flashing eyes, make this by far the best of the many portraits done of this remarkably handsome young man. Mr. W. J. Jenkins has made a very good commencement in his portraits called "Old Heads" and "Young Heads." They are taken with a single lens, and the eye, in consequence, is not distracted by the painful sharpness only too apparent in a large proportion of the work of the professional photographer. Mr. Jenkins is an amateur, and is on the right track. Go in and win, Mr. Jenkins.

Mr. J. P. Gibson has surpassed himself at this Exhibition. Several of his larger pictures are well known; but "A River-side Road" is one of the most perfect landscapes ever done by photography. A river threads its way between hills and loses itself behind a clump of trees on the right. The whole of the picture is made up of tender greys, except some strongly accentuated dark stones in the bed of the river in the foreground. Without these aids to effect, the picture would be regarded by many as tame and rather flat; but with them the picture is perfect. Every object takes its place, and there is harmony everywhere. Another picture, of larger size, is worthy of notice. It is made up of slender materials, but they are used in the most artistic manner. Only a steep, sunlit bank on the right, and a road at its base. A group of children are playing in the foreground, and, like the stones in the last picture, give force to the whole. A bank of white, luminous clouds completes the composition, for it supports and, at the same time, explains the sunshine that dances here and there through the picture. One of its brethren darkens the extreme foreground, but does not obscure the middle distance, where it has full play. This picture is an admirable illustration of the use of clouds when rightly employed.

There are some very fine interiors by Mr. W. J. Byrne, but one of them, "The Drawing-Room at Crewe Hall," is, technically, one of the most perfect, if not the most perfect, interior ever produced. There is detail in the deepest shadow; indeed, there is delicacy of an unusually rare kind, and yet all the force necessary to make a perfect result. What more can be said? The library as a photograph is equally good, but the formality of the carpet makes it not quite so artistic. Keene's interiors are as good as ever, but they are so well known that they do not require more to be said about them.

## WINTER PHOTOGRAPHY.*

BY ERNEST H. JACOB, M.D.

Winter photography, so far as one can judge from exhibitions of lantern slides and pictures, has suffered far too great neglect. The reasons are strong, both artistic and scientific, why the camera should find frequent use in the winter months even more than in summer. Setting aside the slight inconveniences and personal discomforts of operating in cold and windy weather, with benumbed fingers which will hardly work the focussing screw, we find ourselves in winter confronted with an almost monochrome picture, with its well-defined forms of tree and cloud far more perfectly fitted for photographic representation than the summer landscape with its heavy greens, so difficult to render except by special methods. Artistically, the face of nature in its winter garb has a quiet beauty of its own quite as worthy of being pictured as the more vivid colouring of sunnier days. Winter, moreover, brings us certain special forms peculiarly adapted to the photographer; among these may be mentioned:—

1. Buildings which, in the summer months, are largely obscured by trees. There are many of these, and the lover of architectural detail will frequently have to leave unpictured on his holiday tour forms of sculptured beauty which can only be fixed when the falling of the leaf reveals them.

2. Snow scenes. These are generally considered fit objects for photography, but it is difficult to catch the right moment for depicting the effect. On the whole, perhaps, certain kinds of hoar-frost on shrubs or hedges are the most effective forms to photograph.

3. During the time of snow, interiors, as a rule, are better lighted than even during the summer season. Many a dark roof of cathedral or ancient building can only be well photographed when lighted by the reflection from the snow outside.

4. On the whole, however, the most interesting objects to photograph in winter are trees. In summer, a tree is a mass of foliage, beautiful to the eye, but unsatisfactory to picture by chemical means. When the dress of green has fallen, we seem to see the real tree, with its character more firmly defined, and its delicacy or strength not only more easily recognised by the eye, but in such a tone as to enable a picture, exact in the delineation of the finest twig, no less than the strongest bough, to be fixed by the plate; a picture, moreover, compared with which the most delicate brush-work seems a misty array of meaningless scratches. There are a few trees, it is true, rather ugly in their winter bareness. A row of poplars and a clipped hawthorn hedge one need not spend much time in studying; but an oak, an elm, or a group of birches, form truly admirable subjects for pictures. The larger type of forest trees can be studied in the numerous parks which abound in England. Some very fine specimens are to be found in Studley Park, near Ripon (mostly oaks, elms, and Norwegian pines), and in Nuneham Park, near Oxford, where elms and conifers are exceptionally fine. The study of tree forms is valuable not only from an artistic but from the botanical standpoint, and photographs of trees, both in their summer and winter state, should form part of every botanical institute, or school where botany forms part of the curriculum. The study is a most engrossing one, and the photographer who takes it up will find a new pleasure added to his pursuit.

5. It need hardly be mentioned that cliff and coast scenes are no less interesting in winter than in summer, unless the "common objects of the sea-shore" as illustrated by the *genus homo* be the only things sought for; while skies and breaking waves are infinitely finer in the colder months, and in early spring the light is quite good enough for instantaneous views of wave forms.

Lastly, the sombre monochrome of the winter landscape is far more worth picturing than a large number of the objects which crowd our exhibitions. A woodland scene, when lit up by the brilliancy of the silver birch, and enriched by the lace-like delicacy of its drooping branches, forms a picture not only beautiful in itself, but capable of being transferred intact to paper or glass, with its lines as perfect as in nature, and its "values" in absolute accuracy.

[The paper was accompanied by a number of lantern slides illustrating the various points touched upon, including a series of trees mostly photographed in Nuneham and Studley Parks.]

* Abstract of paper read before the Leeds Photographic Society.

Photographic Club.—Wednesday, April 29th, will be the last lantern evening of the season. On May 6th, the subject for discussion will be "Outfits for Landscape Work." Outing on Saturday next, April 25th, to Brentford; train from Broad Street (*via* Kew Bridge) at 2.25.

To Make a Dead-Black Polish on Brass.—For microscopes, &c., mix one ounce of nitrate of silver in a dish with twenty ounces of distilled water. In another dish mix one ounce of nitrate of copper with twenty ounces of distilled water. Mix the two solutions together, dip the brass in the liquid, remove the brass, and heat in an oven until the desired degree of black is obtained.

## ARCHÆOLOGICAL PHOTOGRAPHY.

### Ancient Coast Oratories.

Our good forefathers, although professing a creed which it has been the custom for three centuries and a half for some of us to "protest" against, nevertheless possessed a very large share of sincere piety and true Christian charity, as is evidenced by the grand and lasting memorials and imperishable records which they have left behind them in our glorious cathedrals, hundreds of monasteries, churches, chapels, chantries, oratories, and other religious works. It has been said that the piety and religious fervour of our ancestors was merely formal. Possibly; but if so it is very clear that this dry formality took a most substantial, useful, and unselfish turn when it could expend its energies, and its treasure, in rearing, in a genuine religious spirit, such glorious works as those just mentioned purely "ad majorem Dei gloriam"; and if these high-souled men and women reared the vast cathedral for the country at large, the convent for the special community, the church for the particular parish, and the chapel and chantry for family use or private devotion, their large-hearted goodness went farther still. Never losing sight of the significant fact that this is a maritime country, and that it always possessed a commerce, even from very early times, which so increased in the middle ages that many merchant princes arose, notably in the city of London—Whittington, Gresham, Crosby, Hatton, and others—and remembering that foreign commerce depends entirely on ships, and ships entirely on sailors, these thoughtful and generous people founded, on different parts of the coast, close to the sea, very small oratories, the merest remains of but one or two of which yet exist. As these were not intended for the assembling of congregations, they were just large enough to contain an altar, with its ornaments and crucifix, an effigy of a saint (possibly St. Clement, the patron of sailors), and perhaps little else. Here a priest was engaged to say mass, perhaps two or three times a week, or even oftener, expressly for the double purpose of (1) praying for rest for the souls of those belonging to the place or town where the oratory was situated, who had lost their lives at sea; and (2) for the safety and success of the living then sailing the sea in pursuance of their duties—an idea beautiful in itself, and embodying true Christian charity. One of the largest and most celebrated of these oratories was situated at "Bradstayer," or "Braidestowe," meaning "the broad place," now called Broadstairs, on the east coast of Kent. This little chapel was dedicated to the Holy Virgin, under the name of "Our Lady of Pity," or St. Mary de Braidestowe." In it was a statue of the Patroness, which was held in such extreme veneration that all ships, as they passed the spot, lowered their topsails as a mark of reverent salutation, for it must be remembered that the Blessed Virgin was always regarded with profound love and reverence by sailors and fishermen, and constantly addressed as the "Star of the Sea."

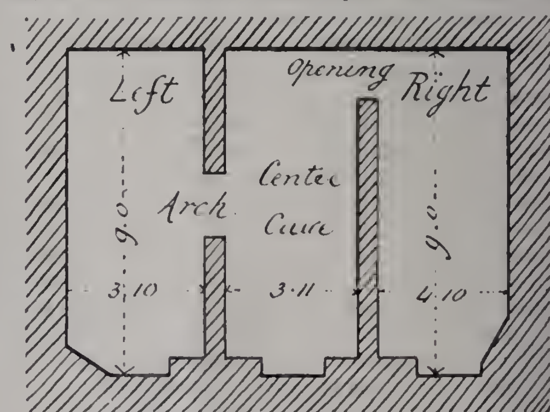
Such oratories also existed at Reculvers, Dover, Whitby, and in other places, though all have now disappeared. They are still, we believe, frequently to be met with on the Continent.

It may not, perhaps, be generally known that the great corporation of "Trinity House," on Tower Hill, which takes charge of and regulates all matters connected with lighthouses, light-ships, buoys, beacons, and other matters connected with the maritime interest on the coasts of England and Wales, was originally founded in the reign of Henry VII. as a simple religious "Guild," the Brethren of which bound themselves to pray for the souls of sailors lost at sea, for the safety of those on the verge of shipwreck, and the lives of sailors then following their duties. It was called the "Guild or Brotherhood of the Holy and undivided Trinity of Deptford, Strand, and St. Clement."

Accompanying this article is an illustration of what we believe to be one of these veritable and undoubted oratories, and known by the name of the "Minnis Rock" (from "Meuys"—Saxon—steep), and which may still be seen

just a little to the north of the Old Town of Hastings, and close to High Wickham, in the western face of the East Hill, which, at its greatest elevation, rises to the height of about 250 feet above the sea level.

The "Minnis Rock Hermitage," as it is sometimes called, consists of three square-headed openings or arches, all of the same height, rudely cut in the face of a huge mass of rock projecting from the side of the hill, and about 12ft. or 15ft. high, and 25ft. or 30ft. broad. The cave is divided into three separate chambers of nearly equal size, as shown in the annexed plan, the centre com-



municating with the two side ones by rudely cut openings; but they are all three now nearly filled up with earth and rubbish, and only their heads are visible above ground. The dimensions of what, at present, can be seen may be taken as follows:—

| | Height above ground. | Breadth. | Depth. |
|---|---|---|---|
| Centre | 2ft. 0ins. ... | 3ft. 11ins. | All about 9ft. |
| Left | 2ft. 2ins. ... | 3ft. 10ins. | |
| Right | 3ft. 1in. ... | 4ft. 10ins. | |

Nothing whatever seems to be known of this curious relic of the deep religious feeling of our forefathers of remote antiquity, and it is very much to be regretted that nobody—not even the freeholder—seems to take the smallest interest in the place. It has been called, as already stated, a hermitage—the supposed abode of a hermit—but this again is most unlikely, for the cave, situated close to the town and church, and just above the old Roman road (now the London Road, leading into Hastings), would be very much too public; as it is well known that hermits invariably sought and preferred quiet and privacy, and would hardly have selected so very exposed a spot as this.

About a century ago the cave was open, and it was said to have been the residence of an aged couple, who were paupers and homeless. After that it was used as a cow-shed; and gradually, from utter neglect and indifference of those who ought to have known better, it has become the ruin we see it, and choked nearly to the roof with dirt and rubbish.

When the interior of this cave was last examined, it was described as having an undoubted ecclesiastical appearance, though very small. Opposite the centre door, and therefore due east, is a slab of stone, which may have once supported an altar, and a cross is said to be cut on the wall above, and on one side is a niche, and below that a recess, which has been called a "fire-place," but it is far more likely that it served for an aumbrey. Now, taking all these circumstances in consideration, there can be little doubt that was this really an oratory, one of those, in fact, where mass was regularly recited for those at sea, dead or alive, such as we have already described. Everything about the cave points to this; its general appearance, the slab, the cross, the niche, the side chambers, which possibly might have served as a sacristry, or even a temporary lodging for the priest—the openings being, of course, boarded up—all tend to confirm the opinion as to its original intention and use. It is much to be lamented that this, the last of these oratories now existing in England, and even yet in sufficient preservation to exhibit its dimensions, is not again opened and cleaned, and thus made an object of interest and curiosity to the public; but where no one, not even the fortunate owner, feels the least sympathy for this relic of the piety and charity of our forefathers, of course nothing will ever be done, unless the "Society for the Preservation of Ancient Monuments" could be induced to interfere for the saving from desecration and decay of so interesting and peculiar a religious relic.

In the immediate neighbourhood of the "Minnis Rock," a few hundred yards to the south of it, is to be found another antiquarian curiosity, and, at the same time, an antiquarian puzzle. On the western face of the East Hill, a little below its summit, a portion of the ground has been scarped so as to present a perpendicular surface of flat rock, about 16 ft. high and 30 ft. broad. On this will be seen, carefully measured and neatly cut, three Gothic arches with early English mouldings, having their centres painted black, and called by the people the "Three Black Arches." They are shown in fig. 3, and here comes the very peculiar puzzle: There is neither grotto, cave, nor opening of any sort whatever behind these arches; they are merely chiselled on the flat surface of the solid rock, as can be distinctly seen by certain geological appearances. The centre is higher than the two side arches, and their dimensions may be thus roughly stated: the centre about 11 ft. high by 7 ft. broad, whilst the two others are about 7 ft. high by 4 ft. broad. As considerable care and much trouble must have been taken in measuring and carving out these arches, so closely resembling the doors of a church, the question at once arises, if the work was to lead to no further result, *Cui bono?* Why take all this trouble for absolutely no object or intention whatever? Nothing is known on the spot, and the two or three idle, stupid tales told by the people carry immediate discredit on their very surface. As it is far from likely that any sane person would take all this trouble for no possible use or object, it is quite reasonable to suppose that these

ecclesiastical-looking arches were begun, centuries ago, for an undoubted purpose, and that purpose a religious one—most probably the formation of a chapel or oratory, such as the "Minnis Rock"; but that the work was suddenly stopped—as many another has been before to-day—possibly by the death of the designer, or, maybe, from want of funds, or other cause, which we shall now never know; and so the work was left much as we now find it, although severely injured by time, neglect, and indifference, like its neighbour, the "Minnis Rock"; and it is very much to be regretted that two such interesting relics of the piety of a long by-gone age should fail to rouse the smallest sympathy or feeling amongst the inhabitants of Hastings. But we suppose the real fact is that, as nothing is to be *gained* or *made* out of these curious relics, they are simply treated with utter neglect and indifference, and suffered to go to slow decay and ultimate ruin.

---

Photographic Society of Great Britain.—April 28th—Discussion on "Animal Photography"; Messrs. T. J. Bright, H. Dixon & Son, A. R. Dresser, F. Haes, L. Medland, W. Wainwright, and F. York have promised to exhibit prints or lantern slides. May 12th—M. Leon Vidal will read a paper on "Photographic Methods of Obtaining Polychromatic Impressions." May 26th—Discussion on the "Influence of Development on Gradation." June 9th—Mr. L. Warnerke will read a paper on "A New Sensitometer."

"The secret of a successful photographer," said one who knows, "is in making pictures which flatter the subject. No person wishes to have a picture which accurately represents him as he appears to others in the street. Each man or woman has a certain mental impression of his or her appearance; it may, and probably does differ from the reality, but in order to please him his photograph must not show the crook in his nose or the slight in his eye."—*Photographic Times.*

## THE PHOTOGRAPHIC LENS.

BY THOS. R. DALLMEYER, F.R.A.S.

In complying with the editor's request to contribute a short article to the first number of *The Optician*, I have chosen a general subject as a heading, although the particular remarks will be confined to the photographic lens. The value of illustrations to give a general idea of instruments is no doubt great, and if the illustrations be accurately drawn to scale, of course they will be of still greater value to a buyer. In most optical instruments, however, something more thau the exterior appearance of an instrument is requisite, and further, as year by year we seem to have a more and more initiated public, the more necessary does it become that we should assist, by every means in our power, in furnishing the fullest information for intending purchasers. I therefore hope that the suggestion for the necessity of accuracy in technical descriptions may be followed by others who are devoting particular attention to one brauch or another of the optical trade. With regard to the photographic lens, nearly as much as is possible has been done in this direction, but having thought of one or two useful additions, I have deemed it worth while to mention them. The utility of one was suggested by a letter from the secretary of a provincial camera club, in which he asked what was the meaning of a lens being described as a particular *dimension of plate* given in connection with the type of lens: *e.g.*, what does an $8\frac{1}{2}$ by $6\frac{1}{2}$ rapid rectilinear mean?—the point of the question being what was the full meauing of $8\frac{1}{2}$ by $6\frac{1}{2}$. With the particulars as set forth iu opticiaus' catalogues, at present only one addition is necessary to fully explain the meaning, and that is that the full diagonal of the circle of illuminatiou covered by the lens should be also furnished. Some types of lenses will only cover very little more than the size of plate for which they are advertised, while other forms will at any rate illuminate and, if well stopped down, cover much larger plates. In addition to furnishing the linear dimension of the circle of illumination covered, it is ouly necessary to tabulate and remember the linear dimension of the diagonal of any aud every current size of plate.

| | | | | | |
|---|---|---|---|---|---|
| Diagonal of | $3\frac{1}{4} \times 3\frac{1}{4} = 4{\cdot}58$ | inches, | or under | $4\frac{3}{4}$ | inches. |
| ,, | $4\frac{1}{4} \times 3\frac{1}{4} = 5{\cdot}30$ | ,, | ,, | $5\frac{1}{3}$ | ,, |
| ,, | $5 \times 4 = 6{\cdot}4$ | ,, | ,, | $6\frac{1}{2}$ | ,, |
| ,, | $6\frac{1}{2} \times 4\frac{3}{4} = 8{\cdot}06$ | ,, | ,, | $8\frac{1}{4}$ | ,, |
| ,, | $8\frac{1}{2} \times 6\frac{1}{2} = 10{\cdot}67$ | ,, | ,, | $10\frac{3}{4}$ | ,, |
| ,, | $10 \times 8 = 12{\cdot}80$ | ,, | ,, | 13 | ,, |
| ,, | $12 \times 10 = 15{\cdot}62$ | ,, | ,, | $15\frac{3}{4}$ | ,, |

Now take, for example, a lens advertised to cover a $5 \times 4$ plate; if the minimum linear dimension of the diagonal covered by the lens is greater thau that of the diagonal of any larger size of plate, it is understood at once that the lens will cover this larger plate if sufficiently stopped down. Further, there is conveyed by this information an approximate idea of how much the sliding front may be moved (without cutting off the corners) either up or down, or sideways, when working on a particular plate. It can always be moved right and left (or up and down) from the centre *at least* half the difference between the diagonal of the full circle covered by the lens, and the diagonal of the plate employed. If it is found that the covering powers of the full diagonal of the lens in question only just correspond with the diagonal of the plate, it is evident that it will be unsafe to use such a lens other thau in a central position as regards the plate. It may frequently occur that a photographer may wish to employ a lens of a certain focus upon a given size of plate, but he finds, on looking through a catalogue, that there is no lens, as advertised, distinctly in accord with his requirements. Of course he knows that if the lens of the requisite focus covers a *larger* plate than that for which he intends to employ it, it will cover the smaller plate, and iu that respect the present technical description of the lens is sufficient. Now, if the optician furuished the information suggested, noting that a lens constructed for, say, an $8\frac{1}{2} \times 6\frac{1}{2}$ plate, diagonal of which, $10\frac{3}{4}$ inches, would cover a circle of illumination linear dimension 16 inches, the photographer can see at once that this linear dimension is greater than the diagonal of a $12 \times 10$ plate, and hence he knows that by stopping the lens down, he is in possession of an iustrument that will, if occasion occurs, cover a plate so much larger, and that on using this lens on its owu plate, there is considerable latitude for movement of the sliding front; it may be moved *at least* $2\frac{1}{2}$ inches longitudinally or vertically from the ceutral position.

A short time ago there appeared in the PHOTOGRAPHIC NEWS a somewhat similar suggestion from Dr. Vogel, viz., that opticians should express the covering power, or the linear dimension of the circle of illumination included, in terms of the equivalent focus. This, of course, furnishes the same information as that suggested, although I have offered it iu a rather more practical form.

The diagonals of current plates would be very shortly as familiar as the dimensions of the current plates themselves, and the column indicative of the liuear dimensions of the circle of illumination covered would then prove a very useful addition for the purpose suggested.

To give a proper technical description, then, of a photographic lcus, it is necessary to furnish the following information accurately:—

1. General information on the type of lens, which should include:—(*a*) The form and number of combinations, and the manner of mounting—illustrations here are useful; (*b*) the intensity of the full working aperture of the series; (*c*) the approximate angle included by the series on the longer side of the plate; (*d*) the concise explanation of the system of diaphragms employed, so that when the exposure for oue given stop in a certain light is found, the relative exposure for any stop is known.

2. Then for each individual lens should be tabulated:—(1) The size of the plate the lens is constructed to cover; (2) the focus for parallel rays—in the case of portrait lenses, I still am of opinion that a column devoted to back-focus is a useful addition, as it gives a photographer some definite idea of the shortest length necessary for a camera when a portion is built of a solid form; (3) the full available aperture that determines the intensity of the lens, and also the diameters of the lenses employed; (4) the diagonal of the full circle of illumination of the lens, or the guide to the largest plate the lens can cover; (5) the dimensions of the flange that must be employed, in order that the photographer may know, in selectiug it, whether it can be employed on the present front of his camera.—*The Optician.*

---

THE last new variation on the common "Please-look-pleasant" formula, seems to be the following, which we clip from *Answers*: "Photographer: 'Now, sir, if you'll look a little less as though you had a bill to meet, and a little more as though you'd been left a legacy, you'll make a beautiful picture.'"

## Patent Intelligence.

### Applications for Letters Patent.

6,261. Jebus Bickle, jun., Thomas Edwin Bickle, and John Baragwanath King, Great Western Docks, Plymouth, "Improvements in Photographic Prints."—April 13th.

6,340. George Teasdale Teasdale-Buckell, 55, Chancery Lane, London, "Improvements iu the Production by the Aid of Photography of Surfaces for Use in Printing iu Colours, and in Means or Apparatus employed therein." —April 14th.

6,341. George Teasdale Teasdale-Buckell, 55, Chancery Lane, Loudon, "Improvements in the Production by the Aid of Photography of Surfaces for Use in Printing in Colours, and in Means or Apparatus employed therein." —April 14th.

6,364. William Bevois Parker, Duncan Frederic Christy, and Robert Overton, 19, Southampton Buildings, London, "Improvements in or relating to Hand or Detective Photographic Cameras."—April 14th.

6,514. John Draper, 154, St. Vincent Street, Glasgow, "A New or Improved Means of Making Direct Vignettes."—April 16th.

6,533. Richard Whitehorne Savage and the Sun Camera Company, Ld., 186, Fleet Street, London, "Improvemeuts in or Pertaining to Photographic Cameras."—April 16th.

6,534. Richard Whitehorne Savage and the Sun Camera Company, Ld., 186, Fleet Street, London, "An Improved Photographic Shutter."—April 16th.

6,571. Eugen Albert, Temple Chambers, Londou, "Improvements in Letter-press and Lithographic Processes Based upon Photography."—April 16th.

6,572. James Yate Johnson, 47, Lincolu's Inu Fields, Loudon, "Improvements in Dark Slides for Photographic Purposes." (Paul Tournachon, France.)—April 16th.

6,594. Frederic Louis Perken, Edgar Theodore Perken, and Arthur Rayment, 34, Southampton Buildings, London, "Improvements in or in Connection with Photographic Cameras."—April 16th.

6,618. Sir Charles Stewart Forbes, 21, Finsbury Pavement, London, "An Improved Device for Washing Photographic Negatives."—April 17th.

6,672. James Ford, 1, Bedford Terrace, Plymouth, "Combined Outdoor Developing Tray and Dark Slide."—April 18th.

6,715. Henry Baker Norton, 77, Chancery Lane, London, "Improvements in and Relating to Shutters for Photographic Cameras." (Date applied for under Patents Act, 1883, Sec. 103. September 18th, 1890, being date of application in United States.)—April 18th.

Hawk-eye Camera.—A detective camera beariug this name has been recently issued by the Blair Camera Company, and the agents for it in this country are Messrs. Taylor, Taylor, and Hobsou, of Leicester and London. It possesses several features which make it valuable not only for hand use, but for occasional employmeut on a stand when long exposures are necessary. For this latter purpose it is furnished with an interior focussing screen, which is accessible only wheu a shutter at the back of the iustrument is removed, the said shutter, by the way, fastening into its place by a unique spring movement. The camera can be fitted to work with plates, with separate films, or with an Eastmau roller which provides for forty-eight exposures. The focussing is brought about by a screw at the back, in coujunction with a sunk dial, which is marked for various distances under 100 feet. The camera is designed for 5 by 4 plates, so as to allow some margin for faulty direction, a fault which is, however, guarded agaiust by the presence of a finder. The lens is a T. T. and H. 6-inch (detective) working at *f*/8 ; but it is provided with a sliding diaphragm plate with three openings of varying diameter. The shutter is set by a simple winding operation without uncoveriug the lens, so that no extra cap or flap is wauted, and its speed can be regulated to a nicety. The eamera is uuobtrusive in appearance, well-made, and has no projecting knobs or studs.

## Correspondence.

CROYDON MICROSCOPICAL AND NATURAL HISTORY CLUB (PHOTOGRAPHIC SECTION.)

Sir,—I regret to find a slight error has occurred in the stylograph copy of my notes supplied to the press of the proceedings of the above Club in your last week's issue.

By the omission of a single letter what should have read "a misleading and *almost* incorrect statement," appeared as "a misleading and *a most* incorrect statement." As I should be sorry to be guilty of any discourtesy of speech to your contemporary to whom the expression refers, I will be glad if you will publish this explanation. Harry D. Gower.

*April 18th.*

## Proceedings of Societies.

Camera Club.

On Thursday, April 16th, Dr. C. S. Patterson in the chair, Mr. J. Howson read a paper entitled "Conventionalism in Colour."

Previous to the lecture, the Hon. Secretary handed round some early prints sent by Messrs. Marion & Co. from the flashlight negatives taken the previous week ; also one of Manson's focussing cloths, which are made in convenient form for covering the whole of the camera. Dr. Patterson showed a Bain's mask-cutter.

Mr. Howson, in his paper, dwelt on the possibility and desirability of suiting the monochrome colour of photographic prints to the special subject in each case represented, and he illustrated his points by handing round several prints on alpha paper.

Criticism and discussion followed from Messrs. Horsley-Hiuton, Davison, Gale, Stephens, Bright, and the chairman.

On Mouday, April 13th, there was a special lantern evening at the Club, and oue of the largest and most interesting collection of slides ever shown at the Club was brought together by members and frieuds.

The extra meeting was appointed for the purpose of working off the arrears into which the lautern exhibition had fallen, owing to the period of removal into the new premises. Over 400 slides were showu—almost all new at the Club—the work of Messrs. Gibbons, Jones, Elder, d'Arcis, Noel-Cox, Carpenter, Bennet, Lawford, Laurie, Maskell, Matthews, Bright, Hughes, H. M. Hastings, Andreae, Huskisson, Burton, Cembrano, Seyd, Chang, and Fitz-Payne.

On Thursday, April 30th, Mr. J. Traill Taylor will read a paper on "Lantern Optics."

London and Provincial Photographic Association.

*April 16th.*—Mr. G. W. Atkins in the chair. A demoustration of polarised light by Mr. J. J. Briginshaw, announced for this date, was postponed to the 30th inst., in consequence of the non-delivery of the oxygeu gas.

Mr. C. H. Cooke made a contribution of several platiuotype prints to the album of the Association. He also exhibited some sepia platiuotype prints that had been developed with a hot bath for black tones ; he was unable to detect any difference from those developed according to the sepia formula.

Mr. P. Everitt drew attention to an advertisement in the journals referring to the use of ammonia with erythrosine. He questioned whether the patent referred to in the advertisement covered the dipping process, and, further, whether the addition of ammonia was absolutely necessary.

To the latter query Mr. C. H. Cooke replied, decidedly not.

Mr. W. E. Debenham said he doubted whether erythrosine of the particular variety now used was suggested by the patent mentioned, as, in all probability, it was not brought out until afterwards ; and he was of opinion that the patent was not valid, from the directions giveu with it not being sufficient to enable it to be a workiug process.

Mr. C. H. Cooke stated that the use of a screeu was not necessary ; equally good results could be obtained without it.

Mr. Weir Brown exhibited some sepia-toned bromide prints; the toning bath used was—

| | |
|---|---|
| Nitrate uranium ... ... ... | 100 grains |
| Ferridcyanide pot. ... ... | 100 grains |
| Water ... ... ... ... | 24 ounces |

The remainder of the evening was occupied with discussing the rules of the forthcoming lantern-slide competition, which was fixed for the second Thursday in October.

### Holborn Camera Club.

At the usual weekly meeting of this Club on Friday last, Mr. Fred. Brocas gave an instructive lecture on "General Hints to Beginners," dealing with the uumerous stumbling-blocks which seem to enter into a compact to frighten a beginner. He specially mentioned the matter of foreground; under-exposure was also dealt with at great length. Most beginuers, he said, always under-expose. It was much better to over-expose, because, by judicious developmeut, a fair negative may be obtained from au over-exposed plate, but an under-exposed one would never give a good negative.

In the discussion which followed, halation formed the chief topic, it being the general opinion of the members that, although troublesome, backing the plate was certainly advantageous.

A vote of thanks was passed to the lecturer, aud the meeting separated.

### Croydon Microscopical and Natural History Club (Photographic Section).

A meeting took place on April 17th, with Mr. Edward Lovett in the chair, when an exhibition of hand-cameras took place.

The next ordinary meeting will be on May 1st, when Mr. D. E. Goddard will read a paper eutitled "Elementary Silver Printing."

On Saturday, April 25th, a half-day excursion to Oxted for Godstone will take place.

### Richmond Amateur Photographic Society.

On the 17th inst., Mr. Jeffrey in the chair, the subject for discussion was "Iuteusifying, Reducing, and Retouching."

Two pieces of home-made apparatus were shown—a frame or box for contact printing, either of paper or transparencies, by Mr. Faulkner, and a shutter by Mr. Richardson, both being of iugenious design and excellent workmanship.

The discussion which followed was productive of many practical hints.

### Leeds Photographic Society.

On the 20th inst. a paper ou "Bromide Printiug and Enlarging" was read by the hon secretary, Mr. S. A. Warburtou, the chair beiug occupied by Mr. J. W. Reffitt.

Mr. Warburton pointed out that the chief advantages of the bromide process were that it can be worked iudepeudent of daylight, the rapidity with which priuts can be produced, and the close resemblance that a good bromide print has to a platinotype picture. In describing the manipulation of the process, the various classes of paper in the market were referred to, the "slow, rough surface" being the one which seemed to yield the best results. The great secret of obtaining pure whites in the prints was a liberal use of the acid solution after fixing, and for this a one per cent. solution of sulphuric acid was the best. In dealing with the subject of enlarging, the kind of apparatus for use, both with daylight aud artificial light, was described, the former as giving the best results, and being less expensive to construct.

Photographing Fishes.—M. Marey has succeeded iu photographing the movements of an auimal under water, taking proofs at the rate of fifty in a secoud, with exposures from 1-2000 to 1-3000 of a second. A set of twelve photographs gives all the phases of the undulatious which the medusa impresses upon its umbrella of a locomotor apparatus. A ray has been taken in profile while waving the edges of its flat body, and the curious mode of progressiou of a comatula has been taken.—*Detroit Free Press.*

## Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.

Mercurius.—*Formula for Sensitising Paper.* Unless very heavily salted, a plain sixty-graiu solution of silver nitrate is generally employed for sensitising paper, which is left on the bath until it lies flat; drained well by passing over horizontal glass rod, and dried vertically whilst suspended from wooden clips. It may then be advantageously fumed with ·880 ammonia in a close chamber. The practice of usiug stale albumen is sometimes resorted to, uuder the impression that it is easier to get with it a uniform coating.

L. E. T. (Jersey).—*Aluminium Mounts and Fittings.* One optician at least now supplies all his lenses in aluminium mounts, and several camera makers employ the metal largely to diminish the weight of tourists' outfits. We are not sure that alumiuium is proof against the attack of sea air, but in inland towns this metal remains untarnished for a considerable time.

W. J. S.—*The Watch Camera.* Messrs. J. Lancaster and Son make two sizes, the smaller taking pictures 1 by $1\frac{1}{2}$ inches, but, from the description, it does not appear that there is any simple contrivance for changing the plates.

Zero.—*Ferrous Oxalate Deposit.* The white veil that you sometimes notice in your negatives may arise from the precipitation of oxalate of lime. If so, it should disappear in the citric clearing solution, or in very dilute hydrochloric acid. Be careful about the use of the latter, for fear of stripping the film.

J. P. Jones.—*French Weights and Measures.* See last page of the Year-Book. A gramme is equal to 15,434 English grains, and a litre is the measure of 1,000 grammes of water at its maximum density, 4° C., or 39° Fahr. For a one-per-cent. solution dissolve, therefore, one gramme in a decilitre, or teu grammes in a litre of water.

Tyro.—*Recovery of Platinum from Waste Solutions.* Mr. Willis stated last week that he acidified strougly with hydrochloric acid, and boiled with some scraps of zinc, when all the precious metal is thrown dowu in the form of platinum black.

A. L. S.—*A River Scene.* The cattle are satisfactory enough, but the horse in the nearer foreground appears too dark. Could you not screen it off a little during the printing, and so get a better effect?

W. B. (Exeter).—*Faded Daguerreotype.* Unless you have had some preliminary experience, or if valuable, it might be well to entrust it for restoration to Mr J. Werge, 11a, Berners Street, W., who will probably clean it with cyanide and re-tone it with sel d'or. You may then copy it with the camera, screening off side lights, as Mr. England suggested some years ago, by sinking it in a square shelving frame for that purpose.

Middlesex.—*The Affiliation Scheme* is not dead, as you suppose, but still under the consideration of the council. The details are not yet quite settled, but there is ample authority for your addressing au application to the secretary of the parent society, or passing a letter to Mr. Biden, at 50, Great Russell Street, W.C.

R. M.—*Brussels Photographic Exhibition.* By notice paper, just received, intendiug exhibitors are requested to communicate, before the first of May, with the Organising Secretary, M. Ch. Puttemans, Ecole Industrielle, Boulevard Du Hainaut, Brussels. The Interuational Congress meeting in that city in August may be expected to bring together a fair assembly of appreciative visitors, and generally to lend interest to the undertaking.

Received.—A. M. M. and other correspondents; also, a copy of "Electricity in Transitu—from Plenum to Vacuum," by Prof. W. Crookes, F.R.S.

CONTENTS.

## SPAIN AS A RECREATION GROUND.

BY ANDREW PRINGLE.

Many amateur photographers are now-a-days sighing for fresh lands to conquer, and a few words about Spain from one who has very lately left that country may be productive of encouragement or act as a warning, according to how the words are taken, and to how the prospect pleases or appals the reader. For there is much to be said on both sides of the question: on the one hand, Spain is certainly much less photographically hackneyed than Italy, France, Germany, &c.; on the other, there are difficulties to be encountered in some parts of Spain which may not be met, or may be met in a less degree, in other better known and more travelled countries.

As to wealth of subjects in Spain, there can be no question, particularly if we have a *penchant* for architecture, external or internal. I know of no country where the architecture is so varied, so striking, and, on the whole, so pure as in Spain. Moorish architecture of a certain period is found in perfection in Southern Spain, while, so far as I know anything of architectural science—which is not far—I doubt whether the Gothic style is to be found in such purity and beauty anywhere as in Northern Spain. Some of the architecture in Spain is of the easiest kind to photograph, exteriors such as those of cathedrals, churches, &c., in the north. Much more difficult, but, perhaps, even finer subjects, will be found in interiors such as those of Moorish origin at Seville and Granada, and those of Christian, or Moorish and Christian, origin at such places as Toledo, Avila, and other towns chiefly in the northern districts.

Taken as a whole, the country cannot lay a general claim to beauty of landscape, yet there are districts exceedingly grand in mountain scenery, notably districts near Malaga, and in the very north, around San Sebastian, for example. I believe that on the east coast there are some very fine landscape districts—Murcia, the neighbourhood of Almeria, Cartagena, and so on—but of these I cannot speak from personal knowledge. One other point is worthy of the photographer's notice. In many districts, characteristic, quaint, and artistic costumes have by no means yet gone out of date. The mantilla certainly seems dying out, but in Avila, Salamanca, Jaen, Valladolid, Burgos, typical costumes and trappings may yet be seen in full force, while in other districts, not visited by me, there are to be found in common use costumes even more quaint than those that came under my notice. Lastly, whatever we may say as to the national *corrida de Toros*, or bull-fight, as a sport or as a crime, there is no denying the fact that it is a grand opportunity for a hand-camera. It is no small matter to see, as we saw in Madrid, about 18,000 people *en fête* watching a party of very richly-dressed men doing their best to tease a bull into activity, causing it to impale horses on its horns, and finally, with every circumstance of ceremony and pomp, killing it according to a code of rules and *secundum artem*. I say that, sport or no sport, harmless or criminal, a bull-fight is good to photograph, and, so far as I know, a bull-fight has never yet been really well photographed. I have only developed a few of my negatives, and, so far as I have gone, all my negatives are useless, thanks to a new and untried, but all the more expensive, hand-camera being hopelessly out of "register," so that I may safely say that as yet I have seen no good bull-fight photographs. Photographs of a bull-fight are sold in Madrid, but they are only poor enlargements from what have evidently been very middling negatives.

I venture, then, to say to my reader that Spain is a first-rate field for photography. Subjects are good, varied, and plentiful, and the camera is just sufficiently known to cause the people to assist rather than impede the worker. True that sometimes I met with *trop de zèle* by people wishing to adorn my views with their persons, but they were always amenable to reason, and, when young, were always quite satisfied with a position well beyond the field of my lens.

Now for the disagreeables of such a tour. I am a pretty well hardened traveller, and quite used to "roughing it," but I should not care to face Spanish travel without a courier or someone to do the unpleasant work at railway stations, diligence offices, and the like. Time is no object to a Spaniard, nor, apparently, is breath, for not only is the waste of time exasperating, but the fluency of language, chiefly strong, is simply appalling. The scene on the arrival of a train at some stations was pandemonium, for it seems that all the "loafers" of a town congregate at the station and distract the alighting passenger with offers of help. Then the formalities of booking and obtaining possession of baggage are maddening, false coins are rife, and beggars everywhere as thick as stones in the street. Even Naples is not "in it" with Spain in the matter of mendicancy. The abominable and, under certain conditions, dangerous custom of deformed and maimed paupers exhibiting their horrors in public is common throughout the country; a serious malformation is a valuable source of income in Spain.

Then, again, the sanitary arrangements, even of many of the best hotels, are anything but good; except in the very best hotels in the south they are horrible. It is pretty well known that a community living habitually in unsanitary conditions often "acquires immunity" from septic diseases, but the chance visitor may fare badly.

No doubt travelling may be cheaply done in Spain, but attempts at economy would greatly lessen the pleasure and increase the difficulty. I do not think that a tour in Spain can be done so cheaply as a tour in Italy or in France; certainly not if the larger cities are visited during holiday times, such as Holy Week. On my late visit I had the same courier as I employed on a previous occasion, and I would not willingly face Spain without him.

On the whole, while I have candidly stated the disadvantages of Spanish travel, I can safely say that I know of no country which will better repay the student or photographer of architecture than Spain. The over-particular or impecunious had better seek other fields, but anyone who wishes something quite out of the beaten track, and something not only unique but good, will do well to spend a month in Spain.

## DR. J. M. EDER'S CRITICAL EXAMINATION OF SCHIENDL'S "HISTORY OF PHOTOGRAPHY."

BY C. SCHIENDL.

Since the critique which appeared in the Photographic News about the above-mentioned book contains perversions and false interpretations of some passages which may deter the success of a work which cost me a great deal of trouble, I trust that you will permit me to make a reply in your columns.

I must first decidedly deny Dr. Eder's statement, published in his *Photographische Correspondenz*, that my first three chapters are simply extracts from his "History of Photo-Chemistry." I have expressly pointed out in my work that I do not aim at introducing any photo-chemical history, and will refer to it only in so far as it forms the precursor of photography, and stands in direct connection with it. Besides, there is a total diversity in the contents of our two works, owing to the different purposes which we pursue. Dr. Eder seeks to prove, in his "History of Photo-Chemistry," that certain facts were known in the earliest ages; for instance, the brighter colouring on those sides of fruits exposed to the sun, and that many colours and materials bleach in sunlight, that the ancients possessed a knowledge of the effects of light; whilst I, in a very short paragraph, attempted to give a mere sketch—in order not to spend unnecessary time—to the effect that the ancients, and even a large part of the people during the middle ages, possessed no knowledge of the effects of light and of optics. My first three chapters contain matter so totally different from Eder's "History of Photo-Chemistry," introduce so many dates, and open out so many different historical points, to those contained in Eder's "Fragments," that one can only describe the attempt to run down my book on the part of this critic—who, at the same time, describes himself as a competitor—as a delusion which has its source in a supposed monopoly of every kind of photographic literature.

I have used many works in writing my book, among others Bischoff, Scheele, Hugh Murray, P. Moyriac de Mailla, Senebier, Herschel, Hunt, Gilbert's "Annalen," Harrison, Fabre, and many articles in journals where the information is authentic. I have sought from Eder's "Fragments" the sources mentioned by him, and, when they were serviceable to me, I used them. On the very few (and most unwilling) occasions on which I have applied his own information, I have quoted him, and called attention to the fact that he was the first, &c., &c. The great historical works of Schlosser, Becker, &c., contain hardly any quotations: but it would not occur to anybody to accuse them, on that account, of being published without sources of information, except "drawn from the works of others." The worth of a history is established, not by mere statements of facts, such as are to be found in Eder's "History," but by the spirit which is to be seen in the setting forth of these facts, and by the just exposition of deserving merit and mistakes which have been committed, and in the assertion of such facts as stand in connection with the subject.

I am fully convinced that an impartial comparison of our two works would prove the evidence of the injustice of Eder's assertion. Respecting his broad statement that I pervert and distort Mungo Ponton's and Vauquelin's claim to precedence (*Phot. Corres.*, p. 149), I affirm that the worth of this statement may be judged by bearing in mind not only the letter, but the spirit of my text. I write (page 16): "The discovery that chromium is an element, and the discovery of chromates, were made by the French chemist, Vauquelin, in the year 1797, and also the discoveries appertaining thereto, viz., that a silver salt, when combined with chromic acid, gives a carmine red precipitate; and these observations he pursued to the discovery that the combination is sensitive to light, for he observed the colour change to purple-red when exposed to sunlight. This discovery of Vauquelin's appears to be the foundation of all later publications (for instance, Ponton's) on the sensitiveness to light of chromates." That chromates change under the influence of sunlight is a fact now well known. Vauquelin discovered it apparently in an accidental manner, and his discovery was used by others (for instance, Ponton) for independent study of this property in conjunction with organic substances, and was used for photographic purposes, which Vauquelin himself did not attempt, and which only Ponton, first, and quite independently, has succeeded in doing. My statement that Vauquelin's discovery appears the foundation of the later discovery which led to chromates being applied to photography might, therefore, be considered completely justified. But Ponton's works may also be pointed to as independent discoveries. Eder's assertion, which closes with these words, "Therefore it appears unjust to ascribe to Ponton only the lot of having discovered photography with chromic compounds," proves itself false, for Vauquelin has not made the smallest contribution to the discovery of photography with chromium salts. My assertion (which Eder endeavours to circumscribe) to the effect that the exclusive merit of having applied this property to photographic purposes is Ponton's, does not appear in the least like a *displacement or a perversion*. These expressions might be more fitly adopted in describing his criticism of my work.

My competitor argues further: "Still more reprehensible is the manner in which Herr Schiendl treats of the further development of photographic methods by means of bichromate of potash, for this part of his "History" rests on a remarkable error on his part, which is seldom committed by the writer of a history. I shall prove conclusively that the author sets forth Ponton's work on chromates quite falsely, and draws quite wrong conclusions therefrom. Herr Schiendl writes on page 89 of his 'History': 'Mungo Ponton studied these salts (chromates) more accurately, and discovered that they, specially the bichromates, when exposed to the light with organic substances, so change as to lose their solubility and their stickiness, and wholly, or in part, according to the effects of light to which they are exposed, their power to absorb or give out water.'

"On this statement, which I have quoted in order that it may be well considered, the author establishes the foundation of his 'History of Photography with Chromium Salts,' and erects a structure of historical description which proves itself a castle in the air, because, in Ponton's report to the Royal Society of Scottish Artists, nothing of the kind occurs. Quite as untenable is the phrase on page 277 of Schiendl's 'History': 'From Ponton we learn the sensitiveness to light of chromated gelatine,' for Ponton does not say a single word, in his above-mentioned report to the Royal Society of Arts, about the sensitiveness of chromated gelatine. Therefore, the historical views propounded by Schiendl are false, and this consideration shakes one's belief in the trustworthiness of other descriptions."

I consider it right to make this announcement. Mungo Ponton, in his first report to the above-mentioned society, has spoken only of chromium salts, which, when charged on to paper, give a picture; but in the space of time which elapsed between 1839 and 1853, when Talbot applied the chromated gelatine to steel (which, apparently, is the foundation of Ponton's statement, for he mentions nothing in his first report, which the reader will find given word for word on page 98 of my "History," of having discovered this property of chromated gelatine, and uses other means; for instance, platinum-chloride), Ponton has made mention of this process in the *Edinburgh New Philosophical Magazine*, and also in many other technical journals which I do not happen to have by me, and specially emphasised the fact that better results are to be obtained with gelatine. I have found this passage frequently repeated in English magazines by reliable authors, although the assertions are so very scattered that a quotation does not appear feasible.

(*To be continued.*)

---

*The Optician*, the new organ of the optical, mathematical, philosophical, electrical, and photographic industries, enters on its fifth issue this week. It promises well, and, although intended as a trade organ, has many features which make it interesting to outsiders. We wish it success.

MESSRS. NEWTON AND CO.'s recently published catalogue is quite a storehouse of good things in the way of lanterns and optical projection apparatus. The section devoted to the scientific application of the instrument is especially interesting, for it contains descriptions and illustrations of the newest devices, including the electric lantern fitted with spectroscopic and microscopic nozzles, and utilising the Brockie-Pell form of lamp; the microscopist's bi-unial lantern, the micro-polariscope, and other well designed appliances for projection purposes.

## THE SECOND TRIENNIAL EXHIBITION AT GLOUCESTER.

### SECOND NOTICE.

"THE Cockle Gatherers" is just one of those subjects that Mr. J. E. Austin and Mr. Frank Sutcliffe know so well how to treat. Wave-ribbed sand and mackerel-ribbed sky furnish the materials for Mr. Glazebrook's *mise-en-scène*, and the busy toilers in their grotesquely assorted costumes furnish strongly the picturesque element. Most of them are busy with their sordid occupation, and are, apparently, quite unconscious of the presence of the now almost ubiquitous camera. Their costume is so nearly masculine that it is only after some considerable inspection of the figures that it dawns upon the beholder that they are women. With such admirable materials Mr. Glazebrook, by two errors, has just missed making an admirable picture. The figures are too large; but the next fault is a much more serious one. Most painters are content to keep the horizon line, when it forms the boundary between sea and sky, exactly parallel with the principal line of the frame or mount. The author of this picture evidently thinks otherwise, and has made the sea to travel up hill at a very considerable angle. One might have charitably thought that the picture had slipped from the mount; but, unfortunately for this argument, there is another photograph by this gentleman with the same fault.

Mr. Bhedwar has sent the "Feast of Roses," and the series shows unusually well in this well-lit gallery, but there is besides a fresh picture that calls for more than a passing notice; it is called "Two's Company," and shows a lady, clad in the diaphanous costume of the East, half sitting, half reclining, with quite Eastern languor. She is daintily toying with a parrot. A short distance away a white bird of the same species is gloomily eyeing the favourite of an idle moment, and is evidently indulging in a fit of sulks. There are some faults in the composition of the picture, but it is so delicate in treatment, and the Eastern feeling of the whole picture is so well conveyed, that it is sure to become a favourite.

Mr. Charles Reid has quite distinguished himself in his instantaneous pictures of animals. Mere rapidity does not count for much in these days, but these have something else besides. Forcible and yet delicate, in spite of the very short exposure, they are all pictures, and not mere examples of difficulties overcome. In one picture, a broken cask helps to furnish an effective background to an interesting group of puppies. One has a bone in its mouth, and is snarling at a white cat who looks with envy at the coveted treasure. The expression is half human, and at once recalls Landseer's "Jack in Office." There are, besides, a number of pictures all equally good—a group of goats, flocks of sheep, herds of horned cattle, ducks, swans, a mare and foal, and others, all of them showing the same technical and artistic skill.

Mr. Lyd. Sawyer is well represented by a large number of his well-known *genre* pictures, but there are, besides, some river scenes, several of which are new to us. The chiaroscuro of one, evidently a Tyne bit, is very fine. Murky smoke in striking contrast to sparkling water plays its part with due effect, and helps to make a striking picture out of very slender materials. Another similar in subject is striking from the peculiar mellowness and harmony of its atmospheric effect.

Mr. Court Cole is quite a coming man. His architectural subjects are always effective and well chosen, and he has sent besides some landscapes that show distinct artistic feeling, and of these, "Evening on the River" deserves special notice. A tree-covered bank of a stream runs away into perspective, and long streaks of evening clouds back the scene. A lazy ripple on the water breaks up the lights and shadows, and carries them on to the extreme foreground—or, in this case, fore-water, for the want of a better expression. The white sails of a yacht are most useful in carrying on light through the picture. There are some lovely cats sent by Mr. Lord, but surely it was not necessary to touch them up. They are much too good to need the brush work.

An extremely effective landscape is completely spoiled by the awkward introduction of a figure. The photograph is of large proportions, and shows a tempest-worn water course. It is winter-time, for the trees are bare, and there is an expression of desolation over all. Unfortunately, exactly in the middle of the picture, a figure with his back to the beholder is busily occupied in doing nothing in particular, and completely destroys an otherwise good picture.

Mr. C. W. Huson's "Early Morning" is a street scene of large dimensions, and the picturesque element is furnished by a quaint, octagon-roofed market house on the right. The whole picture is low in tone, but artistic in treatment, the time of day being well chosen for the subject.

Mr. J. M. Nicholson has sent a frame of six small marine studies taken with hand-camera, that are so well selected and admirably carried out that one could well imagine that the camera-stand had been used, and the most deliberate preparation adopted before the exposure of the plate had been attempted. They are all distinguished by great breadth—a quality often absent when very quick exposures are made—and perfect keeping. Indeed, they are as true to nature as monochromes can ever be. Sky and sea are in harmony, and the chiaroscuro would satisfy even a fastidious marine painter.

Perhaps the importance of the sky in landscape has never been better shown than in one of Mr. H. P. Robinson's pictures hung on the lecturer's rostrum. It is called "What Sport?" A mass of willow pollards form an important feature on the right of the picture, and furnish a strongly marked diagonal, running from right to left, where dark trees and dark shadows on the water support and give solidity to the composition. Figures are introduced with Mr. Robinson's usual skill, and the light dress of the woman tells with great effect against the dark masses of the trees. The whole is put into perfect harmony by the grand masses of clouds, which are exactly in the right place to complete the composition. The whole picture is characterised by great breadth, and we cannot help regarding it as one of the most perfect landscapes ever produced by photography.

Mr. W. H. Kitchen's "On the Lynn, Clovelly," is an enlargement of one of the most photographed spots in England, and this is not to be wondered at by those who know all the possibilities of the subject; but, notwithstanding the extreme beauty of the surroundings, there are more bad than good photographs of this lovely spot. This picture is fortunate in being one of the good ones. The foreground of brambles helps immensely in giving point to the whole scene.

Mr. Martin J. Harding has produced some extremely good small landscapes; but one of them is very striking —a pebbly watercourse, on the banks of which are stunted trees torn by angry winds. Distant mountains bound the distance, and force is given to the foreground by the dark shadows from the trees on the left. There is no black-and-white anywhere, and yet it is a very harmonious photograph.

Mr. Ernest Beck has several artistic pictures. "At Eventide" may be mentioned as one of them, for the mystery of twilight is well expressed. Praise must also be given for "Turning the Corner," a good picture composed of slender materials, for it is simply a ploughing scene; but the light and shade is well distributed, and clearly shows artistic feeling.

Mr. Carl Greger's little views are of unusual excellence. They are, unfortunately, hung very high, and, at a distance, the almost Bartolozzi red colour is not quite agreeable, but on a closer inspection their beauties become manifest, and they must be put in the very front rank among the many very artistic pictures sent to this Exhibition. "The Mountain Solitudes of the Tyrol" resemble the monochrome work of Turner, and it is difficult to give higher praise than this. Among the others sent by this gentleman, a delightful little picture of boys bathing in a stream is most attractive, but it is feared that its exalted position will cause it to be overlooked.

Mr. J. E. Austin is rapidly taking the very first rank as an artist, and many of his pictures seen at Gloucester would, by their extreme excellence, furnish a fitting answer to the unworthy carping of Mr. J. Pennell in his paper recently read at the Conference. They all have extreme individuality, and show, especially in the posing and grouping of his figures, that the artist, even when he has the misfortune to use the camera to express his art, still has command over his materials. "The Road by the Sea" is a complete illustration of this, and so is "The Last of the Ebb." The first is a little fishing hamlet, and the cottages are built above the wash of the waves on the *debris* formed by the crumbling away of the storm-worn cliff above. A fisherman with basket on shoulder pauses to gossip with two women who are resting half way up the steep path that leads from the shore. Magnify this little picture and supply the colour, and then there would be a picture worthy a place on the line at any picture exhibition. The second is simply a boat securely fastened to piles that throw strong shadows to the edge of the picture. The scum on the oily water indicates the turn of the tide. The distance is soft and indistinct, and the attention is arrested by the forcible light and shadow from the boat and its surroundings. Surely these are simple materials, but they were selected by an artist.

Enough has been said to show that the workers in the Gloucestershire Society have reason to congratulate themselves on the striking character of many of the pictures which have been brought together through their energy, and it is to be hoped that the Exhibition has been a financial success. It only remained open ten days in all, and lantern exhibitions were held every evening until the close, which took place on April 20th.

---

Photographers' Benevolent Association.—At a meeting on April 24th, Mr. A. Mackie chairman, two applications for grants were considered and assisted; and Messrs. F. Cherry and Ed. Hobbs were elected subscribers.

Croydon Camera Club.—At the meeting on the 27th April a demonstration of carbon printing was given by representatives of the Autotype Company. Excursions are now arranged to be held every Saturday, and instruction classes on Thursdays.

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Colouring Aristo Prints—A Grainless Gelatino-Bromide Emulsion—Transferring Albumen Prints to Glass without the Use of Gelatine Solution.

*Colouring Aristo Prints.*—Liesegang's aristo paper has found so many friends and adherents everywhere, on account of its really excellent properties, that it will be of interest, no doubt, also to the readers of this journal to learn a method of colouring prints on aristo paper, which has been adopted for some time with much success by many of our leading amateur photographers. It will be easily understood that it would be detrimental to the gelatine surface of the aristo print if it were treated without preliminary preparation with water-colours, the gelatine sucking up the water together with the colour, and becoming soft. The picture must therefore be previously prepared as follows. A mounted print may be used, but it should be one which has been printed not quite so deeply as usual, and one which has not been squeezed on to a smooth surface. It is at first touched up in the usual manner, a small quantity of gelatine solution to which some alum has been added serving as a medium. After touching, the print is slightly smoothened, and then coated with prepared albumen, which latter may be repeated if the first layer proves to be too thin. The print is then laid flat, and allowed to dry spontaneously. If dry, the water-colours may be applied to the albumen layer, care being, however, taken that as little water as possible is used, in order to prevent its penetration into the gelatine film. The colours should not be laid on as thickly as oil-colours, and for the larger portions of the picture—as, for instance, for the backgrounds, dresses, &c.—aniline colours are to be preferred. The shadows of the folds in the drapery, &c., are worked over with transparent colours, in order to preserve clearness. For the face, the hands, and the arms, very little red should be used. To obtain a fine and natural rosy tint, a trace of light red should be taken on the almost dry brush, beginning always in the centre of the cheek, and being careful not to touch twice on the same spot while wet. Let the touches be separated, as in the case of retouching, and when finished rub over the tinted portion very gently with a slightly moistened brush. In the case of light brown hair and beard, commence with a light brown, and finish with sepia. In order to obtain a more harmonious result, the picture may be coated, after colouring, with enamel-collodion.

*A Grainless Gelatino-Bromide Emulsion.*—Mr. F. Gaedicke, of Berlin, has succeeded in producing a gelatino-bromide emulsion in a totally unripe condition without the well-known "grain," the size of which, in the ordinary emulsion, grows, as is generally admitted, with the sensitiveness of the preparation. Only when enlarged five hundred times by a microscope does the new Gaedicke emulsion show what may be called a grain, but still embedded in an apparently structureless mass. For some purposes—for instance, for astronomical and micro-photographs, for transparencies destined for enlargements, for duplicate negatives, stereograms on glass, and for lantern slides—an emulsion without grain would undoubtedly be an advantage; but it is to be regretted that the plates coated with it are very much less sensitive than those commonly in use, an exposure forty times as long as one required by a highly sensitive dry plate giving a strong picture, and but a six hundred times exposure leading to the best result with short development. In comparison with the exceedingly short exposure which is sufficient in the case of the modern dry plates, the insensitiveness of the new emulsion is not so extraordinary as it may seem, and for certain purposes—for instance, for the production of diapositives, &c., in the printing frame—the short additional time of exposure required with it will certainly be of little consequence in comparison with the advantages which it offers. For other purposes, however—above all, for astronomical photography and for portraiture — the Gaedicke emulsion will be practically useless on account of its low sensitiveness. For the development of plates coated with grainless emulsions Mr. Gaedicke recommends, as the only suitable one, the hydroquinone-potash developer diluted with water. With it the plates may be developed in different tones, according to certain additions made to the developer. So they can be developed in greenish-black, Indian red, sepia-brown, in colder or warmer tones, and they may be transferred even in a sulphocyanide gold bath through warm brown into violet, even to blue, with undoubtedly valuable results for some practical purposes, more specially for the production of lantern slides and stereograms on glass.

*Transferring Albumen Prints to Glass without the Use of Gelatine Solution.*—According to Mr. Fr. Wilde, this may be done in the following manner. A small quantity of ox-gall is mixed with an equal quantity of alcohol, and the mixture is allowed to stand for several days with repeated shaking, when it is filtered, and poured evenly over a well-cleaned glass plate. A washed and well-drained albumen print is laid on the prepared plate, the superfluous water being removed by the aid of a squeegee, and the plate placed aside to dry. After about one hour, the print comes off with a highly-glazed surface. In order to preserve the gloss on the print also after mounting, the following may be used. As soon as the albumen print has been transferred to the glass plate, a piece of the finest parchment paper of somewhat larger dimensions, which has been previously coated with starch paste, is squeezed on it, and then coated on its back with a thick solution of gum, or of dextrine. After drying and trimming, the whole is placed on a piece of moistened cardboard, rubbed down with a folder, and pulled through the rolling machine (not burnished) before the picture is quite dry.

---

Claim by a Photographic Operator and Retoucher.—Charles H. Dance, photographic operator and retoucher, sued Thomas Winnett, photographer, Bolton and Blackburn, for £3 12s. 6d. Plaintiff stated that he was engaged by defendant as operator and retoucher at Bolton. He was in the employ of the defendant for about five weeks, when he was summarily dismissed without just cause, defendant refusing to pay his wages (30s.) for the current week. The rest of the claim was made up by 30s. for one week's wages in lieu of notice, and 12s. 6d. for the value of articles purchased by plaintiff in order to satisfactorily carry on his work. The defence was that plaintiff was an incompetent man, and that he was unable to execute work equal to the specimens supplied to the defendant, mainly on the strength of which he was engaged. Specimens of plaintiff's photography were submitted to his Honour for inspection, and he characterised them as, in his opinion, excellent productions. Defendant explained what he considered to be certain technical defects in the photographs, but his Honour, in entering a verdict for the plaintiff for the full amount claimed and costs, said he considered that plaintiff had done his work well.

## THE PROFESSIONAL SHOW-CASE FROM AN AMATEUR'S POINT OF VIEW.*

BY REV. F. C. LAMBERT.

I am quite prepared to be told that any suggestion I may herein make has either been made before, or is quite out of the range of practical application. Now I would respectfully submit that it is not so much with a view to offering ready-made ideas that I pen these jottings, as that I am in hopes that one or two of my suggestions may be just enough to start the thoughtful ones in working out ideas which shall apply to their own special and individual case. Each man who is in earnest will combine or select just those ideas that are likely to be applicable to his own case, and ignore the rest.

One reason which makes me think there is some need for the professional worker to give half an hour's thought to the subject of the show-case is the painful similarity between A's, B's, C's, and D's door-cases all in the same street. This is so much the case that it becomes rather difficult to remember any feature at all distinctive of any one of the four.

The usual thing is a dismal-looking wooden box (usually black) with a glass front. The "case" is lined with velvet (?) of a bilious green. To the back of the case are nailed or pinned the various specimens in a way which reminds one of a case of entomological specimens set out to dry.

Is there any reason why the case should always be attached to and *stick out* from the wall? Why not let it *stick in* for a change? Why not let it sink into a shallow recess in the wall? Even that would be a change. Again, why need it be always the same shape (about two feet by three feet)? Why not of two, three, four parts, and of varying proportions? Or, if it must be one case, then subdivide it by some simple internal division of unequal sizes, putting say, two or three children in one part, a group or two in another, and three or four large heads in another, and so on.

In towns it frequently happens that the photographer's studio is up "ever so many" flights of stairs, the ground floor often being occupied by some other business firm, so that the only way of letting the public know that there is a photographic studio in existence at that place is by displaying one or two show or wall-cases close to the door. However, even in cases of that kind, it often happens that there is a short passage, a porch, or entry, which often might be made more attractive and pleasing than is often the case. In such a case, several small shallow cases let into the wall would tempt the loiterer to glance round. However, where there is a little more room one's ideas expand at once. I should like to see a porch or entry fitted up with one side occupied with several small recessed cases of various designs; on the other, a structure which would call to mind something in the way of an over-mantel, of the simple panel and bracket form. I should make this as real as possible. A few choice specimens in simple frames or stands on the mantel, and perhaps a few more inserted behind a specially-designed panel-piece, so contrived that these could be easily changed. Among my specimens I should be tempted to place a few pieces of good and genuine old china, and perhaps a genuine bronze or two, or even a few pieces of terra cotta or small marbles. But whatever was there placed should be genuine; in fact, what was there should be just the sort of thing that I would have in my own favourite room at home. Real, good, and simple should be my watch-words.

Or perhaps the over-mantel idea would be found impracticable for some reason or other; but suppose I had the corner of a small window, then in that case it should be to me as a favourite corner of a favourite room. Perhaps an easel with an enlargement—one or two—not too many; then one or two small tables, or a corner table with one or two shelves; a bracket or two, perhaps, made of a bit of simple, genuine old oak, carved work if possible; I could then have a couple or more neat albums filled with selected specimens on the tables. In that way I could simply turn over a leaf or two of each every morning, and by the time one had got to the end of the book, it would be time to begin again, so that those who passed my window every morning would have half-a-dozen fresh faces to look at every day. Their curiosity would be stimulated, and set wondering as to who or what the next page would display. As to frames, after all the simplest is usually the best. If the frame is very splendid, then your work becomes obscured and overshadowed. Your object is not to make the spectator say, "What a splendid frame that photograph has round it!" but rather, "What a very nice photograph that frame contains, and how admirably the frame suits the subject!" It may be laid down that *white* or very light-coloured frames are generally to be avoided. A white frame, like a white mount, weakens the strongest light of your picture, and tends to make the shadows dead and dull.

For displaying silver prints, perhaps, after all, the simple, plain glass without frame is best; or if a frame is desired, then a very fine silk velvet of a pure, rich, dark olive green, tending to russet rather than blue, is, perhaps, the most favourable shade with the red purple-brown of the silver print. In platinotype and other black-and-white processes a frame and mount seem to lend an advantage. The mount, however, should not be white, or even near white, otherwise the large white space fills the eye, to the distraction of the small white parts of the picture. There is still an opening for a good tint for mounting black-and-white photographs. What is wanted is a mount with a slight grain, and of a tint something between pale straw and weak coffee—it is a tint one sometimes sees on opening a long-forgotten portfolio of engravings.

As to frames, there is again a difficulty. A black frame is apt to weaken the richness of shadow. Perhaps the best seems a dead black with dead gold, but sometimes a rich, deep brown—old oak or walnut—has a good effect.

Now as to flowers. As one who loves flowers, it is hard to say, do not have flowers in your show-case. Why need one banish our greatest help and treasure? Although it must certainly be remembered that their welcome presence means additional trouble. First of all, it is fatal to your reputation to have flowers and neglect to renew them at least once a day. Nothing can give a worse impression or general effect than neglect. In nothing can greater taste be shown than in the arrangement and disposal of a *few* flowers. Firstly, then, they must be renewed and receive daily attention. Secondly, as their presence entails water and moisture in the air, this calls for the precaution of either thoroughly protecting your specimens, or keeping your flowers in a separate partition, or making up your mind to cast aside any specimen immediately it shows the slightest deterioration; and perhaps, after all, this last plan has the advantage of keeping one's

* Continued from page 315.

stock of specimens constantly under notice and renewal. The cost of a few new specimens now and again is really nothing compared to the loss to one's reputation by never having anything different on view.

To sum up the whole matter into what I should like and not like. I don't want to see any more composite, cut-out mounts with openings of all sorts of shapes and at all sorts of angles; nor any of those very thick mounts which represent nothing in or out of nature or art; nor do I like to see curly mounts. I do not care to see the show-case used for general advertising purposes. It is also a mistake, I think, to have too many specimens, and also to mix prints made by various processes. What I would suggest is a *few* and *good* specimens. Have no two alike; let them differ in subject, size, style, lighting, and even in the frames a little variety is a relief. I venture to commend the suggestion of varying the shape and form of show-case, to line it with a material which is at once good, unobtrusive, and not likely to be affected by light; to have several small cases rather than one large case, to keep different process work apart; to vary the mount and frame so as to help the subject; to carry out some idea of your own, so that, as far as possible, *the spectator may forget that he is looking at a show-case or window*, and may be disposed to think it is just a pleasant corner of a cheerful room, where there happen to be several really nice photographs displayed. Where you introduce china, bronze, or any other object of interest—carved ivory, a miniature or two, &c.—let everything you show be *genuine* and *real*—beyond suspicion.

If you adopt the album idea, let the book be a good one, and not disfigured by *pictures* (?) all over its pages. If you take up the bracket idea, don't forget to change your prints in the under panels. If you go in for landscape work, try and work out a few ideas of your own. There are many ways in which little landscape "bits" might be worked out—as, for instance, menu-holders, banner-screens, lamp-shades, hand fire-screens, letter-weights, &c., &c.

However, in all such matters it is always well to bear in mind the great and fundamental principles of decorative art—viz., that in striving to introduce beauty, we must always remember the *nature* of *material* with which we have to work, the *place* which the object is destined to occupy, and, lastly, the nature of its *office*. With these three ideas present, each may safely be left to work out his own ideas.

---

London and Provincial Photographic Association.—May 7th, "Toning Bromide Paper," J. Weir Brown; May 14th, last lantern night of the season.

Photographic Club.—Subject for May 6th, "Outfits for Landscape Work"; May 13th, "New Hand-Cameras." Saturday outing, May 2nd, Twickenham to Richmond; leave Waterloo Station 2.17, meet at Twickenham at 3 o'clock.

Mr. Thomas Widdop, Hon. Secretary of the Oldham Photographic Society, sends us a neatly got-up card containing a list of the places to which rambles will be made by the members during the ensuing season. A novel feature of the programme is a portrait of the president (Mr T. Heywood), surrounded by miniature copies of various products of his busy camera.

Messrs. C. Schleicher and Schull, of Düren, Rhenish Prussia, Germany, are now manufacturing filtering papers of a novel kind, which possess, even in a damp state, a hardness and durability approaching that of parchment. They will stand a pressure of three atmospheres, and will retain the finest sediments. Such a sediment can be scraped off and the filter paper used again and again.

## ARCHÆOLOGICAL PHOTOGRAPHY.

[Editorial Note.]

Some time ago, the sculptured Gothic arches referred to last week were pointed out to us, and we were definitely told that they formed the entrance to an ancient oratory. Upon examining them closely, however, we were convinced that they were merely cut upon the surface of the sandstone, and that no cavity existed behind them. We were led to this conclusion from observing that the natural bedding lines of the rock were continued within the spaces enclosed by the arched lines and their supporting pillars, and that, in the central arch, a crevice above is continued downwards, and in reality causes a gap in the crown of the arch itself. But our informant was so positive that a cavity existed behind, which had been subsequently bricked up, that we communicated with the rector of All Saints' Church, which lies immediately below the hill where the arches are situated. In his most courteous reply, he writes: "I presume you refer to the arches on the hill to the south-east of the churchyard. These were cut on the solid rock, at the instance, as I have understood, of an old gentleman who lived on the opposite hill, and who wished to have a picturesque view from his garden. These, I suppose, were made nearly, if not quite, a century ago." He then goes on to point out the situation of the ancient oratory already referred to.

Another correspondent gives a totally different origin to the mysterious arches, and traces them to a family of the name of Coussens who held the Old Ship Inn at Hastings (now pulled down) more than one hundred years ago, and he was kind enough to send us an extract from a paper which he had contributed to the *St. Leonard's and Hastings Gazette*. This runs as follows:—

"But just a word or two about the father, who was better known by the soubriquet of Navarage than by his baptismal John. He was one of a party who used to arrange for occasional syllabubs, which consisted of meeting in the open air, to drink rum and milk, and to sing songs; and, having discovered a convenient spot on the west side of the East Hill, he and his sons marked the said spot by chiselling out on the face of the rock a triple design of pointed, arched doors, resembling those of churches. Here they and their friends caroused to their hearts' content whenever they bethought them to celebrate some event of a national character, or some particular occurrence in their own families. A milkman of the name of Robin Foster was he who supplied the milk, whilst the rum (or brandy, if sometimes preferred) could usually be obtained from those whose practice it was to get it duty free. These imitation doors were kept painted for many years by the Coussens family, who, with their friends, would sometimes talk of going to church when bent upon a debauch of rum and milk. Whether permission to form those door panels was ever obtained from Sir Godfrey Webster or Mr. Milward, the successive owners of the hill, this deponent sayeth not; but that the three "black doors" have continued to this day—a puzzle to visitors and residents alike—needs but a glance in their direction to demonstrate."

It seems hardly probable that men who were addicted to illicit drinking should have taken the trouble to carve out these arches, even if they possessed the necessary skill to execute the work. The arches are correctly formed, and at least a couple of tons of stone must have been removed in their construction. If they had merely wanted to mark the site of their revels in any way, surely they would have contented themselves with describing the arches with paint pot and brush. We are inclined to agree with the writer of the foregoing article in believing that the doors have an ecclesiastical origin. The question still remains an open one.

## Notes.

"Art in relation to photography," although a subject which of late years has been much discussed and written about, is one upon which many photographers have very hazy ideas. Those who wish to bring their mental images of the matter to sharper focus cannot do better than attend a course of four lectures at the Polytechnic in Regent Street. The lecturer is Mr. Valentine Blanchard, whose name is at once a guarantee that he has something to impart to his audience which will be worth the hearing. The first lecture takes place next Wednesday, and the fee to outsiders for the whole course is only one guinea.

An unusually good and interesting set of lantern pictures was exhibited at the Crystal Palace on Friday last. They illustrated the principal ports of our Australian colony, Adelaide, Melbourne, Sydney, and Brisbane, and also made the spectators acquainted with the beautiful scenery of the adjacent districts. The pictures were from negatives by Mr. G. H. Royce, C.E., who has travelled thousands of miles over the vast country, and who took the wise precaution to travel always with a quarter-plate camera as part of his kit. The result is a really valuable collection of pictures of Australian life and scenery.

At the outset we are made acquainted with the shockheaded Aborigines, examples, perhaps, of some of the least intellectual of the great human family. With no ideas of agriculture, building, or any other art whatever, they find that civilisation is a problem which they cannot solve; they are fast dying out, and presently their place will know them no more.

How different is it with the whites. Here we have the picture of a settler who has purchased his holding at the rate of £1 per acre, payment to spread over ten years. He has built a rough hut over his head, and while he leads a Robinson Crusoe kind of life his crops grow up around him, and his cattle multiply. Another picture, that of a well-built residence with outbuildings, shows how industry has rewarded the man, for he is now a prosperous farmer.

There were also shown photographs of towns which have sprung up like magic around some formerly desert place where mineral riches have been developed. Take, for instance, a certain one with 20,000 inhabitants, which has grown up round a celebrated silver mine. Six short years ago the place was a waste, and no human habitation was within miles of it. But silver was found here, and the mine was developed with such success that the metal already extracted has been valued at four millions sterling. Other pictures deal with gold mining, sheep farming, sugar growing, and other Australian industries. If all travellers were as successful in their photographic operations as Mr. Royce has been, the old adage which says that "one half the world knows not how the other half lives" would soon cease to have any meaning.

The ease with which an etching can be imitated, copied, and reproduced by photographic methods was certain, sooner or later, to raise the question whether certain works were or were not due to mechanical means rather than to the hand of the etcher. Professor Herkomer has been the first victim to suspicion of this kind, and he complains that "baseless insinuations have been made, and it has been openly stated that these illustrations—those of his recent work, 'An Idyll'—are nothing more than prints from so-called process blocks or photogravures." The professor has hitherto been content to remain silent under this trenchant criticism of his works, but as silence, in these days, is often misconstrued, he at last comes down upon his "self-constituted judges."

He tells them that apparently they do not know the difference between a dry point etching, an etching produced by biting in, and an etching which has as a basis a pen line drawing mechanically transferred to the plate as a preparation for further etched work, executed in the usual manner. He tells us that in his book there are examples of all three methods, and that he has used no other; further, that these are means which, he considers, any conscientious artist is fully entitled, on honourable and artistic grounds, to practise, and we are promised, in his forthcoming lectures at Oxford, to hear more as to the details of these methods of working.

A correspondent of *La Nature* describes a very pretty process for the production of a photographic menu-card. He is an amateur, and when he gives a dinner party he offers his guests a photograph of the house in which they are sitting, or the scenes which they are going to visit if it is the case of a picnic, and on this photograph appears the menu and the name of the host and hostess. All that he does is to block out a sufficient space on the photograph on which he can write the menu, and print it on paper which takes ordinary ink. A platinotype print answers admirably.

A very novel effect in connection with photographs of machinery is described in the American *Manufacturer and Builder*. The example which our contemporary gives presents the two sides of a piece of machinery in one picture. The method followed was to place the machine before the mirror inclined at such an angle that the reflected image of the back of the machine, and the direct image of the front, when photographed together should appear superposed in the picture. The result is seen in the engraving referred to, in which the front and back are obvious at a glance.

Very little notice, it seems, is taken in America of copyrights in mechanical designs by those most interested. It is the current practice in the machinery trades that, unless the designs be wholly novel, little, if any, objection is made to infringement by photography or otherwise, provided that the person who so infringes suggests an "improvement."

A leading manufacturer lately said that, even where one of his draughtsmen leaves him and goes to a rival house, carrying many ideas to be worked out with close resemblance to the original designs, it scarcely pays to fight. So long as this laxity is confined to American designs, it does not very much matter. We are afraid, however, that American designers have the same views regarding English designs. It is a well-known fact that American inventors are diligent searchers in our Patent Office.

They have peculiar ways in Jassy, the Roumanian capital. The distinguished French sculptor, Fremiet, was commissioned in 1881 by the Roumanian minister in Paris to make a colossal statue in bronze of Stephen the First, for which he was paid £5,250. The statue was in the *Salon* of 1882, and afterwards set up in Jassy. "It is now," says an aggrieved writer on Fremiet's work in the *American Architect and Building News*, "well out of the world, as is amply proved by the fact that after some two years of persistent effort it has been found impossible to persuade a Jassy photographer to make a picture of it." Why? Is it the fault of the photographer, or of the municipal regulations?

The bogus photographic club is so easy a swindle, that the wonder is it is not more frequently practised. The latest example comes from the West London Police Court, where a man has been charged with obtaining money under the pretence of taking people's photographs. "The West London Photographic Club" was the inducement put forward, and the prisoner seems to have worked the business pretty successfully, for no less than three hundred persons are said to have been victimised. To carry out the swindle properly, it is necessary to have a studio, and this the prisoner provided himself with, but he does not seem to have been able to take a portrait. This, of course, was of no consequence, as, to the majority of sitters, photography means being told to "smile and look pleasant," while the photographer stands solemnly by with something like the lid of a collar-box in his hand. This ingenious individual was, however, not satisfied with taking in his sitters, but he must needs take in a brother photographer—an unpardonable act. He sold the business, and on the purchaser commencing to work, the crowds of indignant persons clamorous for their photographs revealed the fraud. To this, at least, the evidence seems to point.

Few who look upon Mr. F. Sargent's picture of the Jubilee Garden Party at Buckingham Palace, now on view at Messrs. Graves's, Pall Mall, can form the least idea of the immense labour the work has involved. There are nearly four hundred figures represented, and, as all are portraits, the difficulty not only of obtaining the likeness, but—a far more important matter—of pleasing the originals, must have been enormous. Of course, without the assistance of photographs, such a task, so far as accuracy is concerned, would have been almost impossible. One cannot but admire the adroitness with which Mr. Sargent has overcome what might have been the cause of considerable heart-burning. The only unrecognisable portraits are those of the two ladies who are being presented to her Majesty. This reminds one of the common expedient to which artists are compelled to resort when they have to draw scenes at which they have not been present. If a man whose portrait is unobtainable is to be in the picture, he is always drawn with his back to the spectator.

The picture in the following column is an engraving from an instantaneous photograph by M. Reutlinger. We insert it as a good example of the making of a pretty picture from very common materials. Kittens are certainly not rare animals, and are naturally objects full of graceful movements and attitudes, and a bottle and glass funnel is always at hand in the photographer's laboratory. A glimpse of the picture inspired a friend of the PHOTOGRAPHIC NEWS to write the lines which now appear with it.

## MISCHIEF IN THE GLASS.

BY J. C.

Minx-eyed puss! with roguish glance
Blinking at thine own mischance,
Thy soft footsteps on the shelf
Have erratic led thyself
To mischief in a glass.

So do freaks of fate betide
Endlessly the whole world wide,
And fantastic fortune plays
Many parts in many ways
Of mischief in the glass.

Proudest queens of beauty's reign,
Cloyed of love and lovers slain,
Seek the chamber's fairest nook,
And, in tranquil moments, look
At mischief in the glass.

Still a nobler phase we find
In the healer of his kind;
Yet, not seldom, even he
Has declared his skill to be—
But mischief in the glass.

Now, to him who's next in view,
Sad pre-eminence is due.
He's a chief midst those who are
Called too often to the "bar"
By mischief in the glass.

And, oh! student of the lens,
Claiming meed from many pens,
Think, when chemicals betray,
And the tear is dashed away,
'Tis mischief in the glass.

## COLOUR.*

BY W. E. DEBENHAM.

It seems strange, considering the universal recognition of colour as distinguishing various objects, and the amount of gratification which is afforded by the variety of colours of natural objects, that so many ages have passed by with so little investigation of the subject. Indeed, what has to be told concerning colour is the result of quite modern investigation. We need go no further back than the time of Newton, who found that ordinary light, analysed by a prism, was compound in its nature, and he divided the colours into which light may be resolved into seven—violet, indigo, blue, green, yellow, orange, and red. It is not easy to see why indigo was included as a distinctive colour, unless it was to make up the magic number seven, possibly because there are seven days in the week, or perhaps from analogy with the science of music, because there are seven notes in the diatonic scale. It is quite possible, however, for a reason which will be given later on, that indigo as a distinctive colour may eventually be endowed with more than its original importance.

The colours of the spectrum owe their variety and their characteristics to the different wave-lengths of the rays of its different parts. When white light is analysed by passing through a prism, a band of colours is seen which does not exhaust the whole of the rays passing, but only indicates what our eyes are fitted to observe. Starting with the less refrangible rays, we see a full set of gradations from red, through yellow, green, and blue, to violet at the other end. Beyond both ends of the visible spectrum are rays of longer or shorter wave-length which are not visible to us. Beyond the red end are heat rays, and beyond the violet are rays which can be recognised by their powerful effect upon photographically sensitive compounds, and can also be rendered visible by fluorescence.

It has been a common observation that, by mixing pigments of certain colours, other distinct colours resulted, and, as it was found that with transparent red, yellow, and blue all other colours could be represented or approximated, these three were naturally supposed to be primary colours. This was, and is, perhaps, in some places, still taught. Strictly speaking, every spectrum colour is primary. Each had its own wave-length, fixing its place in the spectrum, and indicating characteristic properties of heating or chemical effect. To understand why some colours have the effect of being compounds of others, we must turn our thoughts from the colours themselves to the consideration of the human eye, the instrument for perceiving them. According to the doctrine first put forth by Thomas Young at the beginning of this century, and now generally accepted, there are in the eye, distributed over the retina, three sets of nerve fibres, one sensitive especially to red, one to green, and one to blue or violet. Each set is sensitive over a considerable range of the spectrum; thus, the red and the green fibres are both sensitive over the yellow region, whilst the green and blue sensitive nerves respond to what is between them, and the blue or violet set is sensitive from the extreme end of the visible spectrum. Each set is thought to be sensitive, more or less, to a great length in the spectrum, but to have a maximum at some particular place in it, corresponding in one set to red, in another to green, and in the third to blue or violet, or a point between them. Maxwell gave blue as the colour to which this set of nerves is most sensitive, but the experiments of Helmholtz confirm those of Muller, which give violet as the colour to which the special set of nerves particularly correspond. Abney considers the place as that of the spectrum line G. The reference made in the beginning of this paper to the possible reinstating of indigo as a primary colour was suggested by the idea that that place might, perhaps, be eventually decided upon as the maximum of sensitiveness for the blue or violet set of nerves, and the name, which is neither blue nor violet, but is distinctive, might be conveniently adopted. Helmholtz, however, said that the precise tint of the maximum of sensitiveness cannot possibly be known by experience. This is not very important. We know approximately the range of sensitiveness of each set of nerves, and pretty nearly the place of maximum sensitiveness.

As to direct anatomical proof of the existence of these three sets of nerve fibres corresponding to the primary colours, none has yet been found in the human eye, or in that of mammals, and this, perhaps, because of the exceeding minuteness which must characterise them in order that we may see minute objects of various colours all over the retina without distinguishing the separate areas for the various tints. In the eyes of birds and reptiles, however, Helmholtz tells us that Schultze found rods or tubes of three kinds, one filled with red oil, one with yellow, and one set colourless. The red would obstruct blue and green rays, whilst the yellow would obstruct the blue, and the colourless rods permit all rays, including blue and violet, to pass.

Primary colours, then, have no existence, except with regard to our sensations of colour, and these are three—violet-blue, green, and red. These three are the primaries, and from them we may compound a sensation answering to any part of the spectrum. The yellow of the spectrum affects both the red and the green sensitive nerves, and it is the combination of sensations transmitted to the brain by these two sets of nerves that gives the sensation of yellow. It should, therefore, be found that green and red simultaneously acting on any portion of the retina will produce the effect of yellow, and this is actually the case. I throw on the screen an image of a green disc from one lantern, whilst with another a red image is projected upon the same spot. The effect, it will be seen, is yellow. It must not be expected that, with the colours available for the purpose, the compound tints will be perfectly pure and brilliant. In the first place, I have not been able to obtain dyes which let through only one particular spectrum ray, and exclude all others. Anyone who has worked with the spectroscope will know that almost all the colours procurable are far from pure, that is to say, that they let through light from a considerable range along the spectrum, and sometimes from two widely different parts. Aniline blues and greens, for instance, generally allow a good deal of red to pass. Farther, we judge a colour very differently according to the presence of other colour wherewith to contrast it. To quote Helmholtz once more: "We know in a general way that candle-light is yellowish compared with daylight, but we only learn how to appreciate how much the two kinds of illuminations differ in colour when we bring them together at the same intensity, as, for example, in the experiment of colour shadows. If we admit light from a cloudy sky through a narrow opening into a dark room, so that it falls sideways on a horizontal sheet of white paper, while candle-light falls on it from the other side; and if we then hold a pencil vertically

* Lecture given at the London and Provincial Photographic Association.

upon the paper, it will, of course, throw two shadows; the one made by the daylight will be orange, and looks so; the other, made by the candle-light, is really white, but appears blue by contrast. The blue and orange of the two shadows are both colours, which we call white when we see them by daylight and candle-light respectively. Seen together, they appear as different and tolerably saturated colours, yet we do not hesitate a moment in recognising white paper by candle-light as white, and very different from orange."

(*To be continued.*)

6,921. HENRY KUHN, 52, Chancery Lane, London, "Improvements in Photographic Mounts."—April 22nd.

7,057. JOSEPH PARKINSON, South Regent Street, Lancaster, "Improvements in Photographic Shutters."—April 24th.

7,186. HENRY WILKINSON, Massey Park, Liscard, Cheshire, "A New Developing Dish, with Cover, for Photographic Plates and other Sensitive Material."—April 25th.

7,201. HENRY MONTAGUE WILSON, 60, Chancery Lane, London, "An Improved Shutter for Photographic Cameras."—April 25th.

### Specifications Published.

17,522. *November 4th*, 1889.—"Photography." V. J. E. DAMOIZEAU, 17, Rue St. Ambroise, Paris.

Relates to apparatus for taking in any desired angle, or the entire horizon, for producing panoramic views for plans, landscapes, &c. The apparatus is also applicable generally for photographic purposes, when sensitive material is wound on rollers or bobbins.

*Cameras and Roller Slides.*—On a platform, which constitutes the top of the stand, a revolving carriage is pivoted, and is provided with rollers, and an actuating disc worked by clockwork. The disc also actuates a drum, which actuates the sensitised film stretched over the holding bobbin, and receiving or taking-off bobbin. The rate of movement of the film is in proportion to the distance travelled over by the focal plane of the lens, due to the rotation of the carriage. A differential indicator or counter serves to register the quantity of sensitised paper used. A division between the negatives is pricked by a pricker, actuated by a spring on a movable board at the back. The front and back are mounted on slides actuated by a pinion. The lens board is adapted for horizontal and vertical adjustment. To adjust the optical centre of the lens, in relation to the centre of rotation of the apparatus, a screw is used. The back can be opened to insert and remove the bobbins.

*Sensitised Plates and Films.*—To dispense with a change box, the film has a piece of black paper attached at each end, which protects the roll from light.

*Lens Fittings.*—The lens case has an opening closed by a sliding shutter for removing and inserting different lenses.

*Shutters.*—The sliding shutter has a rectangular opening, and is actuated by the lever, which also releases and arrests the clockwork by which the apparatus is rotated. A second shutter, worked by hand through sector gearing for regulating the time of exposure, is also used.

17,548. *November 5th*, 1889.—"Photography." F. BEAUCHAMP, "The Poplars," Chadwell Heath, Essex.

Relates to *Cameras and Change-Boxes.* At the back part of the camera are two receptacles formed by a partition for the storage of the plates before, during, and after exposure. The plates are provided with a sheath having flanges along three of its edges, or a spring to grip the plate. They are placed in one of the receptacles for exposure, being passed through a door at the back. When the front plate is exposed, it is withdrawn into the chamber by a hooked lever. The lever is mounted on a spindle, which is actuated by a crank handle. The movement of the spindle also actuates a star or ratchet wheel, connected with an indicator by means of pivoted levers. The front is adjusted for focussing by racks and pinions, or by levers on a rocking shaft, which pinions and levers actuate rods or tubes in the front, which slide in tubes in the back.

17,708. *November 6th*, 1889.—"Photographic Cameras." T. R. DALLMEYER, 25, Newman Street, Oxford Street, London, and F. BEAUCHAMP, Hope Cottage, Whalebone Lane, Chadwell, Romford, Essex.

The bellows is strengthened or supported to prevent sagging by an internal spring, the convolutions of which lie within one another when folded. The spring may be in one continuous piece, or in sections.

17,773. *November 7th*, 1889.—"Photography." E. H. FARMER, 309, Regent Street, Middlesex.

In chromo-gelatine processes for producing phototypes and photo-mechanical printing surfaces, it is found that silver has the same effect as light in rendering the gelatine insoluble. To produce the surface, a silver image is obtained on an unhardened gelatine film in the ordinary manner, and the film or plate is then immersed in a solution of ammonium bichromate. For the gelatine corresponding colloids may be used.

17,998. *November 12th*, 1889.—"Photography." T. COLLEY, 18, Lansdowne Circus, Leamington.

Relates to dark slides and cameras.

*Dark Slides.*—The dark slides, which may be adapted to carry one or more plates, have weighted shutters or doors hinged at the bottom, and secured by fastenings at the top. They are provided with grooves at the sides for insertion vertically into a swing frame pivoted in the camera.

*Cameras.*—The camera may be of the instantaneous kind, or of any other kind in which there is room for the rotation of a swing frame, into which the dark slide is inserted and secured. The frame, which also carries the focussing screen, is provided with an indicator by which the position of the frame can be known when the lid is shut. When the frame is inclined from the vertical, one of the doors, previously unfastened, falls down to expose the plate. The camera is adapted to store or carry a number of the dark slides. A shutter at the back is opened for focussing.

18,224. *November 14th*, 1889.—"Photography." H. G. M. CONYBEARE, The Hut, Ingatestone, Essex.

*Shutters.*—Tapes or bands are attached to rollers, and pass over a third roller, all of which are enclosed in a case having exposure apertures in the front and back. To the tapes is secured a piece of cloth, which serves as a blind. The roller is actuated by a spring, the tension of which is regulated by a ratchet and pawl. To set the shutter, the tapes are wound on one of the rollers until the aperture is covered by the blind. The roller is then arrested by a pawl, which is released by a pneumatic arrangement.

18,167. *November 14th*, 1889.—"Photographic Shutter." W. J. LANCASTER, Colmore Row, Birmingham.

One form of the shutter is adapted for slow or rapid exposures. It consists of two slides with exposure apertures, and which coincide in front of the lens aperture. The slides are connected to opposite ends of a lever. For slow exposures a stop lever is turned down so as to hold the shutter open as long as pressure is kept on the piston by the pneumatic ball; when the pressure is released the shutter closes by gravity.

In another form of shutter the time of exposure is regulated by clockwork. There are two slides, caused to move in opposite directions by a lever, as in the previous case, but actuated by springs. One of the slides is caught by a detent when the shutter is open ; the clockwork is started, at the same instant, by contact with the slide, and releases the detent holding the shutter after the lapse of the required time'

18,583. *November 20th*, 1889.—"Magic Lantern." A. HUGHES, 59, Fenchurch Street, London.

Relates more especially to the multiplex lanterns.

The bodies of the lanterns may be made of various materials, but, preferably, mostly of aluminium, the fronts being collapsible leather bellows instead of brass tubes as usual. The bodies are carried on brackets swivelled to sockets, which slide on uprights, and may be clamped in any required position by screws. By the above arrangement, and by means of connecting the lanterns, or the lowest lantern, and the base-board by adjustable telescopic tie-rods, the whole lantern bodies may be moved in order to bring them into position for registering on the screen, and consequently the objectives are not thrown out of the optical axis. The fronts are opened out by means of rods sliding in tubes, and racked so as to be operated by pinions on arbours. The condensers are mounted in a frame fixed upon the bottom frame, and the body of the lantern, with the lamp rigidly attached, slides on the frame, and may be fixed in any required position relatively to the condensers by screws.

18,547. *November 20th*, 1889.—"A New or Improved Compound or Developer for Use in Photography." BENJAMIN JUMEAUX, 11, Brighton Place, Stretford, in the County of Lancaster, Artist.

This invention relates to a new or improved compound for use in photography as a developer, consisting of eikonogen, chlorate of potash, and sulphite of soda, used in the form of a solution. These ingredients may be used in the following proportions, namely :—

| | |
|---|---|
| Eikonogen (powdered) ... ... ... | 2 drachms |
| Chlorate of potash (powdered)... ... | $1\frac{1}{2}$ ,, |
| Sulphite of soda (powdered) ... ... | 3 ounces |

which are slightly damped and mixed together, and then dissolved in one pint of hot water. The above proportions are those considered to give the best results ; but they may be varied or modified more or less without departing from the invention. For example, the quantities of the chlorate of potash and the sulphate of soda might be either slightly diminished or increased with the same weight of eikonogen.

The chief advantages obtained by this new or improved compound are, that it is self contained—that is to say, it requires no accelerator ; it will develop well with negatives of all makes, opals, lantern slides, and bromide papers, and does not stain either the hands of the operator or the plate except after repeated use, when it will slightly stain paper or opal.

18,689. *November 21st*, 1889.—"Photography." B. ACRES, 131, Richmond Road, Hackney, London.

*Washing Prints* —The print is enclosed in two frames hinged at the base and secured at the top by a clasp, &c. Transverse bars in the one frame are put on so as not to touch the bars in the other. The frame is provided with projections to rest on the tanks, &c.

---

*The Press*, a newspaper which is published at Christchurch, New Zealand, gave in its issue of March 10th, which has just reached us, some account of the doings of the Photographic Society there, from which we gather that quite an active organisation exists in that far-off land. We learn that "the annual general meeting of the above took place last night, when the officers for the ensuing year were elected. After the general meeting, a gathering of the friends of the members, including several ladies, was held. The work of the members of the Society, which was exceedingly creditable, was displayed, and Mr. Seager gave an exhibition of slides by the oxy-hydrogen light. There was also a student's lamp provided of the ordinary pattern, to enable any who desired to do so to exhibit their own pictures. A very pleasant and enjoyable evening was spent by those present."

# Correspondence.

## THE PROFESSIONAL ASSISTANTS' ORGANISATION.

SIR,—Will you give me space for a report on the proposed organisation of photographic artists and assistants ?

Some of our friends are under the impression that we are on the high road to success, while some of our opponents are jubilantly asserting that we are defunct. They are all mistaken ; we have both succeeded and failed—succeeded in securing numerous applications for membership, but failed to secure the class of workers we want. We started this movement with the object of drawing into a business combination all the best in every way of the photographic artists, and we would sooner give up the movement altogether than secure for ourselves a false importance by means of a number of imperfectly skilled members. It stands to reason that if we expect the countenance and co-operation of the employers generally, we must offer *quid pro quo* ; we must be in a position to guarantee that they shall not have duffers and frauds forced on to them by our organisation. This guarantee we strove to effect by instituting qualifying restrictions on membership ; but, out of fifty applications sent in, not more than eight could satisfy our technical requirements. A similar report has been sent us by the provincial secretaries. What does this show ? Not only that there is a large number about of useless workers, but also that the worthy artists persist in standing aloof from our scheme.

We are now simply *in statu quo*. We cheerfully and confidently await the day when the professional artist will arouse himself from this lethargy, and seek in judicious and temperate combination a remedy for the encroachments which threaten the position of his profession, both from above and below. What are his objections to our proposed society ? Briefly, as follows :—

1. "Combination with the object of securing improvements in salary and hours of business has been associated with so many debasing incidents in the recent history of the country, that the professional should hesitate to stoop to similar means."

2. "The programme, rules, manifestoes, speeches, and general tone of the proposed 'Union' were of too aggressive, bitter, and vulgar a character to commend themselves to professional men."

A thousand other details have been raised by those who should rather have aided the improvement of our movement by suggestions of a practical and sympathetic character. For instance, there were objections to the financial estimates of the organisation, but I will only deal here with the above criticisms :—

1. If any of the methods of unionism have been low and degrading—though it would be hard to prove to the poor, ignorant workman that he is degraded by the shorter hours and extra cash obtained thereby—is it necessary that all combinations must be carried on on the same lines ? A coal-porter's strike is probably not the most refined of class struggles ; but does it follow that a request for, say, increased salary by lithographic artists or clerks, who are also organised, will be anything but a dignified and gentlemanly negotiation ?

2. If our proposed rules, or our methods of giving publicity to them, seemed aggressive, it must be remembered that all new movements have the unfortunate habit of over-estimating their own importance. If one reads the reports of early meetings of the new master-photographers' organisation, he becomes conscious of the same aggressive egotism. This is not always intentional, and I repeat here that our object always has been, as our motto says, "Defence, not Defiance" ; and that it shall never be otherwise.

Again, if the professional workers disapproved of any of our proposals, they could have amended them by joining the organisation, as the objects, rules, and working methods will always be entirely subject to the opinion of the members ; in fact, will be formulated by them.

One objection has been forcibly urged in face of our persistent explanations. Our scale of wages has been denounced as being far too low ; whereas, in reality, it was not intended as a schedule of fair wages, but as a notification that nobody would be admitted as a member who earned less than the wages named. As events have proved, the scale was too high rather than too low for the majority of applicants.

There is no doubt that the time is approaching when the increase of competition will drive home our policy with sterner logic than any arguments of ours possessed. The time is not so very distant when the position of those who earn their living by photography will become incomparably worse than it is now ; and I am sure that then they will make a resolute and spontaneous attempt to unitedly improve their lot. Let them look to it that they do not defer their activity until the wave of competition becomes irresistible. I do not doubt that even to the last there will be some who will persist in clinging to their shibboleths of "gentility," preferring to starve in the odour of professional sanctity rather than risk by organisation the appellation of "workmen."

We shall continue to agitate and educate. We are now considering a scheme of amalgamation with the lithographic artists, which would result in a large accession of strength to our movement, from the services of their organisers. The present year will be spent in putting in our foundations.

*Maidstone, April 27th*, 1891. Arthur Field, *Hon. Sec.*

## NEW SOCIETY FOR BIRMINGHAM.

Sir,—At a preliminary meeting, held at the Colonnade Hotel, New Street, on Wednesday night, April 22nd, it was resolved that a photographic club or society be formed, and a provisional committee, consisting of Dr. Leech (chairman), Dr. Hall Edwards, E. Morton, C. R. Lunn, Dr. Mabberley, and Walter D. Welford (hon. sec.), was appointed to draft out a code of rules, and make the necessary general arrangements to be placed before a general meeting for adoption, to be called at an early date. The ideas of the provisional committee are that the name should be the Midland Camera Club, and that the platform of the club should be as follows :—

The advancement of photography in all its branches, and the promotion of social intercourse between all photographers.

1. By the holding of periodical meetings for lectures, papers, discussions, practical demonstration, and friendly competition in photographic subjects.

2. By the provision of club rooms, with dark rooms and other conveniences for the use of members.

3. By the promotion of intercourse between this and other societies.

It is proposed that the work of the club be divided into the following sections:—Scientific, Archæological, Lantern, Cycling and Touring, Ladies, Instruction of Beginners. Each section to hold their own meetings and appoint their own officials. General meetings will be held monthly, probably on Tuesday or Friday nights. The committee think that much detail work could be done by the sections, leaving the general meetings free for lectures, lantern exhibitions, &c., and in this respect the new club will go outside its own ranks to other societies, and thus promote friendly intercourse.

Club rooms have already been secured in a central part ot the town—one fair size for meetings, and two smaller ones attached for dark rooms. For lectures and lantern exhibitions a large hall, holding 200 to 300, will also be at their service.

These plans are, of course, not definite as yet, being subject to a general meeting, but they convey the ideas of the promoters. Walter D. Welford, *Provisional Hon. Sec.*

## PRINTING ON ALBUMENISED PAPER.

Sir,—Considering the rapid strides that have been recently made in the various photographic printing processes, it is a little surprising that the old and well practised method of printing on albumenised paper should still remain so imperfect. The double and brilliant albumenised papers now in the market are advertised as giving "perfect" results ; but the makers have not yet overcome the cause of blistering, which personal experience has shown in many instances takes place immediately they enter the fixing bath, or, in some cases, later on and during the washing. This, notwithstanding that every precaution being taken as recommended by the various vendors—viz., liq. ammonia in some cases, in others chloride of sodium, &c. The albumen which "blisters" is found only on the "highly" surfaced papers, and although they produce a uniform and brilliant print, the amount of waste and annoyance caused, I think counterbalances the advantages over the less highly albumenised surface. Some may think blisters of little consequence, as they go down (unless broken) in the mounting, but as soon as the hot-roller or burnisher is used they reappear, and thus labour is lost, and all ends in disappointment to the photographer as well as his customer. Why not use the single albumenised papers which do not blister? some would say. To this I would reply, from long practice, I find the surface so uneven that several prints from same sheet of paper and negative differ greatly, the thin albumen end producing a mealiness, whilst the upper or most brilliant part produces a richer print.

What photographers appear to be in want of is a good, reliable, and uniform albumen paper, for, although there are many new printing processes, the old one is still more in demand than any other, and from all appearances is likely to be for many years to come for small work.

Surely many photographers have experienced similar annoyances through these dreadful blisters, and if any certain cure is possible, would gladly and gratefully welcome it. It is useless the makers advertising their papers as giving "perfect" prints, "no blisters," because a trial sheet is sufficient, and further business cannot be expected. The writer would like to hear the experience of others in your valuable journal, to the edification of the profession generally. J. Smith.

*April 27th.*

# Proceedings of Societies.

### The Photographic Society of Great Britain.

At the technical meeting of this Society, held on the 28th April, the chair was occupied by Mr. T. Bolas.

The subject of the evening was "Animal Photography," and it was with regret that the Chairman read a telegram from Mr. Gambier Bolton saying that he was unable to leave Windsor Castle so as to be present. Letters of regret were also read from Mr. Marey and from Mr. R. Dresser.

Mr. F. Haes showed a number of slides of animal life taken about the year 1864 in the Zoological Gardens on wet collodion plates. *Apropos* of a picture of the quagga, he said that it was a mistake to suppose that the animal was extinct. He had recently received a letter from a well-known hunter in Mashonaland, who said that he saw plenty of them.

The Chairman said that the collection shown by Mr. Haes was a most interesting one. It should be borne in mind that these negatives were not taken with the advantage of modern rapid processes, but on wet collodion, with which, besides the much greater length of exposure required, there was the inconvenience that each plate had to be prepared as wanted, and these might be spoiled by keeping whilst waiting for the opportunity to take the photograph. There was one particularly of Mr. Haes' pictures of a lion which he thought would compare well with more recent photographs taken with modern advantages.

Mr. H. Sandilands showed a number of slides representing mostly pastoral scenes, and some of animals belonging to a circus.

A collection, by Mr. R. Wainwright, was next exhibited. The negatives had been on $7\frac{1}{2}$ by 5 plates, and the slides made by reduction in the camera upon ordinary bromide plates.

A single slide of great beauty was shown by Mr. T. E. Freshwater.

Mr. J. J. Bright showed a series of slides of domestic animals.

Mr. Lewis Medland exhibited a number of slides of animals, and followed this series by one of photographs made from illustrations of animals, such as were to be found in works on natural history, before photography had had an influence in the matter. Particular attention was called to a slide representing Buffon's idea of a lion.

The Chairman asked for a discussion, which was opened by Mr. W. E. Debenham who pointed out the influence that the photographic representations of animals by Muybridge and others had had upon modern painting and illustration. In the modern French school particularly, the attitudes of the horses in battle subjects were very different from, and much more varied than, those which were thought to suffice up to some twenty or thirty years since. If the illustrations, too, of racing and hunting subjects in the period of the present time were compared with those of the past, the influence of photography in supplanting the few old conventional types of running and jumping horses would be plainly evident.

Mr. Haes thought that many of Muybridge's representations were useless to artists, the positions were so *gauche* and ugly. There were some, however, that were very useful. It would be a great convenience if there was some sort of explanatory index of Muybridge's photographs.

The Chairman said he supposed Mr. Haes meant by ugly, that the photographs referred to were untrue. They were untrue in the sense that they represented phases of motion too quick to be seen. What the eye saw was a resultant of several positions.

Mr. Haes said that the positions he spoke of were useless to artists, although perfectly true. They were so ugly. There were several curious points that he noticed in closely watching the positions of a galloping horse. One was that the legs were at one time closely doubled up under the animal. Another point was that the feet were never in front of the head, although in paintings they had commonly been represented in that position. He had noticed that most people would be deceived as to the proportions of a horse, and if asked the number of heads the animal was in height, would give too many. The actual height to the withers of a horse was about two and three-quarter heads. He thought there were only two proper forms for representing animal life in photography. One was by means of the stereoscope, and the other by lantern slides. He advocated photographing animals in front of a background marked with measures, so that the proportions might be studied.

The Chairman said that he was pleased that Mr. Haes had spoken in favour of stereoscopic photography, a department which had been too long neglected, although there were indications, to some extent, that it might be revived.

Mr. Sandilands said that Mr. Debenham was rather severe on artists of the past with regard to their representations of animals. He thought it would be difficult to produce better pictures, or pictures more true to life, than some that he could call to mind.

Mr. F. Chang showed some slides of animal life, and, after votes of thanks to the exhibitors of the various slides, and to Mr. A. Mackie for working the lantern, the meeting terminated.

It was mentioned that at the meeting of May 12th a paper on "Polychromatic Impressions by Photography" would be read by M. Léon Vidal. At the technical meeting on May 26th, the subject of "The Influence of Development on Gradation" stands for discussion.

### London and Provincial Photographic Association.

*April 23rd.*—Mr. A. Mackie in the chair. Mr. Low Sergeant and Mr. H. D. Gower were elected members of the Association.

Mr. W. E. Debenham read a paper on "Colour" (see page 338). The lecture was interspersed with illustrations showing the effect on the screen of superimposing one colour over another, the effect being contrary to the generally accepted theory with regard to the mixture of colours. Two lanterns were employed; from one, a red disc was projected on the screen; from the other lantern a green disc was then projected, which produced a yellow colour. In the same way, yellow and blue produced a pale yellow tint, and a mixture of red, blue, and green produced white light. Mr. Debenham also passed round slips of black cardboard, pierced with two holes to correspond with the width apart of the two eyes. The apertures were covered with two different coloured pieces of gelatine. On looking through these at a bright light, some curious effects were observable with regard to the colour seen.

A short discussion followed.

### Camera Club.

*April 23rd.*—Sir George Prescott in the chair.

Dr. Patterson showed some binding strips for lantern slides, which he said would stick. They were produced by Schweitzer, of New York.

Mr. Frank Howard then, in a paper entitled "Amongst Byepaths and Field Lanes with the Camera," dwelt on the charm of wandering amongst the beauties of the country, and studying with and without the camera the picturesqueness of rustic people and rural scenes. He gave a few hints as to the most probable way of dropping upon the out-of-the-world picturesqueness which was so fast disappearing. The lecture was illustrated by about eighty slides.

After a vote of thanks to Mr. Howard, slides were shown by Messrs. Austin, Bright, Yale, Hussey, Patterson, and Seyd.

On Thursday, May 7th, Mr. Willis will give a paper entitled "Clam-Chowder."

### Photographic Society of Ireland.

The usual monthly technical meeting was held at 15, Dawson Street, Dublin, on the 23rd of April, Prof. J. A. Scott, M.B., in the chair.

After the usual business of the evening had been transacted, the Boston Camera Club's "Illustrated Boston" set of lantern slides were thrown upon the screen, and admired. The following members also contributed slides:—Messrs. Hargrave, Ruthven, Inglis, and Mathews.

### Holborn Camera Club.

The monthly lantern meeting was held on Friday last, when Mr. T. O. Dear presided.

A number of slides of the Paris Exhibition, lent by Mr. Merne, were passed through the lantern, followed by some from Messrs. Mawson and Swan, showing the various colours, ranging from red to black, obtainable on their lantern plates. Slides by Messrs. Chang, Ebsworth, Gay, Miller, and Thompson, members of the Club, were also shown. The prize for the best "group" taken at the last Club outing, presented by Mr. Brocas, was awarded to Mr. Dear, who announced that he would give a similar prize for the best "group" taken at the outing to Pinner on the 9th of May.

### West London Photographic Society.

*April 24th.*—The President in the chair. Five new members were elected.

The President announced that though the Society had not gained the Challenge Cup at the Crystal Palace, no less than four members had been awarded medals, viz., Messrs. Hodges, Colls, Whiting, and the hon. secretary.

Mr. Blackmore's paper on "Legitimate Photography" was read by Mr. Hodges, the writer having gone to America.

Mr. C. Whiting differed from the opinion of the writer in so far that he considered a certain amount of brush work quite legitimate.

Dr. Low quoted the opinion of an impressionist, that artistic effects could only be obtained by lenses with large apertures, so that the principal object only should be in focus.

Mr. Whiting believed in sharpness all over, and afterwards producing the required effect with collodion masks, which he described.

Mr. Hodges differed from Mr. Blackmore as to the question of flare spot; also as to cutting down prints, and the use of the brush on prints. He saw no harm in doctoring negatives.

Mr. R. Whiting showed a photograph taken with the new automatic machine.

### Brixton and Clapham Camera Club.

This Society held their second annual exhibition of members' work on Friday and Saturday, at Gresham Hall, Brixton. The average quality of the exhibits was higher than that of last year's show. The work in the architectural and portraiture classes evidenced great care and attention. A bronze medal was awarded to Mr. Bevins for his "Coastguard," and certificates to Messrs. Everett and Wilkinson. The award in the class for instautaucous studies fell to Mr. Powell, Mr. Coade comiug in second with a view of "Ramsgate Sauds." The Club's silver medal for the best picture in the exhibition was taken by Mr. J. A. Butler, for an enlarged print from a small negative, "A View in Amsterdam." The president offered a silver medal for the best six lantern slides, and this was also secured by Mr. F. Goldby.

The exhibition was well attended, the eveniugs being devoted to lanteru displays, while, in addition to this, on Saturday evening, a musical programme was provided.

The awards in the competition were as follows:—

*Landscape.*—Bronze medal ("The Grindlewald Glacier"), F. Goldby; certificates ("Is She in Sight?"), F. W. Kent and ("A Brief Rest") F. W. Levett.

*Architecture.*—Brouze medal ("Norman Tower, Christchurch"), F. W. Kent; certificate ("Ruislip Church"), F. W. Levett.

*Instantaneous Work.*—Bronze medal ("Overbacks"), W. H. Powell; certificate ("Ramsgate Sands"), J. W. Coade.

*Portraiture and Figure Studies.*—Bronze medal ("The Coastguard"), W. Bevins; certificates ("A Group of Sailors"), E. J. Everett and ("At Work") A. B. Wilkinson.

*Enlargements.*—Silver medal ("A View in Amsterdam"), J. A. Butler; certificate ("A Stormy Day"), F. W. Kent.

*Lantern Slides.*—The President's silver medal, F. Goldby; certificate, J. A. Butler.

The judges were Messrs. J. Traill Taylor, F. W. Edwards, and A. R. Dresser, while Mr. F. W. Levett, hon. sec., had in hand the general arrangements.

---

### North Middlesex Photographic Society.

On April 25th a number of members took part iu a field-day to Edgware. The first plates were exposed upon Whitchurch, considerable ingenuity being exercised in arranging some cattle to break up the expause of meadow foreground. One very pretty view was obtained by retiring still farther back, bringing the church into the middle distance, and comprising a rushy pool with overhauging trees as the foreground. Stanmore village and church being reached, cameras were directed against every picturesque nook, the population of the village taking much interest in the proceedings. The ruined old church and modern lych gate were taken, and every possible post of vantage having been secured, the party returned to London well satisfied with what had proved a very pleasant day.

On Monday, April 27th, Mr. F. L. Pither in the chair, Mr. Dickenson exhibited and explained the actions of the Radial hand-camera, aud showed samples of eikonogen cartridges. Messrs. Goodhew and Cox reported their test of the plates sent by Messrs. Marion and Co.; and Mr. Taylor showed prints on the chloride of silver emulsion paper seut by Mr. O. Scholzig. A special meeting was then held to elect a presideut iu the place of Mr. Humphries, resigued. Mr. G. W. Marchant was elected.

---

### Hackney Photographic Society.

A meeting was held on Thursday last, Mr. J. O. Grant presiding.

Various books were announced as haviug been presented to the library, which bids fair to become a valuable auxiliary to the Society.

The Hon. Secretary showed a compact little hand-camera called "Itakit," made by Messrs. Matthews, of Biruingham. It was made to take twenty-four plates, lantern size.

Mr. Grant showed some work on Fry's naturalistic paper.

Mr. J. A. Sinclair theu gave a paper aud demonstration on "Lantern Slide Making." After meutioniug the different methods of slide making, Mr. Sinclair proceeded to expose some Ilford alpha and ordinary lantern plates with success, the burners used being the ordinary seven burners of the hall, and, consequeutly, difficult to judge by. Mr. Sinclair afterwards toned the alpha plate, which was shown at different stages of touing (wet) through the lantern.

After the demonstration slides were put through, the work of Messrs. Grant, Funston, W. Feuton Jones, A. Barker, Carpenter, Salmon, Heap, Rader, Gerard Smith, Herbert Smith, W. Smith, E. H. Jones, Hasdell, Hull, Beckett, and others. Messrs. Mawson & Swan also sent their prize set.

---

### Putney Amateur Photographic Society.

*April 25th.*—Mr. J. C. Leman in the chair.

The proceedings embraced a lecture and demonstration on alpha paper; the exhibitiou, by Mr. Faulkner, of a home-made apparatus for printing paper and plates; aud the development of platinotype prints, hot-bath process, with description, by Messrs. Martin.

The Society will make an excursion to Esher and district on May 9th.

---

### Glasgow and West of Scotland Amateur Photographic Association.

The closing monthly meeting for the session was held iu the rooms, 180, West Regent Street, on the eveniug of 20th April, Mr. John Morison, jun., president, in the chair; when five uew members were elected.

The President gave a report ou the International Photographic Exhibition to be held in the Fine Art Institute in September.

Mr. John Stuart showed his system of taking photographs by means of the flash-light. He also exhibited work done by this means. Mr. Stuart then photographed five of the members of council in a group, and the negative was developed and shown to the meeting, which closed with the usual display of lantern slides by the members.

An excursion took place on the 13th April to Dunure and Maybole. Some excellent negatives were secured, and a uumber of lantern slides from the same were shown at the monthly meeting.

---

### Newcastle-on-Tyne and Northern Counties Photographic Association.

The ordinary monthly meeting was held in the Mosley Street Café, Newcastle, on April 21st, Mr. J. P. Gibson in the chair. Arrangeuients were made for a series of competitions confined to amateur members of the Association (particulars of which will be announced shortly), and for five out-door meetings during the season.

Mr. J. Hedley Robinson read a paper on "Carbon Printing," and practically demoustrated the process.

Mr. Gibson, in proposing a vote of thanks to the demonstrator, rather fell foul of what he called the leatheriness and dulness in the shadows, which, he said, were characteristics of the process.

Mr. Robinson, in his reply, vigorously defended carbon, and made out a strong case for his favourite process.

The meeting concluded with a show of members' slides.

---

### Birmingham Photographic Society.

At a meeting held at the Midland Institute on April 23rd, the Chairman, Mr. G. T. Lyndon, congratulated the Society on again winning the National Silver Challenge Cup, and then called upon Mr. Jerome W. Harrison, F.G.S., for his paper aud demoustration ou "Instantaneous Photography."

Mr. Harrison announced that Dr. Norris's new dry collodion plate would be on the market about midsummer. A new factory was being built for its manufacture at Stechford. He explained the working of Decoudin's exposure meter, and Messrs. Hurter and Driffield's—which he had used for the past twelve months with success. Watkins's exposure meter was also shown. Warnerke's sensitometer was exhibited and explained, with examples which had been tested. In working, he preferred to employ Place and Underwood's shutters, instead of using a cap for lens. He advised members to use boiled distilled water when making up their developing solutions, and not to hurry development. If a plate is believed to be over-exposed, it is well to first soak it in a weak solution of bromide of potassium. If under-exposed, it is well to first soak it in a very weak bath of ammonia. Latitude of plates, he said, was often over-rated, and there is generally greater latitude for over-exposure than under.

After some other interesting and instructive remarks, the lecturer developed half-a-dozen plates he had exposed in a hand-camera in the streets of Birmingham that day, the whole of them coming up well. The developers used were Thomas's hydroquinine, pyro, and ferrous oxalate, as put up in their travelling cases. He then took several flash-light pictures of the company present.

---

Sheffield Camera Club.

A lecture was given on April 22nd (Mr G. T. W. Newsholme in the chair), at the Cambridge Hall, Cambridge Street, by Mr. W. Lamond Howie, F.C.S., his subject being "To Ober-Ammergau and back in 1890."

The lecture was illustrated by 120 photographic lantern slides, which Mr. Howie was enabled to take on his way to and from Ober-Ammergau, and also during his stay at that place, including some scenes from the Passion Play. He visited Bonn, Nuremberg, Cologne, Strasbourg, Munich, Innsbruck, the Bavarian Alps, the Tyrol, and many other cities and districts, and from each he showed excellent photographs illustrating the different styles of architecture to be found in the cathedrals and other magnificent buildings. The interior and exterior, and also the notable details of each building were given, besides views of the streets, museums, bridges, art treasures, and other objects of beauty and interest. Special reference was made to Cologne Cathedral. Nor were the country districts through which Mr. Howie passed neglected, as was shown by his remarkably good rural *genre* subjects, including life in the Tyrol. A number of the photographs of the Bavarian Alps were also examined with much interest, and, in alluding to his views of the Passion Play, the lecturer assured the audience that there was no foundation for the rumour that the play would not be repeated in the year 1900. Views of geological interest were also shown, including the curious earth pyramids in the Austrian Tyrol.

---

Received.—"A Survey of Pigeon Houses," by Alfred Watkins (W. Pollard and Co. Exeter). This is a very interesting illustrated pamphlet, reprinted from the *Archæological Journal*. It deals with those substantial, tower-like buildings which were used up to the last century for breeding pigeons, and which often afforded accommodation for five hundred couples. In those days, when fresh meat was often very scarce, pigeons were of great importance as an article of food. Some of these curious buildings are most picturesque, as the reader of this pamphlet may see for himself by studying the excellent photographs taken by the author to illustrate his remarks. Eight of them have been reproduced by collotype in a very perfect manner. We have thoroughly enjoyed a perusal of this pamphlet, affording as it does a peep into the lives of our forefathers from a new standpoint.——From the publishing firm of Knapp, Halle, the second part of Dr. J. M. Eder's "Ausfuhrliches Handbuch der Photographie," the first part of which was noticed in these pages in October of last year. The part to hand contains about 300 pages, with 127 illustrations. The progress of this so-called hand-book seems to justify the prediction that on its completion it will be the most perfect photographic encyclopædia ever published.——From M. Paul Nadar, No 1 of *Paris Photographe*, a monthly illustrated review of photography, and its applications to art, science, and industry. This first number contains forty-eight pages, and includes among its illustrations a portrait of Daguerre, and a series of photographs of Sarah Bernhardt in the rôle of Joan of Arc. There is also an autographic letter of Daguerre, and an autographic reproduction of the treaty made between Niepce and Daguerre in 1829.

## Answers to Correspondents.

**All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.**

**All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.**

**Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.**

Photargus.—*Stripping Films.* Try dilute hydrochloric acid alone, or a mixture of this with the potassium fluoride which you have already in stock. The Eastman gelatine skins should be kept in a dry place, or in a tin box, to prevent them from adhering or becoming mouldy. Get some more, for there is no better method of transfer.

Alpha.—*Collodion Process.* It is just possible that the cyanide fumes from your electro-plating operations may have affected the silver bath. This will be seen by the formation of a white precipitate of silver cyanide; so, if clear, this could not be the cause of your troubles. A transparent and streaky film would seem to indicate that the nitrate bath was too weak; but, instead of boiling it down, it is surely easier to strengthen it by adding fresh silver to the bath.

J. McG. (Belfast).—*Ferrotype.* You will find a very good description of this process in the Year-Book for 1889, pp. 166 and 167. Also in Mr. J. Fallowfield's catalogue, or *Photographic Annual* (London: 146, Charing Cross Road, W.C.), with, of course, in the latter case, a priced list of materials.

M. P.—*Photography in Natural Colours.* Your main question is answered by Dr. G. Lindsay Johnson's letter in the current number of the *Photographic Society's Journal.* We *had* examined the little spectrum by waning daylight before venturing to speak of it at the meeting, but, perhaps, the truest remark about the case was that "we hoped some day to see a finer specimen." Mr. Warnerke's results were inspected earlier in the afternoon, and they are certainly remarkable.

Viator.—*Moisture in Show-Cases.* When the sun shines brightly on a cold day, moisture is almost sure to condense on the front glass. Cutting holes for ventilation at top and bottom might obviate this, but in damp weather these apertures would require to be closed.

F. A. B.—Letter received, with best thanks for promise of future help.

J. P. Jones.—*Grains and Grammes.* By a misprint (comma for a decimal point), the weight of a gramme was vastly exaggerated. It should have been 15·434 English grains are equal to one gramme.

"Bringing Home the May."—Yes, you are right; in this fitful season there will be none to bring—or, at least, none ready by May Day. We have yet to look for a change of wind and April showers.

Middlesex.—*The Affiliation Scheme.* Since writing to you the report has appeared on the last page of the *Photographic Journal.* See the invitation given to local societies, so now you have only to apply and appoint two delegates.

L. F.—*Judges at the Exhibition.* The forms have been sent to every member, and there are *seven* spaces for the nomination of Judges of Awards, 1891. The papers are to be returned by Monday next, 4th May. Artists are eligible.

A. T.—*The Sector and Grease-Spot Photometers.* Capt. Abney and Messrs. Hurter and Driffield have met and come to agreement, the terms of which will be published in the forthcoming *Journal of the Society of Chemical Industry.*

W. Herrmann & Co.—The agency formerly held by Mr. Bucknall was transferred in January last to Messrs. Schwarz & Co. By an oversight, this change did not appear in the advertisement.

Vol. XXXV. No. 1705.—*May* 8, 1891.

CONTENTS.

## THE WORK OF A PHOTOGRAPHIC INSTITUTE.

BY W. E. DEBENHAM.

The claim so vigorously put forward by Mr. H. P. Robinson* for picture-making, and what is called the artistic side of photography, to be the leading subjects for consideration and teaching in the proposed Institute of Photography, will doubtless carry great weight, on account of the recognised ability of the writer in the walk which he represents. It is, therefore, desirable to discuss the question of the usefulness, or otherwise, of acting, in the formation of any general photographic society or institute, on the lines which he proposes.

The question may be put thus: Which is the more desirable to encourage in the public interest: that research which gives us new processes, methods, and appliances, and makes improvements in old ones, together with imparting technical scientific instruction in the various details of photographic work; or the endeavour to produce by photography, as it exists, of work of a more artistic character?

Taking the latter part of the question first in order, it may be noted, to begin with, that it is a phase in which the practicability of teaching is soon found to be exceedingly limited. Mr. Robinson himself puts it that, after a course of instruction to his own mind, "the decimal percentage of students who become artists must be left to evolve themselves." Will they not also, for the most part, after instruction and practice in photographic manipulations, evolve themselves, aided by their own innate artistic perceptions of the beautiful, and by the study of nature, and of photographs and paintings, to be seen in exhibitions and otherwise? Will they not only in this way learn what to imitate and cultivate, but what to avoid? One of our latest writers on art in connection with photography, Mr. P. H. Newman,† says that "art is the next oldest thing, perhaps, to the hills, and its canons are the outcome of the very nature of things, and as irrevocable. Nothing is more talked about to-day, and of nothing is there less to say. It cannot be taught; it may be learnt. It is much more likely to be felt after long, patient years of study; felt imperceptibly at first, than in a flash, and in full revelation." Doubtless the general recognition of the fact which Mr. Newman puts so strongly, that in the artistic development of photography there is more to be done in the way of self-cultivation than can be accomplished by instruction, and that what instruction is available in this way is soon exhausted, is the reason why so few papers and discussions on the subject have occupied—not in the Photographic Society of Great Britain alone, but photographic societies generally—so little time and attention. The exhibitions are natural instructors in this department, and there the student desirous to cultivate his artistic powers does so by considering the effect of certain productions, and the means employed to obtain them. In this respect artistic excellence stands on quite different ground from what is called technical excellence. The former is evident to the observer who feels it, and the means of obtaining it, by contrasted light, introduction of figures, or otherwise, is not concealed, but stands open to observation. No amount of observation, on the other hand, will tell the inquiring student what is the process that has been employed to obtain the photographic excellence of the work before him. This he must learn separately either by instruction, personal study and practice, or both together.

It seems to me to be a curious illustration of the one-sidedness that devotion to a particular branch of a subject may induce, that Mr. Robinson should take such strong views against possible modifications of the developer. He says that a student in the art department of an institute to his liking, found wasting his time over a new developer, or a modification of an old one, should be "dismissed without benefit of clergy." He further says that although he would even endow research, he would "bar any more modifications of developers."

Now, Mr. Robinson may have satisfied himself by experiments—which would have to come under the head of scientific work—that Messrs. Hurter and

* Photographic News, 1891, page 257.

† "Pictorial Composition," Photographic News, page 252.

Driffield's proposition to the effect that gradation is fixed by the exposure, and is incapable of variation by the developer, is true. He may have satisfied himself that this proposition is true not only of existing, but of all possible future developers. If, however, this is not certain—and it is not by any means admitted beyond controversy—it may possibly be just in the direction of development that the removal of the greatest defect in photographic processes may be looked for. The want of range of tone or gradation in the extreme lights and shadows of the subject has long been recognised by scientific photographers as the most serious defect in photographic representation. Owing to this defect, a high light standing visibly upon a light of somewhat less intensity, will, in a negative sufficiently exposed for the darker parts of the picture, come out no stronger—or not to the extent that is visible, stronger—than the light half-tone on which it stands. Capt. Abney put the matter very forcibly some years since that, owing to this defect in existing photographic processes, any subject reproduced a sufficient number of times would eventually lose all half-tones, and be rendered simply by those of two extremes.

Writers on the artistic side of photography, though not exactly of Mr. Robinson's persuasion, have more recently rediscovered this weakness—I think one of them has re-christened gradation as "values"—and urged the desirability of obtaining the gradations of nature on the plate, though without, I believe, giving any clue to fresh methods of securing it. If the registration of gradation of tone truer than at present obtainable should be discovered, it will be due to scientific work, of which the "artistic" professors will, doubtless, be ready to avail themselves. If it should turn out that such an improvement lies in the direction of the developer, Mr. Robinson will surely not allow his present strong view against any modification of that agent to stand in the way of the improvement of his work.

Those who artistically employ photographic methods owe their ability to do so to the scientific experimentalists who have evolved them, and, for further improvements, they must look to the like source. If they undertake the work themselves they become scientific experimentalists. The obligations of science to art in photography are not so clear. The teaching power of science and the improvements possible to continued research and experiment are unlimited; whilst instruction in the artistic department is by no means of the like inexhaustible character, and is such as can, for the most part, be acquired by observation on the part of those naturally gifted with the artistic faculty. In a complete photographic institute, however, there might eventually, as in that at Vienna, be classes for drawing and other subjects connected with artistic development, whilst its characteristic would be instruction and research in photography and reproduction methods.

Most photographic societies have shown themselves quite ready to give attentive consideration to papers on the artistic side. That these have been so few is not due to any discouragement from either the members or the governing bodies, but may rather be referred to the reasons already given.

If Mr. Robinson, and any who may think with him, believe that the most useful photographic society would be one at which art phases were made paramount, and scientific research and experimental investigation kept in the background, "occasionally welcome on technical evenings"; and if none of the many existing societies fulfils these conditions, let them add one more to the list. If such a society is really the model of usefulness, there must be room for it. Let the papers and discussions be made as public as are those of existing societies, so that a judgment may be formed of its comparative utility. This is surely a more reasonable proposition than an endeavour to capture the unformed Institute as a subject for such an experiment.

## THE ANALYSIS OF MOVEMENT BY PHOTOGRAPHY.

Professor E. J. Marey, whose treatise on terrestrial and aerial locomotion is so well known to English readers in the volume entitled "Animal Mechanism," has contributed to the new monthly periodical—which we briefly reviewed in our last number—*Paris Photographe*, an article upon the above subject, in which he describes recent advances in this particular application of photography. In this article he points out that ever since Muybridge, of California, succeeded in photographing twenty-four movements of a horse in the act of galloping—a photograph which, by the way, has now become historical—a precise means has been thus indicated of recording the movements of both men and animals. Muybridge, the pioneer worker, showed in his large work, since published, how many applications this method had to horses and other large quadrupeds, and also proved how the same system could be applied to the principal movements of man. He also showed how the photographs thus obtained, placed in a zœtrope, could be subjected to a synthetical process, and thus could give to the eye all the effect of the original movements. The possibility of applying photography to physiological studies of this nature was thus fully demonstrated. But perfection is seldom attained at the outset, and Mr. Muybridge's method was found to be beset with notable faults, and accompanied by certain difficulties. The introduction of gelatine plates made it possible to obtain with very short exposures well modelled images, in place of the mere silhouettes alone possible when these quick exposures were made in conjunction with the wet collodion process. The intervals of time separating the successive images were rendered more equal, an indispensable condition in determining the phases of movement. Finally, the zœtrope apparatus, destined to reproduce the photographed movements, was so imperfect that it somewhat deformed the images when projected on a screen, but it has now been perfected by M. Anschutz, of Lissa. There still remains in Muybridge's method a fault which greatly reduces its value in scientific applications. This fault is brought about by the employment of a separate lens for each image transferred to the plate. This big battery of photographic apparatus levelled against the animal in movement may be compared to a series of separate observers placed in one line, and who would each see the animal in a slightly different aspect. It is true that the changes in the perspective thus brought about are insignificant if the apparatus be small, and if the object is large and placed at a considerable distance from the lenses. If, for example, twenty-four cameras occupy a line only two metres long, and these are pointed at a horse moving at a distance of 50 metres, the error is unimportant; but if a smaller animal—a bird, for instauce—be placed near the lenses, the difference in perspective would render the analysis of movement quite impossible.

It was thus indicated that iu order to render photography applicable to these physiological studies, it is necessary to employ a single lens, so that the object in movement may be observed from the same point of view. M. Marey explains that he has been working for several years in perfecting apparatus which would work in this way, and he has described, under the name of photo-chronography, various means of obtaining, with very short exposures and with small intervals of time between each, successive images corresponding to the different phases of the movement.

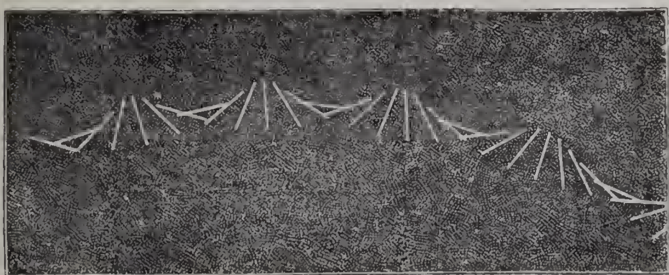

*Fig.* 1.

In certain cases it becomes necessary, in recording these movements, to point the lens to an animal of white colour iu bright sunshine, and with a black backgrouud behind it. A series of exposures are then produced at short intervals of time, which form on the sensitive plate images more or less separated from one another according to the speed of the moving object. In other cases the images are photographed on a long travelling band of sensitive pellicle, such as the Eastman film, but which by mechanism is brought to a standstill at the actual moment when the image is impressed upon it. The realisation of this rapid and jerky movement presented much difficulty, but the results obtained are of great importance; in fact, photo-chronography by means of a travelling film may be applied with few restrictions to all kinds of moving objects. It is no longer necessary to operate upou white objects or those of a light colour, or to place them in actual sunshine; nor is it necessary to use a black background in order that the object photographed may stand out clearly from its surroundings. One may therefore, by means of this more modern method, seek in all places for subjects for study without the restrictions which were once necessary. M. Marey states that certain experiments which are now in progress permit him to affirm that it is possible by this method to deal with objects of a microscopic character. The mechanism attached to the apparatus renders it possible to vary the length of the exposures and their periodicity, according to the nature of the movement studied. Slow movements necessitate comparatively long exposures; but in the case of quick movements, on the contrary, the exposures must be from forty to fifty a second, and their duration of course as short as mechanical means will permit. These rapidly-recurring and short exposures are necessary in the case of a bird or insect on the wing. These conditions once obtained, the apparatus lends itself to the most varied applications, as may be judged by certain examples which are given.

As already iudicated, photo-chronography on a fixed plate requires that the objects shall be light, well illuminated, and depicted on a dark field. Thus fig. 1 allows us to follow the double movement of rotation, and of translatiou of position in a white stick thrown across a dark backgronnd. Fig. 2 is obtained under similar conditions, but as the images of a jumping man present a greater surface, they have a tendency to overlap one another, and to get somewhat confused iu that way. This effect is produced when the speed of the moving object is insufficient, as may be noticed in this figure, at the moment when the jump is concluded, and the movement tends to the vertical instead of the horizontal. This confusion naturally gets more accentuated as the number of images is increased, or iu the case of the object depicted being of great length, such as a horse. In this case it is necessary to give movement to the sensitive surface itself. This is well shown in another figure—which it is not necessary here to reproduce—representing successive movements of a trotting horse, *a la* Muybridge.

*Fig.* 2.

By this latter method one is by no means limited to a dark background; one can, in fact, study the movements of an animal in its natural habitat, either in menageries or in the Zoological Gardens. Runners, gymnasts, &c., also come under the same category. In illustration of what is meant, a picture is shown of twenty successive images, obtained in two seconds of time, of men iu the act of fencing. Such movements, when photographed, permit useful comparisons between the right and wrong methods of doing certain work, and of different bodily exercises. Accideut has lately enabled M. Marey to make a comparison, by means of such photographs, between two fencing schools, which present great differences of motion: the one, the French modern school; and the other the old Spanish school, of which latter certain Neapolitan professors hold the tradition. Anyone can see at a glance the difference of the attitudes assumed by these two typical schools, and an adept at fencing who studied these photographs of successive movements would have the necessary elements for judging of their correctness and rapidity.

It will thus be seen that this improvement on Muybridge's system not only corrects the perspective as already indicated, but the circumstance that the images on a long band of film can be developed at the same time, and in the same dish, must confer greater uniformity on the pictures which result. M. Marey hopes before long to complete his experiments with the microscope, in conjunction with this new method of recording movements, and he believes that every type of life may be subjected to this treatment. He has already succeeded in photographing microscopic creatures with their images enlarged up to one thousand diameters, and has obtained such images at the rate of forty to sixty a second. One example given is that of a fly which is running along, and which at the same time is aiding its progress by movement of its wings.

## PHOTOGRAPHS IN COLOURS.

We have recently had an opportunity of carefully examining the pictures which are being produced by the Art Colour Photograph Company, and which consist of portraits and copies of pictures—notably a very effective reproduction of one of Meissonier's paintings. Almost ever since the first Daguerreotype picture was evolved, inventors have dreamt of producing, by the agency of light, pictures which should glow with all the colours of the natural objects which they depict, and, as all old photographers know, there have not been wanting pseudo discoverers who have asserted that the problem has, under their efforts, been at last achieved. Indeed, such reports have come up almost with the regularity of the appearance of the sea-serpent and the abnormal gooseberry. When, therefore, a new method by which coloured photographs can be obtained is advertised as having been discovered, the experienced photographer is apt to smile and pass it by as a tale which is told, and one that has been told but too frequently.

But the Art Colour Photograph Company differ from those who have preceded them in the same field by avowing frankly that the process by which their coloured pictures are produced is simply mechanical in its nature. They are obliged to withhold details of its working at present, in order that patents may be secured before the secret is out, and there the mystery ends. A process by which photographs are produced by employing different negatives for what are commonly called the three primary colours is familiar to most of our readers, for it crops up as regularly as clockwork, the initial impetus having been given to it by the late Mr. Woodbury about fifteen years ago. We are assured that the new process has nothing whatever in common with that well-worn idea; a single negative only is required. The cost of production will, it is believed, not exceed that of a plain photograph, and if this is the case the profession will doubtless find a large increase in their business by adopting it. Upon what terms this can be done we are ignorant, but information can be obtained from the Secretary at 155, Fenchurch Street, London, E.C.

London and Provincial Photographic Association. — May 14th, last lantern night of the season; May 21st, ordinary meeting; May 28th, "Theory of Ordinary and Polarised Light," Mr. A. Haddon.

The Lantern Society.—On Monday, April 27th, Mr. E. W. Bulkeley gave a lecture on the West Indies, illustrated by Mr. F. York's fine set of lantern slides. This was the last meeting of the present session; the meetings of the Society will be resumed in October next.

## CARBON PRINTING.*

BY J. HEDLEY ROBINSON.

Of all the processes, that of carbon or pigment printing seems to be the least known to members of our Association. This is to be regretted, as it is a method simple and beautiful in its working, and beautiful in its artistic results—in fact, it is the only process which embodies in itself the necessary elasticity to suit the artistic requirements of photographers, as the colour and surface of the finished print can be varied according as the class of work requires, whilst the absolute permanence of the results is undoubted. It is now more than a quarter of a century since the first photographs in carbon were produced by Mr. Joseph Wilson Swan, or by his process, and these are still to the fore, untouched by the action of light, or chemical or other actions which have been the cause of the fading away of so many once beautiful silver prints. The basis of the process is the action of light on bichromatised gelatine, which it renders insoluble, and not only it, but any colouring matter it may contain.

Carbon, or autotype tissue, as it is called, is prepared by coating paper with an emulsion of gelatine and permanent pigment of the colour required. After drying, it is made sensitive by immersing it in a five per cent. solution of bichromate of potash, and when again dry is ready for placing under the negatives. But a much simpler plan is to purchase it sensitive, ready for the printing frames. In process of manufacture, the Autotype Company render it sensitive to light by the incorporation of the bichromate, with the result that the least interesting and only troublesome part of the proceedings is avoided, and users have the assurance that the tissue is in its best working condition, which it will retain for a fortnight from the date of manufacture stamped on each packet.

Before printing, the negatives must have an edging of black varnish, an eighth of an inch wide, all round on the glass side to form a safe edge, the function of which is to keep the margin of the tissue quite soluble, to prevent the edges of the picture from washing up in development.

As the progress of printing cannot be seen, we must regulate that time by an actinometer, which is a box with a glass lid, on which are several tints of graduated densities; a slip of sensitive silver paper is pulled under these, and the box and the printing frames are exposed to light. An average negative will take about two tints of Burton's actinometer, which is the one we have got here, and which, you will see, has six small negatives. When the second lightest of these is printed to the ordinary depth, the tissue will be sufficiently impressed.

I have here pieces which have been so printed, and we will now proceed to develop them. Here I must mention that there is no gold bath or hypo bath used in the process, only clean water. First, pieces of the temporary support, which is wax prepared paper, are soaked till limp in cold water, then the tissue is also put into cold water, and when it has nearly flattened out again, after first curling inwards, it is put on to the support, both being under water, and then both are lifted out together by the finger and thumb of the left hand. Now we place them upon this mounting block and scrape out the water from between the surfaces. You see they now adhere together, and thus we will leave them for a few minutes. The action commenced by the light is continued in the dark, so that the development

* A communication to the Newcastle-on-Tyne and Northern Counties Photographic Association.

ought to be affected as soon as possible after printing, say from one to three hours, or an allowance has to be made. Advantage can be taken of this continuation of action when the prints are known to have had too short an exposure; these, if left overnight, will be found to develop the same as if they had had the correct exposure.

Now let us develop our prints, which we left upon the temporary support; we place them in warm water at 105 degrees, and in a few seconds, when the coloured gelatine begins to ooze out at the edges, as you see, we skin off the paper on which was spread the compound in the first instance, and leave the greater portion on the temporary support. In this is embedded our picture, and by dashing the warm water over it, allowing it to soak a little, and again dashing it, the picture reveals itself. It is properly developed when dark-coloured streaks cease to run from the print. If it has been over-exposed, as this one was done purposely, we have only to increase the temperature of the water, say, up to 115 degrees or more, and we can perfectly reduce it, as you perceive. If under-exposed, we finish the development in cooler water and save the picture. Thus, you see, there is a very great latitude in this carbon process. When finished to our satisfaction, we give it a rinse in cold water and transfer it to a five per cent. solution of alum, which, after ten minutes' action, will free it from all traces of the chromic salt, and will render the gelatine quite insoluble.

Some of you might ask why the picture could not be developed on the paper of the tissue itself. This was a great stumbling-block to the early experimenters, who tried it and failed; because, as was argued, the light acts from the surface backwards towards the paper, leaving a delicate, insoluble skin on the surface of the tissue (which, although not interfering at all with the brilliancy of the finished print, seems to hold the gelatine together during development, preventing it breaking up), and varying degrees of solubility in its thickness according to the different densities of the negative, whilst that portion of the tissue next the paper is left almost wholly soluble, and that, therefore, if the picture is to be developed, that can only be done by dissolving away those portions of the tissue not acted on, or only partially acted on, by the light, and this can only be done from the back. Now, I particularly wish you to notice the evolution of the simplicity of the process as now worked. After the above theory was propounded, the first step was to coat a sheet of glass with bichromatised gelatine compound; this, after exposure, was coated with collodion, and then put into warm water, which attacked the soluble gelatine next the glass, and the picture floated off in a film held together by the skin of collodion. This was caught on a piece of paper, and the development of the picture finished. This was a somewhat difficult process, and I do not think ever got beyond the experimental stage. The next link in the chain was when, about 1862, Mr. Swan took out patents for improvements. Eventually he spread the gelatine compound simply on paper (like what we see here), and, after exposure, coated the surface with india-rubber solution, and mounted it on a piece of paper coated in a similar manner by passing it through the rollers of a copper-plate press. This enabled the paper of the tissue to be skinned off (as we have done to-night), and, after development, left the picture on the india-rubber paper; it was, of course, a reversed one, and to overcome this he made a transfer paper with plain gelatine treated with alum; this, after softening in warm water, was laid upon the picture, and when dry the india-rubber temporary support was peeled off, after moistening with benzine, thus giving the picture in its proper position. This was a perfect process, and by it some of the finest photographs have been produced. But with its heavy copper-plate press, its messy india-rubber solution, and the use of the pungent benzine, it was hardly suited for general photographers. So when, about 1868, Mr. Johnson, one of the founders of the subsequent Autotype Company, simplified it yet more, a great boon was conferred upon the photographic world. He found that no cement at all was required to fix the exposed print on to any support, but that it was enough to lay down the wetted tissue on an air-proof and water-proof surface, remove the air and water from between the two surfaces by the use of the squeegee, as we did, and it would adhere by atmospheric pressure, caused by the vacuum created, in the same way as a boy's sucker or "clagger" sticks to the stone he wishes to lift.

Now we will take our prints from the alum solution. We notice they are reversed. But as the support has been waxed with a solution of resin and beeswax in turpentine, which allows the picture to be eventually stripped, we will take a piece of this final transfer paper, which has been soaking in a two per cent. solution of alum for about an hour, place it and the print in water, bring them out together, place them on the mounting board, squeegee them, and hang them up to dry. When thoroughly dry they can be easily stripped off, leaving the support ready again for use after waxing. The support may be opal glass, when the print will take its matt surface.

This is the double transfer process necessary for ordinary negatives. A simpler one is the single transfer, but this requires reversed negatives or film ones printed from the reverse side. In this case the support is prepared paper without the waxing, and the print is finished as soon as developed, alumed, and rinsed.

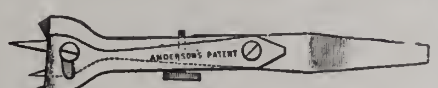
It will be seen that the finished prints are composed of insoluble gelatine, of the nature of vellum, in which is embedded a permanent pigment, and is of all the processes, platinotype perhaps excepted, the only one that can be absolutely relied upon for permanence.

In conclusion, I may say that all patents for this process are run out, so that any who wish may use it without let or hindrance. All materials can be obtained from the Autotype Company, New Oxford Street, London.

---

Messrs. Lancaster and Son, of Birmingham, have sent us a copy of their new catalogue, which contains prices and descriptions of every photographic appliance. As a publication the book is ornate, very well printed, while the numerous woodcuts are of such excellence that they leave an impression on the mind that Messrs. Lancaster must be very particular as to the way in which work should be turned out.

Expanding Centre-Bit.—Mr. R. I. Anderson, of 3, Poulton Road, has invented a form of centre-bit which should be of great use to those who, like photographers, have often to do a little bit of home cabinet-work. As will be seen from the annexed illustration, this ingenious little tool is so arranged that



the vertical cutting edge can be fixed at different distances from the central point, at once giving the power of drilling holes of any size—within certain limits—with a single bit. A tool of larger size, which would cut holes of varying diameter for the accommodation of a lens flange, would be a great boon to all photographers.

## TECHNICAL SCHOOLS FOR PHOTOGRAPHY.*

BY MAX JAFFE.

The objection will now be raised that technical schools, which have been organised on the basis of production, will injure the photographic profession by attracting part of their profits. This may be unhesitatingly denied. One must consider that in all cases in which something is to be done for the public good, the nature of the benefit demands that, from one quarter or another, sacrifices must be made. Moreover, the sacrifice which will be imposed on the photographic profession is insignificant when expressed in figures, because photographic technical schools, for many reasons, can only be found in big towns; consequently, the loss of profit will distribute itself over many institutions, and will be scarcely perceived by individuals. On the other hand, the advantages which good schools will afford our profession will soon become apparent.

From the above discussion, the conclusion is to be drawn that thoroughly instructed, capable scholars can very seldom be produced by photographic technical schools with academical methods, even when they are really well conducted, and provided with the best instructors. Scholars issuing from them will not be clear on the subject of how much knowledge and power they possess; some will even cherish the delusion that they have acquired all that is worth knowing, and will start off to make—with what they know—an independent living. It is quite another thing with regard to the schools where the students are taught practical work. The scholar who has just left one will be perfectly aware that he has acquired a certain amount of capability, and already knows a little; but that this little is unimportant beside that which he must know and be able to do in order to organise and manage a studio. Therefore, he will be much more inclined to endeavour to gather for himself fresh experiences through service in a business studio; consequently, technical workmanship, which has had a suitable pre-education, will be conveyed to the existing studios, and that there is a great need of this is well known to all professional people.

In time it will, perhaps, come to pass that the visiting of photographic technical schools will be more and more regarded as a necessity by those whose education has been provided in entirely empirical ways, and who find they have to withdraw in favour of those who have received artistic, scientific, and practical instruction.

We will not discuss the handling of individual instruction. Only the fact is to be pointed out that scholars, in exactly the same way as assistants in a business studio, have to do certain work, proposed to the school, under the responsible guidance of technical men, who preside over the educational course as teachers. Better and more effectually a scholar can prove his right to practise, and his proficiency, by reference to serviceable work performed by himself, than by splendid certificates and exhibitions.

How much time the scholar shall devote to the educational course depends principally upon which and how many branches he wishes to undertake. Two years ought to be considered the least period to be given by those young people who are inscribed as regular scholars. The educational course should be accessible to strangers, to the possessors of studios, and also to their assistants, and opportunity should be offered to continue their education in this or that branch.

* Continued from page 318.

Whether, and how far, photographic technical schools will be contemporaneously called upon to serve as experimental institutions we will not discuss here. We will state, however, that we should hold it advisable to admit scholars who have half completed their education, and who wish to try new methods. If this were not done, scholars would be easily misled to amateur practice, and there is the danger of their carrying this amateurism into their later business practice.

The teacher must, in every lesson he gives, be it in the form of an exposition, or in the conducting of practical demonstration, so throw himself into his work that the scholar will gain the impression that he possesses a wealth of knowledge.

The drawing studios, as well as the lecture rooms, and the laboratories in which the subordinate sciences are taught, must stand open to the scholar during the whole length of his school course. Although, in the educational course, the professional men are considered to occupy the principal place, the artists, as well as the scientific men who are engaged in the school, should be allowed free licence, in order to prove their powers of stimulating and instructing in every direction. Art, science, and professional practice must have representatives united in a harmonious co-operation, if photographic technical schools are to prosper.

In the foregoing we have striven, on the strength of our personal observations, to portray the manner in which photographic technical schools must be created, and to show how the desired ends can really be attained. We are well aware that we have but superficially touched, in a sketchy manner, on much that merited a closer consideration, as we were mindful of the narrow space which the form of a journal affords us. Nevertheless, we hope to have another opportunity to engage in a further discussion of such points at some future date.

If we contemplate the position of the photographic profession in these days from a commercial point of view, we find that its vocations are becoming more and more narrowed in many directions. This is in consequence of the fact that thousands photograph, not as professional business men, but for scientific and artistic purposes, and also for pleasure, and these, as far as their technical and material means allow them, meet their requirements by their own exertions. Considering the prominent position which, in the widest sense of the word, photography occupies in modern civilised life, it is a question of universal interest that they who manage a business of this kind shall be not pressed back, but that they shall be supported and helped forward. The better education of young people who devote themselves to photography can be regarded as an available means to the purpose, for proper technical schools would materially contribute to the elevation of our profession.

[We regret that, owing to a slight error, our esteemed correspondent, Herr Max Jaffe, was made to say (page 299, Photographic News): "Only a total reformation of our modern *methods of instruction* would be of the slightest use." The sentence should have been rendered, "Only a total reformation of our modern business methods would be of the slightest use."—Ed.]

Photographic Club.—Subject for May 13th, "New Hand-Cameras"; May 20th, "Hand-Camera Possibilities." Saturday outing, May 9th, Dagenham; train from Fenchurch Street at 2.32; meet at Dagenham Station 3.15.

## CRYSTAL PALACE EXHIBITION.

This Exhibition closed on Saturday last, and Mr. Wollaston, together with the general management, is well satisfied with the number of visitors, above the average at this season of the year, which it has attracted to the Palace. We have already stated that the apparatus department was not nearly so large as in former years, but, although this section of the Exhibition was smaller, it could not be looked upon as unimportant. Hitherto, pressure on our space has prevented us paying that attention which is its due, and we will now endeavour to briefly supply the omission.

The Platinotype Company exhibited many of their works, but, of course, the best testimony of the beauty of this process is in the large proportion of pictures produced by its aid which figured in the art section of the Exhibition. The public, however, seemed much interested in watching the demonstrations which took place throughout the day, when the dirty yellow image on the exposed paper was suddenly, and as if by magic, changed to permanent black by dipping into the hot bath. Messrs. Watson & Son, of High Holborn, had one of the most important exhibits in the Palace, and occupied much space. Their well-known "Acme" camera fitted with aluminium mounts attracted great attention, and many visitors were to be seen curiously balancing in one hand a lens with the old heavy brass mount, and in the other one of similar size mounted in the silvery and lighter material. Messrs. Noakes & Son, of Greenwich, also had a very interesting exhibit, in which lanterns and their belongings formed the principal items. A very noticeable feature of Messrs. Noakes' improved lantern is the manner in which the jet is fixed upon its support. This support, instead of being an unwieldy upright rod of iron fixed upon a metal tray, as in most lanterns, consists of a brass fitting attached to the back of the lantern body itself, and outside the instrument. It is so fitted with a nut and screw that the jet can not only be thrust to and fro, so as to be adjusted for different distances of screen, but it can, when centred, be rigidly fixed in its place. A further advantage possessed by this fitting is the very small opening at the back of the lantern through which light can come. Messrs. Noakes also exhibited a number of English condensers, both for lantern and enlarging apparatus. Close by, Messrs. Taylor, Taylor, and Hobson, of Leicester, showed a number of their lenses, including their well-known caskets. The "Hawk's-eye" hand-camera, recently described by us, was also on exhibition here, as well as the finders and levels which this firm have for long made a speciality.

Messrs. Matthews and Co., of Birmingham, showed two forms of cheap hand-cameras, one entitled the "Kinematic," and the other the "Itakit"; this latter is made entirely of metal, and has a magazine of twenty-four plates which, by a very simple arrangement, can be transferred one by one to the camera. Messrs. Parker and Co., of Holborn, showed their "Companion" hand-camera, fitted with a new form of shutter, which appears to work well. Mr. Slater, of Camberwell, showed a well-designed camera, which permits of the use of long-focus lenses, and which is produced at a very cheap rate.

Mr. England, of Notting Hill, exhibited a number of negatives produced by his films, notably one of a pen-line subject, in which the lines were absolutely clear on a dead-black ground, showing how suitable such films would be for process work, in which the wet plate is still almost universally employed. Arundel and Marshall's boxes for storing plates and negatives are well known, and we were reminded of their existence by seeing them here. Messrs. Houghton and Son, of High Holborn, showed a large portable dark room fitted with their well-known sink and every dark room contrivance that the most exacting photographer could desire; and they also exhibited their automatic hand-camera, which we described in these columns only a few weeks back. It is to be hoped that, when the time for the next Crystal Palace Exhibition comes round, the apparatus section will be augmented by several exhibitors who this year have only been conspicuous by their absence.

## THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

Programme of Bath Meeting, 1891.

*July 6th.*—Reception and presidential address.

*July 7th.*—Excursion to Chepstow and Tintern.

*July 8th.*—General Meeting; Meeting of General Committee; Convention Group; Papers from 3 p.m. to 6 p.m., and 8 p.m. to 10 p.m.; "The Photographic Work of Herschel and Fox Talbot" (with illustrations), W. Lang, jun., F.C.S.; "Recent Developments in Printing Processes" (with illustrations), C. H. Bothamley, F.I.C.; "Recent Astronomical Photography," A. A. Common, F.R.S.

*July 9th* (day).—Excursion to Salisbury; ditto to Bristol and Clifton. (Evening)—Report of the Lens Standards Committee; discussion on proposed international standards, opened by L. Warnerke.

*July 10th.*—Excursion to Glastonbury and Wells; ditto to Corsham and Laycock Abbey; (evening)—Dinner and Smoking Concert (tickets 5s.).

*July 11th.*—Council Meeting.

Permission to photograph in the places over which they have control have been granted by Right Rev. and Noble the Lord Bishop of Bath and Wells, the Very Rev. the Dean of Wells, the Very Rev. the Dean of Salisbury, the Very Rev. the Dean of Bristol, the Rev. C. E. Cornish (St. Mary, Redcliffe), and C. H. Talbot, Esq.

The Bath Photographic Society have placed their meeting room and dark room at the service of the Convention.

The White Lion Hotel and the Royal Hotel will be the headquarters of the Convention during the meeting.

Hon. Sec. and Treasurer, J. J. Briginshaw, 128, Southwark Road, S.E.

Messrs. Eyre and Spottiswoode, the well-known printers, announce that they have acquired the business of the Woodbury Company, and that the business will be now carried on by them, but under the same management as heretofore. The change has been brought about by the retirement of the senior partner.

Edward William Parker, a photographer, whose address was given at Hampstead, surrendered to his bail to answer the charge of obtaining money from a large number of persons under the pretence of taking their photographs. Mr. Farman appeared for the prisoner, against whom evidence in eleven cases had been taken. Ellen Harding, the wife of a messenger in the Colonial Office, residing in Brackenbury Road, Hammersmith, said in October last she went to 370, Uxbridge Road, where she saw the prisoner, who took her child's photograph. He said the photograph was too dark, and asked her to call again. The photograph was taken three times, and she paid 6s. 6d. She sent for the photographs, but the prisoner said the weather was bad and he could not turn them out. He promised to send them, but she never received them. Ellen Kearley, of Glenthorne Road, said she paid 12s., but she never received any photographs. Witnesses were called, who proved that a large number of persons called to inquire for the prisoner after he left his addresses in Cambridge Terrace, Fulham, and at 370, Uxbridge Road. The prisoner, who pleaded "Not guilty," and reserved his defence, was committed for trial, bail being allowed.

## Notes.

"The Lodger's Friend" is the somewhat whimsical name for a new form of bottle-lock which has been designed and patented by Mr. T. E. Halford, of 61, Chancery Lane. It consists of a metal belt to embrace the neck of an ordinary wine bottle, with a hinged band attached, which is bent over the cork and fastened to the belt by a tiny padlock. The photographer does not deal with liquids of a kind which tempts the wanton palate, but he has in use certain fluids of a volatile nature which are apt, in hot weather, to force the unprotected stopper from the containing bottle, and we venture to suggest that an adaptation of the same principle—omitting the padlock—would be useful in the laboratory for bottles containing ammonia, ether, and similar compounds.

The *New York Sun* comments upon an interesting fact regarding photographic portraits which, in the course of business, fall into the hands of an engraver. At first glance such a portrait may be regarded as generally attractive, but, as the engraver devotes careful attention to it, day after day dissecting it, so to speak, as he expresses it in lines on his plate, a different feeling arises in his mind, and often he will detect under the exterior polish a bully and a sneak—a man who will do anything to gather in the shekels. On the other hand, he may be repelled at first by the homely, common-place appearance of a man who, on the same closer acquaintance, gradually improves. The hard look gives way under closer acquaintance, and the features grow friendly. So that engraving a man's picture is a good deal like knowing the man himself—intimacy brings out the truth about him.

A correspondent of the *Photographic Times* recently made a suggestion with regard to exhibition photographs which is worthy of consideration. He believes that many would-be exhibitors are prevented from sending in their works for the simple reason that they have little time or inclination to get them framed. He points out that if photographs intended for exhibition were sent in unmounted, they could then be handed over to a professional worker, who would be instructed to mount them all in the same simple manner. A picture would not then claim any adventitious merit from being more tastily mounted and framed than its fellows. He believes that if this course were followed, the number of contributions sent in for exhibition would be largely increased. It will perhaps be remembered, in connection with this matter, that a few months ago we described and advocated a method of exhibiting unframed pictures which has long ago been successfully adopted by the Fine Art Society at Bristol.

Mr. J. R. Gotz, of Buckingham Street, Strand, has shown us some very fine examples of photographic illustrations which have been produced by F. Thevoz and Co., of Geneva, and for which he is the accredited agent. They appear to owe their origin to some modification of the collotype process, but whatever be their nature, the effect given is of the best.

Messrs. Percy Lund and Co. have organised, under the management of Mr. W. E. Henry, C.E., "The Practical Photographers' Federation," the main object of which is an invasion of Canada, to take place next month. In other words, the federation will consist of forty practical photographers, who will each subscribe fifty pounds to a common fund, to enable them to do photographic work with large profits amid the farming and mining districts of Canada. One would have thought that if the said outlying districts had shown signs of hungering after photographers, the old-established Canadian towns and cities would have been able to meet the demand. But it seems that it is not so, and Messrs. Percy Lund and Co. have risen to the occasion. To that enterprising firm we must refer those who wish to learn more about the matter.

Librarians of the numerous free parochial libraries which are springing up all over London must see that photography is well represented, or somebody will want to know the reason why. A correspondent of a contemporary complains that he can get any number of textbooks on angling, golf, and lawn tennis subjects, in which he does not take the least interest, but that in all which concerns photography the library is very deficient. We suppose it depends whether the librarian is a photographer; if he is, there will be no lack of photographic literature.

The question has been asked, Why does not some ingenious and unscrupulous person take to forging postage stamps? It is pointed out that many stamps are neither more nor less than negatives as they stand, while, supposing that the imitation be not very good, no one ever dreams of examining a stamp to see whether it is genuine. A writer in the *Moniteur de la Photographie* lately said: "Without knowing anything, we are perfectly sure that a large system of fraud is being carried on, and by a very easy method." This is rather alarming, and we hope the ingenious forgers are confining their operations to France.

It has been suggested more than once that the reproductions from photographs of pretty women wearing the latest fashions would be a great improvement on the inane prettinesses which form the usual style of illustration in fashion books. This, of course, is an artist's opinion. The experienced costumier knows better. Said the proprietor of a leading fashion magazine the other day: "Yes, I tried photographs once, but never again. A photograph may do when you want to show a bonnet or a hat only; but for a costume, where the full-length figure is wanted, the dumpiness which the camera gives is fatal. Our fashion ladies must be 'divinely tall,' but in photographs they are always short and squat. After all, ladies don't buy fashion plates for the faces, and if the waists which our artists give the figures are impossible, everybody knows they are so. The whole thing is conventional." There is a little logic in what this gentleman says.

It may be a consolation to photographers who live in "cutting" neighbourhoods where competition has forced prices down to a point which yields little more than a bread-and-cheese existence, that artists are not much better off. The schools of art all over the kingdom have resulted in the over-production of tenth-rate artists, who, if they get any commissions at all, take them at an absurd figure. We know a case where a young artist undertakes to draw and colour from photographs military figures, cabinet size, at the rate of eighteen shillings a dozen. These water-colour sketches are sold retail at half a crown each, and, working his hardest, the artist cannot do more than half a dozen a day, so that he earns about the same wage as a decent carpenter.

## THE ROYAL ACADEMY EXHIBITION.

A PRIVATE view at the Royal Academy is hardly an occasion to choose for a careful examination of the works exhibited, for the world of fashion is there, and the attention of the reviewer is perforce distracted occasionally from the pictures to the visitors. Many of these fashionable personages apparently prefer to chatter about their own affairs in loud-voiced tones, rather than to trouble themselves with the claims of art, just as thoughtlessly as they will in their own drawing rooms sometimes, when another branch of art should—if only out of courtesy to the performers—engross their attention. But despite these drawbacks of visiting the annual exhibition at Burlington House on this semi-private occasion, it is possible to make a few notes respecting the general aspect of the show.

Let us say at once that the Academy exhibition of 1891 is, in point of excellence, above the average. It may, perhaps, be more noticeable to one who is in the habit of dealing with the tones of silver prints, and the still more sombre hues of those furnished by the platinotype process, that the pictures hung at Burlington House this year should seem to revel in a wealth of beautiful colouring. Many of the artists, indeed, who are not in the habit of stinting us in this respect of colour, are lavish this year; with the result that the walls of the galleries have a very gay appearance indeed. But it is not alone by rich colouring that the present exhibition will be distinguished; the variety of subject and treatment is astonishing; so that an examination of this year's exhibition is as valuable to the earnest student in something to think about, as it is to the butterfly of fashion in something to talk about.

There are several pictures that at once arrest attention, and we must give the premier place to that of Mr. Luke Fildes' "The Doctor." This is a large and most admirably composed picture, and its great merit is that its story is simple and well told—a pathetic story truly, and one that has been enacted, and must be again and again, in many a household so long as the troubles of this world shall last. In a squalid cabin, upon a bed extemporised upon two chairs, there lies a sick child in the bright light from a partially shaded lamp on the table. A grave, clever-looking doctor—the principal figure in the composition—sits near, earnestly regarding the critical case before him. In the subdued background are the parents, the woman with her head on her folded arms giving way to her grief, and the man looking dreamily towards the child as if he can hardly realise the terrible possibilities of what may happen. These are simple materials from which to form a picture, but it has been done by Mr. Luke Fildes with consummate skill. Those photographers who take pains to produce story pictures, too often with such lamentably wooden results, would do well to study this masterpiece. And with this thought, a suggestion occurs to us which might be valuable to the organisers of coming photographic exhibitions. Why not, instead of allowing competitors to choose their own subjects, take some good example, such as the painting now under discussion, and offer a prize to the photographer who succeeds in reproducing it most cleverly in monochrome, and with the help of living models? The difficulties of such a procedure would be, no doubt, enormous, but the triumph of overcoming them would be proportionately great.

Another picture of a somewhat similar subject is by Mr. Frank Dicksee, and it is called "A Crisis." In this case, a young woman lies supported by pillows, and apparently dying of consumption. Her father, husband, or brother—we know not which—sits by the bedside anxiously and intently watching the invalid. This picture is, as a work of art, inferior to "The Doctor," and although, in the story told, they have so much in common, there seems to be something painful here which does not obtrude itself in the other work. It is certainly not a picture which one would wish to be a permanent feature of a home, but it is fair to say that the figures are most life-like and beautifully painted.

The same may be said of another work by this artist, but not by reason of its subject, but rather because it is on a large scale, and is of that decorative treatment which would render it more suitable for the vestibule of a public institution than for the walls of a private room. In this case Mr. Dicksee has drawn his inspiration from a mythological source. "The Mountain of the Winds," the title of the picture, refers to a certain mountain in Arcadia, where, according to the Greek oracle, "the four winds prepare to take breath for their courses on the earth." Both the drawing and colouring of the figures which typify the winds are very fine.

But it is with the portraits that the earnest photographer will feel the greatest interest. He knows that, of late, photography has been somewhat severely criticised by certain gentlemen of the brush, and, while willing to take a lesson from the higher phase of art, he feels, at the same time, in a critical mood himself.

In viewing some of these portraits, we are certainly at one with the Chancellor of the Exchequer, who offered an apology to the artists assembled the other night at the Academy dinner, "in the name of a colourless, humdrum, prosaic generation, to the genius of art for the commonplace nature of the materials" with which they had to deal. Of course, he had the portraits in his mind, and especially the pictures of the various nobodies who annually make their appearance at Burlington House. Here, for instance, is a picture of a middle-aged gentleman, standing with one hand on his hip, while the other holds his hat. It is a life-sized full-length figure dressed in drab. Now, if it was really necessary to the peace of mind of this amiable being, or that of his family, that his portrait should not only be painted but also exhibited, would not his head, or, say, his head and shoulders, have been sufficient for the purpose? The rest is merely a tribute to his tailor, his hatter, and his bootmaker, and although the goods seem to be of the best quality, there is no need to advertise them at the Royal Academy. There are far too many portraits of this type at the present exhibition, and we fear there is no help for it so long as human nature is as it is; but it is often vexing to find that valuable space is taken up with the counterfeit presentment of personages who are not known beyond their own family circle, and about whom, outside that little ring, no one feels the slightest curiosity or interest. If a man be blessed with a handsome face, or one wherein the beauty of his mind, exalted intellect, or force of character can be plainly read, by all means let his portrait be exhibited, for it will be a delight: but where nature has only produced an impresssion in ordinary clay, it is ridiculous to give it such distinction. We must reserve a more detailed notice of the portraits—good, bad, and indifferent—for a future occasion.

(*To be continued.*)

## A SUGGESTION FOR A POSSIBLE METHOD OF IDENTIFYING THE COLOURS PHOTOGRAPHED.*

BY JULIUS F. SACHSE.

The production of orthochromatic or colour-stained plates, which will yield negatives or prints giving approximately true colour values, is at present one of the most active problems of the photographic world, attracting the attention of specialists and active researchers in almost every country. These colour-sensitive plates, by reason of improvements made in the dyes used, thus ensuring their stability or keeping qualities, in addition to increasing their sensitiveness to shades of colour, together with the reduction in the price of manufacture, have of late increased their popularity with the professional as well as the amateur photographer, so that where, but a short time ago, they were only used by experimentalists, and by a few professionals for copying art paintings and like subjects, they are now coming into general use in all branches of photography, from studio portraiture down to the snapshot of the hand camerist.

Ever since the orthochromatic principle was first broached, the hope was fostered that by some means, in addition to giving true colour values, it would become possible to find a method to distinguish or identify by the print the colours in the original. This problem has for a long time remained a matter of conjecture and research, engaging the attention of the best known photographic students and theorists at home and abroad, as is instanced by the experiments with the solar spectrum and shades of colour—thus far, however, without leading to any practical method—by which the colours in the original might be identified at sight.

In connection with this subject, I wish to bring to your notice a suggestion for a simple method by which this much-desired object may be obtained, at least under certain conditions in suitable subjects, as you will see by the results shown by the negatives and prints as well as on the screen. The experiment may be considered a partial solution of the problem, at least within the scope of the subjects and colours upon which I was able to experiment. The subjects were entomological and ornithological (butterflies and birds), and were selected with reference to the brilliancy of the colours, and the difficulties which they have heretofore presented to the photographer. The suggestion, as you will perceive, is simply to photograph a colour key along with the subject, which shall explain itself. Of course, I do not for a moment wish to claim that this method will work in every case and subject, or where there is a marked admixture of white or black with the respective colours; but under stated conditions, for such subjects as indicated, as well as other departments of natural history, where the colours of the insect, animal, or flower are bright and decided, I do claim that with suitable orthochromatised plates, and where the requisite care is taken to prepare the colour key, and to ensure correct exposure and development, the suggestion, simple as it is, will be found to work satisfactorily, and that the colours of the original can be distinguished or recognised in the print in every case by the student who is able to judge, regardless of how much it might puzzle the general observer who is not at all familiar with the subjects.

I will now call your attention to the negatives and prints, and will state that they were made on the ordinary commercial plate, with a portable outfit, in the Academy of Natural Sciences of Philadelphia, with a poor side light, under very adverse conditions. The first picture was a print of eight butterflies, selected on account of their varied colours, which comprised lemon-yellow, brilliant blue, blood-red, orange, bright red, and black. Care was taken that the specimens, with the colour key, should all be upon the same plane, and to ensure an equal illumination. The colour key was formed of a plain white card, upon which was fastened pieces of tissue paper, matching in colour the hues of the moths; two of the shades, the bright blue and the red orange, I unfortunately was not able to match exactly from the resources at my disposal as well as they might have been. However, crude as this experiment is, the result will prove the correctness of the principle as suggested. With the use of a colour screen or light-filterer much better results can be obtained, which I trust to show you at a future meeting. Still, you will perceive that the four colours can be easily identified in the subjects. The plates used were the regular Carbutt orthochromatic, Sens. 23. The development was with the combined developer as per formula in *American Journal of Photography* (February, 1891, p. 91). I will also state that plates of the same emulsion, but not orthochromatised, did not prove successful, as you will see by comparing the prints numbered I., VII., and VIII., respectively. The attempt to attain the results by pyro and soda developer also resulted unsatisfactorily, all things being equal.

In the next subject, the *Sittace macao*, or red and yellow maccaw—a very unpromising subject—you will see on the print from an orthochromatic plate the five colours, cream, blue, yellow, red, and green are all plainly marked or discernible, while on the print from a plain plate there is but little distinction between the two first colours or the three latter ones.

One matter I overlooked in this experiment, viz., in making a colour key always to include black where it appears in the subject, as where bright, deep red and black appear close together, as in this subject, it would be hard to tell which was the red from the black, especially if strongly printed.

The question may be asked, Of what practical value or extended use is this colour key? In reply I will state, first, from a scientific point of view, that any process of reproduction by which the natural colours can be deciphered, or even approximated, must prove of the greatest value. This is especially true in the department of entomology and ornithology. Further, the absolute truthfulness of the photographic processes is far in advance of the laborious and expensive hand productions which are now used in the study of scientific matters. In addition, our present illustrations too often carry with them the individuality or imagination of the artist, to the detriment of nature, notwithstanding the great care taken by scientists to obtain the pictures true to nature. Then we have the great search power of the camera, with, perhaps, its greatest possibilities yet undeveloped, showing the structure of insect life, with a fidelity to nature in its most minute parts unequalled by any other process, which is now supplemented by the simple process brought to your notice this evening, foreshadowing the possibility of distinguishing the various shades of colour in the original.

From the commercial point of view, the above application cannot be over-estimated, as you will see that, by the aid of the colour key and orthochromatised plate, a nega-

* Read at a meeting of the Photographic Society of Philadelphia.

tive can be obtained from which a half-tone (Ives) process block can be made, retaining the graduations of shade necessary to the identification of the shades of colour in the original, thus opening a field for the production and illustration of scientific works on a scale heretofore impossible, while, at the same time, reducing the price and increasing the value, which cannot but help to popularise the study of the scientific subjects to which the process is applicable.

## PASTEL PAINTING.

THE following directions, recently published in the *Artist*, will be of service to those who wish to try their skill in working-up photographic enlargements by means of pastels.

"The materials employed are soft crayons or chalks of various shades and colours, and some pumice paper stretched on frames, of which there are many sizes, artists preferring pumice paper, as being less liable to hurt the skin of the fingers in the blending together of the colours after they are laid on to the paper, for in pastel painting the work is entirely done, or ought to be done, with the fingers and the palm of the hand. The intended subject having been lightly sketched in with charcoal, proceed to lay on the colours, always commencing to work from the top, carefully blending them together with the fingers in order to put on the necessary tints. The crayons should not be cut or pointed excepting when some little finishing touches are desired to be given to the features and hair, but should be gently rubbed on the paper, one colour over another, and blended into form with the fingers; by which means a marvellous delicacy aud softness can be procured. The shading is done by what is termed cross-hatching. Some pastel painters employ a stump, either of paper or leather, but I have always found that results of a far more satisfactory nature are arrived at by working the entire picture with the fingers alone, and by a careful manipulation of the colours au effect is obtained almost equalling in strength and beauty that of oil colours, combined with that delicacy and transparency which is an essential quality in the highest portrait painting. For all large surfaces, such as backgrounds, &c., the palm of the hand should be used in manipulating the colours after laying them on the paper. It will be found that when working with the crayons they are apt to break of themselves, and the sharp edges thus acquired will be of appreciable benefit in helping the student to produce the form he seeks to achieve. It is important that great care should be exercised in laying on the colours so as to avoid too frequent coatiugs, which tend toward opaqueness. The chief aim to be sought in pastel painting should be trausparency, combined with freshness of colour. Different coloured papers are sold for working on with crayons, but that of a yellowish hue is considered the best for pastels. Should it be found necessary to efface any colour from the work, recourse should be had to a sable or hog-hair brush, with which the offending colour is easily dusted off. Should, however, any small particle still remain on the work, it must be gently blown away. Pastel paintings are usually covered with glass in order to protect them, aud I consider this to be advisable, although I believe there is a way now of so fixing the colours as not to make this obligatory. In conclusiou, I would recommend that, after the student has made himself acquainted with the preliminaries of the art, he should call in the aid of a master."

In connection with this matter, the following paragraph, clipped from an American technical journal, will be of interest.

"Lovers of pastel painting will be glad to hear that at last a way has been found to fix the colours without injuring them. A New York gentleman has invented a uew fluid for this purpose which does not injure the most delicate tiuts, and at the same time it fixes them securely to the paper or canvas so that they cannot be rubbed off. There have been preparations for fixing charcoal crayons, but none which would answer for coloured pastels, the many which have been brought out having either au injurious effect ou the tints, or else being good for nothing for the purpose."

## ON THE INFLUENCE OF MOISTURE UPON VARNISHED PLATES.

BY A. MIETHE.

VARNISHED gelatine emulsion plates frequently present an appearance resembling crystallisation. The glossy surface of the plate shows round or polygonal and confluent spots of silky lustre when viewed by reflected light, resembling infundibutate form. The phenomenon has a remarkable similarity with crystals derived from spreading the solution of an easily crystallisable salt upon a plane surface and crystallising by evaporation.

Experience has shown that moisture is the factor promoting the formation of these figures, and that in reality they can be produced at will, when the film has been sprinkled with a spray of water, or has been covered with a stratum of aluminium hydrate. They often occur spontaneously on plates kept in places not perfectly dry, or when plates in close proximity to each other are removed from a cold room to one of higher temperature. By transmitted light these spots appear of a brown colour, printing light upon a positive copy, even when but slightly visible.

Induced by repeated inquiry as to their possible cause, I have made a series of interesting experiments on the nature of these spots, and the means to remove them.

When examining them under an enlarging lens of limited power, their crystalline nature became discernible; the affected portions showed in polarised light a limited but distinct double light refraction, suggesting the separation of a crystallisable body, induced by the action of moisture, the nearest direct cause of the effect being sylvinic acid probably. But were that so, the same phenomena must certainly occur with any resinous film, when sufficiently moist. A variety of varnish films resting upon different supports, and exposed to a moist atmosphere, were then experimented with.

1. Commercial photographers' varnish upon a gelatine film showed spots after three-quarters of an hour.

2. Shellac varnish upon the same produced spots after ten minutes.

3. Negative varnish upon collodion; no action after 48 hours.

4. The same upon plate glass; none after 24 hours.

5. Japan (Scovill's crystalline) upon gelatine; spots after a few hours.

6. Japan upon chloride of silver collodion diapositives; no effect after 24 hours.

7. Japan upon a tanned pigment print showed spots after 24 hours; and—

8. Negative varnish upon a thoroughly tanned gelatine negative produced the same effect in 24 hours.

These unexpected results excluded altogether the crystallisation hypothesis, spots having occurred with japan, from which a formation of crystals is out of the question. The occurrence of spots depends furthermore upon the existence of a gelatine substratum, the time of producing them upon the aid of water, and the more or less tanned state of the film.

But how can we account for the double refraction of light, and the regular starry formation of spots with japan varnish? What has gelatine to do with the phenomenon, and why does it not occur with collodion films? When viewing the spots by reflected light, and under a powerful microscope, the absence of crystallisation becomes evident. Concentric curves, closely united with each other, and grouped around a common centre, are visible; they consist of narrow bands of varnish, resting not flatly upon the substratum; they are raised in annular form around the centre, imbricated, as it were, the single varnish bands appearing like shingles laid upon each other.

The forming of these structures has been examined under the microscope, and has led to the following explanation.

Through any of the pores, abundantly present in every varnish stratum, moisture enters till the gelatine film is reached; the gelatine begins to swell, the varnish surrounding is broken by this action, more moisture enters, another concentric varnish ring is formed, and so forth, till the above described figure is shaped. By the pressure exercised by one centre upon another, polygonal figures are produced similar to the polyhedric form resulting from soap bubble accumulations, as Plateau has shown. Has the varnish stratum or the gelatine film been scratched or torn, the formation of starry or leafy figures follows distinctly the direction of the fracture. The double light refraction is explained by the high tension of bent varnish particles, similar to that of glass when under pressure or expanded. Collodion plates do not show these effects, simply because a collodion film does not perceptibly swell in water.

But little has been done for the benefit of the practitioner by solving the above question scientifically, and explaining the ultimate cause of these spots, and we must yet consider the best way of how to avert them, or to remove them from where they exist.

Protect your gelatine negative from all possible influence of moisture.* This not being possible under all circumstances, thorough tanning of the gelatine film is highly recommended. A tanned film resists moisture very much, an untanned attracts it. Japan or crystalline varnish, not very liable to moisture in the atmosphere, is preferable to any other.

To remove these spots from varnished negatives is quite a tedious operation. The plate should be devarnished in the first place, soaked in water for several hours, dried quickly, and recoated with a very thin varnish. When the spots appear very dark by transmitted light, which mostly occurs with thickly varnished plates, they will be retained to some extent, even after that operation. Herr Gaedicke proposes to subject the plate after devarnishing to a strong alum bath, a remedy not effective enough in my hands. I have had much better results by brushing the plate repeatedly with a concentrated aqueous tannin solution to which a modicum of alcohol has been added, thoroughly washing it, drying quickly in a warm room, and the application of a new coat of varnish.

Plates treated in this manner show occasionally signs of the spots by reflected light; by looking through them, however, nothing of them is visible.—*The Photographic Times.*

---

Photographic Society of Great Britain.—On May 12th, at 8 p.m., M. Leon Vidal will read a paper on "Photographic Methods of Obtaining Polychromatic Impressions." It is hoped that a collection of coloured prints will be on view. May 26th, subject for discussion, "The Influence of Development on Gradation." June 9th, Mr. Leon Warnerke will read a paper on "A New Sensitometer."

* Coating of a well dried film with collodion, as proposed by Abney, will probably be effective.—Translator.

# Patent Intelligence.

### Applications for Letters Patent.

### Specifications Published.

18,826. *November 23rd*, 1889.—"Photography." C. Lawrance, 141, Fulham Palace Road, London.

*Camera and Change-Box.*—This belongs to the detective class, and consists of a change-box arrangement, shutters, and other necessary parts. The sensitive plates are placed in zinc frames or sheaths, a number of which are combined together in book form, and placed on a shelf. The sides of the sheaths are notched, so as to fold down after exposure. The plates are pressed forward by a spiral spring, and each exposed plate, as it falls forward, is arrested and held in position by springs.

*Shutter.*—A flap shutter is used for covering the lens when necessary, and is held in the open or closed position by a spring. A mechanical shutter is fixed, and may be used for slow or rapid exposures.

19,205. *November 29th*, 1889.—"Photography." J. B. Payne, 33, Soho Square, Middlesex.—(*F. C. Binns, Wellington, New Zealand.*)

Relates to means of treating and mounting prints so as to give them a matt opal surface. An unpolished or ground plate of glass, &c., is coated with a "waxing compound," consisting of bees'-wax and yellow resin dissolved in spirits of turpentine, &c. This, when dry, is covered with a "gelatine zinc compound," which is made up of gelatine, zinc oxide, and glycerine, to which a suitable dye or pigment may be added. On the surface thus prepared is laid the print, face downwards, which is squeezed on to it. A backing is next laid on. When dry, the print, with its backing, is removed from the plate by a knife, &c.

19,319. *December 2nd*, 1889.—"Photography." A. Pearson, 5, New Station Street, Leeds.

Relates to cameras for producing lantern slides. A carrier, which holds the negative to be reduced, is held by flat springs, so that it can be adjusted in any required position. A space is left between the two parts of the camera to give easy access to the lens. Focussing is effected by the screw and rack, and a set screw may be fitted to clamp the camera in any given position. The gap in which the lens is placed may be covered by a focussing cloth when the apparatus is in use.

---

The International Exhibition arranged by the Vienna Amateur Photographers' Club was opened on May 4th by the Archduchess Maria Theresa. It contained about 600 photographs selected for the exhibition out of 4,000 sent in. Among the exhibitors are the Princess of Wales, the Archduchess Maria Theresa, the Grand Duke of Tuscany, Count Bardi, and both Barons de Rothschild. Among the works most admired are the landscapes of Mr. Thurston, "A Villa in the Prater," photographed by moonlight, and the photographs of Messrs. Alfred Maskell, Lyonel Clark, George Davison, and J. Gale. The opening of the Exhibition was attended by the Ministers, the Diplomatic Corps, and numerous distinguished visitors.

# Correspondence.

## THICKNESS OF GLASS FOR DRY PLATES.

Sir,—May I call your atteution to a subject which I venture to think requires consideration, and which I trust you may recognise as one worthy of public ventilation, viz., the thickness of glass used by manufacturers for the small sizes of photographic dry plates. In a packet of one dozen I have frequently found some a bare $\frac{1}{16}$ of an inch thick, whilst others have measured a full $\frac{1}{8}$ inch. In consequence, camera makers now allow a full $\frac{1}{8}$ inch of space in the dark slides for the accommodation of the dry plate. This means that the Alpine climber and the photographic traveller are compelled to carry unnecessary bulk and weight of wood as well as glass.

If plates of a uniform gauge of $\frac{1}{16}$ of an inch could be obtained, many hand-cameras of the magazine type might carry double the number of plates they now do without increasing the dimensions of the instruments.

I feel sure that the enterprising makers of dry plates will best study their own interests and those of the public by giving the matter most careful consideration. Such a decided reduction in bulk and weight, both of plates and apparatus, as would be effected if $\frac{1}{16}$ of an iuch were adopted as the gauge of plates for small field cameras, would tend to reduce the popularity of substances now, to some extent, employed as rivals to glass for supporting sensitive photographic surfaces.

Arthur Rayment.

99, *Hatton Garden, London, E.C., May 2nd.*

## THE PROFESSIONAL SHOW-CASE.

Sir,—I have read with interest the articles recently published in your columns by the Rev. F. C. Lambert on the above subject. I fancy that the reverend gentleman is better acquainted with the theoretical than with the practical part of our business, and I trust that he will forgive me for saying so. What does he think our laudlords would say to the idea of cutting recesses in our walls for the accommodation of show-cases? I am sure that mine would strongly object to such a course, and even if he consented to this cutting about of his property, the walls are so thin in this—as iu most London houses—that the back of the case would most certainly obtrude itself into the adjoining premises. Your reverend correspondent is, of course, more used to church architecture than to the domestic variety, and we know that ecclesiastical buildings have walls of great thickness, and many recesses. Perhaps he had these in his mind when he penned the matter referred to.

Practical.

## THE WOLF AND THE LAMB.

Sir,—I have a grievance agaiust the General Post Office which, in the interests of the entire trade, should, I think, be made public.

The facts are these. Having been favoured with an order by a customer in the West of Englaud for an enlarged negative, 12 by 10, I, on the 3rd of April, despatched the same, carefully packed, to its destination by Parcel Post. On the 7th of April I received uotice from my correspondent that the negative had arrived brokeu (in two pieces only), he, a commercial man, admitting that it was well and carefully packed. I immediately posted my correspondent's letter to the secretary of the G.P.O., and received on the 9th of April the usual formal acknowledgment, which, I noted, contained the following clause: "It should at once be stated, however, that photographic negatives are considered by the Department to be of such an exceptionally fragile nature, that compensation for damage cau only be given where there is clear evidence of negligence or wilful injury in the post."

Though, in my printed list, I expressly state that "all possible care is taken of negatives, but *no responsibility* is undertaken for injury while printing or during transit," I nevertheless made and despatched immediately, *packed in an exactly similar manner*, a second negative, wishing to spare my correspondent inconvenience from delay, pending the remittance from the G.P.O.; but, in view of the above clause in my list, and feeling my lamb-like helplessness in any argument with the official wolf, I charged my customer *half* the usual cost.

On the 18th of April, the following to hand (I quote from the letter): —"I received the 12 by 10 negative this time all safely. I cannot, however, understand the invoice. You charge me with half the risk of the first uegative which was broken, *but you have, of course (or will have), got your 8s. 6d. from the postal authorities.* An official from the post office called to see the broken uegative and box a few days siuce, *and appeared satisfied it was well packed, and that the damage must have been due to rough usage in the post.*"

Similar personal attentiou was evinced in the matter at this end by *two* calls from an official at these works, and on the second occasion he left me so convinced that I should receive what can only be regarded as *just* compensation, that I cancelled the claim ou my customer for half risk.

Judge, therefore, of my surprise at receiving this morning the following:—

"Sir,—With reference to your applicatiou of the 8th inst., I have to inform you that careful inquiry has been made at each of the offices through which the parcel sent by you passed, but nothing has been elicited to afford grouud for supposing that it received rough usage or wilful injury during transit, and when delivered it was, to outward appearance, in good condition. *In the circumstances and for reasons* stated in my communicatiou of the 9th ult., your claim for compensation cannot be allowed. The postage cannot be refunded.—I am, sir, your obedient servant, S. A. Blackwood, Secretary."

Now, sir, as an interested party, I am fully aware that "my opinion" must go for what it is worth, but I should be pleased to hear your opinion, and that of some of your readers, for whom the matter may possess commercial interest, on the abstract case of two boxes, admittedly adequate in strength, each containing a piece of glass 12 by 10, admittedly well packed, each travelling 250 miles by parcel post, each to all outward appearance in good condition when delivered, yet the glass iu one iustance is whole, while the other is broken iuto two pieces only.

Why, sir, the *careful inquiry* consisted, I presume, in a few questions to the parcel carrier, who could hardly be expected to criminate himself by saying he let the parcel fall, or while sorting *threw* it from one side of a room to the other (which I am informed *is* doue); and I maintain that the *slight* damage of being broken into *two pieces* is the best possible evidence "*to afford ground for supposing that it received rough usage during transit,*" for only a sudden, jarring concussion could have done it *in the circumstances and for the reasons*, which must be appareut to any but an official wolf having a lamb at his mercy.

J. Martin,

*Printing and Enlarging Works, 4 and 3, Park Villas, New Southgate, N., 2nd May.*

## PRINTING ON ALBUMENISED PAPERS.

Sir,—As the writer of the letter in your last issue on printing on albumenised paper invites others to state their experience, it is only due to the makers to say that Edwards' double albumenised paper is giving me first-rate satisfaction; an occasional blister may form, but nothing to complain of, and in every way the paper is good and even iu quality. We use hard well water all through.

E. W.

---

For want of space we must defer our report of Mr. Valentine Blanchard's lecture at the Polytechnic, Regent Street, on Wednesday evening last, until next week. We may, however, mention that the lecture was well attended, and was received with every demonstration of satisfaction by the audience.

Holborn Camera Club.—At the meeting held ou Friday last, Mr. T. O. Dear in the chair, Mr. James Sharpe and Miss C. H. Morgan were elected members of the Club; and Mr. E. H. Bayston read an article from *Adams' Annual* on "Photographic Shutters," illustrating the article by showing several form of shutters uow ou the market.

# Proceedings of Societies.

Camera Club.

*April 30th.*—Mr. Lyonel Clark took the chair.

The Secretary handed round specimens of clear gelatine for lantern slide purposes, brought to the meeting by Mr. S. T. Chang.

Mr. J. Traill Taylor then read a paper on "Lantern Optics," in which he first discussed the essential qualities of the several parts of the optical lantern, and then proceeded to describe a special form of condenser calculated to supply the most perfect conditions for working.

Commander Gladstone, amongst others, discussed the quality of glass used in lantern condensers. The greenish glass not only cut off the light, but affected the colour of the print. He thought that no doubt the system advocated by Mr. Taylor was the right one.

Mr. Elder mentioned Professor Boys' method of protecting his condensers from heat.

The discussion was carried on by Messrs. W. H. Harrison, Kapteyn, Little, and the Chairman.

Thursday, May 14th, will be a lantern evening.

National Association of Professional Photographers of Great Britain and Ireland.

A meeting was held on Thursday, April 30th, at the Talbot Hotel, Sheffield, in connection with the above Society. The object was the formation of a Sheffield district branch.

The Chairman, Mr. J. Crosby, Rotherham, explained to those present the objects of the N.A.P.P., how and where the scheme for such a society had first originated.

The members decided that a branch should be formed, and pledged themselves to support it to their uttermost.

The following were elected to the respective official posts:—*Chairman*—Mr. J. Crosby (Rotherham); *Vice-Chairman*—Mr. Dakin (Sheffield); *Treasurer*—Mr. Dickinson (Sheffield); *Committee*—Messrs. A. Seaman (Chesterfield), Yates (Sheffield), J. E. Edison (Barnsley), Whaley (Doncaster), Ainley (Sheffield), Shingler (Sheffield), and Wilkinson (Sheffield); *Secretary*—Mr. A. E. Yates (Sheffield).

The next meeting was decided to be held on May 26th at seven o'clock.

Richmond Amateur Photographic Society.

*May 1st.*—Mr. Ardaseer in the chair. The subject of debate was "Hand-Cameras," and, many makers having responded to the secretary's invitation to send an exhibit, members had the opportunity of inspecting many of the best known types, and, in several instances, having them explained by representatives of the manufacturing firms.

Mr. Parker showed his "Companion" hand-camera, claiming on its behalf extreme simplicity of movement. Mr. Smith, of the Eastman Company, had specimens of the whole series of kodaks, eight in number, and explained their working and distinctive characteristics, touching also upon the manipulation of the rollable film. This led to a short discussion upon films, the merits of which were warmly espoused by Major Nott. Mr. Smith also showed two 15 by 12 enlargements from kodak negatives. A representative of Messrs. Marion and Co. showed the "Radial" with its novel plate-changing arrangement, and Messrs. Mawson and Swan followed with the original and improved pattern "Reflex," which has a focussing mirror and roller-blind shutter working next the plate. Messrs. Watson and Sons had sent the "Vanneck," which was explained by the secretary, and Mr. Cembrano had been entrusted with, and described specimens of, the "Zodiac" by the London Stereoscopic Co., the improved "Facile" by Fallowfield, and the "Key" of the Platinotype Co. Members present also showed hand-cameras of which they were the owners, stating their merits and drawbacks. Commander Tudor produced Shew's "Eclipse"; Mr. Ramsay, Watson's old pattern and the Stereoscopic Co.'s "Artist" (twin lens); Mr. Garrett the "Ideal" (Adams); Major Nott a camera of his own design of extreme lightness and simplicity, which had done good work all the world over; and Mr. Cembrano wound up an instructive evening by showing a camera designed for use with several different lenses, and just specially made for him by Mr. Newman.

Croydon Microscopical and Natural History Club (Photographic Section).

*May 1st.*—In the Club room, Mr. J. A. Carter, M.A., in the chair.

Mr. D. E. Goddard, F.R.M.S., read a paper on "Elementary Silver Printing," and, in an interesting way, set forth the whole routine of silver work, from sensitising paper to the finished and mounted picture. A series of pictures showing results to be obtained by printing under different coloured glasses were exhibited.

At the conclusion a discussion ensued, in which Messrs. J. Weir Brown, Marriott, and the chairman took part.

May 9th, whole day excursion to Arundel.

Bath Photographic Society.

*April 29th.*—Mr. W. Pumphrey, president, in the chair.

The Chairman spoke in feeling terms of the loss by death of a member, Mr. F. J. Saunders, and a letter of condolence with the deceased member's family was ordered to be sent from the Society.

Mr. Ernest Lambert next discoursed on the subject of employing single meniscus lenses for large portraiture, illustrating his remarks with several head and bust portraits about half life size. Mr. Lambert said he was led to work in this direction from a careful perusal of Dr. P. H. Emerson's book, "East Anglian Life." The lens he used did not give an abnormally protracted exposure; eight seconds was about the average, and back focus varied from 48 to 60 inches. The working aperture was about $2\frac{1}{2}$ inches diameter.

The Chairman thought there was a good deal of merit in the examples shown. With a single lens there would be less refraction and more brilliancy. As to the result, all were not agreed as to how sharp a flat print ought to be. In nature the eye accommodated itself with great rapidity to focussing objects at any distance, and objects represented on a flat surface, if unsharp, might appear disappointing.

Mr. P. Braham, Mr. W. Harbutt, and Mr. W. Middleton Ashman took part in the discussion.

The Chairman, alluding to the progress made towards the convention meeting, said that a local committee was now formed, and that Mr. E. J. Appleby had accepted the post of hon. local secretary.

Liverpool Amateur Photographic Association.

A meeting was held at the Association's Club Rooms on the 30th April, Mr. Paul Lange in the chair. The following were elected members of the Association: Messrs. W. R. Melly, W. N. Samuelson, I. Pickering Jones, Thomas Wynne, M. Ganders, C. F. Burne, and W. Elsworth.

The President exhibited Mr. Friese Greene's hand-camera, enabling as many as sixty consecutive photographs to be taken in one minute.

Mr. John Price exhibited and explained Voigtlander's (5 by 4) hand-camera lens; also Ross and Co's. universal symmetrical lens, new rapid series.

Mr. J. T. Norman Thomas showed a framed picture of a view on a lake, which represented four swans in the foreground, whereas, when the photograph was taken, there were only two on the water.

A number of reasons for the phenomenon were given (some of them amusing), the most likely being that a double exposure had been given, and the swans, in the meantime, had sailed nearer to the camera.

Mr. Thomas S. Mayne, exhibition secretary, then made a statement regarding the probable financial results of that undertaking. The accounts, it was expected, would be ready for the meeting on the 28th inst. Although the success had far exceeded all expectations, the expenses had been very heavy;

but it was anticipated the nett profit would be about equal to that of the former exhibition of 1888, which resulted in £250 being handed to the Society's treasurer.

Mr. John Woolfall explained the progress that was being made to get the long-delayed return Boston set of slides completed, viz., "Illustrated Liverpool."

The President drew attention to the excursions for the present season, the first of which had been arranged for Saturday, 9th inst. (whole day), to Chirk and district. Permission had been obtained from Col. Myddleton Biddulph to photograph the castle. An excursion would be made to Quinta, another beautiful mansion, a Chatsworth in miniature.

Mr. J. A. Furnival, of Manchester, then proceeded to give a description of the optical lantern, explaining its various parts, and, after the lantern had been lighted up, gave some curious sound experiments, which represented waves of sound of the human voice on the screen. Microscopic slides were also shown, and the adaptability of the lantern to microscopic work explained.

---

### Brechin Photographic Association.

The last ordinary monthly meeting for the session was held on Tuesday evening, 5th inst., Mr. Wm. Stewart, jun., in the chair.

It was intimated that the committee had arranged to allow visitors to have the use of the reading room and dark room at the nominal charge of one shilling per month.

The secretary, Mr. J. D. Ross, read a short paper on "Stereoscopic Photography with a Quarter-Plate Camera." Although not advocating the use of such a camera for the best stereoscopic work, he pointed out that a stereoscopic camera is not essential to the production of stereoscopic slides, and, in proof, exhibited a number of transparencies and other slides taken with a small camera without extra top for stand or any extra apparatus.

---

### Photographic Society of Philadelphia.

A meeting was held on April 8th, Mr. John G. Bullock in the chair.

The Secretary exhibited a new shutter, the invention of Mr. H. B. Morton, of Minneapolis, known as "The Cloud Catcher." The shutter was of the rotary form, attached to the hood of the lens. The opening in the leaf was of a peculiar shape, allowing full exposure to the foreground and landscape, with considerably less for the sky or distance. The shape and size of the opening could be readily changed to suit the character of the view or intensity of the light.

A modification of the kodak camera was shown, being the contrivance of Mr. S. Ashton Hand, by which the roll-holder could be removed and five double holders put in its place. A ground-glass screen was also provided, which enabled the operator to properly focus a view, as with an ordinary camera. An acid fixing bath in solid form, in the shape of a powder to be dissolved as required, and also a portable developing powder, to which the name of "Phainogen" had been given, were shown.

On the subject of "New Developers," Dr. Mitchell said that there had been a great deal of discussion among members of societies and in scientific journals during the past five or six years, relative to the merits of eikonogen, pyro, hydrochinon, and a combination of these different ingredients. He believed that the two best results were obtained by first developing the negative in pyro, and then following with a solution of eikonogen; and secondly, by developing the negative with hydrochinon, and then following with eikonogen.

Mr. Carbutt said that he had come to the conclusion that, at the present time, a mixture of hydrochinon and eikonogen was the best developer of the day. The two combined—using about two of eikonogen to one of hydrochinon—would give a developer containing the good qualities of both.

Considerable discussion arose at this point in regard to the merits of exposure-meters, in particular the Watkins exposure-meter.

Mr. Charles R. Pancoast, president of the Waterbury Photographic Society, said that last spring, about the middle of April, he made an exposure of Carbutt's B 20 plates, with a Dallmeyer rapid rectilinear lens, stop F 32, and two or three seconds was amply sufficient for a fine negative. Taking these same plates in June, when one would presume the actinic power to be greater, five or six seconds was hardly enough.

Dr. Mitchell said the only exposure-meter of any real scientific value he knew of was the Watkins exposure-meter. Most of the others were conducted on the plan of placing the meter against the ground glass and observing the amount of light, which was rather an unsatisfactory way of judging. Referring to Mr. Pancoast's experiences, Dr. Mitchell said that, on a very bright day, he had often found little actinic power, while on other days, probably overcast, he had found the light act upon his plates very quickly.

Mr. Coates asked whether it was not possible for the makers of plates to come together and agree upon some common basis for designation of the sensitiveness of plates, so that the numbers would always mean the same thing. In his opinion, it was very important that makers should agree upon some uniform basis. As it was, one maker's sensitometer 40 was about equivalent to some other person's 30.

Dr. Mitchell said it seemed to him the only way to attain the desired uniformity would be pressure, and he thought, if this thing was presented in the right way, and through the different societies of the country, it would carry an amount of weight that would influence the action of the plate makers. It only depended upon placing it before them in such a way as to make it appear to their interest to do what was required of them.

After considerable discussion, Mr. Stirling moved that a special committee be appointed by the president to take into consideration the feasibility of starting a movement looking to a uniform method of marking plates, the committee to report to the Society, which was carried.

Mr. Chapman narrated an experience he had had with some pyro developer which he had left in the sunlight with the stopper out. The sun turned the solution to a port wine colour. It was a single solution developer, but with it he could build up to any depth without fog, and get dense black negatives on instantaneous exposures. He had not been able to do such work with fresh pyro, kept from the light, or with old pyro with fresh solution added to it. He used it for six months or more, and always got powerful negatives from instantaneous exposures.

Mr. Julius F. Sachse read a paper entitled "A Suggestion for a Possible Method of Identifying the Colours Photographed" (see page 354), illustrating his experiments with various prints, and exhibiting also a few lantern slides.

Dr. Skinner, an eminent entomologist, who was present, said that this would undoubtedly have great scientific value. The trouble with the present method was that it precluded the possibility of illustrating a great many natural history objects, on account of the great expense. The larger and showier species of insects had been illustrated, but the great majority had not, especially in this country. It was a great desideratum to have these things illustrated, because, of course, numerous discussions were had on them; but it was very laborious to attempt to make anything out from these discussions without having coloured illustrations, or illustrations showing what the colours might be. They could see at a glance the advantages that would accrue from this new method, when it would take anywhere from an hour to a week to hunt up from numerous descriptions the colour values of an object under discussion. The present method on stone was very expensive, took a great deal of time, besides requiring the services of an artist to make drawings, and then the lithographic work, the printing, and finally the colouring by hand. He sincerely hoped that some method of the kind outlined by Mr. Sachse would become successful.

Mr. Carbutt said that the method of illustrating books now by the half-tone process had reached such a state of perfection that he thought, with the aid of orthochromatic photography, it should be possible to make the illustrations for scientific works, with colour patches at the foot of each, made to match the colour of the object, and using the same as a key, as successfully represented by Mr. Sachse. This would save all the research and description of the colours of the objects. He thought it would be of great value, because a person could, by its means, carry in his eye (having the key below) the colour the bird or fly might possess.

The Chairman enquired if Mr. Sachse knew whether the sample tissue colours shown were aniline colours or not. Some of these colours were very fugitive.

Mr. Sachse said he could not answer that question. He had used these tissue colours, on the spur of the moment, as the best set of colours he could get. Of course he would try to match the colours exactly—probably by the use of water colours—but the examples he had used were merely ordiuary commercial samples of tissue paper, the best he could get.

Mr. Cheyney asked whether it would not be possible to flow orthochromatic plates with a stained soluble gelatine, which would act as a colour screen, and thus avoid the necessity of carrying screens to be placed in front of the lens.

Mr. Carbutt said he could only answer that in a theoretical way. He had never tried the experiment, yet did not see why it should not answer. The disadvantages would be, however, that one would be compelled to use the fixed plate as it was, while under present conditions he could use the plate with or without screen, or vary it from the light yellow to the orange, as he desired. This, he thought, was the better plan.

---

Photo-Mechanical Prints with an Ordinary Copying Press.—A Russian photographic paper publishes the following: "On a thick sheet of glass I obtain a cliché by means of bichromated gelatine, which, after developing, I leave to dry at the ordinary temperature for twenty-four hours, after which I flood it with the following 'bain mouilleur': Water, 100 c.c.; glycerine, 200 c.c.; hyposulphite, 2 grammes. This is allowed to act from one to two hours, according to the desired relief. Then I remove the liquid from the glass by means of a very soft pad and blotting paper, and then I ink up the cliché by means of a gelatine roller. The first pull or two are generally poor, and are somewhat spoilt by the dampness of the cliché, but the subsequent impressions are excellent. In order to print iu the copying press, I lay the inked clichés on a piece of india-rubber cloth, a mask of paraffin paper, and theu the paper on which I wish to have the impression, and over this a thin bag of fine cloth filled with wadding. It is the use of this blanket which makes it possible to press the paper into coutact, and to obtain all the fineness and details of the cliché. Of all the formulæ I have tried for the 'bain mouilleur,' I have found the above the best, as well for the relief as for the number of impressions. If after about twenty pulls the details of the high lights begin to show grey, one only need damp the cliché with a pad dipped in the same liquid, in order to make it as good as ever."

Royal Society.—At the meeting held at Burlington House, London, on Thursday, a paper, entitled "Cloud Photography conducted under the Meteorological Council at the Kew Observatory," by Lieut.-General R. Strachey, R.E., F.R.S., and G. M. Whipple, B.Sc., F.R.A.S., superintendent of the Observatory, was read. The authors described the work which had been in progress under their charge since 1878, illustrating it copiously with lantern slides and photographs, many of which were admitted by those who saw them to be uuique and of great beauty, while the methods they employed for determining the heights of the clouds above the earth's surface, and the system adopted for finding the rate of motion of the currents of air in which they floated, were commented upon by the president, Sir William Thompson, Lord Rayleigh, the secretary, and other speakers, as extremely ingenious, aud being capable of rendering far more accurate results than any others hitherto employed, either at home or abroad. The range of observations in the list of results given by the authors extended from clouds floating less than one and a half miles high in air, moving at seven miles per hour to niue miles above the ground, in gales blowing sixty-five miles an hour, whilst the surface wind was only a gentle breeze of five miles per hour. The advantages of a knowledge of such aerial investigations in the preparation of weather forecasts was ably pointed out by Mr. Symons, the secretary of the Royal Meteorological Society.

## Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.

V. B. R.—*Cabinet Mounts.* The cardboard contaius very little chloride, but so large an amount of sulphate of lime (plaster of Paris) as to be positively objectionable. The reduction of this sulphate to sulphide, by organic matter under the influence of moisture and sunshiue, may very possibly account for the yellow staining of the silver film which is now so very marked. Where screened from light, this sulphuration does not appear to have taken place, neither is there any fading.

J. M. Briggs.—*Estimation of Silver.* The hydrometer test would probably meet your case, beiug sufficiently near for all practical purposes. But if you wish to be exact, precipitate, say, two drams of the silver bath with an excess of hydrochloric acid, wash the heavy chloride once or twice with warm water by decantation, draiu closely, and dry nearly to the poiut of fusion in a tared porcelaiu crucible; 143·5 parts by weight of dry chloride correspond to 170 of nitrate of silver; then multiply by four to give the number of grains of real nitrate per fluid ounce.

Referee.—*Operator's Duties.* All depends upou your original agreement, but it cannot be to your advantage to engage a skilled operator to do the work of an ordinary printer. He might be asked to assist in retouching, enlarging, and working-up residues, if you have any occasion for these services. It is possible to overweight the establishment by carrying the division of labour too far in quiet seasons.

A. C. (Macclesfield).—*Cracked Negative.* Try the method of rubbing iu lamp-black, which often succeeds, or at least gives you a print that requires very little working-up by hand.

G. G. M. and F. D. T. (Ediuburgh).—*Historical Photographs.* An excellent portrait of Daguerre (6 in. by 5 in.), together with a photo-lithographed reproduction of the partnership deed drawn up between Nicephore Niepce and Daguerre, appears iu the new monthly, *Paris Photographe*, edited by M. Paul Nadar (Paris: 53, Rue des Mathurins; price 2 fr. 50 c.). You would do well to get this copy.

V. McC.—*Gold Line round Photo on Glass.* If you mean a narrow gold edging, this is done with gold leaf upon the glass itself, properly prepared with oil gold size, or varnish. No pen is required, for it is not done with the so-called gold ink, which, being only a bronze powder, would cause the speedy destruction of a silver photograph laid in contact.

F. R. I. B. A.—*The Renaissance in England.* We called upou the publisher this week, who showed us Part I. of the new work, containing eighteen reproductions from photographs, size 14 by 10 inches, executed by Sinsel, Dorn, and Co., of Leipsig. They are for the most part entirely satisfactory, but two or three of the plates, probably from the nature of the subjects, appear to be grey and flat.

Urban.—*The Crystal Palace Exhibition* closed on Saturday last, so it is now too late to thiuk about coming up to see it.

M. C. (Paisley).—*Aristotype.* Slow toning is a common difficulty; you should try a borax-gold bath made rather strong, and give plenty of time. The priuts are not ouly red, but injured in the mounting, probably from being rolled before they were quite dry. The process is not so easy as with albumenised paper, aud your pretty cabinet print only proves the fact.

C. N. and Co.—*Reducing Furnace for Residues.* Make friends with the nearest brass founder, or his bricklayer, and get him to come and put up such a furnace as he would use. It is simply a square chamber, lined with fire-bricks set in Stourbridge clay, with sunkeu ash pit, cast-iron fire bars, and flattened square flue leading from the back of the furnace into an ordinary upright chimney. A flat, movable slab—iron-bound, Stourbridge square—to cover the top. The fuel is coke.

## A PHOTOGRAPHER AMONGST IMPRESSIONIST PICTURES.

BY GEORGE DAVISON.

Of the several exhibitions now running, the one which photographers will perhaps do best to visit is that being held by the New English Art Club at the Dudley Gallery. The result of a first and superficial examination upon a visitor new to the work of these painters may be to provoke a smile of superiority. The gallery-going public, steeped in the pervading influence of the orthodox exhibitions, loses a true sense of the way many things really look. Long experience of conventional treatment as to point of view, colour, and subject, seems to destroy our power of seeing anything else as natural. Photographers know that something of this kind is true of the movements of animals. The public estimate of what is a correct representation of the gallop of a horse is formed from the average of the great mass of published illustrations drawn by artists. These are, perhaps, not the best artists, and we may learn to see differently from closer observation, from the facts seized and shown us by the more observant ones, or from judiciously selected photographs. The same observation holds good of other matters, such as facts of colour, light, subject, and point of view. Any development that breaks out of a slavish groove, and that opens our eyes to see common things in a new and true way, makes for freedom and livelier pleasure, the joy of the discoverer. Some of the pictures at the Dudley Gallery, on full acquaintance and study, do this in a very charming way. Eccentricity for eccentricity's sake will always provoke ridicule, but that which we think eccentricity may be our own ignorance or conventionality. The Philistine visitor to the New English Art Club Exhibition does not stop long enough to understand his men and their work. They have worked from knowledge, and some of them have much to teach. A stranger who careers round the gallery to quiz frames, colour, subject, and methods superficially, will, no doubt, have, above everything, a feeling of whimsicalities; but the unbiassed observer who cares to stop long enough to know the pictures will find his estimate change. The Exhibition grows upon the mind in a very noticeable way. The colour which, at first, seemed crude gains naturalness, and figures that struck the sense as wooden reveal some fresh and beautiful fact on better acquaintance. Most of these men seem to have had something new to say, and they give it in the most direct method. Perhaps, in giving one particular fact or phase, there is at times a disregard of other common actualities, but generally the artist's meaning is worth finding out. Even where the genius of imitation, the power of subtle characterisation, is absent, the work is generally suggestive and useful. The mere working under comparatively unconventional principles has its influence in spreading those principles. Schools and coteries may be a mistake in art, but it is a way nature has of working, and more of the New English Art Club spirit is what is now wanted. Some of the pictures, such as Nos. 9, 12, 13, I confess I have not as yet understood, but doubtless the artists themselves knew their intention. They cannot be expected to speak down to uncultured sense. Some, again, would probably look better in other than the gallery light. Altogether, a thorough and an open-minded study of the collection will leave the visitor with a very different impression from that gained from a first and prejudiced observation. It is an interesting test, after becoming steeped in the spirit of the Dudley Gallery, to walk into a neighbouring gallery, where the work is of a more conventional type.

There is a special feature in the Exhibition which makes me draw the attention of photographers to it. In the centre of the gallery a large portfolio of photographs of the actual paintings on the walls is placed open for inspection. The photographs appear to be in sepia platinotype, and are by Mr. Fred. Hollyer. Such an opportunity for comparison is of considerable value to the photographer. It helps him materially in understanding the qualities of the works on the walls, and probably removes some prejudices. The photographs are a lesson in translation of colour into tone. They show how imperfect colour may weaken a painting, for in one or two cases the effect of the photograph is more distinguished than that of the painting. They show, also, how much too black the majority of out-door-taken photographs are in their shadows. They are beautiful as direct photographs are rarely beautiful. Something of this attraction lies, no doubt, in the reproduction of the painter's touch in the photograph. We grow to admire handling, perhaps, far too greatly, but still there is always a charm in the felicity of imitation gained by a simple stroke of the brush—the simpler the touch or means, the greater the charm.

Some of the photographs fail in rendering accurately the delicate colour relations, but the excellence of others is just as noteworthy. The reproduction of the very powerful picture entitled "Dieppe," painted by Mr. Walter Sickert, is exceedingly good, and makes one conclude that Mr. Hollyer used orthochromatic plates and screens in his work. Photographers should not fail to examine this and all the photographs with the originals in the gallery. A more interesting and instructive study, even if it lowers photographic conceit, could hardly be provided.

One of the most noticeable pictures in the gallery is No. 33, "Portrait of Mrs. Cyprian Williams and her two little girls," by Mr. P. Wilson Steer. We are frequently given portraits of people seated in arm-chairs, and the conventional view is as seen from the height of the eye of the painter as he sits at his easel. Mr. Steer's view is from the height of one standing, not an uncommon aspect, as everyone will admit. However, we are so accustomed to the ordinary thing that a first and prejudiced impression is that Mr. Steer must have got upon a table or the top of a pair of steps to plan the arrangement; but a simple experiment at home reveals our ignorance, and shows us how blindly we go about. Apart from this, also, notwithstanding an impression of "dolliness" about the little girls, the picture grows upon one, and the portrait is real and living. Another characteristic picture by the same artist is No. 15, "Ballerina Assoluta," an impression of the light and perspective of a theatre stage, with a ballet dancer as seen from a side box high up. The picture is a very long one; the "première danseuse" is at the extreme bottom towards one corner; the stage itself, with streams of light athwart it, forms the background. It is quite safe to say that Mr. Steer knows, from his study of it, more about the truth of this view than anybody who is likely to criticise it, but the one thing that struck me was that the length of the figure was too great for the perspective of the stage and the downward direction of the sight. The light effect would, perhaps, show better in some other situation and light than the gallery affords. Indeed, although the judicious selection in the Dudley Gallery is pleasant after the jam-cram arrangement of the Academy and some other galleries, still the pictures call for such separate treatment as hardly any gallery could be expected to afford.

A noticeable subject is No. 4, "The Skating Rink," by Mr. George Thomson. At first, to a Philistine, this may seem inexplicable or advertisement-like in seeming woodenness, but the go of the figures in one direction, and the electric lighting, have been the aim of the artist, and the effect is not soon forgotten. The vividness of the bit of green upon the lady near the centre of the picture was a stumbling-block to me, and it did not say its word to me, although I waited humbly for it. In Mr. Thomson's other work, No. 11, "At the Window," there is much that is worth studying, but the funnels of the steam-launches appear to be a good deal nearer than the launches themselves.

A picture which has a peculiar fascination is No. 81, "The Common," by Mr. Francis Bate. At first, nothing but the vivid green expanse of foreground can be felt; but on coming and coming again and again, as it is impossible to avoid, this staring character becomes grass in sunshine, and it is one of the prominent memories of the Exhibition.

To mention briefly some of the remaining pictures, where almost all are striking, I would point to No. 1, a clever study of a head, by G. P. Jacomb Hood; No. 20, "Brighton," by Theodore Roussel; No. 22, "Changing Pasture," by A. B. Docharty; No. 26, "The Pink Rose," by J. E. Blanche (note the harmonious frame); No. 34, pastoral, by E. A. Walton, full of life and suggestion; Nos. 48 and 59, popular and delightful pictures, by Harrington Mann; No. 45, "Gathering the Flock," by W. J. Laidlay; No. 50, "'Twixt River and Broad," a delicate bit of pale orange and green, by J. Reffitt Oldfield; and also Nos. 62, 67, 70, 77, 86, 90 (note comparison of outdoor and indoor light), 98 (a fine picture, but is the perspective right from any point of view?), 101, and 105 (done rather as though on opal).

No. 88, "October Ploughing," has some attraction, in spite of many eccentricities. The ploughman's gait reminds one somewhat of the postman in the clever mechanical toy recently in fashion, his bell-trousers have an East-end character about them, the ploughing seems to be going on upon a carpet, a tree grows out of the plough, and the horses have short bodies, long legs, and a queer fixing of their heads. A key would possibly open our eyes, and Mr. Brown Macdougall could, no doubt, supply the key. There are several of the pictures about which the visitor, if he be not too clever, finds himself sitting at the feet of the artists, looking somewhat as a novice examines a photograph in the stereoscope—that is, in a waiting, enquiring attitude, expecting the meaning and truth to burst upon the mind. In most cases this result, when it comes, is worth the waiting for, and it stays. I can only repeat, go and see the pictures.

---

West London Society.—The annual smoking concert was held at the Richmond Hotel, Shepherd's Bush, on May 9th. The attendance was somewhat small, but the entertainment was good, and highly appreciated.

The Lowestoft and District Photographic Society.—A Society under this name was formed on the 5th inst. Mr. F. Mayhew was elected president; Mr. W. J. Roberts, treasurer; Mr. W. Stringfield, chairman; and Miss A. Lee Stringfield, secretary. It was decided to communicate with the committee of the School of Art with a view of this Society forming a technical class in connection with that Institution.

## PHOTOGRAPHY IN AUSTRIA.

NATURE PRINTING—ALUMINIUM LIGHT—TOLUOL MATT VARNISH.

AT the meeting of the Photographic Society on the 20th January, 1891, was read a paper on an historical process. It is not, however, a purely photographic subject which is in question, but the discovery known under the name of "Nature Printing," but now existing only in the shape of Woodburytype. Some people, doubtless, still remember the melancholy Henry Bradbury, the son of Dicken's and Thackeray's publisher of the house of Bradbury and Evans, and himself founder of the firm of Bradbury and Wilkinson, who died in 1860. In 1850, while still a young man, he was a pupil at the State Printing Office in Vienna, just at the time when the discovery was made that it is possible to take impressions of leaves on soft lead and then produce images in intaglio from them by means of galvano-plastics. In this way illustrations were made not only of twigs, but of whole plants. Also cut agates and other veined stones were corroded, and impressions of them taken in this same manner. The affinity of this process to Woodburytype is manifest. In England it was patented by Bradbury. The Austrian patent is dated 12th October, 1852, but the process was thrown open to public use. In proud self-consciousness at that time Auer, the father of the discoverer of the net on incandescent gas-burners, said Russia made Jacobi's use of galvano-plastic free in the year 1837; France, Daguerreotype in 1839. Now Austria has furnished a worthy companion to the two discoveries. But the graphic arts took another direction, and "Nature Printing" was forgotten. Nor was this the first time, for, as Mr. Einsle proved at the January sitting of the Photographic Society, the same process was discovered in 1763. He showed the meeting a book entitled: "Die Nahrungs-Gefaesse in den Blaettern der Baeume nach ihrer unterschiedlichen Austheilung und Zusammen fuegung sowie solche die Natur selbst bildet, abgedruckt von Johann Michael Seligmann, Kupferstecher in Nuernberg. Nebst Tit. Herrn Hof. Raths Christoph Jacob Treue Historischer Bericht von der Anatomie der Pflanzen und von der Absicht dieses Workes. Nuernberg, gedruckt bey Johann Joseph Fleischmann, 1748." This book contains coloured illustrations of leaves exactly like those produced by nature printing, except that they appear to be from relief plates, whereas Auer prepared copper plates. We can obtain only one passing hint as to the manner in which the old Nuremberg master went to work, viz., on page 4, where he says "he will print the thus prepared vessels (*i.e.*, the skeleton leaves) themselves . . . . because it would be impossible to imitate nature perfectly by drawing or copperplate engraving." The second preface, which begins to describe the process employed, is imperfect in the copies of the book to be found here. Should any readers of this journal possess a complete copy, it would be interesting to learn from the second preface in what way Seligmann prepared his plates. Communications on the subject may be addressed to Herr Einsle, Antiquary, Vienna.

*Aluminium Light.*—At the sitting of the Photographic Society on the 3rd March was shown a picture taken by aluminium light. Powdered aluminium, or aluminium waste from the leaf, burns in a spirit of wine flame, although more slowly than magnesium. But with bodies which give off oxygen, or in oxygen itself, it produces an extremely actinic light, and also without smoke, which is its chief advantage. As the experiments are being continued, and as the fact that Messrs. F. Probst and Max Putz are conducting them offers a certain guarantee of success, I hope another time to be able to report again. At present we have some very nice specimen pictures taken by it.

*A New Matt Varnish with Toluol.**—That part of coal-tar which passes over between 100° and 130° centigrade contains essentially toluol (toluene) besides a little benzene. This is the toluol of commerce. It is not so valuable as benzene, boiling at 110° C.; benzene boils at 8° C. Like benzene, toluol has the property of separating resin from an ether solution of sandarac, but toluol possesses this quality in a higher degree than benzene. In order to obtain a matt varnish from 100 c.m.$^3$ of an ether solution of sandarac 1 ÷ 9, an addition of 45-50 c.m.$^3$ of benzene is necessary. In my experiments, 35 c.m.$^3$ did not yield any matt varnish; with 40 c.m.$^3$ of benzene I obtained films more or less dull. But if one uses toluol with 30-35 c.m.$^3$ of it to 100 c.m.$^3$ of solution of sandarac 1÷9, one obtains a varnish which dries matt. The following formula repeatedly produced good results in the preparation of toluol matt varnish:—

| | |
|---|---|
| Ether ... ... ... ... | 100 c.m.$^3$ |
| Sandarac ... ... ... ... | 10 grammes |
| Toluol ... ... ... ... | 35-40 c.m.$^3$ |

Put the ether into a little bottle, and add 10 grammes powdered sandarac; if well shaken, the resin dissolves in a few minutes; then filter the solution through a folded filter, and mix the filtered matter with 35-40 c.m.$^3$ of toluol. Although one obtains a matt varnish with a smaller quantity of toluol, yet, nevertheless, it is advisable to add 25-40 c.m.$^3$ of it, as the layers become more equal, and wavy stripes are not so liable to arise. Pour the matt varnish on to the middle of the plate held horizontally; by tipping the plate gradually, one makes the varnish run into the corners, and, finally, run off the surplus at the corner by tipping the plate, not moving the plate on the level till after that. It is important to observe this procedure exactly, in order to obtain equal matt layers. It is not advisable to swing the plate at the beginning of the pouring on; it should not be done till the plate is vertical. The beginner requires pretty long practice before he succeeds in covering the plate with matt varnish uniformly. This matt film almost at once takes soft pencil (K1) very well and uniformly, and allows of the most varied retouching with stump or colour. The film shows relatively great resistance. The addition of some drops of absolute alcohol influences the formation of grain; if one adds more than thirty drops of alcohol to the above quantity, the shadows easily become wavy. A strong dilution with ether acts similarly. In the above formula, one may use 120 cm.$^3$ instead of 100 cm.$^3$ of ether for dissolving the sandarac, which produces a less covered matt varnish showing a more open grain; but in its total effect it differs little from concentrated varnish, but it permits less dabbling and rubbing with the damp hand ball. As to the current price of materials: Toluol matt varnish costs less than benzene matt varnish; 1 Kg benzene puriss. costs (in Austria) 2s. 6d. to 5s.; ordinary benzine, 1s. 8d. per kilogramme. At the same time, in regard to the cost, one must consider that, under the same conditions, less toluol than benzene is required as an addition to the solutions of

* From the *Photographische Correspondenz.*

sandarac. To all who have difficulty in producing benzene matt varnish, toluol matt varnish is to be warmly recommended for a trial. The addition of more than 40 cm.$^3$ of toluol would cause the separation of flaky resin. A correction might be made by the addition of an ether solution of sandarac. If one adds less than 35 cm.$^3$ of toluol, the matt films become too transparent and unequal. Finally, I would mention that toluol can be obtained of Herr Adlen, 10, Bezirk, Vienna. It has a specific gravity of 0·865 at 19° C. STYX.

## COLOUR.*

BY W. E. DEBENHAM.

There are various other methods, besides that of using several lanterns, of combining the effect of various colours. A very usual lecture experiment is to revolve a disc at such a rate that its various parts appear homogeneous. The disc is divided into sectors, variable in size, and each of some distinctive colour. Thus, if blue, red, and green occupy the proper proportionate spaces, and the disc is revolved whilst a bright light is turned on in front of a dark background, the effect is to produce white. Helmholtz also gives the following method. Lay two discs of the colours to be combined upon a horizontal surface. Then hold a glass plate vertically, so that the reflected image of one disc appears to cover the other disc looked at directly through the glass. This method gives us the opportunity of increasing the effective power of one or other colour according to the greater or less angle at which the plate of glass is observed. The discs should be laid on a dark or black surface; if surrounded by white, they look dark and dingy. Another method which I propose to show to-night, and which has the convenience of demonstrating composition of colour by a single lantern, is to have the colours in alternate stripes, and show them in the lantern first as the two colours distinct, and then, by throwing the image very much out of focus, allow them to blend.

If the lens cannot be sufficiently thrown out of focus for complete blending, a piece of white card or paper can be held so near the lantern as to intercept the rays, and be so completely out of focus as to ensure blending. The grating of red and green now shown in the lantern gives a sharp image on the screen, but by moving the lens, or holding a piece of card on the screen and advancing it to the lens, the lines of the grating disappear, and are substituted by a general yellow.

These methods depend upon the colours to be combined falling upon the same part of the retina. I find, however, that it suffices to allow them to fall upon corresponding portions of the retina of the two eyes. The frames now handed round contain a film of green in the opening for one eye, and of red in the opening for the other eye. If a light be looked at through these spectacles, it will not be seen of the colour of either film, but as a yellow—a greenish yellow. If there were as convenient a way of modifying the illumination to either eye as there is of lowering the light in one of a pair of lanterns, it might be so arranged that the yellow should not be found to incline either to the green or to the red. In another set of these spectacles, I have made the film for one eye red, and for the other eye it is divided. The lower half is of the same green as before, and the upper half of a bluish green. On looking at a light through the red and blue-green it appears white; but a slight shifting, so as to bring the other green into use, gives yellow.

Blue and yellow have been called primary colours, and by mixing these in transparent pigments a good green may be compounded. They do not, however, give green, but white, when their effect is produced simultaneously on the eye. This will be seen by allowing the blue and yellow discs now in the lanterns to overlap on the screen; also by looking at a light through the blue and yellow spectacles shown, and in other ways.

White, which, generally speaking, is a compound of all the colours, may be produced to the eye by compounding two colours, and any two colours which compounded produce the effect of white, are said to be complementary to each other. Starting from the red end of the spectrum, we may take any colour from that to a yellowish green, and we shall find another colour in the spectrum towards the violet which, compounded with the first, will give the effect of white. These whites are to the eye indistinguishable from one another and from ordinary white light, but may be recognised by analysis with the prism, or by holding coloured screens instead of white paper in the path of light. Thus, in the white compounded of greenish blue and red, violet loses its brightness, whilst red comes off badly in the white composed of violet and yellowish green. Green, not inclined to yellow or blue, requires a colour not to be found in the spectrum for its complementary, viz., purple, a compound of violet and red.

If we consider what colours appear to be related and what opposed, we find that a circle may be arranged, commencing with the spectrum violet and going through the series to red, which may be made not quite to close the circle, but may be blended into the violet by purple. In fact, the red and violet, although at the opposite ends of the spectrum, do not strike the eye as being the most opposed in character, nor do they act as complementaries to each other. In the colour circle now shown, I don't think anyone unacquainted with the spectrum would select the place between the violet and red as the starting point in particular any more than that, say, between the yellow and red or the yellow and green.

This approximation in visual character of the two ends of the spectrum, and most contrasted in wave-length and in physical characteristics, may be due to the fact that the violet is approximating in the wave-length to half that of the red, and, in rapidity, double. A little beyond the violet of the visible spectrum this simple proportion holds good. Now, as each colour sensation acts not only at a definite point, but over a considerable portion of the spectrum—recognising wave-lengths, that is, that are anywhere near its maximum of sensitiveness—it seems possible that, as we approach the relation of double rapidity such as exists in the musical octave, that sensation nearest to that of double rapidity may be excited to some extent, and thus the relationship of violet and red as approximating to one another, instead of striking us as the most opposed, may be accounted for. On the other hand, the fact must be remembered that the vibration of actual half wave-length of red is invisible.

The slide next thrown on the screen illustrates the essential difference between combinations of colour sensations, such as have been shown, and combinations of coloured films or pigments. In the first case we have proceeded by additions of sensation; in the present case we proceed by subtraction. In this slide three discs of

* Concluded from page 339.

yellow, violet, and greenish blue respectively overlap, all three at the centre, and in twos for a space along each side. Here, where the blue-green and yellow overlap, we have full green, the yellow and violet transmit red, and the violet and blue-green give blue. In the centre, where all three overlap, is darkness. The explanation is that the violet and yellow films are both transparent to red, the violet and blue-green to the blue, and the blue-green and yellow to the full green. Where all three overlap, as the third film obstructs the particular light passing through the other two, we have darkness. A mixture of pigments is somewhat similar. Here each pigment absorbs some of the rays that would be allowed to pass by another pigment, and the result to the eye is what is left after the absorption by the constituent pigments. With transparent pigments, therefore, of complementary colours we obtain black. A very good water-colour black may be obtained by mixing lake, gamboge, and transparent blue.

The different effect of colours seen, as blended by their separate effects on the eye, and blended by being mixed, may be illustrated by making a small stipple of blue and yellow, compared with a wash of a mixture of the same colours. In the latter case the effect is green; in the former, when looked at at such a distance that the separate dots are no longer noticed, the effect is that of a low white or grey.

The three colour sensations existing in most eyes are not, in all cases, complete. There are some persons who appear to be deficient either of a green or red sensation, and who are, therefore, to a great extent, colour-blind. The sort of vision of colours experienced by the green colour-blind can be approximately understood by holding this sheet of coloured stripes—coloured red, yellow, green, blue, and violet—in the light shown by two lanterns, one of which is furnished with a blue or violet-blue disc, and the other with a red disc. Here the green strip appears almost black, and the other colours somewhat different from what they appear in a white light. The position of the person who is red colour-blind may be estimated by holding the colour strips in a light compounded of green and blue. Here the red is black; the general effect rather inclined to monotony. It has been stated that as many as four per cent. of males are colour-blind. The proportion of females is considerably less.

---

Royal Institution.—Dr. A. C. Mackenzie, principal of the Royal Academy of Music, will on Thursday next (May 21st) begin a course of four lectures on "The Orchestra considered in connection with the Development of the Overture"; and Professor A. H. Church, Professor of Chemistry in the Royal Academy of Arts, will on Saturday (May 30th) begin a course of three lectures on "The Scientific Study of Decorative Colour."

Photographs in Colour.—The newspaper reports which a few months back gave such sanguine accounts of M. Lippmann's experiments, and which told an expectant world, for about the hundredth time, that the art of taking photographs in natural colours had been accomplished, laboured under a mistake; but the error has been the means of calling attention to the undoubted fact that certain photo-mechanical processes can produce pictures in colour which it is extremely difficult to distinguish from the original water-colour drawings from which they are copied. Oil pictures can be reproduced with nearly the same success, and it is not too much to suppose that these new methods will supplant the chromo-lithograph and the oleograph. Those who are interested in knowing what can be done in this direction should pay a visit to the parent society's rooms at 50, Great Russell Street, Bloomsbury, where numerous specimens of photographs in colour are now on view, including examples of the process to which we called attention in our last issue.

## ART IN RELATION TO PHOTOGRAPHY.

As we stated last week, Mr. Valentine Blanchard's promised course of lectures on the above subject commenced on Wednesday. Mr. Blanchard began a most interesting discourse by apologising for the necessarily elementary nature of much which he would have to say. Commencing with straight lines, and building them up into squares, cubes, circles, &c., he showed how more perfect forms were arrived at in the pyramid and the parallelogram, and how such forms benefited by being seen in perspective, and still more improved by the breaking of these straight lines, and the rubbing down of corners, as illustrated in stone work exposed to the action of the weather.

He pointed out that the various methods adopted by painters during the past four hundred years had developed certain art canons. Some of these may have grown rusty and lose their force, while new notions will often make a stir for a time, and threaten to displace the older rules. Painters work under such different conditions to photographers in having the power of selection and arrangement of the objects represented, that it might be argued that the latter, handicapped as they are by the limitations of the camera, can have no use for art canons. But the photographer cannot but benefit by studying the rules which guide the painter in his work, and must gain by such studies in educating his eye and powers of observation. But there must be *capacity* to see. It is a power which a man cannot purchase with his apparatus, and this is the reason why hundreds of amateur workers employ the camera who never produce artistic results.

Mr. Blanchard then pointed out, by numerous architectural examples, shown by the lantern, how primitive man developed, from mere wooden structures, stone buildings, in which the features of the wooden erection—the beams, supporting piers, and joints—were idealised. From such materials the Doric order was evolved, and this in turn gave place to more ornate forms, of which the Corinthian Capital—the origin of which tradition ascribed to an accident—was a good example. From these beginnings gradually grew the Greek temple, and later the architectural monuments which still remain to us. The Gothic nave was probably suggested by tree trunks with their branches intertwining overhead—so art comes from nature; and nature never being formal, pictorial art should avoid all appearance of formality.

Mr. Blanchard then proved, by numerous examples, how the occupation of the centre of a picture by the principal object resulted in weakness of composition, and contrasted a photograph of a church in which the fault was glaringly apparent, with one of the same building taken from another point. He closed his lecture by giving various examples of the pyramidal, wedge form of composition, and angular perspective, taking care to point out how balance can be secured by the introduction of objects in the right place. He advised his hearers to visit the National Gallery in order that they might study the originals from which many of his examples had been copied, and many other pictures to which he directed their attention. He also paid a tribute to the works of certain photographers who, in the old days, had produced pictures which, with all the modern conveniences of dry plates, it would be very hard to beat. Mr. H. P. Robinson's "Fading Away" was one of these. Mr. Blanchard very happily lightened his remarks by many a little reminiscence of those with whom he had been associated.

## DR. J. M. EDER'S CRITICAL EXAMINATION OF SCHIENDL'S "HISTORY OF PHOTOGRAPHY."*

BY C. SCHIENDL.

THE journals that I mention are no longer by me, but I can take Dr. von Monckhoven as a guarantee, for he, in his "Traité Général de Photography" (1856), and more explicitly in his "Historique du Procédé au Charbon," quotes this fact, and writes that Mungo Ponton, in the above quoted pages, makes the remark: "*Le bichromate de potasse est plus facilement reduit par la lumière en présence de matières organiques, et principalement de la gelatine, que s'il est seul* . . . ." (Bichromate of potass is more easily reduced by light in the presence of organic substances, especially gelatine, than it is alone . . .).

In the first years after Ponton's above-mentioned first publication (see PHOTO. NEWS, May 1st, p. 331), he alone repeatedly accentuates the fact of the sensitiveness to light of chromated gelatine; till much later the discovery was practically converted into money by another, through whom it became universally known; so that one can, or, rather, must acknowledge Mungo Ponton as the discoverer not only of the sensitiveness to light of chromates with organic substances in general, but also of gelatine specially for photographic processes. Eder's reproach, which has its sole support in Ponton's first publication, that my "historical delineations" are to be regarded only as castles in the air, as well as his disapproving phrase in reference to this, rest on a total ignorance of the facts, or possibly on an intentional perversion.

On page 151, Herr Eder writes: "We will, however, give a warning against some other stumbling-blocks to historical fact in Schiendl's 'History.' I note, especially, the following statement on page 58 of Schiendl's 'History': 'Farther, Legray gives the application of albumenised instead of salted paper—a discovery which, later on, Fox Talbot endeavoured to claim.' The author credits Le Gray with the discovery of albumenised paper, and dates it as June, 1850. This statement of the discovery of a printing process of so much importance to photography is also incorrect, for, earlier than that, Blanquart Evrard employed albumenised paper for positive printing, and described its properties in a communication to the French Academy of Sciences at a meeting held on May 27th, 1850."

The quotations concerning this discovery involve a complete distortion of my assertions, as well as an unjust statement on his part, for, firstly, I have not represented Legray as the discoverer of albumenised paper, but only mentioned that he also recommends the application of albumen in his "Traité"; and if the critic had read through my "History" with more conscientiousness and less animosity, he would have found that three pages previously (page 55) I expressly quote as follows:—"Blanquart Everard, therefore, mentions in the year 1848 a method of overlaying paper with albumen which contains chloride salts, by which the positives gained considerably in depth of tone." Therefore, both Eder's remark respecting my statement, and his own so-called correction respecting the supposed first publication of the 27th of May, 1850, appear to be imaginary.

The said critic says further (page 151): "In a similar way, Schiendl misdates the publication of the application of hyposulphite of soda as a fixing agent. The author, on page 48, says that Herschel recommended this fixing salt in the year 1840, whereas, in fact, this discovery was made already in the year 1839 by Talbot, with whom he was recognised to be in frequent communication, and was communicated to the Paris Academy March 1st, 1839."

Here Herr Eder has not only set forth my statement wrongly, but has also betrayed a surprising ignorance of the actual discovery of soda as a means of fixing.

In my "History," page 48, it is literally: "Incomprehensibly, none of the said inventors thought of hyposulphite of soda as a means of fixing, which had been already recommended by Herschel in the year 1819 as a means of rendering soluble the silver haloids until Herschel in 1840 recommended it again."

The impartial reader, when comparing this quotation with the above statement of Eder, cannot mistake the malicious intention of this critic, for my wording has been falsely rendered, not only with reference to the first acquaintance, but has also been forcibly mutilated by the omission of the word "again." Besides this, one can see that his own so-called correction with reference to the date 1839 (which date he mentions twice, therefore no printer's error can be inferred) is unjustifiable and incorrect; and with such statements dares to describe *my* statements not only as erroneous, but as false, which word always contains the secondary idea of intentional deception. The unprejudiced reader may therefore judge from the above quotation from Eder's critique, and the wording of my statement, which of the two could be described as "false."

On page 152 he describes as false my manner of writing the name Legray, and asserts that it ought to be written Le Gray.

Concerning this, I refer to the manner of writing of most French journals and books. The Frenchman, Charles Fabre, also, in his great and hitherto unequalled "Traité Encyclopédique de Photographie," writes the name Legray in the manner that Herr Eder calls false. Further, I find in the letters of Frenchmen with whom I have been in correspondence, on account of my "History," the name Legray written after my manner; and after such authorities, I believe I have good ground for upholding my way of writing the name, against the in no way recognised authority of my critic; but, in either case, it is quite immaterial to the proper understanding of the meaning.

Next, Herr Eder declares my quotation of Legray's communication respecting the collodion process false, and writes:—1. "Schiendl tells us that Le Gray employed hydrofluoric acid; Le Gray, however, expressly said 'methylhydrofluoric ether.' 2. Herr Schiendl writes 'fluoride of potassium *or* sodium,' while it should be 'fluoride of potassium *and* sodium.' 3. Le Gray employed 'aceto-nitrate of silver,' and not 'silver nitrate,' as Schiendl tells us. 4. Le Gray only obtained his result with an exposure of *twenty* seconds, and not five seconds."

Finally, the said critic declares that I was not in possession of the original text of Legray's communication, and places against it another text, pointed out to him as the original text. To this statement, I reply that my quotation is the real original text. In a pamphlet which Legray issued in 1850 (I have it no longer by me, for all the works I used I have returned some months since; but I find in Monckhoven's "Traité de Photographie" (1856) a literal extract from the same pamphlet, and, as this author offers indisputable warranty for accuracy, I will here repeat his quotation literally. In the said pamphlet, which Dr. Eder has apparently never seen, or he would have reflected more maturely upon his "correction,"

* Continued from page 331.

stands the following publication, according to Monckhoven:—"Je viens de découvrir un procédé de photographie sur verre par l'éther fluorhydric et le fluorure de potassium, dissons dans l'alcohol à 40°, mêlés à l'éther sulphurique et saturé avec le collodion—je sensibilise ensuite avec aceto nitrate d'argent, et j'obtiens ainsi des épreuves dans la chambre noire en cinq secondes à l'ombie; je developpe l'image par une solution très faible de sulphate de fer. . . ."

As Herr Eder does not appear to be very conversant with the French language, I will give the literal translation in comparison with the quotation contained in my "History of Photography."

| From the Original Text, "Monckhoven." | The Quotation contained in my Work. |
|---|---|
| "I have just discovered a photographic method on glass, by means of hydrofluoric acid and fluoride of potassium in 40° alcohol, and saturated with sulphuric ether and collodion. I afterwards treat it with aceto-nitrate of silver, and obtain pictures with it in the camera in five seconds in the shade. I develop the picture with very weak solution of sulphate of iron." | "I have just discovered a process, by which I obtain photographic pictures on glass by means of hydrofluoric acid and fluoride of potassium mixed with sulphuric ether and collodion. Such a mixture poured upon glass I treat with nitrate of silver, and can obtain pictures with it in the camera in five seconds in the shade. I develop with weak solution of sulphate of iron." |

From the original text quoted above, and that placed opposite to it, there is abundant proof that the four mistakes that Dr. Eder pretends to have found out are based on perfectly wrong information on his side, for, first, Legray does *not* speak of methylhydrofluoric ether, but only of hydrofluoric acid. Herr Eder, in his imperfect knowledge of the French language, takes the term *éther fluorhydrique* (hydrofluoric ether) for a mixture of hydrofluoric acid and ether, whereas it means, in fact, hydrofluoric acid (gas). Of a methylhydrofluoric acid, which, again, Eder takes for a non-existing organic substance, I have found absolutely no mention, and if perhaps the photographer (not the chemist) Legray may have spoken of methylhydrofluoric ether here and there in one of his other essays, which very likely Herr Eder had possession of, it could only have been in reference to the fact that he had added some methylated spirit to it to make a better solution, as, in those days, the latter was generally considered the best means of solution; still, it was not a "non-existing organic substance," for which Professor Eder takes it, but only a simple mixture.

Second. It ought to be, as stated in my work, "fluoride of potassium *or* sodium." Legray mentions later that *instead of* fluoride of potassium, sodium may be used; therefore Eder's assertion that it ought to be fluoride of potassium and sodium is wrong, as it concerns only the formation of fluoride of silver.

Third. That Legray writes "aceto-nitrate of silver" proves, not as Dr. Eder believes, that he applied the double mixture aceto-nitrate of silver, but only silver nitrate mixed with the least quantity of acetic acid, which was then exclusively used, but with which nobody meant the double combination. I could, therefore, quietly pass over the word *acid* as quite irrevelant.

Fourth. Dr. Eder's information that Legray mentioned an exposure of twenty seconds, and not five, as I stated, is not a true statement, as is evident from the above text, authenticated by Monckhoven.

I am, therefore, in the agreeable position of being able to maintain all the "inaccuracies" (so-called by Herr Eder) that exist in the wording of my "History," and, on the other hand, of being able to put down Eder's statements as merely the result of his ignorance of facts, and to the determination on his part to prove unpardonable mistakes in my work.

*(To be continued.)*

## INTERNATIONAL PHOTOGRAPHIC EXHIBITION AT VIENNA.*

The International Photographic Exhibition in Vienna, held in the Austrian Museum, was opened on the 4th inst. by the Grand Duchess Maria Theresa, in the presence of Prince Phillip of Coburg-Gotha, Sir Augustus Paget, the English Ambassador, and many other illustrious art patrons. The exhibition is an exceedingly interesting and artistic one, and among the exhibits may be found many masterpieces. The jury have been very strict in admitting only works taken directly from nature, so that out of four thousand sent in only six hundred were hung. The works of both amateurs and professionals were eligible, and we must, before mentioning individual works, call attention to the artistic excellence of the English photographs, which are undoubtedly the best, both as regards figure studies and landscapes.

Among the honorary exhibitors are the Princess of Wales, the Archduchess Maria Theresa, and Duke Ferdinand of Toscana. The photographs of the Princess of Wales are instantaneous. Two schools of photography are represented, the "old" and the "new," or impressionist school. In the former the desired result is attained by attention to detail; in the latter, the pictures are worked so as to get an artistic and picturesque effect—just the same difference as is to be found in the paintings of to-day and those of some years ago. Some of the new school photographers even work with a pin-hole camera (without objective), as Alfred Maskell; others, like Lionel Clark, touch up their pictures to such a degree that they appear half paintings and half photographs.

Foremost among the impressionists is George Davison, and it must be confessed that both his landscapes and figure pictures make a truly artistic impression. When they are compared with those of J. Gale, who works in the spirit of the old school, one can only say that all roads lead to Rome.

Masterpieces are the animal studies of Gambier Bolton; his young dachshund, his lion, and his tiger are portrayed in a manner which catches their peculiarities to perfection.

There are many charming flower studies, and among the best those of Henry Stevens and Robert von Stockert. The artistic value of the photographs of Harry Tolley, Lyddell Sawyer, and H. P. Robinson is world-renowned, just as the Alpine photos of Vittorio Stella are valued by all lovers of mountain scenery. The exhibition deserves the warmest patronage of the public, and will, without doubt, find it.

Photographic Club.—Subject for May 20th, "Hand-Camera Possibilities"; May 27th, "Cameras and Dark Slides." Bank Holiday outing at Gomshall (Surrey); train from Charing Cross at 9.28, London Bridge, 9.35; does not call at Cannon Street.

* Translated from the *Neue Freie Presse*.

## Notes.

The gentleman who writes the "London letter" for the *Philadelphia Times* has lately taken for his subject the craze which at this time possesses English ladies with regard to photography—not amateur photography, be it understood, but the madness which they have for being photographed by the professional portrait taker. If all be true which is written by this correspondent, the photographers of London must long ago have enriched themselves beyond the dreams of avarice. Many "smart" women in London spend, we are informed, a fourth of their pin-money on photography, with the necessary consequence that the photographic business has increased enormously; indeed, the lucky English photographer "is now regarded as necessary to the well-being of fashionable English society as the baker, the bootmaker, and the dressmaker."

We learn that it is the custom to have each child photographed on its birthday, and that, even a few days after birth, babies are photographed (in buff), and a copy of the portrait is pasted in the family Bible. Ladies are photographed in their different new gowns, and the pictures, touched up with colour, are kept in an album on the dressing table. The owner has then merely to indicate to her maid the number of the picture representing the dress which she wishes to wear, and she is adorned accordingly. At all family gatherings, from weddings to funerals, the photographer is present. He photographs the wedding breakfast at the moment when papa is wishing success to the happy pair, the bride as she leaves the house for her honeymoon, &c., &c. In some houses the whole of the rooms are panelled with family portraits, and every corner, every table, and every bookcase is laden with them. If half of this golden dream should be believed in by our friends across the water, there will soon be a steady stream of needy photographers setting in towards our own shores in the hope of sharing the spoil.

The unfortunate individual who is just now in trouble through his alleged discovery of the philosopher's stone, seems to have carried us back in thought several centuries —to a time when men of all conditions beggared themselves in their search after the same will-o'-the-wisp. The extreme simplicity which so often accompanies the highest inventive genius is well exhibited in the case before us. The new alchemist had, it seems, in his possesion a mass of gold equivalent in value to twenty pounds sterling, and he claims the power of being able, by a metallurgical operation, to increase it three-fold. Now, a simple calculation will show that beginning with that sum, and operating upon it seven several times, its value would be increased to £43,740. The simple minded man did not think of this, but actually asked another person for a smaller sum in order to continue his investigations. If he had been content to avail himself of his own enormous resources, the present trouble would not have come to him.

In a most interesting paper on the sources and applications of borax, which was recently read before the Society of Arts, the author, Mr. E. L. Fleming, gave a most exhaustive account of this most useful salt, and many of those who will later on have an opportunity of reading the paper when published in the Society's journal will learn for the first time what an important agent in our manufactures is this same agent. It is used by goldsmiths, coppersmiths, ironworkers, safe makers, machinists, metallurgists, in the earthenware industries, in glass works, in the manufacture of cement, soap, colours, cosmetics, &c. Indeed, it is difficult to say where the uses of borax end. Of course, its value to photography was referred to, not only its employment in the toning bath, but also as a water varnish, and as a means of giving a gloss to collotype prints. Its use in the preliminary treatment of paper used for Woodburytype prints was also mentioned.

A government, we suppose, is nothing without its "rights"—or what it chooses to call its rights. A series of photographs of public buildings in India has recently been published by the Indian Government, with "a reservation of rights." Commenting on this fact, the *Hindu*, a native journal, remarks that it does not say much for the intelligence of the Government of India that such a restriction should have been allowed. There is nothing to preclude anyone from setting up his camera and obtaining a *fac simile* of the same object. "Having no rights, prescriptive or otherwise, in the original, we fail to see how a 'close preserve' could have arisen or be permitted in reference to objects accessible to all." So says the *Hindu*. This is all very well; still, government or no government, it is not pleasant to have your photographs copied without a by-your-leave, or with-your-leave. If the *Hindu* had ever gone in for photography it would have appreciated this fact.

We do not notice any attempt in the Academy of this year to depict the monsters of the deep. In 1889 Mr. Burne Jones essayed his celebrated mermaid, who was accompanied by a few finny companions more orthodox in shape. In 1890 Mr. Wyllie tried his hand at painting fishes in the deep sea. In 1891 no one is bold enough to make the experiment. Can this be due to the fact that M. Marey has photographed the medusa, the squid, the ray in all their undulations and curves? The instantaneous photographer, with his revelations as to how horses really walk, has more than once made the artist uncomfortable, and, now that he has tackled fishes, it is not surprising that painters have not dared to rival him.

It is satisfactory to note that public men are gradually getting to realise what is expected from them. Directly a man is talked about, the public want to see his portrait; but hitherto the experience of newspaper editors is, that either he has no photograph, or that if he has one it is about twenty years old. Therefore, we express our satisfaction that the Labour Commission, recognising their duty to society, have had themselves photographed in a group. It is only right that they should. Indeed, we do not see why there should not be a State photographer, whose function it should be to take the portraits of everybody who is "wanted."

The Société Photographique du Nord de la France has hit upon a decided novelty. It has opened a competition for the illustrating of a new humorous story, entitled "Le Mortier de Marc Aurèle." Members of all French photographic societies may compete by belonging for one year to the Société du Nord, and paying the fee for that period. French amateur photographers possibly have more invention and sprightliness than those in England. We are afraid that if an English Society were to seek to augment its revenue and its members by a similar plan, it would not meet with much success.

## PHOTOGRAPHY IN FRANCE.

BY LEON VIDAL.

INSTANTANEOUS SHUTTER—A NEW DEVELOPER—PNEUMATIC SHUTTER AND PROPELLER—PHOTOGRAPHY IN COLOURS—ARTIFICIAL LIGHTS—MAGNESIUM LAMP—PLATES ON THIN GLASS—BIBLIOGRAPHY.

*Prize for an Instantaneous Shutter.*—At the meeting of the Society of Photography on May 1st, presided over by M. Janssen, it was announced that the Societé d'Encouragement have just founded a prize of 1,000 francs, to be given to the inventor of a shutter of more perfect type than any of those already existing. The conditions to be fulfilled are: rapidity of action, which ought to occupy about the one-fiftieth of a second or less. The time that it is quite open ought to equal half the time occupied by the action, or more if possible, the remainder being employed in opening and closing. The diameter of the entire opening ought to be equal to at least a tenth of the focal length of the objective with which the shutter is principally employed. The dimensions must be small, and appropriate to a travelling apparatus; the setting must be easily and readily brought about, the position optional, the times of exposure rapidly varied. If possible, the same shutter should be adaptable to lenses of different diameters. The prize, if won, will be awarded in 1892.

*Parmidophenol Developer.*—A paper on this subject has been presented in the names of Messrs. Lumière, jun.; the text will be published in the PHOTOGRAPHIC NEWS next week. We have made a trial of this developer, and have found it to be as stated, and it appears to us to exercise a very rapid action, much more so than either hydroquinone or eikonogen.

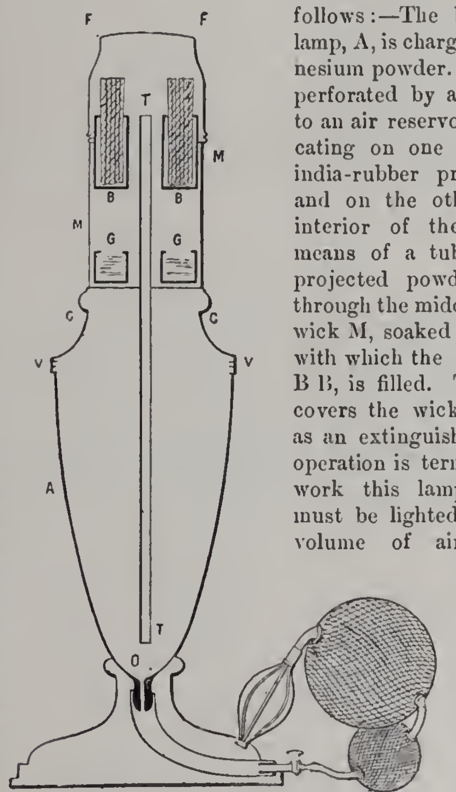
*Pneumatic Shutter and Propeller.*—M. Monti, the successor of M. Jonte, has brought forward a pneumatic shutter with a very simple action, worked by a metallic propeller which supplants the usual india-rubber ball. This propeller is formed of a little cylinder in which a piston works. It is sufficient to press the button of the piston in order to propel the air which works the shutter. M. Monti thinks that this modification will be advantageous in avoiding the wear inseparable from india-rubber bulbs. To perfect the apparatus, the india-rubber tube should be replaced by a material more durable.

*Magazine Camera by M. Lumière.*—This apparatus has been constructed by M. Monti from the designs of M. Louis Lumière. It is a sort of detective camera, carrying a great number of plates in little zinc frames. A simple movement—a pressure on a button—permits a new plate to replace that which has been exposed. This form of camera is compact, and in every way well designed.

*Photography in Colours.*—Following on the communications of M. Lippmann to the Academy of Science, M. de Saint-Florent—whose researches relative to photography in colours presented at that time a certain interest—has undertaken some renewed studies in another direction; little is at present known about the matter. His specimens sent to the Society of Photography have shown us nothing very interesting. One would describe the effect as solarisation produced by over-exposure, for the green bronze metallisation, which alone constitutes a colour, does not appear to be a reproduction of anything that would be green in nature. These proofs, obtained in a camera, required exposures of from eight to nine hours, attaining a result which is, for the time being at least, entirely useless. M. de Saint Florent promises a further report.

*Employment of Artificial Lights.*—M. Lande gives a description of the processes which he employs for photographing with magnesium light. He suspends to a thread of pyroxyline a little packet of flash powder—a mixture of magnesium and chlorate of potash—wrapped in paper and gun-cotton. Underneath there is another piece of thread attached to the other end of the packet, which is ignited by a match. M. Lande finds that great advantage is to be gained by this arrangement, and he shows, in support of his statement, a fairly large series of proofs, in general somewhat under-exposed, obtained by this means—principally figure subjects. The communication is, on the whole, only a *resumé* of the facts relative to this application which are already known, and does not set forth anything new.

*New Magnesium Lamp.*—M. Paul Nadar presented to the Society a magnesium lamp which he has had constructed, and of which the design is as follows:—The body of the lamp, A, is charged with magnesium powder. The foot is perforated by a tube joined to an air reservoir, communicating on one side with an india-rubber pressure bulb, and on the other with the interior of the lamp. By means of a tube T T, the projected powder is blown through the middle of a round wick M, soaked with alcohol, with which the annular cup, B B, is filled. The cap F F covers the wick, and serves as an extinguisher when the operation is terminated. To work this lamp, the wick must be lighted, and a large volume of air previously accumulated in the larger of the balls of the air-propelling apparatus. When the tap is once open, the air runs in a continuous stream, and all that is necessary is to replace that portion which has escaped by continually working the air-propeller. A dazzling flame springs up, and lasts till the magnesium is exhausted, and if it is necessary to have so long an exposure, the action can be maintained for two minutes. M. Nadar made experiments during the meeting with one or two lamps. One was able to take count of the great light thus produced, which permits not only posing, but also working with stopped down lenses, and even exposing a convenient time. The magnificent pictures, of a very large size, which were shown by M. Nadar, are proofs of the facts which he advances. They gained the admiration of the whole assembly, and M. Janssen addressed some well-merited compliments to M. Nadar. There is nothing



to hinder the execution of instantaneous pictures with this lamp. It is simply necessary to work as in broad daylight. This system is of great importance to photography of immovable objects (views of interior and post mortem portraits, &c.), and the employment of magnesium without chlorate puts any danger out of the question. The test of the strength of the light made at the "Conservatoire des Arts et Métiers" has yielded surprising results, surpassing, we believe, the power of 2,000 candles.

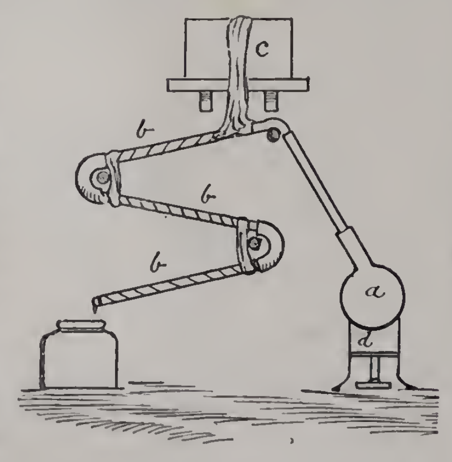
*Plates on Thin Glass.*—Messrs. Dehors and Deslandres are making bromide-gelatine plates on glass of $\frac{1}{30}$ of an inch in thickness. With these, double the number of plates, at least, can be packed in magazine cameras. The weight is diminished about two-thirds in the same number of plates.

*Bibliography.*—The Gauthier-Villars Library has just edited two very interesting numbers: first, "The Photography of Colours by M. Lippmann's Method," by M. Alphonse Berget, an *attaché* to M. Lippmann's laboratory; second, "Hydroquinone and Potash," by M. G. Balagny. Two new photographic journals have just seen the light of day; they are, first, the magnificent monthly *resumé* published by M. Paul Nadar, and already noticed in the Photographic News; secondly, *Heliochromy*, a monthly journal of photography, by M. Ed. Laussedaly, collographic printer, of Cloyes. This journal appears destined to uphold photo-collography in colours in opposition to chromo-lithography.

## A CHEAP STILL.

Mr. H. S. Haselgrove describes, in the *Journal of the Photographic Society of India*, an original form of apparatus for distilling water, which can be cheaply constructed by anyone in want of such a contrivance. We quote his description of it verbatim, leaving our readers to substitute for the Indian terms used their English equivalents:

"*a* is an earthen 'surahi' or goglet fitted with a cork, which has about six inches of glass tubing through it. *b b b* are glass tubes bound with about two thicknesses of linen; they rest at a slant on nails fixed in the wall; the bends are india-rubber tubing. *c* is a trough of water on a bracket, with a strip of cotton folded once or twice touching the bottom of the trough inside and the top of the upper glass pipe. *d* is a 'sigree' or stove. The cloth binding on the glass tubes should join near the elbows, and a small piece should hang near the receiver to let the cooling water drip outside of the bottle or receiver. If steam escapes uncondensed, another tube or two may be added. Without the 'sigree' my still costs less than one rupee."



## REPORT OF THE COMMITTEE ON STANDARDS.

It will be remembered that a Committee was appointed on March 11th, 1890, to consider the question of lens standards, and to report on the advisability of introducing other standards (such as for weights, measures, intensity of light, &c.) for use in photography. It was intended to continue the work carried out by the Society in 1881, but not to alter any of the standards then laid down.

The Committee consisted of the following gentlemen:—Capt. W. de W. Abney, C.B., R.E., F.R.S., A. Cowan, T. R. Dallmeyer, J. Sebastian Davis, W. E. Debenham, A. Haddon, H. Chapman Jones, Sir David Salomons, J. Spiller, W. Taylor, and L. Warnerke.

They have made a report so far as the extension of the lens standards of 1881 is concerned, and the Council have thought it advisable to publish the report without suggesting that it should be adopted by the Society. The question of standards will shortly be discussed at the Congress in Brussels, and it therefore seems premature to come to any definite decision until after the Congress has taken place.

The report of the Committee is as follows:—

### Object of the Council.

*March 11th*, 1890.—Capt. W. Abney, A. Cowan, T. S. Davis, W. E. Debenham, H. Chapman Jones, Sir David Salomons, J. Spiller, W. Taylor, L. Warnerke, T. R. Dallmeyer, and later on A. Haddon (president of the Lens Convention Committee), were appointed to consider whether any, and, if any, what explanatory additions should be appended to the report of the Committee of Standards for 1881, and to report on the question of standards in subjects not dealt with by that Committee.

The Committee held eight meetings, and the following questions were under discussion:—

### New Sizes for Lenses and Flanges.

1. In order to secure more universal acceptance of the Photographic Society's standards, the Committee entered into communication with the leading opticians, and invited members of the Convention Lens Committee to take an active part in the deliberation of this question. After an exhaustive examination of the subject, the Committee decided to recommend the addition to the existing sizes of flanges for lens screws 1 in., 1¼ in., 1¾ in., and 2¼ in. in diameter, with 24 threads to the inch; that no greater number of threads than 24 to the inch be used for photographic lenses and flanges of one inch and over; and that each flange or adapter shall have a mark indicating the top of the flange, so that when the lens is screwed home, the slot for diaphragms or the index of an iris diaphragm shall be uppermost. In addition to the indication of rapidity ratio of various diaphragms, the relation of focus to aperture was recommended to be marked on the diaphragms.

### Standard Sizes for Plates, etc.

2. In order to introduce uniformity in the sizes of plates and apparatus, the Committee recommend the adoption of standard sizes for plates, taking the existing half-plate, 6½ by 4¾, as the unit, and that smaller or larger sizes be produced by doubling or halving one dimension, so as to produce a series, 4¾ by 3¼, 6½ by 4¾, 9½ by 6½, 13 by 9½, 19 by 13, 26 by 19, &c., and a second series with a unit, 5½ by 4—namely, 4 by 2¾, 5½ by 4, 8 by 5½, 11 by 8, 16 by 11, 22 by 16; the optical lantern size to remain 3¼ by 3¼.

### Weights and Measures.

3. On the question of weights and measures, the Committee recommend that photographic formulæ be expressed in parts per thousand of the total volume, using parts by volume of liquids and parts by weight of solids. The units of weight and measure may be grammes and cubic centimetres per litre, or grain weights and grain volumes per 1,000 grain measures.

### Questions for Further Consideration.

Other questions which may require future careful consideration are the following:—

1. Uniform nomenclature of the photographic processes.
2. Unit of light for photographic purposes.
3. Determination of the actinic intensity of light.
4. Determination of the sensitiveness of photographic films.
5. Custom House formalities.
6. Copyright law.

---

## MESSRS. MORGAN AND KIDD'S WORKS, RICHMOND.

We lately had an opportunity of visiting these important works, the increasing business of which has necessitated extra accommodation, to be shortly again added to as soon as bricks and mortar can be put together on the large space of land which has been secured. Extended operations have also necessitated the use of the electric light, so that work shall no longer cease when daylight disappears. And it must be remembered that the light is not only required here for photographic operations proper, but is also wanted in the various studios where enlarged photographs are being finished in crayon, water or oil colours, as the case may be. The electric light installation is as thorough as it is efficient. The dynamo, worked by a large gas engine, stands in an out-house away from the main building. It is of the modern form known as the Kapp dynamo, a notable feature of which is the copper gauze brush, which emits no spark. From this out-house the cables are carried to the enlarging department, where the light is most required.

It may here be stated that the enlarging apparatus adopted by Messrs. Morgan and Kidd is of the simplest possible kind. A slanting mirror outside a square orifice in the wall deflects the daylight from the sky straight through the negative to be enlarged, without the interposition of any condensing lens. The objective, mounted in a simple form of camera, stands in the aperture, and the image formed by it is cast upon a vertical easel which slides to and fro on rails on the floor.

When it becomes necessary to supplant daylight by the less fickle electric lamp, the outside mirror is pushed away on a sliding bar, and the electric globe, pendant from a swing bracket above, takes its position outside the enlarging room aperture, while at the same time that aperture is filled in with a tissue paper screen to diffuse the light. The strength of the current is so regulated that the exposure required with this arrangement is just the same as with daylight. When the operator inside the room requires the light, he touches a switch at his elbow, and it is at his command. The switch is so covered that no visible spark can pass to the prejudice of any sensitive compounds which may be in the vicinity. We have, for the sake of clearness, spoken only of one enlarging apparatus, but it must be understood that there are several, each one having its electric lamp under the ready control of the operator.

As bromide paper owes its origin to Messrs. Morgan and Kidd, it seems only right and proper that they should still remain not only the largest manufacturers, but the greatest users of it. Here it is made, and it is possible to watch it from the moment when it leaves the coating machine to its exit from the building in the form of a handsomely framed work of art. But the bromide of silver emulsion is not only coated on to paper here; a big business is done in opal enlargements, and specially prepared canvas is also made for the reception of the photographic image as a basis for oil painting. The picture on the canvas is so much part and parcel of the ground preparation upon which it is produced that it is simply impossible to scratch up the one without the other. We mention this fact because we know that some artists have a prejudice against working over a photographic base, in the belief that it will eventually peel off. This accident with the canvas prepared by Messrs. Morgan and Kidd can never occur.

Each enlarging apparatus is separated by a curtain from its own developing room. We cannot call it a dark room, for there is abundance of light everywhere, but of course orange light of the right quality. Directly an opal or paper enlargement is exposed, it is placed in a tray with a glass bottom, and flooded with water. While it soaks for a moment, the operator mixes a few ounces of the good old ferrous oxalate developer—no other is used here, and fresh developer is used for every picture—and presently it is flowed over the wet print. In about one minute the image appears and rapidly gains strength, but should any part appear to hold back, possibly through some fault in the negative, a little stronger developer is applied locally, and the fault corrected. The picture now has a rinsing of very dilute acetic acid, and is immediately placed in the hypo bath. Everything is conducted with speed, for the secret of an effective bromide print is prompt development, and prompt everything. We also watched the development of a sheet containing twenty portraits, which had been exposed by contact in a machine devised for the purpose. Every one of these pictures was exactly like its neighbour; there was no variation whatever. At these works both large and small pictures are printed. At one time an order will come in for so many thousand copies from a single half-plate negative; while, on the other hand, the works have turned out a picture measuring 28ft. by 8ft. This was, of course, exposed and developed in sections, the main difficulty being in finding floor space upon which to arrange those sections and attach them to one another.

It would require far more space than we can afford to give a full account of this busy hive at Richmond. Paper, plates, and opals are coated here, the same being cut up, packed, and sent to all parts of the world. At the same time, the amount of all three actually consumed on the premises is enormous, and a large staff of artists, both ladies and gentlemen, is constantly occupied in giving the finishing touches to the pictures produced. The pictures are then mounted and framed in any style desired, the whole of the work being executed on the premises. The firm anticipate that their output of bromide paper will be doubled when the contemplated additions to their premises are completed, for these additions comprise a new paper-coating machine of enormous size.

---

## MR. PENNELL'S ANSWER TO THE DISCUSSION ON "PHOTOGRAPHY AS A HINDRANCE AND A HELP TO ART."

Through the kindness of the editor of the *Camera Club Journal*, I am able to answer some of the very severe charges and assertions made against my paper and myself at the Annual Conference. In appearing again before the members of the Camera Club, I have no intention of arming myself with a tomahawk and a scalping knife, as a speaker suggested, but I hope I carry much more powerful weapons. Although Mr. Maskell and, I believe, some other members were afforded the opportunity of completely annihilating me, I think, considering their opportunities, that they were extremely unsuccessful. Mr. Maskell began by charging me with ignorance "of the great advance in photography, artistically considered, which has taken place within the last two or three years," and nearly every other speaker backed him up in this. It has been my misfortune to have to attend professionally every show which could by any means be construed into an artistic one during the last two or three years, and I am, perhaps, more familiar with photography than the gentlemen who discussed my paper may have imagined. I certainly do not see that the work of any of the gentlemen Mr. Maskell mentions is painter-like, for the simple reason that painters do not produce their work by means of a machine. The subject may be painter-like—the execution is mechanical—photography affords persons with artistic sensibilities the means of carrying out, to a certain extent, their impressions, but it does not make them artists, nor is their work produced in an artistic manner, and work not produced in an artistic manner does not rank among the fine arts. Having both etched and photographed, I know very well the cost of materials in each case. An entire etching outfit, including plates, could be bought for probably the fifth of the price of a good lens. As to the six artists and the six cameras, to explain my point would require a considerable amount of space and time, and Mr. Maskell completely failed to understand my meaning. If Mr. Maskell will show me a photograph in colour, and one with its tones and values right, I shall be deeply indebted to him, and at once relinquish my art and take up photography. He also says that my photographs of cathedrals were bad. This is rather a serious charge to make, especially when I tell him that they were the best transcripts of the buildings which could be obtained. I did suppose that every photographer knew that it is impossible to photograph any great building which is in the least foreshortened, and render the perspective truly. If he would give me a true perspective rendering of a subject which I should suggest to him at Westminister Abbey, it would save me much time and drudgery.

Mr. Davison has impressed upon me that one can photograph any building provided one can get far enough away from it. Of course one can, but by getting away one loses one's wished-for point of view—and picture—and the greater proportion of impressive views of large subjects are beyond the powers of any photographer to render correctly.

I never said that a photograph would look altogether wrong if turned into a drawing; but I do say that it would require much correction, and I should be very happy to prove this to Mr. Maskell.

Mr. Debenham remarked that until twenty or thirty years ago, the regular mode of representing horses in motion was very much that of a rocking-horse. I had a faint idea that the Elgin marbles were produced more than thirty years ago, to give merely one example which Mr. Muybridge has quoted as a very striking one of the correct rendering of motion. And I repeat that the greatest artists merely owe to Mr. Muybridge the sincerest thanks for showing them scientifically, for the first time, facts which Mr. Muybridge himself has admitted have been known since the days of the cave-dwellers.

Mr. King made a most unfortunate assertion. He said he had supplied me with photographs which I had used in Westminister Abbey. It is quite true that he did sell me some photographs of the Abbey, but for my purpose they were quite worthless, as he will see when my article appears. I was not able to turn his photographs into drawings.

To Mr. Davison I would say that if I gave to the Conference the idea that I never used photographs, it was because I did not make myself understood. I often am obliged to use them, but always hate it, as it is much more trouble either to copy, trace, or enlarge a photograph, than it is to work from nature. They are often, however, I agree with Mr. Linley Sambourne, of great value, as I said in my paper. I cannot possibly have made the ridiculous statement that the brush or camera, the machinery used, need not be considered. The painter's tools are everything to him, and the photographer tries to make a machine equal them, and does not succeed. When art becomes as popular as stock-brokering or horse-racing, people will cease to sneer at it—and more than one great English artist has suffered from the sneers of his fellow-countrymen. If Mr. Davison does not understand what "selection" means, I can only refer him to any elementary work on the fine arts. I think Mr. Hamerton explains it very well in his "Etching and Etchers." It is the art of leaving out, selecting, and arranging—something which photography never can do. If Mr. Davison will show me a photograph in which the details and general effect are better rendered than in the Van Eyck in the National Gallery, I should be very glad to see it. I have seen the flowers shown at the Club, and I was not overpowered by the rendering of detail. Mr. Alfred Parsons could express it much better, and Mr. Francis James would have rendered the same flowers vastly more artistically. One may be perfectly ignorant of the use of photographic appliances, and yet, if photographs are artistic, they, the prints, must be governed by the same laws as any other art work; and hence an artist is much better qualified to judge of their artistic value than any photographer, unless the photographer is a skilled practitioner of the fine arts.

Major Nott, whom I must thank for reading my paper, was good enough to make some very plain statements as to my ignorance of photography, and the modern French school of art. This may or may not be; certainly Major Nott's assertions do not prove it.

Mr. Blanchard spoke of Winckle's "Book of Cathedrals," and compared unfavourably with Cassell's. I never heard of Winckle's book, but the only difference between Britton's and Cassell's is that the greater part of the work in the former was done with the camera-lucida, and the latter from photographs. The best work, however, in Cassell's—that by Mr. George Seymour and by Mr. C. E. Mallows—was not done by the camera at all, but drawings were made from points from which no photographs ever could have been taken.

As to Mr. Welford's conclusion that I have tried photography and failed, he is altogether mistaken. I have had more successes than failures. I turn to my "earlier writings" and I discover this sentence: "If the artists of to-day were not possessed of such external aids as photography, they would probably excel all old masters in sketching."

The President remarked that he thought photographic and artistic perspective were the same. I can assure him that they are not, and I should be glad to prove it. The expression I used, that turrets and towers which I saw were not rendered by a photograph, was very carelessly worded. What I meant was, that when standing at my full height I could see certain details which were hidden to the camera placed about a foot lower than my eyes: by stooping I could see other details which the camera, being fixed, could not take in. On moving three feet to the right I would get a vista which would not be taken by the lens; two feet to the left would shut out an unpicturesque object which would be the most prominent detail in the photograph. In fact, a good rendering of a cathedral is the most complete rendering, which may necessitate your taking half-a-dozen points of view, and working them all into one picture. (I don't mean in the photographic fashion.) When a photographer can do this, he will be much further advanced on the road to art than he is at present.

If there is any matter which I have not explained or made clear, I should be only too happy to do so. And I think that the members of the Camera Club must admit that I am not much the worse for my drubbing.

## Patent Intelligence.

### Applications for Letters Patent.

7,785. Bernard Krantz and Hermann Zeissler, 61, Chancery Lane, London, "Method of and Apparatus for Reproducing Photographs."—May 5th.

7,795. David Allan, 157, Whitfield Street, London, "The 'Champion' Metal Film Carrier."—May 5th.

7,876. Frederick William Cory and William Jones, 203, Old Christchurch Road, Bournemouth, "Improvements in Photographic Apparatus."—May 7th.

7,889. Thomas John Perry, 13, Temple Street, Birmingham, "Improvements in Photographic Developing Frames or Baths."—May 7th.

7,905. Wilhelm Hoffmann, 18, Buckingham Street, Strand, London, "An Improved Panorama Photographing Camera." —May 7th.

7,918. Arthur John Buncher and George Tucker, 6, Livery Street, Birmingham, "Improvements in Photographic Camera Shutters and Combined Means of Registering the Number of Exposures."—May 8th.

7,942. William Beyer, 5, Kelly Street, St. Pancras, London, "For Automatically Changing the Sensitive Plates Inside a Photographic Camera."—May 8th.

7,959. Etienne Jules Marey, 47, Lincoln's Inn Fields, London, "Improvements in Photographic Apparatus."—May 8th.

### Specifications Published

19,618. *December 6th*, 1889.—G. Bramley and G. Butterworth, Clay Cross, Derbyshire.

*Changing Boxes and Dark Slides.* Within a rectangular box, provided with sliding lids at the top and bottom, is an open reciprocating frame, which is slid by a push piece and returned by springs. The plates, which are dropped into the box with the film side upwards, are guided into the frame by guides at the sides and ends of the box, the bottom plate resting on ledges on the box and on the projecting end of a lever pivoted to the frame, and engaging at its other end with a pin on the box. When the frame is pushed forward, the end is withdrawn under the frame, with the result that the bottom plate, which has been pushed by the reciprocating frame off the ledges, now falls on the bottom lid and ledge of the box, and, when the frame returns, the end pushes it fully on to the bottom lid. The dark slide is adapted to slide in grooves in the bottom and top of the change box for receiving and returning the plates.

19,691. *December 7th*, 1889.—O. Freeworth, Lenkerbad, County Wallis, Switzerland.

*Cameras.*—The plates or films, held in frames which are connected together by tape, are stored in a compartment of the camera, and from thence pass over a prism, each side of which is the size of a frame, so that when a frame arrives at the front of the prism, it is in position to be exposed. To remove the exposed frame and bring forward the next, the prism is rotated by a knob from the outside. Sensitive paper may be also used, in which case a roller is substituted for the frames.

19,770. *December 9th*, 1889.—F. Miall, 13, Shelgate Road, Battersea Rise, Surrey.

Relates to carriers or sheaths for sensitised plates and films.

19,896. *December 10th*, 1889.—A. J. Boult, 323, High Holborn, Middlesex. (G. Eastman, Rochester, New York, U.S.A.)

Relates to apparatus for producing flexible photographic films.

*Coating Machines.*—The substrata, consisting of a solution of nitro-cellulose and camphor, &c., is distributed evenly on a plate or bed. The solution is contained in a hopper in connection with a traversing carriage actuated by endless chains. By suitable apparatus, consisting of an escape opening and a distributing blade, the solution is run out on the bed. The sensitised coating, consisting of a gelatino-argentic solution, is similarly put over the first.

*Drying.*—To dry the first and second coatings, an exhaust fan is used. The film may be also dried by exposure to the atmosphere, but this, besides rendering the atmosphere impure, has the further disadvantage that the evaporation products cannot be recovered as in the first drying system.

*Stripping-rolls.*—Rolls which may be mounted on the carriage, or on a separate carriage, are used to strip and roll the film off the bed. The film, which will be generally too wide, is divided into longitudinal strips by knives in connection with the carriage, a separate roll being used for each strip. The rolls are preferably mounted in different places, and are actuated by mechanism so that on attaching an end of the strip to the roll, it is automatically stripped off.

20,009. *December 12th*, 1889.—R. Haddan, 18, Buckingham Street, Strand, London. (C. A. Steinheil, Söhne, Munich, Germany.)

This invention relates to shutters and change-boxes in connection with cameras. At the back of the camera is pivoted a plate magazine, which moves within an enclosing case. The magazine has guides at both sides near the top to receive the lugs of the plate sheath. The plates are pressed towards the front for exposure by a spring at the back of the camera. To change the exposed plate, a lever partially ejects the sheath through an opening in the top of the magazine until lugs engage in angle hooks in the outer case.

19,897. *December 10th*, 1889.—A. J. Boult, 323, High Holborn, Middlesex. (G. Eastman, Rochester, New York, U.S.A.)

Relates to means for producing sensitised flexible films. The support, consisting of an alcoholic solution of nitro-cellulose and camphor, to which, preferably, some fusel oil and amyl-acetate are added, is poured on a flat plate which has been treated with wax. When dry, the surface is washed with silicate solution, and the sensitive emulsion applied.

19,926. *December 11th*, 1889.—"Magic Lanterns." H. Bond, 126, Wilderspool Road, Warrington, Lancashire.

This apparatus consists of two optical systems, side by side, lighted from the same lamp. The condensers and objectives are placed at right-angles, and the light is directed from one to the other by means of reflectors.

## Correspondence.

"CURIOUS PEOPLE."

Sir,—I was very much amused (in fact, I am always amused when an English editor takes up things American) by your remarks in the issue of April 17th, anent the *Saucy Chipmonk*, and reference to us as "curious people these Americans." Now it occurred to me that the editorial sanctum of the News must be plethoric of book lore, and why there was no work in which that well-knowu little animal the *chipmonk* was described seemed passing strange. I therefore consulted "Webster's International Dictionary," edition of 1890, and on page 249 I find as follows :—"*Chipmonk*, Indian name, *Zoöl.* A squirrel-like animal of the genus *Tamias*, sometimes called striped squirrel, chipping squirrel, ground squirrel, hackee. The common species in the United States is the *Tamias Striotus*."

These animals are comparatively common in the woods about here and in most parts of the U.S. Their habit of perching on a tree or a rock, and watching one's movements with their large, bright eyes ; their quick and erratic motions, now impudently peering out from one side of a branch, then from another, and in "the drop of a shutter," from a convenient rock, renders the adjective "saucy" most applicable. The poor and long-suffering amateur photographer, who has had all manner of opprobrious epithets heaped upon his unwilling head, should, I think, be spared this additional weight of woe in being styled a "saucy chipmonk." Trusting this may be of interest to you, and which you cau use if you see fit,

C. R. Pancoast,

*One of those "curious people."*

*Waterbury, Conn., U.S.A., May 1st.*

[The writer of the paragraph to which our goodnatured correspondent refers, tells us that by an oversight he omitted to append to it the immortal line, "This is a goak."]

THE QUAGGA.

Sir,—*Re* Mr. York's, or rather York and Son's, disclaimer. I have mentioned in previous letters that I was engaged by Mr. York to photograph in the Zoological Gardens, and in speaking of the camera as *my instrument*, I meant the instrument I was using. I certainly had no intention of laying claim to the particular build of camera or ownership of it, nor, as far as I can see, *have I misled your readers.* B. Harvey.

*March 30th*, 1891.

[Our correspondent's personal explanation is accompanied with a great deal of information about the quagga, interesting from the naturalist's point of view, but for which we have not space. We must now consider the correspondence closed.]

THE ETHER LIGHT.

Sir,—In your article on the ether light, page 301, you quote a correspondent as intimating that I was not the originator of either of the inventions claimed in my two patents. As a matter of fact, there is no record of anything that anticipates either of my claims. My first patent was not for a porous carburetter or saturator (such had been in use many years in other ways), but for the means for producing the blow-pipe flame (and lime-light), which consists in dividing the oxygen supply and passing a portion of it through a porous saturator, &c. That was strictly new. My second patent was applied for in October, 1887 (the date is printed on the patent specification), after the improvement had been in practical use for some months.

European writers frequently assume that the date of a U.S. patent is the date of first legal record of invention. This is a mistake. According to our patent laws, a patent may, under certain circumstances, be issued several years after the date of first legal record. My original photo-mechanical engraving process is often spoken of as if invented in 1881, although it has been recognised by the Patent Office as dating August 12th, 1878. My folding optical lantern was mentioned and illustrated in the Photographic News two years before it was patented. My process of composite heliochromy, patented in 1890, was on legal record in 1888. My patent attorney mentions a case in which the inventor did not even apply for a patent until more than seven years after date of first legal record of invention.

*Philadelphia, April 27th.* Fred. E. Ives.

## Proceedings of Societies.

The Photographic Society of Great Britain.

At the meeting of this Society held on the 12th inst., the chair was occupied by Mr. James Glaisher, F.R.S., president.

The paper on polychromatic impressions by photographic methods, announced for the evening, was read, in the absence of the author, by the assistant secretary. The walls of the room were hung with specimens of photomechanical productions in colours, sent for the occasion by Messrs. Angerer and Goeschl (3), Bouillod Valladon and Co. (7), Frisch (5), F. Hanfstangl (3), Löwy (12), Photographic Art Colour Company (3), Photochrome Company of Zurich (19), Rommel (8), Rouillé (6), and Wezel and Naumann (9). There was also an exhibit by the author of the paper, on a separate screen, of photographs by the Woodbury and collotype processes imposed upon paper on which colour had previously been printed.

In the course of the paper, the author said that he did not propose to go into the question of the probability of obtaining coloured photographic effects direct from the colours themselves. That was a question for the future. The recent investigations had not thrown much light upon the matter, and no practical or artistic effect of commercial value had been arrived at by them. He would refer to well-known methods, and only make use of such pigments as are readily procurable. He was at the outset much struck with the indifference of printers generally, both typographic and lithographic, to photographic methods. The few who did make use of photographic methods were rare, and he would endeavour to rouse others into entering upon the use of these methods, which he believed were neglected by printers from a mistaken impression that phototypy was a speciality presenting difficulties too serious for them to take it up. He would not go into the question of asking light to perform functions which it could not be readily made to perform, but would confine himself to what could be unquestionably and without difficulty achieved. Photo-chromotypic printing could be divided into two kinds. In the first kind, which might be called simple photo-chromotype, the photograph was in monochrome, and was printed upon a base on which colour had previously been printed by mechanical means ; stones or blocks having been prepared by the artist for the purpose of adding the colour where required. This was the method most in use and most commercially valuable. The second method, which he called composite photo-chromotype, depended upon the use of several negatives or plates, each of which had been taken so as to exclude the action of certain colours. These plates, when printed each in its proper coloured ink, on paper in proper register, gave an image in colour. This was the method employed particularly by Ducos du Hauron, and more recently by Ives, of Philadelphia. The latter was, indeed, still busy with investigations and experiments tending towards the perfection of the method. For composite photo-chromotypy, there were generally three plates prepared, one with yellow, one with red, and one with blue ; and, by using these in combination, some approximation to the colours of the original was obtained. It was, however, always necessary to retouch or to mask portions of the separate plates, and he protested against the claims sometimes made, that the colours of nature could be obtained by the selective action of three plates without touching by hand. The plates to be used must be orthochromatised, and that according to the colour required to be reproduced by each particular plate. For red it was useless to employ isochromatic or orthochromatic plates sensitised only to yellow and green. The means published by Wellington in the Photographic News in 1885 would answer very well.

Chlorophyll, methyl-violet, and cyanin sensitised for red ; but eosin and erythrosine did not. A set of photographs was then shown in the lantern, one of which represented a group of flowers in colours, and the others were the plates prepared, each to render certain of the colours contained in the original. Of the photo-mechanical methods most suitable for yielding these impressions, he recommended the collotype and the Woodbury process. If part of the printing was to be of a metallic character, then Woodburytype was better than collotype. An example of mixed colour and metallic printing was shown in the representation of a vase gilt in places. In conclusion, the author expressed his regret at not being able to be present to read his paper in person.

Mr. John Spiller, by way of opening the discussion, directed attention to the remarkable collection of specimens of coloured work hanging round the room. He referred particularly to some photogravures in colour by the successors to the firm of Goupil and Co., and to some exhibits by Hanfstangl, of Munich. He also noted with interest the opinion of the author of the paper with regard to the recent attempts to solve the problem of photography in natural colours, that we are still as far as ever from achieving that consummation.

Mr. Addenbrooke thought the subject one of great interest, and proposed that the discussion should be adjourned till the June meeting, when the members would have been able to read the paper. With regard to this proposal, it was ultimately announced that if, after the paper which stands for the June meeting and discussion thereon, there should be time for further discussion on the present subject, it might be continued on that occasion.

Mr. Valentine Blanchard said that one of the methods employed by Goupil was a method that was in use here as long ago as 1790. With regard to imposing a photograph upon a prepared coloured surface, that was invented in England by Woodbury, and the inventor was very angry at the use that had been made of it by Goupil, but had not succeeded in obtaining any satisfaction.

Dr. Eugene Albert, of Munich, a son of the late Joseph Albert, so well known in connection with collotype printing, showed specimens of a print in three colours, separately and with the conjoined effect, which was excellent, upon one paper. He addressed the meeting through an interpreter, and was understood to say that the specimens round the room were, only to a limited extent, photographic work, as the selection of certain parts of the plates for the several colours was in them made by touching or blocking-out by the artist. In the case of his own specimen, there was only photographic selection, the plates not being touched by hand. He further said that he had used all his endeavours to make the process as practical and cheap as possible, and, therefore, had used not collotypic methods, as his father had done, but typographic ones. He found that it was desirable to have the blocks of different kinds of grain for the different colours.

Mr. W. E. Debenham thought it remarkable that colour screens could be obtained selecting colours so purely as to dispense with the necessity for retouching or blocking-out by hand.

The President moved the thanks of the meeting to M. Vidal for his paper, and to Dr. Albert for his specimen and remarks. He also thanked the various exhibitors for sending the pictures that appeared on the walls, and the assistant secretary for the getting together of such an interesting collection. With the exception of one set, the specimens would remain upon the walls until the end of June.

Dr. L. S. Bruce, Mr. H. Holiday, and Mr. C. E. Pearce were elected members of the Society.

### Camera Club.

*May 7th.*—Mr. F. Machell Smith in the chair.

Mr. Willis gave an address entitled "Clam-Chowder," which treated chiefly of the influence of temperature in developing platinotype prints, and some examples were shown. Amongst other illustrations were shown some excellent examples of platinotype prints upon wood for panels and decorative work. These have since been arranged upon a screen for exhibition at the Club.

In the discussion which followed, Messrs. Maskell, Cobb, Clark, Elder, Lambert, Davison, and the chairman took part.

On May 21st Dr. Acworth will read a paper treating of the flash-light.

### Holborn Camera Club.

Mr. Frederick Brocas presided at the meeting on Friday last, at the club room, 100, High Holborn, when Mr Arthur Lawton was elected a member of the Club.

Two representatives of the Autotype Company attended, and gave a practical demonstration on the autotype or carbon process. After giving an outline of the method of preparing the tissue, the demonstrator went on to speak of the printing, which he characterised as the only obstacle to overcome in the carbon process. The development of the picture was to a great extent under control, but it was quite as well to have a properly exposed print. For this purpose he showed three actinometers ; one, the simplest, acting by colouring a piece of silver paper to a standard tint. The other two were on a different principle, one having a numbered scale, and the other a scale of tiny negatives of varying densities. He then mounted some exposed prints, and developed them by placing in hot water and washing away the soluble gelatine in which the picture is buried. Development was then stopped by placing the print in cold water, and, after placing in a 5 per cent. solution of alum to thoroughly discharge the bichromate salt, it was thoroughly washed and hung up to dry. For negatives made in the ordinary manner, an additional operation becomes necessary ; for if the printed tissue were laid down at once on its final resting place the picture would be inverted. To remedy this the exposed tissue is laid down on a temporary support, such as a thick paper with a hard, highly-polished surface, from which it is finally transferred on to its intended support, such as an opal. The process is an extremely simple one, and recommends itself to all amateurs.

Twenty members attended the club outing to Pinner on Saturday, some eighty plates being exposed.

### Photographic Society of Ireland.

The last ordinary meeting of the session was held at 15, Dawson Street, Dublin, on Friday, 8th inst. (Mr. Geo. Mansfield, J.P., in the chair), when four medals were presented to Mr. John White for the best work in four classes of the Society's annual competition.

Mr. Alfred Werner then read a paper on "Platinum Printing." Having given his hearers a *resumé* of the history of the discovery of platinum and its subsequent conversion to the use of photographic printing, and the various researches of different workers, he proceeded to the chemistry of the subject, and said that platinum printing consisted in the fact that when iron, uranium, mercurial, and analagous compounds are exposed to light they suffer reduction to a lower state of oxidation. The salts found to be the most expedient, the cheapest, and of which there was a large selection, were those of iron, and with salts of that metal alone would he deal. He mentioned that Dr. Eder had, in his "New Researches on Sensitive Iron Salts," thoroughly investigated the sensitiveness of iron compounds, and gave the following list : Iron perchloride and oxalic acid, ferric oxalate, the double salts of amm., sod., pot., ferric oxalate, ferric tartrate, &c. In making a selection from these compounds for platinum printing, care should be taken not to use iron perchloride and oxalic acid, for the reason that HCl was formed. Ferric oxalate, the second on the list, could not well be crystallised, but a very concentrated solution could be prepared by dissolving freshly precipitated ferric hydrate in oxalic acid, according to the equation—

$$Fe_2\,(OH) + 3\,H_2C_2O_4 = Fe_2\,(C_2O_4) + 6\,H_2O.$$

He found that a solution prepared by simply mixing ferric sulphate with excess of oxalic acid (1 part $Fe_2\,(SO_4) + 3\,H_2C_2O_4$) gave a solution which undoubtedly contained ferric oxalate, and answered the purpose just as well. Having explained how to prepare ferric oxalate, Mr. Werner went on to tell his hearers how to prepare some of the platinum compounds generally used, and said that platinum compounds were more easily reduced when in the platinous state, and might mention that, as in the iron, there were two distiuct classes of platinum salts, distinguished as the "ic" and the "ous." In the platinic and in the ferric state platinum acted as a tetrad, fixing four atoms of any monad elemeut ; in the platinous and ferrous these metals acted as diads, fixing two atoms of monad elements. The chemistry of platinum printing admitted of rather easy explanation ; they required a platinum compound and an organic body, one of irou being nsually employed, as before stated. Ferric oxalate, when exposed to light in solution, or in preseuce of orgauic matter, underwent reduction ; $CO_2$ gas is evolved, and ferrous oxalate resulted. It was ferrons oxalate which reduced platinnm, while ferric oxalate did not. Ferrous oxalate was practically insolnble in water, bnt was easily soluble in oxalate solntion, and at the moment of its solution it re-acted with the platinum salt, reduciug it to metallic platinum in a very fiue state of division. The lecturer said that there was no donbt the chemistry of platinum printing had not been thoroughly investigated, and that, recognising that fact, his brother and himself had instituted researches, and expected to be in position shortly to pnblish their views on the subject. What actnally took place was uudoubtedly the decomposition of a molecule of water, the oxygen liberated converting the ferrous iron into ferric.

Mr. Werner then gave a full practical demonstration of platinum printing by both hot and cold bath processes, and also showed, as the result of his own investigation, a platinum replacemeut process, in which albumen and chloride silver prints were totally replaced by platinnm ; also a printing-ont platinnm process which had not yet been brought to perfection.

### Brixton and Clapham Camera Club.

At a meeting on May 7th, Mr. T. J. W. Bartrop gave a lectnre entitled "A Tour in the Ardennes," illustrated by some eighty or ninety lantern slides taken with a hand-camera by the lecturer and his party on a trip last August.

On the 9th inst. the first onting of the season took place to Perivale. The day was dull and the scenery poor, but some good views were obtained of the chnrch and rectory. There are a few pictures to be had along the canal.

The next meeting will be held on the 21st inst., when a lectnre will be given on "Hand-Camera Work" by Mr. W. H. Powell.

### North Middlesex Photographic Society.

Notwithstanding the clondy weather, a fair number of the members attended the field-day arranged for Satnrday, May 9th, to Highgate and district, satisfactory work being done.

On Monday, May 11th, Mr. J. W. Marchant in the chair, a demonstration on the "Working of Platinotype Paper," was given by a member. Prints from the frames were passed ronnd for inspection, showing the depth of printing necessary, and were then developed. The bath was kept at about 75°, and in some instances where shadows were a trifle heavy, the dark portions were withdrawn from the developer while the lighter portions were allowed to gather strength.

On Monday, May 5th, a demonstration on the "Working of Kallitype Paper" will be given by Mr. F. W. Cox, when visitors will be welcome.

### Richmond Camera Club.

At a special general meeting of the Richmond Amateur Photographic Society on Friday, the 8th inst., Mr. Cembrano in the chair, it was resolved that the Society should be called "The Richmond Camera Club," and the alterations in the rules consequent ou the change were made.

At the ordiuary meeting which followed, the Chairman opened discnssion on the snbject of "Fixing and Washing Gelatine Negatives," and recommended the use of two separate fixing baths in the case of valuable negatives.

Mr. Ardaseer explained the chemical changes in fixing, and insisted on the importance of leaving the plate in the fixing bath a sufficient time for the insoluble bromide that was left in the film to be converted into the soluble form, which could be washed out.

## Answers to Correspondents.

**All Communications, except advertisements, intended for publication should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.**

**All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.**

**Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.**

Stamps.—*Adhesive Material for Postage Stamp Portraits.* You cannot do better than employ the same material that is used for the Post Office wrappers and stamps, viz., light brown dextrine, or "British gum," dissolved in cold water. By itself this is apt to dry a little too hard in warm weather, so a small proportion of glycerine is generally added ; but you must be sparing in the use of such ingredient, for fear of the moisture affecting the permanence of the photographs.

L. T. D.—"*Royal Academy Pictures.*" Messrs. Cassell and Co. announce three parts, as last year, the first of which appeared on Friday, the 8th inst. Be sure and get it at once, for it is a good shilling's-worth, and they were soon out of print last time, or went np to a fabnlons price. Do not wait to get all three parts together, or you may be disappointed. *Black and White* also renders a good acconnt of the Royal Academy pictnres.

W. P.—*The Forge.* We agree with yon that the frontispiece of the April *Bulletin Belge* is highly suggestive of "The Smithy," by Mr. Adam Diston, of Fife, issued many years ago. The make-up of the picture is not ideutical, but the pose is very similar, and must necessarily be so.

S. B. S. (Nottingham).—*Cleaning off Old Negatives.* You can do better than simply saving the glass for greenhonse purposes. There is a small quantity of silver to be economised, and this can be got off by soaking the glasses, whether varnished or not, in warm washing soda. Leave them in for a few hours, and then rub them with a tuft of tow tied upon the end of a stick of firewood. The films are loosened, mnch of the gelatine dissolves, but all the silver settles as a precipitate worth collecting and putting into the general residnes. Prolonged immersion etches the surface, but soaking for a whole day does not sensibly affect the glasses.

Nemo.—*Hydrogen-Chlorine Photometer.* The idea may be a good one, but there is always a danger of hydrogen and chlorine exploding in bright snnlight, although you may have taken precautions to preveut snch a result. A better plan would be to use bromine water, and determine by volnmetrical testing the amount of hydrobromic acid formed, or free bromine remaining, at the end of a day's exposnre by standard solutiou of hypo with addition of starch paste. See British Association report of Leeds meeting, page 263, for experimental details.

A. M. S.—*Business for Sale.* Your lease appears to be short, and yon do not say what prospect there may be of getting an extension granted. Consnlt Mr. H. J. Beasley, of 65, Chancery Lane, who may be able to assist you in finding a purchaser.

R. B.—*Chromotypic Specimens.* M. Léon Vidal's paper was read on Tnesday, and an exceedingly interesting collection of coloured work, illnstrative of rcceut processes, remains on view during the present month.

J. Murphy.—*Non-Actinic Varnish.* Aurine cake dissolved in methylated spirit forms a good yellow non-actinic varnish, or gamboge dissolved in methylated ether and filtered. Apply with a brnsh to the parts which yon wish protected. Skies are more often painted ont with Bates's black varnish, or a comuion shellac varnish thickened with lamp-black.

Metallic.—*Reduction of Silver by Iron.* We fail to see wherein your method possesses any advantage over the common process of rednction by zinc. The chloride of zinc is so easily washed away, bnt iron rnsts, and is apt to contaminate the rednced metal.

Old Amateur and D. G. P. received.

## SUGGESTED BY SOME RECENT EXHIBITIONS.
### No. I.

BY H. P. ROBINSON.

The lessons of the past should have a beneficial effect on the performances of the future, and it may be profitable to consider one or two points that have become prominent in some of our more recent shows, that we may perchance attain another step or two in the direction of what we all desire—perfection.

It may be said at once that the Liverpool was the largest, finest, and best managed exhibition of photographs ever held in England, and I think I may add the world. It is probable that no other town has such fine rooms available for the purpose, and the management was beyond all praise. The energy of the president and secretary was so tremendous, that the one has been likened to a tornado, and the other to a hurricane, but the simile is not perfect, for storms are always capricious, and often destructive; the work of Mr. Lange and Mr. Mayne was well-regulated and all for good. The expenditure was wisely lavish, the "side-shows" most admirable, and only one of the numerous lecturers failed to make his appearance, and his place was easily filled. The lantern lectures and exhibitions have probably never been equalled, and were so eagerly sought after that the doors were besieged like those of a popular London theatre on a first night, and the entertainments had to be worked like Richardson's show, one down, another come on. The afternoon musical arrangements were well thought on, and good, and the festivities—for it was a festive time—began with a dinner, and concluded with a dance; nor should the unofficial gaieties be forgotten. The result was that 55,000 people were induced to pass the turnstiles to look at photographs, and with all the expenditure, there is a considerable balance of profit to the good.

Could anything be more satisfactory or apparently less open to criticism? Yet there are one or two things that I humbly think may possibly be improved in the future for the benefit of the art as an art, if not for the good of the gate money, and I know my Liverpool friends will forgive me for mentioning them, and will attribute all to a desire for a nearer approach to what they all wish, which is to produce a still more perfect model show than ever in their next triennial venture.

The leading idea of the managers of the Liverpool exhibition is reform—which there can be no doubt is much needed in exhibitions—and to elevate the standard of public competitions in every way. The first principle they have adopted is that every picture exhibited should be *new*, or never exhibited before, within certain well-defined limitations. This is well intended and plausible in theory, but it does not work out well in practice. The clause in the conditions relating to this matter is as follows: "Except in the champion class, no picture of any description shall be entered or allowed to compete which has been previously exhibited at any public competition in the United Kingdom, an exception being made in favour of the Photographic Society of Great Britain as regards its 1890 exhibition." This clause, at one fell swoop, disqualified all the best work that had been exhibited during the previous autumn and winter, except for the champion class. To show what was disqualified, it is only necessary to mention the Cornwall Polytechnic (the pioneer of prize giving shows, and an important one to which the leading exhibitors always contribute) and the Edinburgh. Thus the Liverpool public were deprived of seeing much of the good work of the year; but the clause has the still more objectionable disadvantages of inducing the feeling in the prize takers that they only obtained their medals after most of the best had been disqualified.

Let us enquire as to what was the effect in the general appearance of the exhibition.

I think it will be admitted that the first function of an exhibition should not be that of a competition at all. To me it seems that the object should be to show the people of the district in which it is held how the art has advanced since the last exhibition; to show the perfections of this marvel of our century; to convince the public that there is something more in it than they see in street show-cases; and if photographers can be encouraged at the same time, so much the better. As things go at present, when the amateur thinks more of the number than of the honourable distinction of his medals, it seems necessary to attract work by offering numerous rewards; but it cannot be said to be encouraging photography to disqualify most of the best work—work that the local world would gladly see—and reward only the best of what was left.

Another inevitable result of competition, especially in classes, is, that the appearance of the rooms must be seriously damaged. When competitors are invited to send their work, it must, to be just, be hung equally well, good and bad together, when it is well known that the best effect is produced, as at exhibitions of paintings, by placing the best pictures in the best places. Moreover, it is much more difficult to reject in these cases, as rejections must be done by the committee instead of the judges.

We will now see how these remarks apply.

What was the great attraction at the Liverpool Exhibition, apart from the unexpected Italian pictures, of which more anon? Was it the classes, numerous as they were, with the regulation four from each exhibitor, *all of them new?* Certainly not—except, perhaps, to the contributors. It was the grand gallery containing the champion classes and pictures sent not for competition. Thus, the exhibition was greatly redeemed from failure as a show by the very pictures which the rules went far towards excluding—those that were not new. That so many contributions were sent to this department is a healthy sign that when photographers have anything good to exhibit, they will contribute without the stimulus of an expected medal, for most of the exhibitors must have sent without any hope of winning one of the two medals allotted to this large class. I must not be mistaken to mean by this that photographers are wrong in competing for medals when they are offered, or that the best results of the year should be disqualified by the fact of its having been successful at some distant exhibition.

The Liverpool system spreading, as it has done, to other societies, has had a different effect to that intended. It was certainly meant to encourage photography, but the mistake was in supposing that the *new* was better than the *best*.

What is expected of an exhibition, either in town or country, is, as I have indicated, to show the best work that has been recently produced, and I have no hesitation in saying that a good deal of the best work done since the last exhibition did not appear at Liverpool, its absence being due simply to the fact that it had been exhibited before at remote exhibitions, where a very small fraction indeed of the 55,000 visitors would have had a chance of seeing it. And if, as I believe was at first contemplated, the enthusiasm for the *new* had included the Pall Mall pictures in the "ban," or, to use the modern word, the "boycott," I fear the exhibition, with the exception of the champion and not for competition classes, would have been confined chiefly to local amateurs and foreign exhibitors.

The rule also acts badly in another way. I admit that a true photographer will always try to do his best, but he will probably not go to any extra trouble or expense in his endeavours to show how far the art can be carried, if his work may be admitted to only one exhibition, except to be shelved in the champion class, which, after all, was only invented as a decent method of burying obnoxiously good work.

When a great work in any art appears, it would be much better to upset the obnoxious thing by capping it with better work, than to knock it out of time by disqualifying it because somebody else has seen it. This would be progress indeed. It would be quite easy to encourage less successful work in some other manner than by clearing off the best out of the way by a time rule, or a previously-exhibited clause.

I have written very frankly on this subject, partly because the exhibition was so vast a success as to be able to bear criticism without damage, and also because I know it is the sincere wish of its very capable managers to make the next—as this has been with all its faults—"the greatest show on earth" connected with our art.

The Gloucester exhibition was also a great success, but, of course, in a smaller way. There was only one gallery, well lighted, but the effect of the room was greatly spoilt by the arrangement in classes. This is inevitable as long as classes exist, and it seems there must be classes as long as it is necessary to offer a large quantity of medals to attract all sorts and conditions of exhibitors. The model exhibition will be the one that offers no medals, or only a few for the very best works, as at the Photographic Society of Great Britain, and rigidly excludes bad or indifferent work—a Utopian state of things that cannot occur at present, for the exhibition that rejected bad and doubtful photographs would be but sparsely filled; and how long would an exhibition holding society exist that rejected most of the work of its members, as it certainly must do if good work only was accepted? The Photographic Society of Great Britain takes the liberty of rejecting timidly the very obviously dreadful, and, to some extent, the obviously commercial, and sometimes loses members thereby; but I don't think that there were many rejections at Liverpool and Gloucester, and certainly much bad work was hung.

In a future article I hope to continue this subject, and to extract a lesson or two from the mistakes of the past.

---

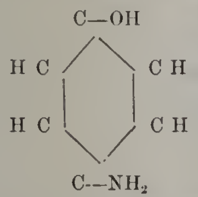
Photographic Club.—Subject for May 27th, "Cameras and Dark Slides"; June 3rd, "Platinotype Possibilities." Saturday outing at Carshalton, May 23rd; train from London Bridge at 2.18; meet at Carshalton 3 to 3.15.

Yellow Prints.—A silver print which has turned yellow by time may be readily brought back to brilliancy and good colour by immersion in the following bath:—Saturated solution mercury bichloride in hydrochloric acid, 8 to 10 drops; distilled water, 500 grammes. As soon as a purple tone has been acquired the print should be removed and carefully washed, then dried and mounted. A warm tone may be obtained by subsequent immersion in chloride of gold and potassium, 1 gramme; distilled water, 125 grammes. This latter bath will keep, and may be used till exhausted.—*Anthony's Bulletin.*

## PARAMIDOPHENOL DEVELOPER.

BY AUGUSTE AND LOUIS LUMIERE.

THEORETICAL considerations have led us to test the paramidophenol developer, the constituents of which are, perhaps, best represented by the following diagram :—



In a recent note, Dr. Andressen, of Berlin, induced by the same considerations, stated that he had experimented in developing photographic pictures with phenylene-diamines and amidophenols.

The first (phenylene-diamines) are the subject of his German patent of the 1st of April, 1888, while the latter (amidophenols) are completely neglected, no doubt because they did not yield the results that he anticipated. Without previous knowledge of these experiments, we have found that paramidophenol, added to an alkaline carbonate, exhibits remarkable powers of reduction, which make it an excellent developer. The water of the developer becomes decomposed, the oxygen goes on to the paramidophenol to furnish quinonime, and the hydrogen reducing the bromide of silver, gives bromhydric acid, which works in its turn on the basis or carbonate alkali to produce a bromide. The paramidophenol can be prepared by reducing paranitrophenol by pure tin and hydrochloric acid $C_6H_4(OH)NO_2$ $(OH : NO_2 = 1 : 4)$ or the dinitrophenol $(C_6H_4)(OH)(NO_2)_2$. It forms very thin crystals, which fuse at 184°, while decomposing at 200°; it is soluble in 90 parts of water, and in 22 parts of pure alcohol. The solubility increases a little with the temperature.

The aqueous solution oxidises in the air, especially in the presence of the carbonate, and takes a purplish-red colour, but the addition of sulphite of soda prevents these alterations. The following formulæ appear convenient to us for the developing of bromide of silver gelatine plates.

| | |
|---|---|
| Water ... | 1,000 |
| Sulphite of soda | 200 |
| Carbonate of soda | 100 |
| Paramidophenol | 12 |

Or still better—

| | |
|---|---|
| Water ... | 1,000 |
| Sulphite of soda | 200 |
| Carbonate of lithia | 12 |
| Paramidophenol | 12 |

The first formula gives a very energetic developer, and is especially convenient in the development of instantaneous photographs. The paramidophenol, which acts as a developer, presents the inconvenience of not being very soluble, so that it is not possible to modify the composition of the developer as in the case of pyrogallic acid.

Hydroquinone and eikonogen have, however, this same inconvenience in an equally high degree, and the paramidophenol has the advantage over these latter, especially the hydroquinone, of never discolouring the gelatine. The solution will last a very long time, even in open-mouthed bottles, and negatives developed with old solution never present that yellow tint that is frequently to be remarked when other developers are used. The deterioration of the developer is very slow, so much so that in 100 grams of solution six or seven plates 13 by 18 can be developed without there being the least appreciable difference between the first and the last. Paramidophenol is expensive, but principally because there are not at present many uses for it, and also because the processes for purifying this agent have not been studied. The substance which is met with commercially under the name of paramidophenol is often very impure; but there is no doubt that on the attention of chemists being directed to its photographic value, this substance will be more easily produced in a state of purity, while, at the same time, its cost will be diminished.

## PHOTOGRAPHIC ANALYSIS OF MOVEMENT.

IN a former article we pointed out the various improvements which had been introduced by M. Marey in his prosecution of this fascinating study, and in what manner he had perfected the work which was first seriously taken up by Muybridge, of California. We also showed that in the portrayal of any quickly moving object, when several exposures in each second were desirable, certain conditions were necessary to success. The Eastman film, upon which the successive images are received, must perforce travel along as well as the moving object itself, but, unlike that object, it must be brought to a brief standstill at the moment that the image is impressed upon it. This difficulty was only surmounted with great trouble, and the apparatus used is necessarily of a somewhat complicated nature, and far more intricate than contrivances of the same kind which may be regarded as the pioneer machines of this class. It is true that the early machines were not used for photography, for they were devised at a time when the art was in its infancy so far as rapidity is concerned. We allude to those contrivances which, exactly the same in principle, were used for giving the appearance of moving figures on the lantern screen.

These were of various forms, and they had fanciful names, but they all depended for their effect upon that curious property of the eye known as persistence of vision, by which the image of anything seen remains, or *persists*, on the retina for about the eighth part of a second. The first of these was Plateau's device, consisting of a wheel perforated with radial apertures, on the back of which figures were painted, which figures, when the spectator twirled the apparatus round in front of a mirror and looked through the apertures, appeared to move.

Plateau's instrument was arranged for use with the oxy-hydrogen light by Duboscq, but the apparatus was extremely complicated. In the zoetrope we have again Plateau's device in another form, the wheel being changed for a cylinder, the upper part of which is pierced with the necessary apertures, and the painted or printed devices placed inside. One advantage of this modification is that the mirror is dispensed with, and another that the figures, printed on slips of paper, can be varied and changed at will. By means of mirrors and a lens, the effect can be projected on a screen, but the loss of light is great. The phenakistiscope was another modification of the same principle, by which the moving figures could be better seen when projected on the lantern screen. This, too, gave place to Beale's choreutoscope, which may be regarded as the modern development of those which came before. This has appeared in two forms. In the first, transparent figures of the zoetrope kind were set in a disc which turned in the slide stage of an ordinary optical lantern; each figure coming to a brief rest, and being shut off by an interposing shutter before the next came into view. In the second, the instrument was modified so that it could be adapted readily to any existing lantern, and in this form it now appears in many dealers' catalogues. We have called attention to these instruments, most of which are obsolete, to show that what is now being done in the construction of apparatus for taking photographs at brief intervals of time is not quite so new in principle as many persons would be apt to think. Another purpose which we had in view was to render plain that one of these modern contrivances would, by the addition of a powerful light, represent a means by which the photographs it produced could be projected upon a screen. By this means, the original movements can be represented with astonishing fidelity to nature, but, of course, in practice a separate instrument would be adapted to the purpose.

Referring once more to Prof. Marey's apparatus, we may point out that the sensitive film is contained on bobbins — or rather reels — which have at each end a broad flange, which is sufficient to protect the edges of the sensitive band from access of light. But another protection is also provided which actually enables the operator to transfer the bobbins to and from the apparatus in full daylight. Each strip of film has fastened to it at one end a band of black paper, and at the other end a similar band of red paper. The red end is first wound on the reel, so that when the winding is complete the outer surface is black. But when a band has been unwound and exposed in the apparatus, and re-wound upon the receiving reel, the red end comes into view and protects the film from light on its new reel. This arrangement not only secures the film from light access, but also shows at a glance the difference between a bobbin which has already been exposed, and one which has not yet been used.

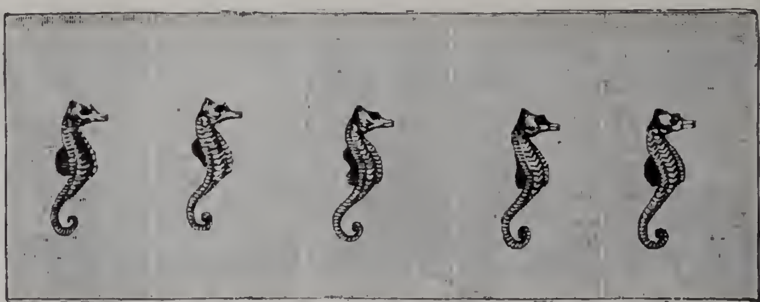


Fig. 1.—Successive Images of a Sea Horse. 20 images per second.

Fig. 2.—Successive Images of a Gull in Flight. 25 images per second.

We have already stated that the instrument has been used by Prof. Marey in studying the movements of animals of minute size, as well as those of larger dimensions. Nor are his studies confined to those which tread the earth, for the inhabitants of the water, as well as those which fly through the air, have been made to bow to his will.

The apparatus has been used by Prof. Marey in studying the movements of various creatures which can be kept in a marine aquarium. In this case, the aquarium is set in a window, and is shielded in such a way that no light can enter the apartment except through the water. Opposite to it is placed the photographic apparatus. In this way the pretty, umbrella-shaped medusa, or jelly fish, has been photographed. Another object which has been submitted to similar scrutiny is the sea-horse, which is able to propel itself through the water by a movement of the dorsal fin so quick that the eye cannot follow it. By securing twenty images per second of this creature, it is shown that these movements are undulatory in character, and that they are from below upwards. An engraving from some of these photographs is appended.

Still more interesting are the photographs which have been secured by aid of this machine of birds in flight. Those who have studied aeronautical science have long ago come to the conclusion that if man is ever destined to conquer the air, in the same sense that he has long ago conquered the water and the land in journeying over both at marvellous speed, it will not be by the agency of the unmanageable balloon. He must rather look to nature for his model of a flying machine, and must study the methods by which birds are enabled to fly. The problem is possibly one which will never be solved, but there are many sanguine persons who believe otherwise. But we may all agree that the study of flight, although it may not lead to the inauguration of a new method of human progression, is full of fascination. Such a study, too, may reasonably be considered as a help to artists, who, from time immemorial, have pictured a bird in the air in a manner as stereotyped as the zig-zag form which they gave to lightning until photography taught them better. This form may be at once expressed by the letter V, and it would not be so positively wrong if it were varied sometimes by being inverted thus Λ, for it stands to reason that in flight a bird must as often place its wings in the downward position as in the upward. This is recognised by those close students of nature, the Japanese artists, who frequently draw flying birds with their wings depressed. The annexed illustration, which is taken from one of Prof. Marey's photographs of a gull in flight, shows not only the two positions referred to, but also a number of intermediate ones. Such a series of different positions ought to be of great use to artists who are in the habit of introducing flying birds into their seascapes.

---

Photographic Society of Great Britain.—Technical meeting May 26th; subject for discussion, "Influence of Development on Gradation." June 9th, ordinary meeting; paper on "A New Sensitometer," by Mr. Leon Warnerke, and adjourned discussion on Mons. Vidal's paper.

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

AGAR-AGAR IN EMULSION-MAKING—STRIPPING NEGATIVES—HIGHLY SENSITIVE COLLODION EMULSION—POSITIVES IN BRONZE.

*Agar-Agar as a Substitute for Gelatine in Emulsion Work.*—I notice that a patent has been granted in Germany to Mr. Wassily Rebikow for the use of agar-agar in emulsion-making. The idea of employing this article as a substitute for gelatine—it has long been used for culinary purposes—in photography is by no means a new one. About fifteen years ago the suggestion was made to employ the material in the collotype process, and at that time I myself conducted some experiments with it with a view to see how it would answer as a vehicle for the salts of silver in the negative process, chiefly for dry plates, in place of gelatine. The results of my experiments were, however, not encouraging. In the first place, the agar-agar proved to be exceedingly difficult to dissolve, even in boiling water; then I found that it decomposed the silver salts exceedingly fast in the dark, so that a carefully washed plate did not even keep well until it was dry. In fixing such plates after development with an acetic acid pyro developer, the iodo-bromide of silver film was scarcely to be removed by the aid of any of the well-known fixing agents. Even cyanide of potassium and a hot concentrated solution of hypo were but partly successful in dissolving out the haloid salts from the envelope of agar-agar by which they were surrounded. Finally, I was never able to cover a plate, even if heated, uniformly with agar-agar solution, on account of its sudden setting. Even if an almost boiling solution of the material was employed, I did not obtain a perfectly even layer. Mr. Rebikow suggests the use of very weak (from one-fourth to two per cent.) solutions, and he recommends two methods to remove the muddiness which results in dissolving the material, and which, if it remained, would lead to fog. In order to make emulsions with agar-agar, he proposes to treat it at first in the dark with a weak solution of chlorine or of bromine, then to wash it out in several changes of water. For bromide emulsions it is preferable to bromise the agar-agar, whilst for chloride emulsions it should be chlorised. After this treatment the agar-agar solution is filtered through flannel, when it is said to be ready for the production of sensitive emulsions by any of the well-known processes. Considering the above-mentioned difficulties arising by the employment of agar-agar solutions, it seems to be doubtful whether the patented process offers any advantage over the use of gelatine solutions in emulsion-making.

*Stripping the Films of Gelatine Negatives.*—The following method is recommended by Mr. Jaffé, editor of *Die Photographie*:—The negative, which should have been taken on a gelatine plate specially prepared for being stripped, is coated after drying with a fifteen per cent. solution of gum arabic, and the solution is allowed to drain until but a small quantity of it remains on the plate. A gelatine film, corresponding in size to the negative to be stripped, is then taken and placed for a short time between sheets of moistened blotting-paper. The film is then laid on the prepared surface of the negative and pressed against it, commencing at one edge of it and gradually giving way. In the case of large negatives, a second person should be present to facilitate the manipulation.

*Highly Sensitive Collodion Emulsion.*—A collodion emulsion equal in sensitiveness to gelatino-bromide emulsion has undoubtedly been a desideratum. It seems that our experimentalists have at last succeeded in its accomplishment, and that the good old collodion will be raised to honours again. It will be remembered that Dr. E. Albert, of Munich, introduced a highly sensitive collodion emulsion a few years ago, which commercially is in two separate solutions, the one consisting of the ordinary collodio-bromide emulsion, the other of eoside of silver, the addition of which increases the sensitiveness of the emulsion forty times. It is now announced by the *Photo. Mittheilungen* that Dr. E. Vogel has succeeded in preparing a highly sensitive emulsion by emulsifying the blue sensitive gelatino-bromide in collodion, and that plates coated with it may be manipulated in the same way and with the same ease as gelatino-bromide plates. Further particulars have been promised by the inventor as soon as the process has been tried theoretically and practically in all directions. We await the results of the experiments with interest.

*The Production of Positives in Bronze.*—In Liesegang's *Photo. Almanach*, M. Eugen von Gothard describes a process to produce positives in bronze, which he has learned from M. F. Veress, of Klausenburg, the well-known experimenter in heliochromy. Such positives may be produced on various supports, such as glass, metal ferrotype plates, &c. The sensitive compound is made as follows:—

| | | |
|---|---|---|
| Distilled water ... ... ... ... | 100 | c.c. |
| Cane sugar ... ... ... ... | 2 | grammes |
| Glucose ... ... ... ... ... | 5 | ,, |
| Gum-arabic (powdered) ... ... ... | 5 | ,, |
| Honey ... ... ... ... ... | 1 | gramme |

After the ingredients have all dissolved, 10 c.c. of a saturated solution of bichromate of ammonia are added to the mixture. It is allowed to stand for some hours, and then carefully filtered from two to three times. With this solution the plates are coated. It is important to obtain an entirely uniform layer, and to prevent dust, or other impurities, coming in contact with the solution and with the prepared plates. It will be better to dry the plates near the fire; after five to fifteen minutes they will be dry, and may then at once be used. They are exposed in the printing frame under a negative in diffused light. The time of exposure depends very much upon the moisture of the air. It is always a good plan to give at first a trial exposure—say of ten minutes. It is better to expose slightly too long than too short. Development is done with bronze powder; a tuft of cotton is charged with the powder and passed lightly over the surface of the plate. This manipulation, as well as the coating, may be effected in a room in weak daylight. As soon as the image has been fully developed, a second clean tuft of cotton is taken, and the surface of the plate brushed over with it until the bronze image begins to become bright, and the deepest shadows are entirely free from bronze powder. Splendid effects may be obtained if differently coloured powder is used in development. After the image has been completely developed, the film is coated with two per cent. collodion to which some glycerine has been added. The plate should then be exposed to sunlight; if it be a glass plate it is exposed from behind, through the glass. After from fifteen to twenty minutes the plate is washed in running water until the yellow colour has been removed and the water remains clear. After drying, the surface is varnished with diluted copal varnish, or with colourless zapon varnish in the case of the support being a metal plate; the glass plates, however, are coated with a dark brown or black varnish, and looked at from the glass side.

## REGISTRATION OF PARCELS BY INLAND POST.

The following changes in the system of compensation for inland parcels and inland registered letters have been made public by the Postmaster-General:—

On the 1st of June next the undermentioned changes will take place:—

1. In respect of the loss or damage of inland parcels for which a certificate of posting shall have been obtained, compensation up to £2, instead of up to £1, will be given without payment of any fee; but, as at present, compensation will not be given for any other unregistered inland postal packets.

2. The separate system of insurance will be merged in a general system of registration. No separate fees for insurance will be charged; but, on prepayment of a single fee (in which will be included the ordinary registration fee of 2d.) in addition to postage, any inland postal packet may be registered, and compensation in the event of loss or damage may be secured up to £25.

3. The fees payable on registering inland letters, parcels, and other postal packets, and the respective limits of compensation, will be as follows: Fee, 2d., limit of compensation, £5; 3d., £10; 4d., £15; 5d., £20; 6d., £25.

The general rules governing the inland registered letter post will apply to registered parcels; and those rules, as well as the rules for the inland parcel post, will remain unchanged, except as mentioned below:—

1. A system of payment in full for damage, whether to letters or to parcels, will in all cases be followed, instead of the present proportionate system.

2. Rural postmen will receive for registration any letter, parcel, post card, book-packet, newspaper, or sample packet, whether the fee be 2d. or more than 2d.

3. The registered parcel post will be available for watches and jewelry, which it has hitherto been necessary to exclude from compensation when sent by the parcels post. Unregistered parcels found to contain money, watches, or jewelry, or on the cover of which is written or impressed the word "Registered," or any other word or phrase to the like effect, or marked in such a way as to indicate special value, will be compulsorily registered, and charged on delivery with a fee of 8d., in addition to the ordinary postage; but compulsory registration will in no case give a title to compensation.

4. The hand-to-hand check, which gives to the registered letter system its security, will be strictly observed in the registered parcel post.

5. As in the case of all other registered articles, an official receipt will be taken on delivery of each registered parcel; and, by prepaying a further fee of 2d., the sender of a registered letter or parcel may obtain, in due course, an acknowledgment of delivery signed by the recipient.

The public are reminded that, as a necessary condition of compensation in any case, the contents of the letter or parcel must have been safely packed and enclosed in a reasonably strong cover, case, or wrapper, fastened securely, and in a manner calculated to preserve the contents from abstraction or damage in the post.

The sender of a letter or parcel intended to be registered must write on the cover, over the address, the word "Registered," and the amount of the fee proper to the value up to which he desires to secure compensation, thus—"Registered 2d.," "Registered 3d.," and so on.

This scheme applies only to the United Kingdom, the Channel Islands, and the Isle of Man, and not at present to letters or parcels addressed to places abroad.

Further particulars may be obtained at any post office.

By command of the Postmaster-General.

*General Post Office, May,* 1891.

## ALUMINIUM.*

BY JOSEPH W. RICHARDS.

The title of my lecture is, "The Aluminium Problem," and for the time being, taking these words as my text, we will first direct our attention to the word "aluminium," the metal of which our discourse treats. It may be interesting to begin by inquiring how this word should be spelled and pronounced. You all know that two ways of spelling it are in common use, both Webster and Worcester sanctioning either way, Webster giving *aluminum* as preferable, and Worcester *aluminium*. You have also observed that I use the longer spelling. Let us inquire into the history of this matter.

Sir Humphrey Davy was the first to give a name to the metallic basis of alumina, although it is not probable that he ever isolated the metal. He said in 1808, that if he had been successful in decomposing alumina and isolating the metal in it, he would have suggested for it the name *alumium*. Davy evidently intended this word to represent "the metal from alum," simply taking *alum*, and adding *ium* as the proper termination for a metal. Objections were at once made to this name—not to the termination *ium*, which was considered absolutely proper, but to the root or stem of the word. It was maintained both in France and Germany that the name of the new metal should be derived from its oxide, and not from such a complex salt as alum, of which it happened to be an ingredient. The French name for the oxide was *alumine*, so they formed, and have always used, *aluminium*. The German name for clay was *Thon*, and for alumina *Thonerde*, so Gilbert suggested, in his famous *Annalen*, to call the metal *Thonerde-metall*, or, for short, *Thon-metall*. Fortunately, none of the German writers adopted this suggestion, but most of them adopted *alumium*. I find one instance of the metal being called, in Sweden, *argillium*, from the French word for clay, *argille*.

Whether Davy recognised the justice of these criticisms, or whether he considered that *alumium* needed an extra consonant simply for euphony's sake, we find him, in 1812, making bad worse by spelling the name *aluminum*. It is probable that he felt that the French were correct, but was unwilling to conform entirely to their mode of spelling. However, the name first proposed by Davy had taken root in Germany, and in 1812 we find the English using *aluminum*, the French *aluminium*, and the Germans *alumium*. The French have always used *aluminium*. The Germans used *alumium* exclusively until 1824, when Wöhler, translating a paper of Berzelius from the Swedish, used *aluminium*, which he also used in his famous memoir describing the isolation of the metal, in 1827, and which has been used in Germany almost exclusively ever since.

As to the English, they used *aluminum* altogether until Wöhler's discovery, when the spelling favoured by Wöhler was almost universally accepted, *aluminum* being used only now and then by some patriotic Englishman averse to foreign innovations. We may say, therefore, that since 1827 the scientific world accepted and used the term *aluminium*.

Americans, however, have been most active in resurrecting the old English term *aluminum*. They say it is the shorter (true) and *ergo* the better way. That is what I should call intensely American. Mr. Eugene H. Cowles tells us that the Cowles Electric Smelting and Aluminum

* A portion of a lecture delivered before the Franklin Institute.

Company was originally organised as the Cowles Electric Smelting and Alumin(*i*)um Company, but that the writing of that extra *i*, and especially the dotting of it, became such an insufferable burden and expense that they went to the court about it, and had the name changed to the Cowles Electric Smelting and *Aluminum* Company.

The question now is, which of these two forms shall we use? If *aluminium* is positively too long for practical, every-day use, and must needs be shortened, it is mere trifling to say that the dropping of one *i*, the removal of one letter out of nine, is any satisfactory means of accomplishing that end. But if a shortening must be made, if manufacturers need it, and public opinion demands it—if, above all, it would, in any way, save dollars and cents, and lower the market price of the metal—then let us make a shortening which will be radical, which cannot be improved upon, and adopt Mr. Oberlin Smith's suggestion to call the metal *alium.* I think the suggestion a happy one, and if any change from *aluminium* should become necessary, I should be in favour of, and be one of the first to use, *alium.* There are two among the electrical processes I now discuss together: Cowles Brothers' and Hèroult's processes for producing aluminium alloys. The principle involved is the interruption of a powerful electric current, the formation of an immense arc, and the reduction in this arc of alumina, by carbon, in the presence of a metal. The working of both of these processes is too well known to require my tarrying to describe them to-night. In Cowles Brothers' furnace the current is interrupted by having to pass through a box filled with broken pieces of carbon, the whole interior is raised to a very high temperature, at which the alumina present is reduced by the carbon and alloys with the metal. That this is the *rationale* of the process there can be almost no question. The Hèroult apparatus is arranged differently. Alumina is fused by the electric arc, and, floating on molten copper, is then treated as though it were an electrolyte, a carbon rod dipping in the alumina being the positive pole and the copper the negative. The patentee of this process claims that it is essentially electrolytic, and, indeed, it may be allowed that some electrolytic action may take place, because the parts are arranged in just the correct way to obtain that result, but, by a quantitative study of the quantity of the electrical current and the amount of metal reduced, both in this furnace and in the Cowles process, it can be shown that several times as much aluminium is produced as the current could be able to separate electrolytically. It is, therefore, evident that the larger part of the reduction in these furnaces is due to some other agency than electrolytic action, and this other agency can only be the reducing action of carbon. Of the two furnaces, I think that the Hèroult is the better arranged, and in best shape for practical working.

From the preceding observations, we may, then, consider the fact established that *alumina can be reduced by carbon*, at a temperature somewhere not far above the fusing point of alumina, which is below 2,600° C. This opens up the possibility of simpler processes of reduction than any yet known. Is it because the alumina is fluid that carbon reduces it, or is it solely because of the high temperature? I cannot but think that the fluidity of the alumina plays an important part in this reduction. But, may it not be possible to render alumina fluid at a lower temperature than now appears necessary? I think that it may. For instance, when I dissolve iodine in alcohol, rubber in carbon bisulphide, do not these substances become fluid at ordinary temperatures? Cryolite and some other salts appear to dissolve alumina mechanically at about a red heat, and if this action be purely mechanical, then we certainly have alumina fluid at that heat. I think it quite probable that alumina thus rendered fluid could be reduced by carbon at a much lower temperature than is required to do it in the electric furnaces.

You will have gathered from these remarks that I am by no means wedded to the idea that we will find the final solution of the aluminium problem in electrical processes. I consider that they are handicapped by an extensive plant, and although electrical processes are "on top" at present, and I think will stay there for some time to come, yet I am far from considering that they may not possibly be superseded by non-electric methods of reduction. I do not consider the sodium processes, however, as ever likely to take part again in the metallurgy of aluminium. I think their day is past, but I now refer to methods of reduction by common reducing agents. Those who have read the literature relating to this subject must have concluded that almost every possible or impossible means of reduction has been tried, with but slender success. Calvert and Johnson produced iron-aluminium alloys with as much as twenty-four per cent. of aluminium by the reducing action of iron on aluminium chloride. A similar alloy, with three and one-half per cent. of aluminium, was made by Faraday and Stodart, by the reducing action of highly-carburetted iron on alumina. Pig irons have been analysed containing as much as one per cent. of aluminium. Zinc will, under some circumstances, reduce small amounts of aluminium chloride and cryolite. Half a dozen of the common metals can reduce aluminium sulphide, among which tin seems to do it easiest and most completely. Under peculiar conditions, zinc will overcome the affinity of aluminium for oxygen. We have in several places come across the fact that carbon reduces alumina at a temperature elevated enough to fuse the alumina. So, while ordinary reducing agents have been tried in almost every conceivable way, I hope and believe that they will yet come to the front as important factors in producing cheap aluminium.

Gathering all the threads together, the general conclusion is, I think, that progress, very satisfactory progress, has been and is being made. Rome was not built in a day, and I, for one, am quite satisfied with the progress of the aluminium industry. Six years ago aluminium sold for 12 dollars a pound, three years ago for 5 dollars, to-day it is being sold in England at 1·50 dollars, and before this year is out it will probably be down to 1 dollar. Aluminium was never before sold as cheaply as it is now. The prospects for cheaper aluminium were never more promising than they are to-day.

---

Messrs. Hinton, of Bedford Street, have shown us a neat little carrier for celluloid films, which can be readily inserted in the double back. It consists of a backing of thin Russian iron, to which is attached by a cloth hinge a frame of the same material. The celluloid film shut in between these, with the dark slide spring pressed against the back, remains perfectly flat during exposure.

What is the Colour of Oxygen?—Till now it was believed to be as colourless in the liquid form as it is in the gaseous. But the Polish chemist Olszewski shows that it is only because thin layers of it have been examined that liquid oxygen has been believed to be without colour. He has succeeded in getting a layer of it 30 millimetres thick, and he finds that it has a bright sky-blue colour. The discovery is very important in point of view of the absorption spectrum of oxygen.

## Notes.

A reminder that there is danger even in the developing cup comes to us from far-off Baltimore. Mr. E. C. Tweedy, a well-known photographer there, met his death the other day by mistaking in the dim light of his dark room a solution of pyrogallic acid for a glass of whisky and water. He knew the danger he was in, and without delay took a powerful emetic, and for the time apparently recovered; but the poison had entered too far into the system, and in three days he was a corpse.

This terrible accident will do some good if it will impress upon the minds of photographers that the pyro which is in such every-day use is a virulent poison. Most men are careful to keep cyanide and corrosive sublimate under lock and key, for they know what terribly poisonous substances they are. The chemist, too, will be careful not to sell the smallest quantity of either without knowing his customer, and getting his signature in the "poisons' book." Nor will he hand the poison over the counter unless it be confined in a stoppered bottle, and labelled with a red inscription. Not so with pyrogallic, which it is customary to sell without any poison label, and which would readily be handed to the smallest child without hesitation.

There is an amusing article in this month's *Strand Magazine*, describing the daily work of an East-End photographer, and how he is constantly called upon to take the portraits of the cosmopolitan inhabitants of that part of London. Anyone who is acquainted with the neighbourhood will know that this account of its population is not far-fetched, for nearly every country in the world is represented here. It would repay any photographer to made a study of this curiously mixed population, and he could do it with comparative safety now, for the stringent police regulations have gradually tamed the wild populace into something like order. Twenty-five years ago it was different, for it was then not safe for a stranger to walk up Ratcliffe Highway after nightfall. Ratcliffe Highway, indeed, gained such an unenviable notoriety that its name was changed, and with its change of name it seems to have changed its character.

In the article referred to, we are told that the stock-in-trade of an East-End photographer is not an elaborate one, and that he may pick up the whole of his apparatus for £5. We are told, too, that the studio and fittings are not expensive. The price of ferrotype plates and frames is also given, and we are informed that the chemicals cost an infinitesimal sum for each photograph taken. At this cheap original outlay the East-End photographer on a good day has a turnover of between £2 and £3. Of course there are ups and downs, and trials of temper and patience to be considered, but we cannot agree with the writer when he alludes to "the unhealthy nature of the business." Perhaps he is not quite up to modern methods of photographic production.

The weak point of photography is, that no sooner has anybody discovered anything, than it is discovered that somebody else has discovered it before him. A paragraph has solemnly gone the rounds of such papers as are interested in photography that a certain Herr Eggenneiler has been trying to take portraits in a studio without a glass roof. We are told, with all the circumstance befitting a novelty, that Herr Eggenneiler's studio faces north, that the northern wall alone is built of glass, and is about twice the height of the southern wall. Wonderful! What a pity that such a studio as this should have been described at least twenty years ago in the Photographic News. It is a bad thing for photographers to have good memories.

A gentleman well known in Edinburgh photographic circles is making an interesting experiment. He is engaged in collecting the portraits of photographic celebrities, and would be glad to enter into communication with others so interested for mutual help. We are afraid he will want a good deal of help. The shoemaker is always the worst shod, and the photographer usually has no portrait of himself. The exceptions to the rule are generally the results of some experiments for the testing of a new lens, or what not, made on those occasions when one photographer, like Dickens's veteran waiter, spends a holiday by helping another in the same line.

The two hundred persons or more who were recently victimised by means of a bogus portrait club owe no thanks to the Public Prosecutor. Although sufficient evidence was laid before this functionary to show the true character of the business, he could not see anything beyond the county court as a remedy for the deluded subscribers. It was owing to the perseverance of the police that the swindler is now suffering a term of imprisonment. Photographic portrait clubs, whether real or fictitious, appear to be beyond the ken of the Public Prosecutor.

An amateur friend complains that all advice given him is not profitable. Comparing notes with one more experienced than himself as to the difficulty of keeping the focussing-cloth in its place when photographing on a breezy day, he was recommended to cut a hole in the cloth and slip it over the lens; this would keep it down in front, while a couple of tapes at the opposite corners tied round the neck would enable him to defy the strongest gale. He tried the method, with the result that he smashed his camera. The plan, no doubt, is an excellent one if you don't forget to untie the tapes on hastily withdrawing your head. For want of this precaution, our friend dragged his camera as well as his head, with the consequence already described. He prefers his old method of stuffing the two corners of the cloth in his mouth and holding them with his teeth. He says you soon get to like the flavour of the cloth.

The Society for the Prevention of Cruelty to Children appreciates the value of photography. The annual report just issued is illustrated with portraits of the unfortunate little ones who have come under the cognizance of the Society. There are photographs of them in all stages of emaciation, and there are photographs of the same children after a few weeks' care and kindness. The idea is of course not new, as it is largely made use of by Dr. Barnardo, and before him by Miss Rye, but it is none the less effective as an appeal for sympathy.

## PHOTOGRAPHIC FRAUD.

BY JAMES MEW.

"IF," says Bossuet, in one of his sermons, "those people of rank whom it has pleased God to place in the highest offices were not ever wont to apply all their strength to sustain truth and right and justice, the earth would be desolate, and fraud unlimited." The learned ecclesiastic had a poor, but perhaps correct, opinion of the majority of mankind, strangely at variance with his view of those set in authority over them. The moral divergence of these two sections of the community, the governors and the governed, is not, however, conclusively established. The Turks have a proverb, *Hamin tash hamin dibac*, to the effect that pestle and mortar is all one. That every art and science, every trade and industry, every branch of human skill or handiwork has been limed by deceit to catch the incautious, will be generally admitted. Photography has not escaped this pollution. Almost as soon as it was born the touch of fraud defiled it, and it has not thrown off the poison in adult age.

Many frauds labelled photographic seem not fitly to be so called. The artist, for instance, who advertises for an assistant—an artist as well known to most men as the "old soldier" in a subscription to a missionary fund for the conversion of the Jews, or some other purpose equally excellent—and requires specimens of that assistant's handicraft, which the advertiser keeps when good, and exposes in his own show-case as his own work to beguile the passer-by, is not to be differentiated, by the fact of his thus obtaining photographs under false pretences, from the ordinary swindler. When, after the police have been set upon his track, he affirms, with all the earnest asseveration of the injured, that he has just returned the specimens by post, his lie is that of the common rogue who also remits any incriminating articles as soon as he sees the policeman's back. The thoughtlessness of the would-be assistant contributes greatly to the success of this species of imposture. A very little acquaintance with mankind should be enough, and more than enough, to induce any person of any degree of any intelligence to verify, before sending his specimens, the address, and profession, and commercial status of the advertiser who asks for them.

The spendthrift who politely begged his rich uncle to sign his name in the slit under his portrait in a photograph album, could hardly be charged with photographic deceit, though the uncle afterwards discovered that, instead of writing on his "cabinet," he had written on a cheque for £500.

About pirated copies of photographs, sold to hawkers at some half-dozen shillings a gross, a loud and bitter cry has gone up, but these are by no means photographic frauds.

By the manufacture of fraudulent lenses, as by the adulteration of chloride of gold, the photographer is himself deceived. As early as 1864 foreign lenses were sold bearing an English name. The celebrated optician, Dallmeyer, suffered considerably from this species of imposture. Treacheries of a cognate kind were all too frequent in many other trades. For instance, Geneva manufactured the works of a watch; England supplied the case. The chronometer was then described as an English watch. Arguments were not wanting to defend such a description, however iniquitous and untrue it may at first sight appear. Finally, such false trade descriptions were prohibited by an Act of Parliament, passed by the legislature, against the fraudulent marking of any goods of sale whatsoever.

This matter of the lenses is also a fraud connected with photography rather than a photographic fraud. It is of a piece with many other impositions in which the photographer is the patient, not the agent. For instance, in the matter of payment, how often is the unhappy artist deceived. What man is there who is not acquainted with the old, old excuses, "I have forgotten to bring my purse with me," "I was never asked to pay so soon before," "I will write and send you a cheque," "If you will call to-morrow I will take care that the money shall be ready," and so on, while the photographer who has had to pay cash for his chemicals, and instruments, and furniture, and instruction, grows as lean as Cassio, or leaner. If, on the other hand, the artist gives credit, let him ponder the true tale of the photographer and the widower's tomb. "I want," said the mourning widower, "the tomb of my late beloved wife photographed." It was done. "This," said the bereaved husband, "is not enough; I should wish some of her relatives to surround it, including my mother-in-law." This also was effected. Then said the unhappy man, "I cannot see the tomb for the relatives; there are too many of them, and the date of my wife's decease is obscured by the feather in my mother-in-law's bonnet." In fine, he would pay nothing. It is gratifying to know that in this case the aggrieved photographer obtained the full amount of his bill and costs.

In 1862, the mania of collecting already used and so, apparently, further useless postage stamps, was in the zenith of its popularity. The end and object of this collection has, it is believed, been never yet clearly understood. Statements have, indeed, been circulated that these old stamps might be sold to Government at a high price; that they were instrumental in procuring the admission of a lunatic into an asylum depending upon charitable donations—a statement which, indeed, might very well be true, though not in the sense in which it is commonly understood by the acolytes of what is called, with perfect gravity, the science of philately; and that they were admirably suited for papering walls, a work which, in loathsome tediousness, might surely eclipse the labour of Hercules in the Augean stables. But whatever the motive of collection may have been, photography was at hand to produce in large numbers the article collected. Counterfeited stamps with cancel marks and all complete, defying detection, were produced by the camera with the greatest ease.

In how many albums—fashionable toys of the time—now forgotten and cast aside into a dusty lumber room, are such photographic relics enshrined, foreign stamps of remote countries and islands far away, printed in dark neutral tint, brown, black, or purple, colours favourable to the fell purpose of the dishonest tradesman. Regarded once with an affectionate reverence to which they were as little entitled as many other objects of veneration which, since it is the highest pleasure to be well deceived, have given so great joy to mankind in their generations, they now lie apart from the busy progress of life, uncared-for and unseen, sad memorials of the transitory nature of the human preferences which called them into existence, through the mechanism of a photographic fraud.

*(To be continued.)*

THE Society of Amateur Photographers of New York has discontinued the publication of its journal, which will now be merged in the new *Photo-American Review*.

## STAINING FILMS TO PREVENT HALATION.

BY P. C. DUCHOCHOIS.

Halation is a blurring, or luminosity, extending in the shadows from the edges of the lights of the picture, often seen around the branches of trees in landscapes, the roofs of buildings, the windows in an interior, &c., so that the edges of these objects, instead of being well defined by sharp lines, seem to be confused, as it were, with the sky or the high lights. It occurs whenever a brilliant light is opposed to shadows or a much less bright light, and when white is just opposite to black; in the latter case by long exposure time.

The most general cause of this defect, so often observed in photographs taken out doors, arises from the rays of light reflected, after passing through the film without being wholly absorbed, by the back of the glass plate acting as a mirror, and again impressing the film, but outward of the point of incidence, according to a well known law of physics. The remedy suggests itself—namely, to paint the back of the plate with an opaque material which absorbs the light; "Gihon's Opaque" is generally employed. A similar water paint can be prepared by grinding into a paste the following ingredients:—

| | |
|---|---|
| Burnt sienna ... ... ... ... | 16 parts |
| Dextrine ... ... ... ... ... | 4 ,, |
| Glycerine ... ... ... ... | 2 to 3 ,, |
| Water ... ... ... ... ... | quant. suff. |

Halation occurs most easily by long exposure time, even with plates backed as said above. The cause is then complicated by the reflection from the molecules of the silver haloids not forming a continuous layer, but agglomerated into grains of more or less volume. It has been said by Captain Abney that these grains not only reflect the light, but disperse it in various directions. This, of course, would produce the defect in question if the exposure time has to be lengthened so long as, for example, it is necessary when photographing the "Milky Way"; for if a bright planet like Jupiter or any other orb is in the field of vision, it will certainly be blurred by irradiation.

The blacking of the back surface of the glass plate, although useful, is, in such a case, insufficient. The sensitive film should be dyed to completely absorb the light, especially the most active rays. Here we must let Mr. Carey Lea explain the best manner of preparing the sensitive film. Moreover, the process is due to him. We quote from his excellent "Manual of Photography":—

I believe that I may claim to have been the first, now many years since,* to propose the method of *colouring the film* to accomplish this result (to prevent blurring). The difficulty lies in this, that most colouring matters applied to the film distinctly diminish the sensitiveness. I have lately compared all the colouring matters that have been suggested for use, and also very many others, and find *scarlet coralline* to be the best. Coralline has been tried before, but always with a diminution of sensitiveness. . . . I have been so fortunate as to find the method of using coralline which avoids this difficulty *wholly*. . . . This result is accomplished in the simplest manner. It is only necessary to add the alcoholic solution of coralline to the finished emulsion, and employ it precisely as usual. Neither is there any necessity of removing the colour from the plate. This I consider a fatal objection. Coralline has the inestimable advantage that it disappears of itself in the operations of developing, fixing, and washing.

The best scarlet coralline (the yellow coralline sometimes called *aurine* is entirely unsuitable) is to be dissolved in alcohol, forty-eight grains to the ounce. The solution takes place rather slowly, and several days should be allowed, with occasional shaking. Neither is it ever entirely complete; a small amount of dark residue always remains, even after standing for months. To each ounce of finished emulsion* from six to ten minims of this coralline solution is to be added and well shaken. The emulsion is then ready for use. It will not have the strong red colour of coralline, but a buff or salmon shade.

* This was written by Mr. Carey Lea in 1876.

We have used this process with our emulsion, and also with silver bromo-gelatine plates dyed by the bath method, and always with good results. This we, perhaps, need not state, for the authority of Mr. Lea is more than sufficient to recommend this process.

It is to be remarked that the coralline dyed plates are orthochromatic, being colour-sensitive to yellow extending to orange.

The process of Mr. Lea reminds us of another one, published, I think, in Seely's *American Journal of Photography* for 1858 or '59, which also gives orthochromatic effects. It was not, however, published for that purpose, for the author of it had not any idea of the principle, discovered by Dr. H. W. Vogel, upon which are based the orthochromatic processes, but to prepare a film *less permeable to the luminous rays, in order to avoid solarisation and obtain better half-tints.*

In my note-book I found the formula following, with the name of Sanders as the photographer who devised it:

| | |
|---|---|
| Ether conc. ... ... ... ... | 4 fl. drams |
| Alcohol, 98 degrees ... ... ... | 4 ,, |
| Ammonium iodide ... ... ... | 10 grains |
| Cadmium bromide ... ... ... | 5 ,, |
| Pyroxyline ... ... ... ... | 10 ,, |

To which should be added 1 ounce of a filtered solution prepared by letting macerate for several days 1 ounce of curcuma in 4 ounces of alcohol. In my note-book I remark that the above quantity was too great, and that by adding only half of it with 4 drams of ether the collodion worked well, yielding good intensity.

It is very curious that so long ago as 1858-59, dyes were used in photography to obtain better half-tints in the dark or coloured parts of the objects to be photographed, and that this should have passed unnoticed.

In concluding, we advise the reader to back *always* the plate with an absorbent of light and to use dyed film, as by so doing he will obtain pictures quite free from halation and exceedingly sharp all over, which is the natural consequence.—*The Photographic Times.*

* The chloro-iodo-bromide (collodion) emulsion, prepared according to the formula given by the author, Mr. Lea.

---

Another Process for Preparing Oxygen Gas.—Another process for preparing oxygen gas is described by G. Kassner as follows:—Bioxide of barium in contact with ferricyanide of potassium, in presence of a little water, evolves a gas which, on examination, proves to be pure oxygen. At the same time a change of colour occurs, as the ferricyanide passes into the state of ferrocyanide. If the quantity of water is sufficient, the whole is dissolved, except any insoluble impurities which may happen to be present in the barium bioxide.

At the County of London Sessions on Thursday, last week, William Edward Parker was brought up before Mr. Loveland Loveland, sitting at Clerkenwell, for sentence. The prisoner was found guilty of having defrauded a number of persons through a "photographic club" which he professed to carry on at Carlton Terrace, Harrow Road, and in the Uxbridge Road. Mr. Burnie was for the prosecution; Mr. Willes for the defence. It was stated that as many as 300 persons have made complaints against the prisoner. He was sentenced to ten months' imprisonment with hard labour. Detective Mott was commended for the manner in which he had investigated the case.

## THE HOKE ENGRAVING PROCESS.

This process, by which a printing block can be produced with great rapidity, has lately come into extensive use for line-work illustrations in newspapers. Although it does not depend upon photography, the matter is one of interest to photographers, if only in showing that they have a rival in a field which they were justified in thinking all their own. The process is wonderfully simple. A blackened iron plate is covered with a soft chalky composition, forming a layer of about $\frac{1}{32}$ of an inch in thickness. Upon this surface the artist makes his sketch, and proceeds to cut through the lines with an etching point until he exposes the dark metal beneath. He is thus able to see the effect of his work as it proceeds as easily as if he were working with pen and ink. The Hoke Engraving Company supply the prepared plates at so much per dozen, and when the drawing has been etched in the manner described, they will undertake to make a printing block from it. To do this, the plate is transferred to a casting box, which consists of a metal receptacle heated by gas, and round its edges are fixed metal bars one inch in thickness. The picture, face upwards, thus lies in a kind of well. A lid is screwed down, and the box turned up to the vertical position. Through an opening left at one end molten stereotype metal is now poured into the box, and not only covers the drawing, but flows into every scratch made by the etching needle. In a few minutes the metal cools, and is then turned out of the casting box in the form of a block ready for the printing press. The annexed sketch was executed in the way described on a plate sent to this office for trial, and by one who had never before practised the method. It proves, we think, that the system, in experienced hands, must be capable of good results, even if specimens examined by us had not already convinced us of the fact. The office of the Company is at 58, Fleet Street, E.C.

## THE DECOMPOSITION OF SILVER CHLORIDE BY LIGHT.

BY ARTHUR RICHARDSON.

The author described experiments which have been made with a view to determine whether silver chloride which has been darkened by exposure to light under water contains oxygen. The nature of the change which occurs during decomposition of the chloride was also studied with reference to the part played by water.

Pure silver chloride was prepared by addition of dilute chlorhydric acid to a solution of pure silver nitrate, the precipitate being washed by decantation till free from acid. The following facts were observed during exposure :—

1. Oxygen was evolved, a part of which was present as ozone.
2. When small quantities of water were present, chlorine and hydrogen chloride were found in solution.
3. When a large volume of water was taken, hydrogen chloride, but no chlorine, was detected.

The influence of hydrogen chloride in retarding the decomposition of silver chloride is considered, and is explained from experimental results given, which show that even minute quantities of hydrogen chloride exercise a marked influence on the stability of chlorine water when exposed to light, the rate of decomposition of the silver chloride being dependent on the readiness with which the chlorine in solution and water interact to form hydrogen chloride. Thus, when silver chloride was exposed to light in a solution of hydrogen chloride containing 0·9 part per 100 of solution, the total chlorine liberated was 0·201 gram, of which 13·7 per cent. represented free chlorine, whilst for the same weight of silver salt in pure water the total chlorine found was 0·276 gram, of which 0·9 per cent. was present as free chlorine.

In the examination of the darkened product for oxygen, a portion of the substance was taken which had lost 8 per cent. of its total chlorine during exposure. After it had been dried at 110° C. till it ceased to lose weight, it was heated in a current of pure hydrogen, the gaseous products of the reduction being passed through a weighed phosphorus pentoxide tube. Before using this substance as an absorbent of moisture, it was ascertained that hydrogen chloride was not absorbed by it after contact for a few hours only, as the weight of the tubes remained unaltered in contact with the dry gas. The hydrogen was prepared by the action of steam on sodium, numerous precautions, which are described in full in the paper, being taken to preclude errors.

The results show that the gain in weight of the drying tubes after the decomposition of the silver compound, which lasted from seven to eight hours, is so small as to preclude the possibility of the presence of an oxygen compound in the darkened product. The darkening of the carefully dried chloride was also observed to take place when exposed to light in a tube containing dry carbon tetrachloride from which all air had been removed by boiling. From these facts the author concludes that the darkened silver compound is of the nature of a subchloride rather than an oxychloride.—*Proceedings of the Chemical Society.*

Club der Amateur-Photographen in Wien.—C. Srna writes that, owing to the printers' strike in Vienna, "the issue of the Exhibition catalogue with the English preface was unduly delayed, as it was impossible to get it printed."

## AUTOMATIC PHOTOGRAPHY.

When first the idea was mooted, now some two years ago, that the penny-in-the-slot principle could be applied to photography, the knowing ones shook their heads and smiled. Perhaps they did not like to admit that an art which had cost them so much pains to acquire, and which they had always been so careful to describe as being dependent upon intelligent handling of apparatus and chemicals rather than mechanical in its nature, could possibly be practised by the mere modification of a machine whose usual work was to dispense chocolate and butter-scotch. Others argued that, seeing that the kodak, with its simple formula, "You touch the button, and we do the rest," was an established success, the penny-in-the-slot machine, being as simple in theory, ought, too, to bring fortune to its promoters. At any rate, many believed so far in the possibilities of the new machine as to back their opinion by cash, and the inevitable company was formed and floated without difficulty.

For some reason or other the promised machines did not make their public appearance very speedily, and many were the comments in the photographic press as to the probable cause of the delay. The whole of last summer slipped by, and the company took no toll from its brilliant sunshine. The chocolate and butter-scotch, the cigars and cigarettes, the squirted drop of scent on your hand-kerchief, the fuzees, the postcards, and all other articles which it is possible to dispense automatically, continued to find ready customers, but the photographic machine was not.

But with the present year the void has been filled, and at most places of public resort the automatic machine may now be noticed. In appearance, a cross between a parish pump and a pillar letter box, rearing its head above its surroundings—a thing not of beauty, but one which seems to arouse much curiosity. At the Naval Exhibition alone there are twenty-one of these automatic machines, and, as far as we could judge from casual observation one day last week, when the sun vouchsafed to show itself for a few hours, they met with much custom from the sight-seers there assembled. Naturally, being well disposed ourselves towards photographic enterprise in any form in which it might show itself, we invested several pennies in these machines, and are, therefore, in a position to say something about the way in which they work, and the pictures which they turn out; and we may at once say that our experience was not solely gleaned in the grounds of the Naval Exhibition, for we had, before its opening, observed the behaviour of several of these penny-in-the-slot contrivances at other places.

Our first interview with the machine—if interview it can be called—was outside a large draper's shop in North London; but upon expressing a wish to have our photograph taken, we were told that the apparatus was not at work. We, however, took stock of the machine, and read the instructions, which were to the following effect: "To obtain a photograph, stand about three feet from the machine, looking into the mirror. Then place one penny in left-hand slot, and remain steady until the bell (inside the machine) rings. In about forty seconds the photograph will be delivered." A further notification pointed out that another penny dropped into the right-hand slit would bring forth a gilt frame. We also learnt that "the Company does not hold itself liable for any failure if the above instructions are not strictly adhered to."

We certainly felt grieved that we were not able to spend our penny, and were beginning to feel annoyed at the closure of the apparatus when a further notice attracted our eye. This one seemed to be a kind of after-thought, for it was a simple printed notice stuck on to the painted surface of the apparatus. "The public are recommended not to be photographed on dull or foggy days." Well, the day in question was certainly dull, but, as the authorities had put it quite out of anybody's power to be photographed, the notice seemed to be superfluous.

The next day was brighter, and we journeyed to Hampstead Heath in order to see what automatic photography could do for us there. Here we found two machines, and we comforted ourselves with the assurance that if one was not available, the other surely would be. The first machine is in the Vale of Health, and we found it without difficulty; but it bore an ominous label padlocked over the lens aperture, and this label bore the word "Closed." A small crowd stood around the contrivance, as if they expected it to "go off," or, at any rate, to perform in some way or other. Their presence was, no doubt, partly due to the circumstance that an attendant stood by the machine, as if ready to act in case of emergency, for a man who has the temerity to stand still and do nothing is pretty sure to attract a crowd. We were told by a bystander that the thing wouldn't work this morning, and that the other machine round the corner had also struck. He further expressed the opinion that "the 'ole bag of tricks is a blooming fraud." We simply repeat his remark in the strange language in which it was expressed.

We then walked round to interview the other machine, in front of which was a larger crowd, perhaps three dozen in all. There was evidently something going on here, for the attendant was in the act of adjusting the mechanism inside the apparatus, through a kind of man-hole in its side. As we approached, he shut up the door with a snap, put an iron cover over the lens opening, locked it up, and walked away, leaving the crowd of would-be models behind, still gazing at the enigmatical machine. On enquiry, we learnt that "something had gone wrong with the concern," and that the man had gone to fetch some "stuff" to put it right again.

We waited patiently for his return, and in due time he made his appearance accompanied by another man, who was evidently his superior. Between them they re-opened the machine, and began to wrestle manfully with the hidden mechanism. After it had clicked spasmodic-ally for a few minutes, we were told that it was ready for work. With a beating heart we stood three feet in front of the mirror, handed the man the penny to drop into the slot, and, after an anxious five seconds, were released from our constrained attitude by the ringing of a bell. Click, click, click, went the machine—and then stopped. With a frown on his brow, the attendant opened the man-hole and shut it again with a bang in order once more to start the mechanism, and again the clicking was resumed. Our thoughts wandered away for the moment to the glories of Astley's amphi-theatre in the days of our boyhood, when there was a tradition to the effect that before Mazeppa's "fiery untamed steed could be induced to start on his wild career," it was necessary to bang an old omnibus door behind the scenes. The bang of the apparatus man-hole had the same effect, and the clicking went on for about forty seconds, when the portrait was duly delivered.

We now approach a rather delicate subject. We have never been afflicted with any great amount of conceit about our personal appearance, but every man has a sort of idea of the kind of man he is—a faulty idea, no doubt, for the image that he sees in the looking-glass is a reversed one. Still, he may be said generally to be able to recognise his own portrait. We recognised the one taken by the automatic machine—which, by the way, is certainly not automatic in its action—by a book which we happened to be holding at the time the picture was taken. This book was the one high-light in the composition. The rest was not only black, but the features were distorted, and the chemicals formed an ornamental marbling over the surface of the picture. We had another try, but it was no better, and since that eventful day, many are the pennies which we have sacrificed in the hope of getting something satisfactory out of the machine. The best of these we picked out and showed it to an intimate friend in triumph. "Who is that?" we said. "Oh! I've seen that thing long ago," was the reply; "it's the mummy of Pharoah." After this we changed the topic of conversation.

## PHOTOGRAPHY IN THE CELESTIAL EMPIRE.

BY ROMYN HITCHCOCK.

I have been somewhat agreeably surprised to discover the interest manifested in photography by many residents in China. Here in Tientsin—which is a very large Chinese city, with only about two hundred foreign residents—the Tientsin Amateur Photographic Association was organised last January, with about twenty members. The United States Consul at this place (Dr. William Bowman) is one of the active members, frequently to be observed active in snapping the detective which he recently obtained, and there are a number of others who are very successful with cameras of various kinds. The secretary of the Society is Mr. H. J. Bostwick. The present writer is not a member, being only a sojourner in the land; but it was his privilege at the first meeting to give a demonstration of eikonogen development with the last portion of that agent he possessed. Eikonogen in crystals does not keep well; the surface turns black, and, to make a solution of the proper colour, it was my custom to weigh out double the quantity required. Wash it in water, which readily dissolves the black portion, and then dissolve the white residue in the sulphite and alkali. A serious loss is thereby sustained. Owing to the difficulty of obtaining good eikonogen, I have returned to the use of pyro. Perhaps the dry powder preparation recently introduced will once more bring the former agent into favour in this distant land. Peking has several very successful amateurs.

At Shanghai there is the China Camera Club, with about forty members. I am not acquainted with the work at Shanghai, but Mr. W. S. Emens, the United States Vice-Consul General, is an active member of the Camera Club, and has had considerable experience.

Plates from the United States are not much favoured in North China. The reason for this is not obvious; but it may be because they are not much known, and that there is nobody to introduce them. Seeking for information, I asked the salesman at Hall and Holtz's why the American plates were not used, as they could be furnished so much cheaper. I thought 6.50 dollars an exorbitant price. He told me that American plates were not good!

The demand for plates in China must be very large. The Chinese do considerable work themselves. Most of it is of an inferior quality, it is true, but the same may be said of much of the work by foreign professionals. These strictures apply to North China and particularly to this city and to Peking. I would gladly do whatever I can to introduce our own plates in China, but as a primary step I would wish positive assurance that the plates should be packed to meet the requirements of the trade. This would involve the use of paraffined paper to protect them from moisture, the plates being wrapped in packages of four, with at least three separate wrappings of such paper. Thus, if shipped in metal-lined cases, they would come *via* Suez Canal in good condition, and they would keep through the wet season at Shanghai or Hong Kong, when unpacked. It is a too common impression in the East, that certain makers of plates in the States have been so unwise as to send inferior plates to Japan and China, thinking to get rid of them to the unsuspecting Celestials. While I do not credit the story, I do know of one instance which partly justifies it to those who did not know the circumstances of the shipment.—*Abstracted from Anthony's Bulletin.*

## Notices of Books.

Monte Rosa and Gressoney. By Vittorio Sella and Domenico Vallino.

This work, lavishly adorned with phototype blocks and collotypes, is a very good example of what photography is capable of in the way of book illustration. Sig. Sella is well known to most of our readers as a photographer who can do good work, and the pictures in this handsome book are a further tribute to his talents. They are full of beauty, and have been so wonderfully reproduced by the collotype process that it is difficult to believe that they are the result of a mechanical operation. The snow scenes are especially admirable, and half-tones and pearly shadows are as well represented as they could be in the most carefully executed silver or platinum print. The pictures have been taken in a district where, up to the present, the footfall of the ordinary tourist is seldom heard, where the people live a primitive life, and where language and costumes are alike strange. There are few such places left in Europe, and the authors have done well to seize photographic records of a state of things which the railway must presently extinguish for ever. In a private letter, Sig. Sella tells us that the book was completed in two months, and that its price is only fifteen shillings, so that he can claim both rapidity of production and cheapness for the form of publication. The text is Italian. Copies of the work can be obtained of Messrs. Spooner, 379, Strand, but they are not likely to remain for long unsold.

The Photo. American Review is a new monthly publication of novel design, and published in magazine form. The first forty pages are occupied by photographic matter, including a large number of well executed phototype reproductions, while the rest of the work—some sixty pages—is taken up with a record of all new books, and a review of no fewer than five hundred and thirty. These works consist of current literature of all kinds. The publication thus appeals to general readers as well as to photographers, and it is so well done that it should, we think, prove both useful and successful. The price is twenty-five cents, and it is published by H. C. Jones, of New York City.

Agenda de L'Amateur Photographie pour 1891.—This is a useful little book of the type of so many published in this country for registering particulars of negatives taken, plates used, time of exposure, and so on. It contains a clever little movable disc, which will give the approximate exposure necessary for different hours in different months. It also comprises a number of useful formulæ, with a column for observations and modifications by the user. It is compiled by E. Forestier, and issued by the *Société Génerale d'Editions*, Paris.

The same publishers have sent us a copy of L. Mathet's Etude Complete sur le Developpement et les Developpateurs, which is uniform with several other little manuals which have been issued under the auspices of the journal, *L'Amateur Photographe.* It deals with the dark room and its fittings, and gives detailed directions for development with pyro, ferrous oxalate, hydroquinone, and eikonogen. It also indicates the modifications which are necessary during development in treating different kinds of subjects. The last chapter is a most useful one, for it points out how temperature influences development—a part of the subject which is too often completely neglected.

## Patent Intelligence.

### Specifications Published.

18,583. *November 20th*, 1889.—"Improvements in Optical Lanterns." Alexander Hughes, 59, Fenchurch Street, London, Optician.

The invention relates to that class of lanterns generally known as "optical lanterns," such as those used for projecting views upon screens by means of artificial light, and is particularly applicable for lanterns of the triunial, biunial, or single type used for producing dissolving views. It consists in the construction and arrangement of the lanterns in triple, double, or single form, whereby the following advantages are obtained over the lanterns now in use.

1. When triple or double lanterns are used of the ordinary description, only one set of lenses, with condensers and lighting apparatus, work upon a true optical axis. Now, assuming that, in a triunial lantern, the centre set of lenses is the one working as above described, the lenses of the upper and lower lanterns have to be inclined to the centre lantern in order that they shall each project the image upon the same part of the screen as the centre lantern. This is usually effected by throwing the front set or objective lenses of each top and bottom lantern out of the optical centre in relation to its condenser, thus causing distortion of the picture, and destroying the sharpness of detail in one part of the view or the other. These disadvantages are entirely obviated by this invention, as each optical system or lantern is complete and independent in itself, and can be tilted to any convenient angle as a whole, with one or other lantern, as may be desired.

2. Considerable reduction in cost of construction is obtained, owing to the simplification and compactness of the design.

3. The weight is greatly reduced, as the material used in construction may be aluminium ; also much less space is occupied by the lantern as a whole.

4. The lantern will allow of all the various mechanical effects and slides now being used in the ordinary form of lanterns being fitted to it and worked, and the adjustments are arranged so as to permit of the projection of pictures from the smallest up to the largest size without further apparatus or adjuncts to the lantern.

20,964. *December 31st*, 1889.—"Pictures." J. R. France, New York, U.S.A.

Relates to the production of waterproof and indelible designs, pictures, prints, photographs, or the like, of any kind or colour, or on any material. Consists in fastening the picture on or between one or more transparent or semi-transparent sheets of pyralin or other pyroxyline compound. When two sheets are employed, they are cut larger than the picture so as to enclose the latter entirely. The pictures may have a backing of wood, cardboard, and the like. The surface of the pyralin is polished before or after fixing the picture thereto by pressing on metal plates, or by other suitable means. The pictures are secured to the plates by wetting them with alcohol, or other solvent of pyroxyline, and then pressing them upon the plates. The pictures thus produced may be used as veneers for furniture.

A New Pinchcock for Burettes.—A. Dannbacher describes a new contrivance for regulating the flow of a liquid from a burette. It may be called a pinchcock for want of a better term. Two circular pieces of wood are centrally bored, the hole being just large enough to permit the pieces being slipped over the rubber tubing connecting the burette with the nozzle. A portion of the interior of each piece is also bored out, and the surfaces of the two pieces which are to be in contact are roughened so that they will not too readily slide upon each other. The upper piece is now slipped over the tube, next the lower piece, while some traction is made on the rubber. This causes the lower piece to become pressed against the upper one and to remain in contact with it, no matter whether it is twisted or not. By twisting the lower piece the flow of the liquid may be exactly regulated, stopped, or kept at any desired rate.—*American Druggist.*

M. Eugene Faller describes in a French journal a plan for vignetting negatives during exposure, and so saving the trouble of using an ordinary vignetting glass or other apparatus in the printing frame, and he advances it as a plan which is not generally known. He claims for the process that a more perfect effect can be obtained than by ordinary means, and that any background can be employed from black to almost white. In a square of white cardboard is cut an oval opening of a size suited to the photograph to be produced, the edges of this opening being serrated. This card is hung by silken cords run through two holes pierced in its upper edge to a head-rest, or other suitable support, so that it can be placed about 12 inches in front of the lens during exposure. The image will thus be framed on the ground glass, and this can be perfected by moving the head-rest to the right or the left, and also vertically, as may be required. The negative is then taken in the usual manner. To obtain the best effect, light should be reflected upon the vignetting card, and this can be done by fitting over the camera another sheet of card provided with a hole through which the lens can point. It will be seen that the method described is identical with that in common use in this country for making vignetted enlargements, in which case a similar serrated opening in a card is kept in movement in front of the lens employed during exposure.

# Correspondence.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

SIR,—The Council of this Society will feel obliged if you can find room for the announcement below, as the exhibition illustrates an important application of photography which is but little used in this country, but is employed considerably on the Continent. The Council will be pleased if those interested will come and examine the specimens.

H. LAWRANCE, *Assistant Sec.*

50, *Great Russell Street, W.C., May 16th.*

*Photographic Society of Great Britain.*—There is on view, at the Society's Rooms, 50, Great Russell Street, W.C., a collection of prints in colours illustrative of the application of photography to chromo-lithography, chromo-typography, chromo-collotype, and chromo-photogravure. The specimens exhibited show the nearest approach that is possible in the present state of our knowledge to the solution of the problem of photography in colours. The exhibition will be open daily to the end of June between 2 and 9 p.m. Admission on presentation of a visiting card.

# Proceedings of Societies.

CAMERA CLUB.

MAY 14th was a lantern evening, and slides were shown by Messrs. D'Arcis, Pinkney, Fitz-Payne, Phipps Lucas, Chang, Charters White, Humphery, and other members.

The subject on Thursday, May 28th, will be a short paper communicated by M. Leon Vidal on "A Process of Mechanical Colouring for Carbon Transparencies, Stereoscopic Views, and Lantern Slides." At this or the subsequent meeting a paper by Prof. W. K. Burton, on "A Modified Silver Printing Process," will be read, and examples shown.

HOLBORN CAMERA CLUB.

THE monthly "instruction to beginners" night was held on Friday last, Mr. R. LUXTON in the chair.

Mr. A. J. GOLDING first demonstrated on the platinotype process. In the course of his remarks on the process, he said it would recommend itself to all amateurs for its simplicity, and also for its permanence. He developed (by the hot-bath process) six prints, all turning out successfully.

Mr. E. H. BAYSTON then demonstrated on bromide paper, printing from the same negatives as Mr. Golding had used for his platinotype prints. Using the hydroquinone developer, he obtained some excellent results.

Before the meeting separated, the secretary read a circular letter *re* Mr. Biden's proposed federation of societies scheme, and it was decided that, as it was understood that the Photographic Society of Great Britain had also a scheme in hand, it was desirable to wait and see if the P. S. G. B.'s scheme came to anything, most of the members being of opinion that two federated societies would end in the downfall of both.

SYDENHAM AMATEUR CAMERA CLUB.

A MEETING was held at the "Greyhound" on the 12th inst., Mr. C. D. BUDD in the chair.

Mr. L. WILTSHIRE read a paper upon "Silver Printing," &c. After a description of the methods of preparing the paper, various sensitising formulæ were given, and several practical suggestions made.

A discussion followed, in which part was taken by the president and other ex-workers of the old wet-plate process.

HACKNEY PHOTOGRAPHIC SOCIETY.

THE annual general meeting was held last Thurday, Mr. WALTER WESSON presiding. The following officers were elected :—*President*—Dr. Roland Smith ; *Vice-Presidents*—Dr. Ambrose Kibbler, Messrs. J. Hubert, Frank Jolly, and J. A. Sinclair ; *Treasurer*—J. O. Grant ; *Curator*—S. H. Barton ; *Council*—W. L. Barker, H. J. Beasley, Walter Wesson, A. Dean, F. Houghton, C. F. Hodges ; *Hon. Secretary*—Mr. Fenton Jones, 6, Victoria Street, Hackney.

The report (third year) was satisfactory, and recorded progress.

After the election, the HON. SECRETARY read a short paper on the different developers now used.

There will be an excursion on May 23rd. Train Liverpool Street (G.E.R.) to Wood Street at 2.16 ; meet at Wood Street 2.40, and at Whip's Cross at 2.50.

ENFIELD CAMERA CLUB.

THE annual general meeting was held on May 13th, the president, Mr. D. G. PINKNEY, in the chair.

The PRESIDENT, in moving the adoption of the annual report and balance sheet, referred to the satisfactory position of the Club, and considered that the members might reasonably congratulate themselves on the credit balance of £8 15s. on the first year's working of the Club.

The president and secretary, and the committee—with two exceptions, gentlemen who had left the neighbourhood—were then unanimously re-elected. One new member was proposed, and it was arranged that the next field-day should be held at Leigh, near Southend, on Saturday, May 30th.

CROYDON MICROSCOPICAL AND NATURAL HISTORY CLUB (PHOTOGRAPHIC SECTION).

AN extra lantern meeting was held on May 15th, with Mr. EDWARD LOVETT in the chair.

Mr. J. A. SINCLAIR, of the Liverpool Amateur Photographic Association, gave an illustrated lecture entitled, "A Scamper across Normandy with the Camera." Mr. Sinclair interspersed his lecture with highly interesting, curious, and laughable incidents. The series of pictures illustrating the lecture were of high technical excellence, the final picture of the evening, entitled a "Farewell to Normandy and the Seine," a sunset picture, being worthy of special notice.

On Saturday, May 23rd, there will be a half-day excursion to Groombridge ; train from London Bridge, L.B. & S.C.R., 1.40, East Croydon at 2.3 p.m.

GLENALMOND PHOTOGRAPHIC CLUB.

THE second meeting for the midsummer term was held on May 16th.

The chair was occupied by Mr. A. S. REID, who gave a lecture on the "Development of Instantaneous Photographs by a Mixture of Hydroquinone and Eikonogen," showing some prints the negatives of which were developed by that mixture.

Mr. R. JOHNSTONE also showed some prints, one of which was a photograph of the members of the Club, taken last Easter by himself.

At the previous meeting the officers of the term were thus elected :—*President*—Mr. A. S. Reid, M.A., F.G.S. ; *Hon. Secretary*—Mr. E. H. C. Craig ; *Hon. Treasurer*—Mr. L. H. Maxwell ; *Keeper of Books*—Mr. W. H. Maxwell ; *Keeper of Album*—Mr. W. G. Harrison. At this meeting five new members were elected.

PHOTOGRAPHIC SOCIETY OF JAPAN.

A MEETING of the Photographic Society of Japan was held in the Masonic Hall, No. 60, Yokohama, on Friday, 18th instant. From a little after midday there was an exhibition of prints on the bromide paper that Mr. Cocking had presented to the Society a few months ago. Mr. Cocking offered three prizes at the time that he presented the paper, and these were awarded by ballot of members and of the public on Friday. Mr. K. Ogura, amateur photographer, won the first prize ; Mr. A. Futami, professional, the second. For the third prize, there were so many prints that received an equal number of votes that no decision could be come to at the time of the meeting. It was decided to leave this matter to Mr. Cocking. The members of the committee exhibited, but did not compete for prizes, and the work of Mr. C. D. West was particularly admired. There was a set of micro-photographs by Mr. I. Isawa that were considered to show great technical merit. Flash-light photographs, taken at various meetings of the

Society, were shown, and some by Mr. Kajima were particularly good.

Mr. K. Ogawa showed a large photograph of the interior of the Russian cathedral in Tokio. This, as a sample of interior photography—always very difficult—and also as a sample of collotype work, is as fine as anything of the kind that we have seen.

Mr. Cocking showed a large number of "Kodak" cameras. These instruments are highly ingenious, and are excellently made. The larger sizes—which have, it is believed, reached Japan for the first time—relieve the instrument from the stigma of being only a toy.

In the evening there was a regular meeting of the Society, when Capt. Kenderdine occupied the chair, and the following were elected members:—Messrs. Allan Owston, A. W. Forbes, George Brinkworth, T. H. Tanner, A. T. Watson, and J. H. Brooke.

Mr. W. K. Burton gave a demonstration of a modified silver printing process. Briefly put, the process consisted in making one solution of nitrate of silver, and another of "salt" (preferably chloride of ammonium), citric acid, carbonate of soda, and a little gelatine. The solutions are warmed and mixed, when an "emulsion" that is immediately ready for application to any surface that can be sensitised results. The process of making the emulsion, sensitising the paper, and toning prints by Clark's platinum method, was shown. Specimens of finished prints were also shown. Mr. Burton said that the process had not yet been long enough in use to know whether it had any real advantages, but the possible advantages that he saw were that a single solution that would keep fairly well could be prepared in a few minutes, and was at once applicable to any surface, whereas in all other silver printing-out processes there were either two operations—that of salting and that of sensitising—or a washed emulsion, which was comparatively troublesome to make, had to be used. The process was a cheap one.

Mr. West thought the saving of trouble was not great. So far as he could see, the advantage of the process was that it made it possible to get a blacker colour, one more nearly approaching to an "engraving black," than by the ordinary process.

Mr. Kajima made two exposures of the meeting by flash-light.

The hall was lent to the Society by Mr. O. Keil for this meeting, which ended with a vote of thanks to the chairman.

---

Explanation of Optical Activity.—Landolt divides optically active substances into three classes: those which rotate polarised light only when in the crystalline form; those which rotate it only in solution or when fused, that is to say, in the amorphous state; and, lastly, those which in both conditions show optical activity. Only one substance, strychnine sulphate, has hitherto been discovered belonging to the last class. The optical activity of crystals is generally explained by assuming for these a screw-shaped structure; that of liquids is referred to the nature of the chemical molecule, and, more particularly, to the presence of an asymmetrical carbon atom. The author does not regard the explanation of the optical activity of crystals usually given as satisfactory. It is not probable, and is not consistent with what is known of the symmetry of crystals. That the laws of circular polarisation are the same for both the crystalline and amorphous states, would also lead to the conclusion that the same explanation would hold in both cases. A key to this explanation may be sought in the fact that substances which are optically active when amorphous, crystallise in hemihedral forms. According to Sohncke, hemihedrism may be explained by assuming a certain polarity in the molecules building up the crystal. The author shows, reasoning from the fact that the molecule of an optically active substance contains an asymmetrical carbon atom, that circular polarisation may be explained by assuming that the axis of polarity of the molecule coincides with its axis of rotation, and with the direction which offers greatest and least resistance, according to the orientation of the molecule, to the passage of a ray of light.—*Journal of the Chemical Society.*

# Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.

Old Amateur.—*Paper in Continuous Rolls.* Both the thick, smooth, and thinner sort can be obtained of Messrs. Waterlow and Sons, Winchester Buildings, E.C.; the paper, uncoated, in the smaller sizes might also be procured from the Eastman Company, 115, Oxford Street, W.

R.B.—*Tinted Films for Isochromatic Work.* Bathing the plates with erythrosine or Vogel's azaline has been recommended, but it is much more advantageous to tint the emulsion before spreading upon the plates. As an indication of your success, try them against the commercial plates of Edwards or Obernetter. The use of a pale yellow screen is not imperative.

D. L. P. (Sheffield).—*International Labels.* Probably by this time you will be able to procure them from Messrs. Percy Lund and Co., St. John Street, Bradford. If not, apply to M. Ch. Puttemans, Ecole Industrielle, Boulevard du Hainaut, Brussels.

Alpha.—*Oyster Shell Markings on Collodion Negatives.* May not these stains be the result of working with your new bath insufficiently saturated with brom-iodide of silver? Leave a coated plate in the bath all night, or shake up with a little of the same collodion and filter; it would then probably work satisfactorily.

Mr. Henry Flather is requested to make known his present address for the purpose of enabling a correspondent to communicate with him.

L. T.—*Prints Mounted in Optical Contact.* You will find the method described by Mr. Edward Dunmore in his article on "Finishing Photographs," which appeared in the News of February 17th, 1888. If at any time cracks appear, the picture must be stripped off and remounted; but flaws at the edges may often be repaired with hot gelatine.

W. J. F.—*Diazotype Printing.* This is merely another name for the primuline process of Messrs. Green, Cross, and Bevan, which has been several times referred to and described in our last volume. See page 707, September 12th, 1890, for the author's original communication.

M. P.—*Relative Cost.* For the smaller sizes, platinotype prints are charged at about double the price of silver prints, but with the whole plate and larger sizes the cost is usually more favourable than this to the platinum; the relative expense is then only four to three, instead of two to one.

Afric.—*Kaffir Types.* A small-framed collection of Dr. Mann's studies of South African natives is to be seen in the Ethnological Department of the British Museum, near Dr. Lindt's series illustrative of the inhabitants of New Guinea.

R. M.—*Decomposition of Chloride of Silver by Light.* At a meeting of the Chemical Society on the 7th inst., Mr. Arthur Richardson, of University College, Bristol, described experiments on this subject, which led him to conclude that the darkened silver compound is of the nature of a sub-chloride rather than an oxychloride. When exposed to sunshine under water oxygen and ozone are evolved, both chlorine and hydrochloric acid being found in solution; but with a larger volume of water *no* free chlorine can be detected. (See article on page 387.)

Colonel Waterhouse.—*Thio-carbamide.* See the report of Dr. Emerson Reynolds' researches making reference to your employment of this body for securing direct positive photographs or reversals. As the result of the Professor's study of some new addition compounds of thio-carbamide, its constitution is held to be unsymmetrical—that is, having a structure represented by $HN : C (SH) NH_2$, instead of the simpler formula $CS(NH_2)_2$. The paper was read on the 7th inst. at the Chemical Society.

CONTENTS.

## SUGGESTED BY SOME RECENT EXHIBITIONS.
## II.

BY H. P. ROBINSON.

THE Gloucester, like the Liverpool Exhibition, had the aid of an energetic band of workers, headed by the president, Mr. W. B. Wood, and also the advantage of an excellent "send-off" in Mr. Lange, the president of the Liverpool Association, who is ever willing to help others, and who opened the show with his admirable lantern lecture on Iceland.

The chief lesson of Gloucester was that amateurs should more carefully study the published conditions. In one case a silver medal was awarded to an amateur, subject to a condition which stated that all the work, from the negative to the printing, should be done by the exhibitor. The work, in this case, was so very remarkable and so like that produced by a well-known firm for the trade, that the judges took the liberty of doubting. The result was that the exhibitor claimed doing all the work *with the exception of the negative!*

It is time much more stringent conditions were made touching the exhibitor being the producer. It sometimes happens that medals are taken by men who could not develop a plate, which is an artistic, if not legal, fraud. If men won't be honest for the love of honesty, they must be made so by Act of Parliament. Take an illustration from another art. Let anyone who is ambitious of artistic distinction buy a picture of a painter and send it to the Royal Academy as his own, and see what would happen. Until we can arrive at some sense of propriety in these matters, the respectability of the art is hopeless.

The necessity of studying the conditions carefully was also shown at Liverpool, where a very hard case occurred. It was in the portrait class. The condition was that a set of four portraits should be sent in competition, and one set was so good as to leave no doubt as to who should have the first medal, but one or two of the judges thought they had seen one of the portraits at a previous exhibition. The exhibitor was telegraphed to, and replied that he had not carefully noted the conditions, and so lost the medal. But, let it be noted, the disqualified portrait was one of the gems of the exhibition, and yet the strict rule should have excluded it.

The mention of portraiture reminds me that some exhibitors have a curiously wide idea of what constitutes a portrait, and send anything that they think will be near enough to beguile the judges. I have seen two classes hanging side by side, the one for genre, the other for portraiture, by one exhibitor, and have not been able to see the difference in class between the exhibits. The same difficulty of classification is found in other departments, especially the scientific. There was a famous example of this at Liverpool.

The delightfully artistic pictures of the Countess Loredana da Porto Bonin, which so surprised us all, were classed as "scientific," as though they were the results of a process rather than of an artistic mind and skilful use of materials. It is time we separated the science from the art of photography. There was no more science in these exquisite pictures than in the average photograph, but there was a great deal more art. I spent some hours over them, returning to them time after time during several days, yet I forget how they were done. I don't seem to remember the flash-light; I could not say whether they were printed on albumenised or matt surface; I only remember the art, the invention, the direct way in which the stories were told, the composition, and expression. If all this was the result of science, then everybody could do it, for the results of science are facts, and can be stated. Flash-light pictures are common now, but there are none like these Italian pictures. History repeats itself, or very nearly, and attributing these pictures to science runs parallel with the endeavour to find out years ago the secret of Adam Salomon's success by analysing the composition of the encaustic paste with which he polished his prints.

In the instantaneous classes similar mistakes are made, and injustice is often done. There should be a very distinct difference made between objects in motion and snap-shot pictures of objects that, although they require a quick exposure, such as a yacht sailing slowly, yet present no such difficulties as acrobats pursuing their vocation or athletes racing. I would abolish these classes altogether, for there is little wonder to be got out of instantaneity now, and there is nothing else left; but, as long as they exist, they should be kept distinct. This separation should be the work of the managers, or, if left to the competitors, work entered in a wrong class should be disqualified. It should not be left to the judges to sort them out.

Is it not time the column for particulars of process was omitted from the forms sent to be filled up by intending exhibitors? Nobody could welcome processes more than I do in an exhibition, especially if they are new, but I do object to all photographs being exhibited as specimens of some particular process. I always now fill up the column with the words "not exhibited as specimens of a process," and, if other exhibitors would do the same, something would be done towards removing the absurdity. A painter is not compelled to declare that his picture is painted in oils, or that it is varnished. If, instead of the process column, one could be inserted in which the exhibitor could declare that the exhibit was his own work, much would be done to purify the art from artistic immorality and commercial pretenders. I notice that the form of the exhibition of the United Amateur Clubs in America has a column to "state whether negative was developed by the exhibitor," and another to "state whether positive is work of exhibitor," which is good as far as it goes, especially if they were followed up by expulsion of the picture if not truly answered in the affirmative; but then the same form contains degrading questions as to lens, developer, printing process, and even the "make or brand of plate," a method of gratuitous (or otherwise) advertisement we should never think of in England.

If a photographer prefers to supplement his exhibit by an account of the lens, stop, modification of the developer, &c., he need not be prevented; but if, as in this case, he insists on exhibiting his photograph as the result of the process, it should be relegated to the scientific division of the exhibition.

In some conditions there is a clause to the effect that exhibitors wishing to compete with the same subject in more than one class must send separate copies for each class. This is very objectionable. Why should space be occupied by, and who wants to be troubled with, duplicates? Certainly not the outside public—nor, may I add, the judges.

There are a couple of lessons to be got out of the Crystal Palace Exhibition. Mention of the pictures of the Countess Loredana reminds us that when pictures are advertised and paragraphed as secured for an exhibition, there should be no doubt as to their appearing; and if, unfortunately, it is found impossible to secure them, the failure should be announced as prominently as the previous advertisement. I have heard of several people making journeys to the Crystal Palace for the sole purpose of seeing these now famous photographs, and being disappointed that they "had not arrived from Liverpool," or were "delayed on the way." I have heard since that they never went astray, but, as originally intended, were returned to the owner immediately on the close of the Liverpool Exhibition.

The other lesson which some of the contributions suggested, is that something must be done to suppress the barefaced plagiarism that is constantly occurring. I gather the following little history from the most authentic source.

One of our most prominent and successful amateurs—we will call him A—conceives a subject, finds and educates his models, collects accessories, and makes a fine picture. While he is at work taking the negative, another amateur, B, who has followed, watches the operation, and takes notice. When A leaves the district, B looks up the models, hires them, and even gets possession of some of the accessories, which A has left behind for use on a future occasion. This plagiarism—to call it nothing worse—is repeated, and the negatives are sold by the amateur to C. D. & Co., who are not photographers, but the proprietors of the photographic business of E. & Co., which they have recently purchased, and the pictures are eventually exhibited at the Crystal Palace as the work of E. & Co.

In this one transaction we have a bit of everything calculated to degrade the art. Yet I believe that it is all—except perhaps in the case of B, and he may have a dull sense of its not being illegal—done innocently. There can be no question whatever that the purchasers of the negatives are men of the highest respectability, who would not lend themselves to anything doubtful if they knew it, and who have a healthy horror of piracy; it is the want of sense of what is right as well as legal, and the regarding everything as a matter of business, that is the root of the evil.

In contrast with our own exhibitions, we have that recently held in Vienna, arranged on the best ideal lines, but for notice of which I have little space. The intention here, again, was excellent, but there seem to have been a few curiosities in connection with it. It was formed on the lines that photography is a fine art, and all who doubted this great fact should have abstained from exhibiting; yet among the contributors I see the name of one who has very recently abjured photography as an art. The jurors were all artists, but only one of them, Fritz Luckhardt, is a photographer as well. It would be interesting to know if the others knew anything of the special art they were judging. A point much to be commended was, that out of 4,000 contributions, 3,400 were rejected, leaving, doubtless, still a few hundreds that should have joined the majority. There was one photograph admitted that should certainly have been rejected. Is it true, or is it only a joke, that one contributor sent in nearly 300 photographs, and had one only accepted? Surely this was bad judging, for if one only in 300 was good, that one must have been a fluke, and the producer would get for a fluke an exhibition diploma equal to the best.

## APPARATUS FOR TESTING THE SPEED OF INSTANTANEOUS SHUTTERS AND MAGNESIUM FLASH-LIGHTS.*

BY HANS H. BAYER.

It falls now-a-days to the lot of every photographer, whether professional or amateur, to work occasionally with an instantaneous shutter. In order to obtain a really clear picture of any object in motion, it is necessary to know beforehand whether the speed of the instantaneous shutter is equal to the speed of movement of the object. Many people will therefore wish to ascertain the speed of their shutters. Now, there are several ways in which the speed of a shutter may be decided; and we can class them into two large groups. In the first, falling bodies are used; and they are photographed during motion by means of the shutter. For instance, sometimes a long black-board is employed, on which a centimetre measure is marked in white. A shining metal ball is held on the top mark of the measure, and then dropped. During the fall, an assistant works the instantaneous shutter. A picture is obtained which reproduces the scale, but on it will be found a streak of light, and from its length and its distance from the top mark of the scale, the length of the exposure may be reckoned by the help of known formulæ. This method, originated by La Baume-Pluvinel, was accepted by the Paris Photographical Congress. It is, however, of very little use in testing very rapidly-working shutters.

The second method is by means of the ascertained speed of shining bodies moving in a circular direction. Such an apparatus has been constructed by Professor J. M. Eder; it consists of a heavy wheel of dark wood,

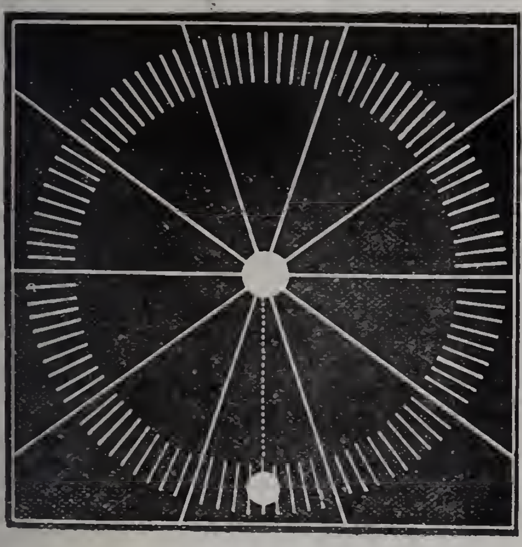

Fig. 1.—Front, with Pointer at rest.

which turns easily, and causes the stroke of a bell to sound with every turn. In the centre-point, as well as in the periphery, a silver-plated half-ball is fixed. An assistant turns the wheel till the strokes of the bell correspond in time to the ticking of a second-pendulum of a clock. The moment this speed is attained, the photograph must be taken. The picture obtained will represent a light spot on an arc of a circle, and from these two the length of the arc and the speed of the shutter may be reckoned.

* A communication to the Vienna Photographic Society.

I have now modified this apparatus. I use a black-board on which a wheel with one hundred white divisions is marked. In front of it a nickle-plated metal ball, which is attached to an arm, moves. This is turned by means of a handle at the back. With every complete revolution, a little spring on a disc with large teeth cut out of it gives

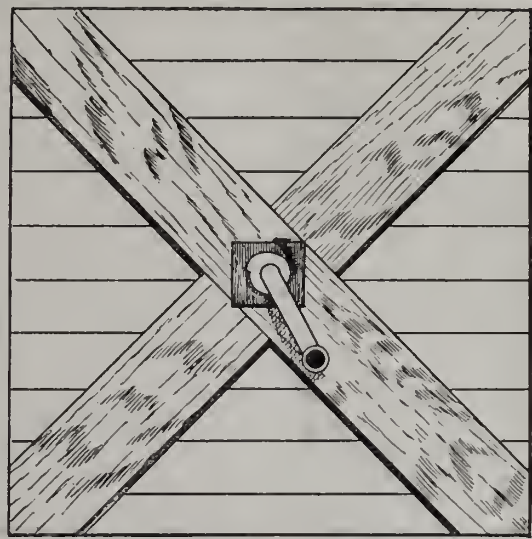

Fig. 2.—Back, with Handle and Signal Apparatus.

a clear note. This apparatus is placed in front of the camera, and an assistant then begins to turn the handle. In a short time the ball acquires an impetus, and it is then possible to make a perfectly even revolution, though the handle be turned slowly. The quicker the instantaneous shutter works, the quicker it must be turned, in order to get accurate results. By counting the seconds, one, two, or three turns a second can easily be made, as every turn is marked by the note of the catching spring. When the desired speed is attained the instantaneous shutter must be worked; or, if testing the speed of magnesium flash-lights, the apparatus put in action.

The picture thus obtained consists of a representation of the board with the white divided circle, and on the latter will be found a white, sharply-defined arc. The length of the arc will be measured on the circle, and must be divided by one, two, or three, according to whether one has made one, two, or three turns per second during the exposure. For instance, if the arc is the length of six divisions, and one turn per second has been made, it gives ·06 or about $\frac{1}{16}$ of a second; if two turns have been made, it will be ·03 or about $\frac{1}{33}$ of a second; by three turns it will become ·02 or $\frac{1}{50}$. The great advantage of this apparatus over other methods is, that any more complicated reckoning is done away with; a glance at the negative obtained is sufficient for ascertaining immediately the exact speed of the instantaneous shutter. The apparatus must be handled with intelligence to obtain accurate results. In the tests which I have made it has given uniform results with the same shutter with mathematical precision.

Camera Club.—The programme on Thursday last included a paper contributed by M. Leon Vidal; also a paper by Prof. W. K. Burton on a new emulsion method for matt-surface silver paper, with illustrations. During the same evening Mr. Woodward showed Schoppen's method of viewing lantern slides stereoscopically.

## DR. J. M. EDER'S CRITICAL EXAMINATION OF C. SCHIENDL'S "HISTORY OF PHOTOGRAPHY."*

BY C. SCHIENDL.

On page 153 (Photo. News, p. 202) Her Eder remarks: "In the first place, one ought not to set down the discoverer Legray as a 'phrase-maker,' when one is not in the position to affirm that Liebig actually was the first to recommend the application of pyrogallic acid to the development of photographic pictures. Regnault made the discovery independently of Liebig, and they acted, as nearly as possible, simultaneously. Without doubt, however, Regnault first brought this developer into practical use. Schiendl owes to us the information that Liebig was before Regnault." This absolute misinterpretation of my statement is rectified as follows:—If I speak of a phrase which Legray has used by describing all the said and other discoveries as clearly French, it is not to be concluded in the least that I describe Legray as a phrase-maker, which would involve an insult, whilst my description will certainly not be held as such by any reasonable thinker. Further, Herr Eder owes to us the information that Regnault made the publication of pyro developers independently of Liebig, and this statement (of the contrary) is simply his own opinion proved by nothing. My statement, however, is supported by Liebig's own sentence, which I quote, and, therefore, if the Frenchman Legray proclaims his countryman Regnault as the discoverer, I, as a German, have at least the same right to reclaim the honour for my countryman Liebig, proved by his own statement, and if Dr. Eder believes himself obliged to take the name of "poor late Legray" under his protection against me—which is certainly not necessary, as I have rendered him all due honour in my work—I can only remark in return that the name of the great Justus Liebig stands far too high for his everlasting renown to be cut short by Dr. Jos. Maria Eder.

On page 154 (Photo. News, 202) the same critic makes the following remark:—"On page 169 of his 'History,' Herr Schiendl asserts that H. W. Vogel published in May, 1884, his colour-sensitive collodion process on the foundation of Schultz-Sellack's observations, published in the year 1871 . . . We now meet with the very astonishing fact that the sources on which Schiendl depends in no way contain one word that would justify his denial of the independence of Vogel's discoveries."

I have to reply to this, that it is not a true statement in which Dr. Eder declares that I deny the discovery of Vogel of colour-sensitive plates, for I have especially set forth, on page 297, that Dr. H. W. Vogel (in the year 1873) was the first who sought to advance the sensitiveness of bromide of silver, with the addition of coralline and aniline-green, to the less refrangible rays of the spectrum. If Herr Eder nevertheless adds further, "I bring forward this example in order to show in what an astonishing manner Herr Schiendl treats weighty historical questions, and how the confiding reader may be led to suppose that his statements have historical basis, whilst a close examination makes it evident that the quotations of Schiendl are wrongly employed," I must reply to it that this remark of Eder's contains an absolute and conscious untruth, as I have made no quotations, and therefore could have used nothing wrongly; whilst that which Herr Eder arbitrarily selects from my book was made public by Vogel in 1884, and I mentioned it in my chapter about emulsions as practical instruction; whilst I could only mention in the scientific part of the year 1873 his practically much older discovery.

My supposition that Vogel made his, in any case, independent discovery on the foundation of the researches of Schultz-Sellack in no way lacks foundation, as Schultz-Sellack was the first who showed that bromide of silver could be made sensitive, by certain additions, especially to the less refrangible rays, even if he did not also mention something of a colouring material, which latter merit of Dr. Vogel's I have also duly recognised in my "History of Photography."

A further perversion of my statement by Herr Eder is found on page 155 (Photo. News, 202): "On page 66 he places himself on the summit of those experimentalists who sought to increase the keeping properties of wet collodion plates by the use of hygroscopic salts, and says that he first made these researches in the year 1853, and that later Spiller and Crooks published the process. . . . It appears to me a very unjust thing that, on the ground of a statement without evidence, Schiendl should place himself before Spiller and Crooks, and seek thereby to lessen the credit of the latter for the priority of this certainly rather unimportant discovery."

The entire absurdity of the statement that I wish to establish myself as the discoverer of a "certainly rather unimportant discovery," and the malicious distortion of the facts, is proved in the text, wherein only the remark is found that this process, published by Spiller and Crooks, had no future, and was also tried by me afterwards in the year 1873, but with no result. Therefore, if I speak of an unsuccessful research, no thoughtful person will entertain the supposition that I aim at pushing myself forward as the discoverer of an unsuccessful and worthless process, to the disadvantage of others. If I had maintained such a purpose about a valuable process—oxalate developer, for instance—the rectitude of a certain reproach could not be gainsaid.

In conclusion, the same critic writes on page 155 (202, Photographic News), as follows:—"The description of the history of the camera obscura in the book before us is wrong, as far as concerns Porta. On this, however, I will no longer dwell, except to mention it as a warning to those who might be depending upon Schiendl's statements."

Dr. Eder consequently asserts here simply that my statement is false without any justification, which assertion, however, has quite as much worth as his foregoing proofs, which have proved quite untenable. The warning against the belief in the thoroughness of my work can only follow the purpose of preventing the photographic public from a further perusal, in order that it may not arrive at the facts, which, in consequence of my dates and quotations—which, although suspected by him, are nevertheless quite exact—might be very uncomfortable for him.

* Concluded from page 367.

---

Photographic Club.—Subject for June 3rd, "Platinotype Processes"; June 10th, "Combination Printing." Outing, May 30th, Hale End; train from Liverpool Street at 2.32.

Mr. Fallowfield sends us a specimen of "Miall's perfect sheath" for quarter-plates, which certainly possesses many advantages over the kind in common use. So many of the hand-cameras now made require that their plates should be held in sheaths, that the new pattern is likely to have an extensive sale. The plate is held at the bottom by a groove, and two movable clips at the top hold it firmly in position. With this aid the operation of charging a dozen sheaths need not occupy more than one minute.

## CAMERA CLUB SOIREE.

On Monday last the Camera Club gave a house-warming in the shape of a most enjoyable soirée. The handsome premises were decorated with flowers, and looked as gay as possible when filled. The company, including many ladies, assembled shortly after eight o'clock.

The entertainment provided by the committee included a capital concert in the large club room from 8.30 to 9.30 p.m., and from 10 to 11 p.m.; a lantern exhibition, lasting from 9.30 to 10 p.m.; an exhibition of photographs by members; an exhibition of mechanical work by members in the lathe room (ornamental turning in ivory, mechanical models, &c.); the phonograph in the library; microscopes, stereoscopes, the thaumatrope (Ottomar Anschutz, for reproducing movements of animals, &c., taken by photography), in the billiard room; Chladni's sound figures and Newton's coloured discs, &c., in the studio; and a clever exhibition of sleight-of-hand by Mr. F. R. Broadbridge.

It will be seen from this programme, which was exceedingly well carried out in every particular, that the whole of the Club premises were thrown open to the visitors. A soirée is too often a very dreary affair, and especially those which are mixed up with anything in the scientific way; but in this case the science was so wisely leavened with the amusing that the evening was a pronounced success. Everyone seemed sorry when the time came to go home.

## EASTMAN PHOTOGRAPHIC COMPANY.

An extraordinary general meeting of the Eastman Photographic Materials Company, Limited, was held yesterday at Winchester House, Colonel J. T. Griffin presiding.

The Chairman stated that the business of the Company had altogether outgrown present means of carrying it on. Its growth, in fact, had been in many respects far beyond the expectations of most sanguine friends. At the last annual meeting the question was asked when the balance of the unpaid capital would be called up. The answer was, "Not until it is required." At that moment the Company had sufficient funds for carrying on its work; but since then the volume of business had so enormously increased that the directors found the capital largely locked up in outstanding accounts. More than that, the building at Harrow was now completed, and within a few weeks would be in a position to manufacture the larger part of the Company's goods. Under those circumstances, the capital was found to be not quite sufficient for trading purposes, and, therefore, the directors came to the conclusion to ask the shareholders' authority for increasing the capital from £150,000 to £200,000. They wanted, at present, only £10,000 or £15,000; and, as showing their confidence in the business being transacted in Europe, the parent company had offered to take up £10,000. The Company at the present moment owed the parent company about £8,000 for goods received, and upon that sum they were obliged to pay interest. The directors wished to relieve themselves of that obligation, and to become their own masters. He might add that the volume of business had increased 50 per cent. during the past three months, whilst orders were still coming in to such an extent that they could not be duly executed. It was also in contemplation to establish branches of the Company at Paris, Berlin, and other places on the Continent, all of which work would require additional capital, inasmuch as it was necessary to keep large stocks at the various depôts.

Mr. J. Spiller (shareholder) moved:—"That the capital of the Company be increased to £200,000 by the creation of 5,000 new ordinary shares of £10 each."

Mr. G. Jupp seconded the motion.

In reply to questions, the Chairman said the new shares would be issued at par to the shareholders on this side. If any were not allotted, they would be offered to the parent company, whose shares sold, when they were sold, at a very heavy premium.

The motion was agreed to.

On the motion of Colonel Allix, seconded by Mr. Jupp, it was resolved:—"That such new shares shall be issued at such times, in such manner, upon such terms and conditions, as the directors shall from time to time determine."

A vote of thanks to the chairman concluded the proceedings.

## SKIES IN LANDSCAPES.

BY XANTHUS SMITH.

The beauty of landscape scenes is so much enhanced, when there is sky appearing, by the introduction of suitable clouds, that we wonder more pains are not taken to introduce agreeable sky effects in photographic landscape views.

Painters set great store upon varied effects which may be attained in the skies of their pictures, independently of the colouring; the mere design and massing of light and dark, which are fully attainable in photography, are matters of much solicitude with them. A brilliant mass of light in a sky gives wonderful life and interest to a picture, and broad masses of shadow are often resorted to in order to unite the sky with the darks of the foreground, and to give support to dark features rising up and cutting upon the sky.

Of course in the photographic art the scope is extremely limited, as compared with that of the painter, for giving play to the fancy in choosing skies and grouping clouds as they should be; but in the simpler forms of composition and effect photographers might enhance the beauty immensely of some of their more careful and successful landscape scenes by the introduction of clouds. Probably the most usual mode in practice for the addition of skies to landscapes is that of printing them in from negatives previously taken of fine skies; but I am not going to urge this mode of obtaining what is wanted, because it is open to several objections, the principal one being that a sky which photographs well is so round and bold in character that it is apt to take too much consequence in the picture, and it is so important that the lighting of the clouds should precisely accord with that of the landscape, that it would require a great stock of cloud negatives from which to secure what might be required. In printing in, also, all opportunity is lost of accentuating certain portions to give artistic effect, and I think, therefore, except, perhaps, in the case of open sea views, that it is much better to paint the sky upon the back of the negative, opportunity being afforded in following this mode to design a sky that will harmonize with the subject of the picture in every respect. The principal obstacle in the way of put-on skies is that it sometimes happens that the sky of the negative is so dense that nothing can be put upon it which will print; but a good negative should not be so dense in the sky, and in such case the only way would seem to be to omit clouds altogether, or print them in from sky negatives.

I have found the following the best mode of procedure for putting skies on negatives. In the first place, they should always be painted on the back or glass side, and the glass must be thoroughly cleaned and washed over with some liquid ox-gall; then, having mixed some "opaque" with water (I have often found beer to answer admirably), fill a good soft-bristle brush—preferably with a rounded end—with the mixture, and flow on your clouds. The negative should lie flat while the colour is being flowed on, and then taken up and held perpendicularly, more or less, and turned around, being watched by transmitted light the while, and the moist colour flowed in such a manner that the greatest amount, and consequently the most density, will be where the highest lights should come. This turning motion of the negative must be continued until the colour sets; and when the colour flows too thick towards one edge it should be laid flat for a little while, so that the latter may become somewhat diffused again. All this will probably appear very difficult of attainment to a novice in the art, but, like some other things, the sleight and confidence attained by some trials will soon bring the experimenter to a successful stage of progress. A great advantage in this mode is that the work is very quickly done—indeed, rapidity of procedure is a concomitant of success, and each failure can be removed in a moment and another attempt made, no injury to the negative resulting from any amount of attempts and failures upon its back. One point which is important is that the mixture of opaque when flowed on should be just of a proper consistency. If it be too thick it will not flow well, and will make the clouds too harsh and brilliant, unless, perhaps, when the sky of the negative is very dense, which will require a thick mixture. If the colour is used too dilute, there will not be sufficient density attained. A knowledge of this can only be attained by practice. It is also important that a large brush be used; one of about a half-inch in width is a good size for 4¼ by 6½ to 6½ by 8½ negatives, and I spoke of its being rounded because the rounded forms of clouds are better got than with a brush that is square on the end, the latter making the forms too angular.

When the sky becomes dry, as it should do in a few minutes, undesirable portions may be removed, and harshness softened, by wetting a camel's-hair or sable brush in clean water and squeezing it out flat, and with this delicately wiping off and shaping the forms, and modifying them to suit the taste.

The fancy can be allowed full scope in the matter of design. The entire range through flat, stratified, and full cumulus, to the most delicate, fleecy cirrus, is open to the aspirant to artistic success. He has nature, the great teacher, before him every day to study and to supply him with the very finest of material; but it must be remembered that grouping and simplicity of design are important elements of success in the addition of skies in pictures. It will not do to spatter our clouds all over the sky; they must be grouped, and large portions left free from them, and in repose, and a repetition of the same form many times over must be avoided. Such repetitions frequently occur in nature, but as these accidents destroy that variety which gives interest and pleasure, it is better to avoid them.—*American Journal of Photography.*

---

Cardiff Exhibition.—An arrangement has been made with the committee of the Glasgow Exhibition by which exhibitors desirous of competing at both exhibitions may have their pictures sent from Cardiff to Glasgow by through truck, carriage paid, to arrive at Glasgow in time for the judging on August 31st.

It is considered by F. Wilde, according to the *Photographic Journal*, that fat in the gelatine tends to produce fog in the dried film, and that treatment with alkalies and clarification with albumen does not remove this fat.

## TWO NOVELTIES.

Messrs. Marion and Co., of Soho Square, who are ever to the fore in discovering what is wanted by the modern photographer, have just introduced a couple of appliances which have not only the merit of novelty, but which pack up into such small space that one can take advantage of them without materially adding to his impedimenta. The first (fig. 1) is a lens shade made of thin metal, which can be readily attached to the camera front, and fixed at any angle which the position of the sun may require. Most photographers who have been in the habit of adapting their hat to this purpose, and have occasionally cut off a portion of their picture in doing so, will appreciate this simple device, which is both cheap and effective.

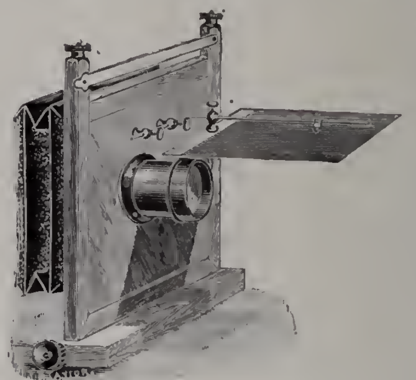

Fig. 1.—Marion's Lens-Shade.

The other appliance to which we call attention is Claringbull's portable changing bag and developing tent,

Fig. 2.—Claringbull's Portable Changing Bag and Developing Tent.

which is used as shown in fig. 2. When closed, the apparatus measures 26½ by 20 by 3 inches, but when opened out its depth is increased from 3 inches to 30. Its weight is 12 lbs. It will thus be seen that a large-sized plate can be developed in this portable dark-room, and there is no doubt that the apparatus will be particularly useful when a large number of negatives have to be taken in a limited time, and when the operator only possesses the normal number of dark slides. The tent is well ventilated, thoroughly light-tight, and provision is made for carrying off wastes during development.

## PHOTOGRAPHY IN GROTTOES AND CAVES.*

Interior photography is in general sufficiently difficult, but when we come to photograph the interior of caves the work becomes more difficult still, for here we have vast halls with sombre shades, the walls of which reflect little light, and where there is little or no relief. Many methods of artificial illumination may be employed in this work. They include :—1. The electric light; 2. The pyrotechnic composition known as Bengal light; 3. Magnesium ribbon lamp; 4. Chemical flash composition; 5. Magnesium powder without admixture. These different methods we will consider *seriatim*.

1. *The Electric Light*.—This will give the best results, but the necessary impedimenta, which is of the most cumbrous nature, cannot be introduced into the devious windings of many caves.

2. *Bengal Fire*.—This is the well known mixture of saltpetre, sulphur, and antimony sulphide, but its use ought to be forbidden, for the fumes given off discolour any stalactites which may be in its neighbourhood when fired. Moreover, the smoke so quickly dims the atmosphere that successive pictures cannot be taken in the same hall after its employment, to say nothing of the sulphurous fumes which render the air so irrespirable. These grave inconveniences almost forbid the use of this mixture, notwithstanding the white and brilliant flame which it affords.

3. *Magnesium Ribbon Lamp*.—With this apparatus it is possible to flood the surfaces to be photographed with light for several minutes, the amount of light being increased by a suitable reflector. MM. Gaupillat and Martel used this method last summer, but the results obtained were far from satisfactory, although the exposure was sometimes prolonged to as much as ten minutes. According to the information furnished by M. Martel, the inconveniences of this method are found in the inequality of the light, the length of exposure (during which other visitors are shut out), and more than all in the heavy smoke which forms a veil over the scene even while the exposure is being made.

4. *Chemical Flash Composition*.—These compositions are often of such an explosive character that it is hardly safe to handle them, for ignition may be brought about by simple percussion. A most dangerous accident might occur from a man while carrying a charge of this description, stumbling in his passage through the dark cave. Besides, the concussion of the explosion might displace loose blocks and boulders, and so tend to further disaster. We have also again here the risks from the irrespirable products of combustion.

5. *Magnesium Powder used alone*.—This we may consider as the best method of all, and in many cases the only practicable one. Magnesium dust is not explosive; it does not necessitate cumbrous apparatus, and it produces a flash so short in duration that figures can be introduced, by which the proportions of the cave can be gauged in the finished picture. The smoke in this case does not constitute any grave difficulty, for the little cloud produced during ignition is soon dissipated. I have made a series of experiments by the help of this agent, and the results being satisfactory, I have thought it well to bring them to the notice of the Society.

*Method of Procedure*.—The first difficulty was to produce a sufficient amount of light, the quantity of powder generally used for portraiture being much too little for the purpose in hand. It was necessary, too, to find a suitable apparatus. Dr. Regnard kindly showed me, in operation, the magnesium signal lamp invented by him, and it is this lamp which I employed in the experiments referred to, after I had somewhat modified it to fulfil the conditions which I thought desirable.

The lamp burns alcohol in a circular wick, and in the annular space thus formed is placed the tube for projecting the magnesium powder into the surrounding flame. The other end of this tube is carried to the outside of the apparatus, and furnished with a small funnel, by the aid of which the charge of magnesium is inserted into the tube. After lighting the wick, which should be sufficiently raised to give a flame two or three inches in height, you charge the tube, remove the funnel, and fix in its place an india-rubber tube attached to a bellows. Pressure upon this bellows brings about a complete and instantaneous combustion of the magnesium powder. Two grammes of magnesium are sufficient to give a beautiful flame of nearly two yards in height, and, after several experiments, this is the charge of powder which I find best to use. The results are only perfect with the most rapid of plates, and with an energetic developer. I have succeeded well with the *Lumiere* plates (blue label), and with the preparation known as the "Perfect" developer of M. Mercier. I may add here that the ordinary pneumatic ball will not give sufficient propulsive power with this lamp; the bellows is indispensable.

If a tube of larger diameter be employed (say of one centimetre), you may project a charge of four grammes of magnesium with each puff of the bellows, but the extremity of the tube where it meets the flame should be narrowed or choked to a slight extent. The lamp may be placed on the ground, but not directly in front of the camera for fear of fogging the negative, but at one side, and at a distance of about two yards from the camera-stand. The lens used should be of the rapid type, and one which will cover well with open aperture. Nadar's detective lens gave me good results. The placing of the camera, and the focussing, are the chief difficulties of subterranean photography. The apparatus once on its stand, you turn it in the required direction, but you can distinguish nothing on the focussing screen by the feeble light of the lanterns, and the focussing glass is of no use. But if the parts to be photographed are accessible, two men furnished with lanterns may be placed at either side, and then the image of the lanterns can themselves be focussed, forming the limit of view on either side of the focussing screen. It will also be a help if a graduated scale be fixed to the tailboard of the camera beforehand, so that the approximate focus can be obtained without viewing the image on the screen. Everything being ready, the plate is inserted and the lens is uncovered, the lanterns outside the field of view having no hurtful effect upon the plate; but any figures introduced should be posed before the cap of the lens is removed. By taking these precautions one is certain to obtain results quite as good as if full daylight had been available.

* A communication by M. J. Vallot to the French Photographic Society.

## Notes.

The *Journal of the Photographic Society of India* gives an obituary notice of the late Mr. Grimwood, one of the victims of the Manipur disaster, for that gentleman was a member of the Society. It would be interesting to know whether he carried a camera with him during this disastrous expedition, and whether, too, he had an opportunity of using it. It is reasonable to suppose that he would not leave his apparatus behind him when about to start upon an expedition so likely to yield photographs of a little known country. That camera and its belongings, if really carried to Manipur, will probably present a problem to the natives as to the use of such a contrivance which may remain for a long time unsolved.

But now-a-days the country must indeed be a wild one where the camera is not known. That its use is still a matter for conjecture in certain parts of Kentucky is evident from a telegram sent per Dalziel's agency which appeared on Tuesday last in the evening papers. According to this authority, a photographer lately came here to take some landscapes, and fell among thieves in the shape of "moonshiners," who are described as being half brigands and half illicit distillers. The poor photographer had no sooner put his head under the focussing-cloth to take his first picture than he was knocked over senseless, and the equally innocent camera—supposed to be some kind of gun—was knocked over too. The poor man when he recovered consciousness found himself in a cave, where he had been thrown—a supposed corpse—by the moonshiners, who fired on him directly he proceeded to show himself. Luckily he was not hit, and when he got a chance of explaining his mission to this inhospitable region, he was allowed to go his way, on promising not to reveal the locality of the cave in which he had been immured.

A notice is now prominently displayed in the Naval Exhibition to the effect that no person is allowed to photograph there, all rights being reserved. It is a sign of the times that such a notice should be necessary, and is evidently a hint to the users of detective cameras. But photography is represented at the exhibition all the same, and there is one stall entirely devoted to the products of the camera. These pictures have, we believe, been taken entirely by officers in the service, and the profit from their sale is to be devoted to a charitable purpose. Among them is a photograph of the two model ironclads in action on the lake, and the picture looks very like a real naval engagement.

There is a curious effect which is produced during the firing of heavy ordnance which is well seen in some of these photographs. We mean the gradual burning of the large cubes of powder which are not wholly consumed in the bore of the gun. These form strings of smoke independently of the main cloud caused by the explosion. We fancy that they are best seen when the gun is firing a blank charge, on which occasion, if such coarse powder is used, much of it is blown from the gun quite unconsumed. It will be remembered that at a recent naval review a yacht was much damaged from this cause, and the owner vented his righteous wrath in the usual British manner—the inevitable letter to the *Times*.

The new Copyright Bill seeks to make it a statutory offence to exhibit the portrait of a person without his or her leave, but in the meantime there is nothing to prevent a photographer exhibiting a photograph of a sitter, or a painter introducing the portraits of well-known individuals into a picture. They order these things better in France. A portrait across the Channel can be made the ground of an action for libel. For fear of after consequences, M. Béraud, the painter of the most talked about picture in the Champ de Mars Salon, at the final moment previous to exhibiting, added beards, moustaches, and mutton-chop whiskers to the fifteen nobilities who comprise his "Chez le Parisien." The ignorant Englishman might be tempted to imagine these additions would intensify the libel, if any existed, but evidently in Paris they think differently.

That there is nothing new under the sun photography is continually showing. When a society journal says "a new and decidedly clever departure is the cabinet cameos which give four different views of a face in one photograph," the memory at once goes back twenty years, when the cameo carte sized portraits had a brief and a not particularly merry existence. Somehow, the cameo portrait never "caught on," but it may have been before its time. It will be interesting to see if the same thing in cabinets will be any more successful. Unfortunately, no matter what the size may be, the quadruple portrait is always open to one drawback—the difficulty of getting four views of one face which are equally pleasing. The general effect used to be too often spoilt by one of the portraits being unfavourable in its aspect or expression.

A statue of "Sandow," which was known to many by reason of the excellent photographs which had been made from it, and distributed, has not been seen in the Academy. The question is asked why, as, according to the *Globe*, some artists have gone so far as to say that the statue expressed the most perfect representation of the human form that had ever been known. Perhaps the hanging committee shook their heads at admitting the counterfeit presentment of a music hall athlete. If this be the reason, they have evidently forgotten a precedent in the shape of the bust of Leotard, who revolutionised acrobatism a quarter of a century ago. *Apropos*, an interesting comparison would be instituted if Sandow were photographed in exactly the same pose as his statue, so as to find out how far the sculptor had idealised the human form.

The writer of a series of articles on photography in the *Weekly Scotsman* denounces the tripod. "It looks," he says, "simple and harmless, but neverthcrless in the wickedness of its nature it is excelled only by the flail." This is perfectly true; but is not everything connected with photography at times afflicted with a perversity which drives one to distraction? Why is it, in spite of the utmost care, some plates persist in being exposed twice over, while others are not exposed at all because you have forgotten to draw the slide? How comes it that it is always the most valuable negative which gets cracked? Who can explain the reason that if you do leave a camera screw at home it is invariably the one you cannot do without? These are only a few of the mysteries the solution of which torments sometimes the most experienced photographer.

## PHOTOGRAPHIC FRAUD.*

BY JAMES MEW.

In 1869 an ingenious deception lightened the purses of many of the people of New York, a city claiming a reputation—which, in the present case, it seems not to have deserved—of exceptional *'cuteness* or intelligence. A photographer of that time appears to have monopolised the sharpness of the general community. By a method about which the photographic schoolboy would not require to be enlightened, this immoral artist secured a lucrative business. By appealing to the superstition of his customers, he flourished like a green bay tree. To such a one of his sitters as seemed to that photographer a suitable subject, he presented that sitter's portrait. The sitter, looking earnestly on his own likeness, discovered something more. Behind him, in the dim background, stood a weird figure, a shadowy presentment, an uncanny shape—in a word, a ghost. This ghost was explained as the occasion required. Now it was a guardian angel, now a malignant demon, now a ministering spirit of a wife deceased, now a hovering wraith of a mischievous but, happily, long dead and gone maiden aunt. These so-called *spirit photographs* obtained a remarkable notoriety. Though now themselves as extinct as those of whom they claimed to be the shadows and representatives, they brought no small gain unto the craftsmen who dealt in them, both in New York, in London, and elsewhere. It is remarkable that the American phographer who invented them was held blameless before the judgment seat. The magistrate appears himself to have hankered after the supernatural. The reason of the faith that was in him was not at all affected by an irreverent remark of the counsel for the prosecution, who asked whether, with all appliances and means to boot, the prisoner could have produced a carte of the ghost of Samuel. Though, at the best, the photograph of a ghost would be, as the flippant might say, but a ghost of a photograph, it would be interesting to obtain, say, a cabinet of Auguste Comte, a negative of a positivist.

But the most important plant of photographic fraud is that bearing cheques and bank notes upon its branches. Before photographic engraving arts had been invented, before the collodion process was born, it was found possible, by the agency of calotypy—the well-known method discovered by Fox Talbot of obtaining a beautiful impression, from which this scion of photography derived its name—to produce counterfeit notes and cheques which not unfrequently deceived the very elect, escaping without challenge not only from the trained inspection of the bank cashiers, but also from that of the argus-eyed adepts hired by the bank authorities for the express purpose of detecting imposture.

In 1863, a person of doubtful name and nationality—seeing that the papers of the time describe him as Regnoldi an Italian, as Renaldi a Swiss, and as Rinaldi a foreigner, with many other variations of addition—was charged with an intent to defraud the Emperor of Austria by the photographic imitation of a one gulden Austrian note. A certain MacGuire, or McGrire, or McQuire—for the leprosy of inaccuracy which appears to infest printed matter clung to his name also—was the photographer employed by Regnoldi. This case, from an ingenuity of pleading in which the photographic world would be little interested, became quite a *cause célèbre*. The counsel for the prosecution spoke of this photographic portrait of an Austrian note on glass as the first attempt to forge bank notes by photographic aid. Possibly his statement was correct; but so much cannot be said in favour of some of the observations of the counsel for the prisoner, a gentleman who amazed his own client and photographers generally by speaking of the glass positive of the bank note as an "evanescent shadow requiring to be transferred to a negative."

In 1865 two Frenchmen were charged with forging a Russian bank note. These ingenious gentlemen had managed to obtain *facsimiles* by means of photography, which were subsequently transferred to plates for engraving. In 1873 a photographer who had established himself in a place called Usti Monvediza, a small town in the Cossack steppes of Southern Russia, distinguished himself by a sumptuous living and a lordly style of expenditure for which the number of portraits taken in his studio utterly failed to account. In an evil hour for himself, the artist decided upon taking a partner in his business. Acquaintance begat friendship, and friendship begat intimacy. The partner was trusted with that photographer's secrets. The usual result followed—the confiding photographer was betrayed. The police came down like a wolf on the fold, and discovered to an inquisitive world that the Usti Monvediza artist took other portraits than those of the inhabitants of that place and its neighbourhood.

In the *Melbourne Argus* of 1874 is immortalized the name of one Perry, who defied the intervention of colour as a preventive of forgery—in other words, as a check to the imitation of cheques. From him the editor of the *Argus* received a copy of a bank note, executed, according to Mr. Perry, with ingredients not likely to be discovered by any person unless his studies had been specially directed to the science of chromo-photography. The publication of the process by which the colour difficulty was set at naught was withholden by the Melbourne photographer on the ground that it was fraught with danger to bankers and the general public. The *Melbourne Argus* editor described the document sent to him as a photograph on a reduced scale of a union bank note—a negative of a note printed in blue and other colours—and a faithful copy. To the dismay of such honest folk as fancied that the colour of their notes constituted for them a fortress of impregnable security, Perry maintained that notes could be reproduced in any colour or colours, and that the use of blue ink in note printing was not, as had been hitherto fondly imagined, any security against photographic forgery.

Indeed, in the very next year the blue bank notes of the Bank of France were extensively photographed, and in 1879 forgeries were attempted in the black-and-white notes of the Bank of England. In these all minute details, including, of course, the secret marks, and the highly finished vignette in the left-hand corner which so many love to look upon so well, were of course accurately copied. The sensitive plate may be said to see better than any human eyes, and divergencies of form, only perceptible under the microscope, were faithfully represented. But the water mark constituted a difficulty which photographic ingenuity misapplied was unable to surmount.

In cheques, the very small letters sometimes used are commonly believed to be a safeguard against imitations, a belief which an elementary knowledge of photography would at once and for ever dispel. The colour of the cheque is also but a poor defence. It has even been

* Concluded from page 385.

maintained that the pigment is an aid to forgery, as helping to conceal errors and erasures. But photography the bane is also photography the antidote. The camera, which has been used to falsify, may be used also to detect, and the best way to determine whether a document has been forged by the aid of photography is to ask photography to examine it. In other than photographic forgeries photography is of service. In the case of a cheque for one hundred and five francs, the words and figures had been effaced, and five thousand francs substituted. The camera showed the deceit. On the photographic film were found plainly depicted the original figures and words.

## AUTOMATIC PHOTOGRAPHY.

In consequence of our article on the above subject which appeared last week, we received a letter from the managing director of the Company to which the automatic machines belong, combating many of our statements. This letter also contained a courteous invitation to visit the headquarters of the Company at Shepherd's Bush, and to try the machine for ourselves—in fact, to do what we liked with it, free from the distractions of Hampstead, the frivolities of the Naval Exhibition, and "far from the madding crowd." We would have chosen a reasonably fine day for our visit had fine days been available in this (so-called) "merry, merry month of May." But, as the American humourist truly pointed out long ago, we have no *weather* in this old country, only samples. The particular sample at hand on the occasion of our visit to Shepherd's Bush was a dull and wet one, and so, all unwittingly, it was our fate to put the automatic machine through its paces under most unfavourable conditions; indeed, it was actually raining all the time that we were having our portraits taken. These portraits, we may say at once, were excellent pennyworths, and as different to those which formed the subject of our comments last week as they possibly could be.

In order that our readers may understand how such different results were attained with the same apparatus, it will be necessary to give a brief description of the working parts of the automatic machine. In the first place, there is a store of sensitive plates which, by suitable mechanism, started by dropping a penny in the slot, are detached one by one, and are brought under the influence of the lens. The plates are made of thin enamelled iron, are coated with a collodion emulsion, and will retain their sensitiveness for about two years. The exposure can be made quicker or slower by a slight alteration of the mechanism, and the lens is furnished with an iris diaphragm, so that the aperture can be altered to suit the light available. We need hardly say that such adjustments cannot be made automatically, but require experienced attention. After exposure, the little plate falls back into a cradle, which travels in a horizontal circle over three baths. The cradle is made of perforated metal, and, by a clever arrangement, is made to dip into each bath one after the other. The first contains the developer (hydrokinone), the second the fixer (hypo), and the third plain water. After immersion in this last bath, the little cradle gives up its burden to an inclined plane, and the now completed portrait is shot out of the machine ready for its owner. The contrivance is wonderfully ingenious, and does its work well considering that it has no brains.

But, it will be asked, how comes it that a particular machine at Shepherd's Bush should work so well on this rainy day, while those to which we referred last week gave, under better conditions, such sorry results?

The reasons for this discrepancy are not far to seek. In the first place, many of the public machines are undoubtedly very badly placed with regard to light. Indeed, it becomes a question whether each machine should not, to attain anything like perfection, be capable of being turned, so that its position may alter with that of the sun. Again, many are pitched so that the model has sky for a background, and a good result under such conditions is next to impossible. It would be to the ultimate gain of the Company if they refused to allow one of their machines to be used unless it were placed in such a position that the light could have ready access to a person standing in front of it.

But the principal difficulty with which the promoters of these machines have to cope is one which is felt more or less in every phase of life, namely, the obtaining of reliable servants who possess a little of that very uncommon attribute miscalled common sense. It is easy enough to point out to a man that the three liquids with which the baths are charged must not be mixed together, but unless he knows something about photography, he will never believe that a hypo-defiled finger can have any harmful effect upon the developing bath, nor will he realise that an occasional change of solutions is any more necessary to the machine than an occasional wash is in the case of his own person. In a word, the average man available for this kind of work is too much of a machine himself to succeed with the apparatus, and the conjunction becomes at once a case of the blind leading the blind. Is it likely that such a man can appreciate the difference in the amount of available light which manifests itself from hour to hour, and from day to day, in such a climate as ours, so that he may be capable of regulating the exposure accordingly? Is it likely, too, that he will master the *raison d'être* of the iris diaphragm?

We need hardly say that our strictures on the performance of the machines were written in no unkind spirit, but we cannot say that they were not true. We think that on reflection the Company will themselves admit that what we wrote was fair comment upon a matter of public interest, and certainly not a libel. We are glad to have had an opportunity of proving that the automatic machines are capable of far better things, and if only the Company can see their way to place each one under better supervision, they need not fear a dearth of clients.

Etching on Glass.—*Cosmos* recommends the following for marking designs or inscriptions on glass bottles, &c.:—Dissolve about 0·72 oz. fluoride of soda with 0·14 oz. sulphate of potash, in half a pint of water. Make another solution of 0·28 oz. chloride of zinc and 1·30 oz. hydrochloric acid in an equal quantity of water. Mix the solutions, and apply to the glass vessel with a pin or brush. At the end of half an hour, the design should be sufficiently etched. Another process, devised by Messrs. Meth and Kreitner, of Berlin, is given in *Invention* as follows:—A mixture consisting of ammonium fluoride, common salt, and carbonate of soda, is prepared, and then placed in a gutta-percha bottle containing fuming hydrofluoric acid and concentrated sulphuric acid. In a separate vessel which is made of lead, potassium fluoride is mixed with hydrochloric acid, and a little of this solution is added to the former, along with a small quantity of sodium silicate and ammonia. Some of the solution is dropped upon a rubber pad, and, by means of a suitable rubber stamp, bearing the design which is to be reproduced, is transferred to the glass vessel that is to be etched.

## PHOTOGRAPHIC METHODS OF OBTAINING POLYCHROMATIC IMPRESSIONS.*

BY LEON VIDAL.

One of the most interesting of questions connected with photography is that of obtaining polychromatic effects, especially now that a high degree of excellence has been obtained as regards the production of pictures in monochrome. We must say at the outset that our object is not to consider the problem of obtaining coloured photographic effects direct from the colours themselves. That is a question for the future. The few investigations and discoveries which have already been made have not thrown much light upon this matter. No practical or artistic effect has been obtained which is of commercial value. We must leave it for our scientific investigators to discover a direct method of photographing in colours, and to crown their labours by putting their discoveries to some practical use. For the present, we propose only to refer to well-known methods, and make use of those pigments only which one finds ready to hand. It is only intended to call upon light to perform those functions which it can so easily carry out in the various photographic processes practised at the present time.

A point which strikes us at the outset is the indifference of typographic and lithographic printers in general to the use of photographic methods. There are, of course, exceptions, but these are rare, and we should be glad to induce a larger number of those engaged in those industries to allow that photography ought to be one of their principal auxiliaries, and to convince them that, by its aid, their work could be executed more cheaply, more thoroughly, and more artistically.

For want of sufficient information it is still thought that photochromy presents serious difficulties, and, for this reason, chromo-lithographers always adhere to their routine methods of copying, either from nature or from works of art. Nevertheless, as we shall presently attempt to show, orthochromatic photography has made sufficient progress for us to be able to use it readily to obtain the real values of the luminosity of different colours, and also for the separation, to a certain extent, of different colours.

In the first of the two methods which we shall describe, the image is copied accurately as regards light and shade by means of photography, and is then coloured by means of rough tones of colour laid on by chromo-lithography, the selection and combination of the colours having been done by an artist in accordance with a pattern. The photographic work is extremely simple, and consists only of the execution of one single negative. This "simple photochromy" (*photochromie simple*) is, at times, of the greatest use, and there are many circumstances under which it is amply sufficient, and it avoids the necessity of having recourse to more complicated methods.

In the second of the two methods, one selects the colours photographically in a manner analogous to that suggested by various investigators, and amongst others by M. Ch. Cros, M. Louis Ducos-du-Hauron, and Ives, of Philadelphia. In this case, the preparation of *several negatives* is useful for obtaining as accurate a selection of colours as possible. We do not say that *three negatives* should be prepared, because it is possible that a larger number may be necessary, or, on the other hand, two or three may suffice. We confine ourselves to methods which are really of commercial and practical value, and we object to the dogmatic theories which lay down that with three primary colours one can reproduce all combinations of colours; that is an ideal which no one has yet attained, either with or without the use of photography. We take this opportunity of protesting against the claim put forward by Cros and others, who have worked on similar lines, that they have succeeded even indirectly in solving the problem of photography in colours. Their method consists simply in obtaining negatives which correspond more or less exactly with certain given colours regardless of the other colours. It is necessary, then, to find the exact tonality of the colours which are to be superimposed, and very rarely will a subject treated according to the indications of pure theory be an accurate reproduction of the original. We, at any rate, have never seen a successful instance. We think, on the contrary, that a photographic selection of colours, however well it may be carried out, ought to be assisted by some retouching. This is all the easier because the whole of the design is present, the modelling is to a great extent exact, and, in a word, it is only necessary to make a few slight corrections on a work already nearly complete. These corrections often consist only of a few blockings out on the negative, or erasures on the printing surface.

In describing, in some detail, this second method, which we designate by the name "composite photochromy" (*photochromie composite*), we hope to explain the services which it can and ought to render to chromo-typographers and chromo-lithographers. We omit not only the numerous varieties of photo-paintings and photo-miniatures, which are only of restricted use, but also photogravure in intaglio, which, except for maps and plans, is unsuitable for polychromatic printing. It is true that by its aid remarkably good work has been done, but it is necessary to paint on the engraved plate, copying the outlines in colours; a delicate and lengthy operation which is necessarily expensive, and only suitable for *éditions de luxe*. It is not a method easy of application, and, moreover, few studios are arranged in such a way as to enable it to be carried out.

Thus, to repeat in a few words the substance of this introduction, we may say that, while we are waiting for the solution of the problem of the direct reproduction in colours of polychromatic originals, there already exist two thoroughly commercial methods of combining photography with the use of colours, so as to give a result which may be as accurate as possible. One of these methods is simply photochromy; the other is composite photochromy.

We will now sketch in outline the nature of these two methods, which, it may be remarked, are by no means mutually exclusive; on the contrary, when the nature of the subject permits, they may be used simultaneously.

*Simple Photochromy.*—This consists, as we have said, in the preparation of one single negative, the positive print taken from which is combined with certain colours, according to the nature of the original. The negative ought evidently to be prepared with all possible accuracy as regards rendering of light and shade, and with this object it will often be necessary to use orthochromatic plates, so as to obtain the best effect. For example, if the subject contains much red, it is necessary to use not the first isochromatic plates which one finds in the market, but plates which have been sensitised for the red rays.

As a rule, ortho or isochromatic plates which are

* Read before the Photographic Society of Great Britain.

sensitive for yellow, are also somewhat more sensitive for green than ordinary plates, but they are absolutely insensitive to red rays. On the other hand, plates which have been sensitised for red by means of chlorophyll, cyanine, or methyl violet, are insensitive to green. If, therefore, the subject contains also an abundance of green (as well as red), it would be impossible to render it accurately by means of a plate sensitive only to yellow and green. (Blue and violet act only too energetically, and with regard to them we need only say that their action must be moderated by means of a yellow screen.) One would also fail to obtain a good result with a plate sensitised only for red and yellow.

If, therefore, one does not possess plates which have a suitable degree of sensitiveness for all the colours, it is recommended that orthochromatic plates already sensitised for yellow and green be used, and that they be further treated with methyl violet, according to the formula given by Wellington in the PHOTOGRAPHIC NEWS of 1885. We thus obtain plates which are sensitive to yellow and green, and also to red.

[A coloured slide of a bouquet of flowers and slides of the three monochromes were shown in the lantern. The red monochrome was prepared by photographing the subject on a Lumiere plate sensitive to the yellow, a yellow screen being used; the yellow monochrome by using an ordinary Lumiere plate without a screen; and the blue monochrome by using a Lumiere plate sensitive to the red, a reddish orange screen being employed to cut off the blue rays.]

(*To be continued.*)

## PHOTOGRAPHIC FORMULÆ.

*A New Hydrochinone Developer.*—Alexander Lainer, of Vienna, for some time past has been experimenting with the various formulæ given for hydrochinone developers, for the purpose of testing, and if possible improving, the same. After many experiments he reached the conclusion, as did Balaguy before him, that the best results were to be obtained by the use of yellow prussiate of potash with caustic potash or caustic soda.

He eventually settled upon a formula for a hydrochinone developer, which permits of exceedingly short exposures, at the same time giving negatives where the detail is well worked out in the shadows; while for reducing power and rapidity of development, it surpasses all other known developers.

Lainer's original formula—the rapid hydrochinone developer—especially useful for instantaneous exposures:

*Solution A.*

| | |
|---|---|
| Water ... ... ... ... ... | 32 ounces |
| Sulphite of soda ... ... ... | 10 drachms |
| Yellow prussiate of potash ... ... | 30 ,, |
| Hydrochinone ... ... ... ... | $2\frac{1}{2}$ ,, |

*Solution B.*

| | |
|---|---|
| Caustic potash ... ... ... ... | 13 drachms |
| Water ... ... ... ... ... | $3\frac{1}{2}$ ounces |

For use, mix for, say, 5 by 7 plate—

| | |
|---|---|
| Solution A ... ... ... ... | 3 ounces |
| Solution B ... ... ... ... | $\frac{1}{2}$ ounce |

For travellers or tourists, Lainer recommends the developer in a concentrated form, viz.:—

A.—(1) Dissolve—

| | |
|---|---|
| Water (warm) ... ... ... ... | $3\frac{1}{2}$ ounces |
| Sulphite of soda ... ... ... | 8 drachms |

Then add—

| | |
|---|---|
| Hydrochinone ... ... ... ... | $2\frac{1}{2}$ drachms |

(2) Dissolve—

| | |
|---|---|
| Yellow prussiate of potash ... ... | $6\frac{1}{2}$ drachms |
| Water ... ... ... ... ... | 3 ounces |

When dissolved, mix both solutions, which will give $6\frac{1}{2}$ ounces.

B.—Dissolve—

| | |
|---|---|
| Water ... ... ... ... ... | 3 ounces |
| Caustic potash ... ... ... ... | $1\frac{1}{2}$ ounce |

Or—

| | |
|---|---|
| C.—Caustic soda ... ... ... ... | 1 ounce |
| Water ... ... ... ... ... | 3 ounces |

To develop cabinet-size plates take—

| | |
|---|---|
| A ... ... ... ... ... | 5 drachms |
| Water ... ... ... ... ... | 10 ,, |
| B ... ... ... ... ... | 2 ,, |

Or—

| | |
|---|---|
| A ... ... ... ... ... | $2\frac{1}{2}$ drachms |
| Water ... ... ... ... ... | 10 ,, |
| C ... ... ... ... ... | $2\frac{1}{2}$ ,, |

If the solutions A and B are mixed it will give $6\frac{1}{2}$ ounces concentrated rapid developer; for use, where rapid development is desirable, 3 ounces of water to each ounce of developer. Where extra rapidity of development is not wanted, take 6 ounces of water to each ounce of developer.

Lainer recommends as a retarder the usual bromide of potash solution (1 : 10), added drop by drop. He further recommends that the well-washed plates be fixed in an acid fixing bath.

When a large number of plates are to be developed with the above developer, it is recommended to have a dish handy with water acidified with several drops of sulphuric acid, to dip the fingers in case they become slippery from the developer.—J. F. S., from *Photographische Rundschau.*

*A Pyro-Hydrochinone Developer.*—Dr. Schleussner recommends the following formula as giving negatives with all the characteristics of the collodion wet plate, showing the finest detail and clearest high-lights, with the advantage of being rapid printers:—

| | |
|---|---|
| A.—Hydrochinone ... ... ... ... | $2\frac{1}{2}$ drachms |
| Distilled water ... ... ... ... | 34 ounces |
| B.—Carbonate of soda ... ... ... | $3\frac{1}{4}$ ,, |
| Distilled water... ... .. ... | 17 ,, |
| C.—Distilled water... ... ... ... | 14 ,, |
| Sulphite of soda ... ... ... | 2 ,, |
| Pyrogallic acid ... ... ... ... | 5 drachms |
| Diluted sulphuric acid ... ... | 10 to 12 drops |

The sulphite of soda is first dissolved in water and acidified with the sulphuric acid, then the pyro is added. For use, take—

| | |
|---|---|
| A ... ... ... ... ... | 4 ounces |
| B ... ... ... ... ... | 1 ounce |
| C ... ... ... ... ... | 1 ,, |

When this solution is slightly warmed the development is much more rapid. It is further recommended to commence the development with old developer until the high-lights appear, then finish with fresh developer.—*American Journal of Photography.*

ELECTION OF JUDGES, 1891 EXHIBITION.—The balloting paper for the election of judges at the forthcoming Exhibition was issued last week with the *Photographic Society's Journal.* It contains the names of twenty-eight nominees, from whom *seven* are to be chosen. The voting papers are returnable by to-morrow, 30th inst., at latest, addressed to the Secretary, Photographic Society, 50, Great Russell Street, W.C. The list is as follows:—Captain Abney, G. L. Addenbrooke, E. A. Austin, W. Bedford, W. S. Bird, V. Blanchard, F. P. Cembrano, jun., Seymour Conway, T. R. Dallmeyer, T. S. Davis, G. Davison, W. E. Debenham, P. H. Emerson, W. England, J. Gale, F. Hollyer, Chapman Jones, H. S. Mendelssohn, H. Moore, A.R.A., P. H. Newman, A. Pringle, H. P. Robinson, J. Spiller, F. M. Sutcliffe, J. T. Taylor, J. B. B. Wellington, B. J. Wilkinson, and Sir H. Trueman Wood.

# Patent Intelligence.

### Applications for Letters Patent.

8,557. ALFRED JULIUS BOULT, 323, High Holborn, London. "Improvements in Photography." (John North, United States).—May 19th.

8,628 WILLIAM GRIFFITH HONEY, 27, Regent Street, Barnsley. "Improvements in Photographic Printing Frames."—May 20th.

8,660. CHARLES HERBERT OFFORD, 15, Tasker Street, Walsall, "A New Hand-Camera."—May 21st.

8,761. GEORGE TEASDALE TEASDALE-BUCKELL, 55, Chancery Lane, London. "Improvements in the Production, by the Aid of Photography, of Surfaces for Use in Printing Colours, and in Means or Apparatus Employed therein."—May 22nd.

### Specifications Published.

28. *January* 1*st*, 1890.—"Feeding Sheets of Paper," &c. R. CRESSWELL, 5, Bedford Place, Russell Square, and M. HESLOP, 100, Houndsditch, both in London.

The pile of sheets is placed on a table, and the bottom sheet is fed forward by a rubber covered or other roller under an adjustable guide bar. The bar keeps back the upper sheets, and may be adjusted for different thicknesses of material by screws, and locked in position by nuts. It may be adjusted laterally by moving certain brackets. Anti-friction rollers may be placed in the table. Rollers may be used when required to receive and deliver the sheets. The feed roller may be driven by a band or by gearing, &c.

36. *January* 1*st*, 1890.—"Stoppering Bottles." R. BROTHERHOOD, Cambria House, Chepstow, Monmouthshire.

A hollow plug, closed at the bottom and surrounded with packing, has ports on opposite sides to correspond with ports or channels in the neck of the bottle. The stopper is held in the bottle by projections, which pass underneath and engage with flanges, and it is turned by lugs or thumb pieces.

40. *January* 1*st*, 1890.—"Decorating Wood." C. HETTWIG, Hollmannstrasse 33, Berlin, and F. HECKNER, Adolphstrasse 51, Braunschwlig, both of Germany.

The wood is first saturated with alum to prevent liquids running in the grain thereof, and then the parts to remain unacted upon are coated with a concentrated solution of caoutchouc in chloroform. The remaining parts are next painted over with copper bichromate, and, before that is perfectly dry, with a solution of pyrogallic acid. The surface is afterwards exposed to the light till the proper colour is developed, which, according to the relative strengths of the solutions used, may range between a greenish hue and a reddish one.

151. *January* 4*th*, 1890.—"Rocking Apparatus for Developing, &c." J. B. BROOKS, Great Charles Street, Birmingham.

The developing, &c , tray is carried on a frame or rest, which is mounted by side trunnions on brackets. Depending from the rest is an arm which is actuated from a crank plate, for rocking the rest by clockwork mechanism provided with a fly, which can be arrested by a push piece to stop the apparatus. Modifications are described in which a gyratory, &c., movement is given to the rest and tray.

173. *January* 4*th*, 1890.—"Picture Frames." F. KITTO, 3, Lower Union Street, Torquay.

Relates to frames for holding photographs and like views, especially for utilising photographers' waste plates by mounting photographs thereon. It comprises a frame, which may be of any material, such as leather, cloth, linen, wood, metal, &c., folded over from the back to the front of the glass plate. In this case a strut is provided to support the frame in a sloping position.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—(Change of Address). All communications and journals should be sent to 50, Great Russell Street, Bloomsbury, London, W.C., instead of 5A, Pall Mall East, or Messrs. Harrison, St. Martin's Lane.

# Correspondence.

### CARDIFF PHOTOGRAPHIC SOCIETY.

SIR,—If we may trespass upon your valuable space, we should like to explain the *raison d'être* of Class 15 at the forthcoming Cardiff Exhibition.

Our object in offering an optical lantern for the best fifty slides of a town or district is merely an incentive to Societies to form such collections; and although we stipulate that the winning slides shall become our property, they are intended to form a loan collection to circulate amongst the British and American Societies. Of course, with the present high standard of lantern slides, the whole of the work sent in should form most interesting collections, and by arrangement with the competing Societies a valuable slide interchange should result, and there, we think, the utility of the scheme comes in. We trust, therefore, it will receive the cordial support of Societies generally.

G. W. BEDFORD, }
T. H. FAULKS, } *Hon. Secs.*

*Cardiff*, 21*st May*.

### "SUN ARTISTS."

SIR,—When the first number of *Sun Artists* was issued, the hopes of those who had faith in photography ran high that something worthy was being done for the art. It was set forth as a "pioneer publication" to teach the world that photography was an art, as well as intended as a monument to the best photography of the time. It began well; the early numbers worthily fulfilled the intentions, but the last three parts have shown a woeful falling off from the high resolve to issue nothing but the best. The decadence began with No. 5, with its violent, controversial, and most ill-advised essay. No. 6 contained pretty but obvious imitations of Mr. Gale's beautiful work, and No. 7, just issued, consists of a selection (and not a good one, for much better results by the same hand may be seen for sale—as is now the fashion with amateurs—in the shop windows) from the works of one of our youngest amateurs, with an essay by a writer who begins by confessing that he has no practical acquaintance with photography.

The lady whose photographs are selected for the new number has shown great talent for the art, but she would have done well to wait until her knowledge became more mature before she allowed herself to appear among the masters. Her portrait of Browning is an exception to the other prints; it is exceedingly fine in all respects. The "Gladstone" is a good illustration of the old-fashioned soot and chalk photograph. The "Rebekah" has a beautiful face and expression, but the figure is very amateurish; the tucking-in of the dress, the hand-made arrangement to represent the effect of motion, has all the merit of good intention, but goes no further; the art does not hide the art. The fourth picture—the "Summer Garden"—has no particular feature beyond the efforts of the ordinary amateur.

The essay is a moderately well-written but hesitating article by a great writer, who, from want of the necessary knowledge of his subject, seems to be in difficulties as to what to say, and it does not appear to have struck the editor that it was his duty to look after the facts of a writer who knows so little of his subject. He speaks of Mrs. Cameron as the *first* to make subject-photographs popular in England. This gifted lady began to photograph in 1864; are Rejlander and Robinson forgotten? I remember reading a cutting from a morning paper of 1858 to the effect that the subject-photographs of these two artists were so popular at that time as to be almost as great a nuisance as nigger minstrels. Of course the writer makes his statement in ignorance, but an efficient editor would have corrected it.

Surely this is not the way to recommend photography to the artistic consideration of the public, or to instruct them in its history.

Is photography so destitute of talent that a few numbers of this publication is sufficient to exhaust it? Where are Mr. Austin's pictures? Inside the cover of No. 6 we are promised that they shall appear in No. 7. Why was the promise not fulfilled? When are we to have Mr. Sutcliffe's photographs?

It is true that he has lately ridiculed the claims of photography to rank as au art; but there was a time, uot long ago, wheu his photographs, which we all thought were pictures, would have graced the collection. Of course, they could not now be admitted as specimeus of photography as an art. Then there is Dr. Emersou; but he also has conscientious scruples. And we are auxiously expecting Mr. Davison's works; but perhaps he is wisely waiting to discover where his strong point lies.

If nothing of the best is left, or to be got, would uot the promoters best fulfil their intention by discontinuing the publication? There has beeu enough published to form a handsome volume, and to do them a great deal of credit for their very praiseworthy intentions. Helios.

## Proceedings of Societies.

The Photographic Society of Great Britain.

At the technical meeting of this Society held on the 26th inst., the chair was occupied by Capt. W. de W. Abney (vice-president).

A magnesium flash-lamp for furnishing a continuous flame of several seconds' duration, sent by M. Nadar, of Paris, was exhibited and explained by the Chairman. Several photographs were also shown to illustrate one of the uses to which the lamp had been put, that of assisting in the exposure of interior subjects. It was said that, by this means, the halation commonly seen round a window iu an interior could be avoided, as the exposure need be no longer than that required for the window, and for any part of the picture seen through it, whilst the lamp would illuminate the dark portions of the iuterior and any figures therein at the same time.

It was pointed out by a member that iu one of the examples sent the window had evidently been masked, and printed deeper than the rest of the picture, so that the lamp had not been entirely relied upon for the effect meutioned.

Mr. W. England said that some of the finest flash-light photographs that he had ever seen had been the work of M. Nadar.

The Chairman agreed as to the excellence of M. Nadar's work in this direction, and also mentioned that some of the very finest hand-camera pictures he had ever seen were in a set of views in Turkestan, taken by M. Nadar with an Eastman half-plate roller slide camera. Paper had been used instead of films, being preferred to the latter by M. Nadar.

"The Influence of Development on Gradation" had been announced as the subject for this evening's discussion, which, at the request of the chairman, was opeued by Mr. G. L. Addenbrooke. He said that he could not do more than repeat what he had said at a meeting when the same subject was discussed, held iu January, 1883. He had then showed a series of negatives that had been exposed under a sensitometer screen, and developed in different ways. The plates had all beeu exposed for just sufficient to enable the figure 25 on the sensitometer to be brought out. One of the deductions he had drawn was that, although the ingredients of the developer might be altered effectively within certain limits, beyond those limits very little effect was produced. Thus, after a certain amount of pyro was added, to put in more only assisted in producing stain, with no appreciable increase of density. So with ammonia; more than a certain quantity had no effect, unless it was to induce fog.

Mr. Atkinson would like to know whether, independent of density, Mr. Addenbrooke had found slow development produce better gradation than rapid development.

Mr. Addenbrooke had not found this to be the case.

Mr. A. Mackie had been making experiments much on the same lines as those of Mr. Addenbrooke, but, in his case, he had developed each plate, whether the developer was a quick or a slow one, until the No. 25 was just visible both by reflected and transmitted light. He passed a number of slides through the lantern to show the effect of variations in the developer, and mentioned that he had found decreasing the amount of pyro or of bromide produced practically the same effect as increasing the amount of ammonia.

Mr. Chapman Jones said that the paper which had been published by Messrs. Hurter and Driffield, and his own observations thereon, had been much misunderstood. He had objected to the statement which had been made without limitations by Messrs. Hurter and Driffield, that the ratios of density were unalterable by development. That statemeut, he considered, required to have certain limitations attached to it. If two plates of a given subject were exposed for a similar time, aud one developed until all procurable details were secured, whilst the other was stopped in a much earlier stage, then, according to Messrs. Hurter and Driffield's proposition, if the latter plate was intensified until the strength of the lights was equal to that of the other plate, the strength of the details in the shadow should be equal too. Those details had, however, never been developed, and he could not find that details which were invisible before intensification showed themselves after that operation. Messrs. Hurter and Driffield's paper was a valuable one, and contained much truth, but there were parts of it to which he took exception. One such part was the statement that difference in formula would not alter the ratios of density. Then, again, differences which he had found to exist had been ascribed by Messrs. Hurter and Driffield to errors in experiment. When these errors all pointed in one direction, he thought their significance ought not to be disregarded. A poiut iu connection with the subject to which he would invite attention was that, although the light worked down from the surface of the plate into the substance of the film, and went deep with strong lights, whilst with faint tones the surface of the plate only was affected; and, although development commenced at the surface, yet these faint tones were the last to appear.

Mr. F. Hurter regretted that his colleague Mr. Driffield was not with him, as he would have been if circumstances had permitted. Photographers were generally under the impression that they could alter the ratio of gradation by changes in the developer, and that impression he and Mr. Driffield had come to the conclusion was a wrong one. That an over-exposed plate could, within limits, be made to yield a uegative giving a passable print was no proof to the contrary. The gradations of such a negative were not the same as in a negative that had received a less exposure. He thought photographers had fallen into the mistake from trusting to the eye instead of making exact measurements. With regard to the case mentioned by Mr. Chapman Jones, he would say that the experiments they had made did not include any in which part of the plate was left undeveloped. The instrument they used for measuring was not perfect, but the errors were not large. They had not found them to exceed five per ceut., and iu Captain Abuey's hands the errors were reduced to still smaller proportions. The use of the word density, as they had employed it, was partly the cause that they had been so much misunderstood by photographers. Mr. Hurter showed by diagrams ou the blackboard his view of the curves density took, and maintained that for any given plate and exposure, the ratios of density as expressed by the length of the ordiuates was the same, whatever developer was used, although the absolute density might vary considerably. Mr. Mackie's experiments he considered defective from two conditions having been altered together instead of being taken siugly. He referred to the alteration of the coustituents of the developer and the time of development. The latter, he thought, should have been kept constant.

Mr. Mackie said that in that case he would, with some of the developers, have had no image at all.

Mr. Addenbrooke believed that differences in the developer did effect a difference in the ratios with which different strengths of the image would appear. Suppose the case of a lady in a white dress, and some very dark object to be included in the same photograph. He would in this case use such a developer as would briug out the details of the dark object before the dress had time to acquire such density as to block up the details. If, on the other haud, he were photographing dark foliage with a bit of bright sky, he would develop so as to bring out the details of the foliage before the sky became too dense.

Mr. Cowan said that the two cases were not of contrary, but of similar character, and the treatment required for the one should suit the other.

Mr. WARNERKE considered that Mr. Mackie was not introducing a second condition when he lengthened the time of development to suit a solution slow in its action, but that it would be introducing a fresh conditiou to cut down the action of the developer in this case before its full effect could be produced.

Mr. DEBENHAM thought the subject of the greatest importance, as no means should be left untried to overcome the principal defect of photography, that of deficient rendering of gradation at the two ends of the scale. So far as the examples shown on the screen that eveuing were concerned, he thonght they were rather in support of Messrs. Hurter and Driffield's contentiou than against it. There was a decided difference in the density of the different plates shown by Mr. Mackie, but not in the comparative density of the varions gradations. Thus, in the most powerfully lighted square, the difference between the place where the glass had been removed was visible in the whole series. He would like to have the opiniou of the chairman as to whether they mnst despair of finding better gradation in the direction of development.

Mr. BENNETT said that he had fonnd a difference of development produce a great difference in gradation of the negative. He had photographed a subject containing white marble and dark woodwork, and, whilst in a photograph developed in the nsnal way the details of the marble were lost, they had been retained in a negative having the same exposnre by the following treatment. Development had been commenced with a solution containing very little pyro and bromide, and a full dose of ammonia, and had been continued with stronger pyro until sufficient density was obtained. In answer to a request, Mr. Bennett promised to bring these negatives to a future meeting.

The CHAIRMAN thanked Mr. Hurter for coming from Liverpool to be present. As to whether gradation conld be affected by development, he could not then presume to say. He very much admired the scientific work done by Messrs. Hurter and Driffield, and, as to their instrument, he hoped to come to an agreement with them. Further discussion on the subject would be resumed at the technical meeting in June, when there might be examples by members of experiments made with the view of discovering more about the subject in hand.

CAMERA CLUB.

ON May 21st, Mr. R. INWARDS in the chair, Dr. J. J. ACWORTH read a paper on "The Flash-Light," and, at the outset, dwelt upon the use made of the flash-light on the Continent for the production of artistic photographs. He exhibited a large number of examples of single figure and group studies, described the appliances in use, and illustrated his remarks by showing specimens of lamps employed in Germany. The working of these was practically demonstrated, and some exposures were made by Mr. Chang. Dr. Acworth then discussed the qualities of the light given by the magnesium flash, and the application of it to orthochromatic work, illustrating his remarks by diagrams.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

A FIELD-DAY was orgauised for the 23rd inst. to Hale End and district. The party proceeded to Chingford old Church, securing several pretty bits on the way. The church was theu taken from several points of view, and the remainder of the afternoon was passed in the meadows beyond the church, where there is to be found ample food for the camera. For these bits, as for the church, a wide-angle lens not longer than the length of the plate is necessary.

On the 25th inst., Mr. F. CHERRY in the chair, Mr. F. W. Cox gave a demonstration on "Kallitype." The paper was coated presumably with a solution of ferric oxalate; this, on exposure to light, is changed to ferrous oxalate, which reduces the silver salt in the developer, and an image iu metallic silver is the result. The paper, both before and after exposnre, presents an almost identical apppearance to platinotype paper. The paper is at least three times as sensitive as silver paper, and, therefore, all developing operations during daytime must be conducted in weak light. A good negative (not necessarily a hard one) will give best resnlts in this as in other processes, and exposure should be stopped when there is a very faint indication of the densest parts of the negative having printed on the paper. Under-exposed prints will develop very slowly, and over-exposed ones come up mealy and muddy in appearance, and are liable to show stains and markings. In developing, the prints are floated, face downwards, upon the developer for a few seconds, and then placed for a short time upon a piece of clean glass to gain density. Shonld bubbles appear, a touch with a camel-hair brush charged with the solution will stop any trouble in that direction. The prints are next immersed in clearing baths, and a final wash iu water completes them prior to drying. The bichromate of potash is to give contrast, and a stock solntion (8 grains in 1 ounce of water), shonld be kept. A drop or two of this added to the developer, when thin negatives are printed from, will be found advantageous. Due allowance must be made, in judging density and brilliancy, for the wet state of the paper, and with the greatest care and cleanliness, stains and markings will sometimes appear. The finished prints range from a bluish black to a purple black in colour, and the demonstrator saw no reason why they shonld not be toned with uranium to a sepia colour, to suit those who prefer a warm effect.

On June 8th, Mr. H. WALKER in the chair, Mr. J. TRAILL TAYLOR will address the Society, when visitors will be welcome.

RICHMOND CAMERA CLUB.

AT the meeting on the 22nd inst. Mr. CEMBRANO presided, and a demonstration of printing on alpha paper was given by Mr. HOWSON. Details of the process were explained, and the queries of members on points of doubt or difficulty were answered.

Field-days now take place once a fortnight, but so far have been marred by the weather.

BRIXTON AND CLAPHAM CAMERA CLUB.

*May 21st.*—Dr. REYNOLDS in the chair. Mr. W. H. Powell, having been suffering from the prevailing epidemic, had been unable to prepare his lecture on "Hand-camera Work," and it was accordingly postponed until June 4th.

Messrs. Hayward, Knight, Palmer, and Reeves were elected members of the club.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

AT the meeting held on May 19th, Mr. J. TRAILL TAYLOR in the chair, Mr. WEIR BROWN explained his method of obtaining warm tones in bromide prints by uranium toning. To obtain the best results he gave a fairly long exposure and obtained, by slow development, a muddy brown coloured image. After fixing and washing, the print was immersed in a bath cousisting of—

| | |
|---|---|
| Nitrate of uranium ... ... ... | 4 grains |
| Ferridcyanide of potassium ... ... | 4 ,, |
| Acetic acid ... ... ... ... | 90 minims |
| Water ... ... ... ... ... | 8 ounces |

The prints required to be slightly over-toned, as the subsequent washing tended to bring back the original colour. In fact, if continued long enough, the whole of the effect of the toning bath would be removed. Mr. Weir Brown passed round a number of specimen prints in illustration of his remarks.

Mr. A. S. NEWMAN read a paper on "High-Speed Shutters," in which he pointed out the difficulties to be overcome in the construction of a shutter designed to work at a speed of over one-hundredth of a second, and explained how he had overcome these difficulties in the shutter which he exhibited. He also, by means of diagrams on the blackboard, showed a graphic method of calculating the effective exposure given by various types of shutters.

The next meeting will be held on June 2nd, when Mr. J. Traill Taylor will lecture on "Stereoscopic Cameras and Appliances."

### Auckland Photographic Club.

The first annual exhibition held under the auspices of the Auckland Photographic Club was opened on the 3rd April at the Auckland Institute Buildings, Princes Street.

His Excellency the Governor, in opening the exhibition, said he thought he belonged to one of two classes of photographers. The first was the artistic class, which possessed all the developments of photography as an art, and gave every subject an artistic treatment; and the other class comprised what were called "shot" photographers, whose only aim and object was to carry away some little reminiscence of a passing scene. He thought he must confess that he belonged to the second class, but, though he was one of the shooting photographers, still he hoped that he had turned out something which might be called creditable work, and that he could not have much sympathy with those who cared only to press a button and let somebody else do the rest. While he did not pretend to be a judge, he felt quite sure that, from its surroundings, Auckland should be one of the leading places in the world for the art of photography. He had seldom seen anything to equal some of the photographs produced in this part of the world. This excellence was no doubt due to the beauty of the natural surroundings, and to the extraordinary clearness of the atmosphere, and he saw no reason why New Zealand, and especially Auckland, should not have a place in the forefront of photographic art.

The exhibition was closed on April 7th, when the lecture room and museum were crowded by eager and interested visitors.

---

Royal Institution.—An extra evening meeting will be held on Tuesday, June 2nd, at nine o'clock, when Dr. Charles Waldstein will give a discourse on the discovery of "The Tomb of Aristotle."

Auckland Photographic Club.—Mr. Henry J. Carson, hon. sec., writes as follows:—"I shall at all times be pleased to enter into correspondence with secretaries of the other clubs, or any photographers, by which means we may be of advantage to each other."

The Queen's Visit to Derby.—The 21st of May was a busy day for the photographers of Derby, both professional and amateur, scores of cameras, from the hand-camera to 18 by 20 size, being called into requisition. Snap-shots were mostly failures, for the day was dark and the hour late. Mr R. Keene had a stand erected in the Market Place, where he obtained some fairly good pictures with exposures of two and three seconds. The ceremony of the presentation of the casket containing the address, by the Mayor, took place in front of the Town Hall, beneath a huge canopy, which stopped the greater part of the little light there was at 6.30. Before leaving the town, the Queen accepted from the Mayoress, on the behalf of Mr. R. Keene, a handsome volume of his platinotypes of the "Interiors of Hardwick."

Received.—From A. Kersha, St. Petersburg, No. 1 of the *Pantobiblion*, the purpose of which is stated to be to help literary men concerned with the applied sciences generally, and particularly those devoted to any technical studies of any speciality, to be promptly, exactly, and completely informed of the correspondent branch of current scientific literature, and that, to attain this purpose, it contains a classified list of all the new books, published in all the principal languages, in all the countries of the civilised world, on different scientific subjects connected with the applied sciences as named above; a series of critical articles on the leading scientific publications of the world; and a review of the current periodical literature of the world, showing the contents of all the chief scientific magazines of the day devoted to the applied sciences, and published in all the principal languages.——From Horne, Thornthwaite, and Wood, "A Photograph, and How to Take It," a combination of manual of instruction and trade catalogue, each useful in its sphere.——"My Camera, and How to Use It," by John Piggott, is a comprehensive illustrated trade list, prefixed with brief instructions on exposure, development, fixing, printing, and toning.——"Practical Amateur Photography," by C. C. Vevers, Leeds. We have received the fourth edition of this useful little manual.

## Answers to Correspondents.

**All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.**

**All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.**

Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.

Ed. Liesegang (Düsseldorf). — *Physical Society of London.* The head-quarters of this society are at South Kensington, S.W., Professor Ayrton, F.R.S., being the president. On the 9th ult. the members paid a visit to the Cavendish Laboratory, Cambridge University, where papers were read and the collection of physical instruments inspected.

H. Dorn (Leipsig).— *Zinc Clichés.* We regret to say that we cannot find any reference to Tulson's process; could you give us a date respecting it, or a few particulars to guide our search? Türcke's zinc etching process is described and illustrated in our Year-Book. Is this what you want?

M. Cappelli (Milan).—*Coating Machine.* The specification to which you refer is dated December, 1890, and can be procured either from the Patent Office or the agent, Mr. A. J. Boult, 323, High Holborn. To save delay and trouble, we are sending you a copy.

Photoman (Paris).—1. *Abney's Collodion Emulsion for Red Rays.* Without going back to the *Phil. Trans.* of 1880, we find in Capt. Abney's "Instruction in Photography," eighth edition, 1888, page 146, the following formula:—Ether 5ozs., alcohol $2\frac{1}{2}$ ozs., pyroxyline 75 grs. Dissolve 200 grs. zinc bromide in smallest possible quantity of alcohol, and add 4 or 5 drops of conc. nitric acid. This bromide is then added to *half* the above collodion. Now dissolve by heat 330 grs. silver nitrate in half an ounce of water, and add $1\frac{1}{2}$ oz. of hot alcohol. Add this solution to the other half of the collodion, and, with brisk stirring and very cautious addition, pour the bromised collodion into it. Precautions:—See that the silver is in excess by testing a drop with potassium chromate, which should give a red colouration or precipitate. Try also the quality of the film, which should appear red by transmitted light. You will notice that the proportion of pyroxyline to zinc bromide is much larger than that given in your letter, and this will render the emulsification easier. 2. *Discussion of Messrs. Hurter and Driffield's Paper.* You will find Capt. Abney's and Mr. Chapman Jones's replies, as given at the Parent Society, in the News of November 14th, 1890, page 893.

A. B. C.—Mr. H. P. Robinson has written two books bearing on portraiture: "The Studio, and What to do in it," and "Pictorial Effect in Photography." There is also a little shilling manual called "Heighway's Practical Portrait Photography." All three are published by Messrs. Piper and Carter.

C. Jones.—*Bromide Enlargements.* The information as regards apparatus is given at page 137 of Mr. W. K. Burton's "Modern Photography." Details of process were fully described in the News of January 17th, 1890.

L. P.—*Competitor's Declaration.* The wording is strictly according to the usual form applicable to such cases.

A. H. C.—*Elementary Book of Instruction.* Either Marion and Co.'s "Manual, or W. K. Burton's "Modern Photography."

G. L. A.—The circular was returned by post on Monday last. We thank you for the opportunity of perusal.

A. H. Greenhill.—*Photographic Paper.* See answer at the head of this column last week. Have you tried the Saxe paper (Steinbach, Malmedy), or that of B. F. K. Rives, size $17\frac{1}{2}$ by $22\frac{1}{2}$ inches?

R. H. M.—*Yellow Spots on Silver Prints.* These are undoubtedly due to sulphide of silver, and appear to be formed in consequence of insufficient agitation in the fixing bath or bubbles not quickly dispersed. Try preliminary washing in a weak borax bath before fixing your prints.

Ed. Cetti.—*Rapid Filtering Funnel.* We believe your idea to be new, but this opinion must not be taken as absolving you from the duty of making a search at the Patent Office.

# THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV. No. 1709.—*June* 5, 1891.

CONTENTS.

## SOME NOTES ABOUT CLOUDS.

In the early spring, when the light is at its best, and when showery weather alternating with brilliant sunshine is the order of the day, it is comparatively easy to secure clouds in the same negative as the landscape, and it need hardly be pointed out that this is an advantage that one cannot value too highly. When such clouds are present in the negative, it is too often the case that they are buried in the film during development. When they first show themselves in the early stage of that operation, the photographer is delighted, but too often leaves them to take care of themselves while the details of the landscape below are unfolding themselves. In nine cases out of ten the sky will, under such circumstances, become so dense that clouds and what should be open space are merged together in one black mass. If, on the other hand, the photographer will take a little trouble, this destructive action can be easily stopped. When the sky first shows itself sufficiently to discover cloud-forms which are worth preserving, let the negative be lifted from the dish and well washed under the tap. Now hold it so that the sky is dowuwards, and, with a camel-hair brush charged with bromide solution, paint the surface of the sky, just as if you were laying-in a water-colour tint. Water-colour artists frequently paint in their skies while the picture is inverted, so that the colour shall not stray where it is not wanted. The inverted position is recommended here for the same reason with regard to the bromide solution. Now place the negative once more in the developing bath, and the landscape portion can be coaxed out without any fear of blotting out the clouds by over-development.

There are numerous shutters which are so contrived that the sky portiou of the picture gets but a fraction of the exposure which the landscape receives. Leisk's sky shutter is a clever contrivance, and one which acts well in securing this end. The use of isochromatic plates with a yellow screen is also a great help in securing printable clouds in negatives, with the disadvantage, however, of a somewhat protracted exposure. Some photographers make use of a sky-shade outside the lens hood for shielding the sky from the negative during the greater part of the exposure, and these sky-shades are of various designs, as anyone can see for himself by referring to the photographic annuals for past years. One writer, we remember, recommends the use of a ruby glass backing to the dark slide, so that, with head under the focussing cloth, one can see the amount of shading to give to the lens in order to mask the sky properly. It is obvious that most of these devices are only applicable to open views and landscapes where there is a visible horizon, that is, a plain line of demarcation between the sky and the rest of the picture. But in seascapes, where the whole of the picture, sky and water, is equally illuminated, no dodging is really necessary, for a very quick exposure will secure clouds and waves at the same instant, and without the least difficulty.

In photographing cloud effects, one is apt to be led away by the beauty of the colouring. A beginner in photography generally makes this mistake with every subject which presents itself. He sees on the ground glass screen a brilliant blue sky embroidered with fleecy clouds, purple hills in the distance, relieved, perhaps, by brilliant green trees, and grass bespangled with cowslips in the foreground. "What a lovely effect!" thinks he, and he takes a photograph, only to find out, later on, what a mistake he has made in supposing that such a view could make a satisfactory picture in monochrome. But more experienced eyes are apt to be deceived in this way by the wondrous colouring of cloudland, and forget that they must study only form and light and shade. A man who is colour-blind would probably make the best photographer of clouds, and an engraver, used to shutting his eyes to colour, would do as well.

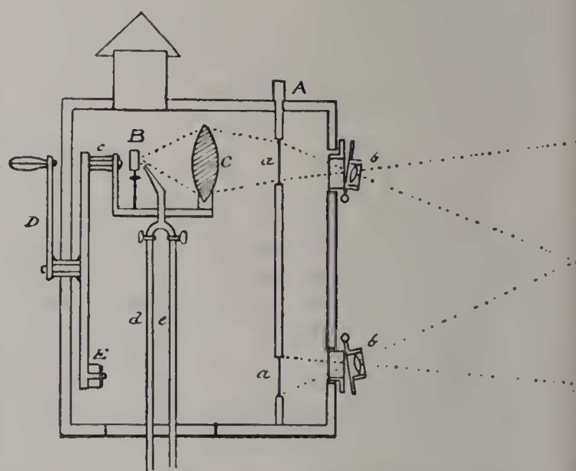
It is pointed out in most of the text-books that the photographer, if he print in a sky from a separate negative, must be careful to see that the direction from which the clouds are lighted agrees with the direction of the light which illuminates the landscape to which they are to be wedded. This is a very trite remark to make, and there is no question of its foundation in truth. But, as a matter of fact, it is sometimes most difficult to determine the place where the sun is in hiding in a cloud negative. This is the case when we have a sky covered with broken clouds of the cumulo-stratus variety. As an example, let us suppose that we are walking westwards along Fleet Street in the late afternoon, and that the sky be fair, but covered with these brilliantly illuminated clouds. The warm-tinted light is reflected upon the houses on *both* sides of the street, and, as there is no direct sunlight, there are no cast shadows. Now, does it not stand to reason that such a sky can be wedded to any landscape, provided that the latter has not been taken in actual sunshine? In such a case the clouds are so well lighted, and their form so permits of the illumination of all their edges in equal proportions, that it is quite impossible to say that the sun is at the right or the left. The power of reflected light from a large mass of cloud is another factor which is not generally taken into consideration, but which, in nature, often modifies the aspect of a landscape to an immeasurable extent.

Another question, which is apt sometimes to be lost sight of, the photographer would often do well to ask himself before he begins to select a sky negative to print into his picture, and it is this: "Ought this picture to have clouds?" In order to answer this question he must refer to his note-book, or trust to his memory, to learn whether there were clouds present when he took the picture. If not, and if a plain grey or blue sky covered the landscape on the occasion when the picture was taken, surely he will do better to endeavour to imitate that appearance by giving the sky portion of the print additional exposure, than by wedding it to clouds which do not belong to it. In pictures taken abroad, in sunny situations where clouds are unknown, their introduction is clearly a mistake, and one which would certainly be resented by anybody familiar with the country. As an extreme case, we might cite the folly of introducing English clouds into a view of the rainless valley of the Nile. Yet such things are done, and are really as ridiculous as the practice of some old artists in dressing up Biblical characters in 16th century English costumes.

Artists in the old days made the common mistake of drawing their feather-bed-pattern clouds — and many of them acknowledged no other form—at or near the zenith of their skies; but supposing that the forms which they drew were actually like the cumulus cloud—and we may take it for granted that they were certainly meant to imitate that form of cloud—they were wrong in putting the cumulus in such a position. For a cloud mass of this character generally rests upon a flat base which is not very much above the horizon, and it stands to reason that, by the time the top of the cloud mass reaches the zenith, the base covers the ground below, and shuts it out of sight. The only observers, therefore, who would be in a position to view a cumulus cloud in such a position must be in a balloon, and adjacent to its sides.

## OPTICAL LANTERN FOR PROJECTING PICTURES OF MOVING OBJECTS.

We will not attempt to decide whether the long-sought solution of the problem of throwing upon a screen lantern pictures of moving objects is to be found in the apparatus described and illustrated here; it is a fact, however, that it has just been constructed by a well-known optical house in Vienna—that of W. Prokesh—and has given satisfactory results. The arrangement is as follows:—The pictures, *a a*, are placed in an upright position in a wooden carrier, and as close together as possible, in a circle. In front of every picture is placed an objective



lens *b b* (in the accompanying engraving only two are shown; in reality, the apparatus possessed twelve), which can be made to incline towards the centre of the apparatus all together, by means of a hinge and adjusting screw. The inclination of each lens is so arranged that the image formed by them will coincide, at whatever distance the screen may be placed.

As an illuminant, the ordinary lime-light can be employed with the lime cylinder *B*, and the condensing lens *C*, which produces somewhat converging rays, lights up one picture after another. The jet and its belongings are turned by means of a simple mechanism, slower or faster as is necessary, in a circle by the handle *D*, so that the lighting apparatus retains its upright position by reason of its own weight. It is fastened very loosely on to the support *c*, so that it moves easily. The two india-rubber tubes, *d* and *e*, pass up and down through an orifice in the bottom of the case. The mass of lead, *E*, serves as a counterweight to the lighting apparatus.

The action is plain. The pictures, lighted one after the other, are thrown on the screen exactly in the same manner as dissolving views, only very much more quickly, and they give perfectly the effect of moving objects. The apparatus is, in this, its original form, constructed for twelve pictures only, but it could be made, however, with very little difficulty to hold a large number of pictures.—Translated from an article in *Photographisches Archiv.*

Royal Institution.—At the general monthly meeting on Monday, June 1st (Sir James Crichton Brown, M.D., LL.D., F.R.S., treasurer and vice-president, in the chair), Messrs. R. W. Peregrine Birch, William Edmonds, Nicholas Eumorfopoulos, Harold Swithinbank, Mrs. Charles Hoare, and Mrs. Edward Singleton were elected members.

## PERSPECTIVE IN PHOTOGRAPHY.

BY W. H. WHEELER.

The remark in Mr. Pennell's paper, read at the late Camera Club Conference, on what he called "photographic perspective," may help to assure us by its very tone that whatever really be the discrepancy felt between that which a cultivated eye sees in a natural view, and that which we may sometimes observe in a wide-angle photograph, we must trust to ourselves, and not to artists, for a real and scientific investigation, that we may know something of the true relations between visual and photographic perspective. At present, whenever an artist who has the slightest knowledge of photography refers to the subject in a reasonable tone, he, as a rule, simply recommends us all to eschew wide-angle lenses. No doubt they are difficult and deceptive tools, and no doubt, also, that when employed without the guidance of principles which have yet to be duly recognised, it is largely a matter of good or bad fortune whether an harmonious perspective results, not to mention the serious distortion, in the ordinarily accepted sense of the term, which results from a comparatively small error in adjusting the camera. The result of my own experience in architectural photography does not agree, however, with the prejudices expressed by artists.

Living and working in what we lovingly claim to be the most beautiful city in the world, and surrounded by architecture which yields to none in its picturesque beauty, problems of artistic perspective have been continually before my mind, as the scenery itself before my eyes. I have used lenses of each extreme, from a focal length of five times the larger dimension of my plates, to less than half that dimension; yet never exceeding, or expecting ever to exceed, the extent of view which artists have chosen to embrace in the views by which they have endeavoured to depict the general effect of an Oxford quadrangle, or, in some cases, of the interior of an Oxford college chapel. Their practice, however, is but little guide to ours; for being free from our limitations and difficulties, they have no occasion to study them. Indeed, to do them justice, it is not natural to expect that they would study our difficulties or our facilities, contenting themselves with such slight knowledge of either as artist amateurs may hastily acquire. And, while it would be presumptuous and foolish to underrate the value of an artist's cultivated perception, his whole method and means differ so fundamentally from ours, that however valuable may be his judgment of results, his advice as to means is rarely of any use. In this matter it is for us to find out what are the conditions of the use, and what of the abuse, of wide-angle lenses; and it is for us to search out the reason *why*, when a general wide-embracing view of buildings is seen by natural vision as picturesquely grouped, and as harmoniously proportioned, the photograph which should, and probably does, depict that view in accurate geometrical perspective, will sometimes, *but not invariably*, appear as violently strained by such perspective. Artists cannot or will not tell us; but philosophers have searched more deeply, and from them we may find the key.

As we know that a well-corrected doublet lens, or indeed, a simple pinhole, will necessarily present a view in absolute geometrical perspective when properly placed, it must follow, when any discrepancy is felt between what the eye demands, and that which the lens supplies, that this strict geometrical perspective does not necessarily agree with the more or less cultivated visual perception with which it is compared. Also, that if the photograph be a strict transcript of natural form, then there must be a difference in our visual perception according to our visual attitude; *i.e.*, according to whether we are looking on nature, or at the photograph. The question is further complicated by the fact that while our photograph is delineated on a plane surface, such a surface corresponds neither to nature itself, nor to our vision of it. This projection on a plane surface is, indeed, an essential part of the problem of geometrical perspective, and is itself one reason why we cannot expect our natural vision to be in accurate accordance with such perspective. Some difference there must be.

It is clear that our first enquiry should be concerning visual perception. Of this the Berkeleian theory is the one universally accepted, having gradually convinced every student, scientific or philosophic, for nearly two centuries. It will probably, however, always present difficulties of conception to those who have not earnestly studied the matter. The prevalent belief that visual perception is wholly the exercise of a natural faculty, instead of being mainly an acquired judgment in interpreting the signs presented to us through sensation, need cause no more surprise than the belief, once universal, that the sun goes round the earth. And both will hold their ground in common speech long after the belief which that speech represents may have died a natural death.

The Berkeleian theory calls upon us to distinguish between the original, natural gift of visual sensation, and those conclusions and inferences which seem to be inextricably associated with it; in an experience dating from our earliest infancy, and commencing long before the rise of consciousness. The mental operations involved are almost always automatically exercised so far as our conscious experience is concerned, and are, to a considerable extent, shared by the lower animal creation—belonging, indeed, to that class of mental results which Mr. G. F. Romanes distinguishes by the term "recepts," from the more elementary "percepts" on the one hand, and, on the other, from the more advanced "concepts," which involve that conscious intellectual effort which is man's special prerogative. In connection with this presumably unconscious mental action, one consideration should be pointed out. In these acquired perceptions of sight, our estimates of distance—and, with them, of the *actual* form and dimension of objects—enable us to recognise those known by previous experience, in spite of the widely differing forms and dimensions of their sensible images on the retina; corresponding, as apparent forms must, to changes of our position and distance. But thus the actual interpreted perception, though really the result of an intellectual process, will never rest in the memory *as such*, whether accompanied by consciousness or no; for it follows, from the natural and general predisposition of the mind to pass from the signs by which we interpret these distances, &c., and to rest on the interpretation sought, that the attention, being thus called from the sign to the object, will of itself inevitably cause the mental process of interpretation to sink out of recognition or memory; and thus, facts which have really been inferred by exercise of intellectual power are quite naturally regarded as having been actually seen through a physical process, the mental interpretation being ignored. Perhaps no illustration of this can be more forcible and obvious than what we suppose ourselves to see in an open book. The wit, the eloquence, the learning, all exist necessarily in the mind only; that which the eye has seen by mere natural sense can be no more than a series of black marks on white paper.

That this distinction was unknown to antiquity we may see from Aristotle (Eth. Nic., lib. ii., c. 1):—"For it is not from seeing often, or from hearing often, that we get these senses; but, on the contrary, instead of getting them by using them, we use them because we have got them." An able modern writer would have made an exactly opposite reflection. The gradual formation of truer mental, as of physical, theories of vision, appears to have commenced with Alhazen, whose discovery of refraction overthrew at once the Greek notion that sight was something emanating from the eye, and also the Democritean effluxes of outward things, which, impinging on the eye, accounted, on atomistic principles, for our visual perceptions. Dugald Stewart says that "some of the chief steps in this progress from Aristotle to Berkeley may be traced in the 'Optics of Alhazen'" (Lib. II., N.N. 10, 12, 39). Dean Milman says of Aquinas that "St. Thomas rejects the Democritean theory," . . . and considers . . . "the conception by the senses is confused, indeterminate, till abstracted, analysed, at once universalised and individualised by the intelligence" (Lat. Christy., V. 6, p. 286). Tennemann says of Telesius, whose teaching in physics was followed by Lord Bacon, that he "maintained that sensation was not absolutely passive, but a perception of changes operated in the mind itself. Knowledge acquired by means of inference he described as a species of imperfect sensation" (Hist. Phil., 298). Dugald Stewart says, concerning Ralph Cudworth, that "the mind, according to Cudworth, perceives by occasion of outward objects as much more than is represented to it by sense; as a learned man does in the best written book than an illiterate person or brute."

And so on through Locke, whose anticipations are acknowledged by Berkeley, until we come to his own far fuller development. Since that time, however, our physiological knowledge has so wonderfully advanced that a further application of Berkeleian theory seems really called for, although Helmholtz, himself a disciple of Berkeley, has done much in this direction. Still, strangely enough, its application to the formation of our sense of perspective has escaped the attention it deserves, and really needs.

The author of a "Practical Guide to Perspective,"* now before me, calling attention in his concluding paragraph to "the *mistakes likely to occur* in drawing from Nature," emphasizes the "endeavouring to draw them rather as they *know them to be*" than "*as they appear to be*" (the italics are his own). In this he unconsciously testifies to natural tendencies in the ordinary observer, which artists rightly combat only so far as found necessary.† Still less necessary is it for them to rigidly carry out in every detail the alterations of form incident to projection on a plane surface. We certainly cannot in this way modify our own pictures in accordance with our perceptions; but a true theory of those visual perceptions may enable us so to oppose our natural recognition of actual form, to our natural revolt from the conditions imposed on us by plane projection, as that they may tend to correct, instead of reinforcing one another, as is too often the case. Also a true psychical theory of those signs which we interpret as "height" and "space" will be found to guide our practice far better than any empirical rule. All this, indeed, we know as enquirers after scientific truth, and I trust I may succeed in calling the attention of other enquirers also to this interesting and important field.

## THE ACTINOMETER AS A GUIDE TO EXPOSURE.

Some time ago two English experimenters, Messrs. Driffield and Hurter, took up the question of the relation of the light intensity to the effect on the photographic plate after development. They attacked the question, not from an artistic point of view, but on the side of purely scientific inquiry. For this purpose they first proved by experiment that a harmonious picture has a gradation of light and shade which varies in a geometric ratio; that is to say, the relation of the highest lights to the deepest shadows is in the proportion of 2 : 4 : 8 : 16 : 32 : 64, &c. By another series of experiments they proved that the silver deposited on the negative taken from such a harmoniously lighted object would vary as the figures 1 : 2 : 3 : 4 : 5 : 6, &c. It was further proved that the light transmitted by such a negative varies as the proportion 2 : 4 : 8 : 16 : 32 : 64, &c. It follows, from this last fact, that a harmoniously lighted object will give a negative that prints correctly if the silver is deposited on the negative in the proportion given above. A certain range of variation from the proportion given is allowable, owing to the fact that the eye does not notice slight differences; but any wide variation is at once noticed in the results that we call under or over-exposure. We cannot give all the proofs which these experiments brought forth, but we take space to quote one of the most interesting sections of the work done on this most interesting problem.

"Three separate exposures were made upon different parts of a Cramer plate, extending across its width. The exposures given were equivalent to one and a-quarter, two and a-half, and five seconds, the light being that of a standard candle placed at a distance of one meter from the plate. The plate was then cut lengthways into three strips, each of them being impressed with the same three exposures. The three strips were next developed in the same solution of ferrous oxalate for four, eight, and twelve minutes respectively:—

| | Exposure CMS. | Density. | Density ratio. | Opacity. | Opacity ratio. |
|---|---|---|---|---|---|
| Strip No. 1, developed four minutes ... | 1·25 | ·310 | 1·0 | 2·04 | 1·0 |
| | 2·5 | ·520 | 1·67 | 3·31 | 1·62 |
| | 5·0 | ·725 | 2·33 | 5·30 | 2·59 |
| Strip No. 2, developed eight minutes ... | 1·25 | ·530 | 1.0 | 3·38 | 1·0 |
| | 2·5 | ·905 | 1·70 | 8·03 | 2·37 |
| | 5·0 | 1·235 | 2·33 | 17·18 | 5·08 |
| Strip No. 3, developed twelve minutes ... | 1·25 | ·695 | 1·0 | 4·95 | 1·0 |
| | 2·5 | 1·140 | 1·64 | 13·80 | 2·78 |
| | 5·0 | 1·625 | 2·33 | 42·17 | 8·51 |

"The second column gives the densities as measured by our photometer, which numbers relatively express the amount of metallic silver deposited per square inch of the plate. The density due to glass, gelatine, and any fog inherent in the film, is deducted. It will be seen that the amount of silver increased for the same exposure as the time of development was prolonged. But the third column, which gives the ratio of densities, shows that, within trifling errors of observation, the relationship between the three densities of each strip is identical; that is to say, prolonged development caused each density to grow, but in such a manner that the amounts of silver on the different strips still bear the same ratio to each other.

"It is this unalterable relationship which we refer to when we say that the photographer has no control over the gradations of a negative. What we believe has given rise to contradiction of this view is the fact that, though the density ratios are unalterable, the opacities, which appeal directly to the eye, actually do alter, not only in amount, but in ratios also, as is shown by columns 4 and 5. In the first strip, for instance, the extreme opacities were 2·04 and 5·30 respectively, while, after eight minutes more development, the opacities became 4·95 and 42·17 respectively. The lightest shade in strip No. 3 is almost as opaque as the darkest in strip No. 1. The opacity ratios have, however, also increased from as 1 : 2·59 to as 3 : 8·51.

"It is this great difference in the opacity ratios, with which the practical photographer is so familiar, which leads him to rashly contradict our statements with respect to the unalterability of the density ratios. The great mistake the photographer makes is in assuming that the opacity ratios are alterable at will. This is not so. The opacity ratios alter in accordance with fixed laws, just as surely as by the same laws the density ratios are unalterable. All the control the photographer can, therefore, exercise in development must result from intelligently working in obedience to these laws, and so rendering them subservient to his own ends. Control in development does exist, but not in the direction popularly supposed."

From these experiments it is extremely important that some method of measuring the intensity of light transmitted by objects to be photographed should be made available for the photographer. Such an instrument is called an actinometer. Various forms of this device have from time to time been proposed depending on the passage of light through varying thicknesses of material that obstructs its passage. In this case no attention has been paid to the quality of light passing, the luminous rays only being taken into consideration. But it is well known that the rays that have an effect on the photographic plate are those that are not brightest to the human eye. The rays that affect the photographic plate are the blue and violet ones, and these are the very rays that are obstructed by the materials most used in the ordinary forms of actinometer. In other words, the light passing through the material consists of those rays that are yellow or near that colour in intensity. Quite recently a form of actinometer has been devised that takes note of the blue and violet rays that are reflected by an object that it is desired to photograph. This actinometer depends on the fact that luminous paint exposed to light acquires its maximum intensity after a certain time of exposure, and if this is now taken out of the influence of the light it will gradually fade, the time of fading being a measure of the value of the light in the blue and violet rays that it contains. These rays are the same as those that affect the photographic plate. It is, therefore, only necessary to have some means of determining the moment of fading, to use this principle as a method of determining the value of light from any source, and by comparison with any kind of dry plate to make a set of tables that shall give the correct exposure for those plates under any circumstances.

This novel form of actinometer is the invention of Mr. E. G. Ballard, and is certainly the simplest and most useful instrument of the kind that we have ever come across for the purpose of obtaining an accurate estimate of the time of exposure for any object that it is desired to photograph. The instrument consists of a tube blackened inside, at one end of which is an opening to view the interior, while at the other end there is a disk carrying a surface of luminous paint with an opening in the centre, behind which is a piece of blue glass covered with tissue paper, to tone down the light transmitted to that evolved by the luminous paint when the latter is excited. To use this actinometer it is only necessary to expose the luminous paint surface to the object to be photographed for thirty seconds, then turn the surface so that the light emitted by it is seen in the blackened tube. By now counting the number of seconds that it takes for the light to fade to the same intensity as that transmitted by the tissue-covered blue glass, a figure is obtained that gives the intensity of the light toward the photographic plate. If the value of the plate has been previously determined for that actinometer, and a table of exposures has been made out, the time of exposure will be accurately known from the observation made. We have used this little instrument with much satisfaction, and under widely differing circumstances, and must say that we are delighted with the results. The exposures that it told us to give were not what our judgment would have given us from ordinary observation of the light, but they proved to be correct, and the negatives obtained were found to be correctly exposed.—*Anthony's Bulletin.*

---

Ammonium Bromide.—Dr. Dutton, says the *Chemical News*, reviewing "Sea Sickness—Cause, Prevention, and Cure," seems to hold that if there is a specific for sea sickness, it is our old photographic friend ammonium bromide taken regularly for some days before going on board. It acts, as it might be expected to do, as a restrainer.

Brixton and Clapham Camera Club.—On 23rd May nineteen members of the club travelled to Bexley by invitation of the president, Mr. A. R. Dresser. After several shots at the church, farmyard, &c., the whole of the cameras belonging to the party were levelled at some sixty or seventy cows, which had gone down to water at the river. This over, a photograph of the party was taken. The members afterwards sat down to a substantial tea, kindly provided by the president. The weather was beautiful, and a total of 170 plates was exposed.

Photographic Exhibition at Leeds.—A National Photographic Exhibition on a large scale is to take place in Leeds towards the end of the year, promoted by the Fine Art Gallery Committee of the Leeds Corporation and the Leeds Photographic Society. The probable time of opening will be towards the end of November, and the Exhibition will remain open until the middle of January. The official prospectus will shortly appear; in the meantime, any information may be obtained from Mr. George Birkett, Curator, Fine Art Gallery, Leeds.

Another Marvellous Invention.—The Paris correspondent of the *Times* telegraphs:—"I went last evening to the central office of the new company which is interested in the instrument known as the theatrophone. As the name indicates, this instrument is intended to transmit, by means of a clever adaptation and application of the ordinary telephone, everything audible which goes on upon the stage of the various Paris theatres. The Théâtre Francais, the Opéra Comique, the Bouffes, the Nouveautés, and some others have already consented to admit the theatrophone, and before long the Grand Opera, Gymnase, Vaudeville, Folies Dramatiques, and, indeed, almost all the theatres will form part of the theatrophonic network. It will thus be possible during the evening to hear and give one's friends the pleasure of hearing all the comedies and operas produced on the Paris stage."

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

NEW PROCESS OF DOCTORING FLAT NEGATIVES—TONING AND FIXING BATH—NEW FLASH LAMPS.

*A New Process of Doctoring Flat Negatives.*—Herr F. Schmidt, who has just published a new and very practical handbook of photography, describes in this book a method of doctoring flat negatives which, as he states, has never before been published, and which is said to give excellent results. It is due to Mr. Döll, of Karlsruhe. The negatives to be treated by this method should not be varnished; or, if they are already so treated, the varnish must be removed beforehand. The process consists essentially in coating the surface of the negative with carmine ink—a solution of carmine in ammonia. If the negative be flat throughout, without any boldness worth mentioning, it is at first soaked for a few minutes in plain water, and then placed in a dish containing real carmine ink diluted with equal parts of water. The plate is allowed to remain in this bath until its film has been sufficiently saturated with the dye, when it is removed and thoroughly washed. The dye taken up by the gelatine film is not removed by the subsequent washing, and the negative comes out with an entirely uniform, beautifully transparent coating, which may be obtained in any desired gradation. Should it be desired to remove the dye from some portions of the film, it is only necessary to pass over these portions a fine brush saturated with a dilute solution of *eau de javelle* (1 : 2 water), and to rinse them at once very thoroughly with water. If the negative shows, however, only partial flatness, it should be treated as follows:—The plate, whilst still wet, is placed between smooth blotting-paper and wiped off slightly; then it is laid horizontally on a larger glass plate, which rests upon two small blocks or boxes. Beneath the negative and the glass plate a mirror should be adjusted so that the negative is uniformly well lighted by it. The diluted carmine ink is now applied to the flat portions by means of a large brush, care being taken that the outlines are not exceeded, and that the work is done quickly. The solution is allowed to act upon the film for a few minutes, when it is removed by means of a soft sponge. The plate is then washed, and, if required, the process may be repeated once or several times after the plate has been again slightly dried between smooth blotting-paper. If it is intended to produce a soft vignetting gradation, diluted carmine ink (about 1 : 3) is applied to the plate whilst still wet by means of a large brush, and the plate rinsed with water after some time, the portions which are to be rendered denser being afterwards treated repeatedly with the ink.

*Toning and Fixing Bath for Emulsion Paper.*—The following combined toning and fixing bath is highly recommended by Joh. Wolf in *Der Amateur Photograph*. It is said to tone well and quickly all emulsion papers and celloidin paper, and it is only necessary to filter it from time to time. It consists of—

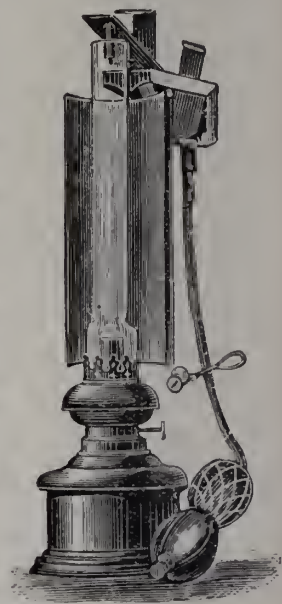
| | |
|---|---|
| Water ... ... ... ... | 1,000 c.c. |
| Hyposulphite of soda ... ... | 250 grammes |
| Sulphocyanide of ammonia... ... | 27 ,, |
| Acetate of lead ... ... ... | 10 ,, |
| Nitrate of lead ... ... ... | 10 ,, |
| Citric acid ... ... ... | 7·5 to 10 ,, |

To which is added—

| | |
|---|---|
| Chloride of gold ... ... ... | 1 gramme |
| Water ... ... ... ... | 200 c.c. |

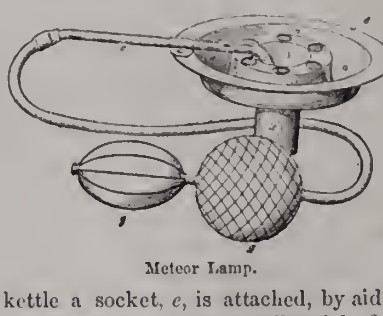
The best effects are said to be obtained when the bath has a temperature of from 66° to 73° F.

*New Flash Lamps.*—The magnesium flash-light apparatus invented by Dr. Leonhard, and introduced under the name "Fulgur lamp" by the firm of Dr. Adolf Hesekiel and Co., of Berlin, is much in favour amongst amateurs and professionals. The arrangements are considerably simplified by the use of the "Fulgur lamp," as it may be attached to any paraffin lamp with a glass chimney. The magnesium powder is not blown into the lamp in the direction of the gas escaping from the lamp, as is the case with some flash lamps, but in an opposite direction, it being thrown by a mechanical arrangement from above into the chimney. By this arrangement, combustion of the magnesium powder is completely and quickly effected with an intense light, the speed of combustion, according to the researches of Prof. Eder, being about one-thirteenth of a second. The instrument, which may be attached, as already mentioned, to the upper end of the chimney of any paraffin or gas lamp, consists of a kind of sling, which is bent by elasticity and released by a pneumatic bellows arrangement. The annexed cut shows the lamp after the release of the spring. The magnesium powder in combustion will adhere only to the inside of the chimney, and may be easily removed after use, so that it will be possible to take photographs by flash-light in the most luxuriously fitted-up *salons* without the least disturbance to the occupants. Several lamps may be used, and, in this case, they must be connected by means of a forked pipe, and ignited by a pressure of a single pressure-bulb.



Fulgur Lamp.

Another simple and effective flash-light lamp is that invented by M. Beaurepaire, and introduced by Mr. A. Leiner, of Berlin, under the name of "Meteor lamp." It is made of nickel sheet-brass, and consists of a plate-shaped receptacle containing in its centre a kettle, *b*, a concentrical groove, *a*, and, between *a* and *b*, a number of air-holes, *d*. A curved tube, *c*, leads into the kettle, *b*, and is provided at its other end with an india-rubber tube. At the bottom of the kettle a socket, *e*, is attached, by aid of which the flash lamp may be fixed to a candle-stick, &c. The groove *a* is filled with a coil of asbestos wick, which, being saturated with alcohol, affords a large surface of flame, completely and instantly burning all the magnesium powder that is



Meteor Lamp.

forced into it out of the kettle. For single portraits and small groups, from 4 to 10 centigrammes of magnesium powder, distributed to two or three lamps, will be sufficient.

## PROPOSED AFFILIATION OF PHOTOGRAPHIC SOCIETIES.

Report of Committee, consisting of Sir H. T. Wood, Mr. L. Warnerke, and Mr. G. L. Addenbrooke, on April 13th, 1891.

The Committee appointed by the Council to consider this question have met and discussed it. Two of the members —Mr. Addenbrooke and Mr. Warnerke—attended the meeting called by Mr. Biden on the 23rd of March. At this meeting a Committee was appointed to consider the matter, and afterwards to confer with the Committee appointed by the Photographic Society of Great Britain, the general wish being that the initiative should proceed from the Photographic Society of Great Britain.

Having regard to the fact that the Camera Club for some time promoted an affiliation scheme, which has not proved very successful, the Committee do not feel very sanguine of the success of any such movement. They think, however, that it would be desirable if the majority of local photographic societies could be affiliated to the Parent Society, and they think that, if too much is not expected of the movement, such a scheme ought to be useful and practicable. A model for it might be found in the British Association list of corresponding societies, a conference of delegates from which is held annually at the time of the Association's meeting. To carry the proposal into effect, the Committee would propose a scheme based on the following considerations:—

1. That any photographic society in the United Kingdom be eligible for affiliation.
2. That the admittance to affiliation be by the Council of the Photographic Society of Great Britain.
3. That each affiliated society pay a small subscription—say 20s. per annum.
4. That a conference of delegates from each society should be held at a convenient time, of which conference the Council of the Photographic Society of Great Britain, or a certain proportion of them, should be members. The object of the conference would be to assist in promoting uniformity of work among the various societies, devising means for their mutual co-operation and intercommunion, &c.
5. That there should be a standing Committee, of which the assistant secretary of the Photographic Society of Great Britain should be secretary, he being paid a small addition to his salary for any additional work involved; that the duty of this Committee should be to facilitate communications between the societies by the interchange of papers, lectures, slides, photographs, &c.
6. Each affiliated society might have, say, two transferable tickets admitting to all meetings of the Photographic Society of Great Britain, and perhaps to the Exhibition. Possibly a reduction of the charge for wall space at the Exhibition might be made to members of the affiliated societies. One copy of the Society's *Journal* should be sent to each affiliated society, and also notices of their meetings.

A meeting in support of the scheme was held on Monday, May 25th, at the rooms of the Photographic Society of Great Britain, 50, Great Russell Street, W.C. There were present ten persons, of whom about one half were delegates of societies authorised to vote. Mr. Barrett occupied the chair. The proceedings were opened by the reading of the report of the Committee appointed at the meeting held on March 23rd. In moving its adoption, Mr. L. M. Biden regretted the smallness of the attendance. He mentioned that since the last meeting he had received communications from several societies to the effect that they would prefer to await the announcement of the Photographic Society's scheme before deciding as to their course.

The motion having been seconded, attention was called to a letter addressed to the provincial societies, dated May 13th, and signed by Mr. Biden, and which had not been read to the meeting. A heated discussion then ensued between the members of the Committee then present and Mr. Biden. The Committee repudiated any knowledge of the letter. Mr. Rumble considered that Mr. Biden had not acted straightforwardly towards the Committee in issuing the letter without their knowledge and sanction. The first notice he had of it was reading it in *Photography*. Other members of the Committee expressed similar views.

Mr. Biden excused his action on the ground that the London societies did not appear to be taking up the movement. He had received a few favourable replies from country societies. The report was then adopted, the majority of those present not voting. Mr. Biden then proposed that the Committee should form the first council. Mr. F. Brocas thought it would be against the rules they had just passed to elect the council at the present meeting. The federation should elect the council, and, as a matter of fact, no federation had yet been formed. A delegate remarked that the Photographic Society had promised a scheme of affiliation, and it appeared to him that directly the Photographic Society moved in this direction, all the societies would join it, and the federation would be without support. Mr. White asked the gentlemen representing the Photographic Society of Great Britain if they could give any definite idea of when their scheme would be completed. Mr. Addenbrooke said that the matter was being pressed forward; additional members had been appointed to the Committee, but it was not considered advisable to act too precipitately.

Mr. Biden said that before the Photographic Society could bring their scheme into operation it was necessary to alter the laws, and this could not be done before the annual meeting in February next. It was pointed out that this statement was not correct, as a special meeting could be called for the purpose at a short notice. Mr. Biden thought they would have to wait a long time for the Photographic Society to decide upon their line of action. He complained that the Society had blocked his scheme, and that it was not until he had brought the matter forward that the Society had thought of affiliation. He had spent much time and money on his project, and intended to have a federation even if he had to appeal personally to each society individually. Mr. Mackie said that the subject of affiliation had been before the Photographic Society for more than two years. As a proof that the matter was not in abeyance, he read an extract from the treasurer's last report, in which a scheme of affiliation was clearly foreshadowed. After some desultory discussion, it was finally resolved that no further steps be taken with regard to the federation unless the Society's scheme be unsuccessful, or be not brought forward.

Richmond Camera Club.—*Programme of June Meetings.*—June 5th, "Demonstration on the Use of Celerotype Paper"; June 12th, "Development of Plates with Unknown Exposures"; June 19th, "Tourist Kits"; June 26th, Result of Development Competition.

## Notes.

Photographs are so constantly being produced in law courts—the latest instance is that of a photograph of the gaming table connected with the sensational baccarat case—that it would be desirable to have some rule laid down as to their value in a legal sense. Some judges refuse to accept photographs as evidence of identity, but we presume these scruples do not extend to photographs of inanimate objects.

A tradesman in the City has put in the window of his shop, newly opened, a large photograph of "the first customer," and underneath it the real penny taken over the counter. We cannot see the attraction of either the one or the other. It is recorded that when the "Universal Provider" commenced business in a very modest way, an old lady, on being told she was the first customer, knelt down and offered up a prayer for the success of the young tradesman. If the story be true, Mr. Whiteley must regret that his stock in those days did not include photographic materials, so that he could have preserved the record of so interesting an incident in his early career.

It would be interesting to learn the motives of the Grand Duke Michael, who, disdaining to live on his wife's relatives, has resolved to take to photography as a means of earning his livelihood. Five and twenty years ago it might have been said he had rushed into photography to force his outraged relations into a recognition of his wife; now it really may be the case that he hopes to make a good income out of a recognised profession. Why does not His Royal Highness set up business in America, where dukes are scarce and much sought after?

Should the Grand Duke Michael carry out his intention, he would not be the only example of an august personage taking to the camera. The last of the Borgias, one of the most famous families in Europe, has just died in a small Tyrolese village, where for twenty years he has been a photographer. We are afraid, however, that the photographic career of the late Baron Frederick Calisto Borgia, the nobleman in question, will not be very encouraging for other scions of noble houses to do likewise, for he died in poverty, and the baroness is recommended to the charitable public by the local newspapers. Perhaps, however, the late baron was but an indifferent photographer.

In the United States, photographs in watches are becoming very popular, especially with young men who are engaged. The *New York Mail* says that one leading jeweller during the past month has taken more than five hundred orders for these horological pictures. They are of course placed in the inner side of the case. The charge is fifteen dollars, and a French photographer makes a speciality of the work. The advantage is that the picture keeps the young man straight. He is never likely to pawn a watch which has a photograph of his sweetheart inside.

Raising a ghost with a column of smoke and the magic lantern has, from time immemorial, formed a portion of the text-books on the lantern. Mr. A. W. Clayden, who read a paper "On Brocken Spectres in a London Fog" at the last meeting of the Meteorological Society, probably had this ancient "bogey" in his mind when he made his experiments with the object of raising his own spectre. He succeeded during the fogs of February last in doing this by placing a steady limelight a few feet behind his head, when his shadow was projected on to the fog. Then this shadow he photographed. Here is a hint for photographers who have a fancy for spiritualism. A more ghostly photograph, we fancy, could hardly be produced.

A "waterproof focussing cloth" which, in addition to its normal object, can be used as a camera protection against dust and rain, is useful for squeegeeing, and can be used as a shoulder cape if caught in the rain, has been exhibited at various photographic societies recently. Is this the pioneer of a sort of photographic costume for amateurs? A waterproof coat which, in addition to having a focussing-cloth cape, would also contain specially devised pockets for the camera and folding tripod, and an arrangement for changing plates, would not be altogether an impossibility. If the inside lining were of a yellow colour, a flap in the back could be made to lift up, and the whole garment could be used to cover up the window of your hotel bedroom. All you would have to do would be to lift up the flap, and there would be your dark room complete.

A photograph has been the cause of a singular libel action. Two architects were in partnership, and together designed, among other buildings, the Café Royal and the Holborn Restaurant. Two years ago the partnership was dissolved, and one of the architects sent round to various people photographs of these buildings, with a superscription, "Designed by Thomas Archer, F.R.I.B.A.," &c. Upon this, Mr. Green, his former partner, brought an action for libel, presumably because he considered that his name being left out conveyed an injurious imputation. The jury, however, were not put to the trouble of deciding this knotty point, for Mr. Justice Denman held that the libel could not be sustained.

In spite of this dictum, it cannot be denied that Mr. Green suffered an injustice. The new Copyright Bill has clauses dealing with cases where a photograph is exhibited inscribed with a name "to produce belief that the work, photograph, or negative was executed by some person who, in fact, did not execute it"; but it does not provide for a case in which the photograph induces the erroneous belief that the original was the work of the person whose name is on the photograph. Perhaps the framers of the Bill will take the action of Green *v.* Archer into consideration. It certainly contains sufficient novelty for an interesting argument as to whether the question of copyright can be so extended as to cover it.

A South African bank, so we read in the *Barberton Herald*, was lately put into a mortal fright when two big, bold, bearded men walked up to the counter and said to the cashier and clerks, "Will you step outside, please; we've come to take the bank." That the bank had been "stuck up"—to use the colonial colloquialism for robbery—was the first thought of the staff, and immediately four manly forms rose erect from four office stools, four revolvers glistened in four firm hands, four pairs of resolute eyes glared defiance. The bearded strangers shook. "Don't fire," they gasped. "We—are—the—photographers—and—want—to—take—a—portrait—of—the—bank—and—clerks." The latter put their revolvers in their pockets, came outside as requested, and were "took."

## ARCHÆOLOGICAL PHOTOGRAPHY.

### The Ypres Tower, Rye.

The pretty and quaint old town of Rye, lying in the extreme eastern corner of Sussex, close on the borders of Kent, may take rank as one of the most ancient in the first-named county, and the history of its manifold vicissitudes and misfortunes from its two-fold enemies, man, and the sea, forms a story as unique and peculiar as it is curious and interesting. Like its neighbour Winchelsea, the ocean has proved both a great friend and a great foe; although, undoubtedly, the latter town has been by far the severer sufferer of the two, inasmuch as that once large flourishing city, with its parishes, its walls, its gates, and defences, is now, with its half-ruined church, little more than the merest wreck of what it once was. Fortunately for Rye, the town itself rests upon a rocky eminence, which to the S., E., and W. is steep and abrupt, whilst to the N. and W. it slopes down to the rich alluvial marshlands at the back of the town; but a very great change has taken place on the coast, and the country surrounding the town during the last few hundred years, as a glance at the map on page 16 of Capt. Montagu Burrows' interesting work on "The Cinque Ports," will at once testify. By this we see that Rye, like the great Roman fortress of Rutupiæ, in East Kent, once stood on an island having an immense harbour, and at high-water was entirely surrounded by the sea, but now, like Rutupiæ, in consequence of the recession of the sea, it is high and dry, and the land, once under water, appears to-day as cultivated fields or rich marshes.

At one period Rye was a very important place, conducting a great trade in wine and other things with France, and stood on the sea facing the entrance of the fine harbour which formerly existed here. It suffered terribly at different times from the plague, from fire, from famine, and from foreign invasion, having been sacked and burnt more than once. Yet, like Sandwich, in Kent, the old place has pulled through it all, and still exists with its magnificent early English and Norman Cruciform Church, its ancient remains, and quaint old timber frame houses, which afford an immense attraction to the archæologist, the antiquarian, and the photographer, who will there find unending subjects for his camera. An elegant modern writer says, speaking of the Rye of the present day: "We breathe the very air of the past in these antique, roughly-paved streets. They ramble deviously up and down, hither and thither, with many an old gabled house, and strange ruins, and mouldering gates and towers. . . . Nothing more recent than the cavalier's cloak, and hat, and feathers should be seen in Rye!"*

It should be mentioned, in special honour to the old town, that before the reign of King John it was made, with Winchelsea, one of the two "Nobiliora membra Quinque Portum." Many, too, will be interested to know that Rye was very much frequented as a port of embarkation to France, and it was, no doubt, from this circumstance that large numbers of French Huguenots sought a refuge there from persecution, between the years 1562 and 1685, and many of their descendants still remain.

It is somewhat remarkable that Rye had neither walls nor gates until the time of Edward III., who ordered walls to be erected at the most accessible parts of the town, namely, the north and west sides; the natural defence of the other sides, from their steep and abrupt character, being considered sufficient. Three gates and a small postern gave access to the town, but of these four, three —namely, the postern, the Ypres, and the Strand gates— have long since disappeared; but the Land Gate is still standing, though in a somewhat ruinous condition, and still forms the entrance to the town by the London and Dover roads. But although there were neither walls nor gates until the time of Edward III., yet from the days of King Stephen (1135—1154) there existed a small but very strong castle or tower, which was erected by a great warrior, the Count William d'Ypres, taking his title from the city of Ypres in Flanders. This man was a great friend of Stephen, who created him Earl of Kent, and appointed him Lord Warden, bestowing on him both lands and lordships. After the death of Stephen, the Count was obliged to quit England, as Matilda's party were in the ascendant; and, becoming disgusted with life, he retired to the Monastery of Laon in Flanders, where he died in 1162. During Stephen's reign the Count founded the monastery of Boxley, in Kent, for Cistertian monks.

The Count seems to have exhibited considerable interest in the town of Rye, and finding that even then the town was doing a fair trade, and that, moreover, it was wholly unprotected by either wall or bastion, the Count at once ordered the erection of the tower referred to, which has ever since borne his name, and ranks amongst the oldest defence works in the county. The Ypres Tower (called by the natives the "High-press," the "Wy-pers," the "E-pers," as it happens) was built according to the usual plan of most defence works of that period, and consists of one very strong, square structure, having a round flanking tower at each corner, and is, in fact, a small castle. Each tower is 25 feet in external and 15 feet in internal circumference. There are two rooms in the building, one on the ground floor and one above, each 15 feet square. There is a door at every corner of each room communicating with one of the towers, but there is one staircase only, and this is in the N.E. tower, and does not reach the top. In the N.E. and N.W. towers are severally four lancet windows, two up high, and two lower

* "Field Paths and Green Lanes," by L. J. Jennings, Esq., M.P.

down. In the S.E. and S.W. towers there are severally five windows—three above, and two below—two on the south face, or curtain, between the towers, and one on the west. The walls are about 40 feet high, and, throughout, are said to be only 4 feet thick—not much, certainly, for an age when massive and heavy walling for defence works was the invariable rule. A sort of wing, built of rough stone, was added in 1837 to enlarge the old building, then occupied as the town prison. For about two hundred and fifty years the Ypres Tower was used as a regular fortress for defensive operations. But neither this defence, nor Edward's walls and gates, would appear to have prevented the plundering and destruction of the town by the French on two separate occasions in the reigns of Richard II. and Henry VI., *i.e.*, between the years 1377 and 1461. This structure also served as a watch-tower, for which it was well fitted, as from its summit the whole coast is visible from Fairlight Hill on the west, to Folkestone cliffs on the east, and on the south-east the coast of France can sometimes be seen; so that no sail could appear without being observed from this point, that is, if the "look-out" was long-sighted, for telescopes were not known in those days.

The site selected for this defence could not have been better chosen. It occupies the south-east corner of the town, and directly faced the entrance of the (then existing) extensive harbour, which it completely commanded, affording great protection to the town, which was always, at that period, surrounded by the sea at high tide.

The Ypres Tower has been called "Little Ease"—at least so it is said by Holloway—a name derived from a kind of boot, so entitled, which was kept there and applied as a mode of punishment or torture to criminals. This inviting instrument appears to have been a buskin of parchment put on wet, and then brought near the fire, which caused it to shrink, and so squeezed the leg sharply, giving intolerable pain. Another kind, it is said, was also used here; four thick boards were bound round with cords, two were put between the legs, and two others on the outside; the cords being then drawn very tight, the limbs were fearfully pinched, and sometimes even the bone would be broken by the cruel pressure. This somewhat resembles the horrible torture once used in Scotland, and known as the "Iron Boot."

So early as 1495 the Corporation of Rye purchased the Ypres Tower, and latterly, and for very many years, it was used as the borough goal. Recently, however, the County Council determined to build a modern prison for the town criminals, so the grim old feudal fortress is now abandoned and empty.

There have been rumours—but let us hope that they are only rumours—that this ancient fortress, now over seven hundred years old and in excellent preservation, is to be ruthlessly removed. Of course such a suggested vandalism could *only* come from the County Council, but we sincerely trust that the Corporation, on behalf of the town, will veto so cruel and tasteless a proposal.

It has even been suggested that the wretched modern brickwork surroundings should be cleared away, and the fine old Tower made an object of interest and exhibition to the public for a small fee; and, let us add, a very good idea too, by which the old fortress would not only be preserved, but made a source of small profit as well.

## EDISON'S LATEST INVENTION.

[BY DALZIEL'S AGENCY.]

*New York, May 28th.*—Mr. Thomas A. Edison, the inventor, gave to a press correspondent to-day a full description of his latest and most surprising device, called the kinetograph, which, in many respects, is a combination of the phonograph with photography. Mr. Edison said:—

"The kinetograph is a machine combining electricity with photography, so that a man may sit in his drawing-room and see reproduced upon a screen the stage of a distant theatre, may observe the actions of the actors exactly, and also hear the voices of the players or the music of an opera. So exact is the instrument that every muscle of the face and every expression is faithfully reproduced. The machine will, for instance, reproduce a boxing match. The whole scene is reproduced, every blow struck is seen perfectly, and even the sound of the blows can be heard. The kinetograph has only to be placed upon a table in front of the stage. The machine photographs the scene and records the minutest sound. It begins to work as soon as the curtain is raised, recording the motions of the actors at the rate of forty-six impressions per second. This is sufficient to give a continuous picture of what is happening. The photographic slips are then developed and replaced in the machine, and a projecting lens is substituted for the photographic lens. Now, by adjusting the phonograph, and by means of a calcium light, the whole scene may be reproduced in your drawing-room. As the impressions are permanently taken, the scene may be reproduced years later, and as many times as anyone desires to see it. The photographs are reproduced in miniature or in life-size, so that nothing of the performance need be lost."

The kinetograph, speaking roughly, is a camera arranged in a new manner to do new work. In a small box containing the camera Mr. Edison places a roll of gelatine film three-quarters of an inch wide and of any length desired. The interior of the camera is arranged in the ordinary way. The gelatine strip is unrolled from one spindle and re-rolled upon another, and it is in passing from the first spindle to the second that it is carried before the lens of the camera. The shutters of the camera are arranged to be worked by a shaft attached to a cylinder of a phonograph. This shaft also works the spindles which carry the rolls of film, and the mechanism of the camera is so arranged that when the shutters are open the spindles stop, and the gelatine film is fixed before the lens. In less than the forty-sixth part of a second the photograph is taken, the shutters snap, and the spindles turn the gelatine strip, which moves on for a new photograph. The arrangement is so complete and extraordinarily rapid that forty-six photographs may be taken in one second.

Mr. Edison took one of the rolls of gelatine film which had been through a kinetograph, and showed it to the press correspondent. Upon it was photographed one of the boys employed in Mr. Edison's laboratory. The photographs were about half an inch square, taken on the film at intervals of about one inch. They represent the boy in the act of taking off his hat and bowing. Between the first view and the last of the series, the complete motion of removing the hat and making the bow was clearly discernible, and there was no apparent change of position between any two consecutive views. The boy's hat was upon his head in the first view, and his hand was at his side. The hand was gradually raised toward the head, which gradually inclined forward, the hat was removed, and the bow completed, after which the hat was placed upon the boy's head. Mr. Edison showed the machine to the correspondent, and to a layman. It appears to be simply a square box, in the upper end of which is a hole one inch in diameter. In the hole is a lens, and on the bottom of the box within is arranged a series of wheels and spindles, upon which the rolls of gelatine film are placed. The film is carried from one of the spindles over the wheels, past the lens, to the other spindle. Fastened to the latter spindle is a belt, which is attached to an electric motor. When the motor is started, the roll of gelatine is transferred from the first to the second spindle, and in the transfer is passed before the lens, and the photographic impression is taken.

The film comes out perfectly when run at the highest speed. The correspondent could see the boy distinctly waving his hand and touching his hat. The lad laughed, shook his head, and bowed. The gelatine film could be seen in rapid motion, but the figures of the boy were always before the lens, and every motion was natural and perfect.

Then Mr. Edison attached the projecting lens to a screen, when the figure came out life-size, every feature being distinct, and the action of the muscles perfect. Mr. Edison slowed the machine down and the difference was apparent, the action of the boy becoming jerky. It was by constantly increasing the rapidity of the machine that the inventor finally determined the fact that forty-six photographs per second are the proper number for the exact production of ordinary motion.

Mr. Edison intends to reproduce an entire opera by means of this invention. He does not mean to show it in miniature, but will represent the stage with the actors moving, speaking, and singing. The players will be life-size, and the music will be exactly reproduced. The result is a gigantic photograph, not merely of the actors, but of the entire stage, scenery, and furniture.

## MOONLIGHT PHOTOGRAPHY.

BY E. B. LUCE.

A brief note in regard to moonlight photography which appeared in recent issue of the *Times* reminded me of my own experience in that line seven or eight years ago. Perhaps it may be of interest to some others.

I believe I had heard of some one trying to take a picture by the light of the moon, but had read of only one such instance.

I had just started in the business then, and photography was a pastime to me instead of an occupation—so I was ready for any experiment. I used a half-size Voigtlander portrait lens, and selected for a subject the house of our nearest neighbour, some two hundred feet distant. At that distance I secured a tolerably good focus on the house with the lens wide open, although the near trees and distant objects were considerably out of focus. We did not have as rapid plates then as are made now. I made an estimate of the exposure likely to be required, based on the comparative brightness of sun and moonlight which I had learned in the study of astronomy, and, strange to say, my first plate was correctly timed.

Any photographer can easily see that a portrait lens wide open would work with extreme rapidity in outdoor work in strong sunlight, but that plate was exposed about three hours in the light of a full moon in a cloudless sky. There were lights burning in the house, which showed plainly in the picture. The exposure was commenced about nine o'clock p.m., and continued until midnight, so there could have been no daylight on the scene. I think the two sides of the house that were visible in the picture were in the direct light nearly all the time; of course, the shadows shifted some—as the moon travelled along its path —which gave a soft effect, no sharp edges to the shadows.

Several young people spent a very pleasant evening, promenading before the house and sitting out among the trees, and one young lady, dressed in white, stopped long enough in one place to make an impression easily seen.

The greatest surprise to us in the result was the very near resemblance to a daylight picture, the soft shadows being the only difference we could detect. Something of a moonlight effect was secured by printing the whole rather dark, and the sky much darker.

I made one or two other attempts, but none were more successful than this.—*Photographic Times.*

## PHOTOGRAPHIC METHODS OF OBTAINING POLYCHROMATIC IMPRESSIONS.*

BY LEON VIDAL.

Since the object is to correct the inaccuracies due to ordinary plates, it is necessary, at the outset, to have a clear idea of the subject to be copied, so as to select a suitable method of orthochromatising the plates. The example just given shows clearly the line to be followed, and it is evident that if the subject only contains blue, yellow, and green, and combinations of these three colours, it will be sufficient to use a plate sensitised for yellow and green.

The eye can judge very well of the relation between the tints of the copy and those of the original, and if the correction above referred to be not satisfactory, one can alter the formula or the screen, and prepare a second negative which shall be nearer the truth. A few trials are of little account when it is a question of doing a piece of work satisfactorily. We insist greatly on the pains which it is necessary to take in the preparation of the negative, because it is on that part of the work that the final result almost entirely depends. It is easy to see, for example, that, if the red has not sufficiently acted upon the plate, the latter will be too transparent in the corresponding portions, and the colour lying beneath will be smudged. The tonality must be accurately rendered to avoid this defect.

The negative having thus been obtained under suitable conditions, it now remains to produce the coloured effect. Several photographic methods may be used, but the two which are especially suitable are collotype and Woodburytype.

As regards the colours lying beneath, we think that chromo-lithography is the method which is of most commercial value. If the final printing is to be done by means of collotype, the following is the procedure. A collotype plate is prepared from the negative, and is inked in with thin red or blue ink, and impressions are taken on transfer paper equal in number to the different colours which one wishes to use. These impressions are transferred to as many grained or polished lithographic stones. The lithographer thus has a design absolutely identical with the original transferred to his lithographic stones. We omitted to recommend that two registering crosses be drawn on the collotype plate with a solution of tannin or gallic acid. This coagulates the gelatine, or causes it to take the ink in the same way as the parts which have been exposed to light.

The separate stones are prepared as usual with black lithographic ink, after careful study of the original and of the transfer. In certain cases flat tints may be suitable, but the colours should be graduated to follow the original, which is an essential condition. The flat tint is in all cases necessary where photography has reproduced a colour the brilliance of which is equivalent to pure white. Thus, if the original is a portrait of a lady wearing a black satin dress, the high-lights produce in the negative intensely black effects, which in the positive becomes pure white. This is an inaccuracy which orthochromatic photography cannot correct. All that could be done would be to over-expose, a remedy which is worse than the trouble to be avoided, as it would produce a monotonous effect over the whole proof. It is better to remedy this defect by means of a local flat tint. Black

* Continued from page 404.

satin, even where it reflects the brightest light, does not appear to be a pure white; in order to be assured of this, one only has to bring near to it a piece of white paper. One will at once see beneath the colour of the satin a sort of light grey colour, which indicates the exact value of the flat tint. It is necessary that the flat tint be under the whole of the design to which it refers. It will be just the same for all the other colours when they produce similar effects. Having finished the colour-stones and the collotype, we proceed to take a proof. It is even better to pull first a light collotype print on white paper, and then to print the colours on it. The first proof serves as a guide, and one ends nevertheless with a collotype impression of the required tone and colour.

This first attempt, which will itself be very pretty, thanks to the irreproachable accuracy of photographic processes, may require slight correction with regard to the distribution and combination of the colours. This, however, is easy, and it will rarely be necessary to make a third trial.

This is, in short, chromo-lithography, in which photography has taken a leading part and done the most difficult portion of the work, giving effects which could only have been otherwise obtained by the employment of highly skilled artists, who would have interpreted the original rather than copied it.

[As examples, coloured facsimiles of Gobelin's tapestries, representing (1) An Audience of Louis XIV. and Cardinal Chigi, and (2) The Triumph of Bacchus, were shown, and also the original collotype of the latter.]

This method can be applied to all coloured subjects which contain no metallic effects. When the latter are present this method fails. Greasy inks, being wanting in transparency, do not lend themselves to the reproduction of metallic subjects. They smudge the surface and reduce the brilliancy, and fail entirely to convey the impression given by the metallic object itself. Only a vitreous ink will suit in this case, and the only method which will give good results by a mechanical process is to prepare Woodburytype prints with gelatinous ink.

For the preparation of the underlying colour print are used not only metallic powders—gold bronze, silver bronze, copper bronze, &c.—but also thin leaves of either bright or dull metal, which give more brilliancy, more metallic solidity, and truer effects. They are applied to the paper by means of lithography, but the paper should be prepared in the method suitable for the Woodburytype process. The impressions are taken on the coloured print, making use of registering marks in the same way as in chromo-lithographic printing. At first sight this seems difficult, but the manipulative skill is easily acquired, and the register is perfect. We have in this way prepared beautiful prints, which could have been produced by no other method.

[The examples shown to illustrate this part of the paper were—

1. The chromo-lithographed portion of a Limoges enamel, and the same with the Woodburytype superposed on it.

2. A Woodburytype from a Limoges enamel representing the "Toilet of Psyche," the coloured design of the same, and the final result obtained by their superposition.

3. The Woodburytype of a jug, and the complete picture obtained by superposing this on the coloured design.]

For a limited number of impressions the carbon process might be used; but here we are leaving commercial methods, and therefore we shall not consider it in detail.

*(To be continued.)*

### Specifications Published.

239. *January 7th*, 1890.—"Photographic Camera and Change-Box. W. S. Rogers, 7, Addison Road, Bedford Park, Chiswick, Middlesex.

The camera belongs to the detective class, and consists of a box divided into compartments for the lens, the dark chamber, the storage chamber for the plates, and for receiving the flexible shutter. To expose a plate, it is dropped, by inverting the camera, from its groove into a light-tight sheath, which has been previously turned about the axis on one end into a vertical position. The shutter is then moved till the end of the sheath comes opposite the end of the exposure groove, into which the plate is dropped by restoring the camera to its original position. By reversing this operation, the plate, after exposure, is restored to its groove in the store chamber. The plates may be placed in metallic sheaths. Part of one side of the sheath is made flexible to enable the plate to be retained in it by the pressure of the finger. A ratchet or pointer indicating arrangement may be fixed to enable the sheath to be placed accurately over any of the grooves.

# Correspondence.

### "SUN ARTISTS."

Sir,—As we were rolling easily along the high road, conscious that already some measure of success had resulted from our uphill journey, an ill-favoured fellow, masked, armed, and calling himself "Helios," appearing out of a thicket hard by, suddenly presented himself at the window, and levelled a pistol at our heads. His demand was exacting, nothing less than the life of our serial. This is the penalty of those who ride in coaches. *Vacuus cantat coram latrone viator.* However, we preserved a cool front, for our weapons were more modern than his appeared to be. We accordingly refused to settle it in the thicket (where, doubtless, other fellows of his kind were ready to assist him), preferring, rather, the vantage ground of the highway, on which we had so far jogged with safety, and for the public good. We also shrewdly called to mind an old fable, in which a certain animal parades in the skin of a lion, and concluded that he who calls himself "Helios" when dealing with a photographic subject, can hardly be as great as he seems. We have suffered much in the cause of seeking wider appreciation for photographic art, but never until now have we come across what I will bluntly call an attempt at assassination. Were not others as well as myself concerned, I should be content to let "Helios" sink into oblivion unassisted, if, indeed, he is not already an extinct sun, whose power for good or ill has ceased.

Whatever his history, I beg of you to allow me to deal briefly with his communication to your columns.

The inference that Mr. John Addington Symonds is incapable of elucidating his subject, or that photographers cannot learn very much from the article in question, needs little notice, for Mr. Symonds' position as an art critic is too well established to be affected in the slightest degree by the opinion of so shallow an observer as "Helios." To say that it is "moderately well written, but hesitating," is simply a contradiction of terms. A further proof of the weakness of "Helios'" position lies in the fact that, so far from being in "difficulties as to what to say" ("Helios'" words), Mr. Symonds has kindly *volunteered* to give us another article for a future number.

Again, "Helios" alleges that I neglected to correct an alleged error. He complains that Mr. Symonds speaks of Mrs. Cameron as the first to make subject-photographs popular in England, and that I did not correct him, and point to Messrs. Robinson and Rejlander. This is practically the only complaint that "Helios" details, and, consequently, the only one necessary to go into fully. It may, however, be observed in passing, to show the value of this criticism, and to throw a light on the spirit in which it is written, that, in a number devoted to Mrs. Myers, "Helios" can only find a statement concerning Mrs. Cameron to cavil at. I now beg to refer "Helios" to page 38 of *Sun Artists* (No. 5). He will see that, so far as Mr. Robinson's subject-photographs are concerned, we have fully recognised their priority. I beg further to say that Mr. Symonds had that number under his notice when he wrote the words in question. The whole matter turns on what is understood by the word popularity as applied to art. "Helios" couples the popularity of Mr. Robinson's earlier pictures with nigger minstrels. I daresay he is right. But I do not remember seeing a more impertinent paragraph in a newspaper than the one in which "Helios" blames me for not asking Mr. Symonds to lower his conception of that word to such a level. I do not wish to be misunderstood. I am now talking only of Mr. Robinson's earlier work. His latest work is of its kind unequalled, and I feel sure Mr. Symonds, who is not by any means so ignorant of photography as he professes to be, would appreciate it. What I have said with respect to Mr. Robinson's early work applies to nearly all of Rejlander's work that I have seen, and, from what I hear, to all the rest. The exhibition of his works at the Camera Club only too clearly showed their ephemeral nature, and when contrasted with Mrs. Cameron's pictures, which were shown in a similar way, the enormous difference between them was very apparent.

I now pass on to another matter. The suggestion as to the course we should pursue, from the mouth of an anonymous writer, whose only claim to consideration is the envy, hatred, and malice of his contribution, is only equalled in insolence by the reflection (based on the arguments disposed of above) as to the good we are doing to artistic photography. We are quite content to leave this question with a public that is rewarding our efforts by an ever-increasing support, and whose verdict is practical and alone worth serious consideration. "Helios" can well afford, holding the opinions he does, to ignore our existence as much as his deserves to be ignored. Nothing more need be said on this point, did he not also favour the world with his views on our "decadence"; and, as he has indicated the point where it commenced, it may interest him to learn the following facts, bearing in mind that humble adage, "the proof of the pudding lies in the eating." In fact, the public demand is a safe criterion of the value of our efforts. Taking, as a basis, the quarter during which our first number was published, our average sales during the first four numbers showed a total improvement of five per cent. Then came the "decadence" with No. 5, and its violent, controversial, and most ill-advised essay (the adjectives are sunbeams). This was published in the fifth quarter, and the sales immediately rose thirty-five per cent. above the said improvement. Again, when No. 6 was issued they rose a further twelve per cent., beyond which point we have as yet no statistics. Thus, it is exactly the period of "decadence" which has been most fruitful in public appreciation. We now stand with sales per quarter about fifty-two per cent. above those we started with. Had it been otherwise, perhaps "Helios'" wish would ere this have been fulfilled.

Finally, I cannot but call indecent all these expressions, so cheap in utterance, which, trying to injure the Sun Artists' Association, and myself personally, cast reflections on an eminent lady photographer and a distinguished art critic who has condescended to throw on photography a glance perhaps more worthily bestowed elsewhere. It is an unfortunate fact that photography creates more lowness of mind than any other pursuit. I am patiently awaiting the day when Alphonse Daudet, seeking our shores in search of fresh material, will see fit to immortalise "Helios" and those of his tribe in a continuation of "Jack." I am also painfully aware that there is another opposition to our efforts which finds expression in a different manner. I have come to call it the "amateur trade" opposition, and it arises from the fact that our price is low and our value good. The rest is explained in my name for it.

As I finish this letter, the post brings me in an extract from an article on our new number in the *British Journal of Photography*, which concludes as follows:— "The essay will prove of much value to photographers. The author's ideas are clearly and temperately expressed." Would that so favourable a memento might truthfully be engraved on the tombstone that so soon will cover "Helios"! W. A. Boord.

*June 3rd*, 1891.

## Proceedings of Societies.

### Camera Club.

On May 28th, Mr. A. Pringle in the chair, a paper communicated by M. Leon Vidal was translated and read by Mr. Lyonel Clark. The subject was "A Method of Mechanical Colouring for Carbon Transparencies, Stereoscopic Views, and Lantern Slides."

This paper was followed by the reading of one sent by Prof. W. K. Burton upon "A New Emulsion for Printing-out Paper." The communication was illustrated by some good examples on Whatman paper, sent by Mr. Burton. The process consists in preparing the salting and sensitising solutions in one emulsion, on which the paper can be floated, or the solution can be brushed on. It was fully described, and the formulæ given for thin, medium, and strong negatives respectively. Some discussion followed, in which Messrs. Warnerke, Clark, and the Chairman took part.

During the evening, Mr. Woodward demonstrated Schoppen's method of viewing lantern pictures stereoscopically by means of coloured glasses.

### Holborn Camera Club.

On Friday night last a large number of hand-cameras was shown. Messrs. Adams and Co. sent a representative, who explained the nature of the working of the "Ideal"; Mr. Benest showed Robert's hand camera, and Mr. Chang the "Eclipse" and "Diamond" hand-cameras. The novelty of the evening was, however, a stereoscopic hand-camera shown by Mr. Raphael, which, by a sliding arrangement of the front, could be used as a quarter-plate as well as a stereoscopic hand-camera.

Mr. Arthur R. Gowing was elected a member of the Club.

### Sydenham Camera Club.

At the meeting held on May 29th at the "Greyhound" Hotel the President took the chair.

Mr. T. Rumble reported that he and Mr. Gray had attended the meeting of delegates at the rooms of the Photographic Society of Great Britain to discuss the federation scheme, and that it had been decided that nothing should be done until the parent society had brought forward its scheme of affiliation, or had abandoned it altogether.

Mr. Reynolds read a paper on "The Dark Room and its Appliances." The paper was illustrated with a number of diagrams showing the best means of ventilating, lighting, and arranging the dark room. Mr. Reynolds was of opinion that electric light was the best for the dark room, though, at present, this was out of the question for most amateurs.

It was announced that the first summer excursion would take place on June 6th.

HACKNEY PHOTOGRAPHIC SOCIETY.

A MEETING was held on Thursday last, Mr. BECKETT presiding.

Mr. BECKETT gave a paper on "Elementary Work," and gave as his preferences a quarter-plate camera, single lens, one-and-a-half or twice length of plate, half-plate tripod for quarter-plate camera to ensure greater rigidity, and the slowest plate that could be obtained. For development he preferred pyro, and gave as an excellent formula:—

| | | |
|---|---|---|
| A.—Pyro | ... ... ... ... ... | 1 ounce |
| Sulphite soda | ... ... ... ... ... | 3 ounces |
| Citric acid... | ... ... ... ... ... | 16 grains |
| Water to ... | ... ... ... ... ... | 16 ounces |

B.—Saturated solution carb. soda with sal ammoniac, or roughly for saturation, 6 ounces sulphite to 1 sal ammoniac.

For use—

| | | |
|---|---|---|
| A ... | ... ... ... ... ... | 10 minims |
| B ... | ... ... ... ... ... | 1 drachm |
| Water | ... ... ... ... ... | 1 ounce |

He had found a mixture of eikonogen and hydroquinone work well and very nearly equal pyro. For exposure the best method was by making notes of those plates which had been exposed and comparing.

Dr. ROLAND SMITH said he had found a good way of bringing out under-exposed plates was by first using pyro and then following with quinol.

A discussion then ensued, in which Messrs. Grant, Gosling, Dean, Gregg, Barton, and others took part.

RICHMOND CAMERA CLUB.

AT the meeting on the 29th ult. Mr. FORD presided.

Mr. KIDD showed and explained the "Adams" hand-camera, and handed round some negatives taken with it during a recent Continental trip.

The subject for discussion was "Finishing and Mounting Prints."

ROYAL MICROSCOPICAL SOCIETY.

AT the last meeting of this Society many items of photographic interest were referred to. In the first place, Mr. Grenfell exhibited a photograph, taken by Mr. Nelson, of a small organism found a short time ago, the nature of which he had been as yet unable to determine, some of the best zoologists and botanists to whom he had shown it being unable to say whether it was vegetable or animal in its nature. The whole of the details were brought out in such a way as to afford a striking instance of the value of photography for such purposes. He also wished to mention that at the present time, in the Botanical Gardens (and, he also believed, in the boating-pond), Regent's Park, there were considerable numbers of a free-swimming infusorian known as Tintillus, formerly described by Claparède. It was remarkable for its chitinous lorica, a specimen of which he had brought for exhibition, the creature itself not being easy to exhibit in consequence of its rapid movements. Claparède mentioned its having been found at Berlin; but hitherto it had only seemed to be found in sea-water.

Mr. E. M. Nelson read a note on the subject of "Lateral Development in Photography," advanced by Mr. Pringle in his note printed in the *Journal* of the Society for April last, pp. 263-264. He had tried many experiments, leading to the conclusion that Mr. Pringle was wholly mistaken in supposing that the width of a flagellum is increased to an extent at least fifty per cent. by lateral development. If lateral development of this kind occurred, it would eat into the image of the flagellum on the negative, and so make it thinner than the image on the screen; but when the negative was printed, this lateral development would act in the opposite direction, and if the actions were equal in extent, the size of the flagellum would be restored to the original size of the image on the screen. In no case could the action of the lateral development on the negative and on the print be cumulative. Mr. Nelson considered it highly important to dispose of the lateral development theory, for if such an error were allowed currency without challenge, it would very soon be said that a photo-micrograph, on account of this lateral development, had no scientific value.

Mr. NELSON also read a short paper "On the Use of Monochromatic Light in Microscopy," and exhibited and described the model of a new and simple apparatus for obtaining the same by means of a glass prism.

Mr. MAYALL said he recollected the original apparatus designed by the late M. Prazmowski at the time he was in partnership with Hartnack; it was troublesome to manage, so that not very much was done with it. That made by Zeiss, later on, was practically the same thing. He thought, however, that the apparatus before them was very likely to do good work, and the facility with which the prism could be turned, and the illumination varied from one end to the other of the spectrum, at once commended it to notice. He understood Mr. Nelson to say that by changing the monochromatic light from yellow to blue, the resolving power of the objective could be plainly seen to be augmented by any amount equivalent to ·1 N.A., and that in many cases an ordinary achromatic objective produced images as perfect as those given by apochromatic objectives. These were points of special scientific interest. He should not be satisfied, however, until Mr. Comber had seen it and put it through its paces, using sunlight, because now they were not content with mere performance with the microscope, but they must have good photographic results as well. Of course, to be of permanent value, the apparatus must not be made of wood, as in the model. There would be no difficulty in adapting an inexpensive form of spectroscope for the purpose.

Mr. NELSON also described a new projection microscope fitted with a special condenser made of three flint lenses, so as to embrace the whole cone of 82°. The only novelty about it was the system of collecting the light, by which a beam of $4\frac{1}{4}$ in. was brought down to one of $1\frac{1}{4}$ in., and by passing through the two lenses placed in a water trough, a beam of parallel rays of great intensity was obtained for use in projecting the image upon the screen. It was necessary to have a different condenser for each objective, as the one must be perfectly adapted for use with the other. He had at present only two, one being for use with Zeiss's A A, equal to about an ordinary 1 in., and the other being a lower power. With the former of these, Mr. Nelson then showed the following slides upon the screen:—Stem of equisetum, stellate tissue of rush, foot of dytiscus, foot of caterpillar, echinus spine, orbitolite, section of limestone and coralline, ovary of poppy, section of mistletoe, section of tooth, section of scalp, trachea, floridiæ, dog flea, earth-mite, hairs of caterpillar, young chick, polyzoa, Ophiocoma, neglecta, and a spiracle. The following were afterwards shown with a lower power:—Tortoise beetle antennæ, larva of potato-beetle, trap of British trapdoor spider, and leg of cricket.

The PRESIDENT said he had been very much struck with the beauty of the views which had been shown, and thought that it would be a great acquisition to anyone who wanted to give exhibitions of microscopical objects. Very few schools should be unprovided with such an apparatus. He was sure those present felt greatly obliged to Mr. Nelson for what he had shown them.

Mr. MAYALL said that some seven or eight years ago, when Dr. Hugo Schroeder first came to England, he gave a description of a microscope for projection purposes which he had devised, examples of which were in use in Germany and in the United States. Figures of this instrument had been given in the *Journal* of the Society, and Mr. Crisp had been so much struck with the importance of having such an instrument for use at the Society's meetings, that it was decided to order one, and, if it proved successful, the Society would have been strongly advised to acquire one. Unfortunately, however, from various causes, the order had never been executed. The intention in Dr. Schroeder's apparatus was much the same as hat of Mr. Nelsou, though the plan of the latter was much less ambitious and much less expensive. He thought Mr. Nelson was rendering valuable services to microscopy in working out these improved forms of condensers for projection apparatus. The images he had shown upon the screen were very clear, sharp, and luminous, comparing most favourably with the exhibition made some time ago at the Society by Mr. Lewis Wright. He might also say that Mr. Nelson's projection images were far superior to anything shown at the Crystal Palace and elsewhere, with microscopes said to magnify fifty thousand diameters. It was interesting to note the extent of sharp field given by objectives of different construction; the projection images enabled the observer to select different qualities of objectives with great facility. He hoped the Society's funds would soon enable them to acquire such an instrument for practical demonstrations in illustration of papers at the meetings—a point which Mr. Crisp and he had long regarded as worthy of the Society's most careful consideration. The possession of a projection lantern for exhibiting photographs, &c., on the screen was, of course, involved in the equipment required by the Society; but the projection microscope itself, with which microscope objectives could be employed effectively, was the essential thing required.

### Glenalmond Photographic Club.

At the meeting held on May 30th, the chair was occupied by the President, who remarked that the Club had to decide upon the subject of a photograph, for which a prize would be given by one of the masters of the college, which, it was decided, should be for the best set of three photographs of river or burn scenery within walking distance.

An inspection then took place of some photographs shown by the President and Messrs. Maxwell.

### Lowestoft and District Photographic Society.

A meeting was held on the 29th May, at the School of Art, Regent Road, Mr. W. Stringfield presiding.

Prints and slides were exhibited by Mrs. J. Lee Barber, Messrs. Estcourt, J. Rose, A. M. Smith, W. R. Smith, and others, and discussions thereon followed. The evening's exhibits included the stereoscopic "snap-shots" of different parts of London, taken from the top of an omnibus by Mr. Estcourt; lantern slides of Old Lowestoft taken from negatives forty years ago, shown by Mr. James Rose; Mr. A. M. Smith's slides of the neighbourhood; and a few photo-micro slides by Mr. W. R. Simpson.

### Liverpool Amateur Photographic Association.

*May 28th.*—Mr. Paul Lange in the chair. The following were elected members:—Messrs. Thomas Rome, Anthony Dod, John Wells, and F. E. Patchett.

The Chairman reported on the excursion to Chirk, which took place on May 9th, when twenty-one members attended, and, although the day was dull, some good photographs were taken.

The Hon. Secretary exhibited the London Rubber Co.'s new water-proof focussing cloth; Mr. B. Boothroyd, Chadwick's new hand-camera fitted with Swift's special lens working at $f/4$ ($4\frac{1}{2}$ inch focus).

Dr. Manton, president of the Sheffield and District Optical Lantern Society, then gave a paper and demonstration on "The Carbon Process."

### Photographic Society of India.

*March 26th.*—"Photo-Micrography." A practical description of the process of photographing the microscopic image was given by Mr. J. J. Meade, of which the following is a brief summary.

Micro-photography is usually understood to mean the process by which ordinary photographs are taken, but so small in size as to be visible only by means of the microscope. During the Franco-Prussian war, despatches were photographed in this manner, and sent in quills by carrier pigeons. The photographs, on arrival, were placed under a microscope used in connection with the optical lantern, and projected on a screen, the result being a magnified image of the original MS.

Photo-micrography, on the contrary, is the process by which the camera is used, in connection with the microscope, to secure a true picture by means of photography of a natural object of microscopic dimensions. The manifest advantages which this latter process has over the antiquated method of drawing is so great that it is now practised universally by all the leading microscopists of the day, for a photograph properly taken cannot be other than a true picture of the original object; whereas the "artistic effect" which may undesignedly creep into a pencil drawing can only render it valueless as a true record of what is invisible to the unaided eye.

The following may perhaps be of service to those wishing to work at photo-micrography, they already being well acquainted with photographic manipulation. The apparatus required by a *beginner*, in addition to his camera, &c., would be a microscope with, say, two objectives, of one inch and one-quarter inch respectively, with two eye-pieces, say A and C, a bull's-eye condenser, a stand, and a common flat wick kerosene lamp as "squat" as possible.

The microscope should be of the "Student's" type, of English, and not Continental make. The body of the instrument should be made to incline to any angle between the vertical and horizontal. The objectives should have the "universal" screw thread, and the substage fitting should be of the "universal" size. Objectives and sub-stage apparatus subsequently purchased according to requirement, may be bought from any English dealer, and, if ordered of the "universal" size, will fit the microscope. As the objectives are adjusted and intended for use with an eye-piece, the latter should always be used for photography.

It is preferable to "expose" at night, as this ensures the light always being the same.

The apparatus is set up as follows:—The camera lens is removed, and the object to be photographed having been clamped on the stage of the microscope, and then focussed, the body of the microscope is inclined to the horizontal position, and the eye-piece end inserted into the camera in the aperture usually occupied by the photographic lens. Care must be taken that the plane of the ground glass of the camera and the micro eye-piece are parallel. The junction between the camera and the microscope must, of course, be made light-tight. The lamp, *with the flame edge on*, should now be placed about a foot away from the microscope, but in a direct line with it, the plane being in line with the object to be photographed. The sub-stage mirror is turned away on one side, and the flame of the lamp is focussed on the object by means of the bull's-eye condenser. The object should now be visible on the ground glass of the camera. Amplification is obtained by drawing out the bellows of the camera, and focussing is done with the fine adjustment of the microscope, which should also have a "coarse adjustment."

Exposure and development are carried out in the usual manner.

Beginners should commence by using, say, the one-inch objective with the A eye-piece on the microscope, working on microscopic specimens which do not exhibit too much intricate detail.

### Photographic Society of Philadelphia.

At the meeting held on May 13th (Mr. John G. Bullock in the chair), the Board of Directors presented their monthly report, reported the purchase of a fine pair of dissolving optical lanterns, including five pairs of lenses of various focal lengths, suitable for rooms or halls of any size; and additions to the library were announced.

The President announced the appointment of a special committee to take into consideration the feasibility of starting a movement looking to a uniform method of marking the sensitiveness of dry plates.

Mr. John Carbutt exhibited a Watkins exposure meter, respecting which considerable discussion ensued.

Mr. Cheyney said there was an article in the current number of *Anthony's Bulletin* on the subject of exposure meters, which seemed to him more rational than any of them. The inventor of the meter referred to coats the bottom of a brass tube with luminous paint, which he exposes to the light the picture is to be taken with. Then a cap is placed on the tube, and through a small peep-hole the time it takes the luminous paint to fade is noted. This luminous paiut is affected eutirely by the blue rays, and a very close approximation can be made as to the proper exposure to be made.

The Chairman said he did not think it could be depended on. The same batch of paint might be constant, but no two batches would be alike.

Mr. Ives remarked that the time in which this paint lost its luminosity depended upon the temperature. If it was warm it lost it quicker ; if cold, it held it for a long time.

Mr. Stirling thought in that case one would require a series of comparative tables. When the thermometer was 32°, so much ; when 70°, so much. Mr. Taylor suggested that it was something like Captaiu Cuttle's watch.

Mr. C. E. Hopkins exhibited a new shutter, called the "Pueumo," of the rotary type, which could be placed either outside or iuside the lens, aud iustautaneous or time exposures could be made at will. Prints made on the Omega seusitised paper were next showu and toned by Mr. Hopkins. The paper is coated with a gelatine emulsiou, and priuted iu sunlight, requiriug about one-third less time thau ordinary albumenised paper. A combined toning and fixing solution is sold for use with the paper, or a formula for preparing the same is furnished with each package. A satisfactory black tone can easily be obtained wheu desired, or by stopping the toning at an earlier point warmer toues are obtained. The print should be made considerably darker thau the fiuished tone desired, aud immersed in the toning solution without first washing, being left therein until the desired tone is obtained, and theu well washed in several changes of water. They may be mouuted directly after washing, or can be hung up to dry or laid face up on blotting-paper, care beiug takeu not to place anything on the top of the prints till thoroughly dry, as it would adhere to the gelatine surface. The prints can be glazed by squeegeeing them face down on a tin-type plate. It was claimed that the paper was more permanent thau albumen paper, aud would not fade if properly used.

Mr. Bell took exception to the toning and fixing in one solutiou ; the prints so treated would fade. In the olden time they were taught to toue separately and fix separately if they desired to get permanent priuts, and the mixture of the gold and hypo together looked as if they were going back to the old fadiug time.

Mr. Hopkins said he had not found this to be the case. The prints in the sample book shown had been made for over a year, and they were just as good now as when they were first made.

---

Photographic Society of Great Britain.—June 9th, at 8 p.m., adjourned discussion on M. Vidal's paper ; Mr. L. Waruerke ou "A New Sensitometer"; Capt. Abney on "Dark Room Illumination." June 23rd, subject for discussion, "Orthochromatic Photography." The exhibition of chromo work will remain open till end of this mouth.

Manchester Amateur Photographic Society.—The next meetiug will be held at the Manchester Athenæum, ou Juue 9th, when Mr. W. Stanley will read a paper on "The Camera," aud Mr. F. W. Parrott one on "The Leus." Members are requested at this meetiug to exhibit uegatives and prints which they may consider suitable for the "Survey" collection.

A Reducer.—M. L. Belitski recommends a very practical reducer, consistiug of a solution of 10 parts of ferrous oxalate of potassium in 200 grammes of water, to which are added 8 parts of sulphite of soda, 2½ to 3 parts of pulverised oxalic acid, 50 parts of hyposulphite of soda. Keep in obscurity.—*Photo. Wochbl.*

Mr. Valentine Blanchard's Lectures at the Polytechnic came to a termiuation last week, aud have beeu considered so successful that there is a strong probability that they will be reuewed uext winter. They were profusely illustrated by the aid of the optical lantern, and besides the old masters, selections from the work of Robinson, Rejlander, Adam Salomon, Van der Weyde, Lyd. Sawyer, P. Gibson, F. Sutcliffe, Gale, Austin, Bright, and many others were thrown on the screen. The last lecture dealt with art in portraiture, aud was highly appreciated.

## Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.

Celluloid.—*Cuprammonium as a Solvent for Cellulose.* It is possible that your failure may be attributed to the use of an impure preparation ; for it is known that by adding ammouia in excess to sulphate of copper, a solution is obtained which does *not* dissolve cellulose, because of the large amount of ammonium sulphate present in the liquor. Use ouly so much ammouia, in the first instance, as will precipitate the blue hydrate, collect this ou a filter, wash with water, and then stir it up with fresh ammonia until dissolved.

C. J. S. (Temple). — *Reproductions.* Make euquiry of the Autotype Company, 74, New Oxford Street, W.C. ; or write to Mr. Edward Dunmore, Keutish Town Road, N.W.

J. R. (Swansea).— *Studio Blinds.* A few words by way of report will be satisfactory, and let us hear in the event of your desiring further particulars.

J. C. S. (Birmiugham).—*Unmounting Photographs.* We should anticipate no difficulty iu getting the gummed photos off the paper or card by soaking them in warm water and gently raising them with a bone spatula ; but going once through the roller press makes it troublesome and uncertain.

Metro.— *Degrees Centigrade.* See the thermometer table at end of the Year-Book. 15·5° C. corresponds to 60° F., and 21 C. to about 70 Fahrenheit. The Reaumur scale is never employed in this country, being too opeu for general use, but survives in certain districts of Germany.

A.M.—*Reducing Hypo Residues.* Instead of throwing down the silver as sulphide, you may employ M. Davanne's method of immersing a copper plate, but the resulting metallic silver is seldom pure. It nearly always retains a certain amount of copper, so that the nitrate made from it has usually a blue tinge.

P. McG.—*Judging Distance.* You have beeu inventing over again an instrument known as the Stadiometer. The principle is described iu Ganot's "Physics," and by wideuing the base line the augles become more convergent and susceptible of measurement with greater accuracy.

Manica.—*The Briefless Barrister.* The iucident in Mr. Grant Alleu's tale—development of faded signatures to a will—seems quite possible on the assumption that the vegetable juice used as an ink by the South Sea Islanders coutains an astriugent, probably tanniu, which, ou the application of nitrate of silver, strikes a black, thus showiug once more the original writing in the document. Works of fiction often draw upon the imagination to a larger extent than is here suggested ; the fact may be literally true, but without kuowing auythiug of the ki plant, we cannot say for certain.

R. E. S.—*Mounting Cards.* The ornameutation of the bridal card may be quite satisfactory if executed in pure silver, but white brouze, an alloy of tiu, is sometimes employed, which would assuredly iujure the photograph. Test the so-called silver printiug for yourself by touching it with a solutiou of silver nitrate, and you will soon see whether there is any reduction.

G. D. — *The Canadian Scheme.* Please make your own enquiries direct, for we know uothing more thau was stated in the advertisement.

L. T.—*Chromo-Lithographic Work.* The specimens are still hanging on the walls at 50, Great Russell Street, aud are well worth your inspection. The assistant-secretary attends every afternoon, and you will be welcome to see them on handiug iu your address card.

No Collodion.—*Insurance Risks.* Now that collodion is seldom or never used, the question of fire risk from this cause does not arise. Do not withhold any information you are bound to give ; but the office will know how to protect itself, and may even make an inspection of your premises.

# THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV. No. 1710.—*June* 12, 1891.

CONTENTS.

## INVENTION AS APPLIED TO NEWSPAPERS.

The new journalism is a remarkable feature of present-day enterprise, which old-fashioned people do not look upon as one of our most satisfactory American imports. But the thirst for news is so great, the hunger for the marvellous so continual, and, more than all, the competition among the myriad publications so keen, that editors have some excuse for adopting any method which proves attractive to the multitude. It is unfortunate, however, that from this new method of conducting newspapers there should have sprung a system of printing that which professes to be news, but which is too often the mere product of the reporter's imagination. In other walks of life a man who deliberately writes down a statement which is false is, to say the least of it, shunned by his fellow men; but it would seem that if he be a journalist, he is not only paid for his wrong doing, but is further encouraged to invent something still more audacious.

The rapid advance in matters scientific during the past few years has given these men a great opportunity, of which they have not failed to take full advantage. One marvellous machine has followed another so rapidly, and each one has been a reality which has so far distanced romance, that the public, unversed in technical matters, have been not only ready but positively eager to swallow anything placed before them, provided that it be of the supernatural or wonder-working kind. It was only a few months ago that one of these stories went the rounds and was believed in, for it was cleverly told, and it had both a local habitation and a name, or rather two names, given to it.

The scene was laid in an Indian village, and the *dramatis personæ* comprised two intelligent Americans—one an artist provided with pencil and sketchbook, the other an amateur photographer armed with a kodak. Another of the principal actors was a travelling fakir, who had come into the village in order to show some conjuring feats. The rest of the stage was filled in with the usual crowd. Now, the two Americans had conceived the notion that these fakirs are able to hypnotise their audiences, and so cause them to see things which do not actually exist, but which are created in the imagination of the fakir, and transferred by him to the minds of the onlookers. To test this theory, they arranged the one to sketch what he saw, or thought he saw, and the other to check him by quietly photographing the same scenes. The fakir went through his programme. He made the mango tree grow from its seed. He threw a ball of twine towards the sky, up which a boy climbed until he disappeared from sight, &c., &c. All these things were recorded in the sketch-book, but the kodak pictures showed only the fakir sitting alone. It was clear that the other images which he had conjured up were but illusions, and that the hypnotic theory was the correct one. This story was told in great detail, but it turns out to be simply an idle tale, and one invented to satisfy the public craving for the marvellous. The wonders of modern photography naturally tempted the narrators, and so the detective camera is brought into employment.

The latest of these wonderful stories, which we printed last week, also depends upon photography for its principal feature, but an examination of its details by anyone who has a knowledge of photographic apparatus will at once show that, if not positively impossible, its narrator certainly does not suppress his power of exaggeration. According to this story, which came *via* Dalziel's Agency, and appeared in most of the daily papers, Mr. Edison has invented a new machine for reproducing both sights and sounds by electricity, and the account professes to be that which the great inventor himself narrated to a press correspondent. From the description, we assume that the machine consists of a combination of phonograph and camera, and it has been christened the kinetograph.

The phonograph is now familiar to most persons, for it has appeared at bazaars and other public functions in plenty, and we have most of us had opportunities of testing its powers. That it will reproduce sounds of all kinds in the most perfect manner must be at once conceded; but anyone who has experimented with the instrument will know that the sounds themselves must first of all be thrown into the machine before a record can be made by it. And this can only be done if the source of sound—the human mouth, for instance—be placed close against the instrument while that record is being made.

The kinetograph, we are told, in which the phonographic principle plays such a leading part, is a box-like instrument which can stand on a table in front of a theatre stage, and which will record the sounds in its neighbourhood, so that they can be reproduced with all their original distinctness. If this statement be founded on fact, it is evident that the phonograph has been improved upon in a very remarkable manner, which has hitherto not been made public. But, at the same time that the phonographic part of tho new machine is recording all the sounds which it hears, the other part of the machine is receiving and recording the movements and facial expressions of the actors, and, as the two parts of the machine synchronise, every sound is illustrated by its proper movement of hand or eye.

Now, we know well enough that it is possible, under certain conditions, to photograph scenes represented upon the stage. Such pictures have been taken in plenty in this and other countries. Some of the first taken in London were photographed by an amateur worker at the Criterion Theatre, and represented scenes from the play of "David Garrick." They soon became familiar enough, for they were exhibited for many weeks in various shop windows as advertisements. If we remember rightly, the photographer had the advantage of a private performance for the production of these pictures, so that the necessary exposure of half a minute could be provided for tableau by tableau. He used a portrait lens and isochromatic plates. This may be taken as a well-known previous experience of this kind of work, and, although the exposure might be lessened by brilliant illumination with electric arc lamps, or magnesium flash-lamps, it certainly could not be brought down to the forty-six exposures per second which are said to be the number adopted in Edison's new apparatus.

But Mr. Edison, it is said—and we certainly do not give him credit for half of these wonderful assertions—aims at the reproduction of an entire opera by means of this new photo-phonographic machine, and it is evident that in the accomplishment of such a scheme the machine must go on working without intermission. Leaving the phonographic part of the business out of the question, we read that the pictures are to be taken on a band of travelling pellicle at intervals of one inch. This means that about sixty yards of film will be used up every minute, so that during one act of an opera, lasting, say, one hour, two miles of film would be utilised, each inch of which would bear a separate picture. Such an opera as Wagner's "Meistersingers," with its four hours of action, we may presume would bo rather trying to the apparatus, for it would be difficult to find storage room for the necessary eight miles of pictures. Then the reporter of this wonderful invention lightly passes over the difficulty of developing this mass of pictorial matter; nor does he concern himself with the circumstance that it would consist of a ribbon of negatives which would require to be reproduced as positives before they could be made available for projection on the screen.

Taking the scheme all in all, we fear that this enterprising reporter doth "protest too much." It may be possible in the future to make the phonograph take up and record all sounds in its reach; to construct lenses which will give sharp lines in all planes with full aperture; to make emulsions sensitive enough to respond to forty-six exposures per second in gaslight; and to make mechanism perfect enough to do the necessary work. But we have not yet arrived at these results, and there is no immediate prospect of our doing so.

## PHOTOGRAPHY IN FRANCE.

BY LEON VIDAL.

French Photographic Society—Paramidophenol—Photographic Shutters—Carpentier's Detective Camera—Papier Iso-Vireur du Nitrate D'Urane—Photo-Micrographic Atlas—Strengthening Large Surfaces on Negatives—Orthochromatism—Photographic Union.

*Comparative Study of Paramidophenol.*—Messrs. Lumière have advanced still further the study of the new developer that they have discovered. They have compared paramidophenol with eikonogen and hydroquinone. Their very interesting notice deserves to be read in its entirety, and we shall publish it later on. We have been able to ascertain the correctness of Messrs. Lumière's assertions. This developer works, in fact, very quickly, and gives regular results, even when the same quantity of developer is used for a very considerable number of plates. The one thing left to be desired is that this product may become easily procurable in the market.

*Photographic Shutters.*—We should like to ask whether purely theoretical questions are not invading the domain of photography a little too much. M. Demarçay has published a paper crammed with curves, with algebra, and with considerations of a purely mathematical order, on the subject of shutters. The question is one of those which, like all others, has nothing to lose in being scientifically treated. It has, however, theories which agree very badly with the putting in practice of certain formulæ and certain instruments. The least friction may vary the working of a shutter, which, on the other hand, may have some variation in action consequent on the weakness of a spring, or because a brake may be worn out. M. Demarçay does not appear to us to have arrived at any practical conclusion in this matter; and it is what we should have expected. Photographic necessities in the matter of shutters vary with the apparatus. The same system is not invariably applicable to all cameras and to all objectives. This is because one must make allowance for properties which often distance the best theoretical adaptations. It matters little if the result is good all the same, and it must be recognised that the latter case is the most frequent.

*Carpentier's Detective Camera.*—Magazine detective cameras become more and more numerous. That of M. Lumière is very ingenious. It is very much the same as that of M. Carpentier. In these instruments the plates which have not received an impression replace those already exposed by the simple movement of a button. The plates having been used, accumulate underneath, and are afterwards taken out in a mass to be developed. Unfortunately, this system requires a space relatively much greater than that which is necessary for the same size of plate in those cameras provided with frames. They are now making plates of a half-millimetre in thickness, which permit the employment of very thin frames, and of the carrying of six double backs in a very small space. A bellows camera reduced to a thickness of two to three centimetres when shut, constitutes with these frames a very portable apparatus.

*Iso-Vireur Paper.*—M. Mercier has been endeavouring to do away with the toning operation by making sensitive paper which has in itself the necessary elements for obtaining an agreeable tone. Certain formulæ for a simultaneous toning and fixing have already been employed. M. Mercier introduces into the sensitising bath for the paper certain chemicals which give it a good tone by means of the fixing alone. He shows some positives thus obtained with a preparation of nitrate of silver and of nitrate of uranium; the tone of these pictures resembling that of the best toned with gold. This is what M. Mercier calls *iso-vireur* paper. There may be cases in which it would be preferable to employ this paper rather than the ordinary sensitive paper.

*Photo-Micrographic Atlas.*—M. Lande has shown the useful and curious application of photography that has been made in the hospital of La Salpetrière, in the practice of Prof. Charcot, namely, photo-micrographic reproductions of the medulla in divers pathological states. Thanks to the sections cleverly prepared and carefully photographed, lesions of the medulla characterising certain affections—for example, that of ataxia—are well indicated. In a manner, all the transformations which the different zones of the medulla undergo, according to the nature of the malady to which they are subjected, may be followed. This is a convincing proof of the immense service that photography can perform in pathological research.

*Strengthening Large Surfaces on Negatives.*—We now describe a method of strengthening large areas on negatives by means of absorption. It is well known how difficult, almost impossible, it is to strengthen large areas with a pencil on negatives, when it is necessary not to suppress, but only to weaken certain parts. On small surfaces the thing is already full of difficulties; but it is another thing altogether when it is a question of surfaces of a certain size. We believe we have found a sure and easy means of practising this mode of correction or modification of negatives; it consists of using dyes, introduced into the gelatine by absorption. This is how to proceed. Every part of the negative must be covered with bitumen varnish except those parts that are to be strengthened. They must be left free. The varnish is made of bitumen dissolved in benzine, and is of a thick consistency. All that part of the negative which it is intended to preserve in its original state is covered with this varnish, which is then allowed to dry perfectly. If there is any need for hurry, the drying may be assisted by placing in a warm place. The varnish should be laid on in a thick coat, and it is better to master the process by making several trials on waste negatives. As soon as the varnish is dry, the entire plate must be immersed in an aqueous solution of yellow aniline, red magenta, green aniline, or chrisoidine, of a previously tried tint, and of a depth sufficient to bring about the desired result. This process may be gone through several times if the first immersion has not given a sufficient degree of opaqueness. The plate must be rapidly washed in water after its bath of dye. After the gelatine is perfectly dry, all the bitumen varnish must be dissolved away by benzine, and there will remain the negative, but with its transparency strengthened in certain parts. This method may be applied to the colouring of lantern slides, by incorporating divers colours successively. For negatives or other proofs on collodion, the same process is applicable, on condition that the collodion is covered with a layer of gelatine, similar in thickness to that which covers gelatine-bromide plates. Thanks to this method, one obtains strengthened surfaces of a perfect purity, and much superior to those made by pouring coloured collodion on to the backs of the plates. The edges of the surfaces obtained by this latter process have very disagreeable aureoles, but nothing of the sort is to be feared with the process of local colouring by absorption. When only very small portions of the negatives are to be treated, they may be surrounded by bitumen varnish, leaving a centre of one centimetre, then with a large brush the dye may be placed on the circumscribed surface. As soon as the desired effect is produced, the colouring matter must be taken off, the plate washed in water, and allowed to dry. It is also possible, and sometimes advisable, to make combinations of different dyes in order to attain such tints as are not to be got by single dyes.

*Orthochromatism.*—A question of great interest has been raised in the sitting of the General Syndicate of Photography; that is, whether a patent specifying a special formula of orthochromatic preparations gives the right to monopolise all orthochromatic preparations. It seems puerile to have to discuss so simple a question, but certain facts lead to this necessity. The General Syndicate will decide, it is to be hoped, this question once for all, in such a manner that it may be certain that a patent covering a certain operation cannot constitute a hindrance to progress. This question is of importance at a time when orthochromatic plates are gradually replacing those of an ordinary kind.

*Photographic Union.*—At a meeting on the 6th of June, the committee of the Photographic Union, a benefit association for needy photographers, rendered an account of its cash resources. Although the formation of the Society dates from one year and a few months only, there is a capital of 10,000 francs. This is a very fortunate start, for such a capital is bound to increase, and the Society is thus founded on a solid basis. Unfortunately, the number of members present was insufficient to nominate a statutory committee. Some help has already been afforded to sufferers, but a sum remains available which will permit the sanctioning of liberal allowances.

---

London and Provincial Photographic Association.—(Programme for June).—On the 18th, "Collodio-Bromide Emulsion"; 20th, outing to Carshalton and Beddington; 25th, "Orthochromatic Photography."

Centenary of the Birth of Michael Faraday.—H.R.H. the Prince of Wales has fixed 4 o'clock on Wednesday, the 17th June, for the delivery by Lord Rayleigh of the first of the two lectures at the Royal Institution in connection with this centenary; and Friday evening, the 26th June, at 9 o'clock, has been appointed for the second of these lectures, which will be given by Professor Dewar.

## NOTES ON PERSPECTIVE DRAWING AND VISION.*

BY DR. P. H. EMERSON AND T. F. GOODALL.

SOME years ago we made some experiments with the object of comparing a monocular perspective drawing with the drawing of an aplanatic photographic lens. We found that under similar conditions they were alike, as was, of course, *a priori*, probable. More than a year ago one of us published a short paper with an experiment, which threw grave doubts upon the truth of perspective drawing when compared with what the eye really sees.

We now offer a series of provisional propositions, experiments, proofs, and deductions, which we venture to think are of fundamental importance to all artists, as well as to physiologists and psychologists. We are working now to still further elucidate the matter, but we decided to publish the following notes, so that specialists might perhaps help us in the matter.

Our experiments and deductions, if correct, will show that for scientific reasons the accepted rules of monocular perspective are likely to mislead the artist, and prove the fallacy of photographic and all mechanical methods of measurement.

*Proposition* A.—The eye does not constitute a symmetrical lens,† the top and bottom portions being different. That portion of the eye which perceives distance and distant objects (*i.e.*, those above the ground) sees the objects on a larger scale than the portion of the eye which views the foreground or nearer objects, therefore our impression of nature is not what we get with a mathematically correct perspective drawing, or the drawing of an aplanatic photographic lens. That is, a perspective drawing surprises us by making the foreground objects look larger in proportion to the distance. Also we see a larger arc with the lower half of the eye than with the upper.

*Proof* 1.—That we do not see the same amount with both halves of the eye (upper and lower) is proved by the observer lying on his back and looking straight up at the sky, when he will find that the field of vision of the upper half is much more limited than the space seen by the lower half of the eye. This holds for either one eye alone, or for both when used together.

The proof is completed when we stand with our legs apart, and, standing with our back to the landscape, bend down and look between our legs. Here the fields are inverted, and consequently the distance appears small and far off, and gives much more the appearance of a sharp photographic rendering of the scene. This peculiar effect has long been well known, and it has puzzled a good many observers, but hitherto no valid scientific explanation has been offered.

*Proposition* B.—We think this may be the result of the naturally selective action of the retinal nerves. It has been to our advantage in the struggle for life to see all the objects near to us and close around clearly, and to compass as wide a field as possible. It has also been to our advantage in the struggle for life for certain parts of nerves to try and draw distant objects nearer and to enlarge them, so that special functions may have developed purely by natural selection.

*Deduction* 1.—That mathematical perspective drawing gives quite a false impression of what we see when using *either one of our eyes or both.*

That such is actually the case we will now endeavour to prove, at the same time still further supporting our contention that the upper and lower portions of the eye see objects in different perspectives.

*Proof* 1.—Let the observer select a church tower or tall chimney for experiment. If the sides are parallel, the object will *appear* to his eye wider at the top than at the bottom when he stands facing it at the distance of the tower itself, and looks steadily at its centre. These experiments are best made in the diffused light of evening. The experimenter must not move his eyes up and down the tower from top to bottom, and so *measure or correct* his impressions, but he must look steadily at the centre of the tower and take his pure sensuous impressions. As most towers and chimneys do taper considerably, the result the observer gets when close to them is that they *look parallel*, or nearly so. This fact was, no doubt, felt by the architects of the Parthenon, and it has never been known why they built the columns leaning inwards, a little out of the perpendicular. That they were built out of plumb has been proved by measurement; that they *look* parallel is well known, and the reason of this we venture to find in our proposition.

*Proof* 2. A very simple proof is to look about the middle of a doorway or door; it will be felt that the door or doorway is wider at the top than the bottom. The same holds with books in a book-case.

*Proof* 3.—Cut two slips of paper: (*a*) 8 inches long by 2 inches wide; (*b*) 8 inches long by 2 inches by $1\frac{7}{8}$ inches wide, so that it tapers $\frac{1}{8}$ of an inch. If the parallel slip (*a*) be held upright 8 inches from the eye (its own length), and looked at straight in the centre—the centre of the paper being opposite to the eye—the paper will appear slightly wider at the top than at the bottom, the same proviso of not correcting the pure impression by measurement (looking up and down it) holding, as we pointed out in the case of the church tower. If the observer now takes the tapering slip (*b*) and holds it narrow end upwards, looking at it in the same way, it will *appear* parallel; if he hold it wide end upwards, it will appear much wider at the top than at the bottom. This holds equally true if the experiments are made either with one eye or both, showing that binocular vision has no effect on the impressions.

*Proof* 4.—Another interesting experiment is to place a penny upright on a table, and a halfpenny 18 inches behind it and a little to the right or left of the penny. The eye must look *over* the penny at the halfpenny, so that the penny is a foreground object and the halfpenny a distant object. If the observer now looks steadily at the halfpenny, at the same time seeing the penny, he will find the impression given is that the halfpenny looks nearly as large as the penny.

Proposition A and proofs deal mainly with what we would describe as *vertical vision*—that is, with the variations in the appearances of objects when placed one over the other, as in a vertical column, or with objects at a distance as compared with objects in the foreground.

But within the radius where binocular vision acts (calculated by Mr. T. R. Dallmeyer to be sixty yards), new and important variations occur. These properties we shall consider under the term of horizontal vision.

* When we use the term "perspective drawing," we mean a mathematical drawing of various objects in the field of vision (*i.e*., angular measurement), as received on a glass plate (ordinary perspective drawing) or upon the screen of a camera, for, under like conditions, they are, as is well known, identical.

† We have ignored for the sake of simplicity the optical law of inversion of the image on the retina; when that is considered, the terms "upper" and "lower" must be merely interchanged.

*Proposition.*—Within the limits where binocular vision is effective—say normal vision (8 inches) to 60 yards—objects *appear smaller when they are compared with objects beyond the binocular limit;* that is, they appear smaller as compared with drawings as given by monocular or mathematical perspective.

An experiment to practically bring the effect of the binocular vision variations entering into the matter may be made as follows:—Take the tapering slip of paper aforesaid (*b*), and place it between the two eyes, the wide end resting upon the bridge of the nose, the slip being inclined at an angle of 30° with the horizon. The result is that the paper vanishes *towards* the eyes—diametrically an opposite result to what perspective would lead us to expect. This phenomenon still holds if the paper be gradually moved away from the eyes, and held at arm's length, but in the same plane.

*Proof.*—Place a book at a distance of six feet from the eyes. Then proceed to measure the width of the book with a pencil (one eye being closed), as a draughtsman draws objects by monocular perspective, and then open the other eye, and measure the width of the book with both eyes; the binocular measurement will be found to be smaller than the monocular measurement. If the height of the book be measured in the same way, there will be no difference in the result obtained with one or both eyes.

But more convincing is Proof 2. Wafer a square sheet of white paper (say eight inches square) on the wall, or on a window, six feet from the observer, and look at it. The impression given will be that it is larger vertically than it is horizontally. This explains the old trick of marking off the height of a tall hat against a wall; as a rule, everybody places the mark too high—the reason is now explained.

Still another proof. Stand a halfpenny and penny on the table, as directed in the previous experiment. Now place the eyes on the same level as the plane of the table and observe. The result will be exactly the reverse to that previously obtained. That is, when looking directly at the halfpenny, at the same time looking (indirectly) at the penny, the penny will appear the larger, and *vice versa*, when looking directly at the penny and indirectly at the halfpenny, the halfpenny will appear nearly as large as the penny.

Another every-day proof. Let a person sit in one end of a long punt with parallel sides, and look at the other end; it will look to him to be wider than where he is, and yet its sides will by perspective laws vanish quickly away from him.

These proofs show the effect of binocular vision, which is to increase the appearance of height and to narrow the appearance of breadth; consequently, it makes objects appear taller than a perspective drawing would do.

*Deduction.*—The reason we get a different impression of relative sizes of objects by normal vision from that given by mathematical perspective drawings and photographs is, that the combination of these properties of vertical and horizontal visions give quite a different result to that of perspective drawings.

*Final.* Having shown how we see forms, it only remains to say that a mathematical perspective drawing, or the drawing of an aplanatic photographic lens, does not give forms as we see them. They are altogether false to the visual impression of the proportions of things, and therefore give a wrong idea of the original scene. On the other hand, a perspective drawing or correct photograph gives the *actual facts* scientifically, *i.e.*, the pillars of the temple as leaning, the paper in experiment as *square*. All such drawings are, therefore, purely scientific diagrams, and artists who wish to render what they see must not rely upon them.

## PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

*Bath, July 6th to 11th*, 1891.—Exhibition of Apparatus, etc., to be held in the Guildhall, Bath.

The following circular has just been issued :—

Dear Sir,—At the above meeting an exhibition of apparatus will be held as usual, and we beg to call your attention to it, and to ask your co-operation. Our desire is to have on show all apparatus of any novelty, and it is proposed to make special features of such articles as the following :—Hand-cameras; apparatus for taking photographs in rapid succession; photomicrographic apparatus; balloon and military photography; flash-light apparatus; apparatus designed for special work—as medical, underground, &c.; optical lanterns and fittings; photometrical apparatus and the like; apparatus for, and specimens of, astronomical and meteorological photography.

In order that proper arrangements may be made for the exhibition of your exhibits, we shall be glad to have from you, at an early date, a list of the articles you propose to show. There is no charge to members for space (membership tickets five shillings), but to non-members the charge is ten shillings.

Whilst the greatest care will be taken of the exhibits, the Executive takes no risk in the matter of loss or damage. Expenses of carriage to be borne by exhibitors. The Committee reserves the right to decline any offered exhibit.

Exhibits to arrive at the Guildhall, Bath, not later than July 4th, addressed to the Convention.

G. Davison, Andrew Pringle, } *Exhibition*
Friese Greene, Henry Sturmey, } *Sub-Committee.*

Glazed Surface on Prints. — The following method is recommended for obtaining a glacé finish on albumen prints without the aid of gelatine. A glass plate is coated with a mixture of ox-gall and alcohol in equal parts, which has first been allowed to stand for several days with repeated shakings, and finally filtered. The washed albumen print is then placed in contact and squeegeed down, and, after drying for about an hour, will come off with a beautiful glazed surface. If the print is to be mounted and the gloss retained, it should be covered as soon as transferred to the glass with a sheet of parchment paper somewhat larger than the print, previously coated with starch paste, and then treated on the back with a good coat of gum or dextrine. It may then, when dry and removed from the glass, be placed in contact with a moistened cardboard and subjected to pressure.—*Anthony's Bulletin.*

Messrs. Taylor, Taylor, and Hobson send a tastefully got up and well illustrated catalogue of photographic lenses and sundries, with a very useful appendix on "The Principles of a Lens' Action." Their adoption of the standard flange screw fittings of the Photographic Society of Great Britain has led Messrs. Taylor, Taylor, and Hobson to adopt a system of providing that all lenses fitting the same flange should screw home with their diaphragm indexes or other fittings in the same convenient position—a system that has now been included in the Society standards. A series of standard screw adapters serve to carry any lens in a flange larger than its own, and to carry it in the standard uniform convenient position. Lens hoods are also standardised. They have included a series of lenses for stereoscopic work, and a series of caskets of lenses which are novel in the manner of grouping different types of lenses in one portable casket. The use of the "C" finder in connection with the table given, for determining the angle of view of lens to be employed on a subject, is thought by the firm to be a new suggestion. The book is supplied in paper covers free to all who apply for it.

## PHOTOGRAPHIC METHODS OF OBTAINING POLYCHROMATIC IMPRESSIONS.*

BY LEON VIDAL.

*Composite Photochromy.*—We borrow this name from Mr. Ives, of Philadelphia, although he gives it a more theoretical meaning.

In this method the various colours are not interpreted by the eye, but are combined by allowing photography to carry out the required selection automatically, and preparing, by means of special negatives, the various monochromes, which, when superimposed, reproduce the colours of the original. This method is somewhat complicated, and the photographic part of the work presents serious difficulties, because of the infinite variety of tones and tints, and the almost theoretical precision with which it is necessary to work in order to arrive at satisfactory results.

There are two distinct series of operations:—First, the preparation of the negatives; and secondly, the printing of the monochromes by whatever method is chosen. Typography, lithography, and collotype are the most suitable. Woodburytype may, in this case, also be reserved for the final printing on the proof required to give metallic effects.

Many different suggestions have been made with regard to colour selection by photography. The principal writers who have considered the question are Henry Collen, Cros, Ducos-du-Hauron, Poirée, Abney, Vogel, Stolze, and lastly, Ives, who, at the present time, is publishing important and remarkable works on this question. From all these researches, carried out by eminent investigators, we must endeavour to deduce some practical or commercial conclusions.

It is more important in this method than in simple photochromy to orthochromatise the plates, because it is necessary, in the case of the refractory colours, not merely to obtain the corresponding values, but even to exaggerate their actinic effect. The red, for example, ought not merely to act upon the plate so as to produce a tint corresponding to its luminous effect; it should produce the same effect as white. Thus, a red flower ought, in the *cliché* corresponding to the blue monochrome, to have the appearance of a white flower.

Up to the present time, having read, and tried experimentally, all that has been published on this subject, we have come to the conclusion that colour selection, by means of three negatives, each intended to eliminate two of the primary colours, does not give an absolutely accurate result. Taking each colour in turn, we wish first to eliminate all colours other than yellow; or, in other words, to obtain a negative which will produce the yellow monochrome. Even admitting that the three primary colours (yellow, blue, and red) are sufficient to reproduce, by their combination, all possible colours and shades (and of this we are very doubtful), it would be necessary to eliminate successively all the colours of the subject which are not yellow, and which are not blue, and which are not red; and this is a thing which cannot be done completely.

As regards the negative belonging to the yellow monochrome, it is clear that it ought to reproduce equally all the red and all the blue, and to leave the yellow, and combinations of the yellow with other colours, represented by clear glass. A method of arriving approximately at this result is to make use of an ordinary gelatino-bromide plate. The action of the blue is, of course, extremely energetic in comparison with that of the yellow. The difference in effect thus utilised will give the yellow monochrome, but with the result of reproducing yellow wherever the original subject contains red. The employment of carmine instead of vermilion, when printing the colours, will permit the yellow to be utilised for obtaining vermilion by its combination with carmine. Thus we obtain one negative which is fairly exact, although it does not completely separate two colours from the third.

We will now consider the negative corresponding to the blue monochrome. This one should separate out the red and the yellow—that is to say, it ought to receive from the blue colour, which is so powerful, hardly any impression, while the yellow and the red, which are so little actinic, ought to give the effect of white. The method of obtaining this result is to employ an orthochromatic plate, which is sensitive to green, red, and yellow, exposed behind a reddish-orange medium. The blue is, to a large extent, cut off, while the yellow and red rays pass through. The length of exposure is naturally considerably increased, but a few minutes' additional exposure are of little importance when photographing inanimate objects. For all practical purposes the negative gives fairly accurate results.

The third negative, corresponding to the red, seems a simple one to prepare by means of an orthochromatic plate, sensitive to yellow, and used without a screen. Evidently it is not necessary to restrain the reds, which produce but a very moderate effect. The blue and yellow will produce a powerful effect, and the required colour selection will take place automatically.

If from each of these three negatives we prepare a collotype print in its corresponding colour, and superimpose these three monochromes, we shall see, in most cases, that we are far from the desired result. Theoretical accuracy is far from being attained, the number of monochromes is insufficient. To produce results of commercial value, we must use at least four *clichés*.

The fourth *cliché* should be obtained with an orthochromatic plate sensitive to green, yellow, and red, using a yellow orange screen to moderate the blue and the violet. This *cliché* gives a body to the work, which would be incomplete with the red, yellow, and blue printings only.

One ought, moreover, after carefully studying the original, to retouch each negative, and remove the imperfections which will inevitably appear, whatever be the process employed. This retouching can be rapidly done; it diminishes in no way the artistic effect or the accuracy of outline, and it enables more exact colour effects to be obtained.

The printer in colours, having the above-mentioned four monochromes, sees at once what their defects may be, and a preliminary trial shows him immediately which portions require to be toned down. The bulk of the work is ready, and it need only be retouched here and there, an operation involving but little labour.

In order to employ phototypography for this kind of polychromatic reproduction, it is necessary to convert the negatives obtained directly into stippled negatives suitable for typography. This is done by making a positive reproduction through a grained screen. The trials can then be made by means of collotype, and afterwards, when the new negatives have been corrected by hand so as to give the proper effects, the typographic *clichés* are prepared.

For this process it is advisable not to use the same screen in every case. The various monochromes should

* Concluded from page 420.

be divided up by different series of points or lines, the resulting picture being better than if the same series is used throughout.

Even in the case of composite photochromy, it may be necessary to print flat tints. The printer must judge what is required, and must not for a moment think that three negatives, three colours, and three printings are sufficient to produce every effect.

Theory itself we need not consider, but practice indicates clearly that, to make good use of scientific data, it is at any rate necessary to know how to combine them with facts which have, through commercial means, been well established.

This second method of composite photochromy is capable of unlimited variations which cannot be enumerated in a short paper. We must remember this, that, by means of colour selection, with the aid of four different *clichés*, one obtains a result which leaves little to be done by hand, and gives excellent polychromatic copies. If a larger number of negatives be necessary, one can prepare two or three more, limiting more closely the colours which are allowed to act on each, but it will rarely be useful to prepare more than four negatives.

In the method described above for colour selective effects, we think it advisable that the worker should follow closely the suggestions here given. This method, although very ingenious from a purely theoretical point of view, falls far short of perfection if retouching be not resorted to, but we repeat once more that this additional labour is nothing compared to the work executed in the photographic part of the process.

Let us not be too dogmatic. Let us at present acknowledge our incapability of reproducing colours directly, and let us combine the advantages which indirect methods afford with those of judicious interpretation and retouching. Photography is already far advanced, but cannot yet be trusted to give immediately the monochromes required to produce by their combinations a polychromatic impression exactly similar to the original.

If we grasp thoroughly the points which are necessarily but briefly described above, all lithographers and typographers can obtain excellent results in copying from nature, or from works of art. Practice will, of course, increase the manipulative skill, and permit the result to be more easily obtained. It appears, then, strange that there are still so few photographic studios devoted to these kinds of printing. How is it that collotype, which is so simple and so easy a process, and which would be of such great assistance to the lithographer, is still only worked by a few specialists? While, on the contrary, no lithographer ought to be able to dispense with it. We should be glad to make lithographers appreciate that it would be of the greatest help to them in all kinds of photochromy.

That is the object of this paper, and we hope that the fact of its being read before the Photographic Society of Great Britain will cause photography to be more generally applied for the production of polychromatic impressions. Space has not permitted the insertion of technical details, but we are convinced that through the great advances which have been made in orthochromatic photography, and with the aid of the remarkable results which have been published on this subject by many investigators, especially in England, it would be easy for anyone who wishes to practise photochromy to do so successfully, by adopting, according to circumstances, one or other of the methods above described.

## A NEW LANTERN EFFECT.

The late Mr. Woodbury devised a number of very pretty lantern effects, which were brought about by the use of a glass tank placed on the lantern stage. Such a tank can easily be made by fixing in a frame two pieces of good, clear glass, and forcing between them a bent piece of india-rubber tubing, which at once forms a water-tight joint. In such a tank as this, and with the help of a few pipettes, coloured fluids could be urged into the water, with the result that on the screen arborescent and moving forms of very curious and beautiful appearance were projected. Many of these experiments depended for their effect upon chemical union between the liquid injected and that in the tank. Other fluids employed were simply diluted aniline dyes.

Mr. H. C. Ogden, of Middletown, N.Y., has adapted this principle to the production of a lantern slide giving the effect of a volcano in eruption. This effect cannot usually be produced except by a double—or, better still, by a triple—instrument, for one lantern stage is occupied with the general view of the mountain, another by the necessary lightning, and the third by the rackwork-wheel arrangement which causes the smoke and fire from the mountain to be vomited out in a circular direction, and in a manner as unlike nature as possible. By Mr. Ogden's method, the whole business can be brought about by one slide; but the effect would doubtless be heightened if another one depicting a general view of the mountain were associated with it. The new arrangement is thus described in a recent number of the *Scientific American*:—

"Not everyone can go to Europe, but, possessed of a lively imagination, one may go there in spirit, provided only that the scenes are presented pictorially in a truthful and artistic way. Thanks first to the skill of the optician, and secondly to the modern photographic art, anyone may be instructed and entertained by the modern lanternist, who will produce storm or sunshine, winter or summer, or the soft effects of moonlight at will upon the screen by the skilful manipulation of the optical lantern with a truly wonderful effect; but there are many effects which seem to be difficult of execution by means of the optical lantern. The saying is, 'See Naples and then die'; but what is seeing Naples without seeing Vesuvius in active eruption? Comparatively few European travellers have the good fortune to witness this phenomenon, and until now, so far as we are aware, no one has been able to faithfully represent this awe-inspiring spectacle.

"Mr. H. C. Ogden, of Middletown, N.Y., has come to the aid of the lanternist and the non-traveller, by producing a very simple apparatus by means of which Vesuvius, in full eruption, may be projected on the screen in a very vivid and realistic manner.

"In a glass tank attached to the lantern are inserted two curved drop tubes, with their extremities placed side by side, and on the rear of the tank is painted a picture of the volcano, which is represented mainly in profile by black varnish applied to the glass. The tips of the drop tubes coincide with the crater of the volcano, and from the crater down the sides there are transparent streaks representing lava. To the side of one of the clamps holding the tank together is attached a spring carrying a strip of metal, which extends along behind the opaque portion of the picture, and is provided with teeth which are designed to irregularly eclipse the transparent streaks. In one of the drop tubes is placed a dark liquid, such as diluted ink, and in the other is placed a bright red liquid, as red aniline ink. The tank is filled with a solution of glycerine and water, and inserted in the lantern. Dexterous manipulation of the flexible bulbs of the drop tubes produces red and dark streaks representing fire and heavy smoke, which are forced down in the tank and have the effect of rising in the image on the screen. At the same time, the manipulation of the spring at the side of the tank alternately displays and covers the streaks representing the lava."

## Notes.

The death of M. Alexandre Edmond Becquerel, at the ripe age of 71, removes from the scientific world a notable man of genius. M. Becquerel was a member of the Academy of Sciences, of the Institute of France, Professor at the Museum of Natural History at Paris, and the Conservatoire des Arts-et-Metiers. In our Year-Book for 1890 we published a portrait of the eminent Frenchman, and devoted several pages to a description of his work in connection with the production of photographs in natural colours, of which branch of research he was certainly the chief exponent. To this description of Becquerel's experimental work we refer all those who are interested. But beyond these useful researches Becquerel contributed much to scientific knowledge, and his original experiments with the phosphoroscope—an instrument invented by himself to show how many substances exhibit the phenomenon of phosphorescence after insolation—would alone prove his title to honourable distinction. M. Becquerel has gone to his rest, but he leaves behind him a name which will not quickly die.

Most persons have been under the pleasing impression that, whatever might be the faults and failings of the country called Great Britain, it at all events was properly mapped. They had a further impression that for a certain sum it was possible to buy a map, in sections, which, founded on the Ordnance survey, was as accurate as such a thing was possible to be. These notions, they are now informed, are founded on a misapprehension altogether, and the mapping of the country seems to be in a very incomplete state.

Upon the vote to complete the sum of £215,770 for the office of the Ordnance survey the other day, an energetic M.P. called attention to the very unsatisfactory rate at which the Ordnance survey was proceeding. It seems that this survey comprises three distinct publications, viz.: a twenty-five inch to the mile map, a six inch to the mile map, and a one inch to the mile map. The survey for the first of these—which is little more than half done—was commenced thirty years ago! The second map is in a more forward state, but it was commenced in 1842, and must therefore comprise much ancient history; and the one inch map dates from the beginning of the century! Well might the indignant M.P. exclaim "that a map forty years old was for many practical purposes quite useless."

Mr. Chaplin's reply showed that the new Minister for Agriculture, under whose department this business comes, does not know very much about map-making, and, at the close of his speech, when he referred to the help that photographic process work could afford, he evidently had very little practical acquaintance with what he was talking about. To speak of "zincography" as a new invention was certainly funny. "The work produced by that invention appeared to him," he said, "to be excellent." And he was informed that the maps, by its aid, "might be completed by the year 1900." We wonder how long these ordnance maps would have lingered on in the absence of this "new invention!"

An enterprising City photographer exhibits a very suggestive show-case, in which, with the assistance of specimens, he points out the varied uses to which photography can be applied. Some of these specimens are decidedly novel. One represents the interior of a drawing-room; very useful in case you want to let your house furnished. A second photograph shows a wall thrown down by the effects of an explosion, and in the event of disputed damages would convince any jury that there was no mistake as to the shattered condition of the wall in question. A third represents the ruins of a fire, and is obviously a hint to the insurance offices. A fourth is entitled "Ancient Lights," and speaks for itself; while a fifth, which is called "A Right of Way," shows how "village Hampdens," whose rights are encroached upon by rapacious lords of the manor, may enlist public sympathy. It is only fair to say that the manipulation of these photographs is very good.

There is a fine opportunity just now at the Paris Hippodrome for the photographer to show his skill in instantaneous work. Hitherto lions and lionesses have been photographed chiefly in a state of repose. Enclosed as they usually are in cages, the circumscribed space and the feeble light in many cases imposed conditions on the photographer which have somewhat fettered him. The managers of the Hippodrome, by the invention of an ingeniously contrived lift, now are able to convey the animals from the cages to a suitable arena, where they can have such gambols as the increased area may tempt them to indulge in. A lion and lioness leaping at some meat which is placed beyond their reach have been photographed by MM. Londe and Yvart, and these photographs are reproduced in *La Nature*. Our contemporary says that the movements of the animals are not at all like what we have been accustomed to see in menageries.

One would like to have Lord Coleridge's opinion on the various likenesses of himself which have appeared in the illustrated and evening papers during the last few days. The Lord Chief Justice used to be rather sensitive on the matter of his portraits—so much so, that for a long time past it has been impossible to get a photograph of his lordship. The story goes that, on one occasion, he entered the shop of a well-known dealer in photographs not a mile from the Law Courts, and, buying up all his portraits, then and there destroyed them. Perhaps, however, he may be now hardened, as it was stated a few days ago that a Devonshire photographer had overcome his objection to sit. If he will also permit his photographs to be sold he will receive the gratitude of journalistic artists, for the face of the Lord Chief Justice is most difficult to draw.

Photographs on the retina run the discovery of photographs in natural colours very hard indeed when the gossipy paragraphist is hard up for material. A paper which certainly ought to know better says that, in the photographic exhibition now being held at St. Petersburgh, one of the most remarkable exhibits is, without doubt, an enlarged photograph of the retina of the eye of a young lady who was murdered several years ago at Samara by a soldier. The likeness of the murderer was found so clearly imprinted on the retina of his victim that it was possible to discover the criminal, and bring him to justice. The falsity of this and similar stories has been demonstrated over and over again. All that is known on the subject was well told some years ago by Mr. W. S. Bird, and nothing has happened since to weaken the conclusion that such photographs had never existed.

## WHY IT IS NECESSARY TO ROCK THE DISH DURING DEVELOPMENT.

BY PROFESSOR W. K. BURTON.

When gelatino-bromide dry plates were first introduced commercially in England, and when there were but few rival makers—either two or three—one of these declared that there was no necessity to rock the dish during development, and that, indeed, it was the reverse of advantageous to do so. Experience soon showed that this statement was wrong, and it has ever since been customary to keep the developer in motion over the sensitive film. The reason why this is necessary has been explained more than once, but the whole of the explanation has seldom been given.

At the time I refer to—about ten years ago—I satisfied myself that it was not only an advantage to keep the developer in motion over the plate, but that it was a *very great* advantage. This was shown by exposing a plate, cutting it in two, and developing each half with half of the same lot of developing solution, keeping the dish containing one half of the plate in motion, and leaving the other at rest. The former developed more quickly than the other, and moreover, even after a much longer development, the latter still appeared thin and flat as compared with the former.

What seemed to me to be the solution of the phenomenon at that time was simply that a developer in motion naturally acted more vigorously than one at rest, because a fresh quantity of developer was continually being brought into contact with each portion of the film. This is, doubtless, a part of the reason, but there is a deal more reason than this.

To follow fully the reason why the use of a developer allowed to remain at rest results in a thin, flat, and sometimes even foggy image, we must imagine two parts of the film, one that has received no light, the other that has received that amount of light that should make it one of the densest parts of a negative. I suppose the developer to be alkaline pyro. The action on that part of the film that has received no light is simply *nil*, if the plate be of such a kind that it does not fog under the developer without the action of light.

Let us follow, however, the action of the developer on the part of the plate that has been acted on by light. We know that it will begin to darken, the bromide of silver of the film being reduced to metallic silver. The action that is supposed to take place is as follows. The alkaline pyro has a strong affinity for oxygen—for that of the water constituting the solution, as well as for any other oxygen. It will not, however, decompose the water, unless there is present some body eager to take up the hydrogen, of which, in water, there are two atoms for every one of oxygen. This is at hand in the bromine of bromide of silver that has been acted on by light. The hydrogen and bromine combine, forming hydrobromic acid ($HBr$). This hydrobromic acid, however, immediately combines with some of the alkali to form a soluble bromide—bromide of ammonium, bromide of sodium, or bromide of potassium, according to the alkali that has been used—and this soluble bromide is a strong restrainer.

Now see what state of affairs we have. On the part of the negative that has not been acted on by light we have still the normal developer acting, whilst on the part that has been affected by light we have a developer that has been modified in the following way. The quantity of pyro has been reduced, the quantity of alkali has been reduced, and a restrainer has been added. Moreover, over the whole surface of the negative we have a developer acting that is reduced in strength in pyro and alkali, whilst it is restrained with bromide just in proportion to the amount of light that has acted on any part of it. In these circumstances we need not expect a strong or brilliant negative. Such is only to be had if we wash out the restrainer from the parts that have been most acted on by light, whilst we add fresh pyro and alkali, and this is only to be done by keeping the developer in motion. Indeed, a more vigorous way of doing this is to continually pour the developer on and off the plate, and this will be found a good way to develop negatives when there is difficulty in otherwise getting vigorous results.

In the case of plates—and this is the case with most—which veil more or less even without the action of light, this veil will be greater in the case of development without rocking than when the developer in kept in motion, and this for obvious reasons. Of course, the result is a still further degradation of the negative developed without motion of the dish.

A phenomenon that is often seen in the case of plates that veil somewhat under the developer, even without the action of light, whether this veiling is due to the plate or to the use of too strong a developer, depends on this fact, that immediately darkening begins at any part of the film, the developer absorbed by that part of the film is both weakened and restrained, and this to a certain extent even if the dish *is* rocked. The phenomenon that I refer to is the appearance of a *positive* image on the back of the plate. From what I have already said, I think the cause of this will be evident. Whenever this positive image appears, it shows that development has been carried about as far as there is any good of carrying it.—*Wilson's Photographic Magazine.*

## PROPERTIES OF ALUMINIUM.

The gradual introduction of this metal as a substitute for brass in photographic apparatus is causing a great deal of attention to be concentrated both upon its manner of production and its properties. At a recent meeting of the American Institute of Electrical Engineers, the subject of aluminium once more came to the front. Professor Crocker stated that in his opinion it is a very common mistake to attribute to aluminium itself the tensile strength of aluminium bronze, which exceeds that of wrought iron, and is about as high as good specimens of steel. It is really one of the most tenacious metals known, but its composition is about nine parts of copper to one part of aluminium; yet its tensile strength is almost invariably attributed to pure aluminium, having a specific gravity of 2·6, which is only one-third that of iron. They take the low specific gravity of pure aluminium and the high tensile strength of aluminium bronze. As a matter of fact, the specific gravity of aluminium bronze is higher than that of iron. Therefore, we do not have lightness combined with high tensile strength. Turning again to aluminium itself, its tensile strength is about 26,000 pounds per square inch; in other words, about one-third that of iron. This just balances the difference in specific gravity, but still leaves the advantage in favour of iron, because one-third of the volume has the same strength and the same weight as a rod of aluminium. Now, the same exaggeration is applied to its other qualifications; for example, its chemical properties. Aluminium bronze is remarkably free from tarnishing. A bright surface of aluminium bronze may be exposed to the atmosphere for several months and retain its polish. That property is attributed to aluminium itself. Aluminium, as Mr. Brown said, is not particularly liable to corrosion, but if it is subjected to salt water or alkaline water, or even ordinary moist air, it does tarnish and oxidise rapidly. Salt water is quite hurtful to it. Therefore, freedom from oxidation is another property that is wrongly attributed to it; and the objection to all this is that it gives a very wrong impression in regard to what would otherwise be a good and legitimate object of admiration. In regard to its real properties, he thought the pure metal entirely too soft for structural purposes, as it can easily be cut with a knife; as to its chemical properties, it oxidises with about the same ease as zinc, tin, and iron. Is eagerly attacked by acids. It is not much affected by sulphur or sulphuretted hydrogen, which is a great advantage. It is very freely dissolved by alkalies, whereas most other common metals are not. In an ordinary alkaline solution, aluminium is dissolved, as most metals are, in acids, with the evolution of hydrogen. This is quite a serious disadvantage for a common metal, which is liable, for example, to have soap used upon it. We do not expect metals to be attacked by alkalies.

Its conductivity is about twice that of copper, weight for weight. The increase of size to get this conductivity, however, would preclude its use in place of copper in rubber insulated wires on account of the increased expense of insulation. The electrical process would undoubtedly monopolise its manufacture, because it offered the only successful way of reducing it; the only competing chemical process being by use of sodium, which is in reality electrical, because the sodium is made electrically.

Society of Arts Conversazione.—The Society's *conversazione* is fixed to take place at the South Kensington Museum (by permission of the Lords of the Committee of Council on Education) on Wednesday, 17th June. The reception by the attorney-general (Sir Richard Webster, M.P.), chairman, and the members of the council of the Society will be held from 9 to 10 p.m. Promenade concerts will be given by the band of the Grenadier Guards, and also a concert of Old English music.

Report of Harvard College Observatory.—Prof. Pickering has just issued his report for last year. He again urges the necessity of a fireproof building for storing the 27,000 photographic plates of spectra, 9,000 of which were taken in 1890. . . . During the past year 1,309 photographs of stellar spectra have been taken with the Bache telescope at the station near Closica, in Peru. Nearly all of them relate to the region south of $-20°$. Mrs. Draper has added another instrument of the same kind to the Henry Draper Memorial. This is mounted in the Observatory grounds at Cambridge, and since Septemper 1889, 2,157 photographs have been taken with it, covering the sky north of $-20°$. By placing a prism of small angle over the objective, the spectra of stars as faint as the tenth magnitude have been obtained. Six stars with Type IV. spectra have been discovered. Spectra of fifteen planetary nebulæ have been photographed. The hydrogen line F has been shown to be bright in eight stars. Bright line stars of the Wolf-Rayet type now number twenty-eight, three having been added to the list during the past year. The names are given of thirty variable stars of long period, in which the hydrogen lines are bright at maximum. This peculiarity has furnished a means of discovering seven new variable stars. . . . . An important accession to the white spot surrounding the southern pole was found by photographs to have occurred between the nights of April 9th and 10th.—*Nature.*

## THE KINESIGRAPH.

In view of the great interest which has recently been aroused in the various plans put forward for photographing animal and other movements, we call attention to an instrument, the "Kinesigraph," which was patented so long ago as August, 1889, by Messrs. W. Donisthorpe and W. C. Crofts. The following is an extract from the Specification, No. 12,921. This document is illustrated with elaborate drawings, and those who are interested in this field of photography should not fail to study it, in order to see how much ground it covers, and possibly to prevent them re-inventing anything comprised within it. We have been informed that already series of photographs of moving objects have been taken with the instrument at a rate of from eight to twelve per second. A portion of the machine is now being slightly modified in order to ensure greater uniformity in the travelling of the band of pictures through the lantern. The experiments show that, owing to the comparatively long time during which each successive picture can be kept absolutely stationary before the spectator's eye, and which constitutes a distinctive feature of the mechanism, a maximum speed of twelve per second need not be exceeded in order to secure the effect of continuous and natural motion.

This invention has for its object improvements in the production and representation of instantaneous photographic pictures.

The pictures are produced upon a sensitive film or surface carried by a long roll of paper or other material. The roll is continuously unwound from one drum and wound upon another, and in its passage a series of images are successively thrown upon it by a photographic lens. A screen is provided between the lens and the exposed sensitive surface. This screen travels out of the way to permit the image to fall on the sensitive surface, and covers the lens again as soon as the exposure is complete. These operations take place with regularity and, usually, great rapidity, so that several pictures are taken in each second during the time that the apparatus remains at work, which will be for many successive seconds, indeed for any length of time which may be desired. The scene selected for photographic presentation will be one of constant movement—for example, a street scene—so that each picture will differ slightly from the preceding and succeeding pictures.

The camera may be arranged in the following manner:—In the fore part is the lens, and immediately behind the lens the screen which regulates the instantaneous exposures. This screen may be an endless band passing around pulleys and travelling at high velocity. In the band there are two perforations or apertures, and twice in each rotation of the band these perforations coincide, and the light is then able to pass from the lens through the perforations on to the sensitive surface. The lens forms the scene upon the sensitive surface. The focus is accurately adjusted before commencing the operation by the aid of a slide on which there is a focussing glass and guide rollers over which the continuous sensitive paper or material passes.

The screen and the winding apparatus are so geared together that the sensitive surface travels the distance necessary to separate the pictures between one exposure and another. In place of the travelling perforated belt a disc perforated with a narrow slit and driven by bevel-wheels may serve the purpose. After the pictures have been taken, the roll is removed from the camera, and the pictures upon it are developed in the ordinary manner. From this continuous band of negative pictures a similar band of positive pictures is produced, and rendered transparent by the application of vaseline, or vaseline oil, or by any other suitable process.

For the exhibition of the pictures a lanthorn similar to the ordinary magic lantern (or if a non-transparent positive band is used, then a lanthorn similar to the opaque magic lanthorn) is employed, in which a brilliant intermittent electric light is provided. The lanthorn is provided with condensing and focussing lenses, by the aid of which the light, after having passed through the transparent positive picture, is focussed upon a screen. Each picture is thus exhibited only by one flash of the intermittent light, for the band of pictures travels on and, by the time the next flash occurs, another picture is in place. Thus, several pictures are exhibited upon the screen in each second of time throughout the whole period of exhibition, which will usually be approximately the same as that occupied in taking the pictures. The change from picture to picture and the flashing of the light is so rapid—about seven flashes per second—as not to be discerned by the eye, and the appearance on the screen is that of a picture in which the animate and other objects exhibited are in movement. In order that the flash may synchronise accurately with the picture in position, contact pieces are provided upon the travelling band, and by the passage of these the flashes are determined. Or a continuous light, electric or other, may be used, and the recurring flashes obtained by a perforated screen travelling at high velocity as in the camera above described, the coincidence of the flashes with the centre of each successive picture being insured by increasing or diminishing the speed of the travelling band of pictures by an arrangement for the insertion or withdrawal of a tapering driving drum or other appropriate means. Speaking in general terms, we effect our object in the following manner. We have a photographic lens fitted to a suitable camera, exposed and shut at intervals (usually at equal intervals recurring from eight to six times in a second), throwing a succession of instantaneous images of moving objects upon a continuous band of sensitive paper unceasingly travelling behind the lens, but, while so unceasingly travelling, the band, by a compensating motion, is rendered stationary relatively to the lens during each successive instantaneous exposure, so that each image is imprinted thereon next to and touching the preceding image, without overlapping it; and from such continuous band of negative pictures duly developed a series of positive pictures, touching but not overlapping one another, are printed upon a continuous band of thin or transparent paper, and this positive band is then made to travel unceasingly behind the lens of a lantern, but, while so unceasingly travelling, the band, by a compensating motion, is rendered stationary relatively to the lens, during each successive exposure, recurring not less than eight to six times in each second, so that at each exposure of the lens, the interval between two exposures being not longer than $\frac{1}{16}$ to $\frac{1}{12}$ of a second, the centre of each picture is opposite the centre of the lens, and the image of each picture thus exposed is thrown by the lens in a magnified form upon a screen or other suitable surface.

In this way we cause the spectator's eye to receive therefrom the impression of each picture just as the impression of the preceding picture is fading from the retina, which retains it until replaced in its turn by the impression of the succeeding picture, and so on. Thus, the blank intervals between the successive exposures of the pictures are not appreciated by the eye, and the general impression produced is that of continuous motion corresponding to the successive positions of the moving objects in the series of positive pictures.

---

Photographic Club.—Subject for June 17th, "Photographing Animals"; 24th, "Actinometers," and a series of lantern slides of Hildersham by Mr. Frank Haes. Saturday outing, June 13th, Whetstone; trains from Moorgate Street to Oakleigh Park at 2.6, from Finsbury Park at 2.25.

Robbery from a Photographic Studio.—The photographic studio at 20, Lower Bridgman Street, lately kept by Messrs. A. and G. Taylor, was broken into between Monday night and Tuesday morning, and some valuable property stolen. The framework of the scullery window had been broken, and the back door was left open, this being the condition in which they were found on Tuesday morning. From the operating room two lenses valued at £20 were taken out of the machine in which they were fixed, whilst from an adjoining room a number of glass copies and the sum of £4 15s. were missed, a desk having been forced open. The police are on the look-out for the marauders.—*Bolton Evening News.*

## THE BRITISH ASTRONOMICAL ASSOCIATION.

At the seventh ordinary meeting of the Association, held on May 27th in the Hall of Barnard's Inn, Dr. W. Huggins, F.R.S., vice-president, in the chair, Mr. Cottam read reports from the Coloured Star and Saturn sections.

The Chairman said that Dr. Gill was present, and had kindly consented to give an account of the recent meeting of the International Astrophotographic Congress at Paris, and of his visit to some of the Continental observatories.

Dr. Gill said he was not able to give them a formal address, but if they would be content with a conversational account, he would be happy to tell them what he could. The purpose of the recent conference at Paris was to bring to a definite conclusion the work of the previous conferences. He would call attention to the name of the committee. It was called the Astrophotographic Committee, and advisedly so; not merely the committee for the Carte de Ciel; for the real work which they were undertaking was not merely to take a number of pretty pictures of the heavens—that might be done by photographers who were not astronomers—but to provide for determining the co-ordinates of the stars shown on the plates. The first point of importance settled at the recent meeting was the adoption of the *réseau*; the next—which was, indeed, the chief point of discussion—was the question of how to define the plates for the catalogue. It had been previously decided to have two exposures of the same field on the same plate—one to show 11th mag. stars, and the other exposure of one quarter the duration of the first; but no reason had been assigned for this decision. The object was, of course, the discrimination of dust marks from the true images of stars; but this arrangement really failed to secure it, for the shorter exposure would not show 11th mag. stars, but only stars of the 9th or 10th mag. The faintest stars—those about which it was easiest to make a mistake—would be shown only once. It had now been decided, however, that the one exposure should be sufficient to give a good, measurable image of an 11th mag. star, and the other should be half as long, yet sufficient to show an 11th mag. star as a faint dot. This was a most important advance, and it placed the accomplishment of the catalogue beyond dispute. The next point was the question of plates for the chart; and the difficulty before them was as to whether it was advisable, in the present state of our knowledge, to extend the chart so as to embrace stars of the 14th mag., seeing how great was the difficulty in defining photometrically what a 14th mag. star must be. The difficulty had been avoided by deciding not to attempt any definition of a 14th magnitude star, but by limiting the exposure to forty minutes. But here a fresh difficulty arose, for plates of different sensitiveness might be used at different observatories, and the clearness of the air might also differ. So it was arranged that the Bros. Henry should experiment at Paris to find what exposure was necessary to give them good images of stars known to be of the 11th mag. Let us call this time $t$; then $n\,t = 40$ min. Each observatory would, in like manner, determine $t$ for themselves; but $n$ would be the same for all observatories, so that the exposure given would in each case correspond to 40 minutes at Paris. It was then resolved to push on with the catalogue plates. Six reference stars were to be selected for each plate—say 60,000 stars in all—which were to be observed with the meridian instruments of different observatories. A good deal of excited discussion took place on this point; but there was neither anger nor discord, and the decisions reached were arrived at unanimously. The grand result was, that a firm basis had been laid of a system of sidereal astronomy, for which their descendants of 200 or 300 years to come would thank them.

Dr. Gill then went on to describe the new equatorial coudé of the Paris Observatory—18 metres in length. It was a marvellous triumph of optical skill that such large plane mirrors should be so successfully worked. The great difficulty in using the instrument was that it required careful protection from the sun during the day, as an even temperature was essential to its good performance. Dr. Gill also referred to M. Loewy's determination of the constant of aberration, and to M. Cornu's repetition of the Cavendish experiment for determining the density of the earth. He had also visited the Berlin Observatory, and had spent much time in discussing with the Director the observation of the refereuce stars for the astrophotographic catalogue. But he would rather speak of the Potsdam Observatory, and the beautiful results obtained there in the spectroscopic determination of the motion of stars in the line of sight. After describing the spectroscope, the definitiou of which upon the suu was most exquisite, Dr. Gill said that Prof. Vogel had in this liue of research made, at oue step, as great an advance as that from the results of Ptolemy to those of Bradley, and he believed that, with a larger telescope, such as he hoped soon to be provided with, of 25 in. or 30 in. aperture, he would be able to obtain results which should resemble an advance from the days of Bradley to those of modern precision. He thought it not only possible, but probable, that ere long they would not be correcting the results of the stellar motions for the earth's orbital motion, but, reversing the process, would determine the speed of the earth's motion, and so determine the solar parallax, from the observations of the stellar motions in the line of sight.

Dr. Gill also said that he had visited Prof. Kapteyu at Groningeu, who was measuring and reducing the plates for the Cape Durchmusterung; 70 per cent. of the work was already accomplished, and by the end of the year he hoped the whole would be ready in catalogue form. The charts and catalogue would then be published as soon as possible, and they would be ready in time to help in the formation of the great Carte de Ciel.

Mr. Downing said that the reports of the proceedings of the Conference in the public press left the impression that the discussiou at times waxed so warm that the meeting had to be adjourned. He should be glad to hear Dr. Gill's account of the matter. He wished to know also, if an observatory simply took photographs for the chart, but did uot carry out the reductious, what was to be done.

Dr. Gill, in reply, said he had no hesitation in clearing up the misunderstaudiug. It would be easily understood that in so large a gathering of scientific men, each with his own views, various opinions would be very strongly expressed, and it soon became obvious that it would be necessary to discuss and arrange some points privately. For this purpose an adjournment was decided upon, but the ultimate resolutions were unanimously arrived at and most loyally accepted by all. With regard to the measurement and reductiou of plates, each director was at liberty to measure his own, and a committee had been appointed and was sitting to decide upon the best method of enlargement and publicatiou. Two or three members asked questions, to which Dr. Gill replied, and at the chairman's proposal a vote of thanks to him was carried by acclamation.

Rev. A. Freeman read a paper on "An Observed Partial Eclipse of Titan," May 5th. Favoured by unusually favourable weather, he had observed Titan shortly after superior conjunction, and had observed the satellite change from bluish-white tint, first to orange, and then to a dull copper colour, recovering through orange to its usual bluish-white tint. There was no simultaneous change in either Saturn or Rhea. This appeared to iudicate a partial immersiou of Titau in the penumbra and umbra of Saturn's shadow.

Mr. Green observed that this change of tint, corresponding exactly as it does with what is seen in the case of our moou during eclipse, might be taken to prove that Saturn had an atmosphere. Referring to the work of the new Saturn Section, of which he, Mr. Green, had just undertaken the direction, he remarked that he had noticed very clearly the white spot on Saturn's ring, but he believed that the appearance was merely the result of contrast with the body of the planet. Artists, if they wished to brighten the lights of a picture, often simply deepened the surroundiug shadows. It appeared to him that if it were a real spot on the ring, it should revolve with it.

Mr. Maunder read a paper on "Stars of the First and Second Types of Spectrum." Secchi's division of stars into four types was familiar to them all, and it had beeu generally assumed that these types represented successive stages in the development of a star, Secchi's type 1 being generally supposed to show the stage of highest temperature; or, in other words, to be typical of the largest stars. Recent discoveries had induced him to doubt if either idea were universally, or scarcely generally true. First of all, Sirian or first type stars were represented in a larger proportion amongst stars of the smaller magnitudes. Next, when double stars were of nearly equal magnitude, they were generally of the same colour and spectrum type; but if the companion was much smaller than the primary, then it was generally of the Sirian type, and the primary of the Solar or second type—never the reverse. Thirdly, when we calculated out the total radiation for those stars for which the parallax had been determined, we found that, on the whole, the solar stars were the larger, one solar star, Arcturus, being, indeed—if we accept Dr. Elkin's parallax —147 times as bright as Sirius. Lastly, the Milky Way was composed, so Prof. Pickering had showed, mainly of first type stars, and the Milky Way was obviously on the whole an aggregation of small stars. Thus, four distinct lines of research pointed to solar stars being usually larger than Sirian. Further, a method originated by Mr. Monck some years ago, enabled them to compare the mass—brightness of binary stars for which the orbits were known. This comparison gave solar stars as denser, in relation to their brightness, than Sirian. Then, again, different districts of the sky abounded iu special types of stars. Both these facts pointed, he thought, to the cause of the particular spectrum of a star lying rather in its chemical constitution than in the particular stage of development to which it had attaiued.

Dr. Gill remarked that the circumstance to which Mr. Maunder had alluded—the prevalence of first type stars in the Milky Way—had an interesting bearing on the photographic work they had been carrying on at the Cape. For, whilst their photographic magnitudes agreed fairly well with Gould's visual magnitudes, yet in the Milky Way they fouud a well marked constant difference. This was now explaiued by Prof. Pickering's discovery that the Milky Way was composed mainly of first type stars, which were, therefore, specially rich in the photographic rays. It was a most far-reaching discovery, and we did uot know where it would lead us; but the Milky Way would seem to be a separate creation from the rest of the stellar universe.

---

Newcastle-on-Tyne and Northern Counties Photographic Association.—The second out-door meetiug of the seasou will be held on Thursday, June 18th, to Ripon and Studley Park; train leaves the Central Station at 7·35 a.m.

Improvement in Microscopic Lenses.—It is stated, says the *Scientific American*, that au immense improvement has recently been effected in the manufacture of glass for optical instruments by means of the addition to the ordinary materials of phosphorus and chlorine, which, in some as yet unexplained way, cause the glass to be very much more transparent, aud euable it to receive a much higher degree of polish than any optical glass hitherto manufactured. Thus, microscopes can be made which will render objects of the diameter of only the one eight-millionth of a millimeter visible, whereas with the best instruments now in use the diameter of the smallest object that can be seen is one sixteen-thousaudth of a millimeter. This news, we fear, is too good to be true.

Mr. John Carbutt, of Philadelphia, has issued a circular to dealers in photographic materials, in which he writes:—"It is scarcely necessary to inform you that for the past twelve years I have manufactured and sold photographic dry plates bearing on their labels the letters A and B, which have become distinctive and recognised brauds of my manufacture, so that the use of the letters A and B had by ordinary usage become to me a valuable trade mark, aud photographers ordering my plates of those brands usually deemed it unnecessary to do more thau mention the brand required. As certain dry plate makers have recently made use of the same letters A and B on their labels, and the U. S. Patent Office having granted me the exclusive use of the letters A and B as a trade mark when applied to photographic dry plates, I hereby give uotice that I intend to maintaiu my exclusive right to the trade marks A and B as applied to dry plates, and will cause proceedings to be taken against anyone who infriuges upou my rights."

## Patent Intelligence.

### Applications for Letters Patent.

9,278. WILLIAM STRINGFIELD, St. Cyres, London Road, Lowestoft, "A New or Improved Method of Photographic Printing Direct from the Negative by Contact, Lantern, or otherwise."—June 2nd.

9,577. ALOIS DVORAK, 79, St. James's Street, Burnley, "Improvements in Detective Cameras."—June 6th.

9,591. WILLIAM PALMER, 87, St. Vincent Street Glasgow, "Improvements in Apparatus for Photographing Engineering Drawings aud the like."—June 6th.

9,598. WILLIAM LLOYD WISE, 46, Lincoln's Inn Fields, London, "Gauges for Centreing Lenses and Making other Optical Instruments." *(Andrew L. Smith, United States.)*—June 6th.

### Specifications Published.

304. *January 7th*, 1890.—"Coating Machines." F. BISHOP, 22, Soho Square, Middlesex, aud A. COWAN, Chase Side, Southgate, Middlesex.

The sensitive emulsion is contained in a trough, from the bottom of which it passes in an even layer to the plates, which are moved uuderneath. The trough consists of glass strips, the former of which is vertical, the other, which is inclined, being attached to a hot-water chamber. The strips are suitably held between end discs, fixed to the hot-water chamber, and by clamps, &c. The discs are mounted on couuterbalanced pivoted levers, which method of mounting permits the passage of different sized plates under the trough. In the case of large plates, the strip has a flexible tougue to compensate for the inequalities of the glass. The plates move between rollers on rails, which take under the edges so as to obviate defects due to local differences of temperature. The surplus emulsion runs over the edges of the plates into troughs, from which it falls into a tank underneath.

359. *January 8th*, 1890.—"Detective Camera." A. J. BOULT, 323, High Holborn, Middlesex. *(F. A. Brownell, Rochester, New York, U.S.A.)*

This belongs to the detective class, and can be packed into a box-form, by pushing the front, with its bellows, inside the case, and turniug up the base-board to close the open side of the case. When open for use, the base-board is held in position by two slotted stays, with spring catches; the front, with the lens, can be fixed in any position on guides, by a cam, for focussing. A finder, having a lens, mirror, and ground glass, is pivoted to one corner of the base-board, so that it can be examined vertically or horizontally. The roller slide case has a bead, which fits light-tight into a recess at the back of the camera. It is supported by pivots at the sides, which are supported in notches on the ends of pivotted springs. Any indicator, audible or otherwise, may be used. Recesses are provided for the admission of air when the bellows is exteuded. The roller of the slide is actuated by a key worked from the outside.

401. *January 9th*, 1890.—"Flash Lamps." T. H. REDWOOD, Bryn Coed, Crescent Road, Chingford, Essex.

Relates to light for photography, stage effects, &c. The flame from the lamp is spread out by impingiug on a metallic sheet or screen, on to which is ejected the magnesium, &c., powder by a deflector or diffuser on the powder nozzle. The lamp may be provided with a hinged cone or hood, a grating, and a damper, but any lamp or a gas jet may be used.

478. *January 10th*, 1890.—"Bottle Stopper." V. C. MONETTE, 23, Boulevard de Strasbourg, Paris.

For delivering liquid in drops or thin streams. Consists of a metal nozzle surrounded by india-rubber packing and provided with a lateral hole from which an air tube descends to the bottom of the bottle. The nozzle passage and air tube are controlled by a piston valve with push-knob and spring.

511. *January 11th*, 1890.—"Shutters." J. E. THORNTON and E. PICKARD, St. Mary's Street, Deansgate, Manchester.

Shutters adapting to lens hoods or mounts of different sizes. Rubber, &c., packing rings of the section shown, and of any required thickness, are inserted in an opening in the shutter frame, which may be provided with an adjusting screw. The strips are shorter along their upper than along their lower edges, so as to be firmly held in place.

611. *January 13th*, 1890.—"Magic Lantern." W. C. HUGHES, Brewster House, 82, Mortimer Road, Kingsland, Middlesex.

*Body.*—This is an open frame-work consisting of a base to which the front, with the tubes, may be set at right-angles, and held by stays; a pillar or pillars rising from the back of the base, carrying adjustable platforms for the lanterns. In a modified form, the platforms may be carried by pins instead of the pillar. The body can readily be taken to pieces for packing.

*The limelight apparatus* is carried upon platforms on the pillar, or the pins mounted thereon, and the dissolving valves or taps are adjustable on the pillar. These taps may be of the form shown, or may be fitted with T junctions, so as to be connected by flexible tubes which will not interfere with the vertical adjustment.

*The shutter* is mounted on a spindle, and is normally held in a position to shut off the light by a weight. When the slide is inserted in the stage, its end strikes au adjusting screw, and moves a sliding rack, thereby turning the shutter aside.

*The slide carrier* is provided with a pair of spring jaws, opeued by pressing a button through a double rack and pinion; the slide can then be iuserted in the carrier, and the jaws closing grip it in position. The guard plate has a bevelled edge round the picture, which may be coated with metal and highly polished. This gives the picture on the screen a clearer definition at its edge.

## Correspondence.

### AUTOMATIC PHOTOGRAPHY.

SIR,—I shall feel obliged if you kindly rectify in your next issue a few errors which occurred in your last article (otherwise impartial) on "Automatic Photography," viz:—

1st. That the premises which you were good enough to visit at Shepherd's Bush are not the head-quarters of the Automatic Photographic Co., but the factory of plaques used in automatic machiues.

2nd. That there is not in the above Company a managing, but technical director, which post is entrusted to me.

3rd. That our Company has actually a sufficient number of trained men to look after the machines and ensure their success.

Please also oblige me by mentioning that the rapidity with which sensitised plates develop and fix in the machines is due neither to collodion emulsion nor hydroquinone, but to a certain process unknown outside our Company, and improved by my own experiments and manipulations. L. NIEVSKY.

5, *Gransden Road, Shepherd's Bush, May 30th.*

### "SUGGESTED BY SOME RECENT EXHIBITIONS."

SIR,—Respecting Mr. Robinson's comments on the Gloucester Exhibition in your issue of May 29th, permit me, as the exhibitor of the picture in question, to protest against the imputation made in the third paragraph. To follow up the second paragraph by such remarks as are made in the third is a fairly direct way of imputing dishonesty to me. The paragraphs are too near together to convey any other meaning. The error arose from the use of the vague term "exposed" in the rule. I read it off, without a second thought, as applying to the *picture* to be exhibited. Had the rule stated distinctly that the enlarged negative as well as the print was to be the work of the exhibitor, all error would have been avoided. By the letter of the rule, all that lost my "very remarkable" picture the medal was my not having asked the firm who made the negative to permit me to remove the cap from the enlarging apparatus. This would have been "exposing" the enlarged negative. After all, what does the error amount to—the error that Mr. Robinson so conspicuously emphasises by italics and a note of exclamation? In this particular instance, the original negative, taken and finished by me, is the result of one exposure both in sea and cloud, and is absolutely untouched, and here any and all art ends in making a seascape or landscape photograph. The enlarged negative is simply a mechanical copy of this, to produce a thousand of which means nothing more than cash, with very little skill and not an atom of art. The picture exhibited by me at Gloucester was a 36 by 28 platinotype from such a negative, printed and in all respects finished by my hands alone. Taking the making of this picture, therefore, from the point of choosing the subject up to finishing the enlarged print, where is the justice or fairness in the comparsson to a man buying a painting and showing it as his own—the deliberate act of a cheat? The "respectability of the art," including that amount represented at the Gloucester Exhibition, has not, and, I trust, never will suffer through either me or my pictures. F. H. Worsley-Benison.

*June 6th.*

MESSRS. MORGAN AND KIDD'S WORKS, RICHMOND.

Sir,—We notice a slight error has crept into your otherwise accurate and admirable article on our works, in your issue of May 15th. Describing our method of making a bromide enlargement, and speaking of the operations after development, you say, "The picture has now a rinsing of very dilute acetic acid, and is immediately placed in the hypo bath." This is, of course, not correct. After rinsing with the acetic acid solution, it is very necessary to sluice the print well under the tap to get rid of the acid before it is passed into the hypo bath. Washing is *not* desirable between development and the acid bath, but *is very necessary* between the acid bath and the hypo bath.

The inaccuracy is slight but important, and as it may mislead some of our friends, if you can spare us space to make this correction, please do so. Morgan and Kidd.

*Kew Foot Road, Richmond, S.W., June 8th.*

## Proceedings of Societies.

The Photographic Society of Great Britain.

At the meeting of this Society held on the 9th inst., the chair was taken by Mr. James Glaisher, F.R.S., president.

Capt. Abney read a paper on "An Undiscussed Point in Dark Room Illumination." He commenced by saying that it might be thought that there was nothing further to say on the subject of dark room illumiuation, and that the subject had been thoroughly threshed out a few years since. He had recently, however, made some experiments which threw some light upou the reason for the comparative safety of rays removed from the red region. He had formerly expressed his opinion (which he still held) that dark orange was better than ruby, which was at that time mostly employed. Then came the advocates of canary medium, and Mr. Debenham had employed a light in which green took part. Some time since he was surprised to find, in a manufactory of dry plates, the amount of cauary light that was used with safety. In making experiments with other objects in view, he had recently met with results which very much explained the efficiency of green and yellow light when of low intensity compared with red. He had found that there was an enormous difference in the amount of light necessary when using different colours in order to produce visible illumination. Takiug rays of each colour of such a strength as to appear equal to the eye when powerful or moderately powerful, wheu they were severally reduced in amount, the proportion of visibility no longer held good at all. After diminishing, say the red, to such a quantity as to just cease to visibly illuminate a white screen, it was found that green might be reduced to about one thirty-sixth part of this amount before its illuminating power ceased. Other instances could be seen from the following amongst other tabular results that were given :—

| | |
|---|---|
| Red ... ... ... ... ... ... | 3,500 |
| Orange... ... ... ... ... ... | 1,000 |
| Yellow ... ... ... ... ... ... | 600 |
| Green ... ... ... ... ... ... | 105 |
| Blue ... ... ... ... ... ... | 5 |
| Violet ... ... ... ... ... ... | 20 |

That is to say, that whilst 3,500 uuits of red light were required to make an object visible, 1,000 of orange, 600 of yellow, &c., sufficed for the same purpose. Another table, showing the illuminating power of mediums in actual use for dark room purposes, read as follows :—

| | |
|---|---|
| Ruby ... .. ... ... ... | 40 feet |
| Stained red ... ... ... ... | 120 ,, |
| Canary medium ... ... ... ... | 220 ,, |
| Orange paper ... ... ... ... | 180 ,, |

The second column showing the distance to which a screen might be moved from the source of illumination before becoming invisible when the several mediums were employed. These results explained pretty evidently why, when canary medium was used, the corners of the dark room were so much better illuminated than when ruby light was employed. The question was one of physiology, and it had before been recognised that the rays of the more refrangible end of the spectrum affected the sensitive nerves when much more diluted than those of the red region, but he did not think that there had been any idea that the difference in this respect was so great as he had found it to be. The difference amounts to a proportiou for certain rays of from 700 to 7,000 to 1. If pure green light could be used, that would be best; but the light transmitted by any of the mediums in use was far from pure, and the results, therefore, were only approximately true with regard to the proportionate sensitiveness of the eye to pure rays. A point to be noted was that wheu light of any colour became faint, it appeared to be white. With various colours, however, the value of this effect was very different. With red, the effect of whiteness only came in just as the light was on the verge of disappearing, whilst with green, the light appeared white some time before being extinguished.

An apparatus for measuring the amount to which a light of given colour might be reduced before ceasing to give visible illumination, was shown and explained, and the effect examined and noted by the President, by Mr. Spiller, and by Mr. Debenham. With all three observers, the green disappeared at about the same point, which, upon measurement, was found to be when it was reduced to about a thirty-sixth of the intensity that had been found necessary for red.

Mr. J. Spiller asked whether, in view of these experiments, it was not a mistake to use—as was done—green for a safety, and red for a danger signal? The danger was what it was important to see when feebly visible, as at the greater distance, and it now seemed that green fulfilled this requirement so much more than red, and should therefore rather be the colour to indicate danger.

Capt. Abney replied that the question of signal lights was very different from that of the illumination of the dark room. Brightness and illumination were not the same thing.

Mr. Debenham added that signals were especially required in foggy weather, and red had the power of penetrating through fog particles much more thau the colours of the other parts of the spectrum.

Capt. Abney confirmed this view, and continued that the great danger with green was, that it appeared white when seen through a fog. Green was much more scattered by fog particles thau was red.

Mr. Cowan asked Capt. Abney whether there was any foundation for the statement so often put forward, that the proportionate intensity of a uegative was altered according to the amount of light used to print or enlarge with it.

Capt. Abney replied that the eye and the photographic plate were by no means the same thing, and physiological causes affected the one and not the other. So far as his experience went, he would say that the effect he had referred to had nothing in character with that on the photographic plate. Within usual limits, he would say that there was no alteration on the effect of the intensity of a negative by alteration of the strength of the light. When they went to extremes—say a difference of from a few seconds in one case to four hours in the other—he thought there was a slight difference, but so slight as not to be discoverable without special means of observation.

Mr. Spiller mentioned that some eighteen months since he had taken a dose of santonine as an experiment, and found that everything appeared green in colour. Was that due to any colouration of the vitreous humour? He would add a caution to others not to repeat the experiment on account of the effect on the nerves.

Capt. Abney said that there was no colouration from santonine, but a paralysis of the violet-sensitive nerves, causing a certain amount of colour-blindness. Colour-blindness was also produced by excessive use of tobacco, particularly by such tobacco as cavendish, and, from his recent experiences in making examinations, he should say that tobacco colour-blindness was much more common, at all events, in some parts of England, than congenital colour-blindness.

Mr. Chapman Jones said that as a practical detail he would mention that the yellow fabric now manufactured was not of the same colour as that first sent out, but was more orange, and, in his estimation, far inferior. He mentioned this in the hope that the attention of the manufacturers would be directed to the subject, and that they would reproduce the original colour.

Mr. Debenham felt grateful to Capt. Abney for the research which had led to the explanation of the cause of the safety of illumination from the yellow and greenish yellow region. The physiological question was one of essential importance in the enquiry.

The President said that the subject of dark room illumination was one in which he had always taken great interest. He thanked Captain Abney for the paper. He read a communication from Mr. Leon Warnerke, who had arranged to read a paper ou "A New Sensitometer," but was prevented by an attack of influenza from leaving the house. The sympathy of the president and of the members having been expressed, the president vacated the chair, which was taken for the remainder of the evening by Mr. J. Spiller, vice-president.

A letter from M. Leon Vidal was read with regard to the recent discussion on polychromatic impressions. He said that it had been stated by Albert and others that polychromatic impressions could be produced by photography by using plates made with colour screens, and without masking or retouching parts of them. He did not doubt this, but the question was, were such impressions identical with the originals? He believed not, but if proofs that they were so could be produced, he should be pleased to examine them. He also sent specimens of various separate colour impressions to form an image, and explained that several plates would be necessary, and that three would not suffice. In the one sent, ultramarine was used as the blue, but the colour, although suitable for the dress, was not so when used with yellow to form green for the grass. If, on the other hand, Prussian blue was used, the grass would be right, but not the dress.

Mr. Debenham thought that where colours were used as separate plates to form other colours by mixture, these colours should be transparent. Ultramarine, as an opaque colour, would not make a good green, but Prussian blue, on the other hand, should be more suitable all round.

Capt. Abney said that opaque colours produced muddy mixtures by reflecting some white light along with that which belonged to them, and which they received from adjacent particles of the other colours with which they were mixed. As to polychromatic impressions generally, if they were to resemble such abortions as the landscapes hanging on the walls, we should be better without them. There were, however, others—some figure subjects particularly—which were remarkably fine. On the subject of colour, he called attention to a criticism by Dr. Phipson, in the *Moniteur de la Photographie*, on a recent lecture by Mr. Debenham. In the criticism, Dr. Phipson charged him (Capt. Abney) with putting forward as something new an old theory of colour belonging to the beginning of the century. There was not the slightest foundation for such a charge, and, with regard to other remarks by Dr. Phipson, he could only be surprised that anyone should venture to put them forth.

A lamp for developing purposes was received from Messrs. Benham, as well as contributions to the library from Messrs. Vanner, Sheppard, Cembrano, and Warnerke, and the thanks of the meeting recorded.

Messrs. D. R. Charrington, T. W. Harrold, and J. Howson were elected members. It was announced that on the 23rd inst. there will be a discussion upon orthochromatic photography.

### Camera Club.

On June 4th, Mr. Maskell read a paper re-opening a discussion on the matters treated in Mr. Pennell's paper ("Photography as a Hindrance and Help to Art") read at the late conference. Capt. Abney occupied the chair. Mr. Penuell himself attended.

After Mr. Maskell's paper, one by Mr. A. Burchett was read, and a very keen discussion followed, in which the Rev. F. C. Lambert, Messrs. F. E. Barber, Pringle, England, Willis, J. S. Whatton, Davison, Teasdale, Hinton, and Major Nott, Rev. A. B. W. Whatton, Dr. Patterson, and the Chairman took part.

Mr. Pennell replied, and the meeting broke up after a vote of thanks to Mr. Pennell aud Mr. Maskell.

### Holborn Camera Club.

At last Friday's meeting, Mr. E. H. Bayston in the chair, Mr. Herbert Thompson read a paper on an "Ideal Hand-Camera," offering suggestions which the writer thought would be improvements on some of the hand-cameras at present in the market, especially in regard to the finder, the lens, and the shutter. Au interesting discussion followed, chiefly on the use of hand-cameras, in which Messrs. Bayston, Golding, Luxton, Benest, and Raphael took part.

Mr. J. Bush was elected a member of the Club.

### Brixton and Clapham Camera Club.

A meeting of the Club was held on June 4th, Dr. Reynolds, vice-president, in the chair.

Mr. W. H. Powell gave au interesting paper on "Hand-Camera Work," and explained the use of several hand-cameras, amongst others, Messrs. Marion's "The Radial," aud Mr, Cusworth's "Repeater," which had been lent by their respective makers.

Mr. J. A. Butler, one of the members, also exhibited an excellent one made by himself, which attracted considerable attention.

### Putney Amateur Photographic Society.

*June 3rd.*—The first monthly summer meeting for the election of new members and discussion of subjects of interest was held, with the Rev. L. Macdona in the chair.

The following were elected as members: Messrs. Brothers, Handcock, Searle, Trengrouse, and Miss Parsons. Dr. Sheppard was elected to fill the vacancy on the Council caused by the resignation of Mr. Manifold.

Next excursion, Saturday, 13th inst., to Burnham Beeches.

### North Middlesex Photographic Society.

On the 6th inst. a few of the members took part in the field-day to West Hampstead, a district where furze, heath, fern, and broken sandy ground afford variety to the foreground, while middle distance and far-extending vistas meet the photographer from every point of view.

On Monday, the 8th inst., Mr. H. Walker in the chair, Mr. J. Traill Taylor addressed the Society on "Faults in the Composition of Photographs." Mr. Taylor dwelt upon the faults to which the photographer is most prone, showing numerous prints illustrating his points, aud showing how, by reducing the expanse of uninteresting foregrouud, many an unsatisfactory view might be transformed into a picture. He pointed out that repeated straight lines and geometrical arrangements were wearisome to the eye. Dealing with the division of land and sky, he showed that while, as a rule, the horizon should be below the centre, that this was an arrangement largely affected by the composition of the picture generally. Touching upon portraiture, the lecturer dealt with the arrangement of single figures and groups, advising his hearers not to yield to the pressure of their lady friends to make the details of the dresses the principal attraction, but to throw central interest upon the face.

Prints from views taken by the members at Hale End were passed round, and a vote taken as to merit.

Three members were elected, and two nominated.

On Monday, the 22nd inst., Mr. F. L. Pither will read a paper on "Art in Landscape." Visitors welcome.

RICHMOND CAMERA CLUB.

At the meeting on the 5th inst., Mr. CEMBRANO presided.

A demonstration of toning celerotype paper was given by Mr. Blackie, of the Blackfriars Sensitising Company, who also showed some fine finished prints, and distributed samples of the paper amongst the members present.

The Chairman showed some beautiful transparencies of the Alcazar of Seville, and the Alhambra.

CROYDON MICROSCOPICAL AND NATURAL HISTORY CLUB (PHOTOGRAPHIC SECTION).

*June 5th.*—Mr. J. A. CARTER, M.A., in the chair.

No paper being down for this evening, results of the past excursions were shown by the members. Mr. WEIR-BROWN exhibited some bromide enlargements toned by uranium, and mentioned, with reference to mounting prints toned in this way, that care must be taken not to damp the face of the print when mounting, as a stain is left when the print has dried, and if by chance the face of the print did get damp he used a damp (wrung out) sponge, and then the face of the print was made equally damp all over.

Mr. CARTER asked if it was necessary to always damp the prints.

Mr. WEIR-BROWN said a sizing of starch at the back of the prints would prevent moisture, when mounting, from appearing on the print.

SHEFFIELD PHOTOGRAPHIC SOCIETY.

THE monthly meeting was held at the Masonic Hall on June 2nd, Mr. B. J. TAYLOR in the chair.

After the transaction of ordinary business, the PRESIDENT gave a practical demonstration on toning and fixing gelatine chloride emulsion paper, and Mr. T. G. Hibbert demonstrated with the ordinary albumenised paper.

Mr. HIBBERT brought before the meeting an interior printed on Obernetter paper, which was admired.

LOWESTOFT AND DISTRICT PHOTOGRAPHIC SOCIETY.

*June 5th.*—Mr. W. STRINGFIELD in the chair.

The Rev. A. WELLS exhibited some interesting slides, illustrating his travels in Constantinople, Florence, and elsewhere.

Mr. ESTCOURT gave a further instalment of his stereoscopic views of Burnham Beeches, the tone and quality of which were excellent.

Mr. A. M. SMITH also produced some half-dozen slides, evincing careful work with due appreciation of the artistic.

LEWES PHOTOGRAPHIC SOCIETY.—At the Fitzroy Library, on June 2nd, Mr. E. J. Bedford gave a practical demonstration of "Development by Eikonogen." Mr. Bedford exemplified the powers of eikonogen by developing bromide paper prints, lantern plates, and also ordinary negatives, admirable results being obtained in each instance.

MESSRS. GEORGE HOUGHTON AND SONS, of Holborn, have sent us a specimen of Shenstone's patent focussing cloth clip, for which they are sole agents. This ingenious contrivance consists of a kind of metal frame, the distance between the uprights of which can be varied, while, by the action of a spring, they tend constantly to approach one another. Sewn into the hem of the focussing cloth, this frame firmly grips the camera, so that the operator can defy the most aggressive wind, and have both his hands at liberty. The attachment does not materially add to the bulk of the focussing cloth, and it is so constructed that it folds into small space. It will be found a most useful aid to outdoor work.

# Answers to Correspondents.

**All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.**

**All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.**

**Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.**

F. R. M. S. — *The Weather in May.* The rainfall for North London was rather above the average, and amounted to 2·79 inches. The low temperature and loss of sunshine were more remarkable. There were twenty rainy days, May 17th and 24th being very wet. The month compares favourably, however, with the corresponding period of 1889, when the total rainfall was 3·58 inches.

R. D. P. (Stafford).—*Dammar Varnish and Marking Ink.* Gum dammar is only partially soluble in alcohol and ether, but dissolves freely in warm turpentine, giving, however, a tacky varnish, or one that may dry too slowly for your purpose. Try pure benzol or methylated chloroform, either of which is a good solvent and dries quickly. *Marking Ink for Linen.* Eighty grains each of silver nitrate and cream of tartar are well rubbed together in a glass or Wedgwood mortar; after a short time add 5 drms. liquor ammonia, and when dissolved, mix in 60 grs. loaf sugar, and 100 grs. of powdered gum arabic, with a little sap green or indigo to colour the ink; after which add enough water to make up the bulk to exactly one ounce. Preserve in a stoppered bottle. Write with a quill pen, and develop by holding near a fire or passing over it a warm iron.

M. L.—*A Good Mountant.* Soak broken pieces of cabinet glue in a large bulk of cold water until thoroughly soddened. Pour off the top liquor, and melt the softened glue by gentle heat over a water bath; now add very gradually and with constant stirring about an equal bulk of methylated spirit, until all becomes smooth and free from clots. When cool, transfer to tightly corked bottles for use. With this mountant the prints do not cockle perceptibly on drying.

ANNE.—*Palpable Retouching.* The proof shows, even through the encaustic paste, the alteration that you complained of, which could quite well have been touched out in the negative. This can yet be done if more prints are required. What induced you to appear in a "cob-web" veil of such very pronounced fashion? Is it considered an improvement, like the patches of court-plaster worn by your maternal ancestors?

L. E. (Folkestone).—*Impure Silver.* The lump of reduced metal, which you say is quite black, is probably rendered impure by the presence of sulphur. In any case, fusion with borax and nitre will be the best way of refining it. By dissolving it up as it is in nitric acid, the amount of sulphate formed might be sufficient to forbid its use in photography.

OLD AMATEUR.—*Paper in Continuous Rolls.* Since replying to you a fortnight ago, we find that Messrs. Joynson & Sons, of St. Mary Cray, Kent, advertise the production of drawing paper in continuous lengths, which might very likely suit your purpose.

GREENLAND.—*Cryolite.* Many years ago this mineral, which is a double fluoride of aluminium and sodium, was used for the direct production of aluminium, but now its employment is restricted to its use as a flux in the purification of that metal.

PHOTOMAN (Paris).—*Abney's Collodion Emulsion.* Another formula, given in Captain Abney's "Treatise on Photography," 1888, fifth edition, p. 118, prescribes almost exactly the same ratio of zinc bromide to silver nitrate as that already reported to you, viz., 5 to 8·5.

T. M.—*Dr. Percy's Portrait.* We are told that Mr. Walter Adams, of Blagrove Street, Reading, has an excellent portrait of the late Dr. Percy, reproduced from an early Daguerreotype.

# THE PHOTOGRAPHIC NEWS.

Vol. XXXV. No. 1711.—*June* 19, 1891.

CONTENTS.

## DARK ROOM ILLUMINATION.

Captain Abney's experiments with differently coloured media for dark room illumination, as explained by him at the last meeting of the Photographic Society, and reported in our last week's issue, may be regarded as an important contribution to photographic knowledge. As he himself said, it might be thought that the subject had already been thoroughly threshed out, but he was able to show that this was not the case, and that there was really a point in dark room illumination which had not before been discussed. Captain Abney's remarks remind us that, although much has been written regarding dark room illumination, it is a subject which too many photographers pay little attention to. It is surprising that such should be the case when it is remembered how much their personal comfort depends upon suitable lighting of their room, and how much their daily work must suffer if a good light is not secured.

It has been our fortune to visit very many dark rooms belonging to both professional and amateur workers, and we have too often found that the amount of red light available is so stinted that it is a wonder that any good work can be done. In one or two flagrant cases of darkness made visible, the light has been so bad that we have no hesitation in saying that the worker would have been as well off, so far as development is concerned, if the light had been shut off altogether. In such an extreme case as this, it stands to reason that the operator must throw his developing fluid on the plate and simply leave matters to take their chance. He is, of course, aware that the exposure is approximately right, and that a developer of certain strength and composition may be trusted to bring out the image in a certain time. He is content, in fact, to leave the building up of the image to itself, and does not exercise any control over it. Under such circumstances photography becomes the mechanical thing that its enemies are so fond of calling it, and the operator reduces himself to the level of an automatic machine.

All earnest workers agree that it is during development that care is necessary if a good negative is to be expected; but this care cannot possibly be exercised as it should be unless there is sufficient light in the dark room to show the progress of the operation. And there is no reason whatever why the light should not be plentiful, so long as it is of the right quality. We admit that there is some difficulty in rendering daylight safe, and, at the same time, allowing sufficient illumination for the dark room, for the light in our climate alters to such an extent from day to day, and from hour to hour, that at one time one thickness of medium may be sufficient to protect the most sensitive film, and shortly afterwards three or four thicknesses may be necessary to secure the same result. For this reason it is, perhaps, best to depend upon artificial light, and, when possible, gas is by far the best for the purpose.

Another point in dark room illumination which is too often neglected is the position of the light with regard to the worker. Many lamps are so made that the flame is almost on a level with the table or work bench, instead of being, as it should be, some inches above that level. The light should be thrown down upon the developing dish. Another important point also sometimes lost sight of is that the actual flame of the lamp should not be seen; in other words, the medium employed should not be clear, but semi-opaque. A medium of this latter character, whether it consist of paper, textile fabric, or glass ground on one side, has the advantage of diffusing the light in such a manner that the room is better illuminated than if the flame were actually visible. Besides this obvious advantage, the gain in shielding the actual flame from the eye cannot be over-estimated.

We advocate the use of gas when it is obtainable, because, all things considered, it is the best possible illuminant for the dark room. It is clean in use, and is, perhaps, the safest form of artificial light known. It should be used with a bat's-wing burner in a lantern that should measure at least eighteen inches square. This lantern should be well ventilated, and, if possible, the burnt air should be carried outside the dark room. The supply pipe for the gas should be furnished with a tap *outside* the lantern within easy reach of the hand, for one of the greatest advantages in the use of gas is the power which one has of turning it up and down from a feeble flame to a powerful one. Everyone knows that a partially developed plate will stand without injury double the amount of red or orange light which it did when first placed in the dish. Such a lantern as we have described can have each of its sides furnished with a different medium—say deep red, orange, and yellow—so that the operator can suit his light according to the sensitiveness of the materials which he may be handling.

If, with all the precautions to which we have adverted, the operator should still have some misgivings as to the safety of the light he is using, he has still the option of protecting the developing dish with a piece of card, which should always be at hand for the purpose. It is astonishing what a flood of light can be indulged in with impunity if the operator is content to glance at his plate only now and again, and will take care that during the first part of the developing process it remains as far as possible under cover.

## THE OPTICS OF THE LANTERN.*

BY J. TRAILL TAYLOR.

From the canal boat to the White Horse is a transition not any more pronounced than is that of the lantern of half a century ago to that of the present period. *Then* a wonderful magical toy; *now* a philosophical instrument replete with huge possibilities of education, art, and amusement.

Some time since, Mr. Pringle discoursed before this Club of the lantern: its illuminants, mechanics, and applications. The duty assigned to me to-night is one of much narrower scope—its optics—and to this theme I shall confine myself as strictly as possible. Lantern optics take cognizance of the light, from its genesis at the lime or other radiator, to its ultimate destiny or termination on the screen, these termini constituting the alpha and omega, or, in optical parlance, the conjugates of such optical system as may intervene.

I shall assume the existence of the light, which, for the sake of simplicity, may be that emitted from incandescent lime. Now, as its rays radiate in every direction, the first consideration is the collecting as many of these as possible, and causing them to travel in just the direction we desire. If only a few of them—in other words, a narrow angle of illumination—be our requirement, the problem of their forward transmission is one of extreme simplicity; but if, on the other hand, the greatest possible angle of illumination be the desideratum (and of course this is the case), then does the problem become slightly more involved. We cannot here institute a comparison between the methods adopted by lighthouse engineers in utilising all their light, and those demanded by the lantern, for in the latter case it is to be employed in the formation of an optical image, whereas in the former it is merely projected into space, and both direct light from the radiant, together with that reflected from either a holophotal or a parabolic reflector, are available. But, while we cannot utilise so much of the light as in the lighthouse, we can use it to much greater advantage for our special purpose.

* A Paper read before the Camera Club.

We now require the greatest angle of light possible to be got advantageously through a condensing system, for this lies at the root of the whole matter, and in doing so have to ascertain how near can the light be approximated to the first surface with safety. From innumerable trials with lenses of a thickness not too great, and set with such a degree of looseness in the brass work as not to be cell-bound, I find that two inches may be considered as quite safe. When condensers crack, it is usually the result of their being too tightly burnished in their cells, brought too suddenly under the influence of the heat of the radiant, or being subjected to currents of cold air. I assume, of course, the perfect annealing of the glass of which they are formed. When this last point is dubious, it may be well to adopt the system employed by the Scotchwomen of a former period, who, when laying in a supply of tumblers intended for whisky toddy, invariably placed them in cold water, which was slowly brought to a boil, and then allowed to cool slowly, by which treatment immunity from subsequent breakage was believed to be ensured.

At this stage we proceed to analyse the functions of a lantern condenser—so-called. We find that these are (1st) the collecting, and (2nd) the condensing of the light. Of these the former is much the more important. What we wish done is the collection of so many rays as to form a large angle, and their projection forward is as near an approach to parallelism as possible. Absolute parallelism cannot be obtained unless the flame were a point, instead of being, as it is, a disc or patch having sensible dimensions of, say, a quarter of an inch upwards.

Some of the cheap French condensers (of which I would not speak disparagingly, for they render excellent service, and are marvels at their price) transmit an angle of light of from 40 deg. to 50 deg., and a higher class of London-made articles claim, I understand, to embrace 60 deg. But, by a slightly increased expenditure of optical means, it is possible to increase this angle to 95 deg., which, I need scarcely observe, somewhat more than doubles the intensity of the illumination. Let us see in what way this is to be accomplished.

Kepler's law, as you all know, is that the focus of a plano-convex lens equals the diameter of the sphere of convexity. This is, of course, for parallel rays, and it is those we are dealing with at present; and we are also dealing with plano-convex lenses, these being the best for condensers, subject, perhaps, to a slight hollowing of the flat surface, of which I shall soon speak. Well, it is very evident that, if we desire a large angle of light, the single Kepler won't do much for us, unless, indeed, it was made enormously thick—even hemispherical—when we would encounter two evils: first, the enormous spherical aberration consequent upon transmitting light through a bull's-eye; and secondly, the proximity of the said bull's-eye to the radiant, which not only emits light, but heat—a heat which would quickly cause our bull's-eye to see stars and stripes. How, then, is it to be accomplished? By borrowing the ideas of the microscopist. Did any of you ever hear of a microscopic objective of even the most distant pretensions to wide-angle being composed of one lens? Can you conceive of such a thing? Well, no more is it possible in our collecting system, which is analogous. We must have at least two lenses for our purpose. One of them—that nearest to the light—must be 4½in. in diameter in order to catch up the 95 deg. of which I spoke. But this cannot render the rays parallel;

still, it transmits them to its colleague under such circumstances that *it* does so, the two lenses thus doing what no one singly could effect.

[The lecturer here submitted drawings made to scale, and transferred them to the black-board.]

The first lens of the collecting system is comparatively thin, which, apart from any optical advantage, is useful in this respect, that it has to bear the first impact of the heat; and, as you can readily understand, this lessens the liability to fracture. It is only sixteen m.m. ($\frac{5}{8}$ in.) thick in the centre, is 8 in. to 9 in. focus, and is formed (by preference) of flint glass. The second element is 5 in. in diameter, and, the radius of curvature being rather shorter, this, combined with its greater diameter, causes it to be proportionately thicker, being twenty-eight m.m. ($1\frac{1}{16}$ in.) at its centre, and 7 in. focus. This lens, too, should be made of colourless glass. The loss of light from absorption is but little, and I anticipate an objection that might be suggested as to that from oblique incidence. This is really so little as to be unworthy of notice, but it carries with it its compensation; for it occurs most at the thinnest portions of the lens, where there is the least absorption, and thus aids in ensuring uniformity of illumination throughout the entire beam. But it may be reduced by rendering the first surface concave instead of plane, and retaining the balance of power by grinding the back surface on a tool of shorter radius. I at one time was madly in love with the meniscus form of lens for this purpose, but, incited thereto by the experience of Dr. H. Morton, and after many trials with lenses both plano and meniscus, and formed of different kinds of glass, from St. Gobian's crown to English flint, I arrived at the conclusion that the plane surface answered every purpose in an effective manner.

If the radiant were infinitesimally small, a parallel beam of a large collected angle could be transmitted with a singular degree of perfection for several yards. With a triple collecting system (that worked out by Dr. Charles Cresson, in which the first lens is a plano-convex $4\frac{1}{2}$ in. radius, the second a meniscus, respectively 30 in. and 6 in., and the third a crossed lens of 52 in. and $8\frac{3}{4}$ in. radii) I projected across my bedroom a very tiny gaslight on to the dial of a French clock, which was thus illuminated a whole season. But such extreme nicety is not required in the practical working of the optical lantern, as, owing to the magnitude of the flame, two elements answer every purpose. The two that I have described should be mounted together as closely as possible, fixed permanently in the lantern, and must always be used together, and not separate. Until a compound collecting system of this nature is tried, one can form no idea of the capabilities of the lantern for certain scientific purposes, such as polarising.

*(To be continued.)*

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—June 23rd, at 8 p.m., subject for discussion, "Orthochromatic Photography." The Rooms will be closed from July 29th to August 4th. The exhibition of photo-chromo work will remain open daily between 2 and 9 p.m., till the 30th inst.

DROPS.—The size of drops varies from various causes, of which the nature of the liquid, the size and shape of the lip of the vessel from which dropped, the extent to which the lip is moistened, and the rapidity of dropping, are the most important. This is, therefore, an uncertain mode of estimating the quantity of liquids, and should be superseded where minim measures can be had.—Quoted in *American Druggist*.

## ROYAL CORNWALL POLYTECHNIC SOCIETY.

THE fifty-ninth annual exhibition of this Society will open at Falmouth, on Tuesday, 25th August. Medals and prizes are offered in various departments, including photography, professional and amateur, photographic appliances, &c.

The following are the general regulations:—

1.—All exhibits must be forwarded so as to reach the Polytechnic Hall, Falmouth, not later than Tuesday, August 18th, after which no article will be eligible for competition, and no space can be guaranteed.

2.—All pictures and photographs must be framed; and if left at one of the following places of the Society's authorised agents on or before Tuesday, August 11th, will be conveyed from these depôts to and from the exhibition, free of charge, namely:—Messrs. Worth and Co., Cathedral Yard, Exeter; Messrs. Harris and Sons, 70, George Street, Plymouth; Messrs. J. Mitchell and Son, 15, Bedford Street, Plymouth; Messrs. Thomas Solomon and Co., King Street, Truro. (The above agents will not receive any article unless delivered to them free of conveyance and other charges.)

3.—The carriage of all other articles must be paid by the exhibitor.

4.—All cases and packages sent to the exhibition must be addressed "The Royal Cornwall Polytechnic Society, Falmouth," and must bear the name and address of the owner; the covers to be fastened with screws. The exhibitor must write on the back of each picture his name and address, its title, whether it is an original or a copy, the name of the artist, and whether he is a professional or an amateur. The works of professional artists may be sold from the gallery, through the secretary of the Society, Mr. E. Kitto, and a commission of five per cent. will be charged thereon.

5.—Exhibitors must enter all articles intended for exhibition on forms provided for that purpose by the Society, which may be obtained from the secretary, or any of the above-named authorised agents.

6.—This entry form must in all cases be returned to the secretary on or before August 8th.

7.—The Society will not be answerable for loss of or damage to any article sent to the exhibition, but every care will be used to prevent injury while in the Society's possession.

8.—After admission no article may be removed until after the close of the exhibition. [*This regulation does not apply to the photographic department for this year.*]

9.—Discretionary power is vested in the officers of the Society as to exhibiting any article sent.

10.—Board of Trade Protection is granted to all new and unpatented inventions.

The following has special reference to photography.

In all cases state whether the work is professional or amateur, and name process of production. All work sent for competition must have been executed within eighteen months of the date of this exhibition. Carte-de-visite portraits are excluded from exhibition, except when illustrating some special process or novelty.

*Professional Photographers.*—Medals are offered by the Society for meritorious productions in the following subjects:—Landscapes, portraits, composition pictures, instantaneous pictures, interiors, transparencies for window decorations, pictures by improved processes, enlargements—portraits, enlargements—landscapes. All enlargements for competition must be the work of the exhibitor,

*Amateur Photographers.*—Medals are offered by the Society for meritorious productions by amateurs in all the above named subjects except for enlargements (portraits.)

*Photographic Appliances.*—Medals are offered for improved apparatus and appliances. All exhibits in this department must be accompanied by a written explanation of their special features.

Information respecting the photographic department may be obtained from Mr. W. Brooks, Laurel Villa, Wray Park, Reigate (member of the General Committee).

## THE PHOTOGRAPHIC EXHIBITION AT THE AUSTRIAN MUSEUM.

BY JAMES VON FALKE.

It is well known that in pictures by the Chinese the near and the distant, foreground and background, are all represented equally clearly and definitely. The reason is not a want of knowledge of perspective, for the Chinese has his reason, which is seemingly quite good and plausible. He says it is a mistake, a failing in our eyes, if we do not see the distant as plainly and exactly as the near, and it is the duty of art to correct this failure—it can do so.

Until now, photography in a certain sense has had the same point of view as the Chinese. It made a trial, and found its duty to be to represent all objects, near or distant, as clearly and sharply as possible. And in this direction it certainly has attained the most wonderful perfection, in which no human eye will ever follow it. Will the eyes ever be able to see a rifle ball in its flight, the waves of air before and behind the ball, the opening and closing of the air before and behind the flying ball? The photographic machine not only sees that, but fixes it. Thus, photography has made the apparently impossible possible. It teaches us to see things we never could have seen with the naked eye. It draws for us the heavenly bodies, every leaf on the tree, every blade of grass; it counts, as it were, the hairs of our heads, and considered photographically that is very satisfactory, considered artistically very Chinese. No objection could have been taken to this had photography been satisfied to be a useful art. It is not contented with portraying everything on earth that lives or does not live, but it will make pictures, pictures in an art sense, but in the so-called Chinese manner the sun will not work.

From this artistically right feeling has arisen among photographers a new tendency, that of the "impressionists," after the nature of the "impressionists" among painters.* It is not a question of what photography can achieve in clearness and distinctness, but of what the human eye sees; it is the impression made on us which should be fixed. We see what is near more distinctly, and the remoter things gradually decrease in distinctness and finally become "verschwimmen," and then disappear; we see air intervene, surround things, soften down light and shade, and make them run into one another. It is this which photography also, if it will be an art—will produce pictures—must represent, subjective not objective truth, things not as they are in themselves, but as they are seen, especially by the artist's eye.

It is this newly-awakened contrast in photography as a graphic art which makes this exhibition of the Club of Amateur Photographers at the Austrian Museum so interesting. Doubtless it is the first time that this contrast appears so decidedly without being expected or intended. This year's international exhibition of the Club of Amateur Photographers, its second, has a purely artistic purpose. Only that was to be exhibited which is acknowledged to be artistic, picturesque, satisfactory, or excellent.

With this intent was formed a jury of artists, painters, and sculptors, who would probably regard the photographs differently from what photographers would. The purely technical was not taken into consideration; all that the artist-eye recognised as artistic was retained. Photography had to prove itself an independent art, as much a means of art as are all colours, indian ink, water-colours, brush, and pencil; but also the photographer had to prove himself to be an artist; and both proofs have been brought. It is true that of the 4,000 photographs sent in, only 600 were hung. The rest fell victims to the eye and judgment of the artist-jury; but, indeed, these 600 afford the purest and finest artistic enjoyment; too fine, perhaps, to make the exhibition popular, as it deserves to be.

Among the 600 photographs, landscape greatly predominates; and again, among the landscapes, English ones. In the second place, come the genre pictures, mostly in connection with landscape scenery; in the third place, portraits. The heroic and historical picture is, of course, absent, for the present, and its history does not present it to the photographer, and he cannot himself compose such a historical picture—say, of a battle. It would be necessary to direct him to an agitated sitting of parliament, such as does happen now-a-days; but it would be somewhat tedious to stand with the apparatus, and wait for such a dramatic moment, like the Englishman who travelled about with a lion-tamer, waiting for the moment when the lion should seize the tamer's head in its jaws; but even in the life of a legislative assembly, such precious moments are not all too numerous.

But landscape is present to the photographer everywhere, and stands still for him; yet he must know how to catch nature, and must have an eye for art; and indeed, these amateur photographers, ladies and gentlemen of the finest breeding, partly from the most elegant circles of human society, have understood how to catch nature, both in her familiarity and her grandeur. As exhibitors *hors de concours*, we find the patroness of the Exhibition, H.I. and R.H. the Archduchess Maria Theresa, then the Princess of Wales, H.I. and R.H. the Grand Duke Ferdinand of Tuscany, H.H. Prince Henry of Bourbon, Count of Bardi, among those who submitted themselves to the judgment of the jury. Prince Henry Liechstenstein, Count Wilezek, Count Charles Brandis, Charles Chotek, and others; further, three members of the Rothschild family, the Albert and Nathan (of Vienna), the Baroness Adolphe Rothschild (of Paris), Prince Antonio Ruffo, the Countess Loredana da Porto, and others. Numerous and distinguished are the names of those who have sent from afar, from France, America, Italy, Russia, and those from England so numerous that the Exhibition may almost be regarded as an English one.

The best landscapes have come from England, and it is the English amateurs in particular that have started the now fashionable school of impressionists who are most brilliantly represented at our exhibition. There are George Davison, of London; J. Gale, of London; Pattison Gibson, of Hexham; and Horsley Hinton, of London; Robinson, of Tunbridge Wells; Frederick Thurston, of Luton, &c., before all of whom we must reckon W. Clement Williams, of Halifax, with his sea-pictures. That which characterises them all is the picturesque reproduction of nature, which does not consist in their individual

* The word "impressionism," so much used in these days, literally means the reproduction of the impression made on the artist's eye. It may, however, have two meanings. Firstly, the common one, the one understood in artistic circles, namely, the dissolving and indefiniteness of the forms and tones, as, for example, a landscape appears to the eye with its foreground and background. Secondly, we may and must understand by it the impression which a landscape produces on the spectator's eye by virtue of its inherent character, and not by one put into it. The reproduction, or "stimmung," as it is generally called in German, also is "impressionism." That nature really possesses such feeling or "stimmung" is proved by photography, which reproduces it most expressively, for photography cannot first put it into nature, as certainly the artist can. In this latter sense it is used throughout this article.

choice and conception of the subject, but in the reproduction with the indistinctness of the human eye, in perspective with the fading and vanishing in the dim distance, with the impressions and humours which lowering or flying clouds, lights and shadows, sunshine and moonlight, morning and evening, mist or a clear sky, make on or produce in us.

It is astonishing with what perfection all this is shown by means of the simple gradation of the tones. A photograph as, *e.g.*, "A Misty Morning," by Thurston, is an admirable picture in itself, quite apart from its technique. Just so the wonderful blue sea pictures by Williams, with the hurrying storm-clouds and the light flashing on the water. There are three of them — "Sturmvolken" ("Storm Clouds"), "Mondnacht auf der See" ("Moonlight Night at Sea"), "In Stiller Nacht" ("The Dead of Night") —which are among the most beautiful things in the exhibition, and probably, too, the most beautiful that photography has yet achieved. Here, in one moment, photography seized and detailed all the details, but all the details—the moving waves, the flashing light—are so subordinated to the general effect that the whole makes an impression as though it were a perfect painting made with deliberate intention. In general, the sea seems to have become a favourite subject with the "impressionists" in England, even in its most agitated and disturbed moments. The rising tide, the water slowly and calmly ebbing from the strand, spray dashing against the rocks, waves rolling one over the other in the surf, all of them motions to be reproduced only by the instantaneous pictures, here they are represented true to nature and with artistic feeling. Other amateurs prefer taking the peaceful quiet of English landscape, the beautiful scenery of the parks, the trees hanging over the brooks, the cornfields on the undulating ground, the comfortable settlements by the wood, the whole charming sweetness of the English landscape, which, under the changing moods of the day, from dawn of day till dark of night, offers so much diversity. And all this usually takes place with characteristic natural figures not placed on purpose, so that here only instantaneous pictures were allowable. How beautiful in this respect is the picture by Thurston, "Changing Pastures," a flock of sheep coming towards us through a wood; or the two others, "Trespassers" and "Our Village." A masterpiece of another sort, by the same master, is "Frosted Trees," *i.e.*, a wood covered with hoar-frost.

In such pictures the English undeniably stand first, but in regard to sharpness many compete with them. Thus, there are altogether excellent strand pictures by Dreesen, of Flensburg, who understands how to represent ship-life in harbour, the sea itself in motion and like a mirror, together with all human scenery. But here the landscape passes over into the genre picture, and that is a second department in which these amateur photographers have earned laurels. There is much in the exhibition uniting landscape and figures, *e. g.*, country people in the fields, herds of cows, or flocks of sheep at pasture, village scenes, fishing scenes, groups of children lying down in the open air, scenes from military life, and many other things almost all demanding only instantaneous exposure, and just for that reason because only the fleeting, unconscious moment is fixed, they appeal to us with the truth of nature in contradistinction to a "posed" picture. Even this "posed" genre picture may have its charms under certain circumstances, as in the two Weidenhof Ninetta pictures, by Baron Adolphus Rothschild, which seem as though the idea were borrowed from Eugen Blaas' well-known pictures. From this point of view of designedness, or rather of avoiding design, genre photographers have had a more difficult task than landscape photographers, or those who have understood how to harmoniously unite landscape and figures. Certainly it is more difficult, in placing the figures, not to allow the intention to be noticed, and at the same time to preserve the naturalness of the motive or the group, and at the same time to give the picture the charm of right gradation, or the opposition of light and shade to make, as it were, a Dutch picture of common life out of photography not only of merely photographic value, but of purely artistic value. In this respect, mention must be made of all of the Countess Loredana da Porto's works. The jury did not do wrong in accepting from this lady alone eighteen photographs, all of the character of genre pictures.

But a yet more difficult task was that of the portrait takers. Here amateurs are in full competition with professionals, who, in this department, perhaps, achieve their best, but also in respect to the purely artistic side, sometimes their worst. Making the picture, or rather the portrait, a perfect likeness and a perfect photograph is the least part of the work that the professional does with ease and certainty. But here the photograph must be raised to a work of art, and the portrait to a painting; the original must be represented in the simple, grand style of the old masters, with the omission of all photographic prettiness. That has been attempted in different ways, and often accomplished, sometimes as a study, sometimes a real portrait. The portrait studies of Prince Antonio Ruffo charm us like portraits in Rembrandt's manner, like Ribera or Caravaggio.

Very beautiful, but somewhat in the far-fetched French manner, are the portraits and figure studies by Edgar de Saint Senoch, of Paris, but quite perfect as a picture and a man is the portrait of Professor Stuart Blackie by R. Faulkner, of London. To these we would add an exceedingly fine lad's portrait in profile by Mrs. Susan Hodgson, and the portrait of Arthur Chevalier de Bourchelt.

In truth we had many others to name, not only as portraits and figure studies, but also genre pictures and landscapes; nay, if we would be just, one would have to copy the whole catalogue, so good is everything the exhibition contains. It affords high enjoyment to the finest and most select taste, presenting a multitude of things interesting to him who is to some extent acquainted with the movement and progress of photography. In this last respect I would now point only to the diapositives, to the pictures in sunlight, and to those on rough water-colour paper, although the technical manner of the English impressionists is still unknown, or at least not clearly known to our photographers.

## CLAM-CHOWDER.*

BY W. WILLIS.

Clam-Chowder is an American dish for which Coney Island is very famous. It is now about ten years since it was my privilege to taste this delicacy, but unfortunately I have forgotten the exact formula. Suffice it to say that although the bivalve clam is the most important ingredient, yet there are many others, and fortunately so, for in this variety lies my safety. It ought to be already evident that "Chowder" is not my theme to-night, and if anyone

* A paper read before the Camera Club.

objects to what he thinks to be a deceptive title, let him visit at least a part of his spleen upon the head of our secretary, for it was in a fit of desperation caused by a telegram from him to "give title or life," that an evil spirit suggested "Clam-Chowder." I thought that under the cover of so multifarious a dish I could introduce anything which might suggest itself.

At a meeting of the Photographic Society of Great Britain, I made some remarks on developing baths for platinotype, and on the influence of temperature and dilution. These remarks form a fitting introduction to what I am to illustrate to-night. The printed scales referred to in that paper I now exhibit, but they are of very little help unless closely studied.

Now, I thought that by exhibiting a series of prints from ordinary negatives, the chief effects of certain variations in development might be readily displayed. I have here several distinct series of prints. Every print of a series is made from the same negative, printed on the same day with paper from the same batch, the difference between the prints being only in the matter of development.

The prints shown illustrate some of the variations to be obtained by cold development of hot-bath paper. The same temperature was used throughout the experiments—namely, 60 deg. Fahr.—and the developing baths were as follows:—

Normal oxalate solution, 1 lb. oxalate of potash dissolved in 54 oz. water.

Strong D solution (a mixture of potassic oxalate and phosphate), 1 lb. of the mixed salts dissolved in 54 oz. water.

Normal D solution, ½ lb. of the mixed salts dissolved in 50 oz. water.

The results obtained may be tabulated thus:—

| | |
|---|---|
| Normal oxalate at 60 deg. Fahr. | Gives a quicker development than either of the D solutions. And stronger middle tones. |
| Strong D solution at 60 deg. Fahr. Normal D solution at 60 deg. Fahr. | These baths give a slower development than the normal oxalate. And less strength in the middle tones. With the normal D solution the scale is slightly shortened. |

If these developers be acidified with oxalic acid the results are different, thus:—

| | |
|---|---|
| Normal oxalate acidified by $C_2H_2O_4$. Temp. 60 deg. Fahr. | Development much slower. The image weaker both in shadow and middle tones. |
| Strong D solution acidified by $C_2H_2O_4$. At 60 deg. Fahr. | The image very slightly weaker. |
| Normal D solution acidified by $C_2H_2O_4$. Temp. 60 deg. Fahr. | Shadows not reduced in strength, but the scale shortened. Hence a good developer for very weak and flat negatives. |

The principal difference between hot and cold development of hot-bath paper is seen in the middle tones of the picture. These middle tones in cold-bath developments are generally much reduced in strength. The other differences are slight, but the shadows are given with rather less vigour by the cold method. In length of scale the hot method has usually a little advantage.

If I am asked which of the developers referred to is the best for cold development, I think, upon the whole, one of the D solutions (but not acidified, unless for special effects). These solutions have less tendency to produce a granulated effect in the prints than a plain oxalate bath. In certain cases, however, especially in large work, granulation is decidedly advantageous in helping to give transparency, and therefore a plain oxalate bath would be more suitable.

In using cool baths it is necessary to print more deeply than for hot development, frequently until the deep shadows are solarised; and a much longer development is necessary. The progress of development should be watched and arrested at the right moment. As a general rule, paper which is two or three weeks old will give better results than fresh. And it is often useful to spread the prints at the bottom of a drawer or in a cupboard for a few hours before developing them. A caution against handling the sensitised surface is very necessary, for in cold development finger-marks and other injuries are very readily brought to light.

In working with baths at low temperatures a few degrees increase or decrease will make very distinct differences in the results obtained; much more marked than with baths at higher temperatures.

To-night I have illustrated only those variations due to a reduction of temperature, but many others may be made; for instance, dilution of the developer, introduction of restrainers, such as potassic chloride, &c.

At the meeting of the Photographic Society of Great Britain I showed some prints on wood, and yesterday I made a few more which I thought might be interesting. I will hand them round. Here is one more beautiful than any print on paper from the same negative; the transparency in the shadows is very wonderful. It was treated after it was dry with starch sizing, and afterwards with a little varnish. Here is a reminiscence of one of our excursions without any after-treatment. I don't really know how to treat the wood after printing. These are merely experiments, but I think wood might be made useful for decorative purposes, but proper subjects should be selected for the purpose; either plain dark or light backgrounds and simple subjects; copies of Japanese embroidery make very good pictures, which might be used for the panels of doors. There are certain difficulties in working with wood; it must be printed by the cold-bath process, as it is almost impossible to obtain first-rate results by the hot process. I should be very glad to receive hints as to the treatment of the wood afterwards. My best results have been obtained by the use of starch sizing and the rubbing in of a small quantity of boiled linseed oil. I have used American holly, which is very beautiful wood. Sycamore is no good for the purpose. Pine I have not tried. Most of the examples shown are on chestnut.

Discussion.

Mr. Maskell: I want to ask how long one may keep an oxalate bath (hot process), and what is the best practical method of restoring it to its normal condition. Is there any method of testing its specific gravity, for instance?

Mr. Willis: I think the bath may be kept for ever. The best method is to return the solution to a bottle after use, and replenish the bottle with fresh solution before using again. I never throw away a bath.

Mr. Davison: I have part of the same bath that I commenced with. When required, I simply put a few ounces of fresh solution to it before using it.

A Member: I would like to ask how long it is safe to keep the paper before using it?

Mr. Willis: I have seen excellent prints made on paper eighteen months old, and which had been round the world. I have seen paper two years old which was in very fair condition. I had some paper developed which was six years old, but the whites were degraded. I think you may say the life of the paper now is at least six months, and that it is as good then as on the day it is made. I am speaking of the A or thin paper. The B paper does not keep so long, but I have never used B paper sufficiently old to ascertain.

Rev. F. C. Lambert: Do your remarks apply to sepia paper?

Mr. Willis: I think sepia paper keeps if anything better than the other. I have seen some four or five months old in splendid condition; but it is a very uncertain paper. It is the most difficult to make, and the most delicate. I have never seen two batches alike yet; it always varies.

Mr. Maskell: I have found that with the extra rough surface paper I have had to print one tint deeper than with the C surface.

Rev. F. C. Lambert: It must require longer printing, because you get reflected light in the shadows.

Mr. Davison: That is so, and that is, perhaps, why it is suited to harsher negatives than the smooth paper. In my experience, sepia paper allows you to do almost what you like with it. I think it stands the damp very well. I have had prints left in the frame in the winter for three months, so that they have printed out, and I have got prints which satisfied me perfectly.

Mr. Willis: Taking the general experience, sepia is uncertain, and it certainly is so in the making. It varies in depth and colour, and is most difficult to control.

Mr. Davison: So much the better. We don't want our processes all cut and dried for us. I am sorry more is not made and used.

Mr. Willis: It is a very fine paper, and I hope some day to master these difficulties.

Rev. F. C. Lambert: You recommended the addition of oxalic acid to the bath for sepia paper; do you still do so?

Mr. Willis: Certainly. My experience recommends it, as does that of two or three of our most experienced workers.

Mr. Davison: Have you made any experiments as to the varying of colour more widely?

Mr. Willis: It is possible to get sepia very hot indeed, but it is then more difficult to manufacture, and requires greater care in handling. It is possible, in respect of colour, to obtain a range extending from blue-black to a hot sepia.

Mr. Davison: The effect of the special solution seems to be to cool the colour, and I do not think it improves it.

Mr. Willis: I much prefer the use of a very acid oxalate bath. I think this bath diluted with two parts of water, and used at 150 degrees Fahr., is very useful.

Mr. Davison: By variation of the treatment of the paper there is no doubt you can get a brown-black, or proper brown, or purple-brown, the latter by the addition of a suitable—that is, a very small—quantity of mercuric chloride.

Mr. Willis: Plain water will almost develop the sepia paper. You can develop it very cold, very hot, or very strong, and you can get corresponding variations in your print. To get the hottest tone the bath should be used at not less than 150 degrees Fahr., and acid.

Mr. Maskell: What is the effect of a considerable increase of the acid? I use two ounces. What would be the effect of doubling it?

Mr. Willis: I don't think you could double it; the binoxalate would be precipitated.

Rev. F. C. Lambert: Are we to have sepia in continuous rolls in time?

Mr. Willis: I hope so, if it can once be made by machinery. I think I can see my way to the machinery now, though I have tried several times and not succeeded.

Mr. Elder: The more I work at the paper the more interesting it becomes. There are so many conditions to be considered, and I have been playing with them a little lately. I have been considering what is the best course to pursue with a soot and whitewash negative, and I came to the conclusion, which Mr. Willis confirms, that the cold and perhaps diluted developer seems to give the best results. But there are so many problems I fear I shall never get a grasp of them all. I think I have learnt more from Mr. Willis's remarks than in the same space of time ever before on the subject. Mr. Willis, on the last occasion, referred to the great possibilities in regard to colour even with the ordinary paper. One does not want for ordinary work, as a rule, these rich, warm colours, but it seems to me that a great deal can be done by leaving the prints a longer or shorter time before developing on the hot bath, and even by damping them. I have damped them in the steam of the bath before developing them. Here are two prints, one of which was damped before developing, and its colour is decidedly warmer than the other.

Mr. Willis: The methods I have dealt with to-night are suited to what are called flat negatives. I intended to have said something about the method for use with very strong negatives. That is more a question of the manufacture of the paper than of anything else. Here is a print developed on a bath composed of 5 parts of oxalate solution, 1 part citric or oxalic acid, ¼ part of 20 per cent. solution of KCl. The print would have been absolutely black if developed in the ordinary way. It is extraordinary how you can make the tone warmer by keeping the print a few hours before development. Another method was to dilute the oxalate developer.

Mr. Elder: In the paper of eight or ten years ago, one wanted a negative of almost soot and whitewash character, but I now find great difficulty in getting a pleasing gradation with such a negative. In this print, however, a diluted bath and low temperature seems to have brought out almost enough detail in the hull of the vessel.

Mr. Davison: What do you say are the conditions in which the warmest sepia colours are obtained?

Mr. Willis: They would not be under the control of the printer.

Mr. Davison: The paper would have to be prepared for it?

Mr. Willis: Yes.

Mr. Lyonel Clark: I should like to have the point cleared up as to the best method of dealing with a hard negative. My own experience agrees with that of Mr. Elder, that a cold developer will give the longest range. My baths were used strongly alkaline, and not acid, like those of Mr. Willis. I used a strong developer at a low temperature. For weak negatives I should print lightly, and use a very hot bath.

Mr. Willis: If you want to make the best of a hard negative, don't use paper too fresh, and don't develop too soon after printing, but first put the print in a drawer for a few hours. One of the best ways to reduce the shadows is to make the bath slightly acid, and then add a little, but not too much, KCl.

Dr. Patterson: I have a sample of the paper showing, to some extent, its keeping qualities. It is the remains of a tube bought in November, and it has since been travelling across the Atlantic open. It was printed two weeks ago, and kept in a drawer for some time. It is not quite so sensitive as fresh paper, and it was quite wet when I picked it out.

Rev. F. C. Lambert: My experience of hard negatives is contrary to Mr. Elder's. The best results I obtained by printing rather deeply, using a saturated solution of oxalate of rather higher temperature than usual, and allowing the print to barely touch the surface of the liquid, and put into the acid bath immediately.

The Chairman: Mr. Willis suggested the dilution of the oxalate solution to me, and I tried some, one part of the solution to five parts of water, printing very deeply, and I got some very good results, but I found that the paper varied. Some batches produced very granular prints. Mr. Willis said the experiment was a very rash one, and he wondered that I got the results that I did. I gave up the experiment, and have gone in for the cold process. I should have brought some specimens had I known what the paper was to be about. I am sure platinotype workers will have been very interested, and that we shall accord a hearty vote of thanks to Mr. Willis for his paper.

A vote of thanks was carried by acclamation.

---

The article on page 444, by Herr von Falke, was kindly forwarded by the Vienna Club of Amateur Photographers.

## Notes.

Mrs. Drew, Mr. Gladstone's daughter, resents the idea that Mr. Hamilton's portrait of the veteran statesman in the Academy was painted from a photograph. The *Athenæum* ventured to say that "probably photographs were freely used." Mrs. Drew says the "portrait is entirely original, no photograph of Mr. Gladstone ever having been taken in that attitude." This may be; but it does not disperse the assumption that photographs may have been used. No painter would deliberately copy a photograph either in attitude or expression, but would not disdain to use a photograph for purposes of accuracy. We do not, of course, say this was the case with Mr. Hamilton's picture.

Photography can be tacked on to almost any trade or profession. The latest combination is that of photography and monumental masonry, and is mentioned by the *Undertakers' Journal.* It is obvious that the two go very well together. Most people, having fulfilled the last duty to their relatives and friends, like to have a photograph of the tombstone, and the monumental mason who can handle the camera reaps the benefit. This opens up a new channel of competition with the professional photographer, who is beginning really to be pressed hard on all sides.

One of the smaller City Company halls, the Coachmakers' Hall, in Noble Street, has been open to the public this week for the exhibition of competitive designs in carriage building. The designs are of no special interest to photographers, but we allude to the subject because of the collection of photographs which hang on the staircase walls. These photographs are perhaps over a hundred in number, and are partly copies of engravings and partly taken from the objects—vehicles of various kinds, ages, and nationalities—themselves. As exemplifying the history of coach building, the photographs are instructive and valuable, and for this reason it is a pity that nearly every one is in process of fading, beginning with the faint, sickly yellow which photographers know so well, and ending with the speckled blotches which denote the last stage of decay. What is to be seen at the Coachmakers' Hall is, we fear, to be found elsewhere. Unless steps are taken to have photographs printed by some permanent process, many pictures of real historical interest must be lost to the next generation. We are afraid that curators are not sufficiently alive to this fact.

Much speculation has been afloat as to why the thief who lately robbed some chambers in the Temple carried off a photograph of Mr. Justice Hawkins. It has been suggested that as the robbery was very slight, the discovery of the features of his lordship, who is rather a terror to evil-doers, effectually stopped the thief from proceeding further in his depredations. On the other hand, it may be that the burglar was an old offender, and carried off the photograph as a memento of his interviews with the learned judge at the Old Bailey. A third supposition is that thieves are developing a taste for photography, and, having begun with purloining the photographs of judges, will end by "taking" the detectives with secret cameras. It would be rather a serious thing if photographs of detectives were systematically distributed among the thieving fraternity.

Some of the principal free libraries are developing energies in directions other than books. The free library committee of Leeds, for instance, has determined to hold a photographic exhibition. There is no reason why this example should not be followed. Local photographic exhibitions would certainly not only spread a taste for the art, but encourage the modest amateur. There are hosts of photographers doing good work who would not mind contributing to a small exhibition, but who would hesitate before sending their pictures to exhibitions open to the world.

There is no department in the army which is not governed, to a more or less extent, by red tape. The latest example is in connection with photography. A short time ago an officer wished his company in the Wellington Barracks to be photographed. There was no difficulty in obtaining the permission of the commanding officer, but this permission was subject to the approval of the authorities at the War Office. The War Office, as most people who have had anything to do with it know, cannot transact the most trifling matter of business without voluminous correspondence, and it was only after about twenty letters, containing all kinds of official questions and answers thereto, had passed that the momentous matter was settled, and the consent of the War Office graciously granted.

The number of periodical photographic publications continues to increase. Scarcely a month passes but one is added to the list. The latest is called the *Paris Photographe*, published by the indefatigable M. Paul Nadar, who, not contented with his recent success in the invention of a magnesium flash-lamp, is now turning his attention to periodical literature. The *Paris Photographe* is in the nature of a review, and is spoken of in very high terms by the press.

What with the photographer and his instantaneous photographs, and what with the scientific critic, the painter just now has rather a hard time of it. According to the camera, the way in which most horses are drawn is altogether wrong. Mr. Hugh Miller, of the Geological Survey, has written an essay, in which we find that the painter's notion of rocks, hills, and mountains is nearly always wrong from the point of view of the geologist. Now comes Mr. A. C. Ranyard, of the Royal Astronomical Society, who falls foul of Mr. Eyre-Crowes' picture of "Jeremiah Horrocks Studying the Planet Venus." Mr. A. C. Ranyard asserts that the planet has been drawn too small, and that Mr. Crowes had no authority for the astronomical instrument he has placed in the observer's hands.

The latest piece of scientific criticism is that called forth by Mr. Fildes' picture of "The Doctor." The case has been diagnosed professionally, and it is settled to be of a nature which would require a 6-oz. bottle of diluted ammonia. Unfortunately, Mr. Fildes has drawn a 2-oz. bottle. It is, however, only fair to the painter to say that he was quite aware of the medical requirements, but that artistic necessity forced him to draw a bottle smaller than he would otherwise have done. All this, however, shows that the lot of the painter in these naturalistic days is not a happy one.

## THE FABRICATION OF PHOTOGRAPHERS' VARNISHES.

BY H. C. STANDAGE.

The rough-and-ready directions of empirical formulæ given in many text-books for varnishes, more often than not express only what the particular person giving such directions has found useful in his experience; but as each photographer has his own method of manipulation, &c., what one man finds suitable, a second cannot work with, to produce anything like favourable results.

This is the case with photographers' varnishes, the formulæ for which vie with developers in number. In these pages we purpose giving technical directions for the production of a perfect varnish.

The varnishes used by the photographer are mostly volatile, and partake more of the character of a lacquer than a varnish. By volatile, we understand all those from which the solvent can be evaporated by heat without suffering decomposition; they therefore include all those varnishes which are not prepared with fat oils.

Until very recently, the only solvents for the production of volatile varnish were spirits of wine, methylated spirits (a modification of alcohol), and oil or spirit of turpentine. Now, however, owing to the great progress made in the tar and petroleum industries, we have other excellent solvents, such as benzole and petroleum naphtha. The addition of these agents has altered the method of producing volatile varnishes, for now it is very often that the resin is dissolved to the consistency of syrup by one of these solvents, and then reduced to the proper consistency for use with spirit of wine or oil of turpentine. As alcohol (spirit of wine) that is below 90 per cent. contains water, and as water is very undesirable in all kinds of varnishes, to make a good varnish necessitates the use of absolute alcohol (*e.g.*, 90 per cent. strength); but this spirit is expensive. We have an excellent substitute for it as regards cheapness in the wood-spirit. For the varnish, when colour is a matter of indifference, methylated spirit answers every purpose. The quality of varnishes varies according to the various resins used, and also according to the nature of the solvent.

Pure spirit of wine varnishes can easily be obtained, of a colour as light as water, if they are prepared in the right manner. They dry very quickly, especially in summer, and produce a smooth, glossy coating which seems to be faultless. But even if the varnished object is protected from all shocks, it will be found, in a very short time, especially after a great change in the temperature, that the varnish has *innumerable fine cracks*, in consequence of which it *loses its lustre*, and even peels off if the layer of varnish has been somewhat thick. The cause of this phenomenon is found in the fact that the layer of varnish consists of nothing else but the unchanged resin, which lies upon the article in a thin layer. As resins are mostly very brittle bodies, a very inconsiderable lowering of the temperature suffices to occasion a separation of the contracting particles, whereby the above-mentioned cracks are formed.

This fault appertains to all volatile varnishes; in fact, the more volatile the solvent is, the quicker the hard coating will be formed, and the easier will it crack. This is very noticeable in those varnishes in the preparing of which ether alone has been used as a solvent. This fault, however, can be checked by dissolving, at the same time with the hard resins, also soft resins, which are nearly allied to the balsams or turpentines; or, not using spirit varnish by itself, but mixed with the oil of turpentine. Varnish—particularly a layer of a spirit varnish—consists, when dry, of a thin layer of resin only, the vehicle that kept the varnish fluid having flown away. When turpentine is used, there is always a small residuum of resin left by the latter spirit, and so such varnishes are not so brittle.

Oil of turpentine varnishes are prepared by dissolving the resins in oil of turpentine. When used by themselves, these varnishes produce as beautiful a coating as spirit varnish, and are also less brittle, because the residuum of turpentine that does not evaporate causes these varnishes to be longer in drying; but, in consequence, the particles of the coating find time to deposit themselves freely, and therefore the coating cracks or breaks less frequently.

Tar oil varnishes, as well as benzole and petroleum naphtha varnishes, possess nearly the same properties as spirit varnishes. The utmost precaution is absolutely necessary in regard to fire in preparing these varnishes, because these fluids evaporate very quickly at an extraordinarily low boiling point; consequently, the air becomes filled with this vapour, and directly this comes in contact with fire an explosion takes place. The safest plan to pursue with these volatile fluids is to add just as much resin as can be dissolved by a given quantity of fluid to form a viscid liquid, and to reduce this with spirit of wine, oil of turpentine, or almond, which shortens the labour considerably, as the resins are dissolved much more quickly in benzole and petroleum naphtha than in alcohol. As has been already mentioned, all alcohol used for dissolving resins must be *absolutely very strong*, and show at least 90 per cent., but a somewhat weaker spirit of wine (about 85 per cent.), or, under certain conditions, even only 80 per cent. strong, may be used for reducing a solution already made.

But it may be recommended in all cases to first determine by a preliminary test, with a small quantity of varnish, how far the use of weaker spirit of wine is advisable, because if it is too much diluted it has not the power of keeping all the resin in solution, and a part of the latter will separate in the form of flakes. When, in testing the varnish, it is observed that it becomes less transparent, especially when exposed to a lower temperature, or even commences to opalize, it is a certain proof that the spirit of wine has been diluted too much. Such spirit of wine varnishes as are required to dry very quickly must, of course, be prepared with spirit of wine containing as little water as possible; in fact, the strongest alcohol obtainable in commerce should be employed for such varnishes.

*Preparing Volatile Varnishes.*—Volatile varnishes on a small scale are easily made, as no particular or elaborate apparatus is necessary. Thus, all that is necessary is to put the resin and solvent into a vessel, and exclude the air. This rough-and-ready plan, however, can be vastly improved on by simple means, thus: break up the resin into pieces about the size of a pea, and tie it up loosely in a small linen bag, and fasten this to a hook fixed in the under side of a bottle cork, so that when the cork is put in the bottle, the volatile solvent just covers the top of the bag; room should be left for the resin to swell. A much better product will be obtained by this means than the former, because, in that case, the solvent can reach the surface only of the resin, and, as the dissolved portion is heavier than the spirit above, a dense layer of dissolved resin will be above the undissolved portion, and so prevent the fresh spirit from reaching the resin. It is for this reason that spirit varnishes require frequent shaking while being prepared. With the resin in the bag at top of the spirit, as it becomes dissolved the heavy mixture falls, and so the bag is continually in contact with fresh spirit.

When varnishes are used on the large scale, they often contain small particles which make them turbid; they therefore have to be clarified. This can only be done with volatile varnishes by allowing them to stand for weeks in large bottles in places where they are safe from all disturbance. The solid bodies will then gradually settle in the bottom, and the clear varnish can be poured off by careful handling. By this method a great number of expensive and easily broken bottles, as well as considerable space for storing them, render the clarification costly, and besides, a certain percentage of the varnish is lost by unavoidable evaporation of alcohol, by spilling, &c.; and, to obtain bright and light colour varnishes, they should be filtered.

*Filtration of Varnishes.*—Owing to the viscosity of varnishes, their filtration occupies considerable time, and, if filtered in uncovered vessels, quite a quantity of alcohol, benzole, &c., is lost by evaporation. Fig. 1 shows a simple yet efficacious apparatus, that is easily made at little cost, for the perfect filtration of small quantities of volatile varnishes, and without loss of spirit by evaporation.

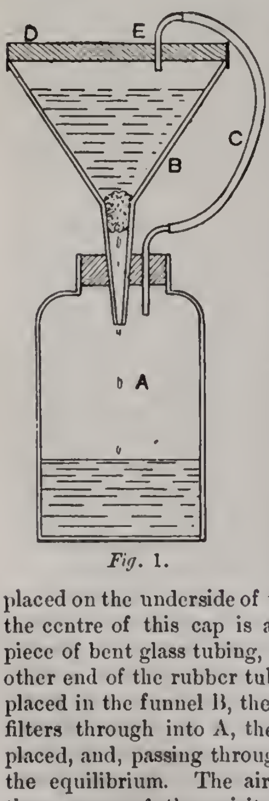

*Fig.* 1.

A is a large bottle, either of glass or tin. This is hermetically closed by a cork with two holes; a caoutchouc stopper is very handy in this case, or a wide bung. B is a glass funnel, the neck of which passes through one of the holes in the cork of A, while a piece of bent glass tubing, connected with a piece of india-rubber tubing, C, passes through the other hole; a plug of cotton-wool — medicated wool I find the best—is put in the neck of the funnel, or else a filter paper is used. I prefer the former for both spirit and volatile varnishes. The top of the funnel is ground smooth, and a piece of mahogany made to fit accurately thereon as a cap, D. A ring of rubber placed on the underside of this cap renders it air-tight. In the centre of this cap is a hole, through which passes a piece of bent glass tubing, E, which is connected with the other end of the rubber tubing, C. The volatile varnish is placed in the funnel B, the cap put on, and, as the varnish filters through into A, the air in the latter vessel is displaced, and, passing through C, enters E, and so keeps up the equilibrium. The air in B becomes saturated with the vapour of the spirit; but, as such vapour cannot escape when the air is saturated therewith, no more vapour is given off from the varnish; thus, the consistency of the filtered varnish is uniform, which is not the case when it is filtered in an open funnel, because, as the spirit evaporates, the proportion mixed with the resin is lessened, and so the latter portion of varnish that is filtered becomes thicker than the first, due to this loss of spirit. When the plug of cotton-wool or filter-paper ceases to act well —*i. e.*, when the varnish filters very slowly—whatever is in B should be poured off, and the filtering body be replaced with fresh material.

*The Decoloration of Varnishes.*—One great drawback to using varnishes is that they possess too much colour for the purpose to which they are required to be put. There are many means of bleaching varnishes and of bleaching the natural resins before use, but the safest and simplest material for general use is animal charcoal. To use this material, it is best employed in small pieces like coarse sand, because when powdered animal charcoal is used the pores soon choke up, and filtering becomes a very tedious operation. Before using the charcoal at all, it must be freed from the salts contained in it to render it suitable for our purpose. This is done by treating it with hydrochloric acid in the following manner. A quantity of raw animal charcoal is placed in a suitably sized stoneware jar with a lid to it, and a quantity of raw hydrochloric acid equal in weight to half or three-quarters of the weight of charcoal used is poured on it, and the whole allowed to stand for one day in the covered jar with frequent stirring. The contents of the jar are then poured into a tub containing about five times the amount of water that the jar would hold, the charcoal allowed to settle, the fluid poured off, and clean water poured over it. This operation is repeated until the water is entirely free from acidity (ascertained by means of a blue litmus paper not becoming red when dipped in it). The washed animal charcoal is then dried by heat.

For preparing small quantities of the varnish, the decolorizing can be done at the same time as the filtering by plunging the animal charcoal in the funnel B, and pouring the varnish to be filtered upon this. This method, however, has its disadvantages in respect to changing the filtering substance or the animal charcoal, if either one of these substances should lose its effect. Therefore it is best to carry on the filtering and decolorizing in separate vessels.

In fig. 2, the varnish that is to be decolorized and filtered is put into the bottle F, which has a stopcock, G, fitted to it near the bottom; this is connected with the bent pipe, H, by a bit of rubber tubing. This pipe dips just below the lid of the vessel P, and the neck of this vessel enters the cap D of vessel B, while the pipe E fits into a hole in the cork of F. This arrangement allows the varnish to flow into G to be decolorized, and from thence into B to be filtered, while the finished product is secured in the vessel A. The

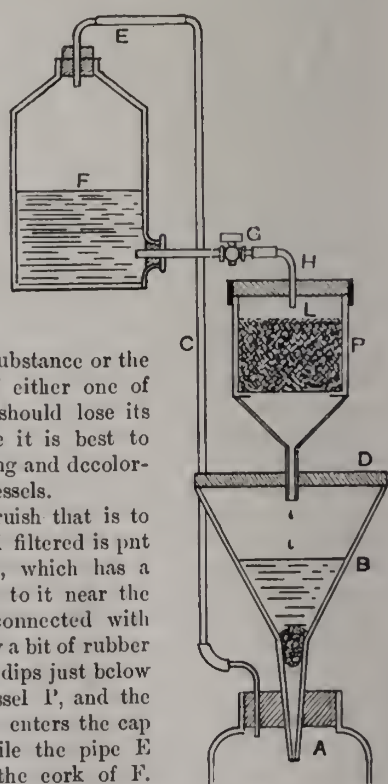

*Fig.* 2.

vessel P is of peculiar construction; it is a cylindrical vessel of sheet iron, with a ring in the bottom, which serves as a support for the cylinder, L. This cylinder is of woven wire, and is filled with coarse-grained animal charcoal. To use this apparatus, the stopcock G is opened, which allows the varnish in F to flow into P, where it is decolorized by the animal charcoal. From this it passes immediately into the filter, and the finished article is collected in A. The arrangement of the entire apparatus is such that, should it become necessary, the filtering material or the animal charcoal can be changed in a short time, and, at the same time, any loss by evaporation is prevented.

(*To be continued.*)

## RUSTIC LIFE STUDIES.*

BY J. J. THORNTON.

Much has been written by eminent writers on nearly every subject of photographic art, with the exception of the rustic life class; and I may, by way of preface, say that I am somewhat surprised that so few students in photography apply themselves to this class of work. But however my praises and enthusiasm of it may at first seem to denote that I have given exclusive attention to it, yet I am the last one to depreciate the other branches; there is plenty of scope in all classes, and all require *taste* and *skill*; but still I contend that the figure study class is one of the most difficult and highest forms of the art

It is sometimes contended that photography is merely a science and not an art, and in Bohemian circles the appellations would have been treated with derision; but this idea is both false and erroneous, and is gradually dying out, for the beauty and success of photographic specimens is due to the artist, and not to the apparatus and material which he has at his disposal. For instance, giving the same advantages to two operators, one may be found to have produced a decided failure, while the other, with the selfsame medium, will be able to show you a picture with true artistic feeling and admirable effect.

But to return to our subject, viz., figure study, which is already pronounced to be the most fascinating form of the art. To achieve success it requires to be studied intellectually, and closer observation is also necessary if the object in view is a true representation of a pleasing picture. It is not my intention to supply a form of practical rules, but merely give a few hints (from my own experience) to those who have not yet given any attention to this class of work. In the first place, if you have not naturally a taste for this subject, you should endeavour to acquire an interest yourselves in the fine arts; not only admire them, but study them minutely, for those who do not commence from the beginning will never derive the full benefit of the pleasure which this art affords to those who do. A thoroughly good camera, with all the latest ingenious improvements and eccentric movements, and a first-class lens with iris diaphragms, are no doubt of invaluable aid; but the secret of success is in the selection of your models and arrangement of them. In landscape photography, happy thoughts may be made almost anywhere. The old thatched cottage overgrown with moss, the winding brook, the glassy lake, the park, the woodland glade, and the shady pool reflecting the majestic trees—all these are subjects of captivating loveliness and picturesque beauty. But you cannot so easily pounce upon models for your figure study subject. Pictures depicting rustic life always afford much admiration and satisfaction on account of the peculiarities and oddities of their dress, and their careless and simple habits. For these you must visit villages, hamlets, farmhouses, and cottages; get on a friendly footing with the villagers, converse with them and study their customs, their manners, and their humours. The most retired neighbourhoods produce the best subjects. There are many quaint villages of this description in the neighbourhood of Southsea, and which are very little explored by the photographic artist, although, strange to say, you will frequently meet with artists with canvas and brush in these picturesque parts; and for old world customs and primitive simplicity, there is no place better to find your models. A very good study is that of a characteristic aged female (being, we are told, in her eightieth year) at her cottage door, whose face is rugged and marked with strong lines. In one of the rudest and poorest habitations we have a girl, slatternly and poorly clad, reclining idly against a water tub, with a listless indifference as to the present, past, and future, quite contented with her native place, and devoid of all curiosity. The boys of the village are generally to be seen paddling in the water, playing with boats, cutting sticks, throwing stones into the water, or very often engaged in a free hand-to-hand fight; always up to some kind of mischief, the younger girls and the smaller fry looking on with supreme delight. An infirm old woman has given her pail to one young rascal to fill for her with water, and on her requesting its return, he impudently looks up and asks her if "she will have it now, or wait till she gets it." Of course this is very tantalizing to her; but she can only retaliate by telling him that she will tell his mother, a threat which need hardly be said is treated by the young imp with laughter and derision. "Washing day" is a busy day in the village, when the "young ladies" are reluctantly compelled to assist their mothers, much to their disgust, when playing would have been more preferable.

Wending your way towards the beach, one of the best studies is the fishermen—strong, robust, healthy men, dressed in blue-coloured jerseys and huge leather sea-boots reaching up to the thighs, the soles studded with heavy iron nails, and oilskin sou'wester worn the front part to the back of the head. They are by no means lazy, for when not engaged in fishing, their time is occupied in mending their nets and repairing and painting their boats. At other times they may be seen lounging about the harbour, in parties of two or three, and each of them accompanied with his short pipe.

But the most charming model of all is the skipper's daughter, a most interesting and amiable child, bright, cheerful, animated, and the favourite of the village. Many of the villagers are, of course, in keeping with their homes and their manners, rather uncouth, but still a hearty welcome is ready to the visitor, provided that permission is in the first place obtained. You will find them very cleanly, and, judging from the freshness of their complexion, and the robustness of their figures, they may be deemed a very healthy lot of people. There is, therefore, nothing objectionable in mixing with them and encouraging them in their various occupations and enjoyments, for preliminary attentions and study must be given to them before attempting to realise them by photographic means. Having endeavoured to put models of various kinds before you,

* Abstracted from a paper read before the East Southsea Photographic Society.

the student must now rely for the success of his picture upon the pose and general composition, for it is there where your originality must be brought to bear. A larger aperture should be used than for landscape work, where definition of distance and surroundings is not so much an object, for when figures are your subject your background requires keeping back, and adds boldness and relief to your figures. Many pictures are spoilt through using too small a stop, thus bringing distance equally sharp with your subject, which frequently comes out weak, flat, and devoid of all contrast. Briefly referring to genre pictures, such as a reproduction of a group of children—whose object is to release the boat from its fixed position—is clearly shown in a picture. Many difficulties will have to be contended with, for as a rule each member tries to make himself more prominent than the rest by getting as near as possible to the centre of your instrument, and gaping into the lens with that pertinacious curiosity which is so irritating to the student, and so fatal to the ultimate result. His or her attentions must be at once directed to something else; give each of them something to think about, or something to do; humour or bribe them when necessary. Having then succeeded in getting them all pursuing their vocations in an easy, unconstrained manner, a quick exposure will do the rest. For pictures of this kind the best results are gained with a sharp shutter exposure on an extra rapid plate, when the movements are actually in motion. Single figure studies, although requiring greater care and attention in the arrangement and posing, are not so troublesome; still, on the other hand, greater care and attention must be observed, and the rules of art more strictly attended to; the surrounding must be in keeping with your subject. The dress of your model should be considered; one in light colour should be placed with dark accessories, and in like manner a figure in dark attire against a light background.

Presuming, therefore, that you have made a selection of your model, you should now focus carefully on some object in the position which your figure will occupy, so that you may avoid wearying or taking up their time in trying experiments upon them. Should you have a friend with you, make use of him for your preliminary arrangements. It is as well here as in groups to have your model in the act of some employment and perfectly natural, being careful at the same time to avoid all semblance of forced or artificial posing, otherwise you are not likely to get a pleasing and easy realistic picture. The exposure should be from two to three seconds, with an open aperture, and a slow plate is much more preferable for this work. The exposure, of course, depends a great deal upon the quality of the light, a subdued light being the best. On no account ever attempt to take a picture with sunlight striking on your sitter or figure. Of course these are merely hints and suggestions from the experience of one man only, but there is no system that is infallible, and it may be useful to know of one which has not altogether been an absolute failure. In cases of failure, which we all have at times, you must repeat the same subject again and again, provided it is one deserving of trouble. In conclusion, I should recommend you to study art if your aim is proficiency. The artist studies how he can get certain effects. Why should not you?

---

In a series of competitions to be held by the Newcastle-on-Tyne and Northern Counties Photographic Association, the class for the best six lantern slides will be open to the world, and two silver medals will be at the disposal of the judges.

## MAGIC LANTERN MISSION.

Mr. W. T. Stead has asked us to give publicity to his proposed scheme for a national society of lanternists. At the time when he first ventilated the subject, we expressed the conviction that lantern entertainments were already somewhat overdone, and that he had long ago been forestalled in many of his suggestions. We further expressed the opinion that it was far better to make use of existing agencies for the manufacture of lantern slides than to endeavour to create new sources of supply. There is something unseasonable in thinking of lantern matters in the month of June, but we comply with Mr. Stead's wish in reprinting the following article from his publication, *Help*:—

### Proposed National Society of Lanternists.

I wish to appeal this month to all who are interested in magic lantern work to send me their views as to whether, if a sufficient number of names could be got together of persons who volunteer to co-operate in carrying out the objects of the Magic Lantern Mission, it would be feasible to form a Lanternist Society, having its headquarters in London, with branches in all the more important districts throughout the United Kingdom, the special points to be kept in view being:—

(*a*) The combination and concentration of individual effort for promoting the education and recreation of the people by the aid of lantern services, lectures, and entertainments.

(*b*) The stimulation and cultivation of slide painting and reproduction as an art.

(*c*) The establishment of a system of exchange bureaus for the interchange and hiring of slides and the diffusion of lantern literature.

The lines upon which such a society should be formed are essentially those which permit of the closest co-operation between its members for the purpose of carrying on the mission. Unlike, therefore, most other societies of the kind, it would fall short of the attainment of its object if its members were dependent upon meetings held at lengthened intervals. On the contrary, its success will depend upon the personal co-operation of the members in their own particular district. Thus, in reality, such a society would consist of an amalgamation of "live" branches, each of which would form in itself an independent organisation. Meetings would be held in the large centres at regular intervals to consider the best means for carrying into effect the needs of the various branch missions embraced by the particular area.

*A Central Committee of Management.*—The management of the Society would be vested in a central committee, or council, having its headquarters, for convenience, in London. Such committee would be popularly elected from year to year, and would be empowered to deal with the subscriptions of members or other funds received for the benefit of the Society.

*Annual General Meeting.*—In order to maintain the working standard of the Society, and for the interchange of ideas for the widening of its basis, as also for the strengthening of the bond of good-fellowship which should bind the members together, it would be necessary to hold an annual general meeting of the Society at headquarters. To this annual conference of lantern mission workers it would be feasible, as well as advantageous, for the members to delegate one or more trustworthy and competent member of their body to represent their views and requirements. In this manner it would be secured that the uttermost extremities of the Society, to which circumstances of distance, &c., would present obstacles to personal attendance, would be adequately represented.

*Working Expenses.*—The working expenses of the Society would have to be arranged on a plan which would take special cognizance of the wants of a particular district. For many reasons it is obvious that a settled subscription should be paid by each member, and that the amount should be fixed at as low a figure as would be consistent with the due fulfilment of the Society's aims. Whatever sum may be agreed upon as adequate for sustaining the Society in efficieut working order, it is apparent that there are two ways of working it.

*The Local Branch to be Dependent.*— One of these is for the local branch to look for its working expenses to grants from the general fund, the amount of such grants to be determined and controlled by the governing body upon the representation of the needs of the particular district. With this plan there would be an equal subscription combined with a most unequal distribution of the fuuds, one district, as a matter of course, drawing more than another.

*Or Self-Supporting.* — The other plan, which would have many local advantages, is that each branch of the Society should be self-supporting. It should have the management and control of its own affairs, subject only to the rules of the Society, and its members, whilst paying a nominal subscription for meuibership to the Society, should regulate their owu expenditure by meaus of a committee appointed from their number, the necessary and special expeuditure to be incurred being met by subscription or funds raised in such ways as may be judged fit and proper. Thus, in an exceedingly poor and populous district, where the ueed for lanteru work would be very great, it would be open for the local committee to fix a charge for admission to entertainments, which would cover the cost of production in each case. The point in question, therefore, is whether the local brauch should be self-governed and self-supporting, or, on the other hand, controlled and governed by a central committee of management at headquarters.

*Qualifications for Membership as Lanternist.*—The qualifications for membership are twofold. It is a *sine quâ non* that a person seeking to enrol himself as a lanteruist should possess a lantern, or access to one. Experience, of eourse, is also necessary, and its amouut would be duly registered. All lanternist members, irrespective of the apparatus they possess, would enjoy equal privileges as members of the Society, but it would follow as a matter of course that the service which a member might be expected to render in his district would be largely determined by the nature and quality of his apparatus.

*As Lecturer.*—The second qualification for membership is the ability to lecture or talk upon certaiu subjects. In this class of membership, likewise, some experience is necessary, so that the lecturer may be presumed to be familiar with his subject. He may, of course, take several subjects, or may confine himself to one. Anyway, the subjects he specially favours would be registered. It will be seeu that a close and harmouious relationship is necessary between the lecturer and the lanternist in working the district placed under their charge, but it is quite open for a member to enrol himself as a lanternist and lecturer in one, if he prefers to do so.

*Associate Members.*—It is hardly necessary to point out iu how many different ways the objects of the mission may be furthered other thau by possessing a lantern or the ability for speaking or lecturing. They will readily suggest themselves to the minds of those who are in full accord with the plan sketched out in the initiatory article, which I published in the December number of the *Review of Reviews*. It would doubtless be possible to arrange for the inclusion of such proffers of service otherwise than by full membership, but for the latter it is necessary that the qualifications should be distiuctly stated.

*Lantern Endowments.*—It may be hoped, if the Society is successfully started, that a fund may come to be provided whereout lanterns and apparatus may be purchased and presented as a free gift to those districts most in need of them. In the meantime, it would be the duty of each lanternist member to do all in his power to secure that his district should be adequately supplied with a lantern outfit.

*Definition of Districts.*—Regarding the district, the working of which would be entrusted to one or more resident members of the Society, its definition should, I think, be based upon the unit of population. Thus, I would suggest that for every 10,000 population the Society should reckon upon one competent lanternist member, and one equally qualified talker or lecturer, who would be prepared to devote at least one evening per week to the purposes of the mission. The precise definition of such districts is a matter that might well be left to the consideration and convenieuce of the local committees.

*Special Features of the Society.*—The special features which should pertaiu to the central committee of management are essentially these :—

(*a*) That there should be a classified list of all the slide sets issued for sale or hire, with the lowest prices at which they can be procured for mission work.
(*b*) That there should be a directory of all competent slide-makers, with the terms at which they will work, and particulars of their productions.
(*c*) That there should be a directory of all lantern makers and appliances, with the prices at which their productions can be bought or hired.
(*d*) That there should be a list of all professional lanternists and lecturers throughout the United Kingdom, with statement of their terms, and particulars as to the nature and subject of their entertainments.
(*e*) That there should be published monthly an official organ of the Society, which shall contain an account of the progress of the Society, together with reports furnished from time to time by the local committees to the central committee of management.

Those in sympathy with the idea of the Mission, and who desire to help in carrying out its aims and objects, are requested to fill in and return to Mr. Stead, at Mowbray House, Temple, W.C., on a form of enrolment, particulars of the service they are prepared to render, adding thereto any suggestions which may strike them as being likely to further the object in view.

## ROYAL OBSERVATORY, GREENWICH.

We are favoured with a copy of the report of the Astrouomer-Royal to the Board of Visitors, read at the annual visitation of the Royal Observatory, June 6th. The report refers to the year from May 11th, 1890, to May 10th, 1891, and exhibits the state of the Observatory on the last-named day ; and from it we present extracts that are of more especial photographic interest.

Under the head of "Buildiugs and Grounds, Movable Property, and Library," are included a computing room for the new astro-photographic branch ; fireproof rooms for the photographic records and books of calculations in these two branches ; a library for the physical branch (magnetical and meteorological, spectroscopic and photographic) ; and a laboratory and dark galleries for spectroscopy and photography. Among the principal movable instruments are mentioned photo-heliographs (at Greenwich) :—One complete (No. 4, mounted iu the South Ground), two tubes (E2, A5, with object glasses), and a driving clock (used for the personal equation instrument), and a complete mounting, with driving clock (No. 3), used last in the Cape Ledo Eclipse Expedition. Photo-heliographs on loan :—One complete at the Cape Observatory, one complete and the mounting of another (without driving clock), lent to the Science and Art Department.

A photographic telescope, with 9-iuch object glass, by Grubb, and a prism of 9 inches diameter, by Hilger, have been generously presented to the Royal Observatory by Sir Henry Thompson. The telescope has been mounted on the Lassell telescope as a photo-heliograph, to give 8-inch pictures of the sun, a camera with Dallmeyer doublet (from photo-heliograph No. 4) and an exposing shutter, specially designed to give very short exposures, being attached to it.

In view of the advantage resulting from the use of electric lighting for the photographic equatorial and for other instruments, it is very desirable that an electric light installation should be provided for the Observatory, so that this method of lighting, which is specially adapted to the requirements of au observatory, may be applied to the instruments generally. The system now in use of charging storage cells from primary batteries is necessarily extravagant, and it does uot admit of the desired extension.

Under the head of "Astronomical Observations," we learn that the photographic equatorial has been brought into working order after some delay, occasioued by the necessity for workin_ out details of plate-holders, réseau-frame, and other accessories after the instrument was set up. Unfortunately, when it was otherwise ready for use, the ratchet to the weight barrel of the driving clock—which was of the sileut form—gave way on October 27th, 1890, letting the heavy weight fall. The barrel was sent to Sir H. Grubb, who applied an ordinary ratchet to it, with a new steel piuion, and returned it on November 24th, 1890. The instrument has since worked very satisfactorily, and is admirably adapted to its purpose, the electrically controlled clockwork in particular being very efficient.

Work with the 13-inch photographic refractor was seriously delayed by this accident to the driving clock, and later by the illuess of Mr. Criswick; but 81 stellar photographs have beeu taken, all of which must be regarded as more or less experimental. Ferrous oxalate development was used throughout, and all the plates were photographically impressed with the réseau kindly supplied by Prof. Vogel. The exposures have varied from a few seconds to about an hour; and trails have beeu taken both ou the equator and near the pole to test the adjustment for orientation. Several different kiuds of plates have been used, includiug Cramer, Seed, Paget, Star, Mawson and Swan, and Ilford, and, on the whole, the choice seems to lie between the Star and the Ilford plates.

Some trial photographs of Polaris have beeu taken with the Dallmeyer 4-inch photo-heliograph object glass, which it is proposed to use as an auxiliary telescope to test the quality of the night by short exposures ou Polaris during the exposures for the chart plates.

*Spectroscopic and Photographic Observations.*—For determiuatiou of motions of approach or recession of stars, 286 measures have been made of the displacement of the F line in the spectra of 31 stars, and 14 of the *b* line in the spectra of 6 stars, besides comparisons with the spectra of Mars, the moon, the sun, or the sky as a check ou the general accuracy of the results. The series of observations with the $12\frac{3}{4}$-iuch refractor is now practically completed, and the results are under discussion. An examination of those for the 21 stars most frequently observed shows that there is a systematic error depending ou the hour angle, thus uecessitating a correction for the position of the spectroscope at the observation.

In the year ending May 10th, 1891, photographs of the sun have beeu takeu at Greenwich on 224 days, and, of these, 483 have been selected for preservation, besides 18 photographs with double images of the sun for determination of zero of position. For the year 1890, Greenwich photographs have been measured on 209 days, and photographs from India and Mauritius filling up the gaps iu the series on 152 days, making a total of 361 out of 365 on which photographs have been measured in this year.

The sun has been free from spots on 175 days in the year 1890, as compared with 211 days in 1889. There were only three spotless periods of more than 14 days in 1890, viz., February 2nd to 27th, March 24th to April 9th, aud June 11th to July 3rd, while iu 1889 there were nine such periods. The mean daily spotted area has increased from 78-millionths of the sun's visible hemisphere in 1889 to 100 in 1890. The measures of the photographs and the reductions of areas and positions of spots and faculæ are complete to the end of 1890. Photographs from India and Mauritius have been received from the Solar Physics Committee as far as February 4th and January 23rd, 1891, respectively.

As regards the further discussion of the results of former years, 46 Melbourne photographs, available for filling up gaps in the series in the year 1877, have been measured, aud these, together with those for the years 1875 and 1876 referred to in the last report, have been completely reduced, the orientation of the wires having been inferred by comparison with measures of Greenwich aud Harvard College photographs on neighbouring days, as no satisfactory details of this adjustment could be furnished from Melbourne. The copy for press, both of the daily results and the ledgers of sun-spots, is completed for these years. Ledgers of the positions and areas of spots for the years 1882 and 1883 are completed and ready for press, and those for 1884 and 1885 are being formed. When this is done, the reductions for the whole series of years from 1875 to the present time will be complete, those of the Indian photographs for the years 1879 to 1881 having been completed at South Kensington uuder the supervision of the Solar Physics Committee.

*Magnetic Observations.*—The photographic record of the three magnetic elements, and the supplemeutary eye observations, have been continued as before. The temperature of the basement in which the photographic instruments are installed has been maintained at about 67° throughout the year, except iu December and part of January, when the gas supply again became deficient, aud the ground iu the park was again opened to clean the pipes, which were found to be so much corroded that it will be necessary to renew them. They have been in use as gas-pipes for forty years, and had previously served as water-pipes before the existing water main was laid down.

The magnetic reductions are completed to the followiug stages:—The eye observations of the upper declination magnet, and of the horizontal and vertical force magnets, are completely reduced to the end of 1890. The time-scales for declination, horizontal force, and vertical force are complete to the end of 1890, and the base line values, deduced from eye observations, are entered on the photographic sheets for declination and for horizontal and vertical force. The hourly ordinates of the photographic curves are read out to the end of 1890 for all three elements, and the daily and hourly means are all taken; the time-scales for earth currents are laid down. The dip observations are completely reduced to the present time, and the deflexion observations for absolute measure of horizontal force to the end of 1890. The temperature of the magnet basement at every hour has been read off from the sheets of the Richard thermograph to the end of 1890, and the daily and hourly means have been taken.

The meteorological reductions are in the following state:—The observations of barometer, thermometers, anemometers, rain gauges, and sunshine recorder (corrected, where necessary, for instrumental error) are reduced up to the present time. On the photographic sheets all the time-scales are laid down, aud the hourly ordinates are read out for the dry and wet bulb thermometers and electrometer to the end of 1890, and some work has been done in taking means.

*General Remarks.*—The preparatory work for the photographic map of the heavens has occupied a good deal of attention during the past year, a number of new questions being raised in this application of photography to systematic astronomical work which have necessarily required careful consideration on the part of the chief assistant and myself. Under these circumstances the want of increased supervising power for the Observatory has been severely felt, and this want has not been iu any way met by the appointment, after a long delay, of an additional second-class assistant. The recent meeting at Paris of the International Committee for the photographic map, in which I took part, settled the bases of the work in a geueral way; but for working out the details, both practical and theoretical, much remains to be done, and, under the existing conditions of the Observatory staff, it is difficult for the chief assistant and myself to supervise this adequately, and to deal effectually with the important points of principle involved in the discussion of the excellent photographs which have been obtained by Mr. Criswick and his assistants.

---

Halifax Camera Club.—At a meeting held on Monday last, it was unanimously resolved to form a photographic club for Halifax and neighbourhood, and to make an effort to obtain suitable premises and have them thoroughly fitted up as a first-rate studio, embracing not only studio proper, dark room, enlarging room, and dressing room, but also a large room for meetings and lantern entertainments, and a reading room provided with the current photographic literature. During the evening no less than £20 was promised towards a furnishing fund in addition to subscriptions. The annual subscription was fixed at 10s., and the Club is to be open to both sexes, and to professiouals and amateurs. At the close of the meeting the names of forty-two persons were taken down as members. The honorary secretary, *pro. tem.*, is Mr. E. Finlinson, Union Bank, Halifax, from whom full information may be obtained.

# Patent Intelligence.

### Applications for Letters Patent.

9,844. Albert Aron, 23, Southampton Buildings, London, "Improvements in Glazed Screens for Photographic and other Pictures." (Adolphe Aron, France.)—June 10th.

9,906. Frederick Dresser, 20, Bixteth Street, Liverpool, "Improved Adjustable Photographic Printing Frame."—June 11.

9,971. Abraham Dirk Loman, 186, Fleet Street, London, "Improvements in or Pertaining to Portable Photographic Cameras."—June 12th.

9,984. James Gray, 4, York Street, Newcastle-on-Tyne, "A New Permanent Photographic Printing Process."—June 12th.

### Specifications Published.

669. *January* 14*th*, 1890.—"Actinometers." E. G. Ballard, 1, Eversley Park, Chester.

An instrument for ascertaining requisite time of exposure in photography, applicable also in other cases where the relative intensity of actinic rays is to be ascertained. A tube blackened internally is provided with an eyepiece and a hinged cap, in which are inserted a disc of ground glass, a disc of plain glass covered with an opaque annular layer of luminous paint, or the like, the central space being left transparent, a piece of blue glass, and a piece of ground or plain glass. The piece of blue glass cuts off all the rays entering the tube except the actinic rays corresponding to those emitted by the luminous paint; it is wrapt in a number of layers of translucent material, such as tissue paper, which lessens the intensity of the rays passing into the apparatus, the degree of obscurity being constant for each type of photographic plate. The cap is turned to expose the luminous paint; when this is fully excited the eye is placed against the eyepiece, the instrument directed towards the object to be photographed, and the hinged cap quickly closed. There will then be visible a blue luminous band surrounding a darker spot. The time taken by the band to assume the same tone as the spot is noted, and from this, by reference to a suitably prepared table, the requisite time of exposure may be determined.

765. *January* 15*th*, 1890. — "Change-box combined with Camera." N. Browne, 73, Cheapside, London. (F. A. Fichtner, Elisenstrasse 6, Dresden, Altstadt, Saxony.)

The sensitive plates are contained in two compartments formed by a transverse partition. The plates are fitted in sheaths or carriers. After exposure, the plates are transferred from one compartment to the other by spring hooks on the ends of racks, which gear with toothed pinions on the axis, which is actuated by a crank outside the box. A fresh plate is thus introduced at the back of one compartment every time an exposed plate is removed from the front. Both compartments are thus always full, except in so far as space is always left to introduce another plate. Suitable springs are fitted in the spaces left to press the plates together.

---

Messrs. Taylor, Taylor, and Hobson forward a sample of a new level for cameras. One of these, used on the side of a camera swing-back, will insure the avoidance of the vertical distortion which is so often noticeable in photographs of buildings, &c. Another on the back of the camera frame will insure its true horizontal position. The firm's circular spirit-levels and T levels, which serve the two purposes at once, must be placed on the top of the camera, and as this position is inconvenient in the case of cameras on high tripods, they have designed the new level to be placed low down on the side and back of the camera, where it is more accessible.

# Correspondence.

### THE PHOTOGRAPHIC CONVENTION AT BATH.

Sir,—Will you kindly allow me to draw the attention of your readers to the forthcoming meeting of the Photographic Convention at Bath?

In the first place, I would point out to those who are not already members, that the Convention has amongst its adherents a very large proportion of the best-known amateur and professional photographers in the kingdom, and affords the best existing means of bringing together photographers from all parts of the country, and thus enabling them to meet their fellow-workers in the art, and discuss with them its later developments and the means of promoting their common interests.

The president at the Bath meeting will be Mr. William Bedford, whose name and work are familiar to every photographer, and his well-known tact and skill in the conduct of affairs are a guarantee that the control of the arrangements, and the guidance of the discussions which it is hoped will follow the papers, will be in safe hands.

With the help of our friends at Bath, we have been able to arrange a programme which, both from the point of view of excursions and papers, will compare favourably with that of previous years.

The railway companies will not give special terms to members on their journey from their homes to Bath, but members from a distance are recommended to avail themselves, as far as possible, of the ordinary tourist tickets. We shall, however, have considerable facilities for making excursions from Bath, either singly or in parties. During the week of the meeting, the Great Western, the Midland, and the Somerset and Dorset Railway Companies, will issue to any member, on production of his *signed* ticket of membership at the booking office at Bath, return tickets at a single fare to any station on their respective lines not more than fifty miles distant.

The excursions are of special interest, and, as already announced, include Chepstow and Tintern, Glastonbury and Wells, Salisbury, Corsham and Lacock Abbey, Bristol and Clifton. In addition, the local committee has obtained permission for members to photograph in the churches and other places of interest in and about Bath.

The papers are fewer in number than in previous years, with a view to prevent hurry, and to give time for discussion, which hitherto has often been cut short in order to make way for the following papers. The paper by Mr. W. Lang on "The Photographic Work of Herschel and Fox Talbot," and that by Mr. Common on "Recent Work in Astronomical Photography," are especially appropriate at a meeting in a district that is so intimately associated with the names of Fox Talbot and of Herschel.

One very important feature of the meeting will be the final report of our Lens Standards Committee, and the discussion thereon; and the discussion on "International Standards" that Mr. Warnerke has promised to open. It is hoped that everyone interested in this important question of standards will take part in the discussion, and that we may afterwards be able to appoint a committee to draw up a report or series of recommendations for presentation at the forthcoming International Congress in Brussels.

The Convention group will be taken on the Wednesday, and the dinner, which has always been such a great success, will, as usual, take place on the Friday evening.

In order that members may know where they are most likely to meet their friends, two hotels, the "Castle," in Northgate Street, and the "Royal," near the Great Western Station, have been appointed headquarters.

An exhibition of lantern slides will form one of the features of the opening meeting, and it is particularly requested that members who have slides of places visited at the last Convention, whether actually taken during the Convention meeting or not, will send them to me at the Yorkshire College, Leeds, or to Mr. W. Bedford, 326, Camden Road, N., at least a week before the opening meeting. Slides of other subjects will also be acceptable for exhibition either on that evening or at the other evening meetings.

The annual subscription is only 5s. Tickets of membership are now ready, and can be obtained from the Hon. General Secretary, Mr. J. J. Briginshaw, 128, Southwark Street, S.E., or from the Hon. Local Secretary, Mr. E. J. Appleby, 8, Argyle Street, Bath. C. H. Bothamley, *President.*

*Yorkshire College, Leeds, June 15th.*

## Proceedings of Societies.

### Holborn Camera Club.

A meeting on Friday last, Mr. D. R. Lowe in the chair, was held to elect a secretary in the place of Mr. J. E. Smith, who had resigned. Mr. Frederick J. Cobb, of 25, South Lambeth Road, S.W., was elected to fill the post, and Mr. A. Plumbridge was elected a member of the committee in the place of Mr. Cobb.

The prize given by Mr. T. O. Dear for the best picture taken at the Pinner outing last month, was awarded to Mr. A. J. Golding, who sent in a pretty picture of an old cottage.

Mr. A. Bell announced that he would give a prize for the best picture taken at the Purfleet outing, and the Chairman said he would also give one for the best picture taken at the London Colney outing on the 28th inst.

Twenty-one members, including five ladies, journeyed down to Purfleet on Saturday last, and spent an enjoyable day there. The members divided the plates in their slides between the annual fair, botany, and the river, taking shots at some of the vessels outward bound.

### Hackney Photographic Society.

A meeting was held on Thursday last, Mr. J. A. Sinclair in the chair. Mr. J. O. Grant presented the Society with twelve books.

Mr. Funston asked what strength should a hypo solution be used.

Mr. Hubert said twenty per cent. for prints, but rather liked a strong bath, though it bleached.

Mr. Beckett advised putting a little gold in the fixing bath for weak prints.

The Chairman liked the alpha combined bath, as it seemed to bring out density.

Messrs. Gosling and Roder showed negatives taken of the sun and the eclipse.

The subject of hand-cameras and plates therefor was considered, the several speakers advocating their special preferences.

Mr. Herbert Smith then gave a paper on "Photography and Cycling." The machine he preferred and used was fitted with the pneumatic tyre, as preventive of vibration. He carried his camera and sundries in a suspended arrangement in front of the steering bar. The only disadvantage he suffered from was dust.

Mr. Hubert thought glycerine would overcome the difficulty.

The Chairman observed that there would be a danger of dampness.

### Sydenham Camera Club.

The first excursion was made on June 6th, when a good muster of the members met at London Bridge Station, whence they journeyed by train. At Waddon, Mr. George Austin took the party through some charming scenery, and many successful exposures were made. On arrival at the "Greyhound," Carshalton, the few remaining plates were exposed on the church, pond, and main street of the village.

On the following Tuesday evening a meeting was held at the headquarters of the Club, the President in the chair. The discussion was upon the work done during Saturday's excursion. Some very good prints were shown by Mr. Zimmer, amongst them a group of the whole party. Mr. G. Austin's hand-camera subjects caused some amusement, he having caught several members unawares. Mr. P. Barlow showed some excellent work in Obernetter. A large number of prints and negatives were passed round and criticised.

Photographic Club.—Subject for June 24th, "Actinometry," to be followed by a series of lantern slides of Hildesheim by Mr. Frank Haes; July 1st, "Sensitometry." Saturday outing, June 20th, Chesham; train from Baker Street, 2.26.

## Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.

L. E. (Stockport).—*Back Numbers.* Whether bound or not, the Photographic Society might be glad to have them to complete their duplicate sets, for, at the present time, we know that there are a few gaps, and some of the Exhibition catalogues are especially wanted. Write to the assistant secretary, at 50, Great Russell Street, Bloomsbury, W.C.

J. McGeorge.—*Silver Printing Bath for Hot Weather.* Loaf sugar or nitrate of soda may be added to the bath in the proportion of five to ten grains per ounce, the object being to prevent the sensitised paper becoming too dry or horny by introduction of a hygroscopic substance. We do not recommend the addition of nitrate of lead at this season, for it would have the opposite effect.

Enquirer.—*Automatic Photography.* A tolerably extensive installation of these machines can now be seen in the grounds of the Royal Naval Exhibition, Chelsea, where, on sunny days, they are being widely patronised. The instruments require a little coaxing at times, and an attendant keeps up the supplies of the various chemicals. The aspect is nicely managed by having the machines grouped at different angles, but the public is not very discriminating, and often as not the customer poses in front of a lens into which is pouring a full blaze of sunshine! "Drop a penny into the slot," and you will hear a bell ring to announce the completion of the exposure; wait five minutes, and you will get a glass positive, dripping wet, but backed with a piece of ferrotype plate. A penny more buys a gilt frame, supplied mechanically.

Barnet.—*The Affiliation Scheme.* A few minor details remain to be settled, but the general scheme has been approved by the Parent Society, and circulars will shortly be sent out, inviting support and asking for the names of two delegates.

P. A. B.—*Enamel Paper.* Precipitated sulphate of baryta made into a cream with albumen or warm gelatine is applied to the surface of the paper, upon which the collodio-chloride emulsion is then poured. It would certainly be advisable to coagulate the albumen by heat before proceeding to sensitise its surface.

M. B. (Cambs).—*Quadrant Hand-Camera.* The ordinary size accommodates one dozen quarter-plates, and then weighs six pounds. The camera could be made larger; we have seen one specially made to order for 5 by 4 plates, but Messrs. Humphries and Co. inform us that they are not usually kept in stock of this size.

W. Manning.—*Seconds Pendulum.* At Greenwich the length of a pendulum beating seconds is 39·14 inches (one French metre), which practically holds good for any part of Great Britain at ordinary levels.

C. H. D. (Shrewsbury).—*Ballard's Actinometer.* The instrument does not appear to be known in this country, but, taking into account the fact of the description coming to us from an American source—*Anthony's Bulletin*—it seems likely that Messrs. E. & H. T. Anthony, of 591, Broadway, New York, would be able to supply it; or possibly the Eastman Company, 115, Oxford Street, W., might be willing to help you.

T. B.—*Permanence of Primuline.* During the fine weather of last week we made several rigorous tests by exposing to sunlight the red and purple developed images in primuline, and found the *former* to be more permanent. Light shades of purple on paper certainly fade to some extent, but the action seems to be arrested after a time, so that it was found impossible to obliterate even faintly printed impressions. The red pictures withstood the test fairly well, although we cannot even say of these that they are absolutely permanent.

J. E. D.—Answered by post, and the foreign letter returned.

## PHOTOGRAPHING INTERIORS.

If dry plates have made the general work of the photographer less irksome than it was when he had the anxieties of a silver bath to cope with, they have certainly brought with them and rendered possible tasks which the men of twenty years ago seldom thought of attempting. To those outside the world of photography, everything that is visible must be capable of being photographed, and some will gravely argue that, because an express train travelling at sixty miles an hour can be made to give its swiftly passing image to the gelatine plate, therefore all things are possible by photography. A list of the impossibilities which some of these patient workers have been asked to perform would be amusing to read as a good example of human credulity. But, although it may seem impolitic to explain to the ignorant why particular subjects are unsuited to the camera, and can, if attempted, never give satisfactory pictures, it is better to do so candidly than to risk one's reputation in sending out a photograph which is a failure.

Among the chief subjects, apart from portraiture, with which the photographer is called upon to deal, are pictures of interiors. These embrace not only public rooms and churches, but also private mansions, and one or two of our foremost photographers appear to have laid themselves out for this particular class of work. They have made an earnest study of it, and, as they do the work well, they obtain plenty of patrons. There is a wide field open for this phase of photography, and those who have not yet turned their attention to it, and still keep to their old groove of portraiture, would do well to consider whether it would not be worth their while to encourage such a profitable branch of business.

Twenty years ago no one would have dreamt of recommending photographers to take up interior work as a profitable thing, and for two very good reasons: the first, that the old wet-plate process was unsuited to the work, unless careful precautions were taken to keep the film moist; and the second, that, so far as domestic interiors are concerned, there was little that was worthy of being photographed. We, of course, had our palaces and show places at that date, but the average rich man had not begun to think it necessary to spend, as many do now, a small fortune on the interior decoration of their dwellings. In many of the West-end squares of London, the exterior aspect of the houses is precisely the same as it was fifty years ago. The fronts of the mansions receive their annual or triennial coat of sober cream colour, and year by year they preserve their stolid appearance of comfort, cleanliness, and intense respectability; but if we step inside, we find what a change this half-century has brought about. The dining room, for instance, has no longer its walls flatted with a coat of green or drab, upon which the oil pictures, hung in massive frames, looked so well, but is now ablaze with the carefully chosen tints worked out by the ancient or modern tapestry weaver, while the lower portion is filled in with the inevitable dado made of inlaid woods. The spotless white-washed ceiling which contented our forefathers has gone, and its site is now panelled in polished woods. The floor is similarly ornamented in beautiful parquetry, and, instead of being hidden from wainscot to wainscot by a Brussels carpet, has a large square of "Turkey" or "Axminster" in its centre. The furniture has undergone the same transforming process, while the whole is brightened up with stained glass in the windows, and with rare flowers and handsome ornaments *ad libitum.* The room, and indeed every room of the house, is itself a picture, and small wonder is it that its proud possessor should desire to have it photographed.

Now, a photograph of such a room as we have described is not generally a difficult operation; but it requires great care if we desire to secure a first-class negative. The best lens to employ is a rectilinear, which may be replaced with advantage by a wide-angle of the portable symmetrical type if space be limited, as it very often is. Windows must be excluded from the picture if possible, and those which are outside its limits must be made to yield all the light available by either removing or tying back temporarily the window curtains. A time of day should be chosen when actual sunlight cannot enter the room, for a patch of bright light falling in one particular place is sure to make an unpleasant flaw in the picture. In London, and other places where the houses are near together, it is generally necessary to give an exposure of nearly half-an-hour; but, of course, exceptional circumstances may modify this to a considerable extent.

Not long ago we were shown two photographs of the interior of a church which were as perfect as could be wished. Such photographs are too often of the "chalk and soot" variety—the soot being represented in the black roof and pews, and the chalk by the windows, which usually spreads its whiteness by halation far beyond the limits of the window frame. These particular photographs were simply perfect. There was not only no halation from the east end window, but every detail in the stained glass pictures could be made out. More than this, the frescoes painted at each side of the window on the church wall were also rich in detail. How was this fine result achieved? was our enquiry. Were the plates backed, or were films used? The photographer used ordinary plates, unprepared in any way, and his success was mainly due to the simple expedient of having the east window of the church covered during the major part of the exposure. This is how it was done. The camera was carefully laid in position and focussed, a plate inserted, and an exposure of ten seconds given, after which the lens was capped. The window was now covered up, outside the building, with a baize carpet, reared on two uprights and a cross-piece, the arrangement being easily handled by a couple of men. The photographer now uncapped his lens once more, and gave an exposure of ten minutes. At the end of this time he put a fresh plate in the camera, and once more gave an exposure of ten minutes, and again capped the lens. It now only remained to take away the screen from the window, and to give a supplemental exposure of ten *seconds*, and two well-exposed and perfect negatives were the ultimate result. The same artifice can be adopted in most cases where it is desirable or necessary to include a window in an interior photograph, and it is by taking the trouble to make use of such expedients that the excellent workman is recognised.

---

THE Dowager Crown Princess the Archduchess Stephanie recently went to the Austrian Museum to inspect the International Exhibition of Artistic Photographers in Vienna. She was received by the director of the Museum, the president, and vice-president of the Club. First she looked at the photographs exhibited by the Archduchess Maria Theresa, the Patroness of the Exhibition, the Grand Duke of Tuscany, the Princess of Wales, and Count Henry Bardi. She told the gentlemen accompanying her that she occupies herself with photography a good deal for making sketches for pictures afterwards. She has taken many photographs at Venice and Naples. It was the seascapes which especially pleased her, and particularly the picture of Jersey, by A. R. Dresser, which work of art she desires to possess. The president will take the steps necessary for procuring her the picture. After staying nearly an hour and a half, her Imperial Highness took leave after again expressing her appreciation.—From the *Neue Freie Presse.*

## THE FABRICATION OF PHOTOGRAPHERS' VARNISHES.*

BY H. C. STANDAGE.

*Colouring of Varnishes.*—Sometimes it is necessary to give varnishes a certain colour, as, for example, a good lac varnish for lacquering brass-work. In such cases colouring substances that are soluble in alcohol are used. It is not necessary in these pages to give details for producing such coloured varnishes; they are not much used in photographers' work. But a few lines as to the best way to colour a varnish will be acceptable to some photographer who wishes to renovate the appearance of his camera, be it the metal work, mahogany frame, or leather bellows.

The suitable colouring material should be dissolved in alcohol, or a tinctorial extract made therewith; this should be filtered, and then this extract should be applied to the varnish. After the entire process of decolourising and filtering is finished, the extract should be as concentrated as possible, and enough of this saturated solution added to the fat varnish to produce the desired shade of colour. As a considerable quantity of the solution of many colouring substances has often to be taken for the purpose, it might be the case that, in consequence of this, the varnish would turn out too thin. This must, therefore, be taken into consideration, and the varnish must be made somewhat more viscid. When aniline colours are used, no attention need be paid to a possible thinning of the varnish in consequence of the addition of the solution of colouring matter, as these colours dissolve evenly, and are very productive in depth of colour.

*Recipes and Directions for Preparing Varnishes.*—Too frequently varnishes are empirically made, which is a most unsatisfactory way, as no haphazard work ever turns out satisfactorily. It is absolutely necessary to know *for what purpose* the varnish is to be used before a properly made product can be obtained. The different properties—as that of great hardness, which is always combined with a certain degree of brittleness, or elasticity and pliancy—can only be obtained by using different kinds of resin. The *hard resins*, like amber and copal, will produce very glossy, but also *quite brittle*, varnishes; whereas sandarac, mastic, elemi, and venetian turpentine possess the property of making varnishes more *pliant and tenacious.* The little variety of purposes, however, which the photographer uses varnish for restricts this quality to a few. The lacs and sandarac resin are the two chief ingredients used in photographic varnishes.

The first comprises several varieties—ruby lac, shellac, seed-lac, and stick-lac. The first is the natural product, while the second and third have been manipulated to give them less colour, so as to suit them for various purposes. The first, or ruby lac, is the best for the photographer to use in making varnishes, as the bleached kinds contain traces of the acids, &c., that have been used in the bleaching process.

If large quantities of the varnish are required, it is as well to keep a stock of dissolved resin, and diluting this to the proper consistency as occasion requires—*e. g.*, take of—

| | |
|---|---|
| Ruby shellac ... ... ... ... | 1 part |
| Alcohol (90 per cent. strength) ... ... | 5 parts |

Allow the resin to digest by frequent shakings or stirrings, and then set aside for several weeks to settle. This will

* Continued from page 451.

require no filtering, as all the solid particles will settle to the bottom, and the clean solution can be poured off for dilution when required.

Should the varnish thus prepared be too limpid or thin, it can be brought to the proper consistency by distilling off the excess of spirit. To do this an ordinary glass retort can be used; or place the varnish in a vessel, which stands in a large saucepan of boiling water, and keep the water boiling for an hour or two.

The peculiar contradictory properties—hardness combined with elasticity—which photographic varnishes must possess render their fabrication not always a certainty, and it is scarcely possible to give equal satisfaction with respect to both of them; for, besides the above qualities, they must be entirely colourless, adhere tightly to the glass, and yet be so constituted as to allow the plate to be retouched with a lead pencil; and yet the varnish must not crack when the plate is laid away, as this would mean the ruin of the photographic negative. Varnishes made according to the following formulæ can, however, be depended on, as they have stood the test of many years' experience.

FORMULÆ FOR VARNISHES.

*Varnish for Photographic Negatives.*

| | |
|---|---|
| Sandarac resin ... ... ... ... | 4 parts |
| Spirits of wine ... ... ... ... | 20 ,, |
| Chloroform... ... ... ... ... | 0·5 part |
| Oil of lavender ... ... ... ... | 3 parts |

To use this varnish, pour it when filtered on to the glass plate, and dry by applying heat. A perfectly colourless form, which does not crack even if the negative be stored away for a long time.

*Hard Lacquer for Photographic Negatives.*

| | |
|---|---|
| Sandarac resin ... ... ... | 7 ounces |
| Venetian resin ... ... ... | 0·7 ounce |
| Oil of lavender ... ... ... | 0·875 ,, |
| Ether... ... ... ... ... | 0·875 ,, |
| Absolute alcohol ... ... ... | 17·5 ounces |

*Retouching Varnish for Photographs.*

| | |
|---|---|
| Shellac ... ... ... ... | 0·035 ounce |
| Sandarac ... ... ... ... | 0·21 ,, |
| Mastic ... ... ... ... | 0·21 ,, |
| Ether... ... ... ... ... | 2·7 fl. dr. |

2·7 fluid drachms of pure benzole are added to the mixture after the resins have dissolved in the ether.

*Monckhoven's Retouching Varnish for Negatives.*—"Shellac is placed for twenty-four hours in a saturated solution of carbonate of ammonia in water. The solution is then poured off, and replaced by an equal quantity of pure water. The fluid is boiled under constant stirring until a complete dissolution has taken place. The proportion between shellac and water should be as 1 : 8. This is poured twice in succession over the negative, which must be thoroughly dry. Retouching can be done more quickly and finer upon this coating than upon any other."

*Elastic Dammar Lacquer for Photographs.*

| | |
|---|---|
| Dammar... ... ... ... ... | 1·4 ounce |
| Acetone (wood spirit) ... ... ... | 6·3 ounces |

The resin will be almost completely dissolved in a fortnight if the well-closed bottle containing the substance is allowed to stand in a moderately warm place. The solution should then be carefully poured off from the residuum. To apply the lacquer use a soft brush, and apply it several times.

*Photographers' Lacquer.*

| | |
|---|---|
| Mastic ... ... ... ... ... | 2 parts |
| Shellac (bleached) ... ... ... ... | 10 ,, |
| Oil of turpentine ... ... ... ... | 2 ,, |
| Spirits of wine ... ... ... ... | 60 ,, |

*Another Formula.*

| | |
|---|---|
| Amber resin ... ... ... ... | 1 part |
| Copal ,, ... ... ... ... | 1 ,, |
| Benzole ... ... ... ... ... | 2 parts |
| Alcohol ... ... ... ... ... | 15 ,, |

*Another Formula.*

| | |
|---|---|
| Amber ... ... ... ... ... | 2 parts |
| Copal ... ... ... ... ... | 2 ,, |
| Mastic ... ... ... ... ... | 1 part |
| Petroleum naphtha ... ... ... | 10 parts |
| Spirits of wine ... ... ... ... | 20 ,, |

Great care should be exercised in choosing the raw materials for photographic lacquers, as it is absolutely necessary that they should be entirely colourless.

There are many other formulæ, but the above will be found efficacious enough to need no addition.

## THE OPTICS OF THE LANTERN.*

BY J. TRAILL TAYLOR.

LET us now direct our attention to the *condensing* element of this optical system. We have seen that the two elements of the collecting portions must be fixed and inseparable. This, on the contrary, should be variable, and selected to suit the special end in view. Its form may be plano-convex, more especially if for use with long-focus objectives; but if the latter is to be short-focus, and the condenser of crown glass, then is the crossed form, in which the curves are as one to six, or two to thirteen, to be preferred.

But dealing, as we now are, with immergent parallel rays, it were folly to imagine that a condenser properly adapted for an objective of 12 in. focus will answer equally well for one of 6 in. Bearing in mind Kepler's law—which, however, applies only to one kind of glass, and must not be held as applicable equally to the flint glasses, especially those of the denser sort procurable at the present day—I would say that, for long-projection lenses of 12 to 15 in. focus, a plano-convex having a radius of curvature of 7 in. will serve every purpose; for an objective of 8 to 10 in., the radius may be 4½ in., while for one of 6 to 8 in., 4 in. will suffice. But, as I have said, this latter may, with advantage, be a crossed lens, in which case the radius of the more convex side will be longer.

One word more before dismissing the condensers. Treat them with the most scrupulous care, both in heating and cooling, and avoid allowing a current of cold air to play upon them during the cooling. With this precaution, superadded to having them set loosely in their cells, a fracture will rarely, if ever, occur.

Turn we now to the objective, the image-former. First, its diameter, especially that of its posterior combination, must be sufficiently large to take in not merely the whole of the cone of rays emerging from the condenser, but by preference a little more. This permits of the utilisation of a small portion of light radiated from the substance of the image itself.

A large back lens also permits it to be brought nearer to the picture, and this is advantageous, especially with

* Concluded from page 443.

the condensers of the common order, as it acts in condensing the scattered rays from those of this class, enabling also the light to be approached nearer to the condenser. The lens tube should be longer than in the case of its application to photography, for, unlike this, all it is required to cover is the very limited area comprised in a plate three and a-quarter inches square, minus the portion occupied by the mat. For the highest class of objective, it suffices that it be achromatic in the sense different from actinic, for, so long as the visual image is perfect, it matters not what becomes of the violet or chemical rays, or what relation they have to the luminous ones.

It is in the construction of a lantern objective of short focus that the skill of the optician is taxed, as it has to cover sharply to the margin with its full aperture, and under circumstances in which the slightest inequality in the definition is instantly detected. To a cultivated eye it is extremely unpleasant to see an image quite sharp in the centre of the disc, and falling off rapidly towards the margin, or by racking in securing marginal sharpness at the expense of the centre. Of the various forms of objective to be met with in commerce, at any rate for those of medium short focus, I incline to give preference to that introduced ten or eleven years ago by J. H. Dallmeyer, judging by the performance of one of this class in my possession, made by Newton and Co. In it the elements of the back lens are separated to an extent which would prove hostile to sharpness in the case of one employed in producing a photographic image in the camera. If photographic lenses are to be employed in the lantern, those of the carte-de-visite (Petzval form), that is, those corrected for flatness of field, even to the extent of there being slight astigmatism, are advantageous. One of the most satisfactory *short*-focus objectives I ever used had a back lens $2\frac{1}{4}$ in. in diameter, the front lens being $1\frac{3}{4}$ in. It gave a very great excess of negative spherical aberration to the back lens, and the front was a nearly plano-convex achromatic of short focus. This gave a field which was singularly flat, the definition at the margin quite equalling that in the centre; but, owing to the excess of aberration spoken of, the image did not quite equal in sharpness that obtained by the ordinary carte-de-visite lens with rounder field. Still, spectators seated at a distance of five yards from the screen were unable readily to appreciate that the definition was imperfect, for, as you know, even the crude brush-work of the scene-painter seems sharp when viewed from a distance.

In objectives of long focus there does not appear to be the same tax on the skill of the optician. Poor, indeed, must be the lens of 10, 12, or 14 in. focus that will not cover sharply and uniformly a plate 3 in. in dimensions.

DISCUSSION.

Commander GLADSTONE: Mr. Taylor said that in the ordinary commercial lanterns the whole of the back lens is not used. I found, in using the ordinary green glass condensers, that even taking the lime 3 in. away, you might cut off half an inch of the condenser all round, so that a 4 in. condenser becomes practically a 3 in. I think the principal point in the condenser is the glass of which it is made. We don't quite realise the amount of light which is lost in passing through the green glass condenser in the ordinary lantern; there is also degradation of tone, for the colour of the glass considerably interferes with the colour of the slide, especially if it has anything of a brown or mauve colour. Mr. Taylor says that the condenser he described takes in an angle of 95 deg.; if the back lens were $4\frac{1}{2}$ in., and the lime 2 in. away, that would be so. But I also understood him to say that the front lens was 5 in. in diameter, and if so, it seems to me that the effective angle is not 95 deg., because, taking the opening of the slide to be 3 in., the whole of the light collected by the back lens does not pass through it, it being in close contact with the condenser. I have no doubt that the system he has described is the proper one; you want first a collecting system to get parallel rays, and then to place in front of it a lens that you can adjust the focus of, and so adjust the cone for whatever lens you want to use.

Mr. ELDER: I might just point out one or two things. First, a method used by Professor Boys for saving his condensers from damage by heat. He places a sheet of plain glass against the condenser at a slight angle. Everyone knows how sensitive the ear is to the crack of glass under heat. When the lime gets pitted, or anything else goes wrong, this piece of glass cracks, he hears it, attends to the lantern, and so saves the condenser. The disadvantage of the plan is that it gives another reflection, and so wastes light. It can be used, unless very large work is being done, ample light passing through the glass for ordinary purposes. I was very much interested in what Mr. Taylor said about the position of the focus of the cone of rays coming from the condenser. But it seems to me there is a difference in practice in using the lantern and using the microscope; the same laws must apply, and yet there does seem to be a difference. My friends who use the microscope habitually say that to get the best effect they find it necessary to focus the radiant with the condenser on the object. One would therefore presume that, to get the best effect on the screen, it would be necessary to focus it on the slide, and not in the centre of the projecting system. It struck me whether it might not be possible to alter the whole system of projection by using a moderately large radiant brought to a focus on the slide. No doubt, if it were possible, the best system would be to use no condenser at all, but to put a large radiant—in fact, a sheet of light—close to the slide. Light is always lost in using condensers, and it is only because it is impossible to do this that we are compelled to use them. The next best thing seems to me to be to focus the radiant on the slide, thus making the slide the luminous object or origin of light as far as the projecting system is concerned.

Commander GLADSTONE: I have cracked a good many condensers, and I tried to see if I could not get something to interpose between them and the light. I tried all kinds of glass, but never found a piece that would stand the heat for ten minutes. I was using a blow-through jet, which I turned on until it was hissing, and left it there. If you attend to your jet, and don't let the lime get pitted, there is no danger at all. I tried chemical glass, Bohemian flask bottoms, unsuccessfully. At last I got a Sugg's lamp chimney, 16 in. long and 5 in. diameter, used for 500 candle-power light; I had it cut into four, and put one piece over the whole jet, and I have never cracked it yet.

Mr. ELDER: Professor Boys told me he found that his plan acted well, though he often cracked the piece of glass.

Mr. KAPTEYN: There is a rule that you must not let the sun shine on the lens. Is the principal reason of this because the glass of the lens is affected by the sunlight coming right into it? There are, of course, other reasons why, when taking a photograph, the direct sunlight should not be admitted.

Mr. TRAILL TAYLOR: If the 3-in. slide is close to a 5-in. condenser, there is a loss of light; but I have always taught that the slide ought to be movable, so that it can be brought to the point where the cone of rays is of the same diameter as the slide. The slide-holder ought to be really the moveble part of the lantern, in conjunction with the condensing lens, and if it were so, even the whole power of the light could be made to pass even through a 1-in. picture. The degradation of tone by green glass is more than anyone has any conception of. But there is another degradation of tone, and that is due to the printing of transparencies upon strongly coloured green glass, and covering them with another piece of the same colour. Most of them are exceedingly offensive in that way. Lay one on white paper and you will see the degradation. Many years ago I had some transparencies made on French crystal glass, the kind which was used for covering Daguerreotypes, and that, even when held edgeways, showed no colour. I was lately talking to Mr. Newton, sen., who pointed out that he had never lost a condenser since he had interposed a piece of slightly curved glass between the light and the condenser. The sun should not be allowed to fall on a photographic lens, because it sets up a variety of reflections which degrade the image, and it also degrades the glass itself. How that applies to the more recently introduced glass I am unable to say. Those who formerly used photograph lenses for solar enlargements complained that after a time they got slower, no doubt from that cause. It could not be from the effect of the light on the Canada balsam, for it bleaches that.

Mr. Little: A member of a photographic firm in Boston told me that they imported in one year £8,000 worth of French crystal glass for lantern slides alone. That may be a reason why the American lantern is ahead of the English lanterns.

Mr. Traill Taylor: The American commercial lanterns are bought in this country. What I had in my mind's eye were those made many years ago by Dr. Cresson and Professor Henry Morton, of Philadelphia. There were many exceedingly clever scientists there who devoted much attention to the lantern—men of the Zentmayer type, gentlemen connected with the Franklin Institution. When Professor Tyndall was lecturing over there he was "flabbergasted" by the great excellence of the lantern appliances, and saw monochromatic polarised light which he had never seen before. The price of the lenses I have described ought not to be great.

## NOTES ON LANDSCAPE.*

BY FRANCIS L. PITHER, ARCHITECT.

The subject we are met here to-night to examine is one that interests us all, from the youngest enthusiast, in the full glory of his spotless apparatus, to the oldest photographic hand, who can tell us all about the mysteries and hard work of the wet plate. And then we all have our own pet ideas on the subject, and with the facilities at our disposal, what easier than to turn out good landscapes? Should, perchance, a too critical friend dare to hint, however delicately, that this or that in our work might with advantage be altered or left out, do we not, in our heart of hearts, either think that he knows nothing at all about it, or else feel just the least twinge of the old enemy, the green-eyed one? Whether our candid friend be right or not, I desire to bring home to your minds what I sincerely believe to be a real stumbling block to the elevation of the study of photography. The facility with which our results are obtained will always be baneful so long as the subject is not studied in a more serious manner from its artistic side than seems to prevail; that is, so long as our minds are not tuned to a proper appreciation of the manifold aspects nature is constantly presenting. I mean an appreciation quite apart from the usual formulæ which now excite us most, such as "Where's the sun?" "Where's my actinometer?" "How long shall I give for this, I wonder?" &c. The truth seems to be that we are so wrapped up in "eiko" this and "pyro" the other, ounces wet and ounces dry, that we are fain to consider that a sharp image on the screen, and a sharper click of the shutter, is all that the field part of our work requires. It is all part of the love of the automatic penny-in-the-slot business that is fast fixing itself into our every-day life. As it bears upon photography, it is nothing short of a spirit of mischief which it should be our business to root out. I hold that we have no more right to think we can turn out pictures without thought and study beforehand, than to expect an elaborate piece of mechanism will work without steam.

I confess that the bulk of these remarks are, perhaps, not so much directed to the actual practice of photography as you might desire, but I must insist that, unless you are content to study the subject as it would be studied by those with less facile means of portrayal, you must be content to have your work qualified by the greatest drawback to all artistic production, viz., that of mechanical hardness. Now, I cannot but think that the line that divides this from one of the cardinal points of belief of a certain school of workers is an extremely fine one—in fact, almost non-existent—and yet we are taught by them to consider that microscopical sharpness from edge to edge is one of the first essentials to be aimed at. Now, in the earnestness, and with the full knowledge of the risk I am running of failing in your esteem, I tell you that this quality is far too much over-rated. That it deserves a certain amount of admiration none will deny, but, encouraged beyond a certain point, it will never fail to be utterly subversive of all feeling and tenderness by robbing your work of a great deal of its breadth. Of this, however, more hereafter.

I should say I am not now referring to photographic work of what might be called the still-life class, because I yield to no one in my admiration of a faithful, well-lighted, and technically perfect work, representing in its fullness of detail a complete transcript of any work in actual existence. Such productions have their proper sphere of usefulness, and are of importance in their way, but they do not rank as works of art, from the mere fact of the utter impossibility of impressing them with even a modicum of individuality. For example, one would not wish to deny that the legion of architectural and still-life photographs in existence have a value, but these things are only beautiful in so far as they are truthful, and, being truthful, admit of but one rendering.

Let me ask you to examine the subject with me as in the old days, when one's impedimenta consisted in nothing more formidable than a sketch block, a few choice pigments, and water from the nearest brook. One of the simplest and grandest rules I learned when sketching from nature, and withal one of the most difficult of application, is the great art of selection—in other words, to discover what may be left out; and, although it may sound paradoxical, I then found that the more one omitted, the better was the result.

Underlying the whole study of the graphic arts, whether applying to painting, portraiture—or photography, I had almost said—and more important than the technics of either study, is this art of selection, or seeing, or whatever other term may best convey to your minds the absolute necessity of not reproducing too much in a given area. It is not too much to say that this is a more neglected study than any other among an average community of photographers. We mostly lack the inclination, being far too busy with our every-day work, to bestow much time on such an apparently insignificant idea. This is, no doubt, how the majority will receive this suggestion, yet it is certainly true that the cultivation of this faculty is one of the chiefest aids to the success of some of our best men. Yet, as I have said, its acquirement is by no means so simple as appears at first sight, and for this reason. Professor Max Muller once told a friend of mine that this same hurry and drive of modern life was fast undermining the purity of the language colloquially speaking.

* Read before the North Middlesex Photographic Society.

People would not give themselves the time to say "thank you," it must be chipped to "thanks"; "doncherno," for "do you not know"; "bus," for "omnibus," and so on, *ad infinitum*; and so it is with photography. Now, it is not even easy to prescribe a sure method of approaching the study of the art of observation, because it holds, so to speak, the genius which finds its outward expresssion in whatever of individuality we may impress in our work, for no two persons will be similarly affected by the same scene. One will think this cloud too heavy, another that road too straight, a third that house too tall, and so on. No doubt some hair-splitter might be able to derive some profit from an examination and comparison of each set of likes and dislikes. I propose no such excursion, not wishing to send you to sleep.

Now there can be no doubt that individuality is the soul of all art work. If we go to any exhibition of paintings, and have a fairly current knowledge of the works of our leading painters, we shall be able to pick out certain works as coming from certain men, because we shall have become acquainted with their several leading characteristics, otherwise their individuality, and I take the liberty of saying that this should be the keynote of our aim in photography, and I care not how it is arrived at, all ranters about pure photography notwithstanding. If you questioned the methods of men who work in oil or water-colours, they would laugh at you for your pains. Why, then, should not all means be open to the production of a good sun picture? All roads lead to Rome; let us then tread forward to excellence along our own path. Be it admitted, however, once for all, that that path does not offer the same possibilities, cramped as we are by the exigencies of our method. Much may be done, however, by studying the works of one or two celebrated landscapists, and, being guided by the conclusions of such study, we shall find that our work will gradually rise from the commonplace in proportion as our intelligence to bend methods is adequate. There is no royal road in this as in other things. As a practical illustration, I would remind you that one of our greatest landscapists built up much of his manner during a certain period of his practice upon the works of a foreign artist. Take any of the less allegorical canvases of Claude, and in the front of the middle distance put a group of Scotch firs, or other prominent mass in the landscape, and you have the difference that exists between a Claude and a Turner. I am aware that the practice is not directly applicable to photography, but if you seize the principle of it, you will find yourself only taking scenes from such points of view as will give you some such prominent feature to qualify your composition, and will thus gain individuality. By this means the planes of your picture will be in better relation the one to the other, a quality not always met with in an average photograph. But you may say, "Granting I have found such a scene, I may have correct exposure, development, and printing, and yet the sought-for individuality may still be wanting." I must say I do not think it should be so, but should you, in the manifold chemical labyrinths with which we are beset, happen to be so far unsuccessful, then with the view in your mind and your shortcomings before you, apply a few broad washes of very light India ink to your negative, and so establish the balance you seek for. I have said it is necessary to exercise a certain process of selection in order to work out a completely satisfactory composition; but quite apart from this there lies a wide field of study for us—a field only rendered possible by the very nature of our craft. Depend upon it, a very respectable reputation awaits the man with time and inclination to go out with his camera into the fields, and, as it were, wait upon Dame Nature. It is no small boon to have at command the means to catch the passing gleam of sunshine as it glides over the landscape, changing in the twinkling of an eye an expanse of dreary grey into a veritable glimpse of fairyland, or again, to be able to carry home in his slide that delicious ripple across the stream, with just a suspicion of movement in the trees or on its banks to account for it. These are things worth watching and waiting for, and not, as we are told, to wait until the beastly wind drops. One who will work in some such manner may, and indeed will, be scoffed at by the aforesaid school as a careless student, and perchance incur the awful risk of being branded as a "naturalistic"; but what are these things to count against honest endeavour to impart that which is sadly wanting in the majority of photographs, viz., just a touch of the soul within us?

*(To be continued.)*

## SOME NEW ADDITION COMPOUNDS OF "THIO-CARBAMIDE" WHICH AFFORD EVIDENCE OF ITS CONSTITUTION.*

BY J. EMERSON REYNOLDS, M.D., F.R.S., PROFESSOR OF CHEMISTRY, UNIVERSITY OF DUBLIN.

In the course of Part IV. of a series of papers on "Silicon Compounds and their Derivatives" (Trans., 1888, 53, 857), I gave some account of a beautiful white crystalline substance which was one of the most abundant products of the action of ethylic alcohol on the compound $(H_4N_2CS)_8SiBr_4$, described in a previous communication (Trans., 1887, 51, 202). The product referred to was shown to consist of the elements of four mols. of thiocarbamide and one mol. of ammonium bromide, whilst its synthesis was effected very simply by heating together the two substances in the above proportions and in presence of absolute alcohol.

It was also pointed out that other halogen compounds of ammonium and of some of its derivatives could be made to unite with thiocarbamide, and afford substances similar to tetrathiocarbamidammonium bromide. But the members of this group of compounds—other than the first—were only mentioned incidentally, as they had not been examined in detail at the time of publication of the paper in which the products of the decomposition of the silicon compound were described. When closely studied, however, they proved to be of more interest than I had supposed, for it soon became evident that they do not all conform to a single type, but exhibit significant variations in composition which is connected with the peculiar constitution of thiocarbamide.

In the following account of these compounds I shall first describe their preparation and properties, then give a summary of these facts, and conclude with some considerations suggested by the evidence.

In the descriptive part, I have given some further details relating to the ammonium bromide compound, as an interesting practical application of the substance has recently been made by Colonel Waterhouse to the production of direct *positive* photographs. So effective is this agent in securing the reversal of the photographic image on gelatino-bromide films, that the presence of less than

* From the *Journal of the Chemical Society*.

$\frac{1}{100}$th of a grain per ounce in "eikonogen" developer causes the negative image that first appears to change into a rich-coloured positive.

DESCRIPTIVE PART.

A.—*Compounds of Thiocarbamide with Ammonium Haloïd Salts.*

It has been already mentioned that the well-defined crystalline solid $(H_4N_2CS)_4NH_4Br$ was obtained, in the first instance, by the action of ethylic alcohol on the compound which results from the union of silicon tetrabromide with 8 mols. of thiocarbamide; and that the same substance was subsequently prepared by the direct action of ammonium bromide on thiocarbamide. The latter or synthetic method is the only one with which I am now concerned; it afforded the best result when conducted in the following manner:—10 grams of ammonium bromide were dissolved in the smallest quantity of hot alcohol required for its solution, and this liquid was added to a boiling and nearly saturated alcoholic solution containing 30·4 grams (4 mols.) of thiocarbamide. The mixture was boiled for five minutes, and then allowed to cool in the containing flask. The contents soon began to deposit warty aggregations of radiating crystals which attached themselves to the bottom and sides of the vessel, and, when quite cold, the whole formed a nearly solid and beautiful white crystalline mass of characteristic appearance. When drained, pressed, and recrystallised from alcohol, it is obtained in a perfectly pure state. In this condition it was analysed, with the results already stated (*loc. cit.*).

Tetrathiocarbamidammonium bromide melts at 173—174°, but begins to decompose at 178—180°. It is easily soluble in boiling absolute alcohol, but is so much less soluble in the cold liquid that the hot saturated solution becomes nearly solid at ordinary temperatures. More dilute solutions, when slowly cooled, deposit the compound in large and beautiful stellate groups of crystals, which often resemble sea anemones in appearance. It is almost insoluble in ether, chloroform, and benzene, but is rather easily soluble in water. When pure, its aqueous solution can be boiled violently for half an hour without undergoing sensible decomposition; but if impure in the first instance, partial decomposition occurs. It is easily broken up by boiling with dilute acids and alkalis, and is readily desulphurised by alkaline lead tartrate.

Having determined the composition and principal properties of the tetrathiocarbamide compound, it remained to be seen whether ammonium bromide could combine with 1, 2, or 3 mols. of thiocarbamide in presence of alcohol. To test this point three separate experiments were made, in each of which 1 molecular proportion of ammonium bromide was heated in alcoholic solution with 1, 2, and 3 mols. respectively of thiocarbamide under precisely the same conditions as those which suffice for the production of the tetrathiocarbamide compound. In each case a quantity of the tetrathiocarbamidammonium bromide was obtained proportional to the amide added, and the excess of ammonium bromide separated when the mother liquors were concentrated. No traces were observed of any but the tetra compound under the abovementioned conditions, or under any other hitherto tried. It therefore appears that ammonium bromide and thiocarbamide do not combine in any other proportion than that of 1 mol. of the former to 4 mols. of the amide.

## Notices of Books.

TRAITE ELEMENTAIRE DE L'OBJECTIF PHOTOGRAPHIQUE. By E. Walton. (*Paris: Gauthier-Villars et fils.*)

THE author of this book, M. E. Walton, who is professor of physics at the *Lycée Janson de Sailly*, has endeavoured to follow on and complete the work initiated by Monckhoven in his "Optical Photography," and he has succeeded in producing a work which is a complete exposition of the subject with which it deals. Here we find explained the phenomena of refraction; the laws by which it is governed; a detailed account of the various lenses employed in photography, from simple forms to compound ones; the effect produced by aberrations, and the means employed for correction, &c. The book contains 300 pages of most useful matter. It is well printed, and is fully illustrated with clearly drawn diagrams. It is issued in paper covers, the leaves are uncut and have a very broad margin. Many of our English publishers would do well to take a hint from this commendable practice, for it is one which tempts the owner of such a work to have it well bound.

HANDBUCH DER PHOTOGRAPHIE FUR AMATEURE UND TOURISTEN. By Major G. Pizzighelli. (*Wilh. Knapp, Halle a S.*)

THIS is a second edition of the first volume of a comprehensive hand-book for the value of which the name of the author is a sufficient guarantee. The first edition was published in 1886, and consisted of 436 royal octavo pages; but since its issue the modifications and advances in photography have been so great and rapid as to necessitate not merely a complete revision, but a substantial enlargement of the book. The present edition is, therefore, extended to 486 pages, the text admirably elucidated by some 531 illustrations, and treats most fully of photographic apparatus. The succeeding volumes will deal with photographic processes, and the practical applications of photography.

TRAVELLERS' COLLOQUIAL GERMAN. By H. Swan. (*London: David Nutt.*)

A USEFUL little compilation, which forms No. 2 of the "Phonetic" series of hand-books for English-speaking travellers and students. No. 1, "Travellers' Colloquial French," in its third edition included an Appendix for Cyclists and Photographers. It may be hoped that, should the book before us attain, as it deserves, a third edition, it also will contain a section which could not fail to be useful to travelling photographers unacquainted with the German language; at present cyclists only are favoured. There is, however, a large amount of general information that will make the little book most serviceable.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.—The second out-door meeting of the season was at Ripon and Studley Park, on Thursday the 18th. Upwards of 200 plates were exposed, mostly upon the ruins of Fountains Abbey.

"FALLOWFIELD'S Photographic Annual for 1891," just received, is a book of over 500 pages, for the most part consisting of a comprehensive illustrated catalogue of photographic materials, chemicals, and apparatus, but containing also a large amount of useful information on various topics connected with the practice of photography.

## Notes.

It has often been rendered painfully apparent to photographers that it is not desirable to photograph all subjects indiscriminately in a French town. If a picture should unfortunately contain the image of a fort, or any other thing of a military nature, or should even be suspected of doing so, the unfortunate possessor of the camera speedily finds himself in durance vile. Many innocent tourists have been put to the gravest inconvenience in being detained in this manner, under the suspicion, of course, of being Prussian spies. Indeed, ever since the Franco-Prussian war our French neighbours have been mad on the subject of spies, and have not yet recovered from the hallucination.

We were not, therefore, very much distressed when we read the other day, in the *Telegraph's* "Paris Day by Day," that a French barrister taking photographs of the German soldiery in one of the conquered provinces—no doubt innocently enough—had been "run in." He was merely amusing himself by taking a few shots with an amateur's camera at a regiment of German dragoons marching back from exercise, when he was arrested and taken before the police authorities, who only allowed him to go on the promise that he would take the next train for the French frontier. The precious plates were detained, and are to be officially examined, but with what object it is hard to determine.

In the meantime, it would seem that the French are about to render France still more uncomfortable to the tourist photographer. The Espionage Bill, which it is proposed to pass, enforces penalties of a most severe description on spies of all kinds. If, for instance, anyone procures admission to a fortress, dockyard, man-of-war, or naval or military establishment by means of a disguise, false name, or untrue statement, and, acting as a spy, obtains information calculated to compromise the defence of the territory, he will be liable to condemnation to death; and the same penalty will be meted out to those who, for purposes of espionage, may have made surveys, drawings, or plans; organised or employed means of correspondence, or collected intelligence with the same detrimental object. If a hurriedly made plan or drawing subjects its author to death, what awful fate is reserved for him who produces the far more accurate and, therefore, more harmful photograph? We advise our friends to steer clear of France if this bill should become law.

It too often happens that the inventor of a good thing gets very little either of credit or profit out of it, the shrewd man of business coming in and possessing himself of both. We were reminded of this truth the other day, when we saw, in a French photographic journal, the description of a "new" dark back for films. This back does not open book-fashion in the usual way, but has a space inside filled in with a removable partition of ebonite. Over this flexible slip is folded a double band of film, sufficient for two exposures, and the partition is replaced. This *new* device was patented in Great Britain about eight years ago by Mr. Vergara, when that gentleman was doing his best to introduce the unfortunate Woodbury film to the notice of photographers. The idea is a good one, and Mr. Vergara should certainly retain the credit for it.

M. Schlumberger, the French chemist whose successful imitations of bank notes led to his being prosecuted by the Government, has convinced the Bank of France that his statements and experiments were made in the interests of the public, and his appeal against the fine of 500 francs will probably be successful. Owing to his demonstration that in these days of scientific photography special precautions are necessary to guard against forgery, a small army of chemists, photographers, and engravers are hard at work in the production of a note which shall baffle the most ingenious imitator. Safety against counterfeiting, it is hoped, will be attained by having several vignettes—each struck in a different colour—placed in superposition, and by having the fabric of the paper made in a special tint. Colours of deep tints are to be used, which will offer an equal resistance to chemical action, and which it will be impossible to separate. In the fabric of the paper will also be introduced a light muslin tissue printed in special colours, visible only when held to the light.

Nothing is sacred to the enterprising advertiser. It is dreadful to think that when the tourist photographs the pyramids, he must also photograph "Popham's Pills." Yet we are within measurable distance of this. Who, for instance, would imagine that the Straits of Magellan would be made use of as an advertising station? There is a small rock in an inlet called Gray Harbour, which is between Wellington Island and the Patagonian mainland, on which rock it is etiquette for steamers passing through the Magellan Straits to leave a card in the shape of a board with the name of the vessel and date painted thereon, and nailed to the rock. The captain of a telegraph ship, anchoring in Gray Harbour, lately took a photograph of the rock, and to his disgust found that the most prominent "card," covering nearly the entire lower face of the rock, was one which contained the advertisement of a well-known soap manufacturer!

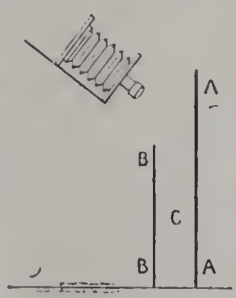
It is not generally known that at the top of that retiring and modest, but extremely useful, building the Patents Office, in Southampton Buildings, is a suite of photographers' rooms. It was lately said by a technical journal that this photographic establishment was a thing of the past. This is not the case. Work is still being carried on when necessary. It is obvious that, in connection with the copying of designs and plans, photographic facilities are indispensable.

The difficulty of securing photographs of notabilities when it is desirable that a complete collection should be made is well known. First, there is the consent of the individual to be obtained, next comes the appointment at the studio, and thirdly, and most important of all, the keeping of the appointment. Indeed, the worry and disappointment are so irritating, that all photographers who have commissions of this kind entrusted to them would welcome an imitation of the plan adopted in the Austrian Parliament, in order to comply with the request of the Emperor Francis Joseph for photographs of all the members. The president, during a full sitting of a House, simply said first to one representative and then to another, just as it was necessary, "Herr So-and-So, do not move," and the photographer secured the necessary portrait. We should like to see this experiment tried by the Speaker of the House of Commons; it would serve to enliven many a dull sitting, and would certainly highly amuse the "strangers" present.

## IMAGES MULTIPLIED BY REFLECTION.

MANY pleasing effects can be produced by the introduction of a mirror into the photographic studio, and in intelligent hands the changes which can be rung on such an aid to picture making are endless. We venture to think that the use of the mirror is not so common as it might be, and that many photographers would do well to show their patrons what can be done in this direction. What more natural than the figure of a lady standing before a pier glass giving that little finishing touch to her dress which is always such a necessary duty of life? The mirror can also be used for giving a back as well as a front view of a model, and this, while adding to the charm of a picture, will be a thing which no lady will object to—for in a measure she will get two pictures at the price of one. Many other attitudes possible with mirrors will suggest themselves to the worker who possesses any originality of ideas. It is almost unnecessary to remark that beyond a little care which is necessary in avoiding reflections which are not wanted, the employment of a mirror in the studio presents no difficulties whatever. No difference in exposure is called for, and the reflected image of the model may, in fact, be left to take care of itself.

Those of an experimental turn of mind can produce by means of two mirrors combined the curious effect illustrated in the accompanying woodcut. This is the copy of a photograph which appeared some time since in a French publication, and it will at once remind our readers of an effect which they must have often noticed in public places where two looking glasses face one another on opposite walls, and lead to reflections repeated again and again. The picture is produced by an arrangement of mirrors placed in exactly the same way, but which is illustrated in the diagram below. Mirrors A A and B B are placed opposite one another, while the model C stands between them. One mirror, B B, is shorter than the other, and behind and above it the photographic camera points downwards at the model. In this way a single son of Mars might be turned into a regiment of soldiers, and one feels sorry that some such means is not available at stage representations, where, time out of mind, it has been the custom to add to the number of an army by causing the same file of men to march round and round the same imitation tree or rock. It is possible that this little photographic curiosity may lead some of our readers to try what they can do with the help of looking-glasses.



## USE OF SILICATE OF POTASH IN LITHOGRAPHY.

SILICATE of potash, dissolved in pure water, plays an important part in chromo-printing. By modifying the liquor gradually as required, its use permits of producing very clear tones by the addition of a thin varnish, without having recourse to magnesia, whiting, or any other white substance, which nearly always entail the risk of producing clamminess. By adding a few drops of silicate to a colour reduced to a syrupy state, strength is imparted without in the least lessening transparency. The addition of varnish renders the colour clearer, while the silicate gives it consistency; only the silicate must be used drop by drop. Experience will be the best guide as to the use of this substance. The liquid silicate should be preserved in a flask corked with emery, as the air decomposes it.

*How to Bring up Crayon Drawings.*—When a drawing becomes thin and pale, the roller is choked up, or the black is not sufficiently ground. This paleness is often caused by the indiscriminate use of acid mixed with distilled water in damping, or by vinegar. In the first case, clean the roller, and take thinner black. In the second, two remedies may be used. Remove the drawing by means of a preparation of thirty parts of essence of distilled turpentine, and two parts of olive oil, thoroughly mixed. The drawing removed, ink it with a black a trifle more adherent than that used in printing; pull a few proofs, and if the drawing recovers its primitive purity and vigour, proceed with the printing. When this remedy fails, recourse should be had to pure essence to remove the drawing. Afterwards ink with a preserving ink, gum, and place the stone aside for twenty-four hours.

*Inconvenience of Enamelled Paper.*—These papers absorb a part of the substances serving to bind together the solid elements of the ink; consequently, the black particles remain like dust on the enamel, and are detached by the least touch. An ink having a greater adherence may be produced by adding a rich resinous varnish, similar to that used for bronzing.

*Glycerine prevents fine colours from drying in the box* if precaution be taken to cover them with a thin layer of this liquid. The surface of the colours should be previously smoothed over.—*Printing Times and Lithographer.*

PHOTOGRAPHIC CLUB.—Subject for discussion on July 1st, "Actinometry and Sensitometry"; July 8th, "View Meters and Finders." Saturday outing, June 27th, the Brent from Hanwell; train to Hanwell from Paddington at 2.50.

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Agar-Agar once more—New Process of Making Printing Plates—Blisters in Gelatino-Bromide Prints—Platinum Printing—Who is Rembrandt?

*Agar-Agar once more.*—With reference to my own remarks on agar-agar as a substitute for gelatine in emulsion making on page 381, I may add here the observations of V. Schumann with regard to the same subject which this eminent investigator published some time ago in the *Phot. Wochenblatt* (vol. xi., p. 164). He writes:—"Agar-agar bromide emulsion is sensitive from about 6½ F. up to the ultra-violet, much like the gelatino-bromide emulsion, the lines being clear. Agar-agar emulsion shows scarcely any tendency to adhere to the glass plate, except at the edges. The plates are entirely matt. Some emulsion poured on glass, dried, then washed and again dried, was totally fogged, though it gave a weak image of the spectrum at an exposure of fifteen minutes (paraffin lamp). Agar-agar soaked with ammonium bromide and cooked dissolved little or none at all. Agar-agar cooked for a longer time, after the addition of bromide, emulsified, and poured at once unwashed on the plate, gave, when the plate, after washing, was treated slightly with alcohol, a rather good negative, provided it was not washed. In the bath following the fixing bath, the agar-agar film left the glass plate, and was lost beyond recovery."

*New Process of Making Printing Plates.*—Mr. Fr. Winterhoff, of Cologne, has patented a process of making glass printing plates for typographic and lithographic purposes, which will, I think, be of interest to photo-lithographers. It consists in the following:—A glass plate is coated with a sensitive solution of asphaltum, or with bichromated gelatine, and dried; a print is then taken from any printing plate—from a negative, for instance—on a well-prepared transfer paper, which is then transferred to the glass plate provided with the sensitive layer. The transfer paper is then removed, and the transferred print on the glass plate dusted with metallic powder—for instance, with bronze or leaf metal—when the plate is well cleaned. It is then exposed to sunlight for about half an hour, and washed with turpentine, which dissolves the unexposed parts of the layer, whilst it leaves unaltered those portions which have been exposed to light. The plate is then etched very deeply with fluoric acid for about half an hour, rinsed, and cleaned, when it may be used as a printing plate. From this plate, transfers may be made at any time, to be transferred to stone or to zinc, or the plate may itself be employed directly as a printing plate without fear of wear and tear. These plates afford a very practical substitute for the expensive lithographic stones or zinc plates.

*Blisters in Gelatino-Bromide Prints.*—Blisters are sometimes met with in work with gelatino-bromide paper. To avoid them, the *Photogr. Archiv* suggests the following procedure. It is necessary to use the water and the various baths as cold as possible, and to do the work in a laboratory the temperature of which is not above 68° F.; use should also be made of alum. After development, the print is washed for a few seconds in two water baths, when it should be placed for three minutes, picture side down, in a bath of

| | |
|---|---|
| Water ... ... ... ... ... | 200 c.c. |
| Alum ... ... ... ... ... | 12 grammes |
| Common salt ... ... ... ... | 6 ,, |
| Soda ... ... ... ... ... | 1 gramme |

The print is then allowed to drain, and, *without washing*, placed in the fixing bath. The latter consists of

| | | |
|---|---|---|
| No. 1.—Water ... ... ... ... | | 200 c.c. |
| | Hyposulphite of soda ... ... | 30 grammes |
| No. 2.—Water ... ... ... ... | | 40 c.c. |
| | Alum ... ... ... ... | 12 grammes |

The mixture of the two solutions is allowed to stand for a day. In this bath the print should remain five minutes in summer and fifteen minutes in winter, during which time it should be repeatedly turned. It is then, *without washing*, placed in the already used alum bath, with the film side down. This alum bath should not be used again.

*Platinum Printing.*—R. Wischeropp recommends the following platinum printing-out process. It is essential to use a chemically pure ferric salt, and to dry the solution as quickly as possible after its application to the paper, in order that it may not penetrate into the paper. For this purpose a dry box is necessary, kept at a temperature of 133° F., so that the prepared paper placed in it may dry within two minutes. The solutions required in this process are, according to the *Phot. Nachrichten*, the following:—

*Solution A.*

| | |
|---|---|
| Sodium ferric oxalate... ... ... | 40 grammes |
| Sodium oxalate solution (3 : 100) ... | 100 c.c. |
| Potassium chlorate ... ... ... | 0·1 gramme |

*Solution B.*

| | |
|---|---|
| Distilled water ... ... ... | 60 c.c. |
| Potassic chloro-platinite ... ... | 10 grammes |

In Solution A the solutions, which are kept separately in the Pizzighelli process, are united; then the addition of glycerine, which is declared needless by the author, is left out. Solution B keeps indefinitely, whilst Solution A should be renewed from time to time. To sensitise one sheet of arrowroot paper, 8 c.c. of Solution A and 5 c.c. of Solution B are required. The sheets of paper are fastened with drawing pins to two wooden strips, one of which projects sufficiently to enable the sheet to be placed on the edges of the dry box. The latter is made of sheet iron, and is warmed by a gas boiler, the paper being suspended in it in such a manner that the second wooden strip remains about four inches distant from the bottom of the box. The solution is quickly applied to the paper with a bristle brush, spread with a round badger-hair brush, and then the sheet is quickly hung therein. In order that the paper, after drying, may give brilliant prints, it should be kept for some time previously in the dark room. It is then laid, together with the negative, in the printing frame, and covered all over with india-rubber cloth. As soon as the desired tone is attained, the print is fixed in a solution of hydrochloric acid 1 : 80. The fresher the paper, and the more quickly it is worked, the more beautiful will be the tones of the prints. For this reason it is advisable to print in direct sunlight.

*Who is Rembrandt?*—A very remarkable book has been published of late by a young literary man, Max Lautner, of Breslau, which has excited much attention in artistic circles in this country. In this work the author endeavours to demonstrate that most of the celebrated paintings attributed hitherto to Rembrandt are really the work of one of his most talented pupils, namely, of Ferdinand Bol, of Metheln, near Antwerp, whose name has been scratched or painted over on his works, and the name of Rembrandt substituted. In his researches, the author has made use of photography, which has been able, so to say, to look through the various layers of colour down to the ground of the painting, and there to detect any falsification. The author has discovered a new process of intensifying, by the use of which one is enabled to intensify without retouching the contrasts of the tones to such a degree that quite faint shades appear black on a white ground. By the aid of this process the author has reproduced about one hundred paintings attributed to Rembrandt, and all of them showed clear traces of the name of Bol scratched in the fresh paint before varnishing. The negatives have been reproduced in photogravure by Riffarth, of Berlin, the impressions being distributed on seven tables, forming part of the important and interesting book.

## PARAMIDOPHENOL COMPARED WITH HYDROQUINONE AND EIKONOGEN.

BY AUGUSTE AND LOUIS LUMIERE.

In a recent article* we indicated generally the principal properties of paramidophenol, considered as a developer of the photographic image, and it seemed to us interesting to establish, with more detail and exactitude, a comparison between these properties and those of the developers most nearly like it as to constituents and mode of action—hydroquinone and eikonogen.

### (a)—Oxidization from the Air.

When aqueous solutions of one-half per cent. of paramidophenol, hydroquinone, and eikonogen are exposed to the air, it is found that paramidophenol oxidises most rapidly; the alteration in eikonogen becomes clearly visible after several hours, which hydroquinone resists still longer.

The product of oxidisation of paramidophenol, which is probably quinonimide, is insoluble in water, hence it results that the aqueous solution does not discolour when exposed to the air; it furnishes gradually a black precipitate, which dissolves with a violet colour in ammonia and the alkalies, and with a red colour in nitric acid.

In the case of eikonogen, the oxidized solution is dark brown; it becomes green when treated with ammonia, and red when treated with nitric acid. The oxidized solution of hydroquinone is reddish; the liquid added to ammonia takes a yellow tint, although it is rendered colourless by the acid. These oxidisations have a different effect upon the gelatine according to the developer used. It takes a yellow tone in the case of hydroquinone and eikonogen; but the gelatine remains perfectly colourless in the case of paramidophenol. This is so much the case that, although one invariably obtains a yellow tinge after developing several negatives in the same bath of hydroquinone and eikonogen, it is easy to develop, in 100 cubic centimetres of paramidophenol, twenty-five negatives 9 by 12, printed under identical conditions, without detecting the least discolouration, and without being able to detect any difference between the first and the twenty-fifth plate developed.

### (b)—Action of Oxygen.

In passing a current of pure oxygen through the aqueous solutions of the three liquids which we have been discussing, we find that the paramidophenol oxidizes first, then the hydroquinone, and lastly the eikonogen. In all three cases the oxidisation by pure oxygen is less rapid than by air, all the other conditions of experiment remaining the same.

### (c)—Action on Salts of Silver.

The aqueous solutions of hydroquinone, paramidophenol, and eikonogen do not reduce the silver haloids without the addition of an alkali or of an alkaline carbonate, although the same solutions reduce soluble salts of silver perfectly without the help of a base. Neither paramidophenol nor hydroquinone possesses the curious property* of eikonogen of reducing solutions of nitrate of silver strongly acidulated by nitric acid.

### (d)—Other Reactions.

The perchloride of iron colours paramidophenol a violet-blue, and eikonogen yellow. With hydroquinone it produces a greenish colouring, which fades very quickly, and ends in becoming yellow. Paramidophenol has a reaction very slightly acid. With eikonogen, nitrate of lead gives a very pale violet-grey precipitate. It gives no effect with paramidophenol or hydroquinone.

### (e)—Determination of the Reducing Power of Paramidophenol.

We have employed the same process which M. Reel† adopted in the case of hydroquinone—a process which consists in determining the weight necessary of a given substance to reduce one gramme of nitrate of silver. We have arrived at the following result:—

| | |
|---|---|
| For hydroquinone ... ... ... ... | 0·07 |
| ,, paramidophenol ... ... ... ... | 0·14 |
| ,, eikonogen ... ... ... ... ... | 0·30 |

Thus, it is to be seen that it requires twice as much paramidophenol and four times as much eikonogen as hydroquinone to reduce the same weight of nitrate of silver. These differences are not important from a practical point of view, for the reducing action in a developer is always greatly in excess of the quantity of silver to be reduced. The developer has done its work long before it is exhausted.

### Conclusion.

The three substances that we have been studying possess, from a photographic point of view, analogous properties. Paramidophenol, however, seems to present the greatest advantages. (1) It oxidizes more rapidly than hydroquinone and eikonogen; it is also more energetic, and, all the conditions being equal, it develops most rapidly. (2) The products of oxidisation have no effect on the latent picture, and do not discolour the gelatine, whence the possibility of developing in the same bath of developer a very much greater number of plates than with the other developers.

In making variations in the developing solution of the proportions of sulphite of soda, carbonate, and paramidophenol, in order to arrive at the best compound and the best working, we have found it convenient to modify the proportions as in the following formula:—

| | | |
|---|---|---|
| Water ... ... ... ... ... | 800 | parts |
| Carbonate of potash ... ... ... | 40 | ,, |
| Sulphite of soda ... ... ... ... | 100 | ,, |
| Paramidophenol ... ... ... ... | 8 | ,, |

Obituary.—We regret to announce the death, on Tuesday last, following an attack of influenza, of Mr. Lachlan McLachlan, of Manchester. Among Mr. McLachlan's great photographic pictures may be especially mentioned the group of members of the Cotton Famine Relief Committee, and that of "The Royal Family at Windsor." The latter work measures 17 by $11\frac{1}{2}$ feet, and the negative 41 by 29 inches. Mr. McLachlan, it is said, spent £16,000 upon its production, and worked for eight years before he considered he had adequately completed his masterpiece. During his career, he had photographed the greatest celebrities of the day, and had visited every Royal circle in the civilised world. He was in the 67th year of his age.

## Patent Intelligence.

### Applications for Letters Patent.

10,101. John Joly, 39, Waterloo Road, Dublin, "Improved Method of Obtaining Solar Altitudes by the Aid of Instantaneous Photography."—June 15th.

10,139. Richard Moser, 4, South Street, Finsbury, London, "Improvements in Photographic Albums."—June 15th.

10,241. George Lyons, 19, Somerset Street, Portman Square, London, "Improvements in Portable Photographic Cameras and Camera Fronts."—June 16th.

10,245. Joseph Robert Mally, 18, Fulham Place, Paddington, London, "Improvements in and relating to Frames for Supporting and Exhibiting Photographs, Views, and the like."—June 16th.

10,246. Joseph Robert Mally, 18, Fulham Place, Paddington, London, "Improvements in and relating to Wall Brackets, for Supporting and Exhibiting Photographs, Views, Figures, and the like."—June 16th.

10,278. Etienne Ricard and Jean Baptist Joseph Lacroix, 323, High Holborn, London, "Improvements in Photographic and Stereoscopic Apparatus." (Date applied for under Patents Act, 1883, Sec. 103, January 8th, 1891, being date of application in France.)—June 16th.

10,379. Frank Sternberg, Hillside Cottage, Bushey, Herts, "An Improved Method of Embellishing Photographs."—June 18th.

10,482. John Alexander Forret and Frederick Dundas Todd, 26, Brougham Place, Edinburgh, "Improvements in Means or Apparatus for Producing a Flash Light more especially Applicable to Photography and Stage Effects."—June 20th.

10,506. Edward James Clifford, 127, Upper Dorset Street, Dublin, "A Hand or Detective Camera and Shutter."—June 20th.

### Specifications Published.

985. *January 20th*, 1890. — "Pigment." H. Grimshaw, Canal Chemical Works, Clayton, Manchester.

A white pigment, consisting of an insoluble zinc compound, is prepared by dissolving metallic zinc, or zinc oxide, in a solution of zinc chloride by the aid of heat, and then precipitating the pigment by cooling, with or without the addition of an alkali. Another process consists in mixing zinc oxide with zinc chloride solution, producing a mixture which sets hard, and may be ground to a powder.

1,015. *January 20th*, 1890. — "Alkali Manufacture." F. Ellershausen, Hebburn-on-Tyne, Durham.

Relates to the manufacture of caustic soda and potash. Sodium sulphide solution is treated with sodium ferrite (ferrate), either by simply stirring up the latter in the solution, or preferably by forming a layer of the ferrite in a granular form about four feet deep, and filtering the solution through it. The reaction which takes place may be expressed as follows:—

$$Fe_2O_3Na_2O + 4H_2O + 4Na_2S = Fe_2Na_2S_4 + 8NaOH.$$

The caustic soda is obtained as the filtrate, while the double sulphide in the filter bed may be treated in any way. The ferrite in the granular form is obtained by roasting a mixture of sodium carbonate and peroxide of iron. Caustic potash is similarly obtained.

1,016. *January 20th*, 1890. — "Alkali Manufacture." F. Ellershausen, Hebburn-on-Tyne, Durham.

Relates to a process for the manufacture of caustic soda and potash, consisting of two stages:—

1. *Preparing ferrite (ferrate).*—This is prepared by mixing a strong solution of black ash or potassium carbonate with powdered iron peroxide to form a thick, pasty mass, which is then calcined in a furnace, forming the ferrite.

Richmond Camera Club.—An excursion to Shepperton was arranged for the 13th inst. The three members who put in an appearance found some excellent subjects in the neighbourhood. The ordinary meeting was held on Friday, the 19th, Mr. Davis in the chair, when the subject for discussion was "Tourist Kits."

## Correspondence.

### THE CAMERA CLUB.

Sir,—Will you kindly allow me to state that the exhibition of photographs by the Marquis Dr. Vianna de Luna and the Countess Loredana da Porto Bonin, which was announced to be opened at the Camera Club on Tuesday, June 25th, is unavoidably postponed.

The exhibition will commence on Thursday, July 16th, after which date the pictures will be open to inspection by visitors under the usual conditions, namely, from 10 a.m. to 4 p.m., on production of tickets which may be obtained from the hon. secretary and from members generally.

G. Davison, Hon. Sec.

*The Camera Club, Charing Cross Road, W.C., June 20th.*

### GLASGOW INTERNATIONAL EXHIBITION.

Sir,—I have pleasure in announcing that the following gentlemen have kindly consented to act as judges at the exhibition (there are three photographers and two painters), namely, Messrs. Valentine Blanchard, Adam Diston, Richard Keene, Francis Powell (Pres. R.S.W.), and William Youug (R.S.W.) I hope shortly to name two gentlemen, with a special knowledge of photo-mechanical work, who will assist the others in that section.

There is a slight error in our prospectus, which may lead to some misunderstanding. In the clauses at the head of the list of classes, "Class 24 (Scientific) may be &c.," should read "Class 25 (Scientific) may be, &c."

I beg to confirm the arrangement already announced by the Cardiff executive, whereby pictures entered for both exhibitions can be sent on here, carriage paid.

Wm. Goodwin, Hon. Sec.

3, *Lynedoch Street, Glasgow, June 18th.*

### "NOTES ON PERSPECTIVE DRAWING AND VISION."

Sir,—The dovecotes of Charing Cross Road have been fluttered; there is no use denying the fact. The god of art (lately arisen) has repudiated his prophets, trumpeting their falseness, denying them fire; aud the worst feature of the whole matter is that this perverse deity is undoubtedly clever, which the prophets are not. *Le bête de bon Dieu* on their tongues, dismay in their hearts. This is the state of affairs when the last thunderbolt is still poised.

"The deathblow to all the artistic pretensions of photography," is entitled "Notes on Perspective Drawing and Vision," by Dr. P. H. Emerson and T. F. Goodall. The share that each has had in the work is, perhaps advisedly, left vague, and a pleasing sense of irresponsibility must fill the breasts of both gentlemen. It is priced at sixpence—surely a moderate figure for such sensational research—and coutains six and a half pages of matter divided into preface, propositions, proofs, and deductions. If what is said in it be true, the "amateur-trade" will be busy repainting their signboards. I write this to save them premature expense in investing in a paint pot. In the end we all have their interests at heart, for without them it would be like unto a world without Pears' soap. Such is the value of advertisement!

Having thus duly set forth my charitable disposition, and explained this intrusiou, I desire to disclaim any attempt to offend the authors of this "bolt from the blue." I propose now to run through these six and a half pages, making a few simple comments, and asking several common-sense questions.

"Proposition A" strikes the keynote of the argument by stating that we see objects on a larger scale with that portion of the eye (the upper portion) which perceives distance, than with that portion which views foreground (the lower portion); and that, on the other hand, the lower portion of the eye sees a larger arc than the upper.

I would ask whether physiology bears this out?

I cannot test my field of vision by lying on my back, as I am at present in London, and there is hardly any other body of men on the face of the earth more unscientific and unsympathetic than the metropolitan police. I have also been unable to test the powers of my eyes between my legs. Samaritan-minded strangers might think me in pain. I regretfully decline to deceive the simple-minded. I therefore pass on to "proposition B."

If any question of the "strug. for life," as the French have it, is involved, surely Dr. Emerson (I omit Mr. Goodall's name for brevity) should not draw his arguments from the habits of such remote periods. We do not, now-a-days, scan the horizon until our eyes bulge. Residence in towns must long ago have corrected this painful state of things.

The attempt to see all "objects near to us and close around clearly" would surely result in magnifying them, and this in itself would prevent the "compassing of as wide a field as possible." We cannot have it in meal and in malt. Again, is it not only that which we are trying to see which materially affects the eye? We do not focus distance and foreground at the same time. Therefore, if we look at one, we are not affected by the other, and no amount of straining the eye will get over the difficulty. To suit Dr. Emerson's theory, I take it, we should have to focus the eye on both foreground and distance at once, and, while straining to see the "objects near us clearly" with the lower part of the eye, should have to "try and draw distant objects nearer, and to enlarge them" with the upper portion. My experience teaches me that this is impossible; but, supposing Dr. Emerson says, "No, I let my eye rest on that which attracts it, and, keeping that in focus, only know the remainder by suggestion." Under these conditions, the distance is magnified at the expense of the foreground, and differs in that respect from its photographic reproduction.

In this case, I stand on even firmer ground, for, knowing that there is only one point in focus, both foreground and background must be out of focus. Now, it is easily demonstrated on the focussing screen—at least, such is my experience—that objects thrown out of focus one way or the other appear larger than when in focus—"loom" is the word—and that, under these circumstances, not only would the image of the distance be larger, but that of the foreground would be so too. This does not appear so to the eye, I take it, because of the greater luminosity of the distance, which practically overawes the foreground, much as the effect called halation enlarges our windows on sunny days. Now this enlargement of the distance, when out of focus, can be produced photographically, as Dr. Emerson's plates themselves show.

Further, the whole of Dr. Emerson's theory presupposes that all human beings are accustomed to see distance frequently. Since the existence of large towns, I venture to assert that the majority of people seldom have that opportunity, and, consequently, we are in this dilemma: either the countryman on coming to town finds part of his eyes unserviceable, or the townsman on going into the country cannot see distance as he ought to. Now, if this were the case, we should have heard of eye troubles whenever people change their surroundings; but I, for my part, have never heard of them as yet. Furthermore, do artists who live in town recognise the damage they are doing to their sense of æsthetic appreciation? And are townsmen less keen-sighted than countrymen?

I therefore venture to submit that Dr. Emerson's explanations of his theory fail; and, more than this, these considerations throw great doubt upon the whole of his case; for I would ask him, with all respect, as we can only focus a very small area at once, and as, in order to do this, the eye must be directed towards it, how he localises the different portions of the retina which receive the impressions of near objects and those more remote. Does he mean to say that when I look at my feet I use a certain portion of my eye, and when I look at the mountains a certain other portion? When we look at a landscape we only grasp its beauty by a succession of rapid glances at its component parts, and this theory implies that my eye in those glances selects the distance and magnifies it at the expense of the foreground. All this sounds very improbable, but I write under correction.

Dr. Emerson now goes on to give his experiences in support of his contention. His first proof has to do with a tall chimney, at the centre of which he looks steadily from a point distant by its height. He says that the top appears wider than it really is in relation to the width of the base. Supposing for the moment that this is so, and that he has succeeded in getting all the chimney in focus. Now, by letting the eye gradually sink to the ground (not "measuring or correcting") the region where expansion appears to set in will also sink gradually, just as if it were a snake standing on tip tail swallowing a mouse whole. All I have to say to Dr. Emerson in this case is to advise him to go at once to a good oculist and have his eyes attended to. If you view the world through bad window panes, you naturally fall into error. What Bacon wrote in the early part of the seventeenth century appears to apply in more than one way to Dr. Emerson at the end of the nineteenth:—"Idols of the den are the idols of every man in particular, for, besides the general aberration of human nature, we every one of us have our particular den or cavern which refracts and corrupts the light of nature, either because every man has his respective temper, education, acquaintance, course of reading, and authorities, or because of the differences of impressions as they happen in a mind prejudiced or prepossessed, or in one that is calm and equal." (*Novum Organum*, translation of Dr. Shaw, 1813.)

Dr. Emerson refers to the Parthenon in support of his argument. I have a photograph of that edifice before me as I write. The columns, even in this photograph, appear parallel to the eye, though by measurement they are not so. Thus, Dr. Emerson will see that the much-abused lens is capable of giving an effect he can only credit to an alleged abnormal condition of the eyesight. Again, *if this photograph be turned upside down, the columns still appear parallel to one another*, with disastrous consequences to his theory. I venture to suggest to Dr. Emerson that, such being the case, the reason why this happens lies in the fact that we are here dealing with what is called an optical illusion, and depends entirely on the proportion and position of the parts of the building itself. Such also are his own experiments with pieces of paper, and, being so, are fitter to help to sell a brand of soap than to convince rational beings.

So far as regards his experiment with a door, I have been looking at one for two days in the manner he directs, but cannot perceive that the top is larger than the bottom. If I did, I should bear in mind the story of the lion on Northumberland House. The crowd saw its tail wag as soon as they were asked to do so.

I have also tried to induce myself to believe that the halfpenny is nearly as big as the penny under the conditions described by Dr. Emerson; but either from early training, intense honesty, commercial instinct, or my short sight, I have not been able to effect my purpose.

I do not, sir, want to trouble you with diagrams, but surely Dr. Emerson's remarks about the lateral angle subtended by a book at six feet from the eyes when viewed by one or both eyes, have a simple geometrical explanation. The error introduced by binocular vision can have but an infinitesimal effect on the sense of height and breadth, the power being almost wholly spent in giving stereoscopic effect or sense of depth.

I believe that I have now, roughly speaking, traversed the whole of Dr. Emerson's ground, and, in conclusion, I would offer a few remarks of my own as to the reason why distance usually appears dwarfed in photographs, as this is, no doubt, what first set Dr. Emerson a-thinking. Distance is, of course, most obvious to us in the case of hills, and it is to these that I now refer.

The question of lenses apart, I cannot help thinking that the true explanation of this curious effect lies in the fact that the eye receives the visual rays, the sensitive plate the chemical rays. Now, mountains attract moisture, and, generally speaking, we look through a screen of moisture—perhaps invisible, but for that reason none the less present—when we look across country. Thus, the eye viewing distant mountains, sees through a screen of more or less moist air, which causes the mountains to "loom" to the eye, as certainly as though they were seen through mist. The chemical rays are not, however, so much affected by this screen, and the mountains appear on the plate in their true proportions. I suggested to a friend an easy test, and Mr. Sutcliffe since writes me that the experiment has been tried. The test is this:—Choose a clear day, and select a view with prominent mountain masses in the distance. Take a large camera and a long focus lens (this for obvious reasons). Now focus on the distance, and, with a fine pencil or crowquill, trace on the reversed ground glass the apparent outline of these mountains, being careful to mark a base line and a few salient points, to obtain register. Without disturbing the camera, but allowing for the focus of the plate, take a sharp negative and see if the two coincide. The result, which I did not know at the time, but which I rightly anticipated, is that the image on the ground-glass—in other words, the visual image—is slightly larger than the image on the plate, or chemical image, and this being so, we have a very simple solution of Dr. Emerson's puzzle. It should also be borne in mind that the brighter colours of nature will always make objects appear larger than their commensurate monochromatic reproductions, and this applies to drawing and painting as well as photography.

It seems to me quite absurd that what is really an excellence of the photographic art—an excellence unattainable in painting or drawing—should be treated as a reason of exclusion from art altogether. Every art has its qualities, and one of the qualities of photography is exactitude. From what I have said it will be seen that the human eye would estimate the size of mountains according to the amount of moisture in the intervening air; in other words, it would hardly ever estimate their height twice alike. Photography, on the other hand, is practically absolute in its estimate. Surely there can be no two ways of thinking about it. But again, I say, I write under correction.

If, in this rather long letter, the temperature has at any time risen above summer heat, I must beg of you, sir, to attribute it to no want of regard for Dr. Emerson, but rather to advocacy of the amateur trader whose business is endangered. And I would put it to the person, who keeps what they call their conscience (but whose name I, at present, abstain from mentioning), whether a notice-board was not in preparation marked "Closed for Repairs," which would shortly have been dangled prominently in the thoroughfare. If I have, in any degree, saved this expense and averted a stoppage of business, I feel sure Dr. Emerson will join me in whitewashing the method employed. Dr. Emerson is a good and clever gentleman—it is something to be good, and clever, and a gentleman after all, particularly in photography—but, in this case, I submit he has presumed a little too much on his undoubtedly admirable abilities. W. A. Boord.

*June 23rd.*

HOLIDAY HOMES.

Sir,—As any readers of the Photographic News who are familar with the offices of this Union, and the walls of its 200 centres will admit, we have been liberal patrons of photography; we now write your readers to help us. The object of our Holiday Homes is a fortnightly holiday in the country for the poor children attending our schools and mission. The homes are situate at Folkstone, Chislehurst, Thursley Common, East Grinstead, Caterham, Pilsea, and Windsor. I mention this in case, for their own purposes, any of your readers may wish to photograph groups of the children. The cost per head for the holiday is 10s., not a large sum, and easy to make up among a circle of friends. Those who prefer to send smaller or larger offerings are invited to do so. Above all, we wish no one to think his or her offering would be *too* small. Trifles total up grandly. John Kirk, Secretary.

*Holiday Homes Fund, Ragged School Union, Exeter Hall, Strand, London, W.C.*

Messrs. Marion & Co. inform us that during their last stock taking they determined to dispose of a large accumulation of surplus stock, and with this view have fixed July 6th as the date for a clearance sale. The stock referred to comprises cameras (ordinary and detective), stands, lenses of all kinds, backgrounds, and a number of articles gleaned from all departments of too varied a nature to particularise. The goods are to be marked at absurd figures, which means that they will be sold at considerably under cost price.

## Proceedings of Societies.

Photographic Society of Great Britain.

At the technical meeting of this Society held on the 23rd inst. the chair was occupied by Mr. W. Bedford.

A short paper sent by Mr. Birt Acres was read, introducing the subject of the discussion of the evening, Orthochromatic Photography. The author of the paper complained of the apathy generally shown to orthochromatic photography. This apathy he attributed to the idea that the use of a yellow screen was a necessity. He maintained that a screen was not necessary, and the idea that it was so was a bogey. In describing the use of the coloured screen, he said that he had found the best to be those of optically worked glass sold by B. J. Edwards and Co.

Mr. J. Traill Taylor said that screens of coloured glass ground and polished for orthochromatic work were introduced some time since by Mr. Gotz, and did not originate, as might be inferred from the paper, with the firm with which Mr. Birt Acres was connected.

Mr. A. Mackie said that Mr. J. B. B. Wellington had, in 1887, recommended the use of patent plate glass coated with stained collodion. The collodion side was cemented to another glass with Canada balsam, as suggested by Mr. Debenham, so that externally there were the plain glass surfaces, and the collodion was preserved from injury. He could not agree with Mr. Acres that the use of orthochromatic plates without a screen was sufficient.

The Chairman said he thought there was prejudice in the statements of the makers of orthochromatic plates, that they would give satisfactory results without the use of a screen in addition. Nothing like a correct orthochromatic effect could be produced without a colour screen. He had hoped to have a discussion on various methods of preparing orthochromatic plates. He had brought specimens of dyes of various kinds, and, with the spectroscope, their absorption could be examined. He would advise the study of Vogel's researches, which were amongst the classics of photography. Amongst the dyes he had brought were cyanine, methyl-violet, turmeric, and erythrosine. To make an orthochromatic emulsion, it sufficed to put in a small quantity of the dye in the course of manufacture. He preferred to use the dye in the bromide solution, so that the formation of the compound of silver went on simultaneously with that of the silver bromide. Erythrosine gave an emulsion the general sensitiveness of which was greater than that with other dyes, and therefore, on the whole, he preferred it, although its orthochromatising power was not so good as methyl-violet or cyanine. Erythrosine sensitised strongly for yellow and green, but not at all for red; in fact, it was rather detrimental to most reds. For ordinary work, one of the best dyes was methyl-violet. There was no necessity for using ammonia with erythrosine; the statement that it was necessary was a mistake.

Col. Waterhouse said that he had used ammonia generally, and had thought that, on the whole, it was better to do so. He had not, however, sensitised the emulsion direct, but had bathed commercial plates in a solution of the dye. In India, where he worked, it was not easy to manage the manufacture of gelatine emulsions, and he simply sensitised plates sent over from England. He used erythrosine silver, and found that plates would keep fairly well; at all events, he had found no change after two months' keeping in a very trying climate.

The Chairman thought that it would be of interest to know why it was that gelatine did not lend itself so well to orthochromatic sensitising as collodion.

Mr. Addenbrooke could quite support what had been said as to the uselessness of orthochromatic plates without a yellow screen. With an orthochromatic plate, yellow did show slightly better than on an ordinary plate, both used without screens; but the difference was exceedingly slight—scarcely perceptible.

The Chairman said that it could be told, during the preparation of the emulsion, whether the dye added to it would have orthochromatising effect or not. If, on washing the emulsion, the colour of the dye disappeared, there would be no orthochromatic effect; if the emulsion retained the colour after washing, there was a combination which would be effective.

Mr. J. R. Gotz showed samples of yellow and orange glass made very thin and polished for use as colour screens. He supplied these for use in the place of the metal diaphragm. A convenient form was to cut a strip long enough to serve for two diaphragms. A piece of opaque paper was pasted on the glass, and openings cut (one at either end) of the sizes for which it was desired to have the openings in the diaphragm. With regard to the use of orthochromatic plates with or without a screen, that was a matter for discretion, according to the circumstances. For natural objects generally a screen was not necessary. Many examples were shown, and of some groups of flowers he said that the screen caused the yellow and orange to come too light, almost white. For such a subject it was better not to use the screen. Water-colour drawings, too, did not generally require a screen. With oil paintings it was quite different, and here the use of a screen was a necessity. A number of negatives and prints of various coloured subjects, and in one case the original (an oil painting), were shown, and the effect of orthochromatic plates with and without screens was pointed out. The plates used were Obernetter's, and the orthochromatising was accomplished with eoside of silver and cyanine.

Col. Waterhouse had used Gotz's colour screens with very good results. He showed photographs taken with them. Amongst these were some in which pencil drawings and pictures on varying tints of paper were photographed simultaneously, and all came out well. He had also used screens made of mica, and varnished with a deep yellow varnish. As the aniline dyes were very insoluble in benzole (the menstruum used), he had dissolved turmeric and annatto to colour the screen.

Mr. A. Pringle said that Mr. Birt Acres attributed the apathy of photographers to orthochromatic work to what he called the yellow screen bogey. He did not believe that anyone had been deterred by the necessity for using a screen. It was not the objection to a yellow screen, but the restrictions that had, by a patent, been put upon orthochromatic photography that was the cause of what apathy existed. This cause had undoubtedly, to a great extent, restricted British investigation. Three years since he had made a large number of experiments, comparing ordinary plates, with and without a screen, with commercial orthochromatic plates, and with plates sensitised by himself with alkaline erythrosine B. He had a series of nearly a hundred of these results at the Camera Club, and the opinion of the members was that of those used without a screen there was no difference between the ordinary and the orthochromatised plates. His own opinion was that there was a slight difference, but so slight as to be almost imperceptible. He entirely disagreed from Mr. Birt Acres' statement that there was no necessity to use a screen with orthochromatic plates.

Mr. Mackie agreed that the apathy of photographers to orthochromatic processes was not due to any yellow screen bogey, but he attributed it to the fact that, in England, orthochromatic plates were manufactured by one firm only. Why should this be? It had been shown over and over again that the one point in the patent—the use of ammonia with the dye—was not a necessity.

Mr. Chapman Jones considered that instead of showing reproductions of pictures, it would be better to photograph even tints of various colours; these could be more readily and exactly compared.

Mr. Gotz said that there were circumstances in which the use of a colour screen was necessary, and other circumstances when it was not so. Towards evening, when the light became yellow, nature supplied the screen, and no other was required. He had found it possible to photograph and get good results much later in the day with orthochromatic than with ordinary plates.

Mr. A. Lawrence (the assist. sec.) showed a series of tints painted on card, each tint in a number of gradations. He also showed negatives taken from this series with and without screens, and on plates variously sensitised. Methyl-violet and cyanine proved particularly effective. One plate was prepared with a chemical sensitiser, not a dye. In another case, potassium nitrite was used in conjunction with a dye.

Col. Waterhouse showed some further experiments with the reversal process. He now used thiocarbamide, which he found rather better than thiosinamine. The developer was made up of eikonogen and carbonate of lithia, one per cent. each, sulphite of soda two per cent., and five drops of a solution of thiocarbamide and ammonium bromide in alcohol were added to each ounce. He noted also that when a film spread on silver and exposed to light, and another film not exposed, were coupled and placed in the developer, an electrical current passed in the contrary direction when thiocarbamide had been added to that which passed in the plain developer.

The Chairman proposed thanks to those who had contributed to the work of the evening, which were passed, and the meeting closed.

---

### Holborn Camera Club.

*June 19th.*—Mr. E. H. Bayston in the chair.

Mr. Frederick J. Cobb demonstrated first on silver printing. He gave a short history of the process, which he thought was the most popular among amateurs, although of late years the numerous processes which had been introduced had tended to a certain extent to decrease its popularity. He gave a few hints on keeping the paper, which, he said, would keep for a considerable time. Even after printing, if the print was well washed, it would keep for an indefinite period. He always used the acetate toning bath, which was, in his opinion, the best that could be used. An old bath would work much better than a new one. He toned a few prints with the acetate bath, which worked exceedingly well.

Mr. A. J. Golding then demonstrated on gelatino-chloride of silver emulsion paper. The extreme simplicity of the working of this paper recommended itself to all amateurs. He had never met with any great success in ordinary silver printing, but he had obtained, without any trouble, excellent results on this paper. The depth of printing depended to a great extent upon the method of finishing the print. If it was finished with a matt surface it need not be printed so deep as if it was to be enamelled. After printing, the prints should be well washed and placed in a 10 per cent. solution of chrome alum to harden the film. The time the print should be left in the bath depended upon the temperature—the warmer the air, the more time it should be left in the bath. He used the following toning bath: Dissolve $2\frac{1}{2}$ drams of sulphocyanide of ammonium in 16 ozs. of water, and one day before it was intended to use the bath add 3 drams of a 15 dram gold solution. He believed in quick toning, because they were dealing with a delicate surface, which would not stand much handling. The richness of the tone depended upon the amount of sulphocyanide of ammonium in the bath. The fixing bath was 2 ozs. of hypo to 20 ozs. of water, leaving the prints in about ten minutes. He had not noticed any loss of tone while in the fixing bath. With regard to the final washing, he thought two hours would be sufficient. In his opinion the prints did not require so much washing as ordinary silver printing, because the hypo was on the surface, and not soaked in the albumen. The print could be finished with a matt surface or enamel, by using plate glass for the latter, or ground glass for the former. The glass, after being thoroughly cleaned, was dusted with talc, and the print squeegeed down, and peeled off when dry. Starch was the best mountant. If the print was finished with an enamel surface, mounting was exceedingly difficult. The prints, after being squeegeed down, should be backed with a piece of waterproof paper, which came off with the print, and prevented the moisture from the mountant going through the paper and affecting the enamel surface of the paper. He then toned and fixed some prints on Obernetter and Liesegang's aristotype, together with one which had been printed some twelve months ago on Fallowfield's paper, all turning out splendid. This he followed up by finishing off some prints with a matt surface.

The Chairman said he had tried both processes. With regard to preserving silver paper, an old piece of sensitised paper placed with the other paper was an excellent preservative. When squeegeeing down an aristotype print on to glass, a great difficulty was to get rid of air-bubbles. He had found that if a pool of water was left on the glass, and the print was placed in the pool, no air-bubbles would result.

Mr. Herbert Thompson said he could quite concur in Mr. Golding's remarks on the simplicity of the working of the paper over ordinary silver paper. He did not recommend the use of chrome alum, but ordinary alum, as the former was liable to give a green colour to the whites. With regard to washing, he thought aristotype prints would require more than ordinary silver prints, as hypo, in his opinion, seemed to cling most tenaciously to gelatine.

Mr. G. Luxton said the best way of thoroughly cleaning glass plates was to use the following: Photographic tripoli, methylated spirits, and water. The quantity of each could easily be ascertained.

Mr. A. G. Golding said, with regard to air-bubbles, if after the print had been peeled from the glass it was found that air-bubbles had been present, the print could be washed in water and squeegeed down on the glass again.

### Glenalmond Photographic Club.

At the fortnightly meeting, the president in the chair, it was decided that the photographs for the two competitions which the Club have now on hand should be sent in by July 11th.

Mr. Craig initiated a discussion as to the position of the Club, and it was generally agreed that it manifested an increase of energy.

The President then showed a new travelling lamp, and Mr. Johnstone an Eclipse hand-camera, after which the meeting became general to inspect some photographs produced by the president and Mr. Johnstone.

### Lowestoft and District Photographic Society.

A meeting was held last Friday at the School of Science and Art, Regent Road, Mr. W. Stringfield presiding.

After the election of members, several topics arose for discussion, among them that of development, and it seemed to be the general opinion that pyro and ammonia afforded the best results. Some few supported hydroquinone, but admitted that negatives produced thereby did not print so satisfactorily. Several prints and negatives were passed round for inspection, after which a few nice lantern slides, principally interiors, were shown.

Cutting Glass Tubes, Bottles, etc.—Have some strips of thick blotting-paper at hand, from a quarter to half an inch in width, and of different lengths. Two pieces of such paper are wetted and wrapped around the bottle, tube, or other vessel to be cut, once or oftener (once is sufficient). These pieces of paper, cut true, are wrapped around the vessel like two bands. They must not be placed too close together—say from a quarter to three-eighths of an inch apart for larger vessels, and rather less than a quarter of an inch apart for tubes of an inch in diameter. When this is arranged, a fine flame about two or three inches long is allowed to play on the glass between the two pieces of wet paper, the vessel being slowly revolved, and the point of the flame kept between the two papers. Within a minute, usually, the vessel separates with a clean cut along the line against which the flame played.—After *Chem. and Drugg.*

Blue Prints.—In a communication to the *Engineering News*, Mr. F. H. Latimer states that he has found that adding oxalic acid to the ordinary blue print mixture materially lessened the necessary time of exposure. The solutions used were:—(1) Ammonio-citrate of iron, 120 grains; water, 1 fluid ounce; to which is added a few drops of strong ammonia solution till the odour is quite perceptible. (2) Potassium ferricyanide, 105 grains; water, 1 fluid ounce. (3) Saturated solution of oxalic acid. Equal quantities of the first two solutions were mixed together, and to 10 parts of this mixture from 1 to 3 parts of the oxalic acid solution are added just before use, with the result that in cloudy weather the solution containing three parts of oxalic acid prints about ten times as quickly as the pure solution. For ordinary purposes, however, it is better not to add more than 20 per cent. of the oxalic acid solution, or difficulty will be found in getting the lines to wash white.

## Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.

Photargus.—*Cutting Board.* The rule to which you doubtless refer is that of taking the diagonals, and *where they cross* must be the exact centre of the glass. Another good plan would be to take and fold a piece of paper cut to the same dimensions as the glass; then use this as a guide to bisect the plate. Mr. Alexander Cowan showed an ingenious cutting board many years ago at one of the technical meetings of the Photographic Society. *Black Specks in Albumenised Paper and Prints.*—Without seeing them, it is so difficult to offer an authoritative opinion. They may arise from ultramarine or metallic particles in the paper, or accidental stains from minute traces of pyro, hypo, or other chemical impurity. The mere weighing out of pyro in the same room during warm weather has been known to produce a plentiful crop of black specks upon paper which was previously quite free from them. The brand you mention is one of those usually held to be thoroughly trustworthy.

M. B.—*Hand Camera Practice.* There is no question about the several movements requiring to be frequently rehearsed as with any kind of manual drill, and you may as well do this with dummies or spoilt plates. Remember to close the sliding front before setting the instantaneous shutter, and adjust the focus as nearly as you can by estimating the distance. Provided the first plate is set fairly in the notch, there should be no possibility of fouling or jamming, as all the rest follow suit and drop down in succession.

Shrewsbury.—*Actinometers.* Since writing to you last week, we found the description (occupying two pages, with explanatory drawings) in the *Journal of the Society of Chemical Industry* for May, 1890. It took the form of a communication to the Liverpool Section, and was read immediately after Messrs. Hurter and Driffield's paper. The instrument is confessedly based upon Mr. Warnerke's earlier luminous paint actinometer, but with sufficient difference in the mode of working to constitute a valid patent claim.

Topo.—*The Chromotypic Specimens.* On Tuesday next, 30th inst., they will be taken down and returned to their owners. Meanwhile they can be seen, from 2 p.m. till dusk daily, at 50, Great Russell Street (third floor), on presenting your address card.

G. J. F.—*For Enamels.* Either Mr. C. A. Rudowsky, 3, Guildhall Chambers, E.C.; or Messrs. Sharpus, McCullum, and Co., Cockspur Street, Charing Cross.

H. T.—*The Proposed National Gallery of British Art.* The terms of Mr. Henry Tate's munificent offer will be found in the *Society of Arts Journal* exactly twelve months ago; or in the *Times* of Saturday, 21st of June, 1890.

L. E. (Southport).—*Terms of Sale.* Any good business ought to be cheap at the price of one year's average takings; but does this include a fair stock of apparatus and requisites? At first blush it seems reasonable; but one ought to take a professional opinion unless you know the locality well yourself.

C. J. S.—Messrs. Morgan and Kidd offer to do the kind of work about which you are enquiring. See their catalogue, page 16.

F. V.—Thanks for letter duly received. We hope to hear again from you shortly.

A. W. W. and Co.—Answered by post, and further information will follow as soon as procured.

Emily.—*Dark Room Lamp.* A good plan is to use above the ruby light a yellow screen, kept covered during the progress of development, but, by raising a curtain in front, permits of examining the negative by its aid, when it is safe to do so.

# THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV. No. 1713.—*July* 3, 1891.

CONTENTS.

## BURNT-IN PHOTOGRAPHIC TRANSPARENCIES.

Before us, as we write, are a number of specimens of photographic transparencies on glass, which have been produced by a new process which has been perfected after five years of incessant work by Messrs. Oeffelein and Co., of 54, Berners Street, Oxford Street. It is easy to see at a glance that no photographic film rests upon the glass, and that the pictures form part and parcel of the material itself. If, with the corner of another plate, we endeavour to scratch the surface, we quite fail in doing so, although a powdery mark is, for the moment, left behind by attrition from the point of glass employed. The photographs are burnt-in to the glass, and are presumably as imperishable as the substance of which they form part. They are of different colours—blue, red, orange, mauve, &c.—and the inventors state that they soon hope to have at their command in the production of these pictures all the varied tints which the richest palette can offer. Some of the work has a coarse grain which gives the softening effect of a stipple, and some is as fine in texture as a skilfully made lantern slide on a gelatine plate. It is thus within the power of the operator to produce fine or coarse work at discretion, and according to the use for which the pictures are destined.

Within the past few years, coloured glass has been largely used for domestic decorative purposes, and there are very few who do not know what material is meant by the term "cathedral glass." By means of Messrs. Oeffelein's new application of photography, this method of decoration is sure to receive a fresh impetus, for by it it will be possible to invest such decoration with an interest which it never before possessed. The life-sized heads taken direct which have formed such a constant feature of recent exhibitions can now be produced in imperishable material, and can be used in windows, fire-screens, lamps, and for other purposes where glass can be employed decoratively. We are not quite certain whether portraits of this kind would be admissible in church windows, but we think that a memorial window might well contain the portrait of the person honoured, inserted, of course, in a manner which would not be obtrusive. A photograph of a nineteenth century man or woman got up to look like a saint would most likely border on the ludicrous. There was a fearful example of this sort of thing shown in the shop windows only a few years ago, at the expense of good Mr. Spurgeon, who was pictured in full armour as *Christian* in the "Pilgrim's Progress." The picture was not an artistic success.

But, of course, the main use of Messrs. Oeffelein's burnt-in photographs will be for secular decorative purposes, and here it has a very wide field of application. Witness the good effect obtained by the use of stained glass in the dining and refreshment rooms at South Kensington Museum. Here we have ornament relieved by apt quotations from many authors upon the subject of the pleasures of the table. How well these burnt-in photographs taken from suitable models would come in here. But we are by no means confined to portraiture, although the specimens before us happen all to be of that nature. Studies of fruit and flowers will be available, and naturally the copies of well-known works of art can be reproduced in this imperishable form. The portraits of favourite animals—dogs, cats, and horses—will also commend themselves as good subjects for such treatment; indeed, the possibilities before this new application of our art are most extensive.

Another use which may be found for this photographic vitrification is the production of lantern slides which will need no mounting or cover glasses. We are not sure whether the production of a picture of this kind on glass suitably thin will not present some difficulty in the annealing operation, but of this we have no certain knowledge. It is also certain that in the case of a negative of great value—such as that of a royal personage, or a public character whose pictures sell well—the new process will be employed for the purpose of duplication in permanent form.

We are not able to furnish details of the method employed, nor will those who desire to know all about it be able to assuage their curiosity by a visit to the Patent Office; for Messrs. Oeffelein have determined to keep their invention unpatented—a course which we think is wise in the case of a process which has cost many years to bring to perfection.

## PHOTOGRAPHIC PERSPECTIVE.*

Chiefly in Reply to Messrs. Emerson and Goodall.

BY W. E. DEBENHAM.

Under the title of "Notes on Perspective Drawing and Vision," Dr. P. H. Emerson and Mr. T. F. Goodall have just published a series of "propositions, experiments, proofs, and deductions," by which they claim to show that, for "scientific reasons," the accepted rules of monocular perspective are likely to mislead, and to prove the fallacy of photographic and all mechanical methods of measurement.

When it is attempted to be shown that accepted rules are wrong for "scientific reasons," we have a right to ask that the proofs by which it is claimed that the overthrow of these rules is accomplished shall be of as exact and definite a character as the cirumstances permit. I think it may be shown that the so-called proofs submitted are of so loose and indefinite a character as not to constitute proofs at all.

The first part of Proposition A sets out with a statement—which they do not support by any anatomical reasons—that objects seen below (which are here assumed to be foreground objects) are seen on a smaller scale than those which are above, and are assumed to be distant. That is (say the authors), "a perspective drawing surprises us by making the foreground objects look larger in proportion to the distance." It is added that we see a larger arc with the lower half of the eye than with the upper.

The second proposition, as to width of included angle, has nothing to do with the first, as to the relative sizes of upper to lower objects, and it is confusing to have the two placed in one proposition. The second one may, however, be disposed of at once by the fact that it has no bearing on perspective, or, generally speaking, even upon the amount of field included in a photographic view. The angle of view seen by the eye is considerably in excess of 45°, both above and below a horizontal axial line. I mention this angle because it represents the view on a photographic plate which is twice the height of the focal length of lens. It is evident that so long as the boundary of the field of vision is greater than that included on the photographic plate, any greater extension of the boundary in one or other direction has nothing to do with the photographic representation. What occurs within the limits of the photographic view is not affected in position by a variation in the limit of vision outside the area.

The "proof" is said to be "completed when we stand with our legs apart, and, standing with our back to the landscape, bend down and look between our legs. Here the fields are inverted, and consequently the distance appears small and far off," &c.

The effect on the disposition of the foreground obtained by choosing a lower point of sight, as by lowering the camera, is well known, and this, together with the confusion arising from seeing things in an unusual position, and perhaps from the rush of blood to the head, seems to afford a more rational explanation of real or fancied differences of aspect than the assumption of different proportions being rendered by the upper and lower halves of the retina.

Proposition B, assuming Proposition A to be established, attributes the result to the naturally selective action of the retinal nerves, and suggests that special functions have been developed by natural selection for the purpose of drawing distant objects nearer. Further on, in Proof 3, we gather that the amount of difference of size, as seen at an angle of 26° 26′ above and below the axial line respectively, is estimated at one-sixteenth of the total. Objects at these distances from the axis are considerably removed from the region of really distinct vision, and it is only objects much nearer to the axis that can be minutely examined, and, consequently, if any difference of scale were proved or admitted, the proportionate difference at such smaller angle would be much less than that at the larger one. Taking the estimate, however, at the angle given, the difference between fifteen and sixteen is so little that there are few, if any, occasions where an object distinguishable on the one scale would be noticeably less so on the other. The deduction, "that mathematical perspective gives quite a false impression of what we see when using either one of our eyes, or both," is supported by "proofs" of the same loose and inexact character as those given under Proposition A. The first three deal with a statement that objects having vertical sides appear wider at the top than the bottom. Proof 2 is that which is most easily tried, and, according to this, if we "look at the middle of a doorway or door, it will be felt that the door or doorway is wider at the top than at the bottom." Now, to an observer standing, the middle of an ordinary door is considerably below the height of the eye, and the line of vision will be directed downwards. The top of the door will, therefore, with regard to the axis of the eye, be in a plane in advance of the lower part, and will, consequently, appear to be larger. If the observer is seated at such a height as for the eye to be level with the centre of the door, and then that is looked at so that the line of vision is at a right angle to its surface, the top no longer appears broader than the bottom; at least, it does not to me, or to anyone else with whom I have compared notes.

Proof 3 directs us to cut two slips of paper 8 inches long, one 2 inches wide at each end, and the other slightly tapering, *i.e.*, from 2 inches to $1\frac{7}{8}$ inches. It is asserted that if both are held at a distance of 8 inches from the centre of the eye, and looked at directly, the parallel piece will appear to be wider at top than bottom, and the tapering piece, if held with narrow end uppermost, will appear parallel. This is the sort of experiment with which anyone may easily deceive himself. A strip of paper does not readily maintain a strictly vertical position, or remain in one true plane. For the experiment to have any value, the material should be capable of being maintained in one unchanging position, and means—not indicated by the authors—taken for truly fixing its height and the position of the eye. Even then the indistinctness of vision over all but a small area near the axis of the eye is so great that if, as required by the proposition, the direction of the eye is not moved up or down, the extremities of the paper will be so much blurred that a little difference of width could probably not be distinguished at all, but a person having an expectancy of seeing either equality or difference could easily imagine that he did so see it.

According to Proof 4, a penny is to be placed "upright on a table, and a halfpenny eighteen inches behind it, and a little to the right or left of the penny. The eye must look over the penny, and at the halfpenny, so that the penny is a foreground object, and the halfpenny a distant object. If the observer now looks steadily at the halfpenny, at the same time seeing the penny, he will find the impression given is that the halfpenny looks nearly as large as the penny."

* A communication to the London and Provincial Photographic Association.

This "proof," like the others, is exceedingly loose and inexact. We are not told at what distance the eye is to be placed, or at what height above the level of the table. As a matter of fact, if the position of the eye is such that the coins come near together in the field of vision, there is no doubt about it their relative proportions are seen, and the smaller coin does not appear relatively larger than it really is. When the level of the eye is much raised, so that the penny is not near enough for comparison, and when it comes far from the limit of distinct vision, it is easy to assume disproportionateness. If, now, the first and leading proposition of Messrs. Emerson and Goodall is a true one, the object seen on the upper part of the retina—the lower half of the eye, they call it—appears smaller in scale than those projected on the lower half, and the penny, on this account, seems smaller than it really is. Then, if the image of the penny is made to fall on the lower half of the retina, by making it a *raised* foreground object, it should appear as much larger in the second case as it did smaller in the first. It seems strange that the authors of the paper under discussion should not have thought it worth while to make this experiment, which is simply the complement of the other. I have here an appliance with which it can be done. There is a horizontal bar lying on the table, fitted with three vertical arms. From the vertical arm at one end of the horizontal bar a halfpenny projects. At a distance of eighteen inches in front is a second vertical arm, with niches in which pennies are fitted above and below the height of the halfpenny. Eighteen inches, again, in front of this is the third vertical arm, in which an eye-hole is bored, level with the halfpenny. A large sheet of white card is placed behind, so that we are not confused by seeing different backgrounds to the different coins. If the halfpenny is looked at direct, I cannot find that the one penny appears to differ from the other in size, nor has anyone else to whom I have shown it found it to be the case.

It may seem to some to be a waste of time to fit up even such an appliance, and it certainly might rather be expected that Messrs. Emerson and Goodall would have done it themselves before announcing their propositions; but, when it is remembered how many people were mystified by the quasi-scientific theories put forward not long since on the subject of definition or focussing, it may not be wasted time after all.

It is remarkable that Messrs. Emerson and Goodall deal with near objects only as below, and distant objects as above. The experiment with the two pennies shows the near object both as above and below. If their proposition is true, that the lower half of the eye sees things on a smaller scale than the upper, and for this reason a perspective drawing surprises us by making the foreground objects look large, then such foreground objects as are above the distance should surprise us by appearing too small in the perspective drawing or photograph. Perhaps one of the most familiar instances of a near object above the central distance is that of a chandelier depending from a ceiling when the interior of a room is photographed. It may be enough simply to ask the question whether such an object really does surprise us by appearing too small in the picture.

A point, however, that it seems very strange should have escaped the notice of the writers, is that we see the photograph or perspective drawing with the same eyes that we see the objects of nature. If, therefore, it were a fact that a natural object, when at the bottom of the scene, appears smaller to our eye than it comes in mathematical perspective, then the same object in the lower part of the drawing, falling on the same diminishing part of the eye as the original object would, suffers a like reduction also, and the true effect will still be produced. The lines from the various points in a drawing in mathematical perspective or in a photograph, seen at a proper distance, fall upon the same parts of the eye as the lines from points in the natural scene would do, and both would suffer alike from the want of equality of vision assumed by the authors. The case is very similar to that of the supposed necessity for the lens to simulate the defects of the eye, which was for some time maintained by Dr. Emerson and a few followers.

Is there any difference between photographic and true mathematical perspective and perspective used by painters? Sometimes there is; painters allow themselves licences. If an interior has to be represented, a photographer must photograph it from a distance limited by that to which he can remove his camera. A painter will often represent the interior, as far as the leading lines are concerned, as it would appear if the observer were so far removed as to give what is called less violent perspective. There is no difficulty in doing this to anyone acquainted with the rules of perspective. If, however, the drawing is to be true throughout to what would be seen at the selected distance, care must be taken to obliterate such objects—as, for instance, a side window—which at a greater distance would be hidden by a pillar, and, in some cases, to show objects covered in the near view, but which would be exposed to view farther off.

Again, in painting figures, they will generally be represented as they would appear (with regard to comparative size of advancing the retiring portions) at such a distance as not to make these differences of size conspicuous. Sometimes, indeed, they are painted rather with the knowledge of the equality of the retiring and advancing portions of a figure than with the effect which perspective has in enlarging or diminishing them. Are these things passing conventions, and will photography cause any change in them, as it has done with other conventions? Time will show.

---

We have recently tried the improved sulphokinone developer sent to us by the Fry Manufacturing Company. The developer is in two solutions, which for a normally exposed plate are mixed in equal parts. In our hands the developer gives very fine results, especially for lantern slides. Several plates can be developed in the same mixed solution before it shows any sign of exhaustion.

Photographing the Dead.—It appears that a somewhat morbid custom exists among the Viennese of having the dead bodies of children and other persons dear to them photographed, and for this purpose the corpse used to be taken to the photographer's studio. The attention of the sanitary authorities having been drawn to the danger of the dissemination of infectious disease by this practice, a decree has been issued by the Austrian Minister of the Interior absolutely forbidding the photographing of corpses in studios open to the public, and the photographing of bodies of persons who have died of any infectious disease by professional photographers, even in private houses. Exception is made of cases in which such photographs may be required for police or medico-legal purposes. In the case of persons who have died of non-infectious disease, the corpses may be photographed at the private residence of the deceased, subject to the approval and on the responsibility of the medical official whose duty it is to verify deaths. This ordinance came into force on April 1st.—*British Medical Journal.*

## A NEW METHOD OF POSITIVE PRINTING.

BY DR. ALPHANDERY.

If the amateur photographer, or the professional himself, has much trouble in attaining perfection in portraiture, it is because the work of the sun generally requires the co-operation of an able artist. Wrinkles on the face, although they may hardly exist, and cannot be detected by the unaided eye, are found on the photographic print deeply engraved, and far more prominent than in nature. The various other blemishes on the skin which it is also difficult to discover, are brought out by the photographer with a kind of malignity, and, as we all know, it requires the adroit hand of the retoucher to do away with markings on the negative which give such unflattering results.

Both amateurs and professionals have tried to correct their negatives by mechanical means, and oftentimes they have given their imagination a free rein. One plan, for instance, which was long ago proposed, was to place before the lens a ground or coloured glass, and to give a short preliminary exposure before taking the photograph. But the general softening effect so obtained was in reality an incipient fogging of the whole plate. Another method suggested was, just before the end of the exposure, to rapidly withdraw the diaphragm from its slit, a procedure which was supposed to soften down by diffused light any portion of the facial lines which might be too greatly accentuated. This movement naturally led to vibration of the apparatus at the supreme moment, and the plan was quickly abandoned. Others, again, have advised that either the sensitive plate or the lens itself should be slightly moved during exposure, with the idea of bringing to a focus successively each part of the model, and of superposing, as it were, a series of sharp images upon another series of images out of focus. But although this method is as ingenious as the one which we have just considered, it is difficult to carry out, and necessitates the employment of special apparatus.

More practicable was the idea of that American who endeavoured to secure the same result during the printing operation. He conceived the employment of a printing frame which allowed the sensitive paper to be exposed close against the negative at the outset of the operation, but caused it to be withdrawn away a certain distance before the printing was completed. But here, again, was required a special apparatus which was relatively costly, and in which it was difficult to maintain complete parallelism between the paper and the glass; hence the contrivance has been quite forgotten.

The whole of these methods, however, depend upon a true principle, and it is only because there has been difficulty in the necessary manipulations that they have been rejected. Seeing this, we have tried to obtain analogous results without in any way thrusting aside the ordinary impedimenta of the photographic printer, and we have been able to solve the problem by a very simple artifice.

In the first place, we must endeavour to preserve the wrinkles, shadows, and general contour of our model, so as not to change his physiognomy; but, at the same time, we may fairly endeavour to prevent exaggerated hardness in the lines represented. But we do not seek to do this during the taking of the negative, which is simply done in the ordinary way, and under the usual conditions. Even the printing of the positive is carried out in the ordinary manner at the outset, and until the print may be considered to be about two-thirds or three-quarters on the way to completion. It is then that the modification comes in. At this juncture we simply take a sheet of glass, or any other transparent body, of from one to three millimetres in thickness, and slide it gently between the negative and the partially printed proof, *without displacing one or the other*. We then re-expose the frame until the print attains full vigour.

The first part of the printing has produced a normally sharp image, and the second, allowing the light to be diffused around each point in a regular and equal fashion, has gently softened those lines which might otherwise become too pronounced, and the desired result is obtained.

The only delicate part of the operation is the insertion of the plate of glass, and this is simplified if a larger printing frame than is actually necessary for the negative is employed. The best plan of procedure in this case is to place the negative in the angle of the larger frame employed, and to use a piece of positive paper for the print, which has an extra length attached, which can be shut in between the negative and the rebate of the frame, so that if the paper be raised for the insertion of the extra sheet of glass, both paper and negative shall remain in register. Printing frames are now made by many makers, the backs of which, instead of being hinged in the centre, are separated at one side, so that nearly the whole of the picture can be examined during the printing operation. It is obvious that such a form of frame is peculiarly fitted for the present purpose.

With regard to the thickness of the supplementary glass plate, it may be one millimetre, or two, or three, according to the discretion of the worker, and it should be put in position over the positive at a time when the picture has nearly attained its full strength. The result is not at once strongly apparent, but the softening effect is there, and it will be found that, by the employment of this device, the disagreeable sharpness and rigidity of feature so often seen in a photographic portrait becomes blended with a bloom and softness which cannot fail to prove attractive. As a general rule, and for an ordinary carte portrait, the best effect is obtained by employing a glass two millimetres in thickness, which should be interposed when the print has attained two-thirds of its correct value; but it must be understood that the thickness of the glass, and the precise moment when it must be inserted, must vary with the kind of negative, and with the particular effect which it is desired to produce. It is hardly necessary to indicate that this method is not indiscriminately applicable to all negatives. It would, for example, be ridiculous to employ it for the portrait of a man the accentuated lines of whose face constitute its chief characteristic. It is quite another thing with the portraits of women and children, where the hard lines come not by nature, but are made so in the process of photography. With platinum, or papers giving a black matt image, the appearance equals that which is seen in a carefully executed chalk drawing which has been softened by means of the leather stump.

The little artifice here described acts, as will be seen, automatically during the printing operation, but it is necessary to employ it with discretion, and with regard to the particular negative in hand. Artistic effect can be obtained by this means, but the operator must have artistic feeling to produce it. A method, however good it may be, requires that a man should know how to employ it, a fact which is too often lost sight of.—Abstracted from *Photo. Gazette.*

## NEW HAND CAMERAS.

Dr. Krugener, whose name is already well known in connection with the invention of an ingenious form of book-camera, which was introduced some five or six years ago, has now placed on the market two new forms of hand or detective cameras which exhibit several points of novelty. The agents in this country for these inventions are Messrs. Marion and Co., of Soho Square, who have kindly permitted us to thoroughly examine the instruments.

We will describe first the camera named the "Delta," which is made in three sizes, the smallest being $3\frac{1}{2}$ by $4\frac{3}{4}$ inches. This, like the others, is a standard French size of plate, and expressed in centimetres is equivalent to 9c. by 12c. This is a better size than the familiar quarter-plate, and Messrs. Marion supply plates of the required dimensions. The next size in which the "Delta" is made is $5\frac{1}{8}$ by $7\frac{1}{16}$, and the other camera of the three is for stereoscopic plates. The principal novelty in the "Delta" (see fig. 1) is the bellows arrangement seen on the top of the box at the end farthest from the lens. This constitutes the main feature of the changing apparatus, for the camera contains twelve plates, held in sheaths, which can successively be brought under the control of the lens. The bellows may be said to take the place of the leather or cloth bag which, in many forms of hand-cameras, is used for changing plates, and which permits the operator to take the front plate from the series after exposure, and to insert it at the back of all. In the "Delta," when it is required to change a plate, the operator unfastens the hooks which hold the bellows down, and inserts his finger and thumb through an orifice in the top, which is furnished with a light-tight cloth. But previously he has moved a button at the side of the instrument, which has the effect of raising the front plate out of its old position. He is thus able to grasp the sheathed plate, and by bending the bellows (as shown in fig. 2) he is able, after pulling it bodily out of its place, to thrust it to the back of the series. The "Delta" is fitted with a rectilinear lens, and all objects at thirteen feet distant and beyond are in focus. Its principal use is naturally for what is called "instantaneous exposures," but it can be used as well for *time* exposures. The lens is furnished with diaphragms, so that the aperture can be altered according to the amount of light available.

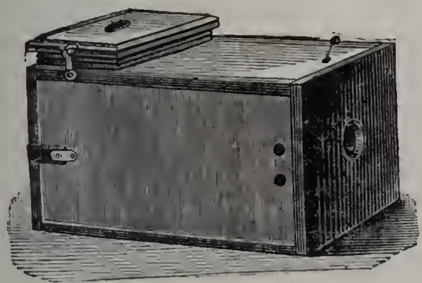

*Fig.* 1.

*Fig.* 2.

Dr. Krugener's other model is named the "Normal Simplex," and while it corresponds somewhat in outward appearance with the "Delta," its design is far more elaborate. In fig. 3 it is shown closed, as it would be during transport from place to place; but when ready for action there would be released from the square aperture, shown at the top, a small directing camera or finder, as seen in fig. 4. This finder pops up with a spring action when required, like a jack-in-the-box. The closed oblong aperture at the further end of the camera (see fig. 3) conceals the changing apparatus, which, as in the "Delta," is connected with a bellows. But whereas in the "Delta" it is necessary to *handle* the plate in its sheath before it can be changed, in the "Normal Simplex" the mere act of pulling out and returning the bellows shifts the foremost plate from front to back, provided always that the camera be held lens upwards during the operation, as shown in fig. 5. The mechanism by which this result is brought about is of the most ingenious character. When the bellows arrangement is pulled out, it brings with it the stock of plates with the exception of the front one, which is prevented from moving by a fixed stop. This plate, when the others are removed, and when the camera is held as described, falls by gravity to the back of the plate chamber, so that when once more the bellows arrangement is pushed home, it takes its place at the back of the series instead of at the front as before. So much ingenuity has been exerted in the contrivance of different methods of changing photographic plates that it would seem hardly possible to design anything of a really novel character, but it will be seen from our description of these inventions of Dr. Krugener that there is still something new to be said about even such a well-worn subject as that of plate-changing.

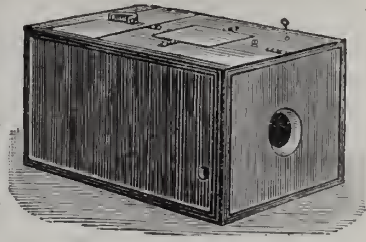

*Fig.* 3.

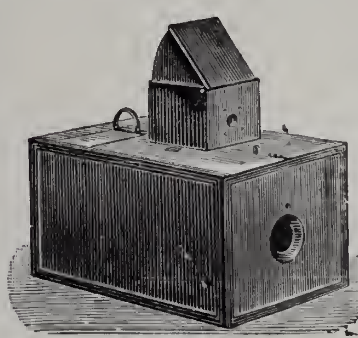

*Fig.* 4.

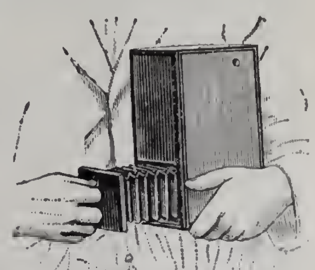

*Fig.* 5.

---

Intensification is a business that most photographers dislike on account of its uncertain effect upon the future of the negative to be treated, and yet it is a process which must occasionally be resorted to. Messrs. Hinton have done their best to simplify the operation by introducing an intensifier in two solutions which is quick in action, and is not in any way troublesome in its application. The first solution, mercury, is followed, after thorough washing, with one of cyanide of silver, and the increased density obtained is very great without any clogging or veiling of the shadows. We commend this intensifier to the attention of photographers.

## LENS DIAPHRAGMS AND STANDARDS.

### A Plea for Uniformity and Exactitude.

From twenty-five to thirty years ago—we might even curtail the period to ten years—any rough and ready system of notation of the diaphragm satisfied photographers. We find three important reasons to account for this ready acceptance of so much inconvenience arising from inexactitude. Firstly, there was a total absence of competition, as two makers monopolised almost the entire field of photographic optics. We do not pretend that the increasing number of present-day competitors renders the facilities for improvement of the optics of instruments any greater, but there can be little doubt that this competition has given a healthy stimulus to emulation for the favour of the public. Latitude of exposure was another reason for the indifference that dispensed with a general system of notation of the diaphragm. Before the advent of the modern dry plate, the difference between the exposures, necessitated by the varying diaphragm apertures, was not so important in the matter of latitude as to-day. With a slow plate, development of two plates, after the same exposure with stops of different apertures, might produce results indistinguishable by even an expert; whereas, now, one and a-half times, or double the "exact" exposure, which is a size larger than the correct diaphragm would yield, might ruin the negative. Then, again, at the period of which we write, education in photographic optics was sadly neglected, and any rough and ready method of diaphragm notation satisfied the photographer. Advances in this direction soon changed the old order of things, and such was the popular clamour for something better than the old clumsy methods of notation, that it could not be denied. Sets of stops, as most of our readers will remember, were originally marked simply with successive numbers from one upwards, according to their diminishing apertures; with, perhaps, an X on a stop where the aperture did not diminish in the same ratio. These numbers were identical, whether the lens with full aperture had an intensity ratio of one-third or one-fifteenth. How, then, was it possible to compare readily, say, the fourth stop of the former with the second stop of the latter with a view of ascertaining the relative exposures?

The Photographic Society of Great Britain, with an amount of energy characteristic of its earlier years, took the subject in hand. A committee was appointed, several meetings were held, and a standard of unity was decided upon. This, we venture to think, made "confusion worse confounded," and, therefore, we are not a little surprised to learn that the Lens Standards Committee has now, after mature consideration and a thorough discussion of the question, adopted exactly the same standard. This standard is $f/4$; that is to say, a stop bearing this ratio would be marked 1; one having an intensity of $f/8$ marked 4; and so on. Why this arbitrary rule, in the name of all that is optical, we do not know. The original reason given was that $f/4$ represented the largest working aperture of the portrait lens then in use; but this reason was as fallacious as it is ridiculous. The largest aperture of lenses then in use was, as nearly as possible, $f/2{\cdot}5$. Then came another lens, that of "B" portrait form of about $f/3$, which both then and to-day is used more extensively than any other in point of initial aperture. Even assuming the reasonings of the committee of the Photographic Society to have been correct, which they certainly were not, what was or is the use of commencing a standard with the aperture of a portrait lens, when the fact remains as notorious to-day as it was then, that ninety-nine out of every hundred professional photographers, to whom the use of portrait lenses is confined, never study any standard at all, nor have they, in fact, ever asked for one. It is the educated amateur photographer who seeks exactitude, and is not content to-day to work by rule-of-thumb.

If no better standard could be devised than one having as its unity the initial intensity of the lenses most in use, surely it might have been obvious that $1/7{\cdot}5$, which is about the intensity with the full aperture of the rapid rectilinear or symmetrical combinations, the lens then used by almost every outdoor or landscape photographer, though bad, would have been far more convenient to the amateurs of to-day, who cannot understand why $F/4$, any more than a theoretical $F/1$, should be adopted as a unit. In fact, we do not know whether such a theoretical unit as the latter, which is, at least, unity, would not be better. Some four or five years ago, when amateurs of an inquiring turn of mind were attempting to understand this "U.S." (which we believe stands for *Uniform* System—save the mark!), a well-known optician startled these enquirers, and horrified the founders of the Photographic Society's standard, by leaping into the gap and suggesting another standard, viz., $1/\sqrt{10}$. Here was a standard ready made, which, for means of calculation of comparative exposures, required—after the division and squaring process, necessary with any system—a mere shifting of the decimal point. This system possessed the advantage, moreover, of enabling any one, by eliminating the decimal and extracting the root, to calculate in a moment what was the actual intensity ratio of the aperture employed.

But some of the photographers of the old school refused to have anything to do with this "new-fangled" notion. This was, apparently, from motives of abject terror at the mathematical symbol, $\sqrt{}$. It was then attempted to alleviate this feeling by pointing out that the square root symbol had nothing but a theoretical significance, being merely used as a convenient substitute for an infinity fraction, but all of no avail. The powers that were remained obdurate, with the result that three systems remained in force, with the consequence that a purchaser of a photographic lens has a "system" thrown in with his instrument. Notwithstanding the decision of the Lens Standards Committee, these three systems will, unhappily, continue to prevail. The Paris Conference has, however, we are pleased to learn, made a move in the right direction by adopting a system—viz., $f/10$. This is, at least, a decimal system, and, for the purpose of ascertaining the intensity ratio, requires a mere shifting of two decimal points. We understand that a conference on the subject is about to be held at Brussels, when further discussion will take place.

There is one other matter of importance, which, in reality, occupied our minds when we commenced this article. We refer to the utter disregard which, in calculating intensity ratios, is paid to the effective aperture of the stops, as opposed to the bare diameters. Very few photographers are aware that the intensity ratio is always greater than the reciprocal of the quotient obtained by dividing the focus of the lens by the diameter of the stop, and that this difference varies much with lenses of different construction. In any system that may be adopted, too much stress cannot be laid upon this point. It should be incumbent upon opticians to give the real, and not the apparent, focal values of each stop. We think, moreover, that the precise equivalent focus of every combination should be engraved upon the mount. Opticians need now no longer fear complaints created by slight variations in focal lengths from those catalogued. Photographers have long ago discovered that specified focal lengths, especially above six inches, are but approximate.

Finally, we would urge that at the Brussels International Conference, to which we have already referred, arguments for different systems should be considered on their own merits, and that no consideration of existing standards should be allowed to prejudice the minds of a committee. It is quite possible that still better methods than those in vogue may be submitted, and that one of them might be adopted. We heartily commend the further ventilation of this subject to our photographic contemporaries and opticians interested in the subject. Photography is young, and there is still time for its optical arrangements to turn over a new leaf and revise its complicated methods. When once a satisfactory and uniform system—uniform in more than the name—is agreed upon, and a concise explanation of that system has been given to all photographers, owners of instruments marked on the old method would soon, we venture to believe, be only too ready to send them to opticians to be re-engraved or re-modelled upon the reformed principle.—*The Optician.*

REMEDY FOR SORE FINGERS CAUSED BY HYDROQUINONE.—M. Dollé sends to the Paris *Moniteur de la Photographie* the following letter :—"I have read in the *Moniteur de la Photographie* a description of a skin disease on the fingers caused by hydroquinone, disease which the fingers afterwards carry to the face. I have met with this accident several times, and the article in question is very exact. Allow me, in the interest of your readers, to furnish you with a remedy, very simple moreover, which causes the eczema in question to disappear in three or four days. Spread over the affected parts, on going to bed, a rather thick coating of lanoline (grease extracted from sheep's wool), cover with an old kid glove, which is to be kept on all night. I have made many experiments, but with lanoline I have been very successful."

A MONKEY TAKES THEIR PICTURES.—The season for the spring campaign of the travelling photographer has coldly opened, and a man who for many years past has had a monopoly of the district lying around High Bridge felt that, if he proposed to hold his own against an opponent who invaded his territory a week before he got there, it would be necessary to hire a more able and industrious assistant than the boy who has hitherto helped him to carry his camera. He began operations yesterday, attended by a tall, lean monkey, dressed in a red coat with brass buttons. His old servitor was there too, for the photographer had found it necessary to retain the lad to attend upon the monkey. Presumably the artist does the work, as formerly, but the monkey seems to be the genius of the camera. Mounted on a forked stick stuck in the ground, he inspects the position of the person about to be photographed, burying his hairy head under the cloth that covers the rear part of the instrument. Then he stretches forward his long arm and removes the cap. For, perhaps, two seconds he holds it in his hand, while he frowningly stares at the subject. Then he covers up the lens, and the picture is taken. It is, perhaps, the first time that an ape has been responsibly engaged in the service of art, and, with the children at least, the innovation is very successful. The fact of having a photograph taken by a monkey is not only irresistibly attractive in itself, but the presence of the animal behind the camera effectually prevents the juvenile attention from wandering, and brings an intensely interested expression, often emphasised by too broad a grin, to the little face in front. It is not expected that the rival photographer, with an improved instrument, and, perhaps, greater skill in using it, can long make headway against the monkey.—*New York Sun.*

# Notices of Books.

PHOTOGRAPHY ANNUAL FOR 1891. (*Iliffe and Son, London*).

THIS bulky volume appears now for the first time, and at a period of the year when it has not any other publications of a similar character to compete with. It contains much useful matter, and has been compiled with skill and care. There are several good illustrations, the reproductions of the photographs of the moon by the Brothers Henry being especially worthy of attention. The book would, in our opinion, have been improved if the section devoted to a description of apparatus—which too closely resembles a trade catalogue—had been either omitted or greatly curtailed.

TRAITE PRATIQUE DES AGRANDISSEMENTS PHOTOGRAPHIQUES. By E. Trutal. (*Paris: Gauthier-Villars et Fils*). Second part.

IN the first volume of this work the author called attention to the different methods by which small negatives may be obtained, and he now, in this second volume, shows how they may be enlarged, and describes the various methods available. Enlargement by means of the camera, and the obtaining of enlarged positives on glass or paper by that means, occupies the first chapter of the book. The second chapter is filled with a description of solar enlarging, and different forms of heliostat. Different kinds of artificial lights come next under review, and the book concludes with a chapter on manipulation and development of positive papers. The work is very fully and well illustrated.

TRAITE PRATIQUE DE ZINCOGRAPHIE. By V. Roux. (*Paris:* Same publishers.)

THE progress in zincographic work has been, within recent times, so rapid, and new modifications are so constantly being introduced, that a book on the subject soon becomes antiquated. In this little volume M. Roux has given a clear account of all the necessary manipulations according to the latest ideas, from the preparation of the negative to the obtaining of a relief in metal. This book is practically a new one, although it is marked second edition, for it has been greatly augmented, and, as we have already indicated, brought up to date. It will be a most valuable work of reference to those who wish to practise or to gain a knowledge of the fascinating art of zincography.

LA FORMATION DES IMAGES PHOTOGRAPHIQUES. By A. de La Baume Pluvinel. (*Paris:* Same publishers.)

THIS volume of 200 pp. is devoted to the chemical aspect of photography, and describes with clearness the changes produced on various substances by the action of luminous rays. It is a work which many who are apt to pay more attention to the practical work of the studio and dark room would do well to read and digest.

PHOTOGRAPHIC EXHIBITION AT THE AUSTRIAN MUSEUM.—We are requested by the translator to insert the following corrections in the article on this subject by Herr James Von Falke :—For "but in the Chinese manner the sun will not work," read "but in the Chinese manner this is impossible"; for "fine lad's portrait of Arthur Chevalier de Bourchelt," read "fine portrait of a lady by Mrs. Susan Hodgson, and the portrait of a knight by Arthur Burchett."

## Notes.

The French paper, *Les Annales Photographiques*, describes a new kind of printing paper which it believes will obtain a certain degree of popularity. It is said to be the outcome of certain experiments by a Russian amateur, Mr. Soukatcheff, to be five or six times more sensitive than ordinary albumenised paper, and to give prints of a rich brown tone. This colour is varied by after treatment, for the paper can be developed, like a blue print, in simple water, or can be toned and fixed like an aristotype print. A specimen of the paper has found its way to Paris, and is favourably reported upon by the journal above named.

No class of photographs are more interesting to stay-at-home town dwellers than those relating to volcanic phenomena. These phenomena are, happily, so far removed from us, and, at the same time, have about them such a spice of the mysterious—we might almost say supernatural—that they possess a fascination of their own. The photographs, moreover, show us something new, for they are vastly different from the conception of volcanic outbursts which we gathered in our childhood from the fatuous engravings which adorned the educational books of the period. Hence it is that Dr. Tempest Anderson's photographs of the volcanic districts of Iceland, shown at the *conversazione* of the Royal Society the other night, were looked upon with profound interest. Some similar pictures taken in the Lipari Islands were shown among the lantern slides at the late *soireé* of the Camera Club, and these, too, were of a noteworthy and interesting character, some of them being taken within the actual crater.

Those who wish to see how well line drawings turned into blocks by photo-zincography can be printed on a quick machine, should buy that wonderfully cheap pennyworth, the holiday number of the *Daily Graphic*. This is, in many respects, the finest number of that journal which has yet appeared. The drawings have, apparently, been reduced from the originals to a greater extent than heretofore, and the result is a fineness of line which brings them into real rivalry with wood engravings. The subjects illustrated are the various sea-side resorts within easy reach of Londoners, and the places can not only be recognised at a glance, but the pictures are full of life and bustle owing to the presence of admirably drawn figures. If the *Daily Graphic* keeps up to its present standard, it will soon double its already large army of admirers.

We are reminded of a useful old method of obtaining from a very thin negative a duplicate which will yield a vigorous print, by seeing it exhumed and published as a new discovery in a foreign journal. The method is applicable in the case of a very thin, over-exposed negative, full of detail, or in the case of an experimental picture taken by gas or other weak light, when the detail has had to be coaxed into appearance by careful and prolonged development. The negative, after fixing and thorough washing, is bleached in a solution of mercuric chloride, and dried. It now appears as a positive when backed by any dark material, black velvet being, perhaps, the best which can be selected. The glass so treated is now set up before the camera, and a new negative is made from it without difficulty. This simple process will often be found of great service, and it has the merit of not subjecting the negative to any risk of destruction.

The resources of advertisers are legion, and, since the optical lantern has been enlisted in their service, they have seen many more loopholes through which the public can be successfully shot at. The proprietor of a hair restorer has just been fined the stereotyped forty shillings for causing an obstruction in Clapham by the exhibition of lantern slides from a waggon, which slides depicted the marvellous growth of hair which might be expected on the human cranium by a steady perseverance in the use of his nostrum. We say *expected*, because we know that promise in these matters does not always lead to realisation. Some time ago we became acquainted with the manager of a large drug store which dealt largely in these so-called restorers, and, seeing that his head was nearly as bald as a billiard ball, we ventured to hint most delicately that he might do worse than try some of these much vaunted specifics himself. He looked up pathetically, and said, "My friend, I've tried every blessed thing in the warehouse!"

When a policeman makes use of a telescope to detect offenders against the law, the employment of a camera cannot be far off. A Merthyr Tydvil constable, the other day, with a powerful glass watched a public house a quarter of a mile away, and witnessed, so he asserted, an infringement of the Licensing Act, and the magistrate, after examining the telescope, convicted the defendant. We are not told in what way the "examination" of the telescope was conducted, whether it was put in the witness box or not, but doubtless its evidence was satisfactory, or the conviction would not have been arrived at. It would, however, have been better had there been an adaptation of the camera to the telescope—by no means an impossible thing. A photograph of whatever the offence was would have been more convincing than the "examination" of a telescope.

It is gratifying to learn, in spite of a foot-note in *Punch* that "drawings will in no case be returned," that Mr. *Punch* does occasionally condescend to send back the drawings to the artists who send them in on approbation. But it is not pleasing to get a drawing doubled in half and practically spoilt—an experience which, it is said, happened to a well-known artist. To avoid this unpleasant contingency, why do not artists become photographers and photograph their drawings, sending in copies to the editors of illustrated papers, and retaining the originals?

The *Globe*, in commenting upon Dr. Emerson's paper in the *Magazine of Art*, is of opinion that before photography becomes (if it ever becomes) absolutely artistic, it will be well for it to become accurate. At present, says our contemporary, the epithet "photographic" by no means conveys the idea of scientific exactitude. Possibly not; but are we still to believe in the time-worn phrase, "The truthful and beautiful are one," of which the late Lord Lytton was so fond? If so, there is a field for discussion open for which even the *Globe* would not be large enough. If the truthful be necessarily the beautiful, another and more important question must first be asked. "What is truth?" said jesting Pilate, and the answer is as difficult to find now as it was in his day.

## THE PORTRAITURE OF THE SUN.

BY JAMES MEW.

THE pursuit of astronomy is entrancing, but, like other entrancing objects of desire, is apt occasionally to lead its votary into a quagmire of distress. More than a score of years ago, Goldsmith, in his *Citizen of the World*, warned the public of his period against the particular infatuation of astronomical study, by the history of a philosopher who suffered no light domestic misfortune while his attention was too much occupied with a compassion for the inhabitants of the moon. In a page of this philosopher's diary we meet with the following entry: "The moon is, I find, at her old pranks. Her appulses, librations, and other irregularities, indeed, amaze me. My daughter, too, has this morning gone off with a grenadier. No way surprising! I was never able to give her a relish for wisdom; she ever promised to be a mere expletive in the creation. But the moon, the moon, gives me real uneasiness," and so on. Now if the moon, which, as compared to the sun, is called religiously rather than scientifically the lesser light—if the moon without the assistance of photography was able to cause this amount of intellectual and emotional disturbance in the mind of articulately speaking man, what is likely to be the result of a photographic interest in the sun, the blaze of whose photosphere so far exceeds all artificial splendour that only the electric light is not absolutely black against its flaming orb.

It has been said that the sun, known to scientists as a cooling cinder, was the first celestial object photographed for scientific purposes. Soon after Daguerre's discovery the moon and stars were "taken," but not for such advancement of knowledge as was intended by early heliographic pictures. Sir W. Herschel, the greatest observational astronomer, in Proctor's opinion, that this world has ever seen, imagined the sun to be a solid globe under a luminous atmosphere. He accounted for the nuclei and their penumbræ, the spots which photography has made so familiar at the present day, by supposing that this atmosphere or garment of light was occasionally removed, so as to discover the naked body of the sun, just as the moon is seen from time to time through the apertures formed by the discontinuous passage of a scudding cloud. Nor was this enough to satisfy the hunger of his fancy. He maintained, with seriousness, if not with vehemence, the probability of a population existing on this solid solar globe. He refused to believe in the sun as a source of light and heat—an attractive centre and nothing more. When met by the objection that the people of this particular star might find their mansion inconveniently warm, he kindly invented, solely for their comfort, a sort of envelope of a substance not clearly defined, and unknown to the physical world. The population of the orb of day is no new thing. Intelligent beings had been found in it long previous to the production of our pretty pictures of sunlight and silver. The poets had already placed in it the blessed spirits of the departed, and Tobias Swinden, with a strange pertinacity of contradiction, the souls of the reprobate and the damned. But Sir John Herschel went beyond his sire. Not content with admitting the possible coolness of the solar globe, he thought it not unlikely that the inhabitants themselves emitted the chief part of the light and heat with which this earth is supplied. Those willow leaves, familiar to the eye of astronomical speculation, roaming over photographic solar charts, those rice grains scattered over the photosphere, like spills in the game of spillikins, were for Sir John organisms possibly partaking of the nature of life—Brobdignagian creatures of some thousand miles in length and some three hundred in breadth. Professor Young, of Dartmouth College, Hanover, U.S., in 1871, differed widely from both the Herschels. He held the sun to be a bubble, gigantic, with gradually thickening walls and diminishing diameter, whose skin, formed by a constant downpour of metallic rain, was continually burst by blasts from within.

As Philoctetes was cured by the rust of the very spear which had wounded him, so, if an ancient historian may be believed, may the solar photographer look for relief to the cause of the disturbance of his mental equipoise. Pliny, in the second book of his "Natural History," speaking of the sun, calls it the mind of the universe, and deity of nature. It is the sun, he says, which dissipates the sadness of the sky, and clears into serenity the clouds of the human intellect. The last portion of the great naturalist's description of our system's self-luminous centre, and our source of life, "of this great world," as Adam and Eve called it in their morning hymn, "both eye and soul," seems almost prophetic of the photographic art.

It were idle to attempt the enumeration of the many ways in which photography has extended knowledge and disseminated delight by the aid of the sun, that most interesting and useful to us of all the stars, which people the blue depths of infinite space. Albeit only $\frac{1}{2300000000}$ part of the heat and light of this resplendent orb is accorded to our earth, a single child of the large solar family, this portion has been found amply sufficient to satisfy the desire of the most covetous of photographers.

Photographs of the sun are, says Janssen, the easiest to obtain and the most difficult. If merely a general reproduction of our central star, with its spots and penumbræ, be desired, no remarkable difficulty stands in the photographer's way; but the path is full of pitfalls for him who wishes an exact likeness of the elements which form its luminous surface. Only lately, according to a well-known artist, has the true construction of these elements been satisfactorily determined. The streaks or *striæ* of the penumbræ and the faculæ of the spots seem to be both formed of those granulations, of which the true shape has been revealed by photography alone. They constitute a primordial element, as it is now believed, of all parts of the photosphere. But they are of widely distinct appearances. The polygonal set, shown in Janssen's pictures, represents the contours of the polygons marked by elongated granules, while their centres are distinguished by granules of a circular form. The vast number of these variations, shown by photography in a fraction of a second, could not be expressed in a day, or a month, or a year, by the most assiduous draughtsman. It is only the camera which can catch arrangements incessantly modified with every passing instant. Our earth, we are told, moves with a rapidity some three-score times greater than that of the swiftest projectile known to modern science, but photospheric granules are hares compared to which our earth is but a tortoise in its motion.

In 1842 the sun, partially eclipsed, was photographed by M. Majocchi. The first complete solar photograph seems to be due to MM. Fizeau and Foucault in 1845. In this Daguerreotype the inferior luminosity of the sun's borders was clearly shown, indicating the probable presence of an absorbent gas extending round the photosphere. A long time elapsed after this before the maculæ and the faculæ containing them made their definite appearance in the sun's photographic likeness.

(*To be continued.*)

## NOTES ON LANDSCAPE.*

BY FRANCIS L. PITHER, ARCHITECT.

Landscape art may almost claim to be indigenous to these islands, living as we do under climatic changes more singular and recurrent than in almost any other quarter of the globe; in a country affording endless variety of conformation, from the dark purple granite of some parts of the north, through the beautiful and romantic lake district, the hills and glades of Derbyshire, with the prospect from some broad crested hill stretching out as far as the eye can see, to the beautiful undulating downs of our southern counties, back to the granite again to be found on the coast of Cornwall. All these make the study of landscape art peculiarly fascinating, and, one might almost say, pre-eminently English. Think for a moment if this is not so. Go back in mind no farther than your last country walk to the vivid recollection of the vast expanse before you in all its many-hued glory of nature's changing moods, and say if you can pick out from a collection of photographs types which shall express nature joyous, nature sorrowful, or nature terrible. This, then, is what we have to aim at. Not that every stone, every bough, every leaf, shall be recognisable, but that our work shall convey a distinct impression of sorrow or of gladness. In a word, this toiling after minutiæ can never help us to translate the latent beauties of nature, for, however excellently done, these things are but dots and specks in the field of our vision, and in measure, as they are prominent, only defeat our aim. This leads up to the consideration of that quality we have before referred to, and which artists describe by the name of breadth. We need not be ashamed to own that it is one of the most difficult to get into our work, for the want of it has marred many a picture otherwise perfect both in colour and composition.

It is a little difficult at first to appreciate the full meaning of the term, because a broad mass of light or shadow will not give breadth, but spottiness, coarse or fine, in proportion as their areas are related to the size of the picture. Speaking generally, therefore, we may say it is the direct negative of spottiness. If you should have more than one point of light, breadth requires that these points shall the one lead up to the other to a point of focus in the whole, and be not in any sense competitive; equal lights or equal darks diminish breadth, as does also abrupt transition from light to dark, or the *vice versa*. To make the definition still clearer, we should say that a large luminary such as the sun affords breadth of light, whereas a lamp or a candle affords breadth of shadow.

Before leaving this branch of our subject, we will just examine one notable instance that comes to mind. Rembrandt, in his "Adoration of the Shepherds," will be found to have employed his customary mass of darks leading up to a group of lights, the form of which is still more emphasised by being contrasted with the dark mass of one of the shepherds.

We will now pass on to consider some of the elements that go to make up the composition of a picture. We have all read in various treatises of the elaborate division and sub-division of the area of the picture into thirds and fifths in length and breadth. Now, inasmuch as these rules have been advised and enlarged upon by highly respectable authorities, it may be considered improper, not to say audacious, in me to take any other view; but I really think that this is one of the advantages we must be content to allow that the painter, with his greater command of leisure, and his more deliberate methods, has over photographers, for it seems to me that these rules are far too cumbersome to put in practice when we are making our selection on the screen, besides which, I can conceive nothing more dreary than some one idea or set of sub-divisions becoming fashionable among us, suggesting a dull uniformity of effect quite the reverse of pleasing; rather should we follow our separate instincts, taking that which appeals to the art feeling within us. Mind, I do not wish to imply that these rules are wrong, but only that they should not form the ground-work of the first building up of our subject, and only being used to resolve any doubts that may arise in the after-process of selecting certain portions of our plate for the finished picture. While I think it quite possible to produce indifferent results by fettering ourselves with too elaborate sub-division, we cannot afford to neglect certain simple first principles, which I put in negative form for the sake of greater emphasis:—1st. No prominent line or feature should equally divide the picture, either in height or breadth; this is too obvious to need enlarging upon. 2nd. No continuous line to run parallel to either edge of the picture. This obviously does not apply to architectural work pure and simple, and exceptions may be allowed where a distinct purpose has to be worked out. 3rd. Parallelism in any direction to be avoided, unless much broken up or counterbalanced, as in the view of one of the side canals at Venice by Gaucherel. The exercise of these three simple rules will keep us clear of any glaring error, and will, I think, be found sufficient to bear in mind when engaged upon the preliminary work of focussing.

The third division to which I wish to draw your attention is that of atmosphere. Painters say a picture is full of air when they wish to express that this quality has been secured. In landscape work it is, of course, indispensable, for it is the one thing needful to qualify the several planes in a picture, and give interest to the whole; in this way it may be said to go hand-in-hand with breadth. A careful study of some contemporary work will explain the *modus operandi* of arriving at effects often exceedingly beautiful. It may even be called the one string that the school of impressionists have established. Whatever of beauty is found in their work, and whether we like their work or not, this much must be allowed: that they have opened up a fresh page of art interpretation at a time when the poetic interpretation of nature seemed an absolute dead letter. I regret exceedingly being unable to instance pictorially the full force of what this means; but a reference to some of the best etchings of Whistler's, Daubigny's, and Corst's—and, secondarily, some of Van Hier's work in Regent Street will sufficiently explain this point. I remember, some years ago, a very fine picture by Wyllie in the Academy; it was afterwards bought by the trustees of the Chantry Bequest. The title was, I think, "Toil, Smoke, and Grime on a Flowing Tide," and affords an excellent example of some of the subtle effects of atmosphere. The scene is in the Pool, with the bows and funnel of a steam-tug in the immediate foreground, backed up by that peculiarly dazzling shimmer which moving water has under a strong sun. And note how the inevitable hard-

* Concluded from page 463.

ness has been escaped; the whole of the outline of the boat against the light background is as restless and uncertain as the water itself.

Now, am I right in saying that ye gentlemen of the sharp definition school should have a little of your hobby. Yet one more instance before leaving this section of our subject. A cathedral city with the minster towers or spire rising from the roofs in the foreground. Let us see how Roberts, or Prout, or Turner would treat it. Shall we find the outline sharply defined from summit to springing? Not at all; as the form nears the buildings in the front it will gradually become less distinct, finally losing itself altogether in the atmosphere that actually divides the planes. Now, both these effects are to be produced on our negatives—if the state of the light has not already done it for us—by a judicious after-treatment with light washes of Indian ink as before explained. Please note that I refer at length to this because my experience of photographs tends to the belief that the average operator would not think it worth while to expose unless he could see all sharp on his screen at the time of focussing.

## STAR PHOTOGRAPHS.

At the last meeting of the Royal Astronomical Society, Mr. Knobel read a paper by Mr. H. C. Russell, director of the Sydney Observatory, entitled, "Notes on some Star Photographs recently taken at the Sydney Observatory." The paper was accompanied by prints of several photographs taken with a camera of 6 in. aperture, and about 30 in. focus, and with the 13 in. photographic telescope with which the Sydney Observatory will join in the international survey of the heavens. With both of these instruments, photographs had been obtained of the $\eta$ Argûs nebula, one with an exposure of eight hours, and another with an exposure of five hours. Though a considerable extent of the nebula has been photographed, its light seems to be less actinic, and to act much less rapidly on the plate than the light of the great Orion nebula. On the other hand, Mr. Russell remarks that the light of many parts of the Milky Way in the southern hemisphere seems to be very actinic, and that, in many regions, stars and nebulosity are photographed where the eye sees nothing with the telescope.

Dr. Gill said: I had the pleasure of examining Mr. Russell's photograph of the $\eta$ Argûs nebula the other day, and I certainly never saw a more beautiful photograph of a nebula. Not only is there a great deal of nebulous detail shown, but the stars, down to the smallest, are represented by exceedingly sharp and well-defined points. This nebula is certainly very deficient in blue light, and photographs very slowly. On the other hand, there seem to be many regions in the Milky Way where the stars photograph very rapidly, and seem to be rich in blue light. This is very interesting in connection with what Prof. Pickering has published with regard to the brighter stars of the Milky Way being all of the Sirius type. We were at first very much puzzled to find the Milky Way stars in the southern heavens showing a greater photographic magnitude than their eye-estimated magnitudes warranted. Their magnitudes as determined by photographs were generally half to three-quarters of a magnitude too great as compared with eye estimates. This might have been due to their being seen on a brighter background than other stars, which might cause the eye estimates to be systematically too small, or it might be due to a difference in the nature of their light. Prof. Pickering's spectroscopic observations showed that the larger Milky Way stars were generally of the Sirius type, and were rich in blue rays. Now, we find the smaller stars of the Milky Way having a photographic magnitude above that which would be indicated by eye estimates, and, consequently, they are probably blue stars; therefore we probably have in the Milky Way a structure in the heavens which, according to the theory of the evolution of stars, seems to be a more recent structure than other parts of the heavens.

Mr. Ranyard said: I have examined Mr. Russell's photographs with a great deal of interest. The larger photograph of the $\eta$ Argûs nebula shows great extensions of the black rifts we were already acquainted with. There is one of them which is very striking, and looks like a dark branching tree on a bright background. I should like to remark, in connection with what Dr. Gill has been saying, that the Milky Way is a region of red stars as well as of blue stars. For example, in the region of the Coal-sack, when Mr. Russell's photographs have brought out streams of small stars over an area where the eye sees only blackness, there are several red stars which seem to be associated with blue in a cluster. Whether the photographing of these small stars is due to their blue colour or not it is difficult to say. It seems to me that everywhere the photographs reach a lower magnitude than can be reached by the eye.

The President: We must return our grateful thanks to Mr. Russell for these valuable photographs; and also, I think, to Sir Howard Grubb for the beautifully defining lenses with which they have been taken.

The Astronomer-Royal showed some photographs which he had obtained of stars when making use of the wire gauze screens recommended by the Photographic Commission. These photographs were thrown upon the screen, and showed that there were spectra symmetrically situated around the image of the star. The Astronomer-Royal thought that slight differences in the screens—for example, if they became bent—would give rise to variations of the amount of light in the central image as well as in the spectra, and that, consequently, they could not be relied upon, as constantly reducing the light of stars through two magnitudes.

Photographing the Empress of Germany.—Thursday was set for making a photograph of the Empress, and, in accordance with the directions received from the Chamberlain, and, in fact, from the Emperor himself, on the occasion of a previous visit, your correspondent, accompanied by photographer Russell, took an early train for Potsdam, where the sitting was to be. Arriving about 10 o'clock at the pretty little station where one leaves the cars for the royal palace, a comfortable coach was found waiting, together with the information that the Empress had not yet returned from Berlin, but was expected on the train that would immediately follow. Meanwhile we were accorded free run of the palace, in order that we might select a spot suitable to serve as a background for her Majesty's portrait. Granted this exceptional privilege, we naturally took time to look about us, and finally decided upon the royal billiard room as presenting the most picturesque possibilities. Fifteen minutes after noon, and just that number of minutes late, the Empress entered the room. She greeted us in the most gracious and unaffected manner, speaking in English with much less accent than is detected in the English of the Emperor. She walked to the further end of the room, where she saw we had arranged a place for her, and signified her readiness for us to proceed. As she sat in an easy and graceful pose upon one of the chairs, with a portion of the rich golden hanging forming a tasteful foil to her sea-green dress, she seemed every bit an Empress. While not beautiful, she has a face which is attractive and charming. It bore a half-laughing expression, and the dignity in her manner was not abated in the least by the almost unceremonious ease with which she permitted Mr. Russell to arrange her dress and surroundings for the photograph. The Empress wore magnificent pearls with this costume, and her neck and shoulders and arms were beautifully white and rounded. When we had taken her in five different positions in this costume, she left the room and presently returned wearing a dress of black lace, with a magnificent display of diamonds. In this costume we made six more negatives. At the conclusion of the sitting, her Majesty asked us a few questions concerning the photographs we had made of the Emperor, how the negatives had developed, and whether we thought the likeness would be good. She then very graciously said that luncheon would be served to us before we left, and with the most pleasing thanks for our services she left us. A servant appeared, who conducted us to the luncheon room, where we were served with a bounteous repast, laid before us on a golden service.—*New York World.*

## THE EDER AND SCHIENDL CONTROVERSY.

WE have received from Dr. Eder a voluminous letter combating many of the statements made by Herr Schiendl which lately appeared in our columns. We regret that we cannot devote any more space to this dispute, which is certainly of no interest to the majority of our readers. Dr. Eder's original communication was inserted in our columns before the present Editor assumed the reins of office, and, as a matter of courtesy and fair dealing, he gave space to the answer of Herr Schiendl. He did so somewhat reluctantly, for the matters in dispute were many of them of a very trivial character, and interesting only to the two contributors. Both disputants have now had their say, and the correspondence must cease.

## SOME NEW ADDITION COMPOUNDS OF "THIOCARBAMIDE" WHICH AFFORD EVIDENCE OF ITS CONSTITUTION.*

BY J. EMERSON REYNOLDS, M.D., F.R.S., PROFESSOR OF CHEMISTRY, UNIVERSITY OF DUBLIN.

*A compound of ammonium iodide with thiocarbamide* was obtained in the same way as the bromide; that is to say, 3·6 grams of ammonium iodide and 7·6 grams of thiocarbamide (1 : 4 mols.) were dissolved in separate quantities of hot alcohol; the solutions were then mixed, and the mixture boiled. Combination took place as in the case of the bromide, and a similar felted mass of crystals separated on cooling. The product was washed with cold alcohol, twice recrystallised from the same solvent, and dried.

The melting point of the pure compound is 186°, but the substance begins to decompose at about 190°.

I. 0·27 gram gave 0·545 $BaSo_4$
II. 0·2475 gram gave 0·131 AgI.

The formula $(H_4N_2CS)_4NH_4I$ requires—

| | Theory. | Found. |
|---|---|---|
| S ... .. ... | 28·50 per cent. | 28·74 per cent. |
| I ... ... ... | 28·28 ,, | 28·60 ,, |

There is, therefore, no doubt that the compound formed by ammonium iodide is similar in composition, as well as in general characters, to that afforded by ammonium bromide with thiocarbamide.

*An ammonium chloride compound with thiocarbamide* was prepared as follows:—1 gram of pure ammonium chloride was dissolved in the least possible quantity of boiling 85-per-cent. alcohol, and was added to a solution, also boiling, of 6 grams (or rather more than 4 mols.) of thiocarbamide in alcohol. Combination took place, and a felted, crystalline mass separated on cooling, closely resembling the bromide of ammonium compound. The substance was recrystallised from boiling alcohol, washed well with cold spirit, and dried. Its melting point was 154°.

A sensible excess of thiocarbamide was used in this preparation, and the crystalline product seems to have the power of carrying down with it and retaining persistently some of the free amide, and, as repeated crystallisation from even moderately strong alcohol tends to decompose it, in the following sulphur and chlorine determinations the former is high and the halogen proportionately low.

I. 0·3535 gram gave 0·9447 $BaSO_4$.
II. 0·256 gram gave 0·0945 AgCl.

The formula $(H_4N_2CS)_4NH_4Cl$ requires—

| | Theory. | Found. |
|---|---|---|
| S ... ... ... | 35·80 per cent. | 36·74 per cent. |
| Cl ... ... ... | 9·93 ,, | 9·12 ,, |

* Continued from page 463.

The results indicate that the product obtained is the tetrathiocarbamidammonium chloride analogous to the bromide and iodide. It may be added that only tetrathiocarbamide compounds were produced in the cases of the iodide and chloride, as well as in that of the bromide.

B.—*Substituted Thiocarbamides and Ammonium Bromide.*

Experiments were next made with substituted thiocarbamides, in order to ascertain whether they can form compounds with ammonium bromide similar to those obtained with the unsubstituted amide. The mode of operating was the same as in the cases already described in which definite compounds were produced, and each of the following mono and di-substituted thiocarbamides was treated with ammonium bromide.

$CSN_2H_3{\cdot}CH_3$
$CSN_2H_3{\cdot}C_2H_5$
$CSN_2H_3{\cdot}C_3H_5$
$CSN_2H_3{\cdot}C_6H_5$
$CSN_2H_2(C_6H_5)_2$
$CSN_2H_2(C_6H_5){\cdot}COCH_3$.

In no instance was any evidence of combination obtained, even under the most favourable conditions, the unchanged thiocarbamides crystallising out from the solutions along with the ammonium bromide used in these experiments.

Considering the number of substituted thiocarbamides examined, and the variety of radicles present, it is clear that the substitution of even one atom of hydrogen by an alkylic or allied group destroyed the power of the compound to combine with ammonium bromide; but it is to be noted that all the thiocarbamides used in the experiments were prepared by similar methods, and were, doubtless, of similar constitution.

C.—*Compounds of Tetrethylammonium Iodide and Bromide with Thiocarbamide.*

The last group of experiments having proved that the introduction of a single alcoholic radicle into thiocarbamide wholly prevented the combination of the product with ammonium bromide, the next step was obviously to ascertain whether the presence of similar radicles in the bromide destroys its power of uniting with unchanged thiocarbamide. Hence a series of experiments were made with the alkylammonium bromides and iodides, the ethylic compounds being those chiefly employed. I shall first describe the results obtained with the tetrethylammonium salts, the iodide being that first used.

Five grammes of pure tetrethylammonium iodide were dissolved in alcohol and added to an alcoholic solution of 6 grams (1 : 4 mols.) of thiocarbamide. The mixture was boiled for rather more than an hour. When cold, no crystals were deposited, though the solution was strong; it was therefore distilled down sufficiently and allowed to cool, when a mixed crystallisation was obtained, consisting of free thiocarbamide with fine, prismatic crystals of a compound of the iodide with thiocarbamide, which contained more iodine than is required even for a compound of only 2 mols. of the amide with 1 of the iodide, but no trace of any tetrathiocarbamide compound could be detected, nor was any obtained after further attempts at combination. As the evidence pointed to the production of a dithiocarbamide compound at most, a further calculated quantity of tetrethylammonium iodide was added, so as to secure the proper proportions in solution. On crystallisation after further heating, a fine crop of large, needle-like crystals separated unmixed with free thiocarbamide. But the appearance of the crystals and their manner of separating from solution presented no similarity whatever to the compounds of thiocarbamide with simple ammonium salts. The new substance was recrystallised from alcohol and carefully dried for analysis.

The melting point of the pure compound is 135°.

0·553 gram gave 0·644 $BaSO_4$.
0·3455 „ 0·1974 AgI.

The formula $(H_4N_2CS)_2(C_2H_5)_4NI$ requires—

| | Theory. | Found. |
|---|---|---|
| I ... ... ... | 31·0 per cent. | 30·85 per cent. |
| S ... ... ... | 15·6 „ | 16·00 „ |

There is, therefore, no doubt that a well defined dithiocarbamide compound (and possibly a 1 : 1 also) is formed with tetrethylammonium iodide, but no higher product was obtained, even in presence of a considerable excess of thiocarbamide.

Similar results to the foregoing were afforded by tetrethylammonium bromide; the single compound obtained separated in fine, rectangular prisms, which were sufficiently purified by one crystallisation.

The pure compound melted at 159-160°.

0·2845 gram gave 0·1486 AgBr.
0·3218 „ 0·399 $BaSO_4$.

The formula $(H_4N_2CS)_2(C_2H_5)_4NBr$ requires—

| | Theory. | Found. |
|---|---|---|
| Br... ... ... | 22·09 per cent. | 22·22 per cent. |
| S ... ... ... | 17·67 „ | 17·04 „ |

The solution from which this compound had separated was mixed with excess of thiocarbamide and heated for half an hour to boiling, but no traces of any tetrathiocarbamide compound was obtained in successive crystallisations from the liquid. The chloride seems to act in the same way.

Thiocarbamide, therefore, combines with the haloïd salts of ammonium and tetrethylammonium, but affords two perfectly distinct classes of compounds, differing alike in characters and in composition.

*(To be continued.)*

At a meeting of the Royal Society, Edinburgh, June 1st, Prof. Tait communicated a paper, by Prof. Piazzi Smyth, on two series of enlarged photographs, one in the visible, the other in the invisible of the violet of the solar spectrum. The paper was accompanied by the photographs. The observations include part of the spectrum as previously observed by Mr. Smyth in the summer of 1884, and extend to an extreme distance in the invisible violet. The previous observations were included in sixty plates; in the present series twelve more plates are added in the violet region, and two independent photographs of each part have been taken. The photographs agree with those of Prof. Rowland in indicating that the Fraunhofer line, "little *d*," is either entirely absent now from the solar spectrum, or has become very unimportant.

In Fear of the Photographer.—Speaking of Ramsgate, in "Seaside Resorts," the holiday number of the *Daily Graphic*, the writer says:—"The whole place literally bristles with photographers. You never know when you are being taken, or what compromising picture the photographer may have at this very moment in course of development. I have only been here thirty minutes, and have been most circumspect in my behaviour, as I always am, but fear to imagine how many times I may have been 'snapped off,' and I tremble when I think I may see these pictures for sale in the shop windows to-morrow morning. Surely one ought to be allowed to have a copyright in one's own face. I was only just now talking to Mr. Montagne Williams, whom I met on the pier while watching the arrival of the London steamer of the General Steam Navigation Company, and I wish I had asked him his opinion on the matter, for I see every chance of being involved in several actions with regard to copyright in my own countenance before I leave the township."

## COLOUR PHOTOGRAPHY.

Mr. Frederic E. Ives, according to the *Philadelphia Ledger*, made an important communication at a meeting of the Franklin Institute, on June 18th, upon the subject of his process of colour photography, in the course of which he explained and illustrated some recent improvements he had made in the means of operating the process, by which it is rendered comparatively simple and reliable, and capable of immediately profitable commercial operation for lantern illustration. When Mr. Ives first published his process, several years ago, the three negatives requisite were made in one camera from one and the same point of view, but last night he showed that, by an improvement on his heliochromic camera, the three negatives, represent- the effect of the object photographed upon the three fundamental colour-sensations, are now not only made from one point of view, by simultaneous and equal exposure, as they were three years ago, but also upon a single sensitive plate; so that the heliochromic negative is obtained with no more trouble than an ordinary one, and any number can be made in which the relation of one element to the others is exactly the same. The colour prints, also, can be made from these negatives by a single exposure in transparent gelatine, and separated only when ready to dip into the dye solutions representing the respective colour-sensations. Mr. Ives showed, however, that it is not necessary to go to the trouble of making the colour prints when only lantern illustrations are required. Lantern positives made from the heliochromic negatives with no more trouble than ordinary lantern slides were projected on the screen in the natural colours in the ordinary lantern, by means of a special front of Mr. Ives's own devising, and which was substituted for the ordinary projecting lens in about one second, so that an exhibition of ordinary lantern slides can be interspersed with projections in natural colours without causing any delays in changing from one to the other.

Several such projections were shown, including some admirable views in the Park, and they were received with prolonged applause. The approximation to the colours of nature were marvellously accurate. The positives were about one-third smaller than the ordinary projections, but were as sharply defined, and in as bright and true colours as those produced two years ago with the more elaborate and troublesome lantern. The lantern front used for these new projections consisted of three prisms, converging light from a single condenser and radient to three small projecting lenses, the necessary colour screens being located just behind the objectives. Mr. Ives also showed one of two cameras which he had devised to produce the heliochromatic negatives, in which three negatives are made on a single plate, the image-forming rays being transmitted to the single gelatine dry plate through three reflecting prisms, and from points of view so close together (less than half an inch apart) as to make perfect registration easy of accomplishment. By the other camera, the three negatives will be made from the same point of view. Mr. Ives also announced that he was at work on a scientific novelty in the form of an optical device for the table, in which these positives could be seen in the natural colours as readily as stereoscopic views are seen in relief in the stereoscope.

Mr. John Carbutt said that he considered Mr. Ives's latest work by far the most important and valuable contribution to the difficult subject of photography in the colours of nature which had yet been made.

# Patent Intelligence.

## Applications for Letters Patent.

10,662. LEWIS HUGHES, 4, Clayton Square, Liverpool, "Improvements in Lifters for Photographic Plates."—June 23rd.

10,665. WILLIAM TYLAR, 12, Cherry Street, Birmingham, "Improvements in Photographic Folding Plate Drainers."—June 23rd.

10,798. JOHN KERSHAW, 53, Arcade Chambers, St. Mary's Gate, Manchester, "Improvements iu Shutters for Photographic Cameras."—June 24th.

## Specifications Published.

1,098. *January 21st*, 1890.—"Chauge-Boxes." H. H. LAKE, Southamptou Buildings, Middlesex. (E. Kipper, 361, Broadway, and E. W. Perry, jun., 42, East Fourteenth Street, both of New York, U.S.A.)

The plates, &c., are placed in a box, and are pressed towards a flange in the front by a support actuated by a screw. The front plate, &c., is exposed by withdrawing a slide. The exposed plate is transferred to a receiving box, which may be hinged, or otherwise attached, to the first. The transference is effected by an open frame, the side bars of which have teeth, which, taking the edges of the plate, &c., carry the latter into a box. Springs, or a push, may be used to throw the plate, &c., off the teeth. The carrier frame is worked by a rack and pinion. A flap shuts the aperture in the partition or ends of the boxes through which the carrier passes. Modifications are described in which the plates are transferred by pinions which engage in the corrugated edgings of sheaths, in which the plates, &c., are held, or by friction wheels, &c. Also the receiving box may be in the rear of the holding box, the plates, &c., in transference passing through a curved guide, which may be provided with guide rollers. Lastly, the frame carrier may be actuated by a cord or rod, &c. The sheath referred to is formed by turning over, and forming teeth or corrugations on the edges.

1,155. *January 22nd*, 1890.—"Tripod Stands and Walking-Sticks." W. R. BAKER, 9, Belmont Villas, Wallington, Surrey.

Relates to camera stands, which may be also used as a walking-stick.

The legs, which are hinged or pivoted to the base of the superstructure on which the camera rests, form, wheu folded together, a walking-stick of circular section, the lower ends being secured by a ferrule, and the top by a tube of the superstructure, which serves as a handle. The superstructure consists of a triaugular base to which is screwed the tube carrying the camera board. The parts are detachable, but in a modification, in which the legs, instead of being pivoted, are hinged, the lower part is small enough to allow the upper part of the tube to pass over it when using the stand as a walking-stick. The provisional specification describes a modification of the superstructure, consisting of two triangles with connecting pieces, which is also adapted for being used apart from the legs.

1,203. *January 23rd*, 1890.—"Detective Camera with Change-Box Arrangement." D. CARTER, 15, Gerrard Street, Warwick.

The plates or films are fitted in sheaths, preferably of metal, and slid into vertical grooves till they rest on a platform fixed to the back of the camera. A frame slides on rails, and, after an exposure, it is pulled forward by a tape (which is marked to act as a register), till the exposed plate slips over the end of the platform, and falls forward into a store receptacle in the bottom of the camera. The frame is pulled back by elastic bands and held iu the correct position for exposing each plate by a detent acting on the teeth of a rack. A shield, which may be hinged, excludes light from the store receptacle. Several modifications of change-box arrangement are described. In one, a spring arrangement is used to break the fall of the exposed plate into the store receptacle. Wings are formed ou the sides of the sheaths to prevent them falling forward till they have reached the bottom of the store receptacle. In another form, the projecting ends of a wire fixed to the bottom of a sheath are pivoted in apertures in the peripheries of the end discs of a reel or roller. By turning the reel the plates are brought successively into position for exposure, and then folded down into the store receptables. Instead of moving forward the frame to bring the plates successively into focus, the front of the camera is connected to the body by a short bellows so that it can be moved backwards. The leus tube is fitted iu a tube fixed at right-angles to a plate which is pivoted so as to bring the lens nearer the base of the picture when the cameras are turned round. The shutter consists of two oscillating plates working in a slot in the lens tube, and actuated by a cam, on the axis of which is a grooved pulley turned by a cord connected to an elastic band at one end, and worked by a lever at the other. The finder consists of two parallel reflectors set at an angle of 45°, the lower reflector being convexed to correspond with the focus of the lens.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—By the kind invitation of Mr. John T. French, a very pleasant excursion of the above Society took place to Keston on Saturday afternoou last. The wind was against anything special being done. After tea, the wind having dropped somewhat, the company was grouped iu the valley, and Mr. Banks had a shot with the Club camera. On July 11th the Society will have an outing at Rochester.

DEATH OF MR. LACHLAN M'LACHLAN.—The Manchester papers devote more than the ordinary amount of space to obituary notices of this well-known photographer, and some of them give a long account of his career from his amateur days to the time when he was called upon to take portraits of the Queen and various members of the Royal family. From one of these notices we extract the following:—"About 1853-4 he commenced as a professional photographic artist in St. Ann's Square; subsequently having a studio very many years in Stamp Office Buildings, Cross Street, near the old offices of the *Guardian* aud *Evening News*. At the latter studio M'Lachlan made his first distinctive mark as the most artistic photographer in the city, a position, we may add, in face of many subsequent accomplished competitors, he maiutained to the last. As was once remarked: 'M'Lachlan is au enthusiast; and nothing but enthusiasm of the noblest order could have reached the goal which he has won. He believes in photography as au art; not in those caricatures at so much per dozen which can be had at any street corner, but specimens where the character of the man photoed can be plainly read.' In his Cross Street studio, M'Lachlan, assisted often by the high-class artistic advice of his great friend, Frederick Shields, turned out some splendid work, both of public and private characters; among the former capital photos of Mr. Charles Calvert as Richard III. and Shylock. His first really important public work was the fine photographic group of members of the Cotton Famine Relief Fund Committee, the portraits in which, especially of the late Lord Derby, the late Lord Egerton of Tatton, Lord Winmarleigh, &c., are as fiue as any ever produced by photographic art. Nearly twenty years ago M'Lachlan commenced, in a temporary photographic studio near Balmoral, the picture on which his uame and fame will hereafter rest—that of the Royal family. We remember him going off in hot haste to Aberdeen to get his first sittings of the Queen and other members of the Royal family, then at Balmoral. Of his theu experiences, and many subsequent ones in connection with that picture, which was really the labour, and, we may add, the bane, of the latter years of his life, no end of amusing stories have been, aud (now that he is gone) will be told. There was, however, one motto in this work which might be safely affixed to him—'Perseverantia omnia vincit.' As Sir Joseph Heron once said of him, 'Mac never knows anything about defeats or being beaten.' Apart from his profession, in which he certainly never knew a superior in Manchester, and apart from his long residence in Manchester, M'Lachlan was a typical Highlander, warm-hearted and generous, high-principled and honest, straightforward and above-board in all he said and did."

# Correspondence.

## THE BOSTON CAMERA CLUB.

SIR,—The next joint exhibition of the Photographic Society of Philadelphia, the Society of Amateur Photographers of New York, and the Boston Camera Club, will be given in Boston in the spring of 1892, and an item in your paper to that effect may interest your readers in Great Britain, especially those who are in the habit of exhibiting their work in this country.

The Boston Club has asked its members to work this season with that exhibition in view, and everything that can be done to make it a success certainly will be done.

*Boston, June 17th.* WILBUR C. BROWN, *Secretary.*

## ORTHOCHROMATIC PHOTOGRAPHY.

SIR,—Presuming that the report in your last issue of the discussion at the meeting of the Photographic Society of Great Britain is correct, I must ask you to allow me to make some explanations and corrections.

In the first place, I resigned my appointment with Messrs. Edwards some months ago, so that I have no longer the smallest possible interest in the patent referred to either directly or indirectly, so that I now have a free hand to investigate for myself without having it thrown in my teeth by writers (some of whom are interested in rival undertakings) that, as I was in the employ of the manufacturers of isochromatic plates, my opinions on the subject were not worth a rush. Now, as this explanation puts me *at least* on level ground with my critics, permit me to correct the misapprehension that your report will probably produce, as to what I actually wrote and think.

I did not in any way imply that optically-worked glass screens were first introduced by Messrs. B. J. Edwards and Co. I did not even mention their name in connection with optically-worked glass. What I did write was, "The best screens that I had seen, *so far as colour was concerned*, were those made in the form of a diaphragm, supplied by Messrs. B. J. Edwards and Co."

With all due deference, I claim to have had a wide experience of practical workers, and, therefore, I still hold the opinion that the "yellow screen bogie" has had a good deal to do with the apathy of photographers to the advantages of colour-sensitive plates. Another reason, doubtless, lies in the fact that those who have to earn their living by photographing have little time, and still less inclination, for investigation.

I have never said that the yellow screen is unnecessary *in all cases*, and I should feel obliged to anyone who will have the goodness to point out to me how, when, and where I said it. I have, however, frequently stated that the indiscriminate use of the yellow screen is to be avoided, and I am absolutely certain that, in many cases, a yellow screen is a positive disadvantage, and in this opinion I was supported by Mr. Gotz during the discussion at the P. S. G. B. on the 23rd inst.

A reference to my short paper read before the Society will show that I wrote :—"The yellow screen, far from being a terror, is a valuable tool which, when better understood and judiciously used, will enable photographers to reproduce the colours of nature in monochromatic values, which some painters might sneer at, but could never excel," or words to that effect, as I did not keep a copy of the paper referred to.

There are some other points in the discussion which I should like to comment on, but the foregoing is sufficient to show that my paper was not prompted by commercial interest, and that I am not opposed to the judicious use of compensating screens.

*Clifton Villa, Ilfracombe.* BIRT ACRES.

---

THE secretary of the International Photographic Exhibition which is to be held in Glasgow in September next, has sent us plans of the Galleries of the Institute of Fine Arts, in which the show is to take place, from which we are able to judge of the very large wall space which will be at the disposal of the committee. The principal room measures 95 by 33 feet, and there are five other smaller apartments in which pictures will be hung. The retiring rooms, lavatories, &c., marked on the plan show that the comfort of visitors will be looked after more than it often is at these exhibitions.

# Proceedings of Societies.

## NATIONAL ASSOCIATION OF PROFESSIONAL PHOTOGRAPHERS OF GREAT BRITAIN AND IRELAND.

A MEETING was held on June 25th at the Colonnade Hotel, New Street, Birmingham, to form a district branch of the above Association. Mr. H. J. Whitlock (Birmingham), president of the Association, who was in the chair, explained the objects of the Association, and heartly welcomed those present, expressing his pleasure at meeting members of the profession, and his belief that much might be done to advance their interests by friendly conference and interchange of opinion on various matters.

After further remarks by Mr. John Lewis, Herr Karoly, Mr. Harold Baker, Mr. Roland White, and others (all of Birmingham), a committee and officers were appointed, and the next meeting fixed for the 15th July next.

## RICHMOND CAMERA CLUB.

AT the meeting on the 26th inst., Mr. CEMBRANO in the chair, the "Development Competition," in which each competitor was required to develop two negatives of unknown exposure (one being under and the other over-exposed), was decided.

Mr. CEMBRANO acted as judge, and awarded the first place to Mr. Ennis for the under-exposed, and to Mr. Hunter for the over-exposed plate.

A discussion on the *modus operandi* of the competitors followed.

## HACKNEY PHOTOGRAPHIC SOCIETY.

A MEETING took place last Thursday under the chairmanship of Mr. J. A. SINCLAIR. Dr. Smith gave an account of the Dorking outing. Mr. J. O. Grant presented the Society with a set of dishes.

From the question-box : "How to get density in rapid plates."

Mr. HUBERT said it was necessary to modify development.

Mr. GRANT advised starting with soda and finish with hydroquinone.

Another question was put as follows :—"How to guide oneself in photographing interiors."

Dr. ROLAND SMITH gave a rule as follows :—Divide area of room in cubic yards by area of window in square feet. This gives results in minutes as a standard. Vary the stop according to light.

Mr. HUBERT showed the difference in development a plate makes by varying the bath. One was developed with pyro and ammonia ; the other was cut into two, and one half was developed with excess of pyro, and the other with excess of ammonia. The results showed, apparently, though equally exposed, correct, under, and over-exposure.

Dr. ROLAND SMITH then gave a demonstration of development, using pyro-ammonia, pyro-soda, hydroquinone and eikonogen mixed, &c.

## LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

*June 25th.*—Mr. PAUL LANGE in the chair.

Mr. John Jarvis was elected a member.

The balance sheet of the Liverpool International Photographic Exhibition was brought up for discussion, and passed.

The thanks of the Society were tendered to Mr. T. S. Mayne, the exhibition hon. secretary, by whose arduous exertions the exhibition was carried through. The Society also asked Mr. Mayne to accept the sum of £50 as a mark of their appreciation of his efforts.

Attention was drawn to the arrangements made for the holding of the photographic convention at Bath in July.

The PRESIDENT stated that the Mersey Yacht Club regatta would be held the following Wednesday, when members intending to photograph the yachts would have special facilities by booking their places on the steamer *America*, which had been engaged to follow the yachts.

The PRESIDENT showed some prints of submarine explosions, taken by him recently outside the river Mersey during experiments of the Submarine Miners Division for the Defences of the Port of Liverpool. The principal picture taken illustrates an explosion of a 100 lbs. gun cotton charge, the column of water forced up rising to over 100 feet.

Mr. W. A. Brown then proceeded to read his paper, illustrated with experiments, on the "Chemistry of Photography."

---

Bath Photographic Society.

The first excursion of the season took place on Wednesday last to Bradford-on-Avon, Avoncliffe, and Winsley. The party left the city by brake early in the afternoon, making the first halt at Bradford railway bridge, where the surrounding scenery proved to be most suitable for practice. A brief stay was next made at the top of the Bradford Road. In Bradford the principal object of attention was the old bridge situated beyond the town. Bradford and environs are so picturesque that it is hardly advisable to attempt too much on any one visit; for this reason the party made all possible haste to the weirs at Avoncliffe in order to secure some views ere the light should be unsuitable. This done, the members were invited to the summer residence of the vice-president, Mr. Austin J. King. After an excellent repast, another very pleasant hour or so was spent in viewing the grounds and peeps of distant scenery obtainable therefrom.

---

Birmingham Photographic Society.

*June 25th.*—Mr. A. H. Carter, M.D., in the chair.

Messrs. Charles Barwell and L. Neal were elected members.

Dr. W. W. J. Nicol gave his paper on "Silver Printing" with the aid of iron salts. He fully described the process of No. 1 and No. 2 kallitype, processes invented by himself, and which, at the present time, he is still improving, going through the chemical technicalities with great detail, and finishing with practically demonstrating the development of the prints, which showed very fine depth of tone.

The Chairman said that, in photographic processes, both the technical and the practical should be known, and these Dr. Nicol had explained most thoroughly.

During the discussion which followed, Dr. Nicol, in answer to questions, said that, in printing from a thin negative, the quantity of bichromate in the developer should always be doubled; and that sepia tones could be obtained by the addition of borax in the developer. Printing by artificial light took too long a time; even with oxyhydrogen or electric light printing is very slow.

---

Kimberley Camera Club.

At the second annual meeting held in the Council Chamber on June 3rd, the following were elected office-bearers for the ensuing year:—*President*—Rev. Father Ogle; *Vice-President*—Mr. F. Skead, B.A.; *Hon. Secretary and Treasurer*—Mr. M. Macfarlane; *Committee*—Messrs. C. A. Chappell, J. Henry, G. D. Pieser, and F. Titmas.

---

Vienna International Photographic Art Exhibition, 1891.—The following circular has been forwarded to us:—"Vienna, May 31st, 1891. According to the rules of the International Photographic Art Exhibition, each exhibitor is to get a diploma of merit, and the jury has the right to advise the patroness, H.I.H. the Archduchess Maria Theresa, to award a very limited number of gold medals. In consequence of this latter rule, the jury has subjected the whole exhibition to a careful examination. The result is that it is found to be impossible, owing to the high merit of the pictures as a whole, and to the great equality of the several ones, to do justice by awarding medals, as of necessity some works must be passed by, which would not be justified, owing to their being so nearly equal to those winning medals. Therefore the jury has unanimously resolved that there shall not be double awards, medals and diplomas. But each exhibitor will receive a diploma bearing the name of the Archduchess, which, owing to the extreme rigour exercised in the selection of pictures for exhibition, is, in itself, an honour of great value.—A. Schaffer (president of the jury), F. Luckhardt (hon. sec. of the jury)."

# Answers to Correspondents.

**All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.**

**All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.**

**Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.**

J. W. (Shanklin).—*Colonial Agency.* We do not know of anyone standing precisely in the position of our mutual friend named in your letter, either in Vancouver or British Columbia; but you might make enquiries of Messrs. T. N. Hibben and Co., of Government Street, Victoria, B.C.; or Messrs. Hall and Lowe, Photographers, of No. 76 in the same street.

B. L.—*New Cabinet Cases.* The leather boxes are made to accommodate twenty-five or fifty photographs, and, whilst preserving them in the smallest possible compass, with very little surrounding air-space, there is only to be noted the disadvantage that the contrivance offers less defence against kleptomania as compared with the old albums, where the removal of a card shows at once an awfully conspicuous blank.

A. F. V.—*Standards of Colour.* With the view of adding precision, and securing the adoption of certain standards of colour for industrial purposes, the council of the Society of Arts has recently appointed a scientific committee to attack this subject, and report during the forthcoming session. Amongst others we find the names of Lord Rayleigh, Captain Abney, Dr. W. J. Russell, Professors Hummel and Meldola, Mr. Brudenell Carter, and Mr. W. Holman Hunt.

F. C. S.—*A New Alloy.* Prof. W. C. Roberts-Austen showed at one of the recent soirées of the Royal Society a beautiful pink alloy, which he prepared from 22 parts of gold and 78 parts of aluminium. Perhaps nearest to this in colour is the pale violet *Regulus Venus*, composed of copper and antimony in equal parts. This latter is a very brittle alloy, known since the days of the ancient alchemists.

J. G. B. (Nelson, N.Z.).—*Sensitive Films of Iodide of Mercury.* The anticipations referred to by Dr. Liesegang in the 1875 Year-Book, p. 39, do not appear to have been realised. We cannot find any account of Dr. Schnauss's process, nor is it mentioned in Dr. Eder's summary of facts bearing on the "Chemical Effect of the Spectrum," published seven years later by the Photographic Society of Great Britain. The action of light upon mercury compounds, excepting in conjunction with oxalic acid for actinometry, does not seem to have led to any practical applications, and, in sensitiveness, the mercury salts stand far behind silver.

T. M.—*Bellows Material in Hot Climates.* To ward off the attack of insects camphor is not always successful, and its volatility renders its action at best only temporary. Probably mustard oil or turpentine combined with an insecticide powder (Keating's) would be most effectual.

J. C. (Barnton).—*Ferrotype Plate.* You will find several pages devoted to the ferrotype process and materials in Mr. J. Fallowfield's "Photographic Annual" (London: 146, Charing Cross Road, W.)

F. R. M. S.—*The Rainfall for Six Months.* The amount for June was less than half the expected quantity, and the total for the past half-year is just under eight inches for North London, which is about two-thirds only of the average rainfall for that period.

Printer.—*Water Glass.* A light wash of silicate is said to be effectual for removing the greasiness, whilst hardening the surface of the litho stone. It is applied with a sponge just in the same manner as gum water. The potash salt is usually employed, although syrupy silicate of soda is more reliable on the score of chemical purity.

---

Photographic Club.—Subject for July 8th, "View Meters and Finders"; July 15th, "Meteorological Subjects." July 4th, outing to Claygate and Claremont; train from Waterloo, 2.27; meet at Claygate at 3.

# THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV. No. 1714.—*July* 10, 1891.

CONTENTS.

## DECEPTIVE PHOTOGRAPHS.

Photography is now used more than ever it was before in the service of advertising—a natural result, possibly, of the many excellent photo-mechanical processes which have been perfected during the past few years. There is hardly a single branch of trade which does not employ photography as an advertising medium, either in the form of illustrations to catalogues and price lists, or in the more public manner of framed advertisements in public places. The bootmaker, the hatter, the clothier, and others who minister to personal adornment, are only too eager to adopt a method which so truthfully describes their wares, for they depend for success upon the outward appearance of what they sell far more than upon any other property which their goods may possess. In our railway stations, in the waiting rooms and other offices – nay, even in the coaches themselves —photographs force themselves upon our attention, whether we want them or not; but, as they are generally of excellent quality, they are looked upon with both pleasure and interest by those who happen to be killing time in their vicinity. These pictures mostly consist of transcripts from nature of the scenery which is accessible by the particular railway in question, and no doubt many tourists are, on the spur of the moment, influenced by them to visit the places photographed.

So long as the photographer confines his attention to studies of hats, boots, or shirts, he cannot play any tricks. The said articles of attire certainly do not lend themselves to artistic treatment, but he does his best to group them in the least offensive manner, and to bring out their gloss and other leading characteristics to the best advantage; but there are subjects in which the photographer employed by the advertiser can give rein to his imagination to a certain extent, and can, by a judicious choice of lens, practise little deceptions which are useful to his employer, but which are apt to be resented by the general public. One or two examples of this kind of deception have occasionally come under our notice, and may here be briefly referred to.

At a certain railway station in Devonshire—we need not be more explicit—we saw advertised a particular hotel which was said to be situated in its own grounds, while the said grounds comprised a beauteous waterfall. As a proof that these statements were true, some half dozen photographs were displayed, and there, sure enough, was the boasted waterfall. We had no idea that such a massive fall of water existed in the county, and we straightway made up our minds to visit this natural wonder of the district. The hotel was not particularly easy of access; that is to say, although upon the map it was only a dozen miles away, the route to it by railway was not direct, and many changes of carriage occurred before we arrived at our destination. But we were comforted under all these difficulties by the certainty of reward when our journey was ended. Alas! for human hopes founded upon the promise of a photograph. The waterfall which we had imagined to leap from a height of forty feet or so was, in reality, a little stream which tumbled over a miniature rock about four feet high, while, to add insult to injury, a man had to be sent to turn on the water before it would even dribble.

A still more flagrant example of photographic fraud of this type we came upon more recently, and for aught we know it is still drawing the shillings from the pockets of simple folk like ourselves. Here again we must be cautious with regard to stating the exact locality, for the awful consequences of imputing in print wrong doing, even to heinous criminals, are, in this enlightened country, not to be lightly regarded. The place referred to is much visited by tourists, and its chief glory consists in a mighty pass between limestone cliffs. In these cliffs some years ago a series of caves were discovered, and as some of the chambers there were decorated with stalactites of curious form, the owner of the place resolved to admit the tourist to the wonders of his caverns on payment of one shilling. In order to bait the trap, a number of photographs are placed outside the entrance to the caves, and it was by means of these pictures that we ourselves were caught.

The pictures bore a well-known name, and they were capital specimens of photographic work. One showed a hall of pillars like the aisle of some noble cathedral, the capitals of the columns being lost in darkness. Another depicted a placid lake, with stalactite above meeting stalagmite below, both being reflected in the mirror-like surface of the water. Another picture showed the curious, blanket-like form in many folds which stalagmitic masses will sometimes assume. Altogether, the scenes depicted were so remarkable and out of the common that we needed no more persuasion to pay our shilling for the "open sesame" to this place of marvels. But where was the hall of columns which we saw in the photograph? Here it was, a little cabin of a place a couple of feet high—a hole in the rock, in fact, where these columns were done in miniature. Where the lake? Here it was in another corner, holding about as much water as a sponge bath, and covering about the same area as that useful domestic appliance. The whole thing was a miniature of what we had expected—genuine enough, no doubt, but increased from pigmy size to gigantic proportions by deceptive photography.

## THE PORTRAITURE OF THE SUN.*

BY JAMES MEW.

In a pamphlet published some ten years ago by Mr. A. Davanne, vice-president of the French Photographic Society, it was asserted that at the Kew Observatory, during the space of some dozen years, more than two thousand photographs of the sun had been produced, giving the elements necessary for the verification of the number, position, and dimensions of the spots and faculæ, or bright streaks of diverse form on the solar surface, especially near the edge of the disc. These faculæ seem to have grown larger since the time of Sir John Herschel. Davanne speaks of some of them extending to forty thousand miles in length and to four thousand in breadth. The spots, first noticed, probably, by Fabricius in 1611, led to the discovery of the sun's rotation by Galileo. They are of irregular form, size, and position; black, surrounded by a striated penumbra, presenting to some the appearance of the edges of a thatched roof. About these spots, of which the discovery has also been ascribed, like that of most other things, to the Chinese, an interesting and early notice may be found in *La Rosa Ursina*, published in 1626.

In the study of the sun's surface, the photographic method has a great advantage in the strength and permanency of its recording picture, and the consequent power of perusing it at leisure. The disadvantage is that great foe of astronomical observation, atmospheric undulation, which renders the sun's image tremulous and confused, except at occasional moments. By taking a large number of photographs and selecting the best, this difficulty may be in some measure obviated. Janssen has taken pictures of the sun up to fifteen inches in diameter. In these the coarsely mottled corrugated surface of the photosphere is shown with much distinctness. Those luminous masses representing rice grains, or nodules, or oblong willow leaves, or blunt arrow heads, or feathers of a duck's wing, or trapeziums with rounded corners, or "things" two or three or even five times as long as they are broad, according to the imagination of the observer, are shown by these photographs to be of different sizes and splendour, which may arise from their different depths, or from bodies analogous to atmospheric clouds. This shape is commonly elliptic, but is subject to considerable variations. They tend, says Janssen, to sphericity, but are deformed more or less by gaseous currents.

Professor Rowland tells us that the spectra of all known elements—with the exception of a few gaseous, and some too rare to be yet obtained—have been photographed in connection with the solar spectrum, and that the greater part of the lines in these photographs has been identified, and the substance producing them noted. He has also presented us with a rough table of some two score solar elements, among which attention may be called to silicon, vanadium, scandium, yttrium, zirconium, glucinum, germanium, and erbium as possibly new. Arranged according to intensity, calcium occupies the first place in these sun elements, and potassium the last. Potassium is also the last if they be arranged after the number of lines in the spectrum, but the first is iron. Ruthenium, tungsten, with some half-dozen others, are classified as doubtful elements. Antimony, boron, gold, rubidium, thallium, and praseodymium, with some ten more, are said to be absent from the spectrum, while bromine, fluorine, holmium, thulium, terbium, &c., are substances not yet tried. "On the whole," says Professor Rowland, "were the earth heated to the temperature of the sun, its spectrum would probably resemble that of the sun very closely." But its inhabitants would, under such circumstances, cease to be interested in spectrum analysis.

Another proof of the scientific value of photography is in the establishment, through its assistance, of the fact that the glory of the sun, called the corona, circling sphery fire like the crown of soft, silvery light set about the heads of their saints by the artists of old, noticed as far back as the time of Kepler, and attended by its tongues or protuberances of rosy flame, is not any result of a lunar atmosphere, or a terrestrial phenomenon owing to the passage of the rays of this, our bright particular star in the galaxy through our earthly air, but a real and true appendage of the sun.

During the solar eclipse of August, 1869, the first piece of adminicular evidence touching the sun's corona came from the dark walls of the camera. Of the corona as well as the chromosphere, or chromatosphere, or sierra, the telescope ordinarily shows nothing. This is visible only during total eclipses or by aid of the spectroscope.

The photographs of the eclipse of July, 1878, show that the corona is not a mass of milky light, as it commonly appears through small telescopes, but has a hairy structure. Its outer limit is very irregular, resembling long tufts of flax. The *Bureau des Longitudes* of 1884 contains a photograph, neither retouched nor enlarged, of the corona during the eclipse of May, 1883, by M. Janssen. The picture was taken with a lens eight inches in diameter; the exposure lasted five minutes. The photograph shows a more extended corona than was visible in the telescope.

In August, 1887, photographs were taken in Russia and Japan, with plates of the same make, and probably of the same emulsion, with the same exposures, and developed by the same operator. In the next total eclipse visible in England, in the extreme north, just after sunrise, in 2290, the majority of our readers will feel comparatively faint interest.

* Concluded from page 482.

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

PHOTO-ENGRAVING IN HALF-TONES—MEASURING THE SPEED OF DROP-SHUTTERS—A NEW ACCELERATOR.

*Photo-Engraving in Half-Tones.*—Herr E. Ammann describes, in the *Phot. Archiv*, a process of making grained negatives, by which an ordinary negative may be employed and converted directly into a grained one. It is only necessary that the negative be clear and without signs of fog, and that it show sufficient density, negatives of such qualities only being suited for the process in question. The negative, which should not be varnished, is coated with a four per cent. solution of plain collodion, to which a few drops of castor oil have been added, when it is placed aside to dry. After the negative has dried, it is coated with the well-known solution of gum-arabic and bichromate, as generally used in the dusting-on process. In my own experiments with this process the following formula answered well:—

| | |
|---|---|
| Water ... ... ... ... ... | 100 c.c. |
| Sugar ... ... ... ... ... | 10 grammes |
| Gum-arabic ... ... ... ... | 10 ,, |
| Bichromate of ammonia ... ... | 4 to 5 ,, |

This solution must be well filtered, and not kept for too long a time. After coating, the layer is allowed to dry at a temperature of from 122° to 140° F. After about ten minutes it will dry with a high gloss, and whilst still warm the plate is exposed beneath a glass screen with pure black lines and clear transparent spaces in an ordinary printing frame in direct sunlight. One minute will be sufficient for exposure in most cases. The plate is then developed by means of a large, soft dust-brush, and with very finely-prepared plumbago. When the grain has attained the required depth, it is necessary to wash the negative thoroughly in order to remove the bichromate from its film, since otherwise spots would be produced in drying. This elimination is best done by means of a solution of 2 parts of caustic potash in 100 parts of water, in which the negative is allowed to remain until the yellowness has entirely disappeared. The grain printed-in in this manner on the negative adheres tightly to it, after which the negative simply requires to be varnished.

*Measuring the Speed of Drop-Shutters.*—The various methods of measuring the speed of drop-shutter exposures which have been suggested from time to time may be divided into two classes. The one consists in the direct measurement of the action by photographing with the shutter a glaring point in rapid motion, the speed of which is known; the other consists in the direct measurement of the speed of the shutter, generally by using a vibrating tuning-fork registering a curve on the blackened shutter during its passage. A simpler and much more certain method, which requires no specially constructed apparatus, has been published recently by Professor Leonhard Weber in the *Phot. Mittheilungen*. It consists in the following. One-half of a dry plate is exposed exactly one second to an uniformly lighted shining surface, with a given stop and a given lens. Then the other half of the dry plate is exposed to the same surface by means of the shutter, strip by strip, the time of exposure in each case being slightly prolonged, the arrangement of the camera being, however, the same as before. After development of the plate, it must be ascertained which of the various strips of the one half—in other words, what number of instantaneous exposures—shows the same density as the first half of the plate, which was exposed for one second. To effect this experiment an ordinary dark slide may be used, arranged as follows. A thin but opaque cardboard is cut up so that it fills up exactly the space of the dark slide destined for the dry plate. A longitudinal incision is then made exactly through the centre of the cardboard down to about one centimetre distance from the lower edge of the cardboard, and from this point a right-angled incision sideways to the lateral edge of the cardboard. The piece included by the incisions is then cut off, so that one-half of the plate is laid open. After this half of the plate has been exposed the cardboard is turned over, leaving open the previously covered half of the plate; the cover of the dark slide is then withdrawn for about one-sixth, and the drop-shutter released ten times successively; then the cover is again withdrawn for one-sixth, and the shutter released again ten times, and so on. After development, one-half of the plate will show an uniform darkening of its film, the other half, however, six strips of successively increasing darkness. It must then be stated at what point between the instantaneously exposed strips the darkening of the film corresponds to that of the timely exposed half, when it will be possible to estimate even by one-tenth. The source of light must, of course, be a constant one during the whole series of exposures.

*A New Accelerator.*—For some years, a solution under the name of "Excelsior" has been sold in Germany, which was recommended by its inventor, Captain E. Himly, as an accelerator in ferrous oxalate development, as well as in pyro development, and which, at the same time, was said to prevent the lights from becoming hard in developing, and to bring out more detail in the light tones of the negative. As far as I am aware, the addition of this composition has answered well in the hands of those operators who have used it. I am glad to see that Captain Himly has now published the formula of his new accelerator, and, according to the *Photo. Archiv*, it consists in the following. Two solutions are made:—

*Solution A.*

| | |
|---|---|
| Water... ... ... ... ... | 500 c.c. |
| Zinc filings ... ... ... ... | 100 grammes |
| Sulphuric acid ... ... ... | 50 drops |

Sulphurous acid is formed by the above. The solution is well shaken, and kept for some days in a well-stoppered bottle. Then are added:—

| | |
|---|---|
| Sodium sulphite ... ... ... | 250 grammes |

After this has dissolved, the solution is again kept for some days in a well-stoppered bottle.

*Solution B.*

| | |
|---|---|
| Water... ... ... ... ... | 500 c.c. |
| Sulphite or sulphate of ammonia ... | 250 grammes |

The solution is filtered, and solution A mixed by equal parts with solution B. This mixture forms the stock solution. If it is intended to use it in combination with the pyro developer, it is necessary to add 1 gramme of sulphocyanide of ammonia to each 50 c.c. of the stock solution. If it is, however, intended to use it as an addition to the ferrous oxalate developer, 4 grammes of citrate of iron and ammonium should be added to each 50 c.c. of the stock solution. The solutions must be all well filtered. For developing with pyro, the "Excelsior" solution should always form 2½ per cent. of the whole quantity of the developing fluid; in developing with ferrous oxalate, however, it should amount to 5 per cent. of the whole bulk. If more be taken, yellow fog will result. Both preparations will keep for years, if filtered from time to time, and they be kept in well-stoppered bottles.

## PLATINUM TONING.

BY M. BRUNEL PAUL.

The divers formulas for toning silver prints have, up to the present time, been objectionable on account of giving a bath of but little permanence. Now the chloride of sodium giving stability to the chloro-platinites used in toning yields good results, as practice has shown. In consequence I was led to compose the following formula :

| | |
|---|---|
| Chloro-platinite of soda ... ... | 2 grammes |
| Chloride of sodium ... ... ... | 2 ,, |
| Bitartrate of soda ... ... ... | 1 gramme |

Dissolve cold in one litre of distilled water. The bitartrate of soda added to the present formula serves to render the bath slightly acid ; toning cannot be obtained in alkaline baths. A bath thus prepared keeps for a long time without decomposition, and gives very beautiful tones. To make use of it, it suffices to plunge the prints, previously separated, in water. First we obtain tones that are purple, brown-purple, brown, and finally of the brilliant black of India ink. The print should be removed as soon as it reaches the point of the tone desired, as in drying it becomes darker. If it were allowed to remain too long a time in the bath, it would become grey, dull, and without relief. Coming from the toning bath, place in a bath of hyposulphite of soda at twenty per cent., followed by abundant washings. Once dry, the print is unchangeable, and has a black tone of a most beautiful effect. Landscapes toned by this process are especially beautiful. This toning succeeds with all the sensitive papers furnished by dealers: albumenised, salted, &c.—*Photo. Gazette.*

Photographic Club.—On July 15, Meteorological subjects will be discussed ; July 22, Report of Convention Delegates. Saturday outing to Kew Gardens ; rendezvous at Kew Gardens Station at 3 p.m.

Copyright Law.—From a letter of inquiry received at the Treasury Department, it is inferred that some persons think the copyrighting here of a photographic reproduction of a foreign painting or other work of art bars any later comer from the priviledge of photographing the same thing and copyrighting his works. Librarian of Congress Spofford, who issues all copyrights, said that this was a decided mistake. Any person who chooses to secure a copyright of a photograph of the work of a foreign artist can do so by making application and paying the fee. That will prevent any other person from reproducing the copyrighted photograph, but it does not hinder anybody from taking an exactly similar photograph of the same painting and getting his photograph copyrighted. Mr. Spofford said that his duty in issuing copyrights was purely ministerial, and he has nothing to do with the question of infringements ; but he is, of course, thoroughly familiar with copyright law. Mr. Spofford pointed out that the uniform decisions of the courts have been that infringement of copyright is the appropriation of the work of the person protected by copyright. The copyrighting of a city directory, for example, prohibits any other publisher from taking the names from the directory and publishing them, but it does not prevent him from collecting the same names, publishing them in the same alphabetical order, and obtaining a copyright for his work. So the person seeking to copyright a photograph must not, by reproducing some other person's photograph, appropriate that person's work. He must take the photograph himself. The new copyright law makes no change in this respect.—*New York Times.*

## PRELIMINARY, SECONDARY, AND SUPPLEMENTAL LIGHTING.

BY DR. J. M. EDER.

At a recent meeting of the Photographic Society of Philadelphia, Mr. J. F. Sachse read a paper with the above title, being a translation from Dr. J. M. Eder's "New Exhaustive Handbook of Photography" (Part 2, Vol. I., pp. 313-320). The reader said the subject will, without doubt, be a revelation to the professional and amateur who knows nothing beyond the commercial dry plate of the present day. In days gone by the proceeding was technically known as "flashing." Our object in reproducing the article in its entirety is a two-fold one ; first, to call the attention of our readers to the exhaustive nature of Dr. Eder's labours ; and secondly, to recall the possibilities of this almost forgotten method of bringing out a negative which would otherwise be lost or valueless. In our own experience we have frequently resorted to this practice, and have rarely lost a plate. Whenever we find a plate undertimed or coming up too slowly, we simply pour off the developer and expose in the tray from two to ten seconds before the ruby glass, then again pour on the developer. In extreme cases we have repeated the operation as often as four times, and almost always with satisfactory results. Again, when we had reason to believe beforehand that we were undertimed, an exposure of two-thirds second in front of the ruby light before development proved of service. The former plan, however, is by far the safest. It is a proceeding, however, which requires care and judgment, and should not be resorted to unless all other manipulations of the developing agents fail to be effective. Still, in our own practice, the method as stated has proved successful with at least three makes of dry plates of varying degrees of rapidity.

*(a) In the Negative Process.*—If a Daguerreotype plate, wet collodion, or gelatine dry plate, after a short exposition in the camera, is subjected to an exposure of several seconds over the whole surface in a weak, diffused light, a favourable result will be attained.

If the exposure in the camera was gauged so short that the development resulted in an imperfect image, this supplemental general lighting continues the first action of the light so far that it results in a substantially better or perfect picture. This action was first noticed over forty years ago with Daguerreotype plates. Becquerel credited this continued action especially to the red and yellow rays, and denominated them as *continuing rays* (*rayous continuateurs*) ; while to the green, blue, and violet rays he attributed the primary cause of the action, and called them *creative rays* (*rayons excitateurs*).

This view was, however, soon found to be erroneous, and Moser was one of the first who recognised the fact that all the rays can commence and complete the action ; later, it was even proved that, in actual practice, it was just the subdued rays of the violet end of the spectrum which were the most active.

In the photographic practice, it has been repeatedly proposed to expose the plate in the camera for a shorter period than called for by ordinary conditions, and then subject the plate for a short time to a diffused light. This proceeding is called secondary lighting.

A similar effect is attained if the plate is subjected to an exposure of a weak diffused light before being placed in the camera (preliminary lighting), or if weak diffused light is introduced into the camera during exposure (supplemental lighting). In all three cases, a reduction of period of exposure in chief is gained, frequently, however, at the expense of the quality of the picture. The means, therefore, are manifold, and are described below.

As early as 1871, Schultz-Sellack declared that the "continuing" action of the light upon a weak image was not a peculiar phenomenon, but the result of the necessary primary action, which explanation contains the greatest probability.

1. *The Wet Collodion Process.*—The action of preliminary and secondary lighting upon the photographic wet collodion plates was discovered by Bazin in 1870. His plan was to introduce a red light on the plate either during, before, or after the exposition. This was done by aid of four openings in the front board of the camera, around the lens; these were protected with glass plates, coated with a solution of carmine in ammonia, which were placed in front of a piece of brown glass. The opening or closing of the lens achieved the same effect upon the four supplemental apparatus. The same effect was obtained when the plate was exposed to a red light, a second either before or after exposure.

Cary Lea, in landscape photography, caused the red light to strike the plate only where the sky did not reach. His plan was to secure a red medium (carmine-stained paper) on the upper part of the camera, so as to cause the darker portions, foliage, &c. (but not the sky) to be strengthened by the red light, and come out stronger in detail. When the foliage was brightly illuminated the red medium was unnecessary.

Newton applied an opening in the first board of the camera, 2 by 5 inches; this was covered with a green glass, so that the plate was flooded with a weak green light during the exposure. This is said to have reduced the time of exposure from twenty to five seconds.

Newton, however, concluded that the best and safest plan was to leave the plate in the camera, and then give a secondary exposure by taking a green, red, black, or grey medium in front of the lens, and thus reflect light upon the plate.

Others, again, exposed the wet plates one-third to one-fourth of the usual time; these introduced a piece of yellow glass in place of the dark slide, and subjected the plate to an exposure of ninety seconds in diffused daylight (Gaenslin).

Coloured papers (blue, green, brown) were also used for the same purpose, in front of the open lens immediately after the exposure (Krüger).

In the year 1887 the secondary lighting by means of violet light was recommended. Scotellari made an opening in the cap of the lens; this he covered with aniline violet. This opening was opened or closed at will by a rotary disc. The plan was to expose with open lens as usual, only much shorter, then put on the cap and turn on the violet light to complete the exposure. This process reduced the time from fifteen to seven seconds; this was exclusive of the supplemental lighting of two seconds.

Gillard recommended these coloured diaphragms not only for a reduction of the time of exposure, but on account of the peculiar mezzo-tint effects. He used diaphragms made of gelatine sheets, which were coloured violet or dark green.

Frequently the preliminary or secondary lighting was made by a white light. Werge used two thicknesses of tissue paper, giving four seconds.

Haugk suggested to expose a trifle less than half the usual time, then for a few seconds (say one-fifth of the usual time) to hold a piece of ground-glass before the lens, and then cap.

Melchion in portraiture exposed his wet collodion plates to a diffused light for two seconds by holding a ground-glass in front of the lens, and then made a normal exposure of eight seconds, the result being a plate equal to an exposure of fifteen seconds without any preliminary lightening.

Foxlee also was a strong advocate in favour of supplemental lighting with diffused white light. It was further recommended to have an opening in the cap, covered with opal glass, this to be two-thirds the diameter of the lens; the preliminary lighting to be one-seventh of the normal, with the result of reducing the actual time of exposure from twenty-four to fourteen seconds.

Richard closed the opening in the cap with a thin piece of tissue paper. The supplemental lighting should not exceed three-fifths of the normal time.

Wyler preferred to make the preliminary or supplemental lighting by candle-light in the dark room, as he had more control over the exposure than in the camera. His plan was to expose the wet plates for ten seconds to the candle-light.

Chapman subjected his astronomical plates to the influence of lamplight before he started development. This was also recommended by Wortley. With under-exposed wet collodion plates Prümm found that the most practical supplemental exposure was to flood the plate with a yellow light in the dark room.

It is requisite with both fore and after-exposures to take the greatest care that the light does not act too long, as this results in fog; while too short an action shows no improvement whatever. For instance, where an exposure under yellow glass of ten to fifteen seconds in diffused daylight already causes fog (wet collodion plates), a ruby glass with five to ten seconds under the same conditions gives perfect results, whereas a combination of the ruby and yellow glass, even with lighted exposure, gave no noticeable effect whatever.

These additional exposures, notwithstanding the occasional results obtained, can only be depended on as a makeshift to save an under-exposed plate, as in almost every case fog results. Further, properly exposed plates are always preferable.

Quidde preferred the subsequent exposure.

A considerable reduction of the light is necessary with all the nodalities of additional lighting, so that the proceeding can be controlled. Therefore, translucent mediums can only be used when violet or white light is used. When green or yellow discs are used, more transparent mediums are available, thanks to the fact that the colours admit but few of the active rays. It will be noted that in all these processes the blue and violet rays are the most active, red carmine paper admitting even a few of these rays. Plain red or yellow glass proves ineffectual.

In this connection we will introduce the proposal made in 1850-51 to use white for photographic purposes. This idea originated with Löscherer, in Munich, who always operated with a camera the inside of which was white instead of black. He declared that thereby the action of the light was greatly increased.

*(To be continued.)*

## COLOURED COMPENSATING SCREENS.*

BY BIRT ACRES.

I BELIEVE that the principal reason of the apathy of photographers generally to the great advantage obtained by using plates corrected for colour lies in the fact that they have been frightened by the "Yellow Screen Bogie." Every photographer who is worthy of the name recognises that the ordinary processes of photography do not give correct colour values, but many refrain from using orthochromatic or isochromatic plates because they have read that they will not work without a screen; and just to give an idea of how vague are some of the existing notions of the use of screens, I was once asked which was the best place to put the yellow screen in making an enlargement from an isochromatic plate.

Coloured compensating screens, far from being a terror, are powerful tools, which, when rightly used, will enable the photographer to render colour values in a manner which some artists may sneer at, but will never excel.

The indiscriminate use of a screen is often worse than having no screen at all. If a plate is highly corrected for colour, then a yellow screen is not necessary in general landscape work, particularly when working without the sun, such as in glens, interiors, &c., although in bright sunshine the screen is a distinct advantage, as it cuts off a good deal of the white reflected light.

Another stumbling block to the tyro was the abominations that have been sold as compensating screens for photographic purposes. Most of them were worse than useless from being of an unsuitable colour, too deep in tint, and of unequal surfaces and thickness.

It is a *sine quâ non*, as everyone knows who has had any experience in this class of work, that glass screens to be used before or behind the lens must be optically worked, so that the two faces, in addition to being perfect planes, must be absolutely parallel to each other.

The question of colour is a much more difficult one. A pale orange tint answers excellently for all general purposes, but, in my experience, a lemon-yellow colour is the best where a great variety of colours has to be dealt with. Green or greenish yellow is, in my opinion, worst of all.

The best method—in fact, I may say the only method—for testing screens for colour is by means of the spectroscope. Thus, a green screen will be found to absorb red and orange, as well as blue and violet, rays in proportion as the green partakes of a blue or yellow character. The more it approaches blue in colour, the more red and orange will be absorbed, whilst if of a yellow green colour, more blue rays and less red and orange will be absorbed. Even a greenish tinge in glass has a very sensible effect in absorbing orange rays.

The effects noted above are equally apparent when the screens are tested photographically; and further, with green screens, there is a decided lowering of tone in the green, unless it just happens that the green to be photographed is identical in tints with the compensating screen employed, for if the green to be photographed approached to yellow in tint, and the compensating screen was of a slightly blue green, then the blue of screen would absorb the yellow of subject, and so *vice versâ*. For the foregoing reasons, I have arrived at the conclusion that, except for special work, a green screen is of no practical use.

A pale orange-coloured screen—one that increases the exposure about two or three times—will be found valuable for general work. The violet and blue rays are partially absorbed without seriously interfering with the green, orange, and red rays, but when it becomes necessary to cut off the whole of the blue and violet rays, thus requiring a screen of deeper tint, then the orange colour is not so suitable, as it absorbs part of the less refrangible rays.

The orange screens are, however, the only really serviceable glass screens at present in the market. There are no pure yellow glass screens manufactured that I am aware of. Doubtless, when photographers wake up to the advantages of using colour correct plates, and the demand warrants it, a suitable glass will be manufactured. Unfortunately for photographers, most of the coloured glass at present produced is made for decorative purposes.

The most perfect screen, so far as colour is concerned, that I have yet seen is that made in the form of a Waterhouse diaphragm, and supplied by Messrs. B. J. Edwards, of Hackney. The aperture of the stop is covered with a thin lemon-yellow medium, which absorbs the violet and blue rays, without appreciably affecting the other rays.

* Read before the Photographic Society of Great Britain.

## THE MOON.

AT a recent meeting of the British Astronomical Association, London, Mr. T. Gwyn Elger read a paper on "The Lunar Walled-Plain Ptolemaus," which was illustrated by lantern slides. After describing the telescopic aspect of this magnificent circumvallation under a low sun, and the more prominent details which may be seen under these conditions, even in a small achromatic of $2\frac{3}{4}$in. or 3in. aperture, he said that it is an hexagonal shaped enclosure some 115 miles in diameter, the area of the floor being about 9,000 square miles, or approximately equal to the combined areas of the counties of York, Lancashire, and Westmoreland. Its dimensions are so great that, were it possible for anyone to be stationed on the floor near the centre of the ring, he might easily imagine that he was standing on a boundless plain, so long as he looked only to the north, east, or south, as not a peak or any indications of the existence of the complex and massive border would be visible.

Even on turning westward, one object only would break the monotony of the horizon, and this the upper one thousand feet of the great peak *n* (nearly 8,700 ft. in height) on the western wall. The rough, rocky barrier of Ptolemaus is broken up by many longitudinal and cross valleys, and abounds in depressions large and small. On the northwest there is a wide, bright plateau falling gently towards the border, which, among other interesting features, includes a very noteworthy crater row running from the wall to the S.E. side of a large crateriform depression, Hipparchus *r*, which has two deep contiguous craters on its S.W. side. The late Rev. Prebendary Webb found that the direction of this crater row was continued down the eastern slope of *r*, by a delicate cleft, now called "Webb's Furrow." Hipparchus *r* has a central mountain, easily visible under a moderately high sun. The shadow of the mountain *n* is very conspicuous and beautiful at sunrise, when the three peaks which surmount it may be well observed in very "common telescopes," and the crater near its highest point is very clearly visible on the wall in instruments of moderate aperture. The north and northeast border, and the neighbourhood of Herschel and Herschel *d*, include a vast amount of detail hitherto unrecorded, but which will be mapped and catalogued in the monograph of the formation which is being prepared under the auspices of the Association.

The floor, in addition to the many craterlets and saucer-shaped depressions and low ridges visible thereon, is traversed by a system of light markings and associated light spots, even more remarkable than those discovered in Plato, Fracastorius, and Archimedes. Between January 1881, and August 1883, Mr. A. Williams recorded at least eighty-five of these faint, light streaks, which objects will, of course, receive the close attention of the section, with a view to confirm his observations. The hexagonal shape of the border of Ptolemaus is far from being a solitary instance of the tendency to a six-sided figure among the larger class of walled and ring plains. The same peculiarity may be noted in the case of Copernicus, and in many other of the so-called rings, large and small. The explanation of this, and also of the fact that arrangement of the mountains and highlands of which it is made up have, in many places, no apparent relation whatever to the contour of the floor (a structural condition also not confined by any means to Ptolemaus), may be left to the ingenuity of the framers of hypotheses. In describing the eastern wall, Mr. Elger referred to a remarkable gap in it, where, for a distance of three or four miles, there is no barrier at all between the floor and the outside country. In conclusion, he contended for the importance of the observer acquiring a correct appreciation of the actual size of the formation he studies, so as not to underrate the true significance of details. He also urged the members of the section not to attempt to draw more of Ptolemaus, or any other formation, than they can reasonably hope to finish during the course of three or four hours' observation, and to devote themselves to a limited area, or their work would not possess any great selenographical value.

Mr. Green then gave a paper on "The Lunar Seas," which was also illustrated by means of the lantern. He said: On examining a map or photograph of the moon it will be evident that these seas follow a definite order of arrangement, the smaller being near the limb, and the larger nearer the centre of the disc. There is not a single instance of these dark areas extending to the limb, and although large craters may be found there, and larger still are revealed by libration, they are not filled with dark matter like the seas. It should also be observed that, even when the dark formations come very near the limb, as on the north-east, there is still an unbroken line of bright surface beyond them, so that we have no reason to expect that similar blotches exist on the side turned from the earth. The brighter portions of the lunar surface are separated most definitely from the seas by being higher, more detailed, and to a great extent covered with crater-like forms. The seas, on the contrary, are lower, comparatively smooth, and craters few and far between. The question then arises, which of these two so widely diversified surfaces is the older? It has been supposed by some that the seas represent the more ancient state of our satellite, and that the crater-covered surface has encroached on them; yet this cannot be the case, for the shapes of the seas would then have been that of the spaces left between invading circular forms; but this is not the case; the seas tend greatly to circles, and press forward into the crater-covered surface with a fairly even line, broken occasionally by the remains of partly destroyed craters. Mr. Green illustrated this point by drawings of Fracastorius, the ruins of the north wall of which, he pointed out, could be seen under favourable circumstances, and of Doppelmeyer, Gassendi, and the Sinus Iridium.

He also showed how the base of the Apennines appeared to be fringed by great masses of débris, which seemed to have fallen from their summits. He then resumed: Thus far we have found that the lunar seas are comparatively a recent formation, that they increase in size from the limb towards the centre, and that, in all probability, they exist only on the side which is turned towards the earth. These circumstances point conclusively to some terrestrial influence in their formation, and for such influence we shall not have long to seek, as it will be found readily in the power of gravity and its tidal disturbances. Time was, doubtless, when the moon had an axial rotation, and when, in consequence of a semi-fluid state, the attraction of the earth raised upon her surface a considerable tidal projection. This wave, by friction and other retarding causes, eventually reduced the rotation, till at last the moon presented the most heavy side towards the earth, and her rotation as a free movement ceased to exist.

Then came the formation of the seas. The still liquid interior, in obedience to the powerful attraction of the earth, welled up through every crack and opening, choosing, of course, the weakest places, and, spreading on the surface, reduced it again to the semi-fluid condition, where now it is to be seen in the various forms of these lunar seas. It need not be supposed that these irruptions rose to a higher level than the older cratered-covered surface; but that the heated mass cut its way into the general surface which it undermined, and gradually reduced the fallen portions. An example of this may be seen on the eastern edge of the Apennines, near Archimedes. The possibility of this remelting process is evident from the frequent cutting of one crater form into another, portions of the older crater being thoroughly destroyed by the contact.

Mr. Alex. J. G. Adams said: The idea that, owing to tidal action by the earth, lunar seas exist upon the side facing us only, was not quite clear to him. Were we to assume a single tide alone? The effect of gravitation was the production of two tides in a line with the disturbing body, and he thought this state would apply to the moon. Moreover, while in no way detracting from the general hypothesis, and while fully allowing for cleanness at the disc edge, the probability of double tide carried with it the idea of seas upon either side of the moon. The point of tidal lag had been touched upon and deserved further remark. Our tidal effects were always in rear of causation, and in some cases there appeared to be a harmonic give and take, as exampled by the fact that, whereas the spring tides lagged more and more each spring lunation, the neaps gained, insomuch as to produce occasional overlapping. In the case of the moon, however, it was probable, owing to coincidence in her periods of orbital and rotative motions, that her tidal lag would be comparatively fixed, and seemingly just such as to produce decrease of sea upon her western limb.

Croydon Microscopical and Natural History Club (Photographic Section).—On July 4th a large assortment of negatives and prints was exhibited by members, taken during the recent excursions. The half-day excursion to Erith and Greenhithe for July 25th has been altered to Kingston-on-Thames; trains from Clapham Junction 2·15 and 2·55 p.m.; Waterloo, 2·5 and 2·40 p.m.

## Notes.

If a certain telegram may be believed which came from Vienna the other day, the price of platinum must speedily sink to its old level, for, according to the missive referred to, its principal employment in the manufacture of incandescent lamps is threatened by the rivalry of other less "noble" metals. According to this authority, we are told that "the electrical world of Vienna is greatly excited over the discovery by Captain Franz Walter, lecturer at the Military Academy, of a method of amalgamating glass with other metals than platinum. The invention, which has been patented in every country in the world, will effect a revolution in the manufacture of electric lamps, which will be immensely cheapened by it, as the use of platinum will be entirely discarded."

We are inclined to regard this announcement with a certain amount of distrust, as we are all apt to do in the case of any statement which bears evidence that the author is unfamiliar with his subject. Platinum does not form an amalgam with glass, and we do not see what end would be gained, in the manufacture of incandescent lamps, if it did so. Its value in relation to glass is found in the circumstance that, under the influence of heat, it expands less than any other metal, and that its expansibility is about equal to that of glass, so that a platinum wire can be carried through and sealed into the side of a glass vessel, and can be used as a carrier of an electrical current from the outer air into that vessel. The incandescent lamp globe is exhausted of air, and, without this means of metallic communication from the outside to the inside, it would be useless. If a method has been found by which baser metals can be persuaded to behave in the same way, photographers will rejoice, for they will then have cheap platinum.

The philanthropic gentlemen who recently advertised so largely that they would give away an enlarged photograph for nothing, and afterwards charged a fancy sum for framing it, were promptly sat upon by one or two energetic magistrates, and their little game was rendered hardly worth the candle. This framing dodge seems to have taken a fresh shape in the far-off region of Ohio, but if found to be successful, it is sure to find its way over here more quickly than some of us would consider desirable. In this case it is not the frame-maker who advertises, but the photographer, who promises to supply a dozen cabinets at the ordinary price, one of them being handsomely framed without extra charge. It seems curious that, while so many of the profession should be endeavouring to keep up the position of photography as one of the fine arts, others should do their best to bring it down to the level of the cheap grocery store, which gives away presents to the purchasers of each pound of tea or sugar.

Mr. F. H. Latimer, in a communication to *Engineering News*, states that the tediously long exposure necessary in the production of ferro-prussiate prints is immensely curtailed by the addition of oxalic acid to the sensitising solution. As a working formula, he gives the following: 1. Ammonio-citrate of iron, 120 grains; water, 1 fluid ounce; to which are added a few drops of strong ammonia solution till the odour is quite perceptible. 2. Potassium ferricyanide, 105 grains; water, 1 fluid ounce. 3. Saturated solution of oxalic acid. Equal quantities of the first two solutions are mixed together, and to 10 parts of this mixture from 1 to 3 parts of the oxalic acid solution are added just before use, with the result that in cloudy weather the solution containing 3 parts of oxalic acid prints about ten times as quickly as the pure solution. For ordinary purposes, however, it is better not to add more than 20 per cent. of the oxalic acid solution, or difficulty will be found in getting the lines to wash white.

Mr. Harrold Frederick, in his timely volume, "The Young Emperor William II. of Germany," writing of the Emperor's expression, says at times he has what may be called an "official countenance." It is this countenance with which the general public is chiefly familiar; for he assumes it in front of the photographer's camera, just as he does on parade, at formal gatherings, and even in his carriage when he drives through the streets. This suggests the question whether all Royal personages have their own particular photographic expression which is totally unlike that known to their familiar friends. So far as our own Queen is concerned, we could almost hope this was the case, as very rarely do her photographs represent her other than looking somewhat cross.

The Prince of Wales, on the other hand, is generally genial in aspect, and a comparison between himself as he appears at various functions, and his photographs, shows the latter to represent him fairly well. But of course he, too, may have an official countenance corresponding with his photographic one, so that after all this comparison does not count for very much. Passing from Royal to distinguished personages, it is certain we do not find that monotony in the photographs of the second which too often marks the photographs of the first. Take Mr. Gladstone, for instance; never does he appear the same in two photographs, and a similar difference is observable in the portraits which have been painted of him. We fancy there is something in the theory of the "official photographic countenance" of Royalty.

Over a year ago we gave an account of a singular book called "Giphantia," published in 1760, which anticipated in a curious way the discovery of photography. "Giphantia"—or "Giphantie," as the name is rendered in French, being an anagram on the name of the author, Tiphaigne de la Roche—has been re-discovered by A. de Rochas, who, in a recent number of *L'Intermediare des Chercheurs et des Curieux*, points out how, in "Giphantie," the experiments of M. Lippmann are forestalled. The parallel is certainly very close, and almost tempts one to enquire whether M. Lippmann was familiar with the dreamings of Tiphaigne de la Roche before he investigated the phenomena connected with his name. Those who are curious on the subject of "Giphantie" will find the book fully described in the Photographic News of April 4th, 1890.

Complaint has been made that the authorities at Stationers' Hall keep no index to the registers of pictures, engravings, and photographs, and the deficiency causes no end of trouble and confusion. Of what use is the register if access cannot be had to it readily? If it be intended as a protection against infringement of copyright, an obstacle is placed in the way of research which is wholly unnecessary.

## THE PHOTOGRAPHIC CONVENTION MEETING AT BATH.

Two years ago, when the Photographic Convention met at Birmingham, it was favoured with very much the same kind of aggravating weather which it experienced the first few days of the present week at Bath; aggravating because of its uncertainty, and its constant showers of rain, alternated with promises of sunshine which were never fulfilled. This, perhaps, did not so much matter on the opening day itself, for the business transacted was in the comfortable shelter of the Guildhall, and no photographic work was in contemplation. But when, after raining all night, Tuesday brought leaden skies and frequent downpours, it was a disappointment to the members who had arranged to visit Chepstow and Tintern, in accordance with the programme already published. First-rate photographs under such damp circumstances were of course impossible; but the weather did not prevent a goodly company assembling at the appointed time on Tuesday morning, *en route* for the valley of the Wye.

But to return to Monday's proceedings. The Convention met at the Guildhall at 6.30, when a formal reception took place under the auspices of the Mayor. The assembly was by no means as large as that at Chester last year, but paucity of numbers was compensated for in the presence of so many representative men. Influenza seems to have specially favoured photographers with its malignant attentions, for many here were heard comparing notes as to their experience of it, and more than one member bore evidence that the epidemic had attacked him.

During and after the reception, the members had an opportunity of inspecting the apparatus which had been sent for exhibition by various manufacturers and others. This exhibition, although smaller than might have been wished, contained some interesting items. Among the pictures were several of remarkable lightning flashes and cloud effects exhibited by the Royal Meteorological Society. The Platinotype Company showed some excellent pictures on wood, apparently intended as ornamental panels, the effect being very soft and beautiful. This Company also showed the key camera, with its effective and novel method of changing plates. Another form of camera shown was Turnbull's cyclists' hand-camera, made for both plates and films. Messrs. Watson and Sons had a representative collection of apparatus, and they also showed the convenient set of materials which they have recently introduced for the practice of the diazotype positive printing process. Each set, contained in a small case, comprises a bottle of primuline, sensitising materials, and developers giving differently coloured results. A convenient opportunity is thus afforded to all to practise a new and most interesting process. Messrs. Shew exhibited a very compact form of stereoscopic hand-camera, "The Eclipse," and Messrs. Newton showed a duplicate of the long range single lantern which they have recently constructed for the use of the Camera Club. Messrs. Ross showed many lenses, and also a well-designed camera of the detective form. A new process of enamel photography was illustrated by a fine example from Prof. C. C. Schirm, of Vienna. A number of lenses by Zeiss were exhibited by Messrs. Baker. Mr. Lancaster had a large space filled with his well-known goods; and lastly, Messrs. Taylor and Hobson, of Leicester, showed a goodly collection of lenses, among which we especially noticed their convenient casket arrangement by which several of different kinds fit one mount.

Mr. Austin King, as chairman of the local committee, introduced the members to the Mayor. He explained that the Convention was an association of gentlemen interested, whether as professionals or amateurs, in the art and science of photography, and it was their custom to meet every year in some district of which the surroundings were peculiarly congenial to the practice of their art. This year Bath had been selected, and he was quite sure that the gentlemen who had honoured them with that visit would return to their homes not only with many beautiful pictures of landscape and building, but also with very vivid recollections more permanent even than the best photographs of many pleasant scenes, pleasant people, and pleasant places. But the Photographic Convention did not base its claim to existence upon the practice of a delightful art amongst delightful surroundings. The members did much earnest work in furthering the interests of photography, in making it more practically useful, and by organising standards, and the equalisation of formulæ and nomenclature. They did much to render it possible for the workers in photography in one part of the world to avail themselves of the labours of other workers in other parts. For those reasons he thought that everybody now admitted that photography owed a very deep debt of gratitude to the Photographic Convention. To the Mayor, who was so well versed in art, and had been for so many years an ardent student of architecture, of archæology, and of literature, he need not develop the further point that, whereas photography owed a great deal to the Photographic Convention, they of the public owed a great deal more even than they were at all times willing to acknowledge to photography itself. It was true that photography did not invade those higher realms of art sanctified by the genius of painter and sculptor; but by its power of reproduction it enabled them to place the masterpieces of art, both ancient and modern, before the public in a way which would otherwise be impossible, and thus multiplied a thousandfold the use of those masterpieces as means of culture and education. But photography did far more than that in science; in every department—in zoology, in botany, in meteorology, and astronomy—photography is not only a useful servant, but an absolutely indispensable handmaiden. By means of photography the worker of one generation was able to begin his work at the point at which the previous worker had left off, because the work which had absorbed the labour of a lifetime was crystallised and made accurate for the use of posterity. For those reasons he asked them to welcome the Photographic Convention of the United Kingdom as gentlemen who, by visiting Bath, did it an honour, and he was quite certain that when they left Bath they would have nothing but pleasant recollections to take back with them.

The Mayor, in welcoming the Convention, said he was old enough to remember the introduction of photography into this country. He could call to mind the first dawning of their beautiful science. He could look back upon the wonder and pleasure which spread from town to town and from country to country when its beneficent power gradually became known. He had observed through half a century its wonderful progress all over the world, increasing incalculably human enjoyment, intellectual expansion, solid, practical, substantial good. Therefore, he could not fail to welcome most cordially those who were associated for its promotion. He could not hesitate, when a gentleman inquired of him whether they could have the use of that building, to say it would be quite at their service, and anything else they could offer. He did not know what the particular objects were for which they were associated; on that and other points they would doubtless enlighten and interest him. But he did know that when science, united with two such powers as the light of heaven and human skill (two of the most subtle and far-reaching powers in the universe), it was difficult to say what could not be done. He hoped that another power would favour them during their visit, he meant genial skies, for he thought they would see that the scenery of this district and the various architectural objects in Bath, Wells, Bristol, Salisbury, and Glastonbury, deserved any aid their art could give them to make their beauties better known. His Worship concluded as follows: We welcome you, then, as devoted to most interesting and important work, and we trust you will like our city and neighbourhood well enough to repeat your visit. There is a fountain in Rome of which it is said that those who taste of its waters always desire to come again; may your experience of this city of the springs be so pleasant as to give you the same desire.

Mr. Bothamley said, in coming to Bath, the Convention were visiting a place intimately associated with the early history of photography, with Fox Talbot, and Herschel, the latter being the first to apply photography to scientific purposes. Mr. Bothamley then relinquished the chair to the President-elect, of whose qualifications for the office he spoke in eulogistic terms.

Mr. Bedford, who mentioned that he was the first professional photographer to occupy the position of president, then delivered the following address.

## Presidential Address.

Five years have now elapsed since the first meeting of the Convention, and this, our sixth annual assembly, finds us in the city of Bath, built on the reputation of its healing waters, but of especial interest to us photographers as being in the neighbourhood of Lacock Abbey, the home of Henry Fox Talbot, and, undoubtedly, the first spot in the Kingdom ever depicted by the photographic camera.

Since our last meeting at Chester, it certainly cannot be said that the general interest taken in photography has in any degree abated; and, to assure ourselves of this, it is only necessary to point to the increasing number of societies and clubs which have sprung up all over the civilised world, to the spread of photographic literature and journalism, and, as a notable instance of the popularity of the art, to the successes claimed for the numerous exhibitions held at Liverpool, Vienna, and elsewhere.

Photographic societies generally have been showing marked activity. Although the scheme for the formation of a photographic institute brought forward by the Photographic Society of Great Britain has at present met with little more than moral support, and it is now clear that there is no immediate prospect of carrying it out in its entirety, the recent acquisition by the Society of premises of its own places it in a position to offer to other societies a scheme of affiliation which promises many advantages, and which can hardly fail to work, in all cases where co-operation is desirable, to the mutual advantage of all, without in any way interfering with individual action.

The new premises of the Camera Club are a monument to the energy and enterprise of its management, and the annually recurring conference of that body, as well as its periodical "one-man" exhibitions, reminds us, as in past years, of the good work it is doing.

The Photo-Survey Council of Warwickshire—a body constituted out of the photographic societies of Birmingham and Warwickshire—is doing excellent work, and challenges friendly rivalry with other counties. It embraces archæology, ethnology, geology, and botany, in addition to the ordinary work of recording the general appearance of the county at the present day.

In speaking of advance in the science of photography, it is difficult to gauge the importance of discoveries which require time to develop their capabilities, and I shall very possibly pass over without notice germs of discoveries more important than those I shall mention. There can, however, be no doubt that, in the province of systematic or specialised investigation, Messrs. Hurter and Driffield, by the further prosecution of their researches into the effect of development on the ratio densities of negatives, and other photographic scientists in critically following them, have been doing most valuable work; and, when it is remembered that these investigations are only a first step towards the establishment of an absolute standard of sensitiveness, it is easy to appreciate the importance of the elimination of all errors of observation and measurement from their calculations.

Perhaps the announcement of most interest to the photographic world has been that of M. Lippmann's discovery of a means of representing by pure photography, and subsequently fixing, the colours of the spectrum. Possibly no discovery is ever announced in the present day without resorting to a long stretch of unscientific imagination, and this has certainly not been absent here; but it seems that M. Lippmann's experiments have been guided by a theory propounded in 1887 by Lord Rayleigh, that the colours of Becquerel's reproductions of the spectrum were possibly due to the action of stationary luminous waves, producing, in a nearly transparent sensitive film, a laminated structure which would copiously reflect the particular kinds of light which had produced them. The essentials, according to M. Lippmann, are the continuity or absence of granularity of the film, and the presence, during exposure, of a reflecting surface behind this film. Spectrum red, yellow, green, and blue have thus, it is said, been vividly reproduced and fixed; but the process is not applicable, so far as can be foreseen, to the reproduction of impure or mixed colours. There seems to be plenty of scope for experiment in this direction, and, it may be added, plenty of scepticism as to the results obtained.

A practical method of producing a direct positive from nature, or a reversed negative direct from another negative, has long been a desideratum, so that unusual importance attaches to the discovery, by Colonel Waterhouse, that the addition of a minute quantity of thio-carbamide or of thio-sinamine to the eikonogen developer has the effect, in favourable conditions, of effecting during development a complete reversal of the photographic image, and this with exposures one-tenth the duration of the normal. The substance he finds to answer the purpose best is Dr. J. Emerson Reynolds' preparation of thio-carbamide with ammonium bromide, which is a combination of four molecules of the former substance with one of the latter. Additional interest attaches to this process by the further observation of Colonel Waterhouse that development is accompanied by electro-chemical action, in which the current passes in the reverse direction to that observed in the ordinary course of development.

In the domain of photographic optics the outlook is encouraging. We have specifications from Dr. Ernst Abbé and Dr. Paul Rudolph of an apochromatic objective composed of two uncemented single lenses and a compound correcting lens of considerable focus; also three forms of unsymmetrical doublets, each possessing special characteristics of its own. The construction of these lenses, which has now been rendered possible for the first time by the introduction of the new kinds of optical glass, has been carried out by Zeiss, of Jena, and they have been favourably reported upon by Dr. Stolze and by Dr. Eder, but they have not at present been introduced commercially.

The primuline printing process of Messrs. Green, Cross, and Bevan, which was brought before the British Association at Leeds, has attracted much attention, and has found useful application in printing on textile fabrics as well as in copying drawings and plans. It is based on the fact that diazotised primuline is decomposed by light, and can then be developed by a phenol or an amine, producing coloured designs on a yellow ground. In Feer's diazo printing process, which preceded the primuline process, similar colours are produced on a pure white ground, without development. The former method requires a reversed positive, the latter an ordinary negative to print from. Both these processes are of special interest, marking as they do a new departure in photographic printing.

Mr. M. Carey Lea, further pursuing his experiments with allotropic silver, has produced a well-defined form between it and ordinary silver, of a bright yellow-gold colour, and describes the effect of different forms of energy upon it, producing varieties of colours not hitherto obtained.

When we look back on the photo-scientific achievements of the past twelve months, I think we must all agree that there has been no lack of progress to record; but it is a question of, perhaps, still more moment to inquire what advance has been made in the artistic direction. With the numerous exhibitions now held, we have, in spite of the unnecessary restrictions imposed, ample means of forming an opinion of the use we are making of the tools which science places at our disposal. At our last meeting, it was deplored that a new school had arisen among photographers, a school whose teaching implies "that art is not to be found in the ruts of tradition, and that beauty is not to be sought in a far country," and was asking if photography, which, by its mere existence, had already done more than anything else to inculcate truth in art, was not itself in dire need of reform; and further, if it was not possible to picture by legitimate means a loftier conception of nature than was attainable by a mere transcript. These are the principles it was thought dangerous to spread; and, pointing to the crude attempts of its disciples to depict their impressions of nature, some went even so far as to suggest that photography was so far counterfeiting other methods of illustration, that it was running imminent risk of survival only by mimicry! This revolutionary school, however, still lives, and not only so, but is reaping due recognition of its merits, though not unmixed with wholesome criticism of its shortcomings, and, in spite of the fact that its former master, by his great act of renunciation, has left it to its own devices. After all, are we to conclude that its work is inimical to progress? Is it all to end in unilluminated dreariness? We are, at least, at liberty to exercise our right of judgment, though it is humiliating to be told that a picture one had admired on the walls of an exhibition has been singled out for distinction as an example of an evanescent printing process, and that another has been similarly honoured partly for the reason that it was taken without a lens. But we must not be too hard on our judges; we voluntarily submit our work, and must abide by the verdict and the reasons which prompt it, though one could wish that rules might be adopted for exhibitions which would tend more to the glory of photography and less to that of the individual photographer and the process he employs. It is, nevertheless, true that science and art react mutually on one another, and are interdependent; consequently, the photographer who is a true artist can as little afford to despise the aids of science as science can afford to ignore the requirements of art. The demand is made for the more accurate rendering of tone and colour, so that we may no longer be shocked by the palpable resort to expedients which constantly meets us in photographs which would be admirable as pictures if it were not for the suspicion of unreality such practices engender. Moreover, let us not imagine that there is any danger of our art being made too easy. Even if automatic photography be an accomplished fact, some measure of responsibility will still rest with the individual who drops in the coin. Though "art is a translation of nature," it must always be remembered that "we make from within us the world which we see" and transcribe. It is true our translations of nature may be cold glitter beside the reality, but photography is our pencil, and if we use her fairly she will not fail us.

It fell to the lot of Mr. Pumphrey, president of the local photographic society, to return thanks to Mr. Bedford for his excellent address. Mr. Pumphrey, in the course of a few happily chosen words, pointed out how photography ought to win the attention of all municipal bodies, because of its help in preserving for us and posterity the images of many things which, in the course of time, were passing away from us. He referred not only to buildings, but to new cuttings on railways where geological sections were exposed. These, he considered, should be photographed in their original freshness, and before their characteristic features were altered by the action of the weather.

Mr. Pringle, in proposing a vote of thanks to the retiring president, Mr. C. H. Bothamley, referred to his untiring energy, his simplicity of speech, and his scientific accuracy, which, he considered, amounted to a marvel. He informed the meeting that the county of Somerset had lately had the good fortune to acquire Mr. Bothamley's services as organising secretary under the Education Act, "and certainly," he said, "no one is better fitted to fill such a responsible post." After a reply from Mr. Bothamley, and a vote of thanks to the Mayor for the kind manner in which he had received the Convention, the formal proceedings terminated.

After a brief interval, a number of lantern slides were shown, from negatives taken by various members during last year's meeting, Mr. Pringle being at the lantern, and Mr. Bothamley acting as a very competent showman.

### Annual Meeting.

The annual meeting of the members of the Convention was held at the Guildhall on Wednesday morning, Mr. W. Bedford, president, in the chair. After business of a routine character, a discussion took place for the purpose of deciding where the Convention should hold its meeting of 1892. Official invitations were received from the Edinburgh Photographic Society and the Devon and Cornwall Camera Club, the latter invitation being to Plymouth, and held good for the summer of 1893 in the event of the place of meeting for 1892 having been decided upon. On the motion of Mr. A. Pringle, it was unanimously decided to accept the Scotch invitation. It was further resolved to write officially to Plymouth and thank the Devon and Cornwall Camera Club for their invitation, and hold out a probable prospect of acceptance for 1893.

The president acknowledged the cordial welcome extended to the Convention by the Mayor of Bath, and votes of thanks were accorded to his worship for the same, to the leaders who had conducted and would conduct excursions, to the gentlemen who had lent dark rooms, and those who had given permission to photograph, to those who had exhibited photographs and novelties, and also to the hon. secretary, Mr. Briginshaw, for his untiring labours on behalf of the Convention.

A scheme of affiliation by which it was proposed to more closely unite the Photographic Societies of the United Kingdom for the better promotion and advancement of their common interests, and pointing out the objects to be attained thereby, was presented for consideration from the Photographic Society of Great Britain. Mr. C. H. Bothamley observed that the matter was a great deal too important to be decided upon off-hand, and proposed that it be referred to the Council. Eventually it was agreed to adjourn discussion of the subject to a meeting on Saturday.

Subsequently, a meeting of the general committee was held, and at noon Mr. Middleton Ashman took photographs of the Convention group in the Sydney Gardens.

---

Photography for Women has been recommended so often and so earnestly as a business that, now that some few are taking it up as a serious occupation, it is interesting to note the special differentiation of the pursuit which attracts the sex that wears and loves gowns. There are a few portrait photographers among women who meet with only moderate success, curiously enough, in posing their subjects, but find a field of usefulness in the picturing of children. There are springing up also dress photographers, whose business, though a new one, appeals so strongly to certain feminine instincts, that the seeds of success seem likely to sprout and thrive. One of the two or three already established was saying: "So far my work has been mostly the reproduction of trousseaus. Brides come to me to be pictured in all their different wraps and hats and gowns. For a girl whose wedding came off last week, I made twenty-six costume pictures. She had them bound into a wedding album. Of course it takes ingenuity to get variety of attitude and to bring out the best points of each toilet. I think women prefer to go to women on such an errand, because they think a man, down in the bottom of his heart, might conceal a smile."—*New York Recorder.*

## A NEW EMULSION FOR PRINTING-OUT PAPER.

BY PROFESSOR W. K. BURTON.

I remember once talking to Mr. W. B. Bolton, to whom we owe so much for our present knowledge of emulsion work, on the genesis of collodio-bromide emulsions. He told me that one of the suggestions came from Rejlander. This artist was always in trouble with his bath, or his collodion, or both, and, speaking with Mr. Bolton and some other experimentalists, he asked, "Cannot some of you clever fellows get over this eternal bother by mixing the whole lot up together?" Well, a collodion emulsion may be looked on as a mixture of the collodion and the wet plate bath. The water is the only thing that is left out, and not the whole of that.

Something of the same thing suggested itself to me some time ago in connection with printing. I had been trying various different ways of sensitising plain paper with silver salts, trying, amongst others, some of the excellent processes of Mr. Lyonel Clark, and I got good results with many of them, if I gave the necessary amount of care and took trouble enough; but the care needed was certainly great, and the trouble of the double process of salting and sensitising more than I liked. Moreover, I found that I was very liable to get defects in the way of spots, streaks, and the like, even after all the care and trouble. Why not, I thought, get over at least half the trouble by mixing the ingredients up together and applying them to the paper in one operation? Every formula that I had been using contained gelatine as one of the constituents, and had the making of an emulsion in it.

There is nothing new in this, it may be said. It is nothing more nor less than the gelatino-chloride emulsion that we are already acquainted with under various names, such as "aristotype," and goodness knows what else. I think, however, that the emulsions that I am going to describe have several novel features. In the first place, they are emulsions that need no washing, and that are made by the extremely simple process of pouring one liquid into, or mixing one liquid with another. The emulsions are, moreover, ready for use at once, and, being liquid at ordinary temperatures, can be applied to paper or other materials either by floating, as in the common method of sensitising albumenised paper, or by brushing them over the material that it is wished to sensitise. Farther than this, no gloss is given to the surface of the paper. I think, indeed, that by this process the preparation of sensitised paper—of any kind so far as surface is concerned—is reduced to the utmost possible simplicity.

I have tried a number of variations in the quantities of chemicals, and have had more or less success with all. In fact, there is great elasticity in the proportions that may be used, and I believe that almost any formula for a printing-out gelatino-chloride emulsion might be taken, and that good results could be got if one or two considerations were not lost sight of. The first is that the quantity of gelatine must be kept so low that it will not cause a gloss on the paper, or cause the emulsion to set at ordinary temperatures. The second is that the formula must insure a large quantity of insoluble silver salt in suspension. The reason for this is that the coating got by an emulsion that does not gelatinise immediately after coating is much thinner than if it does gelatinise.

To those who have not had much experience in emulsion work, it may be worthy of remark that, within very wide limits, the same quantity of an insoluble silver salt is emulsifiable in a given quantity of water, whether the quantity of gelatine used as a menstruum be great or small. Roughly speaking, the haloids, or I imagine the other insoluble or nearly insoluble salts of silver, resulting from the decomposition of one ounce of silver nitrate, can be emulsified in ten ounces of water, but if that quantity of silver be exceeded a part will not emulsify, but will be thrown down in the granular form, in which it is useless for sensitising any surface. The proportions vary, however, with certain conditions—such as alkalinity or acidity of the solutions.

The difference between the failure of a silver haloid to emulsify in a gelatinous solution, and the precipitation of it from that solution afterwards, must not be lost sight of. Thus, if any of the emulsions that I am now writing of be kept for a number of days at a highish temperature—such as that of pretty hot weather—it is likely that a good deal of the insoluble silver salt will be found at the bottom of the vessel holding the emulsion, but this silver salt is not in the granular state, and can be re-emulsified by heating the mixture to about 120° Fahr., and shaking well, the more easily if a little more gelatine be added.

I select three formulæ as follows:—

*Formula* No. 1.

| | | |
|---|---|---|
| A.—Nitrate of silver ... | ... 400 | grains |
| Water ... | 4 | ounces |
| B.—Gelatine (soft) ... | ... 80 | grains |
| Chloride of ammonium ... | ... 80 | ,, |
| Citric acid ... | ... 120 | ,, |
| Water ... | 8 | ounces |

*Formula* No. 2.

| | | |
|---|---|---|
| A.—Nitrate of silver ... | ... 400 | grains |
| Water ... | 4 | ounces |
| B.—Gelatine (soft) ... | ... 80 | grains |
| Chloride of ammonium ... | ... 80 | ,, |
| Citric acid ... | ... 120 | ,, |
| Carbonate of soda (dry) ... | ... 45 | ,, |
| Water ... | 8 | ounces |

*Formula* No. 3.

| | | |
|---|---|---|
| A.—Nitrate of silver ... | ... 400 | grains |
| Water ... | 4 | ounces |
| B.—Gelatine (soft) ... | ... 80 | grains |
| Chloride of ammonium ... | ... 80 | ,, |
| Citric acid ... | ... 60 | ,, |
| Carbonate of soda (dry) ... | ... 80 | ,, |
| Water ... | 8 | ounces |

In my hands the first formula gives an emulsion suitable for preparing paper to be used for printing from dense negatives, the second from medium negatives, and the third from thin negatives.

The third formula is, I am afraid, dreadfully unorthodox. Unless I have made a mistake in my chemistry—which is highly probable—there is just about enough of ammonium chloride and of sodium citrate formed by the double decomposition of the citric acid and of part of the soda to decompose the whole of the nitrate of silver. I don't know whether, in this case, there will be carbonate of silver formed; but if not there remains a large excess of carbonate of soda. All I can say is that the formula works all right, and that the paper that results from the use of it keeps very fairly. The paper resulting from either of the other formulæ will, I have no doubt, keep as long as any ready sensitised paper. I have already kept some nearly a month, and it is still quite white.

The following is the method of emulsifying. The two solutions are heated to a temperature of 110° to 120° Fahr. The temperature should not be greater than 120°, or there is a great chance that some of the insoluble silver salts produced will be thrown down in the granular form. A is then added slowly to B with much stirring. The emulsion is filtered through a double thickness of cambric, and is then immediately ready for use. If it is wished to keep the emulsion for any length of time, 10 per cent. of alcohol, in each ounce of which a few grains of thymol have been dissolved, should be added to the emulsion. It is to be observed, however, that, even with this addition, emulsion by formula No. 3 will not keep for very long.

The best way of coating is certainly by floating, allowing three or four minutes, but the quantity of emulsion needed is considerable. It is possible to get an even coating by brushing with cotton-wool in the following way. The paper is laid on a sheet of glass, or a clean board, and is thoroughly and evenly damped with the solution by brushing over the surface several times in directions at right-angles. It is put on one side for ten minutes or a quarter of an hour to get surface-dry, when the operation is repeated. By working in this way, it is possible to do with a very small quantity of solution emulsion, and it is possible to use what there is to the last drop, but the quantity used will be found to be more per sheet than in the case of floating. The reason, I imagine, is, that it is impossible to get an absolutely even coating by brushing, and that it is, therefore, necessary to make the coating so thick that there will be sufficient silver where it is at its thinnest. I have never been able to get an even enough coating by brushing only once.

The temperature of the operating-room should be not below about 70° Fahr., or else the emulsion should be warmed.

The paper is best dried pretty quickly before a fire, or near a stove, after it has lain face upwards for about four or five minutes to get partly surface-dry. In fact, the paper is best treated, in the matter of drying, like paper that has been coated with the solutions for the "hot bath" platinotype process.

It will be found that it is possible to coat about eight sheets of "medium" sized paper (22 by 17, the orthodox photographic size) with the quantity of emulsion given above by brushing, or ten to twelve sheets with a consumption of the like quantity by floating. It will thus be seen that the process is an economical one.

The colour in the printing frames should be a rich brown with either of the first two formulæ, a deep purple with the third.

The printing is very quick, whichever of the formulæ be used, but with No. 3 it is extraordinarily so. Indeed, paper coated with emulsion prepared by this formula is, I think, more sensitive than that by any other printing-out process that I know of. It is so sensitive that it is quite necessary to take extra precautions in working it. It needs at least all the care that platinotype paper needs, although there is, of course, the difference that, in the case of the silver paper, the result of the action of feeble light is seen at once; in the case of the platinotype paper it is not seen till the time of development. I consider it best to do everything in the way of preparation by gas or lamplight.

Toning may be either by gold or platinum. I prefer Clark's platinum process to any other. I add, however, a good dose of salt to the solution, and put the prints into it dry; that is, at least, when using either of the first two formulæ. When using the third, the prints are washed in a weak solution of citric acid before they go to the toning bath to neutralise the alkalinity.

If a platinotype toning bath that has been used for some time, and that has been repeatedly strengthened with chloro-platinite of potassium, be used, a colour is got that some people dignify with the appellation "sepia tint," but I incline to call it a dirty brown.

I find that the emulsion is readily applicable to wood, and I hope to get good results when I have had some panels made of one or other of the beautiful white woods, with a fibre-like silk, that are peculiar to this country. I have got very fine colours of image by printing lightly and intensifying, as suggested some time ago by Clark, but have not as yet been able to overcome a tendency to staining in the whites. Perhaps Mr. Clark will help me with a hint or two in connection with this matter.

I send a few samples of prints done by the process, but I do not think they are fair examples of what it is capable of. They are all merely some of the results of my experiments, and are on Whatman's drawing-paper, which is not very suitable for photographic purposes unless it is specially sized, and I have not sized it. It is the only pure matt-surface paper at present procurable in this country. The prints on it look tolerable only from some little distance. I hope to have some more creditable results ready later on. There are some words of explanation in pencil on the back of each print.—*Paper read at the Camera Club.*

## RETOUCHING AND SPOTTING PHOTOGRAPHS.

After printing and toning, photographs are often found to have white spots, and the mediums employed to cover them are often removed in the enamelling and burnishing processes. Mr. Beacham, of Litchfield Street, Soho, W.C., has patented a crayon for spotting and retouching, which is made as follows: White wax, 32 parts; curd, yellow, or Castile soap, 27 parts; mutton suet, 4 parts; salts of nitre, 1 part, dissolved in eight times its weight of water; pitch, 4 parts; shellac, 6 parts; calcined lamp-black, 4 parts; dyes or stains in powder—brown $7\frac{1}{4}$ parts, scarlet $3\frac{1}{2}$ parts, blue 3 parts, violet $3\frac{1}{2}$ parts. These colours produce a useful photo-shade, but the proportions can be varied according to the shade required; other colours can also be produced if required. As soap contains more or less moisture, according to age, it must be cut into small pieces and dried before using. The suet and wax are first melted; the soap, having previously been cut into small pieces, is then added a small piece at a time, allowing each piece to dissolve before another is added. When dissolved, they are allowed to burn until reduced to the same volume as before the soap was added. Care must be taken not to allow them to burn too much or too quickly (it may be necessary to take the vessel off the fire to prevent the contents from boiling over). The flame is then put out. When these three ingredients are dissolved, and the salts of nitre has been mixed with eight times its weight of water and warmed, it is added by small quantities to prevent too much effervescence. The shellac and pitch are added. The requisite colours, in powder dyes or stains and calcined lampblack, are mixed with a stiff varnish or suchlike suitable substance. It is essential for the whole to be dissolved into one substance, and kept stirring during the whole of the foregoing process with an iron spatula or palette knife. When a little cool, it is poured out on a marble slab previously rubbed with soap or suet. When set a little, it is cut into small pieces and re-melted—re-melting is done to give a finer texture to the ingredients—then moulded into suitable form and pointed, finally finishing off the point by rubbing on paper; fine glass paper or emery cloth may be used. In spotting a photograph according to the invention, the point of the crayon may be moistened by dipping it in clean water, and if the spots are very obstinate to cover, acetic acid or carbolic acid must be added to the water, about three parts acid to one part water. The acid must always be added to the water when photographs are to be enamelled, and when the film is thin on the negative in spots; if the photographs are spotted in quick succession after mounting, there will be found sufficient moisture to dispense with the use of water, unless the spots are difficult to cover, when the acid, or acid and water, must be used. If photographs are spotted after burnishing, and show dull spots when spotted, a slight rub with a piece of clean rag or chamois leather dipped in French chalk will be sufficient to remove the dullness. The degrees of hardness may be obtained in two ways—first, by increasing the salts of nitre; secondly, by cooking longer. It is better to obtain the degrees of hardness by cooking, as much salts of nitre will make the crayon too brittle. Copal varnish may also be used to mix the colour when required harder. Only two colours are necessary in manufacturing the retouching crayon—viz., brown and black, nine parts of each, added to the ingredients before mentioned, leaving out the other colours. The crayon can be used on the negative film without the retouching medium, or can be used on the retouching medium without the negative varnish. Should the retoucher accidentally stipple too heavily, the spots can be reduced to the shade required by the point of a brass pin, not too sharp, or can be removed by rubbing with a piece of pointed ink-eraser, or piece of chamois leather over the finger, without removing the varnish or retouching medium in the usual way with methylated spirit.—*English Mechanic.*

## Correspondence.

### PHOTOGRAPHIC SOCIETY'S EXHIBITION.

Sir,—The exhibition committee of the Photographic Society of Great Britain desire me to inform you that the annual exhibition of that Society will be held at the Gallery of the Royal Society of Painters in Water Colours, 5a, Pall Mall East, from Monday, the 28th of September, until Thursday, the 12th of November next.

The exhibition will be open daily (Sundays excepted) from 10 a.m., to 5 p.m., and on Monday, Wednesday, Thursday, and Saturday evenings from 7 to 10 p.m.

The following gentlemen have been appointed judges, and have consented to act: Messrs. J. E. Austin, F. Hollyer, P. H. Newman, F. M. Sutcliffe, and J. B. B. Wellington.

Medals will be placed at their disposal for artistic, scientific, and technical excellence of photographs, for lantern transparencies, and for apparatus.

Negatives and transparencies, photo-mechanical prints, photographs of purely scientific interest, photographs coloured by scientific or mechanical means, and apparatus and appliances containing points of special interest, will be admitted, but photographs coloured by hand will not be admitted.

Photographic lantern slides will be shown on the evenings the exhibition is open by means of the Society's optical lantern. The exhibition committee will be glad to receive slides for exhibition, especially such as are illustrative of life and scenery in the British Colonies and Possessions. No charge will be made for exhibiting such slides, which should be delivered at the offices of the Society early in September in order to enable the committee to group and arrange them. Slides, however, will not be eligible for a medal unless the conditions in the prospectus be observed.

Blank entry forms and any further information respecting the exhibition, apparatus, and lantern slides can be obtained on application to the Assistant Secretary, P. S. G. B., 50, Great Russell Street, London, W.C.

H. S. Lawrance, Assistant Sec.

*Photographic Society of Great Britain, 50, Great Russell Street, W.C., July 3rd.*

Mounting Photographs.—The following is a receipt forwarded to *Discovery* by Mr G. E. Thompson, of Liverpool. If large photographs are mounted damp and with starch, the expansion and contraction are so great that the mount is cockled. The correct principle is to mount the print as dry as possible. First, have the prints in a pile, nicely damp and flat. Glue with fine, clear Russian glue and a flat hog's-hair brush, and spread each print out face down to dry. When dried they may be trimmed, and kept any time until required for mounting. To mount, have about twelve half-sheets of thick blotting-paper. Place two dry sheets at the bottom, then one well-damped sheet next; lay, say, twelve photographs on this sheet in a pile, and place another damp sheet on the pile. Have one more damp sheet, and then the rest of the dry sheets. Now take out the top photograph and place it between the two top damp sheets. This is merely to take the hardness out, and the print must not remain long enough to allow expansion. Take it out (putting the top one of the pile in its place) and place it on the top dry sheet. Now sponge it all over with a fine sponge from the middle to the ends, taking care to wet it all over; it must be merely damped, and with as little use of water as possible. Take it up and lay deftly in its place on the mount, smoothing it out from the centre of the print; now take a sheet of paper and a handkerchief and rub it down from the centre to the edges. It is better to have a flat burnisher at hand to smooth any unevenness. If the print has been nicely mounted and with no unnecessary damping, it will soon dry, and, even if only in a paper book, the cockling will not be much. The glueing must be thin and even—something of the nature of the gum on a postage stamp. The sheets of blotting-paper will require redamping if a number of photographs pass through, and it is not well to wet too many on the top sheet without changing it, as the paper is apt to fray up, and small pieces will then stick to the glue and make the finished picture uneven.

# Proceedings of Societies.

Amateur Photographic Association.

A council meeting for the award of prizes was held July 1st, at 58, Pall Mall, S.W., the Right Hon. the Earl of Rosse in the chair.

The secretary, Mr. A. J. Melhuish, laid before the council the pictures for the current year. They had been classified by Mr. Glaisher into classes 1, 2, 3, 4, and 5, and the classification, subject to two alterations, was approved by the council.

Class 1 coutains 139 pictures, contributed as follows :—C. Stephens 3, General Kaye 4, R. Murray 10, F. S. Schwabe 3, Major Board 1, R. O. Milne 9, R. Leventhorpe 7, W. Gaddum 8, Miss J. Wilson 2, Mrs. R. Benson 2, Dr. Drew 4, Surgeon-Major Foster 7, F. G. Smart 10, the Vicomte de Condeixa 6, H. O. Hutchiusou 11, F. Wrigley 4, Miss Mahou 8, Arthur R. Dresser 17, H. Emmons 3, F. Griffith 8, W. Dumergne 8, aud M. de Dóchy 4.

The pictures were considered by the council to be the best ever contributed to the Society. Some by Mr. Dresser were pronounced to be altogether a step in advauce. The interiors at Fontainbleau, by the Vicomte de Condeixa, were also greatly admired. A sunset picture by Mr. Smart was considered quite a work of art. There are also some fine tree studies by Mr. Milne.

The following prizes were awarded : To Mr. Arthur R. Dresser, the first prize, a large silver goblet ; to the Vicomte de Condeixa, the second prize, a silver goblet ; to Mr. F. G. Smart, a silver goblet ; to Mr. R. O. Milne, a large album, handsomely bound ; to Mr. R. Leventhorpe, a handsome portrait album ; to Mr. H. O. Hutchinson, au oil painting in frame by McEvoy ; to Mr. W. Gaddum, a picture in frame ; to Surgeon-Major Foster, a large silver medal ; to Miss Mahon, a handsome portrait album ; to Mr. F. Griffith, a medal ; to Mr. R. Murray, a handsome portrait album ; to Dr. Drew, a handsome portrait album ; and to Mr. W. Dumergne, a medal.

The following members had been previously elected : Messrs. A. Craigie, E. F. Sandeman, Arthur R. Dresser, Francis Gosset (Deputy Sergeant-at-Arms), and Hamilton Emmous.

Putney Amateur Photographic Society.

*July 3rd.*—Mr. W. H. Congreve in the chair.

Prints were showu from negatives of the Buruham Beeches excursion, which was fairly well attended.

Twelve entries were announced for the summer competition, a series of four priuts.

A discussion on slide-making, following the reading of a paper on the subject, theu took place.

Richmond Camera Club.

An outing was arranged to Brentford and Isleworth ou June 27th. Four members only appeared, and the wind was too high to allow of many exposures being made.

The ordinary meeting was held on July 3rd, Mr. Irvine in the chair. The subject for discussion was "Shutters," and a Kershaw, a Thornton-Pickard, and an Automatique were shown and explained.

Glenalmond Photographic Club.

*July 4th.*—The President in the chair.

After the transaction of routine business, a "hat night" took place, in which twelve members took part, speaking on various subjects. There was a large show of photographs, &c. Some opals and aristotype prints were shown by Messrs. Maxwell, and some bromides by Messrs. De Putron and Johnstone, after examination of which the meeting adjourned.

Halifax Camera Club.

*June 29th.*—The report of the provisional committee was adopted, and it was resolved to take for the Club the premises recently occupied by Mr. Gregson as a studio, where the next meeting, arranged for the 6th instant, will be held.

The following officers were elected :—*President*—E. J. Smith ; *Vice-President*—Thos. Illingworth ; *Hon. Treasurer*—J. I. Learoyd ; *Hon. Secretary*—Edgar Booth ; *Committee*—W. Wainhouse, Dr. Leech, E. Finlinson, E. J. Walker, W. H. Ostler.

The formal opening of the Club has been fixed for Tuesday evening, the 4th August.

The number of members has already reached the satisfactory total of 58.

Photographic Society of Japan.

The annual meeting was held at the rooms of the Geographical Society of Japan, Nishikonya-cho, Tokyo, on May 29th.

Mr. Ishikawa having announced that he had received a uote from Viscouut Okabe, vice-president of the Society, who had been asked to preside, to the effect that he would not be able to attend, Mr. Edmond R. Holmes took the chair.

The following report of the secretaries, for the past year, was read :—

Like the last year's report, the preseut one need be but short, as there is little to record save the successful working of the Society for another year. The membership of the Society now exceeds a hundred. Siuce the last annual meetiug there have been only four ordinary meetings, but there have also been two exhibitious of photographs. One was held in Tokyo in the autumn of last year, the exhibits consistiug of the photographs done by members during the vacation. The other was held in Yokohama quite recently, the object being the exhibition of the results of work done ou bromide paper that had been presented to the Society by Mr. S. Cocking, and also to award prizes kindly offered by Mr. Cocking to the exhibitors of the three best pictures. Both exhibitions were highly successful. Besides these there were several outdoor meetings that afforded great pleasure to those who atteuded. It is to be regretted that the atteudance at out-door meetings is not larger. The following processes have beeu described or demonstrated at different times since we presented you with last year's report :—The development of bromide priuts, Husband's photolithographic process, the carbou process, the gelatino-chloride printing process, the renovatiug of spoiled eikouogen, flash-light photography, and a new silver printiug process. As regards the number of membership, attendance of meetiugs, aud work doue, we venture to pronounce the Society a success, but we still have to regret that the Society does not receive more support than it does from the profession generally.

The balance sheet read by the treasurer indicated a decided advance in the prosperity of the Society.

The electiou of officers for the ensuing year was then proceeded with. With the exception of Dr. W. S. Bigelow, vice-presideut, who has left the country, aud Mr. J. Johnstone, member of committee, who resigned some time ago ou account of his not having time to attend to the work of the Society, all the officers of last year were unanimously re-elected. Mr. J. B. Rentiers and Mr. I. Ishikawa were elected members of committee, and Mr. C. D. West was elected a vice-president.

A large number of samples of their manufactures that had been presented to the Society by the Fry Manufacturing Co., of Londou, were distributed amongst the members present. Some excellent work in the way of bromide prints and opals, done on certain of the samples by Mr. S. Kajima, were also shown.

Mr. C. D. West had tried the plates, and had fouud them of very high quality.

Mr. W. K. Burton showed some platinotype prints. These, he explained, had been done on paper that had beeu kept for more than a year, and that gave nothing but deep fog worked in the usual way. Excellent results had, however, been got by printiug very deeply, then developing with a cold solution made up as follows :—A five per cent. solution of washing soda, 20 ounces ; a saturated solution of bromine in water, 50 minims. He did not remember who had first suggested the use of soda as a developer for platinotype prints. The bromine had been suggested by Dr. E. Divers, F.R.S. It formed hypobromite of sodium with the soda solution, and this was a powerful restrainer of fog in platinotype work.

Mr. K. Arito showed some prints on drawiug paper that were of a remarkably fine black tone. They had been prepared by the following formulæ:—

*Salting Solution.*

| | |
|---|---|
| Chloride of ammonium ... ... ... | 50 grains |
| Gelatine ... ... ... ... ... | 100 ,, |
| Water ... ... ... ... ... | 10 ounces |

This was warmed, and 2 ounces of negative varnish were added.

*Sensitising Solution.*

| | |
|---|---|
| Nitrate of silver ... ... ... ... | 2 ounces |
| Water ... ... ... ... ... | 10 ,, |

*Toning Solution.*

| | |
|---|---|
| Chloroplatinite of potassium ... ... | 15 grains |
| Citric acid ... ... ... ... | 50 ,, |
| Water ... ... ... ... ... | 25 ounces |

*Fixing Solution.*

| | |
|---|---|
| Hyposulphite of soda ... ... ... | 2 ounces |
| Water ... ... ... ... ... | 10 ,, |

After the meeting there was a *conversazione*.

Experiments with Selenium Cells.—Selenium cells made in the manner suggested (*Nature*, 23, 58) gradually lose their great resistance and also their sensibility to light. Only one cell out of thirteen retained its original sensitiveness over a space of ten years. A current from a 26-volt battery, passed through a selenium cell with copper electrodes for two days, deposited amorphous selenium and an oxide of selenium at the anode. The resistance of the cell was then different, according as the current passed from anode to cathode or from cathode to anode. When a piece of magnesium ribbon was burnt near this cell, a current from anode to cathode was indicated by the galvanometer, which ceased when the light was extinguished. The current was proved not to be due to thermo-electric action.—*Phil. Mag.*

Royal Institution of Great Britain.—At the general monthly meeting on Monday, July 6th, Sir James Crichton Browne in the chair, Messrs. Henry Claudius Ash, Henry T. C. Knox, and John George Mair-Rumley were elected members of the Royal Institution. The special thanks of the members were returned to Miss Jane Barnard, Dr. J. H. Gladstone, the Rev. A. R. Abbott, Mr. T. F. Deacon, Mr. A. Blaikley, and others, for the loan of the valuable and interesting collection of Faraday memorials shown in the library on the occasion of the two lectures on June 17th and 26th, given in commemoration of the Faraday centenary. The special thanks of the members were returned to Sir Frederick Abel, for his valuable present of an Œrtling balance, and to Mr. Ludwig Mond for his donation of £100 towards expenses connected with the Faraday centenary commemoration.

Received.—From Piper and Carter, "The Handbook of Photographic Terms," by William Heighway. This is the second edition, revised, and considerably enlarged, of an alphabetical arrangement of the processes, formulæ, applications, &c., of photography, and will be found very useful for ready reference.——From Messrs. E. H. T. Anthony and Co., New York, "The International Annual, 1891-2," edited by Messrs. W. Jerome Harrison and A. H. Elliott, with Mr. W. I. Scandlin as associate editor. The writers of articles, says the preface, "represent the cream of the brain force which lies behind the many advances in the science of photography"; while the illustrations "are well fitted to demonstrate the present advanced state of process work." We shall in due course give a further notice of this annual, which contains 470 pages.——From Harry C. Jones, also of New York, No. 2 of "The Photo-American Review," which presents this month, as last, thirty-two pages of artistic illustrations, besides interesting and instructive papers on the subject of photography, and a description of general literature, with comments. Of this also we shall have more to say.——From the Albion Albumenising Company, their "Photographic Price List," 76 pages, illustrated, with index.——We have also received some of the cheap guide books by Percy Lindley, "Tourist Guide to the Continent," "Walks in the Ardennes," &c. These are excellently written and well illustrated. The publishing office is 125, Fleet Street.

## Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.

J. C. W. (Waldhausen).—*Ratios of Exposure.* We should put the snow-covered mountains in the first place as requiring least exposure—practically instantaneous; then the marine subjects or seascapes, which might take *double* the exposure of the former; and lastly, the open mountainous views, presumably lower slopes, which would require a longer time, dependent upon the distance of the principal objects from the camera. In ordinary cases give *three times* the period necessary for the snow scenes. Bear in mind, however, that trap rocks and black cliffs sometimes peep through snow fields, and that figures introduced into such scenes will demand a longer exposure than would otherwise be required.

Printer.—*Blisters on Albumen Prints.* It is important to notice at what stage these blisters make their appearance, for very frequently they only occur when the prints are immersed in the hypo bath, in which case the cure is to avoid too sudden a transition from washing liquors to highly concentrated solutions of greater gravity, by interposing a salt brine to work up gradually from weak to strong. Excessive dryness of the albumen film before sensitising often destroys adhesion and causes blisters. This you ought to be able to see at the time of preparation, and slight damping of the paper or the addition of a little alcohol to the silver bath will generally remedy this defect.

F. I. C.—*Coal-Tar Saccharine.* Dr. Fahlberg's preparation and the para-nitro ortho-toluidine are excessively sweet to the taste—many times more so than ordinary cane sugar—and on this account have been recommended for the use of diabetic patients.

Perplexed.—*An Unscientific Paragraph.* "The older method (of making alkali) in use is to force sulphur through common salt, the result being soda." We agree with our correspondent in regarding the above extract as a most superficial and erroneous account of the main distinction between the Leblanc and Brunner-Mond methods of proceeding, the only substratum of truth being the fact that no sulphur in any form is employed in the manufacture of soda by the last-named process.

Kent.—*Deal Pier Charges.* According to a report in one of the daily papers, a fee of ten shillings and sixpence is demanded for permitting the camera to be used on Deal Pier. Can this be true? For, if so, it would be cheaper to take a passage in a passing steamer, or hire a boatman to put off from the shore; or, better still, select another port, such as Ramsgate or Dover, for marine photographic operations.

F. R. M. S.—*The Weather Forecasts.* It cannot be said that the predictions for the first days of July, in the London district, were singularly fortunate. If reversed, they would have been nearer the mark. Thus, the 1st, 3rd, and 4th of July were to be "fine and warm," "fair as a whole," or "fair and bright"; but on these days we had heavy showers or torrents of rain; whilst on the 2nd inst., "changeable, fair to showery," was predicted, when we had not a drop of rain. The direction of the wind proved incorrect on some of the days, but possibly the error lies in attempting to make the same forecast do duty over too wide an area, for no rain fell in Eastbourne on the 1st, whereas London was treated to a deluge, and yet both are included in district 5, England S. (London and Channel).

Lab.—*The Society of Chemical Industry.* The annual meeting has been held during this week in Dublin, and was largely attended, Professor J. Emerson Reynolds, F.R.S., being elected president for the ensuing year.

## PAINTERS AT FAULT.

Most of us experience a lively satisfaction, although we may not care to give it visible expression, when there comes under our notice a case in which the biter is bitten, or when the cutting edge of the diamond meets with some sharper crystalline angle and is itself cut. More particularly is this the case when some self-constituted judge of the actions of another, who has been in the habit of laying down the law and admonishing right and left, is himself caught tripping, and is found to be guilty of some of the very faults which he was so fond of looking for and correcting when committed by others.

It has for a long time been the fate of photographers to be hardly spoken of by a certain section of the artistic world, and to be told that in their work there is not and never can be any art at all. That they make use of a mechanical contrivance to produce their pictures, and the results cannot be otherwise than mechanical. Photography, in fact, represented everything in an unnatural manner, and those alone who possessed artistic genius and training were competent to look down from their high pedestal and point out that this was the case. In the meantime, if the poor photographer endeavoured to retaliate, and to suggest that such and such a picture exhibited faulty drawing, or could not in some other way be true to nature, he was promptly sat upon as one who knew nothing about the matter. And yet all the time that photographer could prove by his published works that he knew well enough the rules of composition, and that he possessed artistic faculties and knew how to make practical use of them. Many photographers, therefore, will be inclined to chuckle when they learn that "a Daniel has come to judgment," to tell some of these detractors of photographic work that they themselves are constantly guilty of offences of commission and omission against truth and nature which it would be impossible for any photographer to commit, and which, moreover, might often be avoided if the power to use a camera had been acquired. The Daniel to whom we allude is Mr. J. Normau Lockyer, F.R.S., who, in the course of a lecture delivered last month at Bedford College, on the subject of "Physical Science for Artists," took occasion to point out, while advocating the immense importance of a scientific training to artists, the lamentable mistakes commonly made by them for want of such training. He did not indulge in vague generalisations, but gave as examples of the errors adverted to certain pictures now hung at the Academy exhibition and other galleries.

Commencing with the importance to the artist of a knowledge of light—without which there could be neither art nor artists—he showed how many painters disregarded altogether the well-known rule that when light falls upon a body and is reflected, the angle of reflection must be equal to the angle of incidence. Reflection in landscape mostly comes from the surface of water, and the lecturer pointed out that many pictures, both in the Academy and at the New Gallery, transgressed this well-known law by making reflected objects apparent when they could not possibly be visible, and *vice versâ*. It is obvious that such a fault would be impossible in a camera-made picture, and here at least the artist can seek help, as so many of them wisely do, from the revelations of photography.

"Neglect of this same law is also to be found," we learn, "in very many pictures in which we get the reflection of the sun or moon in water," and although certain pictures in the Academy are commended for the admirable way in which such reflections are rendered, one is held up to scornful reproach as a something which is absolutely opposed to physical law.

Next we are told of an instance of artistic bungling that occurred some years ago in which, curiously enough, the artist was led into error from too closely copying a photograph; but we are happy to learn that the fault did not prevent the picture being hung at the Academy. It seems that a book had been published in France, and republished here as a translation, in which there appeared an admirable coloured picture of a soap-bubble. This was copied from a photograph taken in the laboratory in the Collège de France, a place of many windows. These windows were naturally reflected by the surface of the bubble, in the way familiar to anyone who has ever blown a bubble within doors. Now a certain English artist had painted a picture of a garden with some children playing in the foreground, and in order to give a little variety to the group he made one of the little ones to blow soap-bubbles. Unfortunately, however, instead of painting from an actual bubble, he copied the coloured photograph in the book referred to, the bubble with windows; but as gardens generally have no windows, the thing was a little out of place.

We are next told of a picture exhibited last year in which the dark half of the moon was turned towards the sun, and of a still stranger case in which, from the assumed position of the sun, the moon, to be correct, ought to have been painted *full*, but the artist had expressed it as a crescent. He owned that he knew it was wrong, and, in fact, had painted it full originally, but had altered it because "it destroyed the balance of his picture." "That, you see, is where the art comes in," added the lecturer at the close of his anecdote. In another case—the picture is hung in the present Academy exhibition—a painter has fallen foul of the well-known phenomenon of refraction, and has made the apparent bend in a body immersed in water to bend the wrong way. A rainbow seen as an arch viewed in perspective is, from its nature, a simple impossibility, and yet many artists have depicted a rainbow so, possibly because if it were otherwise rendered it might, as the mooney gentleman said, "destroy the balance of the picture."

Many other faults common to artists were pointed out and expatiated upon in this excellent paper, but the greater number refer to mistakes due to a wrong appreciation of the laws which govern colour in nature. In this domain the artist has it all his own way, and photography can be of no service to him; but where mere form is concerned, he will find that the camera can teach him many things, and may possibly be the means of preventing him falling into error.

## NEW ZINCOGRAPHIC PROCESS.

BY AUGUST AND LOUIS LUMIERE.

The method which we propose may be described as a modification of the albumen process. The facility and the rapidity with which it allows you to produce engraved images of the greatest delicacy and fineness, and the employment as a lined screen of a positive phototype, constitute incontestable advantages. The greater part of the mechanical processes in use require the employment of a reversed negative, which must be both transparent in the shadows and opaque in the lights—conditions somewhat difficult to secure—while the manipulations are of a delicate nature, and can only be carried out satisfactorily by experienced hands.

Our new method does not possess these difficulties of procedure, and, by following exactly the directions which follow, it is possible to obtain at the first attempt images perfect in their nature, and susceptible of furnishing excellent lithographic prints, or blocks ready for the typographic press.

The following solution is first of all prepared:—

| | |
|---|---|
| Water ... ... ... ... ... | 1,000 parts |
| Albumen (from fresh eggs) ... ... | 100 ,, |
| Bichromate of ammonia ... ... | 3 ,, |

(The amount of bichromate should be sufficient to colour the solution a light yellow.) This mixture is rapidly stirred, carefully filtered, and, by means of a whirling table, is spread upon a sheet of polished zinc, which has been previously carefully cleaned. As soon as the thin coating of bichromated albumen has been deposited on the zinc in this way, it is necessary to hasten the drying of the compound by lightly heating the metal plate.

The plate is then exposed to the light in a printing frame under a positive, and, when the exposure is judged to be sufficient, it is removed from the frame, and is given a coating of ink, thinned with middle varnish, by means of a roller. The colour of the surface should then be a dark grey, not black, and without any appearance of the image.

The plate is now immersed in tepid water, and before long the image begins to appear, and the action may be helped by lightly rubbing the surface of the zinc with a tuft of cotton-wool.

The image is a negative one, and the shadows of the picture consequently are represented by patches of bare zinc, the albumen on these parts having been protected during the exposure to light, and therefore remaining soluble. It is these portions that have been washed off in the bath of tepid water.

The plate is now thoroughly washed in plenty of water, and plunged into a solution of perchloride of iron at 35° B., in which it should remain from ten to fifteen seconds. It is now again washed and dried.

The zinc plate is next heated to about 50°, and a roller charged with black ink thinned with middle varnish is passed over it, when it will be found that the ink will adhere to the whole of the surface indiscriminately. By means of another roller, passed several times over the surface of the plate, it is possible to remove the ink from those portions still covered with the insoluble albumen. There only remains now to rub the plate with a soft rag charged with strong ammonia, when the image appears in black on a brilliant background of metallic zinc, for the albumen, although insoluble by light, is soluble in ammonia, and a second development is thus brought about which is the reverse of the first. By the friction, as well as by the action of the ammonia, the ink and albumen are removed, while the ink remains on those portions of the plate which have been partially engraved by the action of the perchloride of iron. It is the latter reaction which forms the basis of our method, and which constitutes its novelty. It is very curious to watch this reversal of the image under the influence of the ammonia. Solutions of potash, soda, &c., do not give such clean results, probably because of the saponification which is induced by the presence of the fatty constituents of the ink.

If the plate has to be printed from lithographically, there only remains to prepare it in the usual manner. If, on the contrary, we require the image to be in relief, it is necessary to sprinkle over the surface powdered resin, and warm it in the usual way before proceeding to the first etching, or biting-in with acid. In this latter case it is preferable to shorten the immersion of the plate in the perchloride of iron solution, in order to avoid roughening too much the surfaces which are ultimately destined to stand up in relief.

## THE PHOTOGRAPHIC CONVENTION.

"Convention week is generally wet," was a common remark heard at Bath last week, but, as a matter of fact, the weather cleared up after Wednesday, and for the rest of the week the members of the Convention had little to complain of in the matter of weather. The *Convention Group* on that day was taken in a pouring rain, and Mr. Ashman had to give the word to lower umbrellas, just as if he had been in command of a battalion of soldiers, and had directed them to present arms. Many pictures of the members were taken, for, in additiou to Mr. Ashman's camera, there were many others in positiou.

This very wet trip to the Sydney Gardens, where the group was taken, constituted the sole excursiou on Wednesday, which was, with this exception, devoted to business in the Guildhall. We have already recorded that a general meeting was held earlier in the day. In the afternoou, Mr. W. Lang, jun., F.C.S., read a paper, with illustrations, on "The Photographic Work of Herschel and Fox Talbot," which will be fouud ou another page of our present issue.

In the course of a few remarks in the discussion which followed, Mr. C. H. Talbot, a son of Mr. Fox Talbot, said there could be no doubt whatever that his father obtained definite photographic results in 1834 and 1835. He possessed a few views which he believed to be of the year 1835, but, unfortunately, conclusive proof of this was not forthcoming; but he judged their date from the fact that his father had stated that his earlier views of 1834 and 1835 possessed the characteristic of having (as was the case of the ones in question) their outline come out with distinctness; but the details were indistinct, and, therefore, differed from views dated 1839. There was another specimen of a fern leaf upon paper, of which the watermark was 1835. He should have pleasure in showing these views, and other unique examples of early photographic work produced by his father, to the members of the Convention who visited Lacock Abbey on Friday.

Mr. Lang's paper, which was much applauded, was followed by one by Mr. C. H. Bothamley on "Recent Developments in Printing Processes," which we print on another page, his remarks being rendered additionally interesting by a number of capital illustrations. The experimeuts were watched with great interest, aud at the close Mr. Bothamley was heartily thanked.

Mr. J. Traill Taylor then read a paper, written by Mr. Debenham, on "The Cult of Indistinctness."

There was a large atteudance at the evening meeting, when Mr. A. A. Common, F.R.S., favoured the company with numerous illustrations of recent astronomical photography shown on the disc by Mr. Pringle, and graphically explained by the lecturer. The photographs included representations of nebulæ, the planets Jupiter, Neptune, &c., and photographs of the moon in different stages, these latter showing a wonderful amount of detail. The lecturer was warmly thanked for his extremely interesting remarks and pictures, aud the meetiug terminated with the discussion of one or two matters of interest to the Convention.

On Thursday the members of the Conveution divided their favours between Salisbury and Bristol, to both of which places there were excursions, returning in good time for the meeting at the Guildhall in the evening, where there was a large attendance. The chair was occupied by the President (Mr. Bedford), and Mr. A. Haddon (Royal Naval College, Greenwich) preseuted the report of the Lens Standard Committee appointed to consider the adoption of staudard lens fittings and take steps necessary for their effective establishment. The report was a supplementary one to that submitted at Chester last year. It appeared that immediately after the last Convention the secretary of the committee appointed by the Photographic Society invited the committee to join them and consider standards with regard to lenses, and objections to certain others. The Photographic Society of Great Britain had adopted most of the suggestions which the committee at Chester made, and satisfaction was expressed at the fact that difficulties with the leading opticians had been overcome. Mr. Bothamley proposed the adoption of the report, and congratulated the committee upon the accomplishment of what might be regarded as the most important work the Convention had yet taken in hand. It must also be satisfactory to know that the recommendatious contained in the report had met with the approval of the leading opticiaus of the world, aud that the committee was in agreement with the Photographic Society. Mr. Levy seconded. In the discussion which ensued, Mr. Warnerke spoke as follows:—

There is one point in the recommended staudard I wish to direct the attention of the Convention to—viz., the unit of the rapidity of lenses. Some ten or twelve years ago the Photographic Society of Great Britain chose $f/4$ as the unit, and it is also recommended uow by the committee of the Convention. The ten or twelve years that have elapsed since the introduction of that unit is certainly long enough time to look back and examiue what is the practical outcome of that measure. Constant readers of our numerous publications cannot but observe that whenever the question of rapidity of the lenses occurs, the numbers of the unit standard are not used. The present meeting of the Convention offers au excellent field to verify the popularity of the measure. During our numerous excursions, when everybody is busy using his camera, the most uatural questiou in conversation is, what diaphragm do you use? This question invariably has been answered, $f/10$ or $f/6$, &c. Even members of the past and present lens committee, and opticians marking their lenses with unit standard numbers, do not use them when answering this constantly recurring question.

Certainly there must be something iu the measure proposed that is not practical. In reality, this staudard is not the best, and that, I think, is the reason why it is not practically adopted. It requires too much calculation that cannot be accomplished without pen or pencil. There are two other units —$f\sqrt{10}$, proposed by Mr. Dallmeyer, and $f/10$, adopted by the Paris Congress. To find the unit standard number for a certain diaphragm, it is necessary to find the square of the fraction representing relation of focus to the diameter of aperture of that diaphragm, and divide it by the square of unit diaphragm—viz., by 16 iu the case of the proposed unit, by 100 for French unit, and by 10 for Dallmeyer's unit. It will be readily seen that division of any number by 10 or 100, requiring only removal of the decimal point, is much simpler than division by 16.

However, this is not the only plea in favour of $f/10$ as a unit. We are going to the Brussels Congress, and certainly it will not be becoming to English photographic societies to propose a measure that is not the very best, and consequently one that has no chance of being adopted universally; $f/10$ is better than $f/4$, because it is simpler. It is already adopted by the Paris Congress, and it is clear that for these two reasons it will have all Congress iu its favour.

Supporters of $f/4$ unit put forward an argument that some opticians have already adopted the system for marking their lenses, and that any change of the system will put them to inconvenience. To that I can answer—and that not only on supposition, but as the result of inquiry—that those who have adopted already $f/4$ will adopt without hesitation any other system recommended as best by recognised authority.

There is also a great deal to be said respecting the system of weights and measures sanctioned by the last Convention. If we insist on the adoption of the system that is palpably inferior to the generally used metrical, we shall be put at great disadvantage at the Congress. The same is to be said respecting a system of weights and measures proposed elsewhere, recommending us to express our formulæ in parts. I shall put as an instance, how can you answer a question, "How much emulsion have you to use to cover a sheet of paper of certain size, using parts as measures?"

Photography, like all other sciences, is not national, but belongs to all humanity; therefore, we must use terms that can be intelligible to all humanity, and that is the object of the Congress. The metrical system is that universally intelligible expression of weight and measures.

Mr. Haddon mentioned that a deputation had been appointed by the Photographic Society to attend the Brussels Congress to support the suggestions adopted by them. The report was subsequently adopted with about one dissentient, and a hearty vote of thanks was accorded to Mr. Haddon for the trouble he had taken in the matter.

On Friday the members of the Convention divided their attention between Glastonbury and Wells, and Corsham and Lacock Abbey, privileges being afforded at each place for obtaining views, while at Lacock Abbey the additional advantage was obtained of inspecting the examples of early photographic art produced by Fox Talbot, dating from 1834 downwards. In the evening the Photographic Convention of 1891 was brought to a successful close in true English fashion by a dinner and smoking concert. All the arrangements of the week were carried out in a very complete manner, and we must congratulate Mr. Briginshaw, the energetic hon. secretary, on his talents as a successful organiser.

## SOME NEW ADDITION COMPOUNDS OF "THIOCARBAMIDE" WHICH AFFORD EVIDENCE OF ITS CONSTITUTION.*

BY J. EMERSON REYNOLDS, M.D., F.R.S., PROFESSOR OF CHEMISTRY, UNIVERSITY OF DUBLIN.

### D.—*Compounds of Thiocarbamide with partially substituted Alkylammonium Salts.*

The strongly contrasted results afforded by ammonium and by tetrethylammonium salts invested with much interest the examination of any compounds that could be formed by the union of thiocarbamide with partially substituted alkylammonium salts.

The products first obtained by the union of thiocarbamide with primary, secondary, and tertiary ammonium salts appeared to resemble those prepared with the simple ammoniacal haloid salts as described in A, that is to say, they seemed to be compounds of the tetrathiocarbamidammonium type. But the analytical data obtained with those products were not satisfactory; hence, as soon as time permitted, the work was repeated very carefully, with the results stated below.

The alkylammonium salts used at first were purchased, but those subsequently employed were prepared in my laboratory by the direct action of the required acid on the pure amine, so that ordinary ammoniacal salts were excluded. I shall first describe the results obtained with the diethyl compound; the chief interest attaches to it as being intermediate between ammonium bromide on the one hand, and tetralkylic bromide on the other.

*A compound of diethylammonium bromide with thiocarbamide* was formed when 3·8 grams of the bromide in *absolute* alcohol was boiled with a similar solution of 7·6 grams of thiocarbamide. On cooling, a crop of crystals was obtained which was evidently a mixture of thiocarbamide and a new compound, and contained only 12·08 per cent. of Br, but 31·53 per cent. of S; whilst its melting point was not sharp, liquefaction commenced at 135°, and was not complete under 145°.

The mother liquor, when concentrated, afforded groups of fine, thin prisms, resembling somewhat the ammonium bromide compound in its mode of separation. These crystals were drained, slightly washed with absolute alcohol, and recrystallised from the same solvent.

The melting point of this compound was sharp between 133° and 134°. Some months afterwards this preparation was recrystallised and was found to have the same melting point. It was observed that crystals began to form in the liquid at 174°.

A complete analysis was made, with the following results:—

| | | |
|---|---|---|
| I. 0·3575 gram gave | | 0·2075 $H_2O$ and 0·2891 $CO_2$. |
| II. 0·181 | ,, | 39·3 c.c. of N at 14° and 755 mm. |
| III. 0·228 | ,, | 0·427 $BaSO_4$. |
| IV. 0·272 | ,, | 0·131 AgBr. |

The formula $(H_4N_2CS)_3H_2(C_2H_5)_2NBr$ requires:—

| | Theory. | Found. |
|---|---|---|
| C ... ... | 21·99 per cent. | 22·05 per cent. |
| H ... ... | 6·28 ,, | 6·44 ,, |
| N ... ... | 25·65 ,, | 25·23 ,, |
| S ... ... | 25·14 ,, | 25·74 ,, |
| Br ... ... | 20·94 ,, | 20·49 ,, |
| | 100·00 | |

It is to be noted that this compound is very sensitive to the action of water; anhydrous alcohol must be used in its preparation, and if that used for recrystallisation be much hydrated, a mixed product is obtained which contains free amide and, possibly, a dithiocarbamide compound. Hence great care is required both in the preparation and purification of the trithiocarbamidediethylammonium bromide.

I have not succeeded in preparing a tetrathiocarbamidediethylammonium bromide; if it exists in solution, it is certainly decomposed when crystallisation takes place, even from anhydrous alcohol. At the time my former paper was written (*loc. cit.*), only a rapidly crystallised product, from a concentrated solution, had been obtained, and the bromine in that product was found to be near to the percentage required for a tetra-compound, but I am not satisfied that the material then obtained was homogeneous.

Diethylammonium chloride also unites with thiocarbamide and affords a silky mass, which, however, always contains some free thiocarbamide. The best product melted about 136°, but not sharply; and, like the bromide, when heated to 175° crystals began to form in the molten substance and increased in amount until the whole became nearly solid at 180°.

This somewhat impure material afforded 10·14 per cent. of Cl and 29·90 per cent. of S.

A trithiocarbamide compound requires 10·51 per cent. of Cl and 29·95 cent. of S, while one containing 4 mols. of thiocarbamide requires 8·6 per cent. of Cl and 31 per cent. of S. The latter is, therefore, excluded; hence the crystalline substance examined contains a sensible proportion of free amide adherent to the chloride of trithiocarbamidediethylammonium, analogous to the bromide already described.

*Triethylammonium Bromide Compounds with Thio-*

* Continued from page 485.

*carbamide.*—The earliest small experiment made with the salt and amide seemed to indicate that a tetrathiocarbamide compound was formed, but when the work was repeated on a larger scale, and the product slowly separated from alcoholic solution, it was not found possible to obtain a definite compound with 4 mols. of thiocarbamide under the usual conditions of the series of experiments. In all cases free amine separated along with any substance produced.

The proportion of bromide was then increased so that the solution contained 1 mol. to 3 of thiocarbamide, using 14 grams of the latter, and the materials were heated with absolute alcohol to the boiling point of the latter for three hours. When the liquid was allowed to cool, groups of silky crystals separated, which closely resembled the ammonium bromide compound. These were quickly drained off, washed with cold alcohol, pressed, and dried. The mother liquor, on standing over night, gave some more needles and a small crop of thiocarbamide crystals.

Although microscopic examination of the silky crystals showed that they were all of the same kind, and the ratio of bromine to sulphur in them proved to be 1 : 2·58 or, approximately, 2 : 5, slow recrystallisation failed to give the original substance, but, instead, two distinct forms were obtained—one portion consisting of groups of rather long prisms, resembling nitre in appearance, and the other of somewhat large, modified rhomboids; the latter were in smaller proportion and separated out more slowly, along with some more thiocarbamide.

The nitre-like crystals were separated, as far as possible, by picking and concentration of the liquids; they were redissolved in as small a quantity of strong alcohol as possible (as a large proportion of hot alcohol seemed to partly decompose the compound), and the crystals were again obtained, but in groups of smaller needles. These, indicated by *A* below, were analysed with the following results:—

0·2490 gram gave 0·4118 gram $BaSO_4$.
0·2222 „ 0·1081 „ AgBr.

When again crystallised from alcohol, a purer specimen of shorter crystals, marked *B*, was obtained; but even when absolute alcohol was used, some thiocarbamide separated from the mother liquor; gradual decomposition was found to follow further attempts at complete purification. The crystals were analysed as under:—

0·25 gram gave 0·4247 $BaSO_4$.
0·2798 „ „ 0·126 AgBr.

The two sets of crystals represent the compound $(H_4N_2CS)_3(C_2H_5)_3HNBr$ in somewhat different states of purity, thus:—

| | Theory. | *A* crystals. | *B* crystals. |
|---|---|---|---|
| S ... ... | 23·41 p. c. | 22·7 p. c. | 23·28 p. c. |
| Br ... ... | 19·51 „ | 20·7 „ | 19·16 „ |

The rhomboidal crystals which separated in small quantity along with the above, when washed with alcohol and recrystallised, were obtained in short prisms, and consist of the compound $(H_4N_2CS)_2(C_2H_5)_3HNBr$.

0·1532 gram gave 0·089 gram AgBr = 24·72 per cent. Br.

Theory for the above compound requires 23·91 per cent. of Br.

The mother liquor ultimately afforded a few fine, large prisms mixed with crystals of the other types, which were richer still in bromine, but the quantity of the material obtained was too small to admit of satisfactory purification for analysis.

*(To be continued.)*

## THE PHOTOGRAPHIC WORK OF HERSCHEL AND FOX TALBOT.*

BY WILLIAM LANG, JUN., F.C.S.

The two scientists whose photographic work is dealt with in the following communication were virtually contemporaries, and their connection with the town in which we hold our present Photographic Convention may be described as direct and indirect. Talbot's connection was essentially a direct one, living as he did within a short distance of Bath. Herschel's, on the other hand, has to be accounted for in the fact that his father, Sir Wm. Herschel, resided here for several years before his appointment as private astronomer to George III. necessitated his removal to Slough, in the neighbourhood of Windsor. To the student, therefore, of the history of photography, Bath will have something more than a passing interest for him—it will be for ever classic ground. I only wish that the summarising of the work done by Herschel and Fox Talbot had been placed in worthier hands than mine, but having been entrusted with the task I shall do my best to acquit myself of it.

In the first number of the *Edinburgh Philosophical Journal*, which made its appearance in June, 1819, the second contribution we find to be from Herschel, and its title "On the Hyposulphurous Acid and its Compounds." In the opening sentence we are told that the experiments about to be described are the result of an accident. Experimenting with sulphite of lime, and noticing a bitterness in the liquid when almost wholly decomposed similar to that of Epsom salts, and which could not be accounted for, Herschel was led to examine the properties of the body giving this characteristic bitterness, and which Herschel showed to be hyposulphite of lime. From the hyposulphite thus produced, other hyposulphites were prepared. In the memoir these salts, at all events the more important, have their properties described. The action of hyposulphite of soda and of the corresponding salt of potash on chloride of silver is distinctly set forth. Referring to the soda salt, we find it stated in the memoir, "Muriate of silver, newly precipitated, dissolves in this salt when in a somewhat concentrated solution in large quantity, and almost as readily as sugar in water." Herschel states it broadly that all liquid hyposulphites dissolve muriate, or, as we call it now, chloride of silver. He points out the fact that such a solution possesses great sweetness to the taste, and that most of the ordinary tests for silver fail to show the presence of that metal in the solution. He further shows that zinc can separate metallic silver on being immersed in the hyposulphite solution. In conclusion, it may be noted that the contribution is dated Slough, January 8th, 1819.

Herschel had evidently found congenial work in tracing out further reactions connected with the hyposulphites. In the same volume of the *Edinburgh Philosophical Journal* occurs another contribution—additional facts relative to the hyposulphurous acid. This appeared in the October issue, and the date affixed to the article is 15th May, 1819. Time fails us to refer in detail to the various facts brought forward, but one observation deserves to be noted—viz., that where silver iodide is described as sparingly soluble in hyposulphites. It has to be remembered silver bromide was then unknown. Bromine not being discovered till 1826, the salts of silver thus treated by Herschel were chloride, carbonate, phosphate, borate, matate, sulphite, and arseniate. The second volume of

* Read at the Photographic Convention.

the same journal has one other memoir, some additional facts relating to the habitudes of the hyposulphurous acid and its union with metallic oxides. This contribution is dated Slough, November, 1819. The true importance of these researches did not make itself manifest till some twenty years later, when the necessity of removing the unacted on silver salt from the developed image became apparent. Daguerre and Talbot's methods, as first propounded by their respective authors, were far from perfect, being images not sufficiently fixed. Herschel himself called the attention of these investigators to his early experiments, and the employment of hyposulphite of soda for the final operations made the Frenchman's and the Englishman's processes thoroughly complete.

As Herschel seems to have been the first to analyse coloured flames by means of a prism, it may be as well here to note the fact, although it may not strictly be termed photographic. In 1822, in the Edinburgh Royal Society Transactions, p. 455, a memoir is contributed on the "Absorption of Light by Coloured Media, and on the Colours of the Prismatic Spectrum, with an account of a ready mode of determining the absolute dispersive power of any medium by direct experiment."

In 1827, Herschel, among other articles, wrote that on light in the "Encyclopædia Metropolitana." Up to about this time Herschel had been an adherent of the emission theory of light; but the labours of Young and Fresnel had induced him to accept the undulatory theory.

In 1832, a short communication in the form of a letter was made to the British Association at their second meeting, which was held at Oxford. The title of paper indicates the subject matter, "On the Action of Light in determining the Precipitation of Muriate of Platinum by Lime Water."

Herschel went abroad in the latter end of 1833 to carry out a long-cherished desire to survey the heavens of the Southern Hemisphere. His destination was Feldhausen, six miles from Capetown, and here, for four years, were carried on those astronomical observations which will for all time be associated with the name of Herschel. I am not aware that during the period in question anything bearing sufficiently intimately on what may be called photographic research has to be recorded, although solar radiation observations were made from time to time. The third meeting of the British Association was held at Cambridge in the month of June, 1833. Two papers were contributed by Herschel, "On the Absorption by Light of Coloured Media, viewed in connection with the Undulatory Theory," and "The Principle and Construction of the Actinometer." It has to be noted that the instrument described was one destined to estimate the heating power of the sun's rays, not what we photographers understand by the title. The former paper appears only in abstract in the Association reports, but was printed *in extenso* in the *Lond. and Edin. Phil. Mag. and Journ.*, vol. iii., p. 401.

Before the Royal Society, on March 14th, 1839, a paper was read by Herschel, entitled "Note on the Art of Photography; or the Application of Chemical Rays of Light to the purposes of Pictorial Representation." At the outset the author states that his attention had been but recently called to the subject of Daguerre's concealed photographic processes, and that he had not known that the question had been considered by Talbot, or by anyone in this country; as an enigma to be solved, a variety of processes at once presented themselves. First, the so-called di-oxidising power of the chemical rays in their action on recently precipitated silver chloride; secondly, the instant precipitation of a mixture of platinum chloride and lime water by light, forming an insoluble compound, which might be blackened by various reagents; and fourthly, the decomposition of an argentic compound, soluble in water exposed to light in an atmosphere of peroxide of chlorine. Confining his attention to silver chloride, the author inquires into the methods whereby the blackened traces can be preserved, and the unaltered salt removed. This state of things can best be brought about by the use of the liquid hyposulphites. The author then specifies other salts of silver more sensitive to light than the chloride, viz., the carbonate acetate and nitrate. Commenting on investigations to be made on the spectrum, he advocates that the spectrum be produced not by the prism, but according to Fraunhofer's method, by the interference of the rays of light themselves in passing through gratings, and fixed by the heliostat.

Accompanying the paper thus briefly referred to were twenty-three specimens of photographs, one a picture of the large telescope at Slough produced in the camera. Through the kindness of Prof. A. S. Herschel, I am enabled to show a photographic reproduction of the frame of the great telescope belonging, if not to this particular period of the year, at all events to several months later.

The year 1839, I need scarcely remind a photographic gathering, gave to the world Daguerre's method of securing "sun pictures," and as this had but recently been divulged before the annual meeting of the British Association, we find it engaging the attention of the Mathematics and Physics Section. Talbot's remarks will be referred to when I come to deal with his work. Herschel's contribution on that occasion was a letter addressed to the president of the section, wherein he stated that in experimenting with Talbot's paper and exposing it to the spectrum he got coloured impressions. He also records the action of the red rays on paper which had, in the first instance, been exposed to light. On the 20th February, 1840, Herschel presented to the Royal Society a paper entitled "On the Chemical Action of the Rays of the Solar Spectrum on the Preparations of Silver and other Substances both Metallic and Non-Metallic." The reading of the paper extended over three meetings, viz., 20th and 27th February and 5th March. The whole memoir is full of suggestive material; there is only time to note one or two of the more important points. The terms positive and negative are here introduced for the first time to indicate respectively pictures in which the lights and shades are the same as in nature, and in which they are the opposite (par. 8), and these distinctive terms remain with us to this day. The first part of the memoir is devoted to the fixing of photographs, and the comparative merits of hyposulphites, potassium iodide, potassium ferrocyanide, &c., are discussed. The bleaching of the image by mercuric chloride is here recorded (par. 19). The second part relates to the taking of photographic copies and transfers. The third treats of the preparation of photographic paper, the photographic possibilities of lead compounds. The author describes a method of precipitating on glass sensitive silver compounds, and refers to such films being likely to lead to an extension of the art of photography. After stating results of his experiments with iodide, bromide, and chloride of silver, he suggests that similar experiments be made with silver fluoride. Gold and silver salts were also experimented on.

*(To be continued.)*

## THE DIAZOTYPE PROCESS OF PHOTOGRAPHIC DYEING AND PRINTING.*

BY JOHN CARBUTT.

The subject I have the pleasure to bring before the Section this evening is the "Diazotype Process of Photographic Dyeing and Printing," the discovery of Mr. Arthur G. Green, of London. It is a new method of producing designs in fast colours on cotton, linen, silk, paper, &c., either from hand-drawn designs on a transparent or semi-transparent medium, or by use of a photographic transparency. It was first made public at a meeting of the British Association for the Advancement of Science, held at Leeds last September.

It is distinctly a positive process; that is, it yields a positive from a positive. The operations are five in number, viz., dyeing, sensitising, printing, developing, and washing, corresponding very closely in number of operations required in preparing and printing on paper by the direct silver process of photographic printing. Primuline is the base of the new "diazotype," and is already in extensive use for dyeing calico in various tints.

*Dyeing.*—The first operation, then, is to dye our material with "primuline." To do this take 100 grains of "primuline," add to it 20 ounces of distilled water brought to a boil in a flask over a Bunsen burner; when dissolved, pour into a porcelain dish, and immerse the fabric, cotton cloth (the cotton must be free from dressing), or silk, and as soon as the pieces seem thoroughly impregnated with the dye, remove and rinse in plain water, and squeeze as dry as possible, or place between sheets of blotting-paper. The fabric so prepared has a primrose hue, and so far is insensitive to light.

*Sensitising.*—The second operation, or sensitising, is accomplished by immersing the dyed fabric in a solution formed of sodium nitrate, 60 grains; cold water, 32 ounces; oxalic acid, 100 grains, previously dissolved in two ounces of water. Each piece is immersed separately and soaked for two or three minutes; it is then rinsed in water and dried. The colour of the fabric should be of a reddish-yellow hue, and is sensitive to light. The operation should be performed in a weak light, and the pieces dried in the dark.

*Printing.*—Place in a printing frame a glass transparency, and place over it a diazotised fabric in contact, and expose to daylight ten to twenty minutes, or sunlight four to seven minutes. The greater the contrast in the transparency, the greater will be the contrast in the finished print, the action of daylight being to decompose the azo derivative, and so prevent reaction with the "developers," so-called, to be afterwards applied; but if we take a piece of the sensitive material that has not been exposed to light, and apply one or more of the developers, or, as a dyer would call it, a "mordant," we at once develop the full tint or colour by the action of that particular solution used. This I will now illustrate.

*Developing.*—I have here a piece of porcelain coated with a solution of gelatine and primuline, and sensitised in the same bath as the cotton cloth. I now paint over one-fifth of its surface, consecutively, with each of the following five solutions or developers:—

No. 1 develops a red colour.
No. 2 produces a yellow.
No. 3 produces an orange.
No. 4 produces a purple.
No. 5 produces a dark brown or black.

* Read before the Franklin Institute (Chemical Section).

It only remains to well rinse this in water, when the colours will be found fixed and permanent. This demonstration will illustrate the possibility of producing the several colours on one and the same picture, as follows: Mix a portion of each developer with a thin starch paste, and, with a camel's-hair pencil, paint over the parts wanted of a particular colour with the particular solution intended to supply that colour, of course in a weak light, as the image is faintly visible after exposure under the transparency.

The composition of the five developers just used is as follows—and it is only right to say here that I am indebted for the formulæ of these solutions to two photographic journals, *The British Journal of Photography*, and *Anthony's Photographic Bulletin*:—

DEVELOPERS.

| | |
|---|---|
| *No. 1.—Red.* | |
| Betanaphthol ... ... ... ... | 30 grains |
| Caustic soda ... ... ... ... | 40 ,, |
| Water ... ... ... ... ... | 10 ounces |
| *No. 2.—Yellow.* | |
| Crystallised carbolic acid ... ... | 50 grains |
| Water ... ... ... ... ... | 10 ounces |
| *No. 3.—Orange.* | |
| Resorcin ... ... ... ... ... | 30 grains |
| Water ... ... ... ... ... | 10 ounces |
| Caustic soda ... ... ... ... | 45 grains |
| *No. 4.—Purple.* | |
| Naphthylamin ... ... ... ... | 60 grains |
| Water ... ... ... ... ... | 10 ounces |
| Oxalic acid ... ... ... ... | 6 grains |
| *No. 5.—Black.* | |
| Eikonogen ... ... ... ... | 50 grains |
| Water ... ... ... ... ... | 10 ounces |

Transparencies on glass, and positives on celluloid and opal, can be produced, as shown by the specimens I have here.

The composition of the coating is as follows:—

| | |
|---|---|
| Water (distilled) ... ... ... ... | 20 ounces |
| Gelatine ... ... ... ... ... | 1 ounce |
| Primuline ... ... ... ... | 80 grains |
| Chrome alum ... ... ... ... | 2 ,, |

Put the gelatine to soak in six ounces of water, dissolve the primuline in twelve ounces of hot distilled water, and when dissolved add the gelatine and the chrome alum—dissolved in the remaining two ounces of water—filter through cotton, and flow while warm on the glass or porcelain. When dry, immerse for two minutes in the sensitising solution, wash for five minutes, and allow to dry in the dark. The operation of printing and developing is the same as for prints, or cotton, &c.

---

Broken Negatives.—A very useful receipt for repairing broken negatives is given by *Wilson's Photographic Magazine*. Place the negative, gelatine side down, on a plate rather larger than the negative. Coat the edges of the fragments with warm Canada balsam; join them together, using strong pressure. Remove the excess of balsam, then cover the negative with another plate exactly of the same size, and previously coated on one side with the following varnish:—

| | |
|---|---|
| Sandarac ... ... ... ... | 3 grammes |
| Mastic in tears ... ... ... ... | 3 ,, |
| Sulphuric ether ... ... ... | 50 ,, |
| Benzole (pure) ... ... ... ... | 25 ,, |

Lift together the three plates, turn them over, remove the large one that has served as a support, scrape off from the gelatine side the balsam that may have exuded, then surround the two plates with strips of gummed paper. Heat slightly the fragments before joining them together. This process will yield a print upon which no trace of breaking is to be seen.

## Notes.

The Convention week at Bath will long be remembered by those who were able to be present as a very pleasant and profitable one—the pleasantness being represented by friendly meetings and greetings, and the profit derived from the many excellent papers read. It is true that there was a little unfavourable (convention) weather at the beginning of the week, but this cleared off, and there remained plenty of sunshine for the remaining days. A really successful week of this character, carried out as it was with a complete absence of friction, cannot be organised without plenty of hard work by those at the helm, and the members should not forget this. To Mr. Brigginshaw, the hon. secretary, must be accorded the chief praise, and he, we are sure, will be the first to admit that he met with much goodwill and responsive aid from others. May the next merry meeting pass off as merrily.

Those photographers who are interested in matters artistic —and there are few now-a-days who can afford to do otherwise—would do well to read the course of lectures recently delivered before the Society of Arts on the "Decorative Treatment of Natural Foliage." Here they will pick up plenty of hints which are sure to be of service to them in a number of ways. But, even if we see no immediate result, commercial or otherwise, from a study of this kind, we must know inwardly that the acquirement of such knowledge is in itself a good thing, which cannot fail to reflect itself upon our every-day doings.

Police-court trials are more often held *in camerâ* in Paris than they are on this side of the Channel; but it is not often that a trial takes place *in camerâ* which has for its principal feature the wrongful use of the photographic camera. Such a trial has, however, recently terminated in the French capital, a man of the name of Schneider having been arrested in the neighbourhood of Stains as he was taking photographs of the forts. Of course, it was at once taken for granted that poor Schneider was an agent for the German Government, and, that fact being satisfactorily established to the minds of his judges, he was fined £120, and, at the same time, condemned to five years' imprisonment. Poor Schneider! Is he really a German spy, or some innocent tourist who has been thus used as a scapegoat?

In a bicycle race the other day the judge declared the result to be a dead-heat. But there happened to be a camera on the ground, and the finish of the race was photographed. In the resulting picture, which we have carefully examined, one rider, A, is clearly in front of the other, B. Of course the judge's ruling was accepted—for at the time the picture had not been developed—and the race was run over again. A was now clearly the loser, and the prize went to B. In such a case should the ruling of the judge be upheld, or should the photograph decide the question?

There is one industry in the higher grades of which England occupies the first place. Germany can make cheaper glass than we can, but she cannot compete with us in the better kinds. The German manufacturers of dry plates have discovered this fact, and, in consequence, are complaining of the high duties which have recently been imposed on imported glass. As a result of the tariff, the price of English glass has increased about 50 per cent., and the dry plate trade has been seriously affected. The German photographers, we are afraid, will have no alternative but to pay the increased charges, as the duty will apply equally to the coated glass of the English dry plate manufacturer, as to the uncoated glass imported for the use of the German manufacturer. Possibly the result will be an impetus to film photography.

It is doubtful whether sufficient attention is paid to the framing of photographs. At one time, when a photograph was framed, an acre or so of white margin was considered indispensable. We grew out of this, and went to the opposite extreme, abolishing the margin altogether. It is, perhaps, difficult to lay down a rule which shall apply to all photographs, as so much depends upon the subject, the size, and the tone of the picture. It is pretty clear, however, that the choosing of the frame must not be left to the frame maker. A glance at the various picture galleries is sufficient to show that painters, as a rule, are very fastidious on this point. It is said that most artists now design their own picture frames. If this be needful in the case of a painting, much more is it necessary in regard to photographs.

Photography has not, it would seem, quite lost all its attraction, since a feature of the new Cleopatra Swimming Baths, on the Thames Embankment, is to be a first-class photographic studio. We do not quite see the connection between swimming and photography, but this does not matter very much. The public have been photographed in every kind of dress, from foot-ball pants and jersey to fancy costumes, and we do not see why they should not be photographed in their bathing dress if they so wish it.

The correspondent of the *Daily News*, in describing the lamentable accident on Mount Vesuvius, relates the experience of Dr. Johnson Lavis, who had been on the mountain the whole of the previous day and night taking photographs. Lying on the crumbling edge while a companion held his feet, Dr. Lavis was able to measure the precipitous walls of the shaft, which went sheer down for 170 feet to the glowing lava at the bottom. We are not told whether in this position Dr. Lavis photographed the sides or bottom of the crater, but we should fancy so enthusiastic a photographer would be certain to have a shot, despite the risk.

No one has yet succeeded in photographing Lo Bengula, king of the Matabeles, so that there is one world left for Lord Randolph Churchill to conquer if his lordship has a camera with him. Lo Bengula, like Unibandine, his cousin, and other native potentates, has a rooted objection to being shot at by the camera. The surgeon who accompanied one of the expeditions was promised a "sitting" one morning, but the king had disappeared in the night. The surgeon followed him on horseback some miles, and then His Majesty's excuse was that no Matabele king could be photographed unless in full war paint, which he had not with him there; but it turned out, from a remark dropped by His Majesty to another member of the expedition, that it would never do for him to be photographed, as his people would think that part of him (his soul) had been taken from him.

## ARCHÆOLOGICAL PHOTOGRAPHY.

### CAMBER CASTLE, SUSSEX.

ANY person who may have walked along the fine level road which traverses the marshes between Winchelsea and Rye —a distance of about two miles—must have observed on his right, or east side, the substantial remains of a mediæval defensive work, or castle, consisting of a circular central tower surrounded by outworks, and now standing in the midst of a wide, green marshland, some considerable distance from the sea. This old fortress has been sometimes called Winchelsea, or "Combre" Castle, or "Camber-before-Rye," but is now always known as "Camber Castle," and is evidently a great object of interest to photographers, for we never visited the castle but we noticed one or two artists busily engaged with their cameras either inside or outside these picturesque ruins.

It must not be forgotten that the whole coast between Winchelsea and Romney has undergone a very remarkable change during the last few hundred years, and land, now appearing as green fields or marshes, was once covered by water, and was, in fact, a very extensive arm of the sea, reaching from Winchelsea to Romney on the east, and to Appledore on the north, part of which formed the harbours of Rye and Winchelsea. Many small estuaries, or "cambers," as they were sometimes called, indented these coasts, and it was for the defence of these harbours that the old castle was erected on one of these "cambers" (hence the name) midway between Winchelsea and Rye —a site very well chosen for such a work, because it was close to the water, and completely commanded the harbours on all sides. But, unfortunately, this camber gradually, but surely, went the way of former estuaries hereabouts, and in the course of a century left the castle high and dry nearly two miles from the sea.

The site of this fortress (like those of Sandown, Deal, and Walmer, in Kent) having been carefully surveyed and inspected by Henry VIII. himself in person, the castle was at once erected by order of that monarch in 1540, a period when many defence works were undertaken on the south-east coast, the king having, apparently, some fear of invasion by the Roman Catholic powers, who seemed much dissatisfied with Henry's "reforming" energy, and desired to induce him to return to "the ways of grace" by the gentle process of arms and bloodshed. The outlay for building this castle is said to have been £23,000, and this sum, together with the cost of the three Kentish castles already named, is reported to have been raised out of the spoils of Canterbury Cathedral, and the robbery and plunder of some of the religious houses.

Camber Castle consists of one large circular central tower or keep, surrounded by small towers or lunettes, connected by short curtains. A low battery once existed below the keep, with openings for guns, and loop-holes for small arms; but these are now choked with accumulated earth.

In Elizabeth's day it was a place of much importance, and was repaired by her in 1584 at a cost of £171 13s. 4d., and was armed with nine guns, thus described: "1 iron canone, 8 brasse culverins, demi-culverins, and sacres." As the sea gradually retired, however, the castle became of less and less utility, and in 1626, in the reign of Charles I., it was abandoned as a defence, and its guns and stores removed. Subsequently, in 1642, the Parliament ordered it to be entirely dismantled, and most of the materials sold, exactly as Sandown Castle in Kent was treated about thirty years ago.

The building is now a mere shell, but is still an object of much artistic interest, and forms a very picturesque ruin, reposing in the midst of the wide stretch of green marshland and meadow, and will always very well repay a visit from both the artist and the photographer. It is open to the public.

## PRELIMINARY, SECONDARY, AND SUPPLEMENTAL LIGHTING.*

BY DR. J. M. EDER.

IMMEDIATELY after the publication of this statement, Blanquart-Everard stated that he obtained pictures in shorter time when the interior of the camera was white instead of the usual black. This was substantiated by Kilburn, but denied by Claudet, or at least restricted to such cases where the outer light was not strong enough to form a strong image. Notwithstanding these experiments, they were again brought up by Blair twenty years later, but he soon returned to the dark camera and a preliminary exposure under red light.

Günther, in Hanover, 1855, suggested a modification in which he advised a blue lilac colour in place of black. As a matter of fact, some photographers (Bellac and others) actually reduced the time of exposure with similar apparatus. In the resulting discussion, in which Horn was especially active, it was soon shown that the reduction of time was at the expense of the picture, as the negatives were always flat. As a matter of fact, neither the quantity nor intensity of light within the camera is under any control; and even if in some exceptional cases the requisite measure of supplementary lighting is attained, in the great majority of cases it results in failure. Consequently this expedient is practically useless; it is far more unreliable than the previous processes.

Carey Lea condemned the white and red interiors of the camera. Especially with a strong light (landscapes, &c.), the bright high-lights would spoil the whole view, and result in fog and flatness. De Constant, who again investigated the matter in 1870, found that an entire white camera resulted in a flat picture, little relief, and a confused appearance, as if the plate had been wiped over. If the top and bottom of the camera were black, and the

* Continued from page 493.

sides white, the resulting picture combined sharpness with softness and relief, especially on the part towards the black sides. If the bottom of the camera was black it added to the clearness of the face; if the top of the camera was dark the clothing was clearer. Consequently, as the face in relation to the drapery usually has too much light, better results were obtained when the top and sides were white, and the bottom black. As will be seen from all the above suggestions, no precise method has been evolved which could be adopted in regular practice.

2. *Primary and Secondary Lighting of Gelatine (Bromide of Silver) Dry Plates.*—Gelatine dry plates may also be improved during development if the necessary caution is used. It is, perhaps, superfluous to remark that with the greater sensitiveness of the gelatine dry plate, it is much more difficult to gauge the correct time for supplemental lighting than with the wet collodion plate, and the difficulty of preventing fog is greatly enhanced.

With extra rapid dry plates the period of the primary action is so exceedingly short that even with a slight light-impression a developable image is obtainable, and even the shortest lighting causes a general reduction (fogging). On the contrary, on less sensitive, clear-working plates a marked effect is shown by additional lighting. Candle-light can only be used for this purpose at a very great distance, or when greatly weakened. According to Eder, candle-light worked better when thrown through a ruby glass. His experiments showed that in a slow dry plate of 15 Warnerke, after being exposed from two to six minutes immediately in front of a ruby lamp (candle-flame), the sensibility was raised to 19-20 Warnerke sensitometer, which was equal to a plate three times as sensitive.

E. Himly, in Berlin, patented a so-called (Hilfsbelichter) auxiliary exposer, which introduced diffused light into the camera (D. R. patent 38, 684, August 6th, 1886); *vide* Eder's Year-book, 1889, p. 87. Preliminary lighting with dry plates of high sensibility is partly unnecessary, partly dangerous, and therefore is not advisable in actual practice. In all probability the same results obtained on gelatine dry plates by auxiliary exposure may be reached in a purely chemical manner without the action of light. A minimum reduction of silver bromide must be introduced. This takes place by extending the so-called ripening process. In fact, the continuation of the digestion of the emulsion leads to fogging, and otherwise it is exceedingly dangerous to the rapidity of the emulsion, when treated with reagents, which are apt to change the reduced bromide (sub-bromide) back to its normal condition.

At the conclusion of the reading, Mr. Carbutt inquired on what date the first coloured diaphragm was used in the lens.

Mr. Sachse said he did not know the date, but it was first used by Guillard.

Mr. Carbutt stated that he had used a coloured diaphragm in 1858 or 1859. He was then working in a small gallery in a small way, in an interior town in Indiana. They were using the wet collodion process at that time. He used a blue diaphragm, and obtained a sharp picture in about the same time that would have been required by a very much larger aperture.

Mr. Bell said that in 1872 the photographer of the Treasury Department and himself instituted a series of experiments in preliminary lighting. The plate was exposed from three to five seconds with a red glass in front of the lens, and then exposed on the sitter. The result in all cases was less valuable than if they had not exposed to the red light at all, but had given it proper time. It might be useful where a man's chemicals were in a very insensitive condition, as it would help him to make a much better picture than he could otherwise obtain. He had also used the blue light, by apertures in front of the box, and again in the cap, and after exposure swung in front of a white screen for an instant. At that time he had slow light, and this method helped him very much to get certain pictures, such as children. Still, the results were never very good, not as perfect as would have been the case had he been able to expose the proper time.

The Chairman inquired which colour gave the best results, the blue or the red.

Mr. Bell replied that in the preliminary lighting he found the red glass was the best.

Mr. Cheyney said that it seemed to him they all used this preliminary, &c., lighting. While it was not intentional, they all did exactly what Mr. Sachse had described. In the first place, they took out their plates in a dark room lighted by red light, dusted them, and inserted them in the holders; that was the preliminary lighting. Then they exposed the plates; that was the secondary stage. Next they developed under the red light, and if the development did not proceed fast enough they held the plate up close to the red light to see what was the matter. That was the supplemental lighting. Hence, they all did what Mr. Sachse had described.

In reply to a question from the Chairman, Mr. Sachse said the red light employed was merely the ordinary red light of the lantern.

The Chairman asked where, then, lay the difference between this red light and that used in ordinary development.

Mr. Sachse stated that it differed in this respect, that he personally always filled his holders in the dark. Then, after exposure, he never subjected the plates directly to the red light of the developing room, but put them in the pan in the shadow, and, after a few minutes, held them to the red light to see if the image had appeared. He was always very careful to keep away where the exposure was normal.

Mr. McCollin said he recollected one of the members, Mr. Browne, in the old collodion-emulsion days, brought to him some undeveloped plates; and they were made into fairly good plates by means of candle-light. They were developed in a yellow glass dish.

Mr. Cheyney explained the test he made of his lantern. He exposed a 26 Seeds plate before the lantern for five minutes with a figure cut from cardboard in front of it, and could get no image—the plate was perfectly clear. So he came to the conclusion that he was quite safe in taking his time in development.

Mr. Sachse remarked that he found a difference in the makes of plates. In one make of plates exposure to the lantern invariably resulted in fog. Two other makes he was in the habit of using always came out clear.

The Secretary inquired if this was really an improvement, or only a slight veiling which, as Mr. Carbutt said, made certain details apparent, or softened down the hardness of an under-exposed plate.

Mr. Sachse's experience had been that it did bring out detail. In speaking of the matter three years ago with a professional photographer, that gentleman attributed the improvement to pouring off the developer and leaving the plate exposed to the action of the air. He contended the ruby light had nothing to do with it, and said that when he found under-exposed plates he poured off the developer, exposed to the air, and then put them in the developer again.

The Secretary said it seemed to him that plates grew in detail while being examined, as though the air, coming in contact with the plate, might have that effect.

Mr. Walmsley supposed every one working with a developer had experienced that. His own developer he kept on the plate only long enough to bring out the detail slightly; he then poured it off, put a cover over it, and it would bring out a density in a few minutes so dark that they could not see through it.

Mr. Ives stated that more density would be developed where the air came in contact with the plate than where it was kept from it.

Mr. Cheyney mentioned an instance where he had allowed the negative to rest on the edge of the dish, and the part exposed to the air was better developed than the portion immersed in the developer. In fixing, also, he had found that where the process was slow it was quickened by taking the plate out and letting it stand on edge a little while before returning to the bath. There seemed to be some oxidising action of the air that helped development and fixing along.

Mr. Fox said that in the collodion emulsion days, when they worked with yellow light, it was a common dodge to pour the developer off the plate and let it stand for some time. The negative would come up very well in that way; it brought the detail out rapidly.

Mr. Stirling said it had been suggested that part of the action or the benefit brought about by breathing on the plate was due to the added heat; but he wished to ask for some information. What Mr. Cheyney had said about his developing lamp was at variance with his experience. He had never handled any plate that he could expose within five inches of any lamp he had ever seen without developing fog. He thought it would be interesting to all present if Mr. Cheyney would tell what lamp and what coloured medium he used.

Mr. Cheyney stated that his lamp was a Carbutt's Multum in Parvo. It had a face of ruby-coloured hammered glass in front of it. This he had the misfortune to break, so he took two pieces of Carbutt's yellow paper, and pasted a piece on one side, and one on the other; and he could stand a Seeds 26 plate in front of it, with a figure against it, for five minutes, and nothing but clear glass could be gotten out of it.

Responding to a remark from Mr. Stirling, Mr. Cheyney said he was never more than eighteen inches or two feet away from the lantern, and he could see the details come up, and he had not very good eyes.

Mr. Stirling hinted that as Mr. Cheyney wore glasses he could probably see better than he (Mr. Stirling) could.

This Mr. Cheyney denied, and, continuing, said that when he desired to tell the density he always examined the plate by the clear, red glass in the door of the lantern.

Mr. Bell spoke in favour of the sodium core, or "Aladdin" lamp, used by Mr. Rau. He advocated plenty of light in order to distinguish the density of the plate.

Mr. Rau, in answer to a question, said the sodium core gave a very pale orange light.

Mr. Sachse inquired whether any of the members present had ever had experience with the white or coloured camera interior.

Mr. Bell said that, in the old Daguerreotype times, they had used something like that, but it was abandoned, mostly for the reasons given in Mr. Sachse's paper. The images obtained were very indifferent.

Mr. Ives thought it would be of interest to the members to know that, in the old wet-plate days, a secret method was sold to photographers for $10.00, which consisted of a lighted wax match, to be held until burned out—a very convenient way for supplemental lighting.

## PROPOSED INTERNATIONAL STANDARDS.*

BY LEON WARNERKE.

Responding to the invitation of the past president of Convention to open the discussion on "International Photographic Standards," proposed by the last Paris Congress, I have been prepared to give a detailed account of the work done by the Congress, but want of time decided me to shorten that part of my paper, referring persons interested to the article of *Photography*, published July 2nd, entitled "International Photographic Standards," by C. H. Bothamley, and containing abstract of the decisions of the last Paris Congress.

It is useless to dwell on the extreme importance and imperative urgency of putting our houses in order. Photography has grown to such an extent, so numerous are its applications, that I can compare it to a huge central factory, surrounded by others producing everything that constitutes human industry—social and domestic comfort, science, art, commerce, and trade; all these surrounding factories depending on the central one. It will not only produce some materials and tools necessary, but often control and verify its works. Its resources are inexhaustible; it is capable of supplying any demand. One thing only causes a great anxiety—there is no harmony among different departments of the central factory, and even among the individual workers of the separate departments. They not only each use different tools, different patterns, models, shapes, and sizes, but even different denominations, somewhat like the workers of the Tower of Babel.

To avoid the fate of the unfortunate tower, we must put order into our house. This country was the first to feel the necessity of that order some ten or twelve years ago. That was a good beginning, but it affects only one department of the central factory, and only a very small branch of that department.

That Babelian condition is felt very painfully everywhere where photography is used, and where is it now not used? And that was the motive that brought forward the scheme of the Photographic Congress—universal or international. The first idea was generated in Belgium in 1884. Some unfortunate circumstances prevented the Belgians from organising that Congress in their own country, and the French, taking advantage of the Universal Exhibition of 1889, decided to hold a Photographic Congress. A committee appointed by the Paris Photographic Society, and consisting of the leading luminaries in the French scientific world, prepared a series of questions, and submitted their own solutions, which, after slight discussion, was embodied in the resolutions indicated above.

No doubt the labour of that Congress was great and conscientious, but, unfortunately, the place of congress was not well chosen. Foreigners (from political considerations) did not take part in the deliberation, and that is the reason why the resolutions of the Paris Congress are one-sided, and not international enough. However, the final decision, that the labour of the Paris Congress is to be continued by the following periodical congresses, offers the opportunity to amend indicated shortcomings.

The next Congress is to take place at Brussels, in Belgium, in 1891, from August 23rd to 30th. No better place can be chosen for the Congress. It is central, and the ground politically neutral. Photographic societies of all the world are preparing by sending delegates of their own to submit resolutions and take part in the discussion at that Congress. My object in this communication is to draw the attention of this Convention to the necessity—nay, to the urgency of putting our shoulder to the common wheel. Here I cannot sufficiently accentuate the fact that any photographic standard adopted will not confer complete benefit unless it be universally adopted, and, consequently, international. In order that it can be adjusted to the conditions of this country with the smallest friction, representatives of this country must contribute to its shape, and that is the reason why our duty is to be strongly represented in Brussels.

The organisers of the Brussels Congress have already issued a programme of that Congress. It is physically impossible to discuss the details of the Congress during the few hours this Convention has to exist. Therefore, I think it will be reasonable to appoint delegates and a special (active) committee, whose duty shall be to examine the programme and draw up the instruction for the delegates. If any chosen representative pleads want of know-

* Read at the Photographic Convention.

ledge of the French language, I can assert with sufficient probability of correctness that if English be spoken in the Brussels Congress it will be perfectly understood.

I know that many, even endowed with clear and independent appreciation of things, are apathetically awaiting the sanction by Act of Parliament of an alteration of the impossible habits and rules made by our forefathers.

I am sorry to say that study of the spirit of the House of Parliament will soon persuade any careful and independent observer that sanction by the Act of Parliament of the alterations so urgently demanded is unobtainable. Here is one example: Every year influential deputations, including all Chambers of Commerce of the Kingdom and other bodies, approach Parliament asking for the adoption of the metrical system of weights, measures, &c. Here is an extract from the *Times*, May 9th, 1891, of the last attempt:—

Mr. S. Montagu, M.P., Sir William Thompson, Mr. J. E. Dowson, and Mr. Alexander Smith, on behalf of the Decimal Association, then spoke in favour of the introduction of the decimal system, especially as regards weights and measures.

Mr. Goschen, in reply, said that was not a new subject to him, as they were aware, and if he were a young and active politician he might share in the movement with some faith that it might be of advantage to the country if carried out. But such experience as he had had was that they could not undertake a more difficult and complicated task, or one in which they would be baffled more at every step, than to undertake the revision of our currency, which touched everybody in this country, or the weights, which touched such an enormous class. He could perfectly understand that they might persuade people of the advantages of it, but to change the weights, for instance, must interfere with, and confuse for a time, the transactions of almost everybody in the country, and all those would be satisfied who gained by the change; while, on the other hand, an enormous body who would lose something would be dissatisfied. He did not wish to discourage them, but, if Mr. Montagu could induce the House of Commons to appoint a select committee to inquire into the subject, he would have no objection, though he could not see his way to recommend the Government to appoint a Royal commission. To carry out the change would affect everybody's transactions, and the innate conservatism of the English people—with regard to their habits, he meant, and not politically—would make it an extremely difficult task to carry out. It would be a task which could be undertaken only when there was no other work to be done, when there was general, profound political peace, and when everybody would be prepared to look with the most friendly eye upon every change which might be made. Everybody would have to learn the new weights and measures, and the more ignorant would go to the wall, so that it was highly probable that the tradesman, being more educated than most of his customers, would gain an advantage. He admitted that he was not arguing the question on high grounds, but on practical grounds. He ventured to think that the country was not ripe for a revolution which would affect all their transactions, and he could hold out no hope that the Government would take the initiative in the matter. He would watch the progress of public opinion on the question, for he admitted it to be a reform which would be accompanied by great advantages, but it could not be done unless the country were satisfied, for the sake of ultimate advantage, to go through very great present inconveniences.

In the same issue of the *Times* we find the reason why the question affecting the science cannot obtain the hearing of the legislators. The Earl of Meath, in the course of a speech in the House of Lords on May 8th last, pleaded for the necessity of introducing some instructive lectures in connection with museums, picture galleries, &c. In the course of his speech he says: "These art collections were purchased by our ancestors at a time when this country was, to a large extent, governed by the cultivated classes. Every day, however, England was becoming more and more governed by those who were less cultivated."

It is in the memory of everybody that a few years ago, when Sir Charles Dilke was approached by the advocates of the decimal system, the argument used by that stateman, which upset most logical pleading in favour of the system, was that the diameter of the halfpenny coin being exactly equal to one inch, it was impossible to make alteration.

From what was said, I conclude that, having no chance during the present generation of obtaining that Act of Parliament, we must count on our own forces, and introduce alterations recognised as necessary. This we can do without interfering with law. That was done by the scientist, and we are of the number.

## RECENT DEVELOPMENTS IN PRINTING PROCESSES.*

BY C. H. BOTHAMLEY, F.C.S.

Later developments of printing processes have proceeded along certain well-marked lines, the one common aim being to render the use of albumen unnecessary, and, in view of the want of permanency that characterises albumen prints, it will be admitted that the attainment of this result is much to be desired. For some time the development was all in the direction of the production of prints with a black or even blue-black colour, and we were affected with one of those attacks of artistic cant from which photography suffers now and again. It was urged that, quite apart from any advantage of greater permanency, the new prints are much more artistic, simply because they are black. The preachers of this faith seem to have forgotten that etchings and mezzotints, to say nothing of photogravures, are very rarely printed in black, and that some of the most famous etchers and mezzotint engravers have printed in very warm browns and, at times, in red-browns. Now I, for one, decline to admit that a black print is necessarily more artistic than a brown print simply because the one is brown and the other is black, and I welcome the still later tendency towards the production of prints with warmer colours, provided always that the prints are permanent.

Methods for the production of prints with warm colours—such as gelatino-chloride paper, alpha paper, and Lyonel Clark's platinum toning—are too familiar to require more than passing mention, and I propose to speak in detail of only two or three methods which are based either on novel principles, or on principles that have not hitherto been successfully applied in practice.

Platinotype has long been regarded as the first of the black printing processes; but the present very high price of platinum has stimulated investigation in the direction of replacing the platinum by some cheaper metal that will produce prints of the same character, and, as far as possible, with the same degree of permanence. So far, the only important outcome is the process that is known as kallitype, which in principle is precisely similar to the platinum process, except that the image is formed of metallic silver instead of metallic platinum.

Kallitype is based upon the old observations of Herschel and of Hunt, that when ferric tartrate, citrate, or oxalate is exposed to light, and thus reduced to a ferrous salt, and the ferrous salt is treated with a solution of silver nitrate, metallic silver is precipitated in quantity dependent on the quantity of ferrous salt that has been formed on each

* Read at the Photographic Convention.

part of the surface. Until quite recently these facts had not been utilised, but Dr. W. W. J. Nicol, working with a full knowledge of the chemical changes involved, has succeeded in producing a practicable printing method by making considerable alteration in the details of the process. Kallitype, in fact, is an excellent example of the way in which an old observation, apparently of little practical value, may become of very great utility in the hands of a man who has sufficient knowledge of chemical and other principles to develop it in the right direction and in the right manner.

The details of the process, as first published, are to be found in patent specification No. 5,374, February 15th, 1890 (the *British Journal of Photography*, xxxvii., 170-171; Photographic News, xxxiv., 207). Paper is coated with a solution of ferric citrate, ferric tartrate, or ferric oxalate, or mixtures of all or any of them, and is dried. It is then exposed behind a negative until a faint image is formed, just as in platinotype, and the image is developed by treating it with a solution containing 10 per cent. of sodium citrate, 1 per cent. of silver nitrate, and sufficient ammonia to just keep the silver in solution. The patentee recommends a solution containing 1·5 per cent. of silver nitrate; but I find that better results are obtained with only 1 per cent., and the best method of making up the solution is to dissolve the silver nitrate in a small quantity of water, add dilute ammonia very carefully until the precipitate formed is just, and only just, redissolved; then add the sodium citrate, previously dissolved in five or six parts of water, make up to the required volume, and filter. It is also recommended that a very small quantity of potassium dichromate should be added. The sodium citrate has the double function of dissolving the ferrous salt, and thus enabling it to reduce the silver nitrate, and of preventing precipitation of the iron by the ammonia. After development, the print is immersed in a 20 per cent. solution of an alkaline tartrate or citrate, made strongly alkaline with ammonia, and afterwards in two successive baths of a dilute solution of sodium citrate containing free ammonia. The alkaline tartrate or citrate removes the iron compounds, whilst the ammonia removes the silver compounds, and, finally, the prints are washed in water.

The chief objection to this process was the use of silver compounds in the developing solution, which, of course, was very liable to stain the fingers of the operator, and quite recently a modification of the process has been made, which not only removes this objection, but also enables prints to be obtained with a very warm colour. The silver salt is in the paper instead of being in the developer, and it is interesting to note that the modifications in kallitype have followed the reverse order to the modifications of platinotype; in the latter, the platinum was at first in the paper, but in the latest modification it is in the developer.

The specification of the patent of kallitype No. 2 is not yet published, but Dr. Nicol has kindly informed me that the paper is coated with a solution containing ferric oxalate, ferric nitrate, silver oxalate, silver nitrate, and nitric acid. It must be kept as dry as possible, but does not require the same minute precautions as the old platinotype paper. The pads, &c., of the printing frame must also be dry. My own experience leads me to the conclusion that care in this matter of keeping the paper dry is of very great importance.

The paper is exposed until the detail in the densest parts of the negative is very faintly indicated, the appearance of the image being very much the same as in platinotype, and it is then developed, the composition of the developing solution varying with the colour required in the finished print. For *black prints*, the exposed paper is immersed in a solution containing 10 per cent. of Rochelle salt, and 10 per cent of borax; for *purple prints*, 10 per cent. of Rochelle salt, and 2 to 5 per cent of borax; for *sepia prints*, 5 per cent of Rochelle salt, 1·25 per cent. of borax, and a small quantity of hydrochloric acid. In all three cases a small quantity of a dilute solution of potassium dichromate must be added. The dichromate keeps the whites clear, and increases the contrasts, and the character of the prints can be altered by varying the proportion of this salt; too high a proportion destroys the half-tones. The examples shown demonstrate this point very clearly; in each case two prints were made of as nearly as possible the same intensity, and one was developed with a solution containing no dichromate, the other with a solution to which the dichromate had been added.

The prints are allowed to remain in the developing solution for some time, in order that the Rochelle salt may remove the iron from the paper; and the excess of silver salt is then removed by immersing for about fifteen minutes in—

| | |
|---|---|
| Water ... ... ... ... ... | 80 parts |
| Strong ammonia solution... ... ... | 1 part |

The prints are afterwards washed in water.

My own experience indicates that, even after prolonged immersion in the developer, there is danger of iron salts remaining in the paper, with, of course, loss of purity in the whites, and I recommend that, after removal from the developer, the prints should be immersed in a ten per cent. solution of Rochelle salt before being put into the ammonia. After the Rochelle salt has been used frequently for this purpose, it may be utilised for making up fresh developing solution.

The black prints have a good colour, with a very slight bluish tinge, the whites are clear, and the gradations good. The sepia prints are not so satisfactory; the colour is often too red, and is sometimes not uniform throughout the print. It seems, in fact, that it is more important in this case that the paper should have been kept thoroughly dry. Prints should be somewhat deeper than for the other developers, and the developer, if used frequently, must be kept acid by addition of a few drops of hydrochloric acid.

(*To be continued.*)

## THE CULT OF INDISTINCTNESS.*

BY W. E. DEBENHAM.

Every now and then, in some field or other of art, a disturbance occurs which threatens to be in the nature of a revolution. Some few active minds take up an idea which has been brought into prominence by the peculiarities of some one or more professors of the particular art, and carry on a vigorous crusade on behalf of a view which, to judge from their professions and actions, they think destined to create a revolution. The leading ideas may not be—and, indeed, generally are not—new, but are in the nature of a revival, conscious or unconscious of something which has before been practised to a certain extent, but has been allowed to fall into neglect and so much of oblivion as to give a character of novelty when put forward with energy and some freshness of expression. Within living memory such attempts at upheaval have occurred in the fields of

* Read at the Photographic Convention.

poetry, of music, and at least twice in that of pictorial art, without leaving much permanent effect on the general appreciation of what are to be considered as the highest and most valuable qualities in the respective fields of labour involved.

It could scarcely be expected that photography should be exempt from disturbances of a character similar to those referred to as affecting other arts, and, in fact, there has recently been a revival in a very aggressive manner of a claim for superiority in results, differing mainly from those which have been accepted as representing the best work in photography in the indistinctness characterising them in whole or in part. The renewal in question is, doubtless, very largely due to the energetic advocacy of Dr. Emerson, and, although he has renounced what he had written in that connection, some of those who adopted his suggestions and supported his arguments still maintain the superiority of that photographic work in which indistinctness is the most promising characteristic, and do so with an aggressiveness and an assumption of artistic excellence that seems likely to induce a good deal of acquiescence, especially amongst the newer and less experienced amateurs, who are only too likely to be persuaded that the dimness and indistinctness which are so easy for them to produce, are something more artistic than the class of work with which they would find it harder to compete. These loudly asserted claims of artistic superiority seem, too, to have induced a certain amount of acquiescence among a larger class, photographers often submitting too readily to what claims to be artistically authoritative. It is not easy otherwise to account for medals being awarded to photographs which, independent of the question of indistinctness, one might have expected to be debarred by heavy artificial printing down of skies, a printing down which, in some cases, involves the confusion of such objects as would in nature, in painting, and in simple true photographs, stand out in decided relief against the aerial background.

The claim to artistic superiority for "soft" over "sharp" photographs depends, as has been previously pointed out, very much upon the different meaning attached to the word "sharp" by painters and by photographers, the latter understanding the word to mean minutely defined, and the former harsh in outline. Softness and thorough sharpness, in the photographic sense of fine definition, are quite compatible in a photograph in which, by extreme care in exposure and development, and, when necessary, by the use of orthochromatic methods, the gradations are properly rendered. It is, no doubt, easier to obtain a fictitious kind of softness by losing definition, but to claim a monopoly of artistic merit for this kind of softness seems to be about as reasonable as it would be to do so for those productions of the brush in which the badger softener had been freely employed by the painter.

As an example of the assumption of the monopoly of artistic merit by the professors of the indistinct school, and of the unworthiness of those who do not share in their views, may be mentioned the remarks of Mr. Maskell at the Camera Club Conference on the paper by Mr. Pennell. The last-named writer had condemned photography as false in representation, and as a hindrance rather than as a help to art; and Mr. Maskell replied to the effect that he could assent to these charges if applied to photography as practised until quite recently, but that some of the productions of the last two or three years—naming those workers who belong to the same school of indistinctness that he does—were of so different and superior a character that Mr. Pennell's criticisms were no longer justified. This assumption was more irritating than Mr. Pennell's easily refutable statements as to the inaccuracy of photographic perspective and other condemnations of our art. So, then, works such as those of England, Gale, Wilson, Robinson, Frith, Valentine, Bedford, Abney, Pringle, and hosts of others, English and foreign, are all to be rejected as fit for the denunciations heaped upon photography by Mr. Pennell, and only those of the circle to which Mr. Maskell belongs are useful to the draughtsman or worthy of anything but condemnation.

Then, again, Mr. Davison, at his lecture on "Impressionism in Photography," at the Society of Arts, spoke of those who had smirched photography by taking photographs sharp all over, and printing them on albumenised paper. That is to say, that those who have been recognised as the ablest workers are set down as having "smirched" photography by producing works in which the details and gradation of tone visible in the natural scene are, as far as practicable, reproduced in the picture.

With regard to the true rendering of gradation or tone, it may be remembered that Dr. Emerson particularly insisted upon preserving it as far as possible with the photographic means available. In this point he was at one with Abney and others, and I understand it to be the one point in his teaching which he did not renounce. By such devices as sunning the whole of the print—tending to indistinctness of another kind than that resulting from want of focus—and insisting upon matt surface, and even upon rough-surface paper for printing upon, the range of gradation, already insufficient in photography, is weakened, and truthfulness of representation to some extent sacrificed. An out-of-focus photograph, printed on rough paper, may suggest an unfinished sketch by a painter, but is not on that account really entitled to be called artistic, however loudly such a quality may be claimed for it.

Concerning such an essentially artificial (not the same thing as artistic) practice as sunning a photograph all over, Mr. Davison says (*Photography*, April 3, 1891): "It struck us at the last Pall Mall Exhibition that nine-tenths of the photographs collected there would have been less objectionable for a judicious sunning down, even if applied all over the prints." To set down nine-tenths of the work of one's co-exhibitors as "objectionable," from one cause alone, seems to me to be characteristic of that assumption of superiority by the professors of the cult of indistinctness, to protest against which is the object of the present paper. The remedy or palliative treatment prescribed will probably strike most people, besides the producers of this condemned nine-tenths of the work, as being itself objectionable.

Pretensions to artistic superiority are not necessarily justified in proportion to the dogmatic way in which they may be put forward. Gloom, mist, and indistinctness do not exhaust the beauties of nature, and are not its only phases worthy of representation, although in photography they may be the easiest to suggest, whether existing in the original subject or not.

---

MESSRS. PERCY LUND AND CO., of Bradford, have been clever enough to find out a use for spoilt negative glasses. They are supplying, in boxes, at a cheap rate, "Vista" mounts for different sized plates. These consist of cut-out mounts in ornamental paper, which, by an ingenious device, form elegant frames for photographs when attached to, or merely placed behind, the cleaned negative glass. There are twelve mounts in the half-plate boxes, and twenty in the quarter-plate boxes, and amateur photographers were so quick to note their advantages that upwards of one thousand were sold directly they were introduced.

### Specifications Published.

1,388. *January 27th*, 1890.—"Exposure Calculator." A. Watkins, Imperial Flour Mills, Hereford.

This consists of an apparatus on the principle of the slide rule for calculating the time of exposure to be given to a photographic plate. The time is calculated by multiplying together four factors, representing the actinic force of the light, A, the sensitiveness of the plate, P, the colour of the object and its distauce from the lens, S, and the relation of the diaphragm of the lens to its focal length, D. For multiplying these factors six rings, *g*, *h*, *i*, *j*, *k*, *l*, are fitted on a tube, *a*, the outer rings, *g* aud *l*, being fixed to the ring, while the other four can be rotated upon it. The ring *g* is marked with a scale for A, the ring *h* for P, the ring *i* for S, the ring *j* for D, the *l* with a scale of seconds for time of exposure, or result of the calculation. Inside the tube is fixed an actinometer, consisting of a strip of sensitive paper, which is exposed till it attains a standard tint for determining the value of A. The time for the apparatus is measured by a pendulum cousisting of the cap of tube suspended by a chain. In a modified form discs are used instead of riugs.

1,394. *January 27th*, 1890.—"Levels for Cameras, &c." G. J. Heaton, 2, Coburg Villas, Albert Road, Wiudsor.

Within a metal pillar, preferably square in section, is fitted a glass tube, a fixed rod, and a movable rod, which latter is suspended by a fibre of silk, &c. Wheu the iustrument is in a true vertical position, the two rods are in line. In a modification which is adapted for use in connection with photographic cameras, the glass tube is fitted with cups at the top and bottom, which are secured to a backing which is attached to the swing-back of the camera.

1,412. *January 27th*, 1890.—"Lamps." T. Bergmann, Eisenwerke Gaggenau, Gaggenau, Germany.

*Gas Lamps, Incandescent.*—The heating power of the flame is increased by supplying oxygen through a pipe to the ceutre of the gas-burner. Incandescent material is supported between two jaws, and can be adjusted relatively to the burner by a rack-and-pinion. Several of the burners may be used to form a cluster.

*Gas-Cocks.*—The cock has two passages for the passage of the gas and oxygen respectively. The relative proportions of the gas aud oxygen supplies can be regulated by set screws.

1,715. *February 1st*, 1890.—"Film-changing Apparatus." M. A. Wier, 9, Strand, London.

The camera may or may not be of the detective type, aud is fitted with a film-changing apparatus in the rear part of the dark chamber. One form of this apparatus is shown. The films, which are furnished with backings of uon-actinic paper attached to one edge, or separate backings of cardboard, are contained iu a box. After exposure, the front film is raised by a frame till the upper edge is caught between a band and roller, and is carried round aud deposited at the back of box as the band is wound off the spring roller on to another roller. The plates are pressed forward into focus by a screw, and the exposed plates are separated from the unexposed by a movable partition. When a separate opaque backing is used between the films, it may be used as a focussing screen before it is transferred to the back. Several modified forms of the change-box are described. Two rollers may be employed to increase the distance the plate is carried back, and the frame and push may be worked automatically from the transferring mechanism instead of separately by hand as in the case described.

1,791. *February 3rd*, 1890.—"Advertising and Magic Lanterns." A. Champness, 1, Stockfield Road, Tulse Hill, Surrey.

Advertisements are reflected on water, such as the sea, streams, &c., or on vapour, or the clouds, by a magic lantern as represented. Stencil slides may be used.

2,023. *February 7th*, 1890.—"Photographic Camera for Enlarging." W. Griffiths, Highgate Square, Birmingham.

*Enlarging.*—The body of the enlarging camera is made of metal, millboard, or other suitable material. A frame for carrying the negative fits telescopically in one end of the camera box; in the other end is fitted a dark slide having a plate of clear glass fitted in it to support the sensitive plate or film, and also for focussing purposes. The focussing screen is formed by pressing a piece of ground glass against the surface of the clear glass, this, after focussing, being removed for the insertion of the sensitive plate or film. The enlarging lens is fitted in a central frame or partition which, for focussing purposes, is fitted so as to slide telescopically in the camera box.

2,034. *February 7th*, 1890.—"Combined Tripod and Walking Stick." A. G. Rider, 11, Jewry Street, Winchester, Hants.

Each leg of the tripod is cut through for about one-third of its length, so that it can spring open to fit on the tripod top. The lower third of the leg is made to turn on a pivot, so that it can be extended or folded up. When the pivoted sectiou is extended, it is held in positiou by a notch on one end, which is slipped on to a fixed stud. When the legs are folded up and fitted with ferrules, they form a walking stick.

# Proceedings of Societies.

### Holborn Camera Club.

At last Friday's meeting of the Holborn Camera Club, Mr. T. O. Dear in the chair, Mr. E. Clifton gave a few hints on the method of finishing the negative. He had fonnd that amateurs took a great deal more trouble in developing their negatives than professionals, but in fixing and washing they reduced the careful developing to *nil*. While the print was in the fixing bath they would look at it every now and again and admire; the air, acting upon the silver, caused the film to turn a sickly yellow, and the result was flat negatives. Speaking of the final washing, he said a negative not thoroughly washed was very liable to damp, to say nothing of fading and kindred evils. He finished his hints by some remarks on reducing and iutensifying.

An interesting discussion followed, chiefly on reducing and packing of exposed plates ou a tour.

### North Middlesex Photographic Society.

*July 13th.*—Mr. H. Smith in the chair. This being the opening night of the new session, the meeting partook somewhat of the nature of a conversazioue. Objects of iuterest were passed round for inspection. The new patteru Thornton-Pickard aud the automatic time and instantaneous shutters were shown and thoroughly discussed. Cameras were shown by Mr. Braine and Mr. Gill. An ingenious printing frame to be used in combiuatiou printing, or for makiug lautern slides by contact from selected portions of a larger negative, was shown by the president.

The usual competition of views taken at the Society's field-days was then held; Mr. H. Smith received the vote of merit for views taken at Endfield and High Beech, and printed on "Celerotype" paper.

The president, Mr. J. W. Marchant, then addressed the members, pressing upon them not to hoard up knowledge, but to impart it freely to each other, and upon those beginning the study of photography to make known their difficulties, and to ask for information.

Four new members were elected.

---

Sydenham Camera Club.

*July 7th.*—The President in the chair.

A paper on "Home Portraiture" was read by Mr. J. Goldfinch, in which some valuable suggestions were given as to the lighting of the subject. He mentioned that a plaster bust was a very good object to try effects of lighting on, as it could be placed in whatever position wished, without tiring the sitter. He also went fully into various dodges to be resorted to in default of a studio, described the lens and camera, the best plates and developers to use, backgrounds, &c.

---

Hackney Photographic Society.

*July 9th.*—Mr. Beckett in the chair.

Mr. B. Foulkes Winks read a paper on the "Details of Silver Printing," going through all its stages from sensitising the paper to the mounting of the finished print.

Saturday, July 11th, was a hand-camera day down the river.

---

Sheffield Photographic Society.

*July 7th.*—Mr. B. J. Taylor in the chair.

After routine business, Mr. T. J. Hibbert brought for inspection the automatic hand-camera by G. Houghton & Son, fitted with one of Wray's lenses. Several members brought copies of prints taken at the recent excursion to Lincoln. Mr. E. Beck then gave a practical demonstration on "Platinotype Printing" by the hot-bath process.

It was arranged to have Saturday afternoon excursions as heretofore.

---

Oxford Photographic Society.

On July 7th the new rooms of this Society were opened, and will remain open each day, except Sundays, from 10 a.m. till about 9 p.m., for the members' use. There are already numerous photographic papers and books on the table, and it is hoped that the walls will soon be covered with photographs.

It is requested that all communications for the Society be addressed to the Hon. Secretaries, Photographic Society, 136, High Street, Oxford.

---

Photographic Club.—Subject for July 22nd, "Salting and Sensitising Photographic Papers"; 29th, "Developing en route." Outing on 18th at Welwyn; train from Moorgate Street at 2.15.

Phosphorescence of Minerals.—Various forms of fluorspar from various sources were excited by light, heat, and the electric spark, and the spectrum of the phosphorescence was examined. Measurements of the wave-lengths of the bands are given. In the phosphoroscope, the bands that are visible or have the highest intensity vary with the speed of rotation of the disc, a result due, according to the author, to differences in the persistence of the phosphorescence of the various substances that are present in the fluorspar, and give rise to the different spectra. The electric spark excites phosphorescence in the same way as sunlight, and the spectra are the same. The effect is more intense with the spark than with sunlight, probably because of the high proportion of rays of high refrangibility in the former. When fluorspar is heated, a limited quantity of energy is set free in the form of luminous vibrations, but if the heating is continued the phosphorescence ceases. It can, however, be restored by exposing the substance to light or the electric spark. The bands in the spectrum, when the substance is heated, have the same positions as in the phosphoroscope, but they have different relative intensities. The relative intensities also vary with the temperature. Phosphorescence under the influence of heat belongs, in fact, to the same class of phenomena as phosphorescence excited by light.—*Compt. Rend.*

## Answers to Correspondents.

**All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.**

**All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.**

**Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.**

C. A.—*Question of Copyright.* In the case which you put to us, the wholesale piracy of a series of copyright portraits in the manner indicated is clearly not lawful; but it might be possible to arrange for the assignment on easy terms, for your special purpose, of the copyright of the individual photographs composing your group, particularly as they would have to be reproduced on a much smaller scale. But the fact remains that a *copy of any size* is held to be an infringement of the owner's rights. The law of the case is clearly defined in Mr. C. Fleetwood Pritchard's article on page 87 of the Year-Book.

F. D. T. (Edinburgh).—*Collodio-Chloride Emulsion.* The cellular structure of your collodion films possibly arises from the circumstance of their containing too much extraneous salt—the by-product of double decomposition, sodium nitrate, &c. To overcome this defect, it would be advisable to emulsify a ready-formed chloride, or wash the emulsion as practised in the case of gelatino-bromide. The use of a highly glazed enamelled paper might enable you to succeed even with your existing preparations, but the other course is preferable.

O. C. (Bournemouth).—*Litho Presses.* We are sending you the address of a London firm from whom they can be procured.

L. R. C. (Whitchurch).—*Photo. Enamels.* Messrs. Sharpus, McCullum, and Co., of Cockspur Street, Charing Cross, will supply them.

St. Mungo.—*Silver Residues.* Salt will precipitate the silver from print washings; but all the waste hypo solutions should be mixed together and treated with *hepar sulphuris* until all the silver is thrown down as sulphide; best done on the roof or out of doors. Collect on a filter and send to the refiner, or reduce it by fusion with carbonate and nitrate of soda.

H. B. G.—*Sulphuration of Prints by India-rubber.* The practice of laying vulcanised rubber against the surface of silver prints, wet or dry, is not to be recommended, for the least trace of sulphur or sulphides is apt to cause a dark stain, as it will do even in the case of silver coin. The advice given in the printed account (keeping prints flat) is very good, with exception of this one particular.

Bradford.—*Oldfield's Multi-Colour Apparatus.* The specimen sent out with the prospectus is satisfactory, and reference is made to Patent Specification No. 9,302, A.D. 1889, from which you can doubtless gather further particulars. The invention has, however, nothing to do with chromo-photography, unless you can establish such a connection.

M. W. (Colchester).—*Photo-Training.* Spotting and mounting, book-keeping or reception-room duties, and even printing, is sometimes undertaken by ladies. You might offer to give time in return for instruction in these branches, and, when competent, you can of course submit your qualifications by advertisement. Second letter received.

C. N. & Co.—*Yellow Marks in Printing.* The most fertile source of such defects as those shown in your print is the injudicious handling of the paper in the early stages by fingers contaminated with hypo. We do not think they are due to bubbles or matting in the fixing bath.

F. I. C.—*Some Recent Advances in Photography.* The lecture recently given by Mr. C. H. Bothamley at the meeting of the Nottingham Section of the Society of Chemical Industry is reported in the current number of the official *Journal.* It deals chiefly with the primuline, Feertype, and kallitype processes, and their latest modifications.

# THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV.—No. 1716.—*July* 24, 1891.

CONTENTS.

## HOW GAS CYLINDERS ARE MADE.

The supply of compressed gas in metal cylinders has now assumed the proportions of an important industry, more especially since it was found possible, by the Brin process, to obtain oxygen direct from the atmosphere. The industry is not exactly a new one, for carbon dioxide and nitrous oxide (the latter for the use of dentists) have been supplied in a compressed state for many years. Now, with the creation of the modern amateur photographer who can make lantern slides, and the more general adoption of the optical lantern for purposes of demonstration and amusement, there has arisen a demand for the limelight such as was never experienced before, and as the limelight is dependent upon the two gases hydrogen and oxygen for its support, these gases are now supplied in large quantities commercially. At first the gas cylinders were made of wrought iron; they were cumbrous and heavy, and the pressure of the enclosed gas was so low that a receptacle to hold only ten feet was a most unwieldy concern. But times have changed, and a cylinder of about the same size, but half the weight, is now made to hold four times the quantity of gas at the enormous initial pressure of 1,800 pounds on every square inch. This means the pressure which an ordinary locomotive boiler has to withstand multiplied by twelve. The change is due to improved methods of manufacture, and to the employment of mild steel of special quality in lieu of the wrought iron previously employed. The cylinders are now made without joint or seam, and the process of manufacture is most interesting. A short time ago we had an opportunity of watching the various necessary

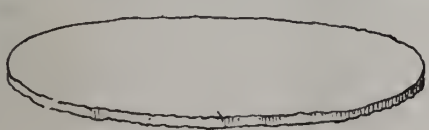

*Fig.* 1.

operations involved in making these cylinders at the Birmingham works of Messrs. Taunton, Delamard, and Co., by whose courtesy we were enabled to make notes of the process.

Beginning with the raw material, we were shown a disc of metal like that shown in fig. 1, and measuring thirty inches in diameter and three-quarters of an inch in thickness. From such a "blank" a cylinder destined to hold 100 feet of compressed gas can be constructed, and the first operation is to heat the "blank" in a furnace, and afterwards to stamp it into the cup-like form shown in fig. 2. To all intents and purposes this represents the end of a finished cylinder, but it is far too bulky to form the end of one of the size indicated; indeed, it in reality contains enough metal to make the entire vessel. By a series of operations it is now heated and drawn out longer and longer, while its thickness diminishes and its diameter grows less. These operations are carried out by means of a number of hydraulic rams which regularly decrease in size. Fig. 3 roughly represents one of these rams with the plunger ready to descend and force its way into the partially formed red-hot gas cylinder, C, and further into the well, W. The plunger may be compared to a finger, and the cylinder to a glove, while the well may represent a hole into which both are thrust in order to reduce the thickness of the glove. With huge tongs the cylinder, fresh from the furnace, is placed in position, but just before the plunger presses into the red-hot cup one of the workmen empties into the latter a little water, so as to partially cool the bottom and prevent it being thrust out by the powerful plunger. Oil is also used plentifully, so

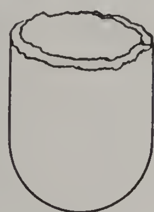

*Fig.* 2.

*Fig.* 3.

that as the plunger works slowly down the red-hot mass, it is surrounded by smoky flames. It presently forces the cylinder into the well, and when the end of the stroke is reached, a stop piece is inserted through an opening in the upper part of the well, so as to arrest the edge of the cylinder while the reverse action of drawing out the plunger is proceeded with. Directly the finger is drawn out of the glove—in other words, immediately the plunger is raised out of the cylinder—the latter drops down below with a heavy thud, still in a red-hot condition.

This operation of hot drawing is repeated again and again in rams of diminishing size until the cylinder assumes the diameter and length required. This hot drawing leaves the surface of the metal marked with longitudinal lines, not unlike the glacier scratches on a rock, albeit they are straighter and more regular. But the next operation not only obliterates these markings, and gives the metal a smooth surface like that of polished silver, but it also confers upon the material a homogeniety which it did not before possess, and without which it would never bear the pressure which it is destined to withstand when finished. This operation consists in a final application of the hydraulic ram while the metal remains perfectly cold, instead of red-hot as in the previous cases.

As a result of these various hydraulic operations, we have a perfectly formed cylinder closed at one end, and we now follow it into another department of the works, when its open end is once more brought in a furnace to a red heat. The object of this is to make the metal soft while the shoulder and neck of the vessel are formed.

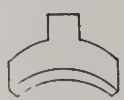

*Fig. 4.*

To accomplish this, the heated open end of the cylinder is laid horizontally upon a kind of semi-circular cradle, and is held there by tongs handled by two men. Another workman places over the open end a die of the form shown in fig. 4, and while the cylinder is slowly turned round in its cradle, two sledge hammers are brought down with frequent blows upon the die, closing in the end of the cylinder, but leaving a central hole as shown in fig. 5. Further operations reduce the opening

*Fig. 5.*

*Fig. 6.*

still more until it is closed altogether, and a projection is formed as shown at fig. 6. This projection is now bored through, and the cylinder is ready for testing.

The cylinder is submitted to a water test, the liquid being forced in until the gauge shows a pressure of two tons to the square inch. Cylinders have been known to give way under this ordeal, but without any dangerous consequences. The metal simply rips up, making a report at the moment of fracture as loud as a gun. The wonderful strength of the metal employed may be gauged by the circumstance that the walls of the cylinder designed to hold 100 feet of gas are only $\frac{5}{16}$ of an inch in thickness.

During the manufacture of the cylinder, as we have already indicated, much oil is used, and, so far as steel can be saturated with that fluid—in the popular sense—the metal is in that state. It is essential that this oil should be completely got rid of, and this is carefully done before the cylinder is charged with gas. Previous to such charging, the vessel has to be fitted with its valve. Of these valves there are three kinds, known respectively as the Brin, the Birmingham, and the Manchester. Each has its admirers, but we cannot here discuss their individual merits.

The charging of the cylinder is brought about by a powerful pump having three cylinders so arranged that the compressed contents of the first cylinder are still further compressed in the second, and still more highly in the third. The filling of a 100-ft. cylinder occupies about half-an-hour.

## THE "OPTIMUS" WORKS.

By the above title the workshops of Messrs. Perken, Son, and Rayment may fairly be called, for "Optimus" is their well-known trade-mark, and it is evident to the most casual visitor that they make every possible effort to turn out "the best" work. Such a visit did we pay to this enterprising firm a week back, and we saw much that was interesting, and work which involves the patient fashioning from the raw materials of such delicate instruments as cameras, lenses, optical lanterns, and all the multifarious things which are constructed for the aid of the modern photographer, cannot fail to be of interest to the spectator.

The premises occupied by this firm are very extensive, and comprise a series of workshops fitted with every appliance for cabinet making, at Saffron Hill, and the main building at Hatton Garden, where the lenses are ground, and where various other operations are carried on with a large staff of workmen. Visiting first of all the cabinet works at Saffron Hill, we are shown, stored in the lower part of the premises, a large stock of wood, which, however, represents only that required for present needs. On the second floor are cutters, vertical and horizontal, circular saws, and planing machines. It is here that the various parts of the cameras and wooden bodies of the lanterns are cut out—one can hardly say in the rough, for everything is done to guage, and the fine grooves, the rebates, and other shapes are cut to the greatest nicety, and far more accurately than they could be done by hand tools.

The making of a camera is no longer, as it was twenty years ago, such a simple affair that any carpenter can turn one out. In those days, one box sliding within another with something like accuracy, and a screw to hold them together, was all that was either looked for or required. Rising fronts, swing-backs, leather bellows, rack-work, and all the other niceties of the present machine were undreamt of. But now that the camera has grown from this primitive form into what may be described as a delicately adjusted philosophical instrument, a different race of workers has become necessary for its manufacture. With the old workmen have been discarded many of the old tools, and, indeed, it would be difficult, if not impossible, to make a modern camera with the old appliances. A new system has, in fact, come into vogue with the introduction of the revolving cutter, which can be set to cut grooves of any width or depth with an accuracy formerly unknown. The same principle is seen in the planing maching, when a slab of rough wood passed beneath a roller comes out at the other side with a smooth surface showing all the beautiful figure and grain of the material. All these aids to camera construction, with others too numerous to mention, are seen in this busy workshop.

In an adjoining department we find the French-polishers at work, each man having before him piles of unfinished bodies of cameras, and working upon each in turn, for good polishing requires that the wood should be left for a time between the various stages, so that the spirit in the polish shall partly evaporate, or that the ground layer shall have time to sufficiently soak into the wood before it is farther worked upon.

Proceeding to the floor above, we find that wood has given place to metal, for here about a dozen lathes are at work turning out such parts of the metal work of cameras and lanterns as can be fashioned in the lathe. These would, of course, comprehend the mounts of lenses, from those intended for 12-inch condensers for enlarging lanterns, to the humble quarter-plate size so dear to beginners. Here also we see a brass rack-cutting machine, and various other appliances for saving labour. All the metal fittings of cameras are made here, from the solid turntable to the smallest hinge—the cameras ranging in size from 36 by 30 (used principally by photo-mechanical workers) to the handy detective, of which favourite type we are shown many varieties.

Repairing now to the main building in Hatton Garden, we are taken first to the lens-grinding department, where we watch the various operations, from grinding and shaping with coarse emery, to the final delicate polishing. We also see how the component parts of a lens are joined together—never to be divorced—by a drop of viscid Canada balsam, and, after a baking operation, are carefully tested to see that the two glasses are central with one another. Here, too, we see how the diaphragms are made, and carefully cut to gauge.

We next visit the tin-workers' shop, not a very busy department at this season, for here lantern bodies and linings are chiefly made, and the time for such things does not set in until the fall of the year. There is machinery here of the most ingenious design—and far too elaborate to be described in the limits of a short article—for stamping, cutting, and bending sheet metal.

Before leaving the premises, we have a glance at the noble array of cameras displayed in the principal showroom. All sizes up to 15 by 12 are kept in stock; but it is found inexpedient to make larger ones except to order, for persons giving such orders have generally special ideas to be carried out, which might not commend themselves to all purchasers. We notice a new form of enlarging apparatus here with double bellows, the condenser situated midway. This arrangement saves woodwork and space. Each bellows is fitted with the patent focussing screw peculiar to this firm, which can be thrown out of action by pressure, and with which all the best cameras manufactured by Messrs. Perken, Son, and Rayment are fitted.

---

CLEVELAND CAMERA CLUB.—We are advised that Mr. Joseph J. Hallam has been appointed honorary secretary to the above Club.

## THE PHOTOGRAPHIC WORK OF HERSCHEL AND FOX TALBOT.*

BY WILLIAM LANG, JUN., F.C.S.

THE fourth division of the paper is occupied with what the author calls the chemical analysis of the solar spectrum. It would be beyond the limits of this communication to go further into all the experiments and speculations recorded in this classical memoir. The paper occupies sixty pages of the printed Transactions of the Royal Society, and it may be regarded as the foundation stone on which subsequent researches and experiments have been reared. One of the Society's medals was awarded to the author for this contribution to science.

The eleventh meeting of the British Association was held at Plymouth in July, 1841. Herschel, on that occasion, addressed a letter to the Physical Section accompanied by fifteen specimens of coloured photographic copies of engravings and mezzotints, "the whole" (as the writer puts it) "being tinted with substances of vegetable origin, variously prepared."

In the following year, viz., 1842, another memoir was presented to the Royal Society, "On the Action of the Rays of the Solar Spectrum on Vegetable Colours, and on some new Photographic Processes." Although appearing in the Philosophical Transactions as one contribution, there were originally three papers read before the Royal Society, the respective dates of which were June 16th and November 17th and 24th. The memoir is a continuation of the one given in 1840. Elaborate experiments with gum guiacium and expressed juices of flowers are first given in detail, and these are followed by others where the salts of iron have their reactions studied, the outcome of which we have in the two photographic processes known as chrysotype and cyanotype. Briefly stated, the first-named consists in coating paper with a solution of ammonia-citrate of iron, exposing to light, and afterwards developing with a solution of gold chloride. Some specimens thus prepared are here by way of illustration. The fixing of chrysotype was effected by means of potassium iodide. The reduced iron compound can also be rendered apparent by means of a solution of silver nitrate. A print thus produced is here for inspection. Cyanotype is perhaps better known to most of us as the blue process. In this method, development is effected by means of a solution of potassium ferricyanide, red prussiate of potash. The memoir closes with some experiments bearing on the photographic properties of mercury.

In these early years of the photographic art the *Athenæum* was in the habit of reporting matters appertaining to photography. In consequence of some discrepancies in the account given by this paper of the foregoing discoveries, we find a letter from Herschel making the necessary corrections. The letter, dated 10th August, 1842, appears in No. 773, p. 748, of the *Athenæum*.

Professor Draper, of New York, having, towards the end of the year 1842, presented Herschel with a Daguerreotype impression of the solar spectrum, the latter, in acknowledging its receipt, contributes to the *Philosophical Magazine* an article entitled "Action of the Rays of the Solar Spectrum on the Daguerreotype Plate." From it we learn that Herschel had himself been experimenting in securing spectrum impressions on Daguerreotype plates, and, although he admits that his manipulation was not all that could be desired, still his results were such that

* Continued from page 510.

comparisons could be instituted between Draper's plate and his own. The whole tenor of the paper is philosophical, and occupies twelve pages of volume xxii. of the journal already referred to.

At the Cork meeting of the British Association in August, 1843, a paper was communicated by Herschel: "Notice of a remarkable Photographic Process by which Dormant Pictures are produced capable of Development by the Breath, or by keeping in a Moist Atmosphere."

In the Philosophical Transactions for 1843 we find another memoir contributed to the Royal Society: "On Certain Improvements in Photographic Processes described in a former communication, and on the Parathermic Rays of the Solar Spectrum." This communication was made on 24th November, and is, in effect, a continuation of the two former memoirs, the numbering of the paragraphs running continuously throughout.

At the York meeting of the British Association, held in September, 1844, Herschel announced a new photographic process, to which he gave the name of amphitype, a term suggested by Talbot, in consequence of the picture, according to the method adopted in the subsequent manipulations, becoming either a positive or a negative reproduction. It may be here remarked that Herschel, in all these experiments, seems to have used engravings instead of the ordinary negative. Herschel, from his researches, had realised the fact that silver bromide was more sensitive to light, or, rather, that it was affected by a wider range of the rays forming the solar spectrum, than silver iodide, which formed the staple of Calotype, and afterwards that of the collodion process. Accordingly, when the Photographic Society of London was formed, in 1853, among the first contributions to its transactions we find one from Herschel, "On the Substitution of Bromine for Iodine in Photographic Processes." This paper was read 2nd June, and I may be allowed to quote one pregnant sentence from it, which may almost be regarded as prophetic—"A new photography has to be created, of which bromine is the basis." In 1855 Herschel advocated the desirability of securing daily photographic representations of the sun. The original communication was read before the Astronomical Society, and will be found in the volume for 1854-55 of the monthly notices of the Society. It is also to be found reported in the *Athenæum*, in No. 1,435.

In 1858, at the Leeds meeting of the British Association, Herschel presided over section B, the chemical, and his introductory remarks, so far as they relate to our own science of photography, may be appropriately quoted. The words used by Herschel in 1858 are no less significant in our own day:—

"Hitherto the more attractive applications of photography have had too much the effect of distracting the attention from the purely chemical question which it raises, but the more we consider them in the abstract, the more strongly they force themselves on our notice, and I look forward to their occupying a much larger space in the domain of chemical enquiry than is the case at present."

The same sentiment regarding photography has been otherwise expressed by Major Russell, who is credited with having said that photography would be a most interesting subject were it not for the pictures.

In 1859 an article from Herschel appeared in the second volume of the Photographic News, in the number for July 22nd, "The Action of the Solar Spectrum upon Certain Compounds of Silver," and in the third volume of the same paper, in the number for September 9th, under the same title, a further communication is to be found. This article has an accompanying illustration of the apparatus employed by the author in securing his spectra impressions.

In the Photographic News of May 11th, 1860 (Vol. IV.), Herschel contributes an article, "Instantaneous Photography." He discusses the possibility of taking a rapid series of pictures of moving objects, and recombining them in the optical apparatus, the phenakistiscope. The appearance of motion is again imparted to the eye when the pictures are rapidly revolved. This method, as you are all aware, has been adopted by Muybridge. A term is used by Herschel in this communication which, although common enough now-a-days, is very significant, and describes well the taking of an instantaneous picture. I refer to the term snap-shot. I make the statement subject, of course, to correction, but I think we may give to Herschel the credit of coining this photographic term for us equally with the better known terms of positive and negative.

In 1861, in the eighth volume, p. 384, of the *British Journal of Photography*, Herschel contributes an article, "Forms of Lenses suited for Destroying Spherical Aberration."

The foregoing represents an epitome of the work done by Herschel. We will now consider Talbot's share in the development of our art.

Talbot's experimental photographic work appears to have been begun about the year 1834. By means of paper impregnated with silver chloride, Talbot asserts that he had secured camera pictures of his residence as early as 1835 (*vide* appendix to second addition of "Tissandier's Photography," written by Talbot). It was not, however, till January 25th, 1839, at one of the Friday meetings of the Royal Institution, that the process was first publicly announced, and as Faraday, who brought the matter forward, explained, it was done so for the purpose of "establishing a date." Daguerre's process had been announced in January, but the particulars were only known to his friend Arago. Talbot had in the meantime sent in a paper to the Royal Society, and he was afraid that Daguerre's process might be divulged before his communication to the Royal Society was published. On the Thursday following, however—viz., the 31st January, 1839—Talbot's paper, entitled "Some Account of the Art of Photographic Drawing; or, the Process by which Natural Objects may be made to Delineate themselves without the aid of the Artist's Pencil," was read. The paper was not published in the "Philosophical Transactions," but an abstract of it is given in the "Proceedings of the Royal Society," vol. iv., p. 120. It was printed *in extenso* in the *London and Edinburgh Philosophical Magazine*, March, 1839, vol. xiv., p. 209. Both at the Royal Institution meeting, and that of the Royal Society, specimens of "photogenic drawing" were exhibited, along with the camera pictures of Talbot's residence. On the 21st Feb., 1839, a paper, entitled "An Account of the Processes Employed in Photogenic Drawing," was communicated to the Royal Society. The memoir divides itself into two parts, first the preparation of the paper, and secondly the fixing of the design, which was effected by a solution of potassium iodide of the proper strength, or by a strong solution of sodium chloride. Talbot at this stage was doing little more than producing negative designs from opaque natural objects.

*(To be continued.)*

## AFFILIATION OF SOCIETIES.

The following circular has been issued by the Parent Society:—

50, *Great Russell Street, Bloomsbury, London, W.C.*

Dear Sir,—A general desire has for some time been expressed that some closer union of the photographic societies of the United Kingdom should be brought about for the better promotion of their common interests.

Taking this into consideration, a committee was appointed by the Photographic Society of Great Britain to examine the question and report upon it. By direction of the Council, a copy of this report I have now the honour to enclose you herewith.

Will you kindly bring the report, together with this letter, to the notice of your members on an early opportunity, in order to elicit their views upon the subject, and then let me know the result.—Yours truly, A. M. Mantell, Capt. R.E., *Hon. Sec.*

### Affiliation.

*Preliminary.*

On the 11th November last, a circular respecting the foundation of a photographic institute was approved of at the meeting of the Photographic Society of Great Britain, and at the next meeting was ordered to be forwarded to the photographic societies in Great Britain.

Replies from fourteen societies were received, and the whole question has been further considered by the council of the Photographic Society of Great Britain.

In the meantime, an independent scheme of federation was drafted, and invitations were sent to the London societies to send delegates to a meeting, at which the subject was to be discussed.

Some of the London societies nominated delegates, and a committee was selected to draft a scheme, which was done, but from the first there seemed a strong feeling in favour of the initiative being taken by the Photographic Society of Great Britain.

This committee of delegates, at its last meeting, dissolved itself, but with a renewed expression of opinion that the Photographic Society of Great Britain should definitely take up the question of affiliation, and an endeavour was made by the delegates present to pledge two members of the council of the Photographic Society of Great Britain, who were informally at the meeting, to take action in this direction.

The committee of the council of the Photographic Society of Great Britain appointed to consider the matter have constantly had the whole question before them, and, in view of these decided expressions of opinion, a preliminary report was submitted to the Society at the meeting on April 13th, which has since appeared in the photographic journals.

This report was of a tentative nature, intended to elicit the opinions of those interested.

The result has been a concensus of opinion that a closer union of photographic societies is desirable, and that the Photographic Society of Great Britain should take the lead in effecting it. Under these circumstances, the committee, which at first consisted of Sir H. T. Wood, Mr. Leon Warnerke, and Mr. G. L. Addenbrooke, was, by resolution of the council, further strengthened by the addition of Mr. W. Bedford, Dr. G. Lindsay Johnson, Mr. W. E. Debenham, and Mr. A. Cowan.

These gentlemen, having given the matter their careful consideration, have embodied their ideas in the following report:—

*Report of Affiliation Committee.*

*June 9th*, 1891.

Although it is now clear that there is no immediate prospect of carrying out the whole of the objects originally included in the scheme of the Photographic Institute, yet some of the advantages which the Institute was intended to confer on photographers could be secured by a scheme of affiliation to the Photographic Society of Great Britain, and this without any great expenditure either of time or funds, by utilising the machinery and facilities at the disposal of the Photographic Society of Great Britain.

As this matter concerns the advancement of photography and the benefit of photographers generally, the committee recommend that the Photographic Society of Great Britain should allow its rooms to be used as a centre, and should arrange the office work necessary for a federation of societies, as the secretaries of the Society occupy a position to conduct with advantage the correspondence and negotiations by which a system of affiliation may be established and worked. A subscription from affiliated societies, &c., will be necessary to cover the cost of clerical labour, postage, office expenses, &c., involved, and as a contribution towards publishing the Society's Journal, which would be supplied to affiliated societies, and would thus become the organ of the affiliation, in addition to its present purpose.

Affiliation would be by the Council of the Photographic Society of Great Britain. All affiliated Societies would have a voice in the management. Delegates appointed by the Societies should meet in London not less than once a year to determine the lines of action, and would appoint a permanent sub-committee to supervise affiliation work for the next year, and to carry out resolutions passed by the assembled delegates.

It is undesirable to hamper the initial stages of affiliation by too strict definitions or restrictions. As the movement is of a novel character it may be expected to develop itself in the best way as it goes along. As a preliminary step, however, the following prospectus has been drafted, which, with a copy of this report, it is proposed should be sent to all photographic societies to invite co-operation and support.

*Scheme of Affiliation.*

The object of affiliating all photographic societies is to promote co-operation with one another and with the Photographic Society of Great Britain for the advancement of photography, and for the promotion of mutual interests. The following desirable objects of attainment may be enumerated:—

1. Assisting societies in obtaining and interchanging lectures, papers, lantern slides, examples of good work, &c.
2. Facilitating the holding of local exhibitions.
3. Arranging for the provision and exchange of dark rooms for the use of members in local centres.
4. Extending the applications of photography to industrial purposes, and in such directions as local surveys, photographing and preserving photographs of ancient buildings, and architectural and archæological records.
5. Assisting scientific research in photography and kindred sciences.
6. Assisting the Photographic Society of Great Britain in its endeavour to promote photographic technical education.
7. Co-operating with the Photographic Society of Great Britain in securing a universal adoption of photographic standards for lenses, screws, size of plates, formulæ, &c.

To carry out these objects efficiently a united effort on the part of existing societies is essential.

The assistant-secretary of the Photographic Society of Great Britain, who will co-operate in carrying out this scheme, will be in attendance at the rooms of the Photographic Society of Great Britain every week-day (with certain exceptions to be arranged later on) from 2·0 to 9·30 p.m., and may be consulted by members of affiliated societies, and will also reply to any communications which may be addressed to him by the secretaries and members of affiliated societies.

The secretary will try to bring societies desiring lectures on particular subjects into direct communication with persons willing to lecture, and will be glad to receive, either as a loan or as a gift, interesting lantern slides, which may remain at his disposal, either permanently or for a time, so that they may be lent to Societies holding lantern exhibitions.

It is suggested that prize pictures and examples of processes might be collected, which would be at the disposal of societies and circulated amongst them, so that all members might have a chance of seeing examples of the best work from time to time; and this, it is hoped, would help to raise the standard of photographic work generally.

It is to be expected that affiliation will strengthen the Parent Society and the affiliated branches alike, to the advantage of photographic science and art ; to contribute to this common end, the Photographic Society of Great Britain offers to the members of the affiliated societies the following advantages :—

1. The use of its rooms and offices, 50, Great Russell Street, W.C., for the meetings of delegates forming the affiliation committee, and for the meetings of the sub-committee it may appoint.
2. The services of the assistant-secretary, and the provision of stationery, postage, &c., for the conduct of federal affairs.
3. Admission of members of all affiliated societies to courses of technical lectures, which the Photographic Society of Great Britain hopes to organise, at half the charges made to non-members.
4. The use of the dark room at 50, Great Russell Street, W.C., by affiliated members upon payment of a small charge for the use of chemicals.
5. Affiliated societies will be supplied with two transferable season tickets for the Society's annual exhibition.
6. Two copies of the "Journal and Transactions" will be supplied to each affiliated society.

The general rules now suggested are few and simple, but may serve as a basis for an approved code.

General Rules.

Affiliation shall be by the council of the Photographic Society of Great Britain.

All societies shall be eligible, whether London, Provincial, Colonial, or Foreign.

Each affiliated society shall be entitled to appoint a delegate, who, in conjunction with a certain number of members to be appointed by the Photographic Society of Great Britain, shall form the affiliation committee, with the right to vote in all matters in which the committee may deal.

The affiliation committee shall have power to nominate certain of their number to supervise and carry on the work of affiliation on such general lines as may meet the approval of the council of the Photographic Society of Great Britain.

The affiliation committee shall have power to make such laws as may be required for conducting the different branches of affiliation work.

The votes of the affiliation committee may be taken in writing on any important subjects which require decision between the annual meetings.

The annual subscription shall be one guinea, payable on election, in advance, on January 1st in every year. Any society whose subscription may be three months overdue shall cease to be a member of the affiliation, but may be reinstated by the council on satisfactory explanation and payment of arrears.

## SOME NEW ADDITION COMPOUNDS OF "THIOCARBAMIDE" WHICH AFFORD EVIDENCE OF ITS CONSTITUTION.*

BY J. EMERSON REYNOLDS, M.D., F.R.S., PROFESSOR OF CHEMISTRY, UNIVERSITY OF DUBLIN.

*Methyl and Ethyl-Ammonium Salts and Thiocarbamide.*—The general results of the experiments in this direction were unexpected, as it was found that methylammonium salts combine with thiocarbamide, but those of ethylammonium do *not* under any conditions yet realised. I shall first describe the experiments which led to the definite combination.

Three grams of pure methylammonium bromide were dissolved in the smallest possible quantity of strong alcohol, and added to a boiling alcoholic solution of 7·8 grams of thiocarbamide. Combination took place on continued heating, and the solution when cooled became nearly solid, owing to the separation of a felted crystalline mass very similar in appearance to that afforded by ammonium bromide and the amide under similar conditions. This product was pressed, washed, and recrystallised, and when so purified was found to melt sharply at 138°, or 35° lower than the melting point of the ammonium bromide compound (173—174°).

On analysis, it afforded the following results :—

0·427 gram gave 0·1915 AgBr.
0·3897 „ „ 0·8642 $BaSO_4$.

The compound is, therefore, $(H_4N_2CS)_4(CH_3)H_3NBr$, which requires—

| | Theory. | Found. |
|---|---|---|
| S ... ... | 30·76 per cent. ... | 30·48 per cent. |
| Br ... ... | 19·23 „ ... | 19·08 „ |

Methylammonium chloride gave a similar compound with thiocarbamide, but it was not examined in detail.

Experiments with ethylammonium salts led to negative results so far as direct union with thiocarbamide is concerned. Ethylamine from various sources was used in the preparation of the salts, and the conditions were varied to a much greater extent than in the previous experiments, but without effect.

As long continued heating to the boiling point of absolute alcohol under atmospheric pressure did not determine combination, 2·5 grams of the pure bromide and 6 grams of thiocarbamide were sealed up in a tube with sufficient alcohol to dissolve the whole at 70°. The tube and its contents were then heated at 110° for two hours, but on cooling no evidence of combination was obtained. The heating was repeated for three hours, but the temperature was maintained at about 135°. On cooling, the contents of the tube now became nearly solid, and the mass resembled the ammonium bromide compound in appearance. When the solid contents were twice recrystallised from alcohol, the product was found to contain bromine and sulphur, and it melted at 175—176°, or very slightly higher than the ammonium bromide compound which it so closely resembled in appearance, and on analysis it proved to be that body.

0·2056 gram gave 0·098 AgBr.
0·2732 „ „ 0 1285 $H_2O$ and 0·1245 $CO_2$.

| | Theory for $NH_4Br$ compound. | Theory for $NEtH_3Br$ compound. | Found. |
|---|---|---|---|
| Br ... ... | 19·98 p. c. | 18·60 p. c. | 20·28 p. c. |
| C ... ... | 11·99 „ | 16·76 „ | 12·42 „ |
| H ... ... | 4·96 „ | 5·58 „ | 5·22 „ |

The determination of carbon was made because of the wide difference in percentages of that element.

There is no doubt, then, that ethylammonium bromide and 4 mols. of thiocarbamide do not directly unite when heated with alcohol at 135°, but rather afford the ammonium bromide compound, with ethyl oxide as a necessary bye-product, according to the equation $4H_4N_2CS + N(CH_5)H_3Br + C_2H_5{\cdot}OH = (H_4N_2CS)_4NH_4Br + (C_2H_5)_2O$.

Summary of the Facts.

It has been shown that—

1. Thiocarbamide combines with ammonium bromide, iodide, and chloride at the temperature of boiling alcohol, and forms characteristic compounds of the type $(H_4N_2CS)_4H_4NR'$. But no compounds could be formed under the conditions specified which contained *less* than four molecular proportions of the amide to one of the ammonium haloïd salt.

2. The following mono- and di-substituted thiocarbamides failed to afford any compounds with ammonium

* Continued from page 509.

bromide at the temperature of boiling alcohol, viz.: methyl-, ethyl-, allyl-, phenyl-, diphenyl-, and acetyl-phenyl-thiocarbamides.

3. Thiocarbamide combines with tetrethylammonium bromide and iodide, and forms well-defined crystalline compounds of the type $(H_4N_2CS)_2Et_4NR'$. But no well-defined substance could be isolated under any of the experimental conditions containing more than 2 mols. of the amide and 1 mol. of the tetrethylammonium salt.

4. Thiocarbamide combines with diethylammonium bromide, and the well-crystallised compound $(H_4N_2CS)_3Et_2H_2NBr$ was separated. If a tetra-compound be formed in solution, it is certainly broken up on slow crystallisation.

5. Thiocarbamide also unites with triethylammonium bromide, and in presence of excess of amide a somewhat felted mass is obtained, which on recrystallisation affords two distinct crystals, namely, $(H_4N_2CS)_3Et_3HNBr$ and $(H_4N_2CS)_2Et_3HNBr$.

6. With methylammonium bromide, thiocarbamide afforded the compound $(H_4N_2CS)_4MeH_3NBr$, which resembles the corresponding ammonium bromide compound in appearance, but melts at a temperature 34° lower. On the other hand, with *ethyl*ammonium bromide no combination whatever could be effected, and when 4 : 1 mols. of the amide and salt were heated in a pressure tube with alcohol at 135°, ethyl oxide and *tetrathiocarbamidammonium bromide* were the products.

*Bearing of the Results on the Question of the Constitution of Thiocarbamide.*

Unless thiocarbamide is held to be a tautomeric substance, its constitution may be represented by either of the following formulæ, viz:—

α-Symmetrical ... .. ... ... $CS{<}^{NH_2}_{NH_2}$

β-Unsymmetrical ... ... ... $HN{:}C{<}^{NH_2}_{SH}$

Of late the evidence in favour of the latter constitution has been considerably strengthened, more especially by the careful work of Mr. Emil A. Werner carried on in my laboratory (see Trans., 1890, 57, 283). I shall now proceed to show that the facts recorded in the present paper supply evidence of a new kind, and altogether in favour of the β or unsymmetrical structure—at least under the conditions of my experiments.

The readiness with which ammonium bromide, iodide, and chloride form tolerably stable *tetra*thiocarbamide compounds—and only these—is evidently connected with the number of atoms of hydrogen in the ammonium haloïd, that is, with the valency of its nitrogen. This necessarily involves the idea of something in the nature of substitution. Moreover, the tendency to form complete and comparatively simple compounds of the order in question must be strong, since we have seen that ethyl is displaced by hydrogen when ethylammonium bromide and 4 mols. of thiocarbamide are heated to 135°, the stable ammonium bromide compound being then formed.

The fact that *none* of the mono- or di-substituted thiocarbamides combine with ammonium bromide under the usual conditions goes far to prove that neither the carbon nor sulphur of thiocarbamide are concerned in the linkage with the ammonium haloïd. It is admitted that alkylic or other radicles of substituted thiocarbamides of the types used are directly united with nitrogen; there is, therefore, no reason why the carbon or sulphur of the primary should be materially affected by such substitution. And further, in regard to sulphur, neither the di- nor tri-ethylammonium bromide compounds formed with thiocarbamide afforded mercaptan or alkylic sulphide, or their products, when heated to 100° with alkalis and alkaline lead solution, in these particulars differing materially from the action of addition compounds of thiocarbamides of the sulphine class.

On the other hand, the loss of power of combination with ammonium bromide when but one atom of hydrogen in thiocarbamide is displaced by a more positive radicle, such as ethyl or phenyl, is inconsistent with the symmetrical constitution of thiocarbamide, which should still have an $NH_2$ group unaffected and available for union; but is quite consistent with its unsymmetrical structure.* In the latter case, the two nitrogen atoms are differently engaged, and the genesis of a monosubstituted thiocarbamide from R·N:CS, and ammonia, points to the structure $R{\cdot}N{:}C{<}^{NH_2}_{SH}$ rather than $\dot{H}N{:}C{<}^{NHR}_{SH}$ for the product. Now the fact that combination takes place with facility between thiocarbamide and ammonium bromide, but not at all with ethyl- or phenyl-thiocarbamide, accords with the structure $RN{:}C{<}^{NH_2}_{SH}$, where the presence of the positive radicle in the imidic group paralyses the power of combination, which appears in consequence to be exclusively due to the NH of the substance we have been accustomed to term thio-carbamide. The ammonium bromide compound would therefore become $[NH_2(SH)CNH_2]_4NBr$; but whether union is effected by breaking the double linkage of carbon and NH, or the change of valency of the latter, remains for determination.

In the ammonium bromide compound, the attraction of the components seems to be at a maximum; but whilst substitution in thiocarbamide reduces it to zero, similar substitution in ammonium bromide (save in the case of the ethylammonium salt†) only lessens the power of forming tetra-compounds without destroying it. These facts seem to point to the development of quinquavalence in one of the nitrogen atoms of thiocarbamide in the course of combination.

I think the true "thiocarbamide" is yet to be discovered, and that we must revert to the name "sulphurea" or "thiourea" as the correct designation of the primary substance from which the above compounds have been obtained.

## BRUSSELS EXHIBITION.

THE following is a list of the awards to the British exhibitors at the Brussels Exhibition:—

Grand Diploma of Honour to J. Pattison Gibson, Hexham.

Silver gilt medals to F. P. Cembrano, Richmond; Lyd. Sawyer, Newcastle-on-Tyne; Col. Waterhouse, Calcutta; Walter Colls, and Window and Grove, London.

Silver medals to Wilson and Son, Aberdeen; Werner and Son, Dublin; W. Clement Williams, Halifax.

Bronze medals to J. Carpenter, London; J. Martin Harding, Shrewsbury; Morgan and Kidd, London; W. Winter, Derby; York and Sons, London; J. Luders, Cape Town; J. W. Ross, Cape Town; A. Hendrey, Godmanchester.

* From a somewhat similar point of view, the production of a tetra- rather than a di-thiocarbamide compound is inconsistent with the symmetrical structure.

† Whose non-combination may be more apparent than real if formed and decomposed at nearly the same temperature level.

## Notes.

Anglo-Indian photographers have lately been protesting in print against the prohibitive prices charged by local dealers. But it is easy to see that this protest would never have seen the light if there were not something still more serious to complain of. The dealers, it is said, are in the habit of supplying stale materials, so that a photographer who may have been at extraordinary pains to secure a picture at a distance from home will often find, on development, that the plate he has confidently used is good for nothing.

It is rather difficult to suggest a remedy for this state of things, unless it be that plates should be specially made for India, and packed under special precautions. This, of course, could not be done unless the amount of trade with India were much greater than it is at present. Or a plate factory might be established in India by some enterprising maker. Anyone who has had experience of gelatine plate making will know what uphill work this would mean in a climate such as that of India. Even in our own more temperate summer, plate-makers, as a rule, confine the work to the cool and early hours of the morning. In India it would probably be necessary to coat the plates in a refrigerating chamber, such as that common on ship board for the preservation of meat. The degree of cold required need only be sufficient to ensure the setting of the gelatine, and such a temperature could be secured at very little expense.

In order to prevent accident from admixture of the two gases hydrogen and oxygen, which, as everyone now knows, form such a terribly explosive compound, it has long been the custom in this country to paint hydrogen cylinders red, and oxygen cylinders black, and, as a further precaution, the hydrogen cylinder has a screw nozzle with a left-hand thread. It has lately been pointed out that in America the oxygen cylinders are painted red, and the hydrogen black, thus reversing the system customary on this side of the Atlantic. It is quite conceivable that accident might arise from American cylinders finding their way over here, or *vice versa*, and it would be far better that we should agree upon some uniform manner of marking them. The inconvenience and expense entailed in making a change would naturally be resisted by either nation, and we suppose that matters must remain as they are, in spite of the manifest risk.

At the forthcoming National Eisteddfod of Wales, which will be held at Swansea next month, there will be several competitions in the Arts and Miscellaneous Section. The committee have given notice that they have decided to make certain subjects in the section "open competitions" —that is to say, they will not be confined to Welshmen. These competitions include painting, carving and sculpture, and photography. The adjudicators are all well-known men, and intending competitors in photography will know that they are in good hands when they learn that Mr. J. Traill Taylor is to adjudicate upon the works sent in.

Photographers who wish to secure pictures of the Upper Thames without much trouble or exertion to themselves may be reminded that Messrs. Salter, the well-known Oxford boat-builders, are running two well-appointed steam launches, which daily ply between Oxford and Kingston. The trip either way occupies two days, and beautiful Henley is the half-way house where travellers rest for the night.

The seizure in London of a number of photographs of pictures in the Salon raises an old question which we suppose will be always hotly debated so long as Mrs. Grundy exercises her present influence over what is supposed to be English taste. One can understand a Vigilance Society, imbued with Mr. Horsley's opinions on the subject of the nude, objecting to certain pictures; it is when it begins to argue that issue must be joined. For this reason Mr. W. A. Coote, secretary of the National Vigilance Association, would have been wiser had he refrained from offering any comments on the subject. However, he has chosen to unburden himself, and we cannot say we are sorry, as he has succeeded in planting himself on ground as debateable as anyone could wish.

For instance, he actually asserts that the photograph of a picture may be objectionable, though the picture itself may not be. These objectionable qualities, he says, are introduced into the copy by "the eccentricities of the photographer's art." Mr. Coote, it seems, sees only indecency when a picture is robbed of its colour and reproduced in black-and-white. This would be very terrible if it were not very stupid, and we should very much like to see Mr. Coote justify his position—if he can. At present it looks as if he is bent upon making this self-appointed Vigilance Association a laughing-stock—a position, by the way, it has already occupied more than once.

One of the most useful items of photographic intelligence which always comes fresh to the non-photographic press is the intimation that the latest fashionable "fad" is for ladies to have their hands and feet photographed. This piece of news has been dished up over and over again for the last three years, and once more came up smiling last week in the pages of a provincial journal. It is really time some photographer came forward and verified the existence of this "fad." For ourselves, we take leave to doubt the whole business, and we do so for the reason that the notion that ladies should have their hands and feet photographed first saw the light in these columns, the suggestion naturally growing out of the craze for palmistry, which was then at its height. Still, we should be willing to record the experience of any photographer, even if he has only had one foot submitted to him.

Mr. Edison has been anticipated in his kinetograph by a Mr. Hartman, who has invented what he calls a "zotograph," which fulfils the same functions as Mr. Edison's apparatus, and was made before Mr. Edison applied for a patent. It is said that the zotograph will see everything which comes within its range, and record the same automatically and correctly. Placed in a car window, it will photograph everything as it goes along. It will also record the babel of sounds as they pass by. It will record even the slightest progressive movement of a horse in its complete race round the track. Hartman claims to fix motions on the sensitive plate at the rate of 50 to 100 per second; Edison does not undertake to record more than 46.

## EARLY BANK-NOTE FORGERIES—A PAGE OF HISTORY.

BY JOHN SPILLER, F.C.S.

The interesting article on "Photographic Fraud," by Mr. James Mew, which appeared in the News of 29th May (page 401), recalls to my mind some experiments made nearly thirty years ago conjointly with a firm of paper makers and bank-note engravers, which resulted in the detection of a photographic fraud that was being practised at that time upon the Bank of Spain. In December, 1861, a couple of Doscientos notes of the Banco de Espana were brought to me at the Royal Arsenal, one of which was stated to be genuine, and the other was believed to be a forgery possibly effected by photographic means. I was requested to try and find out the way in which the latter had been produced; and my opinion was further asked respecting the correctness of a certain certificate given by an expert, which document, after setting forth critically the chief points of physical difference between the true and spurious notes, concluded with the following remark:—"We are not aware of anything more to add except that the imitation has not been effected by photography."

Mere inspection did not at once disclose any very perceptible difference. There was, perhaps, a little want of definition in the geometrical design printed on the body of the forged note, but only such as might readily escape notice in a specimen which had either been a long time in circulation, or become dingy by wear. On comparing the notes superposed, and examining them by transmitted light, there appeared, however, to be a slight difference in dimensions, so that it was inferred that they had *not* been printed from the same engraved plate, although the measurements of the paper absolutely coincided. Such, then, was the problem submitted to me, and I set to work to apply chemical tests. First, by burning small portions of the notes, it was found that the true ink was entirely consumed, whereas the ash left by the spurious note was still legible, *and contained both gold and silver.* Now, by reversing the mode of attack, and soaking the notes—or pieces of them—in cyanide of potassium, the true note resisted well for a long time, whilst the piracy soon cleared up to a fragment of plain paper, as would happen in the event of its being a gold-toned photograph. Here, again, silver and gold were detected in solution. The notes were ornamented with an elaborate green device and red border, which behaved differently when treated with acids, the spurious paper giving up its colours immediately, and the other only after the lapse of a longer time. The numbering of the notes was done alike with printing ink, and the paper was well imitated.

Although the facts were brought to light and reported to my friends before the end of the year 1861, I am not aware that the source of the forgery was ever traced and brought home to the guilty parties; so that it may well happen that the conviction of 1863, mentioned by Mr. Mew in connection with the Austrian Bank, was actually the first prosecution undertaken against a photographic forger, although it would still be untrue to say, as asserted, that it was "the first attempt to forge bank-notes by photographic aid," the Spanish case, proved up to the hilt, and known to certain parties in this country, being evidence to the contrary. However, it is doubtful whether the facts ever came to be widely known either in England or Spain, a policy of silence being usually observed under such circumstances.

Since the invention of the collotype and photo-engraving processes, the nature of the ink might be practically identical with that employed by the authorised bank-note printers, and so new difficulties would be introduced. Now comes in the further advantage of perfecting the system of non-actinic overlays, whereby it would become impossible to secure a photographic counterfeit of the original engraved plate; but to do this, one requires to find a substance of the requisite photo-opacity, which in itself is unattacked by all the ordinary chemical solvents, and yet be possessed of the transparent qualities fitting it for application on the face of a bank-note. Few solid pigments satisfy this requirement, and colours which are opaque give but an indifferent artistic effect. There is room for further experiment in this direction, account being taken of the extraordinary facilities offered to the piratical copyist by the use of isochromatic plates, and reward awaits the successful operator.

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Intensifying Process by Double Printing—Paramidophenol Developer—Chloro-Cyanin as a Sensitiser for Red.

*The Process of Intensifying which has been employed in the work, "Who is Rembrandt?" by the Author of it.*—Herr Max Lautner, the author of that remarkable book, "Who is Rembrandt?"—in which, as I mentioned on a previous occasion, it is demonstrated by photographic reproductions that on many of the magnificent paintings attributed hitherto to Rembrandt the name of this latter has been falsified, and that they are in reality the works of Ferdinand Bol—has just published in Liesegang's *Photogr. Archiv* the method of intensifying which he has employed in reproducing the falsified monograms. The author states that, in order to increase the contrasts of the tones in the photographic reproductions as much as possible, it was necessary to make use of a special intensifying method—one giving a much more powerful intensification than the various processes generally in use for similar purposes. This new method—if it is altogether a new one—consists in the following:—Two negatives of exactly the same size are made from the subject, one of them being reversed as if it be destined for collotype. If a transparent film—for instance, an Eastman gelatino-bromide film, which can be printed from both sides—is used for the reproduction, the process is much simplified, a single negative being then sufficient. For printing, gelatino-chloride paper is used which has been made transparent previously by treating it with paraffin or with benzole. To prevent the evaporation of these volatile oils during printing, the paper is covered with a transparent gelatine paper—as it is used for counter-drawing—which has been treated with a chrome alum solution in order to render it more flexible and resistant. As the oil evaporates entirely after printing, it does not at all affect the subsequent toning, fixing, and washing processes. A mode of double printing, which forms the base of the entire process, is now effected by exposing the gelatino-chloride paper at first from the back beneath the negative, then from the front or film side. During the second printing it is, of course, absolutely necessary that the print produced by the first exposure and the negative are exactly in register. It will be evident that by this method prints are obtained of unusually powerful contrasts, the lights of the positive image turning out perfectly white, whilst the shadows—if only two tones are taken into consideration—have acquired double the depth or intensity in relation to the lights.

*Paramidophenol Developer.* — This new developer, introduced by Messrs. Lumière, has now been tried also by our German authorities, and their judgments are, on the whole, favourable to this reducing agent. Professor Vogel finds that the pure paramidophenol is very insoluble, so that it was impossible to prepare with it the solution recommended by Messrs. Lumière. Dr. Schuchardt, of Görlitz, has, however, succeeded in producing an hydrochloric preparation of this substance which, in the hands of Prof. Vogel, proved to be more soluble than the first one, though it is said to dissolve much less readily in cold water than hydroquinone. It is, therefore, necessary to heat the water previously. The developer thus obtained is very energetic, giving, however, somewhat thin negatives, and the mixed solution soon becomes brown. If the paramidophenol solution and the sodium sulphite solution are kept separately, they will keep clear. Also Prof. Eder and E. Valenta state that the paramidophenol forms an excellent developer, giving, according to its composition, every degree of softness or intensity. The colour of the negatives is greyish-black, the film being free of every bluish or greenish colour, even if a neutral fixing bath is used. The authors recommend the use of a dilute solution, for the reason that then the paramidophenol does not crystallise out of its solution, and the developer becomes less expensive. Moreover, the diluted solutions form equally excellent developers as the concentrated ones. The formulæ recommended by the authors are the following:—

*Paramidophenol-Soda Developer.*

| | | |
|---|---|---|
| Water ... ... ... ... ... | 1,000 | c.c. |
| Sodium sulphite ... ... ... | 80 | grammes |
| Carbonate of soda ... ... ... | 40 | ,, |
| Paramidophenol ... ... ... | 4 | ,, |

*Paramidophenol-Potash Developer.*

| | | |
|---|---|---|
| Water ... ... ... ... ... | 1,000 | c.c. |
| Sodium sulphite ... ... ... | 120 | grammes |
| Carbonate of potash ... ... ... | 40 | ,, |
| Paramidophenol ... ... ... | 4 | ,, |

The latter is specially well suited for plates which tend to give thin negatives, whilst the soda developer yields more delicate images. With the latter, also, transparencies on gelatino-bromide emulsion may be developed very successfully.

*Chloro-Cyanin as a Red Sensitiser.*—Cyanin, which has been introduced in photographic practice by V. Schumann, forms, besides chlorophyl, the best sensitiser for red and orange. Professor Eder, in the *Photogr. Correspondenz*, points out that all commercial cyanin is the so-called iodo-cyanin, by the use of which fog is produced sometimes during developing. He recommends, therefore, to convert the iodo-cyanin into the analogous chloro-cyanin, which latter is said to show less tendency to the formation of fog. This conversion may be easily effected in the following manner:—The cyanin is powdered, placed in a porcelain or platinum dish, and some water and hydrochloric acid poured over it. It is then evaporated in a water-bath (with constant stirring) to dryness, the residuum being again wetted with hydrochloric acid, and then once more evaporated in the water-bath. There remains behind, with evolution of hydric iodide, a residuum of chloro-cyanin, which still contains traces of hydrochloric acid, and is not, therefore, entirely blue. The last traces of hydrochloric acid will, however, escape by heating the dish carefully on a sand-bath until the edges of the film of cyanin become dark. If the dish has been previously weighed, the increased weight will give the amount of chloro-cyanin which it contains after evaporation, which may be dissolved in a corresponding quantity of alcohol.

## RECENT DEVELOPMENTS IN PRINTING PROCESSES.*

BY C. H. BOTHAMLEY, F.C.S.

The permanence of the kallitype images is of considerable interest. The black images by both the first and second method are not altered by exposure for forty-eight hours to the products of the combustion of sulphur in air, nor by immersion in a solution of sulphurous acid for the same length of time. A solution of sulphuretted hydrogen, if dilute, changes the colour to bluish black, but produces no other alteration; if the solution is strong, the bluish black image undergoes a further change, and becomes brown. A dilute solution of ammonium sulphide changes the colour to brown, with no loss of detail and not much loss of intensity; the brown colour thus produced is very suitable to certain subjects.

The sepia paper, likewise, seems unaffected by the products of the combustion of sulphur; sulphuretted hydrogen or ammonium sulphide first changes the sepia image to black, but it afterwards becomes gradually brown.

No prolonged experiments on the behaviour of mounted prints have as yet been possible, but there is no reason to doubt that, under ordinary conditions, kallitype prints are permanent. It is, of course, not to be expected that kallitype can as yet equal platinotype, but it is by no means improbable that in time the difference will be chiefly a possible difference in permanency. The process is already capable of giving very good results, and it is considerably cheaper than platinotype.

The other processes that I shall describe belong to an entirely different class; they are the first practicable photographic processes based on the use of coal-tar colours. Both processes depend on the formation of azo colouring matters from diazo compounds, and they may be spoken of as diazotype, but they differ in the nature of the change that the light produces, and in the condition under which the colouring matter is formed.

Diazo compounds are a class of compounds characterised by their power of uniting with carbolic acid or any other phenol, any naphthol, or any amine to form an azo-colouring matter, the tint of which depends on the nature of the diazo compound, and also on the composition of the particular phenol, naphthol, or amine. Yellow, orange, brown, purple, scarlet, and blue may be cited as examples of the variety of colour that can be obtained in this way.

Feer-type is the first of these processes, and is so called from the inventor, Dr. Adolph Feer (German patent 53,455, December 5th, 1889). It is based on the fact that diazo compounds in contact with acid sulphites form diazo-sulphonic compounds, and these form no colouring matter. If, therefore, a diazo-sulphonic compound is mixed with an equivalent quantity of a phenol or an amine, no colouring matter is formed. If, however, the mixture is exposed to light the diazo-sulphonic compound is decomposed, the diazo compound is set free, and, since a phenol or amine is already present, a colouring matter is formed as fast as the diazo compound is liberated.

* Concluded from page 517.

The process is applicable both to paper and to textile fabrics. The paper or fabric is coated with a solution of a diazo-sulphonic compound of high molecular weight, mixed with an equivalent quantity of a phenol, or a naphthol and an alkali, or with an equivalent quantity of an amine and an acid. The patent specification recommends sodium ditolyltetrazo-sulphonate, but Feer has since recommended sodium diazopseudocumidine-sulphonate, which can be obtained from Dr. Schuchardt, of Görlitz. My own experiments, which are as yet but few in number, were made with this compound and β-naphthol. An exposure of ten seconds to comparatively weak sunlight produces a very decided quantity of colouring matter, and an exposure of a very few minutes gives a deep-coloured print. The rate of formation of the colouring matter decreases as the exposure continues, because the colouring matter formed in the superficial layer acts as a screen to the unaltered material behind. The light from burning magnesium will also produce a print, and prolonged exposure to gaslight will produce an easily recognisable amount of colouring matter. Some "nature prints" from fern leaves are exhibited; they show a very considerable amount of detail as well as the outline.

The primuline process is the second process of this class, and is the invention of Messrs. Green, Cross, and Bevan (English Patent 7,453, May 13th, 1890). Primuline was first made by Mr. Green, and is a yellow colouring matter that contains sulphur. It has the peculiar property of dyeing cotton, linen, paper, or any other material consisting of cellulose, without the use of a mordant. The exact constitution of primuline is not yet known, but it contains an amido group, and, therefore, will yield a diazo compound, which in its turn will form colouring matters. Diazo-primuline in the pure, solid state, is practically unaffected by even prolonged exposure to light, but when in contact with cotton, linen, or cellulose it is rapidly decomposed by light, with complete destruction of the diazo compound and consequent loss of the power to form colouring matters.

The primuline process is applicable to fabrics as well as to paper, and gives better results with the former. Herein, in fact, lies its special merit. Fine calico, linen, &c., free from grease, is immersed for a short time in a boiling solution of primuline (about 3 parts in 1,000) containing a small quantity of common salt, and is then washed with water. If necessary, it may at this stage be dried, and will keep for any length of time. In order to sensitise the material, the primuline is converted into diazo-primuline by immersion for a short time in a dilute solution of sodium or potassium nitrite (1 part in 400), acidified with hydrochloric, sulphuric, oxalic, or some other acid. It is then washed and dried in the dark without the aid of heat. If made too dry the material becomes less sensitive.

The sensitive material is exposed in an ordinary printing frame, a very short time being required in bright sunlight, but a much longer time in a dull light. Since the correct time of exposure cannot be judged by mere inspection, a strip of the same material is exposed outside the printing frame, and is touched from time to time with a drop of the developing solution. When the latter ceases to produce any colour, the diazo-primuline on the test strip is completely decomposed, and it may be taken that decomposition in the high-lights of the transparency is also complete. The print is then ready for development, which is effected by immersing the print in one of the following solutions:—For *yellow*, phenol; for *orange*, resorcinol; for *red*, β-naphthol; for *maroon*, β-naphthol-disulphonic acid. One part of the substance is dissolved in 400 parts of water, made alkaline with caustic potash or caustic soda. Other developers are: for *brown*, meta-phenylenediamine; for *purple*, alpha-naphthylamine; for *deep blue*, eikonogen. The eikonogen is dissolved simply in water; the two amines are dissolved in water acidified with hydrochloric acid. Different developers—stiffened, if necessary, with starch—may be applied with a brush to different parts of the same prints. The developed prints are washed with water, and, in the case of the blue and purple developers, the last wash water should be *slightly* acidified with tartaric acid. In the other cases the prints are improved by being washed with soap and water. In all cases the appearance of the print is improved if, after removal from the printing frame, the back of the print is exposed to light for a short time in order to secure complete decomposition of the diazo-primuline in the high-lights. The ground of the prints always remains pale yellow, and, at present, no method has been discovered by which a white ground can be obtained.

In Feer-type the quantity of colouring matter formed is proportional to the quantity of light action, and hence we obtain a positive from a negative, and *vice versâ*. In the primuline process the quantity of colouring matter is inversely proportional to the amount of light action, and hence we get a positive from a positive, and a negative from a negative.

The prints, being formed of azo-colouring matters, will gradually fade if exposed to sunlight, but are permanent enough if exposed only to the diffused light of ordinary rooms.

Neither of the diazotype processes is at all likely to displace any of the ordinary printing processes, but they may be specially useful for the copying of engineers' plans, &c., upon cloth, and, since a variety of colours can be obtained, the processes are likely to be very useful for decorative purposes. The primuline process is very simple and cleanly, and can be readily used by ladies, who, with the help of dried ferns and other leaves, can produce a great variety of designs on linen, &c., and these can be mounted in any desired manner. In this connection, it may be useful to point out that the disagreeable smell of the purple developer (alphanaphthylamine), which clings very tenaciously to the fingers, can be removed by dipping the fingers into the solution of nitrous acid used for sensitising the primuline.

## WHAT WASTES TO SAVE, AND HOW TO SAVE THEM.

What would the family photographer say to his wife if he knew that one-half of every barrel of flour he provided for his household was allowed to fall under foot, or to be burned in the stove as fuel? And yet we dare to say that one-half the photographers allow at least one-half of the precious metals they purchase for picture making to be wasted as wickedly as though its cost was no greater than that of common flour. One pound of silvered albumenised paper in good health—*i.e.*, when it is clean and free from nails and bits of tintype plates, cardboard, glass, or other dirt and solids—is worth from forty to fifty cents, according to the strength of the silver solution, the amount of salting in the paper, and the treatment of it. This value is somewhat reduced by the exposure of the sensitised paper to the light, for a part of the silver is thus rendered insoluble, and so recovery of all the silver is beyond the power of chemistry. Yet, after all, nearly sixty per cent. of the silver you purchase can be returned to you, and a goodly part of the gold, if you will carefully follow the directions given below.

A. *Developer Drippings.*—Enough protosulphate of iron remains in the drippings from the development of wet plates to precipitate the silver. What is needed, then, is to carefully catch what goes off the plate in a proper vessel, and allow it to settle. Pour off the clear water once a day. This last is important, for when the water is allowed to remain for some days the recovery of the silver becomes more difficult, and therefore the amount recovered is much lessened, owing to the large quantity of iron present. If left any length of time, then test with salt; if same show a precipitate, then proceed as follows:—A small quantity of salt in solution should be stirred into the drippings before the water is poured off, and until the water appears clear. Take time and do the work thoroughly. The precipitate is rich in chloride of silver. Add the salt gradually, stirring up the solution until it no longer forms a precipitate, which you may easily determine by taking a sample of it in a tumbler or white bottle, holding it up to the light when adding a little salt. Don't add too much, as an excess will redissolve the chloride. When the silver is all down, pour in a little acid, either nitric, sulphuric, or muriatic, which will clear the solution; allow it to stand for about twenty-four hours, then draw off your clear water and you have the chloride on the bottom of the vessel.

B. *Fixing Solutions* are very rich in silver. They should be precipitated with sulphuret of potassiums previously dissolved in water, also adding it as long as it will form a precipitate. The latter, when down, may be thrown on a plain muslin filter to allow the water to drain off. Such a filter may be readily constructed by taking a piece of common unbleached muslin, say a yard square, tying loops to the four corners, and hanging it up on sticks.

A good many photographers are in the habit of precipitating their washing solutions with metallic zinc suspended in sheets therein. The action of zinc, however, is slow, and must be accelerated by acidifying the solution. Now it frequently happens that the fixing solution is allowed to run into the same vessel, and the hypo, being an alkali, suspends the action of the zinc. In the course of time a deposit out of the water is formed, but the happy proprietors of the "mud" are sadly disappointed in its value, as it is sometimes even so poor as not to pay for the trouble of refining. All hypo fixing solutions may be treated together in this way. A large barrel serves as the best receptacle for them. Insert a spigot about six inches from the bottom. It has been found economical to use a large crock or stone jar—or it may be glass—for the negative fixing solution; you can use a dipper with it, or let a strong strip of glass remain in and across it at an angle to prevent the smaller plates from going flat to the bottom of the vessel. Once in a while the solution may be emptied into the barrel. The precipitate which results is sulphide of silver.

C. *Impure Solutions and Used Baths.*—Besides salt, muriatic acid, sulphuret of potassium, protosulphate of iron, or sheet copper may be used for the precipitation of silver from any solution very rich in silver; and they should be used, or else the solution boiled down to dryness, when the wastes are sent to the refiner. The reasons are obvious; the freight is less, and the danger of loss from the breakage of bottles and leakage is insured against. See instructions for saving print washings (E). The same course may be followed here.

D. *Silvered Paper.*—All prints should be trimmed before toning, as it saves gold, and besides, toned paper is of hardly any value. Keep the untoned clippings and filters clean, by themselves; do not throw sweepings, pieces of glass, and spoiled ferrotype plates among them, as their bulk only decreases the real value. If you wish to burn the paper, have your stove cleaned of cinders and ashes, and proceed slowly, for a good draught will carry many particles of silver through the flue. Every inch of silvered trimmings is valuable, and should be kept in a box separately. Do not tread them under foot and allow them to become mixed with dirt and grit and dust on the floor. Keep a cover on the box, and do not allow anything but clean, untoned paper trimmings to go into it. We prefer to burn the paper, but if you attempt it, see that every bit of the paper "cinders" is consumed before the ashes are taken from the stove.

E. *Print Washings* may be treated the same as A, only it is best to keep them separate. You save enough extra to more than pay you for the additional trouble. Add the salt gradually, and watch the effect. If precipitation is slow and the solution remains milky in appearance, the addition of a little of the protosulphate of iron solution is of good service. Some workers prefer a mixed solution of salt and alum—say twelve ounces of each ingredient dissolved in two quarts of hot water—for a stock solution. Add this carefully, and not too much of it.

F. *Toning Solutions.*—Precipitate these with protosulphate of iron, but be sure and have the solution "acid," as otherwise the iron will be precipitated, and your gold will be lost. Old toning baths, and the precipitates which form when the toning bath is being neutralised by bicarbonate of soda or other alkali, should all be saved, and separately from any other wastes.

G. *Toned Paper Clippings.*—In a small business it hardly pays to save these, but where quantities are large and fuel and time are cheap, it often does. Printers for the trade, publishers of photographs, and those whose business is large, have found the recovery of gold from these clippings well worth looking after.

H. *Old and Spoiled Dry Plates* are likewise worth taking care of. The emulsion from all such can be best removed by soaking them in a strong hot solution of carbonate of soda (washing soda). When a quantity is collected, strain it through a muslin filter, allowing the solution to drain off. A stone jar is excellent for this work. After filtration the precipitate should be allowed to dry spontaneously, after which it is ready for the refiner.

I. *Barrels, Floors, and Old Hats.*—We have likewise found that the wood of barrels which contained waste solutions for a number of years was quite impregnated with silver, some barrels yielding as many as thirty ounces of metal; so when yours are unfit for further use you know what to do with them.

The same discovery has been made as to the floors of long-used dark rooms and of rooms where the paper is silvered and drained and fixed. Old felt hats are used for developer drippings by some. These with the developer, skins, fragments, and emulsion from dry plates, as well as blotters and filters, are well worth saving.

J. *Aristotype Paper Wastes* should be treated the same as other paper wastes (D). They may go together, but in everything like "wastes" the separate plan is preferable.

K. *Finally, a word or two.*—The end of all waste is silver and gold, if you strive to follow our advice. Dissolve the salt and iron before they are added to the waste solutions. A few drops of acid should be added to the iron solution before it is used. Any acid added to a cyanide solution will precipitate the silver. Have abundant air in circulation about you when you do this, for the fumes—*waste you!* Don't use sheet zinc for anything hereof.

Last, but not least, do not send small lots of waste to be refined, but wait until you have a reasonable quantity, for expenses and charges are then comparatively less.—*St. Louis and Canadian Photographer.*

## PHOTOGRAPHY IN FRANCE.

BY LEON VIDAL.

FRENCH PHOTOGRAPHIC SOCIETY — COLOURED LIQUID SCREENS—SHUTTER—NEW ROLL-HOLDER—DIRECT POSITIVES IN THE CAMERA—NEW CURTAIN SHUTTER—NEW ZINCOGRAPHIC PROCESS—SOCIETE D'ETUDES PHOTOGRAPHIQUE.

*Coloured Liquid Screens.*—M. Franck has introduced some new tanks formed of glasses with parallel sides, between which is injected a coloured liquid, this arrangement taking the place of the coloured screens commonly used. This communication recalls one having the same object which was put forward by M. Chouroude. It is evident that these tanks can render efficient service in connection with orthochromatic work, although one would prefer a solid preparation on glass or pellicle. We need not add to the complications of the work by introducing such manifestly awkward arrangements.

*New Shutter by M. Gillon.*—This contrivance is of metal, and it is placed between the two combinations of the lens. According to the inventor, it gives various speeds, from one of some minutes' duration, to the $\frac{1}{300}$th of a second. It is composed of three eccentric leaves which cross one another, and the opening between them is central.

*New Roll-Holder by M. Flauvel.*—This holder enables the operator to change the rollers in full sunlight upon which the film is carried. They are surrounded by several turns of a non-actinic material, an arrangement which has been suggested and adopted before. This holder, however, is very well designed.

*Direct Positives in the Camera.*—Col. Waterhouse's new method. This is a communication upon a subject which has already been well ventilated in the columns of the PHOTOGRAPHIC NEWS.

*New Curtain Shutter by Commandant Moessard.*—This inventor has produced a shutter on the curtain principle, which is placed in front of the negative plate in the camera, and which has an opening varying from one millimetre to two centimetres. It can be moved with great rapidity, and springs are employed to regulate its movements. But what is the use of such complications when other shutters are available which are so much more simple and convenient?

*Zincographic Process, by MM. Lumiere, Fils.*—We printed last week in the PHOTOGRAPHIC NEWS the full text of this interesting communication.

*Société d'Etudes Photographique.*—A new process for impressing lines on a metal plate has been brought forward by M. Parison. It consists in the employment of a hollow cylinder which has on its surface a series of small holes made in a straight line. Within the tube, or cylinder, is placed a source of light, and as the tube moves over a metal surface made sensitive to light, a line is produced by the light emitted from each hole. The arrangement is a somewhat complicated one, and is not likely to supersede better known methods.

## LIGHTING IN PORTRAITURE.

BY XANTHUS SMITH.

LIGHT and shadow is the soul of art. There is no higher expression of art than in fine sculpture; and as the beauty of form in sculpture is developed by light and shadow only, and as light and shadow is the sole mode of expression of photography, we may, I think, be permitted to use sculpture as a basis from which to draw our comparisons, and upon which to form our principles.

The sun, the great giver of light and of life, is also the great sculptor and painter. We poor mortals, admiring the infinite beauties which he constantly spreads before us, are ever in vain trying to imitate them. To our perceptions, when the sun is doing its great work it is ever above us; as it descends it becomes more feeble, till, as it passes beneath the horizon, its work is done, on our half of this sphere, for the day. The objects which constitute nature, to our perceptions, are never lighted from beneath. Has nature purposely so designed her infinite creations that they may appear the most interesting by this lighting from above? Or are we, through mere habit, so accustomed to it that we accept it as the right? We think we may safely hold that the former is far the more likely, as in both animal and vegetable growths we universally see the greatest beauties of conformation and colouring upturned, as if thus to receive to the best advantage the descending rays of the glorious sun.

In the human countenance and its portrayal to the best advantage, which forms the theme of our present writing, we have the finest example of the influence of light and shadow in developing properly nature's finest work, if we adhere to what she has evidently pointed out as her intention. Let us take the features separately. The forehead, the seat of the highest intellectural qualities—how can it be lighted to show its beautiful conformation but from above? Then the eyes and eyebrows—how else can we see their force and detail and brilliancy than by an upper lighting? Take a fine nose and place a light beneath it, and what can you make of it? Of the mouth, chin, and cheeks—nay, even the ear—can we say aught else than that when lighted from underneath their individual interest is lost, and their beauty destroyed in place of being developed? How, then, taken as a whole, can we make anything but what we may almost call an absurdity of a human head under a false lighting?

Nothing is more easily and plainly exemplified than the unpleasant effect of ill lighting. Let the handsomest member of any family favoured with average good looks—whether it be man or woman, old or young, it matters not—stand himself up at night, or in a darkened apartment, and let another member of the family take a good lamp and place it at any angle or in any position which he may choose with regard to the head and face of the individual posed, so that he always keep it below the level of the head; and let the other members of the family decide whether they would admire and value a picture of the one so seen under any of the varied aspects which he or she would present. I think we may safely say that in ninety-nine cases out of a hundred they would not.

The mode of studying the varied effects of light and shadow by a lamp placed in different positions with regard to the head and face is a very simple and excellent one. It is open to all who feel sufficiently interested in art to give a few minutes to it, and exemplifies the wonderful effects of light and shadow in either the making or marring of a good human countenance.

It may be objected that this mode of lighting is too strong and too exaggerated (and so it would be for refined countenances) to be photographed. Of course we must then have a softer and more diffused light; but the principle is precisely the same, whether it be a soft or a powerful light. It must fall from the proper direction.

From centuries past to the present day, and notwithstanding the various whims and freaks of fashion, which, arising from a vulgar rage for novelty, are constantly assailing all well-founded truths, it has been the custom in academies and schools of art, and in all galleries purposely constructed for the display of sculpture, to use a lighting that falls at an angle of forty-five degrees, or above, on the sculptures used as models to draw and paint from, and to be exhibited to the greatest advantage to intelligent people. What would we know of the solemn grandeur of the bust of Homer, or of the beauty of the head of the Apollo Belvidere, if we had never seen them properly lighted? How could we read the various characteristics of the Greek and Roman philosophers, statesmen, and rulers, as we do in the portrait sculptures that have come down to us, did we not have the power of casting a well-arranged lighting upon them?

The photographer may say, "What have we to do with Homers and Apollos and sculpture; are we not working from and catering to the flesh and blood of to-day?" But I say, Are we not men? Do we not furnish now as fine specimens of the human countenance as existed in the period of Greek art? Certainly. We have our great statesmen, generals, and philosophers, and alas! they are too often trusting to the camera alone for the perpetuation of their semblance. Possibly no mode can so truly convey to us as can the photographic art the actuality of a countenance. But we must never lose sight of the fact that that countenance, if it be the index to a mind worthy of perpetuation, must be portrayed under a lighting in conformity with the inscrutable laws of nature and of art.

We must beg to be pardoned if we speak strongly upon the importance of this matter of lighting in portraiture. During the past few days the subject has presented itself to us more forcibly than it probably has ever done before. One of our most distinguished citizens has just passed away. He stood amongst the few very highest in science of any time or country. Immediately we see large photographs of him placed in the windows of some of the photographers. They are splendid works as regards technique; but why should the noble face have been buried in shadow, a harsh line of light cutting down one edge only? Was it ignorance or thoughtlessness on the part of the person who posed this distinguished sitter? He surely had the means in his skylight of letting nature's illuminating rays fall broadly and truly upon this noble countenance, so that the grandeur and dignity which it possessed might have been perpetuated to us to their full extent and value. Those photographers who profess to do only a respectable business should pay more attention than they do to this all-important subject, and we would admonish those who are at the head of leading galleries, and whose duty it daily becomes to affix the images of our greatest men of the day, that they are doing wrong in not making a regular art study of their pursuit. They should secure a few fine casts from the antique, preferably portrait busts, and study them and photograph them under various lightings; see how they may be made to look dignified or mean, grave or ridiculous.

You will, no doubt, think it a very easy matter to talk, and especially for one who knows little or nothing about the practical business of running a photographic gallery. There is no one better acquainted with the difficulty of producing a very fine photographic likeness than the writer. It is something which he is constantly striving to do, yet never satisfying himself; and, moreover, he is thoroughly acquainted with the trials to be contended with in catering to an uncultivated public. Our ideas upon the subject of art portraiture could not be put universally in practice. Ignorance and fashion cannot be stormed and annihilated. The mind must be led; good comes about gradually.

What we would have is that the portrait photographer properly and conscientiously prepare himself, as an artist does, for the work that is to be his calling, so that whenever an opportunity occurs to get in some real, good, artistic work, he may do it. By artistic I do not mean what the whim of the day may call artistic, but artistic as founded upon the genuine high art of the past, and the rules of good taste and judgment that have stood the test of ages. Let him, when a distinguished man with a fine forehead comes along, secure one or two admirable negatives of him. The man himself possibly may not like them so well as a commonplace portrait. Never mind; a fine work of art will have been put in existence. At a proper time it may be brought forth. If it should be engraved, it will be spread broadcast, and go down to posterity. When it is looked at in future years, by persons of good taste and sound judgment, they cannot say of it, "What a pity the abominable fashion of shadow-pictures was in when that distinguished man was photographed," or "Pity he did not pose to one who had some artistic knowledge." But, on the contrary, they may say, "What a noble head; the man who posed it was truly an artist."

As to the practical details of lighting, all good photographers are pretty well provided with the means of securing almost any lighting which they may require. The main points to be looked after are, to have plenty of height, not too much over-head light nor too much side light, and be very wary of any light below the level of the head. Perhaps the greatest difficulty in lighting is to secure the very nice point between too diffused and too concentrated a light. In too diffused a light we have a want of force and breadth of light and shadow, and consequently a want of expression and vigour in the head; and on the other hand, if the light be too much concentrated, there is a harshness and force of character which is not only less agreeable than when a softer light is used, but far less likely to make a portrait that will be as acceptable to the general run of sitters as the soft lighting.

The timing of the exposure is of the utmost importance. The correct limit is extremely narrow in the highly sensitive plates now used in portraiture. An under-exposed plate is worthless. If we over-expose we have a resulting flatness in the picture which, if to be overcome, as it sometimes may, is only at a too great expenditure of time and pains to be admissible in gallery work.

In a properly lighted head, with correct exposure and development, in many instances very little retouching would be required. Certainly what constitute facial blemishes may in all cases be removed, but with persons of average good looks, as they advance in years, the stopping-out of all marks of time and character, and attempting to restore the look of youth, should be universally deprecated by persons of good sense.—*American Journal of Photography.*

## Patent Intelligence.

### Applications for Letters Patent.

11,900. Georges Messager, 45, Southampton Buildings, London, "Improvements in and Relating to Photographic Shutters."—July 13th.

11,915. Edward John Browne, 43, Smollet Street, Liverpool, "Photo Half-Tone Rubber Stamp."—July 14th.

12,114. Newnham Browne, 73, Cheapside, London, "Improvements in Photographic Apparatus." (R. Hüttig, Germany.)—July 16th.

12,176. Charles Thomas Abbott, 53, Chancery Lane, London, "Improvements in the Manufacture of Picture Frames."—July 16th.

12,218. Newnham Browne, 73, Cheapside, London, "Improvements in Detective Cameras." (Friedrich August Fichtner, Germany.)—July 18th.

### Specifications Published.

2,293. *March 29th*, 1890.—"Glass Frosting." W. H. Akester, 15, Munster Road, Fulham, Middlesex.

Relates to frosting or obscuring glass surfaces, such as glass globes used for incandescent electric lamps, and consists in dipping the article into, or otherwise coating the surface with a solution of nitro-cellulose. If desired, there may be added to the solution any colouring matter, as one of the aniline dyes. The article is afterwards dried in a drying chamber.

2,623. *February 18th*, 1890.—"Modifications of Zoetropes." L. Brennan, Gillingham, Kent.

Consists of a method of, and apparatus for, producing pictures or designs appearing to move and change, that is a method and apparatus for giving the same effects as the ordinary zoetrope. The complete apparatus may be divided into two parts, a fixed part and a removable part. The latter part consists of three frames, between which are bars, round which strips of paper are passed, the ends of each strip being held in the frame. The removable part is placed in frames carried on a suitable stand, and provided with two right and left hand screws, operated simultaneously by handle and gear-wheel. The front frame is fixed, the other two are free to travel towards and away from one another along guide rails when the crank is rotated. Plain paper strips being inserted, a picture is photographed, or in any other suitable way, placed upon all the exposed edges at the front. The crank is slightly turned, fresh surfaces or edges are exposed, on which a second picture, somewhat different from the first, is placed. The crank is again turned, a fresh picture placed on, and so on. By using strips, having pictures thus formed thereon, and by rotating the crank, a design or picture appearing to move and change is witnessed.

Correction.—In Mr. Debenham's paper on "The Cult of Indistinctness" in our last, the word "promising," 19th line, 1st column, page 518, should read "prominent."

The Photographic Club.—Subject for July 29th, "Developing *en route*"; August 5th, "Dark Room Appliances and Photographic Dishes." Outing July 25th, Waustead Park; train leaves Liverpool Street 2.35 for Snaresbrook.

Photographic Society of Great Britain, 50, Great Russell Street, W.C.—The subject for discussion at the technical meeting on July 28th is "Photographic Optics and Perspective." The rooms will be closed from July 29th to August 24th.

## Correspondence.

### THE NAMING OF PHOTOGRAPHS.

Sir,—When travelling abroad I am in the habit of buying photographs of the scenery, and lately I mounted some hundreds of them in scrapbooks. In doing so I noticed that the great majority of the names were marked in pencil on the back of the photos, and a large number of them in a more or less unsatisfactory manner. Some were written in a hand either difficult to read or quite illegible; others were vague and indefinite, such as "Oberland Mountains," or "Rhone Valley," and two were actually named "Swiss Scene" and nothing else, whilst several of the most interesting had no name whatever. I have also bought a great many photographs in England, and I find them just as bad as the continental ones in this respect, if not worse. I ought to add as a climax that I am able from my own knowledge to see that not a few bore entirely wrong names, and I could not but entertain an uneasy suspicion that many others might also be erroneous unknown to me. This state of things is not only a nuisance, but renders the photographs of far less value, and must, I should think, diminish the sale of them. I submit that *the names should in all cases be printed upon them*, as is already done by many photographers, especially in Naples and Venice, and not be left to a possibly ignorant shopman to scrawl something on the back, with the results stated above. W. M. Cooper.

*Guernsey, July 15th.*

### DELAYED FOREIGN EXHIBITS AT THE RECENT NEW YORK EXHIBITION.

Sir,—Some misapprehension having arisen as to the appearance, in the catalogue of the Fourth Annual Exhibition, of the names of one or two foreign exhibitors whose exhibits were not hung when the exhibition opened, an explanation is now deemed necessary in order to show that no injustice was done to such exhibitors.

It should be mentioned that the entry forms filled out for catalogue purposes were received by mail some time in advance of the exhibits sent by express; the committee, expecting they would arrive in time, favoured the exhibitor, as it thought, by inserting in the catalogue his name and description of exhibit.

In the case of Mr. Lyddell Sawyer, of Newcastle-on-Tyne, whose entry form was received ten days before his exhibit, which was delivered three days after the exhibition opened, and after the awards had been made, there was no chance, under the rules, for his exhibit to be framed and judged. It was, accordingly, hung "for exhibition only," by consent of the committee. It took twenty-one days from the time they were sent till received in New York. His work was admired by the many visitors, and would doubtless have taken a medal, as at many other exhibitions, had it come in time.

In the case of Mr. John E. Austen, of Maidstone, whose work has invariably taken a medal wherever exhibited, it should be stated that while his entry form reached the committee in time for the catalogue, his exhibits never came to hand, and at the time, though diligent inquiry was made about them of the forwarding agents, no trace of them could be found. This explanation should prevent Mr. Austen from being put in any false position.

A third case is that of Col. R. W. Stewart, of Devonport, who, instead of sending his entry form by mail, sent it by express with the photographs, which were received the third day after the exhibition opened, too late for entrance in the catalogue and for judging. He had excellent platinotype prints of the Westminster Abbey. They were hung for exhibition, and were much liked.

Few foreigners can imagine the delay even in getting the simplest article through the U. S. Custom House. In some parts of it one man has to do the work of two; then the articles have to be appraised, and must wait their turn. Usually ten days to two weeks are required, hence in sending articles to America this delay must be allowed for. It was for this reason that the committee urged all intending foreign exhibitors to send their pictures, unmounted, by mail. Those who did so had their exhibits here in ample time. Until our laws are changed, the present hindrance to a free interchauge of photographs is likely to continue. F. C. Beach.

*Chairman of the Committee of Arrangements of the Society of Amateur Photographers, New York, July 10th.*

SOCIETY OF AMATEUR PHOTOGRAPHERS OF NEW YORK.

Sir,—I thiuk the enclosed statement of facts may be of sufficient interest to the readers of the Photographic News to warrant your publishing.

Early this year I received a prospectus of an exhibition to be held under the auspices of the Society of Amateur Photographers of New York. As I had some "Interiors" of Westminster Abbey, which I thought would be of exceptional interest to Americans, I wrote to the secretary, Mr. F. C. Beach, and in reply received a form of entry to be filled in. The exhibitiou was to be held in New York between May 25th aud June 6th. I accordingly prepared a series of the interiors in platinotype, mounted them on cardboard, and despatched by S.S. *Umbria*, leaving Liverpool on the 18th April. The series consisted of one view 15 by 10, and twelve views 8 by 10. Early in June I received a postcard as follows:—"Your exhibits not received till yesterday, too late for competition and catalogue; sorry. I had to pay eight shillings charges to get it out of Custom House. We have them on exhibition at gallery, however. Very beautiful pictures.—Yours, F. C. Beach."

I wrote in reply showing date on which the photographs were sent off, &c. To this I had no reply until this moruing, when I received the following:—"Dear Sir,—Mr. F. C. Beach, of New York, has requested me to remit you seven shillings per balance due from sale of photographs, after deducting expeuses, and we uow enclose cheque for the amount, which kiudly acknowledge." The net result is, firstly, owing to the peculiarities of the New York Customs—a parcel leaving England on April 18th is not in time for exhibition in New York on 25th May; secondly, the net value of thirteen "very beautiful photographs," to quote the secretary's words, the catalogue price of which was £3 10s., after paying expenses, is seven shillings. I think comment is unnecessary.

A Member of the Camera Club.

## Proceedings of Societies.

Holborn Camera Club.

The usual weekly meeting of the Holborn Camera Club was held on Friday last, Mr. R. D. Lowe in the chair, when Mr. R. Luxton gave a very instructive and interesting lecture on "Photo-mechanical Work." He made special mention of the method of copying the picture, aud spoke of the various stages through which the plate passes, beginniug with the development and subsequent iutensification of wet plates, varnishing, the preparation of the zinc plate, the printing, washing, rolliug-up, and bitiug iu. He gave various formulæ and numerous hiuts during his lecture. He showed a wet plate after intensification, and zinc plates iu the various stages of process. A vote of thanks was passed to Mr. Luxtou, aud the meeting separated.

Lowestoft and District Photographic Society.

A meeting was held last Friday at the School of Science and Art, Regent Road, Mr. W. Stringfield presiding. Prints and negatives were handed round, including a "Wood Scene" by Mr. Emuss; two prints, shown by Mr. A. M. Smith, one of a camp kitchen, taken during a late encampment of the Volunteers on the Denes, also an enlarged print of Mr. Gladstone leaving the station on the occasiou of his visit to Lowestoft in 1890; examples of a new method of printing, shown by the Chairman, after which some slides were thrown ou the screeu, one by Mr. Hume, of "Cattle on the Marsh."

The meeting terminated with a resolution that all members be requested to produce next month, all the slides they had previously exhibited, with a view of selecting those most suitable for a public exhibition, to be held iu the autumu, on behalf of the funds of the Society.

## Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C S., 2, St. Mary's Road, Canonbury, N.

R. M.—*The Oxy-Chloride Theory.* Dr. A. Richardson, of Bristol, in studying the decomposition of silver chloride by light, has, by a series of conclusive experiments, proved that there is *no oxygen* in the blackened product, and that Prof. Hodgkinson's hypothesis has no foundation in fact.

D. D.—*Law of Copyright.* See answer given to C. A. last week.

E. P. (Ludlow).—*Exhibition,* 1891. The judges have been appointed, and the printed regulations governiug the forthcomiug Pall Mall Exhibition may now be had, together with entry form, from the Assistant-Secretary, 50, Great Russell Street, W.C.

Amateur.—*Permanence of Pyro Solutions.* We have made comparative trial of solutions of pyrogallol preserved respectively by additions of nitric acid and of sodium sulphite with citric acid. Both are fairly and equally permanent if kept in stoppered bottles away from the light.

A. L. B.—*Egg Statistics.* The Minister of Agriculture (Mr. H. Chaplin, M.P.) reported at the Mansion House meeting a fortnight ago that eggs to the value of £3,400,000 were annually imported into this country. This estimate takes no account of a large additional quantity of egg-albumen, which comes over in the form of albumenised paper ready for photographic use. From these statistics it is again made clear that there is room for the development of this item of dairy produce by the efforts of British and Irish agriculturists, besides the extension and promotion of fruit culture, which constituted the maiu object of the Fruiterers' Company in calling the meeting.

M. W.—Second letter answered by post.

Amicus.—*Platinum or Silver.* It is entirely a matter of taste; for portraits, as a rule, we should prefer silver, but they would not be so permanent. Interiors and architectural details ofteu come out better with platiuum, but for foliage aud the usual run of laudscape work we are still inclined to favour the print in silver.

B. E. N.—*Hardwich's Manual of Photographic Chemistry.* The first six editions were prepared by the author; the seventh was edited, in 1863, by Messrs. Dawson and Hadow; the eighth by George Dawson alone in 1873, after which Mr. J. Traill Taylor took it in hand, the ninth edition appearing in 1883 of largely increased size.

R. L.—*Primary Colour Sensations.* You will find these points fully treated of in Professor A. H. Church's Cantor lectures, published just a year ago. See *Journal of the Society of Arts,* July 4th, 1890, page 747.

D. C. (Bolton).—*Reduction by Sodium Amalgam.* We fail to see what advantage your method possesses over the ordinary process of reduction by zinc. Granting that all the silver will be thrown down, you would still have an amalgam to treat, and without special appliances the driving off of mercury fumes might be a deleterious or actually poisonous occupation.

J. H. G.—*The Brussels International Congress* will hold its meetings from the 23rd to 30th August at the Palais du Midi, Boulevard du Hainaut, under the presidency of M. Joseph Maes, and will take into consideration some questions left undecided or remitted from the Paris Conference, besides a goodly number of fresh enquiries arranged uuder ten headings. For particulars apply to M. Ch. Puttemans, organising secretary. Delegates are admitted free, but from other persons wishing to attend a small fee of ten francs has to be paid, which covers for one copy of the report. Unfortunately, the date of the Brussels Conference overlaps the time fixed for the meeting of the British Association at Cardiff.

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV. No. 1717.—*July* 31, 1891.

CONTENTS.

## PHOTOGRAPHS *VERSUS* LITHOGRAPHS.

Of all the varied abominations published under the profaned name of art, surely none can compare with the common lithograph of German origin which confronts one at this season of the year at every seaside lodging-house, and which are to be found in every cottage home in the kingdom. The coloured glass vases on the mantelpiece, the lustres (also "made in Germany"), the uncomfortable antimacassars on the chairs, the Berlin wool mats on the chiffonier—there is always a chiffonier—are disagreeably aggressive, but they are not so terribly self-assertive as that German lithograph in its veneered maple wood frame which hangs on the wall.

As works of art, these pictures are utterly bad, and if there were not, unfortunately, in this country a great lack of artistic discernment among the general populace, they would never have found a sale. But the same feeling which prompts the multitude to listen to and encourage a street band (also "made in Germany"), with its shrieking clarionet, its blatant cornet, and its snorting trombone of three notes, will also influence it in buying and proudly exhibiting on the home walls the lithographic trash which is as nasty as it is cheap. Both bear the semblance of art, and both appear to be good enough to tickle the uncultured senses.

The producer of these lithographs has, after the manner of his countrymen, been keen enough to see a demand and to create a supply in a field which to Englishmen looked unpromising and barren. He knew that cottagers and lodging-house keepers of the more humble kind could not afford oil paintings or line engravings with which to decorate their walls. His knowledge of human nature also told him that pictures of some kind they would have if they could only get them cheaply, and so the German lithograph was conceived.

The German producer has striven to present to the uncultured eye a cheap something which, in subject and size, shall prove attractive, and he has certainly succeeded in his efforts. He has also been clever in at once acknowledging the truth of the Shakespearian adage which tells us how "one touch of nature makes the whole world kin," and has rung the changes on touches of nature to the verge of idiotcy. He is great in scenes which illustrate the domestic virtues, and we have pictures of abnormally clean cottagers and their children sitting down to meals, and engaged in various other laudable and necessary occupations. Or we have a pair of wooden-faced lovers standing near a stile, with the church embosomed in trees in the middle distance, hinting at probable matrimony. Every face is smug and smooth, and has as much expression in it as that of a cabbage. But the teutonic producer does not stop at these original flights of genius, but actually has the audacity to serve up with the same hideous garnishing well-known pictures by our own English artists. Landseer's noble dogs are degraded into stuffed animals with impossible limbs, and with all their force and character washed out of them; and Millais' "Black Brunswicker" takes the form of a pudding-faced youth with an expression of utter vacancy. It is, indeed, a grave reflection upon a people which boasts of a national gallery like our own that such things should gain currency, but that they sell well is a melancholy fact about which "there is no shadow of doubt whatever," and evidence of which is furnished by all the "furnished apartments" in the kingdom.

But it is of little use to diagnose a disease unless we can point out a remedy, and, in this case, we think that we can indicate a means whereby the lithograph can be ousted from the position which it occupies in the estimation of the uneducated public. We must at least thank German enterprise for showing us that there is a vast mass of customers for pictures spread all over the rural parts of the kingdom, and we must now consider whether we cannot supply the demand ourselves, instead of leaving to others that profitable business.

Now, is there not here an opportunity for photography to step in? It may be argued that the people have already an opportunity of hanging their walls with most exquisite pictures gathered from the holiday and Christmas numbers of our leading illustrated papers. This is undoubtedly the case, and the most popular picture ever published in this way—Millais' "Cherry-ripe"—is hung in many a room. But still, there is the feeling, common to us all, that a picture which so many people have a chance of acquiring is not quite so desirable as one which is a little more rare. The German travelling pedlar carries a large variety of works with him, and one dweller in a village will take care that he does not buy the duplicate of a picture already purchased by a neighbour. We may also suppose that the polished frame, with its gilt edge, has something to do in tempting the purchaser.

In pitting photography against these cheap lithographs, we have in mind the number of exquisite pictures annually exhibited at the different exhibitions, the ready means by which such pictures can be enlarged, and the number of processes available for reproducing them. A good photograph of an attractive subject, enlarged if need be, reproduced by the Meisenbach method, and carefully printed, is far finer than anything that lithography can do, and we believe that in quantities it could be produced quite as cheaply. Collotype pictures could be turned out at a slight increase of cost, and would probably meet with a large sale. Higher priced pictures might owe their existence to Woodburytype, and carbon and photogravure would still meet—as they do now—with a fair share of patronage from the more wealthy. Of course such a business cannot be started without effort and energy, for the people will not come to buy; they must be sought out. When once they are able to compare the German monstrosities with the photographs, and receive a guarantee that the latter will not fade, we feel certain that they will not hesitate to avail themselves of the better and newer form of art. We think that there is money in the idea, and manufacturers would do well to give it their consideration.

We are quite aware that in these hard times the producer's first question must be, "Will it pay?" but in the case before us he cannot fail to feel a certain satisfaction in knowing that he is influencing for good the popular taste, and inculcating among our least educated classes a desire for something a great deal better than they have been accustomed to. Better ideas of this nature lead to more noble aspirations in other matters, and such feelings are much wanted in England just now, notwithstanding the boasted march of civilisation.

Brighton Photographic Society.—Mr. A. H. C. Corder, the hon. secretary, asks us to notify his removal from 42, Moutpelier Road, to 77, Buckingham Road, Brightou.

Iodides in the Developer.—Herr Lainer, of the Vieuna Institute of Photography, has been examining the action of iodine and iodides in hydroquinoue, eikonogen, aud pyro developers, and has found that their action is precisely the opposite to that of bromides; the latter, as is well knowu, teuding to the increase of contrast, whereas iodine and iodides tend to produce reduction of contrast, and, if used in excess, to very flat negatives. A 1 per cent. solution of iodine iu equal parts of alcohol and water is recommended, and the addition of 2 or 3 drops of such tincture to every ounce of developer has a striking effect.

## REMARKS ON DR. EMERSON'S "NOTES ON PERSPECTIVE DRAWING AND VISION."

BY W. H. WHEELER.

Dr. Emerson's paper, entitled "Notes on Perspective Drawing and Vision," followed so closely on that in which I had endeavoured to direct attention to the mental theory of visual perception as capable of explaiuiug apparent anomalies in photographic perspective, that some remarks might naturally be looked for on my part. As it happened, I did not see it for some weeks, and being disappointed, for the present, in my hope of finding leisure to continue the development of my own views, I would ask of you space to say that, though welcoming Dr. Emerson's testimouy as to the geueral fact of such discrepancies—which must ever exist, our judgments being continually warped and modified by causes varying momentarily and individually, though some are pretty constant and general—I cannot at all agree with him as to their cause and character. Indeed, I find so much at the outset of what seems to me very like confusion of thought,* aud of the ignoring of well accepted theory, both mental and physical, that I can only now comment on these points.

Dr. Emerson tells us, in Proposition A, that "that portion of the eye which perceives distance and distant objects (*i.e.*, those above the ground) sees the objects on a larger scale thau the portion of the eye which views the foreground or nearer objects, therefore our impression of nature is uot what we get with a mathematically correct perspective drawing, or the drawing of an aplanatic photographic lens. (To say a rectilinear doublet lens would be more accurate—aplanatism has nothing to do with the matter.) That is, a perspective drawing surprises us by making the foreground objects look larger in proportion to the distance"—than what? Presuming Dr. Emerson's meaning to be "than agrees with our ordiuary perception," there is, I think, no doubt about the truth of this last sentence, and a most important truth it is. But the earlier part of the proposition contains implied assumptions which I look on as profound misconceptions, so greatly at variance with the accepted theories, both mental and physical, as to be well worth endeavouring to unravel.

We see, first, that the accepted mental theory, according to which distance can never be directly seeu as such—that is, it can never be apprehended as simple sensation in the way that differences of colour, brightness, &c., are apprehended, but must always be inferred through an act of judgment, interpreting the signs presented to us through sensation—is eutirely ignored; and distance, as well as distant objects, are mentioned as though both were actually seen, aud that, indeed, by a portion only of the eye. Yet not only the comparatively subtle and complex inferences drawn from our knowledge of real or actual magnitudes, compared with our estimates of apparent magnitude, or from running the eye over a succession of intervening objects, or from atmospheric softening—by all which we may estimate considerable distances—are distinctly acts of *judgment*, but also the accommodative action of the ciliary muscles—the co-ordinated movements required in binocular vision to converge the axes of both eyes to the same spot; and all the parallactic effects of moving the head, or otherwise changing the point of view,

* What can be meant by the sentence, "and prove the fallacy of photographic and all mechanical methods of measurement"? Are *actual* or *apparent* magnitude referred to, or is it the difference existing between the two?

by which we generally judge of nearer objects, are only known to sensation *as such.* In themselves, they are merely signs which must be mentally interpreted before we can apprehend *distance.*

The accepted physiological theory fares no better than the mental one. It is well-known that *distinct* vision is obtained only when the part to be distinctly seen is centrally incident on the retina. Let anyone watch his own vision while reading, or, still better, watch the eyes of another reader as the direction of their axes moves along each line of the book under perusal, and he will understand what is meant. Wundt uses the fact as a metaphor to illustrate the psychical doctrine of attention; and Mr. Jas. Sully, in an article headed "Unconscious Psychical Activity,"* says: "To adopt the metaphor of Wundt, the whole mental region (conscious and sub-conscious) answers to the total field of view present to the eye in varying degrees of distinctness at any moment when the organ is fixed in a certain direction. The latter region, that of attention or clear consciousness, corresponds to that narrow area of 'perfect vision' on which the glance is fixed.

It would, perhaps, seem natural to suppose that these facts, relating as they do to our daily experience, should have been generally recognised, and be constantly present to our minds. But we are all accustomed, when gazing on a scene, to turn the eyes instantly on any part we desire to see, and then, having placed at least one clear vision of each part on the memory, it is held there by the faint sub-consciousness of it which sensation can produce when not looked at directly; and, while it is imaged on an outer part of the retina, we are apt—all unaware of the really intricate complexity of these combined mental and physical processes, and perhaps thinking of it all simply as "sight"—innocently to attribute the comparative clearness of the mental image—which, though partly produced by obscure sensation, is illumined by a more vivid memory—wholly to that present sensation, which is, nevertheless, quite insufficient by itself to produce it.

It is thus difficult for us adequately to appreciate the real indistinctness of our visual sense of those parts of the general image which are away from the centre of the retina, and of which we cannot actually have—except as refreshed by at least one direct glance—any sense approaching the clear vision physically accompanying central definition, and the clear consciousness mentally accompanying the directed attention. Without at least one direct glance we can possess only an imperfect or sub-consciousness of them. For to the necessary optical indistinctness of oblique pencils, is here added the difference in sensitiveness between the outer parts of the retina, and of the central parts—especially of the *fovea centralis*, or small central pit—marked by the presence of fewer "cones" and more "rods." To these again is added, in general experience, the effect of comparative inattention, blurring and confusing the mental impression. For our constant habit is always to accompany attention by so directing the eyes as that the point to which that attention is directed shall be imaged on or near the *fovea centralis*; and as the attention is directed, so the axes of both eyes are converged, and also the ciliary accommodation is made. As Helmholtz says, "Just as quickly as the eye turns, does the accommodation change," and "Whatever we want to see we look at, and see it accurately; what we do not look at, we do not care for at the moment, and so do not notice how imperfectly we see it."* In the light of these well accepted theories, it is difficult to treat seriously such a phrase as a "portion of the eye which perceives distance." For, first, the perception of distance is far more than the visual sensation of a distant object, and necessarily includes the mental interpretation which attributes distance to that object. Secondly, the signs which are thus interpreted have been obtained from many complex sources, including distinct sensation on the *fovea centralis*; to which part it is, indeed, very difficult for us, even by direct effort, to *avoid* bringing the image of any object to which attention is even momentarily directed. For these reasons we may be quite sure that both the distant and near parts of the view have all been seen, and the distances all inferred, from vision or the memory of vision, when imaged on this *fovea centralis.* Different parts of the image cannot, therefore, definitely correspond to different parts of the ever-moving eye, as they may with different parts of a photographic lens, whose stony gaze is fixed and unvarying.

It will be found that all the experiments recorded partake more or less of this same character—they are all *judgments.* For they are in no instance merely crude sensations, but perceptions which have been interpreted from sensations by mental action. It is in vain, therefore, to search for their origin among physical causes, such as imagined "naturally selective action of the retinal nerves." For if such action were even demontrated, we could thus only obtain signs to be mentally interpreted. We must turn to the mental rather than to the physical side of our nature, and then all may become comparatively clear.

## GLASS ETCHING.

"White acid" is a name used by glass etchers to designate mixtures of hydrofluoric acid with various chemicals which are used for matting the surface of glass. The discovery of white acid is due to Berzelius, who, while engaged in his investigations on the properties of glass, made the discovery that fluoride of ammonia had the property of matting or opaquing glass. Since that time it has been found that other alkaline fluorides possessed the same power, and during the last few years this has been taken advantage of on a large scale for producing ornaments on glass of the greatest beauty. It is employed, principally, for producing ornamental figures on door lights, although it is used very extensively for decorating glass ware for table use, and also for the various sorts of globes used on lamps and gas fixtures. Extremely fine effects may be obtained on mirrors, and the silvering may be placed on either the same or the opposite side from the etching.

During the last few years etching on glass has shown itself as a formidable rival to the sand blast, the work generally being indistinguishable from that produced by the latter, except that acid is capable of producing effects of a much greater fineness and delicacy. The grinding is much more even, and therefore more easily cleaned.

In Germany, where the art has been carried to a much higher point of perfection than elsewhere, a number of formulæ for matt-etching are in use. Within a short time some of these have been published in various scientific journals, but they all belong to the category of what might be called slow acids, and are very unreliable and uncertain in their action, and possess very poor keeping qualities. They are made without the ammonia salt, and are dependent on soda and potash for their action, take a long time to work, and are too uncertain for practical use.

There is no doubt whatever but that the white acid compounded with fluoride of ammonia is the best. In using other white acids, spots and streaks often form in the glass, and these cannot always be removed by repeating the etching. With ammonia acids, however, any streaks which may appear, either from applying the acid unevenly or from imperfections in the glass, may be removed by repeated etchings. The following recipe is one which is used by several practical glass etchers, and is said to give good results. It is of German origin, and the only objection to it is that it is too complicated, which objection may also be raised to other recipes from the same source.

In a container of lead the following mixture is made :—

| | | |
|---|---|---|
| Distilled water ... ... ... ... | 500 | parts |
| Fluoride of ammonia (strong) ... ... | 500 | ,, |
| Sulphate of ammonia ... ... ... | 50 | ,, |
| Sulphuric acid ... ... ... ... | 100 | ,, |

This solution is ready for use within two hours, and may be tested by immersing a piece of clean glass, which should get a nice, fine matt surface after five or six minutes.

In practical experience the writer has found that a simpler method of preparing the acid than the foregoing is capable of giving good results. Besides being cheaper, it is possible to recover the materials in it, should it for any reason get out of order.

A container of sufficient size is filled one-third full of ordinary commercial hydrofluoric acid. Carbonate of ammonia is then added. About equal parts by weight may be used. When effervescence has ceased, a small slip of clean glass is immersed in the mixture and permitted to remain six or eight minutes. Upon withdrawing, it is rinsed in clean water, wiped, and dried. If examination shows that it has become evenly translucent over its entire surface, the mixture is all right and may be used for regular work. If, however, it is deeply and irregularly etched, with some parts clear and some parts ground, the acid is in excess and carbonate should be added. If, on the other hand, the glass seems to be only partially affected by the acid, and, while being slightly ground all over, is transparent, too great an amount of ammonia has been used, and acid must be added.

With a little experience, it is possible to keep the balance between the alkali and the acid, so that good results can be obtained. All white acids are subject to change in their action from day to day, but in none of the recipes the writer has used can it be so easily regulated as in the foregoing. Before trusting any important work to the action of white acid, the acid should be tested with a clean piece of glass, and by following the hints given the acid can be corrected to give the proper action.

In preparing glass for etching, any of the ordinary resists may be used. The drawing may be either put on glass by means of a ruling pen dipped in asphaltum properly diluted, by means of a brush, or by means of the somewhat antiquated process of covering the entire plate with Brunswick black, and scraping away the parts which it is desired to grind. The best method, however, is that in which tin-foil is used, a description of which must be deferred to some future time. The design can also be transferred or photographed on glass if desired.—*Scientific American.*

## THE PHOTOGRAPHIC WORK OF HERSCHEL AND FOX TALBOT.*

BY WILLIAM LANG, JUN., F.C.S.

A COMMUNICATION from Talbot to the *Philosophical Magazine* on "A New Property of the Iodide of Silver" may be here referred to. It appears at p. 258, vol. xii., and is a note of the appearance that silver iodide presents when heat is applied. A pale primrose yellow, when cold, this salt, when exposed to the heat of a fire, turns to a rich gaudy yellow. Before passing on to consider Talbot's later researches, I may be allowed to refer as briefly as possible to some of his earlier work, giving the original source of publication.

In 1826, "Some Experiments on Coloured Flame," *Edinburgh Journal of Science*, v.

In 1827, on "Monochromatic Light," *Quarterly Journal of Science*, vol. xxii.

In 1833, "Remarks on Chemical Changes of Colour," *Philosophical Magazine*, vol. ii.

In 1834, "Experiments on Light," *Philosophical Magazine*, vol. v., p. 321—334, and "Royal Society Proceedings," p. 298, vol. iii.

In 1835, on "Nature of Light," *Philosophical Magazine*, vol. vii.

The foregoing by no means exhaust the scientific contributions of Talbot. His mathematical memoirs were considerable. A Royal Society's medal was awarded him in 1838 for "Researches in Integral Calculus."

Dealing again with the year 1839, we find Talbot making a short communication to the Royal Society on March 21st, the title of which is "Note respecting a New Kind of Sensitive Paper." In using bromide of potassium instead of sodium chloride, the author finds that greater sensitiveness is manifested. He also refers to a mode of making a negative design on glass by blackening the same by means of the smoke of a candle, and etching out the lines by means of a needle point.

The ninth meeting of the British Association was held at Birmingham, in 1839. It opened its proceedings on the 29th of August, ten days after the public announcement of Daguerre's method. Accordingly, we find Talbot contributing a paper to the section of Physics and Mathematics, dealing with the Frenchman's discovery, "Remarks on M. Daguerre's Photogenic Process." Talbot's paper is, for the most part, taken up with the consideration of the optical phenomena presented when a particle of iodine is laid on a silver plate and afterwards gently treated. He seems, moreover, to doubt the superior sensibility of Daguerre's plate over his photogenic paper. The discussion that ensued is reported in No. 618 of the *Athenæum*, August 31st, 1839.

Up to this point, as we have seen, Talbot had been busying himself with the obtaining of actual images, "printed out" subjects, as we would now call them. Talbot's own words, referring to his calotype process, may be here quoted; they are taken from the appendix already alluded to. "The discovery of the latent image and the mode of its development was made rather suddenly on September 20th and 21st, 1840. This immediately changed my whole system of work in photography. The acceleration obtained was so great, amounting to fully one hundred times, that, whereas it took me an hour to take a pretty large camera view of a building, the same now only took about half a minute, so that instead of having to

* Concluded from page 524.

watch the camera for a long period, and guard against gusts of wind and other accidents, I have now to watch it for barely a minute or so. Portraits were now easily taken in moderate daylight. One of the first portraits taken was sent to the French Academy of Sciences, where it excited great interest, and was passed from hand to hand, and afterwards to the public in the galleries, my friend, M. Biot, being my informant.

"I soon drew up an account of this new process, which I named the calotype, and transmitted it to the Royal Society."

The memoir in question was read at the Royal Society meeting of 10th June, 1841, its title being "An Account of Some Recent Improvements in Photography." The process, briefly stated, consisted in forming silver iodide, in the first instance, on the surface of paper, sensitising thereafter by means of gallo-nitrate of silver, developing the image after exposure by further applications of the gallo-nitrate solution. The fixing was effected by means of a soluble bromide. The process was patented in February, 1841, but in 1852 Talbot, with certain reservations, gave the right to work it to his countrymen. Specimens of early calotypes I have here with me, and can be inspected afterwards. The Calotype, or Talbotype, was a negative picture, the positive reproduction of which was obtained by means of his photogenic paper. By a modification of his process, Talbot worked out a method whereby positives were secured in the camera. The *modus operandi* was as follows: Sensitised calotype paper was exposed to sunlight till a visible browning took place; afterwards it was dipped into a solution of potassium iodide (25 grs. to oz.), washed in water, dried with blotting-paper, and a good full exposure given in the camera. Development by means of the gallo-nitrate solution was then resorted to, when a positive reproduction was obtained. I pass a camera picture round secured by this method.

In 1842 the Rumford gold medal was awarded Talbot in recognition of his photographic discoveries. At the Cork meeting of the British Association in 1843, Talbot was asked by the general committee "for his report on photography and its applications to be presented, if possible, at the next meeting." The report asked for does not appear, but we find a communication from Talbot detailing his experiments on sulphate of iron as a developer in his calotype process. As is well known, the proposal to use ferrous sulphate emanated from Robert Hunt. The short abstract of Talbot's paper will be found at p. 105 of Report of Transactions of British Association for 1844.

In 1843 Talbot was over in Paris for some little time giving lectures and demonstrating his process.

In 1844 the first part of the famous "Pencil of Nature" made its appearance. Its publication extended over a period of two years, several unforeseen difficulties having been met with. There were six parts in all, and twenty calotype illustrations in the complete work. In 1845 another work was published having similar photographic illustrations, with the title of "Sun Pictures in Scotland." Both works are here for inspection of those interested. In 1846, in the *Art Union* number for June 1st, an article entitled "The Talbotype Sun Pictures," evidently inspired by Talbot, forms the first contribution. As a supplement a calotype was furnished with each number. There must be still extant a goodly number of these pictures hidden away in old bookstalls and in libraries. The original issue was something like 7,000, and a large number of negatives seem to have been employed. In all those reproductions which I have seen I have not yet met with a duplicate. I have with me for inspection two of these early Talbotypes.

In June, 1851, a remarkable experiment was performed by Talbot at the Royal Institution. A printed paper was attached to a wheel, which was made to revolve rapidly in the dark. On illuminating the paper for a very brief interval of time by means of the electric spark, a photographic transcript of the printed matter was obtained on a plate prepared by a method described in the *Athenæum* of December 6th, 1851. The process was patented by Talbot.

In 1852 Talbot secured a patent for photo-engraving. He gave the name of photoglyphy to his method, and made use of the well-known action of light on bichromated gelatine, the etching of the plate being performed by means of iron perchloride. A subsequent patent was taken out in 1858, the improvement consisting in the application of a resin to the plate before commencing etching operations. A supplemental illustration of this mode of engraving was issued with No. 10 of the Photographic News, appearing November 12th, 1858. Several plates were employed to give the necessary number of prints for the circulation of the paper; we find, therefore, that the subjects depicted are somewhat varied, and they mostly are all Continental. A more perfect illustration appeared with No. 54 of the Photographic News, September 16th, 1859 (Vol. III). In this supplement there was only the one subject chosen, a view of a portion of the Tuileries. The plate which furnished the proofs was copper, and had been steel faced. I regret that I am not in a position to show specimens illustrative of Talbot's photo-engraving. A specimen of a half-tone engraving appears in a second edition of "Tissandier's Photography" already referred to, as also a specimen of line work. These, as I have the book with me, can be seen. Several other patents connected with photographic applications were applied for. We need only refer to one taken out in conjunction with Malone for the use of unglazed porcelain instead of glass, and employing an albumen process.

Enough has been said to show how very assiduously Talbot must have worked at the various photographic methods he from time to time brought forward, but other scientific matters engaged his attention as well. It would be beyond the limits of this communication to enter into these. We are only more immediately concerned with the facts which we have just glanced at. I regret that the marshalling of these had not fallen into the hands of one more capable of rendering full justice to them. It will be our privilege, as a Convention, to visit the shrine of Lacock Abbey, where the illustrious Talbot worked, and surely that "building which was the first that was ever known to have drawn its own shadow," to use Talbot's own expression, must have an interest and significance to the photographic pilgrim which to the ordinary visitor will be completely wanting.

---

Reducing Over-Dense Negatives.—Belizki recommends the following formula. It must be mixed in the order given:—

| | |
|---|---|
| Water ... ... ... ... ... | 200 parts |
| Potassium ferric oxalate ... ... ... | 10 ,, |
| Sodium sulphite (neutral) ... ... | 8 ,, |
| Oxalic acid ... ... ... ... | 3 ,, |
| Sodium hyposulphite ... ... ... | 50 ,, |

It will retain its working strength if kept in the dark, and may be used over and over so long as it has a green colour.

## SHADOWS IN PORTRAITURE.

BY XANTHUS SMITH.

THERE is so much attention given to the subject of *lighting* in photographic portraiture—so much talking and writing about where the light should come from, and how much there should be of it, and in what way it should fall upon the features—that it seems to the writer that the very important subject of the shadows is being entirely overlooked, and he humbly begs leave to offer some remarks upon this, as he considers it, very important factor—namely, shadow—in the art of making a good likeness and an agreeable picture.

Shadow is the repose of art, the sentiment of art, and the web of setting, as it were, for our lights. It gives us our contrasts and our relief. It is by the breadth and depth of our shadows that we get the true values and brilliancy of our lights, and those forcible effects which are so sought after by great painters.

All who have read about or paid any attention to the subject of art know that the secret of the great painter Rembrandt's success was his skilful mastery of the principles of shadow. He subordinated all else to it, and it is in consequence of the very large proportion of shadow in his works that his lights stand out with such marked effect. While many painters considered one-fourth a sufficient amount of shadow for a picture, Rembrandt often reduced the amount of light in his works to one-eighth, and, although it would not do for all to venture so large a predominance of shadow—for what with Rembrandt produced brilliancy, with imitators resulted in sombreness and heaviness—yet, by a careful study of shadow and its proper management, we may expect to attain some of our finest effects.

Mystery is an important quality in art. The inquiring and inventive faculties of the mind are occupied by it. When all is spread before us at once, under a brilliant illumination, the eye passes over the subject, takes in all with quick comprehension, and is as quickly satisfied; but when much is subordinated, obscured, in a measure hidden, then do we search and build up in our fancies ideas in harmony with the subject and agreeable to ourselves. Poets and lovers of nature, and painters as well, love to dwell upon her in the early morning or in the evening hours. Why do they treat with indifference the brilliant glare of noonday sunshine? Simply because it is in the morning and evening that they find that predominance of shadow which gives nature its repose and sentiment, and, we may further add, its solemnity and impressiveness. It is then that the fancy may have full play in the broad passages of quiet repose, and the eye be gratified by the sparkling lights; it is then that nature gives us her pictures, instead of yielding up her every separate feature.

Shadow is the great modeller, the moulder of form. By its judicious use in portraiture we round up our heads, produce the overhang of our eyebrows, cause our noses to protrude, and give shape to our mouth. We have only to pose a sitter in front of and directly facing a large window, and photograph him thus, to be fully convinced of the just value of well-cast shadows. The head and face will be amply lighted—no one can dispute that; but who would be satisfied with such a miserable, pale, flat representation of themselves as would result from such a picture? Under the eyebrows, under the nose, and under the chin would we have the same illumination as on the forehead, cheeks, and, in fact, all the other prominences? Instead of an intelligent countenance we would have a pale, glaring stare. Now let us obscure the lower half or two-thirds of our window and try another picture, and see what a difference we will have wrought.

A high, soft lighting is undoubtedly the proper one for the majority of sitters. Occasionally we see individuals, more generally ladies and children, possessing some peculiar piquancy of expression, who will make taking pictures in almost any pose or lighting. Such heads are apt to find their way into the show-cases, provided permission be obtained to exhibit them. These pictures are well because their excellence is founded on the intrinsic symmetry of the face. It is when we come to deal with the average man and woman that our greatest difficulty arises, because, being neither picturesque nor beautiful, they drop into the common-place. People do not generally admire themselves treated in a common-place way. They all want to be made to look handsome, and with more dignity than they possess. Like the young fellow who volunteered to pose to his artist friend for the head and figure of Brutus, and, being aware of his very insignificant appearance, said: "Now, Brush, you will have to throw in all the dignity of the noble Roman, you know." The safest way with this large class of sitters is a good bestowal of shadows just where they are wanted. Not too strong and black, but full and soft, and the lights soft also. It is only in the heads of marked character, and when the individuals themselves permit it, that very vigorous shadows may be allowed, and then we have good pictures of a higher artistic order, which may be characterised as picturesque.

We sometimes see in show-cases photographs of individuals taken under some trick treatment, which, though rather attractive at first glance, will not bear analysing and study, and which, if we have occasion to pass the place frequently, become excessively disagreeable and annoying to us. One of these tricks is obscuring the face in shadow with a harsh line of light on one side. If you have a lean, hatchet-faced man or woman with a very prominent nose, and treat them after this manner, especially large, you will have something attractive, certainly, but you won't find its charms lasting. We all know that we may have too much of a good thing, and, indeed, with many things the better they are the sooner we surfeit of them, and so we may have too much shadow. We must remember that a countenance may be overwhelmed with shadow. The shadow is to be used to develop the features, and not to obscure them. We must make shadow our servant, and not allow it to become our master. We too often see in the show-cases at the entrance to prominent photographers' galleries, and where there is a display of an abundance of elaborate work—work which has called forth the greatest knowledge and skill in technique to produce—a universal misconception of the true use of shadow. In many instances, in fact, shadow seems to be the aim and end, as if shadow should be the picture, instead of the means of producing it. How disappointing it is, for instance, to see a series of fine, large heads wherein the sitters have been posed against an even half-shadow background, and the entire face thrown in shadow, or rather half-shadow, except one temple and the nose, the light having been kept well back. Of course the back of the head, ear, and back of the neck are in strong light. This, with a well up-turned face, three-quarters, or nearer profile, and as complacent an expression as can be got, is a favourite mode of treatment, and very absurd when looked upon as anything but a curiosity; and a still more objectionable effect is when the head is posed against a white background and lighted from back, no reflection used on the shadow side, so that the face cuts very harshly against the ground, the whole face appearing very dark except the nose, which, with the upper corner of the forehead, gets a full whack of light. Now you see that, owing to the nose being a very prominent feature, it is difficult in this shadow treatment to make it succumb to the rest; it will stick out and catch some light in spite of us, and even when it is a handsome nose, it ought scarcely to receive all the light when the rest of the features are not receiving any. Another difficulty with shadow pictures is to prevent all the lower portions of the face from falling into too low a tone, because, from the cheeks rounding in, and the chin receding, and the mouth being overshadowed by the nose, the bottom half of the countenance is lost. An excellent way to study these matters is to look at such work with your eyes nearly closed. In this way you will lose all the details, and you will perceive only the main masses of light and dark. You will then perceive how absurd the effect often is, and you should never lose sight of the fact that your main masses of light and dark must be well composed if you are to produce a good picture. The features of man are so formed and combined that, with knowledge and care in the bestowal of the shadows, a perfectly harmonious arrangement is produced even in the blocked-out mass, regardless of the finer details, and when the details are wrought upon a justly arranged foundational effect, we have the most perfect whole as a result.

When it is desirable to make what is called a shadow or Rembrandt picture of a head or half-length, a much better effect is got by using a black or very dark background, because the flesh then at once takes its place as half-shadow, and, by contrast, has a certain luminousness; while against a middle tint or very light background it will appear dull and heavy. But such treatment—that is, casting the face in shadow—is best suited for handsome sitters, and where the plumpness of youth gives the flesh an evenness of texture that aids in securing softness. With the hollowness and wrinkles of age, dullness and hardness is too apt to be the result. Much has been attained in some galleries where great pains has been bestowed in the matter of the casting and formation of shadows. The almost insurmountable difficulty of harshness of contrasts has been greatly overcome. It is a subject that requires much knowledge and practice. Nor should it be a matter of surprise to the photographer that it is so. Is not the work of the beginner in painting hard? and does it not take years of study and practice to enable the portrait-painter to attain the vigour and, at the same time, the softness and harmony of a master? The man who attains the most vigorous contrasts of light and dark —for that is what makes the work telling upon the eye of the spectator, and, at the same time, avoids harshness and consequent hardness in his work—is the successful man from an artistic point of view.

In order to make a good artistic head, the deepest touches of shadow should come under the eyebrows, under the end of the nose, and about the mouth and chin. These should be supported by a proper amount of half-shadow coming about the eyes, under the cheeks, and about the chin, falling in such a way as to give a proper amount of roundness to the face and projection to the features. All this can be greatly aided by a nice timing of the exposure and careful development. How often do we see, even in large, carefully-got-up heads, a perfect uniformity of whiteness in all the directly lighted portions—the flesh, the white hair and beards of old men, and the white linen of collar and shirt-bosom being identical in whiteness. This should not be. The linen should represent the highest light, the hair should come next, and then the light flesh, a little lower in tone than either of the others; and then, in the flesh, we should be able to pick out readily five grades or degrees of tone, from the highest lights, which are accentuated on the upper corner of the forehead, over the eyebrows, over the cheek-bone, and on the bridge and end of the nose, to the very deepest touches of shadow under the eyebrows, under the nose, and about the mouth. These latter are the portions that remain clear in development, and in the old wet-plate days were represented by clear glass in the negative.

In conclusion, I have not said anything about the practical details of arrangement of skylight, its accessories, or posing, because my remarks are intended for those who are supposed to be well versed by actual experience in these matters, are working on a high standard of excellence, and are aiming to bring forth still better work. With all such I am in full sympathy, and, at a future time, will hope to offer some remarks about the very important matter of being able to secure the number of delicate gradations of tone, from high-light to deep shadow, of which I have spoken. It is a matter of emulsion, timing, and development. Unfortunately, the emulsion or brand of plate is not entirely under the control of the general photographer. It is a matter of the best success of the best makers. The development, owing to the difficulty of obtaining absolute equality, is not as satisfactory yet as we will hope it may become, and the timing—well, we all know the difficulty. It is a matter of good judgment and hourly experience.—*American Journal of Photography.*

---

Photo-Mechanical Specimens.—We have received from Messrs. H. Webber and Sons, of Kirkdale Road, Leytonstone, Essex, a fine series of collotypes, including portraits, landscapes, interiors, trade samples, machinery, and copies of old engravings, all of which are well rendered, and indicative of a considerable amount of skill in the working of the collographic processes. They are printed in inks varied according to the character of the subject to be represented.

Antiquity of the Electric Light.—Those who suppose the electric light to be a production of the present decade will be able to correct their apprehension of the subject after reading the following item from the *Scientific American*, December 9th, 1848:—"*New Electrical Light.*—The inventors of a new electrical light, exhibited at the Western Literary Institution, Leicester Square, London, on its recent reopening under the new auspices, expect, it is said, to apply it generally to shop and street illumination, and they state that, while the conveying will cost no more than gas, the expense of illumination will be one-twelfth the price of the latter light. The current of electricity, in passing through the two pieces of charcoal which form the poles of the circuit, and are excluded from all access of air, gives, in this case, it is said, an intense and beautiful white light, with the effect of daylight to a much greater extent than the lime does, and having this advantage, that it is sustained and continuous. If Messrs. Staite and Petrie can thus produce a steady and sustained light they have accomplished what has hitherto been the sole preventive to the substitution of galvanism for gas. The *Mechanics' Magazine* states that this one light completely eclipsed ten gas lights and an oxyhydrogen. The gas companies had better look out. The dissatisfaction of the public with their mismanagement may have begotten a rival destined to eclipse many more than merely ten of their gas lights."

## Notes.

The great progress that has been made in the methods by which rapid movements can be analysed is well seen in a series of photographs lately taken by Anschütz, of Lissa, who has already given to the world some of the best instantaneous pictures ever taken. The subject of the pictures at present under consideration is a dog jumping over a small bush. In the act of making one jump the animal has been photographed twenty-four separate times, and each picture is not a mere silhouette, as was the case with Muybridge's first attempts of this kind, but a little picture showing half-tone and detail. Some of the attitudes are, of course, comic in appearance, for they represent phases of a movement which the eye is unaccustomed to, and cannot possibly appreciate. Notably is this the case in the commencement of the jump, when the dog's hind toes only touch the ground; and again at the finish of the jump, when his legs are gathered together in a heap.

In spite of the greater facilities for patenting inventions in the United States, the number of specifications relating to photography are very few in comparison with those taken out and paid for at so much greater cost at the English Patent Office. What is the reason of this? We fancy that the answer to this question must be found in the circumstance that, in America, the small fee charged Includes the expense of a search through existing specifications, so that no "notion" can receive protection more than once. In the old country, on the other hand, the same idea is patented over and over again, and the heavy fees are taken each time by the authorities without a blush. It is a pity that personal morality and the official variety are such extremely different things.

Photographers who have the misfortune to have pictures left on their hands, or returned to them, cannot surely be many in number, for prepayment is, or should be, the invariable rule. But still, there may be some who are victimised, and they will doubtless be glad to hear of a plan for getting rid of their surplus stock. We must confess that the method is entirely new to us, but it is said to work well, and, like any other formula, it may be worth a trial. It consists in placing a placard in the gallery labelled "Misfit photographs for sale."

We have heard of misfit clothes, misfit boots, and misfit carpets, but a misfit photograph is quite a curiosity. Yet we have the assurance of a writer in *Chambers's Journal* that the inscription quoted above appears over a certain photographic gallery, and that it brings many customers. "Mothers, for instance, who have little children, often buy pictures of children with long hair when the hair of their loved ones hasn't grown, and send them round to friends at a distance. Brides' photographs are also said to sell very well." We are not told what is done with the brides' portraits, but possibly they too are used for the purpose of gammoning friends at a distance. But who is the wily photographer who does these things? We are almost tempted to believe that "there aint no sich pusson."

American lady tourists have invested the passage across the Atlantic with a new terror. Prince George of Greece, it seems, during his journey from New York, was pursued by 150 ladies, all armed with cameras, who persisted in photographing him, despite his protests and his attempts to cover his face. This is really a social nuisance, which ought to be sternly repressed. Celebrities are, of course. the chief victims; but should the fashion spread, no one on his or her travels will be safe. An announcement of "no photographing allowed abaft the funnel" would enable the victims to promenade in peace; but who can effectually guard against the pertinacity of a lady photographer?

The letter of a correspondent of the *Optician*, commenting on the system of advertising ordinary spectacle lenses as articles of special and peculiar excellence, reminds us of the hundreds and hundreds of worthless photographic lenses which at the present moment must be in existence, to the plague of the unfortunate amateur who is unlucky enough to buy one. These useless pieces of glass are usually to be found on the dusty shelves of the pawnbroker's shop, and the only thing which can be said of them is that the longer they remain there the better. In the early days of photography the market was flooded with common French lenses, most of which were incapable of producing a decent picture, but amongst which, occasionally, was one with marvellous powers. It was, of course, quite a matter of chance, but the mischief was that the rash amateur, hoping to get a prize on the cheap, often wasted his money. The general opinion now is, that if you buy a nameless lens you may pick up a bargain, but that if you buy one of an accredited maker you are certain to get your money's worth, even though you may pay a long price.

The Transvaal Mining Conference now sitting at Prætoria is in sad need of a photographer. An application about to come before the Transvaal Parliament for the sole rights of manufacturing cyanide of potassium was hotly discussed by the Conference, the chairman denouncing the application as an "iniquitous" one, while others were as strongly in favour of it because the granting of other concessions had turned out well. Ultimately the matter was postponed, in order that the members of the Conference might find out what cyanide is!

The view-finder attached to most detective cameras has suggested to the captain of a French man-of-war a means of sighting and firing guns with accuracy and, as far as possible, safety. On the cannon is fixed what is virtually a camera having a thick ground glass, upon which is marked a sight; over the cannon, in the side of the ship, is a small hole containing a simple lens. This is the whole of the apparatus. The gun is moved until the object to be fired at is seen on the ground glass, and this accomplished, the gun is fired. The name given to this method is *Tir Optique*, and its efficiency is said to have been amply proved by practical experiments.

The oddest photographic craze that we know is that of a worthy and respected collector of old armour who has had himself photographed in every suit, and as the collection is extremely varied, the photographic album which has resulted is one of the most curious which can be imagined. A wicked friend has maliciously said that he looks best in a helmet with the vizor *closed*. The foible is a harmless one, and we do not see why it should not be indulged in if it pleases the collector. The armour certainly gains by the process, because the wearer is able to throw a little animation into what would otherwise be a lifeless figure.

## SPHERICAL ABERRATION, DIFFUSION OF FOCUS, ETC.

BY W. K. BURTON, JAPAN.

I fear that your readers must, for the most part, be very sick of the subject of diffusion of focus, but I hope that they will have patience with me for a little if I bring the matter up once more, and I think it is but justice that the editor should let me say a few words in connection with a communication that appeared in the Photographic News by Mr. T. R. Dallmeyer, now a good many months ago.

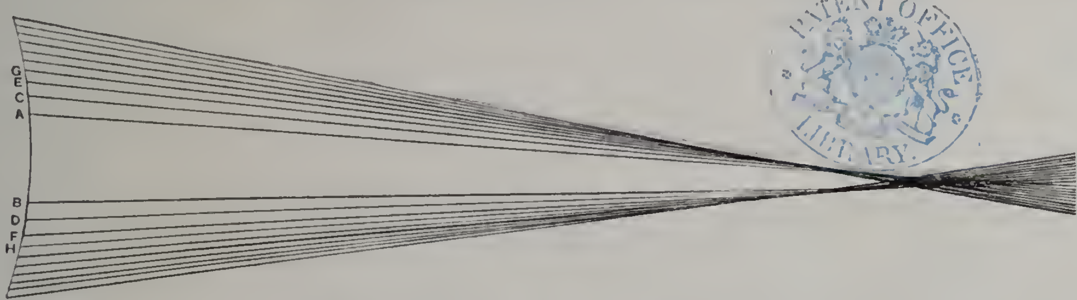
The circumstances were these. Perhaps I ventured on unsafe ground in criticising certain utterances of Mr. Dallmeyer's anent diffusion of focus. I have now to admit, at all events, with all candour, that at the time I wrote I had not thoroughly understood Mr. Dallmeyer. I hope to be able to show that I had not entirely failed to understand the subject,* as Mr. Dallmeyer generously stated at the time. Immediately I read Mr. Dallmeyer's communication I wrote to him saying that I had begun a set of farther investigations of the subject, and intended to write about the results later on. I did so begin, and had nearly finished what I had set myself to do, when my work was interrupted by an occurrence which, as it was of an entirely personal nature, need not be farther spoken of here. It is only within the last little time that I have been able to gather up the threads of the work again.

$\sqrt{5}$, &c. I have not yet noticed that Mr. Dallmeyer acknowledged this correction.

Even the axial line shown by Mr. Debenham in his diagram accompanying the above-mentioned communication should, I consider, be left out, as it gives the impression that there is 50 per cent. more of light enclosed within the limits of the smallest cone than there really is.

The drawing that I send is within the ordinary limits of hand drawing, and, allowing for the thickness of line necessary to permit of reproduction, a correct representation of spherical aberration, the lines representing the boundaries of cones, the diameters of whose bases are as 1, $\sqrt{2}$, $\sqrt{3}$, $\sqrt{4}$, . . . . . . $\sqrt{10}$. This drawing shows very distinctly the greater diameter of the cone of light at a given distance behind the plane of average focus representing the *distance* when a near object is focussed. It also shows not only the smaller diameter of the cone at a like distance in front of the plane of chief focus (representing the foreground), but shows the comparative definiteness of the boundary of this part of the cone.

But Mr. Dallmeyer's contention now is, that there is inward concentration behind the plane of average focus, and it may be said that even this drawing shows distinct inward concentration. I do not deny the appearance of such concentration, nor absolutely the existence, but I suspect that the appearance is produced more from the fact that the lines near the axis are nearly parallel before and after they intersect behind the average focus, whereas



they cross at considerable angles in front of the focus, than because of much real central concentration. At any rate, I tried to find some other measure of central concentration than the mere appearance of a diagram, however correctly drawn—not that I by any means despise such—and it seemed to me that a fair measure would be the intensity of the light on the axis of the lens, at different distances from the lens between that point where the central rays intersect, and that where the extreme marginal rays intersect. This intensity, again, can be measured by finding the length, along the axis of the lens (where that axis is the focus of a point formed by the intersection of rays from different annuli of the lens), through which the light from annuli of the lens of equal areas crosses the axis.

Mr. Dallmeyer, in the first part of the communication referred to, regrets that we live so far apart, that it is difficult to carry on a discussion. He is right so far. It is not possible to carry on a discussion with any satisfaction when several months must elapse between the printing of any two communications, and this even if the language used is always temperate. For this reason I propose to discuss no farther, but, in this communication, to give merely the result of certain experiments and calculations, letting anyone who likes draw his own conclusions.

In the first place, although we have had so many drawings representing spherical aberration already, I wish to bring one more before your readers. It was drawn long before I saw the article by Mr. W. E. Debenham, appearing in the Photographic News for September 19th, 1890, in which he pointed out that it is not a fair representation of the concentration, or otherwise, of light, where there is spherical aberration, to draw lines representing cones of light, the *diameters* of the bases increasing by equal increments. The *areas* of the bases should increase by equal increments. That is to say, that diameters of these bases should be not as 1, 2, 3, 4, 5, &c., but as 1, $\sqrt{2}$, $\sqrt{3}$, $\sqrt{4}$,

Thus, referring to the diagram, we take diameters *ab*, *cd*, *ef*, *gh*, &c., having the ratios 1, $\sqrt{2}$, $\sqrt{3}$, $\sqrt{4}$, &c., and calculate mathematically the distance between the two points where the lines from *a* and *b* intersect each other, and that where the lines from *b* and *c* intersect each other, then do the same for the point where the lines from *b* and *c* intersect each other, and that where the lines from *d* and *e* intersect each other, and so on. These are calculable without much difficulty by trigonometry, assuming a certain index of refraction. If the distance becomes less from without inwards (from a greater to a

* I have lost the number of the Photographic News containing the first part of Mr. Dallmeyer's answer to my communication, and cannot, therefore, quote exact words.

less distance from the lens), the brightness of the axis of the leus is greater within the average focus than without. If the distance becomes greater from without inwards, the brightness of the axis of the lens is greater without thau within the average focus. Working this out with all due care, I find that, for auy amount of spherical aberration at all likely to be used in practice, or even for much more, there is no appreciable differeuce in the brightness of the points on the axis of the leus betweeu the point where the extreme central rays intersect, and that where the extreme marginal rays intersect. It has to be admitted that, if we consider the case of violent spherical aberration, there is a slightly greater illumination of the axis without the average focus than within. Thus, with the enormous spherical aberration given by a plano-convex lens with an opening of one-third its focal length, the iutensity of the light may be greater by about ten per cent. for the point where the central rays intersect, than for that where the marginal rays cross. With any spherical aberration useful in practice, however, the illumination of the axis between the two points just mentioned is so uuiform that any difference there is in brightness between the extremes, if worked out, only shows in the third or fourth decimal figure. The deduction from these calculations being that, so far as brilliancy of light along the axis of the lens between the point where the central rays intersect, and that where the marginal rays intersect, may be taken as a measure of concentration of light; the concentration is equal between the two points. I thought it best to make a set of actual experiments, with a lens having adjustable spherical aberratiou, using more care thau I had in any previous set of experiments. The lens used was J. H. Dallmeyer's "4A Patent" lens—to be quite exact, No. 42,020. All the experiments involving spherical aberration were made with the back cell unscrewed as far as possible.

A few rough preliminiary trials were made, and then the first definite experiment was made in the following manner:—Opposite to the camera, and at a distance of some twenty yards, there was fixed a white stake. At distances in front and behind this (just so far off line that all might be visible) were fixed two other stakes at distances *equivalent* to equal distances behind and in front of the focus of the lens when focussed for the middle stake. (Mr. Dallmeyer, in his communication to the Photographic News, already referred to, assumes—somewhat unnecessarily, I think—that I do not know that such equivalent distances will not be equal; that, in the case under consideration, for example, the distance between the middle stake and the nearer one will be less than the distance between the middle stake and the farther one.) On each stake there were painted circular discs in black of different sizes. The middle stake was focussed for, the back cell of the lens being fully screwed home. The want of definition in the case of the other two stakes was now naturally equal. The cell was then unscrewed to its limit, the middle stake was again focussed for, and the result was observed as well as possible. It seemed in this case that, whereas the definition was distinctly worse than before in the case of the more distant post, it was, if anything, better in the case of the nearer. This result was, so far as the farther stake was concerned, distinctly confirmed by exposing plates, and this *especially if the exposures were fairly ample.* In such cases the black discs sometimes entirely disappeared, whilst they were quite distinct in the case of the nearer stake, and did not disappear with the same exposures, using the lens without spherical aberration, and focussed for the middle stake.

This experiment is not by any means so conclusive as it would appear to be, for oue of the first things that I discovered was that, working in this way, *it would be very easy to prove anything that I wanted to prove*, because of the uncertainty of focussing when a considerable amount of spherical aberration is introduced. Doing one's level best, there are limits some distance apart between which oue is doubtful where to focus; thus, focussing once, marking the place of focus, putting the image out of focus, aud focussing once again, the chances are, that there will be a very appreciable difference of distance between the two planes focussed for. Again, I found that there is a tendency to focus for different planes for different kinds of subjects even at the same distance; thus, there is a tendency to focus in two different planes at some distance apart for two differeut subjects, one of which is of the nature of dark spots on a white ground, the other of which is of the nature of light spots on a dark ground.

The thing, however, brought out by this part of the investigation which I consider most curious is, that there seems to be a *personal equation* in the matter; thus, placing a well-defined object opposite to the camera, whilst the back cell was fully unscrewed to give maximum aberration, aud asking differeut people—noue of whom knew auything of the object of the experiments—to focus (always racking the lens quite out of focus after an experiment was finished) it was found that one person would incline to focus farther forwards or backwards than another. No one of them would always focus for exactly the same plane, but the average focussing of one would always be farther forwards or backwards than that of the other.

Seeing, then, the absolute unreliableness of experiments in which one trusts to trial alone as to what plane to focus for with a lens exhibiting spherical aberration, I considered it advisable to find some more definite way of focussing, and, after some consideration, I came to the conclusion that it would be fair to focus for a plane situated half way between that in which the central rays intersect, and that in which the marginal rays intersect. To discover the position of this plane, an opaque disc was prepared, a little less in diameter than the leus; it was fixed in front of the front combination, and a large lamp flame at a distance of about twenty feet was focussed. The disc was then removed, and there was inserted the smallest diaphragm that would allow of decisive focussing. The result was that it was found necessary to rack the lens just about one-third of an inch farther from the lens to get the image sharp. The effect was then tried of racking the lens equal distances forward and backward of the plane half way between these two. The result was that the flame distinctly retained a fairly well-defined outline for a greater distance racking forwards (bringing the plane of focus nearer to the lens) than racking backwards. Forward racking represents foreground, backward racking distance. These results were corroborated by taking photographs of the flame. The destruction of the form of the flame behind the average focus, when the lens was racked forwards, was particularly emphasised if the exposure was somewhat prolonged.

Another experiment here suggested itself. For the lamp flame—that of a lamp with a large circular wick, and a flame-spreader, giving a flame about three inches in diameter—there was substituted an "artificial star" made by replacing the lamp flame by the bulb of a mercurial thermometer, illuminated by a side light at some distance, and not visible from the camera. Here the result was quite different. In racking the lens away from the ground glass, the point of light was still represented by a spot of almost inappreciable diameter, which, however, had a halo of rapidly increasing diameter around it. In racking in, on the other hand, the point of light very soon assumed the form of a small, distinctly defined ring of light. This is, I believe, quite in accordance with what is observed in using, for purposes of stellar photography, telescopes whose objectives exhibit spherical aberration. Also there is explained, unless I am mistaken, why, in the case of a large mass of light like the lamp flame, or a black disc of considerable size on a white ground, the form of the outline of the object does not become much blurred in racking inwards for some considerable distance. The size of the object is much larger than the diameter of a ring of light representing a point, and the infinite number of small rings of light forming the edge of the image overlap, and there is formed a well-defined edge, only making the whole image a little larger than it should be if it is bright on a dark ground, smaller if it is dark on a light ground.

I may mention that I got several different people to focus for both the lamp and the artificial star, and that, in the case of the lamp flame, some focussed for very nearly the extreme outward plane of focus, some for nearly the extreme inward plane. In the case of the "artificial star" there was also considerable difference, but not so much as in the case of the lamp flame. None of them knew for what reason I asked them to focus.

I do not give these results as conclusively proving anything definite, and, as I have said, I avoid any description of the conclusions that I draw from them myself. Anyone else may draw his own deductions. I think, at any rate, they show that we have not yet got completely to the bottom of the subject, and that more might be said about it were not all mankind that have heard the name of it, probably most heartily sick of it by this time.

There was one entirely different point in connection with which I expressed difference of opinion from Mr. Dallmeyer. If I understand him properly, he holds—in accordance with Emerson's originally expressed views—that no plane in a photograph should be rendered as sharp as a photographic lens can render it, and this not on account of the mere expression of opinion of artists on the matter, but as a scientific fact based on the assumption that a good photographic lens defines better than the human eye, and that, therefore, there will be made visible by it, in a photograph, detail invisible to the eye. I protested against this doctrine on the ground that, whatever failing there may be in the defining power of the eye when viewing objects, there will be exactly the same failing in viewing a photographic image of them, even assuming the definition of the lens to be *absolute*. I do not know whether Mr. Dallmeyer holds the same position as before in respect to this matter, or rather whether he holds it absolutely. In his last communication to the Photographic News in reply to me on the subject, he says: "Mr. Burton's contention *seems** unsound, for the following reasons. First, in viewing any landscape or subject, the retina of the eye is more or less flooded with a diffused light; in the case of a camera with a well stopped-down lens there is comparatively no diffused light to interfere with the powerful discriminating focus that registers the image. Then in viewing any object we have *binocular vision*. Binocular vision is, in one sense, of use only up to a certain distance, but is a very powerful means of discriminating for near planes. I believe that I have normal vision, and I can distinctly see print using two eyes at a greater distance than is possible with one."

* The italics are mine.—W. K. B.

So far as diffused light is concerned, I would ask if it does not enter the eye in viewing the photograph as well as in viewing the "subject?" In fact, is the photograph itself not a "subject" when it is being looked at? In any case, this is a matter easily determined by experiment. Let a sheet of printed matter, or a set of the test letters that oculists use, be placed in good light, and at such a distance that some of the matter—that in the larger type —can be read, whilst some cannot. Let it now be focussed with any lens and any stop, the optical centre of the lens being the same distance from the printed matter that the eye was: let a photograph be taken of it, and see if, in a similar light, and looking at the photograph from a distance equal to the focal length of the lens at the time the photograph was taken—the lesser conjugate focus, more correctly—anything can be read that could not be read before. Of course, binocular vision will be used in looking both at the original printed matter and at the photograph of it. All that I can say is, that I have never found a Dallmeyer lens that had the power (I suppose Mr. Dallmeyer would not consider other lenses a better test), and I shall consider it a miracle when I do find any lens that has. I am writing of definition in one plane only, be it distinctly understood.

## ON SOME MODIFICATIONS OF EIKONOGEN AND HYDROQUINONE DEVELOPERS CONTAINING BORAX, CARBONATE OF LITHIA, ETC.

BY COLONEL J. WATERHOUSE, S.C.

In the October number of the *Journal*, attention was briefly drawn to a new eikonogen developer called *graphol*, the distinguishing features of which were its being self-contained, only requiring solution in water to be ready for use, and borax being the principal alkaline agent. Some further particulars regarding this developer, and of the action of borax, carbonate of lithia, sugar of milk, and some other substances in the eikonogen and hydroquinone developers may be of interest.

The sample of *graphol* was received in Calcutta about the middle of September, at a time when the temperature was high and the air saturated with moisture. It remained quite dry and fairly white for some time, but at the end of six weeks had discoloured to a dark mouse colour, and formed a very dark green solution, whereas, at first, the solution was of a bright yellow or emerald green. It did not, however, at that time seem to have lost its developing power in any very sensible degree. In January it was darker in colour, but still developed well, though it had lost some of its power, and longer exposures were necessary. It had thus kept four months in good condition in a corked bottle, though opened at the worst time of the year. Under favourable conditions it would most probably keep much longer, and it seems likely to prove a useful developer for general purposes, but especially for travelling. Used solutions of it turn brown on keeping, and from this and other indications it seems probable that hydroquinone forms one of the ingredients.

An attempt to make a *graphol* developer by grinding together eikonogen, metabisulphite of potash, borax, hydroquinone, and sugar of milk was not successful.

The mixture, when fresh, worked very well, but very soon darkened, forming a dark brown solution, which had far less developing power than the fresh mixture.

As noticed in my former paper referred to, M. Mercier states that *graphol* contains, among other ingredients besides eikonogen, borax, sugar of milk, and carbonate of lithia. Some experiments were therefore made with eikonogen developers containing these substances, but chiefly in the laboratory, and not by actual practice out of doors.

With regard to the peculiar action of borax—in some cases as an acid, and in others as an alkali—Monsieur Mercier refers to two notes by Monsieur Aug. Lambert, on the action of borax on the polyatomic alcohols, and on the polyatomic phenols, which were published in the *Comptes Rendus* of the French Academy of Sciences (Vol. 108, No. 19, May, 1889). In these notes, Monsieur Lambert states the results of some experiments made in verification of Klein's observation that mannite, glycerine, erythrite, dextrose, lævulose, and galactose, had an acid reaction with borax, while the polyglucosides, including saccharose (cane sugar), lactose (sugar of milk), and quercite did not do so, and he further shows that pyrogallic acid, pyrocatechin, the alkaline gallates and tannates, and other polyatomic phenols of the orthi series behave similarly to glycerine and the mannites, and give an acid reaction to borax by the formation of monoborate of soda and an acid boro-compound capable of decomposing carbonates. This reaction is not shown by orcin, resorcin, and hydroquinone, which belong to the meta or para series, and Monsieur Mercier has discovered that it is also not shown by eikonogen.

Boric acid had already been tried by the writer as a possible preservative of eikonogen, but it was not found altogether satisfactory. Trials with borax have, however, shown that, as stated by Monsieur Mercier, it may replace the caustic alkalies and their carbonates in the eikonogen developer, and has the advantage in a hot, moist, tropical climate, at any rate, of being a definite and quite stable salt, whilst carbonate of soda, which is usually recommended for use with eikonogen, is a somewhat indefinite, and, in its crystalline form, a very unstable salt, being readily deliquescent, and apt to melt in its water of crystallisation. Carbonate of potash, though more definite and stable than the soda salt, is also very deliquescent.

For ordinary work, borax seems to answer very well with eikonogen in combination with sodium sulphite; the solution changes very little in colour, and several plates can be developed successively in the same solution, though more time is required for development in the used solution. The lights are clear and free from stain, and there is a good intensity of image. The following formula has been found to answer well, but should be modified as found desirable with different makes of plates or different classes of work:—

| | |
|---|---|
| Eikonogen ... ... ... ... | 1 part |
| Sodium sulphite ... ... ... ... | 2 parts |
| Borax ... ... ... ... ... | 2 ,, |
| Water ... ... ... ... ... | 100 ,, |

For instantaneous work a more powerful developer would probably be necessary.

Eikonogen with borax alone, without sulphite, in the same proportions as above, forms a strong developer, but the solution soon discolours and loses power.

Hydroquinone also with borax alone does not answer well as a developer; it gives weak images and is liable to stain the film, but, with the addition of sodium sulphite, it gives pictures with good density and detail, does not stain the film, nor does the solution readily discolour.

A mixture of eikonogen, hydroquinone, borax, and sodium sulphite forms a good developer, but the best proportions have not been fixed. The addition of hydroquinone adds considerably to the density of the image, as noted already by other workers. The formula given above, with half to one part per cent. of hydroquinone, has been found to work well, but may also be modified as required.

Carbonate of lithia, which is said to be one of the ingredients of graphol, though it could not be detected with the spectroscope, seems likely to be a very useful substitute for other alkalies. Its stability and definite composition as compared with other alkaline carbonates are a great advantage in an Indian climate. It certainly acts well in the eikonogen developer, giving density and detail without hardness, and in this respect, quantity for quantity, is better than borax. It is, however, only very slightly soluble in water, a saturated solution taking up only about one per cent. of the salt, or barely five grains to the ounce.

It also works very well with hydroquinone, making a very excellent developer for ordinary work, and instantaneous pictures may be made with a mixture of eikonogen, hydroquinone, carbonate of lithia, and sodium sulphite in about the same proportions as given above, but substituting carbonate of lithia for the borax. In some cases it has been found convenient to keep the carbonate of lithia in saturated solution, and add the other salts to it.

Sugar of milk (lactose) seems to be also a useful addition; it increases density and detail in the eikonogen developer. With hydroquinone and eikonogen and borax it was found to give excessive density. As noted by Lambert, lactose does not form an acid compound with borax.

I hoped to have been able to have tried experiments with various other sugars, but they did not arrive in time to be tried before I left Calcutta.

It may be noted, however, that Fahlberg's saccharin, which is not a sugar at all, seems to have some effect in increasing the stability of the ordinary eikonogen developer made up with sodium sulphite and carbonate, but with borax it seems to act rather as a restrainer.

Pyrogallic acid will not work at all as a developer with borax, nor will hydroxylamine hydrochlorate.

It may be noted, too, that the new white eikonogen in powder seems to be a great improvement on the old form of this salt. It certainly keeps its colour very much longer, though, after being open for a short time, black specks appear. It evidently contains a sulphite, but requires the further addition of sodium sulphite to work effectively.

*S. S. Chusan, Aden, May 21st.*

Cement for Parchment Paper.—The best cement for pasting parchment paper, according to a lithographic authority, is casein glue. It is much better than so-called chrome glue, because the latter produces yellow or brownish spots where it has been employed. Casein glue is a solution of casein, which appears as whey or drop when milk is allowed to curdle. The glue is dissolved in a saturated solution of borax. When dried in the form of transparent gelatine it appears as greyish white and somewhat brittle matter, which can be easily dissolved in water, and possesses great adhesiveness. When employed for pasting parchment paper a thin paste is prepared, used in the customary manner, and the jointed places afterwards exposed for a little while to a jet of steam.

## PERMANENT PRINTS.*

BY BROWN SLICK.

THE first thing to be settled is, whether there is such a thing as permanency in prints. The battle between platinotypes and bromides has been generally admitted to be a draw; neither side has been proved to be vanquished. It therefore remains for time alone to prove which will last the longest under ordinary circumstances. Platinotypes are usually credited with having most chance of lasting, but hanging in the Club-room may be seen a good specimen of a print which has now been out here for some years, which has not lost anything to speak of in the strength of the blacks—but what about the whites? They have (like every other photograph in India sooner or later does) lost their purity, and if examined in a good light will be found to have turned quite yellow. So far, my experience with bromides has been that they keep out here quite as well as platinotypes, and until a few days ago I had nothing but the highest opinion of them. Alas! not so to-day.

In the summer of 1890, while in England, I printed a quantity of bromides and platinotypes, and spared no trouble to wash them perfectly with a view to keeping them in India. Some I mounted in a book, and the rest were mounted on cards for framing. Seven months only have gone, which anyone will admit is no test at all, but, unfortunately, quite enough to seal the fate of three bromides. On turning over the pages of my book, I found to my dismay that, where a bromide print faced a platinotype, it had (I mean, of course, the bromide) turned quite brown, and was vanishing into clear white paper. Turning over a few more pages I found the same thing again, and it turned out that wherever a bromide and platinotype came face to face it was all up with the bromide, while in no case has a platinotype suffered in the least. Of course the first answer to this is that there must be some acid left in the platinotypes which acts chemically on the silver of the bromides. Well and good; but it is very poor fun if we are to keep different books for every different sort of print. There is, however, one point about my faded bromides which hardly bears out the acid theory. If there is acid left in the prints the whole of the picture in bromide ought to fade away. Not so, however; the black of the bromide only disappears where it comes in actual contact with the actual black of the platinotype, and I am more inclined to think it is more of a galvanic action between the silver and the platinum.

The bromides mounted on cards and frames have not deteriorated in the least, so that it is not likely that my manipulation was at fault.

---

THE Art Colour Photographic Company invited, last week, several gentlemen interested in photography to a banquet at the Hotel Métropôle, at which numerous examples of pictures produced by their patented process were exhibited. We understand that nearly all the shares in this Company have already been taken up, and that very soon active operations will be commenced.

WE have received from Messrs. Morley and Cooper, of 70, Upper Street, Islington (North London Photographic Stores), their copiously illustrated catalogue. We have carefully looked through this useful little book, and can truly say that nothing essential to the practice of photography is omitted from it. As an example of its variety, we may mention that no fewer than ten different forms of dark room lamps are here described and illustrated.

* Abstract from *The Journal of the Photographic Society of India.*

# Patent Intelligence.

### Applications for Letters Patent.

12,262. HERBERT JOHN ALLISON, 52, Chancery Lane, London, "Improvements in Picture Frames." (Solomon P. Stoddard, United States.)—July 20th.

12,374. WILLIAM FORD STANLEY, 28, Hatton Garden, London, "Improvements in Portable Photographic Apparatus Adapted to Take Views."—July 20th.

12,408. WILLIAM ACKLAND, 18, Fulham Place, Paddington, London, "An Improved Apparatus for Registering Photographs, Applicable to Film Photograph Roll Holders."—July 22nd.

12,527. WALTER O'REILLY, 97, Newgate Street, London, "Improvements in and Connected with Magazine Photographic Cameras."—July 23rd.

12,531. DESIRE BOUCHARD, 35, Southampton Buildings, London, "A New or Improved Apparatus for Producing Pictures upon a Screen in Stereoscopic Relief by Means of Electricity."—July 23rd.

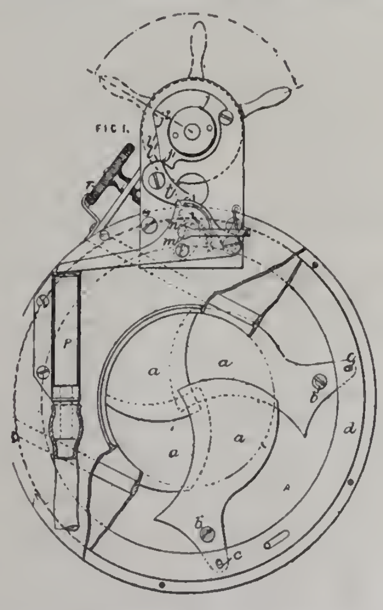
### Specifications Published.

2,628. *February 18th*, 1890.—"Magnesium Flash Lights." A. J. BOULT, 323, High Holborn, Middlesex. (C. Lansiaux and C. Merville, 42, Boulevard Bonne Nouvelle, Paris.)

Relates to apparatus for producing flash-lights for photographic, &c., purposes. The magnesium powder, which is filled into a box through an aperture in the top, falls into a tube through a slit or opening. It is ejected to a lighted fusee, &c., by a pneumatic ball, a finely perforated nozzle preventing the return of the powder to the ball.

2,776. *February 20th*, 1890.—"Lens Shutters." F. BISHOP, 22, Soho Square, Middlesex.—(Voigtländer and Son, Brunswick, Germany.)

Four steel segments or plates *a* are pivoted at *b* to a hollow annular frame A, and are actuated by a ring *d*, which is connected with the tails of the segments by studs C, which engage



in slots therein. The segments, which thus form a shutter of "iris" type, are adapted on being opened and closed to admit and shut off the light almost simultaneously over the whole aperture. The ring *d* is actuated by a crank on a spring barrel to which a plate J, having stops $J^1$, $J^2$, is attached, the one corresponding with the "set" position of the shutter, and the other with the open position. The stops abut against the shoulder $l^1$ of a pivoted lever *l*, which is actuated by an escapement lever *n* on a lever *m*, controlled by a pneumatic arrangement P. The lever *n* is regulated by a cam, so that when it is desired to hold the shutter open for a certain time, the stop $J^2$ is, on the stop J¹ being released, arrested by the shoulder $l^1$. The spring actuating barrel is controlled by a brake arrangement, which is regulated by a micrometer indicator screw *r*, for further regulating the time of exposure. When compound lenses are used the shutter is placed between.

2,671. *February 19th*, 1890.—"Photometry." W. Foster, 14, Clement's Inn, London.

The apparatus is intended for examining the light given by different forms of burners or by different gases with special burners. On a plug having one lateral passage, rotates a series of radial arms, at the end of which burners are placed. Any of the burners may thus be brought into use, the corresponding arm being then in the same straight line with, or parallel to, the bar of the photometer. When the burner is flat-flame, the plug has a groove all round it, supplying gas through lateral apertures, so that the burner can be turned into any required position by a milled head, without altering the supply. The arrangement of the parts may be modified.

2,814. *February 21st*, 1890.—"Mitre Cramps." E. Schievenbusch, Mastrichterstrasse 45, Cologne, Germany.

The sides of the picture frame, &c., to be united are cramped between an angle-piece, and pointed blades adjusted by a set-screw in the block. Either the block or the angle-piece is traversed on the frame by a screw which is rotated in suitable bearings by a handle, and engages with a nut fixed to the back of the movable part.

## Correspondence.

### GLASGOW AND WEST OF SCOTLAND INTERNATIONAL PHOTOGRAPHIC EXHIBITION.

Sir,—I write to inform you that the special judges in the Photo-Mechanical Section of this Exhibition will be Mr. Robert Blackie, of Messrs. Blackie and Son, Ltd., and Mr. W. B. Blaikie, of Messrs. T. and A. Constable.

We have been very fortunate in securing the services of these gentlemen, who, in their connection with these large publishing firms, have acquired a very thorough knowledge of photo-mechanical methods of illustration. Mr. Blackie is also widely known as a highly competent art critic.

There is every indication that this section will be both large and interesting. Wm. Goodwin, *Hon. Sec.*

*Glasgow, July 25th.*

### PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

Sir,—I beg to inform you that at a council meeting held to-day, Mr. George Davison has been elected president of the Convention for 1892. F. P. Cembrano, Hon. Sec.

10, *Cambridge Gardens, Richmond, Surrey, 29th July.*

The Photographic Club.—Subject for August 5th, "Dark Room Appliances and Photographic Dishes"; 12th, report of the delegates to the Convention. Bank Holiday outing at Penshurst; train from Charing Cross at 9.28, London Bridge at 9.35; does not stop at Cannon Street.

Borax in Developing Solutions.—The addition of borax to developing solutions has often been noticed to retard development, yet borax is distinctly alkaline. The apparent anomaly has been explained by M. Aug. Lambert, who calls attention to the well-known fact that borax reacts with the polyhydric alcohols, liberating boric acid. The same thing takes place with pyrogallol and hydroquinone. Thus, borax added in small quantities to pyrogallol converts it into a true acid which reddens litmus. It is the same with tannin and pyrocatechin, so that with these substances the addition of an alkaline borate is equivalent to the addition of an acid, the salt in this case causing retardation. But this reaction is not produced with the isomers of pyrocatechin, *i.e.*, hydroquinone and resorcin. Neither is it produced with the ether-developing agents now in use. Here borax does not give rise to any acid, and acts merely by its alkalinity.

## Proceedings of Societies.

### Photographic Society of Great Britain.

At the technical meeting of this Society held on the 28th inst. Mr. W. Bedford occupied the chair.

It had been announced that the photographic optics and perspective would be discussed, and it was assumed that it was only optics as connected with perspective that was intended. The Chairman requested Messrs. Dallmeyer and Debenham to speak on the subject, and the latter said that photographic perspective had been attacked as other characteristics of photography had been attacked. It had been assumed by superior persons that if they could find any difference between photographic representation, and the ordinary, if not universal, representation of the painter, that photography must be wrong and condemned accordingly. As to the power of photography to render gradation in high-lights and deep shades, he would admit room for improvement, but when it was a question of form he believed that photography was right, and that any differences between its representations and those of the painter were due to the conventions by which the latter had been bound, conventions which photography had broken, and still was breaking, down. As for aerial perspective, that was imperfectly rendered, owing to the want of true gradation in the high-lights, to which he had before referred. The failure had, however, rather the effect of exaggerating than of weakening the loss of clearness in the distance characterising aerial perspective. As to linear perspective, he had recently expressed his views that there was no ground for the attack made upon it by Messrs. Emerson and Goodall. He thought there was no proof of their assumption that the upper and lower halves of the eye saw objects on a different scale. If, however, that were so, it would not affect the truth of mathematical, or—what was the same thing—photographic perspective, as the eye would enlarge or diminish the upper and lower parts of the picture as it was stated to do with the natural objects. It was not uncommon to hear it said that photography exaggerated the size of foreground objects. He thought that those who made such statements should show a complete scheme of what they would consider true perspective. It would be easy to draw any single foreground object smaller than it appeared in the photograph, but it would be at the expense of something else appearing larger. Let there be a complete circle of foreground objects at an equal distance from the point of sight, and then see how any one could be made smaller without enlarging others. He considered that artists had been much limited by conventions. One convention was to confine a perspective drawing to a limit of about sixty degrees. When, therefore, an interior had to be shown, or an exterior if so surrounded by buildings that a view of it could not be obtained within the limits of the conventional angle, it had been the custom to draw the lines as they would appear if the building were viewed at a greater distance than was actually possible. Here, however, in order to give a true representation of what would actually be seen at the assumed distance, not only the direction of the lines would have to be changed, but objects might come into view that at the point used for sketching from might be out of sight; and, on the other hand, objects actually seen by the draughtsman and the spectator might be hidden at the distance indicated by the direction of the lines. Photography was breaking down this as it had done other conventions. As an illustration, he would point to a cut in that day's *Daily Graphic*, where a portion of the interior of Westminster Abbey was shown. Compare the size of the side pillars and roof with the more distant part of the building, and it would be seen that it was in much such proportion as might be seen in a photograph. Photographic is true perspective. By photographic perspective he meant such as is given by a non-distorting lens or a pinhole on a vertical plate.

Mr. T. R. Dallmeyer thought that Mr. Debenham had totally mistaken the ideas of Messrs. Emerson and Goodall, although he could not say that he was altogether with them. He made a diagram on the blackboard showing the effect of binocular vision in the lateral displacement of objects not at the place to which the axes of the eyes were directed. All but one of the effects described by Messrs. Emerson and Goodall he could produce. He found the top of a door to appear wider than the bottom when his eyes were fixed steadily upon it. He found, however, that pillars to appear vertical should not, as they had stated, be inclined inwards at the top, but outwards, the reverse of their proposition. On Langham Church the extinguisher top was bulged to produce the effect required by the eye. There were four kinds of perspective. The aerial, and here Mr. Debenham made a mistake as to the effect of photography. Then there was the perspective of light and shade, by which, for instance, a round tower could be recognised as such. Then there was mathematical perspective, and he thought that artists too much ignored what they owed to mathematical perspective. In one of the papers, in a letter written against Emerson and Goodall, the example was given of a lamp-post appearing in the foreground of a photograph of St. Paul's Cathedral, and coming out too large to appear natural. An artist who sketched such a view would say: I won't stand here, but will fix my standpoint farther, and will draw the whole as it would appear from a greater distance. It was to be deplored that it was out of the power of photography to do this.

Mr. Debenham thought that the introduction of binocular vision was only calculated to confuse the question of perspective. Messrs. Emerson and Goodall had expressly denounced the accepted rules of monocular perspective, and, for clearness, he had confined himself to that issue. In any case, binocular vision did not affect the height of any object, and laterally its effect was, on the whole, to duplicate each object in both directions equally. He then drew on the blackboard a plan of the interior of the building, showing certain objects that would be seen at the greatest distance at which the camera and spectator could be placed. If, now, a draughtsman selected an imaginary standpoint, such as would be possible if the end wall of the building were removed, some objects actually visible from the inside standpoint would be hidden, and other objects not visible from the inside standpoint would come into view. Of some of these objects, the draughtsman could never have obtained a view at all from the spectator's position on the floor of the building. How, then, could he include them in his drawing? Merely altering the direction of the lines would not make the picture a true view of what would be seen at the distance indicated by such direction; there would have to be a change in many particulars.

Mr. G. L. Addenbrooke said that the rules of perspective would enable an artist to select his point of sight at whatever distance he thought proper, and make his drawing true for that distance. He was thus enabled to avoid exaggerating near objects.

Mr. Dallmeyer said that an artist would make drawings from two or three points of sight at different heights, so as to enable him to see what would be seen at the distance he assumed for his perspective drawing, and would combine them.

Mr. Debenham said that the artist would have to make not two or three, but many such drawings, and not only from different heights, but from different positions laterally, if he wanted a true representation of the subject as it would appear from the assumed distant standpoint, and then the picture would include something not visible from the standpoint of the spectator, and exclude others that he would see. Could that be a satisfactory representation?

Mr. Dallmeyer said that Mr. Debenham's remarks would only apply to interiors.

Mr. Debenham said that was not so. They were equally applicable to exteriors where there were surrounding buildings, or where, for other reasons, a distant standpoint including the whole subject was not accessible. Photographic perspective was true, and although the effect of wide-angle pictures was considered to exaggerate near marginal objects, he thought that that idea was wearing off as we became more accustomed to such representation. Short focus lenses had been blamed, but with no more reason than long focussed ones if the subject were photographed from the same place.

Mr. Dallmeyer would like to insist upon the effect of short focus lenses in giving an exaggerated idea of proportion.

Mr. Debenham maintained that the length of focus of the lens had nothing to do with it. The perspective and proportions were fixed by the selection of the standpoint.

Mr. A. Cowan could not admit that it would be right to alter the direction of the lines in a drawing so as to indicate a distant standpoint without at the same time altering the drawing itself by showing or removing such objects as would be shown or hidden at the distance indicated. If this were done, however, the picture of an interior would show what the spectator in the building could never see, and, consequently, could not be a true representation to him.

Mr. Dallmeyer said that from where he was he could see the heads of some members very near, and others at some distance. If this view were photographed with a short focussed lens the near heads would appear disproportionately large.

The Chairman said that that raised the physiological question of what appeared disproportionate because of our knowledge of real equality.

Mr. W. Bedford quite agreed with Mr. Debenham as to the marked change which photography has brought about in the treatment of subjects by artists. Pictures of mountain scenery by Turner, beautiful as they were, would not now be accepted as true renderings on account of the licenses taken with perspective. There had, however, been painters before photography who rendered architectural subject with the perspective such as given by photography; of these, he instanced Prout and David Roberts. He would say that if, as Mr. Dallmeyer contended, photography was a loser in not being able to paint a picture from an impossible standpoint, the advantage was a very doubtful one. It would be absurd to paint, say, the interior of a cathedral, showing as much subject as required to give a general idea of it, but in such perspective proportions as could only be seen from an impossible point of view.

Mr. E. Clifton, referring to the question of binocular vision, said that the most determined opponent of photographic perspective with whom he was acquainted was an artist who did not possess binocular vision, having only one eye.

Mr. J. G. Hudson showed a lamp for producing a continuous flash with magnesium powder, and a portrait of the Chairman was taken by its aid, an exposure of about two seconds being given.

## Hackney Photographic Society.

*July 23rd.*—Dr. Roland Smith in the chair.

The paper and demonstration for the evening was on "The Intensification of Silver Paper," by the Assistant Secretary. Prints were handed round showing the different colours obtainable by this process, which is that introduced by Mr. Lyonel Clark.

Saturday, July 25th, a pleasant afternoon was spent at Hampton Court.

## Bath Photographic Society.

On the 22nd inst. the members paid a second visit to the picturesque grounds at Prior Park. The Society is fortunate in having as an active member the President of the College, Canon Williams, an accomplished photographer, who takes a good deal of interest in photographic matters. The day was unfavourable for an outing, but occasional outbursts of sunshine facilitated the work of the party, and it seems that more pictures were obtained than during the visit of the Photographic Convention to the same place. At five o'clock tea was served in the Mansion, after which the party took leave of their hospitable host, and returned to the city.

## Richmond Camera Club.

*July 24th.*—Mr. Ardaseer in the chair.

Mr. Richardson showed a xylonite developing dish, and the Chairman Adams' lantern slide printing frame.

The subject for discussion was "Dark Rooms." Mr. Garrett described the Davenport portable dark room; Mr. Cembrano, a travelling dark room of black material, and like a mosquito net; Mr. Ramsay, an iron building by Boulton and Paul; Mr. Irvine, an old third-class railway carriage, which he had converted into a dark room and workshop. Other members described makeshifts for the purpose, and the Chairman gave a short account of his adaptation of a wooden shed at the side of his house.

The outing to Virginia Water duly came off on Saturday, and an enjoyable afternoon was spent by the three trippers.

---

Birmingham Photographic Society.

*July 23rd.*—At Midland Institute; Mr. W. Jerome Harrison, F.C.S., in the chair.

The Hon. Secretary brought before the meeting Mr. W. T. Stead's "Magic Lantern Mission." The hon. secretary of excursion committee (Mr. Mousley) read favourable reports of excursions made to Compton Winyates, Tamworth, Lapworth, and Packwood.

The question was asked, "What is the cause of black spots forming on negative films?"

The Chairman thought it might arise from either undissolved pyro or from using town water.

The Chairman then announced the business of the evening, viz., the exhibition of photo-survey prints of the county of Warwick. He hoped all would contribute to the survey, and help, if only by a little. They were workiug on the six-inch ordnance map, and should require an average of about fifteen to twenty-five prints from each member of the survey section. He regretted the weather had, so far, been so unsuitable, but was glad to see so many prints brought forward, and more so because this was merely a preliminary meeting and exhibition in the middle of the season.

The following, amongst others, showed pictures taken by them for the survey, and gave short accouuts of the places visited:—Messrs. J. T. Mousley, of Maxtoke Priory; J. Simkins, of Seccington, Newton Regis, &c.; T. Taylor, of Leake Wootton; E. Uuderwood, of Baddesley Clinton; A. J. Leeson, of Fillougley, Corley, Aston Hall, &c.; G. A. Thomason exhibited some of Packwood, &c.; the Chairman, who had a very large colleotion of prints, of Rowington, Tamworth, Lapworth, Temple Balsall, Coleshill, Knowle, Maxtoke Priory, and Compton Winyates, besides examples of the different means of present-day looomotiou, street scenes, &c.

The Secretary called attention to the next half-day excursion to Arley and Fillougley on August 8th.

---

Our French neighbours, as might be expected in the land which gave birth to Daguerre, possess a large number of photographic publications. An additional one has, however, just appeared. It is called *La Tribune Photographique*, aud will be published on the 1st aud 15th of each month. The first number is now before us. It contains an illustrated article on the various applications of photography, an account of Edison's kinetograph, and other items of interest. It contains 16 pages of matter, and its price is 30 centimes.

Photographic Perspective.—Very few photographs of landscapes are correct in perspective. Mr. A. Mallock has been discussing in *Nature* the optical factors which determine this, and, in the course of his article, he says that any photograph taken with a lens of less than about a foot focal length must exaggerate all the distances or make objects in the picture look smaller than they should. The only remedy for this, in his opinion, is to enlarge the picture until the right distance to view it from becomes also the convenient distance. Even if this be done, however, there is still a tendency to view the picture too far off; for few leuses, except those for portraits, embrace an angle so small as to be taken in at a siugle glance, and people are naturally inclined to stand far enough from a picture to see the whole of it at once. Still, a proper amount of enlargement offers the best means of making a photograph give a true idea of the scene which it represents; and this is especially true of the small pictures taken by so-called "detective" cameras, having lenses varying from four to six inches in focal length; and it is for this end, and uot, in general, to enable more detail to be seen, that the enlarging process is most useful.—*Chemist and Druggist.*

## Answers to Correspondents.

**All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.**

**All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.**

**Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.**

W. J. C. (Chippenham).—*Printing-in Clouds.* The method of printing skies into landscapes is described in most of the text-books; you will find such instructions in Chap. XIX. of Mr. W. K. Burton's "Modern Photography," and another method at page 138 of the Year-Book for 1890; but the best plan, when the view admits of it, is to try and stop off the sky during part of the exposure by a flap shutter delicately manipulated. Look first on the ground glass and see to what angle the flap should be lifted to meet roughly the line of horizon, and then work mainly for this, with a momentary extension to full aperture to take in the sky. You must be quick, but after a little practice the plan succeeds perfectly; indeed, the use of a flap shutter alone often masters the difficulty.

Exhibitor.—*Leeds and London.* There will be plenty of time between the 12th and 21st November for sending on your London exhibit to the Municipal Art Gallery, Leeds. When the time comes round—middle of September for London—it would be as well to acquaint Mr. Bourlet with your intention, puttiug in a card already addressed for that purpose.

C. A.—*Copyright in Small Reproductions.* The fuller information given in your second letter sets the matter at rest. 1. The safest course generally is to assume that *all* portraits of celebrities are registered, although we admit it has become a practice with some photographers to mount most of their portraits on "copyright" cards. 2. Endeavour to get the consent of the remaining four. 3. We are now practically agreed.

C. F. B. (Lynton).—*Aristotype Paper.* The best way is to communicate again with the maker direct, for the finest results are only to be got with freshly-prepared material. The ageut meutioned in your letter is the same to whom we should have referred you with confidence.

W. D. (Dorchester).—*Chloro-Platinite of Soda.* This is produced by the cautious action of heat upon the double chloride of platinum and sodium. If you do not wish to attempt its preparation, enquire of Messrs. Johnson and Matthey, Hatton Garden, E.C.

F. C. S.—*Society of Chemical Industry.* During the recent meeting of the Society at Trinity College, Dublin, a group of 112 members was photographed on the steps of the Dining Hall by Mr. W. Lawrence, of 5, Upper Sackville Street. The plate measures 15 by 12 inches, and is in every way satisfactory, the portraits being all perfectly distinguishable.

G. J. S.—*Monday's Thunderstorm.* The total raiufall in Canonbury amounted to ·68 inch, but of this exactly one-half fell in twenty minutes, soon after four o'clock, the effect of which was to produce flooding in many places.

E. M. (Crewe).—*Tinting Plates for Isochromatic Work.* The use of an alcoholic solution for bathing the plates is hardly satisfactory, for gelatine is totally insoluble in spirit, and the colour would be imperfectly or irregularly distributed. You might try a mixture of half spirit and half water if you wish to hasten the drying of the films, but there must be a great advantage in introducing the colour uniformly by mixing it in with the emulsion.

Cambs.—*Exposure Note-Book.* A very handy little note-book ruled in columns for entry of particulars has just been issued by Messrs. Mawson and Swan, who will supply it gratuitously on application.

---

The business at Birkbeck Road, Kingsland, of Mr. E. G. Platt will in future be carried on under the title of Platt and Witte.

# THE PHOTOGRAPHIC NEWS.

EDITED BY T. C. HEPWORTH, F.C.S.

Vol. XXXV. No. 1718.—*August* 7, 1891.

CONTENTS.

## PHOTOGRAPHIC ADVERTISEMENT.

Time was when the town crier was an important factor in the diffusion of advertised knowledge. The nuisance of this official's drawling and inharmonious acclaim is now, happily, nearly obsolete. Advertisement by means of a bell has always distressed men of a sensitive or nervous constitution. We are not all equally robust with Dr. Johnson, who would probably have listened with equal indifference to the most exquisite of the melodies of Mozart, and the monotonous clang of the evening muffin man. Even the "church-going" bell has been considered by some irreverent people as an unnecessary annoyance. All methods of advertisement which offend the ear are, perhaps, more irritating than those which are submitted to the eye. It is, indeed, utterly vexatious to find in the middle of an interesting story—where, it may be, the hero and heroine, parted by so many columns of distance, are at length about to meet again—a full-page notice of the virtues of Jones's Juniper Gin or Blogg's Poison for Blackbeetles; but this is a momentary torture, an agony less distressing than the continuous instrumental or vocal noises produced by lay or religious advertisers, with the object of making themselves and their wares known far and wide. Pictorial advertisements are, perhaps, less objectionable than those of the letterpress; less time certainly is consumed in their consideration. It is into these that photography most largely enters. Most of the mighty theatrical and other illustrations which adorn the hoardings erected about the waste places of our metropolis are taken originally by photographic aid. Afterwards they are enlarged and retouched and painted in such fashion as, in the workman's opinion, may be most likely to attract the admiration of all beholders.

Curious tales have been told of photographic advertising. There is a story that a secret engagement was on one occasion entered into between a well-known advertiser—whom we will call Robinson—and a photographer of no high repute in his profession, by which the latter, while taking nothing—except, indeed, his portrait—from the sitter, was enabled to secure double fees from the energetic advertiser, Robinson. The sole condition in the agreement was, that in every case the sitter should hold in his hand a book, or card, or newspaper, or other convenient object, on which a legend concerning Robinson's Sauce was so conspicuously and clearly printed that none who looked on the photograph of the sitter could avoid seeing at the same time the advertisement of the sauce. An additional fee was given by Robinson in the exceptional case of the sitter allowing his portrait to be publicly exhibited in the show-case of the photographer. This piece of pushing enterprise is said not to have met with the success which it undoubtedly deserved. Pleasant it surely was for the sitter to have his carte taken for nothing, but when the time came for its presentation to his beloved, or to his aged parents, or to any one of the members of his flock, careful inquiries naturally arose about that sauce of Robinson, which must have troubled considerably the sitter's soul.

Another method of photographic advertisement, unlike that just mentioned in that it was rewarded with no small quantity of success, was originated by some master-mind of photographic invention only a few years ago. Its object was to procure recruits for the army. This desirable result was effected by means of photographs, ungrudgingly coloured with the showiest and most brilliant pigments, of officers and privates of all the leading foot and cavalry regiments of Great Britain—the Royal Artillery, the Royal Engineers, the Army Hospital Corps; in a word, her Majesty's military forces were all displayed on their respective cartes, lustrous in the glory of those bright and glittering uniforms which, it has been asserted—though without sufficient consideration—have, in addition to the pecuniary emolument bestowed by Government, no little power in swelling the ranks of enlistment, and extending the roll of the recruiting sergeant. On the backs of these photographic cartes were commonly printed the advantages to be obtained from a military life; not, indeed, conceived in such a spirit as might have animated them had the late Mr. Bright been their parent, but in such liberal terms as might have been penned by some martial Pindar on the occasion of an exceptionally vinous mess. These cartes acted as very efficient auxiliaries to the huge coloured posters which have proved so attractive on so many occasions to agricolous folk as to lead them up to London, and afterwards—well, into all the pomp and circumstance of glorious war.

Another instance of the photographic puff is only too familiar. It meets us at home and abroad, in the secluded hamlet and the roaring Strand, in the refreshment room, the railway carriage, and the City omnibus; were it not that it is as yet happily excluded from our places of worship, it would be indeed ubiquitous. This omnipresent photographic energy consists in the portraiture of well-known persons in some ingenious connection with an article which it is the life-long purpose of its astute vendor to noise into notoriety and fame. Some time back this puff attained such alarming and offensive proportions on America's congenial soil, that its growth had to be checked in one of the States by the iron clamps of legislative interference. One of those amiable gentlemen, whom we are accustomed to treat with gross ingratitude or careless indifference, who are for ever beseeching us to come to them and be cured of all our bodily and mental ills, what time we with strange, nay, lunatic perversity eye them askance, turn an adder's ear to their invitations, and insist in their despite in remaining sick—in a word, a patent medicine vendor—had introduced, without any authority, the photograph of Mrs. Cleveland, the wife of the President, into his medicinal bundle. The lady appears to have resented, very naturally, this impudent insertion, and one of the American States thereupon passed a law making it a penal offence to use any photographic or other portrait for a purpose of this nature without express permission.

How far the faces of those ladies who smile down upon us from the roofs of our metropolitan vehicles—a smile in harmony with the praise they are represented as uttering of a certain toilet requisite and detergent—how far these simpering faces are paid for is not, perhaps, generally known, nor is it, indeed, in any way material to the public weal. We are content to bask in the sunshine of their beauty, and to ask no questions. But the matter is otherwise when the advertising photograph represents, not a blushing Hebe, but some decrepit and hideous old harridan, snatched from the gaping jaws of death by the timely aid of Peters' Pulmonary Pills. Such a picture as this bears too commonly, in addition to the repulsive nature of the subject, the stamp of unskilful execution. The ghastly portrait is too often a corrupted enlargement of an originally vicious carte. In this photograph, the lady represented is supposed to have been preserved for the light of this world by the all-potent action of certain medicaments. There is, therefore, some *raison d'être* for the exhibition of her portrait; but this reason in photographic pictorial advertisement is not always to be found. For instance, there appears to be no essential connection between the pretty little girl who is manipulating a certain well-known hand-camera, and the camera itself; the work might have been effected as well—or perhaps better, for the purposes of the advertisement—by the failing power of a sexagenarian invalid. Such a picture would show how little physical force was necessary for the management of the machine; but, on the other hand, it would have been destitute of the seductive attraction of adolescent feminine loveliness.

This matter of adscititious loveliness constitutes the chief feature in many advertisements by photographs, as in the notorious example of the girl and the cigarettes. Alien, indeed, from its subject is an advertisement consisting of a photograph of two persons, male and female, standing by the shore of the ocean, with the following printed announcement on the reverse side of the picture: "What are the wild waves saying, sister? Listen, brother, and you will hear. The wild waves are saying that John Smith is making the very best photographs that can be made anywhere in the wide world at the following prices." A list of prices of carte and cabinet follows. "Do not be deceived by egg-shell finish. Listen to what the wild waves are saying. I positively assert, &c." The announcement becomes at the conclusion somewhat profane. "Remember, we are open Sunday—always have been, and always will be—as it is a great accommodation to the public. The churches are also open on Sunday for the accommodation of those that cannot attend during the week. Furthermore, I have made pictures of ministers on Sunday, and delivered the pictures to them on their way from church."

---

Photographs on Silk.—Those chemists who are practical photographers can well utilise silk for presenting their customers with souvenirs—satchets, almanacs, &c.—at Christmas time. Sensitised silk can now be obtained commercially, but there is not much difficulty in preparing it. China silk we have found to be the best, and there is a great variety of ground tints to choose from. The silk must be well washed to free it from dressing, and then immersed in the following solution:—

| | |
|---|---|
| Common salt ... ... ... ... | 4 grammes |
| Arrowroot ... ... ... ... | 4 ,, |
| Acetic acid ... ... ... ... | 15 c.c. |
| Distilled water... ... ... ... | 100 ,, |

The arrowroot is dissolved in the water by the aid of a gentle heat, and then the other ingredients added; and finally—

| | |
|---|---|
| Tannin ... ... ... ... ... | 4 grammes |

dissolved in—

| | |
|---|---|
| Distilled water... ... ... ... | 100 c.c. |

are also added, and the mixture filtered. The silk is allowed to lie in this salting bath for three minutes, hung up to dry, and afterwards sensitised on a silver bath as follows:—

| | |
|---|---|
| Nitrate of silver ... ... ... | 3 grammes |
| Distilled water... ... ... ... | 25 c.c. |
| Nitric acid ... ... ... ... | ½ drop |

The silk is floated on this for one minute, then hung up till surface dry, and finally pinned out on a board till thoroughly dry. It is printed in the usual way, and washed and toned as usual, though we have found the mixed acetate and sulphocyanide bath give the best tones.—*Scientific American.*

## BROMIDE ENLARGING.*

BY G. D. MILBURN.

Enlarging on bromide paper ought to be of interest to all, because a good enlarging process is a great desideratum in every first-class photographic studio.

It is a well known fact that, in the average of cases, small size negatives give better satisfaction to patrons of photographic studios than larger ones. There are many reasons for this, in which the lenses used play no small part, causing more or less distortion, to a much greater degree in large work than in small—the operator is more accustomed to small work—it takes less time of exposure, and costs less if a small plate is spoiled; therefore, he is more willing to try it over again if the first sitting is not up to his usual standard. Many other reasons could be enumerated in support of my assertion that prints from large negatives, as a general rule, do not give as much satisfaction as prints from small negatives.

Having produced a good small negative which pleases the sitter, it is a very easy matter, by using a little honourable business tact, to sell your customer a good, artistically enlarged picture from the same negative. Or will you argue, "A photographer has not the same right to call attention to his goods that other respectable business men have"? or perhaps you will say, "It is not necessary to call especial attention to our large work, for our customers are aware of our facilities for producing that class of work before entering our studios." The latter is, no doubt, true in many cases, but experience has taught every first-class business man in the land that his goods must be prominently brought to the attention of customers and the public time and again if success shall be his. In other words, I contend that, while you practise photography as an art, it behoves you to also practise it as a practical business, and with that end in view I wish to call your attention to the bromide process as a very valuable auxiliary.

A very successful method of introducing large work, as practised by many, is to have an enlarged print ready for the purpose of showing to the customer when the small contact prints are called for, then, by slipping the said enlargement into a convenient, suitable *passepartout* or frame, explaining in the meanwhile the different styles in which the enlarged picture can be finished—such as crayon, oil, or pastel—a sale will invariably follow, and if, occasionally, no sale, the loss in cost of material for making up the print is very trifling indeed.

While on the subject of frames, I wish to show you what enormous difference it makes to a large bromide print to be appropriately framed, also the difference one hour's crayon work makes on a good bromide print.

When first the process was introduced in this country, there was much speculation rife as to the permanency of bromide prints; but this has ceased now, for it has been conclusively proved that when prints are properly made from good permanent bromide paper they are as lasting as any other photographic prints whatsoever.

When the bromide process was first introduced in this country, many photographers began using it, some only soon to give it up, claiming that it was much more difficult than they had anticipated. This was due to the great uncertainty in results, as well as the different methods which can be adopted to secure good results.

* Abstract of a communication to the Buffalo Convention of the P. A. of A.

From a strong negative, it is possible to produce either strong or soft prints, and the same from a soft negative.

Some photographers are successfully using hydrochinone and also eikonogen, as developing agents. After extensive experiments, we have concluded that the iron oxalate is the very best developer for bromide prints. However, I own that there is more latitude in the actual development with the two former developers, inasmuch as the operation can be commenced with weak developer, increasing in strength as it is found necessary. On the other hand, with the oxalate developer, we get a purity of white and blacks unattainable with the others.

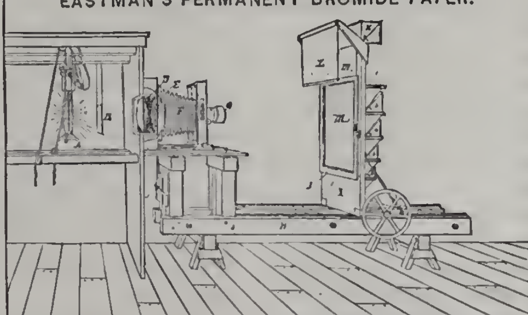
To proceed with the demonstration. If upon examination of the negative to be enlarged, it is found difficult to determine the correct amount of exposure to be employed, do not venture to expose a large sheet of bromide paper, but, as a guide, place in position on the easel a small piece of bromide paper; that is, after the image has been projected to the proper size, and focussed sharply; then expose and develop.

If daylight is used for exposure, care must be taken to permit as little time as possible to elapse between the exposure of guide and print, as the light is apt to vary, making your guide useless. On dense parts of the negative, extra time can be given on the same plan as vignetting, and very deep shadows can easily be held back by means of a shaped card on the end of a strip of glass.

The amount of bromide solution used in developer has great influence on the quality of bromide prints. For weak negatives, the amount of bromide solution can be doubled or trebled to advantage, and, for strong negatives, it can be reduced to half or a quarter the normal amount. However, with fresh, normal developer, some bromide solution ought always to be used, or a measly, mottled deposit may cover the print.

To insure permanence, care must be taken to remove all the iron solution after development, by washing thoroughly with acid solution, and all white light excluded until the print is thoroughly fixed in the hypo, and the final washing must be very complete.

APPARATUS FOR ENLARGING WITH EASTMAN'S PERMANENT BROMIDE PAPER.



The apparatus necessary for bromide enlarging, as you see, is very simple, a camera, lens, and easel, being the most essential parts.

Daylight is very good for enlarging, giving a smooth, even illumination. However, when a large quantity of work is to be provided for, the arc electric light is most convenient, as it is powerful and practically uniform.

Photographic Club.—Subject for Aug. 12th, Report of Delegates to the Convention, illustrated by the lantern; Aug. 19th, "The Primuline Process." Saturday outing (Aug. 8th), Cheam; train from London Bridge 2.18.

## PHOTOGRAPHING LANDSCAPES BY MOONLIGHT.

The many fabulous stories told about moonlight photographs, the incredulously short time of exposure occasionally alleged as sufficient to make them, a few very remarkable facts having come lately to our knowledge, and the desire of several of our readers to learn of the experience of others regarding moonlight photography, have induced us to explain, to the best of our ability, what the light of our satellite is really able to do photographically, and what it is unable to do.

Owing to the extremely feeble actinic force of moonlight it is impossible to obtain instantaneous views by its aid, and a fully exposed negative can be obtained only by large apertures of lenses of great luminous power, and by long exposure upon highly sensitive plates.

To make pictures by the aid of moonlight is nothing new, the first experiments made dating back to the earliest times of Daguerreotypy, and the first moonlit picture exhibited publicly was a white marble bust by Breeze, at the London Exhibition of 1851. On account of technical difficulties resulting from long exposures on wet collodion plates, the attempts made then were but rarely successful, and only after the introduction of collodion dry plates were more satisfactory moonlight pictures really possible.

The first moonlight photograph we ever attempted was that of a white painted frame house, with an exposure of three hours upon a Sutton collodion honey plate, with an 8-inch focus single achromatic lens, stop *f*/16. Result: a very faint image after a long and tedious development with pyro. Later, much better success was had with a view of a brick house, a Fothergill plate, the same objective and stop as before, and an exposure of from 8 p.m., perhaps, to 5.30 a.m., in the light of the full moon of a bright November night.

Burton states positively that to photograph a landscape illuminated by moonlight requires from 300,000 to 3,000,000 times longer than the same landscape illuminated by sunlight. E. Von Gotthardt indorses what Burton says, and speaks of these facts more definitely when describing some experiments he made. To convince himself of the impossibility of certain claims, he exposed first highly sensitive orthochromatic plates, with a No. 1 Euryscope full aperture for three and five minutes, upon a moonlit landscape, without any result, and forty-five minutes produced a very much under-exposed negative; double, and more than double the time presumably being required to make a perfect negative. The experiments were repeated in full sunlight, the lens stopped down to its smallest aperture, and, all other conditions being the same, a beautiful and perfect negative resulted from an exposure as quick as could be made by hand.

Von Gotthardt now reasons thus: Supposing the sunlight exposure had been 0·5 of a second, and the stop used had allowed but $\frac{1}{24}$ part of the light to act which acts with the full aperture, and further supposing that 100 minutes=6,000 seconds in moonlight, would give with the full aperture the same results as obtained in sunlight, that is with the smallest stop in 144,000 seconds, we must then deduce that sunlight is $144{,}000 \times 2 = 288{,}000$, or in round numbers 300,000 times more intense than moonlight.

Eder speaks of an experiment by which he found the intensity of moonlight to be 6,000 times weaker than that of a magnesium wire burnt in the focus of a concave mirror, and states further that he had made a moonlight landscape by an exposure of three hours upon a plate 20 deg. Warnerke, with a Steinheil aplanate, stop *f*/10.

Henderson, under conditions similar to those of Eder, exposed for seven hours, and Jahr had perfect negatives in eight and nine hours.

Dunmore obtained a very rich and harmonious moonlight landscape in five hours, and it is said that Colard and Holmer had the same results in from one to two hours, while Causson and Co. exposed for thirty minutes with the full aperture of a portrait lens. The great difference of the times of exposure stated is owing mainly to the different forms of the objectives employed and their focal length, but is not at all contradictory to the principle laid down by Von Gotthardt. Causson and Co. used a portrait lens, and Jahr a Dallmeyer rectilinear, both with perfect success, it is said.

Our latest attempt to make a moonlight picture was by the full moon of last August, the object being a white building surrounded by trees at a distance of about two hundred yards. The plate, a Carbutt Eclipse, the lens a Gundlach rapid rectigraph No. 3, stop *f*/11. A heavy bank of clouds coming up the horizon interrupted the exposure, intended to be seven hours, and but ninety minutes were given. A tedious and long-continued development with hydrochinon produced the outline of the landscape, and but a feeble impression of the white building.

For scientific purposes, and as a technical object lesson to the photographer, the attempts at making pictures by moonlight are very instructive perhaps, and are otherwise interesting; but artistically they do not amount to much. Light and shade are not distinctly defined, as the motion of the moon obliterates all artistic effect in the prolonged exposure, and the finished picture reminds one of the works of Chinese artists, totally devoid of details, as well as of light and shade.

Moonlight photographs with distinctly pronounced shadows are impossible, and those claiming to be so are invariably made by daylight produced by a variety of clever printing and other dodges, and may be very beautiful so far as the moonlight effect is concerned.—*The Photographic Times.*

---

Mr. Tylar, of Birmingham, seems to have an inexhaustible faculty for devising clever contrivances for the comfort of photographers. His most recent one is a very cheap single dark slide, stamped out of one piece of metal, and neatly reversed to hold the plate or film. The shutter, also of metal, draws right out, and the movement can be executed without any chance of stray light finding its way where it is not wanted.

A New Platinum and Gold Toning Bath.—A well known amateur, the Rev. H. B. Hare, has suggested the use of the ordinary gold and borax toning bath, and then a platinum bath for ordinary albumen prints. The prints are just wetted, then immersed in the ordinary borax bath A:—

| | | |
|---|---|---|
| A.—Chloride of gold | ... ... ... | 2 grains |
| Borax | ... ... ... ... | 90 ,, |
| Water | ... ... ... ... | 12 ounces |

The prints are allowed to remain in this till they assume a warm brown colour, are then removed and placed for a minute in clean water, and then placed in the platinum bath B:—

| | | |
|---|---|---|
| B.—Chloroplatinite of potassium | ... | 24 grains |
| Citric acid | ... ... ... ... | 60 ,, |
| Salt | ... ... ... ... ... | 96 ,, |
| Water | ... ... ... ... | 12 ounces |

When they quickly assume a fine purple black.

## NOTES ON PERSPECTIVE DRAWING AND VISION.

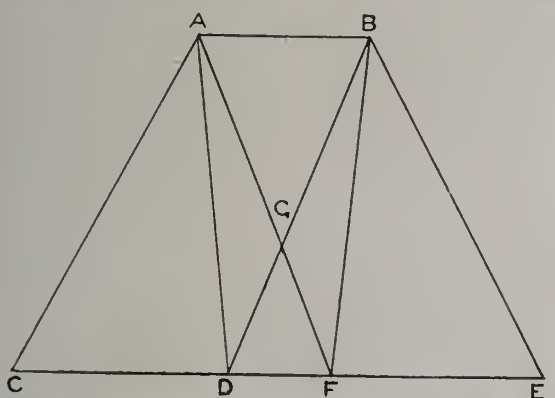
### Replies to Various Criticisms.

BY DR. P. H. EMERSON AND T. F. GOODALL.

We shall reply to our critics in the order of appearance of their papers.

Mr. Slight, an "old perspective draughtsman," is the first to take the field. We omit any comment upon the bad taste shown in his first paragraph, and proceed directly to his intellectual parts. We regret Mr. Slight cannot get the impressions we have obtained, and we can only answer that necessarily such impressions are easiest seen by trained observers. or by persons with delicate nervous organisations such as all good artists possess. We assure Mr. Slight that several artists have, since we pointed these facts out, seen things in the same way as ourselves.

Mr. Slight takes an example which we give to show the effect of *binocular* vision, and immediately proceeds to show that the effect seen by *monocular* vision is different; we refer to the tapering slip of paper experiment. Such criticism is ridiculous, and shows how incompetent Mr. Slight is to discuss such matters. We give a diagram which will roughly explain. Let A B C D and A B E F represent the monocular perspective impressions of the slip of paper, both *vanishing towards* A B. Now, what you get with binocular vision is the figure A B D F vanishing



towards D F—an *inversion* of perspective. What Mr. Slight has seen is the figure C B G; therefore our figure A B D F is not caused by *overlapping*. If Mr. Slight fixes the paper at the normal *distance of vision* (say 5-6 inches) he will get the true impression easier.

Mr. Slight next objects to measuring with two eyes. Undoubtedly, this experiment is difficult to the inexperienced, but it is merely another way of stating Proof 2, page 6—the square sheet of paper experiment. There are persons, however, who can measure with two eyes, and the figure given in answer to the last criticism fully explains the truth of the observation. The experiment is very easily verified by measuring large objects. And these are all Mr. Slight's objections. Mr. Slight then goes on to say that if people shut *one* eye and look at a photograph from one particular point of view, they will see it rightly. In the case of a cyclops we do not dispute this, but we see nature *with two eyes*, and that is the point. Mr. Slight, too, is naturally biassed by his previous training. All photographs and monocular perspective drawings are, we maintain, altogether false to the visual impression.

The next is Mr. Boord, who is, unfortunately, *hors concours*, since he is short-sighted and wears glasses. Mr. Boord has pleasantly advised us to go to our oculist. We have no occasion; our sight is normal.

Mr. Boord avoids the main proposition, ostensibly from fear of the British policeman. We have found others unable to study some of the propositions from an accumulation of adipose tissue, but the policeman is new to us. Mr. Boord asks whether physiology bears this out. We ask Mr. Boord whether physiology does *not* bear this out. Seriously, we are awaiting some researches on this point. Mr. Boord seems to think that he has overthrown Proposition B because evolutions must have eliminated all such defects. Why, then, have we the remains of a caudal appendage? Perhaps Mr. Boord will tell us?

Mr. Boord then gets muddled over foreground and distance. Our researches are for objects seen in one position, which we shall call the real position; one position must be selected as the real position. We therefore take the generally accepted—*i.e.*, a plane at right-angles with the ground plane. When you look at the plane at a distance, you see foreground as well as distance. When you look at the immediate foreground you alter the plane, and it is just the same as if the body were suspended at an inclination, and all the same phenomena will follow, but with different objects. Mr. Boord refers to Dr. Emerson's naturalistic law of focussing. This is the best compromise, both artistically and scientifically, for photographers, but the results are in no way true to the visual impression, but the truest that can be got by the camera.

Next we do hear of "eye troubles." We do not hear of sailors going about in spectacles, and we do hear of most kinder-garten bred Germans doing this. Results of this kind are formed by ages of experience, and outlive their causes. We again refer Mr. Boord to the remains of a tail which he possesses. Mr. Boord has little idea of the difference of delicacy of vision in different persons. It is greater than the difference between a good musical ear and a bad one, though not so easily demonstrated. We have several photographs of the Parthenon, and they do *not* appear parallel to us; neither are they, nor will they appear so to any person of normal vision. Mr. Boord then says if he turns the photo upside down the columns will appear parallel; obviously, they cannot appear parallel *both ways*, for, as he says, by measurement they are not parallel. It appears to us that Mr. Boord has wilfully deceived himself. As to the door, we find most people get the impression we do. Mr. Sutcliffe has published his observations, and we cite Mr. Sutcliffe, as Mr. Boord cites him against us. Mr. Sutcliffe's experience will, then, pass as sufficient answer to Mr. Boord. We shall be glad to consider any geometrical diagram offered by Mr. Boord, but suggestions of such are not proofs. Mr. Boord then goes on to give the difference of visual impressions and chemical impressions due to atmospheric effects. This is a point we are working at. Mr. Boord is quite right; the photograph does not give the "loom" of objects, and this is an *additional* deathblow to the pretensions of photography as an art. Photography gives quite a different result to that seen by the eye as regards atmospheric effect, *in addition* to the difference of perspective when atmosphere is not considered. Mr. Boord seems, however, to make it a virtue of photography that it *does not* give the loom, but gives exactly the objects before it, and that after trying to refute us because we show that photography does give exactly (mathematically) and not visually what is before it. Exactitude is the virtue of photography, which makes it unsurpassed for all purposes of scientific drawing, and which renders it obscure as an art medium.

Next comes C. J. Mr. Chapman Jones refers to us in his leader in *Photography*. We wonder at his temerity in saying drawing and photography are the same thing after the explanation of that accomplished draughtsman, Mr. J. Pennell, that they are not the same. We would recommend Mr. Jones to study an elementary treatise on perspective, and to take some elementary lessons in drawing from the model, and then compare the result of both methods, and perhaps after that he will see reason to alter his last statement. Mr. Jones says without hesitation that photography does not dwarf the distance; he, of course, compares it here with a monocular perspective drawing, which we contend is just as false as photography. Mr. Jones then suggests that the photographer should get further back. This has been the custom with many artists, and the practice we hold to be a fundamental error, and consequent on the teachings of monocular perspective. This is merely a convention, and does not give you a visual impression; it is merely monocular perspective drawing with the errors made to look less glaring; it is a monocular impression, and not a binocular. Such a treatment would preclude the artist from drawing interiors altogether. In short, it still remains a monocular impression, and false to the visual impression. We are combating the whole convention of monocular perspective, which the best artists in France have already discarded in practice. The lengthening of the image by tipping swing-back is merely distorting the monocular perspective drawing, and in no way affects the case; the results are not so true as the throwing distance out of focus. Where there is no difference between the photograph and the draughtsman, so much the worse for the draughtsman. Possibly some misled amateur photographers will rather gouge out an eye from everyone in the world than give up their cyclopean box. How a drawing is to be done we do not enter into, but leave that to each *individual* draughtsman, who, if he possess any ability, will do it in his own method, as did Velasquez, Rembrandt, and others.

Next we come to Mr. Sutcliffe, who seems to be our only critic with sufficient art knowledge and capacity of observation qualifying him to understand our pamphlet. Mr. Sutcliffe only finds difficulty with Proof 1, Prop. B. We would suggest to Mr. Sutcliffe that he must have tilted his head and eyes back in looking at the tower, and consequently changed his plane of vision. We think it possible it was a tall lighthouse, and he was too close to take in all the tower without changing his head. As far as to the bulging and tapering to the base, it coincides with our views.

Mr. Sutcliffe asks whether, because we see a doorway wider at top, we will not also see the doorway corrected in a photograph. We answer possibly; but the whole photograph will not be correct, on account of the extreme disproportion introduced by monocular perspective when objects are reduced and seen on one plane. If people look at a photograph with one eye, and be satisfied, we would suggest at the next Photographic Society of Great Britain exhibition that everybody have one eye bandaged as he goes in, and every picture should have a measure before it of focal length of lens employed. Photographs are all wrong artistically; they are altogether false to our every-day visual impression. The photograph of a man with boots five times as big as himself is correct in Mr. Sutcliffe's sense—*i.e.*, mathematically correct—but that is only an extreme expression of the fallacy which runs through the whole thing. Photography has nothing to do with art. We thank Mr. Sutcliffe for making such careful experiments before committing himself to print, as is the habit of the "amateur."

Lastly, we come to Mr. Debenham. As regards his second paragraph, it might have been left to *finish* his paper with, for then we should have had a clear idea of Mr. Debenham's intellectual powers, and of his vague notions of the meaning of the words "exact," "loose," "indefinite," &c. To disprove our first proposition, Mr. Debenham tells us that *perhaps* a rush of blood to the head, or *perhaps* a lower point of sight, or *perhaps* confusion may do it; and this is "exact" proof, and this is not "loose" nor "indefinite"; it is puerile, at any rate. Has Mr. Debenham any reasons to give why "confusion" or "rush of blood" to the head, &c., does not make the distance look bigger instead of smaller? Mr. Debenham then "plots" Proof 3 mathematically, which was not intended by us, but which we do not object to, for Mr. Debenham's arithmetic now states exactly in figures what we saw exactly with our eyes, but with Mr. Debenham's deductions we entirely disagree, for, although the difference is inappreciable arithmetically with such a small object as the slip of paper, it is of fundamental importance when dealing with buildings; or why did the architects of the Parthenon take such trouble over these matters if the differences were imperceptible? So much for Mr. Debenham's disproof. Mr. Debenham cannot see the door look wider at the top than bottom when looked at as he suggests. Our experiments were made under similar conditions, and we do see the door wider at the top; so does Mr. Sutcliffe and every artist. Mr. Debenham should remember that the Parthenon was to be viewed from the *ground*. This is another of Mr. Debenham's "exact" disproofs.

Mr. Debenham next objects to the material "paper" used for Proof 3, and says "it is asserted if both are held at a distance," &c. Did it not occur to Mr. Debenham to use stiff paper or cardboard? We assumed that the experimentalist had sufficient intelligence to place the slip of paper in the required position for experiments, nor have we been disappointed. We would point out that we did not assert that "both are to be used," but only *one at a time*. To answer Mr. Debenham's objection that people get what they "expected," we answer that the experiments were made by people who had no idea what was "expected" of them. But such criticism is absurd. Anyone can try these experiments with whatever precautions he likes. So far, no one has *disproved them*. Many "loose," "inexact," and captious remarks have been made upon them.

Next we come to the coin experiments. Mr. Debenham, as usual, anticipates his own "disproofs" by his choice words "loose" and "inexact." As to what distance the eye is to be placed, or at what level above the table it is, does not much matter—a pedant might think otherwise, for is not science measurement according to the petty and "unlettered scientist?" Mr. Debenham has invented a gallows-like machine which he has erected for the execution of our coin-proof. Now Mr. Debenham is going to be "exact," and "scientific," and all that is stolid. Mr. Debenham blames us for not erecting a monument to our own damnation. We made the experiment, but not in Mr. Debenham's way. We inserted the penny and halfpenny in a notched stick, so that we could look at it from below and above the line of sight, and we found that our experiment, so far from upsetting our proof, tended to confirm it. When the penny was above the line of vision, it looked larger in proportion to the halfpenny than when it was below. Mr. Debenham said it should, and for once he is right, and *it did*, and does, as anyone can prove to his own satisfaction. Mr. Debenham's great gallows-machine is quite vitiated by the very simple fact that the structure compels one to look at the coins through an eye-hole, the effect of which is to cut off that portion of the field of vision which causes the phenomenon observed. And this is "exact" and not "loose," nor "indefinite," and this in *science* according to the gospel of the photographer.

Mr. Debenham will find the answer to the rest of his paper in the replies to other critics.

Finally, we beg earnestly—since life is short—that untrained and rash persons will not make it necessary for us to waste time in educating them.

P.S.—We are glad to find such an authority on the eye as Dr. Griffith accepting our experiments and observations, but Dr. Griffith goes wrong in his deductions; for, as he says, he is not an artist, or he would have known that the artist gives a compromise, and that the camera does not give correctly the proportion between near and distant objects, nor a compromise in any form.

## CITY AND GUILDS OF LONDON INSTITUTE.

The following concerning the subject of photography is taken from the Programme of Technological Examinations. Among alterations and additions to which attention is called in a circular accompanying the Programme is the following:—"Practical tests have been added to both grades of the examination in photography, the syllabus of which has been rewritten."

I. *Syllabus.*—Candidates will be required to pass both in the written and in the practical parts of the examination. The practical tests will be held on Saturday, May 7th, from 3 to 7.30 p.m.

### Ordinary Grade.

(i) *Written Examination.*—The Written Examination will include questions founded on such subjects as the following:—(1) The studio and lighting of the sitter; (2) the lighting of the dark room; (3) the use of stops, shades, and "instantaneous shutters," as applied to lenses, and the use of the swing-back in the camera; (4) a general knowledge of the practice and theory of the wet plate process; (5) the practice and theory of the gelatine dry plate process—the composition of and defects in gelatine dry plates; (6) various methods of fixing and intensifying negatives, with a general knowledge of the chemicals employed; (7) silver printing, including vignetting and printing in clouds, toning, and fixing; (8) principles of retouching, spotting, and mounting prints.

(ii) *Practical Test.*—Candidates may be required to show proficiency in conducting any of the following practical operations:—(1) To take in a studio $\frac{1}{4}$-plate gelatine negative of some object to be indicated; (2) to print, tone, fix, and mount a print; (3) to retouch and spot a negative; (4) to test a sample of glass or fabric to be used in lighting the dark room; (5) to make a lantern slide by contact.

### Honours Grade.

(i) *Written Examination.*—In the Honours Examination, more difficult questions will be set in some of the subjects for the ordinary grade, and, in addition, a knowledge will be required of—(1) the theory of the photographic image, of development, and intensification; (2) the theory of light as applied to photography, including a general knowledge of spectrum photography, and the construction of lenses; (3) the theory and practical use of sensitometers for testing speed and gradation of plates; (4) the principles of photographic optics; (5) the general principles of the Daguerreotype, and other negative processes which have been employed at different times; (6) platinotype and carbon printing, preparation of a photo-lithographic transfer, collotype printing; Woodburytype and enamels; (7) enlarging and making lantern slides in the camera; (8) applications of photography to scientific purposes.

(ii) *Practical Test.*—Candidates may be required to show proficiency in conducting any of the practical operations for the ordinary grade, and, in addition, the following:—(1) to take a portrait with some special lighting indicated; (2) to find the focus of a lens either corrected or uncorrected; (3) to test the sensitiveness and gradation of a plate; (4) to copy an engraving suitable for the preparation of a lithographic transfer; (5) to make a photo-lithographic transfer from a given negative; (6) to make an enlargement from a $\frac{1}{4}$-plate; (7) to make in the camera a lantern slide from a negative.

II. *Full Technological Certificate.*—A provisional certificate will be granted on the results of the above examination. For the full technological certificate in the ordinary grade, the candidate who is not otherwise qualified (see rule 37) will also be required to have passed the Science and Art Department's Examination in the elementary stage at least, and for the full certificate in the honours grade, in the advanced stage at least, in *two* of the following science subjects:—1, Practical, plane, and solid geometry; 8, light and heat; 10, inorganic chemistry; 11, organic chemistry.

III. *Works of Reference.—For the Ordinary Grade*, "Chemistry of Photography," Meldola; "Instruction in Photography," Abney; "Manual of Photography," Hepworth; "Practice of Photography," Chapman Jones; "Silver Printing," Robinson and Abney (Piper & Carter). *For Honours*, "Researches on Light," Hunt; "Treatise on Photography" (Longman's Text-books of Science); Monckhoven's "Photographic Optics"; "The Chemical Effect of the Spectrum," Dr. Eder; "Light," by Lewis Wright; Roscoe and Schorlemmer's "Inorganic Chemistry."

Absorption Spectrum and Colour of Liquid Oxygen—By K. Olszewski *(Ann. Phys. Chem.* [2]. 42, 663—665).—In his former examination of the absorption spectrum of liquid oxygen (Abstr., 1887, 625), the author found bands corresponding with the wave-lengths 628, 577, 535, and 480. Liveing and Dewar (Abstr., 1891, 1), on examining the absorption spectrum of gaseous oxygen under high pressure, found the same four absorption bands in the visible part of the spectrum, and also two bands in the extreme red corresponding with the Fraunhofer lines A and B. The author has lately had occasion to prepare liquid oxygen in some quantity, and has repeated his examination of the absorption spectrum, more particularly in the extreme red. The column of liquid oxygen obtained had a thickness of 30 mm., and was 50 mm. in height. It was contained in a thin glass vessel surrounded by three glass beakers, in order to protect it, as far as possible, from outside heat. In this condition it was found possible to keep a sufficient quantity for the purpose in view, under atmospheric pressure, and at its boiling point—181·4°—for over half-an-hour. The observations gave the four absorption bands before obtained, and also a fifth corresponding with the Fraunhofer line A. This band is of less intensity than those of wave-lengths 628, 577, and 480, but stronger than the band 535. An absorption band corresponding with the Fraunhofer line B was not observed. Liquid oxygen, as first obtained in small quantity in 1883, was described as being colourless. Since then the author has repeatedly had under examination liquid oxygen in larger quantities, and he has invariably noticed that a layer of greater thickness than 15 mm. has a distinctly blue colour by transmitted light. In the above experiments, in which liquid oxygen was employed in larger quantity than had hitherto been the case, the pale blue colour of the liquid was particularly noticeable. As special precautions were taken in purifying the gas, and the absence of ozone was ascertained by special tests, there seems no reason to doubt that the colour observed is characteristic of oxygen in the liquid state. In the author's opinion, the blue colour of the sky is, therefore, probably due to the oxygen in the atmosphere, since this element, at any rate in the liquid condition, is blue in colour.

# Notes.

The Amateur Photographic Association, under the presidency of the Prince of Wales, is doing a useful work in forming a British Museum of portraits of notable personages. The idea of such a gallery of pictures has been talked about ever since the charge of want of permanence has been removed from the long catalogue of sins with which photography has been credited. On Saturday last a number of such portraits were submitted to the "private view" ordeal at 58, Pall Mall, and on the same occasion a dinner was given by the Association with the Duke of Teck as chairman. Under such auspices the work of the Association is sure to get along apace. We are glad to note that ladies who have distinguished themselves are to find a place in this gallery as well as members of the inferior sex.

There is just now plenty of opportunity for those who are fond of experimental work, and who have also a mind to contribute to the Meteorological Society's collection of pictures, to take photographs of lightning. On our Southern and Eastern coasts thunderstorms have been, during the past week, of daily and nightly occurrence, and the lightning has been of the most vivid description. Watching this lightning the other night, we could not help reflecting that many problems concerning these wonderful outbursts of atmospheric electricity remain to be solved. Why, for instance, do some of these jagged lines of fire remain in sight for a longer time than others which appear at the same instant? Why do others persist in the same position, while, during an incredibly short space of time, they are repeated again and again? Why sometimes does a flash, instead of striking direct to the earth, come near its surface and then return to another part of the sky, making an immense loop? Surely we may hope that some of these puzzles may be unravelled by means of photography.

The latest phase of trade protection is represented in Paris by the combination of artists' models with a view to air a grievance for which there seems to be justification. It would seem that there are middlemen in this business, as in most others; that these men are Italian by birth, and naturally favour their own countrymen and women, to the exclusion of French people. So the French models are up in arms, and assert that they are as well formed, and as well-favoured in other respects by nature, as their Italian rivals. It is intended that artists shall be supplied with a list of the unionists, from whose ranks they will be able to choose their Dianas, Venuses, &c., without troubling the Italians.

Such a demonstration on the part of artists' models will not at present affect photographers; but who knows how soon photography may employ such aids to picture-making? We can recall some exquisite little photographs in which models were employed, which pictures a few years ago deservedly won a prize at one of our exhibitions. They were the work of one who was a painter by profession, and admirably he had adapted his artistic knowledge to their production. The subjects were Pompeian. Carefully arranged accessories in the shape of a fountain-basin, tesselated pavement, &c., all looking as if they had been borrowed for the occasion from the Pompeian house at the Crystal Palace, combined with suitably draped figures of a boy and girl, were the materials employed in the composition. We fancy that many more such pictures would be produced if only models were brought into contact with photographers as they are with knights of the brush.

The artists and sculptors chosen to decide the design for the new coinage are still sitting. We have not heard whether the photographer has yet been called in to assist them, but we fancy that the photographs of her Majesty can hardly be ignored if anything like a portrait is desired. The absurd caricatures which figure in the present jubilee coinage were probably not the fault of the late Sir J. E. Boehm, as he had to adopt the Queen's idea of what she fancied she was like. The approbation of Royalty must always fetter the artist. *Apropos*, one can hardly fancy the Queen approving the statue of herself which now stands conspicuous in the Royal Exchange, yet we suppose she must have expressed her satisfaction at the time. This statue deserves to be photographed, if only to show how an infinitesimal quantity of art satisfies the good citizens of London. If these photographs were publicly exhibited in the print shops of the metropolis, this frightful effigy would not remain another week in its present situation to be laughed at by foreigners.

Human nature in front of the camera is a curious study. Directly persons are told they are about to be photographed they draw themselves up in a stiff drill-sergeant attitude, put on their sternest expression, and prepare to be "took." We had an opportunity of seeing a glaring example of this kind of thing on Bank Holiday at Dunmow, on the occasion of the presentation of the time-honoured flitch. There were three couples as claimants, and previous to the trial it was intimated that the scene on the platform would be photographed. Instantly the smiles fled from the faces of the three husbands, and the simpers from the countenances of the three wives. Had they been quarrelling and had resolved never to speak to each other again, the expressions could not have been more stony. It was a good thing the jury had not to decide as to the fitness of the claims by the photographs of the claimants.

*Apropos* of Bank Holiday, it was impossible not to discover that itinerant photography is no longer what it was. The holiday folk have lost their fancy for posing in the open air in front of the camera; and where a dozen strolling photographers used to make a good living, there is scarcely sufficient trade for one man. The best business is done where picnics most abound, say in the neighbourhood of Epping Forest; but there, we believe, are restrictions which prevent over-competition.

The shareholders in the Automatic Photographic Co. are not at all satisfied with the state of affairs. Lord Kilmorey and another prominent director have retired from the Board; the machines, it is said, have been worked at a loss, and the assets of the Company—so far as can be gathered—are only £1,454 in cash and the value of the machines (which cost £9,000), leaving a deficiency of upwards of £26,000 to be accounted for. These and other statements are contained in a circular which has been sent out by a firm of solicitors whose services have been engaged by a number of dissatisfied shareholders.

## PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Medical Photography—Projecting Microscope—Photographing Clouds—Reversed Titles for Negatives—Rapid Hydroquinone Developer.

*Medical Photography.*—An ingenious arrangement for taking photographs of internal parts of the human or animal body has been invented by Rud. Oelbermann, of Düsseldorf. It consists essentially of a small cylindrical camera, mounted in a small cylindrical case, which latter is provided at its front side with two hemispherical pivoted pieces or shutters serving to shut and to open the case. The case, with the camera, is inserted in that end of an india-rubber tube which is to be introduced into the body. The camera consists of two sliding parts, and is provided at its bottom with a short pipe, over which another tubing may be easily slipped. The latter leads to the outside, and is provided at its other end with a pneumatic ball. To the front sliding part of the camera containing the lens two small, hemispherical, incandescent lamps are fastened, the conducting wires of which lead between the two tubes to the outside, and are connected with two contact points. One of the two conducting wires is joined to the two poles of a battery. For use, the camera is provided with a sensitive plate, and the apparatus is introduced into the body with the case containing the camera, and is shut by the two movable shutters. As soon as the latter is opposite the part to be photographed the pneumatic ball is pressed, when the camera will be pushed forward, so that the short pipe at its back will partly leave the second tube in which it is mounted. By this movement the two hemispherical shutters of the camera case are opened, and, at the same time, the two incandescent lamps will begin to glow, since by the pressure on the pneumatic ball the circuit is established. After the exposure has been made and the pneumatic ball released, the camera will return to its case, and the whole arrangement may then be removed out of the body. It is said that this apparatus has already answered very well in a number of cases.

*A Gigantic Projecting Microscope.*—The well-known optical establishment of M. Poeller, of Munich, is about to construct a gigantic projecting microscope for the World's Exhibition at Chicago. Electricity plays an important part in the working of this magnificent instrument. It furnishes and regulates the source of light, which, mounted in the focus of a parabolic aluminium reflector, has an intensity of 11,000 candle-power. It also provides the centreing of the quadruple condenser, and of the illuminating lenses, by means of an ingenious automatic mechanism. The most important and novel feature, indispensable on account of the enormous heat produced by the intense source of light, is the cooling machine, which provides the several microscopic and polariscopic systems of the apparatus with a fine spray of fluid carbonic acid, which, immediately after its release from the copper kettle, in which it is held under a pressure of twenty-three atmospheres, is converted into the gaseous state, developing thereby such an intense coldness that the minute quantity of 0·0007 gramme of carbonic acid per second is sufficient to give the desired result. The magnifying power of the instrument with ordinary objectives is said to be about 11,000 diameters, but, with the vaseline oil immersions, it may be increased to 16,000 diameters.

*Photographing Clouds.*—At the last meeting of the Freie Photographische Vereinigung, of Berlin, Dr. Neuhauss made some interesting observations with regard to the photographing of clouds. He stated that clouds, more especially the cirrus, could be successfully photographed only by the use of the coloured liquid screen, suggested some time ago by Dr. Zettnow, which completely absorbs the blue rays emitted by the sky, and lets through only the yellowish-green rays which are contained in the white of the clouds. Consequently, the white and delicate clouds in the finished photograph will contrast excellently with the dark sky. If a bluish tone is imparted to the print in the toning bath, it will form the truest reproduction of the reality. The coloured liquid screen mentioned by Dr. Neuhauss is prepared by dissolving 160 grammes of dry, pure nitrate of copper, and 14 grammes of pure chromic acid, in water up to 250 c.c. The solution is poured in a glass tank, in which it should form a film of one centimetre diameter. More easily to prepare, and answering in almost any case if used as a film of from one to two centimetres diameter, is a solution of 175 grammes of sulphate of copper, 17 grammes of bichromate of potash, and 2 c.c. of sulphuric acid, in water up to 500 or 1,000 c.c. This solution will also absorb all the blue and violet rays.

*Writing Reversed Titles for Negatives.*—Mr. Eypert, a skilful amateur photographer, recommends to wash off the gelatine film of a spoiled Kodak or other transparent film negative, then to dry and to varnish it with quickly drying negative varnish, and to write the titles to be transferred with a hard pen and with Indian ink on the dry and varnished side of the film. After the lettering has dried, the film is pasted to the negative to be printed, surface down, so that the lettering comes into contact with the film side of the negative. After printing, the lettering will appear quite white in the finished print.

*Rapid Hydroquinone Developer.*—Professor Lainer has renewed his experiments with hydroquinone together with caustic alkalies and ferrocyanide of potassium, and he now recommends the following developer as the most energetic of all he knows:—

*Solution A.*

| | |
|---|---|
| Water ... ... ... ... | 1,000 c.c. |
| Sodium sulphite ... ... ... | 80 grammes |
| Ferrocyanide of potassium... ... | 30 ,, |
| Hydroquinone ... ... | 10 to 12 ,, |
| Solution of potassium bromide (1:10 water) ... ... | 10 to 20 c.c. |

The mixed developer is said to keep better if 40 c.c. of pure glycerine are added.

*Solution B.*

| | |
|---|---|
| Caustic potash ... ... ... | 100 grammes |
| Water ... ... ... ... | 200 c.c. |

In the case of correct exposure, 60 c.c. of solution A are mixed with 6 to 8 c.c. of solution B. If, however, it is desired to treat with this developer a new and not yet known brand of plates, the following modification is recommended:—

*Solution A.*

| | |
|---|---|
| Water ... ... ... ... | ... 550 c.c. |
| Sodium sulphite ... ... | ... 80 grammes |
| Ferrocyanide of potash ... | ... 30 ,, |
| Potassium bromide solution, 1 : 10 | 10—20 c.c. |
| Hydroquinone ... ... | 10—12 grammes |
| Glycerine ... ... ... | ... 40 c.c. |

*Solution B.*

| | |
|---|---|
| Water... ... ... ... | ... 550 c.c. |
| Caustic potash ... ... | ... 50 grammes |

50 c.c. of solution A and 50 to 70 c.c. of solution B are

measured separately, and at first only 5 c.c. of solution B are added to the 50 c.c. of solution A. During development solution B is gradually added if required, the potassium bromide being also added in accordance with the development. This developer is recommended by Prof. Lainer especially for instantaneous exposures.

## PARA-AMIDOPHENOL AS A DEVELOPER.

BY DR. M. ANDRESEN.

In No. 1707, of May 22nd, 1891, the Photographic News published an article by A. and L. Lumière, recommending para-amidophenol as a developer for photographic purposes.

I desire to call attention to the fact that for some considerable time I have been carefully studying the said product, and similar developers, and that, as far back as the beginning of this year, I have in several countries applied for patents for the use of para-amidophenol and its homologes and derivatives for developing photographic negative images.

This invention is based upon experiments I made in order to find a connection between *the constitution of this and similar compounds, and their capacity to develop the latent photographic negative picture.*

These experiments were made with a large number of organic compounds, and have already led to results which may be of general interest. I will now briefly refer to them, and at some future time report upon them more exhaustively.

It is well-known that many organic compounds possess the property of reducing the salts of silver; but, on the other hand, the number of organic compounds reducing only salt of silver previously exposed in the camera, but leaving intact *non-exposed* salts, is comparatively limited. In order to arrive at clearly defined conclusions on this point, by way of experiment, I first tried substitutes of benzole and naphthaline of well-known constitution. . As to these substitutes, the effect of the amido group ($NH_2$), hydroxyl group (OH), and aldehyd group (COH), were in the first place to be taken into account. Experiments proved that *mono-substitutes do not exercise a reducing power on the latent photographic image.* When treated with aniline, phenole, naphthylamine, naphthole, benzaldehyd, &c., exposed gelatine films of bromide of silver were left altogether uneffected, even in the presence of caustic alkalis. Also the benzidine (diamidodiphenile) acted in this respect exactly like a mono-derivative. However, the property to develop the latent photographic image on gelatines of bromide of silver was clearly shown in the first instance by the di-substitutes. Experiments furthermore proved that, amongst many of di-substitutes, those containing the amido group and the hydroxyl group are especially important, whereas the aldehyde group, even in the presence of an amido or hydroxyl group (as in para-oxybenzaldehyde), did not exercise the least effect.

On the strength of the aforesaid, I would say that from benzole, on replacing two hydrogens by the amido group ($NH_2$), or hydroxyl group (OH), three types of developers may be derived, *i. e.*—

(1) Diamidobenzole (phenylendiamine) $C_6H_4 \ldots \begin{cases} NH_2 \\ NH_2 \end{cases}$

(2) Amido-oxybenzole (amidophenol) $C_6H_4 \ldots \begin{cases} NH_2 \\ O.H \end{cases}$

(3) Dioxybenzole $C_6H_4 \quad \ldots \quad \ldots \quad \ldots \begin{cases} O.H \\ O.H \end{cases}$

As is known, each of these compounds is represented in three isomeric modifications. I therefore took these facts into consideration when making my experiments.

The compounds of the *para and ortho groups have now proved to be powerful developers*, whereas the three compounds of the *meta group did not exercise any reducing power at all* upon the latent photographic image.

*Hydrochinone* (para-dioxybenzole), , belonging to the *para group* OH, has been used as a developer for several years.

The application of *para-phenylendiamine* (para-diamido-benzole)  as a developer had been patented by me in Germany; however, I discontinued the patent, as this product did not act as a sufficiently powerful developer with carbonates of the alkalis, and, furthermore, because it easily produced a greenish veiling of the image when used together with caustic alkalis.

*Para-amidophenol* (para-amido-oxybenzole)  will be dealt with hereafter.

*Brenzcatechin* (ortho-dioxybenzole)  belonging to the *ortho group*, has repeatedly (first by Eder and Toth*) been recommended for developing purposes. On the strength of my experiment, I should that say this substance is in every respect at least equal to hydrochinone. Brenzcatechin will develop quickly, clearly, and powerfully.

*Ortho-amidophenol* (ortho-amido-oxybenzole)  is a fair developer, though, in some respects, not as good as para-amidophenol.

*Ortho-phenylendiamine* (ortho-diamidobenzole)  develops as well, but the isomeric para-phenylendiamine proved to be superior in regard to strength and quickness of developing.

As to the compounda of the *meta group*, Eder and Toth* have already proved that *resorcine* (metadioxybenzole)  will not do for developing photographic negatives on gelatino-bromide of silver. In my opinion, resorcine absolutely free from the two isomerics will not develop at all. On a plate of bromide of silver properly exposed under a negative treated with a solution of resorcine (1 : 50), to which were added four molecules of caustic soda, not a trace of a picture was to be noticed after three minutes.

The same result was arrived at with *meta-amidophenol* (meta-amido-oxybenzole), , and also with *meta-phenylendiamine* (meta-diamidobenzole), 
* Eder, "Die Photographie mit Bromsilber Gelatine," &c., page 101.

After thus proving that not only the compounds of the *para-group*, but also those of the *ortho-group*, exercise a powerful reducing influence on the latent photographic image, it was also of interest to study the processes of oxydation the various substances on their employment as "developers" are undergoing, and especially to get acquainted with the *final products of oxydation*. As to the para-compounds, they have been known for a long time, when oxydised, to get easily converted into chinon, $C_6H_4{\begin{matrix}O\\O\end{matrix}}\!>$, or chinon-like substances. That oxydation, on developing, actually takes place as above described I feel bound to conclude, because *para-amidophenetol*, $C_6H_4{\begin{matrix}NH_2\\OC_2H_5\end{matrix}}$, as I have proved, does *not* develop the latent photographic image. Nevertheless, the process is not a very simple one. The presence of chinon could not be proved in a hydrochinon developer exhausted through frequent usage. The oxydation of these compounds by means of bromide of silver in an alkaline solution apparently leads to different final products. I am now engaged with the investigation of these processes.

The capacity of the aforesaid ortho-compounds of benzole to develop the latent photographic image will have to be attributed to their being able, as lately shown by *Lincke* and *Küster*,* to form chinon-like substances, as has been known for some time with regard to certain ortho-derivatives of naphthaline, and is characteristically shown to be the case with eikonogen, .

As regards *para-amidophenol*, $C_6H_4{\begin{matrix}NH\\OH\end{matrix}}$ in particular, it should be premised that this compound is rather easily soluble in hot water, but comparatively difficult to dissolve in cold water. The para-amidophenol forms two groups of salts. With the aid of *acid*, salts may be got which mostly are *easily* soluble in water, and which, like hydrochloric para-amidophenol, $C_6H_4\begin{cases}NH_2HCl\\OH\end{cases}$, are distinguished by their great capacity to crystallise. From concentrated solutions of these salts, by an addition of carbonates of alkalis, the free para-amidophenol is precipitated. If still more diluted (f. i. 1:200), it will, however, remain undissolved even at the mean temperature of a room.

By means of *caustic alkalis*, salts are produced in which the hydrogen of the hydroxyl-group is replaced by metallic alkali, as, for instance, *para-amidophenolnatrium*.

$$C_6H_4\begin{cases}NH_2\\ONa\end{cases}$$

These salts are *easily* soluble even in cold water. It follows that with the aid of para-amidophenol, *two sets of developers* may be produced, viz., those with carbonates of alkalis, containing the para-amidophenol proper in a dissolved state, and those with caustic alkalis, where an alkalic salt of para-amidophenol renders them effective. *Both kinds may be said to be very useful.*

Para-amidophenolnatrium develops very quickly and powerfully indeed, the better sorts of dry plates in the trade, even without an addition of bromide of potassium, yielding absolutely clear and bright negatives, and showing the blue-black tint known as favourable for copying, which latter may also be obtained with hydrychinone.

* Reports of the German Chemical Society, xxi., 2719.

The following formula has frequently been used: Dissolve in 100 parts of boiling water 30 parts of metabisulphite of potassium, and hereupon 10 parts hydrochloric para-amidophenol. To this solution (which will keep) slowly add, whilst stirring, some concentrated caustic soda until the precipitated para-amidophenol has just been redissolved. For practical use, the solution of the para-amidophenolnatrium obtained has to be weakened by adding 5 to 50 parts water, according to whether a strong or weak developer be required. It may be seen from this recipe that only just as much caustic soda is wanted as is necessary for producing the sodium salt, which is important to know, since certain kinds of dry plates will not stand any surplus quantity of caustic soda. If carbonates of alkalis are used it will be necessary to weaken the developer considerably, owing to the para-amidophenol being difficult to dissolve.

The formula, as recommended by A. and L. Lumière, is, in my opinion, too concentrated. As a rule, I have successfully been working with a solution produced as follows:—

| | |
|---|---|
| Water ... ... ... ... ... | 1000 parts |
| Hydrochloric para-amidophenol ... ... | 5 ,, |
| Sulphite of soda (crys.) ... ... ... | 50 ,, |
| Carbonate of potash ... ... ... | 25 ,, |

This developer, it is true, works a little more slowly than that produced with caustic soda, but it has proved highly useful, especially for time exposures.

Para-amidophenol is thus a substance fully equal to any of the developers now used, but I would certainly give the preference to eikonogen—which, owing to its constitution, stands nearest to para-amidophenol—on account of its general usefulness.

## ADDRESS BY THE PRESIDENT AT THE OPENING OF THE AMERICAN PHOTOGRAPHIC CONFERENCE.

Possibly the best service I can render you is to speak concerning the present and the future of this Conference. In the first place, do not expect that a special national organisation such as this will bound into existence, rounded out and fully inflated like a rubber ball, in the first year of its beginning. Let us rather be content as we are, a small but earnest band of men and women, with the elements of health about us—stability and growth. In this way we can gradually grow up to the situation that we are creating for ourselves, and ready to meet each untried question that is offered for solution. We are now on trial as an experiment. You and I believe that there is a need for us, or we would not be here to-day; but we must show to the great army of camerists that this need applies to them as well as to us. Let us enumerate a few of the benefits that will accrue to the amateur from such an association. No one will deny that the camera club is a necessity to the uncommercial photographer. One cannot contain within himself all knowledge, all experience, limit the subject as you may. We learn from one another, and if a man is right-hearted, he is anxious to impart what he knows. It is true that we have teachers in books, and one may learn from them, but one may learn far more quickly from mental contact with the living teacher. A potent teacher is the work of others. In it you find a standard to measure the merits or defects of your own work. In this way you acquire one of the most valuable traits that make up the mental equipment of the artist—

an ability to be your own critic. There is an active mental stimulant in association. You try new things; you are no longer content with the simple view, but lantern slides, enlargements, transparencies, and new processes invite you into new fields, simply because you are in the atmosphere of these things. Now broaden your atmosphere from your own local camera club to the wide perspective of the Conference. You have simply left home and entered the world, with its variety, its unbounded interests, its grander energies. The best in your own home club will no longer furnish your standard of excellence. Here you will learn that there are master minds, as well as master hands, given up to the work of your chosen craft, and producing work that you would not dream of, except you meet it here. This skill, this art, could never be gathered together except in a national organisation like the Conference. What you had secured in your own club was a good home training; here you get a liberal education.

This personal contact has a more powerful influence in expanding the mind and diverting it into new channels than can be realised without a personal experience. Take my own case, for instance. Why do I feel the necessity of travelling half across the continent at a considerable cost of time, money, and fatigue, to attend a great medical gathering? Simply because I feel that I need it. I know from experience that it is one form of education in the great school of actual life. By this personal contact and mental friction between men in the same line of work, the little personal conceits, the mental eddies wherein the mind gets involved in a hopeless round, become straightened out. You lose your mental angles, and reach a larger and rounder intellectual life. If you believe you know a great deal about photography, come to the conference and find someone that knows more than you do. If you are conceited about the qualities of your picture, come to the Conference, and you will find in all probability a man who can make a better one. In this way you will not stay at home and be content, but you will go home resolved to do better.

So numerous and diverse are the applications of photography to science, art, manufacturing, and domestic life, and so rapidly is the field being widened in these directions, that it would be difficult to form a correct idea of how vast the field of heliographic science and practice really is, except as we are able to bring this multitudinous art within the fold of the Conference.

We are not an association of amateurs simply because we are here not in the interests of commerce. The debt of photography to the amateur calls for no expression from me before such an audience. Some of us are here in the interests of art in its best and widest sense; an art that always holds in the grasp of the vision the beautiful, the true, and the infinite harmonies of nature existing about us. Some of us feel this as an inspiration, with something of that desire that always comes to the æsthetic soul, to reach out and grasp with spiritual hands, and make all their own, something of that art which is eternal.

We have also among us the man of science, who finds that photography has made a pathway before him lit by sunshine. In its subtle chemistry, its delicate and exacting manipulations and ever widening possibilities, he is drawn onward, and finds here ample labour and full reward for the best years of his manhood.

The Conference may extend its influence beyond its own walls, and penetrate into the home-life of every club affiliated with it. The American lantern-slide interchange has done more to create an interest and establish a high standard of excellence among photographic clubs than any other agency that ever existed among us. Yet the number of clubs composing the interchange is necessarily limited. I do not see how it could be usefully extended beyond its present limit. If too many nights are given up to other clubs' work, your club might easily fall off on its trial nights and produce bad work from the need of individual competition. No slide that is worth submitting to the committee ought ever to find its way there without having been previously shown up in the club-room on regular trial nights. In this way you compare your work with each other, as well as having the best work of other clubs as a better and more exacting standard of comparison. This is one reason why I believe that lantern-slide interchange ought to be comparatively limited. Now I suggest that the Conference be divided into circuits of about ten clubs, by any way that may appear practical, each circuit exchanging slides for one year, when new circuits are formed at each annual conference. In this way all the clubs composing the conference will have an opportunity to become familiar with the work of the conference. Clubs already in the existing interchange could, if they saw fit, keep out of the conference interchange, as the number of clubs already in the conference furnish excellent material for two, if not three, additional interchanges. I would suggest that this matter be referred to a committee of the present Conference, so that the subject take practical form the coming winter.

An amateur, like a professional, is considerably exposed to the danger of working in a groove. He fancies that he cannot work but one plate with but one developer, or use but one printing medium. Now, if he is really to enjoy his art, he must be many-sided, and, while nothing can be said against liking the material one uses to the best advantage, yet one must have the stimulus of new things in order to broaden in a technical as well as an artistic sense. To that end, I would suggest that the members and clubs in the Conference institute a system of exchange of prints and finished pictures. In this way clubs will add to the adornment of their walls, and individual members enrich their collection. In this method of exchange a higher standard of criticism will be formed. New printing mediums and methods will be tried and become known. I venture the suggestion that this also be referred to a committee to put in working form. These are but a few of the factors that will draw the clubs and members composing the conference into firmer and closer alliance. We will surely find that we will work with a broader faith in the art possibilities of photography, and reach a more certain attainment of the possibilities in the union of our common interests.

Many—but, on the whole, friendly—criticisms have been made upon our constitution. It has been asserted that we are an exclusive body, by confining the governing power to the clubs instead of the individual amateur. But while I, for one, will disclaim any desire or attempt to create a class, or to favour one amateur to the injury of another, I will call the attention of our critics to the fact that the photographic clubs alone rendered such a body as this possible. Our constitution is a matter of experiment, as must ever be the case with new organisations in new and untried fields, and will require changes and modifications to meet the demands of growth and experience. I assure our friends that they will find members of the Conference who will always work loyally in the interests of photography, and not for individuals or clubs, ever ready to alter or amend our organic law, so as to popularise and extend the influence of the Conference.

And now I wish to thank you for the high and unmerited honour of having been made your first presiding officer. I have had but one thing, which I share in common with you, to recommend me for the place—a love for our art. I have been proud to share with you in the work and care, faith and trust, necessary to the inauguration of our Conference. We will live and we will prosper, for we are founded on truth that we know to-day as "photographic accuracy." We are the last nineteenth century phase of the old Magian worship of the sun, and believe in it not alone for its glories in form and colour, but for the truth it tells—truth so fixed and potent that the emotional æsthetic, or the astronomer who loves nothing warmer than the stars, must alike bend the knee to the gentler art. It thus becomes the sister of the instrument of precision, and with its eternal vigilance makes truthful record where human endurance and watchfulness would fail. In the depths of the ocean, or in the depths of space, where unaided senses falter, in every science and art where faithful record forms the material for the building up of that eternal thing called a fact, the camera and the dry plate make their faithful record; and, with these as our symbols, let us have faith.

Ely Van de Warker.

## FREEHAND DRAWING AND PHOTOGRAPHY.*

BY THE HON. J. G. P. VEREKER.

The purchaser of a microscope, very soon after he begins to use it, finds the necessity of making drawings of the various objects. This he does for the purpose of impressing the details on his mind, and also for making notes of interesting points of structure, either from his own slides, or from those which may pass through his hands from other sources, such as the Postal Microscopical Society. There are three methods of obtaining these pictures—namely, freehand drawing, tracing by means of a camera-lucida, and photography by means of a camera-obscura.

Freehand drawing is chiefly useful in making rapid sketches of simple parts during a continuous investigation of an object; but when a more finished representation is required it ought to be drawn to scale, and some mechanical aid is required. For this purpose, the most convenient instrument is a circular piece of glass ruled into squares (known as a net-micrometer), which is laid on the diaphragm of the ocular; the paper on which the drawing is made is also ruled into squares; by these means a copy of the magnified image can be made with a fair degree of accuracy. The scale is arranged as follows:—Suppose an inch objective is in use, magnifying 50 diameters, place on the stage a stage-micrometer, and, by means of the draw-tube, arrange so that one division of the net-micrometer corresponds exactly with $\frac{1}{100}$ of an inch; make a mark on the draw-tube at this for future reference. Exchange the stage-micrometer for the object, and make a drawing on paper ruled in squares, the sides of which measure half-an-inch. Then, it is evident, the drawing will be 50 times the size of the original in lineal measure.

For more exact and complicated work it is necessary to trace the magnified image as far as possible by means of one of the forms of the camera-lucida, and also to trace some divisions of the stage-micrometer on the same drawing, so as to make a scale; the drawing is then finished up by hand. The above methods are capable of doing very good work, but require a good deal of time, and, when a large amount of small detail is to be put in, are very tedious. There is also a tendency to make the work pretty and to flatter it, and if self-restraint is exercised in this matter, one does not always get credit for doing so.

The third method—viz., photography—is not open to these objections, as detail is given with great facility, because the lens represents all that is set before it, and, as for flattery, there is none; in fact, some people call it "justice without mercy." It is not, however, suitable for some kinds of work, and in that case hand-work is to be preferred.

The art of photo-micrography is not, however, so generally practised as it deserves, and this is not to be wondered at when one considers the cost of the cameras made for it, and the other paraphernalia generally recommended, which are enough to frighten many from attempting a process which may, after all, turn out to be unsatisfactory. For those who aspire to do the highest and most difficult work all this may be necessary; but for those who would like to experiment in the art, and who wish to turn out fairish work and get results good enough for ordinary purposes, a much cheaper and simpler apparatus will answer. Such an apparatus I shall proceed to describe, and, as I find it will work satisfactorily with my highest power ($\frac{1}{14}$ inch, by Nachet), I trust it may prove of use to others.

The first experiments I made in these cheap cameras were with a cigar-box as a camera. The long-shaped cigar-box will just take a $\frac{1}{4}$-plate ($3\frac{1}{4}$ by $4\frac{1}{4}$ inches), and its focal length is about 9 inches. I got a few fairish photographs with this apparatus, but found that it was rather too short, and also had to be covered with an opaque cloth to make it light-tight. I looked about, therefore, for something better, and found it in one of the deal boxes made for storing $\frac{1}{4}$-plate negatives. These boxes have a ledge inside to fit into the cover, and are, therefore, sufficiently light-tight for the purpose, and, being fitted with grooves, there is not so much danger from internal reflection; besides, these grooves enable one to alter the focus if necessary. Their length is also better, those holding 50 plates being about 13 inches internal measurement. They can be purchased at all photographic dealers, and cost from 1s. 8d. to 2s. each. Having got one of these, first of all paint it dead-black inside to guard against internal reflection. Bates' black, which may be obtained from the photographic dealer for sixpence a bottle, will answer perfectly. Now draw diagonals across at each end so as to find the centres at their intersection. At one end bore a hole the exact size of the ocular end of the tube of the microscope. The eye-piece, being then pushed into the tube from the inside of the box, will, by means of its flange, make a light-tight joint, and the box will be rigidly attached to the microscope and move with it in focussing. At the other end of the box a hole is likewise bored, either of a size to take a spare eye-piece, or else much larger, so as to enable one to use a focussing glass. As focussing glasses can be bought from a shilling upwards, the latter plan is most convenient; or an eye-piece with the eye-lens removed, and the field-glass next to the eye, can be used instead; but the focussing glass is preferable.

* Abstracted from the *Journal of Microscopy*.

Having purchased a box of $\frac{1}{4}$-plate dry plates, take one out of the box in the dark room and take it into your working room, in full day or lamplight, and cut a few lines through the gelatine surface with a knife; or, if preferred, a piece of glass of the same size can be used, with a few diamond scratches or paint marks on it. Now hold the marked side away from you, place the focussing glass against the other side, and carefully adjust the lens till you see the lines clearly and sharply, and make a mark on the brass tube so as to be able to reset it at any time. The glass is now adjusted for your eyesight, and should always be used at this focus. This work is easily done against a window-frame. Wash the emulsion off with hot water, and cut a piece of white and black cardboard the same size. Buy a ruby chimney for your paraffin lamp, or else get a dark room lamp, and make a shade or box so as to cut off the light from your paraffin lamp when changing plates.

The apparatus is now complete, and is used as follows:— The object is placed on the stage and focussed in the ordinary way; the eye-piece is now removed, the box is brought up to a level with the horizontal body of the microscope by means of books or a wooden stage, and the tube of the microscope is passed through the hole in the box and the eye-piece replaced. The piece of white cardboard is placed into one of the last divisions of the box, and, the cover being still open, the image is roughly focussed on the card, special care being taken that the illumination is evenly distributed. The card is now replaced by the sheet of glass, and the focussing finished by means of the focussing glass; or if this work is done by means of the spare eye-piece, it is pushed in till its diaphragm occupies the place where the sensitive surface of the plate will rest, the plain glass not being used in this case.

At this stage the diaphragm opening must be arranged so as to give the best image. It is also wise to give a final touch through a piece of blue glass, which can be supported on a cork sliding on the mirror bar, in order to allow for a difference between chemical and visual focus; this glass is then removed.

Now replace the white chimney of the lamp by the ruby one, or else cover up the light and work by the dark room lamp. Reopen the box and place the blackened card at the end, and put the sensitive plate (gelatine surface towards the microscope) in place of the plain glass, and close the box. Place a piece of card or brown paper either between the lens and the object, or the object and the lamp; replace the white chimney or uncover the lamp; remove the card cutting off the light, and make the exposure. Replace the card and remove the plate by means of the ruby light.

Several other exposures may probably be made without disturbing the apparatus by simply re-focussing; but, if much arranging is required, it will be simpler to take the apparatus to pieces. It is best to write the name of the object on the plate; this can be done with a lead pencil on the gelatine surface.

In order to get good results, the light and the centre of the plate must be in prolongation of the optical axis; the plate, if loose, must also be wedged in by blackened card or brown paper placed behind it in the groove. A small bit of wood, such as a match, glued on the bottom of the inside of the box, is a help in keeping the plate vertical.

One of the main difficulties of photo-micrography is the exposure, and this must be learnt by practice. There are many exposure metres and books in existence, and perhaps an instrument like Decoudin's photometer might prove of service, but I have not tried it for this work. The best exposure meter is the eye, judging the brightness of the image as compared with the white ground of the transparent parts; but colour makes a great difference: green, yellow, and brown require long exposures, and red very long. I annex a few exposures taken with an ordinary paraffin lamp, of $\frac{5}{8}$-inch wick, a small, cheap form of the Webster condenser, and Zeiss' projection ocular, magnifying three and a-half diameters; length of camera from eye-piece to plate, twelve and a-half inches.

| | Objective. | Stop of Condenser. | Exposure. |
|---|---|---|---|
| Proboscis of blowfly ... | 1-in. Swift ... | medium ... | 4 min. |
| Green Desmid— | | | |
| *Micrasteria denticulata*... | $\frac{1}{2}$-in. Verick ... | small ... | 2 min. |
| Pleurosigma angulatum | $\frac{1}{14}$-in. Nachet | semi-circular | 4 min. |

For ordinary work a $\frac{1}{4}$-plate ($4\frac{1}{4}$ by $3\frac{1}{4}$ inches) will be found most convenient, and from this size lantern slides can be made by contact. The plate ought to be of good quality and medium sensitiveness (about 20° Warnerke). In the development it is best to suit the exposure to the development, and not *vice versâ*—at any rate, for a beginner. Printing can be done by any of the recognised methods.

I trust that this slight sketch of the subject may induce some members of the Postal Microscopical Society to try this process, even though their camera may not rise above the cigar-box, as I am sure that they will find both pleasure and utility in it. A dark room is not a necessity, as any room or cupboard may be turned into a temporary dark room, so long as it is only illuminated by red or orange light. The magnifying power of the camera ought to be known, and this is best done by measurement in the ordinary way; but a rough approximate rule is as follows:—

Let L be the length of camera.

Let M be the magnifying power in use.

And X the required magnification.

Then as 10 : L : : M : X.

For instance, say L=12 inches.

M=50 (1 inch and A ocular).

10 : 12 : : 50 : $x$.

$\therefore x = 60$ diameters.

---

Solvent for Cellulose.—By C. F. Cross and E. J. Bevan (*Chem. News*, 63, 66).—The authors find that, by dissolving zinc chloride in twice its weight of hydrochloric acid, a solution of sp. gr. 1·44 is obtained, which dissolves cellulose instantly without sensible modification, and hence provides a useful solvent, especially suitable for the chemical or microscopical investigations of the vegetable fibres.

Reversal of the Image.—Mr. Paul Lange, of Liverpool, whose most successful pictures of Norway and Iceland are so well and deservedly admired, had a curious experience in his tour to the latter country last year. Many of his plates were put into the slides in a changing tent, which was, unfortunately, not quite light-proof for the special rapid plates. The consequence was many of these plates were light-fogged, and the point we wish to call attention to is this—these plates turned out to be positives on development, showing that not only does prolonged exposure in the camera produce this reversal of the image, but that supplementary exposure afterwards yields the same result. This is a good field for experimenters, and we trust some of our readers will follow the matter up. Such a clue leads to a large field for investigation, not requiring any great skill or any elaborate apparatus. It would prove a welcome change to the usual well-worn subjects as the subject for a paper at one of our society's meetings.—*Photographic Scraps.*

# Patent Intelligence.

### Applications for Letters Patent.

12,961. BENJAMIN JOSEPH EDWARDS, 45, Southampton Buildings, London, "Improvements Relating to Photographic Cameras, and to Appliances for Changing Plates or Films therein."—*July 31st*, 1891.

### Specifications Published.

3,392. *March 4th*, 1890.—"Hand-Cameras, and Shutters and Slides therefor." W. GRIFFITHS, Highgate Square, Birmingham.

The camera case is of cardboard, &c., coated with cloth, and strengthened with battens. It is provided with a hinged lid, which is fitted with a carrying handle and an ordinary finder. The lens is carried on the inner side of a perforation in the partition, the front side of which is fitted with a sliding spring-actuated shutter, the aperture of which serves also as a stop. The shutter is released by a lever, which is reached through an aperture in the base of the case. The front is closed by a flap, which is provided with an aperture. The dark slides are made up of cardboard, &c., leaves, and an intermediate leaf, which are secured together and hinged to corresponding leaves. Between both sets of leaves is a partition provided with springs to press on the sensitive plates. The aperture in the intermediate leaves may be adapted for lantern slides. The slides are fitted with sheet metal shutters, and are secured when closed by a sliding grooved catch. They are placed in the rear of the box, the front one being pressed forward by springs on the battens.

3,393. *March 4th*, 1890.—"Sensitised Films." E. W. FOXLEE, 22, Goldsmith Road, Acton, London. W.

This relates to the manufacture of sensitised films with celluloid supports for sensitive emulsion. A roll of heavily calendered paper is first coated with a waterproof solution, say of india-rubber, and then with a coating of gelatine containing chrome or other alum. When the gelatinous coating is dry, a fluid or plastic coating of celluloid is applied. After the solvents have evaporated the celluloid is coated in a dark room with the sensitive gelatino-bromide coating; and after the latter is dry a solvent for india-rubber is applied to the back of the paper, which is then stripped off by means of two rollers from the gelatine and the rest of the films. The celluloid support is left with a coating of sensitive gelatine on one side, and of insoluble gelatine on the other. This treatment has the effect of preventing curling. The backing of insoluble gelatine may be non-actinic if desired. The provisioual specification states that the compound film of gelatine and celluloid may be removed from the paper first, and coated with emulsiou afterwards. [Patent opposed. Case not yet decided.]

3,446. *March 4th*, 1890. — "Cameras, Change Boxes, and Shutters." A. P. RILEY, 249, Commercial Road, London.

To an endless band, at the back of the camera, are attached by clips plate sheaths; or the sheaths may be directly secured to the band. The plates are moved in succession to register against a lever by turning a handle on a roller, over which and an adjustable roller the band is stretched. To the roller is also attached a ratchet disc, pins, and teeth, on which move, through links, levers out of contact with the first and next succeeding plate. The last clip may be attached by a cord to a pivoted spring sector indicator, which exhibits through perforation the number of plates exposed. A modificatiou of the indicator consisting of a rack-and-pinion arrangement may be also used. The shutter may be actuated by levers. In the provisional specification is described an arrangement for actuating the shutter through the plate-changing mechanism, aud also a bag or case for the camera.

3,482. *March 4th*, 1890.—"Hand-Cameras." L. VAN NECK, Brussels.

Within a casing is a second casiug, the front lens carrying portion of which is movable, and is actuated by a rack-and-pinion. The flap shutter has a mirror in front, by which the image is reflected to the ground glass screen, the arrangement thus serving as a finder. To expose the plate, &c., which is placed in the rear of the camera, the shutter is lifted so as to clear the lens aperture. This is effected by a vertical spring lever, which, to set the shutter, is caused to ride over and engage with an arm on a pivot, the shutter, meanwhile, remaining closed. When thus in position the lever engages with a catch, which is released by a trigger arrangement. When the shutter reaches its topmost position the lever again rides over the arm, and the shutter drops at a velocity depending on the strength of its spring. For slow exposure the shutter may be lifted by a cord. The plates, &c., at the back of the camera are changed through a bag, the frame of which fits in an aperture covered by a lid, and is secured to the casing by a bail handle and the plate which enters a staple. A plate lifter at the back, which pushes up the rear plate to be grasped by the hand, also actuates an indicator disc.

---

THE LIQUOSCOPE; AN INSTRUMENT FOR COMPARING THE REFRACTIVE INDICES OF LIQUIDS.—By K. Sondén *(Zeit. anal. Chem.*, 30, 196—199*)*.—The apparatus consists of two similar hollow prisms, which are immersed, side by side, in a glycerol-bath, formed of a cylindrical vessel with glass ends. When both prisms are filled with liquids having the same refractive index, a horizontal black liue observed through them appears continuous; but if the indices are different, one part of the line is displaced with respect to the other. The instrument is very serviceable for indicating adulteration of butter, oils, glycerol, &c.—*Journal of the Chem. Soc.*

ACTION OF SUNLIGHT ON ORGANIC COMPOUNDS.—By H. Klinger and O. Standke (*Ber.* 24, 1340—1346; compare Abstr., 1886, 888, 1889, 405.—When a mixture of finely powdered quinone (5 grammes) and benzaldehyde (10 c.c.) is exposed in a sealed tube to direct sunlight, the yellow solution becomes darker, and greenish-black crystals separate, which increase in quantity as the quinone dissolves. No pressure is observed on opening the tube; the crystals are collected, washed with ether, and after crystallising from dilute alcohol, identified as quinhydrone. Dibeuzoylquinhydrone, $C_{32}H_{21}O_8$, is obtained when the filtrate and ethereal washings from the quinhydrone are allowed to evaporate in the sun. The black, semi-crystalline residue is spread upon a porous tile, aud dissolved iu dilute alcohol, when it separates in long, black, flat needles, having a bluish-violet lustre, and a brown colour by trausmitted light; it melts at 116—117°, and dissolves in alcohol, ether, and benzeue with a yellow colour, splitting up into its components (see below); heated with water, it melts, the browu drops gradually become lighter, and quinone passes off with the steam. Benzoylquinol (dihydroxybenzophenone), $C_6H_3Bz(OH)_2$, is obtained, together with quinol, wheu dibenzoylquinhydrone is heated with sulphurous acid; it separates in yellow, oily drops, which solidify ou cooling, whereas quinol remains in solution; it forms long yellow needles from dilute alcohol, and is very readily soluble in ether, benzene, and alcohol; it melts at 125°, and yields dibenzoylquinhydrone when a dilute alcoholic solution is mixed with one of quinone. The tribenzoyl derivative, $C_6H_3Bz(OBz)_2$, which crystallises from alcohol in glistening, white needles, melts at 118°, and is sparingly soluble in cold alcohol, readily in ether and benzene, is formed on treating beuzoylquinol with benzoic chloride; by hydrolysis with alcoholic potash, beuzoylquinol is regenerated. Isovaleroquinhydrone, $C_{17}H_{18}O_5$, is formed together with quinhydroue from quinone and isovaleraldehyde; it crystallises from dilute alcohol in beautiful red tables, with a metallic lustre, which gradually undergo change iu the air and become yellow; it dissolves with a yellow colour in alcohol, ether, benzeue, and glacial acetic acid, and melts at 103°. Isovaleroquinol, $C_4H_9{\cdot}CO{\cdot}C_6H_3(OH)_2$, is obtaiued together with quinol when isovaleroquinhydrone is treated with sulphurous acid; it separates from dilute alcohol in yellow needles, and from benzine in prisms, which become dull in the air, melts at 115°, and dissolves in alkalis with a yellowish-red colour; it combines with quinone to form isovaleroquinhydrone; the dibenzoyl derivative, $C_4H_9{\cdot}CO{\cdot}C_6H_3(OBz)_2$, crystallises from alcohol in white needles, melts at 105°, and yields isovaleroquinol on hydrolysis. The above-mentioned aldehydes have scarcely any action on quinone in the dark, less quinhydrone being formed after a month's action than by an hour's exposure to light.—*Idem.*

## Correspondence.

HACKNEY PHOTOGRAPHIC SOCIETY.

Sir,—The council of the above Society would esteem it a favour if you could find space in your next issue for the following announcement:—The council of the Hackney Photographic Society have decided to hold an exhibitiou on September 23rd and 24th, in the Morley Large Hall, Hackney, when, iu addition to an apparatus section and members' work, there will be an open class. There will be no subdivision of classes, such as architecture, landscape, &c.; the medals going to the best pictures irrespective of subject. Full particulars will be sent on application to the hou. sec., Mr. W. Fenton Jones, 6, Victoria Street, King Edward Road, N.E. S. H. Barton, *Assistant Sec.*

## Proceedings of Societies.

Richmond Camera Club.

At the ordinary meeting on the 31st ult., Mr. Davis in the chair, the subject for discussion was "Photographing Interiors."

Mr. Faulkner showed negatives taken in some of the apartments at Haddon Hall, with only one miuute's exposure, developed with eikonogen, and showing plenty of detail and superabundance of density.

Other members contributed to the discussion hints on levelling the camera, backing plates, exposure, &c.

Glasgow Exhibition.—As will be seen in our advertisement columns, the last date for entries has been postponed to August 20th. The last day for receiving exhibits is August 22nd.

A New Silvering Bath.—M. Dagreve, in *Les Annales Photographiques*, suggests the following method of silvering old plated or copper articles, which may be useful to auy chemist who has some old fixiug baths and some worn electroplate. The articles to be plated are well washed with soap and water, and then immersed in an old fixing bath which has beeu used for fixing plates. In a very short time a deposit of silver forms, and then the article should be taken out, rinsed, polished with a soft leather, and agaiu immersed till the deposited silver is thick enough. When an extra thick coating is desired, a piece of wire is affixed to the object, and at the other end of the wire a sheet of zinc, allowing one square centimetre of ziuc to every square decimetre of the article to be plated. It is not advisable to use old print fixing baths for this purpose, as the silver has a peculiar yellow tinge; but chloride of silver which has not beeu exposed to light may be used.

The Photographic Portraits of Thackeray.—A few words about the photographic portraits of Thackeray are necessary to complete the article given in our July number. During his visits to America (1852-3, 1855-6), in compliance with the wishes of his Trausatlantic friends, he posed before the camera, and the earliest of these sun pictures is a Daguerrotype by Brady, recently engraved for the *Century* magazine. In this, as well as other American photographs in the possession of Mrs. James T. Fields (reproduced in the "Unpublished Letters of Thackeray"), his appearance is rather quaint, owing to the style of his habiliments—such as the broad, turned-up collar, black or striped stock, and check waistcoat of the period. Of the many English photographs, mention must be made of "Thackeray in his Study," by Ernest Edwards, B.A. (1860), where he is seeu "old, white, massive, and melancholy," as his friend, Edward Fitzgerald, remarked; a scarce photograph by Dr. Julius Pollock; and the more familiar ones by the brothers Watkins, who had the honour of producing (for the Loudon Stereoscopic Company) the last photograph ever taken of him. This portrait and the very early bust by Devile were engraved for an article (in the Christmas number, 1889, of *St. Nicholas*) on the "Boyhood of Thackeray," written by his daughter, Mrs. Ritchie, who, with true filial affection, says, "All a lifetime lies betweeu two portraits; all its sorrows and successes, its work, and its endurance."—*Magazine of Art.*

**All Advertisements and communications relating to money matters, or to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.**

**Questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, N.**

C. H. Collings.—*French Photographic Periodicals.* Besides the new monthly illustrated review of M. Paul Nadar, *Paris-Photographe* (53, Rue des Mathurins), there are the *Bulletin de la Société Française de Photographie* (Paris: Gauthier-Villars et Fils, 55, Quai des Grands-Augustins), *Journal de l'Industrie Photographique*, *Moniteur de la Photographie*, *Photographie Industrielle*, *Progres Photographique* and *Revue Photographique*. The "Rapport du Congrès International de Photographie, 1890" (Gauthier-Villars et Fils), is an interesting document, which you may study as preparatory of the forthcoming conference to be held next month in Brussels. In the French language there is likewise the monthly *Bulletin de l'Association Belge de Photographie*, for which address M. Hector Colard, 55, Boulevard du Hainaut, Brussels (27 fr. aunum). All or any of the above may probably be obtained through Messrs. Williams and Norgate, 14, Henrietta Street, W.C.

C. E. W.—Your letter of 1st inst. duly received with thanks.

D. L. P.—*International Labels.* The black star of twelve rays on vermilion ground, with words of caution to douaniers, can now be procured from Mr. W. H. Walker, of the Eastman Company, 115, Oxford Street, W.

J. McL. (Newark).—*Photo-Mechanical Processes.* Either Mr. E. W. Foxlee, of 22, Goldsmith's Road, Acton, W.; or Mr. W. T. Wilkinson, of 3, Perth Street, Cheetham Hill, Manchester, would give instruction of the kind mentioned. The reticulated plates can be had from Mr. J. J. Ayling, 12, Crane Court, Fleet Street. Are not the round marks due to minute air-bubbles in the gelatine coating?

A. M.—*Silver Residues.* You cannot have seen the exhaustive article on the working up of silver waste which appeared in the *News* of July 24th, page 531.

C. B.—*Copyright Decision.* The reserved judgment on appeal in *re* London Printing and Publishing Alliance *v.* Cox, which was delivered on Monday last, is full of interest to artists and photographers, and teaches the uecessity of puttiug on the register of copyright the name of the veritable owner of the picture. The former decision was reversed by Lords Justices Fry and Lopes, carryiug a majority against Lord Justice Lindley on appeal, and against the previous ruling of Mr. Justice Vaughan Williams. A *photograph* had been offered to the proprietor of *The Queen* newspaper, who published it; meanwhile, the *original picture* had been sold to other parties, who again negotiated for its appearance as a coloured supplement to *Myra's Journal*, without, however, making the necessary alteration in the register, and so it was decided that *no one* was entitled to sue for the alleged infringement of copyright.

S. E. Y.—*The March of the Camera Men.* We have read the columu and a half in Tuesday's *Daily Chronicle*, but should not look to a popular account for a serious discussion of the competing iuterests of professionals and amateurs. Many more cameras and appliances are demanded, and much material is wasted, because of the "craze," which, after all, stimulates trade. Although alarm is said to be felt in some quarters, we hold that the failure of first attempts often leads to higher appreciatiou of professional services, and does not supersede them.

Amicus.—*Rain Water.* A slate cistern divided with a partition of porous ware is better thau the cask and stone filter. A conical bag of swan's-down calico (plush side inwards) makes a rapid filter, easily cleaned, and can be hung below the water tap. It should not be allowed to get dry, but answers best when kept constantly in use.

A. B. (Preston).—*Blisters.* Try the addition of borax to the fixing bath, and do not use this too strong.

## PATENT OFFICE FEES.

We have more than once had occasion to remark upon the tax on ingenuity which the fees payable by inventors at the Patent Office undoubtedly represent. That the evil is one which is attracting notice from all quarters is well known, and, in some measure, that fact is an assurance that it will be remedied. No clearer indictment against the system which prevails has ever been formulated than was contained the other day in the speech of Mr. Leng, M.P. for Dundee. This gentleman took the opportunity of moving in the House of Commons the reduction of the vote for the Patent Office by the sum of £100, in order that he might plead the case for the inventors.

In the first place, it appears that the Board of Trade, with which branch of the Civil Service the reduction of the patent fees rests, can afford to relinquish part of the income derived from patentees, for, according to the last annual report, an excess of income over expenditure of no less than £108,000 is recorded. This sum, instead of being spent in some way for the benefit of inventors—by reduction of fees or otherwise—is sent to the Treasury, where it is absorbed into the general revenue of the country. We next find that the cost of a British patent is greater than in any other country in the world, with the sole exception of Germany. The British inventor is charged £154 for patenting an invention for fourteen years, while in America the charge is £7 10s. for seventeen years. But the American Patent Office does far more for this small sum that the establishment in Chancery Lane does for its unfortunate client. It undertakes a search through previous specifications in order to find out whether the would-be patentee has not already been forestalled in what he believes to be an original idea. Does the English Patent Office do nothing of this kind to take care of the interests of the blossoming inventor? Nothing whatever. If Brown, Jones, and Smith were severally to go to the Office to-morrow, and each apply for a patent for, say, bromide paper, or gelatine plates for photographic purposes, the Office would blandly take their fees and comply with their requests, and the entire farce of giving protection, which was not worth the paper upon which it was described, would be carried out, without a hint to the poor inventor that he was throwing his money into the gutter. The case we have cited will seem an impossible one, but anyone who will take the trouble to search through the volumes devoted to abridgments of specifications will find the same ideas patented again and again by different persons.

The heaviness of the fee charged at the English Patent Office can be better appreciated when the fees charged by different countries are computed for the number of years during which the patent rights exist. Measured in this way, we find that the United States charge 8s. 10d. per annum for 17 years; France and Italy, £4 per annum for 15 years; Belgium and Spain, £4 4s. per annum for 20 years; Russia, £5 10s. per annum for 10 years; while Great Britain, poverty-stricken Britain, is obliged to tax those to whom she owes so much of her greatness no less than £11 per annum for 14 years, or more than 100 per cent. more than the fees payable in Russia, and more than 2,500 per cent. than those of the United States. This policy of taxing inventors up to the hilt is as foolish as it is morally indefensible, for it checks inventive enterprise. If we refer to the number of applications made in this country in one year, and compare them with the number made in the United States, we find an extraordinary difference, namely, eighteen thousand in Britain against thirty-five thousand in America. Indeed, everyone in America is encouraged to exert his or her inventive faculties, and, as a result, we find that inventors, both male and female, arise on all sides. They flood our own markets with various clever *notions*, which we eagerly buy, and in doing so we say admiringly, "How clever the Americans are to invent such useful little things!" whereas it would be truer to say, "How silly our home authorities are to prevent these paying little things being invented here."

But perhaps the most telling argument against the authorities was employed by Mr. Leng when he said that "it was extremely inconsistent on the part of the Government to grant large sums on the one hand for technical education, and then, on the other, to tax those who were technically educated and were turning their technical education to good account"; and we are quite ready to endorse his statement that "instead of our Patent Office being a helpful promoter of inventions, it was a hard, niggardly, unsympathising tax collector, bent on screwing all it could out of the poor inventor, while aiding him as little as possible." The seconder of the motion also did well to point out that inventors as a class are poor men, and too often, in their difficulty in paying these heavy fees, they place themselves in the hands of richer members of the community, who eventually reap all the profits which may result.

Now, what answer have the Government to make to these charges of extortion? Very little, we fear, which will bring any comfort to the poor inventor. The President of the Board of Trade does not think that the country ought to look upon the Patent Office as a permanent source of income. This is certainly a hopeful statement as far as it goes. And, in his view, they should consider whether a reduction might not be made in the fees charged in the interval between four years and eight years, so as to extend the chief protection given for four years to a longer period. This is also a move in the right direction, but there is no present intention of making the entire sum charged more in accordance with the fees payable in other countries.

The estimated surplus of the Patent Office for the current year is estimated at £116,000, and we are told that the Government contemplate a large expenditure for the benefit of the service generally. This will take the form of new buildings in place of the inconvenient place which at present exists, and the improvement will more than swallow up the sum just quoted. This is the most favourable part of the speech for the defendants, and is a way of spending the inventors' fees which few will cavil at. But the assertion that the much-required more rapid issue of abridgments of specifications will involve further expenditure is ridiculous, for the work can very well be done, and kept up to date, by a couple of extra clerks. Even this expense would be avoided if each applicant were required to furnish with his specification an abridgment of the same. In this way the work would cost the Government nothing, and it would probably be very much better done than it would by those who are not interested in its correct performance.

We have reverted to this important subject of patent fees because photographers are as much interested in the matter as any other class of the community. It is only by calling attention again and again to any abuse which exists that there is a chance of remedying it, and this is one which cries aloud for fresh legislation.

---

The Meisenbach Company (limited) have removed their City office to 188, Fleet Street. Many improvements which have recently been introduced have brought their process to the highest point of perfection.

## PERSPECTIVE DRAWING AND VISION.

BY W. E. DEBENHAM.

In a characteristically insolent effusion—characteristic at least of one of the signatories—wherein Mr. Chapman Jones is advised "to study an elementary treatise on perspective and take some elementary lessons in drawing," my own "intellectural powers" are, by the help of misquotation, held up to ridicule, and "untrained and rash persons" are entreated not to make it necessary for the writers to waste time in educating them—Dr. P. H. Emerson and Mr. T. F. Goodall profess to reply to the criticisms which have been called forth by their theories concerning perspective and vision. If the intellectual powers of either party in the discussion were the matter in dispute, the judicious reader would probably take into consideration which side had, in default of argument, supplied its place by impertinence, bluster, and misquotation. Mr. Chapman Jones may, for all that has been shown to the contrary, be at least as well acquainted with the rules of perspective as the writers who so contemptuously assume him to be ignorant of them. Mr. Sutcliffe alone receives the doubtful compliment of being the only one capable of understanding Messrs. Emerson and Goodall.

If any further illustration were required of the loose and inexact character of Messrs. Emerson and Goodall's so-called "proofs," it may be found in the fact that the only two persons, so far as I am aware, who have supported their pretensions in public discussion—Mr. P. Everitt and Mr. T. R. Dallmeyer—have each found one of their proofs to operate in the reverse direction from that indicated by the authors. Mr. Dallmeyer says that pillars, to look vertical, should not be inclined inwards at the top, as stated by them, but the other way; Mr. Everitt finds that the door looks narrower instead of wider towards the top. Such a difference may be expected when the looseness of the direction is remembered. The observer is to look at the middle of a doorway. Now, according as the doorway is high or low, or the observer is sitting or standing, the line of vision, when looking at the middle, may be upward or downward. It has before been pointed out that, to obtain results at all comparable, that part of the door level with the eye, and not the middle, should have been directed. Mr. Everitt, however, though observing this more precise direction, still found the "proof" to work contrary to Messrs. Emerson and Goodall's assumption.

Messrs. Emerson and Goodall say that my demonstrations with the coin experiments were vitiated by the use of an eyehole, the effect of which is to cut off the portion of the field of vision causing the phenomenon to be observed. This is not the fact. The eyehole was made of such a size as to allow all the coins concerned to be seen at one view, and the verdict of the members of the Society present, with the exception of Mr. Everitt, was that the upper and lower coins appeared equal to each other. With the notched stick repetition of the experiment, as the upper and lower pennies are not in view simultaneously for comparison, and as no means are indicated for insuring equality of angle above and below, for which the eyehole provides, varying effects may easily be produced or imagined.

The introduction of the question of binocular vision is only calculated to mystify the matter. The difference of outlines to the two eyes of objects at such distances as are generally included in views is so small, that if both were included in a painting, the effect would only be to double the lines to a slight extent without, on the whole, materially enlarging or diminishing each particular object. It should be remembered, too, that the vertical dimension of any object is not in any case affected by binocular vision. If Messrs. Emerson and Goodall say that the lateral dimension is affected, and ought to be represented in a picture as so affected, will they state whether it should be by increase or diminution? Should a circular form, for instance, in any given part of a picture (since its height is not affected) be represented as broader or narrower than the circle? If they can settle this, how would they arrange, not for a single object, but for a series, filling up the picture? It is useless to say, "How a drawing is to be done we do not enter into," and to quote the names of Rembrandt and Velasquez. If the works of these painters really support the contention of Messrs. Emerson and Goodall, it should be possible for them to point out that they paint such an object as less, or such another as greater in width (vertical measure, as before stated, does not enter into the question of binocular perspective), than would be in accordance with mathematical perspective. Perhaps they will not object to a quotation from Reynolds: "An artist ought to see clearly enough to enable him to point out to others the principle on which he works." This is particularly true with respect to those who profess to upset accepted principles and substitute a doctrine of their own.

The writers say that they have answered my criticisms either directly or in reply to other critics. They seem, however, to have quite overlooked the observation that "if their proposition is true, that the lower half of the eye sees things on a smaller scale than the upper, and for this reason a perspective drawing surprises us by making the foreground objects look large, then such foreground objects as are above the distance should surprise us by appearing too small in the perspective drawing or photograph. Perhaps one of the most familiar instances of a near object above the central distance is that of a chandelier depending from the ceiling when the interior of a room is photographed." Do they maintain that such an object as a near chandelier does surprise us by appearing too small in the photograph, as it should do if their statement and explanation are to be accepted?

It may further be noticed that Messrs. Emerson and Goodall have not given any satisfactory reason why, assuming their proposition with regard to the eye to be true, the upper and lower halves of the eye should not see the photograph or perspective drawing enlarged or diminished in the same proportion that they see natural objects, and so why the photograph should not, after all, give a true rendering and impression to the observer.

If possible to find rational answers supporting their contentions in reply to the questions referred to in the last three paragraphs—*i.e.* (1) Whether a raised foreground object, such as a chandelier, really does surprise us by appearing too small in a photograph? (2) Why the alleged difference of the upper and lower halves of the eye in representing dimensions should not act upon the drawing or photograph as stated to do upon natural objects? and, (3) What is the alteration of form which a regard for binocular vision dictates as required in a drawing, since width alone, and not height, can by any possibility be affected by it?—Messrs. Emerson and Goodall would do well to adduce them. If such answers cannot be found, readers will be apt to look elsewhere than in the direction indicated by these writers for the "rash and untrained persons" who make it necessary to waste time in educating them.

## IDLERS ON THE BROADS.

BY E. J. H.

I trust that none of my readers will be misled by the title of this letter to think that those who took part in this excursion are idlers anywhere but on the Broads; in fact, we were all hard-worked and jaded toilers—distinguished members of Her Majesty's Civil Service, doctors, barristers, lawyers, and men of business—all joining to forget the cares and troubles of life in a week of idyllic enjoyment on the Norfolk Broads, where the postman's knock soundeth not, and the rush and turmoil of great cities have no counterpart.

Liverpool Street Station was our meeting point, and here eight of us assembled in time for the 3.20 train for Norwich. There was some difficulty in ascertaining what tickets we should take, some of us taking return tickets to Norwich, only to find that we saved nothing in cost, and might have taken single tickets without any extra expense. The chemical professor, who, in his usual careful way, had made a thorough analysis of all the possible combinations, triumphed over us all, and exultingly flourished a return ticket to Cromer in our faces, for which he had paid about two-thirds the price of a Norwich ticket. The Great Eastern Company, having evidently an Oriental idea of life, and looking upon pleasure as of far more importance than such follies as business, cater for the pleasure-seekers, and let the silly busy-bees who travel for business pay for those who, with a true grasp of the fitness of life, prefer the sweets and pleasures of unadulterated enjoyment.

Arrived at Norwich, however, unexpected trouble awaited the chemical professor, the ticket collector refusing to accept a Cromer ticket unless the professor would consent to journey to Cromer and back; but as dinner was ready, and the professor hungry, he naturally resented the idea of another three hours' journey, but, scorning to bandy words with the hired minion of the company, produced his card, which, with its long list of F.R.S., F.C.S., &c., &c., struck such terror into the trembling official that he made no further opposition, and would doubtless have presented him with a free pass for the rest of his life if we had not impatiently dragged him off to the hotel, where we were joined by the lunatic doctor, who came to look after us, and to inform us that there were still a few vacancies in the asylum for deserving cases.

After dinner several more members of the party turned up, one of whom had lost his luggage, and insisted on sending the hotel omnibus up to meet every train through the night. As this omnibus started from the hotel yard on to which our windows opened, and it was impossible to start the omnibus without shouts from the ostlers and great banging of the gates, sleep was out of the question, and an early start had to be made the next morning. In spite of this, one or two energetic members of the party got up at daybreak to photograph various objects of interest, including the cathedral and the chambermaid.

From Norwich we took the train to Acle, where we found two waggonettes awaiting us, which, being loaded with cameras, portmanteaus, and their human freight, looked like the baggage train of an invading army.

At Acle Bridge we found our two wherries, on one of which was our old friend Skipper Joe (who welcomed us with his usual genial smile) and his mate Arthur, to look after the creature comforts of the hungry passengers. The arrangements had been carefully made by our secretary, who had put the teetotal brigade in one wherry, the other being reserved for those who prefer the national beverage of the Scotch to the insipid decoction of the Chinaman. Skipper Joe was in command of the "Scotch" boat, and, though he is a temperance man, he is no bigot, and looks upon cherry brandy as a non-intoxicating beverage.

The stores which had been sent down were divided between the two wherries, a liberal allowauce of beer and whisky being put on board the temperance boat in case of sudden illness. We set sail, but our progress was not rapid, the wind being dead ahead, and quanting—or punting, as we Southrons call it—had to be resorted to. In this line the professor greatly distinguished himself, but had several narrow escapes, the quant having a playful way of remaining firmly imbedded in the mud, aud it was only by seizing the professor round the waist that he was saved from a watery grave, or from being left, like a monkey up a pole, as a warning to the rash. We presently sighted a strange craft with lovely houris on board (remember this is an Oriental tale). The Fitzboozer, enraptured, was seen to be kissing his hand to the lovely creatures. This fired the breasts of the Major and Signor Grogerino with a determination to supplant the teetotal Fitzboozer in the affections of the damsels; so, leaping on board, they seized the jolly-boat of the Fitzbooser and gave chase, alternately running into either bank in their mad endeavours to come up with the strange craft, and take them captive. After exhausting but fruitless efforts, they found that the crew of the boat had lauded at Horning Ferry, where they were regaling themselves with tea and strawberries, and other Eastern sweetmeats. After tea the wherries came up, the rest of the party having gone off in the sailing dingey to Rangworth Broad. The Major politely offered to show the ladies and their friends over the wherry; so all went below, the Major cleverly capturing the most beautiful of the peerless damsels, and keeping her near the door. After a short time, suggesting that one of the other maidens should play the piauo, and while all were listening to the sweet strains of music, he, unobserved, bore the maiden of his choice off to the other wherry, leaving the Signor Grogerino to entertain their guests. The Signor looking round, and seeing that, in the language of the East, he had been spoofed, persuaded the whole party to follow the errant pair, and found the euraptured Major basking in the smiles of his angel, seated cross-legged on a cushion at her feet, and feeding her with "Turkish Delight," which he apparently thought was the orthodox Eastern way of love-making.

The rest of the party returned shortly after, only to find that the angels had taken flight, and the place knew them no more.

The next day we sailed from Horning to South Walsham, and thence to Ludham Bridge. In the evening we left our craft aud walked over to Horniug Ferry, where we were greeted warmly by the fair Emily, who made tender inquiries after Doctor Pat, who seems to be much loved by all the maidens of the East.

On Monday, from Ludham Bridge to Stalham, *via* Barton, the Major, Buffalo Bill, and the Mad Doctor, sailiug in the Dingey, stopped ou the way, and got some interesting pictures of reed-cutters at work. As we approached Stalham, a stalwart figure was seen leaning against a rail, with a retriever by his side and a gun in his hand. One of the party suggested that it was Dr. Emerson, waiting for our only artist, and masses were promptly said for his soul; but it turned out to be only au inoffeusive gamekeeper, and our only artist breathed freely once more.

On the banks where we moored our craft were two of the most amiable donkeys, which made great friends with the major, and welcomed him as if he had been one of the family. This suggested to several plate-spoilers the title of an Academy picture to be called "When Shall We Three Meet Again."

An irate old woman, who might have been the witch of Endor, then attacked us with a most venomous wrath for having climbed over a gate, but the honied accents of Buffalo Bill soon appeased the dear creature and calmed her wrath. From Stalham we sailed to Potter Heighau, where the professor climbed the mast, and, from that coign of vantage, announced that he could see three pictures at once. This was not caused by over-indulgence in whisky, but was called forth by the beauty of the scene on every side.

The next day we left our wherries at Potter Heigham, and took a sailiug-boat to Horsey Mere, where we had a good stiff breeze, and thence up the dyke to Waxham, where we had a most excellent lunch at a pretty little house at the head of the dyke. After lunch we walked up to the sea coast, where the soul of our only artist was enraptured at the sight of his beloved sand dunes, and, having rigged up his camera with a fine sand heap in front, he departed to pace the sands in search of another equally poetic conception. The guileless Major, who had been dabbling in the sea, quite unconscious that the camera was making pictures by itself, an operation which he imagiued required a man to bury his head under a black cloth, and then stand with watch in hand counting the seconds, sat himself down at the foot of the sand heap, and leisurely dried his feet, aud put on his shoes and socks, taking things very easily, and being, perhaps, nearly ten minutes facing the very centre of the lens. Doubtless, a very charming picture, quite unexpectedly by the artist, will be the result.

Ou Wednesday we sailed with a fair wind from Potter Heigham to Acle, where our only artist and several more of the party left us and returned to town.

On looking over the stores, we discovered that a considerably larger quantity of beer and other gentle stimulants had been consumed on the teetotal wherry than on the other boat—a fact which might have caused some astonishmeut had we not already seen how kindly the Fitzbooser took to whisky straight when he paid a visit to our wherry.

Dr. Woolsey Jackboy, who had joined us on the previous day, remained with us, thus making a small but select party of five. The doctor kept us in roars of laughter by recounting some of his experiences, which, on the ground that fact is strauger than fiction, must certaiuly have been true.
